Abstract

Abdominal cocoon, the idiopathic form of sclerosing encapsulating peritonitis, is a rare condition of unknown etiology that results in an intestinal obstruction due to total or partial encapsulation of the small bowel by a fibrocollagenous membrane. Preoperative diagnosis requires a high index of clinical suspicion. The early clinical features are nonspecific, are often not recognized and it is difficult to make a definite pre-operative diagnosis. Clinical suspicion may be generated by the recurrent episodes of small intestinal obstruction combined with relevant imaging findings and lack of other plausible etiologies. The radiological diagnosis of abdominal cocoon may now be confidently made on computed tomography scan. Surgery is important in the management of this disease. Careful dissection and excision of the thick sac with the release of the small intestine leads to complete recovery in the vast majority of cases.

Key words: Peritonitis; Sclerosis; Encapsulate; Intestinal obstruction; Computed tomography scan; Surgery

INTRODUCTION

Sclerosing encapsulating peritonitis (SEP) is a rare condition of unknown etiology. It is characterized by a thick grayish-white fibrotic membrane, partially or totally encasing the small bowel, and can extend to involve other organs like the large intestine, liver and stomach. It was first observed by Owtschinnikow in 1907 and was called peritonitis chronica fibrosa incapsulata[1-5]. SEP can be classified as idiopathic or secondary. The idiopathic form is also known as abdominal cocoon, was first described by Foo *et al* in 1978. Abdominal cocoon is a relatively rare cause of intestinal obstruction[6-21]. Postoperative adhesions account for about 60% of patients with small bowel obstruction. Unusual cases are encountered in only 6% of patients. Abdominal cocoon is one such unusual case of small bowel obstruction[9]. Based on a review of the literature (case series and case reports), we discuss in this paper, etiology, clinical presentation, radiological appearances, diagnosis, treatment, prognosis, and histopathology of abdominal cocoon.

ETIOLOGY

The etiology of this entity has remained relatively unknown. The abdominal cocoon has been classically

described in young adolescent females from the tropical and subtropical countries, but adult case reports from temperate zones can be encountered in literature[1,22-27]. To explain the etiology, a number of hypotheses have been proposed. These include retrograde menstruation with a superimposed viral infection, retrograde peritonitis and cell-mediated immunological tissue damage incited by gynecological infection. However, since this condition has also been seen to affect males, premenopausal females and children, there seems to be little support for these theories[1,24-28]. Further hypotheses are therefore needed to explain the cause of idiopathic SEP. Since abdominal cocoon is often accompanied by other embryologic abnormalities such as greater omentum hypoplasia, and developmental abnormality may be a probable etiology[1]. Greater omentum hypoplasia and mesenteric vessel malformation was demonstrated in some cases. To elucidate the precise etiology of idiopathic SEP, further studies of cases are necessary.

The secondary form of SEP has been reported in association with continuous ambulatory chronic peritoneal dialysis (PD)[29-38]. SEP is a serious complication of PD which leads to decrease ultrafiltration and ultimately intestinal obstruction. For some authors[37], the incidence of SEP was 1.2%, but rose to 15% after 6 years, and 38% after 9 years on PD. The risk of SEP is low early in the course of PD, but increases progressively at 6 years and beyond. For others, the respective cumulative incidences of peritoneal sclerosis at 3, 5 and 8 years were 0.3%, 0.8% and 3.9%. This condition was independently predicted by younger age and the duration of PD, but not the rate of peritonitis[33]. Other rare causes of secondary form of SEP[39-52] include, prior abdominal surgery, subclinical primary viral peritonitis, recurrent peritonitis, beta-blocker treatment (practolol), peritoneovenous shunting, pertioneoventricular shunting and, more rarely, abdominal tuberculosis, sarcoidosis, familial Mediterranean fever, intraperitoneal chemotherapy, cirrhosis, liver transplantation, gastrointestinal malignancy, luteinized ovarian thecomas, endometriosis, protein S deficiency, dermoid cyst rupture, and fibrogenic foreign material.

CLINICAL PRESENTATION

Preoperative diagnosis requires a high index of clinical suspicion. The early clinical features of SEP are nonspecific and are often not recognized[1-12]. Clinically, it presents with recurrent abdominal pain, nausea, vomiting, anorexia, weight loss, malnutrition, recurrent episodes of acute, subacute or chronic small bowel incomplete or complete obstruction, and at times with a palpable soft non tender abdominal mass, but some patients may be asymptomatic. In some cases, abdominal distension was secondary to ascites. A high index of clinical suspicion may be generated by the recurrent attacks of non-strangulating obstruction in the same individual combined with relevant imaging findings and lack of other etiolo-

gies. The preoperative diagnosis of this entity may be helpful for proper treatment of these patients[2-5].

Less than 1% of PD patients develop overt SEP as manifested by combinations of weight loss, ultrafiltration failure, and intestinal obstruction[33-35].

Clinicians must rigorously pursue a preoperative diagnosis, as it may prevent a "surprise" upon laparotomy and unnecessary procedures for the patient, such as bowel resection. Although it is difficult to make a definite preoperative diagnosis, most cases are diagnosed incidentally at laparotomy. A better awareness of this entity and the imaging techniques may facilitate preoperatively diagnosis[1,6-9].

RADIOLOGY APPEARANCES

Conventional radiographs may show dilated bowel loops and air fluid level. Contrast study of the small intestine in SEP shows varying lengths of small bowel tightly enclosed in a "cocoon" of thickened peritoneum, proximal small bowel dilatation, and increased transit time. It may show a fixed cluster of dilated small bowel loops lying in a concertina like fashion, giving a cauliflower-like appearance ("cauliflower sign")[10,53].

Ultrasound findings described in SEP include a trilaminar appearance of the bowel wall, tethering of the bowel to the posterior abdominal wall, dilatation and fixation of small bowel loops, ascites, and membrane formation. Ultrasonography may show a thick-walled mass containing bowel loops, loculated ascites and fibrous adhesions. Sonography shows the small bowel loops encased in a thick membrane made best visible only in the presence of ascites, and may show small bowel loops arranged in concertina shape with a narrow posterior base, having overall appearance of cauliflower[10,53-55].

The radiological diagnosis of SEP may now be confidently made on computed tomography (CT) scan[10,53-60]. CT of the abdomen may help in obtaining an early, reliable, and noninvasive diagnosis of SEP for which optimal management can be planned (Figure 1A and B). CT gives complete picture of the entity and associated complications with exclusion of other causes of intestinal obstruction. The exact diagnosis of this entity is made by computed tomography of the abdomen demonstrating small bowel loops congregated to the center of abdomen encased by a thick membrane[58]. CT features of peritoneal calcification, peritoneal thickening, marked enhancement of the peritoneum, loculated fluid collections, gross ascites with small-bowel intestine loops congregated in a single area in the peritoneal cavity, clustered small-bowel loops encased by a thin membrane-like sac, tethering or matting of the small bowel loops, thickening of the bowel wall, soft tissue density mantle, serosal bowel wall calcification, and calcification over liver capsule, spleen, posterior peritoneal wall may be diagnostic of SEP in the appropriate clinical setting. Tethering or matting of the small bowel is usually posterior to the loculated fluid collection, although bowel is sometimes

Figure 1 Computed tomography scan. A: Axial contrast enhanced computed tomography (CT) scan of the abdomen showing bowel loop mass encased in a membrane; B: Anterio-posterior CT scan of the abdomen showing thin membrane around bowel loops.

seen to be floating within these collections[57]. Fibrosis results in retraction of the root of the mesentery causing the bowel to clump together leading to obstruction and dysfunction. Retraction of the mesentery can lead to a characteristic appearance of the tethered small bowel loops that we have dubbed the "gingerbread man" sign. In some series, diagnosis of abdominal cocoon was made by a combination of abdominal CT and clinical presentations.

DIAGNOSIS

A high index of clinical suspicion may be generated by the recurrent attacks of non-strangulating obstruction in the same individual combined with relevant imaging findings and lack of other etiologies. The preoperative diagnosis of this entity may be helpful for proper treatment of these patients. Most cases are diagnosed incidentally at laparotomy, although a preoperative diagnosis is purported feasible by a combination of barium follow-through (concertina pattern or cauliflower sign and delayed transit of contrast medium), ultrasound, and computed tomography of the abdomen (small bowel loops congregated to the center of the abdomen encased by a soft-tissue density mantle)[3-5,61].

There are many causes of intestinal obstruction but differential diagnosis of this condition is mainly from internal hernias[11], voluminous intussusception[62], simple localized peritoneal adhesions, and chronic idiopathic

intestinal pseudo-obstruction[63]. The main CT features of an internal hernia are: (1) Central location of the small bowel; (2) Evidence of small bowel obstruction; (3) Clustering of the small bowel; (4) Displacement of and mass effect on adjacent organs; and (5) Stretched, displaced, crowded, and engorged mesenteric vessels. No membrane-like sac can be detected in patients with internal hernias as seen in abdominal cocoon[11]. In chronic idiopathic intestinal pseudo-obstruction, CT scan showed distention of small ad large bowels and no membrane-like sac.

TREATMENT AND PROGNOSIS

Management of SEP is debated. Most authors agreed that surgical treatment is required[64-66]. In some cases, the diagnosis is established at a late stage of the disease at laparotomy when the patient develops partial or complete small bowel obstruction. Laparotomy reveals characteristic gross thickening of the peritoneum, which encloses some or all of the small intestine in a cocoon of opaque tissue (Figure 2). The root of the mesentery may also be sclerotic and retracted. Fibrous bands form between the loops of bowel, and when the mass of bowel is sectioned, many small loculated abscesses due to local perforations are found. The entity was categorized into 3 types according to the extent of the encasing membrane: (1) Type Ⅰ - the membrane encapsulated partial intestine; (2) Type Ⅱ - the entire intestine was encapsulated by the membrane; and (3) Type Ⅲ - the entire intestine and other organs (e.g., appendix, cecum, ascending colon, ovary, *etc.*) were encapsulated by the membrane[4]. Various treatment options are adopted, such as subtotal excision of the membrane, enterolysis, small bowel intubation, bowel resection, and exploratory laparotomy with postoperative medical treatment in patients with high perforative risk. When feasible, a stripping of the membrane with intestinal releasing without intestinal resection is the treatment of choice. A simple surgical release of the entrapped bowel *via* removal of the fibrotic membrane is all that is required to free the bowel if no other cause of obstruction, such as a stricture, is found. In order to avoid complications of postoperative intestinal leakage and short-intestine syndrome, resection of the bowel is indicated only if it is nonviable because resection of the bowel is unnecessary and it increases morbidity and mortality. In some patients, repeated adhesiolysis was required. For some authors, laparoscopic approach was possible to diagnosis and management of abdominal cocoon[67-70]. An excellent long-term postoperative prognosis is most of the times guaranteed with a little risk of recurrence in long term follow-up. No surgical treatment is required in asymptomatic SEP. Surgical complications were reported including intra-abdominal infections, enterocutaneous fistula and perforated bowel[66].

Treatment for secondary SEP in dialysis patients is cessation of PD, nutritional support, and surgery for in-

Figure 2 Laparotomy showing an encapsulating thick, white adherent membrane encasing the small bowel.

testinal obstruction, if required. Treatment was variable, but in recent years, steroids and tamoxifen were generally used when SEP was recognized. Preliminary results suggest that steroids and tamoxifen[37] or Angiotensin II inhibitors[71] are beneficial. Transfer to haemodialysis is necessary. Prognosis of SEP is poor, with death usually occurring within a few weeks or months after surgery as it carries a high mortality (20%-80%). This is the result of diagnosis in the latter stages of disease when patients have already developed bowel obstruction. Earlier diagnosis, biocompatible dialysates, and immunosuppressive therapy may improve the outcome for such patients in the future[30-37].

HISTOPATHOLOGY OF SEP

Histopathology is now seldom required as CT imaging appearances along with the clinical features allow a confident diagnosis of SEP. Histologically, the peritoneum shows a proliferation of fibro-connective tissue, inflammatory infiltrates, and dilated lymphatics, with no evidence of foreign body granulomas, giant cells, or birefringent material[72-74]. "Sclerosing" refers to the progressive formation of sheets of dense collagenous tissue; "encapsulating" describes the sheath of new fibrous tissue that covers and constricts the small bowel and restricts its motility; and "peritonitis" implies an ongoing inflammatory process and the presence of a mononuclear inflammatory infiltrate within the new fibrosing tissue[73].

CONCLUSION

Abdominal cocoon, or idiopathic sclerosing encapsulating peritonitis, is a rare condition of unknown cause characterized by total or partial encasement of the small bowel by a fibrocollagenous cocoon-like sac. Although it was first described in tropical and subtropical adolescent girls, it can occur in all age groups, both genders, and in several regions of the world. The preoperative diagnosis of abdominal cocoon is difficult and the diagnosis should always be considered whenever a patient reports episodes of abdominal pain, nausea and vomiting as-

sociated with weight loss. Combination of diagnostic modalities like sonography and CT scan can help in making preoperative diagnosis of this entity and prevent unnecessary bowel resection. This condition should be managed in specialized centers. Surgery is important in the management of this disease. Careful dissection and excision of the thick sac with the release of the small intestine leads to complete recovery.

Abstract

The prognosis of hepatocellular carcinoma (HCC) depends on tumor extension as well as hepatic function. Hepatic functional reserve is recognized as a factor affecting survival in the treatment of HCC; the Child-Pugh classification system is the most extensively used method for assessing hepatic functional reserve in patients with chronic liver disease, using serum albumin level to achieve accurate assessment of the status of protein metabolism. However, insufficient attention has been given to the status of amino acid (AA) metabolism in chronic liver disease and HCC. Fischer's ratio is the molar ratio of branched-chain AAs (BCAAs: leucine, valine, isoleucine) to aromatic AAs (phenylalanine, tyrosine) and is important for assessing liver metabolism, hepatic functional reserve and the severity of liver dysfunction. Although this ratio is difficult to determine in clinical situations, BCAAs/tyrosine molar concentration ratio (BTR) has been proposed as a simpler substitute. BTR correlates with various liver function examinations, including markers of hepatic fibrosis, hepatic blood flow and hepatocyte function, and can thus be considered as reflecting the degree of hepatic impairment. This manuscript examines the literature to clarify whether BTR can serve as a prognostic factor for treatment of HCC.

TREATMENT OF HEPATOCELLULAR CARCINOMA REGARDING RECURRENCE

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide[1]. With advances in imaging diagnostics, together with the understanding of high-risk patients, HCC can now often be detected at an early stage[2]. Furthermore, HCC is associated with severe complications in patients with cirrhosis or chronic hepatitis with severe fibrosis.

In addition to surgical resection as a treatment for HCC, techniques that can be used alone or in combination include transcatheter arterial embolization, transcatheter arterial chemoembolization, percutaneous ethanol injection therapy, percutaneous microwave coagulation therapy, and percutaneous radiofrequency ablation. Thus, local control of HCC can now be achieved in consideration of the location of the tumors, the area occupied and hepatic functional reserve.

Recently, the prognosis of HCC has improved dra-

matically with the identification of high-risk populations and the advancement of diagnostic imaging and treatment. However, recurrence of HCC is frequent in the early post-treatment period even in patients who have undergone radical hepatectomy or radical local treatment including percutaneous treatment, because HCC arises from chronic liver disease. The recurrence rate after treatment of HCC is higher than that of cancer in other organs.

Therefore, despite initial remission of HCC after surgical and interventional treatments, limits are seen on the prolongation of survival. In other words, the therapeutic options available to deal with recurrence determine survival of patients, because risk of recurrence is high even if radical therapy is undertaken.

Treatment tactics may be selected depending on the tumor stage and severity of underlying liver disease.

The reasons for poor survival are that intrahepatic distant recurrence is common and, even more importantly, decompensation occurs due to a decrease in hepatic functional reserve that accompanies progression of chronic liver disease. Therefore, death due to liver failure represents a major problem. In other words, hepatic functional reserve is recognized as a factor affecting survival. However, sufficient research into the effects of the reserve liver function has not been carried out.

BRANCHED-CHAIN AMINO ACIDS TO TYROSINE RATIO AS STATUS OF AMINO ACID METABOLISM

When treating HCC, the Child-Pugh classification system is the most extensively used method worldwide for assessing the hepatic function in patients with chronic liver disease, and represents an important assessment factor. The Child-Pugh classification has been widely used to evaluate hepatic functional reserve in cirrhotic patients, and has a good correlation with prognosis[3], but cannot be used to predict survival in patients with HCC.

In the Child-Pugh classification, the serum albumin level is used to achieve accurate assessment of the status of protein metabolism. However, to date, no attention has been given to the status of amino acid (AA) metabolism in chronic liver disease and HCC.

Amino acid abnormalities are reportedly common even in patients who have liver cirrhosis but no hepatic encephalopathy and in patients with chronic hepatitis[4]. The amino acid molar ratio called Fischer's ratio [branched chain amino acids (BCAAs): leucine, valine, isoleucine/aromatic amino acids (AAAs): phenylalanine, tyrosine] is important for assessing liver metabolism, hepatic functional reserve and the severity of liver dysfunction[5]. Protein malnutrition is a result of amino acid imbalance. Accordingly, to accurately assess the status of protein metabolism in HCC patients with a background of chronic liver disease, determining not only the serum albumin level but also the status of amino acid metabolism is essential.

Proteins contained in biological cells are broken down into amino acids, while at the same time proteins are newly synthesized from free amino acids. Metabolic turnover is achieved when the breakdown and synthetic processes are in balance. The liver is the main organ involved in protein and amino acid metabolism. Hypoalbuminemia and fluctuations in plasma free-amino acid concentrations are usually seen in patients with chronic liver disease. Serum albumin is a protein that is synthesized and secreted by hepatocytes, and is used as an index of hepatic synthetic capacity for protein. This parameter is particularly important for evaluating the severity and prognosis of cirrhosis.

Fluctuations in plasma free-amino acid concentrations are particularly observed in cirrhosis. These changes include marked decreases in BCAAs and increases in AAAs, methionine, and other amino acids. The molar concentration ratio of BCAAs/AAAs (Fischer's ratio) and the BCAAs/tyrosine molar concentration ratio (BTR) decrease with increasing severity of hepatic damage. The Fischer's ratio has long been used for analysis of plasma free-amino acid concentrations, while BTR represents a simplified version of Fischer's ratio[6]. Azuma et al[6] proposed the BTR as a substitute for Fischer's ratio as an index of hepatic damage, and later reported that BTR reflected the progression of chronic liver disease.

Fluctuations in plasma free-amino acid concentrations are also seen in compensatory cirrhosis. For that reason, amino acid metabolic abnormalities in the liver become more severe as the state of chronic liver disease worsens.

On the other hand, assessing hepatic functional reserve from the perspective of amino acid metabolism can prove useful in different ways compared with investigations of the degree of hepatic fibrosis, hepatic blood flow and hepatocyte function. BTR correlates with each of the various liver function examinations, including fibrosis markers, which indicate the degree of hepatic fibrosis; indocyanine green retention rate 15 min (ICG R15), which primarily indicates hepatic blood flow; and asialo-scintigraphy, which reflects hepatocyte function. BTR also reportedly shows significant correlations with albumin value and cholinesterase (Ch-E) levels[7]. As a result, BTR can be thought to reflect the degree of hepatic impairment.

BTR offers a significant indicator of reserve liver function. However, to date, no reports have clarified the potential of BTR as a prognostic factor at the time of treating HCC.

RELATIONSHIP BETWEEN BTR AND TREATMENT OF HCC

The significance of amino acid analysis for assessing hepatic functional reserve has not been elucidated in patients with HCC.

In the case of poor nutritional status, BTR decreases in advance of decreases in serum albumin level. For

that reason, early identification of patients at risk of hypoalbuminemia is possible; specifically, determination of BTR enables prediction of changes in the serum albumin level[8], in turn allowing prediction of the need for administration of BCAAs. Moreover, because of the existence of that time-lag, monitoring of BTR separately from albumin is necessary when considering prognostic factors for HCC. A large-scale clinical study has demonstrated the usefulness of administering oral BCAA preparations to patients showing decreased BTR[9]. In other words, there is a strong possibility that determining BTR provides a prognostic factor for HCC.

In this paper, I have undertaken a review of the published literature with regard to whether BTR can serve as a prognostic factor for HCC.

A small number of experimental and clinical studies have examined BTR in terms of amino acid fluctuations following hepatectomy[10-12]. In experimental models, BTR is correlated with the extent of hepatectomy, with the post-operative interval time and with the liver weight when animals are sacrificed. In clinical studies, BTR has been determined on the immediate post-operative day and every day during the first post-operative week[10-12]. In addition, BTR reportedly decreased following hepatectomy, but then recovered on post-operative day 3 with administration of a BCAA-rich amino acid transfusion[13]. In that report, BTR on day 14 was lower than immediately before the hepatectomy, and the significance of improvements in BTR due to administration of a BCAA-rich amino acid transfusion for several days following the surgery was unclear.

In general, total bilirubin level is used as an indicator of hepatic functional reserve following hepatectomy, but in some cases hepatic functional reserve cannot be fully understood on the basis of total bilirubin level alone. For that reason, determination of arterial blood ketone bodies has been recommended[14]. However, no association exists between arterial blood ketone body values and the actual disease state, and thus this measurement cannot be claimed to offer a superior index compared with total bilirubin level. Moreover, substances such as serum albumin, fibrinogen and cholinesterase, which are synthesized in the liver, show high levels of specificity as indicators of hepatic functional reserve. However, levels are modified by aggressive replacement therapy, and thus are not useful in the clinic. A simple indicator that will permit objective assessment of recovery of liver function following hepatectomy is therefore needed. On the other hand, Fischer's ratio (BCAAs/AAAs), which decreases in various diseases such as cirrhosis that are characterized by a decrease in liver function, has been reported to be useful for understanding the status of liver function[15]. However, Fischer's ratio is difficult to determine, and is not commonly used as a test value following procedures such as hepatectomy. Furthermore, BTR has been developed as a simpler assay method and costs less, and is starting to be used clinically instead of Fischer's ratio in recent times[6,16].

With regard to assessing liver function from the perspective of amino acid metabolism, BTR (BCAAs/tyrosine) has been shown to be useful in different ways compared with such liver function investigations as determining the degree of hepatic fibrosis, hepatic blood flow or hepatocyte function. However, our preliminary experience suggests that BTR can be considered a survival factor in Stage I / II HCC (data not shown). Thus, overall survival in the high BTR group (4.5 or higher) was significantly longer than in the low BTR groups (4.4 or lower) regardless of serum albumin value, respectively. BTR may represent a contributing factor for hepatic functional reserve and survival at the time of HCC treatment. In the future, closer investigations of this issue in a large number of HCC cases will be needed.

In addition, prospective studies will be required to investigate various aspects, including whether maintenance of hepatic functional reserve by administration of BCAA preparations, as indicated by the BTR, is useful in improving the prognosis of HCC.

CONCLUSION

Nutritional management plays an important role in the treatment of HCC, particularly in patients with chronic liver disease. With the objective of improving protein metabolism in patients with cirrhosis, supplemental therapy using oral BCAA preparations is administered to patients with decreased BTR. We can hope that this approach will be found to improve the prognosis of HCC, and that BTR will be thought to be useful as an indicator of such improvement. In the future, it will be necessary to carry out a large-scale prospective study designed to elucidate these points.

Abstract

This review discusses the pathophysiology, epidemiology, risk factors, classification, clinical evaluation, and current non-operative and operative treatment of hemorrhoids. Hemorrhoids are defined as the symptomatic enlargement and distal displacement of the normal anal cushions. The most common symptom of hemorrhoids is rectal bleeding associated with bowel movement. The abnormal dilatation and distortion of the vascular channel, together with destructive changes in the supporting connective tissue within the anal cushion, is a paramount finding of hemorrhoids. It appears that the dysregulation of the vascular tone and vascular hyperplasia might play an important role in hemorrhoidal development, and could be a potential target for medical treatment. In most instances, hemorrhoids are treated conservatively, using many methods such as lifestyle modification, fiber supplement, suppository-delivered anti-inflammatory drugs, and administration of venotonic drugs. Non-operative approaches include sclerotherapy and, preferably, rubber band ligation. An operation is indicated when non-operative approaches have failed or complications have occurred.

Several surgical approaches for treating hemorrhoids have been introduced including hemorrhoidectomy and stapled hemorrhoidopexy, but postoperative pain is invariable. Some of the surgical treatments potentially cause appreciable morbidity such as anal stricture and incontinence. The applications and outcomes of each treatment are thoroughly discussed.

Key words: Hemorrhoids; Pathophysiology; Treatment; Management; Outcome

INTRODUCTION

Hemorrhoids are a very common anorectal condition defined as the symptomatic enlargement and distal displacement of the normal anal cushions. They affect millions of people around the world, and represent a major medical and socioeconomic problem. Multiple factors have been claimed to be the etiologies of hemorrhoidal development, including constipation and prolonged straining. The abnormal dilatation and distortion of the vascular channel, together with destructive changes in the supporting connective tissue within the anal cushion, is a paramount finding of hemorrhoidal disease[1]. An inflammatory reaction[2] and vascular hyperplasia[3,4] may be evident in hemorrhoids. This article firstly reviewed the pathophysiology and other clinical backgrounds of hemorrhoidal disease, followed by the current approaches to

non-operative and operative management.

PATHOPHYSIOLOGY OF HEMORRHOIDAL DISEASE

The exact pathophysiology of hemorrhoidal development is poorly understood. For years the theory of varicose veins, which postulated that hemorrhoids were caused by varicose veins in the anal canal, had been popular but now it is obsolete because hemorrhoids and anorectal varices are proven to be distinct entities. In fact, patients with portal hypertension and varices do not have an increased incidence of hemorrhoids[5].

Today, the theory of sliding anal canal lining is widely accepted[6]. This proposes that hemorrhoids develop when the supporting tissues of the anal cushions disintegrate or deteriorate. Hemorrhoids are therefore the pathological term to describe the abnormal downward displacement of the anal cushions causing venous dilatation. There are typically three major anal cushions, located in the right anterior, right posterior and left lateral aspect of the anal canal, and various numbers of minor cushions lying between them[7] (Figure 1). The anal cushions of patients with hemorrhoids show significant pathological changes. These changes include abnormal venous dilatation, vascular thrombosis, degenerative process in the collagen fibers and fibroelastic tissues, distortion and rupture of the anal subepithelial muscle (Figure 2). In addition to the above findings, a severe inflammatory reaction involving the vascular wall and surrounding connective tissue has been demonstrated in hemorrhoidal specimens, with associated mucosal ulceration, ischemia and thrombosis[2].

Several enzymes or mediators involving the degradation of supporting tissues in the anal cushions have been studied. Among these, matrix metalloproteinase (MMP), a zinc-dependent proteinase, is one of the most potent enzymes, being capable of degrading extracellular proteins such as elastin, fibronectin, and collagen. MMP-9 was found to be over-expressed in hemorrhoids, in association with the breakdown of elastic fibers[8]. Activation of MMP-2 and MMP-9 by thrombin, plasmin or other proteinases resulted in the disruption of the capillary bed and promotion of angioproliferative activity of transforming growth factor β (TGF-β)[9].

Recently, increased microvascular density was found in hemorrhoidal tissue, suggesting that neovascularization might be another important phenomenon of hemorrhoidal disease. In 2004, Chung et al[4] reported that endoglin (CD105), which is one of the binding sites of TGF-β and is a proliferative marker for neovascularization, was expressed in more than half of hemorrhoidal tissue specimens compared to none taken from the normal anorectal mucosa. This marker was prominently found in venules larger than 100 μm. Moreover, these workers found that microvascular density increased in hemorrhoidal tissue especially when thrombosis and stromal vascular endothelial growth factors (VEGF)

Figure 1 Diagram of common sites of major anal and internal hemorrhoids. A: Diagram of common sites of major anal cushions; B: Common sites of internal hemorrhoids.

Figure 2 Pathological changes in hemorrhoids. *: Marked dilatation of hemorrhoidal venous plexus; #: Fragmented anal subepithelial muscle (the Treitz's muscle or mucosal suspensory ligament) (Scale bar = 1 mm).

were present. Han et al[8] also demonstrated that there was a higher expression of angiogenesis-related protein such as VEGF in hemorrhoids.

Regarding the study of morphology and hemodynamics of the anal cushions and hemorrhoids, Aigner et al[3,10] found that the terminal branches of the superior rectal artery supplying the anal cushion in patients with hemorrhoids had a significantly larger diameter, greater blood flow, higher peak velocity and acceleration velocity, compared to those of healthy volunteers. Moreover, an increase in arterial caliber and flow was well correlated with the grades of hemorrhoids. These abnormal findings still remained after surgical removal of the hemorrhoids, confirming the association between hypervascularization and the development of hemorrhoids.

Using an immunohistochemical approach, Aigner et al[3] also identified a sphincter-like structure, formed by a thickened tunica media containing 5-15 layers of smooth muscle cells, between the vascular plexus within the subepithelial space of the anal transitional zone in normal anorectal specimens. Unlike the normal specimens, hemorrhoids contained remarkably dilated, thin-walled vessels within the submucosal arteriovenous plexus, with absent or nearly-flat sphincter-like constriction on the vessels. These investigators concluded that a smooth muscle sphincter in the arteriovenous plexus helps in reducing the arterial inflow, thus facilitating an effective venous drainage. Aigner et al[3] then proposed that, if this mechanism is impaired, hyperperfusion of the arteriovenous plexus will lead to the formation of hemorrhoids.

Based on the histological findings of abnormal

venous dilatation and distortion in hemorrhoids, dys-regulation of the vascular tone might play a role in hemorrhoidal development. Basically, vascular smooth muscle is regulated by the autonomic nervous system, hormones, cytokines and overlying endothelium. Imbalance between endothelium-derived relaxing factors (such as nitric oxide, prostacyclin, and endothelium-derived hyperpolarizing factor) and endothelium-derived vasoconstricting factors (such as reactive oxygen radicals and endothelin) causes several vascular disorders[11]. In hemorrhoids, nitric oxide synthase, an enzyme which synthesizes nitric oxide from L-arginine, was reported to increase significantly[8].

Several physiological changes in the anal canal of patients with hemorrhoids have been observed. Sun et al[12] revealed that resting anal pressure in patients with non-prolapsing or prolapsing hemorrhoids was much higher than in normal subjects, whereas there was no significant change in the internal sphincter thickness. Ho et al[13] performed anorectal physiological studies in 24 patients with prolapsed hemorrhoids and compared with results in 13 sex- and age-matched normal subjects. Before operation, those with hemorrhoids had significantly higher resting anal pressures, lower rectal compliance, and more perineal descent. The abnormalities found reverted to the normal range within 3 mo after hemorrhoidectomy, suggesting that these physiological changes are more likely to be an effect, rather than the cause, of hemorrhoidal disease.

EPIDEMIOLOGY AND RISK FACTORS OF HEMORRHOIDS

Although hemorrhoids are recognized as a very common cause of rectal bleeding and anal discomfort, the true epidemiology of this disease is unknown because patients have a tendency to use self-medication rather than to seek proper medical attention. An epidemiologic study by Johanson et al[14] in 1990 showed that 10 million people in the United States complained of hemorrhoids, corresponding to a prevalence rate of 4.4%. In both sexes, peak prevalence occurred between age 45-65 years and the development of hemorrhoids before the age of 20 years was unusual. Whites and higher socioeconomic status individuals were affected more frequently than blacks and those of lower socioeconomic status. However, this association may reflect differences in health-seeking behavior rather than true prevalence. In the United Kingdom, hemorrhoids were reported to affect 13%-36% of the general population[1,15]. However, this estimation may be higher than actual prevalence because the community-based studies mainly relied on self-reporting and patients may attribute any anorectal symptoms to hemorrhoids.

Constipation and prolonged straining are widely believed to cause hemorrhoids because hard stool and increased intraabdominal pressure could cause obstruction of venous return, resulting in engorgement of the hemorrhoidal plexus[1]. Defecation of hard fecal material increases shearing force on the anal cushions. However, recent evidence questions the importance of constipation in the development of this common disorder[14,16,17]. Many investigators have failed to demonstrate any significant association between hemorrhoids and constipation, whereas some reports suggested that diarrhea is a risk factor for the development of hemorrhoids[16]. Increase in straining for defecation may precipitate the development of symptoms such as bleeding and prolapse in patients with a history of hemorrhoidal disease. Pregnancy can predispose to congestion of the anal cushion and symptomatic hemorrhoids, which will resolve spontaneously soon after birth. Many dietary factors including low fiber diet, spicy foods and alcohol intake have been implicated, but reported data are inconsistent[1].

CLASSIFICATION AND GRADING OF HEMORRHOIDS

A hemorrhoid classification system is useful not only to help in choosing between treatments, but also to allow the comparison of therapeutic outcomes among them. Hemorrhoids are generally classified on the basis of their location and degree of prolapse. Internal hemorrhoids originate from the inferior hemorrhoidal venous plexus above the dentate line and are covered by mucosa, while external hemorrhoids are dilated venules of this plexus located below the dentate line and are covered with squamous epithelium. Mixed (interno-external) hemorrhoids arise both above and below the dentate line. For practical purposes, internal hemorrhoids are further graded based on their appearance and degree of prolapse, known as Goligher's classification: (1) First-degree hemorrhoids (grade I): The anal cushions bleed but do not prolapse; (2) Second-degree hemorrhoids (grade II): The anal cushions prolapse through the anus on straining but reduce spontaneously; (3) Third-degree hemorrhoids (grade III): The anal cushions prolapse through the anus on straining or exertion and require manual replacement into the anal canal; and (4) Fourth-degree hemorrhoids (grade IV): The prolapse stays out at all times and is irreducible. Acutely thrombosed, incarcerated internal hemorrhoids and incarcerated, thrombosed hemorrhoids involving circumferential rectal mucosal prolapse are also fourth-degree hemorrhoids[18].

Some authors proposed classifications based on anatomical findings of hemorrhoidal position, described as primary (at the typical three sites of the anal cushions), secondary (between the anal cushions), or circumferential, and based on symptoms described as prolapsing and non-prolapsing[19]. However, these classifications are in less widespread use.

CLINICAL EVALUATION OF HEMORRHOIDS

The most common manifestation of hemorrhoids is painless rectal bleeding associated with bowel move-

ment, described by patients as blood drips into toilet bowl. The blood is typically bright red as hemorrhoidal tissue has direct arteriovenous communication[3]. Positive fecal occult blood or anemia should not be attributed to hemorrhoids until the colon is adequately evaluated especially when the bleeding is atypical for hemorrhoids, when no source of bleeding is evident on anorectal examination, or when the patient has significant risk factors for colorectal neoplasia[18].

Prolapsing hemorrhoids may cause perineal irritation or anal itching due to mucous secretion or fecal soiling. A feeling of incomplete evacuation or rectal fullness is also reported in patients with large hemorrhoids. Pain is not usually caused by the hemorrhoids themselves unless thrombosis has occurred, particularly in an external hemorrhoid or if a fourth-degree internal hemorrhoid becomes strangulated. Anal fissure and perianal abscess are more common causes of anal pain in hemorrhoidal patients.

The definite diagnosis of hemorrhoidal disease is based on a precise patient history and careful clinical examination. Assessment should include a digital examination and anoscopy in the left lateral position. The perianal area should be inspected for anal skin tags, external hemorrhoid, perianal dermatitis from anal discharge or fecal soiling, fistula-in-ano and anal fissure. Some physicians prefer patients sitting and straining in the squatting position to watch for the prolapse. Although internal hemorrhoids cannot be palpated, digital examination will detect abnormal anorectal mass, anal stenosis and scar, evaluate anal sphincter tone, and determine the status of prostatic hypertrophy which may be the reason for straining as this aggravates descent of the anal cushions during micturition. Hemorrhoidal size, location, severity of inflammation and bleeding should be noted during anoscopy. Intrarectal retroflexion of the colonoscope or transparent anoscope with flexible endoscope also allow excellent visualization of the anal canal and hemorrhoid, and permit recording pictures[20].

MANAGEMENT OF HEMORRHOIDAL DISEASE

Therapeutic treatment of hemorrhoids ranges from die-tary and lifestyle modification to radical surgery, depending on degree and severity of symptoms[21,22]. The current management of internal hemorrhoids is illustrated in Table 1. In addition, selected meta-analyses showing various treatment options of hemorrhoidal disease are shown in Table 2[23-32].

Dietary and lifestyle modification
Since shearing action of passing hard stool on the anal mucosa may cause damage to the anal cushions and lead to symptomatic hemorrhoids, increasing intake of fiber or providing added bulk in the diet might help eliminate straining during defecation. In clinical studies of hemorrhoids, fiber supplement reduced the risk of persisting symptoms and bleeding by approximately 50%, but did not improve the symptoms of prolapse, pain, and itching[26]. Fiber supplement is therefore regarded as an effective treatment in non-prolapsing hemorrhoids; however, it could take up to 6 wk for a significant improvement to be manifest[33]. As fiber supplements are safe and cheap, they remain an integral part of both initial treatment and of a regimen following other therapeutic modalities of hemorrhoids.

Lifestyle modification should also be advised to any patients with any degree of hemorrhoids as a part of treatment and as a preventive measure. These changes include increasing the intake of dietary fiber and oral fluids, reducing consumption of fat, having regular exercise, improving anal hygiene, abstaining from both straining and reading on the toilet, and avoiding medication that causes constipation or diarrhea.

Medical treatment
Oral flavonoids: These venotonic agents were first described in the treatment of chronic venous insufficiency and edema. They appeared to be capable of increasing vascular tone, reducing venous capacity, decreasing capillary permeability[34], and facilitating lymphatic drainage[35] as well as having anti-inflammatory effects[36]. Although their precise mechanism of action remains unclear, they are used as an oral medication for hemorrhoidal treatment, particularly in Europe and Asia. Micronized purified flavonoid fraction (MPFF), consisting of 90% dios-

Table 2 Selected meta-analyses showing various treatment options for hemorrhoidal disease (in order of publication year)

Authors	Characteristics of comparative studies	Number of trials (total cases)	Results
Johanson et al[23]	IC, IS and RBL	5 (863)	RBL had greater long-term efficacy, but led to a higher incidence of post-treatment pain. IC was associated with both fewer and less severe complications
MacRae et al[24]	IC, IS, RBL, manual anal dilation and hemorrhoidectomy	18 (1952)[1]	Hemorrhoidectomy was more effective than manual anal dilation and RBL, but more pain and complications. RBL had greater efficacy than IS for treating grade Ⅰ-Ⅲ hemorrhoids, with no difference in the complication rate. Patients treated with IC or IS were more likely to require further therapy
Shanmugam et al[25]	RBL vs hemorrhoidectomy	3 (202)	Hemorrhoidectomy was superior to RBL for the long-term treatment of grade Ⅲ, not grade Ⅱ, hemorrhoids. Although hemorrhoidectomy had more pain, higher complications and more time off work, patient satisfaction and acceptance of the two treatment modalities seems to be similar
Alonso-Coello et al[26]	Fiber vs no therapy	7 (378)	Fiber reduced the risk of bleeding and persisting by 50% and 47%, respectively, but it had no significant effect on pain and prolapse
Alonso-Coello et al[27]	Oral flavonoids vs placebo or no therapy	14 (1514)	Flavonoids reduced the risk of bleeding, pain, persisting symptoms and recurrence by 67%, 65%, 58% and 47%, respectively
Ho et al[28]	Closed vs open hemorrhoidectomy	6 (686)	Closed hemorrhoidectomy had faster wound healing but longer operating time. There was no difference in treatment efficacy, pain, complication and hospital stay between the two operations
Nienhuijs et al[29]	Conventional vs ligasure hemorrhoidectomy	12 (1142)	Ligasure hemorrhoidectomy resulted in significantly shorter operative time, less early postoperative pain, earlier recovery, without any difference in recurrent bleeding or incontinence
Burch et al[30]	Hemorrhoidectomy vs SH	27 (2279)	SH had less postoperative pain, shorter operative time, shorter hospital stay, and shorter convalescence, but a higher rate of prolapse and reintervention for prolapse
Giordano et al[31]	Hemorrhoidectomy vs SH (minimum follow-up of 1 yr)	15 (1201)	SH had a significantly higher incidence of recurrences and additional operations
Gan et al[32]	Various TCMH vs another TCMH or Western medicines	9 (1822)	TCMHs significantly improved overall symptoms and bleeding as well as decreased the inflammation of perianal mucosa

[1]With available detailed data on the patients enrolled. IC: Infrared coagulation; IS: Injection sclerotherapy; RBL: Rubber band ligation; SH: Stapled hemorrhoidopexy; TCMH: Traditional Chinese medicinal herbs.

min and 10% hesperidin, is the most common flavonoid used in clinical treatment[27]. The micronization of the drug to particles of less than 2 μm not only improved its solubility and absorption, but also shortened the onset of action. A recent meta-analysis of flavonoids for hemorrhoidal treatment, including 14 randomized trials and 1514 patients, suggested that flavonoids decreased risk of bleeding by 67%, persistent pain by 65% and itching by 35%, and also reduced the recurrence rate by 47%[27]. Some investigators reported that MPFF can reduce rectal discomfort, pain and secondary hemorrhage following hemorrhoidectomy[37].

Oral calcium dobesilate: This is another venotonic drug commonly used in diabetic retinopathy and chronic venous insufficiency as well as in the treatment of acute symptoms of hemorrhoids[38]. It was demonstrated that calcium dobesilate decreased capillary permeability, inhibited platelet aggregation and improved blood viscosity; thus resulting in reduction of tissue edema[39]. A clinical trial of hemorrhoid treatment showed that calcium dobesilate, in conjunction with fiber supplement, provided an effective symptomatic relief from acute bleeding, and it was associated with a significant improvement in the inflammation of hemorrhoids[40].

Topical treatment: The primary objective of most topical treatment aims to control the symptoms rather than to cure the disease. Thus, other therapeutic treatments could be subsequently required. A number of topical preparations are available including creams and suppositories, and most of them can be bought without a prescription. Strong evidence supporting the true efficacy of these drugs is lacking. These topical medications can contain various ingredients such as local anesthesia, corticosteroids, antibiotics and anti-inflammatory drugs[41].

Topical treatment may be effective in selected groups of hemorrhoidal patients. For instance, Tjandra et al[42] showed a good result with topical glyceryl trinitrate 0.2% ointment for relieving hemorrhoidal symptoms in patients with low-grade hemorrhoids and high resting anal canal pressures. However, 43% of the patients experienced headache during the treatment. Perrotti et al[43] reported the good efficacy of local application of nifedipine ointment in treatment of acute thrombosed external hemorrhoids. It is worth noting that the effect of topical application of nitrite and calcium channel blocker on the symptomatic relief of hemorrhoids may be a consequence of their relaxation effect on the internal anal sphincter, rather than on the hemorrhoid tissue *per se* where one might anticipate a predominantly vasodilator effect.

Apart from topical medication influencing tone of the internal anal sphincter, some topical treatment targets vasoconstriction of the vascular channels within hemorrhoids such as Preparation-H® (Pfizer, United States), which contains 0.25% phenylephrine, petrola-

tum, light mineral oil, and shark liver oil. Phenylephrine is a vasoconstrictor having preferential vasopressor effect on the arterial site of circulation, whereas the other ingredients are considered protectants. Preparation-H is available in many forms, including ointment, cream, gel, suppositories, and medicated and portable wipes[44]. It provides temporary relief of acute symptoms of hemorrhoids, such as bleeding and pain on defecation.

Non-operative treatment

Sclerotherapy: This is currently recommended as a treatment option for first- and second-degree hemorrhoids. The rationale of injecting chemical agents is to create a fixation of mucosa to the underlying muscle by fibrosis. The solutions used are 5% phenol in oil, vegetable oil, quinine, and urea hydrochloride or hypertonic salt solution[22]. It is important that the injection be made into submucosa at the base of the hemorrhoidal tissue and not into the hemorrhoids themselves; otherwise, it can cause immediate transient precordial and upper abdominal pain[45]. Misplacement of the injection may also result in mucosal ulceration or necrosis, and rare septic complications such as prostatic abscess and retroperitoneal sepsis[46]. Antibiotic prophylaxis is indicated for patients with predisposing valvular heart disease or immunodeficiency because of the possibility of bacteremia after sclerotherapy[47].

Rubber band ligation: Rubber band ligation (RBL) is a simple, quick, and effective means of treating first- and second-degree hemorrhoids and selected patients with third-degree hemorrhoids. Ligation of the hemorrhoidal tissue with a rubber band causes ischemic necrosis and scarring, leading to fixation of the connective tissue to the rectal wall. Placement of rubber band too close to the dentate line may cause severe pain due to the presence of somatic nerve afferents and requires immediate removal. RBL is safely performed in one or more than one place in a single session[48] with one of several commercially available instruments, including hemorrhoid ligator rectoscope[49] and endoscopic ligator[50] which use suction to draw the redundant tissue in to the applicator to make the procedure a one-person effort.

The most common complication of RBL is pain or rectal discomfort, which is usually relieved by warm sitz baths, mild analgesics and avoidance of hard stool by taking mild laxatives or bulk-forming agents. Other complications include minor bleeding from mucosal ulceration, urinary retention, thrombosed external hemorrhoids, and extremely rarely, pelvic sepsis. The patients should stop taking anticoagulants for one week before and two weeks after RBL.

Infrared coagulation: The infrared coagulator produces infrared radiation which coagulates tissue and evaporizes water in the cell, causing shrinkage of the hemorrhoid mass. A probe is applied to the base of the hemorrhoid through the anoscope and the recommended contact time is between 1.0-1.5 s, depending on the intensity and wavelength of the coagulator[51]. The necrotic tissue is seen as a white spot after the procedure and eventually heals with fibrosis. Compared with sclerotherapy, infrared coagulation (IRC) is less technique-dependent and avoids the potential complications of misplaced sclerosing injection[22]. Although IRC is a safe and rapid procedure, it may not be suitable for large, prolapsing hemorrhoids.

Radiofrequency ablation: Radiofrequency ablation (RFA) is a relatively new modality of hemorrhoidal treatment. A ball electrode connected to a radiofrequency generator is placed on the hemorrhoidal tissue and causes the contacting tissue to be coagulated and evaporized[52]. By this method, vascular components of hemorrhoids are reduced and hemorrhoidal mass will be fixed to the underlying tissue by subsequent fibrosis. RFA can be performed on an outpatient basis and *via* an anoscope similar to sclerotherapy. Its complications include acute urinary retention, wound infection, and perianal thrombosis. Although RFA is a virtually painless procedure, it is associated with a higher rate of recurrent bleeding and prolapse[53].

Cryotherapy: Cryotherapy ablates the hemorrhoidal tissue with a freezing cryoprobe. It has been claimed to cause less pain because sensory nerve endings are destroyed at very low temperature. However, several clinical trials revealed that it was associated with prolonged pain, foul-smelling discharge and a high rate of persistent hemorrhoidal mass[54]. It is therefore rarely used.

There are two meta-analyses comparing outcomes among the three common non-operative treatments of hemorrhoids (sclerotherapy, RBL and IRC)[23,24]. These two studies demonstrated that RBL resulted in the fewest recurrent symptoms of hemorrhoids and the lowest rate of retreatment, but that it led to a significantly higher incidence of pain following the procedure. Hence, RBL could be recommended as the initial non-operative modality for treatment of grade I - III hemorrhoids. In a British survey of almost 900 general and colorectal surgeons[55], RBL was the most common procedure performed, following by sclerotherapy and hemorrhoidectomy.

Operative treatment

An operation is indicated when non-operative approaches have failed or complications have occurred. Different philosophies regarding the pathogenesis of hemorrhoidal disease creates different surgical approaches (Table 3).

Hemorrhoidectomy: Excisional hemorrhoidectomy is the most effective treatment for hemorrhoids with the lowest rate of recurrence compared to other modalities[24]. It can be performed using scissors, diathermy[56,57], or vascular-sealing device such as Ligasure (Covidien, United States)[29,58] and Harmonic scalpel (Ethicon Endosurgery, United States)[59,60]. Excisional hemorrhoidectomy can be performed safely under perianal anesthetic infiltration as an ambulatory surgery[61,62]. Indications for hemorrhoidectomy include failure of non-operative management,

Table 3 Summary of different philosophies regarding the pathogenesis of hemorrhoids and related surgical approaches

Theory	Short description	Surgical approach
Sliding anal cushions	Hemorrhoids develop when the supporting tissues of the anal cushions disintegrate or deteriorate	Hemorrhoidectomy, plication
Rectal redundancy	Hemorrhoidal prolapse is associated with an internal rectal prolapse	Stapled hemorrhoidopexy
Vascular abnormality	Hyperperfusion of arteriovenous plexus within anal cushion results in the formation of hemorrhoids	Doppler-guided hemorrhoidal artery ligation

acute complicated hemorrhoids such as strangulation or thrombosis, patient preference, and concomitant anorectal conditions such as anal fissure or fistula-in-ano which require surgery[18]. In clinical practice, the third-degree or fourth-degree internal hemorrhoids are the main indication for hemorrhoidectomy.

A major drawback of hemorrhoidectomy is postoperative pain[62]. There has been evidence that Ligasure hemorrhoidectomy results in less postoperative pain, shorter hospitalization, faster wound healing and convalescence compared to scissors or diathermy hemorrhoidectomy[63-65]. Other postoperative complications include acute urinary retention (2%-36%), postoperative bleeding (0.03%-6%), bacteremia and septic complications (0.5%-5.5%), wound breakdown, unhealed wound, loss of anal sensation, mucosa prolapse, anal stricture (0%-6%), and even fecal incontinence (2%-12%)[66-69]. Recent evidence has suggested that hemorrhoidal specimens can be exempt from pathological examination if no malignancy is suspected[70].

Plication: Plication is capable of restoring anal cushions to their normal position without excision. This procedure involves oversewing of hemorrhoidal mass and tying a knot at the uppermost vascular pedicle. However, there are still a number of potential complications following this procedure such as bleeding and pelvic pain[21].

Doppler-guided hemorrhoidal artery ligation: A new technique based on doppler-guided ligation of the terminal branches of the superior hemorrhoidal artery was introduced in 1995 as an alternative to hemorrhoidectomy[71]. Doppler-guided hemorrhoidal artery ligation (DGHAL) has become increasingly popular in Europe. The rationale of this treatment was later supported by the findings from vascular studies[3,10], which demonstrated that patients with hemorrhoids had increased caliber and arterial blood flow of the terminal branch of the superior rectal arteries. Therefore, ligating the arterial supply to hemorrhoidal tissue by suture ligation may improve hemorrhoidal symptoms. DGHAL is most effective for second- or third-degree hemorrhoids. Notably, DGHAL may not improve prolapsing symptoms in advanced hemorrhoids. Short-term outcomes and 1-year recurrence rates of DGHAL did not differ from those of conventional hemorrhoidectomy[72]. Given the fact that there is the possibility of revascularization and recurrence of symptomatic hemorrhoids, further studies on the long-term outcomes of DGHAL are still required[73].

Stapled hemorrhoidopexy: Stapled hemorrhoidopexy (SH) has been introduced since 1998[74]. A circular stapling device is used to excise a ring of redundant rectal mucosa proximal to hemorrhoids and resuspend the hemorrhoids back within the anal canal. Apart from lifting the prolapsing hemorrhoids, blood supply to hemorrhoidal tissue is also interrupted. A recent meta-analysis comparing surgical outcomes between SH and hemorrhoidectomy, which included 27 randomized, controlled trials with 2279 procedures, showed that SH was associated with less pain, earlier return of bowel function, shorter hospital stay, earlier return to normal activities, and better wound healing, as well as higher degree of patient satisfaction[30]. However, in the longer term, SH was associated with a higher rate of prolapse[30,31,75]. Considering the recurrence rate, cost of stapling device and potential serious complications including rectovaginal fistula[76] and rectal stricture[77,78], SH is generally reserved for patients with circumferential prolapsing hemorrhoids and having ≥ 3 lesions of advanced internal hemorrhoids.

These two recent surgical options, DGHAL and SH, aim to correct the pathophysiology of hemorrhoids by reducing blood flow to the anal canal (dearterialization) and eliminating anorectal mucosal prolapse (reposition), respectively. A recent retrospective study of 18-mo outcomes of DGHAL ($n = 51$) and SH ($n = 63$) for grade Ⅲ hemorrhoids revealed that both procedures were safe and effective. DGHAL had less pain, shorter hospital stay, and faster functional recovery; however, it was associated with higher recurrence rate and lower patient satisfaction rating[79]. Lately, a smaller prospective trial comparing DGHAL to SH for grade Ⅱ-Ⅲ hemorrhoids showed similar short-term and long-term outcomes of the two procedures[80]. Nevertheless, patients undergoing DGHAL returned to work quicker, and had fewer complication rates than those receiving SH.

CONCLUSION

Therapeutic treatment of hemorrhoids ranges from dietary and lifestyle modification to radical surgery, depending on degree and severity of symptoms. Although surgery is an effective treatment of hemorrhoids, it is reserved for advanced disease and it can be associated with appreciable complications. Meanwhile, non-operative treatments are not fully effective, in particular those of topical or pharmacological approach. Hence, improvements in our understanding of the pathophysiology of hemorrhoids are needed to prompt the development of novel and innova-

tive methods for the treatment of hemorrhoids.

Abstract

Human stem cells are scalable cell populations capable of cellular differentiation. This makes them a very attractive *in vitro* cellular resource and in theory provides unlimited amounts of primary cells. Such an approach has the potential to improve our understanding of human biology and treating disease. In the future it may be possible to deploy novel stem cell-based approaches to treat human liver diseases. In recent years, efficient hepatic differentiation from human stem cells has been achieved by several research groups including our own. In this review we provide an overview of the field and discuss the future potential and limitations of stem cell technology.

INTRODUCTION

End stage liver disease (ESLD) is an irreversible condition that leads to the eventual failure of the liver. It may be the final stage of many liver diseases, for example, viral hepatitis, autoimmune hepatic disorders, fatty liver disease, drug induced liver injury, and hepatocellular carcinoma, with extremely poor prognosis. The incidence of ESLD is increasing worldwide[1], and current optimal treatment for ESLD is orthotopic liver transplantation[2]. However limited availability of donor livers and immunological incompatibilities are two major obstacles to its routine deployment[3]. This highlights the important need for alternative therapeutic strategies. Researchers have proposed that stem cell biology could provide a scalable answer for the treatment of ESLD, providing cells for transplant and/or cell sources for studying liver disorders and identifying novel treatments.

Cell-based therapy requires the use of cells to replace or facilitate the repair of damaged tissue. Candidate cells for this approach include bipotential, multipotent, pluripotent cells, and primary hepatocytes. Pluripotent stem cells (PSCs), including human embryonic stem cells (hESCs) and induced pluripotent stem cells (iPSCs), possess the ability to self renew and differentiate into all somatic cells, offering unlimited potential and are not restricted by donor tissue supply.

hESCs are derived from the inner cell mass of the human blastocyst, and can differentiate into all three primary germ layers[4]. Human iPSCs are produced by forced

expression of specific stem cell genes[5]. In recent years, researchers have developed robust procedures to generate functional hepatocyte-like cells (HLCs) from both PSC populations[6-8]. However, it is notable that PSC strategies have not yielded, as yet, a cell type that appropriately contributes to tissue homeostasis as cell transplantation frequently results in tumour formation[9,10]. As a result, scalable cell-based therapies from PSCs are likely to be longer-term strategies which require significant refinement.

Extra-corporeal support has been proposed as a mid-term strategy, in particular bio-artificial livers, to treat human liver disease. Bio-artificial livers (BALs) are designed to filter and biotransform toxic substances, and have been used successfully to bridge patients to transplant or treat acute liver failure. Research demonstrates that BALs can reduce mortality in acute liver failure compared with traditional standard medical therapy[11,12], but the application has been severely limited by the poor availability of functional human hepatocytes. By employing PSC technology, it may now be possible to produce humanised BAL devices at reasonable cost.

In addition to their important role in the clinic, human hepatocytes have a critical part to play in the drug discovery process. Many candidate compounds fail at late stage or even after approval due to unanticipated toxicity. In routine drug discovery, the pharmaceutical industry deploys the tumor-derived cells and primary hepatocytes to screen compounds. While these models are useful, they do not always extrapolate to human biology and exhibit poor lifespan and variable metabolic activity. PSCs-derived hepatocytes have the potential to overcome these problems. Advances in stem cell biology and reprograming have allowed the development of novel models which have the potential to provide another level of understanding behind the pathophysiology of liver diseases. iPSC modelling also provides us with potential system to better understand the influence of gene polymorphisms.

Human PSCs derived HLCs show great promise for research and clinical applications including cell-based therapies, drug development, and disease modeling. This review gives an overview of human hepatic differentiation from PSCs and their potential application in modern medicine.

CURRENT CELL SOURCES USED IN HEPATOLOGY

Primary human hepatocytes and liver cancer cell lines

Hepatocytes are the principle cell type found in the liver and perform the majority of the liver functions. Primary human hepatocytes (PHHs) are therefore a useful tool for medical applications such as cell-based therapy and drug discovery. However, PHHs are mainly obtained from scarce and low quality resected surgical specimens[13]. The scarcity and variability in these preparations restricts their widespread application *in vitro*[14]. Therefore liver cell lines have been employed routinely as they dem-

onstrate long lifespan and are easy to maintain. HepG2 is a liver cell line derived from fetal tissue which exhibits poor metabolic function and secrete a variety of soluble serum proteins[15]. They have been used as a model system for cytochrome P450 (CYP) metabolism and toxicity. And additionally they have been used in clinical trials with bioartificial liver devices[16,17]. Interestingly, a clonal derivative of the HepG2 line, C3A, demonstrates marked reduction in α-fetoprotein (AFP) and increased albumin (ALB) secretion, indicating a more mature status *in vitro*. More recently, a new human hepatoma cell line has been derived. HepaRG demonstrates a number of liver-specific functions including the expression of CYP 1A2, 2B6, 2C9, 2E1, 3A4[18,19] and better overall performance than existing liver cell lines. Although informative and scalable, liver cancer cell lines show lower drug-metabolizing activity than their adult counterparts and do not accurately predict human drug toxicity[20] and therefore do not constitute a real alternative to the gold standard primary hepatocyte. Moreover, such cells may provide interesting *in vitro* models or the bio-component of the BAL, but they could not be used for cell transplantation *in vivo*.

Oval cells and hepatoblasts

Oval cells are an adult liver cell population that emerges from the biliary tree following chronic liver injury. Several studies have investigated the transplantation of oval cells showing that these bipotential cells could proliferate and contribute to both parenchyma and biliary epithelia *in vivo*[21-28]. Oval cells express the stem cell markers Thy-1 (CD90), CD34 and Sca-1, along with liver-specific markers, including AFP, Gamma-glutamyltransferase, laminin and cytokeratin 19 (CK 19)[23,24].

The tissue microenvironment plays an essential role in orchestrating oval cell-mediated liver regeneration. Laminin contributes to the maintenance of undifferentiated progenitor cells and progenitor cell-mediated tissue repair[29]. Moreover, Kallis *et al*[30] demonstrated that extracellular matrix (ECM) remodelling during resolution and laminin deposition was likely to be important prerequisite to hepatic progenitor cell activation, expansion and repair.

Similar to oval cells, hepatoblasts from fetal liver could also represent a potential source of hepatocytes and biliary epithelial cells[24,31]. The bipotential nature of this cell type also makes it an attractive target for therapy. Transplant studies demonstrate that hepatoblasts may be a potential therapeutic strategy for ESLDs or hepatic failure. Although great progress in the fundamental research and clinical application have been made, there are still limitations to widespread use of these cells, such as low cell number *in vivo*, no specific biomarker for purification and poor expansion *in vitro*.

Bone marrow stem cells and mesenchymal stem cell

The bone marrow (BM) contains stem cells populations *in vivo*. They can be roughly divided into of hematopoietic (HSCs) and nonhematopoietic stem cells usually referred

to as mesenchymal stem cells (MSCs). The great success of BM stem cell for treatment of leukaemia has attracted scientists to use these cells for other serious diseases such as ESLD. Analysis of BM transplant into mouse models and patients have demonstrated that transplanted BM could contribute to partial correction of hepatic function[32-34]. However, the role of BM is controversial; some researchers found that BM didn't contribute to hepatocyte or biliary cell differentiation and liver regeneration, but actually contributed to liver fibrosis[35,36], which raises serious safety concerns.

Similar to BM, MSCs have been successfully transplanted[37]. They are multipotent stem cells capable of mesodermal, neuro-ectodermal and endodermal differentiation depending on surrounding microenvironment[38-41]. In addition, MSCs have anti-fibrotic properties inhibiting activated fibrogenic cells such as hepatic stellate cells[42]. The role of MSCs in liver regeneration and disease has been evidenced in animal models. Moreover MSC based therapies for patients with ESLDs have shown promise in phase I and II clinical trials[37,43,44]. Treatment was well tolerated by all patients with liver fibrosis and heptic function improved following MSCs transplantation[37] and during the follow-up[43]. Peng *et al*[45] reported that the biochemical hepatic index and MELD score were markedly improved from 2-3 wk post transplantation. However, long-term hepatic function were not significantly enhanced in 527 patients with liver failure caused by hepatitis B. Although MSC transplantation confers benefit to patients with liver cirrhosis, it may not be applicable to all kind of ESLDs.

HEPATIC DIFFERENTIATION FROM PLURIPOTENT STEM CELLS

Human ESCs are derived from the inner cell mass of blastocyst stage embryos and are highly primitive cells which exhibit pluripotency and the ability to self-renew[4,46]. Rambhatla *et al*[47] reported the directed differentiation of human ESCs to HLCs for the first time in 2003, which could express some hepatocyte markers. Since then labs have established more robust and efficient procedures to derive better functioning HLCs. Embryoid body (EB) formation has been one method to differentiate ESCs into hepatocytes. However, this approach exhibits limitations to scale and culture definition. Therefore, monolayer adherent culture systems have been developed to direct ESC hepatic differentiation into hepatocytes, which bypass these limitations[6,48-51]. We developed a simple 3-stage procedure by which hESCs can be directly differentiated to HLCs at an efficiency of about 90%[6,8]. Our research demonstrated that Wnt3a signaling was important in this process, improving hepatocellular function both *in vitro* and *in vivo*[6,52]. Most recently we identified a novel polyurethane extra cellular support which delivers long-term and stable HLC function which is drug inducible[53].

In 2006, it was demonstrated that murine fibroblasts

could be reprogrammed into a pluripotent state similar to that observed in ESCs[54]. Subsequently Takahashi *et al*[5] and Park *et al*[55] successfully reprogrammed human somatic cells into iPSCs. They generated PSCs from human skin through ectopic expression of four genes (*Oct3/4, Sox2, c-Myc,* and *Klf4*), which were known to be involved in the induction of murine pluripotency. Since these experiments researchers continue to refine and simplify the reprogramming process.

Human iPSCs and ESCs display similar morphologies, proliferation rates and expression of a number of stem cell biomarkers. However, specific differences between ESCs and iPSCs exist. Obviously the biggest difference is that iPSCs are derived from adult tissues. In addition, some comparative genomic analyses shows that hundreds of genes are differentially expressed in these two cell types[56]. Given their adult origin, iPSCs can contain an epigenetic "memory" of the donor tissue[57,58], which can restrict their differentiation potential and therefore utility.

iPSCs have been differentiated to numerous cell types[59], including hepatocytes. We and others have devised efficient methods to generate hepatocytes *in vitro*[7,60,61]. The derivative HLCs from both hESC and iPSC models demonstrate a similar expression of genes important for normal liver physiology. Jozefczuk *et al*[62] demonstrated 80% similarity of gene expression between HLCs derived from hESCs or iPSCs. Additionally, there were specific differences between the types of HLCs derived from ESCs and iPSCs in particular the *CYP* genes.

Most recently a study reported the direct conversion of murine fibroblasts to HLCs without the need for cellular pluripotency. In two studies HLC differentiation was conferred using either Gata4, Hnf1α and Foxa3, or HNF4a in combination with Foxa1, Foxa2 or Foxa3[63,64]. HLCs exhibited hepatic gene expression and function *in vitro* and rescued fumarylacetoacetate-hydrolase-deficient (Fah-/-) mice *in vivo*[63,64]. These studies provide another alternative method of hepatic conversion, which offer potential for liver research and therapy.

HEPATIC DIFFERENTIATION IN CELL-BASED THERAPIES AND TOOLS

Hepatic differentiation for cell-based therapy

PSCs offer a possible source to treat liver disease. Cell therapy for liver disease includes transplantation (including genome edited cells to correct metabolic defects[65]) and bio-artificial liver devices. The cell-based approaches are very encouraging, but further studies are required to demonstrate long-term safety of cell-based transplantation[9,10]. In the interim BALs containing hepatocytes could provide alternative support for patients with acute hepatic failure or awaiting liver transplantation. Efforts to generate long-lived functional HLCs may allow the development of more highly effective BALs. The potential application of human stem cells in cell-based therapy for liver diseases is summarised in Figure 1.

Figure 1 Potential application of human stem cells in cell based therapy for liver disease. Pluripotent and multipotent stem cells can be reprogrammed or purified from human material that was been ethically sourced. Following expansion and differentiation the derivative hepatocyte like cells can be used for transplantation or bio-artificial liver construction.

Figure 2 Human liver cells in drug discovery[7,53,66,67]. Drug development process is a lengthy and expensive process. The derivation of hepatocyte-like cells from different human genotypes may provide novel *in-vitro* models for the screening of new compounds in the drug discovery process.

Hepatic differentiation for drug discovery

The drug development process is a hugely expensive process, due to its length and high levels of compound attrition. Drug development proceeds through several stages in order to produce a drug that is safe, efficacious, and meets regulatory requirements (Figure 2). The liver plays a central role in the metabolism of a majority of drugs. Therefore, a standardized screening model with human hepatocytes for new drug compounds could help to reduce drug attrition and costs. Traditional cell models for drug discovery include primary human hepatocytes, immortalised cell lines and animal tissues; however, these cell sources possess a number of limitations including poor function, species variability and instability in culture[14,20]. Advances in PSCs research and liver engineering

have provided models that may overcome some of the problems associated with existing technology. Moreover, in parallel with extracorporeal device development, stem-cell-derived HLCs in three dimensional (3D) are more likely to mimic human liver properties *in vitro*.

Hepatic differentiation for disease modelling

PSCs have provided scientists with novel models to study human liver disease. Rashid *et al*[60] reported an effective procedure for hepatocyte generation from iPSCs exhibiting disease mutations. Using these cells, they modeled inherited metabolic disorders that affect the liver; alpha1-antitrypsin deficiency, familial hypercholesterolemia, and glycogen storage disease type 1a. These models accurately reflected elements of the disease process. More recently research iPSCs, obtained from patients with tyrosinemia, glycogen storage disease, progressive familial hereditary cholestasis, and Crigler-Najjar syndrome, were differentiated into functioning HLCs[68]. These inherited liver diseases that mainly arise as a result of loss of function mutation, therefore these studies offers a unique opportunity to study the effects of specific gene defects on human liver biology and to better understand liver pathogenesis in disease.

Improving hepatic differentiation

PSC technologies have the potential to produce unlimited amounts of human liver cells. As discussed above, human hepatocytes from PSCs could be utilized for cell-based therapy, assessment of drug toxicity and disease modelling. Therefore, the PSC-derived HLCs should be reliable, stable in character and display high levels of metabolic activity. A better understanding of human liver development and optimal tissue microenvironments are likely to play an important role in this process.

HUMAN LIVER DEVELOPMENT

Liver development occurs through a series of reciprocal tissue interactions between the embryonic endoderm and

Figure 3 Human fetal liver development[31,74]. The key stages of human liver development are shown in pink and blue. Endoderm formation occurs in the 2nd-3rd wk of fetal development. The liver bud forms between week 3-4 and expands rapidly. Hepatocytes and biliary epithelia differentiate and mature from 7 wk post fertilisation and this process continues in the neo-nate.

nearby mesoderm. Endoderm contributes to the digestive tract and has a principal role in the development of the liver (Figure 3). The secretions of fibroblast growth factor (FGF) and bone morphogenetic protein (BMP) from the cardiac mesoderm and septum transversum mesenchyme (STM) help orchestrate human liver development from foregut endoderm in concert[69] with canonical Wnt signalling[6,70,71]. Three to 4 wk post fertilisation cells called hepatoblasts, positive for CK19 and HepPar1, are detected for the first time[31]. The hepatoblasts proliferate and form the liver bud. The hepatic endoderm thickens into a columnar epithelium, and hepatoblasts delaminate and invade the STM and undergo cellular proliferation and differentiation. Experiments have shown that a number of factors such as FGF, epidermal growth factor (EGF), hepatocyte growth factor (HGF), transforming growth factor (TGF), tumor necrosis factors (TNF), and interleukin-6 contribute to the hepatocytes proliferation and differen-

tiation[72,73]. Between 6-8 wk gestation, the bile duct and hepatic structure are easily identified[31]. Maturation of hepatocytes and bile epithelial cells continues after birth. An overview of embryonic liver development is summarized in Figure 3.

IMPROVING CELL CULTURE MICROENVIRONMENT

The tissue microenvironment also plays an essential role in liver development and hepatic differentiation. Two dimensional (2D) hepatic differentiation is probably the most widely used system in laboratories. While this technology is efficient and scalable, there are several drawbacks related to 2D culture, including poor drug inducibility and rapid cell dedifferentiation. During human liver development, hepatocytes mature in a 3D environment with a number of cell types providing support.

In light of the increasing need for better-differentiated hepatocytes from PSCs, we and others have developed 3D systems to improve and stabilize hepato-cellular phenotype[53,75,76].

Undoubtedly 3D culture leads to improvements in hepatic function. In the future modulation of oxygenation and physiological delivery of nutrients in 3D environment have great potential to improve cell phenotype and therefore utility.

CONCLUSION

The development of hESC and iPSC technology has led to a new era of discovery in liver medicine. Advances in PSC technology offer the promise of scalable human hepatocytes for cell-based therapies, assessment of drug efficacy and toxicity, and disease modelling. The challenge remains to cost effectively scale up this technology for industrial manufacture. A better knowledge of liver development and the use of novel supportive culture systems will help to improve the manner in which we derive mature human hepatocytes.

Abstract

AIM: To investigate the anti-oxidative and anti-fibrotic effects of aloe vera in patients with liver fibrosis.

METHODS: Aloe vera high molecular weight fractions (AHM) were processed by patented hyper-dry system in combination of freeze-dry technique with microwave and far infrared-ray radiation. Fifteen healthy volunteers as the control group and 40 patients were included. The patients were randomly subdivided into two equal groups: the conventional group was treated with placebo (starch), and AHM group was treated with 0.15 gm/d AHM, both for 12 consecutive weeks. The patients were investigated before and after treatment. Serum activity of aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), hyaluronic acid (HA), transforming growth factor-β (TGF-β) and matrixmetalloproteinase-2 (MMP-2) were determined. The reduced glutathione (GSH) and malondialdehyde (MDA) levels in liver were assayed and the expression of hepatic α-smooth muscle actin (α-SMA) was identified by immunohistochemistry.

RESULTS: At the start of the study, the hematoxylin and eosin staining revealed fibro-proliferated bile ductules, thick fibrous septa and dense inflammatory cellular infiltration in the patients before treatment. The use of AHM for 12 wk significantly ameliorated the fibrosis, inhibited the inflammation, and resulted in minimal infiltration and minimal fibrosis compared to the conventional group. The enzyme activities of the liver (ALT, AST and ALP) were attenuated after treatment in both groups, and the decrease in the AHM group was more significant as compared with the conventional group. Similar to the AST, the MDA levels were significantly higher before treatment, and were attenuated after treatment in both groups. In contrast, the hepatic glutathione content in the patients were decreased significantly in the AHM group compared to the controls. The serum levels of the fibrosis markers (HA, TGF-β and MMP-2) were also reduced significantly after treatment. The expression of α-SMA was modified in patients before and after treatment as compared with the normal controls. In the conventional group, there was only thin and incomplete parenchymal α-SMA positive septum joining the thickened centrilobular veins, while in the AHM group, few α-SMA positive cells were present in sinusoid and lobule after treatment.

CONCLUSION: Oral supplementation with AHM could be helpful in alleviating the fibrosis and inflammation of hepatic fibrosis patients.

INTRODUCTION

Hepatic fine periportal fibrosis is a common response to liver injury caused by viral hepatitis, hepatitis B virus (HBV), and hepatitis C virus (HCV) infection, and other factors. The pathophysiological events leading to periportal fibrosis provoke excessive hepatocytes apoptosis and necrosis[1,2]. The damaged hepatocytes are the activators of Kupffer cells. The activated Kupffer cells release a number of soluble agents, including cytokines, reactive oxygen species (ROS), and other factors. These factors act on the hepatic stellate cells (HSCs), which undergo morphological transition to myofibroblast-like cells and proliferate. This transition is characterized by an accelerated production of large amounts of extracellular matrix (ECM) involving molecular and histological re-arrangement of various types of collagens, proteoglycans, structural glycoprotein and hyaloronic acid[3].

Oxidative stress has been recognized as a fundamental factor in the pathological changes observed in various liver diseases[4,5]. It can cause excessive damage to hepatocytes through lipid peroxidation and protein alkylation[6].

Acute and chronic liver diseases constitute a global concern, and treatment for these diseases is difficult and have limited efficacy. Therefore, considerable efforts are being made to obtain useful herbal medicine from documented medicinal plants for a wide variety of clinical conditions. Developing therapeutically effective agents from natural products may reduce the risk of toxicity when the drug is used clinically.

Aloe vera is a cactus-like plant that grows in hot, dry climates. Two distinct preparations of aloe plants are most frequently used. The leaf exudate (aloe) is used as a laxative, and the mucilaginous gel (aloe vera) extracted from the leaf parenchyma is used as a remedy against a variety of skin disorders. Aloe vera gel has been demonstrated to have liver protective effect in rats[7-9], and many toxicity studies have been conducted to determine the LD50 of aloe vera[10-13]. However, the antifibrotic effect of aloe vera on liver fibrosis has not yet been reported. The aim of this study was to investigate the anti-oxidative, and anti-fibrotic effects of aloe vera in patients with acute liver fibrosis.

MATERIALS AND METHODS

Extraction and preparation

Aloe vera high molecular weight fractions (AHM) were obtained from water-washed gel of aloe vera leaves cultivated in Okinawa, Japan. Voucher specimens of aloe vera collected in Okinawa, were compared and de-termined to be *aloe vera L.* plant (syn. Aloe barbadensis Miller) (Herbarium number 54-3 in Medicinal garden, Fukuyama University by Emeritus Prof. A Yagi). AHMs were processed by patented hyper-dry system in combination of freeze-dry technique with microwave and far infrared-ray radiation. AHM contains the following chemical and physical properties: molecular weight (MW): 1119500 D by high performance liquid chromatography (HPLC) analysis; TSK gel GMPW column: two columns in series, 10 μm, 7.8 mm × 30 cm; eluent 0.2 mol $NaNO_3$; flow rate: 1.0 mL/min; temperature: 40 ℃; and use of refractive index detector.

Sample treatment

AHM sample (1 g) was homogenized in 2 mL of 0.2 mol $NaNO_3$. Homogenate was centrifuged at 2000 × g for 1 min. Upper solution was introduced as 200 μL aliquots to size-exclusion-chromatography. Aloin content was less than 10 ppm by HPLC analysis[14], water content: 3% ± 0.5%, colony formulating unit: less than 300/g, Na: 430 mg/100 g, Ca: 2100 mg/100 g. AHM contained the neutral polysaccharides with MW of about 1000 kDa, and 90% carbohydrate and 7% protein. Glycoprotein and verectin composed of carbohydrate and protein in a ratio of 10.7% and 82.0%, respectively, with MW of 29 kDa[15], was obtained in a ratio of 20% by immunochemical assay in AHM. Chemical shifts of AHM were determined in D_2O with a JOEL JNM α-400 and 100 MHz for proton and carbon, respectively. The infrared spectra were determined with a FTIR-8600PC, Shimadzu, Japan.

Patients

The subjects in this study were selected from the Internal Medicine Department, Tanta University Hospitals. They included 15 healthy volunteers as the control group and 40 patients (32 men and 8 women, ranged 25-56 years). Among the 40 patients, 15 had HCV, 24 had HBV and 1 had bilharziasis. Patients were included in the study if they were positive for serum hepatitis B surface antigen or C antibodies and had persistently elevated serum aminotransferase concentrations 1.5 times higher than the upper limit of the reference range for at least 6 mo. All the patients were diagnosed according to the International Autoimmune Hepatitis Group Report protocol[16].

For assessment of liver fibrosis scores, all patients underwent liver biopsy as part of the normal diagnostic procedure and were sub-classified according to the score for the histological activity index (HAI). Patients with a history of gastrointestinal bleeding and chronic liver disease (Wilson's disease, hemochromatosis, α 1-antitrypsin deficiency, or hepatocellular carcinoma), active intravenous drug abuse, and liver transplantation were excluded.

All the patients were subjected to full history taking, thorough clinical examination, biopsy and histological examinations, and laboratory investigations (Table 1).

Informed consent was obtained from all the participants. The protocol of the study was approved by the Ethical Committee of the University.

[1]Patients treated with the conventional treatment with placebo (starch) for 12 consecutive weeks; [2]Patients treated with the conventional treatment with 0.15 g/d AHM for 12 consecutive weeks. AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; INR: International normalization ratio; HBV: Hepatitis B virus; HCV: Hepatitis C virus; AHM: Aloe vera high molecular weight fractions.

Treatment was initiated if they met the inclusion criteria. Treatment of each patient was according to a standard protocol. Hepatitis C patients were treated with pegylated interferon (180 μg/wk) + ribavirin (800-1200 mg/d). Hepatitis B patients were treated with adefovir (10 mg/d) or lamivudin (100 mg/d).

The patients were randomly subdivided into two equal groups: the conventional group treated with the conventional treatment with placebo (starch) for 12 consecutive weeks, and the AHM group treated with the conventional treatment with 0.15 g/d AHM (0.05 g three times daily) for 12 consecutive weeks. The dosage was calculated according to Williams *et al*[10]. The AHM preparation was provided in sachets, which contained powder to be dissolved in 50 mL fresh water. Liver and blood samples were collected at the start and at the end of the study period for assessment.

Histological assessment
Liver biopsy fragments were fixed in 10% neutralized formaldehyde, embedded in paraffin, and then stained with hematoxylin and eosin. Liver biopsy samples were examined in a double-blinded fashion using a METAVIR scoring system. Blood samples were withdrawn; serum was separated and utilized for biochemical analysis of aspartate aminotransferase (AST), alanine aminotransferase (ALT) alkaline phosphatase (ALP), hyaluronic acid (HA), transforming growth factor-β (TGF-β) and matrix metalloproteinase-2 (MMP-2). Liver sample was dried, cut into portions and kept frozen at -80 ℃ until used for analysis. Liver tissues were weighed and homogenized in solution containing ice-cold isotonic saline[17]. The homogenates were centrifuged at 4500 rpm for 15 min at 4 ℃ and the supernatants were taken for determination of reduced glutathione (GSH), and malondialdehyde (MDA). The protein content of the tissue aliquots was determined by the Lowry method[18].

Biochemical assays
Measurement of liver enzyme activities: The serum enzyme activities of ALT and AST were measured colorimetrically according to the method of Reitman and Frankel[19], using Boehringer Mannheim Kit. The optical density was read at 546 nm using UV-160A Shimadzu Spectrophotometer. Serum total alkaline phosphatase activity was estimated by commercially available kits (BioMerieux, France) according to the method of Kind and King[20].

Measurement of fibrosis markers: Serum hyaluronic acid was measured using a kit provided by Corgenix Inc. (Colorado, United States, under license of Chugai Diagnostic Science Co.). It was measured by enzyme-linked immunosorbent assay (ELISA) according to the manufacturer's instructions. Serum TGF-β1 and MMP-2 levels were evaluated using a commercially available human TGF-β1 and MMP-2 ELISA kit according to the manufacturer's instructions (TGF-β1: R and D System, Abingdon, United Kingdom; MMP-: Amersham, Bucks, United Kingdom).

Measurement of liver oxidative markers: Hepatic GSH concentration was determined by the method of Richardson and Murphy[21], using Ellman's reagent (5, 5'-dithiobis-2-nitrobenzoic acid; DTNB) and the absorbance was measured at 412 nm. The results were calculated as μmol GSH/g tissue. Lipid peroxidation was assessed by measuring MDA using thiobarbituric acid according to the method of Yoshioka *et al*[22]. Thiobarbituric acid reactive substances was measured in μmol/g of tissue according to the absorbance at 532 nm.

Immunohistochemical analysis
For immunohistochemical analysis, sections were incubated with anti-α-smooth muscle actin (α-SMA) (1/1000; Dako North America, Inc., Carpenteria, CA) for 30 min. Staining was visualized using the horseradish peroxidase-conjugated Dako staining system (Dako In-Vision; Dako North America, Inc.).

Statistical analysis
Data were statistically analyzed by 2-way analysis of variance (ANOVA) (repeated measure type) to compare the results before (baseline) and after treatment within the same group, and unpaired Student's *t* test was used to compare the means of different groups. Significant differences between the groups were statistically analyzed using one-way ANOVA using the computer program SPSS for Windows version 10 (Chicago, IL, United States). All results were expressed as mean ± SD. The level of significance was set at $P < 0.05$.

Figure 1 Hematoxylin and eosin staining of liver tissues (HE, × 200). A: Control group showed normal lobular architecture and cell structure; B: Patients before treatment showed fibro-proliferated bile ductules, thick fibrous septa and dense inflammatory cellular infiltration; C: The conventional group showed moderate fibrosis with inflammatory infiltration and slight ballooning of liver cells; D: Aloe vera high molecular weight fractions group showed minimal infiltration and minimal fibrosis.

RESULTS

Macroscopic presentation and histological evaluation

The histological findings of liver tissues are presented in Figure 1. There were thick fibrous septa and dense inflammatory cellular infiltration in the patients before treatment. However, the control group showed normal lobular architecture and cell structure. The conventional group showed moderate fibrosis with inflammatory infiltration and slight ballooning of liver cells after treatment. AHM treatment could inhibit the inflammation, and showed minimal infiltration and minimal fibrosis compared to the conventional group. The histopathological evaluation of the two groups before and after treatment is shown in Table 2.

Determination of liver enzyme activities

The serum ALT, AST and ALP activities were significantly higher in the patients at the beginning of the study as compared with the control group. These increases were attenuated after treatment in both the conventional group and the AHM group, and the decrease in the AHM group was more significant than in the conventional group ($P <$ 0.05, Figure 2). There was no significant difference in the liver enzyme activities between HBV-induced fibrosis and HCV after treatment ($P <$ 0.05, Table 3).

Determination of liver oxidative markers

Similar to the aminotransferase activities, the MDA levels were significantly higher in the patients before treatment,

and were attenuated after treatment in both groups ($P <$ 0.05, Figure 3). In contrast, the hepatic glutathione content in the patients was decreased to about 49% of the control. Twelve weeks of treatment could increase the concentration of reduced glutathione. The increase was more significant in the AHM group ($P <$ 0.05, Figure 3). There was no significant difference in the liver oxidative markers between HBV-induced fibrosis and HCV after treatment ($P <$ 0.05, Table 3).

Determination of fibrosis markers

As shown in Figure 4, a significant increase in the serum

Table 3 Biochemical parameters of hepatitis B virus-induced fibrosis and hepatitis C patients after treatment

Parameter	Conventional group		AHM group

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ALP: Alkaline phosphatase; MDA: Malondialdhyde; GSH: Reduced glutathione; TGF-β: Transforming growth factor-β; HA: Hyaluronic acid; MMP-2: Matrix metalloproteinase-2; HBV: Hepatitis B virus; HCV: Hepatitis C virus.

level of TGF-β1, HA and MMP-2 was observed in the patients before treatment. Both the conventional and the AHM groups showed significant decrease in the levels after treatment ($P < 0.05$). There was no significant difference of fibrosis markers between HBV-induced fibrosis and HCV after treatment ($P < 0.05$, Table 3).

The expression of α-SMA was modified in patients before and after treatment as compared with the normal control. Before treatment, α-SMA positive cells were detected in portal space, sinusoid, lobule and areas where fibrotic septum appeared. After treatment, activation of HSC appeared to be strikingly decreased. After 12 wk of conventional treatment, there were only thin and incomplete parenchymal α-SMA positive septum joining thickened centrilobular veins. α-SMA positive cells were mainly found in portal space and areas around fibrotic septum. In AHM group, few α-SMA positive cells were present in sinusoid and lobule (Figure 5).

DISCUSSION

The present study evaluates the anti-inflammatory, anti-oxidative and anti-fibrotic effect of aloe vera in hepatic fine periportal fibrosis. AHM treatment for the hepatic fibrosis patients markedly attenuated the release of ALT, AST and ALP as compared with the control group and the conventional group. Histological findings of liver samples strongly supported the release of aminotransferases by damaged hepatocytes and the protective effect of AHM.

GSH constitutes the first line of defense against free radicals and is a critical determinant of tissue susceptibility to oxidative damage. This is evident in this study by the significant increase in hepatic content of MDA and depletion of GSH in the patients before treatment. AHM exhibited hepato-protective effects by impairing oxidative stress through decreased production of free radical derivatives, as evidenced by the decreased MDA level. Furthermore, it attenuated hepatic glutathione depletion.

Figure 2 Serum activity of alanine aminotransferase, alkaline phosphatase and aspartate aminotransferase of hepatic fibrosis patients and controls. A: Serum activity of alanine aminotransferase (IU/L) of hepatic fibrosis patients and controls; B: Serum activity of aspartate aminotransferase (IU/L) of hepatic fibrosis patients and controls; C: Serum activity of alkaline phosphatase (IU/L) of hepatic fibrosis patients and controls. [a]$P < 0.05$, [c]$P < 0.05$, [e]$P < 0.05$ *vs* before treatment and conventional group; Data are presented as mean ± SD. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ALP: Alkaline phosphatase; AHM: Aloe vera high molecular weight fractions.

This increase in the hepatic glutathione level could result from either its effect on the *de novo* synthesis of glutathione and its regeneration, or both. These results suggest that the antioxidant properties may be one mechanism by which AHM protects against liver damage.

Previous findings are in agreement with the finding by Anilakumar *et al*[23] who showed that aloe vera gel extract is able to reduce azoxymethane (AOM) induced-oxidative stress and toxicity in rat liver. Rajasekaran *et al*[24] also revealed that aloe vera leaf extract has a modulatory effect on oxidative stress in rats treated with streptozotocin by decreasing the thiobarbituric acid reactive substances, and improving reduced glutathione in the pancreas of STZ-

Figure 3 Hepatic malondialdhyde and glutathione of hepatic fibrosis patients and controls. A: Hepatic malondialdhyde (μmol/g) of hepatic fibrosis patients and controls; B: Hepatic reduced glutathione (μg/g) of hepatic fibrosis patients and controls. induced diabetic rats. However, Yang *et al*[25] showed that oral aloe supplementation caused increase in liver enzymes and subsequent acute liver injury.

TGF-β, a multifunctional growth factor, is the most potent fibrogenic cytokine[26]. It is involved in regulation of liver growth and induction of hepatocyte apoptosis. TGF-β can promote the development of liver fibrosis by inducing the synthesis of ECM proteins and down-regulating the expression of matrix[27]. The effect of oral administration of aloe vera gel on the simulation of TGF-β was studied by Atiba *et al*[28]. The present study showed that TGF-β1 increased in the serum of fibrotic patients and decreased after treatment. These results suggest that TGF-β1 is closely correlated with hepatic fibrosis and that the improvement of hepatic fibrosis is related to the decreasing expression of TGF-β1. The serum level of TGF-β1 was low in the AHM group compared with the conventional group and this decrease was not significantly different as compared with the control group, suggesting that AHM can inhibit the expression of TGF-β1. These results coincide with that of Kim *et al*[7] who showed that ACTIValoe®N-931 complex decreased the TGF-β1 level and the hepatic hydroxyproline content in CCl-4-induced hepatotoxicity rats.

HA is mostly synthesized by the hepatic stellate cells and degraded by the sinusoidal endothelial cells[29]. Some investigators[30,31] have shown that there is good correlation between HA and the degree fibrosis. In the present

Figure 4 Serum hyaluronic acid, transforming growth factor-β and matrix metalloproteinase-2 of hepatic fibrosis patients and controls. A: Serum hyaluronic acid (ng/mL) of hepatic fibrosis patients and controls; B: Serum transforming growth factor-β (pg/mL) of hepatic fibrosis patients and controls; C: Serum matrix metalloproteinase-2 (ng/mL) of hepatic fibrosis patients and controls. [a]P < 0.05, [c]P < 0.05, [e]P < 0.05 *vs* before treatment and conventional group. Data are presented as mean ± SD. HA: Hyaluronic acid; TGF-β: Transforming growth factor-β; MMP-2: Matrixmetalloproteinase-2; AHM: Aloe vera high molecular weight fractions.

study, 12 wk co-treatment of AHM and the conventional treatment decreased the serum HA by 25% as compared before treatment. It showed a trend toward greater improvement in the AHM group, however due to the short duration of treatment in our study, this was statistically insignificant as compared with control group.

Matrix metalloproteinases (MMPs) comprise a family of zinc-dependent enzymes that degrade extracellular matrix components and act as a marker of HSCs activation[32]. It was recently shown that it promoted HSCs apoptosis by cleavaging N-cadherin as an essential HSCs survival factor[33]. During fibrogenesis, the expression of MMP-2 increased and decreased significantly after treat-

Figure 5 Immunohistochemical staining of α-smooth muscle actin. A: Section of liver from controls showing negative staining (PAP × 125); B: Section of liver from liver fibrosis patients before treatment showing dense fibrotic reaction with strong positivity for α-smooth muscle actin (α-SMA) ↑↑ and dense mononuclear cellular infiltration ↑ (PAP × 225); C: Section of liver from conventional group after treatment showing dense mononuclear inflammatory infiltration ↑ and moderate positivity for α-SMA in fibrotic lesion↑↑ (PAP × 125); D: Section of liver from AHM group after treatment showing moderate mononuclear cellular infiltration ↑ surrounded by minimal fibrotic reaction stained mildly with α-SMA ↑↑ (PAP × 125).

ment, suggesting that the treatment favored a collagenolytic activity.

The present study showed no significant difference in the serum liver fibrosis markers between HBV and HCV patients which is in agreement with Elmetwally *et al*[34], who revealed that serum HA concentrations did not differ significantly among chronic hepatitis subtypes (HBV *vs* HCV), while its level correlates with the degree of fibrosis. This suggested that progression of liver fibrosis (and inflammation) was accompanied by impairment in the liver endothelial cell function and reduced degradation of this hetero-polysaccharide, eventually resulting in elevation of serum HA concentrations.

α-SMA is a reliable marker of hepatic stellate cell activation which precedes fibrous tissue deposition, and it can be used for identification of the earliest stage of hepatic fibrosis and for monitoring the efficacy of the therapy[35]. In the present study, the expression of α-SMA was detected by immunohistochemistry; it was activated in the fibrotic patients, and the lowest level was observed in the AHM group. These data were consistent with Dechene *et al*[36] who revealed significant increase in serum tissue inhibitors of metalloproteinases and MMP as well as histological evidence of collagen formation and α-SMA expression in acute liver failure patients. They demonstrated an ongoing profibrotic process together with an increased HSC activity. It is possible that a collagen matrix is synthesized and deposited as a structural framework to preserve the liver architecture. Acute liver fibrosis may serve as a part of beneficial wound healing process by transiently conserve the organ's structure until defective tissue areas are replaced by functional hepatocytes.

In conclusion, AHM has antifibrotic effects which could be attributed to its ability to attenuate oxidative stress, and enhance the collagenolytic activity. This study provides evidences that AHM could be used as adjunct treatment to prevent or treat hepatocellular damage in hepatic fine periportal fibrosis.

COMMENTS

Background

Acute and chronic liver diseases constitute a global concern, but medical

treatment up to now has limited efficacy. The therapeutically effective herbal medicine from documented medicinal plants may reduce the risk of drug toxicity. Aloe vera gel has been demonstrated to have liver protective effect in rats, and many toxicity studies have been conducted to determine the LD50 of aloe vera. This study investigated the antifibrotic effects of aloe vera for patients with acute liver fibrosis.

Research frontiers

Various *in vitro* studies have been conducted in an attempt to restore the integrity of damaged hepatocytes and reveal the hepatoprotective role of aloe vera in hepatic fibrosis. This study was undertaken to evaluate the antifibrotic effect of aloe vera in patients with hepatic fine periportal fibrosis and its mechanism of action.

Innovations and breakthroughs

The antifibrotic effect of aloe vera high molecular weight fractions (AHM) is attributed to its ability to attenuate oxidative stress, and enhance the collagenolytic activity. In the light of the potential of aloe vera plant extract, the discoveries of novel low-cost drug of natural non-toxic origin are promising for developing countries.

Applications

This study provides evidences that AHM could be used as adjunct treatment to prevent or treat hepatocellular damage in hepatic fine periportal fibrosis.

Peer review

The study is interesting and goes along with previous studies that showed hepatoprotective effect of aloe vera extracts in experimental models.

Abstract

AIM: To investigate the role of transforming growth factor (TGF)-β-inducible early gene 1 (TIEG1) in TGF-β-induced growth inhibition in hepatocellular carcinoma (HCC) cells.

METHODS: Human hepatocyte and HCC cell lines with varied susceptibilities to TGF-β1 were tested by methylthiazoletetrazolium (MTT) assay. The expression changes of *Smad2*, *Smad3*, *Smad4*, *Smad7*, *TIEG1* and *TIEG2* gene following treatment with TGF-β1 in a TGF-β-sensitive hepatocyte cell line (MIHA), a TGF-β-sensitive hepatoma cell line (Hep3B) and two TGF-β-insensitive hepatoma cell lines (HepG2 and Bel7404) were examined. SiRNA targeting TIEG1 was transfected into Hep3B cells and the sensitivity of cells to TGF-β1 was examined. Overexpression of TIEG1 was induced by lentiviral-mediated transduction in TGF-β1-resistant hepatoma cell lines (Bel7404 and HepG2). MTT assay and 4',6-Diamidino-2-phenylindole staining were used to identify cell viability and apoptosis, respectively. The expression level of stathmin was measured by reverse transcriptase polymerase chain reaction and Western-blotting analysis, and stathmin promoter activity by TIEG1 was monitored by a luciferase reporter gene system.

RESULTS: TIEG1 was significantly upregulated by TGF-β1 in the TGF-β1-sensitive HCC cell line, Hep3B, but not in the resistant cell lines. The suppression of TIEG1 by siRNAs decreased the sensitivity of Hep3B cells to TGF-β1, whereas the overexpression of TIEG1 mediated growth inhibition and apoptosis in TGF-β1-resistant HCC cell lines, which resembled those of TGF-β1-sensitive HCC cells treated with TGF-β1. Our data further suggested that stathmin was a direct target of TIEG1, as stathmin was significantly downregulated by TIEG1 overexpression, and stathmin promoter activity was inhibited by TIEG1 in a dose-dependent manner.

CONCLUSION: Our data suggest that transactivation of TIEG1 conferred growth inhibition of TGF-β-susceptible human HCC cells.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third most common cause of cancer death worldwide, and there are few effective therapeutic options available for those suffering from advanced disease[1]. HCC poses a major challenge because of its clinical heterogeneity and lack of good diagnostic markers and treatment strategies[2]. Transforming growth factor-β (TGF-β) is a multifunctional cytokine which regulates cell proliferation, migration and differentiation[3]. TGF-β has been shown to inhibit cell proliferation and to induce apoptosis to control excessive growth of hepatocytes and maintain liver size, and is considered a liver tumor suppressor[4]. However, many HCC cells are thought to have lost their sensitivity to TGF-β, and thus escape the antiproliferative effect of TGF-β[4,5]. The loss of TGF-β activities resulting in hyperproliferative disorders and cancer in the liver and derangement of TGF-β signaling are associated with an increased incidence of HCC[6]. TGF-β has shown dual effects on tumors, in that it can either be pro- or anti-tumorigenetic, depending on the stage of tumorigenesis and the responsiveness of the tumor cells[7]. Various studies have shown that TGF-β signaling may suppress human hepatocarcinogenesis, possibly *via* cyclin D1 deregulation[8], and that TGF-β could serve as a potential senescence inducer in HCC cells and thereby inhibit tumor growth *in vivo*[9]. However, in advanced cancers, TGF-β has been found to be a tumor enhancer because it can promote tumor progression by facilitating tumor invasion, neoangiogenesis, and immunosuppression[10].

The TGF-β-inducible early gene 1 (*TIEG1*) can be activated at the initial stage of the TGF-β pathway. Previous studies have shown that TIEG1 has an important role in regulating cell growth[11,12]. This gene is classified as a member of the Krüppel-like family of transcription factors (KLF10), all of which bind to GC-rich Sp1-like binding sites to regulate gene transcription[12]. In addi-tion, TIEG1 is also regarded as a potent transcriptional repressor. The overexpression of TIEG1 has been found to induce apoptosis in pancreatic cancer cells, and this indicates that it has a pivotal role in mediating TGF-β-induced apoptosis[13,14]. In addition, TIEG1 was found to induce apoptosis *via* a mechanism which involves the formation of reactive oxygen species[15]. The transcription level of TIEG1 was found to be predominantly expressed in various tissues, and the associated levels were regulated by cytokines and growth factors[12]. It is well known that different HCC cell lines respond differently to TGF-β treatment, and that some HCC cell lines are sensitive to TGF-β, whereas others are resistant. However, the molecular mechanism underlying the differential responses has never been elucidated. In the present study, we investigated the role of TIEG1 in TGF-β-induced growth inhibition in HCC cells. We deduced that transactivation of the TIEG1 conferred growth inhibition of TGF-β-susceptible human HCC cells.

MATERIALS AND METHODS

Cell culture

Immortalized human hepatocyte (MIHA), HCC cell lines (HepG2, Hep3B, Bel7404, Huh-7, and PLC), and human HEK293T cells were cultured in Dulbecco's modified Eagle medium supplemented with 10% fetal bovine serum and 100 U/mL penicillin/streptomycin (Invitrogen, Carlsbad, CA, United States). All cultures were maintained in a humidified 37 ℃ incubator with 5% CO_2.

TGF-β1 treatments

Prior to treatment with TGF-β1, the cells were seeded, allowed to attach for 24 h and then starved in a serum-free medium for another 24 h. The cells were then treated with 5 ng/mL TGF-β1 (R&D System, Minneapolis, MN, United States) for the indicated time periods. Cell survival and changes in nuclei morphology were respectively monitored using methylthiazoletetrazolium (MTT) assays and 4',6-Diamidino-2-phenylindole (DAPI) staining[13] after 96 h of treatment.

Reverse transcriptase-polymerase chain reaction

For gene response studies, the total RNA was extracted using TRIZOL (Invitrogen), and then cDNA synthesis was performed using the Superscript First-Strand Synthesis Kit (Promega, United States)[13]. The mRNA levels of genes were determined by quantitative real-time polymerase chain reaction (PCR) or semi-quantitative reverse transcriptase (RT)-PCR[13]. The following forward and reverse primers were used respectively: TIEG1: 5'-GT-CACATCTGTAGCCACCCA-3' and 5'-CCTCCTTTCA-CAACCTTTCC-3'; TIEG2: 5'-TCTGACTCTGGGGAT-GTCAC-3' and 5'-CGGCAATCTGGAGTCTGGA-3'; Smad2: 5'-GCCACGGTAGAAATGACAAG-3' and 5'-CAGACTGAGCCAGAAGAGCA-3'; Smad3: 5'-GAACGGGCAGGAGGAGAAAT-3' and 5'-ACAG-GCGGCAGTAGATGACA-3'; Smad4: 5'-CCATTTC-

CAATCATCCTGCT-3' and 5'-ACCTTTGCCTATGTG-CAACC-3'; Smad7: 5'-CTTAGCCGACTCTGCGAACT-3' and 5'-CCCAGGCTCCAGAAGAAGTT-3'; Stathmin (STMN): 5'-TTTTCAATCCCAATTCTGTC-3' and 5'-GAAAGTAACAGCTGACCTGG-3'; glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (loading control): 5'-CCAGCCGAGCCACATCGCTC-3' and 5'-AT-GAGCCCCAGCCTTCTCCAT-3'. Quantitative real-time PCR was performed using SYBRs GREEN PCR Master Mix (Applied Biosystems, Warrington, United Kingdom) and an ABI 7500 Real-time PCR system. The relative amount of mRNA expression was normalized based on the expression of human GAPDH. Each of the normalized gene expression values was calibrated to the normalized gene expression of cells with TGF-β1 treatment at time zero. The experiments were repeated thrice to build a geometric mean. Alternatively, RT-PCR was employed for semi-quantitative analysis of gene expression levels. GAPDH acted as the internal control[13].

siRNA transfection

For siRNA transfection, Hep3B cells were transfected with 50 pmol control siRNA or TIEG1 siRNA (Santa Cruz) using oligofectamime (Invitrogen). A second identical transfection was carried out 24 h later. Seventy-two hours after the first transfection, the total RNA was extracted and real-time RT-PCR was performed to evaluate the downregulatory effects. Moreover, 5×10^3 cells were seeded onto 96-well plates and transfected with siRNA twice and then treated with 5 ng/mL TGF-β1 for 72 h. MTT assay was then performed to determine the changes in cell growth.

Lentiviral transduction

Lentiviral vectors expressing TIEG1 were constructed, as previously described[13]. The VSV-G pseudotyped lentiviruses were produced by cotransfecting 293T cells with the transfer vector and three packaging vectors. The cells were transduced with lentivirus, as described[13].

Western blotting

The SDS-PAGE and Western blotting analysis were performed, as previously described[13]. The primary antibodies used were polyclonal antibodies against TIEG1 (sc-23159; Santa Cruz) and Actin (80-50; Abcam).

Luciferase reporter assays

The promoter of STMN was constructed into the pGL3-basic luciferase reporter vector (Promega, Madison, WI, United States) using primer: F-Kpn I : 5'-CCGG-TACCTCTAAGGCACGGTCAGACCA-3', R-Bgl Ⅱ: 5'-CGCAGATCTCCTGACCACACTCTGAGC-3'. For the luciferase assay, 293T cells were co-transfected with pGL3-promoter-STMN vector, a renilla plasmid, along with different amount of TIEG1-expressed construct or pEGFP-N1 vector. Cell extracts were lysed 48 h post-transfection and assayed for luciferase activities using the Dual-Luciferase Reporter Assay System (Promega).

Figure 1 Susceptibilities of various human hepatocyte (MIHA) and hepatocellular carcinoma cells (Hep3B, PLC, Huh7, HepG2, and Bel7404) to transforming growth factor-β**.** A: Cells were treated with 5 ng/mL transforming growth factor (TGF)-β1 for 96 h and cell survival was then determined by methylthiazoletetrazolium assays; B: Nuclear morphology of apoptotic TGF-β-treated Hep3B cells demonstrated by 4',6-Diamidino-2-phenylindole staining and examined by fluorescence microscopy. Scale bar: 50 μm, 400 ×.

Statistical analysis

Data are expressed as the mean ± SD error of the mean. Statistical differences between groups were compared using the Student's *t* test. *P* values less than 0.05 were considered significant.

RESULTS

Susceptibilities of human hepatocyte and HCC cell lines to TGF-β1

The cell proliferation inhibitory effect of TGF-β1 on various cell lines was evaluated by MTT assay (Figure 1A). TGF-β1 exerted the highest inhibitory effect on Hep3B (> 80%), a known TGF-β-sensitive hepatoma cell line, exhib-

Figure 2 Differential responses of TIEGs and Smads in various TGF-β1-treated cells. Cells were treated with 5 ng/mL TGF-β1 for up to 4 h. At indicated time intervals, the mRNA levels of TIEG1, TIEG2, Smad2, Smad3, Smad4, and Smad7 were determined by quantitative real-time RT-PCRs. Data were presented as mRNA levels relative to that of time 0 from three independent experiments.

ited a moderate inhibition (approximately 60%) in MIHA cells, a TGF-β-sensitive hepatocyte cell line, and an inhibition rate of approximately 60% was observed in HCC PLC cells. In addition, TGF-β1 exerted only marginal inhibitory effects on Huh7 cells (approximately 30%). Lastly, HepG2 and Bel7404 cells exhibited resistance to growth inhibition by TGF-β1 and completely lost their sensitivity to TGF-β. Using DAPI staining and subsequent fluorescence it was revealed by microscopic examination that the growth inhibitory effect of TGF-β1 on Hep3B cells was *via* the induction of apoptosis (Figure 1B).

Differential responses of TIEGs and Smads in various TGF-β1-treated cells

Firstly, we employed semi-quantitative PCR analysis to determine the basal mRNA level of eight different genes,

namely, the TGF-β1 receptor 1, the TGF-β1 receptor 2, Smad2, Smad3, Smad4, Smad7, TIEG1 and TIEG2, which are involved in the TGF-β signaling pathway in all the cell lines studied. We found no correlation between the expression of TGF-β-related genes and their sensitivity to TGF-β. All interested genes were present in all cell lines at slightly varied levels (data not shown). Because there was no correlation between the static expression of the TGF-β-related genes and the sensitivity of different HCC cells to TGF-β, we next examined the expression changes of these genes after they had been treated with TGF-β1 in a TGF-β-sensitive hepatocyte cell line (MIHA), a TGF-β-sensitive hepatoma cell line (Hep3B) and two TGF-β-insensitive hepatoma cell lines (HepG2 and Bel7404). Figure 2 shows the relative changes in expression of various genes in response to TGF-β1 over time. The TIEG1 was

Figure 3 Downregulation of transforming growth factor-β-inducible early gene 1 by RNA interference (siRNA) decreased the transforming growth factor-β1 susceptibility of Hep3B cells. A: Decreases in the transforming growth factor (TGF)-β-inducible early gene 1 (TIEG1) mRNA level in siRNAs targeting TIEG1 (siTIEG1)-transfected Hep3B cells with or without TGF-β1 treatment. Cells were transfected with siTIEG1 prior to the TGF-β1 treatments described above. After 4 h of treatment, mRNA levels of TIEG1 were determined by quantitative reverse transcriptase-polymerase chain reaction; B: Increases in the survivability of the siTIEG1-transfected and the TGF-β1-treated Hep3B cells. The decreased growth inhibitory response of Hep3B cells to TGF-β1 treatment was determined by methylthiazoletetrazolium assays after 72 h of TGF-β1 treatment. [a]$P < 0.05$.

sharply upregulated as early as 30 min after TGF-β1 treatment in MIHA and Hep3B cells, which were sensitive to TGF-β. One hour after treatment, TIEG1 was upregulated seven-fold in MIHA and more than ten-fold in Hep3B cells, respectively. However, there was a slight increase in TGF-β-insensitive cells (HepG2 and Bel7404). TIEG1 mRNA levels were more potently induced by TGF-β1 in TGF-β1-sensitive cell lines (Hep3B and MIHA) than in TGF-β1-insensitive cell lines (HepG2 and Bel7404).

We also observed that the *Smad3* gene was upregulated in TGF-β-sensitive cells after TGF-β1 treatment for 4 h, and that there was no significant change in insensitive hepatoma cells. However, the upregulation of TIEG1 expression appeared earlier than upregulation of the *Smad3* gene in TGF-β-sensitive cells. In the case of another gene, namely Smad7, the expression was sharply upregulated after treatment in TGF-β-sensitive cells and weakly upregulated in insensitive hepatoma cells. There was no significant change in *TIEG2*, *Smad2* and *Smad4* gene expression after TGF-β1 treatment. Smad7 is thought to be a TGF-β-inducible antagonist of TGF-β signaling[16], and there are autoregulatory negative-feedback signals in the signal transduction of the TGF-β superfamily[17]. These data imply that the *TIEG1* gene might play a critical role in TGF-β-mediated growth inhibition of HCC cells.

siRNA targeting TIEG1 decreased TGF-β susceptibility of Hep3B cells
To study the role of TIEG1 in TGF-β induced growth inhibition in HCC cells, we used siRNA to target TIEG1 in the TGF-β-sensitive hepatoma cell line Hep3B. The siRNA targeting significantly decreased the mRNA expression of TIEG1 with or without TGF-β1 treatment (Figure 3A), and consequently increased the survival rate of the cells after treatment with TGF-β1 for 72 h (Figure 3B).

Overexpression of TIEG1 by lentiviral-mediated transduction inhibited cell growth and induced apoptosis in TGF-β1-resistant hepatoma cells
As seen in Figure 4, the overexpression of TIEG1 was

successfully induced by lentiviral-mediated transduction in the TGF-β1-resistant hepatoma cell lines (Bel7404 and HepG2) both at transcription (Figure 4A) and translational levels (Figure 4B). MTT assay revealed a very significant inhibitory effect on growth of the two cell lines after the induction of TIEG1 by the lentivirus (Figure 4C). DAPI staining demonstrated a significantly higher amount of apoptotic cells in the two HCC cell lines after the overexpression of TIEG1 (Figure 4D).

Transcriptional regulation of TIEG1 on STMN by binding on STMN promoter
In the present study, the correlation between TIEG1 and STMN was also evaluated. Overexpression of TIEG1 was found to decrease STMN expression at both the transcription and translational levels (Figure 5A and B). STMN promoter activity was reduced in a dose-dependent manner with the induction of *TIEG1* gene (Figure 5C).

DISCUSSION
The present study determined the molecular mechanism underlying the differential susceptibilities of HCC cells to TGF-β treatment. In this study, one TGF-β-sensitive hepatocyte cell line (MIHA) and five TGF-β-various-sensitive hepatoma cell lines were investigated. In general, treatment with TGF-β1 significantly inhibited the growth of the two TGF-β-sensitive cell lines (Hep3B and MIHA). However, HepG2 and Bel7404 cells did not respond to TGF-β1. Taken together, treatment with TGF-β1 caused varied levels of inhibition in different cell lines. Some HCC cell lines were sensitive to TGF-β, whereas others were resistant. Recently, studies on the relationship between HCC and the TGF-β signaling pathway have been extensive. One recent study has reported a negative relationship between interleukin-6, a major stem cell signaling pathway, and the TGF-β signaling pathway in human HCC[18]. TGF-β signaling and Smad adaptor embryonic liver fodrin could suppress HCC *via* cyclin D1 deregulation[8]. Another study showed

Figure 4 The overexpression of transforming growth factor-β-inducible early gene 1 by lentiviral-mediated transfection-induced growth inhibition and apoptosis in transforming growth factor-β1-resistant hepatoma Bel7404 and HepG2 cells. A and B: Increases in mRNA and protein levels of transforming growth factor (TGF)-β-inducible early gene 1 (TIEG1) in Bel7404 and HepG2 cells transfected by lenti-TIEG1, respectively, revealed by reverse transcriptase-polymerase chain reaction and Western blotting analysis; C: The overexpression of TIEG1 by lentiviral-mediated transfection-inhibited cell growth in Bel7404 and HepG2 cells. that human HCC cells could be protected by interleukin-4 from TGF-β-induced apoptosis, which indicated another therapeutic option by the targeting of interleukin-4[19]. Lost sensitivity to TGF-β has been postulated to be an early event in HCC development[18,20].

In the present study, the role of TIEG1 in TGF-β-induced growth inhibition was analyzed in established TGF-β-sensitive and -insensitive cell systems. Our studies revealed that TIEG1 mRNA was dramatically upregulated by TGF-β1 in TGF-β1-sensitive cell lines but not in resistant cell lines. However, expression of the endogenous TIEG1 protein was not detected in all cell lines (namely, Hep3B, MIHA, Bel7404, and HepG2) before and after the TGF-β1 treatment. One of the reasons for this could be that the amounts of endogenous TIEG1 protein in the cells were too low to be detected. We found that the induction of TIEG1 was transient and occurred before the phenomenon of cell growth inhibition. The time course for the induction of TIEG1 expression was similar to that found in human osteoblast cells[21] and

pancreatic epithelial cells[22] following TGF-β1 treatment. Although TIEG1 induction was transient following TGF-β1 treatment, it might participate in the TGF-β1 signaling processes or amplify the TGF-β1 signaling events that inhibited cell growth.

The suppression of TIEG1 by siRNAs decreased the sensitivity of Hep3B cells to TGF-β1, whereas the overexpression of TIEG1 mediated growth inhibition and apoptosis in TGF-β1-resistant HCC cell lines (HepG2 and Bel7404), which resembled those of TGF-β1-sensitive HCC cells treated with TGF-β1. This indicated the pivotal role of TIEG1 in TGF-β1-induced growth inhibition in HCC. In a previous study, the overexpression of TIEG1 was shown to inhibit cell proliferation and growth in TGF-β-sensitive Hep3B cells[15] and in pancreatic carcinoma cell lines[13,22]. Also, TIEG1 plays a role in TGF-β-induced inhibition of cell proliferation and apoptosis in human osteoblast cells[12]. Nevertheless, our data indicated that TIEG1 overexpression alone was capable of inducing sufficient inhibition or apoptosis in HCC tumor cells, despite the cells' sensitivity to TGF-β. We also found that TIEG1 was identified as a transcriptional repressor of STMN, as the mRNA expression and the promoter activity of STMN were significantly reduced in the presence of overexpressed TIEG1. Bioinformatics analysis revealed several Sp1-binding sites in the promoter region of STMN. TIEG1 regulates STMN transcription by binding to the STMN promoter. These findings indicate the pivotal role of STMN in promoting tumor cell survival which has also been reported elsewhere[23-25]. Various strategies have been suggested to target the expression of STMN for treating tumors, including prostate, cervical[26] and breast cancer[27]. In pancreatic carcinoma cells, we have revealed that overexpression of TIEG1 could induce cell growth inhibition and promote gemcitabine chemosensitivity through downregulation of STMN[13]. In this study, the data again suggest a pivotal role for STMN (i.e., downregulation) in diminishing HCC proliferation, or in facilitating tumor cell apoptosis.

Taken together, these results demonstrate that TIEG1 is involved in TGF-β1-mediated growth inhibition. Transactivation of TIEG1 conferred growth inhibition of TGF-β-susceptible human HCC cells. However, it should be noted that this study was based on *in vitro* investigations and *in vivo* models should be explored.

COMMENTS

Background
Transforming growth factor-β (TGF-β) has been shown to inhibit cell proliferation and to induce apoptosis to control excessive growth of hepatocytes and maintain liver size, and is considered a liver tumor suppressor. However, many hepatocellular carcinoma (HCC) cells are thought to have lost their sensitivity to TGF-β, and thus escape the antiproliferative effect of TGF-β. Lost sensitivity to TGF-β has been postulated to be an early event in HCC development. The reasons why some HCC cells are sensitive yet others are resistant to TGF-β mediated growth inhibition are still poorly understood.

Research frontiers
The TGF-β-inducible early gene 1 (*TIEG1*) can be activated at the initial stage of the TGF-β pathway. Recent reports have highlighted the importance of

TIEG1 in the TGF-β signaling pathway and in regulating cell growth. In the present study, the authors demonstrated the role of the *TIEG1* gene in TGF-β-induced growth inhibition in HCC cells.

Innovations and breakthroughs

This study indicated the TIEG1 was significantly upregulated by TGF-β1 in the TGF-β1-sensitive HCC cell line, Hep3B, but not in the resistant cell lines. The suppression of TIEG1 by siRNAs decreased the sensitivity of Hep3B cells to TGF-β1, whereas the overexpression of TIEG1 mediated growth inhibition and apoptosis in TGF-β1-resistant HCC cell lines, which resembled those of TGF-β1-sensitive HCC cells treated with TGF-β1. The studies suggest that transactivation of TIEG1 conferred growth inhibition of TGF-β-susceptible human HCC cells.

Applications

By understanding the molecular mechanism underlying the differential susceptibility of HCC cells to TGF-β, this study may provide new molecular targets for therapeutic intervention in HCC.

Peer review

This paper deals with the transactivation of the TIEG1 in growth inhibition of TGF-β-susceptible HCC cells. The authors aimed to investigate the role of TIEG1 in TGF-β-induced growth inhibition in HCC. They found that transactivation of the TIEG1 conferred growth inhibition of the TGF-β-susceptible human HCC cells. The results are interesting and the design of this study is appropriate.

Abstract

AIM: To investigate the methylation status of secreted protein acidic and rich in cysteine (*SPARC*) in human hepatocellular carcinoma (HCC) and evaluate its clinical implication.

METHODS: The methylation status of *SPARC* was analyzed in one HCC cell line (SMMC-7721) and 60 pairs of HCC and corresponding nontumorous tissues by methylation-specific polymerase chain reaction and bisulfite sequencing. The expression of *SPARC* mRNA and protein were examined by reverse transcription polymerase chain reaction and immunohistochemistry, respectively. The correlations between the methylation status and the gene expression, the clinicopathological parameters, as well as the prognosis after surgery were analyzed.

RESULTS: In the SMMC-7721 cell line, the loss of *SPARC* expression was correlated with the aberrant methylation and could be reactivated by the demethylating agent 5-aza-2'-deoxycytidine. Methylation frequency of *SPARC* in HCC was significantly higher than that in the corresponding nontumorous tissues (45/60 *vs* 7/60, $P < 0.001$), and it was correlated with the pathological classification ($P = 0.019$). The downregulation of the *SPARC* mRNA expression in HCC was correlated with the *SPARC* methylation ($P = 0.040$). The patients with methylated *SPARC* had a poorer overall survival than those without methylated *SPARC* (28.0 mo *vs* 41.0 mo, $P = 0.043$).

CONCLUSION: Aberrant methylation is an important mechanism for *SPARC* inactivation in HCC and *SPARC* methylation may be a promising biomarker for the diagnosis and prognosis of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most

common malignancies and the third leading cause of cancer death in the world[1,2]. To date, surgical resection is still considered the most important treatment for patients with resectable HCC[3]. Unfortunately, most patients are at inoperable stages when the tumor is diagnosed[4]. In addition, the high incidence of tumor recurrence after curative resection also leads to poor clinical outcomes[5,6]. Therefore, the development of biomarkers for early diagnosis and accurate prognosis of HCC is valuable for improving patients' survival.

Although the detailed molecular mechanisms of hepatocarcinogenesis remain largely unclear, the accumulating evidences have shown that aberrant methylation of promoter CpG islands causes inactivation of tumor suppressor genes, which is involved in the occurrence and development of HCC[7-10]. Detections of such an aberrant DNA methylation of tumor suppressor genes could be used as a diagnostic or a prognostic marker for HCC.

Secreted protein acidic and rich in cysteine (*SPARC*) is a matricellular glycoprotein involved in some biological processes, including tissue remodeling, angiogenesis, extracellular matrix production and so on[11-13]. It has been reported that *SPARC* has tumor suppressing properties to various cancers, such as ovarian cancer and pancreatic cancer[14-16]. Moreover, *SPARC* is epigenetically silenced through promoter hypermethylation in these cancers, and the demethylating agent 5-aza-2'-deoxycytidine (5-Aza-CdR) can rescue *SPARC* expression[17-20]. The *SPARC* promoter methylation is an important factor in the carcinogenesis of these cancers and may be a promising epigenetic marker for them. However, up to date, there have been few reports about the methylation status in HCC.

In this study, in order to explore the status of *SPARC* methylation in HCC, we examined the methylation and expression of *SPARC* in HCC cell line and tissues. We correlated the methylation status with clinicopathologic features and evaluated whether the methylation of *SPARC* can serve as a potentially diagnostic or prognostic biomarker for HCC.

MATERIALS AND METHODS

Cell line and patient samples

The SMMC-7721 cell line used in this study was obtained from the Shanghai Institute of Cell Biology (Shanghai, China). HCCs and their corresponding nontumorous tissues were obtained from 60 patients who were diagnosed and treated at the Department of Hepatobiliary Surgery, Tianjin Third Central Hospital in China from October 2003 to June 2008. This study protocol was approved by the Clinical Research Ethics Committee of our institution and the informed consent was obtained from each of these patients. After surgical resection, samples were immediately stored in the liquid nitrogen for later analysis. For the gene expression analysis, the hematoxylin-eosin-stained samples from each tumor block were examined microscopically to confirm

the presence of more than 80% tumor cells. The nontumorous samples from each patient were also microscopically confirmed.

Cell culture and 5-Aza-CdR treatment

SMMC-7721 cells were grown in DMEM supplemented with 100 g/L fetal bovine serum and incubated in 37 ℃ and 50 mL/L CO$_2$. For the 5-Aza-CdR (Sigma, St Louis, MO, United States) treatment, cells were split to 5×10^5 per 75-cm^2 culture bottle and incubated overnight in the growth media. The normal growth media was replaced with the growth media supplemented with 5-Aza-CdR (10 μmol as a final concentration) for 6 d with the media change on day 4. Cells cultured with vehicle alone served as 5-Aza-CdR negative control. After the culture, cells were harvested for the extraction of genomic DNA and total RNA. In order to detect the *SPARC* protein in different groups by immunocytochemical staining, SMMC-7721 cells were also seeded onto 6-well plates containing coverslips to induce cells to spread and adhere to the glass.

DNA extraction and bisulfite treatment

The genomic DNA was extracted from the cell line and tissue samples by digesting with sodium dodecyl sulfate/proteinase K in Tris ethylenediamine tetraacetic acid (TE) buffer followed by a standard phenol/chloroform extraction. The extracted DNA was subjected to the bisulfite treatment as previously described[21-23]. Briefly, 1-2 μg genomic DNA was denatured with 0.3 mol/L NaOH at 37 ℃ for 20 min, and incubated in 3.0 mol/L sodium bisulfite and 10 mmol/L hydroquinone at 55 ℃ for 16 h. The DNA was desalted with a QIAquick gel extraction kit (Qiagen, Valencia, CA, United States) and dissolved in 50 μL of 10 mmol/L TE buffer (pH 8.0). Then, 5.5 μL of 3.0 mol/L NaOH was added and incubated at 37 ℃ for 20 min to desulfonate it. The modified DNA was neutralized with 30 μL of 10 mol/L ammonium acetate, precipitated using 2 volumes of ethanol, and resuspended in 40 μL of 1.0 mmol/L TE buffer (pH 7.6).

Methylation specific polymerase chain reaction and sequencing

Methylation specific polymerase chain reaction (MSP) was performed to examine the methylation status at CpG island of *SPARC* promoter in both SMMC-7721 cells and tissue samples. The primers used in this study for polymerase chain reaction (PCR) are shown in Table 1. A PCR mixture contained 1 × PCR buffer (10 mmol/L Tris, 50 mmol/L KCl, 1.5 mmol/L MgCl$_2$ and 10 mmol/L β-mercaptoethanol), deoxynucleotide triphosphates (each at 0.2 mmol/L), primers (10 pmol each), bisulfite-modified DNA templates (2 μL) and 1 U of Taq polymerase, and the final volume was 25 μL. The PCR conditions were as follows: 94 ℃ for 2 min; then 40 cycles of 94 ℃ for 30 s, at optimum annealing temperature for 30 s and 72 ℃ for 30 s; and final extension for 5 min at 72 ℃. The normal leukocyte DNA methylated *in vitro* with SssI

methyltransferase (New England Biolabs Inc., Beverly, MA, United States) was used as the positive control of methylation, and the normal leukocyte DNA was used as the negative control. The distilled water without template DNA was used as a blank control for all tests. Five microliters of PCR products underwent electrophoresis on 25 g/L agarose gel, and was visualized under ultraviolet illumination with the ethidium bromide staining. To verify the accuracy of MSP, the PCR products of both methylation and unmethylation were randomly chosen and cloned into the pMD-18-T vector (TaKaRa, Dalian, China) followed by a sequencing analysis.

To investigate the status of CpG sites in the region of *SPARC* promoter of SMMC-7721 cells, bisulfite sequencing analysis was performed for the bisulfite-treated DNA. The PCR products were cloned into a pMD-18-T vector and 8 individual clones of each group were sequenced.

RNA preparation and reverse transcription-PCR

RNA was extracted from the cell line and tissues using the Trizol (Tiangen, Beijing, China) according to the manufacturer's instructions. The total mRNA was digested with the DNase I (Ambion, Austin, TX, United States) to remove the genomic DNA contamination and then subjected to reverse transcription using the reverse transcription system (Promega, Madison, WI, United States). *SPARC* expression of SMMC-7721 cells and tissues were tested by reverse transcription (RT)-PCR and quantitative RT-PCR, respectively. Real-time quantitative RT-PCR was done on the ABI Prism 7000 sequence detection system in combination with the SYBR green real-time PCR master mix (Toyobo, Shanghai, China). The PCR amplification was carried out for 2 min at 94 ℃ for the initial denaturation, followed by 35 cycles of 94 ℃ for 30 s, 60 ℃ for 30 s, and 72 ℃ for 30 s. Melting curve analyses following amplification were performed to assure the product specificity. The relative expression of *SPARC* mRNA was normalized to the housekeeping gene Glyceraldehyde 3-phosphate dehydrogenase (*GAPDH*) in the same cDNA using the comparative CT method. For the quantification of gene expression, the target gene (*SPARC*) value normalized to the expression of *GAPDH* was designated as ΔCT [ΔCT = CT (*SPARC*) - CT (*GAPDH*)]. The ΔCT for the nontumorous samples was then subtracted from the ΔCT for the tumorous samples to generate ΔΔCT [ΔΔCT = ΔCT (tumor) - ΔCT (nontumorous sample)]. The ΔΔCT measurement was used to calculate the relative expression ($2^{-\Delta\Delta CT}$).

Immunohistochemistry

The protein expression of *SPARC* was examined in 23 primary HCCs and the corresponding nontumorous tissues by immunohistochemistry. Sections (5 μm) from the tumor and nontumorous tissues were cut onto coated slides and deparaffinized by the routine techniques. The antigen retrieval was performed in 10 mmol sodium citrate buffer (pH 6.0), and heated at 95 ℃ for 10 min. After endogenous peroxidase activity was blocked with 30 g/L H_2O_2 for 5 min, the sections were incubated with an anti-*SPARC* monoclonal antibody at a 1:100 dilution (Santa Cruz Biotecfology, United States) overnight. Labeling was detected with the PV-9000 Kit (Zhongshan, Beijing, China), following the protocol afforded by the manufacturer, and all sections were counterstained with hematoxylin. Cytoplasm staining of more than 90% parenchyma cells (tumor cells or liver cells) was regarded as positive for *SPARC*.

Similarly, *SPARC* protein was also tested in SMMC-7721 cells growing on the coverslips by immunocytochemistry.

Analysis for clinicopathological data and statistics

The gene methylation status in HCC was evaluated in the correlation with the clinicopathological parameters of patients, including age, gender, tumor size, virus infection, liver function, tumor number, vascular infiltration, pathology class and the level of alpha-fetal protein (AFP). The Pearson χ^2 test or the Fisher's exact test was used to analyze associations between methylation frequencies and categorical variables. Disease free or overall survival was calculated from the date of the operation until tumor recurrence or death or the date of the last follow-up (censored). Survival was analysed by the Kaplan-Meier method, and differences in their distribution were evaluated by the log-rank test. A multivariate Cox's proportional-hazard model was developed to evaluate the covariates' joint effects. All *P* values were two-sided, and *P* value less

than 0.05 was defined as being statistically significant. Analyses were performed with SPSS V 13.0 software for Windows (SPSS, Chicago, United States).

RESULTS

Methylation status and expression of SPARC in SMMC-7721 cells

We used MSP to measure both methylated and unmethylated segments in the *SPARC* promoter region. The results demonstrated that only the methylated segment was detected in SMMC-7721 cells of the control group. However, both methylated and unmethylated segments were found in the cells after treated with 5-Aza-CdR. These results indicated that *SPARC* was homologously methylated in SMMC-7721 cells and 5-Aza-CdR could convert the methylation status of *SPARC*. RT-PCR revealed that the *SPARC* mRNA expression was absent in the cells without the 5-Aza-CdR treatment, however, the cells treated with the 5-Aza-CdR restored the *SPARC* mRNA expression. Consistently, the immunocytochemical analysis of the cultured cells displayed that the *SPARC* protein expression was restored in the cells previously lacking

of the *SPARC* expression. The concordance between the loss of gene expression and the aberrant methylation suggested that the DNA methylation played a causal role in the loss of the *SPARC* expression in SMMC-7721 cells. The representative results are shown in Figure 1.

The bisulfite sequencing displayed that the control cells were methylated at almost all the 18 CpG sites in the 8 clones. On the contrary, most of CpG sites were unmethylated in the cells treated with 5-Aza-CdR. Figure 2 shows the methylation pattern of the *SPARC* promoter in SMMC-7721 cells.

Frequent SPARC hypermethylation in human HCC

We used MSP to evaluate the *SPARC* methylation status of the CpG island in 60 pairs of tissues. Methylation alleles in 75.00% (45/60) of HCC samples were detected, however, only 11.67% (7/60) methylated alleles could be found in the corresponding nontumorous tissues. The methylation frequence of *SPARC* in HCC was significantly higher than that in noncancerous liver tissues (Table 2). If methylation was used as an indicator for distincting HCC from nontumorous tissues, the sensitivity, specificity and accuracy were 86.54%, 77.94% and 81.67%, respectively. To validate the accuracy of MSP, we randomly chose the PCR products of methylation or unmethylation for sequencing. The results were according to the PCR aim segments. The representative results of PCR and sequencing are demonstrated in Figure 3.

Correlation between SPARC methylation and mRNA expression

The expression of *SPARC* mRNA was examined in 60 pairs of HCC and nontumorous tissues by quantitative

Figure 2 Bisulfite sequencing of secreted protein acidic and rich in cysteine in SMMC-7721 cell line. *SPARC*: Secreted protein acidic and rich in cysteine; TSS: Transcription start site; BS: Bisulfite sequencing; M: Methylation; U: Unmethylation; 5-Aza-CdR: 5-aza-2'-deoxycytidine; 1-18: CpG sites; - 119 to - 95, + 260 to + 282, + 52 to + 71, + 142 to + 163, + 36 to + 58, + 143 to + 167: Polymerase chain reaction primers position; Black dots: Methylation; Blank rings: Unmethylation.

RT-PCR. Most of primary HCC tissues (65.00%, 39/60) showed a lower expression level when compared with their corresponding nontumorous livers (Figure 4A). Moreover, the median of relative expression was statistically different between the methylated and unmethylated *SPARC* samples of HCC ($P = 0.040$) (Figure 4B). The methylated samples had a lower median of expression.

Methylation and protein expression

The protein expression of *SPARC* was examined in 23 pairs of HCC and nontumorous tissues by immunostaining. The positive frequency of tumor cells in HCC was relatively lower than that of liver cells in nontumorous tissues, but there was no statistical significance between two groups (Table 3). We divided all 46 samples into

methylation and unmethylation groups (14 *vs* 32). There was no statistical correlation between the methylation and the protein expression (Table 4). In some HCC samples, stromal cells around tumor cells showed a positive signal even if the parenchyma cells had no expression of *SPARC*. The representative immunohistochemical staining is shown in Figure 5.

Relationship between methylation and clinical data

We analyzed the association of *SPARC* methylation with clinicopathological parameters in patients with HCC.

Table 5 Correlation between methylation status and clinico-pathological data

There was significant association between the methylation status and the pathological class. The *SPARC* methylation was more frequently observed in cases with a high pathologic grade (33 of 39, 84.6%) than in those with a low grade (12 of 21, 57.1%) (Table 5). However, there was no statistically significant correlation between the methylation status and other clinicopathologic factors.

Prognostic value of SPARC methylation in HCC

We also divided all cases into two groups according to the methylation status of *SPARC* to determine whether this factor had prognostic value. The disease free survival between the two groups had no statistical difference. Patients whose primary tumors exhibited *SPARC* methylation had a lower overall survival rate after resection (28.0 mo *vs* 41.0 mo, *P* = 0.043, Table 6 and Figure 6). Five clinicopathological factors and methylation status of *SPARC* found to be prognostic on the univariate analysis were entered into a multivariate model to identify independent predictors of overall survival. The Cox's multivariate proportional-hazard model indicated that the factors significantly affecting overall survival were tumor size, AFP level and *SPARC* methylation (Table 7).

DISCUSSION

In this current study, we determined the methylation status of *SPARC* gene promoter in SMMC-7721 cell line

and HCC tissues. The data suggested that in SMMC-7721 cell line, hypermethylation of the promoter was an important mechanism for *SPARC* downregulation, which was most likely involved in the development and progression of HCC. Moreover, the methylation frequency of *SPARC* was significantly higher in the HCC tissues than in the corresponding nontumorous tissues. The hypermethylation of *SPARC* was associated with pathological class and patients without *SPARC* methylation had higher rates of overall survival after resection. Our results showed that methylation of *SPARC* could be further evaluated as a tumor marker for the diagnosis and

prognosis of HCC.

In some tumor cell lines, aberrant methylation of *SPARC* has been tested. Functional studies have shown that methylation of *SPARC* could induce gene silence and possess tumor suppressing effects[24-26]. Transcription factors were incapable of binding to the methylated DNA of their recognition sequences, therefore, the gene transcription was blocked[24,25]. However, the demethylating agent could convert the methylation status and restore the gene expression. *SPARC* involved in the occurrence and development of certain cancers[27-31]. In concordance with these studies, we observed that the loss of *SPARC* expression correlated with the aberrant methylation and this loss of expression could be rescued by the demethylating agent 5-Aza-CdR. These data suggested that hypermethylation of the promoter is also an important mechanism for *SPARC* inactivation in SMMC-7721 cell line. The results of our DNA bisulfite sequencing of the *SPARC* promoter also displayed that 5-Aza-CdR could convert the methylation status and affect the expression of *SPARC*.

We observed that *SPARC* methylation occurred more frequently in HCC tissues than in nontumorous tissues. We tested the same segments of putative CpG island near the transcription start site in HCC samples, and compared with the previous groups[15,32]. The results showed that *SPARC* methylation was also a relatively higher frequent incident in HCC and the sequencing results validated that there were high-density methylated CpG sites in the amplified region. The distinct methylation status of *SPARC* gene in the benign and malignant tissues was the prereq-

uisite to determine it as an effective molecular biomarker. *SPARC* could discriminate HCC from the nontumorous tissues with a high sensitivity and a specificity, suggesting that *SPARC* methylation may be a promising epigenetic biomarker for the assistant diagnosis of HCC.

In this study, we observed that 65.0% of the HCC samples showed a relatively lower expression level of *SPARC* mRNA compared with the nontumorous tissues. On the contrary, previous groups have reported that *SPARC* was overexpressed in HCC tissues as compared with the nontumorous tissues, nevertheless, *SPARC* mRNA and protein were mainly detected in the tumor capsule, and fibrous bands within HCC[26,33]. *SPARC* was strongly expressed by the stromal myofibroblasts of HCC[26]. In our study, except for different patient population, we used exclusively tumors with more than 80% of epithelial tumor cells to test the *SPARC* mRNA expression, which could minimise the potential contamination of stromal cells in HCC. Some studies in other cancers have revealed aberrant hypermethylation of the *SPARC* promoter to be responsible for low levels of *SPARC* expression[15,16]. In concordance with these studies, we found that the *SPARC* expression of samples with methylation was significantly lower than that without methylation. Although there were other possible mechanisms for the downregulation of the *SPARC* expression, the concordance between the mRNA expression and the DNA methylation indicated that the gene was downregulated, at least partially, through the DNA methylation in HCC. We found no significant correlation between the *SPARC* protein expression and the DNA methylation. The regulation of the translation process or the degradation of protein might also influence the *SPARC* protein abundance in HCC tissues. On the other hand, the *SPARC* protein might be variably expressed by the heterogeneous hypermethylation in one allele of tumor cells. But, interestingly, we also found the *SPARC* expression in the stromal cells in HCC even though the tumor cells had a negative signal, which was accordant with the report[33].

We demonstrated that the pathological class was the only clinicopathological variable associated with the *SPARC* methylation and patients with the *SPARC* methylation tended to have a poorer overall survival after resection in this study. It may be explained by the function of this gene, which was involved in the tumor progression. *SPARC* could inhibit the progress of tumor by restraining the angiogenesis and affecting the extracellular matrix production[34-36]. Our results suggested a potential clinical use of *SPARC* methylation as a prognostic marker in patients with HCC. Because *SPARC* methylation was a kind of DNA marker, it will be possible to detect the status of *SPARC* methylation in peripheral blood in the future, which might be more convenient and less traumatic than using the pathological tissues. However, since the number of patients in this study is relatively small, these findings need to be verified in a study with more patients and a longer follow-up period.

In conclusion, the results in this study indicated that

SPARC promoter hypermethylation in HCC was most likely related to a disease state, which may provide potential diagnostic or predictive markers of this disease.

COMMENTS

Background
Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world. The development of biomarkers for early diagnosis and accurate prognosis of HCC is important for improving patients' survival. Aberrant DNA methylation of tumor suppressor genes could be used as a new marker for HCC in the future.

Research frontiers
It has been reported that secreted protein acidic and rich in cysteine (*SPARC*) has tumor suppressing properties to some cancers. Moreover, the *SPARC* promoter methylation is an important factor in the carcinogenesis of these cancers and may be a promising epigenetic marker for them. However, up to date, there have been few reports about the methylation status in HCC. In this study, the authors detected the status of *SPARC* methylation in HCC and estimated its clinical implication.

Innovations and breakthroughs
This is the first study to report that *SPARC* hypermethylation is a high frequent event in HCC. The downregulation of the *SPARC* mRNA expression in HCC is correlated with the *SPARC* methylation. The patients with methylated *SPARC* had a poorer overall survival than those without methylated *SPARC*.

Applications
The results in this study indicated that *SPARC* hypermethylation in HCC is most likely related to a disease state, which might be helpful for finding potential diagnostic or predictive markers of this disease.

Peer review
This is a good descriptive study in which authors investigate the methylation status of *SPARC* in HCC and evaluate its clinical implication. The results are interesting and suggest aberrant methylation is an important mechanism for *SPARC* inactivation in HCC and *SPARC* methylation may be a promising biomarker for the diagnosis and prognosis of HCC.

Abstract

AIM: To develop an affinity peptide that binds to gastric cancer used for the detection of early gastric cancer.

METHODS: A peptide screen was performed by biopanning the PhD-12 phage display library, clearing non-specific binders against tumor-adjacent normal appearing gastric mucosa and obtaining selective binding against freshly harvested gastric cancer tissues. Tumor-targeted binding of selected peptides was confirmed by bound phage counts, enzyme-linked immunosorbent assay, competitive inhibition, fluorescence microscopy and semi-quantitative analysis on immunohistochemistry using different types of cancer tissues.

RESULTS: Approximately 92.8% of the non-specific phage clones were subtracted from the original phage library after two rounds of biopanning against normal-appearing gastric mucosa. After the third round of positive screening, the peptide sequence AADNAKTKSFPV (AAD) appeared in 25% (12/48) of the analyzed phages. For the control peptide, these values were 6.8 ± 2.3, 5.1 ± 1.7, 3.5 ± 2.1, 4.6 ± 1.9 and 1.1 ± 0.5, respectively. The values for AAD peptide were statistically significant ($P < 0.01$) for gastric cancer as compared with other histological classifications and control peptide.

CONCLUSION: A novel peptide is discovered to have a specific binding activity to gastric cancer, and can be used to distinguish neoplastic from normal gastric mucosa, demonstrating the potential for early cancer detection on endoscopy.

INTRODUCTION

New methods for the early detection of gastric cancer (GC) are urgently needed. GC is the second most common cause of cancer-related mortality worldwide[1,2]. Early detection is of paramount importance to improve the 5-year survival rate of the patients. Periodic endoscopic surveillance is the only currently available means to diagnose early gastric cancer in high-risk populations who have pre-cancerous lesions such as atrophic gastritis and intestinal metaplasia. However, the current surveillance program and mode of endoscopic diagnosis are labor-intensive and economically unfeasible. White light endoscopy has limited effectiveness for early GC screening. Neoplastic lesions can be less than a millimeter in size which is difficult to localize within regions of precancerous mucosa that usually are several square centimeters. Thus, a rigorous method is needed for selecting and validating molecular probes that bind specifically and highlight neoplastic lesions.

Molecular imaging is a technique that identifies and characterizes tumors and other lesions based on their protein expression pattern, rather than by their macroscopic morphology[3]. The molecular expression pattern of cells and tissues can be visualized with the help of disease-specific molecular probes such as antibodies, antibody fragments, peptides, radioactive probes and nanoparticles[4-6]. Such molecular probes enable the diagnosis of disease *in situ* and in real time. In a previous study, a heptapeptide was isolated from a phage library and conjugated with fluorescein for labeling of colonic dysplasia[7]. Although the molecular target of this sequence has not yet been identified, preferential binding of this targeting moiety to neoplastic cells *in vivo* with a high sensitivity and specificity was observed. In recent clinical studies, molecular imaging has been developed for guiding biopsy of high-grade dysplasia in Barrett's esophagus using fluorescent-labeled peptides. An affinity peptide selected using phage display techniques was administered over a region of intestinal metaplasia in resected specimens of the distal esophagus. The wide-area stereoscopic images of increased fluorescence intensity could predict and localize high-grade dysplasia[8].

In this study, we screened a peptide that has highly specific binding activity to human GC tissues. When labeled with fluorescein isothiocyanate (FITC), the peptide has the potential for *in vivo* use to produce increased fluorescence intensity at the site of neoplastic mucosa. This method can be used as a more specific strategy for early detection of GC.

MATERIALS AND METHODS

Cell culture

The human gastric cancer cell line BGC823 and Epstein-Barr virus-transformed human gastric epithelial cell line GES-1 were maintained in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum, 100 U/mL penicillin and 100 μg/mL streptomycin. Cells were incubated at 37 ℃ in an atmosphere with 5% CO_2.

Human tissue specimens

Peptide screen was conducted in the patients ($n = 3$) with histologically validated intestinal-type gastric adenocarcinoma (Lauren's classification). Paraffin-embedded human tissues from 36 cases of gastric cancer (21 intestinal and 15 diffuse) and 15 cases of adjacent normal appearing gastric mucosa, 12 cases of breast cancer, and 15 cases of colorectal cancer were used for validating the screened peptide. The study was approved by the Bioethics Committee of the First Affiliated Hospital of Xian Jiaotong University Medical College, and written informed consent was obtained from all the patients. For the peptide screen, fresh specimens of cancer and adjacent normal appearing gastric mucosa (5 cm away from the macroscopic margin of the tumor) were collected during subtotal gastrectomy. Half of the tissue was cut into 0.5 cm × 0.5 cm × 0.3 cm pieces immediately and washed with magnesium-free Dulbecco's phosphate-buffered saline (PBS) for 2 min at 4 ℃ to be used for biopanning or immunofluorescence procedures[9]. The other half of the tissue was embedded in optimal cutting temperature freezing compound (Sakura Finetek United States, Torrance, CA) immediately. The tissue was cut into 6-μm sections, mounted onto Poly-D-Lysine-coated slides, and stored at -80 ℃ for the peptide binding assay. All the histopathological specimens were evaluated by two gastrointestinal pathologists who were blinded to each other according to the common procedural criteria for such studies and to the imaging results[10].

Peptide screening

Peptides were selected using the PhD-12™ phage display peptide library (New England BioLabs, Beverly, MA)[11-13]. This library has 1×10^{13} pfu/mL phages, with a diversity of 1.28×10^9 unique peptide sequences and about 70 copies of each sequence. For screening, non-specific binding phage was cleared from the library by panning against normal appearing gastric mucosa adjacent to the tumor. Tissue blocks were placed into 12-well cell culture plates and blocked by adding one mL of 1% bovine serum albumin (BSA) diluted in PBS for 30 min at 4 ℃. Phage (1×10^{11} pfu) in one mL of blocking buffer was incubated with tissue at room temperature (RT) for 30 min with gentle agitation. The supernatant containing unbound phages was collected and added to another well for the second round of clearance. The resulting supernatant was incubated with the gastric cancer specimens for positive selection. After 30 min of biopanning at RT, the tissue specimens were transferred to 1.5 mL tubes and washed 10 times with PBST (PBS/0.1% Tween-20, v/v). The bound phages on the tissue surface were eluted with one mL of 0.2 mol glycine, pH 2.2, 0.1% BSA for 8 min and immediately neutralized with 150 μL of 1 mol Tris, pH 9.5. The eluted phage was amplified and tittered according to the manufacturer's instructions. The resulting phage (10^{11} pfu) was used to perform another round of positive selection, as described above. In the last 2 rounds, elution was first performed for 2 min to remove the weakly bound phages, and new elution buffer was

then added to obtain the stronger bound phage.

Phage clones (n = 48) obtained from the last round of biopanning were randomly selected and sequenced. Peptide sequences that appeared more than twice were selected as candidates for further analysis. These peptide sequences were analyzed by searching the UniProtKB/Swiss-Prot database for homology using the basic local assignment search tool (BLAST, National Center for Biotechnology Information, Bethesda, MD) with the option for short, nearly exact matches to identify potential human protein targets.

Cell enzyme-linked immunosorbent assay

The protocol used for performing the cell enzyme-linked immunosorbent assay (C-ELISA) has been described previously[14]. BGC823 and GES-1 cells were allowed to reach an 80%-90% confluency in 96-well plates. The wells were blocked for 30 min at 37 ℃ with 200 μL BSA. Next, 2×10^7 pfu of candidate phages were incubated separately with each cell type in triplicate at RT for 30 min. The insertless wild-type phage (M13KE, New England Biolabs, Beverly, MA) was used as a control. Bound phages were detected using a horseradish peroxidase-conjugated polyclonal anti-M13 phage antibody (Pharmacia, United States). Tetramethylbenzidine working substrate solution (50 μL/well; Sigma, St Louis, MO) was added and incubated for 20 min at RT. The reaction was stopped by adding 4 mol H_2SO_4. Between each incubation step, the plates were washed three times with 300 μL TBST (0.5% Tween-20). Absorbance was measured at 490 nm using a microplate reader (Bio-Rad model 550, Hercules, CA). Untreated cells were used as controls. The absorbance (A) values between different groups were compared.

Phage binding affinity on human tissues

Specific binding of the candidate phages to gastric cancer was validated by incubating 2×10^{11} pfu of each phage (candidates and M13KE) with fresh gastric cancer or adjacent normal appearing gastric mucosa in wells in triplicate. The steps of incubation, two-step elution, and titration of phages were performed as described above. All of the eluted phages were tittered to determine the mean phage plaque numbers. The ratio of binding of each phage group to gastric cancer relative to that of M13KE was calculated. The level of binding of each phage clone to gastric cancer and normal appearing gastric mucosa was analyzed using the Student's t test.

Peptide synthesis

The candidate peptides were synthesized (Shanghai Biochem, Shanghai, China) using standard solid-phase fluorenylmethyloxycarbonyl chloride chemistry and purified to a minimum purity of 98% using high-performance liquid chromatography (HPLC). Analysis was performed by reverse phase HPLC and mass spectrometry[15]. FITC or biotin was conjugated to the C-terminus of the peptide *via* a flexible linker with the 5 amino acid sequence GGGSK (12-mer peptide-GGGSK-FITC or 12-mer peptide-GGGSK-biotin), the sequence of which is the same as that for the linker on the coat protein pⅢ of the M13 phage. For the control, the candidate peptide was scrambled to form a peptide sequence containing the same amino acids.

Competitive inhibition assay

Preferential binding of the candidate peptide to gastric cancer was further validated by a competitive binding assay. The candidate peptides at concentrations of 0.5, 5, 50, 500 and 5000 μmol were incubated with fresh gastric cancer or adjacent normal appearing gastric mucosa in wells in triplicate. Each phage (2×10^{11} pfu; candidate or M13KE) was then added. Incubation, elution, and tittering of the binding phages were performed as described above. The ratio of binding of each phage clone to gastric cancer and normal appearing gastric mucosa was analyzed.

Peptide binding on fresh human tissues

Peptide-based immunofluorescence analysis was performed to validate binding of the candidate peptide to human gastric cancer[16,17]. Frozen sections of human gastric cancer and adjacent normal appearing gastric mucosa tissues were blocked with PBS containing 3% BSA for 30 min at RT. Slides were then incubated with 100 μmol of the candidate peptide (peptide-FITC) for 30 min at 37 ℃, rinsed 3 times with PBST and fixed in acetone at 4 ℃ for 90 s, counterstained with propidium iodide, and mounted using PBST. Fluorescent images of the sections were recorded at 400× magnification. A FITC-labeled scrambled peptide was used as a negative control.

Peptide binding affinity on paraffin-embedded human tissues

The streptavidin-peroxidase-biotin immunohistochemical method was performed to detect candidate peptide binding on paraffin-embedded human tissues[18] from 36 cases of gastric cancer (21 intestinal and 15 diffuse) and 15 cases of adjacent normal appearing gastric mucosa, 12 cases of breast cancer, and 15 cases of colorectal cancer. In brief, paraffin-embedded specimens were cut into 4-μm sections and kept at 60 ℃ for 60 min. The sections were deparaffinized with xylene and rehydrated. Sections were submerged into ethylenediaminetetracetic acid antigenic retrieval buffer, microwaved for antigenic retrieval, and then cooled at RT for 20 min. The sections were pretreated with 3% hydrogen peroxide in methanol to quench the endogenous peroxidase activity, followed by incubation with normal serum to block non-specific binding. Then the sections were incubated with 100 μmol biotin-conjugated peptide for one hour at 37 ℃. The unbound peptide was rinsed off with PBS. The tissue sections were incubated with the streptavidin-horseradish peroxidase complex (Zhongshan Biotechnology, Beijing, China), and stained with diaminobenzidene (DAB). Finally, the sections were counterstained with hematoxylin. A biotin-labeled scrambled peptide was used as a negative control.

Semi-quantitative image analysis was performed as reported previously[19]. In brief, 3 images with typical

Figure 1 Preferential phage-binding to BGE823 and GES-1 cells. Phage capture enzyme-linked immunosorbent assay revealed a greater optical density at binding sites of AADNAKTKSFPV (AAD) phage to BGE823 cells compared with that of wild type phage ([b]*P* < 0.01) or no phage. No significant difference was found in binding of AAD phage to the control cells. WT: Wild type.

Figure 2 Phage binding affinity. AADNAKTKSFPV (AAD) phage showed an about 615 times higher binding efficiency in gastric cancer (GC) tissues than wild type (WT)-phage, and the binding of AAD phage was about 591 times greater in GC tissues than in gastric mucosa.

features were selected from each slide. The quantitative labeling index was calculated as the ratio of brown membranous area stained by DAB to round blue areas stained by hematoxylin, for the assessment of tumor cell density in the selected image. The extractions of the brown *vs* blue signal were carried out based on an RGB color parameter. The blue areas larger than 0.005 mm^2 were eliminated because of the nuclear staining in cells such as fibroblasts and lymphocytes but not in carcinoma cells. Images were analyzed using NIH Image J software.

Statistical analysis

Differences in the mean *A* value, number of eluted phages, and image intensity for all tissue classifications were compared using a one-way analysis of variance (ANOVA) or two-sided Student's *t* test with unequal variance. Statistical significance was assessed at the level of *P* = 0.01. All results were presented as mean ± SD unless otherwise noted.

RESULTS

Enrichment of phage with specific binding to tumor tissues

Approximately 92.8% of the non-specific phage clones were subtracted from the original phage library after two rounds of biopanning against normal appearing gastric mucosa. After the third round of positive screening, 50 phage clones that specifically bound to human gastric cancer were randomly selected from the enriched phage library. Phage clones were amplified and sequenced. The peptide sequence AADNAKTKSFPV (AAD) appeared in 25% (12/48) of the analyzed phages. Except for 2 phage clones which expressed the same peptide sequence IVWPTSPRALDA, the other 36 clones expressed unique amino acid sequences. These peptide sequences were analyzed by searching the UniProtKB/Swiss-Prot database using BLAST. Peptide AAD has identities = 10/14 (71%) with methyltransferase, which belongs to UbiE/COQ5 family.

Selective phage binding verified by C-enzyme-linked immunosorbent assay

The C-ELISA demonstrated selective binding of the AAD phage to BGC823 cells. As shown in Figure 1, the *A* value for the AAD phage binding to BGC823 cells was 1.15 ± 0.09 compared to 0.61 ± 0.07 and 0.65 ± 0.05 for the wild type (WT)-phage (*P* < 0.01) and no phage (*P* < 0.01), respectively. The *A* for AAD phage binding to the GES-1 cells was 0.123 ± 0.035 compared to 0.189 ± 0.045 and 0.271 ± 0.035 for the WT-phage (*P* > 0.05) and for no phage (*P* > 0.05), respectively. These results suggest that the AAD phage binds specifically to the BGC823 (cancer) cells and not to the GES-1 (control) cells. WT-phage and no phage did not bind significantly to any of the cells.

Phage binding affinity to gastric cancer tissues

The AAD phage showed about 615 times greater binding to gastric cancer than did the WT-phage, with a total phage number of 4.8 × 10^6 *vs* 7.9 × 10^3, as shown in Figure 2 (*P* < 0.01). Similarly, the binding of AAD phage was 591 times greater to gastric cancer than normal appearing gastric mucosa with a total phage number of 7.1 × 10^6 *vs* 1.2 × 10^4, respectively (*P* < 0.01, Figure 2). These results suggest that AAD phage binds specifically to gastric cancer (target) and not to the adjacent normal appearing gastric mucosa (control).

Competitive binding assay

As shown in Figure 3, we observed that the addition of 0.5, 5, 50, 500 and 5000 μmol of the compound consisting of the AAD peptide with the GGGSK linker (AAD-GGGSK) resulted in a significant reduction in the number of bound phages, corresponding to values of 2900 × 10^4, 1680 × 10^4, 1320 × 10^4, 80 × 10^4 and 0 (*P* < 0.01), respectively. Moreover, we did not see any significant change in the number of bound phages with the addition of 0.5, 5, 50, 500 and 5000 μmol of the control peptide (PAKFKAANSDVT), which resulted in a total of (2300 ± 41) × 10^4 bound phage (*P* < 0.01) at 5000 μmol. These

Figure 3 Competition binding assay. Binding of AADNAKTKSFPV (AAD) phage to gastric cancer tissues is reduced by competition with increasing concentrations of AAD peptide ($P < 0.01$) in a dose-dependent manner. The addition of the control peptide at concentrations of 0.5, 5, 50, 500 and 5000 μmol revealed no competitive inhibition.

results suggest that the AAD peptide competes with the AAD phage for binding to gastric cancer, and that binding is determined by the specific sequence of the expressed peptide, rather than by the phage coat proteins.

Peptide-based immunofluorescence assay

The peptide-based immunofluorescence assay was performed to confirm the selective binding of the AAD phage to fresh gastric cancer tissues. As shown in Figure 4, the fluorescence images displayed that the AAD peptide binds to both the tumor cell membrane and cytoplasm (C), but not to adjacent normal appearing gastric mucosa (B). Fluorescence was seen on the membrane and in the perinuclear cytoplasm of gastric cancer cells. The FITC-labeled scrambled control peptide, PAKFKAAN SDVT, did not bind to tumor tissues.

Binding analysis of biotin-AAD by immunohistochemistry

Tissue slides from multiple types of other human cancers were prepared to evaluate specific binding of biotin-labeled AAD peptide. From the results shown in Figure 5, biotin-AAD demonstrates specific binding to intestinal (Figure 5A) and diffuse (Figure 5B) gastric cancer. In contrast, no staining was observed in normal appearing gastric mucosa (Figure 5C), or breast cancer (Figure 5D) and colon cancer (Figure 5E). Weak binding of the AAD peptide to gastric mucosa dysplasia (Figure 5F) and intestinal metaplasia (Figure 5G) was also observed. The negative results were obtained when gastric cancer tissues were stained with biotin-conjugated scramble peptide (Figure 5H) and PBS (Figure 5I). In the positive slides, the area stained dark brown was located at the membrane and perinuclear cytoplasm, which is the same as FITC-conjugated AAD binding on fresh GC tissues, indicating the positive binding region of peptide AAD to GC cells.

Semi-quantitative image analysis was then performed. For the AAD peptide, the values in 37 specimens of gastric cancer (21 intestinal and 15 diffuse), 15 specimens of normal appearing adjacent gastric mucosa, 12

Figure 4 Immunofluorescence analysis of fluorescein isothiocyanate-conjugated AADNAKTKSFPV binding to human gastric cancer tissues. Frozen sections for biopanning were incubated with fluorescein isothiocyanate-conjugated AADNAKTKSFPV (AAD); scrambled peptide PAKFKAANSDVT was used as the control. Immunofluorescence stain with FITC-conjugated AAD showed selective signals (green) located in tumor membrane, cytoplasm (C), but no binding to normal gastric mucosae (B). As a control, the scramble peptide displayed no signals in tumor tissues (A).

specimens of breast cancer, and 15 specimens of colon rectal cancer were 150.0 ± 11.0, 135.5 ± 13.2, 43.5 ± 3.4, 52.3 ± 6.4 and 39.6 ± 5.0, respectively (Figure 6). For the control peptide, these values were 6.8 ± 2.3, 5.1 ± 1.7, 3.5 ± 2.1, 4.6 ± 1.9, and 1.1 ± 0.5, respectively. A one-way ANOVA showed an F-value of 1149.2 ($P < 0.01$), and the pair-wise t test yielded a t value of 15.3 ($P < 0.01$), demonstrating that the result for the AAD peptide is statistically significant for gastric cancer as compared with other histological classifications and control peptides.

DISCUSSION

Other investigators have used phage display technology

Figure 5 Binding analysis of biotin-AADNAKTKSFPV by immunohistochemistry. The results demonstrate that biotin showed a specific binding affinity to gastric cancer (GC) (A: Intestinal; B: Diffuse). In contrast, no positive staining was observed in gastric mucosae (C). In addition, peptide AADNAKTKSFPV (AAD) did not bind to breast cancer (D) or colon cancer (E), suggesting that the AAD peptide is specific to GC. A small amount of binding of the peptide AAD to the gastric mucosa dysplasia (F) and intestinal metaplasia (G) was also observed. The negative results were also obtained when GC tissues were stained with the biotin-conjugated scramble peptide (H) or phosphate-buffered saline (I).

Figure 6 Semi-quantitative image analysis. AADNAKTKSFPV (AAD) peptide is statistically significant for gastric cancer as compared with other histological classifications and control peptide. GC: Gastric cancer.

to select peptides that target specific organs, tumors, and proteins without prior knowledge of the target's molecular structure[20-22]. These libraries often contain more than 10 billion unique sequences, which enable peptide

selection with highly specific binding properties. Peptides specific for endothelial markers in dysplasia have been identified in mice[23-26]. Biopanning using freshly harvested human tissues has successfully isolated peptides that specifically bind to polarized luminal surfaces of dysplastic colonocytes[27,28]. In this study, we selected the 12-mer peptide AAD using the PhD-12 library. This peptide exhibited specific binding to human gastric cancer cells in culture and tissues.

The biopanning protocol used in this study was different from that used by most other investigators. The original phage library was first panned against freshly harvested normal-appearing mucosa adjacent to cancer to clear non-specific phages. After the clearing of normal mucosa binding phage from the original phage library, the likelihood of obtaining gastric cancer-specific peptides in the following tumor-targeted screen increased. We removed 92.8% of the phage clones from the original library after two rounds of subtractive biopanning. To avoid biasing the library, we did not amplify the remaining phage pool between each round. The pep-

tide sequence AAD appeared in more than 20% (12/50) of the analyzed phages after the third round of positive screening. This peptide was found to have no more than a 50% amino acid residue homology to the reported protein sequence. Phage expressing this peptide demonstrated preferential binding to cultured gastric cancer cells and fresh gastric cancer mucosa, and was validated by ELISA and bound phage counts. The binding was inhibited by the addition of competing peptide AAD, thus supporting cell surface binding. Moreover, when conjugated with FITC or biotin, the peptide AAD can be used as an *in vitro* peptide probe to distinguish tumor-adjacent mucosa from gastric cancer.

There is a great clinical need to improve the cancer screening and surveillance methods for diseases such as Barrett's esophagus, gastric intestinal metaplasia, flat and depressed sporadic colonic adenomas, and bladder carcinoma *in situ*. In nuclear medicine, imaging with radioactively labeled probes is routinely used. In contrast, fluorescent-labeled probes in gastrointestinal endoscopy are still being developed. Tumor-specific molecular probes have been used to improve the lesion contrast during gastrointestinal endoscopy to guide tissue biopsies[29]. Most digestive tract neoplasia arises from the epithelial layer, which is compatible with topical administration of the probe. Thus, molecular imaging has a particular advantage in the diagnosis or treatment of disorders of the gastrointestinal and other hollow organs, compared with lesions from solid tumors. Antibodies against epitopes that are over-expressed in gastrointestinal cancers, such as vascular endothelial growth factor (VEGF) or epidermal growth factor receptor (EGFR), have been fluorescently labeled and used for *in vivo* imaging[30,31]. These antibodies have highly selective binding affinities to their target structures, with an optimized signal-to-background ratio. With the disclosure of the biologic relevance of their targets, therapeutic antibodies were developed such as cetuximab and panitumumab against EGFR, and bevacizumab against VEGF.

Peptides have several advantages over antibodies as disease-specific probes for molecular imaging. Peptides consist of only a few amino acids, and have much smaller structures with lower molecular weight. Therefore, peptides have better tissue penetration, shorter plasma half-life, and less associated immunogenicity[32-34]. In this study, peptide AAD showed a weak binding affinity to gastric dysplasia, but a significantly higher binding affinity to gastric cancer. A possible reason is that the targets are expressed at a lower level in pre-cancerous lesions as compared with cancer cells. As a molecular probe, peptide AAD may be used for grading dysplastic tissue and diagnosis of cancerous mucosa in early stage gastric cancer. The difference in binding affinity was not as significant between peptide AAD and the control peptide as reported in some published studies[35,36]. This may indicate a lower sensitivity as a tumor-specific probe and influence its future use. However, because of their pharmacokinetic advantages for *in vivo* imaging, tumor-targeting peptides do not necessarily have the highest binding

affinity. Multiple excitation and detection wavelengths, in conjunction with multiple labels, may further enhance the applicability of this strategy. More than one tumor-specific peptide, each with a different target and fluorescent-label, could be mixed to increase the sensitivity, which may be used as a promising strategy for *in vivo* detection. Even with the limitations of current approaches, molecular imaging has the potential to greatly affect future imaging in gastroenterology. Future efforts should focus on the validation of peptides binding to malignantly-transformed mucosa *in vivo*.

Great progress has been made in molecular imaging in recent years, and technological and scientific advancement in endoscope compatible instruments have provided new imaging tools to improve the detection of early neoplastic lesions. Fluorescence endoscopes and confocal microendoscopes have been developed with a high sensitivity[37-39]. Once integrated with novel screening and surveillance methods, molecular endoscopy will prove effective real-time localization of dysplasia or neoplastic mucosa. Molecular probes that bind to suspected mucosal lesions may guide the doctor to perform a targeted biopsy. *In vivo* molecular imaging of live tissues may be less sensitive to bias from sampling error and tissue processing artifact than conventional histopathology, thus increasing the efficiency of endoscopic screening and surveillance. The peptide AAD identified in this study has the potential to guide tissue biopsy and improve the detection of pre-cancerous lesions in gastric mucosa.

COMMENTS

Background
Periodic endoscopy in high risk populations is most helpful in improving the early detection of gastric cancer (GC). However, the current endoscopic surveillance program for GC is labor-intensive and ineffective. Molecular probes are being developed to increase image contrast from early cancer during endoscopy to guide biopsy in some pioneered reports.

Research frontiers
Molecular imaging is a technique that identifies and characterizes tumors and other lesions based on their protein expression pattern, rather than by their macroscopic morphology. The molecular expression pattern of cells and tissues can be visualized with the help of disease-specific molecular probes such as antibodies, antibody fragments, peptides, activatable probes and nanoparticles. Such molecular probes enable the diagnosis of disease *in situ* and in real time.

Innovations and breakthroughs
In this study the authors discovered a novel peptide that has specific binding activity to GC and can be used to distinguish neoplastic from normal gastric mucosa.

Applications
The peptide AADNAKTKSFPV identified in this study has the potential to guide tissue biopsy and improve the detection of pre-cancerous lesions in gastric mucosa.

Peer review
The topic of the study is interesting and the authors tried to tackle very relevant and clinical important issues, the early detection of GC. The authors identified a peptide that seems to bind to GC tissue like an antibody.

Abstract

AIM: To investigate perioperative patient morbidity/mortality and outcome after cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC).

METHODS: Of 150 patients 100 were treated with cytoreductive surgery and HIPEC and retrospectively analyzed. Clinical and postoperative follow-up data were evaluated. Body mass index (BMI), age and peritoneal carcinomatosis index (PCI) were chosen as selection criteria with regard to tumor-free survival and perioperative morbidity for this multimodal therapy.

RESULTS: CRS with HIPEC was successfully performed in 100 out of 150 patients. Fifty patients were excluded because of intraoperative contraindication. Median PCI was 17 (1-39). In 89% a radical resection (CC0/CC1) was achieved. One patient died postoperatively due to multiorgan failure. Neither PCI, age nor BMI was a risk factor for postoperative complications/outcome according to the DINDO classification. In 9% Re-CRS with HIPEC was performed during the follow-up period.

CONCLUSION: Patient selection remains the most important issue. Neither PCI, age nor BMI alone should be an exclusion criterion for this multimodal therapy.

INTRODUCTION

Peritoneal carcinomatosis (PC) is generally considered to be a terminal disease and for a long time was viewed as incurable. Based on the rationale of a disease limited to the abdominal compartment[1-8], the pioneering work of Sugarbaker made it possible for certain tumor entities with PC to have the option to be cured by radical cytoreduction and hyperthermic intraperitoneal chemotherapy (HIPEC). Patient prognosis is determined by the

feasibility of complete cytoreduction (CC) and therefore a compulsory patient selection remains the Achilles heel[9]. Since the surgical procedure itself is challenging, postoperative morbidity and mortality must be considered in the preoperative evaluation process in addition to the extent of tumor spread. A high tumor load, causing a high peritoneal carcinomatosis index (PCI), is associated with poor prognosis with regard to disease-free and overall survival[10]. Age is commonly widely accepted as a selection criteria *per se* for major tumor resections. Most groups restrict cytoreductive surgery and HIPEC to patients aged under 65 years. Similarly, a high body mass index (BMI) often hampers major surgery and obese patients have more complications in general. A valid surgical complication score was developed by Dindo *et al*[11]. He defines 5 grades of complications, whereas grade 1 is any deviation from normal postoperative course; grade 2 requiring pharmacological treatment; grade 3 any radiological, endoscopic or surgical intervention; grade 4 a life threatening complication and grade 5 death.

We here report our experience with 100 consecutive cytoreductive surgeries (CRS) and HIPEC and lessons learned with respect to the perioperative period.

MATERIALS AND METHODS

During the last five years 150 consecutive patients underwent surgery with the intent to perform complete cytoreduction (CRS) and HIPEC. All patients underwent preoperative anesthesiological and cardiologic evaluation. Extraabdominal metastases were excluded and intraperitoneal tumor load was detected by computed tomography (CT), magnetic resonance imaging (MRI) or positron emission tomography (PET)-CT scan. After surgical exploration 50 (33%) patients were found to not be suitable for CRS and HIPEC due to either extensive intraoperative tumor load, retroperitoneal tumor infiltration or deep infiltration of the mesenteric axis.

In 100 consecutive patients with peritoneal carcinomatosis of various origins (Table 1) cytoreductive surgery was performed with intraoperative hyperthermic chemotherapy. For colorectal or appendiceal cancer intraabdominal locally heated (42 Celcius) mitomycin C 25-35 mg/m^2 was routinely administered for 90 min. For gastric or ovarian cancer cisplatin 50 mg/m^2 was used. For gastric cancer a combination chemotherapy consisting of mitomycin and cisplatin was administered in some cases. Data were analyzed retrospectively.

Surgical procedure

After explorative laparotomy and complete adhesiolysis PCI score was determined, in particular with respect to the ligamentum teres, right upper suphrenic quadrant, space between the vena cava and liver segment 1, retrosplenic sulcus and bursa omentalis, which are most likely to be tumor-infiltrated. Then, after exclusion of contraindications, cytoreductive surgery was performed according to the technique described by Sugarbaker[1-8].

2	24 (24)
3	4 (4)

After maximal cytoreduction and reconstruction of intestinal continuity, if required, HIPEC was administered to the open abdomen for 90 min at 42 degrees Celsius. A rubber drain was routinely placed in the pelvis and an additional drain inserted in the left upper abdominal quadrant for splenectomy. Finally, the abdomen was closed with interrupted sutures.

Statistical analysis

Data are presented as median (min-max) or n (%), unless otherwise stated. Qualitative differences were compared using the χ^2 test, quantitative differences using the Mann-Whitney U test. Survival analysis was performed with the Kaplan-Meier method. For overall survival (OS) and disease-free survival, time to event was calculated as time from cytoreductive surgery until death or time to last contact, if the patient was alive. A P value less than 0.05 was considered significant. R was used for all statistical analysis[12].

RESULTS

Clinical characteristics, tumor types and intraoperative data are listed in Tables 1-3. Most tumors treated were of ovarian ($n = 33$) or colorectal origin ($n = 26$). Median age was 54 (17-76) years. Median BMI was 24 cm/kg^2. CRS with HIPEC was performed in 100 consecutive patients. The resection types are listed in Table 4. In 26 of the 50 patients without HIPEC an explorative laparotomy was performed. The other 24 patients underwent palliative bowel resection or debulking due to tumor obstruction. 66% of these patients died during follow-up with a 50% probability of survival within 224 d. Median operating time was 593 (178-1076) min. Median PCI was 17 (1-39). In 89% a radical resection (CC0/CC1) was achieved. Mitomycin C was used in 60% and Cisplatin in 32% of patients. In 5% a combination of Mitomycin C and Cisplatin was administered. A ureteral splint was perioperatively

on perioperative complications according to the DINDO classification (Table 7). Median time of follow-up was 538 (17-1932) d.

Recurrence-free survival is shown in Figure 1B. Overall survival is shown in Figure 1A. In 9% Re-CRS with HIPEC was performed during the follow-up period.

DISCUSSION

CRS with HIPEC is now a procedure with the potential to cure selected patients suffering from PC[13-17]. PC can be considered a disease limited to the abdominal compartment, and based on this rationale maximal cytoreduction may be justified for various histological entities such as pseudomyxoma, ovarian cancer and colorectal cancer, *etc*., thus improving overall and recurrence-free survival[13-21].

Patient selection is certainly, as already mentioned, the "achilles heel" when including patients in this multimodal therapy. Radiological imaging estimates intraoperative tumor load, but reliable tumor identification in the critical regions such as the small bowel or ligamentum hepatoduodenale is still poor. Especially small lesions of about 1 cm or less are difficult to detect, even by PET-CT scan[22].

In this article we describe our first experiences with CRS and HIPEC. Since this procedure entails a certain morbidity, also due to long operating time, intraoperative

implanted in 17%. Intra- and postoperative complications are listed in Tables 5 and 6. The anastomotic leakage rate was 5.8%. HIPEC was not completed for 90 min in one patient due to cardiac arrhythmia. One patient died due to multi-organ failure. Leucopenia was observed in 29% of patients. Median hospital stay was 18 (3-105) d.

Neither PCI, BMI nor age had a significant influence

Table 7 Neither peritoneal carcinomatosis index, body mass index nor age had a significant influence on perioperative complications according to the DINDO classification *n* (%)

chemotherapy and multivisceral resection, we attempted to detect risk factors for patient selection with a view to perioperative morbidity. The literature currently available gives no conclusive data on age or BMI of patients for the purpose of patient selection for this multimodal therapy.

Since it is generally known that numeric age does not correlate with biological age, it is not acceptable to generally exclude older patients who are in good condition. Moreover, patients with a high BMI are often viewed negatively, because they are more challenging to operate and have a greater risk for perioperative complications.

Additionally, one of the main prognostic factors is PCI and when it exceeds 20 in colorectal cancers no survival benefit is achieved. However, for other entities it is still unclear and in pseudomyxoma the completeness of cytoreduction is the only prognostic factor, not tumor load.

From our results we concluded that tumor load, age and BMI had no significant impact on the perioperative complication rate according to the DINDO classification. Therefore, if desired, a biologically young patient should be included in this therapy if CC0/CC1 resection appears possible. We therefore hypothesize that the probability to achieve a CC0/CC1 resection should be the determining criterion for selection, and not PCI. Patients with a BMI over 25 had complication rates similar to those of patients with a BMI under 25. At any rate, we recommend that caution be exercised with superobese patients, because they were not represented in this study.

In obese patients with a low PCI, a laparoscopic approach with HIPEC might be an option and should be discussed[23].

For patients with a high PCI this also seems valuable. The results of this study show that from the standpoint of postoperative morbidity more patients could be included in this therapy. Resectability should remain the main criteria for performing CRS and HIPEC.

In the beginning we generously applied a ureteral splint during peritonectomy for better orientation in patients with pelvic recurrence. Because of extensive pre- and postoperative pain and the questionable necessity of the splint during the operation we abandoned ureteral splinting completely in patients without hydronephrosis. In one case we had to perform a ureteral resection and end-to-end anastomosis because of tumor infiltration.

Our anastomotic leakage rate of 5.8% is acceptable and comparable with that of the current literature[10]. However, we tended to avoid anastomoses or stomas in favor of meticulous cleaning of the small bowel and large bowel of tumor seedings whenever possible, especially in the most recent patients. Only four patients received a loop ileostomy after anterior rectal resection, two received a terminal ileostomy after colectomy and four patients a terminal colostomy. In our opinion resection of the colon should not be performed according to oncologic criteria with removal of a maximum of lymph nodes, except when there is a synchronous PC of colorectal cancer. More importantly, all macroscopically visible tumor seedings must be removed and the organs should be preserved whenever possible.

Most recurrences occurred in the right upper quadrant or in the retroperitoneum (data not shown). This might have been induced by the large wound surfaces and the increasing risk for tumor adherence[24]. This observation has been known for a long time[25-27]. In this regard, CRS should be performed only in the tumor-affected peritoneum and never in healthy tissue. Nonetheless, it is sometimes easier to begin with the parietal peritonectomy in the healthy region, for example by removing the peritoneum of the whole pelvis and not only the affected region

in the Douglas space.

In the summary of the decision to include or not include a patient in this multimodal therapy is based on a variety of factors and should be done only at centers offering interdisciplinary evaluation by internal medicine specialists, surgical oncologists, anesthetists and radiologists. Lastly, the decision should be taken individually for each patient and high PCI, BMI or age should not be an exclusion criterion *per se* with regard to perioperative morbidity.

COMMENTS

Background
Perioperative patient morbidity/mortality after cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) is a major concern in the selection process for this multimodal therapy.

Research frontiers
Of 150 patients 100 were treated with cytoreductive surgery and HIPEC and retrospectively analyzed. Clinical and postoperative follow-up data were evaluated. Body mass index (BMI), age and peritoneal carcinomatosis index (PCI) were chosen as selection criteria with regard to perioperative morbidity.

Innovations and breakthroughs
Neither PCI, age nor BMI was a risk factor for postoperative complications/outcome according to the Dindo classification. The decision to include or not to include a patient in this multimodal therapy regimen is based on a variety of factors and should be made only at centers offering interdisciplinary evaluation by internal medicine specialists, surgical oncologists, anesthesiologists and radiologists. Finally, the decision should be made individually for each patient and high PCI, BMI or age should not be an a priori exclusion criterion with regard to perioperative morbidity.

Applications
The study results suggest that a high PCI, BMI or advanced age itself are not a contraindication for this multimodal therapy concerning perioperative morbidity.

Terminology
HIPEC is administered with 42 degrees Celcius for 90 min; PCI describes the intraperitoenal tumor load and was developed by Professor Sugarbaker.

Peer review
This is a good descriptive study in which authors analyze perioperative patient morbidity/mortality and outcome after CRS and HIPEC. The results are interesting and suggest that patient selection remains the most important issue. Neither PCI, age nor BMI alone should be an exclusion criterion for this multimodal therapy.

Abstract

AIM: To assess the effects and safety of *Lactobacillus casei rhamnosus* LCR35 complete freeze-dried culture (LCR35) in patients suffering from irritable bowel syndrome (IBS).

METHODS: A randomized, double-blind pilot study was performed in 50 patients complaining of IBS symptoms complying with Rome III criteria. Patients were allocated to receive either LCR35 (n = 25) at a minimum daily dose of 6×10^8 colony forming units or placebo (n = 25) for 4 wk. At inclusion, after treatment and 2 wk later, patients completed the IBS severity scale. Change from baseline in the IBS severity score at the end of treatment was the primary efficacy criterion. Changes were compared between groups in the whole population and in IBS subtypes (IBS with predominance of constipation, IBS with predominance of diarrhoea, mixed IBS, unsubtyped IBS). The presence of *lactobacillus casei rhamnosus* in stools was investigated at inclusion and at the end of treatment. The gastrointestinal quality of life questionnaire and the hospital anxiety and depression (HAD) scale were also completed.

RESULTS: Both groups were balanced for baseline characteristics. In 85% of patients, stool analyses showed that *lactobacillus casei rhamnosus* able to survive in the digestive tract. In the whole population, improvements in the IBS severity score did not differ significantly between treatments with a 25% decrease after 4-wk treatment, and a 15% decrease from baseline 2 wk later in both groups. In IBS subgroups, statistical analysis could not be performed due to small sample size, but a clinical response in favour of LCR35 was observed in IBS patients with predominance of diarrhoea: no change in the symptom severity score was seen with the placebo after 4 wk treatment, whereas a clinically relevant decrease occurred with LCR35 (-37% *vs* -3%). Furthermore, in spite of an increase in symptom intensity, the IBS severity score was maintained below the baseline value 2 wk later with LCR35 (-19% from baseline), whilst a slight 5% increase from baseline was observed with placebo. In the IBS subgroup with predominance of diarrhoea only, a clinically relevant decrease in abdominal pain severity score (-36%)

was observed with LCR35, whereas no change occurred with placebo. In mixed IBS patients, the 20% and 30% decreases in the IBS severity score observed after treatment with LCR35 and placebo, respectively, were maintained 2 wk later in both groups. A clinical response slightly in favour of placebo was observed at the end of the treatment period in IBS patients with predominance of constipation (-41% *vs* -20%) and unsubtyped IBS patients (-47% *vs* -17%), with the same value maintained 2 wk later. In both groups, no clinically relevant changes were observed either for the gastrointestinal quality of life index or HAD score. Thus, these results suggest that sub-grouping of IBS patients may be important for optimizing treatment responses by the physician.

CONCLUSION: This pilot study suggests that LCR35 could have some efficacy in IBS patients complaining of diarrhoea. These preliminary results need to be confirmed in larger studies.

INTRODUCTION

Irritable bowel syndrome (IBS) is a common functional bowel disorder, with an estimated worldwide prevalence of 10%-20% among adults and adolescents[1]. IBS is the most common diagnosis made by gastroenterologists. IBS contributes considerably to disability, absence from work or school and increased health-care costs[2]. As no curative treatment is available, therapy for IBS is palliative and supportive, targeting specific symptoms, but is notoriously unsatisfactory[3,4].

Studies have observed altered intestinal microflora in IBS patients and an increase in symptoms after enteric infections, suggesting that restoration of the intestinal microflora may be a useful therapeutic goal[5-8].

Lactobacilli are a component of the commensal microbiota of both the small and large intestinal tract of humans and animals. They are frequently used as probiotics and have a long history of safe consumption in food[9]. Probiotics, live microbiologic organisms found in foods and supplements, are supported by enough evidence to recommend their use in the treatment of IBS. This therapeutic class is gaining popularity for the treatment of multiple gastrointestinal disorders and a recent meta-analysis suggests that probiotics offer promise for the treatment of IBS[10]. Probiotics reportedly bind to small and large bowel epithelium and produce substances with antibiotic properties that may inhibit attachment and invasion by pathogenic organisms[11,12]. Probiotics may also modulate gastrointestinal luminal immunity by changing the cytokine and cellular milieu from a pro-inflammatory to anti-inflammatory state[13]. This immunomodulatory effect also attenuates the visceral hypersensitivity characteristic of IBS[7,14]. It has been speculated that each individual bacterial strain or a combination of strains may affect select subclasses of symptoms[15]. Whatever the underlying mechanism, in order to produce their health effects, the probiotic microorganisms must be able to survive within the gastrointestinal tract.

LCR35 complete freeze-dried culture has been successfully exploited commercially as a pharmaceutical product for its antidiarrhoeal properties for more than 50 years. *In vitro* investigations showed that this strain has probiotic activities such as the ability to adhere to intestinal cells and antibacterial activity against a large variety of pathogens[16]. Colonization by this probiotic in the gastrointestinal tracts of mice and humans has been studied and the findings suggest that LCR35 is able to survive *in vivo*[17]. In a study on mouse dendritic cells, *Lactobacillus casei* appears to be a probiotic which, in small concentrations, induces the production of large quantities of anti-inflammatory interleukins[18].

Thus, the therapeutic potential of probiotic bacteria - especially lactobacilli- reported in literature, as well as the research performed on LCR35, suggest a beneficial effect of this strain on the symptomatology of IBS patients.

The objective of this pilot study was to assess the efficacy and tolerability of the completely freeze-dried culture of *Lactobacillus casei rhamnosus,* LCR35, by measuring its effects on the symptomatology of IBS and evaluating its impact on the gastrointestinal quality of life and anxiety/depression level in patients suffering from IBS satisfying the Rome Ⅲ diagnostic criteria.

MATERIALS AND METHODS

This was a prospective, multicentre, randomized, double-blind, placebo-controlled pilot trial on two parallel groups. Patients were recruited from the outpatient clinics of the Department of Gastroenterology of 3 university hospitals (in Clermont-Ferrand, Nice and Rouen) and one private medical centre in Clermont-Ferrand. The study was conducted in accordance with Good Clinical Practice (CPMP/ICH/135/95), the French regulations, and the Declaration of Helsinki and subsequent World Medical Assemblies. The trial was approved by the regional Ethics Committee (CPP Sud Est VI) on March 7th, 2008 and was registered by the French Health Authorities with the identifier number 2008-A00010-55.

Patient enrolment

Eligible patients were those fulfilling the Rome Ⅲ criteria for IBS[19], whatever the subtype of IBS: IBS with predominance of constipation, IBS with predominance of diarrhoea, mixed IBS and unsubtyped IBS. At screening, the Hamilton scale[20] was used to exclude depressive patients. Inclusion criteria were: both genders, age between 18 and 70 years, availability of morphological, radiological and/or endoscopic data verifying the integrity of the digestive tract during the last 5 years, moderate symptom intensity (IBS severity score between 150 and 300 -see below-), efficient contraceptive method for women of child-bearing age. The non-inclusion criteria were: denied written informed consent, immunodeficiency or any serious illness or any progressive disease.

The following treatments were prohibited throughout the trial: other probiotics, antibiotics, anti-inflammatories, and any drugs aiming to treat IBS (antispasmodics, clays, *etc*.). Paracetamol was authorized to relieve pain at a daily dose ≤ 3 g/d; bisacodyl (no more than one tablet per day) and loperamide (≤ 6 capsules per day) could be used for no more than 2 consecutive days for constipation and diarrhoea, respectively. Psychotropic drugs (antidepressants or anxiolytics) were authorized if patients had been previously treated for several weeks without any modification of the dosage within the month preceding their enrolment into the study.

Procedures and treatment

After a screening visit (V1) performed 10 to 14 d before inclusion, patients had to attend 3 visits over a 6-wk period: V2 on day 0 involved randomization and treatment initiation; V3 was scheduled at the end of the 4-wk treatment period (between day 28-day 32) and V4 was planned 2 wk after the end of treatment (between day 42-day 46).

At screening, after obtaining informed consent, the Rome Ⅲ criteria were checked. Patients were instructed not to change their eating habits as to dietary fibre intake except for fermented milk and any food supplement likely to contain probiotics which were forbidden throughout the entire study period.

At visit 2, each potentially eligible patient was evaluated by a full review of clinical history and physical examination and their transit was assessed using the Bristol stool form scale[21]. Each subject completed the IBS severity scale[22], the gastrointestinal quality of life index (GIQLI) questionnaire[23] and the hospital anxiety and depression (HAD) scale[24-26]. Subjects eligible for the treatment phase were identified by a serial number and were randomly assigned to receive either LCR35 complete freeze-dried culture or the placebo, in a 1:1 ratio. Each treatment was provided in gelatine capsules and 3 capsules had to be taken once daily in a fasting state for 4 wk. One capsule of LCR35 contained 250 mg of product (total freeze-dried culture of *Lactobacillus casei* variety *rhamnosus* with a concentration of at least 2×10^8 CFU). Placebo capsules were identical in all aspects to the verum, thus allowing effective blinding. All capsules had to be taken in the morning while fasting, with a glass of non-alcoholic drink at ambient temperature in order to avoid a decrease in the number of LCR35.

At visit 3, after 4 wk treatment, a clinical examination was performed and patients completed the IBS severity scale, the GIQLI questionnaire, the HAD scale and the Bristol stool form scale. They did the same at visit 4, 2 wk after the end of the treatment.

Adverse events and medication compliance were monitored throughout the study period.

Compliance was also evaluated by the presence or absence of *Lactobacillus* in the faeces which were collected at inclusion and at the end of the 4-wk treatment period. All samples were aliquoted into 2 faecal culture cups and frozen at -80 ℃. After extraction of total bacterial DNA (kit QIAamp Mini Kit for stool QIAGEN), the presence of *Lactobacillus casei* variety *rhamnosus* was specifically determined by qualitative polymerase chain reaction (PCR - primer pairs hyb-21[27]) - cycles of amplification [(94 ℃, 5 mn - 94 ℃, 30 s; 56 ℃, 30 s; 72 ℃, 1 mn/kb) × 33, 72 ℃, 7 mn].

Questionnaires

The IBS severity scoring system is a self-administered questionnaire initially developed and validated by Francis *et al*[22] of which the French version has been previously validated[28]. It is composed of: (1) two items concerning the presence of abdominal pain and bloating (response yes or no); (2) four visual analogue scales measuring intensity of pain, bloating, relief following defecation and impact of symptoms on general QoL; and (3) an item on the number of days of suffering during the preceding 10 d. It provides a quantitative score ranging from 0 to 500 enabling grouping patients by symptom severity from mild to severe forms [(0-150) = mild, (150-300) = moderate, > 300 = severe]. Furthermore, previous studies have shown a positive correlation between this severity score and QoL of IBS patients[28,29].

In this study, the IBS severity score was used as the primary efficacy variable. Patients with an IBS severity score reduced by 50% after 4 wk of treatment were considered "responders".

The GIQLI[23] is a validated tool to measure quality of life related to gastrointestinal diseases. The GIQLI questionnaire includes 36 items asking about symptoms, physical status, emotions, social dysfunction, and effects of medical treatment. Higher scores, better GI-specific health-related quality of life.

The HAD scale[24-26] was designed to assess the contribution of mood disorder, especially anxiety and depression, in order to understand the experience of suffering in the setting of medical practice. The lower the HAD score, the lower the depression and anxiety level.

Ethical issues

All patients provided informed consent. Participation in the study was voluntary, and patients were allowed to withdraw at any point without giving an explanation.

Statistical analysis

For this pilot study, due to the lack of significant data in the literature, we arbitrarily considered that 60 subjects

Abdominal pain score	36.6 ± 27.2	51.4 ± 12.4
Mixed IBS, n (%)	6 (24.0)	11 (44.0)
IBS severity score	222.3 ± 36.7	245.0 ± 42.0
Unsubtyped IBS, n (%)	4 (16.0)	3 (12.0)
IBS severity score	218.5 ± 27.1	238.0 ± 63.6

NB: No statistical difference was found between the groups; BMI: Body mass index; IBS: Irritable bowel syndrome; GIQLI: Gastrointestinal quality of life index; HAD: Hospital anxiety and depression.

would be enrolled.

Statistical analysis was performed using version 9.1.3 Windows of SAS® software. Inclusion was considered as baseline.

The primary efficacy endpoint was the change in the IBS severity score at the end of the 4-wk treatment period. Other efficacy variables were considered as secondary: changes in the IBS severity composite score at the end of the study, changes in the IBS severity score referring to IBS subtypes, distribution of patients according to symptom severity classes, number of responders, changes in the abdominal pain severity score (sub-item of the IBS

severity score; pain is one of the key features of many of the functional gastrointestinal disorders), changes in the GIQLI and HAD score.

Efficacy results were similar on the "full analysis set" (FAS) and the "per-protocol set", therefore, only results based on the FAS are reported.

Absolute and relative changes from baseline in the IBS severity score, the GIQLI and the HAD score were compared between both treatment groups using the two-sided Student's *t*-test with a 5% significance level. The same test was used to assess changes in the IBS severity score in the IBS sub-groups (IBS with predominance of constipation, IBS with predominance of diarrhoea, mixed IBS and unsubtyped IBS). The distribution of patients according to IBS severity score classes was described in both groups at each visit. In the whole population and in the four IBS sub-groups, the percentages of "responders" were compared between treatment groups using the χ^2 test or the Fisher's exact test. Data from the Bristol stool form scale could not be analysed because of an important number of missing data.

RESULTS

The flow of subjects through the protocol is described in Figure 1.

Fifty-two patients were screened for the study. All of them fulfilled the inclusion criteria and were randomized equally into two groups. Among the 52 included patients, 5 discontinued and 47 completed the study. Prior to un-blinding of the data, 2 patients without primary criterion evaluation at V3 were excluded from the FAS, and 8 subjects were deemed non-evaluable because of major deviations (among them 3 were premature dropouts), thus providing a FAS of 50 patients (25 in each group) and a PP population of 44 (21 in the LCR35 group and 23 in the placebo group).

IBS: Irritable bowel syndrome.

Figure 2 Relative changes in irritable bowel syndrome severity score between V2 and V3, V2 and V4 in irritable bowel syndrome patients with predominance of diarrhoea. V2: Baseline; V3: At the end of the 4-wk treatment period, a more marked decrease in irritable bowel syndrome (IBS) severity score occurred with the test drug (-36.6% *vs* -3.1% with placebo); V4: Two weeks later, the IBS severity score was maintained below baseline with the test drug (-19.1%), whilst it slightly increased over baseline (+4.9%) with placebo.

baseline characteristics of the IBS patients. Except for a higher percentage of mixed IBS patients in the LCR35 group (44.0% *vs* 24.0%), no clinically relevant difference was observed between the groups. As required by the protocol, patients suffered from IBS symptoms of moderate intensity within the interval (150-300), with a mean value close to the upper values of the class in both groups.

Compliance

The presence of *Lactobacillus casei rhamnosus* in stools was investigated in 27 patients (14 LCR35 and 13 Placebo). In 85% of patients treated with LCR35, *Lactobacillus* was found by qualitative PCR. In one patient in the placebo group, no data was available to explain the presence of *Lactobacillus casei* in the faeces collected before and after treatment. Such a result may reflect the presence of LCR35 at a commensal level in some people. Furthermore, in this study, patients suffering from IBS may have been previously treated with probiotics.

Response to treatment

In both groups, no clinically relevant changes *vs* baseline

were observed during the study either for the GIQLI score or for the HAD score.

At the end of the treatment period, a similar improvement in the abdominal pain severity score was observed with the test drug (-13.1 ± 20.5) and the placebo (-11.9 ± 27.5). In patients with predominance of diarrhoea, no change in the abdominal pain severity score was observed with the placebo at the end of the 4-wk treatment period (-0.1 ± 26.5), whereas a clinically relevant decrease occurred with the test drug (-18.4 ± 26.3, i.e., 36%).

In the whole population, the improvements in the IBS severity score observed with LCR35 and placebo were not significantly different. Indeed, after a 25% decrease at the end of the treatment period (-63.2 ± 100.6 and -64.3 ± 95.9, respectively; *P* = 0.9692), a 15% decrease from baseline was observed 2 wk later in both treatment groups (-40.6 ± 110.1 and -36.0 ± 109.5, respectively; *P* = 0.8829).

Absolute and relative changes in the four IBS subgroups are presented in Table 2.

In IBS patients with predominance of diarrhoea, the clinical response was in favour of the active drug. Indeed, no change in the symptom severity score was observed with the placebo at the end of the 4-wk treatment period, whereas a more marked decrease occurred with the test drug (-36.6% *vs* -3.1%). Furthermore, in spite of an increase in the symptom intensity, the IBS severity score was maintained below the baseline value 2 wk later with the test drug (-19.1% from baseline), whilst a slight 4.9% increase from baseline was observed with the placebo.

Even if no statistical analysis could be performed due to the small sample size of this subgroup, the graphic representation of these results (Figure 2) clearly shows the differences in the clinical responses induced by the test drug and the placebo in IBS patients with predominance of diarrhoea.

In mixed IBS patients, the response observed at the end of the treatment (a 20% and 30% decrease in the IBS severity score with LCR35 and placebo, respectively) was maintained at the end of the study for both treat-

Table 3 Distribution of patients according to the irritable bowel syndrome severity score classes *n* (%)

	Placebo (*n* = 25)	LCR35 (*n* = 25)
Baseline IBS severity score (V2)		
150-300 (moderate symptoms)	25 (100.0)	25 (100.0)
Post-treatment IBS severity score (V3)		
0-150 (mild symptoms)	12 (48.0)	8 (32.0)
150-300 (moderate symptoms)	8 (32.0)	13 (52.0)
> 300 (severe symptoms)	5 (20.0)	4 (16.0)
IBS severity score at the end of study (V4)		
0-150 (mild symptoms)	9 (36.0)	6 (24.0)
150-300 (moderate symptoms)	8 (32.0)	13 (52.0)
> 300 (severe symptoms)	8 (32.0)	6 (24.0)

IBS: Irritable bowel syndrome.

ment groups, with no relevant clinical difference between treatments.

A clinical response slightly in favour of placebo was observed at the end of the treatment period in IBS patients with predominance of constipation (-41% *vs* -20%) and unsubtyped IBS patients (-47% *vs* -17%). The same value was maintained 2 wk later.

After 4 wk of treatment, the patient distribution according to the IBS severity score classes was slightly in favour of the placebo (48% *vs* 32% of improved patients, Table 3), and this observation correlates with the results observed on the main criterion.

The results obtained on the responder rates were in accordance with the results reported above. Indeed, the percentage of patients with a 50% reduction in the IBS severity score was higher in the placebo group (40% *vs* 28%), except for IBS patients with predominance of diarrhoea who showed a responder rate higher with LCR35 compared to placebo (43% *vs* 12%).

Adverse events
There were no adverse effects attributable to treatment with either LCR35 or placebo.

DISCUSSION
The results of this placebo-controlled pilot study showed that IBS symptoms assessed by the IBS severity score did not improve with LCR35 complete freeze-dried culture when considering the whole population, and no clinically relevant changes *vs* baseline were observed either for the GIQLI score or the HAD score. Yet, when considering IBS subtyped patients, it can be seen on the graphic representation of the data that a deterioration in the baseline symptom score was never observed with the test drug, and the line graphs show that the evolution pattern of the IBS severity score differed between the IBS subtypes. Indeed, a clinical response in favour of LCR35 complete freeze-dried culture was observed in IBS patients with predominance of diarrhoea.

The efficacy of therapeutics for IBS is undoubtedly impacted by the heterogeneous pathogenesis of IBS, and

up to now there is no recognised reference treatment for this pathology. Results observed in the present study are not surprising because the fact that subgroups of patients with IBS are likely to respond differently to a treatment is often discussed in the literature. Thus, sub-grouping of IBS patients may be important both for optimizing treatment responses by the practicing clinician as well as improving the outcome from clinical trials of novel therapeutic modalities. Thus, some authors also recommend that limiting trials to defined subgroups of patients should be considered to enhance homogeneity of the study population[30,31]. More recently, when validating the Rome III criteria, Longstreth *et al*[19] emphasize that "due to heterogeneity of IBS and to the fact that bowel pattern subtypes are highly instable, it may be desirable, in both research and practice, to base drug use on a stronger bowel pattern predominance".

Many papers have discussed the difficulties of the methodology to be used in IBS clinical research, and recommendations have been drawn to minimize bias in trials of functional GI disorders. Nevertheless, there is no consensus on IBS clinical trial methodology; in particular, there is no standardized outcome assessments[10,32]. Major problems with clinical trial design are the multiple presentations of the disease and the placebo response which is extremely variable and high, up to 70%. Therefore, it is recommended that all IBS trials be placebo controlled and it is essential that clinical trials are conducted on consistently identified patients with clearly defined outcome measures. These outcome measures should not only deal with symptom relief but also improvement in quality of life[30]. As the symptomatology of IBS is highly unstable, the so-called placebo responses may equally well be the temporary spontaneous improvements that are part of the condition[33]. Furthermore, there is evidence that psychiatric disorders have an adverse influence on the outcome of irritable bowel syndrome. Thus, accurate measurement of psychological symptoms as predictors of outcome is an important aspect of trial design for IBS therapy, and selection criteria need to take both physical and psychological domains into account[34]. The results of the present study observed in the placebo group confirm the importance of the psychological impact in IBS patients.

The design of the present study complied with the recommendations in the literature. It was double blinded and placebo controlled and used internationally approved diagnostic criteria for a clinical trial in IBS ("Rome III criteria"[19,35]), in order to allow a homogeneous population to be selected. For the assessment of efficacy, a clear well defined outcome measure was chosen as the primary efficacy parameter. Indeed, the IBS severity scale is a tool which was described in the literature as the only IBS symptom severity scale "shown to be responsive to treatment effects"[36]. Thus, the study complied with the recommendations of the Rome Committee[37]. The duration of treatment was based on the evaluation of medicinal products recommendations with a main efficacy criterion assessed after a 4-wk treatment period[38]. As recom-

mended in a recent meta-analysis highlighting important considerations for the design of probiotic controlled trials[32], every effort was made by the investigators to minimize loss-to-follow-up (none occurred in our study) and to adhere to "Intent-to-Treat" principles analyzing all subjects with the group to which they were originally assigned (our main analysis was done on the FAS set).

In our study population, the female predominance for IBS (70%), the mean age of 47.1 years, and the symptom severity as assessed by the IBS severity score were similar to data published in the literature and support the pertinence of our results. The IBS severity score at inclusion was close to the one reported in a French observational study on 1407 patients in gastroenterological practice (254.3 ± 41.9 with a range of 161-299 *vs* 268.5 ± 85.2 with a range of 10-487) but all of our patients had moderate symptom severity, whilst the observational study included 45% of patients with severe symptom intensity[39]. The distribution of patients according to IBS subtypes (IBS with predominance of constipation: 22%; IBS with predominance of diarrhoea: 30%; mixed IBS: 34%; unsubtyped IBS: 14%) was also similar to that of an observational study carried out in 1092 patients recruited by 159 GPs and 75 gastroenterologists (IBS with predominance of constipation: 22%; IBS with predominance of diarrhoea: 26%; mixed IBS: 29%; unsubtyped IBS: 22%)[40]. The mean value of the GIQLI score at inclusion showed clearly the negative impact of IBS on the QoL of our patients. The baseline value (63.4 ± 8.1) was lower than the value reported in patients in the study carried out to validate the French version of this questionnaire: the mean score was 126 for healthy individuals and 96 for patients[23].

Factors which might explain the absence of statistically significant results in the present trial are as follows: This study was a pilot study performed on a rather small sample size. The results in favour of the test drug might be confirmed with a statistically significant difference *vs* placebo in a future trial on a larger number of patients and, as discussed above, on a defined subgroup of patients (IBS patients with predominance of diarrhoea and mixed IBS subtypes).

Regarding the tool used to assess QoL, it must be pointed out that the GIQLI questionnaire is a generalist questionnaire for gastroenterological practice. As the QoL is known to be particularly altered in patients complaining of diarrhoea, it may be argued that this evaluation tool was not adapted to assess accurately the impact of diarrhoea on daily QoL.

In our study performed by gastroenterologists, patients suffered from marked IBS symptoms with a marked negative impact on QoL as shown by baseline values of IBS severity score (mean value close to the upper values of the moderate intensity class) and GIQLI (30% lower than in patients involved in the study which validated the French version of this questionnaire). The question of the likely impact of recruitment site has been often addressed in the literature[19].

In the French observational study carried out in 2000, the descriptive analysis of management practices demonstrated that patients who referred to gastroenterologists have a rather severe chronic form of IBS. Moreover, a search for a relationship between the qualitative score and the number of consultations nevertheless demonstrated that most patients first consult a general practitioner despite the fact that at that time there was access to specialists in the French healthcare system[39].

Two recent meta-analyses of randomized controlled trials on probiotics for the treatment of IBS showed heterogeneity across studies as to the outcome measures used to assess the severity of IBS symptoms, making it challenging to compare results across studies. Both meta-analyses selected the proportion of subjects with improvement in global IBS symptoms as the primary outcome to demonstrate that probiotics may improve IBS symptoms[10,32]. Thus, it is not possible to compare the results obtained with LCR35 complete freeze-dried culture in this study to results published for other probiotics.

The tolerability of LCR35 complete freeze-dried culture prescribed at the minimum daily dose of 6×10^8 CFU for 4 wk was excellent, and no adverse event was reported throughout the trial in the active group. This dose, used in several published studies, is the dose usually prescribed in daily practice for IBS patients[41-44]. The good tolerability displayed in this study is in accordance with the McFarland's review of probiotics controlled trials which did not find any evidence of significant adverse effects due to these treatments[32]. Given their superior safety profile compared to drug therapies usually prescribed in IBS, and the efficacy results observed with some probiotics against all of the primary IBS symptoms[13], as well as the impact of many probiotics on "gas-related" symptoms[45], probiotics may ultimately prove more acceptable for long-term therapy than medications with adverse effects.

As functional bowel disorders are diseases without morbi-mortality, treatments prescribed should not be more deleterious than the disorder itself[46,47]. Therapies should focus on specific gastrointestinal dysfunctions (e.g., constipation, diarrhoea, pain), and medications only should be used when non-prescription remedies do not work or when symptoms are severe.

This study showed that in 85% of patients treated with LCR35, *Lactobacillus* was found in their stools with a concentration of at least 10^4 living bacteria per gram, indicating that survival in the digestive tract is possible.

As in any pilot study, this study did not aim to definitely demonstrate the efficacy of LCR35 complete freeze-dried culture in IBS patients. It was designed to test the trend in the magnitude of variation in clinical response measures, to evaluate the effect size in an attempt to predict an appropriate sample size and improve upon the study design prior to performance of a full-scale research project. Thus, it is not surprising that small sample size, a strong placebo effect and the lack of uniformity of patients led to results that did not reach statistical sig-

nificance in the global population. Nevertheless, in IBS patients complaining of diarrhoea, the trend to lower global symptom score and abdominal pain sub-score (pain being the most bothersome symptom in IBS patients) after treatment observed with the test drug but not with the placebo, is an interesting observation suggesting that LCR35 complete freeze-dried culture might be useful in this subgroup of IBS patients. This observation made in sub-typed patients is in accordance with the fact that it is recognized that no drug is effective in treating all IBS symptoms because a variety of processes appear to be at work in this disorder and IBS sufferers are not a homogeneous population. As a precise characterization of patients is likely to lead to better therapeutic results, our results are encouraging and need to be confirmed in larger studies. Safety is a main concern in patients with gastrointestinal disorders, and deleterious adverse events are not acceptable in a relatively mild, non-fatal condition. The excellent safety profile of LCR35 complete freeze-dried culture shown in this study makes this probiotic strain, demonstrated to survive in the digestive tract, a reasonable choice for IBS.

ACKNOWLEDGMENTS

COMMENTS

Background

Irritable bowel syndrome (IBS) is the most common diagnosis made by gastro-enterologists. Despite its prevalence and its impact on quality of life and health expenditures, conventional medical treatment is notoriously unsatisfactory, and many patients try alternative or complementary therapies. Among them, probi-otics are generating great interest.

Research frontiers

Studies have observed altered intestinal microflora in IBS patients and an in-crease in symptoms after enteric infections, suggesting that restoration of the intestinal microflora may be a useful therapeutic goal. One strategy to restore normal flora is the use of probiotics. Probiotics are beneficial bacteria or yeasts that are ingested to improve health. Probiotics are also known to modulate the immune response and reduce cytokine production. This pilot study investigated the efficacy and safety of *Lactobacillus casei rhamnosus* LCR35, a probiotic used for its antidiarrhoeal properties for more than 50 years and shown *in vitro* to adhere to intestinal cells and to display antibacterial activity against a large variety of pathogens. Major problems in clinical research on IBS are the multiple presentations of this disease, the high placebo response and the absence of any consensus on the main outcome measure.

Innovations and breakthroughs

This study showed a clinically significant improvement in global symptomatol-ogy, and especially in abdominal pain (the most bothersome symptom in this pathology), in one subgroup of patients called "IBS patients with predominance of diarrhoea". Stool analysis demonstrated that *Lactobacillus casei rhamnosus* LCR35 was able to survive in the digestive tract. The improvement in symptom severity observed in sub-typed patients is in accordance with the fact that it is recognized that no drug is effective in treating all IBS symptoms because IBS sufferers are not a homogeneous population. The small sample size, a strong

placebo effect and the lack of uniformity of patients may contribute to the ab-sence of significant results in the global population. The clinical results and the excellent safety profile of LCR35 shown in this study make this probiotic strain a reasonable choice for IBS.

Applications

The findings in this pilot study indicate that subgrouping of patients with IBS may be important both for optimizing treatment responses by the practicing clinician as well as improving the outcome from future clinical trials on larger numbers of patients.

Peer review

In this pilot study, the authors evaluate the efficacy and safety profile of a newer probiotic in IBS patients. Treatment of IBS is still largely unsatisfactory, and thus newer treatments would add to the armamentarium of IBS therapy. The ques-tion posed by the authors is novel and well defined. However, the title should probably be changed to better reflect the nature of the study (e.g., "Efficacy and safety profile of LCR35 complete freeze-dried culture in irritable bowel syndrome: A randomized, double-blind study"). The methods are appropriate and well described. The data are sound and well controlled. The discussion and conclusions are well balanced and adequately supported by the data. On the other hand, the sample size is small, though the authors have stated this clearly as a limitation of their study.

Abstract

AIM: To assess the role of *Helicobacter pylori* (*H. pylori*), gastroesophageal reflux disease (GERD), age, smoking and body weight on the development of intestinal metaplasia of the gastric cardia (IMC).

METHODS: Two hundred and seventeen patients scheduled for esophagogastroduodenoscopy were enrolled in this study. Endoscopic biopsies from the esophagus, gastroesophageal junction and stomach were evaluated for inflammation, the presence of *H. pylori* and intestinal metaplasia. The correlation of these factors with the presence of IMC was assessed using logistic regression.

RESULTS: IMC was observed in 42% of the patients. Patient age, smoking habit and body mass index (BMI) were found as potential contributors to IMC. The risk of developing IMC can be predicted in theory by combining these factors according to the following formula: Risk of IMC = a + s - 2B where a = 2,...6 decade of age, s = 0 for non-smokers or ex-smokers, 1 for < 10 cigarettes/d, 2 for > 10 cigarettes/d and B = 0 for BMI < 25 kg/m^2 (BMI < 27 kg/m^2 in females), 1 for BMI > 25 kg/m^2 (BMI > 27 kg/m^2 in females). Among potential factors associated with IMC, *H. pylori* had borderline significance (*P* = 0.07), while GERD showed no significance.

CONCLUSION: Age, smoking and BMI are potential factors associated with IMC, while *H. pylori* and GERD show no significant association. IMC can be predicted in theory by logistic regression analysis.

INTRODUCTION

The development of gastric cancer involves an interplay of bacterial, host, and environmental facts, including dietary factors, lifestyle factors and *Helicobacter pylori* (*H. pylori*)[1-3].

The worldwide incidence of gastric cancer has declined over the recent decades[4]. Part of this decline is due to the recognition of risk factors such as *H. pylori* infection and other environmental risk factors[3,5]. Despite the overall decline in gastric cancer, there has been a significant increase in the incidence of cancer of the gastric cardia[6]. The shift from distal to proximal stomach may be due to the decrease in the distal cancers.

However, it has also been proposed that adenocarcinomas at the cardia represent a different entity of antral gastric adenocarcinomas[7]. Indeed, environmental factors or chemical carcinogens may be more strongly associated with cardia carcinomas compared with more distal gastric carcinoma[8]. On the other hand, the proximal gastric carcinomas differ from distal gastric carcinomas as they are not associated with a severe form of gastritis characterized by atrophy and/or intestinal metaplasia[9,10].

Carcinomas of the gastric cardia appear to be similar to those associated with Barrett's esophagus, with which they share some demographic features[9]. Several studies indicated that obesity satisfies several criteria for a causal association with gastroesophageal reflux disease (GERD) and some of its complications, including erosive esophagitis, and esophageal adenocarcinoma[11-13]. Therefore, obesity could represent an important factor in the development of cardia carcinoma.

The development of cardia carcinoma seems to be preceded by intestinal metaplasia, which is secondary to chronic inflammation[1,14-16]. However, the etiology of intestinal metaplasia of the gastric cardia (IMC) remains controversial. To our knowledge, no study has evaluated the effects of age, smoking and body weight on IMC. Thus, our aim was to set up a cross-sectional study to examine these the role of these factors, and also *H. pylori* and GERD. To evaluate the incidence of IMC and the respective role of these factors on the development of IMC at a particular point in time, we enrolled a population of outpatients with upper gastrointestinal (GI) endoscopy scheduled for various reasons.

MATERIALS AND METHODS

Study design and population
The study complied with the Declaration of Helsinki regarding investigation in humans and was approved by our institutional Ethics committee (Commission Centrale d'Ethique) (Controlled-trials.com, Number ISRCTN15324190, www.con trolled-trials.com). This was an investigator-initiated study with no involvement of industry.

Inclusion criteria
All outpatients scheduled for an elective upper GI endoscopy were eligible for inclusion in the study. Exclusion criteria were: age < 18 years, pregnancy, patients unable to give their own consent, a previous history of upper GI surgery, severe bleeding diathesis (platelet count < 50 000/mm^3, prothrombin rate < 50%), psychiatric dis-

eases, allergy to lidocaine. All patients signed an informed consent form.

For this study, 250 consecutive patients scheduled for upper GI endoscopy for a variety of conditions were recruited over a 2.5-year period. Among them, 217 accepted the study protocol (acceptance rate of 86%). Endoscopy was performed in the left lateral position after local anesthesia using a 10% xylocaine spray with the patient under conscious sedation using midazolam as reported previously[17]. A standard endoscopy was performed, including retroflexion in the stomach (Table 1).

Endoscopic biopsies
Each patient had 2 biopsies performed in the esophagus 2 cm above the Z-line, 4 biopsies at the esophagogastric junction, 2 biopsies in the cardia located within 10 mm below the Z-line, 2 biopsies in the fundus (greater and lesser curvature), 2 biopsies in the antrum (greater and lesser curvature), and one biopsy in the angulus. In the case of Barrett's esophagus, 4 biopsies were performed every cm in the Barrett's segment. All biopsy specimens were fixed in 0.5% formaldehyde solution and stained with haematoxylin eosin, Giemsa, and Gomori-aldehyde-fuschin. Two experienced GI pathologists (BH, MB), who were blinded to the clinical diagnosis, analyzed the biopsies. The diagnosis of IMC was reserved for patients with intestinal metaplasia detected in biopsy specimens sampled from the macroscopically normal-appearing gastroesophageal junction.

Study variables and data collection
As previously defined by Vakil *et al*[18], clinically significant GERD was diagnosed when reflux of the gastric contents caused troublesome symptoms and/or complications. It was considered negative if there were no such symptoms (Score 0), positive if the patient presented symptoms once a month (Score 1) or more than once a month (Score 2).

The presence of a hiatus hernia was defined as widening of the muscular hiatal tunnel and circumferential laxity of the phrenoesophageal membrane[19], allowing a portion of the stomach to slide into the thorax.

Smoking habit (never smoking: score 0; past smoker: score 1; current smoker < 1 pack per day: score 2; current smoker > 1 pack per day: score 3), body mass index (BMI) and age were recorded.

Endoscopic biopsies from the esophagus, the Z-line, the cardia, the fundus and the antrum were histologically evaluated for the following criteria: (1) Acute and chronic inflammation using a visual analogue scale from 0 to 3 as proposed by Dixon *et al*[20] in an updated Sydney system, 0 being none and 3 being marked; (2) Absence or presence of incomplete (types Ⅰ, Ⅱ) or complete (type Ⅲ) intestinal metaplasia as defined by Filipe *et al*[21]; and (3) Absence or presence of *H. pylori*.

Barrett's esophagus was defined as "a change in the distal esophageal epithelium of any length that can be recognized as metaplastic mucosa at endoscopy and confirmed to have intestinal metaplasia by biopsy of the tubu-

lar esophagus"[22]. Short segment Barrett's esophagus was considered if metaplasia extended < 3 cm into the tubular esophagus or long segment Barrett's esophagus if metaplasia extended > 3 cm into the tubular esophagus. Patients taking nonsteroidal anti-inflammatory drugs and/or proton pump inhibitors (PPI) during the last month before inclusion and continuously for more than 6 mo were defined as regular non steroidal antiinflammatory drug or PPI users.

Statistical analysis

The analysis of group variables was studied primarily using cross-tabulation analysis (Fischer's exact test). The Kruskal-Wallis test was used to test equality of the population. Multivariate analysis of predictors of IMC was performed by linear logistic regression. To accomplish this goal, a model was created that included all predictor variables. Multiple logistic regression analysis was used to develop an equation to predict a logit transformation of the probability of IMC based on risk factors that included in the equation: age (years), BMI (kg/m^2), smoking habit, sex, reflux disease and hiatal hernia. Age and BMI, were modeled as continuous variables, and sex was modeled as a categorical variable (0 = male and 1 = female). The final mathematical equation provided an estimate of a subject's likelihood of having IMC. *P* values < 0.05 were interpreted as statistically significant. *P* values > 0.05 were taken as non significant (NS). SPSS advanced models 10.0 was used for statistical analysis.

RESULTS

A total of 217 patients were enrolled in the current study.

Table 1 presents the characteristics of the group according to the sex distribution. There were no significant differences among the two groups except a higher frequency of Barrett's esophagus in men and a higher rate of gastric bypass in women. BMI exceeded 25 kg/m^2 in 54 males (56%) and 27 kg/m^2 in 61 females (51%). Because our surgical team has a long lasting program of bariatric surgery[23], a substantial number of patients evaluated for gastric bypass (22%) was included but the mean BMI in the overall cohort was < 30 kg/m^2. Epigastric pain and gastroesophageal reflux were the major causes for endoscopy. Of note, almost half of the patients was taking a PPI and 45% of the patients were past or current tobacco users.

Endoscopy was normal in 36% of the patients whereas erosive esophagitis and hiatus hernia were the main endoscopic findings in our population (Table 2). Barrett's esophagus was histologically confirmed in 13% of the patients. *H. pylori* was present in the gastric biopsies of 70 patients (32%).

We analyzed the potential relationship between the presence of *H. pylori* and various factors including GERD, Barrett's esophagus, hiatus hernia, tobacco use, sex and BMI (Table 3). There were statistically more patients infected by *H. pylori* with a normal esophagogastric junction (45%) than with long (16%) or short segment Barrett's esophagus (11%) (*P* < 0.05). Patients with a hiatus hernia were less frequently infected by *H. pylori* than patients without (*P* < 0.05). Current tobacco users were more frequently infected by *H. pylori* than non or past smokers (*P* < 0.05).

P value indicates results of the comparison of male and female patients. [1]Patients may have more than one pathology. NS: Not significant; *H. pylori*: *Helicobacter pylori*.

The correlation between the presence of reflux symptoms, and Barrett's esophagus, hiatus hernia, tobacco use, sex, age and BMI was shown in Table 4. All patients with short segment Barrett's esophagus and 90% of patients with long segment Barrett's esophagus had significant reflux ($P < 0.01$). The presence of reflux was not statistically significantly associated with the presence of hiatus hernia or increased BMI.

IMC was observed in 92 patients (42%), 48 were men and 44 were female, and the mean age was 27.3 years. IMC was not statistically associated (although there was a tendency) with the presence of *H. pylori* ($P > 0.05$), whereas *H. pylori* was strongly associated with the presence of inflammation of the cardia (carditis) since 82% of patients infected with *H. pylori* had carditis compared with 30% in the group without *H. pylori* infection ($P < 0.001$). Furthermore, there was a strong relationship between IMC and metaplasia found in other gastric areas, including the antrum and the corpus of the stomach. This relationship was not present in patients with Barrett's esophagus. BMI was found to be significantly lower and age significantly greater in patients with IMC than in patients with normal cardia mucosa. *H. pylori* played a pivotal role in the development of metaplasia of the antrum and the fundus, with an odds ratio reaching 7.4 and 11.2 respectively compared with patients not infected with *H. pylori* (Table 5).

GERD was not significantly associated with acute and chronic inflammation of the gastroesophageal junction, and it was not associated with the presence of IMC (borderline significance 0.06) (Table 5). Compared with patients with either short or long segment Barrett's esophagus, patients with IMC had significantly fewer GERD symptoms.

In univariate analysis, age, BMI and tobacco use were statistically significantly associated with IMC (Table 5). Using logistic regression analysis, the presence of IMC could be predicted by the patient's age, smoking habit

Figure 1 The curve indicates the actual risk (with standard deviation) of cardia metaplasia as a function of the personal clinical score.

and the absence of overweight according to the following formula: Risk score of IMC = a + s - 2B where a = 2,… 6 decade of age, s = 0 for non-smokers or ex-smokers, 1 for < 10 cigarettes per day, 2 for > 10 cigarettes per day, and B = 0 for BMI < 25 kg/m^2 (BMI < 27 kg/m^2), 1 for BMI > 25 kg/m^2 (BMI > 27 kg/m^2) for males (females), respectively. In the presence of these factors, *H. pylori* had only a borderline significance ($P = 0.07$) and would contribute only 1 point on the above scale which ranges from 0 to 8. Therefore, for a 50-year-old patient smoking 15 cigarettes per day and with a BMI of 26 kg/m^2, the theoretical risk of having IMC is 5. The data of 82 patients with IMC were analyzed to obtain the actual frequency in percent of IMC as a function of the calculated risk score for a given patient using the above equation (Figure 1). Finally, the presence of *H. pylori* was associated with severe acute and chronic inflammation in the antrum ($P < 0.01$), corpus ($P < 0.01$) and in the Z-line area ($P < 0.01$).

DISCUSSION

During the last few decades there has been a marked increase in the incidence of adenocarcinoma of the esophagogastric junction in Western countries in contrast to the reduction in incidence of distal gastric cancer. Most observers believe that this is the consequence of an increased rate of adenocarcinoma of the distal esophagus and a decreased incidence of distal gastric cancer related to *H. pylori* eradication. If the above-mentioned epidemiologic relationships are correct, this could indicate that the so-called cardia adenocarcinomas are not related to *H. pylori* infection but to other factors, and eventually may not be considered to be "gastric" cancers.

Because of the debated roles of different clinical factors in the emergence of malignant neoplasia of the gastric cardia, and because many reports have stated that IMC precedes the development of cardiac cancer, our study was aimed at assessing the respective roles of *H. pylori*, GERD, age, smoking habit and body weight on the development of IMC in a large group of patients. To this end our cross-sectional study enrolled outpatients scheduled for upper GI endoscopy for various reasons and specifi-

cally searched for the presence of IMC. The study then examined all the above mentioned variables to evaluate their respective role on the development of IMC at a particular point in time. For this purpose, each patient had endoscopic gastric and esophageal biopsies. We paid specific attention to the cardia area because the location and extent of the gastric cardia are controversial. Today,

the vast majority of the data available on the cardia and cardia cancer are not comparable because of variations in the diagnostic criteria. Thus, to avoid any problem in "cardia" definition, we followed rigorous anatomist and endoscopist recommendations that defined the cardia as being the part of the stomach that lies around the orifice of the tubular esophagus, and which corresponds to the

P value indicates results of the comparison of patients with or without intestinal metaplasia of the cardia. [1]patients may have more than one reason for endoscopy; [2]data are missing. GERD: Gastroesophageal reflux disease; OR: Odds ratio; BMI: Body mass index; NS: Not significant; *H. pylori*: *Helicobacter pylori*.

point at which the tubular esophagus joins the saccular stomach[24-26].

In our study, IMC was histologically found in 92 patients (42%). Whereas *H. pylori* was present in 70 patients (32%), the distribution of *H. pylori* was similar in patients with or without IMC, suggesting that no significant relationship between *H. pylori* and IMC exists. We found that *H. pylori* was strongly associated with the presence of carditis without IMC, as previously reported. Indeed, Sotoudeh *et al*[3] found a significant relationship between carditis and *H. pylori* infection in an Iranian cohort of patients in which the infection rate was as high as 85% whereas our infection rate was close to 32%. In contrast to our study, Goldblum *et al*[10] found that not only was *H. pylori* associated with carditis but also with IMC. In our series there was a strong correlation between the presence of *H. pylori* and acute or chronic inflammation in biopsies taken at different sites of the stomach. This finding is consistent with several other eastern observations showing that carditis is more associated with *H. pylori* infection than with GERD. In our study, GERD was present in 141 patients (65%) and was not found to be significantly associated with IMC, whereas GERD was strongly associated with acute and chronic inflammation of the gastroesophageal junction, a feature already

reported by others[27,28]. Voutilainen *et al*[14] reported that there are two dissimilar types of chronic inflammation of the gastric cardiac mucosa that seem to occur: one existing in conjunction with chronic *H. pylori* infection and the other with normal stomach and erosive GERD. Patients with IMC also had significantly higher rates of metaplasia of other gastric areas. Therefore finding antral or corporeal metaplasia should alert the gastroenterologist to redo a biopsy of the cardia in a subsequent endoscopy. The absence of any correlation between the presence of IMC and Barrett's esophagus might indicate that IMC is a distinct entity from Barrett's esophagus as proposed by Golblum[16]. Similar inflammation and mucosal alteration in the antrum and the corpus should be regarded as a potential sign of predisposition to IMC. We found that the risk of having IMC was associated with increasing age since 70.5% of patients with IMC were > 40 years old, a feature also reported by McNamara *et al*[29] in a cohort of 36 patients with IMC. Among other factors associated with IMC, tobacco use was found to be strongly associated with the development of IMC and 68% of patients with IMC were smokers, data never reported before, to our knowledge. Indeed, Koizumi *et al*[5] reported an increased risk of IMC of 1.84 (1.39-2.43 95% CI) only for antral cancer in current smokers compared with subjects

who had never smoked. BMI was surprisingly found to be a protective factor: the greater the BMI the less it contributed to the risk of IMC. This specific point should be balanced by the fact that the majority of our population was under the threshold of obesity. This finding could seem controversial against the current literature that suggests a link between obesity, GERD and carcinoma[30].

Although a real prospective study design is needed to assess a prediction, our statistician has tried to find the best fitting model to describe the relationship between the presence of IMC and various predisposing factors. The final mathematical equation provided an evaluation (and not the risk) of a subject's likelihood of having IMC. In the current study, the presence of IMC could be predicted by age, smoking habit and low or normal BMI. The evaluation showed no association with GERD. *H. pylori* had only a borderline significance ($P = 0.07$) if any. Nevertheless, this point must be emphasized because recent studies have found two types of cardia cancer, one linked to *H. pylori*-associated atrophic gastritis, and the other associated with nonatrophic gastritis, resembling esophageal adenocarcinoma[7].

Although our study was not prospective, it gives results at a particular point in time, and points out the greater need for endoscopic surveillance of gastric cardia mucosal changes in individuals aged 40 and over. Regarding the epidemiology of adenocarcinoma of the esophagus and gastroesophageal junction, the patterns of each disease are sufficiently alike to implicate shared risk factors or even to represent a single neoplastic entity. Although studies at the molecular level have produced conflicting results, many have demonstrated the similarity between adenocarcinomas of the cardia and esophagus. Most important is the evidence that the overall survival is similar in patients with gastroesophageal junction and esophageal adenocarcinoma.

In summary, this study indicates that chronically inflamed gastric mucosa in the cardia area can be replaced by intestinal metaplasia, a finding which has been shown to precede the development of cardia cancer. Whereas esophageal adenocarcinomas are strongly associated with GERD and obesity and are inversely associated with *H. pylori*, we suggest that IMC is not convincingly associated with GERD, is inversely correlated with BMI and has a dubious association with the presence of *H. pylori,* but is associated with increased age and a smoking habit. A prospective study aimed at evaluating the true incidence and natural history of IMC is therefore clearly needed.

COMMENTS

Background
Development of carcinoma of the cardia seems to be preceded by intestinal metaplasia. Gastroesophageal reflux and *Helicobacter pylori* (*H. pylori*) infection are together believed to cause intestinal metaplasia of the cardia (IMC).

Research frontiers
Despite the overall decline in gastric cancer, there has been a significant increase in the incidence of cancer of the gastric cardia. Because the roles of different clinical factors in the emergence of cardia malignancy are still debated,

there is a need to carry out further studies aiming at defining the risk factors for developing IMC.

Innovations and breakthroughs
This cross-sectional study indicated that IMC is associated with increased age and smoking, but is not strongly associated with *H. pylori infection* and gastroesophageal reflux disease.

Applications
The study indicates there is a greater need for endoscopic surveillance of gastric cardia mucosal changes in individuals aged 40 and over.

Terminology
Intestinal metaplasia of the cardia represents a mucosal change of the gastric cardia that is secondary to chronic inflammation and that can be considered as a potential precursor of cancer.

Peer review
The paper is a well-written manuscript with an important topic in clinical epidemiology. The authors tried to study the risk factors for intestinal metaplasia of the cardia. In addition they compared these factors with the epidemiological criteria of patients with Barrett's esophagus. The results show that Barrett mucosa and IMC differed according their etiological factors.

Abstract

AIM: To compare rifaximin and insulin-like growth factor (IGF)-1 treatment of hyperammonemia and brain edema in cirrhotic rats with portal occlusion.

METHODS: Rats with CCl_4-induced cirrhosis with ascites plus portal vein occlusion and controls were randomized into six groups: Cirrhosis; Cirrhosis + IGF-1; Cirrhosis + rifaximin; Controls; Controls + IGF-1; and Controls + rifaximin. An oral glutamine-challenge test was performed, and plasma and cerebral ammonia, glucose, bilirubin, transaminases, endotoxemia, brain water content and ileocecal cultures were measured and liver histology was assessed.

RESULTS: Rifaximin treatment significantly reduced bacterial overgrowth and endotoxemia compared with cirrhosis groups, and improved some liver function parameters (bilirubin, alanine aminotransferase and aspartate aminotransferase). These effects were associated with a significant reduction in cerebral water content. Blood and cerebral ammonia levels, and area-under-the-curve values for oral glutamine-challenge tests were similar in rifaximin-treated cirrhotic rats and control group animals. By contrast, IGF-1 administration failed to improve most alterations observed in cirrhosis.

CONCLUSION: By reducing gut bacterial overgrowth, only rifaximin was capable of normalizing plasma and brain ammonia and thereby abolishing low-grade brain edema, alterations associated with hepatic encephalopathy.

Òdena G, Miquel M, Serafin A, Galan A, Morillas R, Planas R, Bartolí R. Rifaximin, but not growth factor 1, reduces brain edema in cirrhotic rats. *World J Gastroenterol* 2012; 18(17): 2084-2091 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i17/2084.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i17.2084

INTRODUCTION

Hepatic encephalopathy (HE) is a complication of advanced hepatic insufficiency characterized by a wide range of neurological and neuropsychiatric symptoms, ranging from subclinical manifestations to hepatic coma[1]. When cirrhotic patients develop HE, their survival prognosis considerably worsens[2], and liver transplantation has to be considered[3].

It is well known that high plasma ammonia levels play a central role in the multifactorial network of mechanisms leading to HE[4-6]. In fact, ammonia reaches the liver *via* the portal vein from the intestine as a result of bacterial degradation of nitrogenous compounds and as a consequence of the metabolism of glutamine by the enzyme glutaminase[7]. In addition, urea cycle activity in cirrhotic patients is decreased due to the reduction of liver cell mass[8]. Both the presence of portosystemic shunts and the loss of parenchymal cells in the liver of cirrhotic patients lead to an increase in plasma ammonia levels and are key factors in the development of HE in these patients[9]. A traditional therapeutic approach to HE is to decrease plasma ammonia levels by decreasing ammoniagenic substrates, as well as inhibiting ammonia generation, reducing its intestinal absorption, and facilitating its elimination[10].

Non-absorbable antibiotics and/or non-absorbable disaccharides have been used as a standard treatment of HE in human cirrhosis[10-14]. Recent studies have demonstrated that rifaximin reduces the risk of hospitalization involving HE without producing side effects[11,15]. Rifaximin is a non-absorbable rifamycin derivative with activity against aerobic and anaerobic microorganisms, which are an important source of ammonia[7,11,16]. Furthermore, rifaximin is not absorbed by the gut, thereby allowing the antibiotic to reach high concentrations in the intestinal tract and to remain in the feces in its active form[10,17].

Insulin-like growth factor (IGF)-1 is a powerful anabolic hormone that exerts anabolic and trophic effects in many tissues, acting in an endocrine, paracrine and autocrine manner[18]. Levels of IGF-1 are markedly decreased in liver cirrhosis. Several studies have shown that the administration of low doses of IGF-1 (i.e., 4 μg/100 g body weight per day) reduces liver fibrosis, improves liver function, increases intestinal absorption of nutrients and corrects osteopenia and hypogonadism in experimental liver cirrhosis[19-22]. Previous work from our laboratory has demonstrated that IGF-1 therapy enhances intestinal barrier function, and reduces endotoxemia and bacterial translocation in cirrhotic rats[23]. Most of these alterations are considered to be precipitating factors leading to HE, therefore, the administration of IGF-1 could be a novel therapeutic approach for this condition.

The aim of this study was to compare the efficacy of rifaximin and IGF-1 in the treatment of HE using a combined model of intrahepatic hypertension (CCl4-induced cirrhosis plus ascites) and extrahepatic hypertension generated through portal vein occlusion - a proven new animal model of hyperammonemia and brain edema related to decompensated advanced liver cirrhosis, recently described in our laboratory[24], which exhibits most of the alterations present in type C HE.

MATERIALS AND METHODS

Male Sprague-Dawley OFA rats weighing about 100 g were included in the study. All animals were caged individually at a constant room temperature of 21 ℃, exposed to a 12/12-h light/dark cycle and provided free access to a standard rodent chow (A04; Harlan Ibérica S.A, Barcelona, Spain). Rats received 1.5 mmol/L phenobarbital, an inducer of cytochrome P450 enzymatic activity, in their drinking water. The study was conducted according to guidelines established by the Guide for the Care and Use of Laboratory Animals and was approved by the Ethical and Research Committee of our research institute.

Experimental design

Six groups of rats were studied. (1) Cirrhosis (group 1; $n = 9$): rats with CCl4-induced liver cirrhosis with ascites plus portal vein occlusion treated with placebo (saline); (2) Control (group 2; $n = 10$): sham-operated control rats treated with placebo; (3) Cirrhosis + IGF-1 (group 3; $n = 9$): rats with CCl4-induced liver cirrhosis with ascites plus portal vein occlusion treated with IGF-1 (2 μg/100 g s.c. twice daily for 14 d); (4) Control + IGF-1 (group 4; $n = 9$): sham-operated control rats treated with IGF-1 (2 μg/100 g s.c. twice daily for 14 d); (5) Cirrhosis + R (group 5; $n = 9$): rats with CCl4-induced liver cirrhosis with ascites plus portal vein occlusion treated with rifaximin (50 mg/kg daily by gavage for 14 d); and (6) Control + R (group 6; $n = 9$): sham-operated control rats treated with rifaximin (50 mg/kg daily for 14 d).

Animal procedures

Ascitic cirrhotic rats with portal occlusion were assessed as previously described[24]. Briefly, when animals reached a body weight of 200 g, cirrhosis was induced by intragastric administration of CCl4 through an orogastric stainless steel tube (Poper and Sons, New Hyde Park, NY, United States). The initial dose was 20 μL, and subsequent doses were adjusted based on changes in body weight[25]. Six weeks after starting cirrhosis induction, animals underwent partial portal vein occlusion (> 0.9 mm portal diameter) achieved by ligating around a 20 G needle, followed by complete portal vein occlusion 48 h later[26]. Surgical procedures were performed under strict aseptic conditions; animals were anesthetized for surgery using ketamine, diazepam and atropine, and were subsequently administered 30 μg (s.c.) buprenorphine (Buprex; Schering-Plough, Madrid, Spain) for 3 d. Cirrhosis induction was continued (CCl4 administration) until ascites developed. When ascites was diagnosed (by abdominal paracentesis), animals were randomized to receive the corresponding treatment (placebo, rifaximin or IGF-1) for 14 d. Control rats were subjected to sham operation and were also randomized in parallel. Twelve hours after

finishing treatment, rats underwent an oral glutamine-challenge test, and immediately afterward were sacrificed by bilateral thoracotomy. Peripheral and portal blood, cecum fecal content, and solid tissue (brain and liver) were obtained.

Oral glutamine-challenge test

A load of 100 mg/kg of L-glutamine (SHS S.A., Barcelona, Spain) was administered through an orogastric stainless steel tube. Venous blood samples (150 μL) from the femoral vein were drawn preload (baseline) and every 30 min for 4 h for ammonia determination. Body temperature was monitored and maintained between 36 ℃ and 38 ℃ using an infrared lamp. Samples were centrifuged *in situ* for 10 min at 2000 × *g*, and plasma was stored at -80 ℃ until analysis. The area under the curve (AUC) of the ammonemia response was also calculated using Graph Pad Prism for Windows version 5.01 (La Jolla CA, United States).

Biochemical characterization

Blood samples were obtained during sacrifice. Biochemical determinations [aspartate aminotransferase (AST), alanine aminotransferase (ALT), bilirubin, and glucose] were made using an autoanalyzer (Dimension Clinical Chemistry System, Dade Behring-Siemens, Madrid, Spain).

Endotoxin levels

Endotoxemia was quantified in all groups of rats using a Limulus amebocyte lysate kinetic test (Endosafe Charles River, L'Abresle Cedex, France*)*. Briefly, plasma samples were diluted 1:5 with endotoxin-free water and then heated to 70 ℃ for 5 min. Afterwards, samples were further diluted (final dilution, 1:50) and assessed.

Cecal bacterial content

During the course of laparotomy and after harvesting all other samples, the cecal region was identified and 1 mL of content was obtained by cecal puncture. Cecal bacterial content was measured by culturing serially diluted samples (1/8000 and 1/160 000) on non-selective blood agar plates. All samples were cultured in triplicate. After an incubation period of 48 h, the number of colony-forming units (CFU) was counted. The composition of isolated flora was determined using standard bacteriological identification techniques. The results were expressed as CFU/mL of cecal content. Cecal bacterial overgrowth was defined as a stool bacterial count greater than the mean of healthy control rats plus two standard deviations[27].

Determination of plasma and brain ammonia

Ammonia was measured in plasma and cerebral cortex. Briefly, blood (150 μL) was drawn from the femoral vein and centrifuged in heparinized tubes. The resulting plasma samples were stored at -80 ℃ until analysis. Brain samples were weighed, homogenized, and deproteinized by adding five volumes of cold perchloric acid (6%)

and then centrifugation at 12 000 × *g* for 20 min. After neutralization with KHCO₃ (25% w/v), samples were stored at -80 ℃ until analysis, which was performed using a commercial enzymatic Ammonia Assay Kit (Sigma-Aldrich, Madrid, Spain).

Low-grade brain edema

Low-grade brain edema was measured as brain water content. Briefly, a frontal left hemisphere brain sample from each rat was excised, weighed, and heated to 90 ℃ for 48 h in a drying oven to evaporate all water content. Then, dried samples were weighed again. The difference between initial and final weight was considered as the water content[28].

Hepatic histology

Liver samples for histological examination were collected in 4% formaldehyde, subsequently embedded in paraffin wax, sliced into 5-μm sections, and stained with hematoxylin and eosin. Liver samples were evaluated using the Scheuer scoring system[29].

Statistical analysis

Unless otherwise indicated, results are expressed as mean ± SE or proportions, as appropriate. Comparisons of means among groups were performed using one-way analysis of variance or corresponding non-parametric (Kruskal-Wallis) tests; *post hoc* comparisons to identify pairs of groups significantly different at the 0.05 level were made using the Duncan test or the Mann-Whitney *U* test, respectively. Differences in proportions among groups were compared using the χ^2 test. Statistical analysis were performed with SPSS for Windows version 13.0 (Chicago, IL, United States).

RESULTS

General features

No differences in any of the parameters studied, except for fecal bacterial count (as expected), were observed among the three sham-operated control groups. In contrast, all parameters were significantly altered in cirrhosis plus portal vein occlusion groups compared to control groups.

Body weight and ascites development

Body weight at sacrifice was similar in cirrhotic groups and was significantly lower than in controls (overall *P* = 0.017). No differences in the time elapsed between the first CCl₄ dose and ascites development were observed among the groups (range: 8-15 wk). None of the ascitic rats showed any signs of infection or sepsis.

Biochemical characterization

Liver function and liver damage parameters are summarized in Table 1. Liver cirrhosis plus portal vein occlusion resulted in a significant increase in serum AST, ALT and bilirubin, and a decrease in serum glucose con-

	Endotoxin (EU)	Glucose (mmol/L)	Bilirubin (μmol/L)	ALT (UI/L)	AST (UI/L)

[a]$P < 0.05$ *vs* all control groups; [c]$P < 0.05$ *vs* cirrhosis + R; [e]$P < 0.05$ *vs* control + R. IGF: Insulin-like growth factor; R: Rifaximin; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase.

Figure 1 Blood ammonia levels. Comparison of the concentrations of basal plasma ammonia in cirrhotic groups (closed bars) and control groups (open bars). Cirrhosis plus portal vein occlusion resulted in a significant increase in basal ammonia levels. Rifaximin-treated cirrhotic rats showed plasma ammonia levels similar to those observed in controls; by contrast, insulin-like growth factor (IGF)-1 treatment was unable to normalize these values. [a]$P < 0.05$ *vs* each control group. Cirr: Cirrhosis; Cont: Control; R: Rifaximin.

Figure 2 Brain ammonia levels. Comparison of the concentrations of brain ammonia in cirrhotic groups (closed bars) and control groups (open bars). Liver cirrhosis plus portal vein occlusion resulted in an increase in brain ammonia levels compared to controls, whereas in rifaximin-treated cirrhotic rats, these levels remained similar to those in controls. insulin-like growth factor (IGF)-1 did not significantly decrease these values compared to the respective controls. [a]$P < 0.05$ *vs* each control group. Cirr: Cirrhosis; Cont: Control; R: Rifaximin.

centrations. However, in rifaximin-treated cirrhotic rats, these alterations tended to be less marked. In fact, no differences in bilirubin or transaminases were observed in this group compared to controls. By contrast, all of these biochemical parameters remained significantly altered in the IGF-1-treated group compared to control groups, indicating that IGF-1 treatment was unable to improve liver function.

Endotoxin levels
Portal blood endotoxin levels were significantly increased only in placebo-treated cirrhotic rats (0.582 ± 0.069 *vs* 0.374 ± 0.037; $P = 0.044$). By contrast, both IGF-1 and rifaximin treatments normalized endotoxemia levels, producing similar values relative to their respective controls (Table 1).

Blood and brain ammonia levels and oral glutamine-challenge test
Liver cirrhosis plus portal vein occlusion resulted in hyperammonemia. Blood ammonia levels were increased in placebo-treated cirrhotic rats compared to placebo-treated controls (284 ± 29 μmol/L *vs* 144 ± 47 μmol/L; $P = 0.007$). Rifaximin treatment improved ammonemia in cirrhotic rats, reducing ammonia to levels similar to those observed in rifaximin-treated controls (205 ± 47 μmol/L *vs* 128 ± 37 μmol/L; $P = 0.122$). By contrast,

IFG-1 treatment failed to reduce plasma ammonia levels, which remained significantly increased compared to those observed in controls (323 ± 58 μmol/L *vs* 142 ± 35 μmol/L; $P = 0.004$; Figure 1).

Similarly to ammonemia, brain ammonia levels were significantly higher in placebo-treated cirrhotic rats than in placebo-treated controls (0.38 ± 0.03 mmol/kg *vs* 0.22 ± 0.01 mmol/kg; $P = 0.006$). Rifaximin treatment normalized brain ammonia levels in cirrhosis, yielding values similar to those observed in rifaximin-treated control rats (0.27 ± 0.03 mmol/kg *vs* 0.24 ± 0.03 mmol/kg; $P = 0.429$). Again, IGF-1 treatment was ineffective; brain ammonia levels in IGF-1-treated cirrhotic rats were significantly higher than those in controls (0.35 ± 0.04 mmol/kg *vs* 0.25 ± 0.02 mmol/kg; $P = 0.039$; Figure 2).

Further analysis of these results (Figure 3) showed that AUCs after oral glutamine-challenge tests were significantly increased in placebo and IGF-1 treatments in cirrhotic rats compared with each control group (3770 ± 501 *vs* 2419 ± 501; $P = 0.043$ and 5216 ± 1144 *vs* 2120 ± 428; $P = 0.021$). By contrast, the AUC in rifaximin-treated cirrhotic rats was similar to that observed in controls (3310 ± 870 *vs* 2525 ± 302; $P = 0.240$).

Cecal bacterial content
Cecal bacterial content was significantly increased in

Figure 3 Ammonia response to oral glutamine-challenge tests. The area under the curve (AUC) was significantly increased by both placebo and insulin-like growth factor (IGF)-1-treatment in cirrhotic rats. By contrast, the AUC in rifaximin-treated cirrhotic rats was similar to that observed in controls. Cirr: Cirrhosis; Cont: Control; R: Rifaximin.

Figure 4 Cecal bacterial populations. Comparison of cecal bacterial content in cirrhotic groups (●) and control groups (○). Bacterial overgrowth was defined as a colony-forming units (CFU) count greater than the mean ± 2SD of the control group (dashed line). CCl₄-induced cirrhosis plus portal vein occlusion resulted in cecal bacterial overgrowth in placebo and insulin-like growth factor (IGF)-1-treated cirrhotic rats ([a]$P < 0.05$ *vs* all others). Rifaximin treatment reduced bacterial content in cirrhotic rats to a level similar to that observed in the rifaximin-treated control group; bacterial counts in these latter groups were the lowest among all groups ([c]$P < 0.05$). Cirr: Cirrhosis; Cont: Control; R: Rifaximin.

both the placebo-treated cirrhosis group and cirrhotic rats treated with IGF-1 compared with their respective controls ($18.6 \pm 3.6 \times 10^6$ CFU/mL *vs* $8.4 \pm 1.3 \times 10^6$ CFU/mL; $P = 0.042$ and $20.4 \pm 4.6 \times 10^6$ CFU/mL *vs* $8.9 \pm 1.4 \times 10^6$ CFU/mL; $P = 0.047$). Only rifaximin treatment reduced bacterial content in cirrhotic rats; the values in rifaximin-treated cirrhotic rats were similar to those observed in the rifaximin-treated control group ($4.4 \pm 1.4 \times 10^6$ CFU/mL *vs* $4.4 \pm 1.3 \times 10^6$ CFU/mL; $P = 0.931$), and were significantly lower than those in the placebo-treated cirrhosis group ($P = 0.003$) and cirrhosis + IGF-1 group ($P = 0.002$). Moreover, as shown in Figure 4, rifaximin eliminated bacterial overgrowth (threshold value, 17.64×10^6 CFU/mL) in cirrhotic rats, whereas almost 50% of rats in the placebo-treated cirrhosis group (4/9 rats) and cirrhosis + IGF-1 group (5/9 rats) showed bacterial overgrowth (overall $P < 0.05$ *vs* each control and cirrhosis + rifaximin groups).

Brain water content
Liver cirrhosis plus portal vein occlusion resulted in a significant increase in brain water content compared to placebo-treated controls ($79.17\% \pm 0.22\%$ *vs* $78.26\% \pm 0.04\%$;

Figure 5 Low-grade brain edema. Low-grade brain edema was determined by measuring the percentage brain water content in cirrhotic groups (closed bars) and control groups (open bars). Placebo-treated cirrhotic rats showed the presence of low-grade brain edema. Brain water content in rifaximin-treated cirrhotic rats was similar to that in control groups, and was significantly lower to that observed in placebo-treated cirrhotic rats. Insulin-like growth factor (IGF)-1 treatment did not diminish brain edema; brain water content in the cirrhosis + IGF-1 group was similar to that observed in the cirrhosis + placebo group. [a]$P < 0.05$ *vs* all control groups; [c]$P < 0.05$ *vs* cirrhosis + R. Cirr: Cirrhosis; Cont: Control; R: Rifaximin.

$P = 0.002$). Rifaximin treatment was accompanied by a significant reduction in low-grade brain edema, as demonstrated by the fact that brain water content in this group of cirrhotic rats was similar to that measured in rifaximin-treated control rats ($78.61\% \pm 0.31\%$ *vs* $78.24\% \pm 0.19\%$; $P = 0.233$) and significantly lower than that observed in placebo-treated cirrhotic rats ($P = 0.046$). IGF-1 treatment did not diminish brain edema; brain water content in the cirrhosis + IGF-1 group was similar to that observed in the placebo-treated cirrhosis group ($P = 0.566$) and was significantly higher than that observed in the control + IGF-1 group ($78.94\% \pm 0.08\%$ *vs* $78.34\% \pm 0.19\%$; $P = 0.009$; Figure 5).

Histology
All ascitic cirrhotic rats with portal vein occlusion developed liver cirrhosis with regeneration nodules, necrosis, and steatosis regardless of treatment received. All CCl₄-treated animals scored F4 with the Scheuer system. As expected, all control groups showed normal hepatic histology (Figure 6).

DISCUSSION
In this study, we demonstrated the effectiveness of rifaximin in normalizing both ammonemia and brain ammonia levels, and consequently averting the appearance of low-grade brain edema in ascitic cirrhotic rats with portal vein occlusion; an experimental model of hyperammonemia related to decompensated advanced cirrhosis. These alterations play a central role in the multifactorial mechanisms leading to HE as a result of chronic liver disease.

Although administration of low doses of IGF-1 has been proposed as a promising therapy for cirrhotic patients on the basis of preclinical data showing that this hormone displays hepatoprotective and antifibrogenic

Figure 6 Photomicrographs of liver sections. All cirrhotic rats developed micronodular cirrhosis with regeneration nodules, necrosis and steatosis regardless of treatment (A: Cirrhosis; B: Cirrhosis + IGF-1; C: Cirrhosis + rifaximin). All control rats showed normal cellular architecture (D: Control; E: Control + IGF-1; F: Control + rifaximin).

activities[7,9,21], we observed virtually no positive effect of IGF-1 on most of the alterations that lead to HE in this experimental model.

Given that the major precipitating factor leading to HE in cirrhosis is the presence of large amounts of ammonia, not only in the bloodstream but especially in the brain, and further considering that the main source of this ammonia is production by enteric bacteria, the two key factors that warrant particular attention are: (1) Deranged function of the liver, which introduces ammonia into the urea cycle and is the main ammonia-detoxifying organ; and (2) The presence of bacterial overgrowth related to disturbed intestinal transit.

In this context, rifaximin treatment was accompanied by a slight, but significant, improvement of some parameters of liver function, such as glucose, bilirubin and ALT. This improvement cannot be mainly attributed to a decrease in endotoxin levels, which is known to promote activation and release of proinflammatory cytokines such as tumor necrosis factor (TNF)-α[30,31], because these parameters were also diminished in the IGF-1 treated group (group 3) without producing any positive effect on liver function.

Notwithstanding these observations, a recent study

has observed a direct effect of norfloxacin, another "non-absorbable" antibiotic widely used for selective intestinal bacterial decontamination, in cirrhotic patients. Norfloxacin actively accumulates in polymorphonuclear cells, leading to a decrease in plasma TNF-α and interferon-γ levels, and a reduction in oxidative stress[32]. Although these mechanisms were not explored in the present study, we cannot rule out the possibility that a similar action of rifaximin could explain our results. Further studies are needed to examine this possibility.

However, we did not observe the hepatoprotective effects of IGF-1 administration in experimental cirrhosis that have been reported by others[20]. In our study, hepatic function (glucose, bilirubin, AST, ALT) in IGF-1-treated cirrhotic rats was similar to that observed in untreated cirrhotic rats. We attribute these differences to the fact that, in our study, all animals presented with well-established cirrhosis plus ascitic decompensation.

As mentioned previously, cirrhotic patients present several alterations in gut motility that could lead to an increase in gut bacterial content[33]. A close cause and effect relationship between bacterial overgrowth and plasma ammonia levels has been reported, reflecting the fact that enteric bacterial fermentation is the main source

of ammonia. In our study, cirrhotic groups treated with placebo or IGF-1 (groups 1 and 2) showed a significant increase in cecal bacterial content compared with control groups. By contrast, rifaximin treatment dramatically reduced cecal bacterial content, not only in cirrhotic rats but also in control rats (groups 3 and 6), as reported in other studies[34,35]. As a consequence of this reduction in bacterial content, plasma ammonia levels in rifaximin-treated cirrhotic rats (group 3) remained similar to those observed in controls (groups 4-6). Similarly, brain ammonia levels were normalized in rifaximin-treated rats. In keeping with this, low-grade brain edema was absent in this group of rats. Again, consistent with its inability to modify cecal bacterial content, IGF-1 failed to improve any of these parameters.

In conclusion, our data indicate that, by reducing gut bacterial overgrowth and improving liver function, rifaximin may be useful in the treatment of most alterations associated with HE in experimental cirrhosis, whereas the administration of low doses of IGF-1 is not indicated in this condition.

COMMENTS

Background
Hepatic encephalopathy (HE) in cirrhosis appears as a consequence of hepatic failure and/or the presence of portosystemic shunting that leads to the passage of nitrogenate compounds such as ammonia from the gut to the systemic circulation, which in turn, lead to an increase of brain water content. Non-absorbable antibiotics and/or non-absorbable disaccharides have been used as a standard treatment of HE in human cirrhosis.

Research frontiers
Rifaximin has been reported to be useful for its activity against aerobic and anaerobic microorganisms, which are an important source of ammonia. However, no data regarding the effect of rifaximin on low-grade brain edema in experimental HE in cirrhotic rats has been reported. Also, insulin-like growth factor (IGF)-1 could be useful for the treatment of that pathology for its antifibrogenic and anabolic effects.

Innovations and breakthroughs
For the first time, authors have demonstrated in an experimental model of hyperammonemia related to decompensated cirrhosis that the effectiveness of rifaximin for the treatment of HE is mainly due to its efficacy in reducing low-grade brain edema. On the contrary, low doses of IGF-1 have no effects in preventing liver damage or hyperammonemia.

Applications
By understanding unequivocally that rifaximin is a useful therapy in the treatment of hyperammonemia and most of the alterations associated with HE in cirrhosis. The data suggest that the use of non-absorbable antibiotics could be a good therapeutic strategy.

Terminology
Rifaximin is a non-absorbable rifamycin derivative, with activity against enteric aerobic and anaerobic microorganisms. IGF-1 is a powerful anabolic hormone with diverse endocrine, paracrine and autocrine effects. In cirrhosis, the reduction of functional hepatocellular mass causes a marked fall in IGF-1 serum levels.

Peer review
This is an experimental study comparing the efficacy of rifaximin and IGF-1 in the treatment of some of the alterations observed in HE such as hyperammonemia and low-grade brain edema. The results showed that only rifaximin, by abolishing bacterial overgrowth, is capable of reducing hyperammonemia and low-grade brain edema in cirrhotic rats. By contrast, low doses of IGF-1 are not indicated for this pathology.

Abstract

AIM: To evaluate the effectiveness of our proposed bowel preparation method for colon capsule endoscopy.

METHODS: A pilot, multicenter, randomized controlled trial compared our proposed "reduced volume method" (group A) with the "conventional volume method" (group B) preparation regimens. Group A did not drink polyethylene glycol electrolyte lavage solution (PEG-ELS) the day before the capsule procedure, while group B drank 2 L. During the procedure day, groups A and B drank 2 L and 1 L of PEG-ELS, respectively, and swallowed the colon capsule (PillCam COLON® capsule). Two hours later the first booster of 100 g magnesium citrate mixed with 900 mL water was administered to both groups, and the second booster was administered six hours post capsule ingestion as long as the capsule had not been excreted by that time. Capsule videos were reviewed for grading of cleansing level.

RESULTS: Sixty-four subjects were enrolled, with results from 60 analyzed. Groups A and B included 31 and 29 subjects, respectively. Twenty-nine (94%) subjects in group A and 25 (86%) subjects in group B had adequate bowel preparation (ns). Twenty-two (71%) of the 31 subjects in group A excreted the capsule within its battery life compared to 16 (55%) of the 29 subjects in group B (ns). Of the remaining 22 subjects whose capsules were not excreted within the battery life, all of the capsules reached the left side colon before they stopped functioning. A single adverse event was reported in one subject who had mild symptoms of nausea and vomiting one hour after starting to drink PEG-ELS, due to ingesting the PEG-ELS faster than recommended.

CONCLUSION: Our proposed reduced volume bowel preparation method for colon capsule without PEG-ELS during the days before the procedure was as effective

as the conventional volume method.

INTRODUCTION

Colorectal cancer is the second leading cause of cancer mortality in developed countries[1,2]. In recent years, colon capsule endoscopy has received widespread attention as an emerging minimally invasive endoscopic technique that is likely to impact on colorectal examination[3-10]. It is gradually being accepted as a useful diagnostic technique, particularly in Europe. Van Gossum *et al*[6] evaluated the first generation PillCam colon capsule and reported that the sensitivity for detecting patients with advanced polyps was 73% regardless of colon cleansing level, increasing to 88% in the subgroup of patients having adequate bowel preparation. These results have clearly shown that colon cleanliness plays an important role in providing optimal colon visualization when using colon capsule endoscopy.

However, the most commonly used preparation method may require as much as 6 L of fluid intake over two days. Reducing the volume of fluid intake is an important consideration in increasing patient acceptance of colon capsule endoscopy. Regarding traditional colonoscopy, there have been efforts to reduce patient stress by limiting fluid intake for bowel preparation to the day of examination which has resulted in better cleansing quality compared with the conventional volume method[11,12]. With respect to colon capsule endoscopy, there is no presently published report on bowel preparation during the day of examination only.

We intended to simplify the bowel preparation method by eliminating polyethylene glycol electrolyte lavage solution (PEG-ELS) on the day before the examination and to increase acceptance for colon capsule endoscopy. The aim of this study was to evaluate the effectiveness of the proposed reduced bowel preparation method for colon capsule endoscopy in terms of colon cleanliness and colon capsule excretion rates within the capsule's

battery life.

MATERIALS AND METHODS

Study group

The study was a pilot, multicenter (six medical facilities), prospective, randomized controlled trial comparing our proposed "reduced volume method" with the "conventional volume method" of bowel preparation used with colon capsule endoscopy. The subjects were recruited between October 2009 and March 2010, and included men and women between 18 and 79 years of age who were either asymptomatic healthy volunteers or symptomatic patients. The study protocol was approved by the institutional review boards at each of the six participating medical facilities. This study was registered in the *UMIN Clinical Trials Registry* (registration ID number: UMIN000002562). Written informed consent was obtained from all subjects prior to enrollment in the study.

Subjects were stratified according to their specific medical facility, gender, age ($\geq$ 40 years or < 40 years), and whether they were asymptomatic or symptomatic. Subjects were randomly assigned to one of the two study groups with different PEG-ELS (Muben®; Nihon Pharmaceutical Co., Ltd., Tokyo, Japan) administration protocols: Group A (reduced volume method) received 2 L PEG-ELS during the procedure day, before capsule ingestion; Group B (conventional volume method) received 2 L PEG-ELS on the night before the procedure day and an additional 1 L during procedure day, before capsule ingestion.

Exclusion criteria included presence of dysphagia, constipation, congestive heart failure, renal insufficiency, diabetes, digestive tract diverticulum, a history of radiotherapy, accompanying cancerous peritonitis, Crohn's disease or ulcerative colitis, familial adenomatous polyposis or hereditary nonpolyposis colorectal cancer; individuals taking non-steroidal anti-inflammatory drugs, morphine hydrochloride or tranquilizers or having a history of allergic reaction to any of the medications planned for use in this study, a cardiac pacemaker or other implanted electromedical devices; as well as anyone currently pregnant, having had abdominal surgery, suspected of symptoms or having a history of intestinal obstruction or stenosis; and any other cases in which a doctor considered it inappropriate.

According to a four-point scale grading system assessing colon cleanliness[5], based on an assumption that the average cleansing score of groups A and B are 3.5 and 3.0 with a standard deviation of 0.70 within each group, and α error of 0.05 and β error of 0.20, the required sample size is 27 subjects per group, with a total of 54 subjects.

Bowel preparation

The bowel preparation procedure is shown in Table 1. On the day before examination, all subjects had three meals consisting of a low fiber diet using ENIMACLIN® (Glico,

Table 1 Bowel preparation procedures for colon capsule endoscopy

PEG-ELS: Polyethylene glycol electrolyte lavage solution. [1]If capsule excreted early, remaining regimen discontinued immediately; [2]If bowel preparation judged as complete by checking the color of evacuation, 4th step skipped and subjects permitted to ingest colon capsule. In cases of inadequate preparation, additional PEG-ELS permitted in both groups; [3]In the case of capsule still present in stomach, subject received 5 mg of mosapride as prokinetic agent (maximum dosage, 15 mg).

Osaka, Japan) and 24 mg oral sennoside prior to bedtime. Group A did not receive any PEG-ELS the night before examination, while group B received 2 L PEG-ELS at 7 p.m.

On the day of examination, all subjects drank 100 mL water which contained 1 g pronase and 2.5 g sodium bicarbonate followed by 15 mg mosapride. Then, group A subjects drank 2 L PEG-ELS with 400 mg dimethicone over 2 h, while group B subjects drank 1 L PEG-ELS with 400 mg dimethicone over 1 h. Experienced medical staff assessed the quality of the bowel preparation by checking the clarity of subjects' evacuation before the subjects were given the colon capsule. A reference which we use to evaluate the quality of bowel preparation as a standard procedure of total colonoscopic examination in our facilities is outlined in Figure 1. Using this reference, we define that the capsule is ready to be ingested when a grade 5 quality is achieved.

In cases of unsatisfactory preparation, additional amounts of PEG-ELS (maximum total dosage, 0.6 L) were administered prior to capsule ingestion (Table 1).

When bowel preparation was judged to be complete, each subject ingested the first generation colon capsule (PillCam colon capsule, Given Imaging Inc., Yoqneam, Israel). Two hours later, the capsule location was checked with a real-time viewing monitor (RAPID® Access Real Time Tablet PC; Given Imaging). If the capsule had

passed through the stomach, the subject received the first booster consisting of 50 g magnesium citrate (Magcorol P®, Horii Pharmacological Co. Ltd, Osaka, Japan) in 900 mL water in which 200 mg dimethicone was dissolved. If the capsule was in the stomach, the subjects received 5 mg mosapride as a prokinetic agent every 15 min until the capsule passed through the stomach or up to a maximum mosapride dosage of 15 mg. If the capsule was not excreted by 6 h after ingestion, subjects received a second booster similar to the first booster.

If the capsule was not excreted by 7 h after ingestion, subjects ingested 5 mg mosapride and were then permitted to eat dinner. Defecation should have been completed within eight hours so a suppository of 10 mg bisacodyl was administered to those subjects who had not excreted the colon capsule within that timeframe.

Colon capsule examination
The study employed a first generation PillCam COLON capsule, and the examinations were conducted without colon intubation and insufflations or sedation. The capsule enabled recording of images for 3 min after activation, then became inactive for 1 h 45 min (sleep mode) to save battery energy. After the capsule reactivated ("woke up"), its normal operational time was approximately 6-8 h depending on the capsule's actual battery life.

Evaluation of colon cleanliness and capsule excretion
Overall colon cleanliness was determined in accordance with a four-point grading scale consisting of excellent (no more than small bits of adherent feces), good (small amount of feces or dark fluid not interfering with the examination), fair (enough feces or dark fluid present to prevent a reliable examination) and poor (large amount of fecal residue precluding a complete examination) based on previously published reports[3,4,6]. Excellent or good grades were categorized as adequate cleansing, and fair or poor as inadequate. We also scored colon cleanliness using a four-point scale grading system from 1 to 4 (excellent, good, fair and poor)[5].

Excretion of the capsule was defined as occurring when the capsule was either expelled from the subject's body or had reached and visualized the hemorrhoidal plexus within the capsule's battery life. Location within the colon was determined using both colorectal images and the rapid localization system.

Before commencing this study, the 20 principal investigators received two half-days of training on managing the colon capsule endoscopy examination with particular emphasis on estimation of colon cleanliness levels and procedure completion. Three selected clinicians (Kakugawa Y, Saito S and Watanabe K) who were blinded to the study groups graded the cleanliness levels. An additional independent physician (Saito Y) supervised the blinding process.

Adverse events
All subjects were interviewed for any associated adverse

Figure 1 Reference used to evaluate the quality of bowel preparation prior to capsule ingestion. Experienced medical staff assessed the quality of the bowel preparation by checking the clarity of subjects' evacuation before the subjects were given the colon capsule. We define that the capsule is ready to be ingested when a grade 5 quality is achieved.

Standard PEG-ELS preparation before capsule ingestion	Without/with additional PEG-ELS prescription	30/1	26/3
Total volume amount of intake for 2 d	Median, liter (range)	3.8 (2.9-4.1)	4.8 (3.9-5.1)

PEG-ELS: Polyethylene glycol electrolyte lavage solution.

symptoms at the outpatient clinic following the colon capsule endoscopy. Adverse events were recorded as mild, moderate or severe by the physicians who performed the colon capsule procedures. A condition not requiring treatment was defined as mild, a condition needing any kind of treatment was regarded as moderate, and a condition that required any emergency treatment was considered severe.

Statistical analysis

Univariate analysis using Fisher's exact test was performed to compare differences in colon cleansing level and capsule excretion rate between the two groups. Values of $P < 0.05$ were considered significant.

RESULTS

Subjects

Sixty-four subjects enrolled in this study. Thirty-three sub-

jects were randomly assigned to group A and 31 to group B. The colon capsules failed to "wake up" in 2 subjects of group A and 2 subjects in group B. As a result, 31 subjects in group A and 29 subjects in group B were included in our analysis (Table 2). All subjects consumed the specified initial amount of PEG-ELS. In four subjects, the quality of the bowel preparation by checking the clarity of subjects' evacuation was not adequate prior to capsule ingestion, so an additional 0.3 L of PEG-ELS was prescribed prior to capsule ingestion for one subject in group A and 3 subjects in group B. Median fluid solution intake including boosts was 3.8 L (range, 2.9-4.1 L) in group A, while it was 4.8 L (range, 3.9-5.1 L) in group B.

Location when capsule "woke up"

The colon capsule was located in the stomach of six subjects, the small bowel of 44 subjects, and the colon of 10 subjects when it "woke up" at 1 h 45 min post-ingestion. Of the latter 10 subjects, capsules were located in either the cecum (*n* = 9) or the ascending colon (*n* = 1).

Colon cleanliness

Colon cleanliness is shown in Table 3. Colon cleanliness was evaluated as adequate in 29 subjects (94%) in group A, compared to 25 subjects (86%) in group B. The average scores of groups A and B were 3.60 ± 0.61 and 3.50 ± 0.72, respectively (ns). The level of colon cleanliness was evaluated to be excellent in all 4 of those subjects who were prescribed additional PEG-ELS just prior to colon capsule endoscopy.

Capsule excretion

In 25% of subjects (15/60) the capsule was excreted from the body within 6 h post-ingestion, in 53% (32/60)

Table 3 Colon cleansing level

	Group A (*n* = 31)	Group B (*n* = 29)
Colon cleansing level		
Adequate	29 (94%)	25 (86%)
Excellent	13	14
Good	16	11
Inadequate	2 (6%)	4 (14%)
Fair	2	4
Poor	0	0

Table 4 Capsule excretion within battery life (%)

		Group A (*n* = 31)	Group B (*n* = 29)	Total
Capsule excretion within battery life		22/31 (71)	16/29 (55)	38/60 (63)
According to colon cleansing level	Adequate	21/29 (72)	15/25 (60)	36/54 (67)
	Inadequate	1/2 (50)	1/4 (25)	2/6 (33)
According to location when capsule woke up	Stomach	2/3 (67)	0/3 (0)	2/6 (33)
	Small bowel	16/24 (66)	11/20 (55)	27/44 (61)
	Colon	4/4 (100)	5/6 (83)	9/10 (90)

within 8 h, in 58% (35/60) within 10 h, and in 63% (38/60) within the capsule's battery life. Twenty-two (71%) of the 31 subjects in group A excreted the capsule compared to 16 (55%) of the 29 subjects in group B (ns) (Table 4). Of the remaining 9 subjects in group A and 13 subjects in group B whose capsules were not excreted, all of the capsules were located in the left side colon when they stopped functioning.

Adverse events

Only one subject, a 70-year-old female in group A, experienced mild symptoms of nausea and vomiting 1 h after starting to drink PEG-ELS, due to ingesting the PEG-ELS faster than recommended. She was advised to slow down the rate of ingestion for the remaining PEG-ELS and was able to continue with the colon capsule procedure. After capsule examination, the colon cleansing level was evaluated as being excellent.

DISCUSSION

This is the first study aimed at reducing the total amount of bowel preparation intake for colon capsule endoscopy procedures. While colon cleanliness is essential for optimal visualization during colon capsule endoscopy, fluid intake during bowel preparation can be as high as a total of 6 L over two days[4,6,7,9,10], an amount considered excessive for some patients. Reducing the volume of fluid intake is an important consideration in increasing patient acceptance of colon capsule endoscopy. We propose reducing the total amount of bowel preparation fluid by eliminating PEG-ELS intake on the day before the examination. Therefore, we conducted a multicenter, prospective, randomized controlled trial, comparing our proposed "reduced volume method" with the "conventional volume method" of bowel preparation for colon capsule endoscopy.

In this study, the level of cleansing was defined as adequate in 94% of group A subjects (reduced volume method), despite the elimination of drinking any PEG-ELS on the day before the examination. This result was higher than that of previous studies (52%-88%)[3-7,9]. We successfully reduced median fluid intake to 3.8 L (range, 2.9-4.1 L) using the reduced volume method compared to total fluid intake ranging from 4.5 to 6 L using the conventional volume method in previously reported studies[3-10]. These results indicate that the intake

of PEG-ELS on the day of the examination promotes colon cleansing, whereas intake on the day before the examination may have very limited, if any, impact on the cleansing. A possible reason for this is that after ingesting and evacuating 2 L PEG-ELS on the day before the examination, biliary and intestinal secretion occurs (processes necessary for stool production) and the ingestion of only 1 L PEG-ELS on the day of the examination is then insufficient to clean the whole colon. Regarding total colonoscopy, in most Japanese facilities patients take 2 L PEG-ELS in the endoscopy waiting room on the day of the examination and the examination then starts when the fecal matter becomes liquid and transparent. In this way, we usually obtain an adequate preparation for performing total colonoscopy. The Japanese preparation method for total colonoscopy has evidence of achieving an adequate cleansing level[11,12]. Therefore, we believe that our proposed reduced volume method for colon capsule endoscopy is also adequate.

There has been no previously published report on the use of experienced medical staff in this respect. In this study, we established a method in which experienced medical staff assessed the quality of the bowel preparation by checking the clarity of subjects' evacuation before the subjects were given the colon capsule (Figure 1). In cases of unsatisfactory preparation, an additional PEG-ELS was prescribed, with additional PEG-ELS required for one subject in group A and three subjects in group B. Following this additional PEG-ELS, colon cleanliness was judged as adequate in all four subjects. In most Japanese institutes, experienced medical staff assess the quality of the bowel preparation by checking the clarity of subjects' evacuation before starting total colonoscopy. This may be one of the key points why we achieved a high cleansing level. Experienced medical endoscopy staff could also be utilized to help achieve a high level of colon cleanliness when performing colon capsule endoscopy.

It is also important to note that small changes in technique can make significant differences in achieving a high quality of colon cleansing. The difference between this study and previous reports[3-7,9,10] is that we used pronase and dimethicone as adjuncts, and isotonic magnesium citrate as a booster. It has previously been re-

Figure 2 Example of the contribution of dimethicone to improved mucosal visualization by the colon capsule. A: A lesion (arrow) is clearly observed on the transverse colon by colon capsule endoscopy. Dimethicone worked to join numerous microbubbles to form groups of large bubbles, resulting in better mucosal visualization; B: Colonoscopy image of the lesion post-capsule procedure. The lesion was diagnosed as a laterally spreading tumor. Endoscopic submucosal dissection was performed, and intramucosal cancer consisting of well differentiated adenocarcinoma was identified on the resected specimen.

ported that pronase was effective as a mucolytic agent[13] and dimethicone was useful in dissolving intraluminal air bubbles[14,15]. Accordingly, we used pronase dissolved into 100 mL of water as the first step on the day of examination, and dimethicone was added to the solution of PEG-ELS and magnesium citrate. We believe that dimethicone worked to join numerous microbubbles to form groups of large bubbles, resulting in better mucosal visualization, and that pronase and dimethicone should be used routinely as adjuncts to bowel preparation (Figure 2).

It is possible to conclude that our method is superior in terms of safety. Sodium phosphate has served as a booster in a number of studies[3-10], and PEG-ELS in one published report[16], but the use of magnesium citrate as a booster has not been reported. In this study, we used isotonic magnesium citrate instead of sodium phosphate as a booster, principally because it is very easy to drink since it has a similar taste to sports drinks. Japan is the only country in the world as far as we know in which isotonic magnesium citrate is available as a laxative. Secondly, isotonic magnesium citrate might reduce the level of electrolytic imbalance, while sodium phosphate has been reported as causing major problems including acute phosphate nephropathy[17,18]. Therefore, both patient ac-

ceptance and safety are increased using isotonic magnesium citrate instead of sodium phosphate as a booster.

Van Gossum *et al*[6] reported 6.7% adverse events related to the bowel preparation; however, in our study, a mild adverse event related to the bowel preparation was observed in only one case (3%). Moreover, this single case was then able to continue with the procedure, and the subject's colon cleanliness level was subsequently rated as excellent. These results may indicate the higher degree of acceptance and improved safety of the reduced volume method.

Our results do not deny the cleansing ability of the conventional volume method (group B) which achieved an adequate cleansing level of 86%. There is no statistically significant difference between the two groups. However, in terms of a better quality of life and improved acceptability for patients, the reduced volume method (group A) is a preferred option for colon cleansing associated with colon capsule endoscopy.

Our proposed reduced volume method had a lower rate of capsule excretion before the battery life ended. The excretion rate was 71%, which was lower in comparison with the 64%-94% reported in previous studies[3-7,9,10]. Those reports and the present study differed in the use of bisacodyl suppository. Such use was mandatory in the earlier studies, but it was left to each individual subject in this study, with a bisacodyl suppository requested in only one case. Considering the fact that the capsule was located in the left descending colon in all cases where the capsule was not excreted within the capsule's battery life, the use of bisacodyl suppository could have increased the excretion rate to be much higher. There may be a possibility that some subjects feel unwilling to use the suppository because of embarrassment; therefore, it may be an effective option to administer a third oral booster in order to achieve a higher excretion rate.

The size of this study was small because it was a pilot study and the median age of 39 years for all participating subjects was relatively young. Further studies are necessary to clarify the efficiency of the reduced volume method, especially in terms of increasing the excretion rate of the colon capsule. PillCam COLON2 capsule, the second generation of colon capsule, has no sleep mode and has a small bowel detection function to indicate the presence of the capsule in the small bowel[8,19]. This should allow more appropriate timing for administering the first booster, which can be expected to shorten the procedure time and improve the capsule excretion rate.

In this study, we clarified that our newly proposed regimen with a reduced volume of bowel preparation when conducting colon capsule endoscopy was as effective as the commonly used higher volume method. An important advantage of the reduced volume method is that subjects do not need to drink any PEG-ELS and can eat three low fiber meals on the day before the examination. Our proposed reduced volume bowel preparation method could be useful in encouraging subjects who have not undergone colorectal screening to under-

take colon capsule endoscopy in the future.

COMMENTS

Background
Adequate colon cleanliness is essential for optimal visualization during colon capsule endoscopy, but the widely used preparation method may require as much as 6 L of fluid intake over two days.

Research frontiers
The authors propose a reduced volume method without polyethylene glycol electrolyte lavage solution intake in the days before the capsule procedure.

Innovations and breakthroughs
In this study, the authors demonstrate that a new preparation method for colon capsule endoscopy was as effective as the conventional method.

Applications
In terms of a better quality of life and improved acceptability for patients, the reduced volume method is a useful option for colon cleansing when undertaking colon capsule endoscopy.

Peer review
A well conducted study on a very important issue, even if as stated by the authors "the size of this study was small because it was a pilot study".

Abstract

AIM: To investigate differences in clinical features between diffuse- and focal-type autoimmune pancreatitis (AIP).

METHODS: Based on radiological findings by computed tomography and/or magnetic resonance imaging, we divided 67 AIP patients into diffuse type (D type) and focal type (F type). We further divided F type into head type (H type) and body and/or tail type (B/T type) according to the location of enlargement. Finally, we classified the 67 AIP patients into three groups: D type, H type and B/T type. We compared the three types of AIP in terms of clinical, laboratory, radiological, functional and histological findings and clinical course.

RESULTS: There were 34 patients with D-type, 19 with H-type and 14 with B/T-type AIP. Although obstructive jaundice was frequently detected in D-type patients (88%) and H-type patients (68%), no B/T-type patients showed jaundice as an initial symptom ($P < 0.001$). There were no differences in frequency of abdominal pain, but acute pancreatitis was associated more frequently in B/T-type patients (36%) than in D-type patients (3%) ($P = 0.017$). Serum immunoglobulin G (IgG)4 levels were significantly higher in D-type patients (median 309 mg/dL) than in B/T-type patients (133.5 mg/dL) ($P = 0.042$). Serum amylase levels in B/T-type patients (median: 114 IU/L) were significantly greater than in H-type patients (72 IU/L) ($P = 0.049$). Lymphoplasmacytic sclerosing pancreatitis (LPSP) was histologically confirmed in 6 D-type, 7 H-type and 4 B/T-type patients; idiopathic duct-centric pancreatitis was observed in no patients. Marked fibrosis and abundant infiltration of CD20-positive B lymphocytes with few IgG4-positive plasma cells were detected in 2 B/T-type patients. Steroid therapy was effective in all 50 patients (31 D type, 13 H type and 6 B/T type). Although AIP relapsed during tapering or after stopping steroids in 3 D-type and 3 H-type patients, no patients relapsed in B/T type. During follow-up, radiological features of 6 B/T-type patients were not changed and 1 B/T-type patient improved naturally.

CONCLUSION: Clinical features of H-type AIP were similar to those of D-type, but B/T-type differed from D and H types. B/T-type may involve diseases other than LPSP.

INTRODUCTION

Autoimmune pancreatitis (AIP) is a type of pancreatitis that is thought to have an autoimmune etiology. AIP responds dramatically to steroid therapy, therefore, differentiating AIP from pancreatic cancer is important to avoid unnecessary pancreatic resection[1-3]. According to the Asian Diagnostic Criteria for AIP[4], AIP is diagnosed based on the following items: diffuse or focal enlargement of the pancreas and narrowing of the main pancreatic duct; increased serum immunoglobulin G (IgG) or IgG4 levels or the presence of autoantibodies in the serum; histological findings of lymphoplasmacytic infiltration and fibrosis in the pancreas [lymphoplasmacytic sclerosing pancreatitis (LPSP)[5]]; and responsiveness to steroids. AIP occurs frequently in elderly men. The primary initial symptom is obstructive jaundice, and diabetes mellitus occurs in half of patients. AIP is rarely associated with acute pancreatitis or ulcerative colitis. AIP is associated with several sclerosing extrapancreatic lesions such as sclerosing cholangitis, sclerosing sialadenitis, and retroperitoneal fibrosis, and is currently recognized as a pancreatic lesion of IgG4-related systemic disease. AIP responds well to steroid therapy, but it sometimes relapses[1,2].

Recently, another histological pattern of AIP, characterized by ductal epithelial granulocytic infiltration, has been recognized[6,7]. This pattern is referred to as idiopathic duct-centric pancreatitis (IDCP)[6]. Clinical features of IDCP patients are different from those of LPSP patients. The terms, type 1 and type 2 AIP, are proposed to describe the clinical features associated with LPSP and IDCP, respectively[8-11].

Radiologically, AIP is classified into diffuse type (D type) and focal type (F type)[1-3,12-14]. Although diffuse enlargement of the pancreas is rather specific to AIP, F-type AIP should be strictly differentiated from pancreatic cancer. However, only a few studies[13,14] have investigated the differences between D- and F-type AIP, and it is unknown whether F-type AIP is an initial stage of D-type AIP, or a different type of AIP. This study aimed to clarify differences in clinical features between D- and F-type AIP.

MATERIALS AND METHODS

Study patients

From 1988 to 2010, 67 AIP patients (47 men and 20 women; median age: 60.3 years; range: 27-83 years) were diagnosed according to the Asian Diagnostic Criteria for AIP[4] in Tokyo Metropolitan Komagome Hospital. Based on radiological findings by computed tomography

and/or magnetic resonance imaging, we divided the AIP patients into D type and F type. We further divided F type into head type (H type) and body and/or tail type (B/T type) according to the location of enlargement. Finally, we classified the 67 AIP patients into three groups: D type, H type, and B/T type. D-type AIP patients showed diffuse enlargement of the pancreas (Figure 1A-C), H-type patients showed focal enlargement of only the pancreatic head (Figure 2A-C), and B/T-type patients showed enlargement of only the pancreatic body and/or tail (Figure 3A and B). We compared clinical, laboratory, radiological, functional, and histological findings and clinical course among the three types of AIP.

Clinical, radiological and laboratory analysis

Clinical assessments were as follows: age at time of diagnosis; sex; drinking and smoking habits; presence and/or history of allergic diseases; initial symptoms such as obstructive jaundice and abdominal pain; and associated diseases such as diabetes mellitus, acute pancreatitis and ulcerative colitis. Drinking habit was defined as drinking > 80 g/d alcohol for > 7 years. Smoking habit was defined as smoking > 20 pack-years. Diabetes mellitus was diagnosed if fasting serum glucose levels and/or hemoglobin A1c levels were higher than normal levels (126 mg/dL and 6.1%, respectively)[15]. Acute pancreatitis was diagnosed when both severe abdominal pain and elevation of serum amylase level (> 3 times normal; normal: 115 IU/L) were seen.

Stenosis of the lower bile duct was evaluated on endoscopic retrograde cholangiopancreatography and/or magnetic resonance cholangiopancreatography. Three extrapancreatic lesions that are frequently associated with AIP (sclerosing cholangitis of the hilar or intrahepatic bile duct, swelling of salivary glands, and retroperitoneal fibrosis) were evaluated radiologically.

Laboratory findings were assessed including serum IgG ($n = 67$), IgG4 ($n = 65$) and immunoglobulin E (IgE) ($n = 43$) levels, peripheral eosinophil count ($n = 56$), serum amylase levels ($n = 66$), and autoantibodies including antinuclear antigen ($n = 60$) and rheumatoid factor ($n = 58$). Serum IgG4 levels were measured by nephelometry using IgG subclass (BS-NIA) kits. A cutoff value of 135 mg/dL, which is widely accepted, was used.

Histological and immunohistological studies

The pancreas was assessed by surgical resection ($n = 7$), surgical or ultrasound-guided biopsy ($n = 6$), and endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA, $n = 10$) and examined histologically and immunohistochemically using anti-CD3, anti-CD20, and anti-IgG4 antibodies.

Clinical course

Ten patients were initially treated with surgical procedures on suspicion of pancreatic cancer (pancreatoduodenectomy, $n = 6$; distal pancreatectomy, $n = 1$; choledochoduodenostomy with pancreatic biopsy, $n = 3$). Fifty patients,

Figure 1 Computed tomography scan showing diffuse type autoimmune pancreatitis. Swelling of the head (A), body (B) and tail (C) of the pancreas was seen.

Figure 2 Computed tomography scan showing head type autoimmune pancreatitis. There was swelling of the only pancreatic head (A), but the pancreatic body (B) and tail (C) were a normal size.

Figure 3 Computed tomography scan showing body and/or tail type autoimmune pancreatitis. Pancreatic body and tail was swollen (A), but the pancreatic head was within a normal size (B).

including one surgically treated, were treated with oral steroids. Prednisolone at an initial dose of 30-40 mg/d was given for 2-3 wk. It was then tapered by 5 mg every 1-3 wk to 5 mg/d. Maintenance therapy (2.5-5 mg/d, 1-3 years) was used in all patients. Recurrence of AIP was defined as the reappearance of symptoms with the development or reappearance of pancreatic and/or extrapancreatic abnormalities on imaging studies. Eight patients were followed up conservatively without steroid therapy.

Statistical analysis
Differences between groups were analyzed using Fisher's exact probability test, and Mann-Whitney's *U* test. *P* values were corrected by Bonferroni's method, and *P* < 0.05 was considered statistically significant.

RESULTS
Clinical, radiological and laboratory differences
Sixty-seven AIP patients were classified into D-type (*n* = 34), H-type (*n* = 19) and B/T-type (*n* = 14) AIP. There were no significant differences in age, sex, drinking,

smoking habits and history of allergic diseases among the groups. Although obstructive jaundice was frequently detected in D-type (88%) and H-type (68%) patients, no B/T-type patients showed jaundice as an initial symptom (*P* < 0.001). Although there were no differences in frequency of abdominal pain, acute pancreatitis was seen more frequently in B/T-type (36%) than in D-type (3%) patients (*P* = 0.017). Although stenosis of the lower bile duct was seen frequently in D-type (94%) and H-type (95%) patients, no B/T-type patients showed stenosis of the lower bile duct (*P* < 0.001). There were no differences between groups in associated extrapancreatic lesions (Table 1).

Serum IgG4 levels were significantly higher in D-type (median: 309 mg/dL) than in B/T-type (133.5 mg/dL) patients (*P* = 0.042). Serum IgG4 levels were more frequently elevated in D-type (88%) than in B/T-type (50%) patients (*P* = 0.030). There were no significant differences in serum IgE levels and peripheral eosinophil count among the groups. Serum amylase levels in B/T-type patients (median: 114 IU/L) were significantly greater than in H-type patients (72 IU/L) (*P* = 0.049). There were no

differences among the groups in terms of the ratio of antinuclear antigen and rheumatoid factor (Table 2).

Histological and immunohistochemical studies

LPSP was histologically confirmed with abundant infiltration of CD3-positive T lymphocytes and IgG4-positive plasma cells in 6 D-type, 7 H-type and 4 B/T-type patients. In the pancreas of 2 B/T-type patients (1 surgical biopsy specimen and 1 EUS-FNA specimen), marked fibrosis and abundant infiltration of CD20-positive B lymphocytes rather than T lymphocytes were detected, but few IgG4-positive plasma cells or neutrophils were detected. IDCP was not observed in any patients. EUS-FNA of 4 AIP patients could not confirm the histological diagnosis due to insufficient specimens (Table 3).

Clinical course

Steroid therapy was effective in all 50 patients (31 D type, 13 H type and 6 B/T type). AIP relapsed during tapering or after stopping steroids in 3 D-type and 3 H-type patients. In 8 conservatively followed-up patients (1 H type and 7 B/T type), radiological features were not changed in seven patients, but enlargement of the pancreatic tail improved naturally in 1 B/T-type patient. During the course prior to our hospitalization, focal enlargement of the pancreatic head developed to diffuse enlargement in three cases, and focal enlargement of the pancreatic tail

DISCUSSION

Radiologically, AIP is classified into diffuse and focal forms. Diffuse enlargement of the pancreas, called sausage-like enlargement, is a typical feature of AIP. However, F-type AIP, sometimes forming a mass, is frequently difficult to differentiate from pancreatic cancer[1-3,12-14]. Possible differences in clinical presentations between the D and F types of AIP are unclear.

In the present study, we classified 67 AIP patients into D type (*n* = 34), H type (*n* = 19) and B/T type (*n* = 14). D and H types showed similar clinical features. However, the B/T-type was different from D and H types in several aspects. Obstructive jaundice and stenosis of the lower bile duct were frequently detected in D- and H-type patients, but no B/T-type patients showed these features. According to Ghazale *et al*[16], stenosis of the lower bile duct was present in 70% of 53 AIP patients. Hirano *et al*[17] have stated that both pancreatic edema due to inflammation of the pancreatic head and biliary wall thickening influence stenosis of the lower bile duct in AIP, based on EUS findings and the fact that 93% of pancreatic head lesion-positive AIP patients had stenosis of the lower bile duct, compared with only 17% of lesion-negative patients.

In this study, the serum IgG4 level was significantly lower in B/T-type than in D-type patients, and elevation of serum IgG4 levels was less in B/T-type than in D-type patients. Acute pancreatitis was seen more frequently in B/T-type than in D-type patients, and serum amylase levels were significantly higher in B/T-type than in H-type patients. As to the diagnosis and frequency of acute pancreatitis, the high percentage in B/T type patients seems to depend mostly on the higher amylase levels. Acute pancreatitis or some acute inflammatory attack in chronic pancreatitis cases may not be associated with high amylase levels because of the atrophic acinar tissue. There was no difference in the frequency of abdominal pain, therefore, some cases in D-type and H-type might have been overlooked.

No B/T-type patients relapsed after steroid therapy, compared with 10% of D-type and 23% of H-type patients. It has become clear that there are two histological subtypes (LPSP and IDCP) in AIP[6-11]. Most AIP patients in Asia have LPSP, and half of AIP patients in Europe have IDCP[8,10]. The clinical features of these two subtypes differ substantially. It is generally reported that IDCP patients are younger at diagnosis, and IDCP patients are less likely to show elevated serum IgG4 levels. IDCP is more likely associated with acute pancreatitis and inflammatory bowel disease. According to a comparative study of LPSP and IDCP patients by Sah *et al*[9], IDCP patients tended to have more focal features than LPSP (84% *vs* 60%), and no relapse of IDCP was seen in any patient, whereas LPSP relapsed in 47% of patients. To diagnose IDCP, histological examination of

an adequate pancreatic specimen is needed, and the need for histological examination to diagnose IDCP at present makes clinical diagnosis difficult.

In histological examination of the present cases, LPSP was confirmed in 17, but IDCP was not detected. Clinical files of D-type and H-type AIP were compatible with those of LPSP patients. However, considering low serum IgG4 levels and frequent association with acute pancreatitis, there is a possibility that some IDCP cases may be involved in B/T-type cases. For example, a 32-year-old man with B/T-type AIP showed normal serum IgG4 levels, association with ulcerative colitis, and good responsiveness to steroid therapy, but histological diagnosis by EUS-FNA could not be confirmed due to an insufficient biopsy specimen. Interestingly, histology of two B/T-type patients included abundant infiltration of B cells with little infiltration of IgG4-positive cells or neutrophils, which might be another type of AIP other than LPSP and IDCP. B/T-type AIP may involve a disease other than LPSP.

Three H-type and one B/T-type patient progressed to D type during the natural course. It has also been reported that H-type AIP progresses to D-type[18,19], and B/T-type AIP to D-type[20]. There have also been reports of relapse in the remnant pancreas after resection, such as relapse in the remnant pancreatic head 1 year after distal pancreatectomy[21], and relapse in the remnant pancreatic body and tail 4 mo after pancreatoduodenectomy[22]. Steroid therapy was effective for those lesions that had progressed or relapsed. These findings indicate that the focal inflammation may advance to subsequent diffuse changes throughout the pancreas or develop repeatedly at different sites and at different times in some AIP patients. Diffuse change in the pancreas may be the final appearance of AIP, and whether this inflammatory process affects the gland diffusely or focally may merely reflect the stage of the disease. In seven conservatively followed up B/T-type patients, six showed no change and one improved naturally. Kubota *et al*[23] have reported that all eight AIP patients who improved spontaneously showed focal pancreatic enlargement. B/T-type AIP may involve a disease other than D-type and H-type AIP.

In conclusion, although clinical features of H-type AIP are similar to those of D-type AIP, B/T-type AIP differed in several aspects from D and H types. B/T-type AIP may involve a disease other than LPSP.

COMMENTS

Background
Autoimmune pancreatitis (AIP) is a particular type of pancreatitis that is thought to have an autoimmune etiology. Recently, AIP has been radiologically classified into diffuse type (D type) and focal type (F type). However, the differences between D- and F-type AIP are not well known.

Research frontiers
Differences in clinical, radiological, laboratory and histological findings between D- and F-type AIP were investigated.

Innovations and breakthroughs
AIP patients were divided into D type and F type. Furthermore, F type was

divided into head type (H type) and body and/or tail type (B/T type). No B/T-type patients showed jaundice as an initial symptom, but acute pancreatitis was associated more frequently in B/T type than in D type. Serum amylase levels were significantly higher in B/T-type than in H-type patients. Serum immunoglobulin G (IgG)4 levels were significantly higher in D-type than in B/T-type patients. No B/T-type patients relapsed after steroid therapy, compared with 10% of D-type and 23% of H-type patients. Two B/T-type patients included abundant infiltration of B cells with little infiltration of IgG4-positive cells or neutrophils.

Applications
B/T-type AIP differed in several aspects from D and H types, and some B/T-type AIP may involve a disease other than lymphoplasmacytic sclerosing pancreatitis.

Peer review
The study itself seems reasonable and the results are interesting and of etiological importance.

Abstract

AIM: To compare genotype of *Helicobacter pylori* (*H. pylori*) isolated from saliva, dental plaques, gastric biopsy, and stool of each patient in order to evaluate the mode of transmission of *H. pylori* infection.

METHODS: This cross-sectional descriptive study was performed on 300 antral gastric biopsy, saliva, dental plaque and stool samples which were obtained from patients undergoing upper gastrointestinal tract endoscopy referred to endoscopy centre of Hajar hospital of Shahrekord, Iran from March 2010 to February 2011. Initially, *H. pylori* strains were identified by rapid urease test (RUT) and polymerase chain reaction (PCR) were applied to determine the presence of *H. pylori* (*ureC*) and for genotyping of voculating cytotoxin gene A (*vacA*) and cytotoxin associated gene A (*cagA*) genes in each specimen. Finally the data were analyzed by using statistical formulas such as Chi-square and Fisher's exact tests to find any significant relationship between these genes and patient's diseases. *P* < 0.05 was considered statistically significant.

RESULTS: Of 300 gastric biopsy samples, 77.66% were confirmed to be *H. pylori* positive by PCR assay while this bacterium were detected in 10.72% of saliva, 71.67% of stool samples. We were not able to find it in dental plaque specimens. The prevalence of *H. pylori* was 90.47% among patients with peptic ulcer disease (PUD), 80% among patients with gastric cancer, and 74.13% among patients with none ulcer dyspepsia (NUD) by PCR assay. The evaluation of *vacA* and *cagA* genes showed 6 differences between gastric biopsy and saliva specimens and 11 differences between gastric and stool specimens. 94.42% of *H. pylori* positive specimens were *cagA* positive and all samples had amplified band both for *vacA s* and *m* regions. There was significant relationship between *vacA s1a/m1a* and PUD diseases (*P* = 0.04), *s2/m2* genotype and NUD diseases (*P* = 0.05). No statically significant relationship was found between *cagA* status with clinical outcomes and *vacA* genotypes (*P* = 0.65). The evaluation of *vacA* and *cagA* genes showed 6 differences between gastric biopsy and saliva specimens and 11 differences between gastric and stool specimens.

CONCLUSION: Regard to high similarity in genotype of *H. pylori* isolates from saliva, stomach and stool, this study support the idea which fecal- oral is the main route of *H. pylori* transmission and oral cavity may serve as a reservoir for *H. pylori*, however, remarkable genotype diversity among stomach, saliva and stool samples showed that more than one *H. pylori* genotype may exist in a same patient.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is the organism responsible for diseases such as atrophic gastritis, chronic gastritis, duodenal ulcers, gastric mucosa-associated lymphoid tissue lymphoma, and gastric cancer[1]. *H. pylori* is distributed worldwide and is found in developing countries in particular. For instance, more than 90% of Iranian individuals are infected with *H. pylori*[2]. Although there is much information about *H. pylori* infection, several aspects of the pathogenesis and epidemiology of this organism remains unclear[3]. The transmission route of *H. pylori* infection has been the topic of several studies. Most infections are probably acquired in childhood, mainly *via* oral-oral or fecal-oral routes[4], however, the exact mode(s) of transmission is still unknown.

H. pylori has been found in saliva, dental plaques and feces, which shows that oral and fecal cavities are probably involved in *H. pylori* transmission[5]. The role of *H. pylori* in the oral cavity remains controversial since the detection rate of the bacterium in the mouth is very diverse, ranging between 0% and 100%[6]. Different typing methods have been proposed for the study of correlations between *H. pylori* isolates from different anatomical sites for epidemiological purposes[7]. Genotyping using some well-known virulence marker genes, such as the cytotoxin associated gene A (*cagA*) and voculating cytotoxin gene A (*vacA*), are considered as one of the best approaches[8]. The *cagA* gene is located at the end of the *cag* pathogenicity island (PAI) and has been proposed as a marker for the *cag* PAI, and the presence of certain *cagA* alleles (e.g., *cagA1a* in East Asian strains) have been associated with severe clinical outcomes[9]. The *vacA* gene is present in virtually all strains of *H. pylori* but it is polymorphic, comprising variable signal regions (type *s1* or *s2*) and mid-regions (type *m1* or *m2*). Type *s1/m1 vacA* causes more epithelial cell damage than type *s1/m2*, whereas type *s2/m2* and the rare *s2/m1* are non-toxic due to the presence of a short 12-residue hydrophilic extension on the *s2* form[10,11]. The s-region is classified into *s1* and *s2* types and the m-region into *m*1 and *m*2 types. The *s*1 type is further subtyped into *s1a*, *s1b* and *s1c* subtypes, and the *m1* into *m1a* and *m1b* subtypes. The mosaic combination of sand m-region allelic types determines the particular cytotoxin and, con-

sequently, the pathogenicity of the bacterium[12,13]. Recently, several studies have examined the presence of *H. pylori* in saliva, dental plaque, gastric biopsies and stool, but few studies have evaluated the relationship between genotypes *of H. pylori* isolated from these specimens in a single patient. Therefore, we aimed to compare *H. pylori cagA* and the *vacA* allelic status among strains isolated from saliva, dental plaque, gastric biopsies and stool samples in the same patient with dyspepsia manifestations in order to evaluate the mode of transmission of *H. pylori* infection.

MATERIALS AND METHODS

Patients and samples

Samples were obtained over a year (March 2010 to February 2011) from patients with gastroduodenal diseases that were referred to the endoscopy center of Hagar Hospital of Shahrekord, Iran.

Prior to sampling, the questionnaire, including medical history and demographic data, were recorded for each patient. All studied patients signed an informed consent form before endoscopy and declared their willingness to allow the application of their anonymous data for research purposes. Gastric biopsies, saliva, dental plaques and stool samples were collected from each patient. Saliva and dental plaque sampling was done in the morning before undergoing endoscopy. All patients were asked to wash their mouth with normal saline prior to saliva and dental plaque sampling. Saliva samples, in a volume of 2-3 mL, were collected using sterile toothpicks and filter paper. Dental floss was used to remove the dental plaque from the interdental spaces and both samples were transported in sterile flasks containing digestion buffer [100 mmol NaCl, 10 mmol Tris-HCl (pH 8.0), 250 mmol ethylenediaminetetraacetic acid (EDTA) (pH 8.0) and 1% sodium lauryl sarcosine] on the day of sampling and were stored at -70 ℃ until DNA extraction[6]. For each patient, two biopsy specimens from the antrum were taken using a disinfected endoscope. One was used for screening of *H. pylori* positive specimens by a rapid urease test (RUT). The second piece from RUT-positive patients was placed in 1 mL of sterile phosphate buffer saline solution. Stool was collected in a container with a screw cap and was transported immediately to the biotechnology research center of Islamic Azad University, Shahrekord Branch for molecular analysis.

Rapid urease test

One biopsy piece from each patient was inoculated immediately after collection into 1.5 mL to 2 mL of urea broth (Merck, Germany). It was incubated at 37 ℃ in the incubator for 1.5 h. The change in color of the broth from yellow to pink was taken as a positive test.

Genomic DNA extraction and polymerase chain reaction

DNA was extracted from biopsies and stool specimens using a Genomic DNA Purification kit (Fermentas, Ger-

many) according to the manufacturer's instructions. To prepare DNA from saliva and dental plaque, one volume of the digestion buffer and 100 g/mL proteinase K were added to the saliva samples and incubated at 55 ℃ for 3 h. DNA was extracted twice with an equal volume of phenol-chloroform-isoamyl alcohol (25:24:1) and precipitated with 3 mol sodium acetate and 0.7 mL volume of isopropanol. Rinsed and dried DNA pellets were dissolved in Tris-EDTA (TE) buffer (Tris 10 mmol, EDTA 1 mmol and pH 8.0)[8]. The concentration and quality of DNA preparations were determined spectrophotometrically by measuring absorbance at 260 nm and 280 nm by agarose gel electrophoresis. The DNA preparations were stored at -20 ℃. The presence of *ureC* and *cagA* and the genotypes of *vacA* alleles (*s1a, s1b, s1c, m1a, m1b* and *m2*) were determined by polymerase chain reaction (PCR). The primer sequences are shown in Table 1[8,11,14].

DNA samples from *H. pylori* (D0008, Genekam, Germany) were used as positive controls for *ureC, cagA* and *vacA* genes, and sterile distilled water was used as a negative control. All PCR mixtures were prepared in a volume of 25 μL containing 1X PCR buffer, 0.4 μmol of each primer, 0.3 U Taq DNA polymerase and 2 μL DNA sample[5]. The mixture was placed in a thermocycler (Eppendrof Mastercycler 5330; Eppendorf-Nethel-Hinz GmbH, Hamburg, Germany), and PCR products were visualized by electrophoresis in a 1.5% agarose gel,

strained with ethidium bromide, and examined under ultraviolet illumination.

Statistical analysis
The data were analyzed using SPSS software (Version 17.SPSS Inc, United States) and *P* values were calculated using Chi-square and *F* test to find any significant relationship. *P* < 0.05 was considered statistically significant.

RESULTS
The study population consisted of 300 patients; 143 men and 157 women with mean age 46 ± 17 years. The patients were classified at the time of endoscopy and histopathology as having peptic ulcer disease (PUD: *n* = 63), gastric cancer (GC: *n* = 5) and none ulcer dyspepsia (NUD: *n* = 232) regardless of *H. pylori* status. Based on RUTs, 271 (90.33%) patients were positive for *H. pylori* while 233 (77.66%) patients had positive PCR results by using specific primers (*ureC*) looking for *H. pylori* DNA in their gastric specimens. *H. pylori* was detected in 25 (10.72%) of saliva and 167 (71.67%) of stool samples but we were not able to detect this bacterium in the dental plaques of studied patients.

According to gastric specimen results, the prevalence of *H. pylori* was 90.47% (57 of 63) among patients with PUD, 80% (4 of 5) among patients with GC, and 74.13% (172 of 232) among patients with NUD by PCR assay. Generally, of 233 *H. pylori* positive isolates from gastric biopsy specimens, 220 samples (94.42%) were *cagA* positive and all samples had amplified bands both for *vacA* s and m regions. Overall, 114 (48.92%) samples had *vacA s1a*, 32 (13.73%) had *vacA s1b*, 52 (22.31%) had *vacA s1c* and 35 (15.00%) had *vacA s2* alleles, whereas the frequency of *m1a, m1b* and *m2* alleles were 76 (32.61%), 13 (5.57%) and 144 (61.80%), respectively. There was a significant relationship between *vacA s1a/m1a* and PUD diseases (*P* = 0.04) and the *s2/m2* genotype and NUD diseases (*P* = 0.05). No statically significant relationship was found between *cagA* status with clinical outcomes and *vacA* genotypes (*P* = 0.65). There was a statistically significant correlation between *H. pylori s2/m2* genotypes and the development of NUD (*P* = 0.05) and among *s1a/m1a* and PUD outcomes (*P* = 0.04).

Of 25 saliva samples positive for *H. pylori*, all were *cagA* positive while 18 (72.00%) samples had *s1a/m2*, 5 (20.00%) samples had *s1a/m1a*, 2 (8.00%) samples had *s2/m2* genotypes and all of the samples were *cagA* positive (Table 2). There was no association between genotypes of *H. pylori* from saliva with clinical outcomes (*P* > 0.05).

In stool samples, of 167 positive strains, the *cagA* gene was positive in 162 (97.00%) specimens. One hundred twenty (71.85%) had *s1a/m2*, 22 (13.17%) had *s2/m2*, 14 (8.38%) had *s1a/m1a*, 3 (1.79%) had *s1c/m2*, 3 (1.79%) had *s1c/m1a*, 2 (1.19%) had *s1b/m2*, 2 (1.19%) had *s1b/m1a* and *s1a/m1b* genotypes (Table 2). There was a significant relationship between NUD manifestation and the *s2/m2* genotype of *H. pylori* from stool samples (*P* = 0.04).

PCR tests for dental samples looking for *H. pylori* gene clues were negative. The *H. pylori* detection rate was statistically associated with the type of sample ($P = 0.01$). All patients with positive *H. pylori* in their saliva had a positive PCR reaction for gastric biopsy samples simultaneously.

Upon analysis of the results, in some cases we found different genotypes of *H. pylori* from the saliva, gastric biopsies and stool of the same patient. As presented in Table 3, in 6 (24.00%) patients, isolated *H. pylori* strains from gastric biopsies and the saliva of every patient showed a different genotype. In 11 (6.58%) patients, the genotypes of stool strains differed from genotypes of gastric isolates, and in one (4.00%) patient there were three different genotypes in his gastric biopsy, saliva and stool specimen (Table 3). However, variation of *H. pylori* genotypes in different studied sites were statistically non-significant ($P > 0.05$).

DISCUSSION

Infection by *H. pylori* remains one of the most important scientific phenomena in the biomedical literature worldwide and represents the most prevalent chronic bacterial disease because it affects more than half of the world's population, with a distribution related to the degree of economic development in each country[3]. The prevalence of *H. pylori* differs significantly both between and within countries, with high rates of infection being associated with low socioeconomic status and high densities of living[15]. For instance, in Japan, South America, Turkey and Pakistan, the prevalence is more than 80%, while in Scandinavia and England, the prevalence is between 20% and 40%[11]. The prevalence of this bacterium in Iran is 60%-90%, indicating Iran is a high risk region for *H. pylori* infection. The prevalence of this bacterium was 77.66% in our study and it was therefore compatible with other reports in Iran[2,11]. In our study, the rate of *H. pylori* in different sites of the gastric tract (0% dental plaques, 10.72% saliva, 77.66% gastric biopsy and 71.67% stool) varied, which is inconsistent with other studies[16,17]. There are several hypotheses which can explain the low rate of *H. pylori* in oral cavity compare to gastric biopsy and stool samples. First may be due to the fact that eradication therapy usually removes the gastric infection while it does not necessarily affect oral and intestinal colonization[16]. The second reason for such decreasing level of the rate of bacterium can be related to the presence of oral normal flora, which is able to affect the *H. pylori* growth by producing bacteriocin-like inhibitory proteins against *H. pylori* strains[1]. The third reason is based on the hypothesis that the *H. pylori* may persists in yeast while is in mouth. The *Candida spp.* could be the reservoir for *H. pylori* and play an important role in the bacterial re-inoculation in gastric tissue or transmission to a new host[18], so may yeast protects *H. pylori* from the stressful conditions in the mouth and carries it to the gastrointestinal tract of human[19]. According to Gatti *et al*[20] from Brazil and Bindayna *et al*[21] from India in 2006, there was a significant relationship between *cagA* gene and the inflammation of gastric tissue. The prevalence of *cagA*+ gene in their samples was 79% and 59% respectively. However, Kangsadalampai *et al*[22] from Thailand in 2005 and Cirak *et al*[23] from Turkey in 2003, and Gutiérrez *et al*[24] from Cuba in 2005 failed to confirm such relationship between *cagA* status and gastric disorders. The prevalence of *cagA* gene was 31% in Thailand, 71% in Turkey and 88.5% in Cuba. In our survey, the prevalence of *cagA* gene was 94.42% in gastric biopsy samples and due to high prevalence of *cagA* in our studied isolates, we did not find any significant relationship between this gene and gastric disorders. The prevalence of *cagA* gene in our study was in accordance with our previous report[9] and similar to East Asian countries where the most of isolates are positive for *cagA* gene. Also this finding was different with major of previous

Table 4 Summary of studies which analysed *Helicobacter pylori* status in different oral cavity, stool and gastric sample

Author name	Country	Target population	Number of sample	Type of specimens	Method	Positive rate %

reports from Iran, which the *cagA* positive rate was 44% to 91% and similar to European isolates[11,25,26]. This phenomenon may be because of changes in Iranian isolates status or targeting different part of *cagA* gene for amplification. According to López-Vidal et al[27] from Mexico in 2008 *vacA s1b/m1*, Linpisarn et al[28] from Thailand in 2007, *vacA s1a/m1* and *vacA s1c/m1*, Ahmad et al[29] from Pakistan in 2009, *vacA s1b/m2* and *vacA s1a/m1a*, Rudi et al[30] from Germany in 1998, Miciuleviciene et al[31] from Lithuania in 2008 and Saribasak et al[32] from Turkey in 2004, Hussein et al[33] from Iraq in 2008 and Momenah et al[34] from Saudi Arabia in 2006, *vacA s1a/m2* were the prominent strains in their country. We have found *vacA s1a/m2* as a predominant genotype in gastric specimens of Iranian patients with gastroduodenal diseases which was similar to Germany, Lithuania, Turkey, Iraq and Saudi Arabia but far different with Mexico, Thailand and Pakistan. There was statically significant correlation between *vacA s2/m2* genotype and NUD ($P = 0.05$) and *vacA s1a/m1a* genotype with PUD ($P = 0.04$). This finding is in accordance with the major of studies which believe *s1/m1* isolate are more virulent than *s2/m2*[27,29]. Similar to the previous reports from Iran, from statistical point of view no relationship was found between gastric cancer and *vacA* status ($P = 0.1$)[2,11]. Gastric epithelial cells seem to be the main niche of the *H. pylori*, however there are limited studies considering *H. pylori* status in oral cavity. Some of studies have detected *H. pylori* from different sites of the oral cavity[7,9] and some other groups failed to detect *H. pylori* from saliva, subgingival plaques and gingival pockets[35,36].

Medina et al[3] from Argentina in 2010 found *H. pylori* in 18.4% of saliva and Fernández-Tilapa et al[5] from Mexico in 17% of dental plaque during 2011. Cześnikiewicz-Guzik et al[16] from Poland in 2004 find this bacterium in 54% of saliva and 48.3% of gingival packets while Iamaroon et al[7] from Thailand in 2003

did not find *H. pylori* in oral aphtous ulceration patients (Table 4). In this study we found *H. pylori* in 10.72% of saliva and none of dental plaques. That's may be because of the high level of hygiene in our studied population[1]. Some authors have suggested that *H. pylori* may belong to the normal oral flora of the human oral cavity, maintaining a commensal relation with the host, but sometimes present in very low numbers which is difficult for identification. Others have suggested that *H. pylori* are not consistently present in dental plaque and saliva so when present, may be the result of occasional gastroesophageal reflux[1]. Some researchers suggest that *H. pylori* in oral cavity may serve as a source of gastric reinfection by this bacterium[7]. According to Tanahashi et al[37] from Austria, 93.7% of stool samples were *H. pylori* positive and Parsonnet et al[17] found this bacterium in 88% of the specimens. Both of them applied PCR assay for detection of *H. pylori*. In our study, 71.67% of stool samples of infected patients were *H. pylori* positive which is somehow accordance with other studies[17,38]. The lower prevalence of *H. pylori* in feces rather than stomach may is due to the effect of the intestinal tract normal flora. Our results showed high homology (58%) in *vacA* genotype in saliva and gastric samples from the same patients. This result was consistent with the findings of study by Wang et al[8] which showed 64% homology between saliva and gastric samples from the same patients. These findings support the hypothesis that saliva is a possible source of *H. pylori* infection. The major difference between gastric biopsy, stool and saliva is that saliva represents the entire oral cavity, but punch biopsy and stool sample serve only as a fraction of the total gastric mucosal surface. Interestingly the *H. pylori* isolated from gastric samples showed high diversity compare to those isolated from saliva and stool which may indicate that gastric biological nature support survive of all different genotype of *H. pylori*. Saliva is more likely to contain the

entire DNA from every strain colonizing the oral cavity but at concentrations that may be close to or below the detection level of our PCR assay. In current study we found several genotypic diversities between *H. pylori* strains isolated from saliva, stool and stomach of the same patient. Our data indicated that isolates from different sites of a single individual tend to be more a like than strains isolated from the same site of different individuals ($P = 0.001$). This is in agreement with our previous report which there was 61% homology between *H. pylori vacA* genotypes in saliva and gastric biopsy of same individuals[9]. The heterogeneity of *H. pylori* may be due to genotypic variation among strains and/or variations in *H. pylori* populations within an individual host, as proposed by Blaser[13]. Genotypic variation of *H. pylori* has been documented in point mutations and variation in the gene order[31,32]. Although high rate of similarity was seen among *H. pylori* isolates from different anatomical sites, but 16% of patients were infected with 3 different strains. This finding supports the idea that humans can be simultaneously infected with two or more *H. pylori* genotypes[39]. Variation might be because of co-existence of these bacteria together or occurring mutations[1].

In conclusion, there is high similarity between *H. pylori* strains isolated from saliva, stool and gastric specimens so it indicates that the possibly role of saliva and stool as *H. pylori* infection sources. However, the diversity of *H. pylori* genotypes between stomach, stool and saliva in the same patient suggest that more than one *H. pylori* strains may exist in the saliva and stomach of the same patient due to co-infection or genetic variation.

ACKNOWLEDGMENTS

COMMENTS

Background

Helicobacter pylori (*H. pylori*) infection is widespread throughout the world, and it is estimated that more than half of people are infected with this bacterium, but the exact route of transmission has not yet been fully clarified and remains poorly understood.

Research frontiers

Overall there are limited studies considering *H. pylori* status in oral cavity or feces. Some limited studies suggest that dental plaques, oral cavity and feces have important role in infection transmission and may serve as a reservoir for *H. pylori*, however some other studies did not find such correlation.

Innovations and breakthroughs

To date there has been a very limited study considering genotyping of *H. pylori* in oral cavity and feces. In this study, the authors employed genotyping in more detail using well-known virulence marker genes such as cytotoxin associated gene A (*cagA*) and voculating cytotoxin gene A (*vacA*). Furthermore, more anatomical sites of each patient including dental plaques, saliva, gastric and stool were analyzed for *H. pylori* genotyping by authors. Current study confirmed the significant role of saliva and feces but not dental plaques as a possible mean of

H. pylori transmission and reservoir.

Applications

By finding correlation between *H. pylori* genotypes isolated from saliva and stool with gastric biopsy, the authors concluded that control of *H. pylori* in saliva and stool is crucial for managing of *H. pylori* infection in gastric tissue.

Terminology

Genotype: The genotype is the genes makeup and characteristic of an organism, a cell or an individual which reflect genetic profile of the cell. Genotyping is the process of determining and classification of organisms or cell based on differences in the genetic makeup (genotype) using biological techniques. Compare to observable characteristics (phenotype) of organisms, genotyping can provide a more accurate view of the biological and genetical status and be expected to be more useful for evaluating, for example, the source of infection, the mode of infection transmission and genetic variation.

Peer review

In the current cross-sectional study on high number of patients, the authors analyzed *H. pylori* genotype status in digestive system from mouth to rectum by targeting 8 regions of two important virulence marker genes, *cagA* and *vacA* alleles. The result indicate that although saliva and stool seems to be major source of *H. pylori* which infects gastric, however remarkable number of patients carry different genotypes in their gastrointestinal tract.

Abstract

AIM: To investigate the association between the tag single nucleotide polymorphisms (TagSNPs) of NOD1 and NOD2 and the risk of developing gastric cancer.

METHODS: We conducted a hospital-based case-control study including 296 incident gastric cancer patients and 160 gastritis controls. Eight TagSNPs in the NOD1 and NOD2 genes were selected from the Hapmap database using the haploview software and genotyped by the Sequenom MassArray system. The serum levels of anti-*Helicobacter pylori* (*H. pylori*) IgG were measured by enzyme-linked immunosorbent assay to indicate *H. pylori* infection. The odds ratios (OR) and 95% confidence intervals (CI) were calculated by unconditional logistic regression, including sex and age as confounding factors.

RESULTS: The NOD1 rs2907749 GG genotype showed a decreased risk for gastric cancer (OR 0.50, 95% CI: 0.26-0.95, P = 0.04) while the rs7789045 TT genotype showed an increased risk (OR 2.14, 95% CI: 1.20-3.82, P = 0.01). An elevated susceptibility to gastric cancer was observed in the subjects with *H. pylori* infection and the NaOD1 rs7789045 TT genotype (OR 2.05, 95% CI: 1.07-3.94, P = 0.03) or the NOD2 rs7205423 GC genotype (OR 2.52, 95% CI: 1.05-6.04, P = 0.04). Haplotype analysis suggested that the distribution of AGT (rs2907749, rs2075820 and rs7789045) in NOD1 between the cases and control groups was significantly different (P corrected: 0.04), and the diplotype AGT/AGT was associated with an elevated gastric cancer risk (OR 1.98, 95% CI: 1.04-3.79, P = 0.04). The association of the NOD1 rs7789045 TT genotype and the diplotype AGT/AGT was significant with *H. pylori*-related diffuse-type gastric cancer (OR 3.00, 95% CI: 1.38-6.53, P = 0.01; OR 4.02, 95% CI: 1.61-10.05, P < 0.01, respectively).

CONCLUSION: Genetic polymorphisms in NOD1 and NOD2 may interact with *H. pylori* infection and may play important roles in promoting the development of gastric cancer in the Chinese population.

INTRODUCTION

The average prevalence of *Helicobacter pylori* (*H. pylori*) infection in people worldwide is approximately 50%. An epidemiology meta analysis has indicated that the *H. pylori* prevalence ranges from 35% to 81% in different districts within China, and the average infection rate is 58%[1]. *H. pylori* was estimated to be responsible for approximately 65% of all stomach cancers worldwide[2]. It has been reported that gastric cancer-associated mortality rates accounted for nearly one-quarter of the total malignant tumor-related mortalities in China[3]. Together with *H. pylori* infection, host genetic susceptibility, diet, a high salt intake and smoking have all been proposed to be risk factors for gastric cancer.

Clinical and epidemiologic studies have suggested a strong association between chronic infection, inflammation, and cancer[4-6]. Gastric cancer develops very rarely in the normal gastric mucosa. Most of the *H. pylori*-infected individuals showed gastritis, but very few people develop gastric cancer. The genetic variations between the gastritis and gastric cancer patients may play important roles in the *H. pylori*-related clinical outcomes[7]. The host immune response has a strong role in determining the outcome of *H. pylori* infection, and the polymorphisms in genes that control this immune response have been shown to affect the risk of gastric cancer[8-11]. *H. pylori* trigger inflammation through activation of the receptors that recognize pathogen-associated molecular patterns (PAMPs), and these PAMPs are recognized through a set of germline-encoded pattern recognition receptors (PRRs). The activation of PRRs leads to rapid production of a range of pro-inflammatory cytokines with a profound impact on both the innate and adaptive immune responses.

Among the cytosolic PRRs is the nucleotide-binding oligomerization domain (NOD)-like receptor family. Two members of this family, known as NOD1 and NOD2, have been recently identified[12]. NOD1 and NOD2 are characterized by a central NOD, an N-terminal effector-binding domain (CARD) and a C-terminal ligand recognition domain that is comprised of leucine-rich repeats (LRR)[13]. NOD1 senses a muropeptide found mostly in Gram-negative bacterial peptidoglycans, whereas NOD2 senses bacterial molecules produced during peptidoglycan synthesis or degradation[14]. NOD1 and NOD2 are be-

coming known as key regulators of chronic inflammatory conditions[15]. The NODs ultimately activate transcription factors such as nuclear factor (NF)-κB, STAT1 and so on, which play important roles in inflammation-linked tumor development. It is important to understand how the NOD family proteins work together in coordinating the host response to a given pathogen. Direct evidence for NOD family-mediated host defense derived mostly from an *in vivo* study in which NOD1-deficient mice were reported to be more susceptible to infection by *H. pylori* strains with functional type IV secretion systems[16]. Additionally, NOD2 was reported to regulate antimicrobial peptide synthesis as part of the host defense strategies against *L. monocytogenes* infection *in vivo*[17].

There are several reports that demonstrated that the polymorphisms of the NOD1 and NOD2 genes in different populations were related to variant clinical outcomes of *H. pylori* infection. Although two studies have shown that the NOD1 E266K (rs2075820) mutation increased the risk of peptic ulceration, antral atrophy and intestinal metaplasia[18,19], there is little research related to the association between NOD1 polymorphisms and gastric cancer. NOD2 polymorphisms have been proven to significantly correlate with the incidence of gastric cancer in European populations[20-22], whereas all of the SNPs studied proved to be monomorphic sites in the Chinese population. To verify that the polymorphisms of the *H. pylori*-recognized NOD1 and NOD2 contribute to gastric cancer carcinogenesis through gene-gene and gene-environment interactions, we performed a hospital-based case-control study with 296 incident gastric cancer patients (hospital case subjects) and 160 gastritis patients (hospital control subjects).

MATERIALS AND METHODS

Study population

The hospital-based case-control study consisted of 466 hospitalized patients recruited sequentially in the China People's Liberation Army General Hospital from January 2009 to June 2010. The 296 case subjects were histopathologically verified gastric cancer patients (GC group) and the 160 control subjects were gastritis patients (GA group) who had undergone gastroscopy. All subjects were unrelated Han Chinese. The exclusion criteria for the hospital control subjects included previous cancer and previous chemotherapy or radiotherapy. Upon recruitment, informed consent was obtained from each subject or their relatives, and this study was approved by the Institutional Review Board of the Institute of Biotechnology.

Genotyping and tag single nucleotide polymorphisms selection

Eight TagSNPs for the NOD1 and NOD2 genes were chosen from the designable set of common SNPs [minor allele frequency (MAF) ≥ 0.05] genotyped in the Han Chinese (CHB) population samples of the HapMap Project (Data Release 24/Phase II, NCBI B36 assembly, dbSNP b126). The TagSNPs selection was done using

SNP: Single nucleotide polymorphism; PCR: Polymerase chain reaction.

the software Haploview version 4.0 with pairwise tagging mode. For the NOD1 gene, four TagSNPs were selected (rs17159048, rs2907749, rs2075820 and rs7789045), which captured 36 out of 45 (80%) of the SNPs covering the whole gene. For the NOD2 gene, four TagSNPs were selected (rs2067085, rs1861759, rs3135500 and rs72054230), which captured 17 out of 21 (80%) of the SNPs covering the whole gene, and the 3'-flanking 2 kb regions; TagSNPs were selected with pairwise $r^2 \geq 0.80$.

The genotypes of all the SNPs were determined by the MassArray system (Sequenom iPLEXassay, San Diego, United States). The polymerase chain reaction (PCR) primers (MassExtend; Sequenom) used in this study were listed in Table 1. Briefly, approximately 15 ng of genomic DNAs isolated from the peripheral blood lymphocytes of the study subjects were used to genotype each sample. Locus-specific PCR and detection primers were designed using the MassARRAY Assay Design 3.0 software (Sequenom, San Diego, United States). The sample DNA was amplified by a multiplex PCR reaction, and the PCR products were then used for locus-specific single-base extension reaction. The resulting products were desalted and transferred to a 384-element SpectroCHIP array. The alleles were discriminated by mass spectrometry. (Sequenom, San Diego, United States). Genotyping was performed without knowledge of the case or control status. Twenty random samples were tested in duplicate by different persons, and the reproducibility was 100%.

Helicobacter pylori detection
The *H. pylori* infection status was evaluated by the detection of serum-specific IgG antibodies against *H. pylori* in duplicate with enzyme-linked immunosorbent assay procedures. The sonicated *H. pylori* strain SS1 antigen was used to coat 96-well microplates at a concentration of 2 μg/mL. The sera of the samples were diluted 1:100 when measured. Twenty serum samples, which were verified by *H. pylori* histology culture, rapid urease test and

Carbon-14-Urea Breath Test, were considered the candidate positive controls, whereas twenty serum samples were considered candidate negative controls by the same three tests. Six serum samples were ultimately confirmed as the negative control criteria, the mean absorbance of which was identical to that of the 20 candidate negative controls. Finally, the samples with a mean absorbance 2.1-fold or greater than the mean absorbance of the six negative reference samples were considered to be positive reactions. The sensitivity of the *H. pylori* detection system was 100% (20 of 20) in the control groups.

Haplotype construction and statistical analysis
The Pearson's χ^2 test was used to examine the differences between the case and the control groups in sex, *H. pylori* infection and age groups. The genotype frequencies in the cases and controls were compared and both the OR and 95% CI: of each genotype were estimated by applying unconditional logistic regression adjusting for age, sex and *H. pylori* infection when it was appropriate. The homozygotes of the most frequent allele in controls were used as the reference group. The Hardy-Weinberg equilibrium was performed using PLINK version1.07[23]. The haplotypes were inferred using Haploview 4.0[24]. The pairwise linkage disequilibrium (LD) among the SNPs was assessed using Haploview 4.0. The case-control comparisons of the haplotype distributions were carried out by applying the inbuilt permutation test based on 10 000 permutations. SPSS, version 15.0 (Chicago, IL, United States) was used for all the statistical analyses.

RESULTS
Characteristics of the study population
A total of 296 incident patients with gastric cancer and 160 incident patients with gastritis were enrolled in this case-control study. Table 2 shows that the distributions of sex between the two groups were not significantly dif-

Table 2 Baseline clinical characteristics of cases and controls *n* (%)

[1]Two-sided χ^2 test. GC: Gastric cancer group; GA: Gastritis group.

ferent. The age groups distribution between the gastric cancer patients and gastritis controls was also similar. The percentage of patients having *H. pylori* infection was almost the same in both the cases and controls. Among the gastric cancer cases, 129 (44%) were intestinal-type cancer, 125 (42%) were diffuse-type cancer, and 42 (14%) were unknown histology-type cases.

Genetic association of the polymorphisms in NOD1 and NOD2 with gastric cancer

The distribution of each of the eight SNPs genotyped in the gastric cancer and gastritis group fitted the Hardy-Weinberg equilibrium law except for NOD1 rs7789045. For rs7789045, this Hardy-Weinberg equilibrium option is available for the gastritis subjects (χ^2 = 0.735, *P* = 0.391) but not for the gastric cancer subjects (χ^2 = 5.221, *P* = 0.022). The major allele homozygotes in all the SNPs were used as the reference genotypes. There were no significant differences between the gastric cancer case and gastritis control in the genotype frequency of the 4 polymorphisms of NOD2 gene. For NOD1 gene, the rs2907749 GG homozygote genotype and the recessive model (genotype GG *vs* GA + AA) showed a reduced risk for gastric cancer (adjusted OR, 0.50, 95% CI: 0.26-0.95, *P* = 0.04 and adjusted OR, 0.52, 95% CI: 0.28-0.96, *P* = 0.04, respectively), whereas the rs7789045 TT homozygote genotype and both the dominant model (genotype TT + TA *vs* AA) and the recessive model (genotype TT *vs* TA + AA) showed an elevated risk for gastric cancer (adjusted OR, 2.14, 95% CI: 1.20-3.82, *P* = 0.01; adjusted OR, 1.50, 95% CI: 1.01-2.22, *P* = 0.04 and adjusted OR, 1.87, 95% CI: 1.09-3.20, *P* = 0.02, respectively) (Table 3).

We next examined the joint effects of NOD1, NOD2 polymorphisms and *H. pylori* infection. Because of the limited number in *H. pylori* seronegative subjects (with 75 and 41 subjects in gastric cancer and gastritis groups, respectively), only the *H. pylori* seropositive subjects were considered for analysis. Logistic regression analysis

showed that the NOD1 rs7789045 TT homozygote and the recessive model (genotype TT *vs* TA+AA) carriers had an elevated risk for gastric cancer, with adjusted OR, 2.05, 95% CI: 1.07-3.94, *P* = 0.03 and adjusted OR, 2.06, 95% CI: 1.13-3.76, *P* = 0.02, respectively. For the NOD2 gene, the rs3135500 AG heterozygote genotype had an increased risk for gastric cancer in *H. pylori*-positive subjects (adjusted OR, 2.65, 95% CI: 1.02-6.89, *P* = 0.05). Both the GC heterozygote and the dominant model (genotype CC+GC *vs* GG) of rs7205423 showed an elevated risk for gastric cancer (adjusted OR, 2.52, 95% CI: 1.05-6.04, *P* = 0.04 and adjusted OR, 2.38, 95% CI: 1.03-5.48, *P* = 0.04, respectively). We examined the association of the gene variations in NOD1 and NOD2 with intestinal-type and diffuse-type gastric cancer as well. The results showed that the NOD1 rs2907749 AA homozygote and the dominant model (genotype AA+GA *vs* GG) carriers (adjusted OR, 2.66, 95% CI: 1.10-6.44, *P* = 0.03 and adjusted OR, 2.47, 95% CI: 1.05-5.81, *P* = 0.04, respectively) together with the rs7789045 TT homozygote and the recessive model (genotype TT *vs* TA+AA) carriers (adjusted OR 2.97, 95% CI: 1.49-5.95, *P* < 0.01 and adjusted OR 2.53, 95% CI: 1.35-4.74, *P* < 0.01, respectively) had a significantly elevated risk for developing diffuse-type gastric cancer. When *H. pylori* infection and the gastric cancer type were considered simultaneously, both the recessive model of rs2075820 (genotype GG *vs* GA+AA) and the rs7789045 TT homozygote or the recessive model (genotype TT *vs* TA+AA) in the NOD1 gene showed a significantly elevated risk for developing diffuse-type gastric cancer in *H. pylori*-positive subjects (adjusted OR 1.89, 95% CI: 1.07-3.32, *P* = 0.03; adjusted OR 3.00, 95% CI: 1.38-6.53, *P* < 0.01; and adjusted OR 2.91, 95% CI: 1.45-5.87, *P* < 0.01, respectively) (Table 4).

Haplotype and diplotype analysis of NOD1 tag single nucleotide polymorphisms selection

In a linkage disequilibrium analysis for all of the polymorphisms, we found suggestive evidence for the linkage of rs2907749, rs2075820 and rs7789045 polymorphisms (for rs2907749 and rs2075820, D':0.935, LOD:19.93, r2:0.168; for rs2075820 and rs7789045, D':1.0, LOD:49.28, r2:0.307; for rs2907749 and rs7789045, D':0.949, LOD:38.97, r2:0.251) in the NOD1 gene. The five common haplotypes (AGT, AAA, GGA, GAA and AGA) in the gastritis control group accounted for 99% of all haplotypes (Table 5). The most common haplotype was AGT, occurring in 42% and 33% of the case and control groups, respectively, and the distribution of AGT was significantly different between cases and controls (*P* = 0.01).

For the NOD1 gene, the diplotypes with frequencies > 5% include AGT/AAA, AAA/GGA, AGT/GGA, AGT/AGT, GGA/GGA and AAA/AAA, which accounted for 94% of all the diplotypes in the controls. Using the most common diplotype AGT/AAA as a reference group, our data showed that diplotype AGT/AGT was significantly associated with elevated gastric cancer risk, with OR, 1.98, 95% CI: 1.04-3.79, *P* = 0.04 (Table 6).

[1]Genotypes are shown as AA for risk allele homozygotes, Aa for heterozygotes and aa for the nonrisk allele homozygotes; [2]ORs were adjusted for the covariates (age, sex and/or Helicobacter pylori infection). [a]P < 0.05, [b]P < 0.01, cases vs controls.

The distribution of the NOD1 diplotypes between gastric cancer and gastritis subjects infected with *H. pylori* was significantly different from when the *H. pylori* infection status was not considered. The results showed that the diplotypes AGT/GGA, AGT/AGT and AAA/AAA were significantly associated with elevated gastric cancer risk when compared with the diplotype AGT/AAA, with adjusted OR, 2.14, 95% CI: 1.01-4.51, P = 0.05, adjusted OR, 3.07, 95% CI: 1.47-6.41, P < 0.01, adjusted OR, 2.96, 95% CI: 1.10-7.92, P = 0.03, respectively. The risks of intestinal-type and diffuse-type gastric cancer associated with diplotypes in the NOD1 and NOD2 genes were also estimated. The results showed that AGT/AGT was significantly associated with elevated diffuse-type gastric cancer risk compared with the diplotype AGT/AAA, with adjusted OR, 2.56, 95% CI: 1.17-5.58, P = 0.02. The risk of diffuse-type gastric cancer related to the NOD1 diplotype AGT/AGT was further examined with stratification by *H. pylori* infection. As expected, the OR value of diffuse-type gastric cancer with *H. pylori* infection for subjects carrying the AGT/AGT diplotype was 4.02, 95% CI: 1.61-10.05, P < 0.01, which was higher than that of the *H. pylori* infection group or diffuse-type group alone (Table 7). The NOD2 polymorphism was associated with neither the intestinal-type nor the diffuse-type gastric cancer in this study.

Table 5 Frequencies of haplotype of NOD1

Haplotype[1]	Frequency		P	P corrected[2]
	GC (n = 296)	GA (n = 160)		
AGT	0.42	0.33	0.01[a]	0.04
AAA	0.29	0.32	0.37	0.84

Others	22 (7)	9 (6)	1.58 (0.65-3.81)	0.31

[1]ORs were adjusted for the covariates (age, sex and Helicobacter pylori infection). GC: Gastric cancer group; GA: Gastritis group. [a]P < 0.05, GC vs GA.

DISCUSSION

In the present study, we investigated the association between NOD1 and NOD2 gene polymorphisms and the risk of gastric cancer in a Chinese population. To clarify the impact of genetic variation in NOD1 and NOD2 on the difference of H. pylori-related clinical outcomes, gastritis patients and gastric cancer patients were selected as cases and controls. We found that subjects who carried the NOD1 rs7789045 TT genotype had an increased risk for gastric cancer. Furthermore, the risk was even more distinct when stratified by H. pylori infection and in the diffuse-type gastric cancer group. Moreover, individuals with certain haplotypes and diplotypes derived from three TagSNPs of the NOD1 gene had a significantly elevated risk of gastric cancer, suggesting that the combined effects of several SNPs may be detected by haplotype-based analyses. To our best knowledge, this is the first study investigating the impact of the NOD1 and NOD2 polymorphisms on susceptibility to gastric cancer in a Chinese population.

NOD1 consists of a C-terminal LRR (Leucine-rich region), a central NOD, and an N-terminal CARD (caspase-activating domain) domain[14]. NOD1 has emerged as a crucial factor for maintaining a basal level of immune activation. Clarke et al[25] showed the important role for peptidoglycan in priming systemic innate immunity and for NOD1 as a homeostatic regulator. The majority of patients with H. pylori-associated gastritis have higher NOD1 expression in gastric epithelial cells as compared

with controls or H. pylori-non-associated gastritis[21], which suggests the involvement of NOD1 signaling in the development of human gastric inflammation. Recently, it has been demonstrated that H. pylori virulence factors and the NOD1 receptor ubiquitin-activating enzyme E1 accumulated in human superficial-foveolar epithelium and its metaplastic or dysplastic foci in a discrete cytoplasmic structure named the particle-rich cytoplasmic structure (PaCS). PaCS modulates immune-inflammatory and proliferative responses of the gastric epithelium of potential pathologic relevance[26]. Therefore, the function alteration of NOD1 due to the gene polymorphisms may contribute to the development of H. pylori-related gastric cancer.

It has been suggested that the AA homozygote of the E266K (rs2075820) NOD1 gene polymorphism increases the risk of peptic ulceration in H. pylori-positive patients in the Hungarian population[18]. Another report indicated that E266K A allele carriers have an increased risk of occurrence of intestinal metaplasia and atrophy and eradication failure in the Turkish population[19]. The rs2075820 SNP was chosen in the coding sequence of the NOD1 gene in exon 3 as it was earlier reported to encode a changed protein (E266K) in the nucleotide-binding domain altering a glutamic acid residue, suggesting a potential functional effect of the mutation[27]. Our result indicated that the AG heterozygote of rs2075820 was protective against the risk of gastric cancer (P = 0.026) while the AA homozygote showed moderate risk of gastric cancer (P = 0.397) in the H. pylori-positive subjects. There are no exact data that demonstrate how the NOD1 polymorphism alters the function of NOD1, but our results suggest that the change of negatively-charged glutamine to positively-charged lysine may cause a drastic change in the structure or regulation of the NOD1 protein that alters the reactivity to H. pylori or the nature of downstream inflammatory pathways.

Two studies focusing on the association of several NOD1 polymorphisms with colorectal and endometrial cancer, which include SNP rs2907749, did not find any relationship between individual NOD1 genotypes and the susceptibility to these cancers[28,29]. However, an association of the NOD1 polymorphisms with atopic eczema in the German population has been reported in a study that examined the effects of 11 SNPs, which covering the complete NOD1 gene, on atopy phenotypes[30]. One NOD1 haplotype and three polymorphisms (rs2907748, rs2907749, and rs2075822) were significantly associated with atopic eczema in a population-based cohort, case-control population, and/or family-based association analysis. The results indicated that genetic variants within the NOD1 gene were important determinants of atopy susceptibility. Especially, it showed that the A allele at rs2907749 is significantly associated with elevated IgE levels. Similarly, our study found that the A allele at rs2907749 elevated the risk of gastric cancer; moreover, the risk association was strengthened in diffuse-type gastric cancer patients. Rs2907749 is located in intron 9 of the NOD1 gene where two putative transcription factor-

binding sites for Pax1 are found. The alteration of the allele changes the computer-predicted Pax1-binding probability next to exon 9, which may influence the T-regulatory cell development[30].

The NOD1 rs7789045 TT genotype was at a significantly elevated risk for gastric cancer in this study. Few studies have addressed the relationship of the polymorphism in rs7789045 with clinical diseases before, whereas our result indicated that this polymorphism was worthy to be further studied because it may play important roles in the *H. pylori*-related gastric carcinogenesis. Rs7789045 is located in intron 5 of the NOD1 gene, which is in the splicing region. The possible significance of T/A alteration was predicted by NetGene2 and SpliceView computer programs[31-33]. Different splicing may lead to the alteration of NOD1 caspase activity in the CARD domain; therefore, this may imply a difference in the signal pathway regulation downstream.

Because haplotype analyses may be of higher informative value to draw associations between the phenotypes and genetic variation than SNPs[34], we also assessed the effects of haplotypes and diplotypes in our studies. Analyses revealed significant association between the NOD1 haplotype AGT (rs2907749, rs2075820, and rs7789045) and gastric cancer, and the difference remained significant after a 10 000-times permutation test. Our results also showed that the AGT/AGT diplotype was associated with an increased risk of diffuse-type gastric cancer, and the risk was more evident in *H. pylori*-positive subjects. Some studies have observed the inverse associations of *H. pylori* and atopic diseases such as asthma and atopic eczema[35,36]. Epidemiological observations are consistent with the hypothesis that *H. pylori*, which has been colonizing the human stomach for ≥ 58 000 years and is usually acquired within the first few years of life, may play distinct roles in the maturation of the immune system[37]. Weidinger *et al*[30] demonstrated that the haplotype A-G-T-A-C-C-G-T-A-

C-G, defined by the eleven polymorphic alleles of NOD1 including rs2907749 A allele and rs2075818 C allele, rs2235099 C allele, rs2075821 G allele, the last three of which are in a linkage with rs2075820 G allele in the AGT haplotype, is significantly protective against the development of atopic eczema, whereas haplotype AGT is associated with an increased risk of *H. pylori*-related gastric cancer in this study. The different relationships of the similar haplotype of NOD1 between two diseases may imply the distinct roles of NOD1 in the pathogenesis of atopy and gastric cancer.

Some studies have investigated the relationships among the three major mutations, R702W (rs2066844), G908R (rs2066845) and 3020insC (rs5743293), in the coding region of the NOD2 gene with colorectal cancer[38], gastric cancer[20] and gastrointestinal diseases[22] in the European population. The results showed that NOD2 polymorphisms increase the susceptibility to gastrointestinal cancer. These three polymorphisms were shown to be monomorphic sites in the Chinese population due to the ethnic difference (Hapmap and Genome Variation Server). In this study, the association between the other four NOD1 SNPs and gastric cancer was investigated in the Chinese population. Although no significant differences on genotype distribution were found between gastric cancer and gastritis patients, our results indicated that the AG heterozygote genotype of rs3135500 and CC genotype of rs7205423 were associated with an increased risk for gastric cancer in *H. pylori*-positive subjects. It is notable that rs3135500 is located in the 3'UTR of the NOD2 gene while rs7205423 is located in the intergenic region between the NOD2 gene and the CYLD gene. The latter is a de-ubiquitinating enzyme that inhibits the activation of the NF-κB, which has key roles in inflammation, immune responses, carcinogenesis, and protection against apoptosis[39]. And the G allele of rs7205423 may be at a splice site, which was predicted by NetGene2

and SpliceView computer programs[31-33]. Another article of Weidinger *et al*[40] showed that the presence of the A allele at rs3135500 was significantly associated with an increased risk of developing asthma. On the contrary, our results showed that A allele at rs3135500 was associated with a slightly reduced risk of developing gastric cancer. The results of the two association studies of the NOD2 polymorphisms were in accordance with those of the NOD1 polymorphisms we mentioned above. These results emphasized that polymorphisms of NOD1 and NOD2 may contribute differently to the development of atopic diseases and gastric cancer.

Our study has some limitations. The number of participants in this study was relatively small, and thus, future replication studies with large cohorts are needed. Further expression analysis and transcription factor-binding studies are needed to clarify the functional role of NOD1 and NOD2 polymorphisms. Finally, *H. pylori* is genetically a highly diverse bacteria, and the virulence of *H. pylori* is related to different subtypes that contribute differently to clinical outcomes. However, anti-CagA antibodies were not available in our study.

In conclusion, to our knowledge, this study is the first one to indicate that the NOD1 rs7789045 polymorphism increases the genetic susceptibility of gastric cancer in a Chinese population, and it is observed to be enhanced in *H. pylori*-positive and diffuse-type gastric cancer subjects. The other two polymorphisms, rs2907749 and rs2075820, showed an association with gastric cancer as well. In addition, *H. pylori*-positive subjects carrying the NOD2 rs7205423 C allele have an increased risk of gastric cancer. These findings suggest that the polymorphisms of the NOD1 and NOD2 genes may play a role between *H. pylori* infection and development of gastric cancer. The underlying mechanism needs further investigation.

COMMENTS

Background

The role of *Helicobacter pylori* (*H. pylori*) in the development of gastric cancer has been confirmed. It is known that *H. pylori* is an important factor in both the induction of gastritis and the histological progression to gastric cancer. The NOD (nucleotide-binding oligomerization domain) proteins NOD1 and NOD2 play distinct roles in innate immunity as sensors of *H. pylori* components derived from bacterial peptidoglycan. The *H. pylori* infection may interact with the polymorphisms of NOD1 and NOD2, which influence the development of gastric cancer. In this hospital-based case-control study, the author analyzed the associations between the polymorphisms of NOD1 and NOD2 and the risk for *H. pylori*-related gastric cancer in a Chinese population.

Research frontiers

It has been confirmed that the *H. pylori* peptidoglycan delivered by the type IV secretion system can be sensed *via* NOD1. The polymorphisms of NOD2 was associated with gastric lymphoma. The current study is the first to access the impact of the TagSNPs of NOD1 and NOD2 and disease susceptibility to gastric cancer in a Chinese population.

Innovations and breakthroughs

This study indicated that genetic polymorphisms of NOD1 and NOD2 may interaction with *H. pylori* infection and may play distinct roles in developing gastric cancer in the Chinese population.

Applications

This is an original report of the association between NOD1 and NOD2 polymorphisms and Chinese patients with gastric cancer. It is believed these findings

will be valuable in clarifying the relationship between genetic variation within innate immune molecules and *H. pylori* infection-related gastric cancer.

Peer review

The study examined NOD1/NOD2 polymorphisms in association with *H. pylori* infection in the patients of gastric cancer (296) *vs* gastritis (160). The results indicate that *H. pylori*-induced gastric cancer is associated with the genetic background of the patients. The data are useful. The study is in focus but can be expanded to include more factors such as smoking status, body mass index, age, *etc*. The written English needs some improvement.

Abstract

AIM: To determine whether serum levels of carcinoembryonic antigen (CEA) correlate with the presence of primary colorectal cancer (CRC), and/or recurrent CRC following radical resection.

METHODS: A total of 413 patients with CRC underwent radical surgery between January 1998 and December 2002 in our department and were enrolled in this study. The median follow-up period was 69 mo (range, 3-118 mo), and CRC recurrence was experienced by 90/413 (21.8%) patients. Serum levels of CEA were assayed preoperatively, and using a cutoff value of 5 ng/mL, patients were divided into two groups, those with normal serum CEA levels (e.g., $\leq$ 5 ng/mL) and those with elevated CEA levels (> 5 ng/mL).

RESULTS: The overall sensitivity of CEA for the detection of primary CRC was 37.0%. The sensitivity of CEA according to stage, was 21.4%, 38.9%, and 41.7% for stages Ⅰ-Ⅲ, respectively. Moreover, for stage Ⅱ and stage Ⅲ cases, the 5-year disease-free survival rates were reduced for patients with elevated preoperative serum CEA levels (P < 0.05). The overall sensitivity of CEA for detecting recurrent CRC was 54.4%, and sensitivity rates of 36.6%, 66.7%, and 75.0% were associated with cases of local recurrence, single metastasis, and multiple metastases, respectively. In patients with normal serum levels of CEA preoperatively, the sensitivity of CEA for detecting recurrence was reduced compared with patients having a history of elevated CEA prior to radical resection (32.6% *vs* 77.3%, respectively, P < 0.05).

CONCLUSION: CRC patients with normal serum CEA levels prior to resection maintained these levels during CRC recurrence, especially in cases of local recurrence *vs* cases of metastasis.

INTRODUCTION

Globally, colorectal cancer (CRC) is the third most common cancer diagnosed, and is associated with high rates of incidence and mortality for both men and women[1]. Furthermore, despite progress that has been made in the treatment of advanced cases of CRC, the clinical outcome of this disease still remains poor[2]. Carcinoembryonic antigen (CEA) is a classic tumor marker for CRC,

and has been used to monitor CRC recurrence and as a prognostic factor for CRC patients. Currently, the serum CEA test is recommended by the American Society of Clinical Oncology[3] and the European Group on Tumor Markers[4] as a prognostic biomarker for recurrent CRC following curative resection. However, the effectiveness of CEA as a preoperative and postoperative marker for CRC remains to be evaluated. In particular, it remains unclear how accurate a negative CEA value is for excluding primary and recurrent CRC, and under what conditions CEA values are inaccurate. Therefore, this study was designed to evaluate the role of serum CEA levels in the diagnosis of primary and recurrent CRC following radical resection.

MATERIALS AND METHODS

Patients

A total of 464 patients with stage I, II, or III CRC were admitted to our hospital between January 1998 and December 2002. Of these patients, 51/464 did not have preoperative serum CEA data available. Therefore, a total of 413 CRC patients were included in this retrospective study.

Surgical procedures

Enrolled patients underwent curative resection for the treatment of CRC. Curative resection was defined as the absence of any gross residual CRC in the surgical bed, in addition to a surgical resection margin that was pathologically negative for tumor invasion. Recurrence in this study included metastasis and local recurrence that was secondary to primary CRC at least 3 mo after radical resection. Recurrent CRC was confirmed by at least one of the following examinations: pathology, computed tomography (CT), magnetic resonance imaging, or X-ray. Of these examinations, a pathologic diagnosis based on biopsy and body-fluid cytological examinations represents the most reliable detection method for CRC. For an imaging-based diagnosis of CRC, successive imaging examinations are required to verify cancer progression. Patient characteristics are summarized in Table 1. The median follow-up time was 69 mo (range, 3-118 mo), during which CRC recurred in 90 patients. For these patients, serum CEA assays were performed within 1 wk of CRC recurrence being confirmed.

Measurement of serum CEA levels

Serum CEA levels in CRC patients were measured using CEA Elecsys analyzers (Roche Diagnostics GmbH, United States) with a reference range of 5.0 ng/mL. CRC patients were then divided into two groups, those with normal serum CEA levels (e.g., $\leq$ 5 ng/mL) and those with elevated serum CEA levels (> 5 ng/mL).

Statistical analysis

All data were analyzed using SPSS, version 11.5 (SPSS Inc., Chicago, IL). A *P*-value less than 0.05 was consid-

ered statistically significant. In addition, a two-sided Pearson χ^2 test and Fisher's exact test were used to analyze the potential correlation between serum levels of CEA and clinicopathologic features of the study subjects. Variables associated with a *P* value less than 0.10 by univariate analysis were applied to a Cox model for multivariate analysis. Disease-free survival (DFS) rates were analyzed using the Kaplan-Meier method and compared using the log-rank test.

RESULTS

For a total of 413 patients that were diagnosed with CRC between January 1998 and December 2002 in our department and were enrolled in this retrospective study, serum levels of CEA were assayed prior to surgical resection. Based on a cutoff value of 5 ng/mL, two patient groups were established. One group was associated with elevated levels of serum CEA (e.g., > 5 ng/mL) (*n* = 153; 37.0%), while the second group was associated with normal levels of serum CEA (e.g., < 5 ng/mL) (*n* = 260; 63%). The stages of CRC associated with these cases included stage I (*n* = 70), IIA (*n* = 140), IIB (*n* = 35), IIIA (*n* = 23), IIIB (*n* = 85), and IIIC (*n* = 60), ac-

cording to the 6th International Union Against Cancer (UICC) Tumor Node Metastasis (TNM) staging system[5]. Moreover, elevated serum levels of CEA were detected preoperatively in 21.4% of stage Ⅰ CRC patients, 38.9% of stage Ⅱ CRC patients, and in 41.7% of stage Ⅲ CRC patients, respectively. As a result, preoperative CEA levels were found to correlate with CRC diagnoses according to the UICC TNM staging system ($P = 0.01$). A comparison of preoperative CEA levels with clinicopathological characteristics of the enrolled patients further detected a significant association between serum CEA levels and tumor size and T category (Table 2). However, serum CEA levels did not correlate with patient age, patient gender, tumor location, tumor differentiation, N category, or lymphovascular invasion.

The median follow-up time for this study was 69 mo (range, 3-118 mo), and the 5-year DFS rate was 67% after patients underwent radical resection. Moreover, univariate and multivariate analysis revealed that preoperative serum levels of CEA were a significant independent prognostic factor for 5-year DFS rates (Table 3). The 5-year DFS rate was also found to significantly differ for stage Ⅱ and

stage Ⅲ CRC patients independent of serum CEA levels ($P < 0.05$), yet did not differ for stage Ⅰ CRC patients following radical resection. When stage Ⅱ and stage Ⅲ CRC cases were further subdivided into ⅡA, ⅡB, ⅢA, ⅢB, and ⅢC stages, the 5-year DFS rate for normal and elevated levels of serum CEA patient groups were 84% and 62% for stage ⅡA CRC patients, and 64% and 21% for the stage ⅢB CRC patients, respectively in each case ($P < 0.05$, Figure 1A and B). However, no significant difference in the 5-year DFS rates associated with stage ⅡB, ⅢA, and ⅢC CRC was observed.

Recurrence of CRC was experienced by 90/413 patients, with local recurrence, single CRC metastasis, and multiple CRC metastases occurring in 41/90 (45.6%),

surgery in 32.6% of cases (Table 5). Univariate and multivariate analysis also revealed that preoperative serum levels of CEA and recurrence patterns were significantly associated with serum levels of CEA detected during recurrence (Table 6).

DISCUSSION

Since Gold *et al*[6] first described and characterized CEA in 1965, it has become the one of the most widely known tumor markers for gastrointestinal tract diseases, especially for CRC. However, although 90% of CRCs produce CEA[7], elevated serum levels of CEA are not often detected at the time of diagnosis. In this study, normal serum levels of CEA (e.g., < 5 ng/mL) were detected in 67% of the CRC patients assayed, and in 79% of stage I CRC patients. While a correlation between stage of CRC and preoperative CEA levels has previously been observed, a low sensitivity is associated with serum CEA assays in the detection of early stage CRC[8-10]. Accordingly, the usefulness of serum CEA assays for screening of CRC is limited. Despite this, a semi-quantitative relationship between CEA levels and tumor volume has previously been described[11], suggesting that elevated serum levels of CEA detected preoperatively may indicate a larger tumor burden. In the present study, preoperative levels of serum CEA were found to be significantly associated with tumor size and T category, but not with N category or tumor differentiation. Moreover, preoperative CEA levels also correlated with stage of disease, while providing a prognostic determinant of survival. These results are consistent with other studies[12-14], and also confirmed that elevated levels of serum CEA represent an independent prognostic factor for 5-year DFS, especially for cases of stage ⅡA and ⅢB CRC.

In colon cancer, CEA modulates intercellular adhesion, functions as a promoter of cellular aggregation, regulates the innate immune system, and mediates signal transduction[15-17]. Accordingly, it is hypothesized that CEA plays an important role in tumor invasion and metastasis. In this study, the 5-year DFS rate of stage Ⅱ CRC patients with elevated levels of serum CEA were compared with stage Ⅲ CRC patients with normal levels of serum CEA, and no significant difference was found (data not shown). This finding is consistent with another study[18], and suggests that a diagnosis of CRC accompanied by elevated levels of serum CEA may be an indica-

49/90 (54.4%), and 16/90 (17.8%) patients, respectively. The types of metastasis detected included hepatic (*n* = 17), pulmonary (*n* = 10), osseous (*n* = 7), renal (*n* = 2), adrenal (*n* = 3), distal lymphatic (*n* = 2), brain (*n* = 1), and spinal (*n* = 1). Serum CEA levels were found to be higher in patients with CRC metastases compared to patients with local recurrent CRC (*P* < 0.05). Moreover, the percentage of patients with elevated CEA levels and local recurrence was less than that of CRC patients with elevated CEA levels and single or multiple metastases (36.6% *vs* 66.7% and 75.0%, respectively) (*P* < 0.05, Table 4). Patients with a history of elevated CEA levels prior to surgery were also associated with elevated CEA levels directly prior to surgery in 77.3% of cases, whereas patients with no prior history of elevated CEA levels exhibited elevated levels of CEA levels directly prior to

tor for tumor restaging even after surgery. Furthermore, it has been shown that genetic vaccines targeting CEA may be a feasible strategy for the treatment of CRC[19]. For example, Ogata *et al*[20] observed that stage II CRC patients with elevated levels of CEA may be candidates for adjuvant chemotherapy following curative resection.

CRC recurrence has been reported for 30%-40% of patients who undergo curative resection. During the follow-up period of surgical resection, CEA monitoring is typically performed. However, the accuracy and efficacy of CEA monitoring is not always consistent. For example, in the present study, only 54.5% of patients experiencing recurrence had elevated serum levels of CEA. Moreover, these results are consistent with previously reported findings[21]. Typically, elevated levels of CEA detected postoperatively have a high probability of indicating tumor recurrence, while normal levels of CEA detected postoperatively are not useful for excluding the probability of recurrence[22,23]. Therefore, the need for monitoring CEA levels in patients who initially exhibit normal levels of CEA remains to be determined[24]. In the present study, according to the preoperative CEA levels assayed, 77% of recurrent CRC patients had elevated CEA levels, while 32% had normal CEA levels. These results indicate that normal CEA levels may be associated with the relatively early stages of tumor progression, and also with the presence of a non-CEA producing tumor. For example, production of CEA may be reduced in poorly differentiated adenocarcinomas. Furthermore, some studies[25,26] have reported an inverse relationship between tumor grade and CEA levels among patients with nodal metastases and unresectable disease.

Another consideration is the rate of rise for CEA levels that can vary depending on the site of recurrence. It has previously been proposed that monitoring of serum CEA levels is useful for the detection of liver metastases, yet is not useful for the detection of local recurrence or other types of metastasis[27]. In the present study, patients with CRC metastasis, especially multiple metastases, were associated with higher CEA levels, whereas those with local recurrent CRC had a lower CEA level during recurrence (75.0% *vs* 36.6%, respectively, *P* < 0.05). In combination, these results suggest that CEA alone should not determine whether "second-look" surgeries are performed, or whether CT scan or other imaging tools should be required to identify precise sites of recurrence.

As a retrospective study, the limitations associated with this work include the absence of a standard adjuvant therapy protocol and monitoring strategy. For example, CRC monitoring was not at regular time intervals, resulting in a sensitivity bias. In comparison, the cut-off values used to determine elevated CEA levels in other studies have ranged from 3-15 ng/mL[28-30], thereby affecting the sensitivity of serum CEA assays for tumor detection. Furthermore, since CEA levels were found to be associated with T stage and tumor size in the present study, additional large-scale studies are needed to establish the specific cut-off value needed, according to different tu-

mor burden volumes, in order to facilitate the detection of primary and recurrent CRC.

Currently, an ideal tumor marker for CRC is not available[31]. For example, although CEA is a well-known tumor marker for CRC, the detection of serum CEA levels has not proven to be sufficiently sensitive for detecting primary CRC, especially early stage CRC. However, preoperative serum levels have been found to be an independent prognostic factor for patients with CRC following curative resection. Moreover, CRC patients with normal serum levels of CEA have a higher probability of maintaining these levels during CRC recurrence, especially during local recurrence compared with metastasis. Therefore, monitoring of serum CEA levels can facilitate the detection of primary and recurrent CRC; however, this assay must be complemented by other clinical and laboratory assessments.

COMMENTS

Background
Although detection of serum carcinoembryonic antigen (CEA) is widely used to monitor recurrence following curative resection for colorectal cancer (CRC), the sensitivity associated with this readout is not ideal. Therefore, it is important that factors associated with a negative CEA test, when recurrence has been confirmed, be further studied.

Research frontiers
The presence of elevated serum levels of CEA prior to surgical resection for CRC has previously been identified as a prognostic factor for CRC, and therefore, has been well studied. For these patients, postoperative serum CEA surveillance is effective for detecting recurrence. However, for patients who initially present with normal levels of CEA, the need to further monitor CEA levels remains controversial

Innovations and breakthroughs
In this study, CRC patients with normal CEA levels prior to operation were more likely to maintain these levels when recurrence occurred, especially in cases of local recurrence compared with metastasis.

Applications
The findings of this study provide further insight into CRC monitoring strategies, especially for patients with normal CEA levels prior to surgical resection.

Peer review
This is a well designed study, which formally needs few revisions.

Abstract

AIM: To investigate the possible reasons and suggest therapeutic plan of stress-induced intestinal necrosis resulting from the severe trauma.

METHODS: Three patients in our study were trapped inside collapsed structures for 22, 21 and 37 h, respectively. The patients underwent 3-4 operations after sustaining their injuries. Mechanical ventilation, intermittent hemodialysis and other treatments were also provided. The patients showed signs of peritoneal irritation on postoperative days 10-38. Small intestinal necrosis was confirmed by emergency laparotomy, and for each patient, part of the small bowel was removed.

RESULTS: Two patients who all performed 3 operations died of respiratory complications on the first and second postoperative days respectively. The third patient who performed 4 operations was discharged and made a full recovery. Three patients had the following common characteristics: (1) Multiple severe trauma events with no direct penetrating gastrointestinal injury; (2) Multiple surgeries with impaired renal function and intermittent hemodialysis treatment; (3) Progressive abdominal pain and tenderness, and peritoneal irritation was present on post-traumatic days 10-38; (4) Abdominal operations confirmed segment ulcer, necrosis of the small intestine, hyperplasia and stiffness of the intestinal wall; and (5) Pathological examinations suggested submucosal hemorrhage, necrosis, fibrosis and hyalinization of the vascular wall. Pathological examinations of all 3 patients suggested intestinal necrosis with fistulas.

CONCLUSION: Intestinal necrosis is strongly associated with stress from trauma and post-traumatic complications; timely exploratory laparotomy maybe an effective method for preventing and treating stress-induced intestinal necrosis.

Stress-induced intestinal necrosis resulting from severe trauma of an earthquake. *World J Gastroenterol* 2012; 18(17): 2127-2131 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i17/2127.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i17.2127

INTRODUCTION

Intestinal necrosis is a common condition that is fre-

quently seen in clinical practice[1-6]. It is generally associated with mesenteric thrombosis or bacterial infection after eating contaminated foods[5,6]. However, few cases of stress-induced intestinal necrosis have been reported. Although animal studies have confirmed that stress can cause intestinal mucosal barrier disturbances[7,8], stress-induced intestinal necrosis has not been confirmed. We analyzed the clinical data of 3210 patients who were admitted to our hospital after the Wenchuan earthquake on May 12, 2008. In the laparotomy examinations of 3 patients with no penetrating abdominal trauma, intestinal necrosis was confirmed on postoperative days 10-38. Two of these patients died, while 1 survived and made a full recovery. For these 3 cases, we made the diagnosis of "stress-induced intestinal necrosis" after repeated careful consideration.

MATERIALS AND METHODS

The 3 male patients were 27, 36 and 42 years old, respectively (average age of 35 years). They were trapped inside collapsed structures for 22, 21 and 37 h, respectively (average time of 26.3 h). They were admitted into our hospital at 37, 44 and 39 h, respectively, after trapped in the buildings. Their primary earthquake-related traumatic injuries mainly occurred on the head and extremities, including 1 case with a left thorax crush injury. The physician specialists in various departments of our hospital consulted and discussed the cases with experts from The Liberation Army General Hospital of Beijing immediately after the patients' admission. Treatment plans were designed individually by a multi-disciplinary team. The patients underwent 4, 3 and 3 surgeries, respectively, according to their clinical features. The final operation for each patient, which was a small bowel resection, was performed on postoperative days 38, 21 and 10, respectively. Antibiotic therapy, intravenous fluid hydration, mechanical ventilation and intermittent hemodialysis were administered to all 3 patients after admission.

Representative case report

A 27-year-old healthy male patient with a relatively healthy medical history had multiple body injuries due to high-force impacts from a building collapse in the Wenchuan earthquake on May 12, 2008. He was rescued after being trapped in building debris for 22 h. He was admitted to our hospital on May 14. He remained conscious and presented with multiple contusions on the head and both lower extremities at the time of admission. Neither of his legs could be moved freely, and both were significantly swollen. The pulse of the bilateral dorsalis pedis was absent. The patient's toes presented as dark purple with poor blood circulation. A physical examination showed no signs of abdominal trauma. At the time of admission, emergency decompression surgery was performed on the osteofascial compartment of the left lower extremities under local anesthesia. We suspected that the patient had acute renal failure due

Figure 1 Anesthesia was administrated to the patient who underwent amputation of the bilateral extremities. The surgical area was sterilized in preparation for the operation.

to a lack of urination, and hemodialysis was administrated. On May 16, the patient underwent emergency amputation of both legs at the mid-thigh. On May 20, the patient experienced abdominal distension with diarrhea; blood appeared in a stool sample. On May 24, the patient developed worse abdominal distention, mild tenderness around the belly button and no rebound tenderness or muscle tension. Bowel sounds were absent. An ultrasound test revealed intestinal expansion and a small amount of peritoneal fluid. On May 26, jejunum drainage was placed under gastroscopy. The drainage output was 1000 mL, and the abdominal distension was significantly relieved. On May 30, the patient developed infections in right lower extremitie. A second amputation operation was performed on his right thigh. On June 3, thoracentesis was performed on his left chest cavity due to significantly increased pleural effusion. On June 7, the patient developed dark bloody stool that occurred 3-4 times per day. The patient's urine output gradually returned to normal by intermittent hemodialysis. On June 19, the patient developed worsening abdominal pain and tenderness, and a mass was noted around the middle and lower abdomen. Peritoneal irritation was obviously present. On emergency abdominal exploration (Figure 1), significant intestinal adhesion was noted. The intestine approximately 210 cm below the Treitz ligament and 50 cm above the ileocecal valve was expanded, thickened and twisted into a mass, with a large amount of inflammatory exudate. Intestinal adhesion, necrosis and perforation with fistula were noted (Figure 2). The proximal jejunum was expanded and thickening. The patient underwent small bowel resection, which revealed scattered erosion with hemorrhage in the intestinal mucosa. The postoperative pathology report included hemorrhagic enteritis and intestinal adhesion with fistula formation (Figure 3). The patient experienced dark bloody or tarry stools 2 wk after surgery (approximately 200-800 g/d). Antihemorrhagic, antacid therapy and nutritional support were administrated. Eventually, the patient was discharged and made a full recovery.

Figure 2 The damaged small intestine was adhered into a mass with a fistula. Thickness and hyperplasia were noted on the small intestinal wall after the part of damaged intestine was cleaned.

Figure 3 Large necrotic lesions along with macrophage infiltration were observed in the intestinal mucosa. Collagen fiber hyperplasia was also present on the submucosal membrane.

RESULTS

Two patients from this study died of respiratory failure on the first and second postoperative day (post-traumatic days 22 and 12, respectively). One patient survived. Our patients had the following common characteristics: (1) Multiple severe trauma events with no direct penetrating gastrointestinal injury; (2) Multiple surgeries with impaired renal function and intermittent hemodialysis treatment; (3) Progressive abdominal pain and tenderness, and peritoneal irritation was present on post-traumatic days 10-38; (4) Abdominal operations confirmed segment ulcer, necrosis of the small intestine, hyperplasia and stiffness of the intestinal wall; and (5) Pathological examinations suggested submucosal hemorrhage, necrosis, fibrosis and hyalinization of the vascular wall.

DISCUSSION

Diagnosis of intestinal necrosis: Stress-induced intestinal necrosis

How did we make the diagnosis of intestinal necrosis in these patients? We reviewed the relevant literature and found no related cases. However, cases of stress-induced intestinal injury were relatively common[9-11]. Lu *et al*[10] studied the stress response in rats under heat conditions.

They found severe intestinal mucosal damage associated with changes in gene expression that were related to stress-induced immune regulation in the rat small intestine. Smith *et al*[11] studied the stress response to early weaning in porcine intestines and found that early weaning in pigs can induce stress and lead to impaired mucosal barrier function. The response to trauma, as a comprehensive stress reaction, can cause stress-induced damage to multiple organs in the body[12,13]. However, stress-induced intestinal necrosis has not been reported previously. There are many reports of gastrointestinal feeding tubes leading to partial necrosis of the small intestine, which were thought to be the result of bacterial infections[14,15].

In the 3 patients in our study, no gastrointestinal feeding tubes were placed. After careful consideration, we made the diagnosis of "stress-induced intestine necrosis". The differential diagnosis of "acute intestinal necrosis" includes the following: (1) "Stress-induced intestine necrosis" occurs in severe trauma or multiple surgeries, while "acute intestinal necrosis" occurs for unknown reasons and may be related to contaminated food[16]; (2) "Stress-induced intestinal necrosis" has a relatively slow onset, as the 3 patients in this study had signs of peritoneal irritation on post-trauma days 10-38; "acute intestinal necrosis" develops early, usually within

5 d; (3) "Stress-induced intestinal necrosis" has no obvious abdominal pain and mainly presents as abdominal distention with no signs of peritoneal irritation, while "acute intestinal necrosis" presents with acute abdominal pain and unbearable and obvious signs of peritoneal irritation; (4) With regard to intraoperative findings, "stress-induced intestinal necrosis" usually has intestinal epithelial hyperplasia, segmental ulceration induced necrosis and fistula formation, while "acute intestinal necrosis" has segmental necrosis without intestinal wall thickening; and (5) With regard to pathological results, "stress-induced intestinal necrosis" has submucosal necrosis, hyperplasia, fibrosis and a large number of macrophages and cells with hemosiderin within the tissue, while "acute intestinal necrosis" has fibrin deposition within the small arteries, intestinal hemorrhage and necrosis[17].

Reasons for intestinal necrosis after trauma

We believe that intestinal necrosis is associated with a continuous high level of stress due to primary turuma and traumatic complications. Under stress: (1) Intestinal mucosal permeability increases, which results in increases in peritoneal inflammatory exudate[18]; (2) Intestinal bacteria can translocate peritoneally and worsen peritoneal infections[19-21]; (3) The intracellular space within the endothelium of mesenteric vessels increases, allowing blood cells and plasma to leak through the connective tissue and vessel lamina, leading to vascular hyalinization, sclerosis and fibrosis; (4) As the response to stress continues, the sympathetic adrenergic medullary system is highly excited, which can lead to intestinal vasoconstriction and a reduction in the blood supply[22]; (5) As arteriosclerosis and contraction of the mesenteric vessels continues, the blood supply continues to decrease, resulting in hypoxia of the mucosal tissue, acidosis, mucosal necrosis and sloughing, and ulcers; and (6) Another explanation is that stress induces vagal inactivation and consequently suppresses the "cholinergic anti-inflammatory pathway" which might lead to intestinal injury ,even intestinal necrosis[23].

The 3 patients in this study suffered from long periods of crush injuries followed by several surgeries and intermittent hemodialysis. Their bodies were in a state of continuous stress. The long-term reduction in the mesenteric blood supply led to intestinal necrosis.

Treatment of stress-induced intestinal necrosis

Relative to acute intestinal necrosis, stress-induced intestinal necrosis is a slow progressive process that is difficult to identify. In the Wenchuan earthquake, we only made diagnoses of stress-induced intestinal necrosis for 3 cases. Two of these patients died, and 1 survived, indicating the difficulty of treating this condition. Due to the small number of cases analyzed, our treatment experience is limited, but the following recommendations can be made. First, the primary trauma should be controlled as soon as possible. Stress was continuously present in part because the primary injury was not treated directly. In the representative case, after both legs were amputated, the infection of the amputated surface was not well controlled, resulting in a second right leg amputation. In addition, intermittent dialysis after renal failure could cause intestinal ischemia-reperfusion injury. Second, early administration of appropriate vasodilator could improve intestinal microcirculation. Third, vasoconstrictors should be used as little as possible. As the blood pressure drops, the application of a vasoconstrictor can increase the blood supply of vital organs such as the heart and brain, but it can reduce the intestinal blood supply. Fourth, intestinal flora should be adjusted appropriately. Many studies indicate that in cases of trauma or weakened immune systems, the intestinal flora can translocate, leading to infections in other parts of the body. A large amount of inflammatory secretions were found in the abdominal cavity of all 3 patients in this study, which may be directly related to intestinal flora that translocated peritoneally. Fifth, the timing of surgery is a key factor. All 3 patients in this study underwent laparotomies after they showed signs of peritoneal irritation. As the results showed, the optimal timing might be prior to this point. We believe that the late diagnosis of intestinal necrosis occurred for the following reasons: (1) Stress-induced intestinal necrosis is a relatively slow process; (2) Intestinal ischemia will inevitably lead to inflammatory exudate. At the same time, the omentum and surrounding intestine can wrap around the injured intestinal regions; and (3) It is only after multiple necroses occur and inflammatory substances cannot be contained that the peritoneum will be stimulated, and signs of peritoneal irritation will be presented. Therefore, the optimal timing of surgery is before the signs of peritoneal irritation. Frequent abdominal ultrasounds and abdominal biopsies can help in determining the optimal timing of surgery.

Early signs/warnings/precautions

During intestinal stress-induced injury, fatty acid binding protein (FABP) is widely recognized as a specific marker of intestinal damage[24,25]. FABP is released by epithelial cells of the intestinal mucosa into the circulation following mucosal damage. Studies have shown that the plasma concentration of FABP gradually increases with the severity of shock. Pathological examinations have suggested that the intestinal mucosal damage was becoming progressively worse[26].

Therefore, we could use FABP as a routine test marker for patients with severe trauma. The increased plasma levels of FABP, combined with other abdominal physical signs and ultrasound results, could aid in early abdominal exploration and facilitate the early diagnosis of this condition.

COMMENTS

Background

Stress-induced intestinal injury is generally associated with damage to the intestinal mucosal barrier. This type of injury has been confirmed in many animal experiments, but few studies have reported stress-induced intestinal necrosis.

Research frontiers
There are many reports of partial of the small intestinal necrosis, which were thought to be the results of mesenteric thrombosis or bacterial infection. However, few authors have reported stress-induced intestinal necrosis.

Innovations and breakthroughs
In this paper, the authors investigated the possible reasons and suggested therapeutic plan of stress-induced intestinal necrosis resulting from the severe trauma of an earthquake. Concolund: Stress-induced intestinal necrosis is strongly associated with high level of stress from trauma and post-traumatic complications; For the therapeutic strategy, the primary trauma should be controlled as soon as possible, and timely exploratory laparotomy maybe an effective method for preventing and treating stress-induced intestinal necrosis.

Applications
The patients suffered stress-induced intestinal necrosis should be rarely identified. However, this disease is very dangerous, and even result in death. This paper will offer an alert and instructions for preventing and treating stress-induced intestinal necrosis due to trauma.

Terminology
Fatty acid binding protein is widely recognized as a specific marker of intestinal damage, and which is released by epithelial cells of the intestinal mucosa into the circulation following mucosal damage.

Peer review
In this paper, the authors reported 3 patients who suffered Wenchuan earthquake, had no direct abdominal trauma, and presented small intestinal necrosis diagnosed as "stress-induced intestinal necrosis". This is an interesting paper since, effectively, few data have been published in this domain. And this paper may offer an alert and instructions for preventing and treating stress-induced intestinal necrosis due to trauma.

Abstract

AIM: To investigate the effect of emodin on pancreatic claudin-5 and occludin expression, and pancreatic paracellular permeability in acute pancreatitis (AP).

METHODS: Experimental pancreatitis was induced by retrograde injection of 5% sodium taurocholate into the biliopancreatic duct. Emodin was injected *via* the external jugular vein 0 or 6 h after induction of AP. Rats from sham operation and AP groups were injected with normal saline at the same time. Samples of pancreas were obtained 6 or 12 h after drug administration. Pancreatic morphology was examined with hematoxylin and eosin staining. Pancreatic edema was estimated by measuring tissue water content. Tumor necrosis factor (TNF)-α and interleukin (IL)-6 level were measured by enzyme-linked immunosorbent assay. Pancreatic paracellular permeability was assessed by tissue dye extravasation. Expression of pancreatic claudin-5 and occludin was examined by immunohistology, quantitative real-time reverse transcriptase polymerase chain reaction and western blotting.

RESULTS: Pancreatic TNF-α and IL-6 levels, wet/dry ratio, dye extravasation, and histological score were significantly elevated at 3, 6 and 12 h following sodium taurocholate infusion; treatment with emodin prevented these changes at all time points. Immunostaining of claudin-5 and occludin was detected in rat pancreas, which was distributed in pancreatic acinar cells, ductal cells and vascular endothelial cells, respectively. Sodium taurocholate infusion significantly decreased pancreatic claudin-5 and occludin mRNA and protein levels at 3, 6 and 12 h, and that could be promoted by intravenous administration of emodin at all time points.

CONCLUSION: These results demonstrate that emodin could promote pancreatic claudin-5 and occludin expression, and reduce pancreatic paracellular permeability.

Emodin promoted pancreatic claudin-5 and occludin expression in experimental acute pancreatitis rats. *World J Gastroenterol* 2012; 18(17): 2132-2139 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i17/2132.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i17.2132

INTRODUCTION

Acute pancreatitis (AP) is an inflammatory disease char-

acterized by interstitial edema, acinar necrosis, hemorrhage, and inflammatory infiltration in the pancreas[1]. Increased paracellular permeability and loss of barrier function in pancreas have been demonstrated at early stages of AP[2-4], but the molecular basis for these phenomena is poorly understood.

Tight junctions, the major apical structures in epithelium and endothelium, have been recently reported to play important roles in barrier function by forming cell-to-cell contacts and sealing paracellular pathway[5,6]. Tight junctions comprise the integral transmembrane proteins occludin, junctional adhesion molecules, and members of the claudin multigene family[4-7]. In mammals, the claudin family of 20-24 kDa integral membrane proteins includes at least 24 members; most of them have been shown to control the permeability of the paracellular pathway[6-8]. Sharing similar membrane location with claudins, occludin also plays an important role in maintaining epithelial and endothelial barriers[9]. Previous studies have demonstrated that claudin-1-5 and occludin are expressed in the pancreas[3,10-12]. Schmitt *et al*[3] have reported that claudin-1 and occludin expression in pancreas is significantly decreased in caerulein-induced AP, suggesting a possible role of tight junctions disruption in interstitial edema formation.

Emodin (1,3,8-trihydroxy-6-methyl-anthraquinone), an anthraquinone derivative from the Chinese herb *Radix et Rhizoma Rhei*, has been reported to inhibit production of inflammatory cytokines such as tumor necrosis factor (TNF)-α, interleukin (IL)-6 and IL-1[13,14]. Our previous study has demonstrated that emodin significantly reduces serum amylase and inflammatory cytokines and attenuates pancreatic damage in AP rats[15]. However, the effects of emodin on claudin and occludin expression, as well as pancreatic paracellular permeability remain largely undefined.

We have previously found that 6 h after duct infusion of sodium taurocholate, pancreatic claudin-1 and claudin-4 were slightly elevated, claudin-5 and occludin were significantly decreased, whereas claudin-2 and claudin-3 remained unchanged (data not shown). Thus, in the present study, we assessed the effects of emodin on claudin-5 and occludin expression. Time course of pancreatic paracellular permeability, edema, and cytokines were also determined.

MATERIALS AND METHODS

Reagents
All chemicals were purchased from Sigma (St. Louis, MO, United States) unless otherwise indicated. TNF-α and IL-6 enzyme-linked immunosorbent assay (ELISA) kits were obtained from Jingmei Biotech (Beijing, China). TRIzol kit and SYBR Green SuperMix-UDG were purchased from Invitrogen (Carlsbad, CA, United States). A first-strand cDNA synthesis kit was purchased from Fermentas (Burlington, Ont., Canada). Antibodies for claudin-5 and occludin were obtained from Zymed

Laboratories (South San Francisco, CA, United States). The Power Vision Two-Step Histostaining Reagent was purchased from ImmunoVision Technologies (Norwell, MA, United States). Glyceraldehyde phosphate dehydrogenase (GAPDH) antibody was purchased from Abcam (Cambridge, United Kingdom). Horseradish peroxidase (HRP)-conjugated secondary antibody was purchased from Kangchen Biotech (Shanghai, China). Immobilon western chemiluminescent HRP substrate was purchased from Millipore (Boston, MA, United States).

Experimental model
Adult male Sprague-Dawley rats (200-250 g body weight) were obtained from the Animal Facility of Anhui Medical University (Hefei, China). Animals were housed under controlled temperature, humidity and day-night cycles, with free access to standard laboratory feed and water. The Animal Studies Ethics Committee of Anhui Medical University approved all of the experiments.

AP was induced as described by Pereda *et al*[16]. Briefly, animals were anesthetized with intraperitoneal administration of ketamine (80 mg/kg body weight) and acepromazine (2.5 mg/kg body weight). The biliopancreatic duct was cannulated through the duodenum, and the hepatic duct was closed by a small bulldog clamp. Pancreatitis was induced by retrograde injection into the biliopancreatic duct of 5% sodium taurocholate in a volume of 1 mL/kg body weight, at a constant infusion pressure of 20 mmHg. Presenting as controls, sham group received retrograde infusion of sterile saline.

Study design
AP rats were randomly allocated into two groups: the model group and emodin group (2.5 mg/kg body weight). Emodin was injected *via* the external jugular vein immediately after duct infusion of sodium taurocholate. Both the sham group and model group were injected with normal saline of equivalent volume. Samples were obtained 3, 6 and 12 h after duct infusion. For animals that were euthanized at the 12-h time point, a second administration of emodin or saline was adopted, 6 h after duct infusion of sodium taurocholate.

Samples of pancreas were obtained at 3, 6 and 12 h after intraductal infusion, immediately frozen and maintained at -80 ℃ until assayed. Blood samples were obtained from the inferior cava vein by direct puncture. For histological examination, the central body of the pancreas was fixed in 4% neutral phosphate-buffered formalin and then embedded in paraffin wax. Serum amylase activity was measured to confirm the appropriate induction of pancreatitis.

An additional experiment was adopted to assess the effect of emodin on pancreatic dye extravasation (marker of paracellular permeability). Animals were distributed in the same groups as in the previous series.

Histological examination
Rat pancreas was washed in phosphate buffered saline

Table 1 Histological scoring for acute pancreatitis

Condition	Score	Description
Edema	0	Absent
	1	Diffuse expansion of interlobular septa
	2	1 + diffuse expansion of interlobular septa
	3	2 + diffuse expansion of interlobular septa
Inflammation (%)	0	Absent
	1	In parenchyma (< 50 of lobules)
	2	In parenchyma (51-75 of lobules)
	3	In parenchyma (> 75 of lobules)
Vacuolization (%)	0	Absent
	1	Focal (5-20)
	2	Diffuse (21-50)
	3	Severe (> 50)

(PBS), fixed in 10% neutral-buffered formalin, and embedded in paraffin wax. Five-micrometer sections were deparaffinized with xylene, stained with hematoxylin and eosin, and examined by two experienced pathologists in blinded fashion. Pancreatic damage was scored using a grading system described by Ryan *et al*[17]. The grading was based on the number of acinar cell ghosts, the presence of vacuolization, interstitial edema and interstitial inflammation, and to what extent these characteristics affected the pancreas (0 being normal and 3 being severe), giving a maximum score of 12 (Table 1).

Measurement of pancreatic edema and cytokines

The extent of pancreatic edema was estimated by measuring tissue water content. Freshly obtained blotted samples of pancreas were weighed on aluminum foil, dried for 24 h at 95 ℃, and reweighed. The difference between the wet and dry tissue weights was calculated and expressed as wet/dry ratio.

Pancreatic TNF-α and IL-6 were examined using a sandwich ELISA according to the manufacturer's instructions. The tissue homogenate ELISA was corrected by the concentration of protein, and expressed as the content per protein of the tissue (pg/mg protein).

Measurement of paracellular permeability

Paracellular permeability of the pancreas was evaluated by the measurement of Evans blue extravasation[18]. Briefly, Evans blue (20 mg/kg) was injected into the jugular vein of rats, 30 min before duct infusion. Samples of pancreas were obtained 3, 6 and 12 h after duct infusion. A portion of the splenic segment was sectioned and immersed in formamide solution, and homogenized for 2 min. After incubation at room temperature for 24 h, the suspension was centrifuged at 4000 *g* for 30 min. The quantity of dye extracted was determined spectrophotometrically at 620 nm and calculated from a standard curve established with known amounts of Evans blue. Results were corrected by the wet/dry ratio of the pancreas and expressed as the dye content per dry weight of the pancreatic tissue (μg/g tissue).

Western blotting

Western blotting was performed as described by Hi-

etaranta *et al*[19]. From each sample, 20 μg total protein was separated on 4%-20% sodium dodecyl sulfate polyacrylamide gel electrophoresis and electroblotted onto polyvinylidene difluoride membranes. Membranes were blocked in blocking solution, incubated overnight with primary antibodies, and developed with an HRP-conjugated secondary antibody (1:1000 dilution). Dilutions for primary antibody were as follows: claudin-5, 1:100; and occludin, 1:300. The immune complexes were then visualized using chemiluminescent HRP substrate and X-ray film. Additional immunoblots were performed using GAPDH antibody as the primary antibody to evaluate equal loading.

Immunohistological analysis

Pancreas sections (4 μm) were dewaxed in graded alcohols, and finally washed in tap water. Endogenous peroxidase activity was blocked by 3% (v/v) H_2O_2, and the antigen was retrieved by microwave in 0.01 mol/L citrate buffer. Sections were then washed in PBS (0.1 mol/L). Mouse anti-rat claudin-5, and rabbit anti-rat occludin polyclonal antibodies were applied at 1:100 and incubated overnight at 4 ℃. Sections were washed four times in PBS for 20 min. The Power Vision Two-Step Histostaining Reagent was used for detection. All sections were developed using diaminobenzidine, and subsequently counterstained with hematoxylin.

Quantitative real-time reverse transcription polymerase chain reaction analysis

Total RNA was extracted using TRIzol Kit and converted to first-strand cDNA according to the manufacturer's instructions. Quantitative real-time polymerase chain reaction (PCR) was performed using SYBR Green SuperMix-UDG in Prism 7000 Q real-time PCR detection system (Applied Biosystems, Foster City, CA, United States). The primer sequences used for PCR were as follows: claudin-5 (forward 5'-TACTCAGCACCAAGGCGAAC-CAC-3', reverse 5'-GCGGCTT CCCACATCG-GTC-3'), occludin (forward 5'-AGTACATGGCTGCTGCTGAT G-3', reverse 5'-CCCACCATCCTCTTGAT GTGT-3'), GAPDH (forward 5'-CA GTGCCAGCC-TCGTCTCA-TA-3', reverse 5'-TGCCGTGGGTAGAGTCAT A-3'). Amplification was performed with use of the following cycles: 50 ℃ for 2 min (UDG incubation), 95 ℃ for 2 min, followed by 40 cycles of denaturing at 95 ℃ for 15 s and annealing at 60 ℃ for 30 s. All reactions were performed in triplicate. Melting curve analysis was performed to ensure the specificity of quantitative PCR. Data analysis was performed using the $2^{-\Delta\Delta CT}$ method described by Livak *et al*[20], where GAPDH was used as reference gene.

Statistical analysis

Results are presented as mean ± SE. One-way repeated-measures analysis of variance (followed by multiple pairwise comparisons using Student-Newman-Keuls method) was used for the analysis of differences between the

Figure 1 Effects of emodin on pancreatic injury in sham group (A), pancreatitis group (B), emodin group (C) and (D) histological score. (Original magnification, × 200). Six rats were studied in each experimental group at each time point. Results are mean ± SD. [a]$P < 0.05$ *vs* sham group; [c]$P < 0.05$ *vs* pancreatitis group.

experimental and control groups. All statistical analysis were carried out using SPSS for Windows version 11.5, with statistical significance set at $P < 0.05$.

RESULTS

Effects of emodin on pancreatic paracellular permeability, edema and cytokines in acute pancreatitis rats

Histological sections from representative pancreas are shown in Figure 1. Pancreatic damage was characterized by leukocyte infiltrate, acinar cell necrosis, hemorrhage and fat necrosis (Figure 1B), and the histological score was significantly elevated as compared with the sham operation group at all time points (Figure 1D). Treatment with emodin obviously ameliorated pancreatic damage (Figure 1C), thus decreasing pancreatic pathological scores.

Time course of pancreatic TNF-α and IL-6 was also examined. Pancreatic TNF-α and IL-6 levels were significantly elevated at 3, 6 and 12 h following sodium taurocholate infusion, and treatment with emodin significantly reduced pancreatic TNF-α and IL-6 level at all time points (Figure 2A and B).

Pancreatic edema was evaluated by measuring the pancreatic water content, expressed as wet/dry ratio. As shown in Figure 2C, pancreatic wet/dry ratio was significantly elevated at 3, 6 and 12 h following sodium taurocholate infusion; emodin treatment significantly decreased pancreatic wet/dry ratio at all time points.

Pancreatic dye extravasation, as a marker of paracellular permeability, was examined in the present study.

Figure 2D showed that pancreatic dye extravasation was significantly elevated at 3, 6 and 12 h after induction of AP; emodin treatment significantly inhibited pancreatic dye extravasation at all time points. These findings indicated that emodin could reduce pancreatic paracellular permeability.

Effects of emodin on pancreatic claudin-5 and occludin expression in acute pancreatitis rats

We further evaluated the effect of emodin on pancreatic claudin-5 and occludin expression in sodium taurocholate induced AP rats. Immunolocalization of claudin-5 and occludin in pancreas was investigated using immunohistochemical staining. In sham rats, moderate claudin-5 immunostaining was detected in pancreatic acinar cells and vascular endothelial cells (Figure 3A), and intense occludin immunostaining was detected in pancreatic acinar cells, ductal cells and vascular endothelial cells (Figure 3D). Duct infusion of sodium taurocholate markedly decreased the immunostaining of claudin-5 and occludin (Figure 3B and E), and the immunostaining was enhanced when treated with emodin (Figure 3C and F).

Claudin-5 and occludin protein levels in pancreas were evaluated using western blotting. As shown in Figure 4, sodium taurocholate infusion significantly decreased pancreatic claudin-5 and occludin levels at 3, 6 and 12 h, as compared with sham rats; treatment with emodin markedly arrested the decline at all time points.

Kinetics of claudin-5 and occludin mRNA expression in pancreas was examined using quantitative real-time

Figure 2 Effects of emodin on pancreatic (A) tumor necrosis factor-α, (B) interleukin-6, (C) edema and (D) dye extravasation. Six rats were studied in each experimental group at each time point. Results are mean ± SD. [a]$P < 0.05$ *vs* sham group; [c]$P < 0.05$ *vs* pancreatitis group. TNF-α: Tumor necrosis factor-α; IL-6: Interleukin-6.

creatic claudin-5 and occludin expression at the level of mRNA transcription and protein synthesis.

DISCUSSION

The present study investigated the kinetic expression of claudin-5 and occludin in sodium-taurocholate-induced AP, and identified the effects of emodin on pancreatic claudin-5 and occludin expression, as well as pancreatic paracellular permeability in AP rats.

The fundamental functions of epithelia and endothelia in pancreas are to separate distinct compartments and regulate the exchange of small solutes and other substances between them[4]. Increased paracellular permeability may allow noxious contents from the luminal ductal system to enter the interstitium of the pancreatic gland, which results in local inflammation and early edema formation in AP[3]. Lerch *et al*[21] have pointed out that the sealing junctions of the interstitial space in the pancreas are the tight junctions and their proteins. They play crucial roles in the barrier function by constituting tight junction strands and by regulating the tightness of the paracellular pathway[6].

Previous studies have reported that claudin-5 is expressed in the pancreas and localized to the tight junctions[10,22,23]. The role of claudin-5 in barrier function has been investigated in several inflammatory models. Decreased expression and redistribution of claudin-5 is found in acute colitis[24]. Downregulation of claudin-5 has also been demonstrated in experimental autoimmune encephalomyelitis, correlated with breakdown of the blood-brain barrier; recombinant claudin-5 protected brain microvascular endothelial cell cultures from vascular-endothelial-growth-factor-induced increase in paracellular permeability, showing claudin-5 to be a key determinant at the blood-brain barrier[25]. However, in experimental AP, Meriläinen *et al*[26] have reported that the expression of claudin-5 is not changed during pancreatitis. Whether claudin-5 plays a role in pancreatic paracellular permeability therefore needs further investigation.

Occludin shares very similar membrane location with claudins. Based on the staining feature of claudins and occludin along endothelial cell borders in and outside the central nervous system, Persidsky *et al*[8] have speculated that claudins formed the primary make-up of the tight junctions, and occludin further enhances tight junction tightness. Tai *et al*[9] have previously reported that increased paracellular permeability is associated with a specific decrease in occludin, both at the protein and mRNA levels, in hCMEC/D3 cells. Drugs prevent downregulation of occluding, which could decrease paracellular permeability, suggesting an important role of occludin in the blood-brain barrier. In caerulein-

induced AP rats, the disintegration of occludin precedes the increase of serum lipase and amylase, accompanied by increased paracellular permeability, indicating a possible role of occludin in pancreatic barrier function[3].

In the present study, we identified the localization of claudin-5 and occludin in rat pancreas. In normal rats, intense occludin immunostaining was detected in pancreatic acinar cells, ductal cells and vascular endothelial cells, and this was consistent with results from Schmitt *et al*[3] and Borka *et al*[11]. In addition, we also detected moderate claudin-5 immunostaining in pancreatic acinar cells and vascular endothelial cells. Using RT-PCR and Western blotting, our present study confirmed the downregulation of occludin in pancreas of AP rats, which was in keeping with the results of Schmitt *et al*[3]. Our present study also identified the decrease of claudin-5 expression in pancreas of AP rats. It was found that the increase of pancreatic edema and paracellular permeability (marked by extravasation of Evans blue) was accompanied by a decrease of pancreatic claudin-5 and occludin. As demonstrated in previous studies in which paracellular permeability was associated with changes of occludin and claudin multigenes[4-7,23-25], our results suggested possible roles of claudin-5 and occludin in pancreatic barrier function.

Our present study also investigated the effects of emodin on pancreatic edema and paracellular permeability, as well as pancreatic claudin-5 and occludin expression in AP rats. Emodin significantly increased pancreatic claudin-5 and occludin expression at the level of mRNA transcription and protein synthesis, accompanied with decreased pancreatic edema and paracellular permeability. Based on results from previous and present studies, we speculate that the amelioration of pancreatic damage by emodin may contribute, in part at least, to the promotion of claudin-5 and occludin expression.

Disruption of tight junctions results in leakage of amylase and lipase, which could increase production of proinflammatory cytokines; cytokines further impair epithelial barrier function by regulation of expression of the barrier-builders such as the claudin family and occludin[27-29]. In agreement, our present study showed that elevated pancreatic TNF-α and IL-6 levels were paralleled with increased paracellular permeability and decreased expression of claudin-5 and occludin. Emodin could reduce pancreatic TNF-α and IL-6 levels, decrease paracellular permeability, and promote claudin-5 and occludin expression in AP rats, thus it plays an important role in pancreas protection.

In conclusion, our results demonstrate that emodin treatment could ameliorate pancreatic inflammation and edema, reduce paracellular permeability, and promote pancreatic claudin-5 and occludin expression. The decrease of pancreatic paracellular permeability by emodin may contribute, in part at least, to the promotion of claudin-5 and occludin expression.

COMMENTS

Background
Increased paracellular permeability and loss of barrier function in pancreas have been demonstrated at early stages of acute pancreatitis (AP), but the molecular basis for these phenomena is poorly understood.

Research frontiers
Claudin and occludin, the major components of tight junctions in epithelium and endothelium, have been reported to play important roles in barrier function by sealing paracellular pathway. Emodin, an anthraquinone derivative from the Chinese herb Radix et Rhizoma Rhei, has been used for anti-inflammatory purposes. Weather emodin has effects on pancreatic tight junction expression and pancreatic paracellular permeability has not been defined.

Innovations and breakthroughs
A recent report has demonstrated that claudin-1 and occludin expression in pancreas is significantly decreased in caerulein-induced AP, suggesting a possible role of tight junction disruption in interstitial edema formation. This is the first study to report that decreased pancreatic claudin-5 and occludin expression is parallel with increased pancreatic edema and paracellular permeability. Emodin can promote pancreatic claudin-5 and occludin expression, decrease pancreatic paracellular permeability, and inhibit pancreatic inflammation.

Applications
The results of this study may improve the understanding of the pathogenesis of AP, and also provide evidence for emodin in treatment of AP.

Peer review
This is an observational study representing an incremental advance in treatment of acute pancreatitis with emodin. The discussion is adequately developed and focused on the experimental results.

Abstract

Extranodal natural killer (NK)/T-cell lymphoma, nasal type, exhibits aggressive tumor behavior and carries a poor prognosis. Recently, lymphomatoid gastropathy with NK/T cell infiltration into gastric mucosa has been recognized as a pseudo-malignant disease which regresses without treatment. Because the conventional immunohistochemical criteria of lymphomatoid gastropathy is similar to that of extranodal NK/T-cell lymphoma nasal type, it is difficult to distinguish between the two conditions by histopathological evaluation only. Here, we report a rare case of lymphomatoid gastropathy in a 57-year-old female. Gastroendoscopy on routine check-up revealed elevated reddish lesions < 1 cm in diameter in the gastric fornix and body. Although repeat endoscopies at 1 and 6 mo later revealed no gastric lesions at any locations without any treatments, at 12 mo later gastric lymphomatoid lesions recurred at gastric fornix and body. Histological examination of endoscopic biopsy specimens at 12 mo showed atypical NK cell infiltration with CD3$^+$, CD4$^-$, CD5$^-$, CD7$^+$, CD8$^-$, CD20$^-$, CD30$^-$, CD56$^+$, CD79a$^-$ and T-cell-restricted intracellular antigen-1$^+$ into gastric mucosa. After treatment for *Helicobacter pylori* (*H. pylori*) eradication, the lesions disappeared in all locations of the gastric fornix and body over the subsequent 12 mo. Here, we report a case of *H. pylori*-positive lymphomatoid gastropathy with massive NK-cell proliferation, and also review the literature concerning newly identified lymphomatoid gastropathy based on comparison of extra nodal NK/T-cell lymphoma nasal type. In any case, these lesions are evaluated with biopsy specimens, the possibility of this benign entity should be considered, and excessive treatment should be carefully avoided. Close follow-up for this case of lymphomatoid gastropathy is necessary to exclude any underlying malignancy.

INTRODUCTION

Extranodal natural killer (NK)/T-cell lymphoma, nasal

type, has the distinctive morphologic features of an angiocentric and angiodestructive growth pattern with frequent necrosis and apoptosis[1]. NK/T cell lymphoma frequently presents as a disease of infiltrative and ulcerative lesions around the nasal cavity, "nasal" and other midline structures, such as skin, gastrointestinal tract, salivary gland and testis, "nasal type"[2]. Characteristic immunohistochemical findings include CD56[+] (NK cell marker), sCD3[-], cCD3[+], and Epstein-Barr virus (EBV)[+] *in situ* hybridization[3]. Long-term outcomes of NK/T cell lymphoma are generally poor due to frequent systemic relapses, and only 40% of patients survive longer than 5 years[4]. Primary NK/T cell lymphoma nasal type in the stomach is rare, and the etiology, pathogenesis, and clinical characteristics are unclear[5,6].

Recently, several cases of NK-cell proliferation in gastric mucosa were reported as lymphomatoid gastropathy or NK-cell enteropathy. Newly identified lymphomatoid gastropathy has been characterized as self-limited pseudomalignant NK-cell proliferation in gastric mucosa, and to have a good prognosis irrespective of a good prognosis even when left untreated. Histological findings reveal diffuse infiltrations of medium-sized to large atypical NK/T cells in the lamina propria and glandular epithelium. The cells were CD2[+/-], sCD3[-], cCD3[+], CD4[-], CD5[-], CD7[+], CD8[-], CD16[-], CD20[-], CD45[+], CD56[+], CD117[-], CD158a[-], CD161[-] and granzyme B[+]. Previously, most cases of lymphomatoid gastropathy were expected to be diagnosed as extranodal NK/T-cell lymphoma nasal type, because of their similar histopathologic findings, and to be treated with chemotherapy, surgery or both[7,8].

Here, we report a case of *Helicobacter pylori* (*H. pylori*)-positive lymphomatoid gastropathy with massive NK-cell proliferation in the stomach, and also review the literature concerning newly identified lymphomatoid gastropathy based on comparison of extra nodal NK/T-cell lymphoma nasal type.

CASE REPORT

A 57-year-old Japanese female without symptoms such as epigastric discomfort, nausea or heart burn showed an erythematous dish-like elevated lesion less than 1 cm in diameter in the greater curvature of the lower body of the stomach and atrophic gastritis with *H. pylori* infection at check-up gastroendoscopy (Figure 1A and B). However, histological findings were no atypical lymphoid cell infiltrations or atypical glands of the gastric mucosa. Follow-up at 1 and 6 mo showed that the elevated erythematous lesion had resolved without treatment (Figure 1C and D).

Twelve months later, repeated endoscopy revealed a similar erythematous elevated lesion < 1 cm in diameter in the anterior wall of the middle body and an erythematous lesion in the fornix (Figure 1E-H). Histological examination of biopsy specimens of the two lesions showed massive atypical medium- to large-sized NK lymphocyte infiltrations with slightly irregular nuclear contours, a dispersed chromatin pattern, and clear cyto-

plasm (Figure 2A and B). Immunohistochemical stains of NK cells showed CD3[+], CD4[-], CD5[-], CD7[+], CD8[-], CD20[-], CD30[-], CD56[+], CD79a[-] (Figure 2C-I). Cytotoxic molecule-associated proteins of T-cell restricted intracellular antigen-1 (TIA-1) and granzyme B were both positive (Figure 2J and K). *In situ* hybridization for EBV-encoded RNA was negative(Figure 2L). There was no evidence of the involvement of tumor cells in peripheral blood or bone marrow, or of the involvement of small intestine, colon or other organs by computed tomography and positron emission tomography.

A diagnosis of extranodal NK/T-cell lymphoma nasal type was initially considered based on the atypical NK/T-cell infiltrations into gastric mucosa. However, owing to the negative hematological evaluation for EBV infection, including Epstein-Barr anti-viral capsid antigen immunoglobulin M (< 10 times) and anti-Epstein-Barr nuclear antigen (< 10 times), lack of any evidence of the involvement of other organs, stage IE according to the Ann Arbor classification, and lack of aggressive tumor behavior during observation period, the diagnosis was changed to lymphomatoid gastropathy. The patient was not treated with chemotherapy or gastrectomy but rather *H. pylori* eradication therapy consisting of rabeprazole 10 mg bid, clarithromycin 200 mg bid and amoxicillin 750 mg bid for 7 d. After eradication, no further manifestation of lymphomatoid gastropathy occurred endoscopically and pathologically during 12 mo of follow-up.

DISCUSSION

CD16/CD56[+] NK cells are a subset of lymphocytes which are associated with innate immunity and cytotoxic function against viruses and tumor cells in peripheral blood, lymphoid tissue, spleen and extranodal sites, such as gastrointestinal mucosa[9]. Nevertheless, little is known about the presence and function of these or other NK cells in gastric mucosa. Here, we reported a rare case of self-limited lymphomatoid gastropathy mimicking extranodal NK/T-cell lymphoma, nasal type, in the stomach. Microscopic observation showed sheets of large peculiar cells with indented nuclei and clear cytoplasm with eosinophilic granules. Immunohistochemical analysis of these atypical cells showed CD3[+], CD4[-], CD5[-], CD7[+], CD8[-], CD20[-], CD30[-], CD56[+], CD79a[-], TIA-1[+] and granzyme B[+]. In general, although NK cells in gastric mucosa have no cytotoxic function and low levels of TIA-1 and Granzyme B[10], the relatively high TIA-1 and Granzyme B expression of gastric mucosal NK cell infiltrates in this case suggested that these cells did in fact have a cytotoxic function in this patient, most probably in responding to local inflammation or autoimmunity.

The most important differential diagnosis of lymphomatoid gastropathy is to distinguish it from extranodal NK/T cell lymphoma, nasal type, in stomach. In the present case, a diagnosis of "extranodal NK/T cell lymphoma nasal type" was suspected from the immunohistochemical finding of a strong expression of CD56

Figure 1 Gastroendoscopy revealed an erythematous dish-like elevated lesion in the greater curvature of the lower body at check-up (A and B), and at one (C) and six months later (D); Twelve months later, endoscopy revealed a similar lesion in the anterior wall of the middlebody (E and F), and an erythematous lesion in the fornix (G and H).

Figure 2 Histological examination showed massive atypical medium- to large-sized natural killer lymphocyte infiltrations with slightly irregular nuclear contours. A dispersed chromatin pattern and clear cytoplasm in the gastric mucosa, × 100 (A) and × 400 (B); Immunohistochemical stains showed CD3+ (C), CD4- (D), CD5- (E), CD7+ (F), CD8- (G), CD20- (H), CD56+ (I), T-cell restricted intracellular antigen-1+ (J), granzyme B+ (K) and Epstein-Barr virus-encoded RNA *in-situ* hybridization (L).

and CD3. Extranodal NK/T-cell lymphoma, nasal type, is rarely seen in Western countries but is relatively common in Asia and Central-South American countries[7,11,12], where it accounts for < 2% of all newly diagnosed lymphoma in Japan, 6% in Hong Kong, 8% in Korea, and 5% in Taiwan[13-16]. Histologically, the lymphoma often shows an angiocentric and angiodestructive infiltrate of atypical lymphocytes leading to extensive necrosis. The differential diagnosis of gastrointestinal NK-cell and T-cell lymphomas includes enteropathy-associated T-cell

lymphoma, T-cell lymphoma, and more rarely anaplastic large cell lymphoma[17]. Moreover, histopathological diagnosis for several reactive or borderline lesions is also required, including infectious mononucleosis, drug-induced lymphadenitis, and histiocytic/subacute necrotizing lymphadenitis; these lesions histopathologically mimic lymphoma and are occasionally misdiagnosed as malignancy.

The differentiation of extranodal NK/T-cell lymphoma nasal type and lymphomatoid gastropathy by histological findings only is difficult. The differential diagnosis of the two diseases is considered to be as follows. First, the stomach is not a common site of origin of extranodal NK/T-cell lymphoma, nasal type, and most cases of extranodal NK/T-cell lymphoma and NK-cell enteropathy in the stomach are not limited to the stomach at the time the condition is diagnosed[5,18-20]. Previous cases of lymphomatoid gastropathy in the stomach and duodenum extended further down into the gastrointestinal tract, including as far as the colon (Table 1)[5,8]. Second, although some cases of lymphomatoid gastropathy showed necrosis, none showed angiocentric or angiodestructive growth patterns, or prominent apoptotic bodies, which are common features of extranodal NK/T-cell lymphoma, nasal type[7]. Our present case also showed no angiocentric or angiodestructive growth patterns. Third, Epstein-Barr virus-encoded RNA *in situ* hybridization, which is almost always positive in NK/T-cell lymphoma, nasal type, is consistently negative

in lymphomatoid gastropathy (Table 2)[3,21].

NK cells function as cytokine-producing effectors and can act as regulatory cells during inflammation and influence subsequent adaptive immune responses[22]. In acute/chronic inflammation or autoimmune reactions, localization of NK cells has been observed at variousanatomic sites, including skin and gastrointestinal tract[9]. *H. pylori* infection is characterized by marked neutrophil, lymphocyte, monocyte and plasma cell infiltration of gastric mucosa[23]. Chronic *H. pylori* gastric mucosal infection leads to chronic gastritis with severe inflammatory cell infiltration, which results in progressive gastric mucosal atrophy and intestinal metaplasia with higher potential for the development of gastric tumors[24,25]. Mucosa-associated lymphoid tissue (MALT) lymphoma (70%-80%) is well known to be caused by chronic *H. pylori* infection into gastric mucosa and after eradication therapy *H. pylori*-positive MALT lymphoma regresses. Therefore, we have lead to the hypothesis that the pathogenesis of lymphomatoid gastropathy is associated with the gastric mucosal inflammation produced by chronic *H. pylori* infection. Takeuchi *et al*[7] reported that 90% cases of lymphomatoid gastropathy were positive for *H pylori* infection and that lymphomatoid gastropathy in several patients receiving eradication therapy regressed during follow-up observation. In our case, no further manifestation of lymphomatoid gastropathy was seen for 12 mo after *H. pylori* eradication. However, other patients have also shown complete resolution without treatment for *H. pylori* eradication[7,8]. Although lymphomatoid gastropathy may be related with *H pylori* infection, a better understanding of lymphomatoid gastropathy and its relationship with *H pylori* infection awaits further study.

As shown in Table 1, endoscopic characteristics may include raised ulcers or reddish and congestive flat eleva-

tions with a shallow depression[7]. In all cases, multiple lesions of reddish flat elevations were seen. While some cases may resemble early gastric carcinoma, the endoscopic characteristics of lymphomatoid gastropathy are not clearly understood.

In conclusion, we experienced the rare case of lymphomatoid gastropathy, in which eradication treatment for *H. pylori* appeared to be effective. Differentiation of extranodal NK/T-cell lymphoma, nasal type and lymphomatoid gastropathy is difficult, and biological and endoscopic characteristics, prognosis and treatment of lymphomatoid gastropathy are unclear. Therefore, it will be better to clarify those characteristics by further case studies or basic research in feature. In any case, at the time these lesions are evaluated with biopsy specimens, the possibility of this benign entity should be closely considered, and excessive treatment should be carefully avoided. In finally, close follow-up for this case of lymphomatoid gastropathy is necessary to exclude any underlying malignancy, because nobody knows etiology of this NK-cell lymphomatoid gastropathy.

INTRODUCTION

Hemolymphangiomas are rare benign tumors that appear to arise from congenital malformations of the vascular system. The formation of these tumors may be explained by obstruction of venolymphatic communication, dysembrioplastic vascular tissue and systemic circulation[1]. Hemolymphangiomas most commonly present as cystic or cavernous lesions.

Herein, we report a case of hemolymphangioma of the small intestine with bleeding.

CASE REPORT

The patient was a 57-year-old woman who complained of recurrent melena for more than 2 mo. The complete blood count showed severe anemia, and stool occult blood (OB) was positive. Gastroscopy showed chronic superficial gastritis with erosion and duodenal erosion. Enteroscopy showed a gray mass with ulcers and erosion in the small intestine 30 cm distal to the flexor tendon. The mass was ill-defined, and the size was approximately 5.0 cm × 4.0 cm (Figure 1). Pathological analysis showed

Abstract

Small intestinal hemolymphangioma is a very rare benign tumor. There was only one report of a hemolymphangioma of the pancreas invading to the duodenum until March 2011. Here we describe the first case of small intestinal hemolymphangioma with bleeding in a 57-year-old woman. She presented with persistent gastrointestinal bleeding and endoscopy revealed a small intestinal tumor. Partial resection of the small intestine was thus performed and the final pathological diagnosis was hemolymphangioma. We also highlight the difficultly in making an accurate preoperative diagnosis in spite of modern imaging techniques. To arrive at a definitive diagnosis and exclude malignancy, partial resection of the small intestine was considered to be the required treatment.

Figure 1 Enteroscopy revealed a mass at the small intestine (arrow).

Figure 2 Histological analysis revealed a benign soft tissue mass (arrow) consisting of lymphatic and blood vessels (hematoxylin and eosin, × 100).

an intrinsic layer of dilated lymphatic vessels, a small amount of interstitial neutrophil, eosinophil, plasma cell infiltration. After admission, the stool OB continued to be positive, and the anemia was not corrected. Partial resection of the small intestine was thus performed. The small intestinal tumor was soft, and the final pathological diagnosis was a hemolymphangioma (Figure 2). The patient was discharged 7 d after the successful surgical resection of the tumor. At the annual follow-up, no recurrence was observed, and the patient is currently enjoying normal life.

DISCUSSION

Lymphangiomas are a heterogeneous group of vascular malformations that are composed of cystically dilated lymphatics. These malformations can occur at any age and may involve any part of the body; however, 90% occur in children who are less than 2 years of age and involve the head and neck. These lesions are rarely found in adult patients. Those benign malformations are classified into four categories[2]: Capillary lymphangioma, cavernous lymphangioma, cystic lymphangioma (hygroma) and hemolymphangioma (a combination of hemangioma and lymphangioma).

The incidence of hemolymphangiomas varies from 1.2 to 2.8 per 1000 newborns[3], and both genders are equally affected. The diagnosis in most cases (90%) is made before the age of two[4], 60% of those patients display symptoms at the time of birth. Hemolymphangioma of the small intestine is an uncommon and benign tumor. In a literature review of studies published until March, 2011 (PubMed), there was only one report of a hemolymphangioma of the pancreas invading to the duodenum[4]. However, there are no reports that describe small intestinal hemolymphangioma with bleeding.

The clinical onset of hemolymphangiomas can vary from a slowly growing cyst over a period of years to an aggressively enlarging but non-invasive tumor. Their size varies based on the anatomical location and relationship to the neighboring tissues. Small tumors are usually superficial, whereas the larger ones are located in deeper layers and have a cystic texture. The most common complications are spontaneous or traumatic hemor-

rhage, rupture and infection. On physical examination, the tumors are usually palpated as soft and compressible masses. Histologically, hemolymphangiomas consist of blood vessels and lymphatic channels.

Surgical resection appears to be the most effective treatment for hemolymphangioma, especially when the tumor increases in size and applies pressure on the surrounding tissues. Surgeons usually perform complete removal of the tumor with the surrounding organs that may be potentially invaded, because there is a possibility of recurrence and invasion of surrounding organs[5]. The recurrence rates vary depending on the complexity of the tumors, the anatomical location and the adequacy of the excision. However, lesions that have been completely excised present 10%-27% recurrence, while 50%-100% of partially resected tumors may recur. Partial or incomplete tumor removal may also be associated with complications such as infection, fistula, and hemorrhage[6].

In conclusion, our report describes on a patient with gastrointestinal bleeding due to hemolymphangioma. Surgical resection is the most effective treatment, and the case was associated with a good prognosis. Despite its low frequency, this disease should be considered when gastrointestinal bleeding is observed.

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT
All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (n). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the P value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present P values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. [a]$P < 0.05$, [b]$P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, [c]$P < 0.05$ and [d]$P < 0.01$ are used. A third series of P values can be expressed as [e]$P < 0.05$ and [f]$P < 0.01$. Other notes in tables or under illustrations should be expressed as [1]F, [2]F, [3]F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634   DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express t test as t (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as r (in italics), degree of freedom as υ (in Greek), sample number as n (in italics), and probability as P (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formal-dehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: t time or temperature, c concentration, A area, l length, m mass, V volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H. pylori*, *E coli*, *etc*.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

BRIEF ARTICLE

Endoclips *vs* large or small-volume epinephrine in peptic ulcer recurrent bleeding

Abstract

AIM: To compare the recurrent bleeding after endoscopic injection of different epinephrine volumes with hemoclips in patients with bleeding peptic ulcer.

METHODS: Between January 2005 and December 2009, 150 patients with gastric or duodenal bleeding ulcer with major stigmata of hemorrhage and nonbleeding visible vessel in an ulcer bed (Forrest Ⅱa) were included in the study. Patients were randomized to receive a small-volume epinephrine group (15 to 25 mL injection group; Group 1, *n* = 50), a large-volume epinephrine group (30 to 40 mL injection group; Group 2, *n* = 50) and a hemoclip group (Group 3, *n* = 50). The rate of recurrent bleeding, as the primary outcome, was compared between the groups of patients included in the study. Secondary outcomes compared between the groups were primary hemostasis rate, permanent hemostasis, need for emergency surgery, 30 d mortality, bleeding-related deaths, length of hospital stay and transfusion requirements.

RESULTS: Initial hemostasis was obtained in all patients. The rate of early recurrent bleeding was 30% (15/50) in the small-volume epinephrine group (Group 1) and 16% (8/50) in the large-volume epinephrine group (Group 2) (*P* = 0.09). The rate of recurrent bleeding was 4% (2/50) in the hemoclip group (Group 3); the difference was statistically significant with regard to patients treated with either small-volume or large-volume epinephrine solution (*P* = 0.0005 and *P* = 0.045, respectively). Duration of hospital stay was significantly shorter among patients treated with hemoclips than among patients treated with epinephrine whereas there were no differences in transfusion requirement or even 30 d mortality between the groups.

CONCLUSION: Endoclip is superior to both small and large volume injection of epinephrine in the prevention of recurrent bleeding in patients with peptic ulcer.

INTRODUCTION

Peptic ulcer disease accounts for 50% to 70% of cases

of acute nonvariceal upper gastrointestinal bleeding (UGIB)[1,2]. Initial haemostatic rates of 80% to almost 100% can be achieved with various endoscopic techniques. However, after initial control, bleeding recurs in 10% to 30% of patients[3].

Among various endoscopic techniques a recent International consensus on nonvariceal UGIB recommends combination therapy with clear statement that epinephrine injection alone provides suboptimal efficacy and should be used in combination with another methods[4]. However, several recent studies found injection of a large volume of epinephrine to be superior to injection of a small epinephrine volume with respect to recurrent bleeding from peptic ulcer[5,6]. Since epinephrine injection is effective (initial hemostasis obtained with epinephrine injection range from 85% to 100%), safe, inexpensive and technically easy, the concept of a beneficial effect of large volumes of epinephrine in preventing recurrent ulcer bleeding seems to be very challenging. Therefore, the aim of this prospective study was to compare the rates of recurrent bleeding after endoscopic injection of two different volumes of an epinephrine solution (15-25 mL *vs* 30-40 mL) with endoscopic placement of hemoclips in patients with peptic ulcer bleeding. Since it has been suggested that the useful baseline factor for stratification in UGIB trials may be stigmata of hemorrhage in an ulcer, we decided to include in the study only patients presenting with acute UGIB and endoscopically proven gastric or duodenal ulcer with visible vessel in an ulcer bed (Forrest Ⅱa)[7].

MATERIALS AND METHODS

Between January 2005 and December 2009, consecutive patients presenting with acute UGIB were considered for this study. These patients were referred to the Emergency Unit of the Department of Internal Medicine at the "Sestre milosrdnice" University Hospital, Zagreb, Croatia and then if necessary hospitalized at the Interventional Gastroenterology Unit at the same hospital.

UGIB was suspected if hematemesis, melena or hematochezia were seen and/or bloody nasogastric aspirate was observed. In all those patients upper gastrointestinal endoscopy was performed within 6 h of hospital admission. Patients were included only if emergency endoscopy disclosed a gastric or duodenal bleeding ulcer with major stigmata of hemorrhage ("coffee ground" material or blood in the stomach and/or duodenum) and nonbleeding visible vessel in an ulcer bed (Forrest Ⅱ a)[8]. Exclusion criteria were as follows: major comorbid or terminal illness that made endoscopy hazardous; inability or unwillingness to consent to endoscopy and endoscopic therapy; gastric malignancy; minor stigmata of hemorrhage at endoscopy such as oozing from ulcer borders without a visible vessel, flat-pigmented spots, or clean ulcer base. Patients with gastric and duodenal ulcer with either an actively bleeding vessel (spurting or oozing; Forrest Ⅰ), or adherent clot (Forrest Ⅱb) were also excluded.

Endoscopy was performed with standard upper endoscopes (GIF Q140 and GIF Q160, Olympus Optical Co., Japan). Endotherapy was carried out by the well-trained endoscopists, each with at least five years experience in the treatment of patients with GI bleeding. Endoscopic characteristics, including ulcer localization, ulcer size, and type of stigmata, were recorded (Endobase, Olympus, Japan).

Possible complications of endoscopic treatment and complete study protocol were discussed with patients and their relatives, and written informed consent was obtained before endoscopy and entry into the trial. The ethics committee of our hospital approved the treatment protocol. Randomization of eligible patients was carried out at the time of endoscopy by an individual uninvolved with the procedure who opened sealed numbered envelopes containing treatment assignments generated with a computer randomization program. The treatment group allocation was then communicated to the endoscopist in the endoscopy suite. Patients were randomized to a small-volume epinephrine group (15 to 25 mL injection group; Group 1), a large-volume epinephrine group (30 to 40 mL injection group; Group 2) and a hemoclip group (Group 3). In the small-volume epinephrine group (Group 1) 15 to 25 mL of a 1:10 000 solution of epinephrine was injected around the visible vessel (2-4 mL/injection at 2-3 mm from the visible vessel). In the large-volume epinephrine group (Group 2), 30-40 mL of a 1:10 000 solution of epinephrine was injected around the visible vessel at the ulcer bed as in the small-volume epinephrine group. Mechanical hemostasis was performed with stainless steel hemoclips (Olympus, Japan) as has been previously described[9,10]. During endoscopy and endotherapy, electrocardiographic monitoring was used to detect arrhythmias.

Once hemostasis was achieved the bleeding site was observed for at least 10 min and it was assessed by water irrigation at maximal pressure. Failure of the initial hemostasis has been defined if any hemorrhage occurred immediately (within 10 min) after initial endoscopic hemostasis. In these patients crossing over to the other treatment group was not allowed. In all patients two biopsy specimens were taken from the gastric antrum and body, and the presence of *Helicobacter pylori* (*H. pylori*) infection was assessed by histopathological examination of the specimens. In patients with gastric ulcer in whom recurrent bleeding was not observed, control endoscopy was performed 4 d to 5 d after initial hemostasis and biopsy specimens were obtained from the margins and base of gastric ulcers to exclude malignancy.

After initial endoscopic hemostasis, patients were hospitalized and cared for by a physician who was blinded to the endoscopic treatment that had been delivered. Vital signs were monitored hourly whereas blood counts were observed every 6 h for the first 48 h and every 12 h to 24 h thereafter. All patients were given acid suppressive therapy: pantoprazole 80 mg iv, (bolus) and then 40 mg iv, every 8 h for at least 48 h, followed by 40 mg daily by mouth, or esomeprazole 80mg iv, (bolus) and then 40 mg iv, every 8 h for at least 48 h, followed by 20 mg once a day by mouth. Shock was defined as a systolic blood

pressure of less than 90mmHg with symptoms or signs of organ hypoperfusion.

Recurrent bleeding was defined as one or more signs of ongoing bleeding, including fresh hematemesis or melena, hematochezia, aspiration of fresh blood *via* nasogastric tube, instability of vital signs, and a reduction of Hb by more than 2 g/dL over a 24 h period (early recurrence) or over a 7 d period (late recurrence) after initial stabilization of puls, blood pressure and Hb concentration. If recurrent bleeding was suspected, endoscopy was performed immediately. If "coffee ground" material or blood in the stomach and/or duodenum has been found together with active bleeding or a fresh blood clot in the ulcer base were found, recurrent bleeding was considered confirmed. For ethical reasons, additional endoscopic methods for treatment of recurrent bleeding were discussed with patients and their relatives and therapeutic option in all patients with recurrent bleeding was hemoclip application. Patients in whom endoscopic treatment or retreatment was unsuccessful underwent emergency surgery.

The rate of recurrent bleeding, as the primary outcome, was compared between the groups of patients included in the study. Secondary outcomes compared between the groups were primary hemostasis rate (defined as the absence of hemorrhage occurred immediately after initial endoscopic hemostasis), permanent hemostasis (defined as the absence of recurrent bleeding within the 30 d period after initial or secondary endoscopic hemostasis), need for emergency surgery, 30 d mortality and bleeding-related deaths, length of hospital stay, and transfusion requirements.

Statistical analysis

Base on assumption that injection of a large-volume epinephrine decreased the expected rate of recurrent bleeding from 17.1% after injection of small-volume epinephrine solution to zero, 39 patients would have been needed in each group for a power of 80% and a significance level of 0.05[6].

Continuous data were summarized as mean [95% confidence interval (CI)]. The Student *t* test was used to compare the mean values of continuous variables. The Pearson chi-square test and the Fisher exact test were used when appropriate for the comparison of categorical variables. All analyses were performed with a statistical package (SPSS for Windows, United States). A *P* values less than 0.05 were regarded as statistically significant.

RESULTS

From January 2005 to December 2009, 150 patients were included in this study; they were randomly assigned to receive small-volume (15 to 25 mL) injection of epinephrine (Group 1, *n* = 50), large-volume (30 to 40 mL) injection of epinephrine (Group 2, *n* = 50), and hemoclip (Group 3, *n* = 50). During the same period a total of 1516 patients with UGIB were encountered; of these 47.8% had gastric or duodenal bleeding ulcer, 41.2% had non-ulcer lesions

(acute erosive gastropathy, portal hypertensive gastropathy, malignancy, Mallory-Weiss tear, angiomata, Dieulafoy's lesion), 9.1% had esophageal or gastric variceal bleeding, and 1.9% had no source of bleeding (Figure 1). Among the 161 patients with UGIB and endoscopically proven peptic ulcer with visible vessel (Forrest Ⅱa), randomly assigned to receive small-volume or large-volume of epinephrine, or hemoclip, 11 patients were excluded because they refused to participate in the study.

Clinical and endoscopic data obtained for patients included in the study are outlined in Table 1. There were no significant differences between the groups with respect to age, gender, ulcer size and location, positive *H. pylori* status, NSAID or alcohol consumption, shock, bleeding stigmata, history of previous peptic ulcer or peptic ulcer

Figure 1 Patients with upper gastrointestinal bleeding. UGIB: Upper gastrointestinal bleeding.

bleeding, comorbid diseases or hemoglobin and hematocrit levels at admission.

Clinical outcome data are summarized in Table 2. Initial hemostasis was obtained in all patients. In the small-volume epinephrine group (Group 1) the mean volume of epinephrine injected was 19.1 mL (range, 16 to 25 mL) whereas in the large-volume epinephrine group (Group 2) the mean volume of epinephrine injected was 37.9 mL (range, 30 to 40 mL). Among patients endoscopically treated with hemoclips (Group 3), multiple clips (up to three) were needed in majority of cases with a median of 1.6 clips per patient.

The rate of early recurrent bleeding was 30% (15/50) in the small-volume epinephrine group (Group 1) and 16% (8/50) in the large-volume epinephrine group (Group 2); the difference did not reach statistical significance ($P = 0.09$). The rate of recurrent bleeding was 4% (2/50) in the hemoclip group (Group 3); the difference was statistically significant with regard to patients treated with either small-volume or large-volume epinephrine solution ($P = 0.0005$ and $P = 0.045$, respectively). Late recurrent hemorrhage was not observed in our patients. With regard to ulcer location and ulcer size as well, there were no significant differences in the rate of early recurrent bleeding between the groups. Also, there were no differences in transfusion requirement or even 30 d mortality between the groups. However, duration of hospital stay was significantly shorter among patients treated with hemoclips than among patients treated with epinephrine (Table 2). There was no bleeding-related death or procedure-related death. Three patients from Group 1 (causes of death were colon malignancy in one patient, cardiac failure in one patient, and obstructive pulmonary disease

with pneumonia in one patient) and four patients from Group 3 died (pulmonary embolism in two patients and myocardial infarction in one patient). Among patients from Group 2 no one died. One patient in whom large-volume injection of the epinephrine solution was administered (35 mL) required emergent surgery because of a perforation.

Of the 15 patients in the small-volume epinephrine group (Group 1), eight patients in the large-volume epinephrine group (Group 2), and two patients in the hemoclip group (Group 3) who had recurrent bleeding, all were treated with hemoclips. Emergency surgery was performed in all patients in whom re-treatment with hemoclips did not produce hemostasis: six patients from group 1, three patients from Group 2, and two patients from Group 3. Majority of patients in whom emergency surgery has been performed had duodenal ulcer located on the duodenal bulb posterior wall (Group 1, 5/6; Group 2, 2/3; Group 3, 3/3, respectively). Successful permanent hemostasis was not statistically different among groups of patients (Table 2).

Therapeutic efficacy of the small-volume epinephrine *vs* large-volume epinephrine and hemoclips is given in Table 3. Small-volume *vs* large-volume epinephrine was not significant in NNT benefit prediction, although small-volume epinephrine (NNT = 4) and large-volume epinephrine (NNT = 9) showed different significant benefits concerning hemoclip treatment.

There were no procedure-related cardiovascular complications in the three groups. Electrocardiographic monitoring did not record any serious cardiac arrhythmia except of occasional sinus tachycardia and isolated supraventricular extrasystoles observed among all patients

Table 3 Therapeutic efficacy of small-volume and large-volume epinephrine, and hemoclips in reducing recurrent bleeding (95% CI)

Recurrent bleeding rate (%)	RRR (%)	ARR (%)	NNT
Small-volume *vs* large-volume epinephrine	46.6 (-11.2-75.0)	14.0 (-2.6-30.3)	8.0 (37.7-3.3)
Small-volume epinephrine *vs* hemoclips	86.7 (51.7-96.5)	26.0 (12.3-40.4)	4.0 (2.5-8.1)
Large-volume epinephrine *vs* hemoclips	75.0 (9.0-23.0)	12.0 (0.2-25.0)	9.0 (4.0-476.0)

RRR: Relative risk reduction; ARR: Absolute risk reduction; NNT: Number needs to treat.

treated with large-volume epinephrine injection. The number of patients who complained of epigastric pain during and/or immediately after the procedure of endotherapy was significantly higher in the large-volume epinephrine group (34/50) than in the small-volume epinephrine (3/50) or hemoclips (2/50) groups ($P < 0.001$).

DISCUSSION

Emergency endoscopy is accepted as the method of choice in the early identification and treatment of a bleeding peptic ulcer[10]. A variety of endoscopic hemostatic methods have been developed and all were found to be similarly effective[3,11]. Epinephrine as the most commonly used agent for endoscopic injection therapy has been demonstrated to be effective for initial hemostasis but appears less effective in preventing further bleeding than other monotherapies, and definitely is less effective than epinephrine followed by a second modality such as sclerosant or a thermal contact device[4,12]. However, when the analysis was restricted to studies that used routine second-look endoscopy with re-treatment of high-risk stigmata, epinephrine injection was not found to be less effective than other monotherapies or epinephrine followed by second modality[12]. On the other hand, limited data indicate that injection of a large volume epinephrine seems to be superior to injection of a small epinephrine volume with respect to recurrent bleeding[5,6,13]. These studies suggested local tamponade is the major effect in sustained hemostasis and that injection of larger volumes of epinephrine may be beneficial in preventing recurrent bleeding by prolonging the hemostatic effect of mechanical compression. Lin *et al*[5] demonstrated that injection of a large volume (13-20 mL) of epinephrine can reduce the rate of recurrent bleeding in patients with high-risk peptic ulcer and is superior to injection of lesser volumes (5-10 mL) of epinephrine (15.4% *vs* 30.8%). Park *et al*[6] reported that injection of 35 to 45 mL of a epinephrine solution was more effective in preventing recurrent bleeding than an injection of 15 to 25 mL of the same solution (0% *vs* 17.1%). Similar results have been found by Liou *et al*[13,14] demonstrated that injection of a large volume (30 to 40 mL) of epinephrine significantly reducing the rebleeding rate in patients with active bleeding ulcer.

The current study clarifies the low value of endoscopic injection therapy with epinephrine alone in patients with peptic ulcer bleeding showing major stigmata of hemorrhage (patients with endoscopically proven peptic ulcer with a visible vessel in an ulcer bed; Forrest Ⅱa). Disparities in inclusion criteria using Forrest classification, across the majority of studies that demonstrated higher effectiveness of large volume diluted epinephrine injection significantly limit the interpretation of those results. Unlike many mentioned studies, this trial was carried out on adequate patient's sample with clearly predefined groups of patients.

Our results have clearly shown that endoscopic therapy with hemoclip represents safe and effective method, superior to both, small-volume (15 to 25 mL) and large-volume (30 to 40 mL) injection of diluted epinephrine in the prevention of early recurrent bleeding from peptic ulcer. Reduction in recurrent hemorrhage rates observed among our peptic ulcer patients treated with hemoclip method positively affected length of hospital stay, reflecting the possibility of significant cost savings.

It has been postulated that possible mechanisms that underlie hemostasis in response to endoscopic injection of diluted epinephrine are vasoconstriction, vessel compression, and platelet aggregation[15,16]. Among these, mechanical compression of the bleeding vessel is the most important factor with respect to initial hemostasis[6,16]. Therefore, it has been assumed that injection of larger volumes of diluted epinephrine may be beneficial in preventing recurrent peptic ulcer bleeding by prolonging the hemostatic effect of mechanical effect and compression[5,6,14]. Despite the fact that previously mentioned assumption has been indirectly confirmed by several studies demonstrating a significantly lower rate of recurrent peptic ulcer bleeding following large volume epinephrine injection, we strongly believe that even sustained mechanical compression achieved by a larger volumes of diluted epinephrine injection is not sufficiently sustained to produce vessel compression that will last enough to provoke platelet aggregation in a greater extent, that would finally result vessel thrombosis. The results observed in this study indicate that local tamponade observed even after larger volumes of diluted epinephrine injection was not effective as hemoclip for the preventing of recurrent bleeding. This observation strongly suggested that vessel compression, produced by a hemoclip has an important role in the mechanisms involved in vessel occlusion, thus preventing the recurrent bleeding.

To our knowledge, this is the first prospective randomized study comparing the rates of the recurrent bleeding after endoscopic injection of two different volumes of an epinephrine solution and mechanical endoscopic method in patients with UGIB and endoscopically proven peptic ulcer with nonbleeding visible vessel in an ulcer bed (Forrest Ⅱa). Our results have confirmed that

endoclip is safe and effective method, pointing out to its superiority to both, small volume and large volume injection of diluted epinephrine in the prevention of early recurrent bleeding from peptic ulcer.

COMMENTS

Background

Peptic ulcer disease accounts for 50% to 70% of cases of acute nonvariceal upper gastrointestinal bleeding (UGIB). Initial haemostatic rates of 80% to almost 100% can be achieved with various endoscopic techniques, but, after initial control, bleeding recurs in 10% to 30% of patients. Several recent studies found injection of a large volume of epinephrine to be superior to injection of a small epinephrine volume with respect to recurrent bleeding from peptic ulcer. Since epinephrine injection is effective (initial hemostasis obtained with epinephrine injection range from 85% to 100%), safe, inexpensive and technically easy, the concept of a beneficial effect of large volumes of epinephrine in preventing recurrent ulcer bleeding seems to be very challenging.

Research frontiers

To compare the rates of recurrent bleeding after endoscopic injection of two different volumes of an epinephrine solution (15-25 mL *vs* 30-40 mL) with endoscopic placement of hemoclips in patients with acute peptic ulcer bleeding and endoscopically proven gastric or duodenal ulcers with visible vessel in an ulcer bed (Forrest Ⅱa).

Innovations and breakthroughs

This is the first prospective randomized study comparing the rates of the recurrent bleeding after endoscopic injection of two different volumes of an epinephrine solution and mechanical endoscopic method in patients with UGIB and endoscopically proven peptic ulcer with nonbleeding visible vessel in an ulcer bed (Forrest Ⅱa). Unlike many studies, this trial was carried out on adequate patient's sample with clearly predefined groups of patients, in a unique center. A detailed description is provided to allow other investigators to reproduce or validate.

Applications

The results provide sufficient experimental evidence to draw firm scientific conclusions. The results have clearly shown that endoscopic therapy with hemoclip represents safe and effective method, superior to both, small-volume (15 to 25 mL) and large-volume (30 to 40 mL) injection of diluted epinephrine in the prevention of early recurrent bleeding from peptic ulcer. Reduction in recurrent hemorrhage rates observed among our peptic ulcer patients treated with hemoclip method positively affected length of hospital stay, reflecting the possibility of significant cost savings.

Peer review

This is the paper in which authors compere two most commonly used hemostatic methods in patients with bleeding peptic ulcer. The sample size is adequate, in a unique center. A detailed description is provided to allow other investigators to reproduce or validate. The statistical methods used are appropriate. The results provide sufficient experimental evidence or data to draw firm scientific conclusions. The discussion is well organized and provide systematic theoretical analyses and valuable conclusions.

Abstract

AIM: To evaluate the effects of fucoidan, a complex sulfated polysaccharide extract from marine seaweed, on hepatitis C virus (HCV) RNA load both *in vitro* and *in vivo*.

METHODS: HCV-1b replicon-expressing cells were cultured in the presence of fucoidan obtained from *Cladosiphon okamuranus Tokida* cultivated in Okinawa, Japan, and quantified the level of HCV replication. In an open-label uncontrolled study, 15 patients with chronic hepatitis C, and HCV-related cirrhosis and hepatocellular carcinoma were treated with fucoidan (0.83 g/d) for 12 mo. The clinical symptoms, biochemical tests, and HCV RNA levels were assessed before, during, and after treatment.

RESULTS: Fucoidan dose-dependently inhibited the expression of HCV replicon. At 8-10 mo of treatment with fucoidan, HCV RNA levels were significantly lower relative to the baseline. The same treatment also tended to lower serum alanine aminotransferase levels, and the latter correlated with HCV RNA levels. However, the improved laboratory tests did not translate into significant clinical improvement. Fucoidan had no serious adverse effects.

CONCLUSION: Our findings suggest that fucoidan is safe and useful in the treatment of patients with HCV-related chronic liver diseases. Further controlled clinical trials are needed to confirm the present findings.

INTRODUCTION

Hepatitis C virus (HCV) infection often advances to chronic hepatitis due to the low viral clearance rate, leading to liver cirrhosis (LC) and subsequent development of hepatocellular carcinoma (HCC)[1,2]. The estimated global number of people infected with HCV is 170 million and more than 3.5 million new sufferers are diagnosed annually[3]. Currently, there is no vaccine available

for prevention of HCV infection due to the extreme sequence variability within the HCV genome. The first-line treatment for chronic hepatitis C (CHC) includes the combination of pegylated α-interferon (IFN) and ribavirin, a broad spectrum antiviral drug[4,5]. Although the reported HCV eradication rate by this combination therapy is 75%-90% for genotypes Ⅱ and Ⅲ and 45%-52% for genotypes Ⅰ and Ⅳ[6], these rates are still far from ideal. Because of the high rate of nonresponders among those infected with genotype Ⅰ, the predominant strain in Japan, and because antiviral treatment causes frequent, unpleasant and sometimes serious adverse effects[7], the establishment of a new treatment modality without serious adverse effects is desirable[8].

Considering the prolonged period (20-30 years) required for development of LC and HCC in individuals infected with HCV, progression of the disease might be influenced by nutritional status and diet. Although herbal supplements, including silymarin (an extract of milk thistle), are frequently used by patients with chronic liver diseases[9,10], the available scientific evidence for the beneficial effects of these supplements is limited[11]. However, administration of EH0202, a mixture of four herbal extracts, is reported to induce IFN activity and reduce HCV RNA levels in patients with high viral titers[12]. Furthermore, a recent study reported the hepatoprotective effect of birch bark extract in patients with CHC[13].

Fucoidan is a sulfated polysaccharide extracted from marine brown seaweeds that possess some biological activities including anti-inflammatory properties[14,15]. Sulfated polysaccharides, including fucoidan, are also reported to inhibit the replication of viruses such as herpes simplex virus, Sindbis virus, human immunodeficiency virus, parainfluenza virus type Ⅱ, and dengue virus[16-18]. We have also reported recently that oral administration of fucoidan for 12 mo resulted in 42.4% decrease in the human T-cell leukemia virus type Ⅰ proviral load in patients with human T-cell leukemia virus type Ⅰ -associated neurological disease[19]. Since fucoidan shows no toxicity or irritation in humans, it may be useful also as an anti-HCV agent.

To our knowledge, there are no data on the anti-HCV effect of fucoidan. In the present study, we examined the anti-HCV activity of fucoidan extracted from the marine alga, *Cladosiphon okamuranus Tokida* (*C. okamuranus Tokida*) cultivated in Okinawa, Japan. Our pilot study is the first clinical trial that investigated the effect of fucoidan in patients with HCV-related chronic liver diseases.

MATERIALS AND METHODS

Preparation of fucoidan from seaweed
The unsalted brown seaweed *C. okamuranus Tokida* cultivated in Okinawa, Japan, was suspended in water, 0.57% (w/v) citric acid was added to the solution, and then heated at 90 ℃ for 40 min. The suspension was neutralized with NaOH and cooled to 40 ℃. It was centrifuged at 3500 *g* by decantation centrifugal separator. The su-

pernatant was collected, filtered using Cohlo filter, and concentrated by ultrafiltration (molecular weight cutoff 6000). The extracts were dried by spraydrier. They were composed of carbohydrates (72%), uronic acids (24%), and sulfate (8%). Total carbohydrates were determined by the phenol-H2SO4 method using fucose as the standard. Uronic acids were determined by the carbazole-H2SO4 method using D-glucuronic acid as the standard. The sulfate contents were measured by ion chromatography. The main carbohydrates were fucose. Fucoidan content determined by high-performance liquid chromatography was 83% and the molecular weight was 21-kDa. Fucoidan was dissolved in phosphate-buffered saline at a concentration of 30 mg/mL.

Inhibition assay of HCV replicon cells by fucoidan
Fucoidan was added to Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum of HCV subgenomic replicon cells FLR3-1 (genotype Ⅰ b, Con-1;)[20] at a final concentration of 62.5, 125, 250, 500, 1000, 2000, and 3000 μg/mL. FLR3-1 cells were established from human hepatoma HuH-7 cells[21] by stable transfection with subgenomic selectable RNA in which the encoding HCV structural proteins were replaced by the firefly luciferase gene, the internal ribosome entry site of the *Encephalomyocarditis* virus, and the neomycin phosphotransferase gene[22]. After 72 h-incubation, the cells were washed in phosphate buffered saline and lysed in reporter lysis buffer (Promega, Madison, WI). Lysates were assayed for luciferase activity with the luciferase assay system (Promega) using the instructions provided by the manufacturer. With this HCV subgenome, the efficiency of subgenomic HCV expression could be estimated by measuring luciferase activity in the replicon cells.

Measurement of cell viability
Cell viability was measured using the cell proliferation reagent, WST-8 (Wako Pure Chemicals, Osaka, Japan). This method relies on mitochondrial dehydrogenase cleavage of WST-8 to formazan dye to estimate the level of cell viability. Briefly, FLR3-1 cells were incubated in a 96-well microculture plate. After 24 h incubation, fucoidan was added to the cells at various concentrations. After 72 h culture, WST-8 (5 μL) was added for the last 4 h of incubation and absorbance at 450 nm was measured using an automated microplate reader. WST-8 solution was added to the media-only wells to correct for background.

Patients
Table 1 lists the characteristics of the patients. The subjects included in the study were 15 patients with chronic liver diseases (7 men and 8 women; age, 66.1 ± 11.1 years; mean ± SD, range, 42-86), who visited the Nakasonekazu Medical Clinic. This study was carried out as an open-label study. All patients were infected with HCV genotype Ⅰ b, with a serum viral load in excess of 10^5 copies/mL. Nine patients had been diagnosed with CHC, 4 with HCV-related LC, and 2 with HCV-related cirrhosis and HCC.

Table 1 Characteristics of patients

Patient No.	Age (yr)	Gender	Diagnosis	Previous IFN therapy	Other medications
1	73	F	LC	Not eligible	Glycyrrhizin
2	78	F	LC	Not eligible	Glycyrrhizin
3	49	M	LC	Not eligible	Glycyrrhizin
4	72	M	LC + HCC	Not eligible	Glycyrrhizin
5	66	M	LC + HCC	Not eligible	Glycyrrhizin
6	70	M	LC	Not eligible	None
7	70	F	CHC	Not eligible	Glycyrrhizin
8	86	F	CHC	Not eligible	Glycyrrhizin
9	55	M	CHC	Intolerant	None
10	69	M	CHC	Non-responder	Glycyrrhizin
11	71	M	CHC	Non-responder	Glycyrrhizin
12	68	F	CHC	Non-responder	Glycyrrhizin
13	61	F	CHC	Non-responder	Glycyrrhizin
14	62	F	CHC	Non-responder	None
15	42	F	CHC	Non-responder	None

M: Male; F: Female; LC: Liver cirrhosis; CHC: Chronic hepatitis C; HCC: Hepatocellular carcinoma; IFN: Interferon.

Eight patients were not eligible for IFN treatment because of LC, complication (depression), or advanced age. Seven patients had received IFN therapy in the past. Six patients were non-responders to IFN and 1 discontinued therapy because of side effect (depression). All patients assessed the tolerability as excellent.

During fucoidan treatment, 11 patients received a glycyrrhizin preparation. Fucoidan (provided by Kanehide Bio Co., Okinawa, Japan) was given orally as capsules containing 166 mg of dry extract from *C. okumuranus Tokida* per capsule in a dose of five capsules daily for 12 mo. Informed consent was obtained from all patients enrolled in the study, after a thorough explanation of the aims, risks, and benefits of this therapy.

Test parameters

The outcome parameters included the course of alanine aminotransferase (ALT), aspartate aminotransferase (AST), quantitative HCV RNA levels, subjective symptoms associated with CHC, LC, and HCC (such as fatigue, abdominal discomfort, depression, and dyspepsia), safety, and compliance. Data on all clinical parameters were documented at each visit. HCV RNA levels were determined using the AMPLICOR GT HCV Monitor test (Roche Diagnostics, Basel, Switzerland), which has a lower limit of quantitation of 0.5 kIU/mL at a linear range up to 850 kIU/mL.

Statistical analysis

Data are expressed as mean ± SD. The results of biochemical tests and HCV RNA levels were compared by the Student's *t* test. A *P* < 0.05 was considered significant.

RESULTS

Fucoidan suppresses HCV replication

To assess the effects of fucoidan on intracellular replica-

Figure 1 Anti-hepatitis C virus effects of fucoidan in hepatitis C virus replicon cells. Luciferase (LUC) activity (a marker of replication level) and cell viability of FLR3-1 cells, which constitutively express hepatitis C virus replicon, were measured in the presence of various concentrations of fucoidan. LUC and WST-8 assays were performed in triplicate. Data are mean ± SD.

tion of the HCV genome, HCV subgenomic replicon cells FLR3-1 were cultured in the presence of various concentrations of fucoidan in the medium. The luciferase activities of the FLR3-1 cells showed a concentration-dependent suppression of replication of HCV replicon by fucoidan. The WST-8 assay showed that fucoidan had negligible effect on cell viability (Figure 1). These results suggest that fucoidan inhibits HCV replication but does not have cytotoxic effects.

Effect of fucoidan therapy on HCV RNA and alanine aminotransferase levels

Changes in HCV RNA and serum ALT levels in patients treated with fucoidan are shown in Figure 2. The mean HCV RNA for the 15 patients was 736 ± 118 kIU/mL (range, 100-850 kIU/mL) before fucoidan therapy. As shown in Figure 2A, fucoidan tended to reduce the mean HCV RNA level with time relative to the baseline, with significant falls registered at 8-10 mo of treatment. However, HCV RNA increased after 11 and 12 mo. Biochemical tests showed that the mean serum ALT level, but not AST, correlated with the mean HCV RNA level, although the decrease in ALT level was not significant relative to the baseline (Figure 2B). Whereas the above changes were not associated with improvement in clinical symptoms in every patient, none of the patients showed progression of LC or adverse events.

DISCUSSION

It is estimated that 170 million people worldwide are infected with HCV[3], and some 2 million (1%) of these reside in Japan[23]. Of the HCC cases in Japan, around 80% are caused by HCV infection. The increase in the number of HCC patients contributes to the increase in total deaths in Japan from HCC. This trend is expected to continue until 2015[23]. The general strategies followed in the treatment of CHC include eradication of HCV and suppression of hepatitis.

Figure 2 Effects of treatment with fucoidan on hepatitis C virus RNA and alanine aminotransferase levels in patients with liver diseases. A: Hepatitis C virus (HCV) RNA levels; B: Serum alanine aminotransferase (ALT) levels. Values are mean ± SD. [b]$P < 0.01$ *vs* pretreatment value.

Sulfated polysaccharides including fucoidan are reported to inhibit the growth of various enveloped viruses[16-18]. Fucoidan is thought to inhibit virus adsorption to the cell surface by binding to the cell surface, with subsequent prevention of cell infection[18]. In addition, fucoidan interacts directly with the envelope glycoprotein on dengue virus type II[17]. In the present study, we demonstrated a novel mechanism of action for fucoidan. Using the HCV replicon system, we demonstrated here that fucoidan inhibits intracellular replication of the HCV genome *in vitro*.

To our knowledge, this is the first clinical study to investigate the effects of fucoidan in patients with liver diseases. The rationale for this study was stimulated by experimental data showing the efficiency of fucoidan in cell cultures. Patients with chronic HCV infection, who were not eligible for, did not respond to, or were intolerant of IFN treatment, were treated for 12 mo with fucoidan at 830 mg/d to investigate the effect of this treatment on HCV RNA level. In Case 6 (baseline HCV RNA 380 kIU/mL), fucoidan treatment successfully eradicated HCV at 9 mo, although HCV RNA was 5 kIU/mL at 10 mo. Thus, fucoidan was effective in lowering HCV RNA level in this study, although its effect was temporary. There was a significant decrease in HCV RNA at month 8, 9 and 10 of fucoidan commencement ($P < 0.01$). However, the level increased later at month 12 to become equivalent to the baseline.

We also measured serum IFNα levels to determine the indirect effect of fucoidan on IFNs, especially whether it increases the antiviral activity of IFNs. However, IFNα could not be detected in the serum of patients treated with fucoidan. Furthermore, fucoidan did not enhance IFNs expression in FLR3-1 replicon cells (data not shown). It has been reported that the protective effect of fucoidan is based on direct inhibition of viral replication and stimulation of both innate and adaptive immune defense functions[24]. We are currently investigating the effect of fucoidan on the host immune system including natural killer cell cytotoxic activity.

Our study has certain limitations. First, the study comprised only a small number of patients, including 6 patients who were known non-responders to IFN therapy. Second, all patients harbored HCV virus genotype I b and 6 had cirrhosis. Thus, at least some patients in this cohort could be classified as likely non-responders to IFN therapy[25,26]. Thus, the selection criteria employed in the present study may have favored a poor response to fucoidan.

The abnormally high levels of ALT tended to decrease temporarily during fucoidan treatment, suggesting a correlation between viral load and indices of hepatic dysfunction. Thus, fucoidan may be effective in the management of HCV-related chronic liver diseases, although long-term clinical improvement was not observed in the present study. Importantly, no adverse events were observed in all patients, similar to the results reported in a previously study on fucoidan[19], suggesting that daily oral administration of fucoidan for 12 mo is safe and tolerable.

There is no doubt that patients who fail to respond to conventional treatments often seek alternative therapies. In conclusion, our study demonstrated that fucoidan from *C. okamuranus Tokida* has HCV replication suppressive effects in a replicon cell system. Furthermore, our relatively small uncontrolled pilot study showed that fucoidan has temporary but beneficial effects on HCV RNA levels in HCV infected patients. The preliminary findings suggest that fucoidan may be a useful health-food additive with antiviral activity to be used in the treatment of chronic liver diseases. To suppress the viral titer as much and for as long as possible, we need to define the daily effective dosage. Further studies on the mechanism of fucoidan-induced HCV inhibition may provide alternative strategies for the design of novel anti-HCV drugs.

COMMENTS

Background

Hepatitis C virus (HCV) is a major cause of chronic liver diseases including chronic hepatitis, cirrhosis, and hepatocellular carcinoma. The standard care

for chronic hepatitis C involves the administration of pegylated α-interferon in combination with the nucleotide analog ribavirin. However, this regimen has limited success rate for genotype Ⅰ and Ⅳ, and unfavorable side effects. Thus, it is important to discover more effective and safer agents to improve the clinical treatment on HCV carriers. Fucoidan, a sulfated polysaccharide, has significant biological activities, such as antiviral and anti-inflammatory effects. Nevertheless, there has been no investigation on the efficacy of fucoidan against HCV infection.

Research frontiers

Natural products have been used for the treatment of various diseases as an alternative to conventional chemical agents. So far, several natural products have been screened for their antiviral effect against various viral infections. Screening of natural potent inhibitors for HCV has also become a research hotspot.

Innovations and breakthroughs

Previous studies have shown the efficacy of natural products against HCV replication in a cell-based HCV replicon system. However, there have been few clinical studies that evaluated the safety and efficacy of these natural products. In the present study, the authors investigated the anti-HCV activity of fucoidan obtained from the *Cladosiphon okamuranus Tokida* cultivated in Okinawa, Japan, both *in vitro* and *in vivo*. This pilot study is the first clinical trial that investigated the effect of fucoidan in patients with HCV-related chronic liver diseases.

Applications

Fucoidan inhibited HCV RNA replication in the HCV replicon assay system. The experimental data on fucoidan efficiency in cell culture stimulated the rationale for clinical study. Oral fucoidan administration resulted in temporary reduction of viral loads of genotype Ⅰ b in patients with chronic HCV infection, who were not eligible for, did not respond to, or were intolerant of interferon therapy. Fucoidan is well tolerated and no serious adverse events were observed in any of the patients. Fucoidan exhibited antiviral properties against HCV both *in vitro* and *in vivo*, and would be expected to become a new strategy for HCV infection. Further controlled clinical trials will be required to confirm the present findings.

Terminology

Fucoidan is a complex sulfated polysaccharide found in the cell walls of several edible brown algae, including *Fucus vesiculosus*. The HCV replicon system replicates a modified HCV genome containing luciferase gene to high levels in human hepatoma cells. The efficacy of subgenomic HCV expression was estimated by measuring luciferase activity in the replicon cells. This system provides a powerful tool for studying virus replication and for screening anti-HCV drugs.

Peer review

The paper studied the effects of fucoidan, a complex sulfated polysaccharide extracted from marine seaweed, on HCV RNA load *in vitro* and *in vivo*. The research is of significance because of the high rate of nonresponders in HCV genotype Ⅰ , which is the predominant strain in Japan. Moreover, antiviral treatment causes frequent, unpleasant and sometimes serious adverse effects, Thus the search for a new treatment modality without serious adverse effects is desirable.

Abstract

AIM: To investigate the relationship between plasma acylated ghrelin levels and the pathophysiology of functional dyspepsia.

METHODS: Twenty-two female patients with functional dyspepsia and twelve healthy volunteers were recruited for the study. The functional dyspepsia patients were each diagnosed based on the Rome Ⅲ criteria. Eligible patients completed a questionnaire concerning the severity of 10 symptoms. Plasma acylated ghrelin levels before and after a meal were determined in the study participants using a commercial human acylated enzyme immunoassay kit; electrogastrograms were performed for 50 min before and after a standardized 10-min meal containing 265 kcal.

RESULTS: There were no significant differences in plasma acylated ghrelin levels between healthy volunteers and patients with functional dyspepsia. However, in patients with functional dyspepsia, there was a negative correlation between fasting plasma acylated ghrelin levels and the sum score of epigastric pain (r = -0.427, P = 0.047) and a positive correlation between the postprandial/fasting plasma acylated ghrelin ratio and the sum score of early satiety (r = 0.428, P =0.047). Additionally, there was a negative correlation between fasting acylated ghrelin plasma levels and fasting normogastria (%) (r = -0.522, P = 0.013). Interestingly, two functional dyspepsia patients showed paradoxically elevated plasma acylated ghrelin levels after the meal.

CONCLUSION: Abnormal plasma acylated ghrelin levels before or after a meal may be related to several of the dyspeptic symptoms seen in patients with functional dyspepsia.

INTRODUCTION

Functional dyspepsia is defined as the presence of dyspeptic symptoms thought to originate in the gastroduodenal region that occur in the absence of any organic, systemic, or metabolic disease that is likely to explain the symptoms[1,2]. To date, functional dyspepsia has been associated with various physiological abnormalities, including delayed gastric emptying[3], altered antro-duodenal motility[4], impaired gastric accommodation[5], visceral hypersensitivity[6], gastric dysrhythmia[7-10]; functional dyspepsia has also been associated with multiple psychiatric and personal factors, such as somatization[11], depression, anxiety[12], and changes in coping skills[13]. However, a number of studies have failed to find associations between dyspeptic symptoms and the putative pathophysiology of functional dyspepsia in patients. The underlying etiology of functional dyspepsia remains unclear.

Ghrelin is the endogenous ligand for the growth hormone secretagogue receptor, and it has potent growth hormone-releasing activity. Ghrelin is predominately produced by endocrine cells in the oxyntic mucosa of the stomach[14,15]. Ghrelin has two subtypes: a deacylated form and an acylated form[16]. The physiologic functions of ghrelin are pleiotropic as follows. First, ghrelin stimulates food intake. An appetite stimulatory effect is associated with both central regulation and peripheral signals[17,18]. Second, ghrelin regulates gastric acid secretion. Ghrelin acts in the central nervous system to stimulate gastric acid secretion[19]. Third, ghrelin induces the migrating motor complex and promotes gastric emptying. Lastly, ghrelin has also been reported to have a gastroprotective effect in the context of the generation of nitric oxide and prostaglandins[20,21].

Given these diverse functions, ghrelin has been hypothesized to play a role in the pathophysiology of functional dyspepsia. The aim of this study was to investigate the role of acylated ghrelin in the pathophysiology of functional dyspepsia. This study measured plasma acylated ghrelin levels of female subjects, before and after a meal; these data were then compared between females with functional dyspepsia and healthy female volunteers. Also, in patients with functional dyspepsia, we determined the correlation between plasma acylated ghrelin levels, symptom scores, and electrogastrogram (EGG) parameters. In addition, patients with functional dyspepsia were divided into two subgroups according to the Rome Ⅲ criteria: patients with postprandial distress syndrome (PDS) and patients with epigastric pain syndrome (EPS). Differences in plasma acylated ghrelin levels between these two subgroups were also evaluated.

MATERIALS AND METHODS

Study subjects

Female subjects between 18 and 60 years of age were recruited from Sep. 2006 to Jan. 2007 at Soonchunhyang University Hospital, Seoul, South Korea. We recruited healthy volunteers by advertisement. Consecutive patients who were diagnosed with functional dyspepsia were invited to participate in the study. To diagnose functional dyspepsia, patients with dyspeptic symptoms thought to originate in the gastroduodenal region were asked to answer a questionnaire based on the Rome Ⅲ functional dyspepsia criteria after the exclusion of organic disease using endoscopic examination. In addition, eligible patients were asked to complete a questionnaire regarding the severity of 10 symptoms; severity was determined using a self-devised scale of absent (0), mild (1), relevant (2), moderate (3), and severe (4). The 10 symptoms were epigastric pain, epigastric burning, upper abdominal discomfort, nausea, upper abdominal fullness, gastric retention, upper abdominal distention, early satiation, vomiting, and belching. According to the predominant symptom, patients were classified as either PDS or EPS. Patients were examined for *Helicobacter pylori (H. pylori)* infection with a rapid urease test (Pronto Dry, Gastrex Corp., Warsaw, Poland) or the ^{13}C-urea breath test (UBiT-IR 300, Otsuka Pharmaceutical Co., Ltd, Tokyo, Japan). The study protocol was approved by the Soonchunhyang University Hospital Institutional Review Board. Written informed consent was obtained from all participants at the time of enrollment.

Study design

This prospective case-control study was designed to elucidate the role of plasma acylated ghrelin levels in the pathophysiology of functional dyspepsia. The primary endpoint was to investigate the difference in the plasma levels of acylated ghrelin between the two investigated groups. The second endpoint was to evaluate correlations between fasting and postprandial plasma acylated ghrelin levels, symptom severity, the EGG parameters in patients with functional dyspepsia. The tertiary endpoint was to examine whether there were any differences in plasma acylated ghrelin levels between patients with PDS and EPS.

Inclusion and exclusion criteria

To be included in the study, patients had to meet the following inclusion criteria: (1) one or more bothersome dyspeptic symptoms, such as postprandial fullness, early satiation, epigastric pain, and epigastric burning, for the last 3 mo, with symptom onset at least 6 mo prior to diagnosis; (2) the ability to cease all medical treatment that could influence the gastrointestinal motility at least 1 wk prior to the test; and (3) informed written consent.

The following exclusion criteria were utilized: (1) subjects who suffered from structural diseases, such as esophagitis, erosive gastroduodenal lesions or ulcers that could explain symptoms; (2) subjects who suffered from systemic diseases, such as diabetes mellitus or thyroid disease; (3) subjects with a history of peptic ulcers or major abdominal surgery; and (4) subjects who were obese, as defined by a body mass index of over 30.

Plasma acylated ghrelin measurement

Fasting blood samples were taken and analyzed for plasma levels of acylated ghrelin, glucose, insulin and growth

Table 1 Baseline subject characteristics

	Healthy volunteers (*n* = 12)	Patients with functional dyspepsia (*n* = 22)	*P* value
Age (yr)	24 (23-34)	46 (23-59)	0.000[1]
Height (cm)	162 (154-167)	160 (150-175)	0.435[1]
Weight (kg)	52.8 (44-58)	55 (45-70)	0.170[1]
Body mass index (kg/m^2)	20.2 (18.1-22.9)	21.2 (17.6-27.3)	0.135[1]
Growth hormone (ng/mL)	0.8 (0.1-3.3)	0.4 (0.01-14.7)	0.339[1]
Insulin (μIU/mL)	8.3 (2.3-14.6)	8.3 (4.0-14.4)	0.639[1]
Fasting blood sugar (mg/dL)	82 (72-97)	88.5 (70-107)	0.026[1]
Helicobacter pylori infection rate (%)	66.7 (8/12)	36.4 (8/22)	0.151[2]

[1]Analysis by Mann-Whitney *U* test; [2]Analysis by Fisher's exact test.

hormone. Postprandial blood samples were obtained fifty minutes after a 10-min meal and analyzed for postprandial plasma levels of acylated ghrelin. For each sample, whole blood was directly drawn into a centrifuge tube that contained 500 U of aprotinin and 1.25 mg of EDTA - 2Na per 1 mL of whole blood. Blood samples in the tubes were immediately centrifuged at 1500 × *g* for 15 min at 4 ℃. Plasma samples were stored at -80 ℃ for later use after immediately adding 100 μL of 1 mol/L HCl per 1 mL of collected plasma. The commercially available human acylated ghrelin enzyme immunoassay kit (Cayman Chemical Co., Michigan, United States) was used to measure the acylated ghrelin levels.

Electrogastrogram

Study subjects visited the office in the morning, after an overnight fast. Three EGG electrodes were connected to the subject's abdomen according to standard method[9,10]. The EGG electrodes were then attached to the Digitrapper EGG recorder (Medtronic Co. WA, United States). A fasting EGG signal was obtained for fifty minutes. After a 10-min break for a standardized meal, the postprandial EGG was also recorded for fifty minutes. Subjects were given a standardized soft diet that contained a total of 265 kcal, composed of 72% carbohydrate, 16% protein, and 12% fat. Nine parameters were measured, namely, the proportions of bradygastria (%), normogastria (%), and tachygastria (%) during the fasting and postprandial periods, the instability coefficient for both periods and the power ratio. The instability coefficient represents the stability of the slow wave and the power ratio represents the fasting electrical power of the slow wave divided by the postprandial electrical power.

Statistics analysis

SPSS software version 17.0 was used for statistical analyses. The Mann-Whitney *U* test was utilized to compare plasma acylated ghrelin levels between healthy volunteers and patients with functional dyspepsia. Fisher's exact test was used to compare the prevalence of *H. pylori* infection between the two groups. In patients with functional dyspepsia, correlation analysis by the Spearman's rho correlation coefficient was performed to assess the correlations between plasma acylated ghrelin levels, symptom scores and EGG parameters.

RESULTS

Subject characteristics

In total, thirty-four female subjects were enrolled. Twelve women were healthy volunteers and twenty-two were patients suffering from functional dyspepsia. Patient baseline characteristics are summarized in Table 1.

The healthy volunteers were significantly younger compared to the patients with functional dyspepsia (*P* = 0.00). The median fasting blood glucose level was significantly higher in patients with functional dyspepsia compared to healthy volunteers (*P* = 0.03), because two functional dyspepsia patients exhibited glucose intolerance. However, no significant differences were observed between the two groups for median growth hormone and insulin levels and body mass index values.

For the assessment of *H. pylori* infection status, thirty participants were tested by upper endoscopy with the rapid urease test, while the remaining four subjects underwent urea breath tests because they had undergone an upper endoscopy within 6 mo preceding study enrollment. *H. pylori* infection rates were 66.7% (8/12) in healthy volunteers, and 36.4% (8/22) in patients with functional dyspepsia. However, the prevalence of *H. pylori* between the two groups was not statistically significant.

The difference in plasma acylated ghrelin levels between healthy volunteers and patients with functional dyspepsia

In healthy volunteers, the median level of plasma acylated ghrelin was 52.2 pg/mL (1.6-228) during fasting and 32.1 pg/mL (1.1-104.2) postprandially. In patients with functional dyspepsia, the median levels of plasma acylated ghrelin during fasting and postprandially were 56.4 pg/mL (25.6-139.1) and 34.2 pg/mL (12.4-141.2), respectively. Interestingly, two patients with functional dyspepsia exhibited a paradoxical increase in postprandial plasma acylated ghrelin levels (Figure 1).

The association between plasma acylated ghelin levels, symptom scores, and electrogastrogram parameters in twenty patients with functional dyspepsia

Correlations between plasma acylated ghrelin levels and the symptom scores of the 10-investigated symptoms: There was negative correlation between fasting plasma levels of acylated ghrelin and total epigastric pain

A Healthy volunteers (*n* = 12)

B Functional dyspepsia (*n* = 22)

Figure 1 Plasma acylated ghrelin levels before and after a meal in healthy volunteers (A) and in patients with functional dyspepsia (B). Bars represent the median values. Note that two patients with functional dyspepsia (*) showed a paradoxical increase in postprandial plasma acylated ghrelin levels.

scores (r = -0.427, P = 0.047) (Figure 2A). In contrast, we found a positive correlation between the postprandial/fasting acylated ghrelin ratio and the total early satiety scores (r = 0.428, P = 0.047) (Figure 2B).

Correlations between plasma acylated ghrelin levels and the nine electrogastrogram parameters: There was a negative correlation between fasting plasma levels of acylated ghrelin and fasting normogastria (%) (r = -0.522, P = 0.013) (Figure 3).

The difference in plasma acylated ghrelin levels between postprandial distress syndrome and epigastric pain syndrome patients

In the thirteen PDS patients, the median plasma level of acylated ghrelin was 58.31 pg/mL (30.53-139.12) during fasting and 35.66 pg/mL (19.61-112.25) postprandially. In the 9 EPS patients, the median plasma level of acylated ghrelin was 49.79 pg/mL (25.56-95.14) during fasting and 32.78 pg/mL (12.35-141.16) postprandially. The

Postprandial plasma levels of acylated ghrelin (pg/mL)	35.66 (19.61-112.25)	32.78 (12.35-141.16)	0.616[1]

[1]Analysis by Mann-Whitney *U* test; [2]Analysis by Fisher's exact test.

DISCUSSION

Ghrelin has two subtypes: deacylated ghrelin, which lacks an acyl group at third serine residue, and acylated ghrelin, which has the acyl modification necessary for noctanoic acid hormonal activity[16]. Although deacylated ghrelin circulates in far greater amounts compared to the acylated form and is involved in cell proliferation and adipogenesis, only acylated ghrelin exhibits physiologic activity and can stimulate growth hormone release and food intake[22-25]. Therefore, we focused our investigation on acylated ghrelin.

In a study by Takamori *et al*[26] that focused on two age-matched groups, the authors found that fasting levels of deacylated ghrelin were significantly lower in patients with functional dyspepsia compared to controls; however, they reported that both fasting and postprandial levels of acylated ghrelin and postprandial levels of deacylated ghrelin were similar in the two groups. Consistent with these findings, our study did not show any differences in either fasting or postprandial plasma acylated ghrelin levels between healthy volunteers and patients with functional dyspepsia. These results suggest that plasma acylated ghrelin levels may not be directly associated with the pathophysiology of functional dyspepsia.

Plasma acylated ghrelin levels differ significantly in males and females. A study by Akamizu *et al*[16] showed that fasting levels of acylated, but not deacylated ghrelin, in female subjects were higher compared to males after adjustment for body mass index. For this reason, we limited our study to female participants.

H. pylori infection was more prevalent in the healthy volunteers compared to the patients with functional dyspepsia in our study; however, the difference in prevalence was not statistically significant. Although the prevalence of *H. pylori* infection in Korea has been decreasing from 66.9% in 1998 to 59.6% in 2005[27,28], it is still high even in asymptomatic adult subjects. This could be the reason why *H. pylori* was present more in the healthy volunteers in our study.

In our study, fasting plasma acylated ghrelin levels ranged from 1.61 to 227.98 pg/mL and postprandial plasma acylated ghrelin levels ranged from 1.09 to 141.16 pg/mL. Interestingly, plasma acylated ghrelin levels vary more than 100-fold between the extremes.

Most studies have reported the plasma levels of total ghrelin between 300 and 800 pg/mL[19]. Low total plasma ghrelin levels during fasting are associated with insulin resistance, hypertension, and type 2 diabetes[29]. Plasma ghrelin levels rise before the meal and sharply decline as soon as eating commences[30]. The surge of ghrelin levels before the meal is similar to the increase of gastric acid that occurs in the cephalic phase. Plasma ghrelin levels do not begin to recover until thirty minutes after a meal. This delayed recovery suggests that the mechanism for immediate intragastric inhibition of ghrelin release is not present in the stomach, but is instead associated with feedback inhibition, either *via* the release of an intestinal hormone or by insulin release in conjunction with food intake[31]. Interestingly, in our study, postprandial plasma acylated ghrelin levels were paradoxically higher compared to fasting levels in two individuals. Test repetition confirmed these results. One individual had a fasting ghrelin level of 95.1 pg/mL with a postprandial ghrelin level of 141.2 pg/mL. In the other individual, the fasting and postprandial plasma ghrelin levels were 41.1 pg/mL and 46.4 pg/mL, respectively. Both individuals listed epigastric pain and burning sensations as their main symptoms. These results suggest that an abnormal acylated ghrelin response after a meal may be one of the mechanisms involved in the pathophysiology of functional dyspepsia. Further study including more subjects will be needed to confirm this hypothesis.

A study by Shinomiya *et al*[32] revealed that the fasting levels of plasma acylated ghrelin correlated with subjective symptoms of functional dyspepsia in female patients. Similarly, we observed that plasma acylated ghrelin levels were associated with symptom scores and several EGG parameters. First, there was a negative correlation between fasting plasma acylated ghrelin levels and total epigastric pain scores (*r* = -0.427, *P* = 0.047). Therefore, patients with higher plasma levels of acylated ghrelin before the meal suffered from less epigastric pain. Taking into consideration a previous report showed that basal gastric acid secretion was normal in patients with functional dyspepsia[33],the relationship between higher fasting

plasma levels of acylated ghrelin and decreased epigastric pain appear to result from a gastroprotective effect exerted by ghrelin on the gastric mucosa[19-21]. Second, we found a positive correlation between the ratio of acylated ghrelin level (i.e., the postprandial plasma acylated ghrelin level divided by the fasting plasma acylated ghrelin level) and the total early satiety scores (r = 0.428). Thus, blunted ghrelin decreases after the meal were associated with higher early satiety scores. Our results suggest that abnormal responses following a meal might play a role in the impairment of gastric accommodation. Third, we report a negative correlation between fasting plasma acylated ghrelin levels and fasting normogastria (3 cpm) (%). Accordingly, in patients with functional dyspepsia, higher fasting plasma acylated ghrelin levels were associated with fasting gastric dysrhythmia. Gastric dysrhythmia is reported in 40%-50% of patients with dysmotility-like dyspepsia[7,8]; also,abnormal myoelectric activity of the stomach is associated with dyspeptic symptoms, especially nausea and vomiting[9,10]. Further study will be required to evaluate the relationship between fasting plasma acylated ghrelin levels and fasting gastric dysrhythmia.

A study by Shindo *et al*[34] showed that fasting plasma levels of acylated ghrelin in PDS patients were significantly lower compared to healthy volunteers; these levels also tended to be lower compared to EPS patients. However, in our study, no significant differences were observed in either the fasting or postprandial plasma levels of acylated ghrelin between PDS and EPS patients. Interestingly, the two patients who exhibited paradoxical increases in postprandial plasma acylated ghrelin levels had EPS.

The limitations of our study should be noted. These limitations include the small sample, which permitted only the use of non-parametric tests in the statistical analysis. Also, the study group and the control group were not age-matched. Although plasma ghrelin levels are not known to change with age, age may be important factor for this kind of functional study. Additionally, the high level of *H. pylori* infection in our participants was not ideal. However, *H. pylori* infection has no direct relationship to the diagnostic criteria for functional dyspepsia[2]. Further, although a study by Isomoto *et al*[35] showed that the fasting levels of total ghrelin in *H. pylori*-positive patients were significantly lower compared to *H. pylori*-negative patients, the relationship of the plasma acylated ghrelin levels to *H. pylori* infection status has not been evaluated to date. Another factor that was not taken into account was the phase of the participants' menstrual cycles. This is potentially an important variable to control for because a study from De Souza *et al*[36] found that fasting ghrelin plasma concentrations were at least 85% greater in subjects with exercise-associated amenorrhea. Finally, as approximately one third of ghrelin is produced in extra-intestinal organs such as the pancreas and the hypothalamus[14,15], further studies measuring exclusively gastric ghrelin levels are needed.

In conclusion, although no significant differences in plasma acylated ghrelin levels between healthy volunteers and patients with functional dyspepsia were observed, we found that abnormal plasma acylated ghrelin levels before and after the meal may be related to several dyspeptic symptoms in patients with functional dyspepsia. We also observed a paradoxical increase in postprandial plasma ghrelin levels in two patients with EPS, suggesting that abnormal plasma acylated ghrelin levels might be involved in the pathophysiology of functional dyspepsia. Further study in a larger sample size is needed to elucidate the complicated pathophysiology of functional dyspepsia.

COMMENTS

Background
Dyspepsia occurs in approximately 25 percent of the population each year. The most common cause of dyspepsia is functional dyspepsia. However, the pathophysiology of functional dyspepsia is unclear. As ghrelin, an acylated peptide produced predominantly by the stomach, has a well-established role in increasing appetite and food intake and in stimulating gastric emptying and acid secretion, it may play a role in the pathophysiology of functional dyspepsia.

Research frontiers
Ghrelin is the endogenous ligand for the growth hormone secretagogue receptor, which is present on pituitary cells that secrete growth hormone. However, ghrelin exerts many endocrine and extraendocrine biological activities beyond the control of growth hormone secretion. In this study, the authors demonstrate that abnormal plasma acylated ghrelin levels before and after a meal may be related to several dyspeptic symptoms in patients with functional dyspepsia.

Innovations and breakthroughs
The authors found a negative correlation between fasting plasma levels of acylated ghrelin and epigastric pain scores, and a positive correlation between the postprandial/fasting acylated ghrelin ratio and early satiety scores. Further, they also found a negative correlation between fasting plasma acylated ghrelin levels and fasting normogastria. The results regarding the relationship between plasma ghrelin levels and epigastric pain and early satiety scores are interesting.

Applications
By revealing which symptoms in patients with functional dyspepsia is associated with plasma ghrelin levels, this study may represent a future strategy for the research on the relationship between plasma ghrelin levels and the pathophysiology of functional dyspespsia.

Peer review
The authors examined whether fasting and postprandial plasma acylated ghrelin levels exhibited differences in patients with functional dyspepsia compared to healthy volunteers. In addition, they attempted to demonstrate which dyspeptic symptoms and electrogastrogram parameters in patients with functional dyspepsia correlated with fasting and postprandial levels of plasma acylated ghrelin. Overall, this paper is unique despite several weak points.

Abstract

AIM: To study knowledge levels and attitudes of health care providers toward patients with hepatitis C virus infection in Guilan, a northern province of Iran.

METHODS: This cross-sectional study was performed on 239 health care professionals from the Razi Hospital, including doctors, nurses, and operating room technicians. The questionnaires consisted of questions on demographic characteristics, knowledge levels, and attitudes toward hepatitis C patients. The questionnaire was tested in a pilot study and validated by Cronbach's alpha coefficient. Data were analyzed using SPSS16 software.

RESULTS: The mean ± SD knowledge score was 17.43 ± 2.65 (from a total of 22). 51.9% of the participants achieved scores higher than the mean. There was a significant relationship between knowledge score and age ($P = 0.001$), gender ($P = 0.0001$), occupational history ($P = 0.0001$), and educational history ($P = 0.027$). There was also a significant relationship between attitude level and age ($P = 0.002$), gender ($P = 0.0001$), occupational history ($P = 0.0001$), and educational history ($P = 0.035$). Physicians were significantly more knowledgeable and showed more positive attitudes. There was a positive correlation between knowledge and attitude scores ($P = 0.02$).

CONCLUSION: Discriminatory attitudes are common among health care providers toward hepatitis C patients. It is therefore necessary to improve their knowledge level and attitude toward this disease.

INTRODUCTION

Hepatitis C is a hepatotropic viral infection caused by hepatitis C virus (HCV), which is a major cause of acute hepatitis and chronic liver disease. It is estimated that 170 million people worldwide (3% of the world population) are chronically infected with HCV and are under the risk of cirrhosis and liver cancer. Chronic HCV infec-

tion is usually slowly progressive. HCV infection leads to chronic hepatitis in 50% to 80% of individuals[1-5]. The increasing global prevalence of this disease puts extra demands on health care services and increases the likelihood that health care workers (HCWs) will care for, or have personal contact with, people with hepatitis C[6]. Occupational exposure from percutaneous injuries is a substantial source of infection by blood borne pathogens among HCWs. However, studies of HCWs exposed to HCV by a needle stick injury (NSI), or any other percutaneous injury, have found that the incidence of anti HCV seroconversion is 1.8% (0%-7%) on average[7]. Physicians, laboratory technicians, nurses, and dialysis unit personnel are the main HCWs at risk. Nurses are the most at risk group because they have close contact with patients and are more likely to be exposed to a NSI[8].

NSIs are common in our country. In a study in Qazvin, 52.9% of nurses had a history of NSI[9]. Patients with hepatitis C have met with discrimination and stigmatization in the work place, by family members and by members of their communities. In addition, they may face discrimination from HCWs[10,11]. The discriminatory practices of HCWs may result from a lack of knowledge and negative attitudes toward these kinds of diseases, which could interfere with their willingness to treat these patients because of a fear of contracting hepatitis C. In a study by Richmond *et al*[6], most health care workers had sufficient knowledge about hepatitis C; however, some of them showed discriminatory attitudes toward patients with hepatitis C. Until now, little research has been conducted on HCW knowledge levels and attitudes toward people with hepatitis C in Iran. We therefore studied HCW knowledge levels and attitudes toward treating people with hepatitis C as a blood borne disease, to investigate how attitudes can be influenced by education and how this can affect their willingness to treat these patients.

MATERIALS AND METHODS

A cross-sectional study was conducted using a questionnaire that was created and standardized by Richmond *et al*[6] and translated into Persian. The questionnaire was considered by a panel of consulting experts and its validity was documented by a pilot study using a random sample ($n = 20$) drawn from the subgroups to be surveyed in the main study. The sample was calculated as 345 health care workers, based on the positive attitude proportion among the random subgroup (32%) and considering the precision of 0.06 and the type one error of 0.05. The questionnaire's validity and reliability were also confirmed by Cronbach's alpha coefficient (alpha = 0.7). We used this specifically designed questionnaire for the study because no other instrument was identified that explored HCW attitudes toward treating people with hepatitis C in the detail that was required for the current research. The questionnaire consisted of four parts and 49 questions. Seven questions obtained demographic characteristics,

22 questions were used to explore knowledge levels, 10 questions determined attitudes, and 10 questions were designed to determine compassion levels toward hepatitis C patients, willingness to treat hepatitis C patients, their self reported fear of contracting hepatitis C, and their self reported behavior toward injecting drug users. The mean of the total score from a possible score of 22, based on 22 questions, was used as the discriminant level. Scores higher than the mean indicated a good knowledge level and lower than the mean indicated a poor knowledge level[12].

Regarding attitude, participants were asked to what extent they agreed or disagreed (using a five-point Likert scale ranging from "strongly agree" to "strongly disagree") with each of the statements. For the 10 statements, total scores that could be achieved ranged from 10 to 50. Scores between 10 and 30 were considered as negative attitudes and scores higher than 30 were considered as positive attitudes[13,14]. The knowledge level, attitude questions, and self-behavior statements are shown in Table 1. Demographic data containing participants' age, sex, working history (years which health care workers had worked for health care service), occupation (doctor, nurse), needle stick injury (NSI) history, education (participation in education classes on NSI), were registered for each participant. Questionnaires were filled by direct interviews, which were performed by a trained general practitioner from the research team.

Statistical analysis
Data were entered into SPSS 16 software and analyzed by descriptive statistics (i.e., mean, SD, frequency) and comparison means (i.e., one way ANOVA, χ^2 test). A *P* value less than 0.05 was considered statistically significant.

RESULTS

Response rate and demographic data
The mean age of the participants was 33.06 ± 7.72 years and the mean working history was 7.51 ± 6.49 years. The overall response rate was 69% (239 of 345 HCWs). There was no significant difference between the age, sex, occupation, and working history of responders and non-responders. Table 2 presents the demographic data. Overall, 52.3% of the participants reported having a history of NSI with hepatitis C patients.

Nurses (54%) were most likely to have a history of NSI. Most of the HCWs (79.1%) reported that they had received information on hepatitis C patients and NSI (although they did not refer to the type of education they had received). Nurses (85.3%) were significantly more likely to have received training on hepatitis C, while 72.2% of the physicians had received training and operating room technicians (40%) were the least likely to have received training ($P = 0.001$).

Hepatitis C knowledge level and education
Overall, HCW level of knowledge was satisfactory and

Table 1 Hepatitis C knowledge level, attitude and self-reported statement questions in the questionnaire

Hepatitis C knowledge questions (response options: true, false and uncertain)
  Hepatitis C is caused by a virus
  Hepatitis C is caused by bacteria
  Hepatitis C can be spread through close personal contact such as kissing
  Hepatitis C can be spread through sharing injecting equipment, such as needles, tourniquets, spoons, filters and swabs
  Hepatitis C can be spread by mosquitoes
  Hepatitis C is spread through blood-to-blood contact
  Having a medical and/or dental procedure performed in the Middle East, South East Asia or the Mediterranean increases a person's chances of contracting hepatitis C
  Hepatitis C is spread through the air in an enclosed environment (e.g., crowded buses and elevators)
  Sexual transmission is a common way hepatitis C is spread
  Some people with hepatitis C were infected through unsterile tattooing
  Some people with hepatitis C were infected through blood transfusions
  People with hepatitis C should be restricted from working in the food industry
  Hepatitis C can lead to cirrhosis
  Hepatitis C is associated with an increased risk of liver cancer
  Hepatitis C is a mutation of hepatitis B
  A person can be infected with hepatitis C and not have any symptoms of the disease
  There is a pharmaceutical treatment available for hepatitis C
  There is a vaccine for hepatitis C
  HIV is easier to catch than hepatitis C
  An individual can have hepatitis C antibodies without being currently infected with the virus
  People with hepatitis C should restrict their alcohol intake
  Once you have had hepatitis C, you cannot catch it again because you are immune
Attitudes and self-reported behavior statements according to theme (response options: strongly agree, agree, uncertain, disagree and strongly disagree)
  Attitudes and self-reported behavior toward the implementation of infection control guidelines
    When receiving health care, patients with hepatitis C (HCV) should be identified for safety reasons
    Patients with HCV should be given the last appointment for the day (ICG)
    Health professionals who are HCV positive should be discouraged from having contact with patients
    All patients should be tested for HCV before they receive health care
    I deliver the same standard of care to patients with HCV as I do for other patients
    I feel that I do not have the skills needed to effectively and safely treat patients with HCV
    Following infection control guidelines will protect me from being infected with HCV at work
    I often use additional infection control precautions when treating patients with HCV
    I would prefer to wear two pairs of gloves when treating a bleeding person with HCV
    The infection control guidelines necessary to treat patients with hepatitis C would be a financial burden on my practice/ward
  Attitudes and self-reported compassion toward people with hepatitis C
  I feel sorry for people who contracted HCV through a blood transfusion
  I feel sorry for people who contracted HCV through HIV drug use
Attitudes and self-reported willingness to treat people with hepatitis C
  I do not like treating people with HCV
  I am willing to treat people with HCV
  I believe my profession should have central role in the treatment of HCV

HIV: Human immunodeficiency virus; HCV: Hepatitis C virus; ICG: International crisis group.

Education	Yes	189 (79.1)
	No	50 (20.9)

NSI: Needle stick injury.

the mean knowledge score was 17.43 ± 2.65 from a total score of 22. Scores higher than 17.43 indicated a good knowledge level and lower than 17.43 indicated a poor knowledge level. For example, 95.4% of the participants answered the questions about cirrhosis correctly, 97.5% knew that hepatitis C is contracted through blood contact, 95% knew that non-sterile tattoos are also a method of transmission, and 98.3% of HCWs knew that HCV can be spread through sharing injection equipment, such as needles, tourniquets, spoons, filters, and swabs. However, some deficits were identified in their knowledge level. For example, only 37.7% of HCWs answered correctly to the statement: Sexual contact is a common mode of transmission.

Only 54.8% knew that there are effective treatments for hepatitis C, 35.1% did not know, and 10% were not sure about it.

The mean knowledge score of males was 18.78 ±

Table 3 Health care workers' hepatitis C knowledge scores in association with different variables (mean ± SD)

Variables		n	Mean knowledge score (SD)	P value
Sex	Male	47	18.78 (2.12)	0.0001

Professional group	0.0001
NSI history	NS
Education	0.035
Knowledge score	0.0001

NSI: Needle stick injury; NS: Not significant.

2.12 and the mean knowledge score of physicians was 19.26 ± 1.97. Physicians were the most knowledgeable, while technicians were the least knowledgeable group (P = 0.0001). Those who were more than 30 years old were the least knowledgeable group among different professional groups (P = 0.0001) (Table 3). In this study, 55.6% of the HCWs who had received training had a good knowledge score, but only 38% of those who had not received training showed good scores (P = 0.027).

Attitudes and self-reported behaviors

In this sample, 159 HCWs (66.5%) showed negative attitudes (score = 10-30) and 80 HCWs (33.5%) showed positive attitudes (score = 31-50). Males who were over 40 years old and had a working history of more than 10 years were more likely to show positive attitudes toward patients with hepatitis C (P = 0.002 for both) (Table 4). In the physicians group, 55.7% showed positive attitudes and, in the nurses group, 24% showed positive attitudes. Physicians were significantly more positive (P = 0.0001). All of the technicians showed negative attitudes. Those who received training also showed significantly more positive attitudes (P = 0.035).

HCWs who were weak in knowledge were more likely to show negative attitudes and those who were knowledgeable were more likely to show positive attitudes (P =

Figure 1 Pearson correlation between health care workers knowledge levels and attitudes.

0.02. There was a positive correlation between knowledge score and attitude (r = 0.227, Figure 1).

Regarding attitude statements, 95.8% of the HCWs believed that hepatitis C patients should be identified for infection control purposes, 82.8% of the participants indicated that they used additional infection control precautions when they knew patients had hepatitis C; 74.4% were double-gloved when they treated a bleeding person with hepatitis C. 48.5% of the participants indicated that patients with hepatitis C should be given the last appointment of the day.

Compassion toward people with hepatitis C was measured in two statements (Table 1). Among the HCWs, 92.1% felt compassion when hepatitis C was acquired through a blood transfusion, compared with 55.6% when it was contracted through injection drug use. Participants' willingness to care for people with hepatitis C was identified by responses to three questions (Table 1). Among HCWs, 82.8% believed that they liked to treat these patients and 15.5% said that they did not like treating these patients. Regarding attitudes toward intravenous (IV)-drug users, 78.7% showed fear toward IV-drug users, while 77% said that they were worried they might contract a disease from them. 35.6% believed that IV-drug users deserved the disease and 40.2% indicated that they did not want to treat IV-drug users. 26.8% believed that opiates should not be used for pain relief in patients with a history of injection drug use. There was an association between HCW knowledge level and fear of contracting a disease (P = 0.0001) and attitudes toward IV-drug users (P = 0.0001); however, there was no association between knowledge level and willingness to treat these patients. In addition, HCW attitudes toward IV-drug users emerged as a significant issue that affected willingness to treat people with hepatitis C (P = 0.035).

DISCUSSION

The total response rate in the present study was rather

high compared to other studies on this issue[6,11,15]. In the present study, the reasons for not responding included not having enough time and not having enough interest. Some part of not having enough interest may have been because of incomplete knowledge on the issue.

In the current study, 49.4% of physicians and 54% of nurses had a history of NSI and the difference, unlike in Zafar's study[16], was not significant. Vitale *et al*[17] and Wicker *et al*[18] reported a lower rate of NSI history. Perhaps the reason for the high rate of NSI among HCWs was not receiving enough practical education, HCW stress, or carelessness because of an increased workload.

HCWs are currently receiving training about blood borne diseases. In the present study, however, we did not refer to the contents and efficacy of training. Nurses in the current study were most likely to have received training, possibly because of their close contact with these patients and their greater interest in having a correct approach toward them.

In the current study, the mean knowledge level score was acceptable. Physicians were more knowledgeable than other groups. Richmond showed a significant relationship between medical groups and mean knowledge scores: doctors were the most knowledgeable group[6]. In the study by Shehab *et al*[19], the knowledge level of internal medicine residents on hepatitis was suboptimal. The higher knowledge level of physicians was likely because of more advanced and professional education on gastrointestinal and liver diseases.

In the present study, males and HCWs who were more than 40 years old were more knowledgeable. In Richmond's study[6], HCWs who were 30-49 years old were the most knowledgeable and those above 40 were the least knowledgeable. This finding shows that older age and greater experience can be associated with greater knowledge. However, in elders, the efficacy of initial education decreases.

In the present survey, HCWs were insufficiently knowledgeable about the complications of hepatitis C. Sood *et al*[20] showed that more than half of the participants answered correctly to the questions about hepatitis C complications. In a study by Nicklin *et al*[21], half of the personnel indicated cirrhosis was caused by hepatitis C and 37% thought it caused liver cancer. In the present study, the knowledge about modes of transmission was also acceptable. In the studies of D'Souza *et al*[11] and van de Mortel *et al*[22], most of the participants indicated that blood transfusion is a major mode of transmission. However, some deficits were seen in HCW knowledge on sexual contact as a mode of transmission for hepatitis C.

In some prospective studies, in which the effect of HCW training on HCV knowledge was investigated, participants who received training showed significant advances in their knowledge levels[23-25]. Zdanuk *et al*[25] showed the same advances after receiving training. However, D'Souza *et al*[11] and Shehab *et al*[19] indicated that education did not produce any advance in knowledge levels. In the current study, education was introduced as an effective agent for developing HCW knowledge. How-

ever, we should not ignore the role of clinical practice as a form of education. For example, in Richmond's survey, while complementary therapists were the group most likely to have been educated about hepatitis C, they were not the most knowledgeable[6]. In addition, in the current study, nurses were the most likely group to have been educated, but were not the most knowledgeable. Therefore, other factors must influence the knowledge level of HCWs. However, we should not deny the fact that the information presented cannot be effective if it has not been repeated and recorded in the mind. In some studies, it has been suggested that one method for getting better results is active and problem-based learning[6,20].

In the present study, attitude scores were significantly different among different groups ($P = 0.0001$). Physicians were the most positive group towards people with hepatitis C and technicians showed negative attitudes. This may be related to the fact that physicians were the most knowledgeable group and the better attitudes of males and elders reflect this, as these groups are mainly composed of physicians. Perhaps the positive attitudes are not related to age or experience.

Education had a significant influence on developing positive attitudes, which was also noted by van de Mortel[22] and Richmond *et al*[6]. However, it should be considered that HCW attitudes on hepatitis C patients might be influenced by the attitudes of colleagues. A problem associated with consulting colleagues is that the information provided could be inaccurate, outdated, or reflect just subjective clinical experiences about people with hepatitis C.

In the current study, most of the participants indicated willingness to treat patients with hepatitis C, as in the studies by Hu *et al*[26] in dentistry students and a study by van de Mortel[22].

The HCWs' approach toward giving opiates to the IV-drug users for pain relief reflects deficits in their understanding of pain management and drug dependence. This also demonstrates the powerful influence of attitude on their clinical behavior. In the present study, some HCWs said that IV-drug users deserved to contract hepatitis C and this attitude was affected by their knowledge level and influenced their willingness to treat patients with hepatitis C. In addition, Richmond *et al*[6] showed that HCW willingness to treat patients with hepatitis C was significantly under the influence of their belief on injection drug users, rather than their knowledge of hepatitis C. This shows the role of social prejudice on self-reported behavior. Access to health services could be difficult for people with hepatitis C because HCWs believe that they are injection drug users[27].

Finally, as we expected, there was a significant correlation between HCW knowledge levels and attitudes ($P = 0.0001$). This finding was also reported in the studies of Richmond[6], Vitale *et al*[17] and van de Mortel[22]. We suggest that occupational experience and fear of contracting hepatitis C can also influence the willingness to treat people with hepatitis C.

This study had the advantage of direct interviews

with the responders, and not just distributing the questionnaires among them. The response rate in the present study (69%) was higher than some other similar surveys[6,11,15]. However, some limitations should be noted. For example, like other similar studies, self-reported behavior was not validated against actual clinical behavior. Self-reported responses may not reflect responders' actual attitudes[6].

In conclusion, we showed that discriminatory behaviors are common among HCWs towards patients with hepatitis C. Attitudes are directly under the influence of knowledge levels; therefore, it is necessary to increase the level and quality of training among HCWs to prevent discrimination and prejudice towards patients with hepatitis C.

ACKNOWLEDGMENTS

COMMENTS

Background

Hepatitis C is a chronic prevalent liver infection worldwide which is caused by a blood borne pathogen (hepatitis C virus, HCV). Occupational exposure due to percutaneous injuries is a source of infection with this pathogen among health care workers. Because this group are in close contact with the patients with hepatitis C their knowledge and attitude toward the disease and the patients is so critical and can influence on their own health and their behavior toward the patients. This issue has not evaluated enough until now.

Research frontiers

In contacting with hepatitis C patients, prejudice and discrimination is so prevalent. The research hotspot is to evaluate health care workers' knowledge toward hepatitis C and its effect on their attitude toward the patients and this way lowering discrimination against the patients through improving the knowledge level among this critical group.

Innovations and breakthroughs

Until now no survey has investigated the association of knowledge and attitude of health care workers toward patients with hepatitis C in Iran, a country with high prevalence of the disease. In most of the previous surveys, the questionnaires were passively distributed among the participants. But the present study has the advantage of direct interviewing with the responders. Also the response rate in this study was much higher than some other similar investigations.

Applications

The present study showed that health care professionals' attitude and behavior toward hepatitis C patients is directly under the influence of their knowledge and education on hepatitis C. So by increasing education on this issue maybe we can do something on the care given to the patients with hepatitis C.

Terminology

Hepatitis C: A viral liver infection caused by hepatitis C virus which can be transmitted by blood. This kind of hepatitis will usually end to chronic liver disease and cause cirrhosis; Knowledge: Mental perception and clearly realizing the information and learning; Attitude: Mental backgrounds which are achieved by experiences and can influence person's reactions and behaviors toward others and have close association with the personality.

Peer review

This is a good study which gives important information which could be used in improvement of the treatment of the hepatitis C patients. The survey reports the knowledge and attitudes of health care worker (HCW) impacting on the care given to patients with HCV. Their findings reflect on the significant relationship between attitude level and knowledge score, and various demographic factors of HCW. The study is well reported and holds significant value (on a regional level) towards the care of HCV patients.

Abstract

AIM: To determine antibiotic resistance of *Helicobacter pylori* (*H. pylori*) in Pakistan and its correlation with host and pathogen associated factors.

METHODS: A total of 178 strains of *H. pylori* were isolated from gastric biopsies of dyspeptic patients. Susceptibility patterns against first and second-line antibiotics were determined and trends of resistance were analyzed in relation to the sampling period, gastric conditions and *cagA* gene carriage. The effect of *cagA* gene on the acquisition of resistance was investigated by mutant selection assay.

RESULTS: The observations showed that monoresistant strains were prevalent with rates of 89% for metronidazole, 36% for clarithromycin, 37% for amoxicillin, 18.5% for ofloxacin and 12% for tetracycline. Furthermore, clarithromycin resistance was on the rise from 2005 to 2008 (32% *vs* 38%, $P = 0.004$) and it is significantly observed in non ulcerative dyspeptic patients compared to gastritis, gastric ulcer and duodenal ulcer cases (53% *vs* 20%, 18% and 19%, $P = 0.000$). On the contrary, metronidazole and ofloxacin resistance were more common in gastritis and gastric ulcer cases. Distribution analysis and frequencies of resistant mutants *in vitro* correlated with the absence of *cagA* gene with metronidazole and ofloxacin resistance.

CONCLUSION: The study confirms the alarming levels of antibiotic resistance associated with the degree of gastric inflammation and *cagA* gene carriage in *H. pylori* strains.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is among the most widespread infectious agents because of its high colonization rate and persistent nature in its host's stomach. Mostly the colonization is silent but overt damage of gastric mucosa occurs in certain cases leading to the development of gastritis, duodenal ulcer (DU), gastric ulcer (GU), gastric cancer (GC) and mucosa associated lymphoid tissue lymphoma. It is believed that CagA toxin is responsible for the underlying virulence mechanism because of its ability to translocate into gastric epithelial cells. In host cells, it binds with cellular SRC homology 2 domain-containing tyrosine phosphatase (SHP-2) protein and subsequently damage of gastric mucosa.

Triple therapy constituting the combination of a proton pump inhibitor or bismuth citrate and two antibiotics such as amoxicillin (AML), clarithromycin (CLR) or metronidazole (MTZ) is the internationally recommended first-line regime to eradicate *H. pylori* in symptomatic patients[1,2]. However, the combination might be delivered concomitantly, sequentially or in the form of a traditional straight course for 10-15 d to attain the highest cure rate[3]. In case of treatment failure, several other antibiotics such as fluoroquinolones and tetracycline (TE) are used as secondary options[3,4]. The increased rates of CLR and MTZ resistance have further compounded the already challenging treatment strategy within the harsh acidic environment of the stomach. Patient compliance has declined to less than 80% due to resistance against one of the antibiotics used in the first-line regime[5,6].

Pakistan is among the countries with high prevalence of *H. pylori* infection. The organism is not only associated with severe clinical outcomes[7] but is also carried by the healthy population. Empirical treatment has always been in practice without examining whether it matches *in vitro* antibiotics susceptibility testing (AST) or not. As a result, patient compliance has diminished up to 70%-75% in the last decade[8,9]. As most of studies from Pakistan are based on the outcome of therapy, information is scanty on the status of AST profiles of local isolates. Previous attempts, some of which are based on alternate AST methods, provide limited information[10,11], while no data is available on AST profiles for second-line options.

The paucity of information on the issue and the key role it plays in controlling *H. pylori* infection led us to conduct the present investigation that not only provides a detailed AST profile of local *H. pylori* isolates against first- and second-line regimes but also analyzes their distribution in various groups of patients. The study also contributes toward the better understanding of the role of *cagA* gene in the evolution of resistance.

MATERIALS AND METHODS

Patients and sampling

A total of 178 *H. pylori* strains isolated from gastroduodenal biopsies were included in this study. Biopsy samples were taken from symptomatic patients (*n* = 450) who underwent gastroduodenal endoscopy at Medical Unit Ⅱ, Civil Hospital, Dow University of Health Sciences, Karachi, from March 2005 to November 2008. They were grouped as non ulcerative dyspepsia (NUD), gastritis, GU and DU on the basis of endoscopic findings. Patients with previous treatment history for *H. pylori* infection and/ or GC were excluded. Samples were collected in 20% sterile glucose solution, transported in ice, and processed within two hours of collection. The study was conducted upon approval from the ethical review board of the University of Karachi, Pakistan.

Molecular diagnosis

Genomic DNAs were extracted from crushed tissue samples by SDS-PK method[12] (Khan, 2006 No. 354). Molecular diagnosis for the presence of *H. pylori* was conducted by polymerase chain reaction (PCR) targeting the *16SrRNA* gene as described previously[13]. Samples that were found positive with the *16SrRNA* gene of *H. pylori* were further examined for the presence of the *cagA* gene by PCR using primers designed for the entire 3' repeat conserved region. Amplification was performed at 35 cycles of 95 ℃ for 1 min, 52 ℃ for 1 min, and 72 ℃ for 1 min with a final extension of 7 min at 72 ℃[14]. A segment of human β-globulin gene was amplified as the internal control.

Isolation and identification of Helicobacter pylori strains

For the isolation of *H. pylori,* biopsy samples were crushed with the help of a sterile disposable tissue homogenizer and inoculated on Columbia Blood Agar (Oxoid, United Kingdom) containing 7% laked horse blood (Oxoid, United Kingdom) and *H. pylori* selective supplement Dent (Oxoid, United Kingdom). Plates were incubated at 37 ℃ for 5 d under microaerophilic conditions using a Campygen gas generating kit (Oxoid, United Kingdom). Suspicious small dew drop colonies were subjected for morphological and biochemical identification.

For further confirmation, genomic DNA was extracted and subjected to PCR analysis for the *16SrRNA* gene of *H. pylori* per the above-mentioned protocol.

Determination of minimum inhibitory concentrations of antibiotics

Susceptibility patterns of *H. pylori* isolates was determined against a battery of antibiotics including MTZ, AML, CLR, DA, TE, ofloxacin (OFX) and erythromycin (E). Various concentrations of antibiotics were added to Mueller-Hinton agar containing 5% old sheep blood (SBMHA). Bacterial suspensions were prepared in sterile phosphate buffered saline (PBS) with density equivalent to 3 McFarland's turbidity standard. Ten microliters of each strain was spotted on the plates and incubated for 72 h under microaerophilic conditions. The lowest concentration of antibiotic able to inhibit visible bacterial growth was considered as minimum inhibitory concentrations (MIC). Results were interpreted according to standard criteria[15].

Figure 1 Prevalence of *Helicobacter pylori* resistance to first-line drugs. Dotted box represents the distribution of resistant strains at different minimum inhibitory concentrations (MICs). MIC breakpoints were ≥ 8 μg/mL (A), ≥ 1 μg/mL (B) and ≥ 2 μg/mL (C). S: Sensitive; R: Resistant.

Mutant selection assay

To determine the role of *cagA* gene in the emergence of resistance, two *cagA*+ and two *cagA* strains were subjected to mutant selection assay. A total of 1.2×10^{6}-1.5×10^{6} colony forming units (CFU) of bacterial strains suspended in PBS was spread over SB-MHA plates contain-

ing varying concentrations of antibiotics and incubated for 72 h at 37 ℃ under microaerophilic conditions. Frequency of resistant mutants was determined as the CFU of each strain grown on antibiotic supplemented plates divided by the starting inocula[16].

Statistical analysis

Statistical analyses were performed by PASW statistics 18 (SPSS Inc., Chicago, IL, United States). Pearson's χ^2 test was applied to compare categorical data. Linear regression was applied to correlate the frequency of resistance with *cagA* gene. A *P* value of < 0.05 was considered statistically significant.

RESULTS

Antibiotic susceptibility profile

Out of 450 dyspeptic patients, 201 (45%) were found positive for *H. pylori* by PCR and 178 (40%) by culture. AST profile of 178 *H. pylori* strains revealed high levels of resistance against the first-line regime. A total of 149 (84%) were found to be resistant (MIC ≥ 8 μg/mL) to MTZ. As shown in Figure 1A, 34 (19%) strains had MIC 16 μg/mL, 16 (9%) had 32 μg/mL, 27 (15%) had 64 μg/mL, 12 (7%) had 128 μg/mL and 35 (20%) had MIC 256 μg/mL whereas 27 (15%) isolates were inhibited at boarder-line concentration 8 μg/mL. In case of CLR, 64 (36%) strains showed resistance with MICs ≥ 1 μg/mL. The highest MIC 32 μg/mL was observed only in 4 (2.2%) isolates while 25 (14%) had MIC 2 μg/mL (Figure 1B). Sixty six (37%) strains showed resistance to AML with MICs ≥ 2 μg/mL. Surprisingly, 44 (24.7%) strains exhibited MIC 8 μg/mL (Figure 1C).

Emergence of resistance against first-line therapy led us to investigate the susceptibility patterns of antibiotics usually given as second-line treatment options, such as TE, fluoroquinolones and clindamycin (DA). Data analysis shows an evenly distributed pattern of DA activity with MICs ranging from 0.25 to 32 μg/mL (Figure 2A). Resistance to TE was found in 21 (12%) strains. MIC 4 μg/mL was observed in 15 (8.4%) strains and 8 μg/mL in 7(3.9%) strains (Figure 2B). As shown in Figure 2C, a total of 33 (18.5%) strains were resistant to OFX. MIC of OFX was 2 μg/mL and 4 μg/mL for 21 (11.8%) and 12 (6.7%) strains respectively. We further analyzed the rate of multidrug resistance (MDR) in our studied population. A total of 46 (26%) of the isolates were resistant to two antibiotics i.e. MTZ and AML whereas 62 (35%) were resistant to MTZ and CLR. MDR isolates who were resistant to all first-line antibiotics (R-phenotype; MTZ[r]CLR[r]AML[r]) were 20 (11%). Of these 7 (4%) were also resistant to tetracycline (R-phenotype; MTZ[r]CLR[r]AML[r]TE[r]) as shown in Figure 2D.

Correlation of resistance with demographic and disease factors

We next examined whether the proportion of strains showing antibiotic resistance were increased over time or not. For the purpose, the strains were divided into four groups; 2005 (*n* = 24), 2006 (*n* = 55), 2007 (*n* = 73) and

Figure 2 The prevalence of *Helicobacter pylori* resistance to second-line drugs. Dotted box represents the distribution of resistant strains at different minimum inhibitory concentrations (MICs). MIC breakpoints were ≥ 1 μg/mL (A), ≥ 4 μg/mL (B) and ≥ 2 μg/mL (C); D: Distribution of multidrug resistant strains. AML: Amoxicillin; CLR: Clarithromycin; MTZ: Metronidazole; TE: Tetracycline. S: Sensitive; R: Resistant.

2008 (n = 26) according to the year of sample collection. In general, a significantly progressive trend was only observed in CLR resistance from 32% (n = 8) in 2005 to 35% (n = 19) in 2006, 37.5% (n = 27) and 38% (n = 19) in 2008 (P = 0.004). On the contrary, MTZ resistant strains went down by year from 72% (n = 17) in 2005 to 69% (n = 38) in 2006, 68% (n = 50) in 2007 and 65% (n = 17) in 2008. However AML and OFX resistance remained steady with the rates of approximately 37% and 19% throughout the study period whereas overall resistance rates of TE were 10% (n = 2) in 2005, 13% (n = 7) in 2006, 12% (n = 9) in 2007 and 11% (n = 3) in 2008 (Figure 3A).

Comparative analysis was also performed according to the endoscopic findings of each patient from which *H. pylori* strains were isolated. Out of 178, a total of 25 strains were isolated from NUD cases, 89 gastritis cases, 26 GU cases and 38 from DU cases. Our findings indicate that AML and OFX resistance rates were more common in gastritis patients at 48% (n = 43) (P = 0.005) and 22% (n = 20) of cases (P = 0.08) respectively. In contrast, respective resistance rates of AML and OFX were 31%

(n = 8) and 19% (n = 5) in GU and 16% (n = 6) and 21% (n = 8) in DU patients while no OFX resistant strain was found in NUD group. In case of MTZ, resistance rate was significantly higher among the patients with damaged mucosa such as gastritis (90%), GU (100%) and DU (92%) compared with NUD cases (70%) (P = 0.001). CLR resistance was observed in 53% (n = 13) of NUD, 20% (n = 18) gastritis, 18% (n = 4) GU and 19% (n = 5) of DU cases (P = 0.000) as shown in Figure 3B.

Correlation of drug resistance with cagA gene

The *cagA* genotypes of *H. pylori* usually correlate with the severity of disease; therefore, we determined the relationship of *cagA* gene with the susceptibility profile in local isolates. In this study 83 out of 178 (47%) *H. pylori* strains carried the *cagA* gene. The percentage of *cagA*+ strains was 49% (n = 44) among patients with gastritis, 69% (n = 18) GU and 60% (n = 23) DU whereas only 8% (n = 2) of the strains isolated from NUD cases carried this gene. Due to the low frequency of *CagA*+ strains in NUD cases, further analysis was only based only on a total of 153 strains which were isolated from gastritis, GU and DU

Figure 3 The trend analysis antimicrobial drug resistance in *Helicobacter pylori* strains (*n* = 178). A: From 2005 to 2008, significant increase in clarithromycin resistance was observed by linear regression (*P* = 0.004); B: Correlation of drug resistant strains in various groups of patients. Significant distribution of metronidazole (*P* = 0.001), clarithromycin (*P* < 0.000) and amoxicillin (*P* = 0.005) resistance was observed by Pearson's χ^2 test. NUD: Non ulcerative dyspepsia; GU: Gastric ulcer; DU: Duodenal ulcer.

Figure 4 The correlation of antimicrobial drug resistance with *cagA* gene. A: Rate of drug resistance in *Helicobacter pylori* (*H. pylori*) strains carrying (*n* = 81) and devoid of (*n* = 72) of *cagA* gene. Statistical differences were observed by Pearson's χ^2 test. To determine the effect of cagA carriage on the development of resistance, cagA[+] (*n* = 2) and cagA[-] (*n* = 2) *H. pylori* strains were exposed to the increasing concentrations of metronidazole (B) clarithromycin (C) and ofloxacin (D). Bacterial growth was monitored at different concentration of antibiotic and frequencies of resistant mutants were determined as the colony forming units of *H. pylori* strain divided by the starting inocula.

cases. Of these, 81 (53%) were *cagA*[+] and 72 (47%) were *cagA*[-]. Analysis of the drug resistance indicates the lower prevalence of OFX (11%, *n* = 9), MTZ (83%, *n* = 67) and AML (25%, *n* = 20) resistance in *cagA*[+] strains compared with 22% (*n* = 16), 100% (*n* = 72) and 32% (*n* = 23) in *cagA*[-] strains respectively (Figure 4A). In contrast, CLR resistance was more prevalent in *cagA*[+] strains (43%, *n* = 35) than in *cagA*[-] (33%, *n* = 24). The analysis indicates a possible link between *cagA* gene and the development of drug resistance.

To determine whether the rate of acquisition of antibiotic resistance varies between *cagA*[+] and *cagA*[-] strains, we exposed selected strains to increasing concentrations of MTZ, OFX and CLR. Bacterial growth was monitored at each concentration of antibiotics and frequency of resistant mutants was determined as the CFU of *H. pylori* strain divided by the starting inocula. We observed that *cagA*[-] strains were able to mutate more frequently under the selective pressure of MTZ since they were able maintain their frequencies even after the exposure of 6 × MIC of MTZ (r^2 0.9966, *P* = 0.0374). In contrast, more than 1 $\log_{10}$ decrease in bacterial growth was observed in *cagA*[+] strains with increasing concentrations of MTZ (Figure 4B). Similarly *cagA*[-] strains maintained their frequency in the increasing concentration of OFX (r^2 = 0.9966, *P* = 0.0374) whereas a sharp decline was observed in the development of resistant mutants of *cagA*[+] strains (Figure 4D). However, no significant difference was observed in the case of clarithromycin (Figure 4C).

DISCUSSION

H. pylori is often neglected for antimicrobial susceptibility testing because of its complex growth requirement and low recovery rate by bacterial culture. Increasing reports of treatment failure necessitate surveillance studies to analyze the trend of drug resistance especially in developing countries where MDR is quite common in other bacterial species. To determine the trend of antibiotic resistance in Pakistan, we conducted a 4-year longitudinal study comprised of 178 *H. pylori* strains. AST profile revealed high levels of resistance against the first-line regime including MTZ (84%), CLR (36%) and AML (37%). Our results and those from recently published papers from other countries show comparable prevalence rates; for example 33% resistance to AML was observed in the United States[17] whereas MTZ and CLR resistance rates were 31% and 33% in Ireland[18], 61% and 26% in France[19], 48% and 28% in Saudi Arabia[20], 80% and 45% in India[21], and 77% and 15% in Bangladesh respectively[22]. Moreover the trends of CLR and MTZ resistance were also in agreement with previously published reports[6,23]. In contrast with our observations, available data indicate a low occurrence of such strains in southeast Asian countries such as Malaysia and Taiwan where *H. pylori* is endemic[6,24]. However, the distinct genotypic nature of Southeast Asian strains provides a possible explanation for the differences in resistance profiles compared with rest of the world, including Pakistan.

The global analysis of clinical data clearly indicates that drug resistance to AML, MTZ and CLR has a central role in poor patient compliance to "gold standard" triple therapy to *H. pylori* infection, especially in the case of CLR if the point mutations in peptidyltransferase of 23S *rRNA* gene are responsible to phenotypic behavior[25]. Therefore, Maastricht Ⅲ consensus guidelines proposed not to provide CLR based empirical therapy if primary resistance rates are more than 15%-20% in the respective territory[4]. The present study clearly indicates the upward trend in the primary resistance to CLR in our population with an average of 36% in mono-resistance and 22% in MDR (*R-phenotype*; MTZ[r]CLR[r]AML[r]) strains which provides an possible reason for the poor patient compliance (up to 70%-75%) with CLR based therapies in Pakistan as reported earlier.[8,9] Although MDR strains were equally present in our studied population when compared with the rates in other countries[26,27], they were less prevalent than mono-resistant strains.

Fluroquinolones such as ofloxacin or ciprofloxacin and tetracycline are usually considered as second-line therapy for *H. pylori* infection. In this study, the prevalence of TE resistance was comparable to that of other countries, however resistance to OFX was at a higher level than that seen other countries[18,28]. Mutations in the *gyrA* gene that are responsible for fluoroquinolone resistance have been directly linked with the failure of *H. pylori* eradication[29] therefore the higher rate of OFX resistance is alarming. These antibiotics are generally used to treat gastrointestinal infections in Pakistan; consequently, the resistance occurs in other Gram negative bacteria such as *Salmonella, Shigella* and *Escherichia coli*[30] and therefore the transmission of resistance in *H. pylori* can be anticipated. To combat the situation, broad-spectrum fluoroquinolones such as levofloxacin have been introduced; however, the development of resistance and intense side effects hamper its wide use despite its better compliance rate[31].

Genotypic differences of *H. pylori* directly influence the pathogenesis of infection. Such effects have been widely evidenced with the *cagA* gene carriage however the exact mechanism remains elusive. In this study, the differential prevalence of MTZ and OFX resistance in *cagA*[+] and *cagA*[-] strains clearly indicate the absence of *cagA* gene contributes in the acquisition of resistance which was further evidenced by the differential frequencies of resistant mutants developed with the increasing amount of each antibiotic as previously observed by Taneike *et al*[16] previously. The underlying phenomenon is usually explained by the ability of *cagA*[+] strains to cause intense inflammation which might increase the availability of antibiotics at the site of infection and eventually lead to better eradication of infection. In other words, it describes no direct role of *cagA* gene in antibiotic resistance. However, undermining the hypothesis, we observed that drug sensitive strains were more prevalent in NUD cases, despite of the absence of *cagA* gene, compared to those patients with damaged gastric mucosa. Taken together, the present study suggests that *cagA* gene and the degree

of tissue damage might be two independent factors that affect the drug susceptibility of *H. pylori*.

In summary, we observed that the magnitude of drug resistance in *H. pylori* strains is alarming in Pakistan. The degrees of gastric inflammation and bacterial genotypes are independently implicated in the development of resistance. The study reaffirms the need for both the continuous surveillance for drug resistance and the development of effective prevention and treatment strategies at national and regional levels.

ACKNOWLEDGMENTS

COMMENTS

Background
Eradication of *Helicobacter pylori* (*H. pylori*) is directly associated with symptomatic relief in the patients of gastroduodenal diseases. However, the failure of combination therapy containing two antibiotics and a proton pump inhibitor often results because of antibiotic resistance.

Research frontiers
Pattern of antibiotic resistance in *H. pylori* varies in different settings. However it is yet to determine that how host and pathogenic factors affect the prevalence of resistance.

Innovations and breakthroughs
This study indicates the alarming level of antibiotic resistance among Pakistani strains of *H. pylori* especially the magnitude of clarithromycin resistance is on rise and more commonly observed in non ulcerative dyspeptic patients. We further describe that *cagA* gene carriage and the degree of gastric inflammation are two independent factors affecting the metronizadole and ofloxacin resistance in *H. pylori*.

Applications
It is important to conduct continuous surveillance of antibiotic resistance in *H. pylori*. This study helps to comprehend antibiotic resistance pattern in *H. pylori* that facilitate to developing effective treatment strategy in different groups of patients.

Terminology
Non ulcerative dyspepsia (NUD) is defined as presence of upper gastrointestinal tract symptoms such as stomachache, indigestion and vomiting in patients who did not have damaged gastric mucosa.

Peer review
Overall, the study was well carried out and generally well written. However there are a few areas that needs further clarification mainly in the results section.

Abstract

AIM: To investigate the relationship and molecular features of CD74/macrophage migration inhibitory factor (MIF)/Toll-like receptor 4 (TLR4) in gastric cancer.

METHODS: CD74, MIF and TLR4 expression in the paraffin-embedded sections of gastric cancer from 120 patients were detected by immunohistochemical staining. Knock down of CD74 expression in gastric cancer cell line MKN-45 was performed by lentivirus transduction and detected by Western blotting. MKN-45 cell proliferation assay under the stimulants was measured by the cell counting kit 8 (CCK8) assay and MIF concentration in the culture medium was detected by enzyme-linked immunosorbent assay. Surface staining of CD74 in the MKN-45 cell line under the stimulation of lipopolysaccharide (LPS) was measured by flow cytometry. MIF, CD74 and TLR4 co-localization in the MKN-45 cell line was performed by the immunoprecipitation.

RESULTS: CD74, MIF and TLR4 were found to be expressed in gastric cancer and increased significantly in the advanced stage, and were also associated with lymph node metastasis. Correlation analysis revealed that CD74 was positively correlated with MIF ($r = 0.2367$, $P < 0.01$) and both proteins were also associated with TLR4 ($r = 0.4414$, $r = 0.5001$, respectively, $P < 0.01$). LPS can significantly promote MKN-45 cell proliferation (3.027 ± 0.388 *vs* 4.201 ± 0.092, $P < 0.05$), induce MIF production (54.333 ± 2.906 pg/mL *vs* 29.667 ± 3.180 pg/mL, $P < 0.01$) and cell surface expression of CD74 ($75.6\% \pm 4.046\%$ *vs* $9.4\% \pm 0.964\%$, $P < 0.01$) at LPS concentration of 1 μg/mL compared to medium control. Knockdown of CD74 or using anti-CD74 and MIF antagonist ISO-1 significantly reduced LPS-induced MKN-45 cell proliferation (4.201 ± 0.092 *vs* 3.337 ± 0.087, 4.534 ± 0.222 *vs* 3.368 ± 0.290, 4.058 ± 0.292 *vs* 2.934 ± 0.197, respectively, $P < 0.01$). MIF, CD74 and TLR4 could co-localize in the MKN-45 cell line.

CONCLUSION: Upregulation of MIF, CD74 and TLR4 are associated with increasing clinical stage and provide an opportunity as novel gastric cancer chemoprevention and/or treatment strategy.

INTRODUCTION

CD74 is a transmembrane glycoprotein that associates with MHC Ⅱ, and is an important chaperone that regulates antigen presentation for the immune response. CD74 is expressed at high levels by antigen-presenting cells (APCs), including B cells, monocytes, macrophages and dendritic cells in normal tissues[1,2]. Although cell surface expression of CD74 is low in many cell types, rapid internalization with concomitant re-expression at the cell surface provides a steady state level of CD74-MHC Ⅱ complex at the cell surface that is sufficient for biological function[3]. More recently, CD74 expression has been examined in cell types other than APCs, such as epithelial cells, and is particularly important in the complex immunological mechanisms and in the link between chronic inflammation and carcinogenesis in the gastrointestinal tract[4]. Substantial evidence has demonstrated that CD74 protein is upregulated in cancer cells, indicating its role in tumorigenesis and angiogenesis[5]. The contribution of CD74 to carcinogenesis is multifaceted. High levels of CD74 expression associated with class Ⅱ MHC expression might prevent tumor antigen presentation by blocking the peptide binding cleft and preventing antigenic peptide binding for presentation to T cells, rendering tumors less immunogenic[6]. In addition, CD74 is the receptor for macrophage migration inhibitory factor (MIF), which, when bound to CD74, initiates survival pathways and cell proliferation[7,8] and facilitates adhesion of *Helicobacter pylori* to gastric epithelial cells (GECs)[9,10].

MIF is an upstream activator of innate immunity that regulates subsequent adaptive responses. In addition to its roles in inflammation and immunity, recent studies have shown that MIF contributes to tumorigenesis. MIF is overexpressed in several tumors including breast cancer, gastric cancer, lung cancer, hepatocellular carcinoma, and cervical cancer[11-15]. MIF binding to CD74 might contribute to carcinogenesis in chronic conditions through the upregulation of proinflammatory cytokines, including interleukin (IL)-8, which upregulates CD74 and has its own mechanisms leading to increased proliferation, tumor growth, and angiogenesis[16]. MIF binding to CD74 affects proliferation and cell cycle events, including antagonism of p53, inhibition of retinoblastoma function, and activation of Akt[17]. This combination of properties suggests that MIF may play a pivotal role in tumor biology.

Pattern-recognition receptors such as Toll-like receptors (TLRs) act as sensors that detect microbial infections and induce a proinflammatory response[18]. TLRs are a family of mammalian homologs of the *Drosophila* Toll proteins and they recognize pathogen-associated molecular patterns that are expressed on infectious agents, and mediate the production of cytokines necessary for the development of effective immunity. In mammalian systems, TLR4 confers responsiveness to Gram-negative lipopolysaccharide (LPS), induces cyclo-oxygenase (COX)2, and is important for proliferation and apoptosis in response to gastrointestinal injury[19].

In previous studies, it has been reported that CD74 and MIF are upregulated in gastric cancer[12,20]. However, how CD74 and MIF are elevated in gastric cancer remains unclear. The relationship between MIF/CD74/TLR4 expression by the tumor and clinicopathological factors in gastric carcinoma needs to be further demonstrated. In this study, we examined CD74, MIF and TLR4 expression in gastric cancer and analyzed their correlations with clinicopathological factors. Also, we used the gastric cancer epithelial cell line MKN-45 to confirm that, under LPS stimulation, MIF production and surface CD74 expression increased, thus promoting cell proliferation. These results suggest that the MIF/CD74 pathway may greatly induce gastric tumorigenesis in infection.

MATERIALS AND METHODS

Patients, specimens and immunohistochemistry

One hundred and twenty patients with gastric cancer, who underwent surgery at Xinhua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, China, were included in this study. Prior to sample collection, appropriate permission was granted from the research ethical committee of Xinhua Hospital. The surgical specimens were fixed in formalin and embedded in paraffin before they were archived. For immunohistochemical staining, paraffin-embedded sections were deparaffinized in xylene and hydrated in 95%, 85%, 75% and 50% ethanol sequentially. Antigens were retrieved by heating for 15 min with 10 mmol citrate buffer (pH 6.0) in a microwave oven. The sections were incubated with 3% hydrogen peroxide to quench endogenous tissue peroxidase activity, and normal goat serum was used as the blocking agent (DakoCytomation, Glostrup, Denmark). The sections were then incubated with CD74 monoclonal antibody (mAb) (1/200 dilution; clone LN2; BD Pharmingen) or MIF Ab (1/100 dilution; clone 2A10-4D3; Sigma-Aldrich) or TLR4 antibody (1/100 dilution; clone 76B357.1; Abcam) at 4 ℃ overnight. Affinity-purified goat anti-mouse IgG conjugated with peroxidase (Santa Cruz Biotechnology, Santa Cruz, CA, USA) was used as secondary antibody. The sections were developed using the liquid diaminobenzidine-substrate chromogen system (DakoCytomation). CD74, MIF and TLR4 expression was separately assessed by two observers who were blinded to the clinical data. CD74 expression was evaluated based on Ishigami's classification[12], by which, according to the percentage of positive cells, cases were divided into two groups: negative, CD74-positive cells < 10%, and positive, CD74-positive cells ≥ 10%. MIF and TLR4 staining was evaluated as follows: -: undetectable;

+: weakly positive; ++: moderately positive; and +++: strongly positive.

Cell culture

The gastric epithelial cell line MKN-45 was obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences (Shanghai, China) and maintained in RPMI 1640 medium supplemented with 10% fetal calf serum (FCS), 100 U/mL penicillin and 100 μg/mL streptomycin (Gibco) in 5% CO_2 at 37 ℃.

CD74 shRNA and cell sorting

Four different shRNA sequences for CD74 (NM_00 1025158.1) were purchased (GeneChem, Shanghai, China). These sequences were inserted into the pGCSIL-green fluorescent protein (GFP) plasmid (Takara Bio Inc, Otsu, Shiga, Japan) and transformed in *Escherichia coli* for propagation. Purified shRNA plasmids were then used to generate lentiviral particles by expressing them together with a gag-pol-env-encoding plasmid in a HEK293T packaging cell line. Centrifuged cell culture supernatants that contained lentivirus particles were used to infect MKN-45 cells. On day 5, GFP[+] cells were sorted by FACSAria (BD Biosciences, NJ, USA) to > 98% purity. Cells that had been infected with the lentiviral shRNA that gave rise to the strongest CD74 knockdown (target sequence: GCAT-GAAGCTTCCCAAGCCTC) were cultured and used for further experiments.

Flow cytometry

For surface staining of CD74 in the MKN-45 cell line, cells were harvested and washed with PBS supplemented with 2% FBS. Mouse anti-human FITC-conjugated CD74 and isotype control (BD Biosciences) were used and cultured at 4 ℃ for 30 min, after two washes and detected by flow cytometry (BD Biosciences).

Immunoprecipitation

Two nanograms of recombinant MIF (rMIF) (R&D Systems, Mineapolis, MN, USA) was added to MKN-45 cell lysates, which were rotated for 2 h at 4 ℃. Lysate mixtures were precleared with protein A/G beads (GE Healthcare, Pittsburgh, PA, USA) for 2 h at 4 ℃. MIF was immunoprecipitated using protein A/G beads that were preincubated with anti-MIF mAb (R&D Systems) for 2 h at room temperature. After washing, beads were incubated with the lysate mixture of MIF and cell lysates. Beads were then washed four times and the bound material was eluted for immunoblotting.

Immunoblot analysis

GFP[+] MKN-45 cell lysates or eluted antigens were subjected to 10% SDS-PAGE. Immunoblot analysis was performed by transfer of proteins onto nitrocellulose membranes (Schleicher and Schuell Microscience, Dassel, Germany) using a mini Trans-Blot apparatus (Bio-Rad, Hercules, CA, USA). After 2 h blocking, the membranes were incubated overnight at 4 ℃ with anti-human CD74

(clone EPR4064; Origene, Rockville, MD, USA), anti-human TLR4 (clone 76B357.1; Abcam) specific antibody, and β-actin antibody (Sigma-Aldrich, St Louis, MO, USA). After washing, subsequent incubation with appropriate horseradish-peroxidase-conjugated secondary Antibodies for 1 h at room temperature, and extensive washing, signals were visualized by ECL substrate (Pierce Chemical, Rockford, IL, USA).

LPS and MIF stimulation and proliferation assay

Approximately 10^4 cells/well were grown in 96-well microtiter plates and incubated overnight in 200 μL culture medium. Cells were starved without FCS overnight at 80%-90% confluence and then treated with recombinant human MIF (R&D Systems) and LPS (Sigma-Aldrich) at different concentrations, with or without 2 h pretreatment with ISO-1 [(S,R)-3-(4-hydroxyphenyl)-4,5- dihydro-5-isoxazole acetic acid methyl ester] at 100 nmol (Cal-Biochem, Darmstadt, Germany), or anti-CD74 5 μg/mL (C-16; Santa Cruz Biotechnology) and isotype control (BD Biosciences). Cells without any treatment were used as controls. After 24 h culture, OD was measured using the microplate computer software (Bio-Rad Laboratories) according to the protocol of the CCK8 assay kit (Dojindo, Kumamoto, Japan).

MIF enzyme-linked immunosorbent assay

MKN-45 cells were cultured in 96-well plates and stimulated with the LPS at different concentrations for 24 h. Supernatants from wells were used to quantitate the production of MIF by enzyme-linked immunosorbent assay. The MIF enzyme-linked immunosorbent assay kit was obtained from R&D Systems, and assays were performed according to the manufacturer's instructions.

Statistical analysis

Data are expressed as the mean ± SD. Comparison of any two groups was performed by Student's *t* test, and one-way ANOVA was performed for multiple comparisons. CD74, MIF and TLR4 protein expression related to clinicopathological parameters was tested using the Mann-Whitney *U* test and Kruskal-Wallis ANOVA. The relationship between immunohistochemistry scores for CD74, MIF and TLR4 was explored using Spearman's correlation coefficient. Statistical significance was assumed if the *P* value was < 0.05. All analyses were performed using SPSS v14.0.

RESULTS

Overexpression of CD74, MIF and TLR4 in gastric cancer

We routinely collected tissue specimens from patients undergoing surgical operation of known gastric cancer and cut 4-μm-thick sections to stain for the presence of CD74, MIF and TLR4 in the adjacent sections. We stained a total of 120 specimens. CD74, MIF and TLR4 immunoreactivity was identified on the surface of the tumor cells. Some populations of tumor-infiltrating lymphocytes were

CD74   MIF   TLR4

Figure 1 **Representative sections show CD74, migration inhibitory factor and toll-like receptor 4 staining pattern in gastric cancer in each clinical stage.** Gastric tumor sections stained for CD74 (A, D, G and J), MIF (B, E,H and K), toll-like receptor 4 (TLR4) (C, F, I and L) in each clinical stage, and CD74, Migration inhibitory factor (MIF) and TLR4 staining for the same stage are from the same patient, demonstrating that MIF and its receptor CD74 and TLR4 are expressed in close proximity in the tumor microenvironment. Original magnifications: 200 ×.

also immunopositive for those markers (Figure 1). Positive antigen expression of CD74 was observed in 100 of 120 specimens (81%), with the overwhelming majority of CD74-positive specimens with localization of the marker to the apical and perinuclear region of the cytoplasm (Figure 1A, D, G and J and Table 1). There was no difference in CD74 scores between adenocarcinoma from patients aged above or below 60 years (Table 1, $P = 0.5969$). Also, there was no difference between male and female patients (Table 1, $P = 0.9910$) and cell differentiation ($P = 0.3565$). However, a significant difference in CD74 scores between adenocarcinoma with different clinical stage was observed (Table 1, $P = 0.0141$) and lymph node metastasis ($P = 0.0158$).

Immunohistochemical staining also showed that MIF and TLR4 were primarily localized in the cytoplasm and occasionally on the membrane or nuclei of GECs (Figure 1). The positive staining of MIF and TLR4 was observed in 97 (81%) and 99 (83%) respectively of 120 gastric cancer, and the representative example of positive staining in each stage was shown in Figure 1. Like the CD74 staining, there was no difference in age, sex, and cell differentiation, but there were significant in clinical stage and lymph node metastasis (Table 1).

TLR4 and its correlation with CD74 or MIF in gastric cancer

The function of cell surface CD74 as a receptor for MIF provided the rationale for dual analysis of CD74 and MIF immunoreactivity in gastric cancer. A combined MIF and CD74 epithelial score might have a higher predictive value than either parameter alone. Table 2 shows the distribution of CD74 and MIF epithelial staining. There was a significant correlation between MIF and CD74 epithelial scores in individual adenocarcinomas ($r = 0.2367$, $P < 0.01$). TLR4 engagement by ligands such as bacterial LPS leads to proinflammatory cytokine production. Furthermore, from the correlation analysis, we observed that TLR4 had a significant correlation with CD74 ($r = 0.4414$, $P < 0.01$) and MIF ($r = 0.5501$, $P < 0.01$) (Table 2), which suggests that chronic inflammation might have an important association with gastric carcinogenesis.

LPS induces MIF production and surface CD74 expression in gastric cancer cell line

As with immunohistochemical staining, TLR4, CD74 and MIF were highly correlated with the tumor stage and lymph node metastasis, thus, we sought to determine MIF production or CD74 expression by GECs in response to LPS stimulation. Gastric epithelial cell line

MKN-45 was cultured in 96-well plates and stimulated with LPS (0.1, 0.5, 1 and 5 μg/mL) for 24 h. LPS significantly induced MIF production (54.333 ± 2.906 pg/mL *vs* 29.667 ± 3.180 pg/mL, *P* < 0.01) at a concentration of 1 μg/mL (Figure 2A), suggesting that under conditions of inflammation, such as Gram-negative infection, MIF can be induced. MKN-45 cell line expressed high amounts of TLR4, but LPS stimulation did not significantly induce TLR4 expression (Figure 2B). Although immunohistochemistry confirmed the presence of MIF receptor in gastric tumors, for extracellular MIF signaling to be mediated by CD74 *in vivo*, it must be present on the cell surface. Therefore, we analyzed the MKN-45 cell line with LPS stimulation, to determine whether surface expression of CD74 was present. We detected CD74 by flow cytometry and revealed a detectable but low level of surface CD74 expression. Stimulation with 1 μg/mL LPS for 24 h increased surface expression of CD74 from the basal level of 9.4% ± 0.964% to 75.6 ± 4.046% (*P* < 0.01) (Figure 2C), suggesting that surface CD74 expression by GECs is dependent on LPS stimulation. LPS stimulation can greatly induce MIF and surface CD74 expression and enhance the MIF/CD74 pathway.

LPS induces MIF and CD74 expression increases GEC proliferation

Various reports have shown that MIF or LPS increases proliferation of some cell types[21,22]. We investigated the ability of MIF or LPS to induce proliferation of GECs. rMIF or LPS were incubated with MKN-45 cells for 24 h. Proliferation was measured by nonradioactive cell proliferation colorimetric assay, as used in several recent studies[23]. Standard curves of known numbers of cells were run with each assay to extrapolate cell number from treated samples. As seen in Figure 3B and C, MKN-45 cell proliferation was significantly increased when stimulated with LPS (3.027 ± 0.388 *vs* 4.201 ± 0.092, *P* < 0.01) or MIF (3.160 ± 0.054 *vs* 4.856 ± 0.068, *P* < 0.05) at 1 μg/mL compared with medium control.

To investigate the role of CD74 in the observed proliferation, we used lentivirus shRNA that targeted CD74. Figure 3A shows that the transduction efficiency of MKN-45 cells between the control and CD74 shRNAs was equal, and after sorting, the GFP[+] cells reached 98%. Western blotting showed that CD74 expression was strongly knocked down (Figure 3B). When CD74 expression was knocked down, the proliferation of MKN-45 cells

Figure 2 Lipopolysaccharide stimulation induced migration inhibitory factor and surface CD74 expression in gastric cancer cell line MKN-45. A: MKN-45 cell line was stimulated with lipopolysaccharide (LPS) at the indicated concentration respectively for 24 h, the supernatants were collected and migration inhibitory factor (MIF) concentration was measured by enzyme-linked immunosorbent assay; B and C: MKN-45 cell line was stimulated with or without LPS (1 μg/mL) for 24 h, toll-like receptor 4 (TLR4) (B) and CD74 surface expression was detected by flow cytometry (C, left panel), the mean values of CD74-positive cells were compared between the medium and condition group (right panel). [b]*P* < 0.01 *vs* medium group.

after stimulation by LPS or MIF was greatly inhibited (4.201 ± 0.092 *vs* 3.337 ± 0.087, 4.856 ± 0.068 *vs* 3.160 ± 0.054, respectively, *P* < 0.01) (Figure 3C and D). The same effect was observed when anti-CD74 blocking antibodies were incubated with cells at 2 h before addition of LPS (4.534 ± 0.222 *vs* 3.368 ± 0.290, *P* < 0.01), (Figure 3E). Notably, after anti-CD74 treatment, proliferation levels were decreased to levels similar to those of untreated cells. To investigate further the role of MIF in LPS-induced GEC proliferation, using the MIF specific inhibitor ISO-1, MKN-45 cell proliferation was greatly inhibited (4.058 ± 0.292 *vs* 2.934 ± 0.197, *P* < 0.01) (Figure 3F). These data suggest that LPS stimulated GEC proliferation through the MIF/CD74 pathway.

TLR4 and MIF/CD74 co-localization

CD74 has been suggested to act as a receptor for MIF in several studies. We have shown that GECs express large amounts of CD74, which is upregulated under inflammatory conditions. Consequently, we examined the role of CD74 as a receptor for MIF on GEC by immunoprecipitation and western blotting. rMIF was incubated with MKN-45 cell lysates. MIF was immunoprecipitated by the MIF antibody along with GEC proteins bound to it. Western blotting using anti-CD74 mAb revealed that CD74 was co-precipitated with MIF, and TLR4 was co-precipitated with MIF (Figure 4). These results suggest that TLR4/CD74/MIF can form a complex to promote cell proliferation.

DISCUSSION

Recent data have expanded the concept that inflammation is a critical component of tumor progression. Many cancers arise from chronic irritation and inflammation. It is now becoming clear that the tumor microenvironment, which is largely orchestrated by inflammatory cells, is an indispensable participant in the neoplastic process, fostering proliferation, survival and migration[24,25]. TLRs are evolutionarily conserved transmembrane molecules that help the immune system to recognize pathogen-associated molecular patterns, and TLR4 sensitizes immune cells to bacterial LPS. When stimulated by LPS, many intracellular signaling pathways are activated, and lead to the generation of nuclear factor-κB, which in turn promotes proinflammatory cytokine production and release[26]. The unique biological activities of MIF have the potential to contribute to an *in vivo* microenvironment favoring tumor growth and invasiveness. These functional activities include: tumor suppressor downregulation, COX-2 and prostaglandin E2 upregulation, and potent induction of angiogenesis[27,28]. Recent evidence has suggested another important role for the CD74 molecule in the activation of cell survival pathways. CD74 is a cell receptor for the proinflammatory cytokine, MIF. Although CD74 itself is able to bind MIF, when bound to surface expressed CD44, the CD74-CD44 complex is able to initiate several survival pathways, including the extracellular signal-regulated kinase-1/2-mitogen-activated protein kinase

Figure 3 Lipopolysaccharide stimulation induced migration inhibitory factor and surface CD74 expression in gastric cancer cell line MKN45. A: MKN-45 cells were transduced with control or CD74-specific shRNA, and the percentage of GFP+ cells is shown before or after flow cytometry sorting; B: CD74 expression was measured by western blotting when the MKN-45 cells were infected by control or CD74-specific shRNA; C and D: MKN-45 cells were knocked down for CD74 and stimulated with lipopolysaccharide (LPS) (C) or migration inhibitory factor (MIF) (D) for 24 h; cell proliferation was measured by CCK8; E and F: MKN-45 cells were stimulated with LPS at 1 μg/mL, and blocked with MIF antagonist ISO-1 (E) or CD74 antibody (F) for 24 h, and cell proliferation was measured by CCK8. GFP: Green fluorescent protein.[a]*P* < 0.05, [b]*P* < 0.01.

signaling cascade, and to stimulate cell proliferation by enhanced expression of cyclins and other regulatory factors[29].

It has been reported that CD74 surface expression is increased under inflammatory conditions and during *H. pylori* infection, and the bacterium can also use CD74 as a point of attachment to GECs[30]. The dramatic increase in CD74 expression during infection and the high turnover rate of CD74 suggests that both MIF and *H. pylori* can use CD74 as a receptor. Our data demonstrate that in gastric cancer, TLR4 expression is increased and has a strong association with disease stage and lymph node metastasis. GEC proliferation was significantly in-

creased by LPS stimulation, suggesting that gastric cancer is strongly correlated with inflammation. Similarly, rMIF induced proliferation of GECs in a dose-dependent manner. Proliferation was decreased when CD74 was blocked by knockdown of CD74 gene or with antibodies or MIF was blocked by the antagonist ISO-1.

Immunohistochemical staining showed that CD74, MIF and TLR4 has a strong association with cancer stage, suggesting that CD74, MIF and TLR4 have a role in tumor progression. Ishigami *et al*[12] have reported that CD74 expression in gastric cancer is a useful prognostic marker and is correlated with surgical outcome. McClelland *et al*[13] have observed coexpression of CD74 in close proxim-

Figure 4 Migration inhibitory factor binds to CD74 and toll-like receptor 4 on gastric epithelial cells. r-Migration inhibitory factor (MIF) was mixed with MKN-45 cell lysates and immunoprecipitated with anti-MIF with bound cell proteins. Western blotting analysis with anti-CD74 and anti-toll-like receptor 4 (TLR4). MKN-45 lysates were run as a control in the right lane, and MKN-45 cell lysates immunoprecipitated with isotype control antibody were run in the left lane.

ity to the ligand MIF in non-small cell lung cancer, and have found that coexpression is associated with higher levels of CXC chemokines. In the current study, we also found positive correlation between MIF and CD74 and TLR4 in gastric cancer through correlation analysis. We further showed that CD74, MIF and TLR4 could form a complex, and under LPS stimulation, greatly induced cell proliferation. These findings suggest that TLR4, MIF and CD74 overexpression may be related to the pathogenesis of gastric cancer, and they could become promising therapeutic targets.

In summary, our study demonstrated the positive correlation of CD74/MIF/TLR4 in gastric cancer, suggesting that inflammation, as induced by LPS stimulation, can enhance the CD74/MIF pathway, promoting GEC proliferation and gastric carcinogenesis. Blocking of CD74 or MIF may provide a novel strategy for gastric cancer chemoprevention and/or treatment.

ACKNOWLEDGMENTS

COMMENTS

Background
CD74 is an important chaperone of MHC Ⅱ that regulates antigen presentation for the immune response. It is also expressed on epithelial cells, and is particularly important in the complex immunological mechanisms and in the link between chronic inflammation and carcinogenesis in the gastrointestinal tract. Macrophage migration inhibitory factor (MIF) binding to CD74 might contribute to carcinogenesis in chronic conditions, leading to increased proliferation, tumor growth, and angiogenesis. Toll-like receptor 4 (TLR4) confers responsiveness to Gram-negative lipopolysaccharide (LPS), and is important for proliferation and apoptosis in response to gastrointestinal injury.

Research frontiers
Recent data have expanded the concept that inflammation is a critical component of tumor progression. In a previous study, it has been reported that CD74 and MIF are upregulated in the gastric cancer. However, how CD74 and MIF are elevated in gastric cancer remains unclear. The relationship between MIF/CD74/TLR4 expression by the tumor and clinicopathological factors in gastric carcinoma needs to be further investigated.

Innovations and breakthroughs
In this study, CD74, MIF and TLR4 were found to be expressed in gastric cancer and increased significantly in the advanced stage; they were also associated with lymph node metastasis. Correlation analysis revealed that CD74 was positively correlated with MIF and both proteins were also associated with TLR4. LPS can significantly promote MKN-45 gastric cancer cell proliferation, and induce MIF production and cell surface expression of CD74. Knockdown of CD74 or using anti-CD74 and MIF antagonist ISO-1 significantly reduces LPS-induced MKN-45 cell proliferation. MIF, CD74 and TLR4 can co-localize in MKN-45 cells.

Applications
The study demonstrates the positive correlation of CD74/MIF/TLR4 in gastric cancer, suggesting that inflammation, as caused by LPS stimulation, can enhance the CD74/MIF pathway, promoting gastric epithelial cell proliferation and gastric carcinogenesis. Blocking of CD74 or MIF may provide a novel strategy for gastric cancer chemoprevention and/or treatment.

Terminology
CD74, also known as the invariant chain, participates in several key processes of the immune system, including antigen presentation, B-cell differentiation and inflammatory signaling. Recently, studies have revealed that CD74 is a receptor for macrophage MIF and is upregulated in inflammation, which has the potential to contribute to an *in vivo* microenvironment favoring tumor growth and invasiveness. As a participant in several immunological processes and an indicator of disease in some conditions, CD74 has potential as a therapeutic target.

Peer review
In this study, the authors demonstrated the positive correlation between CD74, MIF and TLR4 in gastric cancer and their association with clinicopathological factors. They revealed that LPS stimulation induced gastric cancer cell proliferation through enhanced MIF production and CD74 expression, and that knockdown of CD74 or using anti-CD74 antibody and MIF antagonist could reduce LPS-induced MKN-45 cell proliferation. This study certainly provides a novel mechanism of gastric carcinogenesis associated with the CD74/MIF pathway. The results suggest that CD74 and MIF could be novel therapeutic and chemopreventive targets in gastric cancer treatment.

Abstract

AIM: To establish a rat ethanol gastritis model, we evaluated the effects of ethanol on gastric mucosa and studied the preventive effects of geranylgeranylacetone on ethanol-induced chronic gastritis.

METHODS: One hundred male Sprague-Dawley rats were randomly divided into 4 equal groups: normal control group, undergoing gastric perfusion of normal saline (NS) by gastrogavage; model control group and 2 model therapy groups that underwent gastric perfusion with ethanol (distillate spirits with 56% ethanol content) by gastrogavage for 4 wk. Low or high doses of geranylgeranylacetone were added 1 h before ethanol perfusion in the 2 model therapy groups, while the same amount of NS, instead of geranylgeranylacetone was used in that model control group. The rats were then sacrificed and stomachs were removed. The injury level of the gastric mucosa was observed by light and electron microscopy, and the levels of prostaglandin 2 (PGE2), endothelin-1 (ET-1) and nitric oxide (NO) were measured by radioimmunoassay and the Griess method.

RESULTS: The gastric mucosal epidermal damage score (EDS; 4.5) and ulcer index (UI; 12.0) of the model control group were significantly higher than that of the normal control group (0 and 0 respectively, all *P* = 0.000). The gastric mucosal EDS and UI of the 2 model therapy groups (EDS: 2.5 and 2.0; UI: 3.5 and 3.0) were significantly lower than that of the model control group (all *P* < 0.01). There was no statistically significant difference between the low-dose and high-dose model therapy groups. The expression value of plasma ET-1 of the model control group was higher than that of the normal control group (*P* < 0.01) and the 2 model therapy groups (all *P* < 0.01). The expression values of gastric mucosal PGE2 and serum NO of the model control group were lower than those of the normal control group (all *P* < 0.05) and the 2 model therapy groups (all *P* < 0.05). The thickness of the gastric mucous layerand the hexosamine content in the model control group were significantly lower than that in the normal control group (all *P* < 0.01) and the 2 model therapy groups (all *P* < 0.05). Scanning and transmission electron microscopy observation showed that in the model control group, the epithelial junctions were vague, the intercellular joints disappeared and damage of the intracellular organelles were significantly worse than those in the normal control group. However, in the 2 model therapy groups, damage to the intercellular joints and organelles was ameliorate relative to the model control group.

CONCLUSION: Administration of geranylgeranylacetone was correlated with a more favorable pattern of gastric mucosa damage after ethanol perfusion. The mechanism could be related to regulation of ET-1, NO and PGE2.

INTRODUCTION

The liver is a main organ for ethanol metabolism. The gastrointestinal tract is also involved in the ethanol metabolic process. Research[1] has reported that binge drinking or long-term drinking can cause acute or chronic gastric mucosal injury. Ethanol can be converted into acetaldehyde in first-pass metabolism in the gastrointestinal tract, which may have a carcinogenic affect on the gastrointestinal tract through local toxic effects. Geranylgeranylacetone is a derivative of terpenes. Studies have shown that geranylgeranylacetone has a therapeutic effect on chronic gastritis, digestive ulcers and portal hypertensive gastropathy[2-5]. There have been few studies on the repair mechanisms of gastric mucosal damage caused by ethanol. By using a rat ethanol gastritis model, we aimed to study the effect and mechanisms of geranylgeranylacetone on repairing gastric mucosa by observing the histological and ultrastructure changes and detecting the expression levels of plasma endothelin-1 (ET-1), serum nitric oxide (NO) and gastric mucosal prostaglandin 2 (PGE2) in this research.

MATERIALS AND METHODS

Materials

Adult male Sprague-Dawley (SD) rats, 8 wk old, weighing 200 ± 50 g, were purchased from the Animal Center of Zhejiang University of Traditional Chinese Medicine. They were fed in a specific pathogen free environment with 12 h of light a day with unlimited drinking water. Geranylgeranylacetone was manufactured by Japan Eisai Co., Ltd., and packed by the Suzhou Eisai Pharmaceutical Co. A kind of liquor (Trade name: Red Star Erguotou, with 56% ethanol, manufactured by a general Beijing brewing factory) was used for gastrogavage to establish an ethanol-induced gastritis model in rats. The ET-1 radioimmunoassay determination kit was purchased from Beijing North Institute of Biotechnology Technology. The PGE2 radioimmunoassay kit was purchased from the Beijing Huaying Biotechnology Research Institute.

Animal treatments

Groups: One hundred adult male SD rats were randomly divided into four groups, including the normal control group, the model control group, the low-dose model therapy group (50 mg/kg) and the high-dose model therapy group (200 mg/kg). The ethanol gastritis model was built by following an established procedure[6]. Red Star Erguotou liquor with 56% ethanol content was used for feeding the laboratory rats by gastrogavage. On every Tuesday and Friday, the rats were fed with ethanol after fasting for 12 h (food was removed on every Monday and Thursday at 9 pm, and gastrogavage was performed on the next day at 9 am). The dose of ethanol was 8 g/kg body weight. The conversion formula was: weight of ethanol (A) = liquor volume (mL) × ethanol content (vol/vol) × ethanol density (8 g/kg). The normal control group received the same amount of normal saline instead of ethanol. All laboratory rats were administered treatment for 4 wk. In the model therapy group, geranylgeranylacetone was dissolved in pure water and was administered by gastrogavage 1 h before ethanol feeding each time. In the normal control and model control groups, only normal saline, instead of geranylgeranylacetone was administered.

Specimen collection: Observations were made of the reactivity, activity and death of rats in each group during the experiment. The animals were killed by cervical dislocation after administration of an overdose of sodium pentobarbital on the 4th weekend of the experiment. The abdomen was opeded immediately. The whole stomach was cut and removed 1.5 cm away from the cardia and the pylorus. Dissection was done along the greater curvature for general specimen observation. The obviously damaged gastric mucosa specimen was rinsed in cold saline solution. Then, the specimen was placed in formaldehyde and glutaraldehyde, and stored in liquid nitrogen solution for later observation. All operations of all specimens were assigned to the same experienced professional laboratory personnel. All animal studies were approved by the Animal Care and Use Committee of Zhejiang University in accordance with the Chinese guidelines for the care and use of laboratory animals.

Determination of gastric mucosal injury index: The length and the width of the injured gastric mucosa region were measured with a vernier caliper. The gastric mucosa ulcer index (UI) was determined according to the Guth standard[7]: spot erosion was recorded as 1 point, erosion length < 1 mm was recorded as 2 points, 1-2 mm was recorded as 3 points, 2-3 mm was recorded as 4 points, and > 3 mm was recorded as 5 points, the score doubled if the erosion width was > 1 mm.

Determination of the thickness of the gastric mucous layer and the mucus glycoprotein content: The thickness of the gastric mucous layer in each group was measured by converted fluorescence microscopy with a thick smear method (using an ink staining method to enhance the contrast). The thickness of the gastric mucous gel layer was detected by measuring the thickness of the

centric bright area with a micrometer eyepiece. Detection of the levels of hexosamine (the main component of mucus glycoprotein) was performed by colorimetric assay using a spectrophotometer.

Histopathology: Four percent formalin-fixed gastric mucosa tissues were embedded by paraffin after gradient dehydration, 4 μm serial sections were obtained and HE staining was performed. We used the epithelial damage score (EDS) to rate morphological changes in the gastric mucosa under light microscopy: normal gastric mucosa was is recorded as 1 point, mucosal epithelial cell damage was recorded as 2 points, damage involving the glandular cells was recorded as 3 points, and mucosal erosion, bleeding or ulceration was recorded as 4 points. We observed a 1 cm length in each slice under light microscopy, and then calculated the cumulative score for each slice. Light microscopy was used to evaluate the degree of gastric damage, which was performed by two pathologists who were unaware of the treatment.

Observation of the ultrastructure of the gastric mucosa: We took 5 mm × 5 mm specimens close to the gastric antrum. According to the electron microscopy procedure, specimens were double fixed by 2.5% glutaraldehyde and 2% osmium tetroxide and subjected to conventional ethanol dehydration, and iso-amyl acetate transition. Critical point drying was carried out on a HCP-2 type critical point drying apparatus. The sample was stuck and a gilded target alloy was placed on the specimens using an IB-5 ion sputter coater. Specimens were observed on the sample stage of the electron microscope. We observed the cell morphology of the gastric mucosa, the junctions of the gastric mucosa epithelial cells, the shape of the gastric pit, and the ultrastructural changes of the intracellular mitochondria as well as the Golgi apparatus and other organelles in all of the laboratory rats by scanning electron microscopy and transmission electron microscopy.

Detection of the levels of serum nitric oxide, plasma endothelin-1, and gastric mucosal prostaglandin 2: We drawed 2 mL of blood from the abdominal aortic vein and injected it into the anticoagulant tube containing 30 μL 10% ethylenediaminetetraacetic acid disodium and 800 U aprotinin and mixed it well. We carried out centrifugal separation of the plasma at 4 ℃ at 3000 r/min for 30 min. Detection of plasma ET-1 levels and gastric mucosal PGE_2 content was carried out by a radioimmunoassay method with strict attention to the instructions. Detection of serum NO levels was carried out by a chemiluminescence method (according to the Griess method).

Statistical analysis
All values are expressed as mean ± SE. The Tukey test or the Student's *t*-test for unpaired results was used to evaluate differences between more than three groups or between two groups, respectively. Differences were considered to be significant for values of $P < 0.05$.

RESULTS

Observation of the general situation of rats
In the model control group, 3 of 25 rats died and most of the others were listless, had a bad appetite, and were unresponsive to external stimuli. In the normal control group and the model therapy groups, most of the rats had alert consciousness, normal appetites, agile responses to outside stimuli, and no deaths. The differences between the model control group and the other groups were significant.

The gastric mucosa ulcer index and the gastric epithelial damage score
In the normal control group, there were only 2 rats (2/25, 8%) that had punctate erosion on the gastric body mucosa. The mucosa of the others was not damaged and the UI was 0. In the model control group, the erosion and ulcers on the gastric mucosa were obvious and the median ulcer index was 12.0, which was significantly different ($P < 0.01$) from the normal control group. The gastric mucosal damage of the low-dose and high-dose model therapy groups was significantly reduced and the UIs were decreased (3.5 and 3.0, respectively). The results were statistically significant difference ($P < 0.01$) compared with the model control group. But there was no statistically significant difference between the low-dose and high-dose model therapy groups($P > 0.05$). In the model control group, the EDS values (median 4.5) were higher than that in the normal control group (median 0, $P < 0.01$). However, in the low-dose and high-dose therapy groups, the EDS values (median 2.5 and 2.0 respectively) were lower than the model control group (median 4.5, $P < 0.05$). The EDS values of the low-dose and the high-dose model therapy groups were not statistically significantly different ($P > 0.05$) (Figure 1 and Table 1).

Histological changes
In the control group, the gastric mucosa was smooth, the layers of the gastric mucosa had clear boundaries under high-power microscopy, and there was no significant inflammatory cell infiltration and edema. In the model control groups, the gastric mucosal surface was uneven with erosion, ulcers and bleeding, and under high-power microscopy the gastric mucosa were congested and had edema. With telangiectasia, the surface mucus layers were damaged and the submucosal gastric glands were incomplete. In the model therapy groups, the gastric mucosal injuries were obviously slighter than the model control group. In the model control group, there was only scattered mucosal damage and local congestion. Under high-power microscopy, the gastric surface mucus layer in the model therapy groups was basically intact and the submucosal layers were slight congested and had less inflammatory cell infiltration, especially in the high-dose model therapy groups (Figure 2).

Figure 1 The gross anatomy of gastric mucosa in different groups. A: Gastric mucosa of normal control group was non-destructive; B Gastric mucosa of model control group showed erosion and ulcer; C: The gastric mucosa damage of low-dose model therapy group was relatively reduced according to model control group; D: The gastric mucosa damage of high-dose model therapy group was significantly reduced according to model control group.

Ultrastructural changes

Ultrastructural changes under scanning electron microscopy: In the normal control group, the gastric mucosa epithelial cells were closely joined and were ring-wise arranged around the gastric gland openings. The gastric pits were clear with ordered cells (according to the arrow). The model control group showed extensive gastric epithelial cell loss, disappearance of gastric pits, and revealed the glandular epithelium (according to the arrow). In the low-dose and high-dose model therapy groups, the gastric epithelial cells showed a basically complete structure and a small amount of ruptured epithelial cells (according to the arrow) (Figure 3).

Ultrastructural changes under transmission electron microscopy: In the normal control group, the gastric mucosal organelles had integrated structures with no degeneration, and the microvillis were arranged in neat rows with no loss. The model control group showed widened cell gaps, vague intercellular junctions, sparse and deciduous microvillis, and swollen mitochondria and endoplasmic reticulum. In the model therapy groups, the cells were arranged in neat rows and the intercellular junctions were clear. The structures of the mitochondria and endoplasmic reticulum were clear with mild swelling (Figure 4).

The thickness of the gastric mucous layer and hexosamine assay results

The thickness of the gastric mucous layer and the contents of the hexosamine in the model control group were significantly lower than the normal control group ($P < 0.01$). While the thickness of the gastric mucous layer and the contents of the hexosamine in the model therapy groups were lower than the normal control group, they obviously were higher than the model control group, and the differences was statistically significant ($P < 0.05$) (Table 2).

Detection of plasma endothelin-1, serum nitric oxide and gastric prostaglandin 2 levels

Plasma endothelin-1 levels: Compared with the normal control group, the levels of plasma ET-1 were significantly higher in the model control group ($P < 0.01$) and were significantly lower in the high-dose model therapy group ($P < 0.05$). While the levels of plasma ET-1 in the model therapy groups (including both the high-dose and low-dose groups) were significantly decreased compared to the model control group ($P < 0.01$) (Table 2).

Serum nitric oxide levels and gastric mucosal prostaglandin 2 levels: Compared with the normal control group, the levels of serum NO and gastric mucosal PGE₂ were significantly decreased in the model control group ($P < 0.05$). In both model therapy groups, the content was significantly higher than in the model control group ($P < 0.05$), and this was especially the case in the high-dose model therapy group (Table 2).

DISCUSSION

The integrity of the gastric mucosa depends on the protec-

Table 1 A comparison of the injury of gastric mucosa in different groups

Figure 2 Histological changes of different groups. A: Normal control group: gastric mucosa was smooth, with clear boundaries, and no significant inflammatory cell infiltration and edema (HE staining × 200); B: Model control group: the gastric mucosa surface was uneven with erosion, ulcer bleeding, edema and telangiectasia, the submucosal gastric glands was incompleted (HE staining × 200); C: Geranylgeranylacetone treated group: the gastric surface mucus layer was basic intact, with scattered mucosal damage, local congestion and edema, fewer inflammatory cell infiltration (HE staining × 200).

tion of the gastric mucosal barrier (including, for example, the mucus-bicarbonate barrier and mucosal microcirculation) and can be damaged by a variety of factors (internal or external) with the production of a number of inflammatory mediators and cytokines, resulting in secondary mucosal damage[8-10]. Of the damaging factors, ethanol is an important external factor. With both hydrophobic alkyl and hydrophilic hydroxyl in its molecular stucture, ethanol can damage the gastric mucosal barrier defense system, diminish the capacity of the gastric mucosa to defend the invasion of gastric acid, bile and many digestive enzymes, causing mucosal edema, erosion, hemorrhage and necrosis. In this study, excessive ethanol intake can cause laboratory rats to become apathetic, lose appetites, have slow responses, and have increased mortality. In our study, damage of the gastric mucosa in the model control group, including the general view, microscopic structures and ultrastructure changes, was significantly serious compared to the normal control group.

The gastric mucous layer is the first defensive line of the gastric mucosa to against external stimuli. Studies[11-13] have shown that changes in thickness and content; i.e., mucous glycoprotein (hexosamine) can reflect the anti-invasive ability of the gastric mucous. The results of this study showed that excessive ethanol intake can significantly reduce the thickness of the gastric mucous layer, reduce the content of hexosamine in the mucus gel layer, and finally result in the decline of the anti-invasive ability of the gastric mucosa to ethanol and other external attacks.

Studies[14,15] in recent years have shown that the impaired microcirculation is one of the pathological reasons for gastric mucosal barrier damage, which is accompanied by elevated levels of ET-1, and declining levels NO and PGE2 in blood and the gastric mucosa. NO and PGE2 are recognized vasodilator factors *in vivo*, which can inhibit platelet aggregation and thrombosis, accelerate the flow of the gastric mucosal microcirculation, promote the

secretion of bicarbonate, mediate the adaptive immune protective function, increase protein synthesis and cell renewal, and finally enhance the repair ability of the damaged gastric mucosa. ET-1 is the strongest vasoconstrictor *in vivo*. Lazaratos *et al*[16] reported that after injection of exogenous ET-1 in the rat gastric artery, the gastric mucosa was obviously damaged, while injection of an endothelin receptor antagonist in advance can significantly reduce the gastric mucosal damage. Under physiological conditions, these factors work together to regulate the gastric mucosal microcirculation and maintain homeostasis. However, imbalanced regulation caused by various factors will disorder the gastric mucosal microcirculation, affect the integrity of the gastric mucosa, and thus lead to a variety of gastrointestinal diseases. This study[16] showed that the content of gastric mucosal PGE_2 and serum NO were decreased in the model control group compared with the normal control group, and were negatively correlated with the gastric mucosal UI and EDS. The study also found that the levels of plasma ET-1 in excessive ethanol intake rats were higher than that in the normal control group, and were positively correlated with the UI and EDS. All these results suggested that the role of ethanol in damage to the gastric mucosa and weakening of its ability to repair may be caused by it stimulating the secretion of ET-1, and inhibiting the synthesis and secretion of endogenous NO and PGE_2.

Geranylgeranylacetone

Geranylgeranylacetone (a derivatives of terpenes with a molecular formula of $C_{23}H_{38}O$) has been a widely used gastrointestinal mucosa protective agent in recent years. It can stimulate the synthesis and secretion of macromolecule glycoprotein and phospholipids in the gastric mucus layer and maintain the normal structure and function of the gastric mucus layer. It therefore has a strong role in renovation of various experimental and clinical gastric mucosal lesions. Studies[17,18] have shown that geranylgeranylacetone can stimulate the regenerated gastric mucosal cells to secrete hexosamine and carry out the biosynthesis of gastric mucosal PGE_2. The mechanism may be related to the fact that geranylgeranylacetone changes the fluidity of membrane phospholipids, and increases the production of phospholipase A2, which is an important intermediate product for the PGE_2 and hexosamine. Hexosamine is an essential component of polymer glycoprotein in the gastric mucosa gel layer, and PGE_2 is a local hormone in the gastric mucosa. Studies have reported that PGE_2 is involved in the improvement of gastric mucosal microcirculation, and the continuous secretion of PGE_2 under the external stimulation helps to renovate gastric mucosa lesions[19-21]. Studies[22-24] have also shown that NO takes part in the process of geranylgeranylacetone inducing gastric mucus synthesis, in which NO synthase plays an important role, Meanwhile the synthesis of ET-1 is inhibited. Geranylgeranylacetone was used to pre-treat ethanol gastritis in the rat model in this study. We also showed that geranylgeranylacetone can elevate the serum

NO and gastric mucosal PGE_2 content and decrease the plasma ET-1 content to varying degrees with different dosages. Meanwhile, the gastric anti-invasion ability of ethanol showed a corresponding increase. In conclusion, Administration of GGA was correlated with a more favourable pattern of gastric mucosa damage after alcohol perfusion. The mechanism could be related to regulation of ET-1, NO and PGE_2. The molecular pathways and mechanisms, however, need to be studied further.

COMMENTS

Background
Binge drinking or long-term drinking can cause acute or chronic gastric mucosal injury. Ethanol can be converted into acetaldehyde in the first-pass metabolism in the gastrointestinal tract, which may have a carcinogenic affect on the gastrointestinal tract through local toxic effects. Studies have shown that geranylgeranylacetone has a therapeutic effect on chronic gastritis, digestive ulcers and portal hypertensive gastropathy.

Research frontiers
By establishing rat ethanol gastritis model, the authors evaluated the effects of ethanol on the gastric mucosa and studied the preventive effects of geranylgeranylacetone on ethanol-induced chronic gastritis.

Innovations and breakthroughs
There have been few studies on repair mechanisms for gastric mucosal damage caused by ethanol. Moreover, the effect and mechanisms of geranylgeranylacetone on repairing ethanol-induced gastritis have seldom been evaluated. This study demonstrated the administration of geranylgeranylacetone was correlated with a more favorable pattern of gastric mucosa damage after ethanol perfusion. The mechanism could be related to regulation of prostaglandin 2 (PGE_2), endothelin-1 (ET-1) and nitric oxide (NO).

Applications
The study results suggest that geranylgeranylacetone can protect the rat gastric mucosa from ethanol-induced injury by changing the mobility of the cell membrane phospholipid bilayer, which further promotes the synthesis of endogenous PGE_2 and NO, and inhibits the secretion of ET-1.

Terminology
Geranylgeranylacetone is a derivative of terpenes, which has a therapeutic effect on chronic gastritis, digestive ulcers and portal hypertensive gastropathy. NO and PGE_2 are recognized vasodilator factors *in vivo*, which can inhibit platelet aggregation and thrombosis, accelerate the flow of the gastric mucosal microcirculation, promote the secretion of bicarbonate, mediate the adaptive immune protective function and increase protein synthesis and cell renewal. ET-1 is the strongest vasoconstrictor *in vivo*.

Peer review
It is an interesting study that confirms alcohol can damage the gastric mucosa. The study demonstrated the protective effect of geranylgeranylacetone on alcohol damage to the gastric mucosa and it elucidated the underlying mechanisms of this protective action.

Abstract

AIM: To investigate the role and potential mechanisms of bone marrow mesenchymal stem cells (MSCs) in severe acute peritonitis (SAP).

METHODS: Pancreatic acinar cells from Sprague Dawley rats were randomly divided into three groups: non-sodium deoxycholate (SDOC) group (non-SODC group), SDOC group, and a MSCs intervention group (i.e., a co-culture system of MSCs and pancreatic acinar cells + SDOC). The cell survival rate, the concentration of malonaldehyde (MDA), the density of superoxide dismutase (SOD), serum amylase (AMS) secretion rate and lactate dehydrogenase (LDH) leakage rate were detected at various time points. In a separate study, Sprague Dawley rats were randomly divided into either an SAP group or an SAP + MSCs group. Serum AMS, MDA and SOD, interleukin (IL)-6, IL-10, and tumor necrosis factor (TNF)-α levels, intestinal mucosa injury scores and proliferating cells of small intestinal mucosa were measured at various time points after injecting either MSCs or saline into rats. In both studies, the protective effect of MSCs was evaluated.

RESULTS: *In vitro*, The cell survival rate of pancreatic acinar cells and the density of SOD were significantly reduced, and the concentration of MDA, AMS secretion rate and LDH leakage rate were significantly increased in the SDOC group compared with the MSCs intervention group and the Non-SDOC group at each time point. *In vivo*, Serum AMS, IL-6, TNF-α and MAD level in the SAP + MSCs group were lower than the SAP group; however serum IL-10 level was higher than the SAP group. Serum SOD level was higher than the SAP group at each time point, whereas a significant between-group difference in SOD level was only noted after 24 h. Intestinal mucosa injury scores was significantly reduced and the proliferating cells of small intestinal mucosa became obvious after injecting MSCs.

CONCLUSION: MSCs can effectively relieve injury to pancreatic acinar cells and small intestinal epithelium, promote the proliferation of enteric epithelium and repair of the mucosa, attenuate systemic inflammation in rats with SAP.

INTRODUCTION

Acute pancreatitis (AP) is characterized by a rapid onset and disease progression, with high fatality. Severe acute pancreatitis (SAP) is extremely challenging to treat and the mortality rate is approximately 20%-40%[1]. Several studies currently suggest that the pathogenesis of AP involves complicated cascade reactions that start from the activation of pancreatin in pancreatic acinar cells. Pancreatin causes injury to the acinar cells and induces both local and systemic inflammation[2]. Inflammatory factors such as C-reactive protein, tumor necrosis factor (TNF), interleukin (IL)-1, IL-6, IL-8, nitric oxide (NO) and endothelin (among others) are thought to be involved in both the genesis and progression of AP and play a critical role in the progression from slight acute pancreatitis to severe acute pancreatitis[3]. Intestinal barricade function is significantly injured in SAP permitting bacteria to invade the enteric cavity and allowing endotoxin to enter the circulatory system thereby inducing a systemic inflammatory factor cascade reaction that aggravates the condition[4].

Mesenchymal stem cells (MSCs) are multipotent stem cells. One previous study demonstrated that MSCs had strong immunoregulatory effects and multidirectional differentiation potency[5]. Other recent studies found that MSCs also played a special role in inhibiting inflammatory reactions and promoting tissue repair[6]. For example, Hagiwara *et al*[7] found that rats with renal injury caused by ischemia-reperfusion induced a significant reduction in renal cell apoptosis after the injection of thymidine kinase-expressing MSCs (TK-MSCs). In addition, nitric oxide synthase (NOS) and NO levels were significantly reduced, which significantly inhibited: the infiltration of neutrophils and mononuclear macrophages; reduced the activity of peroxidase; delayed the production of peroxide, phosphorylation of p38 extracellular signal regulated kinase, the expression of TNF-α, and monocyte chemoattractant protein-1 cell adhesion. TK-MSCs also inhibited H_2O_2-induced cell apoptosis and increased Akt phosphorylation and cell activity in the periphery of the renal tubular cells. Tögel *et al*[8] administered MSCs to mice with acute renal failure for 24 h. The proinflammatory cytokines IL-1β, TNF-α, IFN-γ and NOS were all significantly reduced, whereas the anti-inflammatory factors IL-10, β fibroblast growth factor, TGF-α and B cell lymphoma-2 appeared highly expressed. In a pulmonary injured animal model, Iyer *et al*[9] found that MSCs attenuated a self-inflammatory reaction and enhanced the anti-inflammatory reaction by regulating the proliferation, differentiation, and delomorphous nature of immunocytes.

MSCs have also been demonstrated to have therapeutic effects in inflammatory diseases. For example, Imberti *et al*[10] injected MSCs in a cisplatin-induced acute renal injury model in mice and found that the MSCs enhanced mitosis. In addition, the production of insulin-like growth-factor-1 promoted the repair of renal tubules. In the treatment of chronic ischemic cardiomyopathy, MSCs were injected into ligate ramus descendens anterior arteril coronariae sinistrae. They were also injected into acute myocardial infarction regions. MSCs in both cases enhanced the contractile force of the cardiac muscle cells, regulated the contents and composition of collagen fibers in the tissue, and prevented the reconstruction of cardiac ventricles, thereby protecting the basic structure of cardiac muscle[11]. After intravenous injection of MSCs in experimental rats with spinal injury, MSCs assembled and survived in the host injury spinal cord and promoted the neural repair and recovery of nerve function[12]. In yet another study, rats with a radioactive intestinal injury were injected with labeled MSCs and the intestinal chorioepithelium regeneration occurred in the injured intestinal mucosa for 3 d and the radial related regions (e.g., kidney, spleen, stomach) also had MSCs[13]. Finally, after injecting MSCs into rats with an intestinal injury (ischemia/reperfusion), the permeability of the intestine was reduced and the injury to the intestinal villi was attenuated[14]. Together, these data indicate that MSCs can reduce the expression of various inflammatory factors and promote the repair of various tissues and organ injury.

Because the treatment of AP with stem cells has not been studied to date, and based on the ability of MSCs to inhibit inflammatory reactions and promote tissue repair, the purpose of this study was to explore the role, and the possible mechanisms, of MSCs in rats with SAP.

MATERIALS AND METHODS

Animals

Healthy Sprague Dawley rats weighing 200-300 g were provided by Shanghai SLK experimental animal Company [Batch No. SCXK (Shanghai) 2007-0005, China]. The study was approval by the Institutional Animal Care and Use Committee Fujian Medical University. The care and handling of all animals were in accordance with guidelines for animal ethics.

Drugs, reagents and instruments

The following reagents were used in the experiments: sodium deoxycholate (SDOC) , 3-(4,5-dimethylthiazol-2-yl)-2-,5-diphenyltetrazolium bromide (MTT; Sigma), fetal bovine serum (Purpleflower holly leaf, Hangzhou), Dulbecco's modified Eagle's medium (DMEM; Thermo Fisher, United States), ethylenediaminetetraaceticacid (EDTA)-trypsin (Amersco Co., United States), 4,6-diamidino-2-phenylindole (DAPI; Roche, Switzerland), malonaldehyde (MDA), superoxide dismutase (SOD), amylase (AMS) secretion rate and lactate dehydrogenase (LDH) kits (Nanjing Jianchen Scientific Co. Ltd), transwell double layer culture dish (Corning Costar, United States), IL-10 enzyme-linked immunosorbent assay (ELISA) kit for rats, IL-10 ELISA for rats, and TNF-α ELISA kit for rats (all ELISAs from Wuhan Youer Bio-scientific Co., Ltd), and antibody against proliferating cell nuclear antigen (Shanghai Zhuokang Bio-scientific Co., Ltd).

Culture, identification, and labeling of mesenchymal stem cells

Male rats weighting about 200 g were humanely sacrificed by cervical dislocation. The bone marrow was aseptically collected and subsequently cultured using whole marrow differential adherence methods. MSCs were obtained by multiple digestions and passages. The cellular identification of the expression of MSCs surface markers (i.e., CD29, CD34, CD45 and CD90) were detected using flow cytometry. The cells were labeled with DAPI and observed under fluorescence microscope. Third generation MSCs was acquired for subsequent experimentation.

Cell experiments

Pancreatic acinar cells from the rats were separated using the collagenase method[15]. The cells were seeded in Hanks buffer solution containing 10% fetal calf serum at a density of 1×10^6 cells/mL. The purity of the pancreatic acinar cells was > 80% and the survival rate was > 90%). Cells were seeded in 35 mm × 35 mm culture dishes and incubated at 37 ℃ and 55% CO_2 for 2 h. Cell morphology was examined using phase contrast microscopy. The cultured acinar cells were seeded in the underlayer of transwell double-deck culture dishes.

Pancreatic acinar cells were randomly divided into three groups: non-sodium deoxycholate group (non-SODC group), SDOC group, and a MSCs intervention group. In the SDOC group, the pancreatic acinar cells were seeded in the bottom of the transwell double-layer culture dishes and had a final concentration of 50 μmol/L SDOC. In the Non-SDOC group, the pancreatic acinar cells were seeded in the bottom of the transwell double-layer culture dishes and were not cultured with SDOC. In MSCs intervention group, the insert of the transwell plates was inserted into the poles and the third generation MSCs were seeded at a density of 1×10^6 cell/mL. The culture medium in the insert and the six-pole plate were fused, thereby establishing the co-culture system of MSCs and acinar cells. The co-culture medium was LG-DMEM with SDOC at a final concentration of 50 μmol/L. Subsequently, the cells in each group were incubated for 0.5 h, 1 h, 4 h and 10 h. Alterations in cell morphology were examined and cell survival was quantitatively detected by the MTT assay. The cell survival rate was expressed by the percentage in each group using the following equation: 100% × absorbance at 490 in each group/absorbance at 490 in the fresh separated pancreatic acinar culture medium.

The supernatants were also collected and the concentration of MDA was determined using the thiobarbituric acid method. The density of culture serum SOD was also determined using the xanthine oxidase method. The AMS secretion rate and LDH leakage rate of acinar cells were measured by enzyme kinetics methods. The AMS secretion rate was cell supernatant AMS/cell total AMS × 100% and the LDH leakage rate was cell supernatant LDH/cell total LDH × 100%.

Animal experiment

Thirty-six male rats were randomly divided into either the SAP group or the SAP + MSCs group. The SAP model was established by injecting deoxy-STC under the pancreatic capsule[16]. Specifically, following a peritoneal injection of 2.5% thiopental sodium, the pancreas of each rat was sufficiently exposed after entering into the abdomen *via* a median abdominal incision. Next, 1 mL of 3.8% STC was slowly injected into the inferior aspect of capsule using a No. 4 needle from the tail of pancreas, which made the entire pancreas swell. The pancreas was replaced 2 min later and the abdominal cavity was sutured closed routinely. In the SAP + MSCs group, 2 mL of the MSCs cell suspension (containing approximately 1×10^6 cells/mL determined *via* DAPI fluorescence immunity labeling) were injected into the caudal vein. In the SAP group, 2 mL of normal saline was injected. Six mice were randomly collected from both groups 6 h, 24 h and 72 h postinjection. Blood was collected from the apex of the heart and 5 cm of the small intestine (the section from the terminal ileum and extending distally) was obtained. Serum AMS was detected and the concentrations of serum IL-6, IL-10 and TNF-α were determined using ELISAs. Serum MDA concentration was determined using the thiobarbituric acid method, and the concentration of serum SOD was measured *via* the xanthine oxidase method.

The small intestinal tissue was flash frozen, and the number of DAPI positive cells was measured under fluorescence microscopy. Conventional hematoxylin and eosin staining was performed on sections of small intestine and injury to the intestinal mucosa was assessed in six different, randomly selected, high-power fields (original magnification × 400). According to the injury scoring criteria of Chiu's intestinal tissue[17], injury to intestinal mucosa, infiltration of inflammatory cells, and degree of hemorrhage and hyperemia were scored. The proliferating cell nuclear antigen Ki-67 immunohistochemistry staining was performed to note any proliferation of intestinal mucosa cells. Again, six different high-power fields (× 400) were randomly selected and the number positive cells were counted.

Statistical analysis

All data were expressed by mean ± SD. The mono-factor variance analysis was applied for comparisons between groups. A $P < 0.05$ was considered statistically significant, and all analyses were performed using SPSS 13.0.

RESULTS

General morphology of mesenchymal stem cells and the expression of surface markers

Third generation of MSCs were examined under an inverted microscope. The cells assumed a fusiform and swirling colony (Figure 1). As shown in Figure 2, the positive rate of CD29 was 98.6% and the positive rate of CD90 was 99.6%. In contrast, CD34 and CD45 were

Figure 1 Third generation mesenchymal stem cells were spindle-shaped and formed spiral-like colonies (original magnification × 100).

negative (0.56% and 0.89%, respectively), demonstrating that the purity of the MSCs was > 95%.

Morphology of pancreatic acinar cells

After the pancreatic acinar cells were cultured for 2 h, no adherence was noted under the inverted microscope. Instead, the cells assumed a cluster formation and assembled with lumping. The boundary of the cells was clear and the refraction was strong. High density particles containing proenzymes could be seen in the cells (Figure 3).

The cell survival rate of fresh separated pancreatic acinar cell was comparatively high and that in each group was reduced. This reduction was most evident in the SDOC group. The cell survival rate at each time point in the MSCs intervention group was significantly increased compared with the SDOC group (Table 1).

Amylase secretion and lactate dehydrogenase leakage rates

The AMS secretion rate and LDH leakage rate of pancreatic acinar cell in the SDOC group at each time point was significantly higher than the other two groups. The AMS secretion rate and LDH leakage rate in the MSCs intervention group at each time point was significantly reduced compared with the SDOC group (Table 2).

Oxidative stress

MDA and SOD were measured in the supernatants collected from each group (Table 3). In SDOC group, SOD activity significantly reduced and this difference was significant compared with the non-SDOC group ($P < 0.05$). With the extension of SDOC reaction time, the SOD activity in the cell culture supernatants was further reduced, which was also significantly lower than the non-SDOC group at the same time points ($P < 0.05$). However, MDA content in cell culture supernatants was significantly higher in the SDOC group than the non-SDOC group at the corresponding time points ($P < 0.05$). The SOD activity in the MSCs intervention group at each time point was significantly increased compared with the SDOC group, whereas MDA content was significantly lower than the SDOC group ($P < 0.05$).

Figure 2 The expression of mesenchymal stem cells surface markers detected by flow cytometry. The proportion of CD29+ (A) cells was 98.6%, the proportion of CD90+ (B) cells was 99.6%, the proportion of CD45+ (C) cells was 0.89% and CD34+ (D) cells was 0.56%. B: The boundary of the cells.

Figure 3 Separated pancreatic acinar cells (original magnification × 100).

Permanent planting of mesenchymal stem cells in small intestine

Blue fluorescing cells (DAPI positive cells) were observed in sections of small intestinal tissue of rats that were flash frozen in the rats included in the SAP + MSCs group (Figure 4).

Effect of mesenchymal stem cells transplantation on serum amylase levels and oxidative stress

Serum AMS levels of rats in the SAP group at each time point was significantly enhanced compared with those measured in the SAP + MSCs group ($P < 0.05$, Table 4). Serum MDA and SOD levels have been summarized in Table 5. Serum MDA levels tended to initially increase, but were then reduced following the injection of MSCs. Serum MDA levels at each time point in the SAP + MSCs group were significantly lower than in the SAP group ($P < 0.05$). Serum SOD levels in the SAP + MSCs group was higher than in the SAP group, whereas a significant between-group difference in SOD level was only noted after 24 h ($P < 0.01$).

Regulation of mesenchymal stem cells transplantation on inflammatory factors

Serum IL-6, IL-10 and TNF-α levels in the two groups have been summarized in Table 5. Serum IL-10 and TNF-α after MSCs transplantation tended to increase then decrease. IL-6 was persistently elevated and was obvious in the SAP + MSCs group. After MSCs transplantation, serum IL-6 and TNF-α levels were significantly lower than in the SAP group ($P < 0.05$), Further, serum IL-10 was significantly higher in the SAP + MSCs group than the SAP group ($P < 0.05$). After 72 h, each cytokine was not significantly different between the two groups.

Assessment and scoring of intestinal tissues at different time points after mesenchymal stem cells transplantation

Using a conventional light microscope, the intestinal mucosa was clearly damaged in the SAP group. Specifically, the lamina propria was destroyed, the blood capillary network was exposed, there was bulk infiltration of neutrophils, local regions of hemorrhage, there was a depopulation of intestinal villi, and the glands of the lamina propria showed a variable degree of destruction. In contrast, these changes were rarely noted in the SAP + MSCs group. The main changes noted were neutrophil infiltration of the proper layer and engorgement of the capillaries. The Chiu intestinal tissue damage score in the SAP + MSCs group was significantly lower than that in the SAP group after 6 h (36.33 ± 5.72, $P = 0.045$), 24 h (46.33 ± 2.80, $P < 0.05$), and 72 h (26.67 ± 3.08, $P < 0.05$) as described in Table 6.

Cell proliferation in the small intestinal mucosa at different time points following mesenchymal stem cells transplantation

Cellular regeneration in the small intestinal mucosa in the SAP + MSCs group was more obvious than that in the SAP group, which was in accordance with conventional pathology (Figure 5). For 6 h after transplantation, neither of the two groups had any evidence of proliferation. Then the cell proliferation of small intestinal mucosa in the SAP + MSCs group became significant different than the SAP group ($P < 0.05$) as shown in Table 6 and Figure 6.

DISCUSSION

The goal of this study was to explore the role of bone marrow MSCs in a model of SAP to provide a new, practical basis for the intervention of this often fatal disease. The results of this study are supported by a recently published study on the inhibition of inflammation and reduction of acute pancreatitis in rats by human bone marrow-derived clonal mesenchymal stem cells[18]. Other studies have also demonstrated that SAP induces functional disturbances of the intestinal barrier, resulting in the displacement of bacteria in enteric cavity. Endotoxin subsequently enters the blood and induces a systemic inflammatory factors cascade reaction that aggravates the pathogenic condition. In this course, impairment of free radicals is thought to be one of the most important links between endotoxin and inflammatory reaction. Specifically, oxygen-derived free radicals can induce lipid peroxidation of biological membranes, change the activity of proteins and enzymes, and directly assault DNA and injure the mitochondria, *etc.*, thereby elevating oxidative stress levels in cells[19,20].

Previous studies have also demonstrated that MSCs reduce oxygen-derived free radical levels in the body *via* multiple pathways and maintain the stability of membranes. Exogenous MSCs protected vascular endothelial cells to avoid the damage of oxidative stress[21], and relieve the oxidative damage of neuroblastoma[22]. In one study[23], Kallikrein-modified MSCs were transplanted into the renal tissues of rats with ischemic/reperfusion injury. Those MSCs inhibited the infiltration of neutrophils and mononuclear macrophages, reduced the activity of myeloperoxidases, diminished the formation of superoxides, and relieved H_2O_2-induced apoptosis. Another study reported that MSCs reduced amylase and lipase levels in the serum of rats with injury to the pancreas and

repaired the necrotic pancreatic tissue. MSCs might also inhibit inflammation and involve in the reaction by producing some soluble materials[24].

The production of MDA and lipid peroxidation are parallel; therefore, detecting MDA is thought to represent lipid peroxidation. In addition, SOD is a critical free radical scavenger in mammals and its concentration reflects the ability of the body to scavenge oxygen-derived free radicals[25,26]. In this study, serum MDA of rats in the SAP + MSCs group was reduced while SOD level was heightened, indicating that MSCs transplantation could reduce the oxidative stress level of SAP rats, relieve lipid peroxidation, protect the stability of the membranes, improve the

scavenging ability of oxygen-derived free radicals, relieve oxygen-derived free radical-induced multiple injury, and protect SAP-induced intestinal tissue damage.

After functional damage of the intestinal barrier, the displacement of endotoxin has multiple pathologic and physiologic consequences. For instance, endotoxin induces pyrogenic reactions, activates the complement system, affects mononuclear macrophages and endothelial cells, induces the genesis of endogenous mediators including TNF, IL, oxygen-free radicals, interferons, *etc*.[27], resulting in the aggravation of pathogenic conditions or even death. The displacement of endotoxin impairs intestinal epithelial cells and increases intestinal permeability[25]. MSCs also inhibit multiple immunocytes, such as T lymphocytes[28], secrete inhibitory mediators of inflammation such as IL-4 and IL-10, parasecrete IL-10, HGF, VEGF, reduce apoptosis signals[29], and relieve endotoxin-induced inflammatory reactions[30]. In the current study, mediators of inflammation, including serum IL-6 and TNF-α of rats in the SAP + MSCs group was higher than the SAP group, whereas IL-10 levels (an anti-inflammatory mediator) were lower in the SAP + MSCs group than the SAP group. This result is similar to several previous studies[13,31] indicating that MSCs might have a role in immunosuppression by reducing the expression of inflammatory factors and promoting the expression of anti-inflammatory mediators. The study reported herein also found that the Chiu intestinal tissue injury scores at

6 h, 24 h and 72 h after transplantation were significantly lower in the SAP + MSCs group than the SAP group, and cellular regeneration in the small intestinal mucosa in the SAP + MSCs group was more evident than in the SAP group. Therefore, MSCs appear to relieve the degree of injury to the small intestinal epithelium, promote the repair of enteric epithelium of rats, and maintain the integrity of the barrier of the intestinal mucosa.

Pancreatic acinar cells are the functional unit for the external secretion of the pancreas, which accounts for 80% of pancreatic tissue. SAP is caused by a functional disorder and impairment of pancreatic acinar cells[32]. During the process of SAP, inflammatory mediators, metabolic products of arachidonic acid, and oxygen-derived free radicals might reduce the antioxidative ability of pancreatic cells[33], enhance vascular permeability, and cause tissue thrombosis and hemorrhage, thereby inducing necrosis of the pancreas[34]. Thus, maintaining the function of pancreatic cells has a critical significance in relieving the severity of SAP. In this study, MDA levels in the MSCs intervention group were lower than in the SDOC group; however, SOD levels in the MSCs intervention group were higher than the SDOC group indicating that MSCs could impact the oxidative stress level of pancreatic acinar cells of injury rats inducted by SDOC, abrogate lipid peroxidation, protect the stability of membranes, improve the scavenging ability of free radicals, relieve free radical-induced injury to protect pancreatic acinar cells.

Figure 5 Description of the intestinal pathologic manifestations 6 h after mesenchymal stem cells transplantation. A: Extensive injury of the intestinal mucosa was obvious in the severe acute pancreatitis (SAP) group; B: The dissection of the upper cortex of the intestinal mucosa was noted in the SAP + marrow mesenchymal stem cells (MSCs) group; C, D: Injury to the intestinal mucosa in the SAP (C) and SAP + MSCs groups (D) 24 h after MSCs transplantation were more severe than at 6 h; E, F: Repair of the intestinal mucosa was seen in the SAP (E) and SAP + MSCs groups (F) (HE staining, original magnification × 200).

Figure 6 The immunohistochemical staining of proliferating cell nuclear antigen Ki-067 after mesenchymal stem cells transplantation at 6 h (A, B), 24 h (C, **D) and 72 h (E, F).** Cell proliferation (brown cells) was obvious. The number of stained (brown) cells in the severe acute pancreatitis (SAP) + mesenchymal stem cells group (B, D, F) were significantly higher than the SAP group. Cell numbers gradually increased with time (original magnification × 400).

In conclusion, this study found that MSCs could relieve injury to pancreatic acinar cells in rats with SAP, attenuate inflammation and injury in the small intestinal epithelium, promote the proliferation of enteric epithe-

lium and repair of the mucosa, and maintain the integrity of the intestinal barrier function. Potential mechanisms might involve regulating the oxidative stress levels of rats with SAP, inhibiting the extensive release of mediators of inflammation and cytokines, promoting the secretion of mediators of inflammation, and scavenging oxygen-derived free radicals. The specific mechanisms remain worthy of further study.

COMMENTS

Background

Acute pancreatitis (AP) is characterized by a rapid onset and disease progression with high fatality. Severe acute pancreatitis (SAP) is extremely challenging to treat. Several studies currently suggest that the pathogenesis of AP involves complicated cascade reactions of inflammation. Mesenchymal stem cells (MSCs) are multipotent stem cells which had strong immunoregulatory effects and multidirectional differentiation potency. Recent studies found that MSCs also played a special role in inhibiting inflammatory reactions and promoting tissue repair in various inflammation-based diseases such as kidney disease in ischemia/reperfusion injury, collagen-induced arthritis, and acute renal failure. However, very few studies to date have investigated the potential role of cell therapy for pancreatitis.

Research frontiers

Inflammation plays an important role in the pathology of AP. Tumor necrosis factor (TNF)-α and interleukin (IL)-6 as proinflammatory cytokines are produced mainly during AP. The research hotspot is to explore whether MSCs could reduce the level of inflammatory factors and promote the repair of various tissues and organ injury in AP.

Innovations and breakthroughs

Recent reports have indicated that MSCs can reduce the expression of various inflammatory factors and promote the repair of tissues and organ injury. In the present study the authors found that MSCs can also effectively relieve injury to pancreatic acinar cells and small intestinal epithelium, promote the proliferation of enteric epithelium and repair of the mucosa, attenuate systemic inflammation in rats with SAP.

Applications

The study results suggest that MSCs have a special role in inhibiting inflammatory reactions and promoting tissue repair in rats with SAP that might be developed as a cell therapy for pancreatitis.

Terminology

Severe acute pancreatitis (SAP): SAP is a serous gastrointestinal disorder which caused by a functional disorder and impairment of pancreatic acinar cells. The disease is characterized by a rapid onset and disease progression which has a high fatality. Mesenchymal stem cells (MSCs): MSCs are multipotent stem cells which derived form bone marrow. They have strong immunoregulatory effects and multidirectional differentiation potency.

Peer review

The authous detected the cell survival rate, the concentration of malonaldehyde (MDA), the density of superoxide dismutase (SOD), serum amylase (AMS) secretion rate and lactate dehydrogenase leakage rate in pancreatic acinar cell experiments, and measured serum AMS, MDA and SOD, IL-6, IL-10, and TNF-α levels, intestinal mucosa injury scores and proliferating cells of small intestinal mucosa at various time points in animal experiments. The results are interesting and suggest that MSCs could relieve injury to pancreatic acinar cells in rats with SAP, attenuate inflammation and injury in the small intestinal epithelium, promote the proliferation of enteric epithelium and repair of the mucosa. It is believable that MSCs infusion might be a promising treatment method for AP or SAP.

Abstract

AIM: To determine the utility of connective tissue growth factor (CCN2/CTGF) for assessing hepatic fibrosis in hepatitis B virus (HBV)-induced chronic liver diseases (CLD-B).

METHODS: Enzyme-linked immunosorbent assay was used to measure CCN2 in sera from 107 patients with chronic hepatitis B (CHB) and 39 patients with HBV-induced active liver cirrhosis and 30 healthy individuals. Liver samples from 31 patients with CHB, 8 patients with HBV-induced liver cirrhosis and 8 HBV carriers with normal liver histology were examined for transforming growth factor β-1 (TGF-β1) or CCN2 mRNA levels by *in situ* hybridization, and computer image analysis was performed to measure integrated optimal density (IOD) of CCN2 mRNA-positive cells in liver tissues. Histological inflammation grading and fibrosis staging were evaluated by H and E staining and Van Gieson's method.

RESULTS: Serum CCN2 concentrations were, respectively, 4.0- or 4.9-fold higher in patients with CHB or active liver cirrhosis as compared to healthy individuals ($P < 0.01$). There was good consistency between the levels of CCN2 in sera and CCN2 mRNA expression in liver tissues ($r = 0.87$, $P < 0.01$). The levels of CCN2 in sera were increased with the enhancement of histological fibrosis staging in patients with CLD-B ($r = 0.85$, $P < 0.01$). Serum CCN2 was a reliable marker for the assessment of liver fibrosis, with areas under the receiver operating characteristic (ROC) curves (AUC) of 0.94 or 0.85 for, respectively, distinguishing normal liver controls from patients with F1 stage liver fibrosis or discriminating between mild and significant fibrosis.

CONCLUSION: Detection of serum CCN2 in patients with CLD-B may have clinical significance for assessment of severity of hepatic fibrosis.

INTRODUCTION

Hepatic fibrosis, characterized by an excessive accumu-

lation of extracellular matrix (ECM) components, is a common feature of many chronic liver diseases (CLD-B) and can ultimately lead to liver cirrhosis[1,2]. Hepatitis B virus (HBV) is a predominant cause of chronic liver disease and presents a high risk of fibrosis progression[3]. While the pathobiology of HBV-induced hepatic fibrosis has not been fully clarified, HBV presents a huge medical challenge because one third of the world's population has been infected and 350 million people are carriers of the virus. Hepatitis B is endemic in China (> 8% prevalence) and has caused epidemics in other parts of Asia and Africa.

Over last two decades, hepatic stellate cells (HSCs) have dominated studies exploring mechanisms of hepatic fibrosis[4]. In response to chronic liver injury, quiescent HSCs become activated myofibroblast-like cells that express α-smooth muscle actin (α-SMA) and produce components of the ECM, including fibrillar collagens[1,2]. This process is driven by a variety of growth factors, cytokines and matricellular proteins. Connective tissue growth factor (CCN2, also known as CTGF) is a secreted matricellular protein that is recognized increasingly as a central player in hepatic fibrosis[5]. Previously, we have shown that CCN2 production and secretion is enhanced by transforming growth factor-β1 (TGF-β1) in rat HSC and exposure of HSCs to CCN2 induces cell adhesion, migration, and proliferation[6,7]. We and others have shown that CCN2 induces expression of α-SMA or type I collagen in HSCs consistent with a role in activation and fibrogenesis[8,9]. In addition, CCN2 also stimulates survival pathways in activated HSCs thereby prolonging their fibrogenic potential[10]. In human or experimental liver fibrosis, CCN2 expression is higher than in normal liver, with strong correlation between hepatic CCN2 production and the degree of liver fibrosis[11].

Given the central role of CCN2 in hepatic fibrosis, we investigated the levels of serum CCN2 of patients with HBV-induced CLD-B, and determined the potential clinical value of hepatic or serum CCN2 levels in diagnosing the severity of HBV-induced hepatic fibrosis.

MATERIALS AND METHODS

Ethics
This work was approved by First Hospital of Jilin University and was carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. Informed consent was obtained from all patients prior to sample collection.

Clinical data
Serum was collected from 146 patients with CLD-B who were either outpatients or inpatients at First Hospital (Jilin University, Changchun, China) from June 2008 to September 2011. Of the 146 patients, there were 107 cases with chronic hepatitis B (CHB) (69 men and 38 women; mean age: 43.9 years, range: 18-76 years), 39 cases with active liver cirrhosis (27 men and 12 women; mean age:

41.9 years, range: 26-68 years). As determined using the Child-Pugh score to assess the severity of liver cirrhosis, 25 cases were class A and 14 cases were class B.

Serum was collected from 30 healthy individuals (18 men and 12 women; mean age: 33.6 years, range: 19-56 years) for controls. Serum and liver samples were collected from 8 HBV carriers who had histological normal livers (6 men and 2 women; mean age: 28.6 years, range: 19-38 years), and were studied as normal controls for the assessment of liver fibrosis of CLD-B patients. Patients and HBV carriers meet the diagnostic criteria for chronic HBV infection[12].

Liver tissue samples from 39 CLD-B patients and 8 HBV carriers were obtained using a percutaneous needle. The length of each sample was more than 1.5 cm. There were 31 cases with CHB (23 men and 8 women; mean age: 29.8 years, range: 18-50 years) and 8 cases with HBV-induced active liver cirrhosis (6 men and 2 women; mean age: 36.6 years, range: 26-54 years). Importantly, initial studies showed that levels of serum CTGF, Collagen I, Collagen III or aminotransferases in CLD-B patients receiving a liver biopsy were not significantly different as compared to CLD-B patients without a biopsy.

CCN2 enzyme linked immunosorbent assay
Sera were stored at -70 ℃ for 1 to 6 mo before analysis. The level of CCN2 in sera from 146 patients with CLD-B, 8 HBV carriers and 30 healthy individuals were measured with a commercial enzyme-linked immunosorbent assay (ELISA) kit, according to manufacturer's protocols (USCN Life Science and Technology Co, TX, United States). Briefly, microtiter wells were pre-coated for 2 h at 37 ℃, with 100 μL of each standard or 1:20 dilutions of sera. The plates were then developed by sequential addition of biotinylated anti-CCN2 antibody, avidin-conjugated horseradish peroxidase and tetramethylbenzidine substrate solution, and the color reaction was measured at 450 nm.

Grading and staging of liver biopsies
Liver tissue samples from 31 CHB patients, 8 patients with HBV-induced liver cirrhosis and 8 HBV carriers were individually fixed, paraffin-embedded and subjected to H and E staining or Van Gieson's method to determining histological inflammation and fibrosis which were scored using the Metavir system. Fibrosis was staged on a 4-point scale (F0: No fibrosis; F1: Minimal fibrosis; F2: Fibrosis with a few septa; F3: Numerous bridging fibrosis without cirrhosis; F4: Cirrhosis or advanced severe fibrosis). F1-F2 was defined as mild fibrosis and F3-F4 as significant fibrosis. Inflammation was graded on a four-point scale from A0, which indicated no inflammatory activity, up to A3, which indicated severe activity.

In situ hybridization
In situ hybridization (ISH) was performed using digoxigenin-labled sense or anti-sense probes for CCN2 or TGF-β1 (*Boster Biotechnology* Co. Ltd. Wuhan, China). In

Figure 1 Production of connective tissue growth factor or transforming growth factor β-1 in fibrous septa of hepatitis B virus-infected livers. Connective tissue growth factor mRNA (A) or protein (B) were detected by *in situ* hybridization (ISH) or immunohistochemistry respectively. transforming growth factor β-1 mRNA (C) was detected by ISH while collagen bundles (D) were stained red using Van Gieson's method. Original magnification, × 200 in A, B, C and D. Examples of positively stained cells or structures in each panel are arrowed.

brief, liver tissue samples from CLD-B patients were formaldehyde-fixed and parafin-embedded. The tissue sections (5 μm) were deparaffinized, rehydrated with PBS, digested with pepsin (30 μg/mL) for 10 min at 37 ℃, fixed in 4% paraformaldehyde in PBS and washed in 3 ×SSC. The samples were pre-hybridized at 40 ℃ for 2 h, and hybridization was performed overnight at 40 ℃ with sense or anti-sense probes. After hybridization, excess probes were removed by sequential washing in twice concentrated (2×) saline-solution citrate buffer (SSC), 0.5×SSC and then 0.2×SSC at 37 ℃ for 2 h. The tissue sections were incubated at 37 ℃ for 1 h with biotinylated mouse anti-digoxigenin, followed by addition of the streptavidin-biotin-peroxidase complex for 20 min. The slides were then developed with 3-amino-9-ethylcarbazole (Boster Biotechnology). Ten random images (original magnification ×400) of each slide underwent computer image analysis using Image-Pro Plus 6.0 software to assess the integrated optimal density (IOD) of CCN2-positive cells in liver tissues.

Immunohistochemistry

Formalin-fixed, paraffin-embedded sections (5 μm) were de-waxed and re-hydrated. Sections were incubated overnight at 4 ℃ with mouse anti-human α-SMA monoclonal antibody (Zhongshan Goldbridge Biotechnology, Beijing, China) or rabbit anti-human CCN2 polyclonal antibody (Santa Cruz, Heidelberg, Germany) or rabbit anti-human

F4/80 polyclonal antibody (Spring Bioscience, United States). Sections were washed in PBS and incubated at room temperature for 10 min with biotinylated *goat anti-mouse* and *rabbit* IgG (Maixin Bio, Fuzhou, China). After washing with PBS, sections were incubated with streptavidin-peroxidase (Maixin Bio, Fuzhou, China) for 10 min and then developed with diaminobenzidine or 3-amino-9-ethylcarbazole.

Statistical analysis

The values reported represent the median [95% confidence interval (CI)] of the measurements. Statistical analysis of the data was performed using SPSS 13.0 for Windows (SPSS Inc, Chicago, IL, United States). The nonparametric Wilcoxon signed ranks test was used for pair-wise comparison of groups and Spearman's rank correlation analysis was used to determine the relationship between two variables. Areas under the receiver operating characteristic (ROC) curves (AUC) were calculated for comparing the accuracy of the CCN2 in sera in different subgroups.

RESULTS

Localization of CCN2 mRNA or protein in HBV-induced chronic liver disease

In normal livers, only mild CCN2 mRNA staining was detected in portal tracts and there was no staining in the

Figure 2 Cellular localization of key fibrotic markers in hepatitis B virus -induced liver fibrosis. α-SMA-positive hepatic stellate cells (HSCs) were not detectable in hepatitis B virus carriers who had normal liver histology (A) but were present in chronic hepatitis B (CHB) liver (B). In CHB liver samples, there was no staining when the *in situ* hybridization probes were omitted (C) but their inclusion demonstrated the presence of either connective tissue growth factor mRNA in activated HSCs (D) or transforming growth factor β-1 mRNA in activated HSCs (E) or Kupffer cells (F). F4/80 antigen-positive Kupffer cells (G). Original magnification, × 400 in A-G. Examples of postively stained cells in each panel are arrowed.

central vein or lobule (data not shown). However, CCN2 mRNA and protein were localized to fibrotic septa in CLD-B patients with hepatic fibrosis (Figure 1A and B) or cirrhosis (data not shown), and the pattern of CCN2 staining was well correlated with the distribution of collagen fibers (Figure 1D). By comparison to normal livers, CHB patients demonstrated strong α-SMA-positive staining in presumptive activated HSC (Figure 2A and B) and these cells also stained strongly for CCN2 mRNA (Figure 2C and D).

Since CCN2 acts downstream of TGF-β1 to drive fibrosis[13], we examined the expression and distribution of TGF-β1 mRNA in the liver of CLD-B patients. TGF-β1 mRNA was detected in the fibrotic septa of patients with hepatic fibrosis (Figure 1C) or cirrhosis (data not

shown) and was localized to activated HSCs in the lobule (Figure 2E) and Kupffer cells (Figure 2F and G) within inflammatory area in the livers of CHB patients.

Serum levels of CCN2 in HBV-induced chronic liver diseases

Since CCN2 is synthesized with a signal peptide and can exist extracellularly in soluble or matrix-associated forms, we examined serum from CLD-B patients for the presence of CCN2 protein by ELISA. As shown in Table 1, serum CCN2 concentrations were, respectively, 4.0- or 4.9-fold higher in patients with CHB or active liver cirrhosis as compared to healthy individuals ($P < 0.01$). There was no difference in the serum CCN2 levels between the HBV carriers and healthy individuals.

Table 1 Serum connective tissue growth factor concentrations in patients with chronic liver diseases (μg/L)

Group	*n*	Median (95% CI)
Healthy control	30	2.2 (1.6-2.8)
HBV carrier	8	2.2 (1.5-2.9)
Chronic hepatitis B	107	8.8 (6.0-12.3)
Active liver cirrhosis	39	10.9 (7.0-14.6)

HBV: Hepatitis B virus.

Table 2 Relationship between fibrosis stage and hepatic or serum connective tissue growth factor content

Fibrosis stage	*n*	Serum CCN2 (μg/L) median (95% CI)	Hepatic CCN2 mRNA (IOD) median (95% CI)
Normal control	8	2.2 (1.5-2.9)	6.0 (3.9-8.8)
F1	11	6.8 (5.0-8.9)	19.4 (12.3-26.4)
F2	9	8.9 (7.1-10.7)	25.6 (13.9-34.8)
F3	11	9.4 (7.3-12.0)	31.9 (19.7-44.6)
F4	8	10.1 (8.2-12.1)	39.6 (25.5-52.8)

Normal Control samples were from hepatitis B virus carriers and had normal liver histology; F1-F2: Mild fibrosis; F3-F4: Significant fibrosis. CCN2: Connective tissue growth factor; IOD: integrated optimal density.

Figure 3 Receiver operating characteristic curve of connective tissue growth factor. Receiver operating characteristic (ROC) curves of connective tissue growth factor distinguishing normal liver controls from patients with F1 stage liver fibrosis (A) or discriminating between mild and significant fibrosis (B) with areas under the ROC curves of 0.94 or 0.85, respectively.

CCN2 production as a function of severity of fibrosis or inflammation

Having shown that hepatic and serum CCN2 concentrations were higher in CLD-B patients than in healthy individuals, we next investigated if there was a correlation between CCN2 and fibrosis stage. As shown in Table 2, serum concentrations and hepatic content of CCN2 increased in proportion to the severity of fibrosis; Spearman's rank correlation analysis showed that correlation coefficients were 0.85 and 0.89 (both $P < 0.01$), respectively. However, the levels of CCN2 in sera were not correlated with the degree of inflammation in CHB patients.

Diagnostic performance of serum CCN2

We further analyzed the diagnostic performance of serum CCN2 for assessing liver fibrosis using the ROC curves. Calculation of the areas under ROC curves (AUC) showed that serum CCN2 could be used to distinguish either normal liver controls from patients with F1 stage liver fibrosis (AUC = 0.94) or mild fibrosis (F1/F2) from significant fibrosis (F3/F4) (AUC = 0. 85) (Figure 3).

DISCUSSION

Chronic HBV infection can cause hepatic fibrosis and eventually cirrhosis. Over the last few years, HBV infection has been studied extensively *in vitro* with the finding that expression of the HBV X protein (HBx) in hepatocytes results in paracrine activation and proliferation of human or rat HSC resulting in their increased expression of collagen I , CCN2, α-SMA, matrix metalloproteinase-2, or TGF-β[14,15]. Although hepatocytes serve as a suitable host for HBV and permit viral replication and antigen production, HBV can also transiently infect and replicate in human HSCs which directly increases the production of collagen type in the cells[3,16]. Collectively, these findings have shown that activation of fibrogenic pathways in HSC following HBV infection of either hepatocytes or HSC is a key event in HBV-mediated hepatic fibrosis. In this regard, CCN2 has emerged as a potential key fibrogenic mediator in response to HBV in as much as CCN2 supports HSC activation, promotes HSC proliferation and survival, and acts downstream of TGF-β to drive HSC collagen production[6,7,10,13,17]. In this study, we showed that CCN2 mRNA and protein were expressed at high levels by myofibroblasts (including presumptive activated HSC) in fibrotic septa in CLD-B patients with hepatic fibrosis or cirrhosis, and that increased levels of hepatic or circulating CCN2 were associated with severe fibrosis. This result is consistent with previous observations by others[11].

Activation of Kupffer cells, the resident macrophage population of the liver, serves as a central determinant of the liver's response to injury and repair, and the resulting inflammatory reaction is an important prerequisite for HSC activation and progression to hepatic fibrosis[18,19]. Macrophage-derived TGF-β1 has been identified as a potential paracrine stimulator of HSC activation[20] and addition of TGF-β antibodies to Kupffer cell conditioned medium inhibits its ability to induce expression of

CCN2, collagen I and TIMP-1 when added to cultured HSC[21]. In the present study, both TGF-β1 and CCN2 mRNA were detected in presumptive activated HSCs, while TGF-β1 mRNA alone was detected in Kupffer cells within inflamed areas of livers from CHB patients. These data support the notion that TGF-β1 upregulates CCN2 production in HSCs *via* paracrine and autocrine pathways, and further enhance the effects of CCN2 during fibrogenesis. This is supported by *in vitro* studies showing that CCN2 is a downstream mediator of TGF-β1-induced collagen I production in human HSCs[16].

CCN2 is a secreted protein that has been detected in several human body fluids including serum, cerebrospinal fluid, follicular fluid, uterine fluid, or urine[22]. This has led to examination of the potential utility of evaluating CCN2 concentrations in highly accessible fluids such as serum or plasma for non-invasive diagnostic evaluation of the extent or severity of various fibrotic pathologies. Thus, serum levels of CCN2 have been shown to be correlated with the extent of systemic skin sclerosis and severity of pulmonary fibrosis in human subjects[23] and to serve as a biomarker of progressive kidney fibrosis in chronic allograft nephropathy in a clinical and experimental study[24]. Studies on circulating CCN2 levels in assessment of hepatic fibrosis have just begun to gain momentum and are founded on the well documented over-expression of CCN2 in fibrotic livers due to its production by multiple cell types (including HSC, hepatocytes, biliary epithelial cells). An early study reported as association between elevated CCN2 serum levels and progression of hepatic fibrosis in biliary atresia[25] while a more recent investigation demonstrated significantly elevated serum levels of CCN2 in patients with chronic hepatitis and cirrhosis that were well correlated with the progression of hepatic fibrosis[26-28]. In the present research, we found that increased CCN2 concentrations were present in the serum of patients with CHB and HBV-induced cirrhosis. Serum CCN2 levels were consistent with those in liver tissue and were strongly correlated with the stage of hepatic fibrosis. Taken together, our data indicate that CCN2 is a potential valuable biomarker of HBV-induced hepatic fibrosis, and further support the classification of CCN2 as class I fibrosis biomarker, defined as one that is derived from changes of the fibrogenic cell types and which reflects the activity of the fibrogenic and/or fibrolytic process[29].

Finding the best method to evaluate and diagnose the stage of liver fibrosis continues to be a challenge[30]. Although liver biopsy is a gold-standard procedure for determining the grade of liver inflammation and stage of fibrosis[30-33], there are well recognized difficulties including complications, high hospital expenses[30,34], false sample recording[35], contra-indications during the procedure, and dependence on the pathologists' skills in examining samples. Serum fibrosis tests with AUCs ranging from 0.85 to 0.90 have been proposed as good biochemical markers with high diagnostic value[36,37]. In our research, serum CCN2 was valuable not only in distinguishing normal liver controls from patients with F1 stage liver fibro-

sis but also in distinguishing between mild and significant liver fibrosis. We therefore propose that further studies are warranted to further evaluate the potential utility of serum CCN2 as a biomarker of liver fibrosis in HBV-induced CLD-B.

COMMENTS

Background
Millions of individuals around the world are infected with hepatitis B virus (HBV), resulting in chronic liver disease. In many cases, affected individuals suffer from hepatic fibrosis, a highly debilitating pathology in which the normal cellular architecture and function in the liver are severely compromised through the deposition of collagen and other insoluble extracellular matrix molecules. This process is driven by connective tissue growth factor (CCN2) which is known to be produced at high levels in fibrotic livers and which acts to drive fibrogenic pathways in hepatic stellate cells (HSCs), a principal fibrotic cell type in the liver.

Research frontiers
Currently, parameters used to assess liver fibrosis are inaccurate. There is optimism that measurement of CCN2 levels in either the livers or serum of affected patients will have useful diagnostic or prognostic value.

Innovations and breakthroughs
To date, there have been a limited number of studies regarding the value of serum CCN2 for assessment of hepatic fibrosis. In this study, the authors employed more systemic detection techniques to evaluate the relationship among serum CCN2 levels, hepatic CCN2 content and liver fibrosis severity in patients with chronic liver diseases. Furthermore, the authors described the expression characteristics of CCN2 in liver tissues and its role and mechanism in HBV-induced hepatic fibrosis.

Applications
These studies suggest that serum CCN2 concentrations are a reliable diagnostic indicator of HBV-induced liver fibrosis and that CCN2 can be used a part of the platform for evaluation of the severity of liver fibrosis.

Terminology
CCN2: a pro-fibrogenic molecule that is over-expressed in many fibrotic diseases and which stimulates collagen synthesis in HSC.

Peer review
This is an interesting and important issue in the utility of CCN2 for assessing hepatic fibrosis. Correlations of the serum levels of CCN2 in HBV infected patients with hepatic fibrosis have been well documented in literature.

Abstract

Systemic corticosteroids represent the standard treatment for autoimmune pancreatitis with IgG4-associated cholangitis. For steroid-dependent disease, azathioprine has been used for maintenance of remission. Mycophenolate mofetil has been used for transplant immunosuppression and more recently for autoimmune hepatitis; however, there are no case reports to date on the use of mycophenolate mofetil in adult patients with autoimmune pancreatitis. A patient with IgG4-mediated autoimmune pancreatitis and IgG4-associated cholangitis refractory to steroids and intolerant of azathioprine was treated with mycophenolate mofetil, which inhibits de novo guanosine synthesis and blockade of both B and T lymphocyte production. Introduction of mycophenolate mofetil and uptitration to 1000 mg by mouth twice daily over a treatment period of 4 mo was associated with improvement in the patient's energy level and blood glucose control and was not associated with any adverse events. The patient was managed without a biliary stent. However, there was a return of symptoms, jaundice, increase in transaminases, and hyperbilirubinemia when the prednisone dose reached 11 mg per day. In the first report of mycophenolate mofetil use in an adult patient with IgG4-associated autoimmune pancreatitis and IgG4-associated cholangitis, the introduction of mycophenolate mofetil was safe and well-tolerated without adverse events, but it did not enable discontinuation of the steroids. Mycophenolate mofetil and other immunomodulatory therapies should continue to be studied for maintenance of remission in the large subset of patients with refractory or recurrent autoimmune pancreatitis.

INTRODUCTION

Autoimmune pancreatitis (AIP) represents a chronic dis-

ease of the pancreas with a presumed autoimmune etiology. There are characteristic serologic, morphologic, clinical and pathologic features, specifically, lymphoplasmacytic infiltration with parenchymal fibrosis. Some patients develop comorbid involvement of the biliary tract characterized by steroid responsive stricturing, a condition that has been termed IgG4-associated cholangitis (IAC). Steroid therapy is the first-line and mainstay treatment for AIP but relapse is frequent on steroid withdrawal. Azathioprine has been used for patients who fail steroid tapering, but is not tolerated by some patients and may be contraindicated in patients with deficient thiopurine methyltransferase (TPMT) activity. The use of mycophenolate mofetil as a possible treatment alternative for autoimmune pancreatitis with IAC has been described once in the pediatric population[1] and has been mentioned in discussions of AIP[2,3]. However, there have been no case reports to date in an adult population. We describe a 65-year-old man with a history of AIP and IAC who failed multiple attempts at steroid tapering and was intolerant of azathioprine. This is the first case report of the use of mycophenolate mofetil in an adult patient with IgG4-mediated AIP and IAC.

CASE REPORT

A 65-year-old Caucasian male presented to another medical center for a routine colonoscopy. A chest radiograph obtained prior to the procedure revealed multiple nodules in the lower lung fields with pleural scarring and a small pleural effusion. A subsequent computed tomography (CT) scan of the chest revealed multiple pulmonary nodules in the right lower lobe, right lateral middle lobe, and left middle lobe, as well as intrathoracic lymphadenopathy. Because of concerns of malignancy, bronchoalveolar lavage was performed, which revealed infection with *Aspergillosis fumigatus*. The patient began treatment with micofungin.

At the time of bronchoscopy, the patient was also noted to be jaundiced. Laboratory findings revealed an elevated serum total bilirubin level of 4.8 mg/dL and an elevated conjugated bilirubin level of 4 mg/dL. Serum lipase was 16 U/L and serum amylase was 40 U/L, both within normal limits. CT scan of the abdomen revealed diffuse enlargement of the pancreas, evidence of cholelithiasis, as well as biliary ductal dilatation. An upper endoscopic ultrasound with fine-needle aspiration of the pancreas revealed ductal epithelium with fibrosis, inflammatory cells, and debris and no evidence of malignancy, suggestive of autoimmune pancreatitis. Endoscopic retrograde cholangiopancreatography (ERCP) revealed a stricture in the intra-pancreatic portion of the main bile duct, for which the patient underwent stent placement. Biliary ductal brushings revealed no malignant cells. The serum IgG4 level was elevated at 213 mg/dL. Treatment with a tapering course of prednisone for 6 weeks was initiated, with significant improvement in symptoms, reduction in the size of the pancreas on cross sectional imaging, and normalization of the liver enzymes.

After 3 mo, the patient presented to the same hospital emergency department with a relapse of jaundice, steatorrhea, and chills. The total bilirubin was 6 mg/dL, direct bilirubin was 5.2 mg/dL, aspartate aminotransferase (AST) was 122 U/L, alkaline phosphatase (ALP) was 557 U/L, and lactate dehydrogenase was 369 mg/dL. Ultrasound of the gallbladder showed development of mild intrahepatic biliary dilatation, possibly representing stent malfunction. CT of the abdomen revealed significant interval increase in the size of the pancreas. ERCP was performed with exchange of the common bile duct stent. Cholangiography revealed diffuse irregular stricturing of the common bile duct to the hilum of the liver. The patient was restarted on prednisone 40 mg daily. There was symptomatic and clinical improvement.

The patient was referred to our medical center to receive care closer to his home. He was taking 30 mg prednisone daily on presentation and reported feeling well. The biliary stent was extracted. His serum IgG4 level was elevated at 120 mg/dL. The other autoimmune work-up was negative: Anti-nuclear antibody IgG was not detected, Anti-neutrophil cytoplasmic antibody IgG was less than 1:20, f-actin antibody IgG was 15 units (negative), anti-mitochondrial M2 antibody IgG was 0.9 units (negative), and liver kidney microsomal antibody IgG was less than 1:20 (negative). Two months later, the patient presented once again with recurrent jaundice, fatigue, and discomfort. By this time, he had been tapered to a dose of 15 mg prednisone daily and had completed micafungin treatment for his pulmonary aspergillosis. Magnetic resonance imaging (MRI) of the abdomen with and without gadolinium revealed a diminished T1 signal and abnormal delayed enhancement in the pancreas. There was no pancreatic ductal dilatation, and the overall morphology was normal to mildly enlarged. The T2 signal was mildly elevated in the pancreatic parenchyma. The impression was of changes consistent with autoimmune pancreatitis. The MRI also revealed diffuse intrahepatic biliary ductal dilatation and intrahepatic ductal stenosis as well as periportal arterial blush enhancement and delayed uptake of contrast, consistent with active cholangitis. ERCP showed a single severe 18 mm stricture in the distal common bile duct with irregular stricturing of the bilateral intrahepatic ducts (Figure 1). A stent was placed in the bile duct. Biopsy of the pancreatic ampulla demonstrated chronic active inflammation with approximately 20-25 IgG4-containing plasma cells/high power field, consistent with the clinical impression of autoimmune pancreatitis (Figure 2). The patient was maintained on 15 mg prednisone and was started on 50 mg azathioprine daily in an attempt to transition to a steroid-sparing immunosuppressive regimen. However, he was unable to tolerate azathioprine due to debilitating nausea, fatigue, lethargy and diarrhea despite dose reduction, evening administration, and concurrent antiemetic therapy.

Over the next 6 mo, the patient underwent 2 additional biliary stent exchanges at 3-mo intervals. Brush specimens obtained from the common bile duct stricture were

Figure 1 Cholangiogram obtained during endoscopic retrograde cholangiopancreatography demonstrating a marked 18 mm stricture in the distal common bile duct with diffuse irregular stricturing of the intrahepatic ducts bilaterally.

negative for malignant cells by cytology and fluorescence *in situ* hybridization analysis. The patient was maintained on 15 mg prednisone daily. Mycophenolate mofetil was discussed as an alternative immunomodulatory treatment and an alternative to long-term prednisone. The patient was initiated on mycophenolate mofetil at a dose of 750 mg twice daily.

The patient tolerated the mycophenolate mofetil without side effects. At this point, he was being maintained on mycophenolate mofetil and prednisone. After 3 mo on mycophenolate mofetil and prednisone, he had no jaundice or steatorrhea. His hyperglycemia was mild and his diabetes medications were being tapered, likely a result of the lower dose of prednisone required. He required 3 half-tablets of glipizide 5 mg per month to maintain normal serum glucose values. The serum AST level was 30 U/L, ALP level was 101 U/L, total bilirubin level was 0.7 mg/dL, albumin was 3.4 mg/dL, amylase was 43 U/L and lipase was 16 U/L. At the time of his last scheduled stent exchange, the stent had passed spontaneously and no procedure was performed. However, over this 3-mo period, he had several self-limited episodes of fatigue, malaise, and pruritus lasting 24 to 48 h, associated with transient elevations in his liver enzymes. He remained without a biliary stent and felt well overall. Given this course, the mycophenolate mofetil dosage was increased to 1000 mg twice daily and a steroid taper was again resumed, decreasing the dose by 1 mg per week from an initial dose of 15 mg prednisone daily. When the patient reached 10 mg prednisone daily, he experienced a recurrence of nausea and abdominal pain, as well as darkened urine. His total bilirubin was elevated to 9.5 mg/dL, AST 146 IU/L, and ALT 266 IU/L. His prednisone dosage was increased back to 15 mg per day and his symptoms again resolved. He is presently maintained on 15 mg prednisone per day and the mycophenolate mofetil is being tapered due to an inability to stop systemic corticosteroids. He is able to continue an active lifestyle working 12-14 h days on his farm. He is being considered for alternative immunomodulatory therapy.

Figure 2 Histopathologic images demonstrating the findings from the patient's ampullary biopsy. A: A hematoxylin eosin stained biopsy at 20 × magnification revealed chronic active inflammation; B: An IgG4 stain revealed approximately 20-25 IgG4-containing plasma cells/high power field, consistent with autoimmune pancreatitis.

DISCUSSION

Systemic corticosteroid therapy is the standard treatment for AIP with IAC[3]. AIP and IAC likely represent organ-specific manifestations of a broader systemic disease described as IgG4-related sclerosing disease. The disease process involves deposition of IgG4 antibodies into various tissues, causing fibrosis and organ dysfunction. Other proposed manifestations of IgG4-associated disease include Sjögren's syndrome, primary sclerosing cholangitis, and retroperitoneal fibrosis[4]. There is a strong association between AIP and IAC, as was seen in our patient[5].

Although the response to corticosteroids is a defining feature of AIP, representing one of the 5 diagnostic criteria (histology, imaging, serology, other organ involvement and response to therapy) for the disease[6], relapse of biliary strictures after steroid withdrawal in cases of IAC is not uncommon. In one recent study of 53 patients with IAC, 54% of patients experienced relapse after steroid withdrawal[3]. In such cases, alternative treatment with immunomodulating medications such as azathioprine and 6-mercaptopurine has been proposed to avoid long-term steroid use and its associated consequences[3]. However, azathioprine and 6-mercaptopurine are not tolerated by all patients. In addition, reduced TPMT activity may be found in approximately 11% of the population, and undetectable enzyme activity in 0.3% of the population[7]. Patients with insufficient TMPT activity may develop

bone marrow toxicity and myelosuppression[8]. In addition, while azathioprine and 6-mercaptopurine may be tolerated, not all patients started on these medications will be able to taper their steroid therapy. For these reasons, alternatives are being examined. For example, a patient refractory to steroid taper and 6-mercaptopurine was successfully managed with rituximab, experiencing cholangiographic improvement, normalization of liver enzymes, and resolution of extrapancreatic manifestations of IgG4 disease[2]. However, rituximab requires infusional therapy, is not indicated for AIP, and has a high cost, which limits its use in this setting.

There have been 2 references to mycophenolate mofetil as a potential alternative treatment in refractory cases of autoimmune pancreatitis[2,3]; however, there are no case reports in the adult populations to date. Mycophenolate mofetil acts as an inhibitor of inosine monophosphate dehydrogenase, which inhibits *de novo* guanosine nucleotide synthesis. Through this mechanism, mycophenolate mofetil exhibits a cytostatic effect on T and B lymphocytes by blocking proliferation[9]. Mycophenolate mofetil has been used in transplantation medicine, inflammatory bowel disease, and rheumatoid arthritis, often as a second-line immunosuppressant. More recently, mycophenolate mofetil use has been described in cases of refractory autoimmune hepatitis[10].

In the case described herein, the steroid taper was not successful with the use of mycophenolate mofetil and the patient had recurrence of symptoms, jaundice and elevated liver enzymes; however, the medication may be efficacious in a subset of patients with refractory disease, and we believe that this merits further investigation in larger studies.

In summary, this is the first case report of mycophenolate mofetil for AIP and IAC. The addition of mycophenolate mofetil to the patient's therapy was well-tolerated but did not permit steroid tapering below 11 mg prednisone per day. The patient may have experienced an improvement in energy and in remission of mild diabetes while on mycophenolate mofetil, possibly because the treatment allowed for a lower dose of prednisone.

However, the decision was made to taper and ultimately discontinue the mycophenolate mofetil due to failure to enable cessation of systemic corticosteroids. We believe that mycophenolate mofetil should continue to be examined for use in patients with steroid-dependent AIP and/or IAC, especially in the subset for whom azathioprine and 6-mercaptopurine are ineffective or contraindicated. Additional immunomodulatory therapies are needed for maintenance of remission in the large cohort of AIP and IAC patients who fail steroid tapering.

Abstract

Hepatic artery pseudoaneurysm (HAP) is a very rare disease but in cases of complication, there is a very high mortality. The most common cause of HAP is iatrogenic trauma such as liver biopsy, transhepatic biliary drainage, cholecystectomy and hepatectomy. HAP may also occur with complications such as infections or inflammation associated with septic emboli. HAP has been reported rarely in patients with acute pancreatitis. As far as we are aware, there is no report of a case caused by acute idiopathic pancreatitis, particularly. We report a case of HAP caused by acute idiopathic pancreatitis which developed in a 61-year-old woman. The woman initially presented with acute pancreatitis due to unknown cause. After conservative management, her symptoms seemed to have improved. But eight days after admission, abdominal pain abruptly became worse again. Abdominal computed tomography (CT) was rechecked and it detected a new HAP that was not seen in a previous abdominal CT. Endoscopic retrograde cholangiopancreatography (ERCP) was per-

formed because of a suspicion of hemobilia as a cause of aggravated abdominal pain. ERCP confirmed hemobilia by observing fresh blood clots at the opening of the ampulla and several filling defects in the distal common bile duct on cholangiogram. Without any particular treatment such as embolization or surgical ligation, HAP thrombosed spontaneously. Three months after discharge, abdominal CT demonstrated that HAP in the left lateral segment had disappeared.

Hepatic artery pseudoaneurysm caused by acute idiopathic pancreatitis. *World J Gastroenterol* 2012; 18(18): 2291-2294 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i18/2291.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i18.2291

INTRODUCTION

Hepatic artery pseudoaneurysm (HAP) is rare[1,2]. But rupture is common and occurs in 76% of patients with HAP. There are many causes of HAP, but it usually results from procedures such as liver biopsy, transhepatic biliary drainage, cholecystectomy, and hepatectomy[3]. HAP may also occur with complications such as infections or inflammation associated with septic emboli[4-7]. HAP has rarely been reported in patients with acute pancreatitis[8,9]. As far as we are aware, there is no report of a case caused by acute idiopathic pancreatitis. We report a case of HAP thought to be caused by acute pancreatitis due to unknown cause, in a 61-year-old Korean woman.

HAP spontaneously thrombosed without any particular treatment and finally disappeared several months later. We also review the literature concerning HAP.

CASE REPORT

A 61-year-old Korean woman was admitted to the emergency room with right upper quadrant pain and vomiting starting 8 h before admission. She was previously well-nourished, and had no past medical history. The patient denied a history of percutaneous intervention, abdominal surgery, trauma, viral hepatitis, bleeding disorders, jaundice or blood transfusion. On admission, her blood pressure was 120/80 mmHg, pulse rate was 78/min, and body temperature was 36.8 ℃. On examination, her appearance was that of acute illness and her tongue was mildly dehydrated. But she was clinically non-anemic and non-icteric. Abdominal examination revealed right upper quadrant tenderness without rebound and hepatomegaly. Rectal examination showed no melena.

Laboratory data on admission were as follows: white blood cell count 14 900/μL with 90.5% increase in neutrophils; hemoglobin 13.4 g/dL; hematocrit 39.0%; platelet count 226 000/μL; prothrombin time 15.0 [international normalized ratio (INR) 1.27]; serum total protein 7.0 g/dL; albumin 4.4 g/dL; alkaline phosphatase 103 U/L; total bilirubin 1.0 g/dL; Alanine aminotransferase (ALT) 87 U/L; aspartate aminotransferase (AST) 56 U/L; gamma-glutamyl transferase 46 U/L. Amylase (1167 U/L) and lipase (2630 U/L) were increased. Abdominal computed tomography (CT) demonstrated infiltration with swelling in an uncinate process of the pancreas head and infiltration and mural enhancement in adjacent duodenum, described as grade C according to Balthazar classification (Figure 1).

After conservative management, her symptoms were improved but eight days after admission, her abdominal pain abruptly deteriorated again. Laboratory data were as follows: hemoglobin 12.2 g/dL; hematocrit 35.7%; white blood cell count 9200/μL with 69.2% neutrophils; platelet count 118 000/μL; prothrombin time 14.1 s (INR 1.20); alkaline phosphatase 83 U/L; total bilirubin 0.6 g/dL; ALT 13 U/L; AST 22 U/L; gamma-glutamyl transferase 33 U/L. Amylase (69 U/L) and lipase (153 U/L) were within normal ranges. On a second check-up with abdominal CT, the infiltration and swelling of the pancreas head was improved and there was no stone in the biliary tract. But it showed a newly developed hepatic artery pseudoaneurysm in the left lateral segment and no evidence of acute bleeding related to it as a complication (Figure 2). We performed endoscopic retrograde cholangiopancreatography (ERCP) in order to find the cause of aggravated pain with suspicion of hemobilia. Several filling defects with labile and indeterminate shapes were observed on cholangiogram and, after sphincterotomy, these findings were confirmed to be caused by fresh blood clots without a stone, and blood clots were removed with a balloon catheter and basket (Figure 3). Emergent

Figure 1 Abdominal computed tomography scans showed diffuse swelling and infiltration in head, body (A) and tail (B) of pancreas without obvious stone, indicating acute pancreatitis.

Figure 2 Follow up of abdominal computed tomography scan (A) due to abruptly aggravated abdominal pain and reconstructed computed tomography angiogram (B) showed newly developed hepatic artery pseudoaneurysm in the left lateral segment of liver (white arrows).

Figure 3 Cholangiogram by endoscopic retrograde cholangiopancrea-tography showed several amorphous filling defects in the common bile duct (A) and lots of blood clots were seen and removed by basket after endoscopic sphincterotomy (B).

Figure 5 Follow-up of abdominal computed tomography scans 3 mo later showed that both previously noted hepatic artery pseudoaneurysm in the left lateral segment (A) and diffuse swelling and infiltration of pancreas (B) had disappeared.

Figure 4 Magnetic resonance imaging scans of the abdomen revealed that hepatic artery pseudoaneurysm was replaced by thrombus formation (white arrows) in the left lateral segment in-phase (A) and out-of-phase (B) T1-weighted images and T2-weighted image (C).

angiography was not performed due to no further acute bleeding evidence.

After ERCP, the patient's pain improved and filling defects caused by blood clots of the extrahepatic duct were not observed on endoscopic nasobiliary drainage cholangiogram. Magnetic resonance imaging showed that dilatation or filling defects of the bile duct disappeared and bleeding of proximal HAP was replaced by throm-bus formation (Figure 4). Two days later, angiography re-vealed no visible contrast leakage and definite HAP. Her symptoms resolved rapidly, and she was discharged on the 16th day after clot removal.

Three months after discharge, abdominal CT dem-onstrated that minimal bile duct dilatation was noted but HAP in the left lateral segment had disappeared and pan-creatitis improved (Figure 5).

DISCUSSION

HAP is mainly caused by acute or chronic artery injuries such as blunt or penetrating injuries and interventional radiological procedures[10]. A minority of their formation may occur as a result of bile duct damage usually associated with stone impaction or procedure-related infection[4-6]. Unlike these reports, this case suggests that HAP occurred due to no invasive procedure and infection but acute pancreatitis. In this case, acute pancreatitis due to unknown cause may have eroded the arterial wall and led to pseudoaneurysm formation and then HAP's rupture causing hemobilia. The mechanism of pseudo-aneurysm formation in pancreatitis is thought to be due to autodigestion of pancreatic enzymes. Among HAP caused by pancreatitis, most cases have been reported to be due to chronic pancreatitis, but HAP caused by acute pancreatitis has only rarely been reported[11]. Furthermore, among reports of HAP due to acute pancreatitis, acute idiopathic pancreatitis causing HAP has not been reported so far.

In this case, it can be presumed that a rupture of preexisting HAP was not detected on initial abdominal CT imaging, resulting in hemobilia and eventually, acute pancreatitis was complicated by hemobilia. However, considering the fact the patient had normal levels of hemoglobin and no bile duct dilatation or filling defects when visiting hospital and the clinical course worsened (e.g., pain) despite the improvement of acute pancreatitis during the treatment, this possibility is very low. She was hospitalized for 8 d without any evidence of this procedure, and hemobilia-induced abdominal pain developed without aggravation of acute pancreatitis. This makes the scenario of pancreatitis-induced HAP more reasonable.

HAP is a rare and potentially fatal disease if it ruptures. In most cases, conservative management is not recommended due to the high rupture rate. Treatment comprises reconstructive surgery, or ligation depending on the size of the lesion and its location in the past. Today, the treatment of choice is selective transcatheter embolization[10,12,13]. However, in very limited cases, which means, unless HAP is not at risk of immediate rupture because of progressively enlarging size or instability, it can be managed by closed medical observation and imaging follow-up with appropriate treatment of the associated infection[14]. In this case, there was only conservative management of acute pancreatitis which is thought to be a cause of HAP. But we could confirm that HAP spontaneously thrombosed without any particular treatment at the image study. Three months after discharge, abdominal CT demonstrated that HAP in the left lateral segment had disappeared.

In summary, we report a rare case of a 61-year-old Korean woman who had HAP caused by acute idiopathic pancreatitis. In this case, HAP spontaneously thrombosed and then disappeared after recovery of acute pancreatitis. This case alerts clinicians that acute pancreatitis can be considered as a potential cause of HAP.

Abstract

This article reviews the pathogenic mechanism of non-steroidal anti-inflammatory drug (NSAID)-induced gastric damage, focusing on the relation between cyclooxygenase (COX) inhibition and various functional events. NSAIDs, such as indomethacin, at a dose that inhibits prostaglandin (PG) production, enhance gastric motility, resulting in an increase in mucosal permeability, neutrophil infiltration and oxyradical production, and eventually producing gastric lesions. These lesions are prevented by pretreatment with PGE_2 and antisecretory drugs, and also *via* an atropine-sensitive mechanism, not related to antisecretory action. Although neither rofecoxib (a selective COX-2 inhibitor) nor SC-560 (a selective COX-1 inhibitor) alone damages the stomach, the combined administration of these drugs provokes gastric lesions. SC-560, but not rofecoxib, decreases prostaglandin E_2 (PGE_2) production and causes gastric hypermotility and an increase in mucosal permeability. COX-2 mRNA is expressed in the stomach after administration of indomethacin and SC-560 but not rofecoxib. The up-regulation of indomethacin-induced COX-2 expression is prevented by atropine at a dose that inhibits gastric hypermotility. In addition, selective COX-2 inhibitors have deleterious influences on the stomach when COX-2 is overexpressed under various conditions, including adrenalectomy, arthritis, and *Helicobacter pylori*-infection. In summary, gastric hypermotility plays a primary role in the pathogenesis of NSAID-induced gastric damage, and the response, causally related with PG deficiency due to COX-1 inhibition, occurs prior to other pathogenic events such as increased mucosal permeability; and the ulcerogenic properties of NSAIDs require the inhibition of both COX-1 and COX-2, the inhibition of COX-1 upregulates COX-2 expression in association with gastric hypermotility, and PGs produced by COX-2 counteract the deleterious effect of COX-1 inhibition.

Takeuchi K. Pathogenesis of NSAID-induced gastric damage: Importance of cyclooxygenase inhibition and gastric hypermotility. *World J Gastroenterol* 2012; 18(18): 2147-2160 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i18/2147.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i18.2147

INTRODUCTION

Non-steroidal anti-inflammatory drugs (NSAIDs) are frequently used to treat inflammatory pain. A major limitation to their use, however, is the adverse reaction they cause to the gastrointestinal (GI) tract, including the formation of gastric lesions, the potentiation of ulcerogenic responses to stress, and the impairment of gastric ulcer healing[1-4]. Concerning the mechanism of NSAID-induced gastric damage, prostaglandin (PG) deficiency is

of prime importance to the gastric ulcerogenic response to NSAIDs, yet it has proven to be more complicated than expected and involves multiple, closely interacting elements, including hypermotility, neutrophils, free radicals, and so on[1,5-13].

The PG deficiency caused by NSAIDs is due to the inhibition of cyclooxygenase (COX). COX exists in two isozymes, COX-1 and COX-2; the former is constitutively expressed in various tissues, including the stomach, while the latter appears to be expressed in most tissues in response to growth factors and cytokines[14,15]. This tissue specificity of the COX isozymes has led to the idea that COX-1 is critical for housekeeping actions in the GI mucosa, whereas COX-2 functions under pathological conditions such as inflammation. Indeed, it has been reported that the gastric ulcerogenic properties of NSAIDs are due to the inhibition of COX-1, but not COX-2[16]. However, studies using selective COX-1 and COX-2 inhibitors demonstrated that the GI ulcerogenic effects of NSAIDs are not accounted for solely by inhibition of COX-1, but require inhibition of COX-2 as well[17-21]. It has also been shown that inhibition of COX-1 upregulated COX-2 expression in the GI mucosa, and PGs produced by COX-2 may help maintain the mucosal integrity when there is a deficiency of PGs due to COX-1 inhibition[18,20,21]. This idea was supported by the finding that the selective COX-2 inhibitor by itself damaged the gastric mucosa when the expression of COX-2 was upregulated in the stomach of rats subjected to adrenalectomy (glucocorticoid deficiency) or induction of adjuvant arthritis or *Helicobacter pylori* (*H. pylori*) infection[22-24].

In this article, we reviewed the pathogenesis of NSAID-induced gastric damage, mainly based on our own publications, including the roles of functional events, particularly, gastric hypermotility, as well as the influences of arthritis and *H. pylori* infection, and discussed the relation between COX-1 or COX-2 inhibition and pathogenic elements such as gastric motility and neutrophil infiltration.

GENERAL ASPECTS OF NSAID-INDUCED GASTRIC DAMAGE

Relation to PG deficiency

There is no doubt that a deficiency of endogenous PG is a background factor in NSAID-induced gastric ulceration. Indeed, when various NSAIDs, such as indomethacin (30 mg/kg), flurbiprofen (20 mg/kg), naproxen (40 mg/kg), dicrofenac (40 mg/kg) and aspirin (200 mg/kg), were administered to rats subcutaneously, all of these agents, except aspirin, produced damage in the stomach at doses that significantly decreased the mucosal prostaglandin E2 (**PGE2**) concentration[18,19] (Figure 1). Characteristically, the damage was observed along the long axis of the stomach and consisted mostly of hemorrhagic lesions, with a few non-hemorrhagic lesions. Interestingly, aspirin given subcutaneously did not produce any damage, despite inhibiting PG production as effectively as other NSAIDs[18,25]. Notwithstanding, it is assumed that PG deficiency is causally related to the gastric ulcerogenic

Figure 1 Gastric ulcerogenic responses (A) and changes in mucosal prostaglandin E2 content (B) induced by various non-steroidal anti-inflammatory drugs in rat stomach. The animals were given indomethacin (30 mg/kg), aspirin (200 mg/kg), naproxen (40 mg/kg), flurbiprofen (20 mg/kg) and diclofenac (40 mg/kg) s.c., and killed 4 h later. Data are presented as the mean ± SE in 5 rats. [a]$P <$ 0.05 *vs* control (data from ref. 18 after modification).

action of NSAIDs, but this factor alone is not sufficient for the development of gastric lesions. The reason why parenterally administered aspirin does not cause gastric damage will be discussed in another section of this article.

Effect of various drugs

The development of gastric lesions in response to indomethacin was inhibited by prior administration of PGE2. These lesions were also prevented by antisecretory drugs such as cimetidine, omeprazole and atropine[6,26,27], confirming the importance of luminal acid in the pathogenesis of these lesions. Of interest, since atropine was effective even when 150 mmol of HCl was applied to the lumen, it is assumed that this protective action is not associated with the antisecretory effect and initiated by factors other than inhibition of acid secretion (Figure 2). Neither cimetidine nor omeprazole was effective against indomethacin-induced gastric damage in the presence of exogenous acid. In addition, anti-neutrophil antiserum also reduced the severity of these lesions, but much less effectively than other agents[28]. Pretreatment with both

Figure 2 Effects of atropine, cimetidine and omeprazole on gastric lesions produced by indomethacin in rats. The animals were given indomethacin (30 mg/kg, s.c.) and killed 4 h later. Omeprazole (30 mg/kg), cimetidine (100 mg/kg) and atropine (3 mg/kg, s.c.) were given 1 h before indomethacin. In some cases, the animals were given 1 mL of 100 mmol HCl p.o. immediately after the administration of indomethacin. Data are presented as the mean ± SE for 5-8 rats. [a]$P < 0.05$ vs vehicle (data from refs. 6, 26 and 27 after modification).

atropine and dmPGE2 significantly inhibited the development of gastric lesions at all time points during a 4 h-test period following administration of indomethacin. By contrast, the anti-neutrophil antiserum did not affect the onset but significantly reduced the severity of lesions at 4 h after indomethacin treatment. It is assumed that the gastric ulcerogenic response to indomethacin is prevented by supplementation with PGE2 and inhibition of acid secretion as well as an atropine-sensitive mechanism, not related to the antisecretory action. Neutrophils do not play a role in the onset of these lesions but may be involved in the later extension of the damage. Suematsu et al[29] recently reported that the severity of gastric lesions produced by indomethacin was worse in mice lacking heat shock factor 1 (HSF1), a transcription factor for *HSP* genes, than in control mice, while these lesions were ameliorated in transgenic mice expressing HSP70. They suggested that expression of HSP70 ameliorates indomethacin-induced gastric damage by affecting mucosal apoptosis, probably *via* the activation of Bax.

Functional alterations involved in pathogenesis
Gastric hypermotility: Mersereau et al[7] first emphasized the importance of stomach hypermotility and mucosal foldings in the genesis of gastric lesions in response to phenylbutazone. As expected, all NSAIDs, except aspirin, increased gastric motility at ulcerogenic doses, leading to the development of gastric lesions[19] (Figure 3). Gastric hypermotility causes microvascular disturbances, especially at specific sites on mucosal foldings, leading to various events including neutrophil-endothelial interaction. Garrick et al[30] reported that high-amplitude contractions during cold-restraint stress resulted in a temporal restriction of mucosal blood flow and lowered the mucosal resistance to injury. The gastric damage induced by indomethacin occurred linearly along the long axis of the

stomach, and microscopically, was seen at the top or the bottom of mucosal foldings, the sites most influenced by mucosal compression due to contraction of the stomach, where mucosal blood flow is restricted, leading to microvascular disturbances (Figure 4A and B). The inhibition of gastric motility may lead to a flattening of the mucosal foldings and a decrease in microvascular disturbances, resulting in prevention of the fold-related band-like lesions, as observed after the administration of indomethacin[6,10,26,31]. A role for muscle elements in the pathogenic mechanism of gastric ulceration has been demonstrated[6,10,31-33]. Yamaguchi et al[32] monitored gastric mucosal hemodynamics and motility simultaneously and found oscillatory changes in the hemodynamics during gastric hypermotility induced by water-immersion stress. We also found that indomethacin caused oscillatory changes in mucosal blood flow associated with hypermotility of the stomach, and such blood flow changes were prevented when the hypermotility was inhibited by atropine[10] (Figure 4C). It is assumed that indomethacin induces the sequential events in the early stage of lesion formation in the stomach during hypermotility; the microcirculatory disturbances due to abnormal compression of the gastric wall, followed by increased vascular permeability, leading to cellular damage[10,33]. Anyway, the indomethacin-induced gastric hypermotility was inhibited by both atropine and PGE2 but not by either omeprazole or the anti-neutrophil antiserum[6,10]. Since atropine prevented indomethacin-induced gastric damage, even in the presence of exogenous acid[26], the inhibitory effect on gastric hypermotility may account for the protective action of this agent. In addition, indomethacin caused oxyradical production and lipid peroxidation in the gastric mucosa, probably resulting from the ischemic-reperfusion changes due to rhythmic hypercontraction of the stomach[10]. Certainly, these changes were prevented by atropine, again confirming an importance of gastric hypermotility. At present, the exact mechanism by which NSAIDs cause gastric hypermotility remains unknown. However, it is assumed that indomethacin-induced gastric hypermotility is mediated by a vagal-cholinergic mechanism, involving a glycoprivic response[6,31].

Neutrophils: Neutrophils have been implicated in the damage associated with NSAIDs[35]. These cells are recruited to a site of injury by chemotaxins and participate in amplifying the inflammatory response. Many studies including ours have shown that indomethacin-induced gastric damage could be prevented by an anti-neutrophil antiserum or monoclonal antibody against the CD18 adhesion molecule[13,34,35]. However, there have been few studies showing the less importance of neutrophils in NSAID-induced gastric damage[36,37]. Trevethick et al[36] reported that neutrophil infiltration does not contribute to the ulcerogenic effects of indomethacin in the rat gastric mucosa. Similarly, Melange et al[37] showed that neutropenia does not prevent indomethacin-induced gastrointestinal damage in rats. Santucci et al[38] even showed that

Figure 3 Representative recordings showing the effects of various non-steroidal anti-inflammatory drug on gastric motility in rats. Indomethacin (35 g/kg), aspirin (200 mg/kg), naproxen (40 mg/kg), flurbiprofen (20 mg/kg) or diclofenac (40 mg/kg) was given s.c. after basal motility had stabilized (data from ref.18 after modification).

Figure 4 Macro- and microscopical observations of gastric lesions induced by indomethacin in rats (A and B) and simultaneous recordings of gastric motility and mucosal blood flow in the rat before and after administration of indomethacin (C). A, B: The animals were given indomethacin (25 mg/kg, s.c.), and the stomachs were excised 4 h later. Note that the lesions were located, in most cases, on the upper part of the mucosal folds (arrow) and in some cases at the base of the folds (arrows); C: Indomethacin (25 mg/kg, s.c.) was given, while atropine (1 mg/kg, s.c.) was given 1 h after indomethacin treatment. Note that during hypermotility states the mucosal blood flow repeated a decrease and an increase, respectively, corresponding to contraction and relaxation of the stomach wall (data from refs. 8 and 33 after modification). GMBF: Gastric mucosal blood flow.

Figure 5 Time-course of changes in gastric lesions following administration of indomethacin (30 mg/kg, s.c.) in rats, with or without pretreatment. Atropine (1 mg/kg) was given s.c. 30 min before indomethacin, while dmPGE₂ (10 μg/kg) or anti-neutrophil antiserum (ANS, 0.2 mL/rat) was given i.v. 10 min and 1 h, respectively, before indomethacin. Data are presented as the mean ± SE in 4-6 rats. $^aP < 0.05$ vs control group given normal serum (data from ref. 28 after modification).

Figure 6 Effects of various prostaglandin E agonists on gastric lesions generated by indomethacin in rats. The animals were given indomethacin (30 mg/kg) s.c. and killed 4 h later. Prostaglandin E₂ (PGE₂, 0.3 mg/kg), 17-phenyl PGE₂ (0.3 mg/kg; EP1 agonist), sulprostone (0.3 mg/kg; EP1/EP3 agonist), butaprost (10 mg/kg; EP2 agonist), ONO-NT-012 (10 mg/kg; EP3 agonist) and 11-deoxy PGE₁ (3 mg/kg; EP3/EP4 agonist) were given i.v. 10 min before indomethacin. Data are presented as the mean ± SE in 4-6 rats. $^aP < 0.05$ vs control (data from ref. 39 after modification).

granulocyte colony stimulating factor, though it markedly increased myeloperoxidase (MPO) activity, significantly prevented gastric lesions from forming, suggesting no relationship between MPO activity and the ulcerogenic response to indomethacin. A study by Morise et al[34] also showed that indomethacin provoked the development of gastric lesions even in CD18, intercellular adhesion molecule 1, or P-selectin-deficient mice, the degree of severity being about 70% of that in wild-type mice. We reported that the anti-neutrophil antiserum caused a significant inhibition of indomethacin- induced gastric damage, yet the degree of inhibition was much less than that shown by atropine or dmPGE₂[28] (Figure 5). Furthermore, it was shown that the anti-neutrophil antiserum did not prevent the onset of damage until 3 h after indomethacin treat-

ment and significantly reduced the severity of damage 4 h later. These results suggest that the neutralization of neutrophils itself is not sufficient to prevent the onset of damage but reduces the overall expression of gastric lesions in response to indomethacin. Anthony et al[32] examined the sequence of histological changes in the rat stomach after indomethacin treatment and identified an early phase of injury that involves mucosal contraction and vascular fibrin deposition but does not involve neutrophil infiltration. Thus, the neutrophil infiltration may be secondary to the events associated with gastric hypermotility, and not a primary event preceding the onset of gastric damage. Indeed, the increase in MPO activity as well as formation of lesions induced by indomethacin was prevented when the enhanced gastric motility was inhibited by atropine[28].

PROSTAGLANDIN E RECEPTOR SUBTYPE INVOLVED IN PGE₂-INDUCED PROTECTION

Although exogenous PGs, especially PGE₂, prevent NSAID-induced gastric damage, how they do so remains unknown. We examined the effect of various prostanoids, subtype-specific prostaglandin E (EP) agonists, on the development of gastric lesions in response to indomethacin and determined which functional alteration is most closely associated with this action[39]. Such an approach would be helpful to understanding of which event(s) may be critically important to the pathogenic mechanism of NSAID-induced gastric damage.

Gastric ulcerogenic response
PGE₂ exhibited a potent inhibitory effect on indomethacin-induced gastric damage. This effect was mimicked by other prostanoids such as 17-phenyl PGE₂ (EP1 agonist) and sulprostone (EP1/EP3 agonist)[39] (Figure 6). Neither

Figure 7 Effect of sulprostone on the increased gastric motility caused by indomethacin in rats. Indomethacin (35 mg/kg) was given s.c.. Sulprostone (Sul, 1 mg/kg) was given i.v. as a single injection 2 h after indomethacin, while ONO-AE-829 (40 mg/kg) was given s.c. 30 min before the administration of sulprostone. Data are presented as the mean ± SE of values determined every 10 min in 4-5 rats. Significant difference at $P < 0.05$; [a]from basal values in the corresponding group; [c]from saline group; [e]from indomethacin plus sulprostone (data from ref. 39 after modification).

butaprost (EP2 agonist), ONO-NT-012 (EP3 agonist), nor 11-deoxy PGE₁ (EP3/EP4 agonist), was effective in reducing the severity of these lesions, indicating that the activation of the EP2, EP3, and EP4 receptors does not provide gastric protection against indomethacin[39,40]. These results strongly suggest that the protective effect of PGE₂ against indomethacin- induced gastric damage is brought about by activation of the EP1 receptor. This idea is supported by the finding that the protective action of PGE₂ against indomethacin was totally mitigated by prior administration of ONO-AE-829, a selective EP1 receptor antagonist. In addition, indomethacin caused gastric damage similarly in both wild-type and knockout mice lacking EP1 or EP3 receptors, yet the protective action of PGE₂ was observed in wild-type and EP3-receptor knockout mice but not in mice lacking EP1 receptors. Given the above findings, it is assumed that PGE₂ prevents indomethacin-induced gastric ulceration through the activation of EP1 receptors.

Gastric functional alterations

The prostanoids exhibiting a preference for the EP1 receptors inhibited gastric hypermotility and damage in response to indomethacin (Figure 7). These effects were antagonized by ONO-AE-829, an EP1 antagonist, strongly suggesting that the antigastric motility effect of PGE is paralleled by a reduction in gross mucosal injury of the stomach with the use of indomethacin. Both butaprost and ONO-NT-012 reportedly increased gastric mucosal blood flow[41], yet these drugs did not provide any protection against indomethacin-induced gastric damage, suggesting that the protective action is not functionally associated with the increased mucosal blood flow.

Certainly, since inhibition of gastric motility may lead to an attenuation of microvascular disturbances due to contraction of the stomach, prostanoids acting through EP1 receptors may help maintain mucosal blood flow after the administration of indomethacin. It is assumed that the actions of PGE₂ to prevent indomethacin-induced gastric damage are functionally associated with the inhibition of gastric hypermotility. The mechanism by which PGE₂ inhibits gastric motility through EP1 receptors remains unknown. Milenov *et al*[42] reported that PGE₂ relaxed the circular muscle but contracted the longitudinal muscle of the canine stomach. Narumiya and his group reported the distribution of mRNA of the EP receptors along the gastrointestinal tract[43,44]. They found that strong signals for EP1 transcripts occurred in the smooth muscle cells in the muscularis mucosa throughout the tract. Since EP1 receptors are coupled to phosphatidyl inositol turnover[45], it is assumed that contraction of longitudinal smooth muscle by PGE₂ is associated with an increase of cytosolic calcium. Contraction of circular smooth muscle leads to the appearance of mucosal folds, which have been implicated in the pathogenesis of ulcers including indomethacin-generated gastric lesions[6-8,10,13]. At present, the mechanism by which PGE₂ relaxes circular smooth muscle through activation of EP1 receptors still remains unclear.

It is known that PGE₂ has an inhibitory effect on neutrophil functions, including chemotaxis[46]. We confirmed that PGE₂ exhibited an inhibitory effect on the migration of neutrophils caused by formyl-methionyl-leucyl-phenylalanine *in vitro*[39]. The same inhibitory action was shown by both butaprost and 11-deoxy PGE₁, but not by 17-phenyl PGE₂, sulprostone, or ONO-NT-012, clearly indicating that the anti-neutrophil chemotaxis action of PGE₂ is mediated by activation of EP2 and EP4 receptors (Figure 8). Thus, it is assumed that the inhibition of neutrophil migration by itself is not sufficient to reduce the overall expression of gastric lesions in response to indomethacin. Since the increase in MPO activity as well as ulceration induced by indomethacin was prevented when the enhanced gastric motility was inhibited by atropine[13,28,47], it is likely that the neutrophil infiltration is secondary to the event associated with gastric hypermotility following indomethacin treatment. As mentioned before, Melange *et al*[37] even showed that NSAID-induced gastric injury is neutrophil-independent in the neutropenic rats. These results strongly suggest that the protective effect of PGE₂ is functionally associated with the inhibition of gastric motility, but not neutrophil infiltration.

ROLE OF COX INHIBITION IN NSAID-INDUCED GASTRIC DAMAGE

Ulcerogenic properties of various COX inhibitors

COX, the enzyme responsible for PG production, exists in two isozymes, the constitutively expressed COX-1 and the inducible COX-2[14,15]. NSAIDs inhibit the activity of both COX-1 and COX-2, yet it is believed that the inhibi-

Figure 8 Effects of atropine and various prostaglandin E agonists on the neutrophil chemotaxis stimulated by formyl-methionyl-leucyl-phenylalanine. Neutrophils were pretreated for 45 min with atropine and various prostaglandin E agonists such as PGE_2, 17-phenyl PGE_2, butaprost, ONO-NT-012 and 11-deoxy PGE_1 at the indicated concentrations, and then the cells were stimulated by incubation with formyl-methionyl-leucyl-phenylalanine (fMLP, 1×10^{-7} mol) for another 45 min. Data are expressed as a percentage of the stimulated values (control) observed in the presence of fMLP and represent the mean ± SE from 4 experiments. Significant difference at $P < 0.05$; [a]from normal; [c]from control (data from ref. 39 after modification).

Figure 9 Gastric ulcerogenic responses to various cyclooxygenase inhibitors and their effects on prostaglandin E_2 content in rat stomachs. A: Gastric ulcerogenic responses induced by various cyclooxygenase (COX) inhibitors in rat stomach. The animals were given indomethacin (nonselective COX inhibitor; 10 and 30 mg/kg), SC-560 (selective COX-1 inhibitor; 10 and 30 mg/kg), or rofecoxib (selective COX-2 inhibitor; 10 and 30 mg/kg) p.o. and killed 8 h later; B: Effects of various COX inhibitors on gastric mucosal prostaglandin E_2 (PGE_2) content in rats. The animals were given indomethacin (10 mg/kg), SC-560 (10 mg/kg), or rofecoxib (10 mg/kg) p.o. and killed 2 h later. Data are presented as the mean ± SE in 5-6 rats. [a]$P < 0.05$ vs control (data from refs. 18 and 19 after modification).

tion of COX-1 is critical for their ulcerogenic properties in the stomach. However, Wallace et al[17] reported that inhibition of both COX-1 and COX-2 is required for the induction of gastric lesions. This finding was confirmed in our experiment using the selective COX-1 inhibitor SC-560 and the COX-2 inhibitor rofecoxib[19,20,40]. As shown in Figure 9, indomethacin at 30 mg/kg produced gastric lesions with a marked decrease in mucosal PGE_2 content. As expected, the selective COX-2 inhibitor rofecoxib did not induce any damage at 30 mg/kg, with no effect on mucosal PGE_2 content. Likewise, the COX-1 inhibitor SC-560 did not cause gastric damage even at 30 mg/kg, despite inhibiting PGE_2 production, as effectively as indomethacin. However, these agents given together provoked damage in the stomach. In this case, when SC-560 at 10 mg/kg was given together with various doses of rofecoxib, the severity of the damage increased depending on the dose of the selective COX-2 inhibitor (Figure 10). Similarly, when rofecoxib at 10 mg/kg was given together with SC-560, the damage increased in a manner dependent on the dose of SC-560. These results do not support the paradigm that COX-1 but not COX-2 plays a "housekeeping" role in the stomach, and strongly suggest that inhibition of both COX-1 and COX-2 is required for the occurrence of NSAID-induced gastric injury. Langenbach et al[47] reported that the indomethacin-induced gastric lesions were inhibited in animals lacking

the COX-1 enzyme, casting a doubt on the role of PG/COX-1 in the pathogenesis. However, since the inhibition of COX-1 induces the expression of COX-2[19,48], it is possible that the PGs produced by COX-2 compensate for the PG deficiency in COX-1 knockout animals.

COX inhibition and various pathogenic events
The pathogenic mechanism of NSAID-induced gastric damage involves multiple functional alterations, including gastric hypermotility, microcirculatory disturbance, neutrophil activation, and microvascular permeability[5-13]. A marked increase in gastric motility was observed after the administration of SC-560 but not rofecoxib, although the duration of the hypermotility was short as compared with that induced by nonselective COX inhibitors, suggesting that gastric hypermotility induced by NSAIDs is associated with a PG deficiency caused by COX-1 inhibition[18]. Likewise, SC-560 but not rofecoxib increased

Figure 10 Gastric ulcerogenic response induced by combined administration of SC-560 and rofecoxib in rats. The animals were administered SC-560 (3-30 mg/kg) and rofecoxib (3-30 mg/kg) p.o. either alone or in combination, and killed 8 h later. Data are presented as the means ± SE in 5-6 rats (data from ref. 18 after modification).

Figure 11 Gene expression of cyclooxygenase-1 and cyclooxygenase-2 in rat gastric mucosa after administration of various non-steroidal anti-inflammatory drugs (A) or various cyclooxygenase inhibitors (B). The animals were given indomethacin (IM, 30 mg/kg), naproxen (NAP, 40 mg/kg), flurbiprofen (FLU, 20 mg/kg), dicrofenac (DIC, 40 mg/kg), SC-560 (SC, 30 mg/kg), or rofecoxib (Rof, 30 mg/kg) p.o., and the expression of cyclooxygenase (COX)-1 and COX-2 mRNA was examined by reverse transcription polymerase chain reaction 4 h later. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; M: Marker, V: Vehicle (data from refs. 18 and 19 after modification).

microvascular permeability in the stomach, similar to indomethacin. These results for SC-560 are reasonable, because indomethacin at an ulcerogenic dose is known to cause microcirculatory disturbances resulting from abnormal mucosal compression of the stomach wall due to gastric hypermotility[10]. On the other hand, Wallace *et al*[17] reported that SC-560, but not celecoxib, decreased the gastric mucosal blood flow, suggesting a role for PGs derived from COX-1 in the maintenance of mucosal blood flow. They also showed that the selective COX-2 inhibitor celecoxib elicited neutrophil adherence in mesenteric venules, as potently as indomethacin, whereas the selective COX-1 inhibitor SC-560 did not. However, we observed that neither SC-560 nor rofecoxib alone affected MPO activity in the gastric mucosa, yet these two agents together apparently increased MPO activity to the levels comparable to those induced by indomethacin[19]. This event might be hampered by PGs derived from COX-2, probably at later stages following gastric hypermotility, since microcirculatory disturbances are known to enhance the adhesion of neutrophils to endothelial cells[13,34]. These results strongly suggest that the inhibition of both COX-1 and COX-2 is required for enhancement of neutrophil migration in the gastric mucosa and that neutrophils may be involved in the damage process later on, but do not play a role in the onset of gastric damage induced by NSAIDs.

Upregulation of COX-2 expression

The most important event is that the expression of COX-2 mRNA was induced in the gastric mucosa after administration of NSAIDs[18,19] (Figure 11A). The upregulation of COX-2 expression was similarly observed in the rat stomach after administration of SC-560 but not rofecoxib, suggesting a causal relationship between COX-1 inhibition and COX-2 expression (Figure 11B). We also reported the upregulation of COX-2 expression

in the small intestine following administration of both indomethacin and SC-560[20,48,49]. It is assumed that inhibition of COX-1 induces a PG deficiency but upregulates the expression of COX-2, which contributes to a restoration of PG production. Indeed, the mucosal PGE2 content of the stomach was markedly decreased by SC-560, yet values recovered significantly 8 h after the administration in a rofecoxib-sensitive manner[18] (Figure 12A). Thus, the upregulation of COX-2 expression following inhibition of COX-1 may represent a compensatory response to inhibition of PG biosynthesis and contribute to maintenance of the mucosal integrity of the stomach. This speculation is supported by the fact that combined treatment with SC-560 and rofecoxib did provoke gross damage in the stomach, and that such damage was prevented by administration of PGE2 4 h after the use of COX inhibitors[19]. The exact mechanism by which the expression of COX-2 is induced by inhibition of COX-1 remains unknown. Since the expression of COX-2 induced by indomethacin was attenuated by atropine at the dose that inhibited the gastric hypermotility[6,21,48], it is possible that the upregulation of COX-2 expression is due to vascular injury caused by abnormal mucosal compression of the stomach wall during gastric hypermotility (Figure 12B). Indeed, atropine significantly inhibited the recovery of PGE2 levels following administration of SC-560, similar to rofecoxib[48]. Alternatively, because NSAIDs release tumor necrosis factor α (TNF-α)[38,50],

Figure 12 Effects of various drugs on prostaglandin E₂ production and cyclooxygenase-2 expression in rat gastric mucosa. A: Effects of various drugs on prostaglandin E₂ (PGE₂) levels in the rat gastric mucosa at 8 h after administration of SC-560. The animals were administered SC-560 (10 mg/kg) p.o., and killed 2 or 8 h later. Rofecoxib (30 mg/kg) was given p.o. together with SC-560 while omeprazole (OM, 30 mg/kg) or atropine (AT, 3 mg/kg) was given s.c. 1 h before the administration of SC-560. Data are presented as the mean ± SE in 6 rats. Significant difference at $P < 0.05$; ^{a}from control; ^{c}from SC-560 (2 h); ^{e}from vehicle; B: Effect of OM and AT on cyclooxygenase (COX)-2 expression after administration of indomethacin (IM) in rat stomach. The animals were administered IM (30 mg/kg) p.o., and killed 4 h later. OM (30 mg/kg) or AT (3 mg/kg) was given s.c. 1 h before indomethacin. Some animals were given 1 mL of 100 mmol HCl immediately after administration of IM. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; M: Marker; V: Vehicle (data from ref. 48 after modification).

the upregulation of COX-2 expression observed under COX-1 inhibition is mediated by TNF-α. Omeprazole had no effect on the expression of COX-2 induced by indomethacin, suggesting no role for luminal acid in this phenomenon[48].

POTENTIATION OF NSAID-INDUCED GASTRIC DAMAGE

Adrenalectomy

Takeuchi et al[9] demonstrated that indomethacin-induced gastric damage was markedly aggravated in adrenalectomized rats and the dose required to produce lesions was decreased in these rats. Filaretova et al[22] confirmed the aggravation of NSAID-induced gastric ulceration in adrenalectomized rats (glucocorticoid-deficient conditions)

and further investigated the influence of adrenalectomy on the expression of COX-2 in the stomach as well as the ulcerogenic effect of celecoxib (a selective COX-2 inhibitor) in these rat stomachs. It was found that adrenalectomy decreased plasma corticosterone levels and markedly aggravated indomethacin-induced gastric lesions. This aggravation was significantly prevented by corticosterone replacement, suggesting that glucocorticoid deficiency is the reason for the aggravation of indomethacin-induced gastric injury in adrenalectomized rats. Moreover, in adrenalectomized rats, celecoxib provoked gross damage that was prevented by corticosterone pretreatment. Mucosal PGE₂ content was increased 3-fold after adrenalectomy, and this response was prevented by both celecoxib and corticosterone. COX-2 mRNA expression was up-regulated in the stomach of adrenalectomized rats, but suppressed by corticosterone replacement. It is assumed that adrenalectomy, probably via a glucocorticoid deficiency, increases PGE₂ production in the stomach due to COX-2 expression, and the selective COX-2 inhibitor produces gastric lesions by suppressing this additional PG production in adrenalectomized rats. These findings also support the idea that COX-2 as well as COX-1 play a role in maintaining gastric mucosal integrity under glucocorticoid-deficient conditions.

Adjuvant arthritis

Patients with rheumatoid arthritis (RA) are reportedly more susceptible to NSAID-induced gastropathy than other NSAID users[51,52]. This observation has been validated in arthritic rat models induced by injecting Freund's complete adjuvant into the planter region of a hindfoot, where the gastric ulcerogenic response to indomethacin was markedly aggravated in comparison with normal animals[23,53,54]. Since the aggravation of these lesions in arthritic rats was dependent on the degree of arthritic change, it is assumed that there is a cause-effect relationship between the systemic inflammation and the increased gastric mucosal susceptibility to indomethacin. As several studies including ours showed increased serum gastrin levels and acid secretion in arthritic rats[53,55], it is speculated that the increased gastric ulcerogenic response is partly attributable to hyperacidity in the stomach. However, because the aggravation of these lesions was similarly observed in arthritic rats, even in the presence of exogenous acid to mask endogenous hyperacidic conditions[53], it is unlikely that the increased mucosal susceptibility to indomethacin in arthritic rats is associated with the increase of acid secretion. Interestingly, the aggravation of indomethacin-induced gastric damage in arthritic rats was prevented by prior administration of N^G-nitro-L-arginine methyl ester, a nonselective nitric oxide synthase (NOS) inhibitor, and aminoguanidine, a selective inducible NOS (iNOS) inhibitor, as well as dexamethasone, an inhibitor of iNOS mRNA transcription, although they did not affect the severity of the lesions observed in normal rats[53]. Moreover, the distinct expression of iNOS mRNA was observed in the stomach of arthritic rats, accompanied with an increase in NO production. These

Figure 13 Gastric ulcerogenic effect of indomethacin, rofecoxib and SC-560 and the expression of cyclooxygenase-1 and cyclooxygenase-2 mRNA in the gastric mucosa of normal and arthritic rats. A: Arthritis was induced by injecting Freund's complete adjuvant (FCA) into the plantar region of the right hindfoot, and the experiments were performed 14 d after the injection. Indomethacin (Indo) (3 mg/kg), rofecoxib (Rof) (30 mg/kg), or SC-560 (SC) (30 mg/kg) were administered p.o., and the animals were killed 4 h later. Data are presented as the mean ± SE in 4-8 animals, [a]$P < 0.05$ vs the corresponding group in normal rats; B: COX-2 mRNA was not detected in the normal rats, but clearly observed in the arthritic rats on day 14 after the FCA injection, whereas COX-1 mRNA was observed in the stomach of both normal and arthritic rats. Lane 1, marker; lanes 2-4, normal rats; lanes 5-7, arthritic rats (data from ref. 23 after modification). GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

findings suggest that the increased ulcerogenic response to NSAIDs in arthritic rats is associated at least partly with endogenous NO, mainly produced by iNOS. It is possible that the increased susceptibility of arthritic rat stomachs to NSAIDs might be explained by production of peroxynitrite, resulting from the interaction of NO/iNOS with superoxide radicals[56].

As mentioned, selective COX-2 inhibitors such as rofecoxib and celecoxib, even at a higher dose (100 mg/kg), did not damage the normal rat stomach[18]. However, they produced gross lesions in the stomach of arthritic rats[23] (Figure 13A). Moreover, PG generation in the arthritic rat stomach was significantly enhanced with a concomitant increase of COX-2 expression (Figure 13B). Certainly, the mucosal PG content was reduced by indomethacin in both normal and arthritic rat stomachs. In contrast, the COX-2 inhibitor rofecoxib did not affect PG generation in normal rats but significantly decreased PG content in

the stomach of arthritic rats, suggesting that COX-2 activity caused the increase in PG production in arthritic rat stomachs. These findings suggest that COX-2 plays an important role in maintaining the integrity of the gastric mucosa in arthritic rats. It is possible that the increased COX-2 expression level in the stomach occur in association with inflammation or stress caused by pain. Since SC-560, a selective COX-1 inhibitor, worsened stress-induced gastric lesions[57], SC-560 may produce hemorrhagic lesions in the stomach by potentiating the ulcerogenic response to arthritis-related stress. Further study is certainly required to verify this point.

H. pylori infection

Takahashi et al[24] examined the expression of COX proteins and production of PGE2 in the gastric mucosa during H. pylori infection. The level of COX-1 remained nearly constant during the infection. In contrast, the COX-2 protein was not found in normal mucosa or in H. pylori -infected mucosa at 2 wk, but was markedly elevated 4 wk after the infection, with a significant rise in PGE2 production. To investigate the role of COX-2 in H. pylori-induced gastritis, they also examined the effects of NSAIDs on PGE2 production and gastric pathology caused by H. pylori. NS-398 (a COX-2-selective inhibitor) at 10 mg/kg or indomethacin at 2 mg/kg was administered for 4 wk to normal and H. pylori-infected animals. NS-398 failed to inhibit PGE2 production in normal mucosa but significantly reduced the H. pylori-increased PGE2 production. In contrast, indomethacin potently inhibited PGE2 production in both normal and H. pylori-infected mucosa. Hemorrhagic erosions, neutrophil infiltration, lymphoid follicles, and epithelium damage were induced by H. pylori infection. NS-398 and indomethacin aggravated these pathological changes, but did not increase viable H. pylori numbers. Overall, these results indicate that both COX-2 and COX-1 might play anti-inflammatory roles in H. pylori-induced gastritis. Similar findings were also obtained by Tanigawa et al[58] who showed that PGE2 derived from either COX-1 or COX-2 is involved in the regulation of gastric mucosal inflammation and contributes to the maintenance of mucosal integrity during H. pylori infection via inhibition of TNF-α expression.

BIPHASIC EFFECT OF ASPIRIN

Conventional NSAIDs cause gastric damage with a concomitant decrease in mucosal PGE2 production, irrespective of the route of administration[18,19]. However, since aspirin is not ulcerogenic in the stomach, despite that it reduces mucosal PGE2 production as effectively as other NSAIDs, it is likely that a depletion of endogenous PGs by itself is not sufficient for gastric lesions to form and other factors are required for the onset of gastric damage. However, when administered orally, aspirin damages the stomach, similar to other NSAIDs. Several studies have proposed a role for neutrophils or TNF-α in the

Figure 14 Effects of aspirin and salicylic acid on gastric lesions (A) and gastric hypermotility (B) caused by indomethacin in rats. A: The animals were given indomethacin (35 mg/kg) s.c., and killed 24 h later. Aspirin (20-200 mg/kg) or salicylic acid (17.8-178 mg/kg) was given s.c. 30 min before indomethacin. Data are presented as the mean ± SE in 4-6 rats. [a]$P < 0.05$ *vs* control; B: Animals were given indomethacin (30 mg/kg) s.c. and subsequently aspirin (200 mg/kg) or salicylic acid (178 mg/kg) s.c. 2 h later. Note that both aspirin and salicylic acid markedly inhibited the intestinal hypermotility induced by indomethacin, with the effect of salicylic acid appearing much earlier than that of aspirin (data from ref. 25 after modification).

pathogenesis of NSAID-induced gastric damage[34,35,50]. These events are considered to occur in relation to a decrease in PG biosynthesis in the gastric mucosa due to suppression of COX activity. However, aspirin given parenterally inhibited PGE2 production in the stomach, yet did not cause any damage in the mucosa[19]. Furthermore, salicylate reportedly inhibited TNF-α production by suppressing nuclear factor kappa B[59]. Considering all these points, we assumed that the topical irritant action of oral aspirin is most crucial in causing gastric mucosal damage.

As mentioned earlier, aspirin does not damage the stomach but shows a dose-dependent inhibition of indomethacin-induced gastric injury[24] (Figure 14A). This result is consistent with the finding by Robert *et al*[60], who showed for the first time that aspirin provided protection against gastric damage in response to various noxious

agents including indomethacin. Following the subcutaneous administration of aspirin (200 mg/kg) in rats, plasma levels of salicylate increased with time, reaching almost a plateau within 30 min, and remained elevated for more than 4 h. A small amount of aspirin was detected in the blood for the first 15 min, but it had disappeared almost totally 30 min later. As expected, since salicylate, the major metabolite of aspirin, also prevented indomethacin-induced gastric damage, it is possible that the protective action of aspirin is mediated by salicylate. Interestingly, aspirin and salicylate did not increase basal gastric motility but suppressed the enhanced gastric motility following indomethacin treatment, suggesting again a relationship between the inhibition of gastric hypermotility and prevention of gastric damage (Figure 14B)[25]. At present, the exact mechanism by which salicylate (aspirin) suppresses the gastric hypermotility induced by indomethacin remains unknown.

Unlike other NSAIDs, COX-2's acetylation by aspirin switches eicosanoid biosynthesis from PGE2 to lipoxin A4, which exerts protective effects in the stomach. Co-administration of aspirin and a selective COX-2 inhibitor, such as celecoxib or rofecoxib, resulted in substantially more severe gastric injury than that produced with either agent alone[61,62]. We also observed that the gastric ulcerogenic response to aspirin was significantly worsened by co-administration of rofecoxib but not SC-560[63]. These results confirmed the importance of COX-2's inhibition in this phenomenon related to the suppression of lipoxin A4's production.

SUMMARY AND FUTURE PROSPECTS

The gastric ulcerogenic properties of NSAIDs are not accounted for solely by the inhibition of COX-1 and require the inhibition of both COX-1 and COX-2[17-19]. This idea is supported by the finding that neither the selective COX-1 nor COX-2 inhibitor alone caused gross damage in the stomach, but the combined administration of these two inhibitors provoked the development of gastric lesions. Indomethacin caused an increase of gastric motility, microvascular permeability and MPO activity following administration of indomethacin[6,10,26,28,34,64,65] and showed that the former two events were due to COX-1 inhibition, but the increase of MPO activity occurred only when both COX-1 and COX-2 were inhibited[19]. On the other hand, NSAIDs up-regulate the expression of COX-2, and the PGs produced by COX-2 may suppress the neutrophil-endothelial interaction caused by the vascular disturbances due to COX-1 inhibition. These sequential events related to COX-1 and/or COX-2 inhibition explain why gastric damage occurs only when both COX-1 and COX-2 are inhibited (Figure 15). It should also be noted that selective COX-2 inhibitors by themselves damage the gastric mucosa when an overexpression of COX-2 occurs in the stomach under conditions of adrenalectomy, arthritis, or *H. pylori* infection[22-24]. Independent of the type of NSAIDs, the users of NSAIDs should be aware of these side effects if they are

Figure 15 Working hypothesis on the roles of COX-1 and COX-2 in the pathogenic mechanism of non-steroidal anti-inflammatory drug-induced gastric damage. Non-steroidal anti-inflammatory drugs (NSAIDs) cause gastric hypermotility, followed by microvascular disturbances and neutrophil activation, leading to gastric damage. Gastric hypermotility and subsequent vascular disturbances are associated with a prostaglandin (PG) deficiency caused by COX-1 inhibition. The inhibition of COX-1 up-regulates COX-2 expression, and PGs produced by COX-2 may suppress the neutrophil-endothelial interaction caused by microvascular disturbances due to COX-1 inhibition.

infected with *H. pylori* or have a glucocorticoid deficiency or arthritic condition. Interestingly, aspirin acts to protect against indomethacin-induced gastric damage, although this agent given p.o. damages the stomach due to its direct irritative action. The failure of aspirin to induce gastric injury may be explained, at least partly, by a protective action of salicylic acid, the metabolite of aspirin, and this action is also functionally associated with inhibition of gastric hypermotility in response to indomethacin.

There is no doubt that gastric hypermotility plays a primary role in the pathogenesis of NSAID-induced damage in the stomach[3-7]. This response, causally related with PG depletion due to COX-1 inhibition, occurs prior to other pathogenic events involved in NSAID-induced gastric damage, such as microvascular disturbances and neutrophil infiltration as well as COX-2 expression[6,10,19,28,63]. However, the mechanism underlying NSAID-induced gastric hypermotility remains unknown. Since the gastric hypermotility induced by indomethacin was inhibited by atropine and vagotomy as well as intravenous glucose infusion[6,7,66], it is assumed that the response occurs in association with PG deficiency caused by COX-1 inhibition and is mediated by the vagal-cholinergic pathway through central glucose receptors. The upregulation of NSAID-induced COX-2 expression is functionally associated with gastric hypermotility[47]. Because atropine prevented both gastric hypermotility and COX-2 expression in response to indomethacin[21,47] and because gastric microvascular permeability increased in association with gastric hypermotility[8,63], the upregulation of COX-2 expression may result from

mild mucosal injury and/or vascular injury caused by gastric hypermotility. However, the cells responsible for COX-2 expression induced by COX-1 inhibition also remain to be identified. In addition, other possible actions, such as inhibition of phosphorylative oxidation, injury of mitochondrial membrane and cell apoptotic change, have been demonstrated as the cellular mechanisms of NSAID-induced gastropathy[66-70], although these effects are shared by NSAIDs, including aspirin that does not cause gastric damage through parenteral administration. Further study is certainly needed to clarify these points, and these approaches should contribute to the development of gastric-sparing NSAIDs that are devoid of ulcerogenic properties.

BIOGRAPHY

Professor Koji Takeuchi received his PhD degree from the University of Tokyo, Tokyo, Japan. He had an extensive 4-year postdoctoral training at Department of Physiology and Cell Biology, University of Texas, Houston and Department of Surgery, Harvard Medical School, Boston, United States. He is presently Professor and Chairman of the Department of Pharmacology and Experimental Therapeutics, Dean of the Graduate School and Vice President of the Kyoto Pharmaceutical University, Kyoto, Japan. His research interest covers numerous areas of GI pharmacology and physiology, and one of his most notable contributions is the understanding of mucosal defense, focusing on the regulation of acid/bicarbonate secretion, the influences of non-steroidal anti-inflammatory drugs and prostaglandins; their mode of action, cyclooxygenase isoforms, receptors that drive physiological responses, and their role in mucosal injury, protection and healing. He has had 448 papers published on peer-reviewed journals, including 45 book chapters, and gave numerous presentations at national and international meetings. Professor Koji Takeuchi has enjoyed quite a few prestigious academic awards and honors.

Abstract

Clopidogrel in association with aspirine is considered state of the art of medical treatment for acute coronary syndrome by reducing the risk of new ischemic events. Concomitant treatment with proton pump inhibitors in order to prevent gastrointestinal side effects is recommended by clinical guidelines. Clopidogrel needs metabolic activation predominantly by the hepatic cytochrome P450 isoenzyme Cytochrome 2C19 (CYP2C19) and proton pump inhibitors (PPIs) are extensively metabolized by the CYP2C19 isoenzyme as well. Several pharmacodynamic studies investigating a potential clopidogrel-PPI interaction found a significant decrease of the clopidogrel platelet antiaggregation effect for omeprazole, but not for pantoprazole. Initial clinical cohort studies in 2009 reported an increased risk for adverse cardiovascular events, when under clopidogrel and PPI treatment at the same time. These observations led the United States Food and Drug Administration and the European Medecines Agency to discourage the combination of clopidogrel and PPI (especially omeprazole) in the same year. In contrast, more recent retrospective cohort studies including propensity score matching and the only existing randomized trial have not shown any difference concerning adverse cardiovascular events when concomitantly on clopidogrel and PPI or only on clopidogrel. Three meta-analyses report an inverse correlation between clopidogrel-PPI interaction and study quality, with high and moderate quality studies not reporting any association, rising concern about unmeasured confounders biasing the low quality studies. Thus, no definite evidence exists for an effect on mortality. Because PPI induced risk reduction clearly overweighs the possible adverse cardiovascular risk in patients with high risk of gastrointestinal bleeding, combination of clopidogrel with the less CYP2C19 inhibiting pantoprazole should be recommended.

CLOPIDOGREL AND PROTON PUMP INHIBITORS - WHERE DO WE STAND IN 2011?

Clopidogrel in association with Aspirine has become

Figure 1 Potential intrahepatic mechanism of Proton pump inhibitor-clopidogrel interaction by the example of omeprazole (adapted from Tantry et al[50]). CYP2C19: Cytochrome 2C19; CYP2C19*2: Poor metabolizing cytochrome 2C19 isoenzyme.

the basis of pharmaceutical treatment in patients treated either medically or with percutaneous coronary intervention (PCI) for acute coronary syndrome (ACS), by significantly reducing the risk of new ischemic cardiovascular events[1].

To prevent gastrointestinal bleeding as a drug-induced side effect, proton pump inhibitors (PPI) are often associated with clopidogrel use. This strategy is recommended by consensus guidelines[2] and endorsed by a recent meta-analysis, especially for patients taking dual antiplatelet therapy but in a lesser extent for those on clopidogrel alone due to sparse data[3-5]. Gilard et al[6,7] first reported in 2006 and 2008 a significant decrease of the clopidogrel effect in association with omeprazole in vitro. In opposite to that, no decrease was found in further pharmacodynamic studies for pantoprazole or esomeprazole[8-13]. Several retrospective observational studies showed an increased risk of new cardiovascular events in patients on clopidogrel-PPI association[14-22], thus leading the United States Food and Drug Administration and the European Medicines Agency to recommend to avoid the clopidogrel-PPI combination, especially with omeprazole[23,24]. More recently, one randomized double-blind trial[25], one post-hoc analysis of a randomized double-blind trial comparing prasugrel with clopidogrel[26] and several predominantly propensity matched cohort studies[27-35] have not shown clinically relevant adverse cardiovascular interaction between clopidogrel and PPI. Moreover, three recent meta-analyses, one by Kwok et al[36] reviewing 23 studies with the majority in abstract form, one by Siller-Matula et al[37] including 25 studies and the most recent by Lima et al[38] reviewing 18 studies pointed out that an elevated risk of bias was present in these studies indicating a possible interaction between clopidogrel and PPI. Furthermore, there was no significance for a drug interaction by analysing propensity matched and randomized trials.

The aim of this review is to focus on these recent studies, in order to reevaluate the present recommendations.

CLOPIDOGREL

Clopidogrel is a thienopyridine, inhibiting adenosine diphosphate (ADP) induced platelet activation by blocking the $P2Y_{12}$ receptor on the platelet surface. It is a prodrug that needs to be metabolized in an intrahepatic two-step oxidative process. First, the cytochrome P450 isoenzymes CYP1A2, CYP2B6 and CYP2C19 form 2-oxo-clopidogrel, which is then oxidized by CYP2B6, CYP2C19 and CYP3A4 to the clopidogrel active metabolite. The further formation of a disulfide bond with the $P2Y_{12}$ receptor unables the binding of ADP and finally platelet activation[12,39]. This is associated with dephosphorylation of intraplatelet vasodilator-stimulated phosphoprotein (VASP), providing an index of platelet reactivity to clopidogrel: the higher the platelet reactivity index (PRI), the less important the antithrombotic effect of clopidogrel[7]. Cytochrome P450 CYP2C19 seems to be of major importance in the metabolisation and activation of clopidogrel (Figure 1). Recent studies investigating the genetic polymorphism of the CYP2C19 allele have found a decreased platelet inhibition and increased cardiovascular risk in patients treated by clopidogrel, when carriers of even one reduced function CYP2C19 allele[40-42]. The CYP2C19*2 mutation was the most frequent variant found in the poor metabolizer (decreased platelet inhibition) group[43-45]. The prevalence of reduced function alleles differs among various populations, while an increase effect is observed from West to East: In the Caucasian population, 30%-40% of the normal function *1/*2 genotype and 2%-5% of the reduced function *2/*2 genotype are reported, whereas in East Asian and Chinese populations up to 24% of the poor metabolizing genotypes *2/*2, *2/*3 and *3/*3 are present[46-48].

PROTON PUMP INHIBITORS

PPI are benzimidazole derivates consisting of two heterocyclic moieties linked via a methylsulfinyl group. Being weak bases, they reach the parietal cell membrane as prodrugs and can thereby cross cell membrane to accumulate in the canalicular space, where the environment is highly acid. After a two step pronation, the drug reacts with cysteine sulfhydryls on the gastric H+/K+-ATPase by forming covalent disulfide bonds and inhibiting its activity[49-53]. So far, we dispose of five different PPIs on the market: omeprazole, esomeprazole, lansoprazole, pantoprazole and rabeprazole. Each among them is mainly metabolized by the intrahepatic P450 cytochrome system, especially CYP2C19 and CYP3A4, inhibiting them competitively. Interestingly, in vitro studies showed important differences in the inhibition of CYP2C19, with lansoprazole

and omeprazole being the most powerful inhibitors while pantoprazole and rabeprazole are the less potent inhibitors[49,54,55]. Of note, only pantoprazole showed significant acid inhibition after a single dose in the fast metabolizing genotype CYP2C19*1[46].

PHARMACODYNAMIC STUDIES ON CLOPIDOGREL- PPI INTERACTION

Gilard *et al*[6] demonstrated in 2006 an *in vitro* reduction of the antiaggregatory activity of clopidogrel in patients after coronary revascularisation under PPI treatment. The same group ran out the randomized double-blind OCLA (Omeprazole Clopidogrel Aspirine) trial in 2008: 124 patients undergoing elective coronary artery stent implantation receiving 75 mg of aspirine and clopidogrel daily, were randomized to receive either omeprazole 20 mg/d or placebo. The clopidogrel effect was assessed by measuring the phosphorylated VASP expressed in the PRI on day 1 and 7. On day 7, the mean PRI was significantly higher in the omeprazole-associated group (51.4% *vs* 39.8%, *P* > 0.0001), indicating less effective platelet antiaggregation. To investigate whether this potential interaction was due to a class effect, Cuisset *et al*[11] compared in the PACA (PPI And Clopidogrel Association) study 104 patients undergoing coronary stent implantation for non-ST-elevation ACS by randomizing them to a 20 mg omeprazole or pantoprazole treatment in association with 75 mg of aspirine and 150 mg of clopidogrel. After 1 mo, the VASP PRI was significantly lower in the pantoprazole group (36% ± 20% *vs* 48% ± 17%, *P* = 0.007), suggesting that pantoprazole, being a less potent CYP2C19 inhibitor, leads to a lower decrease of the clopidogrel antithrombotic effect. These results were confirmed in a prospective observational study, including a multivariable logistic regression analysis on 300 patients with coronary artery disease undergoing PCI and being already under aspirine 100 mg/d and clopidogrel 75 mg/d for at least 5 d. No difference was found for the VASP-PRI and the ADP induced platelet aggregation (ADP Ag) either between the PPI and no-PPI-group (51% *vs* 49%, *P* = 0.724) or between the different PPIs (pantoprazole and esomeprazole)[8]. In the same line, a prospective observational study including 336 patients undergoing coronary stent implantation showed no difference in ADP induced platelet aggregation between patients treated concomitantly by clopidogrel (600 mg loading and 75 mg maintenance dose) and pantoprazole *vs* clopidogrel only (OR 0.59, 95% CI: 0.31-1.13). For omeprazole and esomeprazole, a non significant increase in platelet aggregation persisted even after multiple adjustment (OR 1.84, 95% CI: 0.64-5.31), but due to the relatively small number of patients (26 *vs* 122 pantoprazole users), definite conclusions couldn't be drawn[13]. The authors of the post-hoc analysis of the PRINCIPLE (Prasugrel In Comparison to Clopidogrel for Inhibition of Platelet Activation and Aggregation)-TIMI 44 study evaluated the impact of concomitant PPI use in 201 patients undergoing planned PCI and random-

ly assigned to either prasugrel (a new third generation thienopyridine) or high dose clopidogrel (600 mg loading dose and 150 mg/d maintenance dose) treatment. Fifty-six patients (26.4 %) were recorded to take a PPI at the time of randomization and the mean inhibition of platelet aggregation measured by ADP induced platelet aggregation was significantly lower at 2, 6 and 24 h after the loading dose, with a non-significant trend still persisting after 15 d. For prasugrel, no significant lowering of the mean inhibition of platelet aggregation was observed in the first 24 h, becoming only significant after 15 d in patient treated by PPI[26]. Recently, Angiolillo *et al*[12] conducted four randomized placebo-controlled crossover comparison studies among 282 healthy subjects, addressing the questions whether the PPI-clopidogrel interaction should be considered as a class effect or is rather due to more or less potent CYP2C19 inhibition and if a time interval between clopidogrel and PPI administration might diminish the inhibitory effect as evoked by the rapid metabolization of clopidogrel and omeprazole. After randomization in either interventional or placebo groups, the interventional arm entered a two period (clopidogrel only and clopidogrel with PPI) crossover study with four interventions during the clopidogrel-PPI period: The first study investigated an interaction between clopidogrel (300 mg loading and 75 mg maintenance dose) and omeprazole 80 mg/d when administered simultaneously. Study 2 investigated the administration of clopidogrel and omeprazole staggered by 12 h and study 3 an increased clopidogrel dose (600 mg loading and 150 mg maintenance dose) with omeprazole 80 mg/d. Finally, study 4 used a standard clopidogrel dose with pantoprazole 80 mg/d. Dosages of the active metabolite of clopidogrel (clopi H4) were significantly decreased in study 1, 2 and 3 while ADP induced platelet aggregation as well as VASP-PRI were significantly increased, indicating a less effective platelet antiaggregation in patients treated concomitantly with clopidogrel and omeprazole. Of note, these results were irrespective of the administration time or the clopidogrel dose. In contrast, the decrease of clopi H4 (40%, *P* < 0.001 for omeprazole and 14%, *P* < 0.002 for pantoprazole) was smaller in study 4 as well as the increase of ADP induced platelet aggregation, both differences remaining statistically significant. The increase of VASP-PRI was not significant when treated with pantoprazole, leading the authors to conclude that the clopidogrel-PPI interaction was not a class effect, whereas the combination with pantoprazole was a more optimal treatment option[12]. However, omeprazole was given at 80 mg per day, which represents 2 to 4 times the dose commonly prescribed, leaving unclear the hypothesis of a possible interaction when using standard doses. Furthermore, other molecules like rabeprazole, which does not inhibit the CYP2C19 isoenzyme, haven't been tested. In the same line, Ferreiro *et al*[56] conducted two supplementary randomized crossover studies in healthy subjects: In the first study, 20 volunteers received a 600 mg loading dose followed by 75 mg of clopidogrel combined with 40 mg of omeprazole concomitantly or staggered by 8-12 h with

Table 1 Overview of important pharmacodynamic studies on the clopidogrel-proton pump inhibitor interaction

Study	PPIs used	Population	Primary outcome	Author's conclusions
Gilard *et al*[7] OCLA study (double-blind, placebo-controled, randomized)	Omeprazole	124 patients undergoing elective coronary stent implantation	VASP-PRI on 7 d	Omeprazole significantly decreases clopidogrel inhibitory effect
Cuisset *et al*[11] PACA study (prospective, randomized)	Omeprazole *vs* Pantoprazole	104 NSTE-ACS patients undergoing coronary stenting	VASP-PRI/ADP-Ag after 1 mo	Significantly better platelet response under pantoprazole (VASP-PRI), no difference for ADP-Ag
O'Donoghue *et al*[26] PRINCIPLE-TIMI 44 (post hoc analysis of a RCT)	Not specified	201 patients undergoing planned PCI	ADP Ag	Mean inhibition of platelet aggregation significantly lower for patients on PPI
Siller-Matula *et al*[8] (prospective observational)	Pantoprazole esomeprazole	300 patients with CAD undergoing PCI	VASP-PRI/ADP-Ag in the catheter laboratory	No association of PPIs with impaired response to clopidogrel
Neubauer *et al*[13] (prospective observational)	Pantoprazole omeprazole esomeprazole	336 patients undergoing coronary stent implantation	ADP Ag	Pantoprazole does not diminish the antiplatelet effectiveness of clopidogrel
Angiolillo *et al*[12] (placebo controlled, randomized, cross-over)	Omeprazole pantoprazole	282 healthy subjects	Clopi H4 ADP Ag VASP-PRI after 5 d	Presence of a metabolic drug-drug interaction between clopidogrel and omeprazole but not for pantoprazole

VASP-PRI: Vasodilator-stimulated phosphoprotein platelet reactivity index; NSTE-ACS: Non-ST-elevation acute coronary syndrome; ADP Ag: Adenosine DiPhospate induced platelet aggregation; CAD: Coronary artery disease; PCI: Percutaneous coronary intervention; PPI: Proton pump inhibitor; OCLA: Omeprazole Clopidogrel Aspirine; PACA: PPI and clopidogrel association; **PRINCIPLE-TIMI: Prasugrel in comparison to clopidogrel for inhibition of platelet activation and aggregation-TIMI.**

a crossover washout period after a 2-4 wk followed by 1 wk of clopidogrel alone after a new washout period: No difference was observed in VASP-PRI after 1 wk between the concomitant and the staggered omeprazole administration, but PRI was significantly lower in the clopidogrel alone period compared with the omeprazole period, irrespective of the timing of administration (comcomitant omeprazole: $P = 0.02$; staggered omeprazole: $P = 0.001$). In the second study, 80 mg of pantoprazole were administered with the same regimen, but no differences in VASP-PRI were found between a concomitant or staggered administration of pantoprazole. Moreover, no difference was noted between clopidogrel alone and clopidogrel plus pantoprazole after 1 wk of treatment. The authors concluded that a time interval between the administration of clopidogrel and PPI doesn't afford any benefit and that pantoprazole seems to be a safer choice when combined with clopidogrel[57] (Table 1).

CLINICAL TRIALS ON CLOPIDOGREL- PPI INTERACTION

In 2009, Ho *et al*[15] published a retrospective cohort study including 8205 patients hospitalized for ACS in Veterans Affairs Hospitals. Analysis of prescription records identified 63.9% of patients being concomitantly under clopidogrel and PPI with a mean follow-up of 521 d. Concomitant use of clopidogrel and PPI (predominantly omeprazole and rabeprazole) was associated with an elevated risk of death or rehospitalisation for ACS after multivariable analysis (OR 1.25, 95% CI: 1.11-1.41). Of note, 98% were men and no information on the patient's race was available. In the same line, a Canadian popula-

tion-based nested case-control study based on discharge abstracts and prescription records of 13636 patients being hospitalized for ACS, found an increased risk of reinfarction when under concomitant clopidogrel and PPI use (OR 1.27, 95% CI: 1.03-1.57). An analysis according to the PPI molecule used found no association with increased myocardial reinfarction for pantoprazole users in contrast to a 40% risk increase when using other PPIs (OR 1.40, 95% CI: 1.10-1.77). This result should be interpreted carefully, due to the small number of pantoprazole users (46 of 734 reinfarction patients)[16]. Moreover, only patients aged 66 years or older were included, introducing potential age bias. Another retrospective observational study based on diagnosis and prescription records of two Dutch health insurances, included 18139 new clopidogrel users, of whom 5734 (32%) were on concomitant PPI treatment. In this particular study, patients under PPI cotherapy had a significantly higher risk for the composite endpoint of myocardial infarction, unstable angina, stroke and all-cause mortality (HR 1.75, 95% CI: 1.58-1.94). In the subanalysis of secondary endpoints, PPI use was associated with a higher risk of myocardial infarction (ST-elevation and non-ST-elevation), unstable angina and all-cause mortality, but not with stroke[14]. Selection bias may be present in these two insurance databases, covering only 25% of the Dutch population. All three studies evidence significant differences in the baseline characteristics between the clopidogrel and the clopidogrel-PPI groups with significantly older patients with several comorbidities (e.g., heart failure, diabetes mellitus and renal failure) in the latter group, raising concern about unmeasured confounders in patients whith cardiovascular risk treated by PPI. In addition to that, no data about the efficacy of antihypertensive and statin treatment as well as on smok-

ing status were available. Finally as the medication exposure was based on prescription records, drug compliance data were not available.

More recently, several studies have been designed to include propensity scores in their analysis to improve confounding adjustment. Especially confounding by indication, an important bias in pharmacoepidemiologic studies, is diminished by using propensity score matching by calculating the probability to be exposed to a treatment or not. Moreover, adjustment for unmeasured or mismeasured covariates is improved by including hundreds of items in the propensity score calibration[58]. However, by the fact that many unexposed subjects of the initial study population aren't matched to exposed subjects and unmatched exposed subjects are excluded from the propensity matched analysis, precision of the estimated drug interaction could be decreased[59-62]. Rassen *et al*[31] analysed 18 565 patients aged over 65 years having been hospitalized for ACS and consecutive PCI in a retrospective cohort study based on Canadian and United states insurance records. Patients under clopidogrel and PPI had a slightly increased risk for rehospitalization for myocardial infarction or death of any cause (RR 1.26, 95% CI: 0.97- 1.63) leading the authors to conclude to no evidence of a substantial interaction. Major efforts for bias reduction have been made in this study by including only clopidogrel naïve patients, using a 7 d run-in period and a high-dimensional propensity score, permitting further adjustment for 400 additional variables empirically identified in their databases[63]. However, Aspirine use was unfortunately not measured in this coronary disease population[31]. A similar analysis was conducted on 20 596 patients of the Tennessee Medicaid program after hospitalization for ACS and PCI. Concomitant clopidogrel and PPI use was not associated with serious cardiovascular disease (HR 0.99, 95% CI: 0.82-1.19). Subanalysis concerning the different types of PPI has not found any increased risk of serious cardiovascular disease either, but confidence bounds were wide except for pantoprazole[27]. Another retrospective cohort study using the national Danish patient and prescription registry, included 56 406 patients older than 30 years and hospitalized for acute myocardial infarction. Concomitant clopidogrel and PPI users had a significant increased risk for cardiovascular death or rehospitalization for myocardial infarction and stroke compared to non-PPI users (HR 1.35, 95% CI: 1.22-1.50). In the same time, PPI users not receiving clopidogrel presented a similar increased risk (HR 1.43, 95% CI: 1.34-1.53), indicating no interaction between clopidogrel and PPI. The authors suspected that the increased cardiovascular risk in PPI users might be due to imperfectly measured differences in the baseline characteristics (lack of data on smoking status, lipid levels and body mass index)[28]. The strength of this study lies in the unselected nationwide population (patients older than 30 years hopitalized for myocardial infarction allover in Denmark) and the probably high concordance between the measured drug dispension (from data of the Danish national prescription registry) and real drug consumption

due to only partial reimboursement of drug expenses and the fact that PPIs weren't available over the counter during the study period. However, the study is based on data from 2000 to 2006 and the low antiplatelet drug exposure (only 50%-70% of patients were under aspirine and 27% under clopidogrel on follow-up) dramatically contrasts with the current practice and questions the validity of the final conclusions.

In 2011, two analyses of PCI registries, including large data on cardiovascular risk factors and comorbities, were not able to show any difference on cardiovascular events: The American Guthrie Health Off-Lable Stent (GHOST) investigators studied 2651 patients discharged after coronary stenting and found no increase of Major Adverse Cardiovascular Events (MACE: death, myocardial infarction, target vessel revascularisation or stent thrombosis) for PPI users after propensity adjusted analysis (HR 0.89, 95% CI: 0.63-1.27) and in the propensity matched subgroup including 685 pairs of patients [42 (6.1%) without PPI against 40 (5.8%) with PPI; adjusted *P* = 0.60], the latter indicating even a trend to a protective effect of PPI treatment when under clopidogrel, perhaps due to less discontinuation of the antiaggregation as shown at the 6 mo follow-up (78% under clopidogrel in the PPI group against 70% without PPI, *P* = 0.0085). Furthermore, no difference according to the PPI used (omeprazole and esomeprazole) was observed[29]. Similar results came from the French Registry of Acute ST-Elevation and Non-ST Elevation Myocardial Infarction (FAST-MI), including 3670 post myocardial infarction patients. No increase in death, reinfarction or stroke was observed for concomitant PPI and clopidogrel use after one year (HR 0.98, 95% CI: 0.90-1.08). Furthermore, no difference existed regarding the PPI used (predominantly omeprazole and esomeprazole) and the presence of no or 1 to 2 CYP2C19 loss-of-function alleles. Of note, only a low number of 2 CYP2C19 loss-of-function alleles patients has been integrated (44 of 1579), leaving a higher risk of adverse cardiovascular outcome in this group still possible[30]. Both studies are based on PCI registries with detailed data assessment on baseline until hospital discharge. In contrast, follow-up was restricted on recording the patient's hospital readmission or death, without reliable information on medication exposure after hospitalization. The analysis restricted to the clopidogrel naïve population (2651 of 4421 respectively 2744 of 3670 patients) in order to avoid bias du to the occurrence of the index episode, limited the number of patients included, and may have underpowered the individual subgroups to detect a significant difference. Pointing out that the majority of the previous observational studies relied on discharge prescription records, Banerjee *et al*[32]. conducted a study on 23 200 post-PCI patients, including postdischarge drug exposure patterns using data from the Veteran Affairs Pharmacy Benefits Management database to assess drug exposure during the follow-up throughout a 6 years period. After propensity score adjustment, no difference in MACE (composite of all-cause death, nonfatal myocardial infarction or repeated revasularisation)

was observed between PPI and no PPI use in the group of continuous clopidogrel users (HR 0.97, 95% CI: 0.65-1.44). A rigorous control according to the consistency and duration of the clopidogrel and PPI exposure has been done, by revising daily exposure derived from prescription release dates and days of supply-a method considered superior to patient self-reported medication use[64]. In a subanalysis, rescue nitroglycerin and/or PPI use in patients < 30 d before MACE was significantly greater in patients taking clopidogrel and PPI ($P < 0.001$), suggesting a potential indication bias for PPI use due to misdiagnosed angina, a fact that may have contributed to a confounding bias in previous observational studies[32].

Conducting a post hoc analysis of the randomized Clopidogrel for Reduction of Events During Observation (CREDO) trial, Dunn *et al*[65] reported an increased risk of death, myocardial reinfarction or urgent target vessel revascularization at 28 d for patients using PPIs, independent on the underlying treatment [clopidogrel (OR 1.63, 95% CI: 1.02-2.63) or placebo (OR 1.55, 95% CI: 1.03-2.34)]. Baseline characteristics of the PPI group are not available, but as already discussed by Charlot *et al*[28], patients under PPI might be sicker than those who are not, explaining the higher rate of adverse cardiovascular events. Another post hoc analysis of a double-blind randomized trial, the Trial to Assess Improvement in Therapeutic Outcomes by Optimizing Platelet Inhibition with Prasugrel (TRITON)-TIMI 38 trial included 13 608 patients with an ACS undergoing PCI and being randomly assigned to prasugrel or clopidogrel. Thirty three percent (4529 patients) were on PPIs at randomisation and exposure during the follow-up was identified by landmark analyses at 3 d, 3 and 6 mo and at the end of follow-up. Baseline characteristics showed that patients treated with PPIs were once again significantly older and had more often preexisting cardiovascular disease. After multivariable adjustment and propensity score matching, PPI use was not associated with the composite endpoint of cardiovascular death, myocardial infarction or stroke when prescribed with either clopidogrel (HR 0.94, 95% CI: 0.80-1.11) or prasugrel (HR 1.00, 95% CI: 8.84-1.20). Sensitivity analysis of patients being on PPI during the whole follow-up and patients never taking PPIs has not found any increase in adverse cardiovascular events either. Finally, no difference regarding the PPI subtype prescribed was found[26]. Both analyses have the advantage, that each end-point was strictly defined and controlled according to the initial randomized design. However, the analyses weren't designed to assess PPI use and therefore didn't randomize PPI treatment, leaving a potential risk of residual confounding even after multivariable adjustment and propensity score analysis. Furthermore, PPI compliance has not been memorized during follow-up- a fact attempt to be adjusted by landmark analyses in the second study.

So far, the only existing randomized controlled double-blind multicenter trial is the Clopidogrel and the Optimization of Gastrointestinal Events (COGENT) trial, including 3878 patients presenting with an ACS or undergoing PCI. Patients were randomized to receive CGT-2168, a fixed combination of 75 mg of clopidogrel and 20 mg of omeprazole *vs* 75 mg of clopidogrel alone. After a median follow-up of 106 d, a significant reduction in the primary endpoint, a composite of upper gastrointestinal bleeding, was observed in the CGT-2168 group (1.1% *vs* 2.9%, HR 0.34, 95% CI: 0.18-0.63, $P < 0.001$). Moreover, analysis of the primary cardiovascular safety end-point, (a composite of death from cardiovascular causes, myocardial infarction, coronary revascularisation and ischemic stroke) have not shown any difference between the placebo and omeprazole group (HR with omeprazole 0.99, 95% CI: 0.68-1.44, $P = 0.96$). Unfortunately, the study was interrupted prematurely due to the bankruptcy of the sponsor, after having included only 3873 of the 5000 initially planned patients. Moreover, wide confidence intervals around the hazard ratio of cardiovascular events and the fact that 94% of the study population was white, do not permit to rule out any significant clinical interaction between clopidogrel and omeprazole[25].

The first of three recent meta-analyses was conducted by Kwok *et al*[36] selecting 23 studies with 93 278 patients. Of note, more than half of the included studies have been available only as abstracts (12 of 23). Studies have been divided into three groups: nonrandomized studies with unadjusted risk ratios, nonrandomized studies with adjusted RR and randomized trials or studies including propensity score matching. Overall analysis of 19 studies reporting the incidence of MACE showed a significantly increased risk in the PPI group (RR 1.43, 95% CI: 1.15-1.77), but data were substantially heterogeneous ($I^2 = 77\%$), partially due to considerable variation of the definition of MACE within the studies. Of interest, subanalysis of the propensity matched and randomized trails didn't show any increased risk (RR 1.15, 95% CI: 0.89-1.48) and data were much less heterogeneous ($I^2 = 53\%$). Identical results were found when analysing the risk of myocardial infarction or ACS, leading the authors to conclude that unmeasured confounders may contribute to the results of the lower quality studies[36]. Siller-Matula *et al*[37] re-analysed 25 studies with 159 138 patients, finding a 29% increase of MACE (RR 1.29, 95% CI: 1.15-1.44) and myocardial infarction (RR 1.31, 95% CI: 1.12-1.53) for concomitant PPI and clopidogrel use. Again heterogeneity in the overall analysis was very important ($I^2 = 72\%$ *vs* 77%, respectively) and sensitivity analysis assessing the study quality showed a decreased risk of MACE in high quality studies (RR 1.23, 95% CI: 1.09-1.39) *vs* low quality studies (RR 1.65, 95% CI: 1.43-1.90), rising again the question of unmeasured confounders and differences in baseline characteristics[37]. Lima *et al*[38] reviewed 18 studies according to the PRISMA guidelines[66] by classifying them into high (well-performed randomized clinical trials), moderate (post hoc analysis of RCTs and propensity matched studies) and low (observational studies without propensity matching) quality studies. Due to important study heterogeneity, data pooling was a priori not effected. A stratified analysis comparing studies of low (13) with those of moderate quality (5) demonstrated an inverse correlation

Table 2 Overview of important clinical studies on the proton pump inhibitor-clopidogrel interaction

Study	PPIs used	Procedures to minimize bias	Population	Primary outcome	Results
Bhatt *et al*[25] (randomized, controlled, double-blind trial)	Omeprazole		3873 patients with ACS or undergoing PCI	Mean 133 d- composite safety endpoint of cardiovascular death, MI, coronary revascularisation	No difference between PPI and placebo group (HR with omeprazole 0.99, 95% CI: 0.68-1.44)
O'Donaghue *et al*[26] (post-hoc analysis of a RCT)	Pantoprazole omeprazole esomeprazole lansoprazole rabeprazole	Propensity score matching; multivariable and sensitivity analysis	13 608 patients undergoing planned PCI for ACS	Composite endpoint of cardiovascular death, MI or stroke after 6-15 mo	No difference between PPI and clopidogrel alone group (HR 0.94, 95% CI: 0.80-1.11)
Dunn *et al*[65] (post-hoc analysis of a RCT)	Not specified	Multivariable analysis	2116 patients undergoing PCI	28 d death, MI, urgent target vessel revascularisation 1 yr death, MI or stroke	Increased risk for adverse cardiovascular outcome regardless of clopidogrel use (clopidogrel/PPI: OR 1.63, 95% CI: 1.02-2.63 *vs* placebo/PPI: OR 1.55, 95% CI: 1.03-2.34)
Charlot *et al*[28] (retrospective cohort study)	Esomeprazole pantoprazole lansoprazole omeprazole rabeprazole	Propensity score matching; multivariable and sensitivity analysis	56 406 patients discharged with first-time myocardial infarction	1 yr composite end point of MI, stroke or cardiovascular death	Increased risk for adverse cardiovascular outcomes in PPI users regardless of clopidogrel use (HR for PPI/clopidogrel: 1.35, 95% CI: 1.22-1.50 *vs* HR for PPI alone: 1.43, 95% CI: 1.34-1.53)
Banerjee *et al*[32] (retrospective cohort study)	Predominantly omeprazole (88,9%)	Propensity score matching; multivariable and sensitivity analysis	23 200 post PCI patients	6-yr MACE	No increased risk for MACE in PPI users (HR 0,97, 95% CI: 0.65-1.44)
Ray *et al*[27] (retrospective cohort study)	Pantoprazole lansoprazole esomeprazole omeprazole rabeprazole	Propensity score matching; multivariable and sensitivity analysis	20 596 patients discharged after PCI or ACS	1 yr composite end point of ACS, stroke or cardiovascular death	No increased risk for serious cardiovascular disease in PPI users (HR 0.99, 95% CI: 0.82-1.19)
Rassen *et al*[31] (retrospective cohort study)	Pantoprazole omeprazole rabeprazole lansoprazole esomeprazole	Propensity score matching;	18 565 patients discharged after PCI or ACS (age > 65 yr)	180 d composite end point of hospitalization for MI and PCI or death of any cause	Trend towards a higher risk of composite end point in PPI users (RR 1.26, 95% CI: 0.97-1.63)
Simon *et al*[30] (retrospective cohort study)	Omeprazole esomeprazole pantoprazole lansoprazole	Propensity score matching; multivariable and sensitivity analysis	2744 clopidogrel and PPI-naive patients with definite MI	In hospital and 1-yr death, reinfarction or stroke	No increased risk of cardiovascular events and mortality in PPI users (HR 0.98, 95% CI: 0.90-1.08)
Harjai *et al*[29] (retrospective cohort study)	Omeprazole esomeprazole	Propensity score matching; multivariable and sensitivity analysis	2651 patients discharged after PCI for stable and unstable CAD	6-mo MACE	No increased risk for MACE in PPI users (HR 0.89, 95% CI: 0.63-1.27)
van Boxel *et al*[14] (retrospective cohort study)	Pantoprazole omeprazole rabeprazole lansoprazole	Multivariable analysis	18 139 clopidogrel users	2 yr composite endpoint of ACS, stroke and any cause death	Increased risk of composite endpoint (HR 1.75, 95% CI: 1.58-1.94), myocardial infarction (HR 1.93, 95% CI: 1.40-2.65) and unstable angina pectoris (HR 1.79, 95% CI: 1.60-2.03)
Juurlink *et al*[16] (population-based nested case-control study)	Omeprazole rabeprazole lansoprazole pantoprazole	Nested case –control; multivariable and sensitivity analysis	13 636 patients discharged after ACS (age > 65 yr)	90-d readmission for acute MI	Increased risk of reinfarction (OR 1.27, 95% CI: 1.03-1.57) in PPI users except pantoprazole
Ho *et al*[15] (retrospective cohort study)	Omeprazole rabeprazole lansoprazole pantoprazole	Multivariable and sensitivity analysis	8205 patients discharged after ACS	3 yr death or rehospitalization for ACS	Increased risk for death or rehospitalization in PPI users (OR 1.25, 95% CI: 1.11-1.41)

between clopidogrel-PPI interaction and study quality (P = 0.007), as none of the moderate quality studies reported an association *vs* 10 in the low quality group[38]. The

authors pointed out that according to the large CURE (Clopidogrel in Unstable Angina to Prevent Recurent Events) trial[67] no or very little advantage in reduction of

Table 3 Summary of studies reporting on adverse bleeding events

Study	Observed adverse event	Ascertainment	Results
Bhatt *et al*[25]	Composite of upper gastrointestinal bleeding (of known and unknown origin): overt bleeding, ulcers, symptomatic erosions, obstruction, perforation or decrease in hemoglobin of 2 g/dL	Endoscopic and radiologic confirmation (in known origin subgroup)	Significative reduction of upper gastrointestinal bleeding in the omeprazole treated group (1.1% against 2.9% under placebo; HR 0.34, 95% CI: 0.18-0.63)
Ray *et al*[27]	Hospitalization for bleeding at a gastroduodenal site (excluding angiodysplasia) or other gastrointestinal and non-gastrointestinal sites	Validated diagnostic codes with PPV of 91%	Adjusted 50% reduction of hospitalization in the PPI treated group (HR 0.50, 95% CI: 0.39-0.65), no significant difference concerning bleeding at other sites
van Boxel *et al*[14]	Occurence of complicated or non complicated peptic ulcer disease	ICD-9 diagnostic codes	Low incidence (0.7% with PPI against 0.2%) but significant increase of peptic ulcer disease in the PPI treated group even after multivariable adjusting (HR 4.76, 95% CI: 1.18-19.17)
Charlot *et al*[28]	Hospitalization for gastrointestinal bleeding	ICD-9 diagnostic codes	No reduction between the clopidogrel with PPI and clopidogrel alone group
Harjai *et al*[29]	TIMI major bleeding: intracranial hemorrage or a ≥ 5 g/dL decrease in hemoglobine TIMI minor bleeding: observed blood loss with decrease ≥ 3 g/dL in hemoglobine	Guthrie Health System database	No significant difference between the clopidogrel with PPI and clopidogrel alone group
Simon *et al*[30]	In-hospital major bleeding (not specified) or need for blood transfusion	FAST-MI registry	No significant difference between the clopidogrel with PPI and clopidogrel alone group

HR: Hazard ratio; CI: Confidence interval; PPV: Positive predictive value; PPI: Proton pump inhibitor; ICD-9: International classification of disease-9th revision; FAST-MI: French registry of acute-ST-elevation and non-ST-elevation myocardial infarction.

adverse cardiovascular events when treated with clopidogrel was observed later than 3 mo after an ACS. In contrast to that, in the study of Ho *et al*[15] the increased risk of adverse cardiovascular events for concomitant PPI and clopidogrel use appears in the long term (not before 180 d), a period when clopidogrel has not been shown to be therapeutically useful any more[38]. Theses results might be explained by unmeasured residual confounders rather than by the existence of a clopidogrel-PPI interaction, a hypothesis endorsed by the three studies having found an elevated risk for adverse cardiovascular events in PPI-users, regardless whether on clopidogrel or not[28,65,68]. Characteristics and results of the cited studies are overviewed in Table 2 by classifying them according to their scientific weight, while Table 3 summarizes the studies reporting on adverse bleeding events.

To summarize, pharmacodynamic studies suggest an existing interaction between clopidogrel and omeprazole but not with pantoprazole, a phenomenon that may be explained by the higher inhibitory potency of omeprazole for the cytochrome P450 CYP2C19[54], a key enzyme in the metabolic activation of clopidogrel[39].

Nevertheless, the clinical impact of this biochemical interaction still remains unclear, as several cohort studies report an interaction and consecutive increase in adverse cardiovascular events for omeprazole[14-22]. In contrast to that, recent retrospective studies including propensity score matching in order to minimise underlying bias have not show any clopidogrel-PPI interaction[27-35] (except one recent study using a larger endpoint including overall death, myocardial infarction, stroke and critical limb ischemia[69]). In addition to that, post-hoc analyses of randomized trials[26,65] and the only randomized double blinded trial available so far have not found any increase in adverse cardiovascular events for the PPI treated group[25]. Finally, several meta-analyses pointed out that

there was an inverse correlation between study quality and a reported statistically positive interaction[36-38]. Despite of that, the United states Food and Drug Administration and the European Medecines Agency still discourage the use of PPI (especially omeprazole) concomitantly with clopidogrel[23,24].

Three recommendations to health care providers could therefore be made for the moment: (1) A gastrointestinal risk evaluation (e.g., history of gastrointestinal bleeding, dyspepsia, therapeutic anticoagulation, concomitant NSAIDS use especially in elderly persons and in the presence of helicobacter pylori[70-73]) has to be performed in each patient, as clopidogrel treatment and dual antiplatelet therapy rise the risk of adverse gastrointestinal events and mortality[3,4,25,74,75]. Patients at high risk of gastrointestinal bleeding should have prescribed concomitant PPIs when under clopidogrel, due to the high mortality rate in case of bleeding[2]; (2) Favoring pantoprazole over omeprazole pharmacologically leads to less inhibition of the CYP2C19 isoenzyme, but the clinical impact of this pharmacologic difference has not been proved so far. Nevertheless, to the best of our knowledge, no clinical trial (regardless of its quality) has ever demonstrated a clear interaction for pantoprazole, making it a rather safe choice, especially regarding recent moderate and high quality publications. Furthermore the standard daily dose of 40 mg doesn't seem to induce any significant pharmacodynamic interaction with clopidogrel, as none was found for a 80 mg/d dose[12,57]; and (3) Widening the delay between clopidogrel and PPI intake by a minimum of 12 h (a concept based on the rapid metabolization of clopidogrel[49]), doesn't seem to avoid the possible drug interaction between clopidogrel and PPIs[12,56,57].

In conclusion, rising evidence accumulates to infirm an interaction between PPIs and clopidogrel. This point

suggests that the bleeding reduction benefit overweighs the possible adverse cardiovascular risk in patients with an indication for PPI treatment taking dual antiplatelet treatment. Of course, adequate powered randomized controlled trials with pharmacodynamic assessment are still needed to infirm the persisting doubt upon the PPI-clopidogrel interaction.

Abstract

Hepatitis C (HCV)-infected patients have a poorer survival post-liver transplantation compared to patients transplanted for other indications, since HCV recurrence post-transplant is universal and commonly follows an aggressive course. There is increasing evidence that in the non-transplant setting, induction of hepatocyte apoptosis is one of the main mechanisms by which HCV drives liver inflammation and fibrosis, and that HCV proteins directly promote apoptosis. Recent studies have shown that post-liver transplant, there is a link between high levels of HCV replication, enhanced hepatocyte apoptosis and the subsequent development of rapidly progressive liver fibrosis. Although the responsible mechanisms remain unclear, it is likely that immunosuppressive drugs play an important role. It is well known that immunosuppressants impair immune control of HCV, thereby allowing increased viral replication. However there is also evidence that immunosuppressants may directly induce apoptosis and this may be facilitated by the presence of high levels of HCV replication. Thus HCV and immunosuppressants may synergistically interact to further enhance apoptosis and drive more rapid fibrosis. These findings suggest that modulation of apoptosis within the liver either by changing immunosuppressive therapy or the use of apoptosis inhibitors may help prevent fibrosis progression in patients with post-transplant HCV disease.

Enhanced apoptosis in post-liver transplant hepatitis C: Effects of virus and immunosuppressants. *World J Gastroenterol* 2012; 18(18): 2172-2179 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i18/2172.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i18.2172

INTRODUCTION

Hepatitis C (HCV)-related liver failure is now the commonest indication for liver transplantation in the United States, Australia and Europe[1]. HCV-infected patients have a poorer survival post-transplantation compared to patients transplanted for other indications[2]. This is because HCV recurrence occurs in virtually all patients and commonly follows an aggressive course, with 20%

or more of patients developing cirrhosis within 5 years of transplantation[3]. The cause of this accelerated disease has not been fully elucidated, but risk factors include advanced donor age, early high HCV viral load post-transplant[4], acute graft rejection and treatment thereof, and the degree of immunosuppression[5].

In the non-transplant setting, induction of hepatocyte apoptosis is one of the main mechanisms via which HCV drives liver inflammation and fibrosis[6]. Recent evidence suggests a link between high levels of HCV replication, high rates of apoptosis and the subsequent development of rapidly progressive graft injury and fibrosis after liver transplantation[7]. The mechanisms responsible for this high levels of apoptosis found in aggressive post-liver transplant HCV disease remain unclear. It is well known that immunosuppressants impair immune control of HCV, thereby allowing increased viral replication. There is also recent evidence that some commonly used immunosuppressants may directly induce apoptosis and this may be facilitated by the presence of high levels of HCV replication. This suggests that HCV and immunosuppressants may synergistically interact to enhance apoptosis and drive rapid fibrosis.

OVERVIEW OF APOPTOSIS

Apoptosis is a highly regulated physiological process that plays an important role in organogenesis and the maintenance of tissue homeostasis[8]. Cells posing a threat to the integrity of an organ, such as virus-infected cells, may be eliminated by apoptosis, which occurs by two major pathways - extrinsic and intrinsic. The extrinsic pathway is activated when death ligands [tumor necrosis factor (TNF), FasL/CD95L and TRAIL] secreted by cells of the immune system in response to foreign (for example, viral) antigens bind to their respective cell surface receptors, to trigger signaling pathways that result in the activation of caspases[9]. The caspases are a class of enzymes responsible for the execution of apoptosis within the cell. In the intrinsic pathway, intracellular apoptotic stimuli, such as viral antigens, cause disruption of mitochondrial membrane integrity, releasing cytochrome c that activates the caspase pathway[10]. The integrity of the outer mitochondrial membrane is predominantly maintained by anti-apoptotic members of the Bcl-2 family (e.g., Bcl-2 and Bcl-xL), which antagonize pro-apoptotic members (for example, Bax and Bak).

LINK BETWEEN HEPATOCYTE APOPTOSIS AND LIVER FIBROSIS

There are increasing amounts of experimental data implicating apoptosis as a driving force for fibrogenesis in a range of different liver diseases, including alcohol-related and cholestatic liver diseases and viral hepatitis[11]. Apoptotic hepatocytes are engulfed and cleared by both Kupffer cells and hepatic stellate cells (HSCs). Activated HSCs are the primary cell type responsible for promoting

fibrogenesis within the damaged liver, and the uptake of apoptotic bodies by HSCs result in their activation and secretion of the key pro-fibrogenic cytokine transforming growth factor-β (TGF-β)[12]. In activated HSCs, TGF-β induces a marked upregulation of genes encoding fibrillar collagens and other extracellular matrix components, resulting in the abnormal deposition of collagen within the liver[13]. Kupffer cells, which are the resident liver macrophages, upon ingestion of apoptotic hepatocytes, also secrete TGF-β, thereby promoting a pro-fibrogenic response in activated HSCs[14]. Furthermore, TGF-β itself induces hepatocyte apoptosis via two independent pathways, SMAD and DAXX[15], thus providing a positive feedback loop that could further potentiate apoptosis-induced fibrosis. In support of these *in vitro* observations, inhibition of apoptosis reduces hepatic inflammation and fibrosis in experimental models of fibrotic liver disease[16].

HEPATITIS C AND HEPATOCYTE APOPTOSIS

In HCV infection, hepatocyte apoptosis is an important part of the host anti-viral defense mechanism since it interrupts viral replication and assists in the elimination of virus-infected cells. However, in keeping with the observed effects of apoptosis in laboratory studies, there is now evidence to suggest that the severity of liver damage in chronic HCV is associated with the degree of hepatocyte apoptosis[6]. Furthermore, the degree of apoptosis correlates with the level of viraemia[17]. Bantel and colleagues have studied a serum apoptosis biomarker, the proteolytic neoepitope of the caspase substrate cytokeratin-18, as a means of determining caspase activity to monitor liver injury and predict the progression of hepatic fibrosis in HCV-infected patients[18]. This biomarker was markedly elevated in the sera of HCV-infected patients compared to healthy controls, and in patients with normal transaminase levels, raised serum caspase activity was associated with advanced fibrosis on liver biopsy.

Hepatocyte apoptotic rates on liver biopsy are significantly greater in HCV-positive patients post-liver transplant compared to the non-transplant setting, with the severity of liver inflammation correlating with the level of hepatocyte apoptosis[7], and HCV viral load is known to be higher post-liver transplantation[19]. Thus one potential explanation for accelerated fibrosis post-transplantation is that the high levels of HCV replication that occurs due to impaired immune control of HCV replication may drive increased hepatocyte apoptosis.

How then does HCV affect apoptosis? One likely mechanism is that virus-specific cytotoxic T-cells may induce apoptosis of HCV-infected hepatocytes by upregulating death receptor ligands (TNF, FasL/CD95L and TRAIL), by producing antiviral cytokines (for example, interferon-γ), and by direct cell killing with perforins and granzymes[20]. HCV infection is also associated with an upregulation of death receptors on hepatocytes, and the levels of Fas/CD95 and FasL/CD95L have been shown

Figure 1 Where the hepatitis C proteins and immunosuppressants are thought to interact with the apoptotic pathways within the hepatocyte. CyA: Cyclosporine; FK506: Tacrolimus; MMF: Mycophenolate mofetil; Sirol: Sirolimus; TNF-α: Tumor necrosis factor-alpha.

to increase in parallel with the severity of inflammation and disease progression[21].

There is also considerable experimental evidence that HCV structural proteins can directly influence hepatocyte apoptosis. HCV core protein has been reported to sensitize hepatocytes to TNF-α-[22] and FasL/CD95L-[23] mediated apoptosis, by interacting with the cytoplasmic domains of TNFR1 and Fas/CD95 to enhance downstream signaling events. It also induces oxidative stress, enhances mitochondrial-mediated hepatocyte apoptosis[24] and upregulates *TGF-β1* gene expression, thereby promoting apoptosis and fibrogenesis. However, the expression of core protein has also been shown to have a number of possible anti-apoptotic effects. These include inhibition of TNF-α- and Fas/CD95-mediated apoptosis through the upregulation NF-κB[25], and interaction with cFLIP, an endogenous caspase-8 inhibitor[26]. Core protein has also been reported to promote the anti-apoptotic Bcl-xL expression, inhibit interferon-α-mediated STAT1 signaling and activate STAT3, thereby protecting infected hepatocytes from T-cell-mediated apoptosis[27]. Both the E1 and E2 glycoproteins of HCV have been shown to induce hepatocyte apoptosis[28], with the E2 protein noted to activate the mitochondrial caspase pathway. However,

E2 protein has also been shown to inhibit interferon-α-mediated STAT1 signaling and TRAIL-induced apoptosis, as well as enhance the proliferation of transfected Huh7 human hepatoma cells[29]. The data on the effect of HCV on caspase-independent apoptosis are lacking. One study showed that core protein expression promoted apoptosis-like caspase-independent cell death in osteosarcoma-derived cells[30], but the effect in liver cells is unknown.

The non-structural proteins of HCV have also been shown to affect hepatocyte apoptosis. By using a NS3-5B subgenomic replicon of HCV, Huh7.5 human hepatoma cells were shown to be sensitized to TRAIL-induced apoptosis[31]. Accumulation of NS4A on mitochondria has been found to promote mitochondrial-mediated apoptosis[32]. Similarly, the HCV protease NS3, can induce apoptosis in a caspase 8-dependent manner. On the other hand, NS2 has been found to inhibit the mitochondrial release of cytochrome c, thereby inhibiting mitochondrial-mediated apoptosis[33]. NS5A inhibits interferon-α-mediated STAT1 signaling[34] and protects hepatocytes against interferon-α- and TNF-α-mediated apoptosis. NS5A also prevents apoptosis by activating NF-κB, inhibiting TGF-β, and upregulating STAT3 expression to

promote hepatocyte proliferation[35].

Thus HCV proteins have been shown to have a number of both pro- and anti-apoptotic effects in cultured hepatocytes but the net of contribution of these changes to hepatocyte apoptotic rates and liver fibrosis *in vivo* remains unclear. The discrepancies in these effects may be partly explained by differences in experimental conditions, cell types, apoptotic stimuli and HCV genotype-specific proteins expressed in various *in vitro* systems that may not mimic the true *in vivo* situation. Our current understanding of how the HCV proteins interact with apoptotic pathways within the hepatocyte is summarized in Figure 1.

HEPATITIS C AND APOPTOSIS OF OTHER LIVER CELL TYPES

Activated HSCs are the key cell type promoting fibrogenesis in the liver. HSC activation is increased in patients with chronic HCV infection and the degree of activation correlates with necroinflammatory grade and fibrosis stage[36]. Interestingly, patients with chronic HCV infection have elevated plasma levels of TGF-β1 and increased expression of TGF-β1 in the liver, while the clearance of HCV infection with anti-viral treatment is associated with normalization of plasma TGF-β1 levels[37]. This argues for an important role of TGF-β in HCV-mediated HSC activation and liver fibrogenesis.

Normally, hepatocytes do not express TGF-β, but hepatocytes exposed to HCV non-structural proteins upregulate TGF-β expression, resulting in the activation of HSCs[38]. HSCs express CD81 and LDL receptor, the putative receptors for HCV, and may perhaps be infected by HCV *in vivo*[39]. Expression of HCV core and non-structural proteins in HSCs was found to activate HSCs, resulting in upregulation of TGF-β and procollagen 1 expression[39]. The interaction of HCV E2 glycoprotein with HSCs is noted to upregulate HSC expression of matrix metalloproteinase 2, thus facilitating hepatic fibrogenesis.

Activated HSCs are primarily cleared by apoptosis, a process that would normally restrict the fibrogenic response within an inflamed liver. However, in patients with chronic HCV and advanced fibrosis, HSC apoptosis is reduced compared to patients with mild fibrosis[40]. This suggests that the inhibition of HSC apoptosis by HCV may contribute to the progression of liver fibrosis in this disease. Also, HCV-infected patients who are noted to have a high number of activated HSCs in liver biopsies done several months after liver transplantation developed advanced fibrosis within 2 years of transplantation, indicating that the degree of HSC activation may be an early predictor of post-transplant rapid fibrosis[41].

Kupffer cells have an integral role in the development of chronic liver inflammation in response to hepatocyte injury. Activated Kupffer cells contribute to HSC activation and thereby promote liver fibrosis. The interaction between HCV core protein and toll-like receptor (TLR) 2 on human Kupffer cells has been shown to upregulate cell surface programmed death-ligand 1 (PD-L1). The binding of Kupffer cell PD-L1 to PD-1 receptors on T-cells promotes T-cell apoptosis, thereby impairing the host adaptive anti-viral response[42]. HCV core protein has also been shown to inhibit TLR3-mediated induction of interferon-α, interferon-β and TRAIL, and this may impair the anti-viral activity of Kupffer cells[42]. HCV has not been shown to affect Kupffer cell apoptosis.

IMMUNOSUPPRESSIVE DRUGS AND APOPTOSIS

The aim of post-liver transplant immunosuppression is to dampen the adaptive immune response and prevent graft rejection. However, robust CD4+ and cytotoxic CD8+ T-cell responses play a central role in controlling HCV replication. The experimental evidence that the increased HCV viraemia that occurs post-transplant may directly drive higher rates of apoptosis suggests a likely link between immunosuppressive drug therapy, the resultant loss of immune control of HCV replication, and apoptosis-induced liver injury and fibrosis.

It is has been suggested that the overall level of immunosuppression, rather than the individual agent, is associated with the level of HCV viraemia and the degree of hepatic injury on liver biopsy in patients with post-transplant HCV recurrence[43]. Thus the use of pulse methylprednisolone for the treatment of acute graft rejection has been shown to dramatically elevate HCV viral load[43], while OKT3, another highly potent immunosuppressant used to treat steroid-refractory acute rejection, has been shown to accelerate HCV-associated liver fibrosis.

However, there is emerging evidence that individual immunosuppressive drugs used in long-term maintenance therapy may also have individual specific effects on both HCV replication and HCV-mediated liver injury. Some groups have shown that cyclosporine therapy is associated with less severe histological recurrence and improved graft survival post-liver transplantation compared to tacrolimus[44]. One possible explanation for this effect is that cyclosporine is known to inhibit HCV replication *in vitro* by the inhibition of NS2 and NS5A[45]. Tacrolimus, on the other hand exhibits no anti-viral effect *in vitro* and in fact impairs interferon-α activity by interfering with STAT-1 phosphorylation, and thus, may promote viral replication and persistence[46]. Mycophenolic acid (MPA), the active metabolite of mycophenolate mofetil (MMF), inhibits HCV replication in Huh7 human hepatoma cells without inhibiting cell proliferation or inducing apoptosis[47]. A synergistic inhibition of viral replication has also been shown when MPA was combined with cyclosporine or interferon-α[48].

In addition to their possible effects on viral replication, there is increasing evidence that some of the immunosuppressive agents may also directly contribute to apoptosis. Figure 1 summarizes our current understand-

ing of where individual immunosuppressants interact with intracellular apoptotic pathways.

Cyclosporine has been shown to prevent hepatocyte necrosis in mice exposed to concanavalin A[49], but data on its effect on hepatocyte apoptosis are lacking. Cyclosporine is noted to cause apoptosis of renal vascular endothelial cells via endoplasmic reticulum stress, as well as fibrosis of the renal tubulointerstitium by upregulating TGF-β expression[50]. These findings raise concerns that similar effects may occur within the liver. Indeed, cyclosporine has been found to promote hepatocyte expression of pro-apoptotic Bak in a rat model of liver injury[51]. On the other hand, cyclosporine has also been shown to prevent apoptosis of human gingival fibroblasts by inhibiting Bax and upregulating anti-apoptotic Bcl-2[52], as well as reducing mitochondrial permeability and inhibiting cytochrome c release in human platelets and rat vascular endothelial cells *in vitro*[53]. In an animal model of colitis, cyclosporine was found to have a protective role against epithelial apoptosis through the upregulation of anti-apoptotic cFLIP and inhibition of caspase-8 activity[54].

Tacrolimus has also been shown to have both pro-apoptotic and anti-apoptotic effects in various cell lines in culture. Treatment with tacrolimus promotes Jurkat T-cell G0/G1 phase cell cycle arrest and the generation of reactive oxygen species, mitochondrial dysfunction and thereby apoptosis[55]. In contrast, in human islet cells exposed to pro-inflammatory cytokines such as IL-1 and interferon-γ, tacrolimus has an anti-apoptotic effect, causing a reduction in TNF-α and down-regulation of caspase-3, -8 and -9[56]. Tacrolimus has also been shown to promote hepatic expression of anti-apoptotic Bcl-2 in a rat model of liver injury[51]. However the effect of tacrolimus on apoptosis in human liver is unknown.

After solid organ transplantation, treatment with MMF has been associated with increased mucosal apoptosis in the upper gastrointestinal tract and colon, producing an appearance similar to graft-*vs*-host disease[57]. While MMF has been shown to induce apoptosis via promoting endoplasmic reticulum stress and increasing caspase-3 activity in human pancreatic islet cells[58], the opposite effect has been observed in renal transplant recipients, where reduced apoptosis of renal tubular epithelial, glomerular and interstitial cells was noted[59]. MMF has also been shown to reduce pancreatic β-cell apoptosis in a rodent model of diabetes, and reduce hepatocyte oxidative stress and apoptosis in a rat model of ischaemia/reperfusion injury[60]. The effect of MMF on human hepatocyte apoptosis is currently unknown.

Sirolimus has been found to induce apoptosis in acute lymphoblastic leukemia cells by inhibiting the PI3K/Akt pathway[61]. It also induces apoptosis in vascular smooth muscle cells by activating caspase-3 and inhibiting NF-κB nuclear translocation[62]. However, sirolimus is known to inhibit HSC proliferation *in vitro*, reduce TGF-β expression and inhibit collagen deposition, thereby reducing hepatic fibrosis in a rat model of liver injury[63]. Indeed, sirolimus has also been shown to reduce liver fibrogen-

esis, improve liver function and enhance survival in rats with established cirrhosis[64]. Huh7 hepatoma cells transfected with the HCV-1b genome have upregulated PI3K-Akt-mTOR signaling[65], possibly rendering HCV-infected cells more resistant to apoptosis. Sirolimus, by inhibiting the mTOR pathway, has been shown to inhibit NS5A phosphorylation, thereby inhibiting HCV replication[66]. Sirolimus-based maintenance immunosuppression has been associated with lower HCV RNA levels at 12 mo following liver transplantation and improved patient survival at 6 years compared to calcineurin inhibitors[67].

THERAPEUTIC IMPLICATIONS

Understanding the role of hepatocyte apoptosis in the pathogenesis of post-transplant HCV-mediated liver injury and the likely contributing role of the immunosuppressive agents has a number of important therapeutic implications. It is hoped that increased knowledge of the pro- or anti-apoptotic effects of different immunosuppressive agents and whether they exacerbate HCV-induced apoptosis may allow the development of immunosuppressive regimes that minimize this aspect of HCV-mediated liver injury. In this regard, sirolimus is of particular interest given its possible anti-apoptotic and anti-fibrotic effects both *in vitro* and in animal models.

These findings also suggest a possible therapeutic role for apoptosis inhibitors in post-transplant HCV. There is increasing experimental and clinical experience with the use of this class of compounds in liver disease. The pan-caspase inhibitor IDN-6556 was found to reduce hepatocyte apoptosis and liver fibrosis in bile duct-ligated mice[16], and improve liver function tests in patients with hepatic dysfunction[68]. VX-166, another pan-caspase inhibitor, has been shown to reduce hepatocyte caspase-3 expression and apoptosis, thereby decreasing hepatic fibrosis in a murine model of non-alcoholic steatohepatitis[69]. Given the evidence linking HCV-induced hepatocyte apoptosis with liver fibrosis, 2 randomized, double-blind, placebo-controlled studies have been conducted using pan-caspase inhibitors in patients with chronic HCV, one using PF-03491390[70] and the other using IDN-6556[71]. In both studies, the orally administered pan-caspase inhibitors were well tolerated with minimal adverse effects and showed significant reductions in serum transaminases. Besides directly targeting caspases, compounds that inhibit other components of the apoptotic pathway upstream to caspases are currently in development. There are currently no drugs that inhibit the caspase-independent apoptotic pathway in the literature.

Conversely, the promotion of HSC apoptosis may also act to reduce hepatic fibrosis. Cortex Dictamni extract was noted to induce apoptosis of activated HSCs, resulting in decreased hepatic collagen deposition and attenuated fibrosis in a murine model of liver injury[72]. Another compound, 2',4',6'-tris(methoxymethoxy) chalcone, is noted to induce apoptosis of activated HSCs by enhancing FasL/CD95L expression without affecting

hepatocyte apoptosis[73]. The tyrosine kinase inhibitor sorafenib has also been found to increase HSC expression of caspase-3 and induce HSC apoptosis resulting in reduced hepatic collagen deposition and fibrosis in bile duct-ligated rats[74]. These compounds raise the possibility of treatment to reduce the population of activated HSCs within the transplanted liver in HCV-recurrence.

In conclusion, the management of post-liver transplant HCV disease remains one of the major challenges in transplant medicine. Enhanced hepatocyte apoptosis appears to contribute to much of the liver injury that drives rapid liver fibrosis in this disease, and in the near future clinically useful serum biomarkers of apoptosis may be available to monitor for this. The precise mechanisms that drive this accelerated hepatocyte apoptosis post-transplant require further study, but it appears that both HCV itself and immunosuppressants play contributory and possibly synergistic roles. In the future as the effects of various immunosuppressive agents on HCV-induced liver cell apoptosis are clarified, a combination of fine-tuning immunosuppressive regimens as well as the manipulation of apoptosis within the liver represents novel therapeutic possibilities for the management of this complex disease.

Abstract

AIM: To investigate the effect of side-stream smoking on gut microflora composition, intestinal inflammation and expression of tight junction proteins.

METHODS: C57BL/6 mice were exposed to side-stream cigarette smoking for one hour daily over eight weeks. Cecal contents were collected for microbial composition analysis. Large intestine was collected for immunoblotting and quantitative reverse transcriptase polymerase chain reaction analyses of the inflammatory pathway and tight junction proteins.

RESULTS: Side-stream smoking induced significant changes in the gut microbiota with increased mouse intestinal bacteria, *Clostridium* but decreased *Fermicutes* (*Lactoccoci* and *Ruminococcus*), *Enterobacteriaceae* family and *Segmented filamentous baceteria* compared to the control mice. Meanwhile, side-stream smoking inhibited the nuclear factor-κB pathway with reduced phosphorylation of p65 and IκBα, accompanied with unchanged mRNA expression of tumor necrosis factor-α or interleukin-6. The contents of tight junction proteins, claudin3 and ZO2 were up-regulated in the large intestine of mice exposed side-stream smoking. In addition, side-stream smoking increased c-Jun N-terminal kinase and p38 MAPK kinase signaling, while inhibiting AMP-activated protein kinase in the large intestine.

CONCLUSION: Side-stream smoking altered gut microflora composition and reduced the inflammatory response, which was associated with increased expression of tight junction proteins.

INTRODUCTION

Cigarette smoking is a remarkable etiological factor in the pathogenesis of cardiovascular diseases, hypertension, pulmonary diseases and gastroenterological diseases[1-4]. Meanwhile, passive smoking (second-hand smoking) is also a contributing factor for the development of coronary artery disease[5-7], lung cancer[7] and Crohn's disease[8], which pose a substantial health risk to non-smoking adults and young children worldwide[9]. It was estimated in 2004 that more than 600 thousand deaths were due to

second-hand smoke, which accounted for about 1% of worldwide mortality[9]. On the other hand, it was reported that smoking had a protective effect in reducing ulcerative colitis mostly based on the epidemiologic studies[8,10,11].

Chronic inflammatory bowel diseases, mainly Crohn's disease and ulcerative colitis, are characterized by chronic inflammation of the intestines[8]. Recent studies clearly show that gut epithelial integrity and barrier function are the central predisposing factors in inflammatory bowel diseases, autoimmune and related allergic diseases[12-16]. The intestinal epithelium is composed of tightly assembled intestinal epithelial cells which form a protective barrier against pathogenic and commensal bacteria, preventing their penetration from the lumen to initiate inflammatory responses in the mucosal system[17]. Impairment of the tight junction barrier is associated with chronic diseases such as inflammatory bowel diseases, obesity and type 1 diabetes[18-21]. Epithelial cells form an integrated web through interaction of tight junction proteins including intracellular proteins, zona occludens (ZO)-1, (ZO)-2 and (ZO)-3, cingulin, 7H6 and ZA-1, and membrane proteins, occludin, claudin and junctional adhesion molecules[22,23]. The tight junction functions are affected by extracellular stimuli such as the microbial components, pro-inflammatory cytokines and stress[24,25].

Inflammation disrupts tight junctions. Inflammatory cytokines such as interleukin (IL)-13, and IL-6, increase tight junction permeability through increasing claudin 2 expression[26,27]. The activation of the inflammatory pathway nuclear factor (NF)-κB by TNF-α, down-regulates *ZO-1* gene expression and induces its relocation in Caco-2 cells[28]. Therefore, local inflammation impairs the barrier function of gut epithelium.

The "microflora hypothesis" suggests that gut microflora composition plays an important role in the immunological response of the gut[29]. Lactic acid bacteria are known to have an anti-inflammatory effect[30-34], and alteration of microflora composition is linked to the incidence of inflammatory bowel diseases[35,36]. Up to now, there is no published studies assessed gut microflora changes due to smoking.

We hypothesized that side stream smoking may possess a potent anti-inflammatory effect on the gut mucosal immune system which promotes the expression of tight junction proteins in the intestine, exerting beneficial effects on the prevention of ulcerative colitis.

MATERIALS AND METHODS

Animal care and experiment design
C57BL/6 female mice at 6 mo of age were housed in a temperature-controlled room with a 12 h light and 12 h darkness cycle and were given food and water *ad libitum*. Mice were placed in an exposure box and exposed to side-stream smoke for 1 h daily for 40 d. Commercial cigarettes (golden monkey, tar: 13 mg; nicotine: 1.1 mg; CO: 15 mg) were used at a dose equivalent to one commercial cigarette's smoke per day[37]. The animal care procedures described in this study was approved by the University of Wyoming Institutional Animal Use and Care Committee.

Tissue collection
On the day of necropsy, mice were anesthetized intraperitoneally with tribromoethanol (250 mg/kg body wt). Blood samples were collected from the orbital sinus while mice were under general anesthesia. Mice were then sacrificed by cervical dislocation. Large intestines were dissected, flushed with phosphate-buffer saline and then frozen in liquid nitrogen for immunoblotting and quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) analyses. Cecal contents from each mouse were collected and frozen for microflora analyses.

Reagents and antibodies
Antibodies against ZO1, ZO2, Claudin3 and Occludin were purchased from Invitrogen (Camarillo, CA). Antibodies against phospho- c-Jun N-terminal kinase (SAPK/JNK) (Thr183/Tyr185), SAPK/JNK, phospho-NF-κB p65 (ser536), NF-κB p65, phospho-IκB kinase (IKK) α/β (Ser176/180), IKKβ, phospho-IκBα, IκBα, phosho-p38 MAP kinase and p38 MAP kinase, phospho-AMP-activated protein kinase (AMPK) α and AMPKα were purchased from Cell Signaling Technology (Beverly, MA). Antibodies against xanthine oxidase (XO), heat shock protein (HSP) 60 and superoxide dismutase (SOD) 1 were purchased from Santa Cruz Biotech Inc. (Santa Cruz, CA). Anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) antibody was purchased from Affinity BioReagents (Golden, CO).

Quantitative reverse transcription PCR
Total RNA was extracted from powdered large intestine using Trizol®Reagent (Sigma, St. Louis, MO), treated with DNase I (Qiagen, Valencia, CA) and purified with RNeasy Mini kit (Qiagen). cDNA was synthesized with the iScript™ cDNA synthesis kit (Bio-Rad Laboratories, Hercules, CA). qRT-PCR was conducted on a Bio-Rad CFX96 machine and SYBR Green Master Mix (Bio-Rad Laboratories, Hercules, CA) was used for all qRT-PCR reactions. Mouse GAPDH was used as the housekeeping gene. Primer sequences are listed in Table 1. The final primer concentration was 200 nmol for each gene. The amplification efficiency was 0.90-0.99. The qRT-PCR conditions were 95 ℃, 3 min, and 35 cycles of 95 ℃ for 10 s, 58 ℃ for 20 s and elongation step at 72 ℃ for 20 s. At the end of each run, dissociation melting curve was obtained to confirm the purity of PCR products[38].

Microflora analyses
The frozen caecal contents (0.1 g) were homogenized and bacterial genomic DNA was extracted using a QIAamp DNA stool mini kit according to the manufacturer's instructions (Qiagen, Valencia, CA). The abundance of specific intestinal bacterial groups was measured by qPCR using Bio-Rad CFX96 machine (Bio-Rad Laboratories, Hercules, CA) as described above. Group specific

or kingdom specific 16S rRNA gene primers were listed in Table 2. Eubacteria 16S rRNA was used as the housekeeping gene.

Immunoblotting analyses

Immunoblotting analyses were conducted as previously described[39,40]. Briefly, protein extracts from the mouse large intestine were separated by 5%-15% sodium dodecylsulfate polyacrylamide gel electrophoresis (SDS-PAGE) gradient gels and transferred to nitrocellulose membranes for immunoblotting analyses. Band density was normalized according to the GAPDH content[39,40].

Statistical analysis

Statistical analyses were conducted as previously described[41-43]. Data were analyzed as a complete randomized design using General Linear Model of Statistical Analysis System (2000). Mean ± SEM are reported. Mean difference was separated by a least significant difference multiple comparison test. Statistical significance is considered as *P* < 0.05.

RESULTS

Effect of side-stream cigarette smoking on the gut microflora composition

Quantitative PCR analysis of 16S rRNA showed that exposure of C57BL6 mice to side-stream cigarette smoking increased the amount of *Clostridium clostridiforme* and mouse intestinal bacteria (MIB) in the cecal microflora, while decreasing the content of *Lactoccoci, Ruminococcus albus, Enterobacteriaceae* and segmented filamentous bacteria

Figure 1 Cecal microflora composition of Con and side-stream smoking mice. [a]$P < 0.05$, [b]$P < 0.01$ *vs* control group (mean ± SEM; *n* = 6 per group).

Figure 2 NF-κB signaling pathway in large intestine of Con and side-stream smoking mice. A: Phos-p65 and p65; B: Phos-IκBa and IκBa; C: Phos-IKKα/β and IKKβ. [a]$P < 0.05$, [b]$P < 0.01$ *vs* control group (mean ± SEM; *n* = 6 per group).

(SFB) compared with those of control mice (Figure 1).

Intestinal inflammatory responses of gut to side stream smoking

Side-stream smoking decreased phosphorylation of NF-κB p65, a key mediator of the NF-κB inflammatory signaling pathway. Consistently, phosphorylation of IκBα and IKKα/β were also down-regulated in mice exposed to side-stream smoking, indicating that smoking is capable of reducing inflammation in the gut (Figure 2). qRT-PCR analysis indicated that mRNA expression of the two main inflammatory cytokines, TNFα and IL-6, were not changed (data not shown).

Side-stream smoking induced oxidative stress in large intestine

There was an enhanced oxidative stress in side-stream

smoking mice compared to that of control mice, as indicated by increased XO ($P = 0.06$) and decreased SOD1 ($P < 0.01$) protein content in the side-stream smoking mice (Figure 3). Meanwhile, the heat shock protein 60 (HSP60) decreased in the side-stream smoking mouse large intestine when compared to that of control mice (Figure 3). Consistently, the phosphorylation of stress signaling mediators, JNK and p38 MAP kinase, were increased in the large intestine of side-stream smoking mice (Figure 4). However, the phosphorylation of another kinase related to stress, AMPK, was reduced in response to side-stream smoking (Figure 5).

Tight junction protein expression

Both mRNA expression and protein content of selected tight junction proteins were further analyzed. Protein content of claudin3 ($P < 0.01$) and ZO2 ($P < 0.05$) were

Figure 3 Xanthine oxidase, superoxide dismutase 1 and heat shock protein 60 content in large intestine of Con and side-stream smoking mice. [b]P < 0.01 *vs* control group (mean ± SEM; n = 6 per group). XO: Xanthine oxidase; SOD1: Superoxide dismutase 1; HSP60: Heat shock protein 60.

increased in the large intestine of side-stream smoking mice (Figure 6B), while there is no difference in their mRNA expression (Figure 6A).

DISCUSSION

Epidemiology studies have shown that smoking, including passive smoke inhalation, reduces the incidence of ulcerative colitis, which may be due to the reduction of epithelial permeability[44]. Intestinal permeability was reduced in healthy smokers compared to the non-smokers[45,46].

Mechanisms by which side-stream smoking improves intestinal tight junctions are not well understood. Previous studies suggest that activation of NF-κB signaling increases intestinal permeability[47]. In this study, we observed that the NF-κB signaling was down-regulated in mice exposed to side-stream smoking. This indicates that side-stream smoking negatively regulates NF-κB signaling which might be a contributing factor to the reduction of intestinal permeability. We also observed that side-stream smoking increased Claudin3 and ZO-2 content without affecting Occludin and ZO-1. In summary, our data revealed that side-stream smoking up-regulated the expression of tight junction proteins and inhibited NF-κB signaling, which may be responsible for the preventive effect of smoking on ulcerative colitis.

Smoking generates reactive oxygen species and nitrogen species in blood, resulting in oxidative stress[48-50]. In this study, we also observed that oxidative stress related enzymes such as xanthine oxidase and superoxide dismutase 1 were altered in the large intestine due to side-stream smoking. Consistent with altered oxidative stress, two pivotal stress signaling mediators, the activation of JNK and p38 signaling were enhanced in the large intes-

Figure 4 MAP kinase signaling pathways in large intestine of Con and side-stream smoking mice. A: JNK; B: MAP kinase p38. [a]P < 0.05, [b]P < 0.01 *vs* control group (mean ± SEM; n = 6 per group).

tine of mice exposed to side stream smoking. Previously, it was reported that oxidative stress related signaling promotes tight junction protein claudin1 expression in hepatocytes and Sertoli cells[51,52].

A recent published study in gut epithelial cells shows that AMPK is related to the impairment of tight junction and barrier properties of gut induced by inflammation[53]. Our data showed that AMPK activity was dramatically inhibited in the gut tissue of side-stream smoking mice, which may provide an additional mechanism for the association between passive smoking and gut epithelial barrier function.

Furthermore, we found that microflora were altered due to the side-stream smoking. The "microflora hypothesis" suggests that gut microflora composition plays an important role in the immunological response of the gut[29]. Up to now, there have been no published studies assessing changes in gut microflora due to smoking. Our data showed that exposure to side-stream smoking altered the composition of cecal microflora, reducing *Fermicutes*

Figure 5 Total AMP-activated protein kinase α **subunit content and its phosphorylation at Thr 172 in large intestine of Con and side-stream smoking mice.** [b]$P < 0.01$ *vs* control group (mean ± SEM; $n = 6$ per group). AMPK: Total AMP-activated protein kinase.

Figure 6 Tight junction protein content in large intestine of Con and side-stream smoking mice. A: mRNA expression; B: Protein content. [a]$P < 0.05$, [b]$P < 0.01$ *vs* control group (mean ± SEM; $n = 6$ per group).

and *Enterobacteriaceae*. Both *Fermicutes* and *Enterobacteriaceae* belong to a group of bacteria contributing to fermentation and nutrient intake. *Lactoccoci* and other lactic acid bacteria are known to have anti-inflammatory effects[30-34]. The dramatic reduction of *Lactoccoci* in side-stream smoking mice indicates that *Lactoccoci* might not be responsible for the reduced inflammation in the gut of side-stream smoking mice. The reason for the reduction of *Lactoccoci* in cecal microflora due to smoking is unclear, but might be related to oxidative stress. Many *Lactoccoci* lack catalase and are sensitive to oxidative stress[54], which may render them less competitive in the oxidative environment induced by smoking. We also observed that MIB was increased while SFB was decreased in smoking mice. Because SFB is known to have important roles in maturation of the gut immune system, its reduction in smoking mice could be associated with the adverse effect of smoking on Crohn's disease[55]. MIB refers to a group of bacteria called *Cytophaga-Flavobacter-Bacteroides* phylum[56], and their abundance in the gut is known to be altered by environmental factors[57]. The biological effect of MIB alteration due to smoking is unclear.

In conclusion, data from our present study demonstrated that exposure to side-stream smoking inhibited mucosal inflammation and enhanced the expression of tight junction proteins in the large intestine. Further, side-stream smoking increased oxidative stress and altered gut microflora composition.

COMMENTS

Background

Despite its apparent harmful effects, side-stream smoking reduces the risk of inflammatory gastrointestinal diseases. Gut epithelial integrity and barrier function is a central predisposing factor to inflammatory bowel diseases. Local inflammation impairs the barrier function of gut epithelium. We hypothesized that side stream smoking may possess potent anti-inflammatory effects, which promote the expression of tight junction proteins in the intestine, exerting ben-

eficial effects on the prevention of ulcerative colitis.

Research frontiers

Epidemiologic studies indicate that smoking had a protective effect on ulcerative colitis though the underlying mechanisms remain elusive. In this study, we demonstrated that exposure to side-stream smoking inhibited mucosal inflammation, improved gut tight junction protein expression, and altered gut microflora composition in mice, which could partially explain the preventive effects of smoking on ulcerative colitis.

Innovations and breakthroughs

Recent epidemiologic studies have highlighted the preventive effect of smoking on ulcerative colitis. This is the first study to report that side-stream smoking has anti-inflammatory effect on gut mucosal, improving gut tight junction protein expression and altering gut microflora composition.

Applications

By understanding how side-stream smoking affects gut mucosal immune response and tight junction protein expression, the authors can develop alternative strategies to reduce the risk of ulcerative colitis and possibly other inflammatory bowel diseases without the harmful effects of smoking.

Terminology

Inflammatory bowel diseases are characterized by chronic inflammation in the intestine. Side-stream smoking, mimicking secondhand smoking, has anti-inflammatory effect, which may be responsible for its beneficial effects against ulcerative colitis.

Peer review

The authors address the observation that passive smoking decreases inflammatory response in large intestine. The authors are to be commended for excel-

lent work in performing a very important and informative study. The experimental methods are well summarized and explained. The statistics are appropriate for this study.

Abstract

AIM: To investigate the effect of administration of agmatine (AGM) on gastric protection against ischemia reperfusion (I/R) injury.

METHODS: Three groups of rats (6/group); sham, gastric I/R injury, and gastric I/R + AGM (100 mg/kg, i.p. given 15 min prior to gastric ischemia) were recruited. Gastric injury was conducted by ligating celiac artery for 30 min and reperfusion for another 30 min. Gastric tissues were histologically studied and immunostained with angiopoietin 1 (Ang-1) and Ang-2. Vascular endothelial growth factor (VEGF) and monocyte chemoattractant protein-1 (MCP-1) were measured in gastric tissue homogenate. To assess whether AKt/phosphatidyl inositol-3-kinase (PI3K) mediated the effect of AGM, an additional group was pretreated with Wortmannin (WM) (inhibitor of Akt/PI3K, 15 μg/kg, i.p.), prior to ischemic injury and AGM treatment, and examined histologically and immunostained. Another set of experiments was run to study vascular permeability of the stomach using Evan's blue dye.

RESULTS: AGM markedly reduced Evan's blue dye extravasation (3.58 ± 0.975 μg/stomach *vs* 1.175 ± 0.374 μg/stomach, $P < 0.05$), and VEGF (36.87 ± 2.71 pg/100 mg protein *vs* 48.4 ± 6.53 pg/100 mg protein, $P < 0.05$) and MCP-1 tissue level (29.5 ± 7 pg/100 mg protein *vs* 41.17 ± 10.4 pg/100 mg protein, $P < 0.01$). It preserved gastric histology and reduced congestion. Ang-1 and Ang-2 immunostaining were reduced in stomach sections of AGM-treated animals. The administration of WM abolished the protective effects of AGM and extensive hemorrhage and ulcerations were seen.

CONCLUSION: AGM protects the stomach against I/R injury by reducing vascular permeability and inflammation. This protection is possibly mediated by Akt/PI3K.

Al Masri AA, El Eter E. Agmatine induces gastric protection against ischemic injury by reducing vascular permeability in rats. *World J Gastroenterol* 2012; 18(18): 2188-2196 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i18/2188.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i18.2188

INTRODUCTION

Agmatine (AGM), 4-(aminobutyl) guanidine, is a natural biogenic endogenous dicationic amine metabolite mainly present in the deprotonated form at physiological pH and produced by decarboxylation of L-arginine *via* arginine decarboxylase in bacteria, plants, invertebrates, and mammals[1-5]. It is not supplied by nutritional com-

ponents or bacterial colonization. AGM is metabolized by two distinct pathways depending on the tissue where it is contained: by "agmatinase" (AGM uryl hydrolase) to putrescine with cleavage of urea, mainly in the brain, and by "diamineoxidase" (DAO), in peripheral tissues, to 4-guanidinobutyraldehyde, then dehydrogenated and hydrolyzed by specific enzymes and excreted out of the body. The heterogeneous location of DAO suggests that certain tissues or organs may have the capacity to regulate local AGM levels[6,7]. AGM is transported to organs by an energy-dependent mechanism which is inhibited by dose-dependent administration of putrescine, suggesting a correspondence between the transport mechanism of polyamines and AGM, probably using a carrier[8,9].

After its discovery in the brain, AGM was demonstrated in nearly all organs of rats, with organ-specific distribution. Its highest concentrations were found in the stomach (71 ng/g wet weight), followed by the aorta, small and large intestine, and spleen[10,11]. AGM was also shown in vascular smooth muscle and endothelial cells[12], and in plasma of rats at a concentration of 0.45 ng/mL, which is similar to that of catecholamines[10]. The source of circulating AGM remains undefined. In humans, higher plasma concentrations (47 ng/mL) were determined in comparison to rats[13]. The reasons underlying this large difference remain to be clarified.

It is becoming clear that AGM has multiple physiological functions in the body. It acts as a potential neurotransmitter in the brain[14,15], and a regulator of polyamine concentration[16] by acting on different enzymes involved in the polyamine pathway. It inhibits all isoforms of nitric oxide synthase (NOS), providing evidence of its important role in modulating NO production as an endogenous regulator[17]. In particular, AGM irreversibly inhibits the endothelial NOS and downregulates the inducible form (iNOS), and exhibiting a neuroprotective role since NO contributes to ischemic brain injury[18].

It has been reported that AGM is protective against ischemia reperfusion (I/R) injury in different organs including the brain, retina, kidney and heart[19-22]. However, no previous reports on its protective effect in gastric reperfusion injury have been investigated. Despite the fact that AGM is a strong base[23] and is found in mucous-secreting cells and in parietal cells where it localizes in the canaliculi, it was reported to be deleterious in ethanol-induced gastric lesions[5] as well as in gastric stress-induced lesions[24,25]. Therefore, the aim of the present study was to investigate whether or not the administration of AGM is protective to rat stomach subjected to I/R injury, and the mechanisms involved.

MATERIALS AND METHODS

Animals
Male Wistar rats weighing 170-210 g were obtained from the College of Medicine Animal House at King Saud University. Rats were maintained on standard rat chow and tap water *ad libitum*. Rats were kept in an air-condi-

tioned room with a 12 h day/light cycle. Animals were fasted 12 h prior to the experimental procedure. All studies were approved by the Ethics Committee of King Saud University.

Experimental design
Rats were divided into 3 experimental groups (6 rats/group): (1) control sham-operated group; (2) a gastric I/R group; and (3) I/R + AGM (100 mg/kg) group, administered AGM 15 min prior to I/R injury induction. Rats were anesthetized by i.p. injection of urethane at a dose of 125 mg/100 g body weight (BW). To investigate whether or not the protection induced by AGM is mediated by the Akt/IPK3 pathway, wortmannin (WM), an inhibitor of this pathway, was given at a dose of 15 μg/kg, i.p.[26], 15 min prior to AGM treatment in an additional I/R injury group. The stomach was observed macroscopically for hemorrhages and ulceration. The dose of AGM, selected for the current study was based on the previously published doses used in models of brain[19] and myocardial I/R injury[22]. AGM was dissolved in normal saline and controls received saline in an equivalent volume. WM was dissolved in dimethyl sulfoxide (10%).

Experimental model
Gastric IR lesions were produced as described by Yoshikawa *et al*[27]. Briefly, the stomach was exposed and the esophagus and the pylorus were occluded using bulldog clamps. The celiac artery was clamped and 100 mmol hydrochloric acid (HCL, 1 mL/100 g BW) was placed in the stomach to maintain acid levels during ischemia. The acid was then removed 25 min after ischemia and clamps were removed 30 min after ischemia. The tissues were allowed to re-perfuse for 30 min and then the stomach was removed and examined. AGM 100 mg/kg was found to be effective depending on histological examination and Evans blue (EB) dye extravasation.

At the end of the experiment gastric tissues were collected. Gastric samples were snap-frozen in liquid nitrogen and stored at -80 ℃ for subsequent assays of vascular endothelial growth factor (VEGF) and monocyte chemoattractant protein-1 (MCP-1). A piece of each stomach was fixed in 4% phosphate-buffered formalin, embedded in paraffin, and cut. Paraffin sections were hydrated and stained with hematoxylin and eosin (HE) for assessment of mucosal damage or stained with sera specific for angiopoietin-1 (Ang-1) and Ang-2, (R and D Systems, United States).

Determination of vascular permeability
EB dye, an azo dye, is widely used as an indicator of increased capillary permeability[28-30]. Systemic administration of EB leads to the formation of a dissociable complex with serum albumin, and when there is microvascular tissue damage, EB extravasates. In another three experimental groups, 1 mL of EB (0.5% v/w) was injected i.v. after reperfusion or sham operation. The amount of EB that accumulated in the stomach within

Figure 1 Evan's blue extravasation as a measure of vascular permeability in the studied groups. Gastric ischemia reperfusion (I/R) injury induced extravasation of Evan's blue dye due to increased vascular permeability. Agmatine (AGM) pre-treatment (100 mg/kg, i.p.) significantly attenuated the vascular leakage (gastric I/R *vs* I/R + agmatine, [b]*P* < 0.001). Results are expressed as mean ± SD.

the reperfusion period was measured. Briefly, the animals were killed and the stomach was removed. After collecting the gastric content carefully by lavage with 5 mL cold distilled water, the stomach was opened along the greater curvature and the corpus mucosa was scraped off and put into a tube containing 5 mL distilled water. The EB was extracted by a modified method of Lange *et al*[29] and its concentration was spectrophotometrically quantified. The EB present in the gastric contents and mucosa was extracted by adding 5 mL formamide to each tube and kept in a shaking water bath at a temperature of 50 ℃ for 24 h. This was followed by centrifugation at 3000 *g* for 10 min and the absorbance of supernatant was measured at 612 nm (Lambada 5, Perkin-Elmer, Pomona, CA, United States). The amount of EB was calculated from a previously prepared standard curve and expressed as μg per stomach.

Histological study
Gastric tissues from the studied groups were fixed in 10% phosphate-buffered formalin, embedded in paraffin and 4 μm sections were made, followed by staining with HE and were examined histologically for mucosal damage.

Enzyme-linked immunosorbent assay
VEGF and MCP-1 were assayed in a supernatant of gastric tissue homogenate and calculated according to protein concentration in each sample. Protein was determined in each sample using Bradford Reagent (Biorad, United States). Concentrations of VEGF and MCP-1 were measured using an ELISA kit according to the manufacturer's instructions (R and D Systems, United States).

Immunohistochemistry
Immunostaining was performed using formalin fixed, paraffin-embedded sections (4 μm) after dewaxing and rehydration. Endogenous peroxidase was quenched with 3% H$_2$O$_2$ for 30 min and sections were blocked with 10% normal goat serum (Sigma). Sections were incubated with

Ang-1 and Ang-2 (Santa Cruz, Biotech., United States) at a concentration of 1:200 and were kept at room temperature for 2 h. Sections were then washed and incubated with secondary antibody, and immunoperoxidase staining was carried out using the Vectastain ABC Elite reagent kit (Vector Laboratories, CA, United States). Di-amino-benzidine was used as a chromogen. All slides were counterstained with HE.

Chemicals and reagents
All chemicals were purchased from Sigma (St, Louis, MO, United States) unless otherwise specified.

Statistical analysis
All values are expressed as the mean ± SD. Statistical significance of differences was determined using one-way analysis of variance. Further statistical analysis for *post hoc* comparisons was carried out using the Tukey test. A level of *P* < 0.05 was considered statistically significant.

RESULTS

Effect of AGM on gastric tissue vascular permeability
Gastric perfusion for 30 min following 30 min of ischemia induced a marked leakage of EB dye in the stomach lumen (3.58 ± 0.975 μg/stomach). The administration of AGM 100 mg/kg prior to induction of ischemia attenuated the leakage by about 60% when compared with no treatment (1.173 ± 0.374 μg/stomach, *P* < 0.05) (Figure 1).

Histological assessment
The histological features of gastric I/R injury included hemorrhage, and ulceration of the mucosa with inflammatory cell infiltration (Figure 2B). Gastric mucosa of normal rats showed intact mucosa and sub-mucosa (Figure 2A). The administration of AGM at a dose of 100 mg/kg attenuated the mucosal damage by some of 80% of the surface exposed (Figure 2C) with reduction in hemorrhage, ulceration and cellular infiltration. WM prevented the protective effect resulting in extensive ulceration, edema, and hemorrhage (Figure 2D).

Effect of AGM on VEGF gastric tissue level
Following ischemic injury to the stomach, VEGF demonstrated an increase in gastric tissue homogenate (48.4 ± 6.53 pg/100 mg protein) compared with normal gastric tissue (32.725 ± 37.7 pg/100 mg protein). AGM treatment significantly reduced this increase (36.87 ± 2.71 pg/100 mg protein *vs* 48.4 ± 6.53 pg/100 mg protein, *P* < 0.05) (Figure 3).

Effect of AGM on MCP-1 gastric tissue level
As shown in Figure 4, the I/R injury of the gastric mucosa induced an increase in the level of MCP-1 compared with the mucosa in control sham rats (41.17 ± 10.3 pg/100 mg protein *vs* 18.3 ± 7.4 pg/100 mg protein, *P* < 0.01). AGM pretreatment markedly reduced the MCP-1

Figure 2 Histological appearance of the gastric mucosa of HE stained sections of the studied groups. A: Sham-operated showing intact mucosa; B: Gastric ischemia reperfusion (I/R) showing hemorrhages, edema and ulceration; C: Agmatine (AGM) treated group (100 mg/kg, i.p. prior to I/R) with marked preservation of gastric mucosa and disappearance of ulceration and hemorrhages; D: Effect of inhibition of Akt/phosphatidyl inositol-3-kinase (PI3K) (wortmannin 15 μg/kg, i.p.) prior to AGM treatment, showing extensive lesions and salvage of gastric mucosa into the lumen (× 20 magnification).

Figure 3 Effect of administration of agmatine on gastric vascular endothelial growth factor tissue level. Gastric vascular endothelial growth factor (VEGF) protein significantly increased after ischemia reperfusion (I/R) injury, [b]*P* < 0.01 *vs* sham group. Administration of agmatine administration (100 mg/kg, i.p.) 15 min prior to gastric I/R reduced the VEGF level in gastric tissue homogenate, [d]*P* < 0.01 *vs* I/R group. Results are expressed as mean ± SD.

Figure 4 Effect of AGM administration on gastric monocyte chemoattractant protein-1 tissue level. Gastric monocyte chemoattractant protein-1 (MCP-1) protein significantly increased after ischemia reperfusion (I/R) injury, [b]*P* < 0.01 *vs* sham group. Administration of agmatine (100 mg/kg, i.p.) 15 min prior to gastric I/R reduced the MCP-1 level in gastric tissue homogenate, [d]*P* < 0.01 *vs* I/R group. Results are expressed as mean ± SD.

levels relative to I/R injury (29.5 ± 7 pg/100 mg protein *vs* 41.17 ± 10.4 pg/100 mg protein; *P* < 0.01).

Ang-1 and Ang-2 immunostaining

A very faint staining for Ang-1 was seen in normal rat stomach (Figure 5A), while it was extensively expressed in areas where congestion and damage occurred in ischemia reperfused stomach (Figure 5B). However, AGM pretreatment (100 mg/kg) markedly attenuated the expression of Ang-1 (Figure 5C). Ang-2 expression of normal rat stomach (Figure 6A), was almost undetected. Exten-

sive expression of Ang-2 was seen mostly in the mucosa of ischemia reperfused stomach (Figure 6B). AGM markedly attenuated Ang-2 expression and protected the mucosa from injury (Figure 6C).

Effect of blocking the phosphatidyl inositol-3-kinase pathway on protection induced by AGM

AKt/phosphatidyl inositol-3-kinase (PI3K) is described as an important component of cell survival pathways in many cell types[26]. Pretreatment of rats with WM (15 μg/kg per i.p.), an inhibitor of AKt/PI3K, 15 min prior to

Figure 5 Photomicrographs representative of angiopoietin-1 immunostaining of gastric sections of the studied groups. A: Sham-operated showing lack of expression of angiopoietin-1 (Ang-1); B: Gastric ischemia reperfusion (I/R) group showing extensive cytoplasmic expression of Ang-1 particularly in areas of congestion and damage; C: Agmatine (AGM) treated group (100 mg/kg, i.p.), with marked attenuation of Ang-1 expression in intact mucosa; D: Wortmannin (15 μg/kg, i.p.) treated group prior to AGM administration abolished the effect of AGM and the expression of Ang-1 is marked (× 20 magnification).

Figure 6 Photomicrographs representative of angiopoietin-2 immunostaining of gastric sections of the studied groups. A: Sham-operated showing faint expression of angiopoietin-2 (Ang-2); B: Gastric ischemia reperfusion (I/R) group showing extensive cytoplasmic expression of Ang-2 in areas of congestion and damage, and in the submucosa; C: Agmatine (AGM) treated group (100 mg/kg, i.p.), with marked attenuation of Ang-2 expression in intact mucosa; D: Wortmannin (15 μg/kg, i.p.) treated group prior to AGM administration abolished the effect of AGM and the expression of Ang-2 is marked in mucosa and sloughed tissues (× 20 magnification).

AGM administration, markedly prevented its protective effect and extensive hemorrhages and ulceration were demonstrated microscopically (Figure 2D), suggesting that AGM probably acted on this signaling pathway to protect the stomach from I/R injury. The administration of WM prior to AGM also induced marked expression of both Ang-1 and Ang-2 in the mucosa and even in the submucosa (Figures 5D and 6D).

DISCUSSION

As mentioned earlier, the present study examined whether or not the administration of AGM prior to gastric I/R injury has a protective effect. Our results revealed a gastroprotective effect of AGM by reducing vascular permeability of the gastric mucosa as evidenced by reduction of EB dye extravasation, Ang-1 and Ang-2 protein expression in gastric sections, as well as VEGF and MCP-1 concentrations in gastric tissue homogenate. This effect is probably mediated by the Akt/PI3K pathway.

The gastric injury model we used in the present study is a gastric ischemia reperfusion model. In this model we injected 100 mmol HCL (1 mL/100 g BW) to maintain the gastric acid level during the procedure. The acid was then removed 25 min after ischemia and clamps were removed 30 min after ischemia. I/R injury was demonstrated macroscopically and microscopically in the form of congestion, hemorrhages, and mucosal ulceration. With prior administration of AGM, hemorrhages, blood clots and ulceration were attenuated. This protective effect, while supported by some studies, was opposed by others.

Circumstantial evidence was provided in a recent study that AGM is protective to the gastric mucosa[23]. That study, utilizing immunohistochemistry, showed that AGM is found in the mucus-secreting cells of the stomach and in the parietal cells where it is localized in the lumen of the canaliculi. Biochemically, basic amino acids are ideally suited to act as a source of carbon dioxide in the stomach, and the most basic amino acid is arginine (isoelectric point 11.15). A significant source of arginine is found in the stomach[23]. CO_2 can be produced from the decarboxylation of arginine. The activation segment of pepsinogen in the parietal cell canaliculi can provide a source of arginine[31]. AGM is the decarboxylation product of arginine. Interestingly, the highest concentration of AGM is found in the stomach[10]. The fact that AGM is such a strong base and its cellular localization is in the gastric mucosa makes AGM a strong candidate for a protective role against HCL formed in the stomach[23]. In addition, *Helicobacter pylori* (*H. pylori*) infection is associated with a decrease in the amount of mucous-secreting cells in the stomach. This change is associated with a decrease in the amount of AGM in these mucous-secreting cells[32]. It was speculated that such a decrease in the amount of AGM in the epithelium of the *H. pylori*-infected stomach would make this epithelium more vulnerable to damage by gastric acid[23]. On the other hand, a group of inves-

tigators reported higher AGM concentrations in gastric juice from *H. pylori*-positive patients than from *H. pylori*-negative patients, and concluded that AGM is deleterious to the stomach and may be involved in the pathogenesis of gastroduodenal lesions[33]. However, these results suggest an association rather than a causal link. Furthermore, these results might implicate AGM as a counter-regulatory molecule to *H. pylori*. Supporting our speculation, a recent report demonstrated that bacteria such as *Escherichia coli* and *H. pylori* utilize AGM to survive the highly acidic medium of the stomach and even prevent AGM being taken up by stomach cells[34]. This explains the high levels of AGM previously reported in gastric juice of *H. pylori* patients, suggesting a compensatory mechanism.

The pattern of gastric response to AGM in our study is opposite to what has been reported by some other previous studies[24,25], which showed that AGM augments gastric acid and pepsin secretion, decreases gastric adherent mucus and worsens experimental gastric mucosal injury in rats in a pylorus-ligated ischemic stress model. Similar results demonstrating exacerbation of gastric mucosal injury by AGM pretreatment in ethanol-induced stress model in rats have been reported[5]. The inconsistency of these results with ours could be attributed to the models used and the duration of gastric stress. In our model, the rats were exposed to 30 min of ischemia and 30 min of reperfusion, while these investigators exposed the animals to 4 h of stress. In addition, these studies administered AGM at a dose of 10 mg/kg[24] or 20 mg/kg[5], which is much lower than that used in the present study or other studies. For example in a rat model of brain I/R injury AGM was given at a dose of 100 mg/kg[19].

The mechanisms by which AGM induced gastric protection were the focus of the present study. Increased vascular permeability occurs after insult to the gut[35] and hence, reduction of hyper-permeability can induce tissue protection. The current work provides evidence that AGM works by reducing vascular permeability of the stomach in response to I/R injury. This was investigated using EB dye extravasation as a measure of vascular permeability. Also, we measured VEGF concentration in gastric tissues and Ang-1 and Ang-2 distribution in gastric sections. The present study showed an elevation of VEGF content in the stomach following 30 min of ischemia and 30 min of reperfusion. This increase is most probably due to increased blood to the tissue upon reperfusion, but the possibility of increased expression of VEGF protein could be a factor. The prevention of this increase by AGM could be explained by the capability of AGM to reduce vascular permeability as was seen in the present study by the EB dye experiment. Interestingly, previous studies showed that transgenic mice overexpressing VEGF induced hyper-permeable vessels[36], providing evidence that VEGF increases vascular permeability. VEGF has been implicated in the pathophysiology of liver I/R injury, and its increase during reperfusion injury was seen to mediate leukocyte trafficking and ischemic injury response early after reperfusion, whereby

VEGF acts *via* MCP-1[37]. Interestingly, the administration of VEGF antibodies was reported to block reperfusion injury[37]. The proinflammatory functions of VEGF have been demonstrated by previous studies[37-39]. Therefore, agents attenuating VEGF during the early period of reperfusion could possibly indirectly reduce the inflammatory response resulting from reperfusion injury.

Other vascular molecules studied in the current work were Ang-1 and Ang-2. We demonstrated the attenuation of both Ang-1 and Ang-2 expression in rats receiving AGM prior to induction of gastric I/R, compared with untreated rats. Ang-2, in contrast to Ang-1, was shown to increase vascular permeability, and to promote vascular leakage from blood vessels *in vivo*[40]. AGM seems to reduce vascular permeability at least partly by reducing VEGF and Ang-2 in gastric tissues.

MCP-1 is an inflammatory mediator molecule[41] whose upregulation is responsible for recruitment of inflammatory cells after I/R injury[42]. Importantly, the interaction of MCP-1 with its receptor CCR2 has been attributed a central role in experimental cardiac, renal and cerebral I/R models[43]. Therefore, decreased MCP-1 production will attenuate attraction and recruitment of monocytes and subsequently ameliorate the post-ischemic inflammatory responses. The present study demonstrated an increase in gastric tissue content of MCP-1 after I/R which was suppressed by AGM pre-treatment. Indeed, we provided evidence for the protective anti-inflammatory effect of AGM, whereby it reduced gastric MCP-1 in the ischemic group. In support of our observation, previous reports also showed an anti-inflammatory effect of AGM[44,45], a mechanism by which AGM can attenuate I/R injury. Furthermore, AGM was shown to inhibit the production of NO in macrophages, thus providing a molecular basis for the anti-inflammatory actions of AGM[42]. We, previously demonstrated that iNOS is upregulated in the gastric mucosa in response to I/R injury[46]. Interestingly, Mu *et al*[18] reported that iNOS was also upregulated in brain in response to I/R injury and was significantly downregulated by AGM. With these data in mind we may speculate that AGM could contribute to gastric protection against I/R injury by reducing NO production, possibly by inhibiting iNOS. Other suggested mechanisms that might be involved in the protection offered by AGM could be *via* preservation of endothelial dysfunction[47] and inhibition of matrix metalloproteinase-9, which is known to be upregulated in ischemic injury and degrades the basement membrane of blood vessels[48].

The signaling pathway by which AGM induced gastric protection is possibly mediated *via* Akt/PI3K. The present study provided indirect evidence, as inhibition of this pathway by WN, prior to AGM administration, prevented protection offered by AGM. A limitation to this study is that we did not measure Akt/PI3K activity in gastric tissues.

There are many reasons making AGM a good candidate for gastric protection. First, it is a strong base[22]; second, the highest concentration of AGM is found in the stomach[10]; third, AGM is localized in the mucus-secret-

ing cells[22]. In the parietal cells, it is localized to the lumen of the canaliculi. Finally, a decrease in AGM concentration in mucus-secreting cells in *H. pylori* infection of the stomach is also associated with a decrease in the amount of mucus in the mucus-secreting cells of the stomach[32]. Recently, it has been reported that bacteria such as *E-coli* and *H. pylori* utilize AGM to survive the highly acidic medium of the stomach and even prevent AGM being taken up by stomach cells[34].

In conclusion, the present study revealed that AGM protects the rat stomach exposed to I/R injury at least for brief periods by reducing vascular permeability possibly mediated *via* Akt/PI3K pathway.

COMMENTS

Background

Gastric ischemia reperfusion (I/R) injury which can occur after major surgeries, may lead to extensive gastric ulceration and even perforation if it is not prevented/treated. Although there are therapies that treat gastric lesions, the search for novel molecules is needed. Agmatine (AGM) an endogenously produced amine has its highest concentration in the stomach with alkaline pH. Many studies reported that AGM protected rat kidneys and brains against ischemic injury. Its effectiveness in a model of gastric ischemia reperfusion injury needs investigation.

Research frontiers

AGM is a biological amine found in most cells with the highest concentration in the stomach. The study focused on the effectiveness of AGM in protecting the stomach against I/R injury.

Innovations and breakthroughs

Previous application of AGM to rats in which gastric injury was performed by ethanol administration was found to be unprotective. It was given at a dose of 20 mg/kg. The present study used a model of gastric I/R injury by clamping the gastric vessels for 30 min followed by declamping. AGM was administered at 100 mg/kg before reperfusion. I/R injury induced gastric ulceration and hemorrhages and increased gastric permeability. AGM treatment was accompanied by preservation of gastric histology and vascularity. Also this protection was produced by an anti-inflammatory effect. AGM was demonstrated to be effective in preventing gastric injury induced by I/R.

Applications

The study results suggest that the AGM can be a potential therapeutic option that could be used in preventing gastric injury induced by I/R injury.

Terminology

Ischemia reperfusion (I/R) injury: Injury induced in tissue when blood supply to a tissue/organ stops for a while and then resumes. During reperfusion some injurious substances are released from the tissues including inflammatory, vasodilator and oxidative stress molecules. Therefore it is important to protect tissues against reperfusion injury. Agmatine (AGM): A naturally occurring amine found in our body organs, with the highest concentration in the stomach. It is also found in bacteria and animals. It has diverse functions that deserve future investigations.

Peer review

The authors demonstrated the protection against gastric ischemia-reperfusion injury in rats by agmatine. This study has an interesting finding.

Abstract

AIM: To investigate the hepatic protective effects of 5-methoxypsoralen (5-MOP) and to learn if 5-MOP causes hepatotoxicity at protective doses.

METHODS: C57BL/6J mice were administrated orally with 5-MOP at doses of 12.5, 25 and 50 mg/kg body weight respectively every morning for 4 d before given acetaminophen (APAP) subcutaneously at a dose of 500 mg/kg. The 5-MOP alone group was treated with 5-MOP orally at a dose of 50 mg/kg body weight for 4 d without APAP. Twenty-four hours after APAP administration, blood samples of mice were analyzed for serum enzyme alanine transaminase (ALT), aspartate transaminase (AST), lactate dehydrogenase (LDH) levels, and malondialdehyde (MDA), reduced glutathione (GSH) and oxidized glutathione (GSSG) of liver tissues were measured and histopathologic changes of the liver were observed.

RESULTS: Compared with the vehicle control group, the serum levels (IU/L) of ALT, AST and LDH were all increased significantly in APAP group (8355 ± 3940 *vs* 30 ± 21, $P < 0.05$; 6482 ± 4018 *vs* 146 ± 58, $P <$ 0.05; 24627 ± 10975 *vs* 1504 ± 410, $P < 0.05$). Compared with APAP group, the serum ALT levels (IU/L) (1674 ± 1810 *vs* 8355 ± 3940, $P < 0.05$; 54 ± 39 *vs* 8355 ± 3940, $P < 0.05$; 19 ± 9 *vs* 8355 ± 3940, $P < 0.05$), AST levels (IU/L) (729 ± 685 *vs* 6482 ± 4108, $P < 0.05$; 187 ± 149 *vs* 6482 ± 4108, $P < 0.05$; 141 ± 12 *vs* 6482 ± 4108, $P < 0.05$) and LDH levels (IU/L) (7220 ± 6317 *vs* 24 627 ± 10 975, $P < 0.05$; 1618 ± 719 *vs* 24 627 ± 10 975, $P < 0.05$; 1394 ± 469 *vs* 24 627 ± 10 975, $P < 0.05$) were all decreased drastically in the three-dosage 5-MOP pretreatment groups. Pretreatment of 5-MOP could attenuate histopathologic changes induced by APAP, including hepatocellular necrosis and infiltration of inflammatory cells, and the effect was dose-dependent. MDA levels (nmol/mg) were decreased by 5-MOP in a dose-dependent manner (0.98 ± 0.45 *vs* 2.15 ± 1.07, $P > 0.05$; 0.59 ± 0.07 *vs* 2.15 ± 1.07, $P < 0.05$; 0.47 ± 0.06 *vs* 2.15 ± 1.07, $P < 0.05$). The pretreatment of 5-MOP could also increase the GSH/GSSG ratio (3.834 ± 0.340 *vs* 3.306 ± 0.282, $P > 0.05$; 5.330 ± 0.421 *vs* 3.306 ± 0.282, $P < 0.05$; 6.180 ± 0.212 *vs* 3.306 ± 0.282, $P < 0.05$). In the group treated with 5-MOP but without APAP, the serum enzyme levels, the liver histopathologic manifestation, and the values of MDA and GSH/GSSG ratio were all normal.

CONCLUSION: 5-MOP can effectively protect C57BL/6J mice from APAP-induced hepatotoxicity and possesses an antioxidative activity, and does not cause liver injury at the protective doses.

INTRODUCTION

Acetaminophen (APAP), a widely used antipyretic and analgesic drug, could induce hepatotoxicity and even acute liver failure (ALF) when taken at overdose[1]. APAP overdose is a common cause of adult and children ALF in the United States and other countries[2-5]. APAP can be metabolized by cytochrome P450 enzymes (CYPs) to N-acetyl-P-benzoquinoneimine (NAPQI)[6]. At overdoses of APAP, a large number of NAPQIs is generated, which can deplete reduced glutathione (GSH) and then bind to mitochondrial proteins to cause mitochondrial dysfunction and oxidant stress[7,8], leading to hepatocellular damage and centrilobular hepatic necrosis. In this process, APAP can increase the level of malondialdehyde (MDA) both in the liver and plasma[9] and NAPQI is capable of lowering GSH/oxidized glutathione (GSSG) ratio by oxidizing the thiol group of GSH[10]. Oxidant stress plays a central role in the hepatic damage induced by APAP[11].

5-methoxypsoralen (5-MOP), a furocoumarin found in many medicinal plants, possesses slight antioxidative activity evidenced from researches *in vitro*[12,13]. 5-MOP has been used in combination with UV radiation in skin photochemotherapy for decades[14], and some studies also found that it has anticancer[15-19], antidepressant[20-24], anticonvulsion[25] and anti-inflammatory effects[26,27], but none of previous studies have shown that 5-MOP could prevent hepatotoxicity.

In addition, some patients suffered from toxic hepatitis induced by 5-MOP when it was used as photochemotherapeutic agent[28,29], and one animal experiment demonstrated that high doses of 5-MOP can induce hepatotoxicity in mice[30]. So it is essential to examine if 5-MOP can cause liver injury at therapeutic doses.

This study was designed to determine the protective effects of 5-MOP in APAP-induced hepatotoxicity using mouse hepatotoxic models, and to investigate if 5-MOP can cause hepatotoxicity in mice at effective doses.

MATERIALS AND METHODS

Chemicals

5-MOP was purchased from Tokyo Chemical Industry (Tokyo, Japan), and APAP from Jiaozuo Xin'An Science and Technology Company (Henan, China). Tween 80, which was used to prepare 5-MOP suspension, was bought from Biodee Biotechnology Company (Beijing, China). APAP was dissolved in normal saline before use. GSH and N-ethylmathione gained from Lizhudongfeng Biotechnology Company (Shanghai, China), GSSG from Hongxing Biotechnology Company (Beijing, China), o-phthalaldehyde (OPT) from Jinlong Chemical Company (Beijing, China), and thiobarbituric acid (TBA) from Acros (United States).

Animals and treatment

Male C57BL/6J mice, 18-22 g in weight, were purchased from Peking University Laboratory Animal Department, Beijing, China. They were housed in a well-ventilated room and the room temperature was controlled at 21 ℃ -23 ℃ and humidity at 65%-70% with a 12 h light-12 h dark cycle. All the mice were fed adaptively for three d before experiment, and they had free access to water and were fed with forage supplied by Laboratory Animal Center of Military Medical Science Academy.

5-MOP was suspended in 1% Tween 80 at different concentrations of 1.25 mg/mL, 2.5 mg/mL, and 5 mg/mL, and all of these suspensions were administrated to mice at 10 mL/kg body weight; that is, mice were administrated with 5-MOP at doses of 12.5 mg/kg, 25 mg/kg and 50 mg/kg, respectively. A 5-d experiment was performed with 36 mice which were randomly divided into 6 groups by weight. Group 1 was the vehicle control group and group 2 was APAP alone group, both groups were orally treated with 1% Tween 80 (10 mL/kg body weight) every morning for 4 d. Groups 3, 4 and 5 were 5-MOP multiple-dose groups administered with oral 5-MOP at doses of 12.5, 25 and 50 mg/kg body weight respectively every morning for 4 d. Group 6 was 5-MOP alone group treated with oral 5-MOP at a dose of 50 mg/kg body weight also for 4 d. Thirty minutes after the administrations, all mice except those in the vehicle control group and 5-MOP alone group were subcutaneously administrated with APAP (500 mg/kg body weight). Twenty hours after APAP administration, blood samples were collected from orbital venous plexus of the mice. After the mice were sacrificed, their livers were dissected out immediately and washed with normal saline, dried on a filter paper and weighted. Then the livers were prepared immediately for further examinations.

The animal care and surgical procedures were performed in compliance with the Guidelines for Animal Care and Use of Peking University.

Biochemical test

The blood samples were collected to determine serum enzyme [alanine transaminase (ALT), aspartate transaminase (AST), lactate dehydrogenase (LDH)] levels by HI-TACHI-7170A automatic analyzer. The liver tissues were homogenized with potassium chloride (KCl) solution (0.15 mol/L) on ice to yield a 5% (w/v) homogenates for MDA test. The hepatic MDA levels were determined as thiobarbituric acid reactive substances levels using a published colorimetric method[31].

The liver tissues were homogenized with phosphate buffered solution on ice to yield a 5% (w/v) homogenates for glutathione test. The GSH and GSSG levels in liver tissues were measured by the improved Hission method[32], a fluorometric method that uses OPT as a fluorescent reagent. Then GSH/GSSG ratio was calculated.

Table 1 Effects of acetaminophen alone, 5-methoxypsoralen multi-dose and 5-methoxypsoralen alone on alanine aminotransferase, aspartate aminotransferase, lactate dehydrogenase activities, hepatic malondialdehyde and reduced glutathione/oxidized glutathione ratio in mice (mean ± SE)

Treatments groups	ALT (IU/L)	AST (IU/L)	LDH (IU/L)	MDA (nmol/mg)	GSH/GSSH
Vehicle control	30 ± 21	146 ± 58	1504 ± 410	0.18 ± 0.11	6.045 ± 0.629
APAP alone at 500 mg/kg	8355 ± 3940[a]	6482 ± 4018[a]	24 627 ± 10975[a]	2.15 ± 1.07[a]	3.306 ± 0.282[a]
5-MOP at 12.5 mg/kg	1674 ± 1810[c]	729 ± 685[c]	7220 ± 6317[c]	0.98 ± 0.45	3.834 ± 0.340
5-MOP at 25 mg/kg	54 ± 39[c]	187 ± 149[c]	1618 ± 719[c]	0.59 ± 0.07[c]	5.330 ± 0.421[c]
5-MOP at 50 mg/kg	19 ± 9[c]	141 ± 12[c]	1394 ± 469[c]	0.47 ± 0.06[c]	6.180 ± 0.212[c]
5-MOP alone at 50 mg/kg	37 ± 20	138 ± 22	1471 ± 191	0.15 ± 0.09	6.858 ± 0.678

[a]$P < 0.05$ *vs* vehicle control group; [c]$P < 0.05$ *vs* acetaminophen (APAP) alone group. 5-MOP: 5-methoxypsoralen; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; LDH: Lactate dehydrogenase; MDA: Malondialdehyde; GSH: Reduced glutathione; GSSG: Oxidized glutathione.

Histopathologic examination

The left liver lobes were scissored out and fixed in 10% formalin solution for 48 h. The liver samples were then cut into thin transverse sections with the help of microtome and permanent slides were prepared with HE staining. Liver histopathologic changes were examined under an optical microscope with the original magnification × 200.

Data treatment and statistical analysis

The experimental results were expressed as mean ± SE (standard error). Statistical comparison between groups was performed by one-way analysis of variance with SPSS 13.0 statistical software. A P value < 0.05 was indicated as a statistically significant difference.

RESULTS

Effects of APAP alone, 5-MOP multiple-dose and 5-MOP alone on serum enzyme levels

The hepatocellular damage induced by a toxic dose (500 mg/kg) of APAP and the effects of pretreatment with 5-MOP were investigated by measuring the serum levels of ALT, AST and LDH. As shown in Table 1, APAP significantly increased the serum ALT, AST and LDH levels compared with the control group, and the multiple-dose 5-MOP pretreatment significantly prevented the increases of serum enzyme levels. The effect of 5-MOP was dose-dependent, and in the highest dose group, serum levels of ALT, AST and LDH were close to the normal levels as compared with the vehicle control group ($P > 0.05$).

The influences of 5-MOP alone on serum enzyme levels were also observed. There were no statistically significant differences in the serum levels of ALT, AST and LDH between 5-MOP alone group (50 mg/kg) and the vehicle control group ($P > 0.05$).

Effects of APAP alone, 5-MOP multiple-dose and 5-MOP alone on liver tissue MDA and GSH/GSSG ratio

As seen in Table 1, compared with the vehicle control group, a toxic dose of APAP elevated liver MDA and lowered the hepatic GSH/GSSG ratio. With the escalating dose of 5-MOP (12.5, 25 and 50 mg/kg), the content of MDA decreased and ratio of GSH/GSSG increased.

In the 5-MOP alone group, the MDA level in liver was as low as that in the vehicle control group (0.15 ± 0.09 *vs* 0.18 ± 0.11, $P > 0.05$). In addition, the hepatic GSH/GSSG ratio in the 5-MOP alone group was not significantly changed as compared with that in the vehicle control group (6.858 ± 0.678 *vs* 6.045 ± 0.629, $P > 0.05$).

Effects of APAP alone, 5-MOP multi-dose and 5-MOP alone on histopathologic changes

The liver histopathologic changes of mice in the six groups are shown in Figure 1. The liver sections displayed the representative hepatocellular morphological changes of each group.

In the vehicle control group, hepatocytes, presenting normal morphology, arranged around the central vein in a radical pattern, and liver lobule structures were clear and regular (Figure 1A). Normal liver lobule structures were damaged and collapsed in the APAP alone group. Large areas of hepatocellular necrosis and infiltration of inflammatory cells were also observed (Figure 1B). 5-MOP administration could alleviate the pathological injury induced by APAP in a dose-dependent manner. 5-MOP at a dose of 12.5 mg/kg could slightly relieve the pathological injury. In this group, no hepatocellular necrosis and infiltration of inflammatory cells were observed, but hepatocellular hydropic degeneration and sinusoidal dilation occurred (Figure 1C). There was no necrosis and hydropic degeneration of hepatocytes, no sinusoidal dilation and infiltration of inflammatory cells in the 25 mg/kg 5-MOP dose group. However, liver lobule structures were still not clear in this group (Figure 1D). 5-MOP at a dose of 50 mg/kg could significantly prevent APAP-induced hepatotoxicity with an almost normal lobular structure comparable to the vehicle control group (Figure 1E). There were no significant liver histopathologic changes in the 5-MOP alone group (Figure 1F).

DISCUSSION

The protective effect of 5-MOP against hepatocellular injury and oxidative stress, and the potential toxic effect of 5-MOP on the liver were investigated in this study. C57BL/6J mice were used because our previous research found that C57BL/6J mice were more suscep-

Figure 1 Representative pathological changes of liver section of the six groups (original magnification × 200). A: Section of liver from the vehicle control group showing a normal lobular structure; B: Section of liver from acetaminophen alone group showing large areas of centrilobular necrosis with inflammatory cell infiltration; C: Section of liver from the 12.5 mg/kg 5-methoxypsoralen (5-MOP) dose group showing absence of hepatocellular necrosis and infiltration of inflammatory cells but presence of hepatocellular hydropic degeneration and sinusoidal dilation; D: Section of liver from the 25 mg/kg 5-MOP dose group showing normal hepatocellular morphology but liver lobule structure damage; E: Section of liver from the 50 mg/kg 5-MOP dose group showing a significant alleviation of liver pathological injury with an almost normal lobular structure; F: Section of liver from 5-MOP alone group (50 mg/kg) showing presence of normal lobular structure.

tible to APAP[33]. The serum levels of ALT, AST and LDH are main indices of liver injury[34] and the levels of MDA, GSH and GSSG can be used as indices of oxidative stress[9]. We evaluated the hepatic protective effect of 5-MOP based on these indices. It is well known that any chemical can be toxic if its dose is high enough, so a 5-MOP alone group was designed to see if the highest therapeutic dose of 5-MOP could cause hepatotoxicity.

APAP used alone can significantly increase the serum levels of ALT, AST and LDH and cause pathological changes as compared with the vehicle control group. Oxidative stress also took place as shown by the increase of MDA level and decrease of GSH/GSSG ratio. The model of APAP-induced hepatotoxicity was successfully established in this experiment.

5-MOP can protect mice from APAP-induced acute liver injury based on the fact that it can decrease the serum ALT, AST and LDH levels in a dose-dependent manner and alleviate the liver histopathologic alterations. Moreover, 5-MOP decreased the MDA level and increased the GSH/GSSG ratio in a dose-related manner, which reflected that 5-MOP could significantly attenuate the oxidative stress induced by APAP and suggested that the hepatoprotective effect of 5-MOP may be associated with its antioxidative activity.

However, besides antioxidant activity, 5-MOP also possesses biological activities to inhibit the mouse and human CYPs both *in vivo* and *in vitro*[14]. And CYPs-catalyzed formation of NAPQI is the key mechanism in APAP-induced hepatotoxicity[35]. So we presume that

inhibition of CYPs of 5-MOP may also account for the protective mechanism against APAP-induced hepatotoxicity, which should be further investigated.

In the 5-MOP alone group, the serum enzyme (ALT, AST and LDH) levels and histopathologic changes were as normal as in the vehicle control group, which indicated that 5-MOP could not cause liver injury at a dose of 50 mg/kg (the highest therapeutic dose used in this study). The MDA level and the GSH/GSSG ratio were not significantly changed as compared with the vehicle control group, which showed that 5-MOP did not influence the normal oxido-reduction levels.

In conclusion, 5-MOP could protect against APAP-induced hepatotoxicity in mice and had an antioxidative activity, and caused no hepatotoxicity at protective doses.

COMMENTS

Background
Overdose of acetaminophen (APAP) can induce hepatotoxicity and oxidative stress plays a central role in the hepatic damage. Though 5-methoxypsoralen (5-MOP) possesses antioxidative activity suggested by researches *in vitro*, none of previous studies has found that 5-MOP could prevent APAP-induced hepatotoxicity.

Research frontiers
It is important to search for effective methods to protect human from APAP-induced hepatotoxicity. Despite the various applications of 5-MOP, no research has been conducted to determine if 5-MOP could prevent APAP-induced hepatotoxicity. In addition, although the antioxidative activity of 5-MOP has been evidenced from researches *in vitro*, this activity was not manifested *in vivo*. Besides, 5-MOP may also cause hepatotoxicity when taken at high doses.

Innovations and breakthroughs
This study manifested that 5-MOP could protect mice from APAP-induced hepatotoxicity *in vivo*, and this hepatoprotective effect was associated with its antioxidation activities. In addition, 5-MOP caused no hepatotoxicity at protective doses.

Applications
This study has suggested that 5-MOP can be used at appropriate doses as a drug against APAP-induced hepatotoxicity in human. However, before clinical use, more researches are needed to confirm the safety of APAP administration at protective doses.

Peer review
The authors investigated the protective effects of 5-MOP against APAP-induced hepatotoxicity and whether 5-MOP could cause hepatotoxicity in mice. The results suggested that 5-MOP resisted APAP-induced hepatotoxicity, reduced APAP-induced oxidative stress, and did not cause liver injury at protective doses.

Abstract

AIM: To evaluate the effects of soy supplementation on insulin resistance, fatty liver and alanine aminotransferase (ALT) levels in non-diabetic patients with chronic hepatitis C (CHC).

METHODS: In a prospective, randomized and single-blinded clinical trial, we compared patients with CHC who had casein as a supplement (n = 80) (control group), with patients who consumed a soy supplement diet (n = 80) [intervention group (IG)]. Both groups received 32 g/d of protein for 12 wk.

RESULTS: Patients' baseline features showed that 48.1% were overweight, 43.7% had abdominal fat accumulation, 34.7% had hepatic steatosis and 36.3% had an homeostasis model assessment index of insulin resistance (HOMA-IR) $\geqslant$ 3.0. Descriptive analysis showed that protein supplementation diet reduced hepatic steatosis in both groups; however, significant reductions in ALT levels occurred in the soy group. Multiple regression modeling indicated that in the presence of severe fibrosis (F3/F4), γ glutamyl transferase elevation and high density lipoprotein (HDL) reduction, the intervention group had 75% less chance of developing hepatic steatosis (OR= 0.25; 95% CI: 0.06-0.82) and 55% less chance of presenting with an ALT level $\geqslant$ 1.5 × the upper limit of normal (ULN) (OR = 0.45, 95% CI: 0.22-0.89). Soy treatment did not have any effect on insulin resistance (OR = 1.92; 95% CI: 0.80-4.83), which might be attributed to the fact that the HOMA-IR values at baseline in most of our patients were in the normal range. Advanced hepatic fibrosis, an ALT level > 1.5 × ULN and visceral fat were predictors of an HOMA-IR $\geqslant$ 3. The IG group had a reduced risk of an ALT level > 1.5 × ULN. An HOMA-IR $\geqslant$ 3.0 and HDL < 35 mg/dL were also risk factors for increased ALT.

CONCLUSION: Soy supplementation decreased ALT

levels and thus may improve liver inflammation in hepatitis C virus (HCV) patients; it also reduced hepatic steatosis in a subgroup of patients but did not change insulin resistance. It should be considered in the nutritional care of HCV patients.

Key words: Chronic hepatitis C; Soy supplementation; Insulin resistance; Hepatic steatosis; Hepatitis C virus

INTRODUCTION

Hepatitis C virus (HCV) infection is considered an important public health problem[1] and is the leading cause of liver transplantation in the Western world. Chronic HCV infection increases the risk for hepatic steatosis, insulin resistance, glucose intolerance and type 2 diabetes[2-4].

The pathophysiology of nonalcoholic fatty liver disease (NAFLD) involves histology ranging from fat alone (hepatic steatosis) to fat plus inflammation (nonalcoholic steatohepatitis, NASH) to fat plus hepatocyte injury (ballooning degeneration) with or without fibrosis or Mallory's bodies which can lead to liver failure[5]. NAFLD and NASH have been associated with insulin resistance resulting in glucose intolerance and hyperglycemia[6]. Insulin resistance also contributes to increased lipolysis, which reduces fat uptake and oxidation by peripheral tissues. Both mechanisms lead to fat influx and accumulation in hepatic tissue[7].

Insulin resistance induced by HCV may involve several mechanisms, such as an immune response mediated by Th1 lymphocytes, the action of pro-inflammatory cytokines [tumor necrosis factor-alpha (TNF-α), interleukin (IL)-1 and IL-6], the degradation of intracellular components that participate in the insulin signaling system, including insulin receptor substrates (IRS-1 and IRS-2), and the reduced activation of phosphatidyl inositol 3-kinase (PI3-K) and protein kinase B (AKT)[8-12].

Considering these factors, appropriate nutrition becomes an essential tool to minimize HCV's comorbidities such as fatty liver, inflammation and insulin resistance. Recently, functional foods have been considered essential for promoting and maintaining health. According to some reports, soy protein and its derivatives might be able to lower insulin resistance in patients with chronic liver diseases due its constituents, such as fiber, isoflavones and high biological value protein[13], and modulation of hepatic lipid metabolism[14,15]. The aim of this study was to evaluate the influence of soy protein supplementation on insulin resistance, liver fat content and alanine transaminase (ALT) levels in non-diabetic patients with chronic hepatitis C.

MATERIALS AND METHODS

Subjects

Non-diabetic patients with chronic hepatitis C were recruited from a reference ambulatory unit of the Federal University of Bahia's Hospital between June 2008 and December 2009. The diagnosis of HCV infection was made by the presence of serum anti-HCV, which was confirmed by qualitative determination of HCV RNA. Inclusion criteria were the following: patients aged over 18 years, with or without liver cirrhosis; patients with ethanol consumption below 20 g/d; patients with normal liver function (Child-Pugh A); and patients who were not under antiviral therapy or who had discontinued antiviral therapy for at least three months.

Patients co-infected with HIV and/or HBV with renal failure as well as those with heart disease, decompensated cirrhosis, pregnancy, any malignancy, diabetes mellitus or obesity (BMI > 30 kg/m^2) were excluded. The subjects gave written informed consent before participating in the study. The Ethics Committee of the Federal University of Bahia approved the study.

Study design

The study was a prospective, randomized and single-blinded clinical trial. Patients who were regularly followed in the Hepatology outpatient clinic were informed about the protocol and referred to the Nutrition clinic. Subjects who met the inclusion criteria of the study were randomly allocated into one of two study groups. The study was single-blinded (only blinded for patients). The estimated sample size was 160 patients.

The 160 patients were equally divided into two groups ($n = 80$), and each group received isonitrogenous protein supplementation with 32 g of protein per day for twelve weeks. The control group (CG) was supplemented with animal protein (casein), and the intervention group (IG) was supplemented with vegetable protein (soy). The nutritional composition of the supplements used in this study is reported in Table 1.

Patients were instructed to dissolve the protein supplement in water, juice, soup, porridge or to consume it with fruits. Additionally, considering their nutritional status and dietary habits, patients received dietary guidelines to promote healthy eating and weight control. Diet counseling aimed to promote the ingestion of a normocaloric, normoglycidic and high protein (1.5 g/kg per day) diet by both groups. Patients returned monthly to receive their supplements.

Table 1 Nutritional content per 100 g of supplement

	Whole soy powder[1]	Calcium caseinate
Energy (Kcal)	392	371
Carbohydrate (g)	14	0.2
Protein (g)	40	97.4
Total fat (g)	18.8	2.4
Alpha linolenic acid (mg)	1252	0
Linoleic acid (mg)	9332	0
Dietary fiber (g)	18	0
Isoflavones (mg)	53.82	0

Clinical parameters

Clinical survey data such as clinical diagnosis, viral genotype, necroinflammatory activity index and fibrosis (METAVIR classification) were either collected from medical records or from patient examinations.

Patients underwent ultrasonography of the upper abdomen with a team of three examiners using a single piece of equipment at the University Hospital's radiology service. Hepatic steatosis was graded as mild, moderate or severe according to the classification of Saverumuttu *et al*[16].

Measurement of waist circumference was performed according to the World Health Organization recommendations using an inelastic tape measure (TBW Import Ltd.) that was 0.5 cm wide and 200 cm in length. Waist circumference was measured at a level midway between the superior aspect of the iliac crests and the lower lateral margins of the ribs. The cutoff points adopted for classifying central obesity and increased risk of metabolic complications were above 80 cm for women and 94 cm for men[17]. Socio-demographic and lifestyle information was also collected using a structured questionnaire during the first appointment of follow-up (baseline).

Patients underwent follow-up visits once a month with registered dietitians to elucidate the adherence to the diet prescription and protein supplementation. Schedule monitoring also included weekly telephone calls in the first month and biweekly thereafter. After 12 wk of supplementation, physical, biochemical and anthropometric tests as well as a questionnaire were applied to evaluate possible changes during the intervention program. Ultrasound was also performed in patients with a diagnosis of hepatic steatosis at baseline. All procedures were performed within a maximum interval of ten days after the nutrition counseling.

Laboratory measurement

After a 12-h fast, a blood sample was collected for the determination of aspartate aminotransferase (AST), ALT, gamma glutamyl transferase (γGT), alkaline phosphatase, plasma glucose, insulin, total cholesterol and cholesterol fractions. Analyses were performed on a Beckman Coulter LX-20 PRO and CX-9 equipment. Serum insulin was measured using an electrochemiluminescence method with an Elecsys 2010 device.

The insulin resistance index was predicted according to the homeostasis model assessment index of insulin resistance (HOMA-IR). The formula was as follows: insulin resistance (HOMA-IR) = fasting insulinemia (microU/mL) × fasting glycemia (mmol/L)/22.5[18]. We considered $\geqslant 3.0$ as the cutoff point to define insulin resistance.

Virological tests

An enzyme linked immunosorbent assay was performed on all serum samples to detect the presence of anti-HCV using third generation commercial kits (anti-HCV Hepatitis C® Wiener Lab.) following the manufacturer's instructions. Reverse transcription-polymerase chain reaction (RT-PCR) was performed on all samples for qualitative determination of HCV RNA. The method used was the nested PCR (HCV-RNA detectable using the COBAS® AMPLICOR HCV Test, v2.0, Roche). HCV genotyping was performed using the technique of restriction fragment polymorphism (RFLP-PCR).

Histological analysis

The stages of fibrosis and inflammation were determined according to the METAVIR scoring system: F0 = no fibrosis, F1 = expansion of fibrosis in portal areas without septa, F2 = fibrous portal expansion with septa, F3 = numerous septa or fibers with nodular transformation, and F4 = cirrhosis[19].

Statistical analysis

Descriptive analysis was performed to characterize the population. Mann-Whitney *U* and Wilcoxon's rank sum tests were used to compare the biochemical values in the intervention and control groups and to evaluate the differences obtained at baseline and after intervention. Logistic regression analysis was used to evaluate risk predictor factors for hepatic steatosis, insulin resistance (HOMA-IR $\geqslant 3.0$) and changes in ALT levels (1.5 above the upper limit of normal). Confounding and interaction analyses were performed to select the final models. Multiple regression analysis was performed after the intervention considering the groups had similar demographic, clinical and laboratory features before protein supplementation.

The sample size was calculated using an estimated 20% loss to follow-up, a confidence level of 95% and 80% power. A statistical significance was inferred at $P < 0.05$. In some biochemical analyses, the Bonferroni method was applied to adjust the multiple comparisons *P*-value between the groups at the significance level of 0.007. Statistical analysis was performed with the statistical package R version 2.12[20].

RESULTS

Characteristics of patients

The characterization of the study population is presented in Table 2. Males (63.8%) were predominant. The prevalence of HCV genotype 1 infected patients was 83.5%.

[1]Fisher's exact test; [2]Mann-Whitney; iq r: Interquartile range. *n* = 160. CG-casein: Control group-casein; IG-soy: Intervention group-soy; Adequate waist circumference: ⩽ 80 cm for women and ⩽ 94 cm for men. HOMA-IR: Homeostasis model assessment index of insulin resistance; HDL: High density lipoprotein; LDL: Low density lipoprotein; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; γGT: Gamma glutamyl transferase.

Advanced fibrosis (Metavir F3/F4) was detected in 40.5% of patients. The average age was 52.2 (± 10.5) years, 48.1% were overweight and 51.9% had a BMI < 25 kg/m^2; 43.7% individuals had abdominal fat accumulation. It was also observed that 34.7% of the patients had hepatic steatosis, and 36.3% had an HOMA-IR ⩾ 3.0 at baseline.

Biochemical data presented in Table 2 show that glucose and lipid profiles were not altered; however, high transaminase levels were observed in both groups. It is also observed that the median value for γGT is greater

Table 3 Comparison of the distribution of hepatic steatosis before and after intervention between groups of patients with hepatitis C virus

Hepatic Steatosis	*n*	Yes	No	*P* value

[1]Fisher's exact test: Comparison between groups before and after intervention; [2]Paired analysis: McNemar's test: Comparison in each group. CG-casein: Control group-casein; IG-soy: Intervention group-soy.

Figure 1 Hepatic esteatosis before and after intervention between groups of patients with hepatitis C virus.

in the CG than in the IG (102.0 U/L *vs* 87.0 U/L); however, no significant difference was detected between the groups. Median alkaline phosphatase was in the normal range for both groups. Baseline demographic, anthropometric, clinical and laboratory data show that the study population had a homogeneous distribution between the groups.

Prevalence of steatosis at baseline and after intervention

Table 3 shows the comparison of the prevalence of hepatic steatosis before and after the intervention in the IG and CG. The prevalence of hepatic steatosis was different between the groups at baseline (29.7% *vs* 40.0%) and remained different after the interventions (15.6% *vs* 26.7%), but without statistical significance in both instances (Figure 1).

Paired analysis, within groups (before and after protein supplementation), showed the reduction in hepatic steatosis was significant for both groups. The IG showed a reduction from 19 to 10 cases (47.4% reduction, *P* =

Figure 2 Prevalence of hepatic steatosis condition after intervention for those who begin with hepatic steatosis.

Table 4 Median values of biochemical tests in patients with hepatitis C virus after protein supplementation

HOMA-IR	79	2.4 (2.7)	80	2.6 (2.2)	0.91

[1]Mann-Whitney test ($P < 0.05$): comparison between groups; Bonferroni correction ($P < 0.007$); CG-casein: Control group-casein; IG-soy: Intervention group-soy; iq r: Interquartile range; $n < 80$: When an examination was not performed; HOMA-IR: Homeostasis model assessment index of insulin resistance; HDL: High density lipoprotein; LDL: Low density lipoprotein; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; γGT: Gamma glutamyl transferase.

0.0076) and the CG decreased from 24 to 16 cases (33.3% reduction, $P = 0.0133$) (Figure 2 and Table 3).

Biochemical data before and after intervention
After protein supplementation, a significant reduction was observed in the transaminase levels of the IG *vs* the CG (AST: 49.5 U/L *vs* 61.5 U/L, $P = 0.02$; ALT: 64.0 U/L *vs* 73.0 U/L, $P = 0.007$). A reduction in the levels of γGT was observed in the IG compared to the CG (84.0 U/L *vs* 108.0 U/L, $P = 0.09$) but without statistical significance (Table 4).

The IG had a significant reduction in ALT levels (73.5 U/L *vs* 64.0 U/L; 12.92% change, $P = 0.006$) (Figure 3) and γGT levels (87.0 U/L *vs* 84.0 U/L; 3.45% change, $P = 0.007$) after 12 wk of intervention. Reductions were also observed in total cholesterol (160.0 mg/dL *vs* 153.0 mg/dL; 4.37% change), but without statistical significance (Table 5). It is noteworthy that the CG did not present improvements in these biochemical tests.

Figure 3 Distribution of alanine aminotransferase and homeostasis model assessment according to intervention groups and time.

Predictors of hepatic steatosis after intervention
Table 6 presents the logistic regression analysis for predictive factors of hepatic steatosis. Multiple regression modeling indicates that, in the presence of severe fibrosis (F3/F4), γGT elevation and HDL reduction, the IG had a 75% less chance of developing hepatic steatosis (OR = 0.25; 95% CI: 0.06-0.82). Nevertheless, in the IG, those with an HOMA-IR ≥ 3 were three times more likely to develop hepatic steatosis (OR = 3.49; 95% CI: 1.10-11.90) (Table 6). The bivariate analysis also revealed that an age ≥ 60 years (crude OR = 3.81; 95% CI: 1.50-9.70), abdominal fat accumulation (crude OR = 3.87; 95% CI: 1.57-10.29) and BMI ≥ 25.0 kg/m² (crude OR = 1.32; 95% CI: 1.12-1.61) were independent risk factors for hepatic steatosis (data not shown).

Predictors of insulin resistance (HOMA-IR ≥ 3.0) after intervention
Soy treatment did not have any effect on insulin resistance (OR = 1.92; 95% CI: 0.80-4.83). In patients with advanced fibrosis, an ALT level ≥ 1.5 times upper limit of normal (ULN) and increased abdominal fat accumulation were independent risk factors for insulin resistance.

Adequate	1		1	
Inadequate	2.62 (1.37-5.16)	0.004	5.57 (2.23-15.27)	0.0004

[1]Adjusted for the other variables shown in the table; [2]Adequate waist circumference: ≤ 80 cm for women and ≤ 94 cm for men; ULN: Upper limit of normal; OR: Odd ratio; 95% IC: 95% confidence interval.

Logistic regression analysis showed that the presence of severe fibrosis promoted a five-fold increase in the chance (OR = 5.25; 95% CI: 2.17-13.67) for an HOMA-IR ≥ 3.0 as well as accumulation of abdominal fat (OR = 5.57; 95% CI: 2.23-15.27). Those with an ALT level ≥ 1.5 × ULN had a three times greater chance of developing insulin resistance. Being single, widowed or divorced was a protective factor (OR: 0.24; 95% CI: 0.08-0.65) for an HOMA-IR ≥ 3.0 (Table 7).

Predictors of elevated an ALT level after intervention

The independent predictive factors for changes in ALT levels (≥ 1.5 × ULN) were an HOMA-IR ≥ 3.0, HDL < 35 mg/dL and being a male subject (Table 8). Severe fibrosis and alterations in AST and γGT levels were also

independent predictors of an increased ALT level (≥ 1.5 × ULN). Multivariate analysis showed that supplementation with soy protein *per se* represents a protective factor; the IG had a 55% less chance of presenting with an ALT level ≥ 1.5 × ULN (OR = 0.45, 95% CI: 0.22-0.89), and subjects with an HOMA-IR ≥ 3.0 were three times more likely to have an increased ALT level (OR = 3.16, 95% CI: 1.51-6.93). However, females had 72% less chance to have an increased ALT level (OR = 0.28, 95% CI: 0.12-0.60) (Table 8).

DISCUSSION

Our population was predominantly male, infected with HCV genotype 1, overweight and presented abdominal

fat accumulation. Both studied groups had similar characteristics. These clinical conditions increase the chances of developing insulin resistance and hepatic steatosis, which have a negative impact in patients with chronic hepatitis C[21]. In patients infected with HCV genotype 1, steatosis is frequently associated with metabolic syndrome and insulin resistance and is also called "metabolic steatosis"[4,8,21].

A large proportion of our patients had increased liver enzymes (i.e., ALT, AST, γGT) and had not yet been subjected to antiviral treatment. In our population, at baseline, there was a 34.7% prevalence of hepatic steatosis and a 36.3% prevalence of an HOMA-IR ≥ 3.0. The prevalence of hepatic steatosis associated with HCV varies widely in the literature[22,23] and may differ depending on the population profiles[24].

In this study, protein supplementation caused a significant reduction of hepatic steatosis in both groups; however, this reduction was not significant between the groups. The probable mechanism is not associated with the quality of protein supplementation (animal or vegetable) but likely the nutritional care offered to both groups, which promoted changes in eating habits and consequently improved the overall quality of the diet. Of note, there was no change in body mass index (BMI) or in the pattern of physical activity of these patients.

It is controversial whether insulin resistance is a cause or consequence of steatosis, however the literature suggests that it seems to work more like a cause than a consequence of steatosis in patients infected with HCV genotype 1[2]. In the present study, the regression model showed that an HOMA-IR ≥ 3 increased the chances of hepatic steatosis more than three-fold. The regression model also revealed that advanced age (≥ 60 years) and a higher waist circumference and BMI were independent predictor factors for hepatic steatosis. These results are in agreement with other studies which have observed a

direct correlation between BMI, visceral obesity and liver steatosis[25-27].

Clinical and experimental studies suggest that soy protein and isoflavones can synergistically act to promote a greater benefit in controlling hypercholesterolemia, hypertriglyceridemia, insulin resistance and steatosis[13,28,29]. We observed that consumption of soy protein had a protective effect and was associated with 75% less chance of having hepatic steatosis.

In an experimental study with obese Zucker rats, a diet with isolated soy protein favored reduced triglycerides in the liver. The proportions of AST/ALT, alkaline phosphatase, bile acids in plasma and pro-inflammatory cytokines (TNF-α and IL1) were also reduced. The authors suggested that soy protein enriched with isoflavones has a favorable effect on the inflammatory status of obese mice, which may promote a favorable outcome in NAFLD patients[28]. It is known that oxidative stress is a decisive factor in the progression of steatosis[30,31]; thus, if isoflavones can act as an antioxidant, then they may minimize the negative progression of steatosis[32,33]. The morbidity of hepatic steatosis is increasing and has been recognized as a liver component of the metabolic syndrome, which also has a negative effect on HCV treatment[8,26,34-36].

Our data revealed a significant decrease in ALT values after supplementation with soy protein compared to the control patients who consumed casein. These findings agree with experimental studies, which have found that soy protein enriched with isoflavones reduces plasma aminotransferase levels[32] and the proportion of AST/ALT[28]. However, a reduction in HOMA-IR levels after supplementation with soy was not observed in our study, which can be attributed to the fact that the HOMA-IR values at baseline in most of our patients were in the normal range. In contrast, Jayagopal *et al*[13] in a study conducted with diabetic women in which the mean value of the HOMA-IR was 5.54 in the intervention group and 5.14 in the control group, supplementation with soy protein enriched with isoflavones significantly reduced serum insulin and the HOMA-IR.

We found that insulin resistance (HOMA-IR ≥ 3.0) and lower HDL values were predictors for increased ALT. Soy protein intervention in female subjects presented *per se* as a protective factor for increased ALT levels. Our data are in agreement with a recent study that showed higher levels of ALT were significantly associated with gender, a low HDL level and a high HOMA-IR[25]. When evaluating patients with HCV with and without changes of ALT levels and healthy controls, Addel-Azziz *et al*[37] found a higher value of HOMA-IR in patients with abnormal ALT levels compared with those with no change in ALT levels and healthy controls (3.98 *vs* 2.69 *vs* 1.92, respectively), with a significant difference between those with abnormal ALT levels and controls (3.98 *vs* 1.92).

In our study, abdominal fat concentration, an ALT level ≥ 1.5 the upper limit of normal and the presence of advanced fibrosis were independent predictors of insulin resistance, and even in a multivariate model, they

remained significant. Addel-Azziz *et al*[37] also detected a positive correlation between the HOMA-IR and fibrosis. We detected that marital status was a predictor for insulin resistance as well; single, widowed or divorced patients were less susceptible to inadequacy of the HOMA-IR. This could be associated with the fact that a higher prevalence of overweight and abdominal fat accumulation has been described among married subjects.

In patients with hepatitis C, the presence of a high BMI, insulin resistance and high cholesterol are important predictors for mortality. Multivariate analysis has shown increased mortality associated with metabolic disorders such as diabetes, hypertension and a higher BMI[36,38]. Mehta *et al*[39] found that individuals with HCV and an age above 40 years had a three-fold higher chance of presenting with type 2 diabetes. Therefore, it is recommended that all patients with chronic hepatitis C avoid excess weight and maintain blood glucose, cholesterol levels and blood pressure within normal ranges[40].

Soy supplementation decreased ALT levels and thus may improve liver inflammation in HCV patients. It also reduced hepatic steatosis in a subgroup of individuals with advanced fibrosis, insulin resistance, increased γGT levels and low HDL. On the other hand, soy supplementation did not change insulin resistance, which might be attributed to the fact that the HOMA-IR values at baseline in most of our patients were in the normal range. To our knowledge, this is the first study to show that soy protein supplementation reduces hepatic steatosis and decreases ALT levels in chronic hepatitis C patients. Control of insulin resistance, hepatic steatosis, abdominal obesity and body weight seems to play an essential role in nonpharmacological therapies for chronic hepatitis C treatment. These practices should therefore be encouraged by a multidisciplinary team. Supplementation with soy protein should be considered as an important choice of nutritional management of patients with chronic hepatitis C.

COMMENTS

Background
Hepatitis C virus (HCV) infection is an important public health problem and is the leading cause of liver transplantation in the Western world. Chronic HCV infection increases the risk for hepatic steatosis, insulin resistance, glucose intolerance and type 2 diabetes. The improvement of these comorbidities may benefit the clinical course of the patients.

Research frontiers
Several studies have shown that soy protein may stimulate peroxisome proliferator-activated receptors-α and thus might increase liver fatty oxidation and decrease hepatic steatosis. It also may inhibit sterol regulatory element-binding transcription factor 1 and decrease hepatic lipogenesis. Clinical studies have previously demonstrated that soy consumption may reduce plasma lipid levels, promote insulin resistance reduction and maintain normal glucose levels. HCV infection may be associated with hepatic steatosis and increased insulin resistance. The morbidity of hepatic steatosis is increasing and it has been recognized as a liver component of the metabolic syndrome, which also has a negative effect on HCV treatment. The role of soy supplementation in the improvement of liver diseases is still a matter of debate and there are no studies that have evaluated its effect on insulin resistance, liver fat content and alanine transaminase (ALT) levels in non-diabetic patients with chronic hepatitis C.

Innovations and breakthroughs
Our work is characterized by its originality since it evaluated the impact of soy nutritional intervention in a population of patients infected with hepatitis C. To our knowledge, this is the first study to show that soy protein supplementation decreases ALT levels and reduces hepatic steatosis in a subgroup of individuals with advanced fibrosis, insulin resistance, increased γGT levels and low HDL in chronic hepatitis C. In an experimental study with obese Zucker rats, a diet with isolated soy protein favored reduced triglycerides in the liver. The AST/ALT ratio, alkaline phosphatase, bile acids in plasma and pro-inflammatory cytokines (tumor necrosis factor-α and interleukin-1) were also reduced. However, there are no clinical studies that have evaluated the role of soy supplementation on liver enzymes levels, insulin resistance and hepatic steatosis of patients with chronic HCV infection. The authors emphasize the need for further clinical trials to confirm the soy effects on ALT levels and hepatic steatosis of patients with chronic HCV infection.

Applications
This study showed that soy supplementation may improve liver inflammation (decrease ALT level), and may improve steatosis in a sub-group of patients with HCV. Therefore, supplementation with soy protein should be considered in the nutritional management of patients with chronic hepatitis C. However, further clinical trials are necessary to confirm our results.

Terminology
HOMA-IR: Homeostasis model assessment index of insulin resistance; PPARs: Peroxisome proliferator-activated receptors. These are nuclear receptors that function as transcription factors regulating the expression of genes. PPARs play essential roles in the regulation of cellular differentiation and metabolism (carbohydrate, lipid, protein); SREBP-1: Sterol regulatory element-binding transcription factor 1 is a transcription factor involved in sterol biosynthesis.

Peer review
The topic of the study is interesting and based on rational logic. The design of the study is appropriate, but to be sure of that we need to know some more information about the recruitment, randomization and blinding method. In a clinical trial design the conclusions are based only in the analysis performed for the main objectives of the study, otherwise the conclusion from sub-analysis must be biased.

Abstract

AIM: To assess the reasons for, and factors associated with, patient-initiated changes in treating specialist in inflammatory bowel diseases (IBD).

METHODS: Prospectively identified IBD patients (n = 256) with $\geq$ 1 encounter at a metropolitan hospital were surveyed, including whether they had changed treating specialist and why. Negative reasons included loss of confidence, disagreement, and/or personality clash with the specialist.

RESULTS: Of 162 respondents, 70 (43%) had ever changed specialists; 30/70 (43%) for negative reasons, 52/70 (74%) in the preceding year. Patients with negative reasons for changing (n = 30) were younger (median, 35.2 years *vs* 45.3 years) ,had higher IBD knowledge (median, 5.0 years *vs* 4.0 years), yet had lower medication adherence and satisfaction scores (median, 19.0 years *vs* 22.0 years, 14.0 years *vs* 16.0 years respectively, Mann-Whitney tests, all P < 0.05), compared to all other responders (n = 132). Patients

with a recent change (for any reason) were more likely to have Crohn's disease, currently active disease, previous bowel resection and recent hospitalization [OR 2.6, 95% CI (1.3-5.4), 2.2 (1.0-4.7), 5.56 (1.92-16.67), 2.0 (1.3-3.0), each P < 0.05].

CONCLUSION: Changing specialist appears associated with patient- related (age, nonadherence) and contemporaneous disease-related factors (recent relapse) which, where modifiable, may enhance patient-doctor relationships and therefore quality of care.

INTRODUCTION

In chronic inflammatory bowel diseases (IBD), a positive patient-doctor relationship (PDR) appears integral to optimizing quality of care (QoC). Although specific IBD data are lacking, a positive PDR is associated with improved patient satisfaction and health outcomes in other chronic diseases like diabetes and hypertension[1]. In a consumer-driven society, patient-centered care appears essential for a positive PDR[2], and thus assessing patients' satisfaction with their specialist is important[3]. A positive PDR should facilitate the development of trust essential

to the therapeutic process and ensure continuity of care, thus consolidating high-quality care[4,5].

Conversely therefore, PDR discord may compromise QoC, leading to adverse outcomes[6]. Discord may result from personality clashes, lack of rapport, misunderstandings, patient disenfranchisement over management decisions, or adverse disease outcomes. Yet, quantifying PDRs is difficult. Patient self-report instruments to rate PDRs are emerging, but understanding of their relevance to QoC is limited[7,8].

In Australia, as in many countries worldwide, there is significant variation in care models available to IBD patients; ranging from those managed solely by their primary care practitioner; those seen by a colorectal or general surgeon, general physician/internist, or by a specialist gastroenterologist either in private rooms or within a local hospital clinic setting; to those seen in the secondary/tertiary care setting within a dedicated hospital-based "IBD service" with multiple gastroenterologists and clinicians co-located with specific interests in IBD[9]. Each model has inherent strengths and weaknesses and may be attractive to different patients for various reasons. Moreover, with the multiple options potentially available, patients are theoretically able to select and change treating specialist (either in the government-funded public or private sectors), pending appropriate referral from their primary care practitioner and subject to regional availability. Thus one may theoretically assume the patient, as the consumer, may change their treating IBD specialist if their perceived PDR discord "threshold" was overcome and a suitable alternative existed (i.e., "voting with their feet").

Hence, we aimed to explore PDRs in an IBD cohort with the simple, tangible measure of whether patients changed treating specialists and whether this had occurred recently and/or for negative reasons, as a marker of patient satisfaction with the PDR and their medical care. We also explored potential factors associated with patients switching specialist for their care. Although patients logically may report changing specialists for innocuous reasons (e.g., relocation), instances where change occurs, especially for negative reasons from the patients' perspective, represent vulnerable moments in QoC delivery, but also provide an insight into the importance of the PDR, and its continuity[10].

MATERIALS AND METHODS

Subjects and recruitment

All patients with confirmed IBD diagnoses who had an inpatient or outpatient encounter for any reason at the Royal Adelaide hospital (RAH), in a 6-mo period from November 1 2007 to April 30 2008, were prospectively identified as previously described[9].

Subsequently, medical record review was performed to verify diagnoses, and extract further data including demographics, psychological comorbidity, previous surgery and healthcare utilization data. A contemporaneous (± median 14 d), physician global assessment[11] of disease activity (0 = inactive through to 4 = severe) was

Patient satisfaction with their medical care' questionnaire
(four questions used in study)

In response to each of the statements below, please mark on the line exactly where you think most accurately describes your own feelings:

1. I have a good relationship with my inflammatory bowel diseases (IBD) doctor and look forward to my appointments with him/her.

| Never | Rarely | Sometimes | Often | Very often |

2. The hassle of taking medications for IBD makes me wonder if it is worthwhile

| Never | Rarely | Sometimes | Often | Very often |

3. I wonder if there was another doctor available who could manage my IBD better.

| Never | Rarely | Sometimes | Often | Very often |

4. Overall I am satisfied with the treatment I am taking for IBD

| Never | Rarely | Sometimes | Often | Very often |

Figure 1 Scoring system. Maximum 5 points per question, maximum total of 20 indicates complete, 100% satisfaction with medical care. Score less than 16 indicates "suboptimal" satisfaction. Before scoring, responses to questions 2 and 3 must be inverted (i.e., never = 5, rarely = 4, *etc.*) prior to calculating absolute scores.

performed based on all information available, including clinical data (Harvey-Bradshaw criteria)[12], pathology and histological/endoscopic activity grading.

Patient survey

Surveys were distributed to each patient comprising multiple components; IBD patient knowledge was assessed using two validated questionnaires[13,14], health-related quality of life was assessed using the shortened inflammatory bowel disease questionnaire (sIBDQ10)[15], the medication adherence report scale (MARS-5) assessed medication adherence[16], and the hospital anxiety depression scale screened for anxiety and depression[17]. Patient satisfaction with medical care was measured using a novel instrument (Figure 1), yet to be validated but the use of which has previously been reported[9]. This comprises four questions with a total score of 20 indicating 100% patient satisfaction. A score < 16 arbitrarily indicates suboptimal satisfaction.

Endpoints relating to change in treating specialist

IBD patients were asked "Have you ever changed your treating specialist," and "If yes, why?" Reasons for changing were deemed negative if the patients' response included at least one of: (1) loss of confidence; (2) disagreement/dissatisfaction regarding management; (3) personality clash with specialist; or (4) other (including "specialist too busy", "waiting time too long"). Alternative reasons including "doctor retired", "doctor/patient moved" or "financial reasons" were not deemed negative responses. The endpoint "Change within 12 mo of survey completion, for any reason" was used to determine contemporaneous disease- and patient-related associations with chang-

Table 1 Clinical and disease characteristics of inflammatory bowel diseases patients who responded to survey (*n* = 162)

Patient variable	*n* (%)
Female sex	85 (52.5)
Crohn's disease	95 (58.6)
Ulcerative colitis	65 (40.1)
Previous bowel resection surgery (ever)	50 (30.9)
Recent inpatient admission[1]	80 (49.4)
Active disease[2]	69 (42.6)
Current stoma	19 (11.7)
Current perianal disease	29 (18.0)
Current cigarette smoker	31 (19.1)
Documented history of psychological comorbidity	41 (25.3)
Currently unable to work due to illness	39 (24.1)
Proportion of lowest socioeconomic group[3]	16 (9.9)

[1]Inpatient admission in period between January 1, 2007-April 31, 2008; [2]as determined by physician global assessment at time of survey completion; [3]according to Social Health atlas, Central Northern Adelaide Health Service, Department of Health, SA 2004.

ing specialist. At the time of survey, 108 (66.6%) of the cohort saw their current treating specialist at an outpatient clinic at RAH, whereas 54 (33.3%) had a current treating specialist based externally to the hospital (either in public or private sector).

Analysis
Statistical analyses were performed using SPSS 15.0.1.1 (Chicago, IL, United States). Bivariate correlations were conducted between variables and changing endpoints. Subsequently, exploratory logistic regression analyses assessed variables for inclusion in the final multivariable model. Those of definite clinical relevance were retained in the model regardless of statistical significance or fit; continuous variables remained unchanged wherever possible.

Ethics
The study was approved by the RAH Research Ethics Committee. Return of a completed survey was accepted as implied patient consent.

RESULTS
Patient characteristics
Two hundred and fifty-six confirmed IBD patients were prospectively identified over 6 mo, and 162 (63.3%) returned a completed survey. Responders had a median age of 43 years (range, 18-90), median IBD duration of 7 years (range, 0-47) (Table 1). As reported elsewhere, survey responders and non-responders did not differ significantly[9].

Changing specialist for any reason
Overall, 70/162 (43.2%) respondents had ≥ 1 change in specialist for any reason since IBD diagnosis. Of these, the median number of changes per patient since diagnosis was 2.0 (range: 1-6, Figure 2). Thirty of 70 patients

who changed specialists (42.9%) gave a negative reason, and 52/70 patients changing specialist (74.3%) had done so within the prior 12 mo (for any reason). The total number of changes per patient correlated weakly positively with IBD duration (r_s = 0.19), and when controlling for disease duration, positively with IBD knowledge (r_s = 0.20) and negatively with age (r_s = -0.22) (Spearman's partial correlations, all *P* < 0.02).

IBD patients with four or more changes in specialists had lower median quality of life scores (sIBDQ10, median score 37 *vs* 48 respectively, *P* = 0.01) and higher disease activity scores (median score 2.75 *vs* 2.28 respectively, *P* = 0.04) than those with a lower number of changes over their total duration of IBD.

Recent change in specialist
In order to identify temporal associations with changing specialist, bivariable (Table 2) then multivariable logistic regression analyses were conducted with the endpoint of specialist change within 12 mo prior to survey completion. The multivariable model (incorporating associations from bivariable analyses where *P* ≤ 0.05 plus age) showed those with a recent change were more likely to have Crohn's disease, had recent hospitalization, had a past bowel resection, and trended towards having currently active disease (Table 3).

Patients reporting negative reasons for changing specialist
Thirty patients gave 34 negative reasons for changing specialist, including dissatisfaction with management (*n* = 23), lost confidence (*n* = 10) and personality clash (*n* = 1) (Figure 3). These 30 patients were generally younger (median, 35.2 years *vs* 45.3 years), had higher IBD knowledge (median, 5.0 score *vs* 4.0 score respectively), yet had lower medication adherence and satisfaction scores (median, 19.0 score *vs* 22.0, respectively, 14.0 score *vs* 16.0, respectively, Mann-Whitney, all *P* < 0.05) compared to all other responders (*n* = 132). There were no other statistically significant differences including no difference in disease duration, IBD-related characteristics, hospitalization outcomes, or QoL scores between patients changing for negative reasons and other responders (data not shown). However, the frequency of changing specialist [i.e. the duration (years) since IBD diagnosis divided by the total number of changes in specialist over the same period] trended towards being higher in those with one or more negative reasons for changing specialist, compared to other responders (median, 2.8 *vs* 4.0 years between each change, *P* = 0.06, Mann-Whitney).

Finally, in order to identify factors associated with changing specialist for a negative reason, bivariable (Table 2) then multivariable logistic regression analyses were conducted where a negative reason for change in specialist was the dependent variable. The multivariable model (incorporating associations from bivariable analyses with *P* ≤ 0.05, plus sex) showed those with a negative reason had poorer medication adherence and trended towards being of male sex (Table 4).

Table 2 Bivariable logistic regression analyses of relevant clinical and demographic factors potentially associated with a change in treating specialist

Variable	Associated with change in treating specialist within 12 mo of survey completion		Associated with change in specialist for a "negative" reason at any time

DISCUSSION

Accepted IBD dogma dictates that expert specialist care is vital in optimizing outcomes, as per recent IBD consensus guidelines[18,19]. However, these guidelines do not specifically address continuity of care or patient satisfaction with their PDR. Moreover, the United Kingdom IBD Standards Group emphasizes the importance of maintaining

Figure 2 Number of changes in specialist ever by each patient. N.A.: Not available.

Figure 3 Reasons stated for patient change of treating specialist (72 reasons from 70 patients).

patient-centered care (Standard C), "offering personalized and responsive healthcare so that any patient can migrate between models of care according to activity and

complexity of disease, local facilities and personal preference[20]. In this prospectively encountered IBD cohort, we showed that patients frequently changed treating specialist (43.2% of responders) and of these, many changed (42.9%) for negative reasons, which appears to represent a high prevalence of discordant/poor PDR, which has not previously been documented. Suboptimal PDRs and/or discontinuity of care appear to impair QoC[18], therefore, clinicians (for both the sake of the patient and retaining their own practice) should be cognizant of and, wherever possible, endeavor to address when and why this discord exists[21].

Quantifying PDRs is inherently difficult, however assessing past and hence, risk of future changes in treating specialist *via* patient self-report is a novel, tangible method of surrogately measuring patient satisfaction with the PDR and their medical care. Increasingly, health providers are utilizing patient feedback *via* satisfaction questionnaires as a means to establish a patient-centered approach and for evaluating and improving quality performance[22,23]. In IBD, this has led to development of a limited number of disease-specific satisfaction questionnaires such as the comprehensive QUOTE-IBD survey[24] and others such as the Treatment Satisfaction Questionnaire for Crohn's disease[25]. Given the lack of brief but validated surveys focusing on specialist care in IBD, an unvalidated four-item survey was used in this study[9]. Further refinement and validation of this and similar surveys are needed, whereupon specialists may utilize these in routine practice as a means to identify and address problems with patient dissatisfaction and thus potentially enhance the PDR, and hence quality of care[26].

We thus examined the data to identify characteristics of patients likely to opt for change. Patient factors temporally associated with a recent change, accepting these associations may not be causal, although nevertheless potentially modifiable, include higher disease activity, diagnosis of Crohn's disease, and previous surgery. We believe that these adverse disease factors may jeopardize patient satisfaction and the PDR. In this context, subsequent hospitalization may be the "final straw" in an already vulnerable PDR, prompting a patient-initiated change[10]. Additionally, given all patients were identified *via* a recent hospital encounter at the study centre (RAH), this encounter may have resulted in a sample biased towards those provided with an opportunity to change IBD specialist, given that their inpatient care may have been conducted by a different treating specialist than their usual doctor. However as mentioned, one-third of the cohort continued seeing a treating specialist external/unaffiliated to the study hospital at the time of survey.

Indeed, the data may also reflect societal changes. First, patient care is increasingly often disjointedly administered across multiple primary care, hyper-specialized and provider-specific boundaries[5]. This frequently tests the ability of health systems to ensure a seamless flow of clinical information and correspondence responsive to patient transitions between health providers, especially where larger institutions are involved[27,28]. For instance, a gastroenterologist with a solely community-based practice caring for a patient who suffers an IBD flare may remain unaware when their patient is admitted to a tertiary hospital, and conversely the hospital staff may not be aware of the treating specialist's long-term relationship with the patient. Post-discharge follow-up may then be routinely arranged in the hospital-based IBD clinic instead of the private gastroenterologist's rooms. Hence, depending on the patient's own initiative, a "system-induced change" in specialist may occur, resulting in a loss of continuity of care and potentially, reduced patient satisfaction and jeopardized QoC. Second, consumer expectations of doctors and health outcomes, congruent with medical technological advances, continue to escalate, thus conceivably, patients do (and will) change specialists more readily than ever before[5,29]. Finally, there is a consumer perception that larger entities (e.g., large department stores analogous to large hospitals) offer better products, more conveniently at a lower cost which may also drive patient-initiated changes[30].

Interestingly, we also found that patients with superior IBD knowledge appeared more likely to change specialists. Potentially, knowledgeable IBD patients who expect to participate in management decisions, desire a patient-centered emphasis within the PDR, otherwise this unmet need may drive patients to change specialist[10,31]. Moreover, given those with negative reasons generally exhibited lower adherence again underlines potential disadvantages of a discordant PDR, although these data cannot ascertain whether this discord elicits nonadherence or vice versa. Hence, these patients may be deemed at risk of future adverse disease outcomes in the context of nonadherence, which is unlikely to be salved by changing specialist[21,32].

Regardless in many ways, the patient's self-reported reasons for changing specialist may over-simplify the complex interplay of patient beliefs and expectations, their underlying illness and the PDR, resulting in the change. Hence the fact that the change occurred, rather than the stated reason may be more relevant to consider. For instance, we showed that patients with four or more changes for any reason had lower QoL scores, yet there was no statistically significant difference between patients stating a negative reason for changing specialist and other responders. Thus, the prevalence and frequency of changes (regardless of reason or timing) warrant attention so as to determine whether these lead to increased risk of adverse outcomes *via* disjointed care and underlying dissatisfaction, and whether these outcomes are potentially preventable. Possible avenues begin with the specialist, including engendering patient involvement in clinical decision making and self-empowerment[33], patient-friendly doctor-patient communication, and regular opportunities for patients to provide feedback on their care received[34,35]. Furthermore, patients suspected of medication nonadherence must be sensitively confronted and efforts made to rectify this as previously documented elsewhere[36,37]. Also, fail-safe systems of timely referral and correspondence between health providers must be instituted in order to prevent

loss to treating specialist follow-up and discontinuity of care, which often may occur during times of disease deterioration where continuity and high QoC may in fact be most needed[20,38]. Indeed, in occasional scenarios where a discordant PDR is irreconcilable, and upon mutual agreement between doctor and patient, patients may ultimately benefit from referral on to alternative colleagues or services for ongoing care[39].

In conclusion, in this novel study, we demonstrated that a patient-initiated change in treating specialist in IBD occurs frequently and appears temporally associated with adverse disease traits. Continuity of care, within a positive PDR, is an important element of high-quality care, thus, we recommend that treating specialists should monitor their patients for history and future risk of changing specialists. In view of the recent genesis of national standards in the United Kingdom and United States[20,40], we recommend that continuity of care and institution of efficient, fail-safe referral mechanisms are included as markers of quality in IBD. Adopting a patient-centered approach to IBD management, regularly surveying patient satisfaction and maintaining best practice therapeutic strategies, may result in durable benefits to both patients and doctors alike, although proven formulae to minimize avoidable change in specialist and maintain positive PDRs require further evaluation.

COMMENTS

Background
Inflammatory bowel diseases (IBD) is typically an unpredictable, relapsing- remitting condition and thus patient satisfaction and a robust patient-doctor relationship (PDR) are fundamental to high quality care. Conversely however, relational discord between patient and doctor may compromise quality of care (QoC), leading to adverse outcomes. Thus, in this study, we aimed to explore whether patients changed treating specialists as a tangible marker of patient satisfaction with the PDR and their medical care.

Research frontiers
In the 21st century, patient-centered care is integral in chronic disease management. Measuring patient satisfaction is an important component of ensuring a high standard of care delivery. A compromised PDR, and therefore, QoC, may result in inferior disease outcomes.

Innovations and breakthroughs
A patient-initiated change in treating specialist represents a vulnerable moment in delivery of care but also is a surrogate, tangible measure of patient satisfaction. By establishing factors associated with a change in specialist, one may better understand to what extent these are preventable, and/or how these are best identified so as to minimize disruptions to QoC, thus avoiding adverse outcomes.

Applications
Monitoring patient satisfaction is important to maintain continuity of care and therefore quality. Ensuring failsafe referral and follow-up mechanisms, especially in times of IBD relapse may reduce contemporaneous changes in specialists, thus ultimately improving outcomes for patients.

Peer review
This is an interesting study that sheds some light on the nature and complexity of the PDR in IBD patients. Given the importance of a positive PDR in IBD, such a study is necessary to understand the full dynamics of that relationship. The manuscript should be a good addition to the existing literature on the subject.

World Journal of Gastroenterology

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Instructions to authors

Editor-in-chief

Ferruccio Bonino, MD, PhD, Professor of Gastroenterology, Director of Liver and Digestive Disease Division, Department of Internal Medicine, University of Pisa, Director of General Medicine 2 Unit University Hospital of Pisa, Via Roma 67, 56124 Pisa, Italy

Myung-Hwan Kim, MD, PhD, Professor, Head, Department of Gastroenterology, Director, Center for Biliary Diseases, University of Ulsan College of Medicine, Asan Medical Center, 388-1 Pungnap-2dong, Songpa-gu, Seoul 138-736, South Korea

Kjell Öberg, MD, PhD, Professor, Department of Endocrine Oncology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden

Matt D Rutter, MBBS, MD, FRCP, Consultant Gastroenterologist, Senior Lecturer, Director, Tees Bowel Cancer Screening Centre, University Hospital of North Tees, Durham University, Stockton-on-Tees, Cleveland TS19 8PE, United Kingdom

Andrzej S Tarnawski, MD, PhD, DSc (Med), Professor of Medicine, Chief Gastroenterology, VA Long Beach Health Care System, University of California, Irvine, CA, 5901 E. Seventh Str., Long Beach, CA 90822, United States

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (n). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, *P* < 0.001; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. [a]P < 0.05, [b]P < 0.01 should be noted (P > 0.05 should not be noted). If there are other series of P values, [c]P < 0.05 and [d]P < 0.01 are used. A third series of P values can be expressed as [e]P < 0.05 and [f]P < 0.01. Other notes in tables or under illustrations should be expressed as [1]F, [2]F, [3]F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634   DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express t test as t (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as r (in italics), degree of freedom as υ (in Greek), sample number as n (in italics), and probability as P (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: t time or temperature, c concentration, A area, l length, m mass, V volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Hepatitis C virus (HCV) hepatitis and other diseases related to HCV, such as cryoglobulinemia, lymphoma and renal failure, impair health-related quality of life (HRQoL). In addition, HCV *per se* might directly influence HRQoL *via* colonization of microglia in the brain or, indirectly, *via* the effect of systemic inflammatory cytokines which, in turn, can trigger brain interleukin production. The treatment of HCV-related disorders with interferon (IFN) has an effect on HRQoL. Initially, IFN causes a transient deterioration of HRQoL, due to the induction of depression and other side effects of treatment. Subsequently, the subjects who obtain a sustained virologic response experience an improvement in HRQoL. Only rarely does interferon treatment causes permanent detrimental effects on HRQoL, due to residual psychiatric or neurologic side effects. Liver transplantation is the only treatment for end-stage HCV-related liver disease. HRQoL generally improves massively a few months after transplantation, except in the case of serious complications of the transplant procedure. Furthermore, high levels of anxiety and neuroticism pre-transplant are associated with lower HRQoL one year after transplant. Additionally, six months after transplant, patients with HCV who experience virologic recurrence show significantly greater depression, anxiety, phobic anxiety, and paranoid ideation than anti-HCV-negative patients. In conclusion, optimal care for the overall well-being of patients with HCV infection requires adequate knowledge of their neurological and psychological status.

INTRODUCTION

The concept of quality of life (QoL) is an attempt to define, in analyzable terms, the effect of functional outcome of a disease and its treatment on the patient. What emerges should be a functional definition that is measurable over time. The questions that are included in the evaluation of QoL are drawn from various domains of the experience of the patient and should, therefore, represent in the most complete way his/her self-perception concerning physical, psychological, relational and working experience. This conceptualization is based on the World Health Organization definition of health as "A state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity". This definition is so broad that it includes elements which are beyond the traditional domain of medicine and health

caring systems. Opportunity, education, spiritual attitudes, social security, working satisfaction, social relationships, goods availability are elements of QoL that are independent of medicine. What we deal with, by using the concept of health-related quality of life (HRQoL), is the functional effect of an illness and of its therapy on an individual.

Four broad domains contribute to HRQoL: (1) somatic sensations; (2) psychological state; (3) social interactions; and (4) physical and occupational functions.

Various questionnaires, if possible self-administered, have been developed to assess HRQoL. They are subdivided into generic tools, which encompass a global overview of the above-mentioned domains, and specific tools which are oriented to the peculiar consequences of a disease or a class of diseases.

The interest of HRQoL assessment in relation to hepatitis C virus (HCV) infection depends firstly on the acknowledgment that HCV infection is a major public health problem. It has been estimated that about 3% of humans in the word are infected by the HCV[1]. In Europe, it is estimated that there are approximately 5 million HCV carriers; the peak prevalence among individuals is in the fifth decade of age[2]. Therefore, HCV infection mainly involves adults in the period of their active life.

About 10%-20% of the individuals who are chronically infected by HCV are likely to develop liver cirrhosis over a median period of about 30 years[3] and, out of the HCV-infected patients with liver cirrhosis, 2%-6% per year develop hepatocellular carcinoma[4]. In addition, a minority of subjects will develop immunological disorders, such as cryoglobulinemia and lymphoma[5]. Obviously all these individuals will suffer from symptoms due to the diseases caused by HCV infection (but that can also have other causes), rather than from the virus infection *per se*.

Decompensated liver cirrhosis, the final stage of cirrhosis, has an ominous consequence both on survival[6,7] and on HRQoL[8]. This group of subjects display obvious limitations to HRQoL that are mainly related to the consequences of liver insufficiency and portal hypertension (*i.e.*, hepatic encephalopathy, ascites, upper intestinal tract bleeding, sexual dysfunction, lower leg cramps and itch)[8]. However, the number of subjects with these complications of end-stage liver disease is relatively small, compared with the vast majority of patients having HCV in the absence of clinically significant liver disease.

Despite the initial idea that the majority of patients with HCV infection have merely asymptomatic seropositivity, some data suggest that HCV itself may diminish HRQoL even in the absence of advanced liver disease, perhaps due to HCV brain colonization or to systemic activation of cytokines which, in turn, influence brain cytokine production and neurotransmission.

Other important issues concerning HRQoL in HCV-infected patients are those related to the side effects of interferon (IFN) treatment and to liver transplantation, which is the treatment of choice of end-stage liver disease (Figure 1).

Figure 1 Pathways producing a reduction of health-related quality of life in hepatitis C virus-infected patients: both direct and indirect mechanisms play a role. HCV: Hepatitis C virus; HRQoL: Health-related quality of life.

HCV INFECTION *PER SE*

The issue of whether HCV infection *per se* (i.e., independent of the development of liver disease or other severe organic diseases related to HCV infection) may have an effect of HRQoL is a focus of debate. Several studies reported that patients with chronic HCV have a significant reduction in their HRQoL that is not related to the severity of the liver disease[9].

Depression can account for a reduction of HRQoL, since HRQoL depends on a patient's self-perception and evaluation. Therefore, any change in mood can obviously influence HRQoL. The prevalence of depression in HCV-infected individuals was reported to be higher than that in the general population (59% *vs* 21%)[10]. It should be noted, however, that depressive symptoms in patients with HCV infection might be due to pre-existing psychiatric disorders, to a reaction to the awareness of being infected, to adverse biological effects of HCV and, finally, to the consequences of liver disease; at least in the individuals who develop severe chronic hepatitis. In addition, coping styles and sources of information are of paramount importance in perceiving disease severity and disability, since they influence patients' stress levels and/or a pessimistic/optimistic view about the future[11].

An association between HCV infection and depression is therefore likely. However, the role of confounders-such as intravenous substance abuse or promiscuous sexual behaviour-related both to HCV infection and possibly to mood and psychological dimensions may bias statistical assessment. Therefore, further studies are required to determine with certainty the existence of a true association between depression and chronic HCV infection, together with its extent and the mechanisms implicated.

Moreover, strong clues for the existence of a true pathophysiological link between HCV infection and depression derive from the observation that depression has a higher prevalence in drug addicts who are infected with

HCV compared to those who are not infected[12]. In addition, HCV-infected patients who report no history of intravenous drug abuse complain of lower HRQoL compared with healthy normal subjects[13].

As mentioned above, the most difficult confounder to be controlled is the effect of the patient's awareness of his/her infection. In fact, it is reasonable to assume that the awareness of being infected with a virus which potentially is both life-threatening and transmittable by sexual intercourse may have an adverse emotional affect *per se*, regardless of any biological effect of the virus. However, the observation that patients with chronic HCV infection have reduced HRQoL scores compared to those with hepatitis B virus infection, suggests that HCV infection *per se* reduces HRQoL, rather than the non-specific patient awareness of a viral infection[13]. Also, HRQoL was found to be reduced even in patients who were not aware of being HCV carriers[14].

Some pathophysiological insight into the possible mechanisms involved in the reduction of HRQoL due to HCV reduction was provided by Weissenborn *et al*[15] who reported alterations of mood (increased anxiety and depression) and cognition, together with changes in both the midbrain serotoninergic and striatal dopaminergic systems, irrespective of viraemia and normal liver function, in patients with HCV infection. The existence of brain alteration directly caused by HCV is provided by the evidence of deficits of attention, executive function and verbal learning, of electroencephalogram slowing in the absence of liver cirrhosis and/or substance use disorder, and of peculiar alterations on magnetic resonance spectroscopy in HCV-infected patients[16-18]. It has been suggested that monocytes infected by HCV can cross the blood-brain barrier producing a secondary infection of microglia[19-22]. Such an infection is thought to be facilitated by immunosuppression caused by human immunodeficiency virus or by immunosuppressive treatment in transplanted patients[17,21-23].

Microglia infection by HCV may disturb neuronal function due to local cytokine production[16,20,23]. Another hypothesis is that the noxious effect on the brain is due to systemic induction of inflammatory cytokines [interleukin (IL)-1, IL-6 and tumor necrosis factor-α] by HCV which, *via* the blood-brain barrier, cause microglial activation and in-brain cytokine production[24]. This is the mechanism of the "sickness behaviour" syndrome, which includes non-specific depressive symptoms: fatigue, anhedonia, apathy, emotional lability, irritability, agitation, anorexia, psychomotor retardation, sleep disturbance, social withdrawal, hyperalgesia, decreased libido, and cognitive impairment[25-27].

HCV INFECTION AND IFN TREATMENT

Another approach to solve the problem of the existence, if any, of a direct effect of HCV infection on mood and HRQoL, is to examine the results of trials on HCV treatment. Such studies concern patients with chronic viral

hepatitis; therefore, the dimension of liver disease cannot be dissociated from that of HCV infection *per se*. At any rate, large studies based on the SF36 health questionnaire have shown a significant improvement in quality of life scores in those patients with chronic hepatitis who obtain a sustained viral response[28,29]. However, these kinds of studies cannot remove the bias caused by patient satisfaction due to the awareness of being healed of hepatitis C.

In addition, the interpretation of the change of HRQoL in HCV-infected patients who are treated with IFN is biased by the fact that IFN itself is a proinflammatory cytokine that induces neuropsychiatric symptoms. In fact, 12%-41% of subjects with HCV hepatitis who are treated with IFN develop neuropsychiatric symptoms, even if they did not have a history of previous mental disorder[10]. An even higher percentage of individuals, ranging from 17%-58%, develop neuropsychiatric symptoms, mainly depression, if they had had a history of previous mental disorder[10]. The depressive syndrome induced by IFN has two expressions: (1) a depression-specific syndrome characterized by depressed mood, anhedonia, anxiety, subjective cognitive disturbance and sometimes suicidal ideation; and (2) a neurovegetative syndrome, characterized by fatigue, insomnia, anorexia, pain, psychomotor slowness. Generally, symptoms remit within 2-3 wk of discontinuation of IFN treatment[30]. Nevertheless, some patients may continue to complain of cognitive difficulties 12-24 mo after discontinuation of IFN treatment[31]. Obviously, these neuropsychiatric IFN side effects influence HRQoL, which depends on subjective perception and self-report of personal well-being. Therefore, the cessation of IFN treatment and, thus, of the discomfort caused by treatment itself, might explain a rebound perception of increased HRQoL.

LIVER TRANSPLANTATION

Liver transplantation (LT) is a life-saving intervention for many patients with end-stage liver disease: survival after this intervention ranges between 90%-70% at one and five years, respectively. Many studies have reported significant improvements in HRQoL and satisfactory psychological outcome after LT[32,33]. The topic was recently reviewed by Tome *et al*[34] who observed that general HRQoL improves dramatically after LT; however, when compared with the general population, the vast majority of LT patients have significant deficits in most HRQoL domains. In addition, while some domains, such as physical functioning and psychosocial adaptation, significantly improve after transplantation, psychological health shows a lower improvement than physical functioning. On the whole, sexual life does not improve significantly; however, results in the literature so far are extremely heterogeneous, suggesting that this effect is essentially unpredictable in individual patients. A relationship between the aetiology of liver disease and HRQoL has been reported: HCV infections impinge on HRQoL in the patients with recur-

rence of liver disease[35]. The impairment is mainly related to physical functioning and fatigue[35,36]. An intriguing issue is the interplay amongst HRQoL, psychological status and brain function. Interestingly, elevated levels of anxiety and neuroticism on pre-transplantation assessment were associated with poor psychological outcome one year after transplantation. These findings suggest that personality and affective status may be important determinants of long-term psychological health after LT. Accordingly, patients with HCV who experienced virologic recurrence within 6 mo of LT showed significantly greater depression, anxiety, phobic anxiety, and paranoid ideation than anti-HCV-negative patients[33].

In conclusion, independent of the underlying pathophysiologic mechanisms, HCV infection is a signal of vulnerability for poor HRQoL and should be considered in patient assessment.

Histopathology

Abstract

Nonalcoholic fatty liver disease (NAFLD) is a condition in which excess fat accumulates in the liver of a patient without a history of alcohol abuse. Nonalcoholic steatohepatitis (NASH), a severe form of NAFLD, can progress to liver cirrhosis and hepatocellular carcinoma. NAFLD is regarded as a hepatic manifestation of metabolic syndrome and incidence has been increasing worldwide in line with the increased prevalence of obesity, type 2 diabetes, and hyperlipemia. Animal models of NAFLD/NASH give crucial information, not only in elucidating pathogenesis of NAFLD/NASH but also in examining therapeutic effects of various agents. An ideal model of NAFLD/NASH should correctly reflect both hepatic histopathology and pathophysiology of human NAFLD/NASH. Animal models of NAFLD/NASH are divided into genetic, dietary, and combination models. In this paper, we review commonly used animal models of NAFLD/NASH referring to their advantages and disadvantages.

Key words: Animal model; Nonalcoholic fatty liver disease; Nonalcoholic steatohepatitis; Metabolic syndrome;

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a condition in which excess fat accumulates in the liver of a patient without a history of alcohol abuse[1]. NAFLD is classified into simple steatosis and nonalcoholic steatohepatitis (NASH). In NASH, not only steatosis but also intralobular inflammation and hepatocellular ballooning are present, often accompanied by progressive fibrosis[2]. Long-standing NASH may progress to liver cirrhosis, and hepatocellular carcinoma (HCC) may be an outcome[3-5].

NAFLD is regarded as a hepatic manifestation of metabolic syndrome[6,7]. NAFLD has been increasing worldwide over recent decades in line with the increased prevalence of obesity, type 2 diabetes, and hyperlipemia. NAFLD/NASH is currently regarded as the most common chronic liver disease worldwide. It is estimated that about 20% of all adults have NAFLD and 2%-3% of adults have NASH[8].

The pathogenesis of NASH has not been completely elucidated, and treatments for NASH other than lifestyle modification by diet and exercise have not been fully established[5]. Studies of NAFLD/NASH using human materials have limitations, because the occurrence and progression of NAFLD/NASH require a long period of several decades, and ethical limitations exist in admin-

istering drugs to patients or collecting liver tissues from patients. Animal models of NAFLD/NASH give crucial information, not only in elucidating the pathogenesis of NAFLD/NASH but also in examining therapeutic effects of various agents. These animal models need to reflect correctly both the histopathology and pathophysiology of human NAFLD/NASH. Recently, several review articles on animal models of NAFLD/NASH have been published[9,10]. In this paper, we firstly review the histopathology and pathogenesis of NAFLD/NASH, and thereafter, we review current animal models of NAFLD/NASH referring to their advantages and disadvantages, with emphasis on a fructose-enriched diet model that was established by us.

HISTOPATHOLOGY OF NAFLD

The most important histological characteristic of NAFLD is steatosis of hepatocytes. Steatosis of hepatocytes is classified into macrovesicular and microvesicular. Macrovesicular steatosis is characterized by large vacuoles occupying almost the entire cytoplasm and pushing the nucleus to the periphery of the cell. Microvesicular steatosis is characterized by multiple small lipid vacuoles, and the nucleus is located at the center of the cell. Typically, steatosis in NAFLD is centrilobular and macrovesicular. However, steatosis may be present throughout the lobule, and microvesicular steatosis may also be present. Steatosis in more than 5% of hepatocytes is necessary for a diagnosis of NAFLD[11].

In NASH, not only steatosis but also intralobular inflammation and hepatocellular ballooning are present, and this is usually accompanied by fibrosis. Mallory's hyaline (MH) may also be present. Intralobular inflammation in NASH is typically mild and of a mixed type and includes a small number of lymphocytes, macrophages, and neutrophils. Neutrophils tend to infiltrate in the area of marked steatosis and around MH. Portal inflammation is usually mild; however, relatively intense chronic inflammation may be present in the portal area.

Hepatocellular ballooning is a form of liver cell injury recognized as a swollen hepatocyte with a rarefied cytoplasm. It is most apparent near steatotic liver cells, typically in zone 3.

MH is an eosinophilic and amorphous structure in the cytoplasm of hepatocytes and is observed in alcoholic hepatitis, NASH, chronic cholestasis, and HCC[2]. MH in NASH is most frequently found in the areas of perisinusoidal fibrosis in zone 3 and may be accompanied by neutrophilic infiltration. MH in NASH is usually less distinct than that in alcoholic hepatitis. Immunohistochemically, MH is positive for cytokeratin (CK) 8, CK 18, p62, and ubiquitin[2].

Other pathological features that are often observed in NASH include fat cysts and lipogranulomas, and glycogenated nuclei frequently occur in hepatocytes in zone 1. Furthermore, megamitochondria and iron deposition may be observed in NASH.

Fibrosis usually originates in the perisinusoidal regions of zone 3 (perisinusoidal fibrosis) and may also be present in the periportal area. As the disease progresses, bridging fibrosis and liver cirrhosis may develop. In the process, steatosis and lesion activity may resolve, resulting in a diagnosis of "cryptogenic cirrhosis" (burn-out NASH).

Brunt *et al*[12] proposed the grading and staging system of NASH, and the NASH Clinical Research Network designed and validated the NAFLD activity score[13]. These systems are frequently used in both clinical studies and animal experiments. Intralobular changes are milder and portal inflammation is more severe in pediatric NAFLD than in adult NAFLD[14,15]. Furthermore, steatosis in pediatric NAFLD is not necessarily predominant in zone 3[15,16].

PATHOGENESIS OF NAFLD/NASH

The "two-hit" hypothesis proposed by Day *et al*[17] is widely accepted as the pathogenesis of NAFLD/NASH; the first hit causes fat accumulation in hepatocytes, and the second hit causes inflammation and fibrosis. Fat accumulation in the liver is closely associated with metabolic derangements that are related to central obesity and insulin resistance[18]. The most reproducible risk factors for NAFLD/NASH are central obesity, insulin resistance, fasting hyperglycemia, and hypertriglyceridemia[19], and NAFLD/NASH is regarded as a hepatic manifestation of metabolic syndrome[6,7].

Hepatic steatosis occurs when the rate of import or synthesis of fatty acids by hepatocytes exceeds the rate of export or catabolism[20,21]. Accordingly, the following 4 mechanisms are possible causes of lipid accumulation within the liver: (1) increased delivery and uptake into hepatocytes of long-chain fatty acids (LCFA) due to excess dietary intake or release from adipose tissue; (2) increased *de novo* hepatic LCFA and triglyceride synthesis; (3) failure of very low-density lipoprotein (VLDL) synthesis and triglyceride export; and (4) failure of LCFA elimination due to impaired hepatic mitochondrial β-oxidation[22].

Once steatosis has developed, the liver is sensitized; thus, an inflammatory response may be precipitated by a variety of stimuli[22]. Oxidative stress, pro-inflammatory cytokine [e.g., tumor necrosis factor (TNF)-α]-mediated hepatocyte injury, altered lipid partitioning and hepatotoxicity mediated by free fatty acids, abnormal intrahepatic cholesterol loading, hyperinsulinemia, hyperleptinemia, hypoadiponectinemia, and apoptosis are all thought to be important second hits causing NASH[22-24].

ANIMAL MODELS OF NAFLD/NASH

An ideal animal model of NAFLD/NASH should reflect hepatic histopathology and pathophysiology of human NAFLD/NASH. Accordingly, the liver of the animal model of NASH should show steatosis, intralobular inflammation, hepatocellular ballooning, and, ideally, perisinusoidal fibrosis in zone 3 and susceptibility to liver

Table 1 Biochemical and pathological characteristics of animal models of nonalcoholic fatty liver disease/nonalcoholic steatohepatitis

Model	Obesity	Insulin resistance	Steatosis	Steatohepatitis	Fibrosis
SREBP-1c transgenic mice	No (decreased adiposity)	Yes	Yes	Yes	Yes
Ob/ob mice	Yes	Yes	Yes	No (does not develop spontaneously)	No (resistant to fibrosis)
Db/db mice	Yes	Yes	Yes	No (does not develop spontaneously)	No (does not develop spontaneously)
KK-A^y mice	Yes	Yes	Yes	No (does not develop spontaneously)	No (does not develop spontaneously)
PTEN null mice	No	No	Yes	Yes	Yes
PPAR-α knockout mice	No	No	No (steatosis occurs in the starved state)	No	No
AOX null mice	No	No	Yes	Yes	No
MAT1A null mice	No	No	Yes	Yes	Yes
Methionine and choline deficiency	No (decreased weight and adiposity)	Hepatic insulin resistance	Yes	Yes (severe)	Yes
High fat	Yes	Yes	Yes	Yes (mild)	Yes
Cholesterol and cholate (atherogenic diet)	No (decreased weight)	Hepatic insulin resistance	Yes	Yes	Yes
Fructose	No	Yes	Yes	No/Yes	No

SREBP: Sterol regulatory element binding protein; PTEN: Phosphatase and tensin homologue deleted on chromosome 10; AOX: Acyl-coenzyme A oxidase; MAT1A: Methionine adenosyltransferase-1A; PPAR: Peroxisome proliferator-activated receptor.

tumors. Furthermore, the animal should show metabolic abnormalities such as obesity, insulin resistance, fasting hyperglycemia, dyslipidemia, and altered adipokine profile. It is questionable whether the results of a study using an animal model that does not completely fulfill these conditions can be extrapolated to human disease. Animal models of NAFLD/NASH are classified into genetic models, nutritional models, and combination models of genetic and nutritional factors. Numerous animal models of NAFLD/NASH have been reported to date; however, no animal model completely reflects hepatic histopathology and pathophysiology of human NAFLD/NASH. It is, therefore, important to select the animal model that best conforms to the aim of the study. Biochemical and pathological characteristics of animal models described in this paper are summarized in Table 1. As described below, in many of the genetic models of NASH [e.g., sterol regulatory element binding protein (SREBP)-1c transgenic mice and phosphatase and tensin homologue deleted on chromosome 10 (PTEN) null mice], hepatic steatosis occurs first, and steatohepatitis develops later. Ob/ob, db/db, and KK-A^y mice do not progress to steatohepatitis spontaneously. On the other hand, in a dietary model induced by methionine and choline deficiency, steatohepatitis occurs very quickly.

GENETIC MODELS

SREBP-1c transgenic mice
In the fat tissue of these mice, SREBP-1c, a lipogenic transcription factor, is overexpressed. This creates a model of congenital lipodystrophy in which severe insulin resistance and diabetes develop secondary to impaired adipose differentiation[25]. In these mice, decreased fat tissue with lipid accumulation in the liver is observed,

and marked hepatic steatosis occurs by 8 d of age. When fed a standard diet, steatosis, lobular inflammation, and perivenular and pericellular fibrosis develop at 20 wk[26]; ballooned hepatocytes and MH are also observed. These mice appear to be appropriate for the lipodystrophy-associated steatohepatitis model. However, it is questionable whether they can be used as a model for typical NAFLD/NASH, because visceral fat characteristically increases in human NAFLD/NASH.

Ob/ob mice
Ob/ob mice possess a spontaneous mutation in the leptin gene (leptin-deficient). Leptin is an adipokine produced by white adipose tissue and operates on the hypothalamic ventral median nucleus exerting a marked anorexic effect[22]. Ob/ob mice are hyperphagic, inactive, and extremely obese, and show hyperglycemia, insulin resistance, and hyperinsulinemia[27]. Ob/ob mice develop spontaneous hepatic steatosis[28]; this does not, however, progress to steatohepatitis spontaneously. Secondary insults such as a methionine- and choline-deficient (MCD) diet, a high fat (HF) diet, or low-dose lipopolysaccharide (endotoxin) are needed to trigger steatohepatitis in ob/ob mice[29,30]. Another feature of ob/ob mice is that they are protected against fibrosis[31], a phenomenon which led to the characterization of leptin as an essential mediator of hepatic fibrogenesis[31,32]. Mutations in the *ob* gene are not prevalent in obese subjects or NASH patients, and leptin levels correlate poorly with the development of NASH[33].

Db/db mice
Db/db mice possess a natural mutation in the leptin receptor (*Ob-Rb*) gene[34] and, therefore, show normal or elevated levels of leptin but are resistant to the effects of leptin. These mice are obese, insulin resistant, and dia-

betic, and develop macrovesicular hepatic steatosis. They develop NASH when a second hit such as an MCD diet is added[35]. When db/db mice are fed an MCD diet, significant liver fibrosis is observed as compared to that in ob/ob mice[36]. The advantage of ob/ob and db/db mice is that the phenotype of these mice simulates the human condition of metabolic syndrome in many aspects. However, these mice have the disadvantage that they do not spontaneously develop steatohepatitis or liver fibrosis.

KK-A^y mice

A heterozygous mutation of the agouti gene (*KK-Ay/a*) results in a loss of melanocortin and an obese phenotype due to hyperphagia from impaired hypothalamic appetite suppression[9]. Although these mice develop hepatic steatosis in conjunction with obesity and insulin resistance, significant steatohepatitis does not occur spontaneously. It was reported that KK-A^y mice exhibited increased susceptibility to MCD diet-induced steatohepatitis, where hypoadiponectinemia most likely played a key role in exacerbation of both inflammatory and profibrogenic responses[37].

PTEN 10 null mice

PTEN is a tumor suppressor gene encoding a lipid phosphatase whose major substrate is phosphatidylinositol-3,4,5-triphosphate (PIP3). PTEN is a negative regulator of several signaling pathways such as phosphatidylinositol 3-kinase and serine-threonine protein kinase B (PKB, or Akt)[38]. These pathways regulate apoptosis, cell proliferation, and tumor formation[38]. Liver-specific *Pten* knockout mice (*AlbCrePTEN flox/flox* mice) show extensive hepatomegaly and steatohepatitis, and the histopathology is similar to that in human NASH[39]. Steatosis is observed at 10 wk of age, and steatohepatitis with fibrosis is observed at 40 wk. Hepatocellular adenomas occur with an incidence of 47% by 44 wk, and by 74-78 wk, all of the livers show adenomas, whereas 66% develop HCCs[40]. *Pten* knockout mice are hypersensitive to insulin, and *Pten* null hepatocytes have high proliferative activity *in vitro*[40]. The advantage of this model is that the histological phenotype resembles that of human NASH. The disadvantage of this model is that it is hypersensitive to insulin.

Peroxisome proliferator-activated receptor-α knockout mice

Peroxisome proliferator-activated receptor-α (PPAR-α) is a key regulator of genes involved in peroxisomal, mitochondrial, and microsomal fatty acid oxidation systems in the liver, and a significant decrease in PPAR-α is observed in the HF diet model[41]. Fat does not accumulate in the liver of mice with a homozygous mutation of the *PPAR*-α gene under conditions of normal feeding, but in the starved state, hepatic steatosis occurs because fatty acid oxidation is inhibited[42].

Acyl-coenzyme A oxidase null mice

Acyl-coenzyme A oxidase (AOX) is the rate-limiting enzyme of peroxisomal β-oxidation of LCFA. *AOX* null (*AOX* -/-) mice have defective peroxisomal β-oxidation of LCFA, which accumulate in the liver and lead to steatohepatitis. *AOX* -/- mice begin to exhibit microvesicular fatty change of hepatocytes in zones 2 and 3 of liver lobules at 7 d of age[43]. By 30 d of age, the *AOX* -/- mouse liver shows increased severity of steatosis of liver parenchymal cells and concomitant occurrence of focal inflammatory cell infiltrate[43]. At 2 mo of age, clusters of hepatocytes with peroxisome-rich eosinophilic granular cytoplasm are observed in periportal areas[43]. By 4-5 mo of age, increased expressions of PPAR-α, cytochrome P450 (Cyp) 4a10 and Cyp 4a14, and increased levels of H_2O_2 are observed[44]. However, compensative increase of fatty acid oxidation is observed by 6-7 mo of age, and hepatic steatosis recovers by regeneration of hepatocytes. *AOX* -/- mice develop hepatocellular adenomas and HCCs by 15 mo of age[44].

Methionine adenosyltransferase-1A null mice

Methionine adenosyltransferase-1A (MAT1A) is a liver-specific rate-limiting enzyme of methionine metabolism and catalyzes the formation of S-adenosylmethionine. *MAT1A* null mice have decreased levels of antioxidants, including glutathione, and decreased expressions of genes involved in lipid oxidation such as Cyp 4a10 and Cyp 4a14[44]. *MAT1A* null mice spontaneously develop steatohepatitis after 8 mo of age, and proliferation of hepatocytes increases, resulting in tumor development[45,46]. The mice are susceptible to choline-deficient diet-induced fatty liver at 3 mo of age[45]. Although *MAT1A* null mice are hyperglycemic, their insulin levels are normal and they do not appear to develop other features of metabolic syndrome[46].

DIETARY MODELS OF NASH

Methionine and choline deficiency

The MCD diet contains high sucrose and fat (40% sucrose, 10% fat) but lacks methionine and choline, which are essential for hepatic β-oxidation and production of VLDL[22]. In addition, choline deficiency impairs hepatic VLDL secretion[47]. As a result, lipid is deposited in the liver. Furthermore, oxidative stress[48,49] and changes in cytokines and adipocytokines[50] occur, contributing to the liver injury. Antagonizing oxidative stress by increasing antioxidant capacities attenuates the degree of steatohepatitis and stresses the importance of reactive oxygen species in this model[51].

Serum alanine aminotransferase (ALT) level is consistently increased after MCD-diet feeding in mice[52]. Steatohepatitis occurs at day 10[52], and perisinusoidal fibrosis is observed by 8-10 wk in mice[48,53]. After 10 wk of MCD feeding, extensive macrovesicular steatosis is observed in

all areas except for the periportal region, and many necro-inflammatory foci containing lymphocytes and neutrophils are observed in mice[54]. Although the MCD model causes more severe inflammation, oxidative stress, mitochondrial damage, apoptosis, and fibrogenesis than other animal nutritional models of NASH[55], the severity of NASH in rodents fed the MCD diet may depend on the species, gender, and strain of the animal[56]. Kirsch *et al*[57] compared the effects of MCD diet using male and female Wistar, Long-Evans, and Sprague-Dawley rats, and C57BL/6 mice. As a result, the Wistar strain and the male sex were associated with the greatest degree of steatosis in rats. Of the groups studied, male C57BL/6 mice developed the most inflammation and necrosis, and best approximated the histological features of NASH.

The main disadvantage of the MCD model is that the metabolic profile of the model is opposite to that of typical human NASH. Namely, mice fed the MCD diet show significant weight loss (often, more than 20% weight loss after 3 wk), low fasting blood sugar, peripheral insulin sensitivity, low serum insulin and leptin levels, and unchanged or increased serum adiponectin levels[50,58-61]. To improve these problems, genetically obese mice, such as ob/ob and db/db mice, are occasionally used as the MCD-fed animal. The main advantages of the MCD diet are that it is easy to obtain and use.

HF diet

Lieber *et al*[62] reported a diet model of NASH by using an HF diet (71% of energy from fat, 11% from carbohydrates, and 18% from proteins). Rats fed this diet *ad libitum* for 3 wk showed elevated plasma insulin levels reflecting insulin resistance. Rats fed the HF diet developed marked panlobular steatosis, and the hepatic lipid concentrations of these rats were approximately twice those of control rats fed the standard Lieber-DeCarli diet (35% fat, 47% carbohydrates, and 18% protein). Like human NASH, the rats fed the HF diet developed oxidative damage in the liver. When dietary consumption was restricted, steatosis and inflammation in the liver, oxidative stress, and plasma insulin levels were decreased. Feeding of an HF emulsion to Sprague-Dawley rats also induced changes closely resembling human NASH[63]. In the longitudinal study by Ito *et al*[64], chronic administration of an HF diet (60% of calories from fat) caused steatohepatitis in male C57BL/6J mice.

Intragastric overfeeding of mice with an HF diet up to 85% in excess of standard intake for 9 wk has been reported to replicate the histopathological and pathogenic features of NASH[65]. Overfed C57BL/6 mice became obese (71% higher body weight), had increased visceral fat (white adipose tissue: WAT), and showed hyperglycemia, hyperinsulinemia, hyperleptinemia, glucose intolerance, and insulin resistance. Almost half (46%) of the animals developed NASH, and their plasma ALT levels showed 9- to 10-fold increases. Neutrophilic infiltration and perisinusoidal fibrosis reminiscent of human NASH were observed. The WAT exhibited increased TNF-α and leptin

expressions and reduced adiponectin expression.

An HF diet is widely used to cause hepatic steatosis and NASH in experimental animals. However, it seems that the HF diet model produces variable results with regard to the degree of steatosis, inflammation, and fibrosis, and the results depend on rodent species and strain, the fat content in the diet, the composition of dietary fat, and the duration of treatment. For example, Sprague-Dawley rats appear susceptible to steatohepatitis development when fed an HF diet, and this is likely associated with their susceptibility to diet-induced obesity[54]. On the other hand, it was reported that long term high saturated fat feeding did not induce hepatic steatosis and NASH in Wistar rats[66]. In mice, it was reported that BALB/c male mice accumulated more hepatic lipid than C57BL/6J male mice when fed an HF diet[67]. In general, compared with the MCD model, the degree of liver injury in the HF model is less severe[10]. Among the HF models, the histopathology and pathophysiology of the intragastric overfeeding method most resemble those of human NASH. However, this method is difficult to implement, because it requires specific equipment and expertise. The optimization of the composition of the HF diet to reliably cause NASH in animals by *ad libitum* administration warrants future investigation. Recently, Ogasawara *et al*[68] reported a combined model of HF diet and gold thioglucose (GTG) administration. GTG is known to induce lesions in the ventromedial hypothalamus, leading to hyperphagia and obesity. They administered GTG intraperitoneally to C57BL/6 mice, and thereafter, fed an HF diet to the mice for 12 wk. As a result, obesity with increased abdominal adiposity, glucose intolerance, insulin resistance, and steatohepatitis with hepatocyte ballooning, MH, and pericellular fibrosis were induced.

Cholesterol and cholate

Matsuzawa *et al*[69] fed mice an atherogenic diet containing 1.25% cholesterol and 0.5% cholate and observed the progressive formation of steatosis, inflammation, and fibrosis in a time-dependent manner over 6-24 wk. In the model, hepatocellular ballooning, characteristic of human NASH, was observed at 24 wk. When 60% fat (cocoa butter) was added to the diet, development of these histopathological features was accelerated, and hepatocellular ballooning was observed at 12 wk. Furthermore, the atherogenic diet induced oxidative stress. Thus, it is conceivable that a combination diet of HF, cholesterol, and cholate in animals would cause histological features reminiscent of human NASH. However, the mice fed this diet were systematically insulin sensitive, albeit they showed hepatic insulin resistance. In fact, the mice lost 9% body weight during the experiment and had small epididymal fat pads and low plasma triglyceride levels compared with those in control mice. Therefore, this model appears to differ from human NASH in metabolic status.

Fructose

NAFLD/NASH is regarded as a hepatic manifestation of

Figure 1 Liver histology of rats fed a high-fructose diet for 5 wk. A: Hepatic steatosis, mainly distributed in zone 1, is observed (azan stain, × 40); B: Both macrovesicular and microvesicular steatosis are evident as well as scattered necroinflammatory foci (arrows) (hematoxylin and eosin stain, × 200).

Figure 2 Liver histology of rats fed a high-fructose diet + plant leaf extract. Hepatic fatty change is completely suppressed by the plant leaf extract (hematoxylin and eosin stain, × 40).

metabolic syndrome. Experimental animals fed a fructose-enriched diet are recognized as good models of metabolic syndrome. We examined livers of Wistar rats fed a high-fructose (70%) diet for 5 wk and found significantly higher macrovesicular steatosis (Figure 1A) and intralobular inflammation (Figure 1B) grades, liver:body weight ratios, and hepatic triglyceride concentrations than those in control rats[70]. In this study, the distribution of steatosis in the rats fed a high-fructose diet was characteristically predominant in zone 1. This pattern differs from that of human adult NAFLD, in which steatosis is usually predominant in zone 3. Rats fed a high-fructose diet showed significantly higher expressions of interleukin (IL)-6 protein and TNF-α protein in the liver compared with those in control rats (unpublished data). By adding plant leaf extract to the high-fructose diet, hepatic fatty change (Figure 2) and expression of IL-6 protein in the liver were completely suppressed (unpublished data).

Other groups also reported induction of NAFLD/NASH by fructose in experimental animals. Ackerman et al[71] found that male Sprague-Dawley rats fed a fructose-enriched (60%) diet developed macrovesicular and microvesicular steatosis in the liver. Armutcu et al[72] reported that male Wistar albino rats provided with drinking water containing 10% fructose for 10 d developed macrovesicular and microvesicular steatosis but did not develop inflammation in the liver. In mice, by adding 30% fructose to the drinking water, 3- to 4-fold increases in

hepatic triglyceride levels and marked increases in hepatic steatosis and weight were observed at 8 wk[73]. Recently, it was reported that C57BL/6 mice fed a high-fat high-carbohydrate diet and provided with drinking water containing 55% fructose for 16 wk developed a NASH-like phenotype with significant fibrosis as well as obesity[74]. Inflammation caused by endogenous toxins of fructose metabolites is suggested as one of the mechanisms of the second hit in the pathogenesis of NASH[75].

COMBINED MODEL OF GENETIC MODIFICATION AND NUTRITIONAL/ DIETARY CHALLENGES

Many animal models combine naturally occurring genetic mutations or targeted gene modifications with dietary or chemical challenges so that the histopathology and pathophysiology of the models more closely resemble those of human NAFLD. Sahai et al[36] fed an MCD diet to ob/ob and db/db mice and observed that db/db mice had significantly higher serum ALT levels and more severe hepatic inflammation and fibrosis than those in ob/ob and wild-type mice. PPAR-α null mice fed an MCD diet show more severe steatohepatitis than that in wild-type mice fed the same diet[76,77]. Many other models combining genetic abnormalities with nutritional challenges have been reported[78-80].

CONCLUSION

As reviewed in this paper, many animal models of NASH have been developed to date. These animal models do not replicate the full spectrum of the disease in humans; however, they can be used in verifying hypotheses on the pathogenesis of NASH and in performing interventional studies. We hope that animal models which more closely reflect the histopathology and pathophysiology of human NASH will be developed in the future, and information on pathogenesis and treatment of NASH will increase by using these models.

Abstract

The prevalence of obesity is growing to epidemic proportions, and there is clearly a need for minimally invasive therapies with few adverse effects that allow for sustained weight loss. Behavior and lifestyle therapy are safe treatments for obesity in the short term, but the durability of the weight loss is limited. Although promising obesity drugs are in development, the currently available drugs lack efficacy or have unacceptable side effects. Surgery leads to long-term weight loss, but it is associated with morbidity and mortality. Gastric electrical stimulation (GES) has received increasing attention as a potential tool for treating obesity and gastrointestinal dysmotility disorders. GES is a promising, minimally invasive, safe, and effective method for treating obesity. External gastric pacing is aimed at alteration of the motility of the gastrointestinal tract in a way that will alter absorption due to alteration of transit time. In addition, data from animal models and preliminary data from human trials suggest a role for the gut-brain axis in the mechanism of GES. This may involve alteration of secretion of hormones associated with hunger or satiety. Patient selection for gastric stimulation therapy seems to be an important determinant of the treatment's outcome. Here, we review the current status, potential mechanisms of action, and possible future applications of gastric stimulation for obesity.

INTRODUCTION

Obesity is a major public health challenge. The evolving concepts of how nutrient excess and inflammation modulate metabolism provide new opportunities for strategies to correct the damaging health consequences of obesity. The traditional approaches of caloric restriction, exercise, and behavioral therapies can each produce substantial weight loss, but it is not sustained in the majority of patients. The pharmacological agents that are currently licensed for weight loss produce only modest results and may have unwanted side effects. Clearly, a safe, effective, and durable treatment for obesity is needed.

The role of the gastrointestinal tract in regulating energy balance is now well recognized, and the expanding understanding of gut endocrinology and electrical signaling has produced a number of potentially fruitful avenues for developing obesity therapies.

In the last few years, gastric stimulation has gained attention as a possible new approach for treating obesity. Gastric electrical stimulation (GES) is a new method for invoking gastric contractions using a microprocessor con-

troller. The effect of this long-term gastric stimulation on food intake and body weight was first studied in pigs[1,2]. Pigs treated for eight months with electrical antral stimulation showed a net decrease of food intake[1]. In other studies, a significant decrease in food intake has been noted with gastric stimulation in dogs, and a significant decrease in fat absorption has been reported in rats[3-6].

Because GES has shown promising results in several animal models, the technique has been further refined for obesity treatment in humans. In 1995, the technique of an implantable gastric pacing device was studied in 24 morbidly obese patients. The results demonstrated the safety of the method and revealed changes in eating habits that resulted in reduced food intake and weight loss[7]. In a subsequent human study, there was a reported increase in meal-related satiety and enhanced inter-meal satiety during the treatment[8]. From this information, gastric pacing was hypothesized to facilitate weight loss by enhancing neuroendocrine satiety mechanisms.

Here, we review some of the techniques and the potential mechanisms associated with using gastric stimulation for treating obesity.

ROLE OF THE GUT-BRAIN AXIS IN REGULATING APPETITE

Food intake is influenced by emotional factors, social cues, and learned behavior. These influences overlay highly conserved systems within the brain that sense and integrate signals reflecting overall energy stores, recent energy intake and the presence of specific classes of nutrients.

Signals from the gut are important for controlling appetite and for regulating energy balance and glucose homeostasis. The active brain-gut axis sets the basis for options to stimulate different brain areas or neural connections between the brain and the gut to induce sensations of satiety.

There are several potential means by which the gut and the brain are associated. Some involve connections from the gut to hormones and from hormones to the nervous system. The gut continuously sends information to the brain regarding the quality and quantity of ingested food. These signals are not only important for satiation and meal termination but also for the appetitive phase of eating behavior[9]. By acting on the brainstem and hypothalamus, this flow of sensory information from the gut to the brain generates the feeling of satisfaction that is observed after a satiating meal[9].

The vagus nerve (VN) contributes to the bidirectional communications between the gastrointestinal tract and central nervous system (CNS)[10]. Afferent neurons of the VN are important targets of gut hormones, particularly the hormones involved in controlling food intake. Vago-vagal reflexes are involved in feeding homeostasis, making neuromodulation an attractive method for managing obesity[10].

Ziomber *et al*[10] have described the parameters of vagal neuromodulation required to decrease food intake in rats and cause a resulting reduction in body mass. Rats with solenoid electrodes placed on the left VN significantly decreased their food intake, weight gain and serum leptin concentrations. Another study has shown the suppressive effects of vagal nerve stimulation (VNS) on long-term feeding regulation in rats[11]. VNS has been shown to increase vagal afferent satiety signals, leading to reduced food intake and decreased weight gain[11]. Chronic microchip vagal stimulation significantly decreases epididymal fat pad weight and meal size in VNS rats, which causes decreased weight gain.

In addition to the VN, several other areas in the brain are involved in regulating gastrointestinal motility and satiety. The central nervous system regulates the homeostasis between nutrient intake and body reserves by sensing nutrient levels, integrating the information, and regulating energy intake and/or energy expenditure[12]. Grill *et al*[13] have summarized several potential mechanisms for connections between the gut and the brain. The nucleus tractus solitarius (NTS) and circuits within the hindbrain mediate the intake-inhibition effects of gastrointestinal (GI) signals. Short-term eating behavior is also controlled by the hindbrain. The NTS receives inputs from VN afferent neurons, while the area postrema is a target for circulating factors, such as amylin and glucagon-like peptide 1 (GLP-1)[14]. Classical studies have shown that when the higher inputs are surgically interrupted, the hindbrain can continue to regulate food intake in response to peripheral signals[15].

GASTRIC HORMONES ASSOCIATED WITH HUNGER AND SATIETY

The mechanisms that modulate gut-related satiety signals are now being recognized. The apparent importance of alterations in the gut hormonal milieu caused by surgical interventions in the GI tract has led to new surgical approaches and devices. Interventions (such as gastric pacing) that modulate gut-related satiety signals may offer approaches for curbing the threat of obesity to human health. The enteroendocrine cells of the GI tract act as a luminal surveillance system, responding to either the presence or absence of food in the gut lumen[16]. Their secretion products regulate the course of digestion and determine the delivery of nutrients to the gut by controlling food intake[16]. The gut is the source of numerous peptides, many of which can alter appetite. These peptides have numerous targets, including gastrointestinal exocrine glands, smooth muscles, afferent nerve terminals, and the brain[17].

GLP-1

This incretin hormone is secreted from the lower gut in response to food intake stimulates insulin secretion and

inhibits gastric emptying[18,19]. Following an oral glucose load, insulin secretion is enhanced when compared with an intravenous glucose infusion in the presence of similar plasma glucose concentrations[20]. This phenomenon is referred to as the incretin effect. In patients with type 2 diabetes mellitus (T2DM), however, the incretin effect is significantly impaired and postprandial GLP-1 secretion is diminished[20]. Because both the incretin effect and postprandial GLP-1 concentrations are markedly reduced in T2DM patients[21], the first clinical studies addressed the question of whether raising GLP-1 levels by exogenous administration of the incretin hormone could help to restore normal glucose regulation. However, GLP-1 has a plasma half-life of just a few minutes because it is readily degraded by the ubiquitous enzyme dipeptidyl peptidase-IV. Although the beneficial clinical effects of GLP-1 are evident, the need to continuously infuse it have hampered its broad clinical applications. Therefore, incretin mimetic agents, such as exenatide and dipeptidyl peptidase-IV inhibitors, are used to treat patients with T2DM[22]. Some studies have indicated that this treatment also results in weight loss[23,24]. Because of its short half-life, it has been shown that peripheral administration of GLP-1 lowers postprandial glucose dysregulation by inhibiting glucagon secretion. Beta-cell function is also improved, along with increased satiety and decreased food intake, which then results in weight loss. GLP-1 stimulates insulin secretion, which also delays gastric emptying[25-27]. Obese subjects have less GLP-1 release after a meal, which may lead to less inter-meal satiety when compared with lean subjects[28]. Low postprandial levels of GLP-1 in obese children are responsible for excessive ingestion of food and decreased inhibition of gastric emptying, both of which result in obesity[29]. The ability of Roux-en-Y gastric bypass surgery to increase GLP-1 levels has been reported[30]. In gastric pacing, up to 40% of excess body weight can be lost after 2 years of treatment[31]. A limited study in morbidly obese patients has shown that gastric pacing is associated with decreased peripheral levels of GLP-1. This effect correlates with decreased food intake and the resulting weight loss. From these results, a mechanistic role for the stimulation of vagal afferents has also been propounded[8].

Leptin

The nervous system regulates energy balance at the whole-body level by constantly adjusting energy intake, expenditure, and storage[32,33]. The *ob* gene encodes the protein leptin, which is an adipose tissue-derived circulating hormone. Since the identification of *ob* as the first example of human monogenic obesity, it has become clear that leptin plays a key role in controlling mammalian food intake and body fat stores[34,35]. A leptin deficiency in mice homozygous for a mutant *ob* gene (*ob*/*ob* mice) causes morbid obesity and diabetes. Leptin replacement leads to decreased food intake, normalized glucose homeostasis and increased energy expenditure[36-39]. Leptin induces

transcriptional changes for several genes *via* the JAK/STAT3 pathway, and rapid changes in cellular activity and membrane potential may underlie the acute actions of leptin[40]. Leptin resistance limits its utility in ordinary obesity, as reflected by the increased levels of leptin in obese subjects relative to their increased body fat[41]. Therefore, while the actions of leptin in peripheral tissues have been identified, studies in genetically modified mice have demonstrated that leptin action in the CNS is sufficient to regulate body weight, feeding, energy expenditure, and glucose metabolism[42-44]. The effect of leptin on metabolism is supported by neurons distributed in the hypothalamus, midbrain, and brainstem. It has been suggested that morphological changes progressively develop in the brain during obesity[45-47], and further inquiry into the cellular mechanisms linking obesity, neural plasticity, and food cravings are needed. Certain gut peptides (e.g., ghrelin) act in an additive manner with leptin to regulate energy balance[48], which has led to the development of combination therapies to enhance leptin sensitivity in obese states. Roux-en-Y gastric bypass in obese patients is associated with a decrease in leptin levels after only minimal changes in BMI have occurred[49]. Gastric pacing in morbidly obese patients results in significant weight loss that correlates with a decrease in leptin levels[8].

Peptide YY

The gut hormone peptide YY (PYY) belongs to a family of peptides that includes pancreatic polypeptide and neuropeptide Y (NPY). It is secreted by the L cells of the lower intestine after ingesting a meal and is released into the circulation[50], where it exists in two endogenous forms: PYY $_{1-36}$ and PYY $_{3-36}$[51]. PYY $_{1-36}$ is the major form of PYY in the fasting state[51]. The latter form is produced by the action of the dipeptidyl peptidase-IV enzyme in response to food intake[52]. Between 1% and 10% of PYY is also found in the esophagus, stomach, duodenum and jejunum[53]. PYY exerts its action through NPY receptors. PYY inhibits gastric motility and increases water and electrolyte absorption in the colon[54].

Endogenous PYY may be involved in the long-term regulation of body weight. PYY enhances a reduction in hunger and food intake[55]. Peripheral administration of PYY $_{1-36}$ decreases food intake in rodents. PYY $_{3-36}$ also markedly inhibits food intake in rodents[56,57] In humans, an intravenous infusion of physiological levels of PYY$_{3-36}$ reduces caloric intake in both normal weight[56] and obese subjects[58]. This effect is not achieved exclusively by affecting energy intake; there is evidence that PYY may have some effects on energy expenditure and lipid metabolism[59]. PYY levels are higher in rats treated with solenoid electrodes placed on the left VN than in untreated controls[10]. PYY may also be associated with the rapid improvement in carbohydrate homoeostasis observed after bypass surgery. This improvement is secondary to an increase in insulin sensitivity rather than an increase in insulin secretion, which occurs later[60]. Increases in

the secretion of GLP-1 and PYY are involved in the disappearance of hypertriglyceridemia and decreases in the levels of circulating fatty acids[60]. Some studies have reported that Roux-en-Y gastric bypass surgery increases PYY levels[30].

Cholecystokinin

Cholecystokinin (CCK) is the major hormone responsible for gallbladder contraction and pancreatic enzyme secretion. Like other gastrointestinal hormones, CCK is produced in discrete endocrine cells that line the mucosa of the small intestine. CCK stimulates vagal afferent neuron discharge and controls the expression of G-protein coupled receptors and peptide neurotransmitters in these neurons[16,61]. A gatekeeper function is attributed to CCK because its presence or absence influences the capacity of vagal afferent neurons to respond to other neurohormonal signals[16]. CCK reduces food intake by exerting an effect on the CCK-1 receptors residing in the VN[62].

During fasting, plasma CCK concentrations are low and vagal afferent neurons express cannabinoid CB1 and melanin concentrating hormone (MCH)-1 receptors, which stimulate food intake[16]. Post-prandial release of CCK down-regulates the expression of both receptors and stimulates the expression of Y2 receptors in neurons projecting to the stomach. In fasting, there is increased expression in the neurons of the appetite-stimulating neuropeptide transmitter MCH, along with decreased expression of the satiety-peptide cocaine and amphetamine-regulated transcript (CART). The secretion of CCK decreases the expression of MCH and increases the expression of CART. At low plasma concentrations of CCK, vagal afferent neurons exhibit increased capacity for appetite-stimulation, while post-prandial concentrations of CCK lead to enhanced capacity for satiety signaling[16].

CCK antagonists induce hunger, leading to larger meals sizes. CCK also delays the rate at which food empties from the stomach[62]. CCK expression can be altered by prolonged gastric stimulation. Following 14 d of GES, the number of CCK-immunoreactive neurons in the hippocampus increased compared with a control group[63]. In another study performed on morbidly obese patients treated with gastric pacing, the gastric pacing resulted in decreased CCK levels[8].

Ghrelin

Ghrelin was the first identified circulating hunger hormone[64]. In contrast to the GI peptide hormones (such as GLP-1, PYY and others) that increase satiety through CNS-mediated pathways[65,66], the gastric hormone ghrelin stimulates hunger through a different CNS-mediated pathway[65]. Ghrelin is produced primarily by cells in the oxyntic glands of the stomach and intestines[67] and is secreted into the bloodstream. Ghrelin is a potent stimulator of growth hormone (GH) secretion and is the only circulatory hormone known to potently enhance feeding and weight gain and to regulate energy homeostasis fol-

lowing central and systemic administration. When administered either peripherally or centrally to rodents, ghrelin increases food intake and body weight[68-70] and stimulates gastric motility and acid secretion[71]. In humans, there is a pre-prandial rise in plasma ghrelin levels[72,73]. When administered to rodents at supra-physiological doses, ghrelin is able to activate hypothalamic neuropeptide Y agouti-related protein neurons and increase both food intake and body weight. Ghrelin participates in meal initiation. When administered either peripherally or centrally to rodents, ghrelin rapidly increases food intake and body weight[48]. Therapeutic intervention with ghrelin in catabolic situations enhances food intake and increases gastric emptying and nutrient storage. These effects, coupled with an increase in GH, link nutrient partitioning with growth and repair processes. Ghrelin-based compounds may have therapeutic utility for treating the malnutrition and wasting that are induced by various sub-acute and chronic disorders. Conversely, compounds that inhibit ghrelin action may be useful for preventing or treating components of the metabolic syndrome, such as obesity, impaired lipid metabolism and insulin resistance.

Peripheral blood ghrelin levels were studied one month prior to gastric pacing, one month following implantation, and six months after activation of the electrical stimulation. Ghrelin levels were decreased significantly in response to food intake at all these evaluations. After activating the pacemaker, ghrelin levels were significantly increased above their levels prior to activation. The weight loss was significantly correlated with the increased ghrelin levels[74]. A decrease in the number of ghrelin-immunoreactive neurons in the hypothalamic paraventricular nucleus and in the supraoptic nucleus has been reported after a short period of gastric stimulation in rats[63]. In Roux-en-Y gastric bypass surgery, the total fasting plasma ghrelin levels were nearly identical between the subjects and the matched controls[30].

METHODS OF GASTRIC STIMULATION FOR THE TREATMENT OF OBESITY

Many aspects of cell functioning are controlled by intrinsic or extrinsic electrical activity. In the normal physiological state, an action potential is generated and then causes a cellular response. When electrical signals are applied externally, they increase the rate at which this response occurs, which is called electrical pacing. Nevertheless, if the electrical signal is applied during the refractory period of the normal action potential, it does not increase the response rate. However, it has been shown in several studies that application of the electrical signal is still able to change the biochemistry of the cell, which leads to greatly increased responses to the next normal action potential[75]. Stimulating the stomach, the sub-diaphragmatic sympathetics, the vagal nerve (with or without unilateral vagotomy), and the intestines are some of the pacing approaches that have been used for treating obesity[76].

Gastric pacing with short pulse width and high frequency for the treatment of obesity

Dilatation of the stomach by food ingestion sends afferent signals through the VN to the CNS and increases satiety, thus regulating food intake[77,78-80]. Because of the many neuro-hormonal functions of the stomach and the modification of these hormones by food ingestion, modifying the function of the stomach has been hypothesized to be a potential mechanism for treating obesity.

Several methods have been used to electrically stimulate the stomachs of obese patients[76]. Changes in the intensity of the stimulus, the duration of the pacing, and the anatomical site of stimulation determine the effect of the treatment. The responses to gastric pacing are dependent on the stimulus intensity, with shorter duration stimuli being sufficient when the impulse strength is increased. The antrum can be paced to significantly higher frequencies than the more proximal gastric regions.

GES is a method for invoking gastric contractions. The main effect of the technique was originally thought to be longer retention of food in the stomach that induces early satiety and diminishes food intake. The first clinical use of gastric pacing in the early 1990s was preceded by an exploration of gastric electrical physiology in the 1980s[81] Human GES for obesity began in 1995. There have now been more than 500 subjects treated for obesity with gastric pacing. With proper screening, the weight loss can be in the range of 40% of the excess body weight[76,82].

GES uses an electrical device called a gastric pacemaker to provide mild electrical stimulation to the lower abdominal nerves. Utilizing minimally-invasive surgical techniques, the gastric pacemaker is placed subcutaneously in the abdomen. It is intended to induce early satiety through electrical stimulation of the gastric wall. Several gastric stimulation protocols have demonstrated their weight-reduction efficacy in animal obesity models and in patients with morbid obesity. The implantable gastric stimulator (IGS) induces stomach expansion *via* electrical stimulation of the VN. This type of stimulation induces neurobiological responses by using brain circuits that lead to decreased food intake[83].

IGS has been used for the treatment of obesity[84]. IGS reduces appetite and increases satiety. Its efficacy is attributed to its inhibitory effects on gastric motility and its direct effects on the central nervous system and hormones related to satiety and/or appetite[84]. Chronic gastric stimulation impairs intrinsic gastric myoelectrical activity in the fed state, induces gastric distention in the fasting state and inhibits postprandial antral contractions[84]. The impairment of gastric myoelectrical activity and contractions are associated with impaired digestion and emptying of the stomach, which leads to early satiety and reduced food intake. The induction of gastric distention in the fasting state results in activation of stretch receptors, causing satiety[84]. Modulation of neuronal activities and the release of certain hormones in response to an IGS may also explain the reduction in appetite and increase in satiety.

The first studies of GES as a treatment for obesity employed the Transcend™ Implantable Gastric Stimulator. In 2002, Favretti and colleagues showed that the Transcend device was safe and effective at inducing and maintaining weight loss in 20 morbidly obese patients[85]. The pacemaker was implanted laparoscopically below the pes anserinus, 3 cm from the edge of the lesser gastric curvature and 6 cm from the pylorus. The lead was fixed within a tunnel in the gastric muscular wall by a suture, and gastroscopy was performed to ensure that the lead did not perforate the stomach wall. The operative time was less than an hour, and the stimulator was activated 30 d after its implantation. The stimulus parameters were an amplitude of 10 mA, a pulse width of 208 ms, and a frequency of 40 Hz with 2 s on and 3 s off[85]. The Transcend device blocks vagal efferents and delays gastric emptying, leading to a 40% loss of excess body weight[76]. The pacemaker delivers 2 s pulse trains with a 40-100 Hz frequency, 3-10 mA of current, and a short pulse duration of 0.18-0.4 ms, with intervening 3 s periods of no stimulation[7,86]. In another study, two electrode positions along the lesser curvature of the stomach were used, with the low insertions 6 cm proximal to the pylorus and the high insertions just distal to the esophageal-gastric junction. Short-term weight loss has been achieved in a subset of these patients[86]. The clinical response is most often defined by the excess weight lost (EWL) in these studies; however, improvements in symptoms, quality of life and nutritional status have also been reported by most open-labeled studies[87].

Gastric pacing with long pulse width and low frequency for obesity

Other types of stimuli have been tested in animal models and in humans. In dogs, retrograde stimulation through two electrode pairs positioned proximal to the pylorus for 8 s at a frequency of 50 Hz and a voltage of 16 V with intervening periods of no stimulation elicits retrograde contractions, reduces food intake and promotes weight reduction[88]. In another animal study, electrical stimulation has been shown to reduce food intake and increase gastric volume[89]. Studies in dogs using a pulse width in milliseconds at a frequency of six cycles per minute induced gastric relaxation when the pacing occurred in the proximal stomach but not when it occurred in the distal stomach[90]. These studies demonstrated the ability to inhibit gastric contractions and delay gastric emptying[90,91]. Temporary retrograde pacing with a mucosal electrode placed endoscopically on the greater curvature of the stomach, 5 cm above the pylorus, was performed in 12 normal volunteers. The gastric slow waves were entrained at nine cycles per minute, and the symptoms of satiety, bloating, discomfort, and nausea were linearly correlated with the energy stimulation in milliamps[92]. Later, 12 normal volunteers were studied for 3 d using temporary electrodes endoscopically placed

on the greater curvature stomach, 5 cm above the pylorus. Retrograde gastric pacing at nine cycles per minute resulted in retrograde propagation of electrical waves from the antrum. These waves disrupted the normal electrical waves that propagate distally and caused gastric hypomotility. Food intake decreased by 16% and gastric retention of solids increased by 15% during this retrograde pacing. These changes were accompanied by tolerable dyspeptic symptoms[92]. Another study in 12 normal volunteers using a stimulus intensity below the threshold that induces dyspepsia was able to delay gastric emptying, decrease food intake, and decrease water intake compared with sham controls. These results suggested the possibility of performing longer stimulations to treat obesity[93].

VNS for weight loss

The VN has a role in regulating hippocampal activity, and the hippocampus has a role in modulating eating behaviors[83]. Studies with the Transcend gastric pacemaker have suggested that blocking the efferent vagal impulses can reduce gastric tone, which is accompanied by slower gastric emptying, decreased food intake, and weight loss. A laparoscopically implanted electrical device that intermittently blocked both VNs near the esophageal-gastric junction led to EWL in obese patients[94]. A vagal blocking algorithm with a duration of 90-150 s was associated with greater EWL than were either shorter- or longer-duration algorithms[94]. An association was found between the number of 90-150 s algorithms delivered daily and greater EWL. In a study conducted in rabbits, the animals had a microchip implanted on the posterior vagus by laparotomy. Over a 4-wk period, body weight decreased by 12%, food intake decreased by 40%, and pulse rate decreased. Heart rate changes suggested stimulation of the afferent vagus in addition to blocking of the efferent vagus[95]. In another study, pigs were implanted with microchips on both vagal nerves by laparotomy. At an amplitude of 170 mV, a frequency of 1 Hz, and a 170-ms impulse duration, their food intake was decreased and their body weight gain was reduced with no observable side effects. Normogastria was reduced and tachygastria was increased, which is consistent with reduced efferent vagal transmission[96]. The human data on weight loss through VN stimulation comes from trials using VN stimulators for treating epilepsy. These patients had cervical vagal stimulation, which caused hoarseness, cough, throat pain, and dyspnea. Thirty-two patients were evaluated and 17 lost weight[97].

Stimulation during the electrical refractory period to treat obesity

Stimulating the gastric antrum in rats during the absolute refractory period increases the strength of gastric contractions and increases vagal afferent firing, similar to its effects on gastric distension[98]. Pyloric stimulation in dogs decreases food intake, decreases antral contractions, and delays gastric emptying[99]. The Tantalus system (MetaCure Ltd.) is implanted laparoscopically for gastric stimulation

that does not exhibit malabsorptive or restrictive characteristics[100]. It was developed to electrically stimulate the gastric antral muscle immediately following the entrance of food into the stomach. It increases antral muscular contractions and delays gastric emptying by delivering stimulation during the absolute refractory period[76]. The Tantalus system has a pulse generator and three bipolar leads. Two pairs of electrodes are implanted in the gastric antrum and two pairs in the gastric fundus. The electrodes in the gastric fundus sense the beginning of a meal and signal the pulse generator to stimulate the antral electrodes during the absolute antral refractory period, which enhances spontaneous gastric contractions and sends a signal through the afferent vagus that the stomach is distended. The device applies gastric contractility modulation signals to the gastric antrum. The system is designed to automatically detect when eating begins and to only then deliver GES sessions using electrical pulses that are synchronized to the intrinsic antral slow waves[100,101]. This method involves surgical placement of three electrode pairs; one pair in the fundus detects food ingestion, and two pairs in the antrum detect the intrinsic slow waves and deliver stimuli in synchrony with these signals[102]. The gastric stimulation begins when food enters the stomach, so it is only delivered postprandially. The device is believed to work by increasing antral contractions. This stimulated phased motor activity enhances the satiety that is normally elicited by postprandial gastric distention[98]. The stimulation parameters that enhance the phased antral contractions include a frequency of 80 Hz, a pulse width of 1-2 s, and a current of 0.5-1 mA[98]. Because of its energy requirements, the device must be recharged weekly by an external charger.

A trial in 12 obese subjects demonstrated that the fundal electrodes were able to sense the start of a meal > 75% of the time. The subjects lost 10 kg over 20 wk, and 9 subjects who continued till week 52 lost an additional 7 kg, for a total of 30.5% of their excess body weight lost[102]. In a European multicenter, open-label study, thirteen T2DM obese patients were laparoscopically implanted with the Tantalus device. The thirteen subjects that completed 3 mo of treatment showed a significant reduction in weight that was accompanied by glycemic improvement[100]. In the eleven patients that completed 6 mo of therapy, HbA1c was significantly reduced. However, the improvement in glucose control did not correlate with weight loss[101]. The data support the hypothesis that GES can improve glucose metabolism and induce weight loss in obese diabetic patients[103].

Intestinal electrical pacing for obesity

Intestinal electrical stimulation (IES) may have promising applications for treating motility disorders associated with altered intestinal contractile activity. However, recent studies have also revealed possible applications of intestinal electrical stimulation in obesity treatment[104]. IES applied to the duodenum reduces postprandial blood

glucose levels by modulating gastric emptying and the intestinal flow rate[105]. Both vagal and extra-vagal pathways are involved in the modulatory effects of IES on the central neurons of the satiety center[106]. Electrical stimulation of the stomach, intestine, or colon with long pulses has an inhibitory effect on gastric tone[107]. IES has been reported to alter intestinal slow waves, contractions and transit, effects that are mediated by both vagal and adrenergic pathways[108]. Duodenal stimulation in 12 healthy human volunteers did not induce dyspepsia, but it did reduce water intake and slowed gastric emptying[43]. Intestinal stimulation in dogs using seven sequential electrodes with a frequency of 24 cycles per minute, a pulse duration of 50 ms, and a pulse amplitude of 1-3 mA entrains the intestinal pacesetter. This treatment is effective at stimulating intestinal transit, even in the face of fat in the distal small intestine[109]. Intestinal stimulation in rats accelerates intestinal transit and reduces fat absorption[110]. Clinical trials of intestinal pacing in humans have yet to be reported.

Some potential mechanisms for the effect of gastric pacing in obesity

Obesity is the result of an imbalance between nutrient consumption, absorption, and energy expenditure[111]. GI motility regulates the rates at which nutrients are processed and absorbed and participates in controlling appetite and satiety *via* mechanical and neuro-hormonal pathways. The relatively extensive information on gastric pacing for motility disorders has shed light on the possible mechanisms of this treatment's beneficial effects on obesity. The effects of pacing may depend on the stimulus parameters and stimulation sites. Both the entrainment of intrinsic gastric electrical activity, eliciting propagating contractions and reducing symptomatology in patients with gastroparesis and reducing appetite and food intake in morbid obesity were suggested[112]. Additionally, gastric stimulation parameters have extra-gastrointestinal effects, including altering systemic hormonal and autonomic neural activity and modulating afferent nerve pathways projecting to the central nervous system[112].

Obesity that is induced by hypothalamic damage is associated with increased vagal tone, increased insulin secretion, increased food intake, and weight gain[113]. Performing a vagotomy below the diaphragm reverses the obesity caused by hypothalamic damage in rodents. Because trials have shown that placing a gastric pacemaker is the safest and simplest surgical treatment for morbid obesity, there has been considerable interest in defining the mechanisms by which it works[31]. Obesity seems to be associated with efferent vagal stimulation, which is inhibited by the Transcend pacemaker that is currently used. Short pulse widths and high-frequency stimulation induces gastric distention, inhibits postprandial antral contractions, and slows gastric emptying, which then leads to early satiety, reduced food intake and weight loss[114]. Cholinergic vagal efferents increase gastric tone,

while nitric oxide pathways decrease it[115]. Gastric stimulation blocks the efferent vagal pathway and releases nitric oxide pathways from inhibition, resulting in gastric dilatation[84,116,117]. The gastric slow waves are inhibited postprandially, which may also contribute to the delayed gastric emptying and promotion of satiety[118].

The decreased levels of GI hormones may be more compatible with depressed vagal tone than with vagal electrical stimulation of the pes anserinus area (the spreading zone of the vagal branches in the lesser curvature of the stomach). However, it is also possible that gastric pacing leads to parasympathetic hyperstimulation and the depletion of stored peptides, which may explain the reduced plasma levels of certain gastrointestinal hormones[8]. GES may also affect several brain areas associated with satiety and hunger, and may exert an effect on the hormonal gut-brain axis. Information on the current metabolic state is transmitted to the appetite control centers of the brain by a diverse array of signals, such as VN activity and metabolic "feedback" factors that are derived from the pituitary gland, adipose tissue, stomach, intestines, pancreas and muscle[12]. These signals act directly on the neurons located in the arcuate nucleus of the medio-basal hypothalamus, a key integration and hunger (orexigenic) and satiety (anorexigenic) control center of the brain[12].

CONCLUSION

Obesity is an epidemic disease that is increasing in prevalence and is associated with a rising incidence of diabetes. Behavior and lifestyle therapy are safe and effective treatments for obesity in the short term, but the durability of the weight loss is limited. Although promising obesity drugs are in development, the currently available drugs lack efficacy or have unacceptable side effects. Surgery leads to long-term weight loss, but it is associated with morbidity and mortality. GES is a promising, minimally invasive, safe, and effective method for treating obesity. Patient selection for gastric stimulation therapy seems to be an important determinant of the treatment's outcome[86,119-121]. Several approaches with different physiologic mechanisms are in various stages of development. The use of GES as an obesity treatment should produce exciting new developments in the foreseeable future.

Abstract

AIM: To investigate the effect of matrix metalloproteinase-9 (MMP-9) on the remnant liver after massive hepatectomy in the mouse.

METHODS: Age-matched, C57BL/6 wild-type (WT), MMP-9(-/-), and tissue inhibitors of metalloproteinases (TIMP)-1(-/-) mice were used. The mice received 80%-partial hepatectomy (PH). Samples were obtained at 6 h after 80%-PH, and we used histology, immunohistochemical staining, western blotting analysis and zymography to investigate the effect of PH on MMP-9. The role of MMP-9 after PH was investigated using a monoclonal antibody and MMP inhibitor.

RESULTS: We examined the remnant liver 6 h after 80%-PH and found that MMP-9 deficiency attenuated the formation of hemorrhage and necrosis. There were significantly fewer and smaller hemorrhagic and necrotic lesions in MMP-9(-/-) remnant livers compared with WT and TIMP-1(-/-) livers ($P < 0.01$), with no difference between WT and TIMP-1(-/-) mice. Serum alanine aminotransaminase levels were significantly lower in MMP-9(-/-) mice compared with those in TIMP-1(-/-) mice (WT: 476 ± 83 IU/L, MMP-9(-/-): 392 ± 30 IU/L, TIMP-1(-/-): 673 ± 73 IU/L, $P < 0.01$). Western blotting and gelatin zymography demonstrated a lack of MMP-9 expression and activity in MMP-9(-/-) mice, which was in contrast to WT and TIMP-1(-/-) mice. No change in MMP-2 expression was observed in any of the study groups. Similar to MMP-9(-/-) mice, when WT mice were treated with MMP-9 monoclonal antibody or the synthetic inhibitor GM6001, hemorrhagic and necrotic lesions were significantly smaller and fewer than in control mice ($P < 0.05$). These results suggest that MMP-9 plays an important role in the development of parenchymal hemorrhage and necrosis in the small remnant liver.

CONCLUSION: Successful MMP-9 inhibition attenuates the formation of hemorrhage and necrosis and might

be a potential therapy to ameliorate liver injury after massive hepatectomy.

INTRODUCTION

In the field of hepatobiliary surgery, liver resection is considered the standard treatment for primary liver tumor and colorectal liver metastases[1-3]. Major liver resections have been associated with an increased morbidity and mortality compared with more limited resections. In particular, the outcomes are worsened when a chronic underlying liver disease is present[4]. Recent studies have shown that the volume of the remnant liver is correlated with perioperative morbidity and mortality[5-7], and an insufficient hepatic remnant (IHR) after extended hepatectomy is a critical issue.

On the other hand, liver transplantation (LT) is the treatment of choice for end-stage liver diseases. However, in the LT field, donor shortage and small-for-size grafts (SFSGs) are critical issues. Although split-liver transplantation (SOLT) is promising, failure of SFSGs in adult LT recipients[8,9] and after extensive hepatectomy for metastatic cancer hinders its application[10]. SFSG failure results in postoperative coagulopathy, cholestasis, ascites, encephalopathy, and death[11,12]. The mechanisms of SFSG failure remain incompletely understood.

One mechanism that has been implicated in the early development of SFSG failure is the formation of parenchymal hemorrhage and necrosis[13,14]. Previous investigators used electron microscopic studies to demonstrate sinusoidal breakdown leading to hemorrhage and necrosis after chemically or endotoxin-induced liver failure[15-17], hepatic ischemia-reperfusion injury[18-19], extensive hepatectomy[18,20,21], and LT with SFSG or SOLT[22-25]. These findings suggested that although the inciting factors might have different causes, the pathogenesis of sinusoidal breakdown leading to hemorrhage and necrosis might be similar.

Matrix metalloproteinases (MMPs) comprise a family of zinc-dependent neutral proteases that can degrade the extracellular matrix and basement membrane. MMPs play significant roles in cellular regulation, cell-cell communication, and tumor progression[26,27]. MMP-2 and MMP-9 have been implicated in liver injury and remodeling. Knocking out MMP-9 and other MMPs attenuate liver injury associated with interferon treatment[28]. MMP-9 contributes to the pathogenesis of experimental acute liver failure[29]. Specifically, MMP-9 has been implicated in sinusoidal breakdown leading to extravasation of circulating cells and hemorrhage[14,30]. MMP-9 plays a pivotal role in ischemia-reperfusion injury[31-33]. When MMP-9 is blocked with a synthetic inhibitor or by MMP-9 gene deletion, it successfully reverses ischemia-reperfusion injury[34,35] and cold preservation-warm reperfusion injury after LT[35]. Collectively, these data show that MMP-9 is involved in sinusoidal injury in liver failure. However, the role of MMP-9 in the pathogenesis of failure in IHR or SFSGs is not well known.

We hypothesized that MMP-9 plays an important role in the development of liver parenchymal hemorrhage and necrosis in IHR/SFSG failure. Tissue inhibitors of metalloproteinases (TIMP)-1 are physiological tissue inhibitors of MMP-9, which increase MMP-9 activity when deleted[36,37]. We hypothesized that a deletion or decrease in MMP-9 has a beneficial effect after hepatectomy. In the current study, we examined this hypothesis in IHR after 80%-partial hepatectomy (PH) in wild-type (WT), MMP-9(-/-), and TIMP-1(-/-) mice. We also examined the efficacy of MMP-9 blockade with a monoclonal antibody and synthetic MMP-9 inhibitor.

MATERIALS AND METHODS

Animals

Male C57BL/6 mice (10-14 wk old) were obtained from Jackson Laboratory (Bar Harbor, ME), housed with a 12-h light/dark cycle, and given food and water *ad libitum*. MMP-9(-/-) mice, obtained from Dr. Robert Senior (Washington University, St. Louis, MO), and TIMP-1(-/-) mice, purchased from Jackson Laboratory, both with a C57BL/6 background, were bred in our facility. The study was institutionally approved in accordance with the National Institutes of Health "Guide for the Care and Use of Laboratory Animals".

PH in mice

Our institutional procedures for PH and postoperative care have been described elsewhere in detail[38]. Left and right posterior and left and right anterior segments were resected for an 80%-PH, similar to that described in a previous report[39]. In brief, under general anesthesia, liver lobes were mobilized. A hemostatic clip (Teleflex Medical, Triangle Park, NC) was applied across the pedicle, and the liver lobes were removed, without any obstruction of portal flow and hepatic venous drainage[38]. Laparotomy alone was performed for sham operations. Before closure, 2 mL of warm saline was administered

intraperitoneally. Cephalexin (30 mg/kg) and buprenorphine (0.1 mg/kg) were given subcutaneously. Postoperatively, the mice were kept in a temperature-controlled environment with free access to food and water. All mice were sacrificed 6 h after 80%-PH. The remnant livers were harvested, and blood samples were collected. We chose the extended hepatectomy model in mice because we hypothesized that MMP-9 plays an important role in the development of liver parenchymal hemorrhage and necrosis in IHR/SFSG failure.

MMP-9 inhibition by anti-MMP-9 monoclonal antibody and the MMP inhibitor GM6001

WT mice received 3 mg/kg of anti-MMP-9 neutralizing monoclonal antibody intravenously (clone 6-6B; EMD Chemicals, Gibbstown, NJ) 1 h before 80%-PH (MMP-9 mAb, $n = 6$). Control mice received normal IgG (EMD, Gibbstown, NJ) (control IgG, $n = 6$). The broad-spectrum MMP-inhibitor GM6001 (Millipore, Billerica, MA) at a concentration of 100 mg/kg in 10% dimethyl sulfoxide (DMSO) was administrated intraperitoneally 2 h before 80%-PH ($n = 10$), and controls received DMSO only ($n = 10$). An inhibitor of MMP-9 itself may affect liver regeneration after PH. Therefore, for the inhibition of MMP-9, we employed two inhibitory methods (*i.e.*, a monoclonal antibody and inhibitor) and used MMP-9(-/-) mice in this study.

Biochemical analysis

Serum levels of aspartate aminotransferase (AST) and alanine aminotransaminase (ALT) were determined by using a kinetic detection kit (Pointe Scientific, Inc, Canton, MI), and total bilirubin was determined by using the QuantiChrom™ Bilirubin Assay Kit (BioAssay Systems, Hayward, CA).

Western blotting analysis

Liver samples were homogenized in a buffer containing 10 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 1% Triton-X, 0.1% sodium dodecyl sulfate (SDS), 1 mmol/L ethylene diamine tetra-acetic acid (EDTA), 1 mmol/L ethylene glycol tetra-acetic acid, 1 mmol/L phenyl-methyl-sulfonyl fluoride, and protease and phosphatase inhibitors. Homogenates were centrifuged at 105 000 × *g* for 1 h at 4 ℃. Supernatants were collected, and protein concentration was determined by bicinchoninic acid assay (Pierce, Rockford, IL). Forty micrograms of protein was separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to a polyvinylidene fluoride membrane (Millipore, Bedford, MA). Membranes were blocked with 5% nonfat milk in Tris-buffered saline with Tween 20 [20 mmol/L Tris-buffered saline (pH 7.4), 500 mmol/L NaCl, and 0.05% Tween 20] and probed using the antibody for MMP-9 (R and D Systems, Minneapolis, MN), and were then incubated with peroxidase-conjugated secondary antibodies (Santa Cruz Biotechnology, Santa Cruz, CA) followed by enhanced chemi-luminescence (ECL) or ECL Plus reagent (Am-

ersham Biosciences, Piscataway, NJ). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) served as control (Imgenex Corporation, San Diego, CA). Signals were quantified by using ImageQuant software (Molecular Dynamics, Sunnyvale, CA).

Gelatin zymography

Liver homogenates were analyzed by gelatin zymography with affinity chromatography[40]. In brief, 400 µg of liver extract samples were incubated with 100 µL of gelatin-Sepharose 4B (GE Healthcare, Piscataway, NJ) and equilibrated buffer containing 50 mmol/L Tris-HCL pH 7.5, 150 mmol/L NaCl, 5 mmol/L CaCl₂, 0.02% Tween 20, and 10 mmol/L EDTA for 2 h at 4 ℃. After being washed three times, gelatin-Sepharose beads were resuspended in the same volume of 2 × zymography sample buffer (Bio-Rad Laboratories, Inc., Hercules, CA) and loaded onto a 10% SDS-PAGE gel containing 1 mg/mL of gelatin (Bio-Rad Laboratories, Inc.). After electrophoresis, the gel was washed twice for 30 min with 2.5% Triton X-100 for renaturing and then incubated in development buffer (Bio-Rad Laboratories, Inc.) for 20 h at 37 ℃. The gel was then fixed and stained with 0.5% Coomassie Blue R-250 (Bio-Rad Laboratories, Inc.) for 1 h and destained with 10% acetic acid in 40% methanol solution. Gelatinase zymography standards (Millipore, Billerica, MA) were used as a positive control.

Histology and immunohistochemical staining

Formalin-fixed, paraffin-embedded liver specimens in 5-µm sections were stained with hematoxylin and eosin. Immunohistochemical staining for CD11b (MAC-1) and CD68 was performed on frozen sections, and staining for desmin, myeloperoxidase, and MMP-9 was performed on paraffin-embedded sections after heat-induced antigen retrieval. We used 0.3% H₂O₂ to quench the endogenous peroxidase activity. An ABC kit (Vector Laboratories, Inc, Burlingame, CA) was used according to the manufacturer's instructions for HRP-based staining with 3,3' diaminobenzidine (DAB) tetrahydrochloride (Dako, Carpinteria, CA). Antibodies for MMP-9 [antigen affinity-purified, lyophilized from a 0.2 µm filtrated solution in phosphate buffered saline (PBS) with trehalose; AF909; R and D Systems, Minneapolis, MN], CD11b (clone M1/70, R and D Systems), CD68 (clone FA-11, Abcam Inc., Cambridge, MA), desmin (Abcam Inc.), and myeloperoxidase (Ab-1) (Thermo Scientific, Fremont, CA) were incubated for the primary reaction. Alexa Fluor 568 donkey anti-goat IgG (H + L), Alexa Fluor 488 donkey anti-rabbit IgG, and Alexa Fluor 488 donkey anti-rat antibody (Invitrogen, Carlsbad, CA) were used for secondary reactions.

Histological analysis

The HE-stained sections were scanned with a Scanscope XT system and analyzed with Aperio Imagescope software (Aperio Technologies, Inc., Vista, CA). Histologically positive areas were counted and measured by investigators blinded to the study group in three randomly

selected 3-mm^2 fields. DAB-positive staining of MMP-9 was calculated using the positive-pixel-count function of Imagescope software in 10 randomly selected fields. The value was quantified as the percentage of positive pixels per total pixels. The number of infiltrated neutrophils in the remnant liver was evaluated in five randomly captured 40 × high-power fields (hpf) with an Olympus BX50 fluorescence microscope (Olympus Optical, Tokyo, Japan).

In situ zymography

In situ gelatinolytic activity was determined using 20-μm cryostat sections for the EnzChek Gelatinase assay kit (Molecular Probes, Eugene, OR)[40]. Sections were incubated with 20 μg/mL of fluorescence-conjugated gelatin in reaction buffer (50 mmol/L Tris-HCl, 150 mmol/L NaCl, 5 mmol/L CaCl$_2$, and 0.2 mmol/L sodium azide) for 2 h at 37 ℃. After three washes with PBS, they were fixed in 4% paraformaldehyde. The sections were mounted with Vectashield (Vector Laboratories Inc., Burlingame, CA). Gelatinase activity was visualized using fluorescence microscopy (Olympus BX50; Olympus Optical, Tokyo, Japan).

Preliminary study

In our institution, 90%-PH (10% of the liver remnant with an omental segment), 80%-PH (20% of the liver remnant with right middle and omental segments) and 75%-PH (25% of the liver remnant with right middle and posterior segments) are available[38]. Initially, we performed 90%-PH in WT, MMP-9(-/-) and TIMP-1(-/-) mice, as a preliminary study. A survival study after 90%-PH was performed in each murine strain. Moreover, liver damage scores in HE staining[41], serum AST and ALT levels, and the ratios of terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling-positive nuclei/all nuclei per mm^2 and caspase 3-positive nuclei/all nuclei per mm^2 in immunohistological staining were assessed in serum or liver samples 6 h after 90%-PH in each murine strain. The results for each factor did not reach significant differences between WT and MMP-9(-/-) mice and between WT and TIMP-1(-/-) mice. Even in WT mice (control group), all mice received 90%-PH without any surgical issues but showed considerable damage and subsequently died in the early postoperative period. We therefore considered that 90%-PH is not suitable to investigate the effect of MMP-9 and TIMP-1 on the hepatic remnant after hepatectomy. To obtain relevant data according to clinical background[1-10], we finally employed 80%-PH in each strain for further experiments in this study. We decided to evaluate 80%-PH because mice could survive for a long time after surgery.

Statistical analysis

Data are presented as the mean ± SE. Statistical comparisons were performed using analysis of variance followed by a two-sample *t*-test with Bonferroni adjustment. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Parenchymal hepatic hemorrhage and necrosis occurs soon after 80%-PH

First, 80%-PH was performed in WT mice. Six hours after 80%-PH, the animals were killed and divided into two groups according to the status of parenchymal hemorrhage and necrosis in the remnant livers. Murine behavior in hepatic failure has been well described[42,43]. The animals with hemorrhage and necrosis were observed to be sick and inactive, whereas the mice without such injury were asymptomatic and active. As shown in Figure 1A and B, the groups consisted of mice with minimal or no hemorrhage and necrosis (group Ⅰ, *n* = 6) or those with multifocal hemorrhage and necrosis (group Ⅱ, *n* = 5). Group Ⅰ had a significantly greater area of necrosis (2.97% ± 0.92% *vs* 0.11% ± 0.08%, *P* < 0.05) (Figure 1C) and number of necrotic foci compared with group Ⅱ (3.60 ± 0.87 *vs* 0.26 ± 0.17, *P* < 0.01) (Figure 1D). Group Ⅱ had significantly higher AST (893 ± 72 IU/L *vs* 28 ± 12 IU/L, *P* < 0.05) (Figure 1E), ALT (744 ± 35 IU/L *vs* 32 ± 77 IU/L, *P* < 0.05) (Figure 1F) and total bilirubin levels than those in group Ⅰ (4.45 ± 0.63 mg/dL *vs* 1.41 ± 0.19 mg/dL, *P* < 0.01) (Figure 1G). These results suggested that group Ⅱ mice were in the process of liver failure, and these results are consistent with previous reports[13,44-46].

Focal and/or patchy necrosis is an important finding after hepatectomy[13,44]. Progressive necrosis is found from the early postoperative period[13,44-46]. We observed that parenchymal hemorrhage and necrosis occurred as early as 1 h after 80%-PH, and increased in number and size at 12 h and 24 h (data not shown), consistent with recent reports[13,44-46].

MMP-9 is upregulated in the remnant liver with hemorrhage and necrosis

MMP-9 has been implicated in acute liver failure[14,29]. We investigated MMP-9 expression in the remnant livers of both groups Ⅰ and Ⅱ 6 h after 80%-PH. Western blotting analysis demonstrated that MMP-9 was upregulated in group Ⅱ compared with group Ⅰ (*P* < 0.01) (Figure 2A and B). When we examined immunohistochemical staining for MMP-9, hepatocytes showed no expression of MMP-9. However, MMP-9 was mainly observed in round-shaped cells and in stellate-shaped cells (Figure 3A and B). To evaluate the association between necrosis and MMP-9, we compared the expression of MMP-9 in 10 randomly selected fields of 3-mm^2 in area with and without hemorrhage and necrosis. MMP-9 expression in the foci of hemorrhage and necrosis was higher than that in normal liver parenchyma (*P* < 0.05) (Figure 3C). These results suggest that MMP-9 expression is associated with the development of hemorrhage and necrosis in the remnant liver after 80%-PH, which is consistent with previous reports[14,29].

CD11b-positive neutrophils are the main source of MMP-9 in the remnant liver

To determine the source of upregulated MMP-9 in the

Figure 1 Histological and hematological differences between groups Ⅰ and Ⅱ at 6 h after 80%-partial hepatectomy. A: Histological findings in group Ⅰ mice; B: Representative images of remnant liver histology demonstrating significant multiple foci of hemorrhage and necrosis in group Ⅱ mice; C: Quantitation of the size (area percentage) of hemorrhage and necrosis: Significantly larger areas and more hemorrhagic and necrotic foci were observed in group Ⅱ mice than in group Ⅰ mice ([a]P < 0.05); D: Quantitation of the number of foci of hemorrhage and necrosis per mm^2: Significantly larger areas and more hemorrhagic and necrotic foci were observed in group Ⅱ mice than in group Ⅰ mice ([b]P < 0.01); E: Aspartate aminotransferase (AST) levels were significantly higher in group Ⅱ mice than those in group Ⅰ mice ([a]P < 0.05); F: Alanine aminotransaminase (ALT) levels were significantly higher in group Ⅱ mice than those in group Ⅰ mice ([a]P < 0.05); G: Total bilirubin levels were significantly higher in group Ⅱ mice than those in group Ⅰ mice ([b]P < 0.01).

remnant liver, we performed double immunofluorescent analysis with MMP-9 and cell marker antibodies. CD68 and desmin were used for Kupffer cells and hepatic stellate cells, respectively. MMP-9 was not observed in CD68-positive Kupffer cells (Figure 4A-C). Weak immunoreactivity to MMP-9 was observed in desmin-positive hepatic stellate cells (Figure 4D-F). In contrast, we consistently found MMP-9 expression in CD11b-positive cells (Figure 4G-I). These results suggest that infiltrating

neutrophils are the source of MMP-9 found in the foci of hemorrhage and necrosis in the remnant liver after 80%-PH, which is consistent with previous reports[28,35].

MMP-9 deletion reduces parenchymal hemorrhage and necrosis

To further confirm the role of MMP-9 in the development of liver hemorrhage and necrosis after 80%-PH, we performed liver resections in WT, MMP-9(-/-), and

Figure 2 Western blotting analysis for matrix metalloproteinase-9 in remnant livers with (group Ⅱ) and without (group Ⅰ) foci of hemorrhage and necrosis after 80%-partial hepatectomy. Representative immunoblot (A) and histogram (B) show enhanced expression of matrix metalloproteinase (MMP)-9 protein in group Ⅱ mice compared with that in group Ⅰ mice and sham controls ([b]$P < 0.01$).

TIMP-1(-/-) mice. TIMP-1 is a physiological tissue inhibitor of MMP-9, which increases MMP-9 activity when deleted[36,37]. We compared the size (area percentage) and the number of hemorrhagic and necrotic foci in the remnant livers. There were significantly fewer and smaller hemorrhagic and necrotic lesions in MMP-9(-/-) mice compared with WT and TIMP-1(-/-) mice (Figure 5A-C), (necrotic area: 0.49% ± 0.14% *vs* 1.74% ± 0.27% *vs* 1.82% ± 0.40%, $P < 0.01$, Figure 5D) (number of necrotic foci: 0.64 ± 0.18 *vs* 1.50 ± 0.21 *vs* 1.76 ± 0.39, $P < 0.05$, Figure 5E). There were no differences in the size and number of necrotic foci in WT and TIMP-1(-/-) animals.

Western blotting and gelatin zymography showed that MMP-9 expression and activity were present in WT and TIMP-1(-/-) mice but were absent in MMP-9(-/-) mice (Figure 6A and B). There was no difference in MMP-2 expression, a gelatinase, which is closely related to MMP-9, in the three groups of mice. In situ gelatin zymography showed significantly less MMP-9 activity in the remnant liver of MMP-9(-/-) mice compared with that in WT and TIMP-1(-/-) mice (Figure 6C-E). These results support our other findings that MMP-9 contributes to the development of parenchymal hemorrhage and necrosis in the remnant liver after 80%-PH.

MMP-9 deletion inhibits hepatic infiltration of neutrophils
To evaluate the effect of MMP-9 deficiency on hepatic neutrophil infiltration, we performed double immunofluorescent analysis of MMP-9 and myeloperoxidase,

Figure 3 Immunohistochemical staining for matrix metalloproteinase-9 in the remnant liver. A: Representative images of matrix metalloproteinase (MMP)-9 staining in a non-necrotic area in group Ⅱ; B: Representative images of MMP-9 staining in a necrotic area in group Ⅱ; C: Histogram of MMP-9 expression as described in the material and methods section: Enhanced MMP-9 expression was observed in areas close to the focus of necrosis ([a]$P < 0.05$).

as previously described[47]. As shown in Figure 7A-C, we identified myeloperoxidase-positive neutrophils by their characteristic staining pattern in cytoplasmic azurophilic granules[48]. There were significantly fewer infiltrated neutrophils in MMP-9(-/-) mice than in WT and TIMP-1(-/-) mice (3.3 ± 0.4 *vs* 7.0 ± 1.1 *vs* 6.0 ± 0.8 per hpf, $P < 0.05$) (Figure 7D). These results suggest that MMP-9 deletion inhibits neutrophil infiltration of the remnant liver after massive hepatectomy.

Inhibition of MMP-9 with MMP-9 mAb or GM6001 ameliorates liver hemorrhage and necrosis
We performed an MMP-9 inhibition experiment with a

Figure 4 Co-localization analysis by dual immunofluorescence in the remnant liver after 80%-partial hepatectomy. Co-localization analysis by dual immu-nofluorescence in the remnant liver for (A) matrix metalloproteinase (MMP)-9 labeled in red (Alexa Fluor 568), (B) CD68 labeled in green (Alexa Fluor 488), and (C) both MMP-9 and CD68; for (D) MMP-9 labeled in red (Alexa Fluor 568), (E) desmin labeled in green (Alexa Fluor 488), and (F) both MMP-9 and desmin; and for (G) MMP-9 labeled in red (Alexa Fluor 568), (H) CD11b labeled in green (Alexa Fluor 488), and (I) both MMP-9 and CD11b. These co-localization results demonstrate that MMP-9 protein expression is mainly localized in CD11b-positive cells, and to a lesser extent in desmin-positive cells.

specific MMP-9 monoclonal antibody (MMP-9 mAb) and the broad-spectrum MMP inhibitor GM6001, as previously described[40]. There were significantly smaller and fewer necrotic areas in the remnant liver in mice treated with MMP-9 mAb than in control IgG mice (necrotic area: $0.17\% \pm 0.15\%$ *vs* $1.81\% \pm 0.66\%$, $P < 0.05$; number of necrotic foci: 0.23 ± 0.16 *vs* 1.23 ± 0.44, $P < 0.05$) (Figure 8A and B). We showed inhibition of gelatinolytic activity with *in situ* gelatin zymography[40], which demonstrated significantly reduced MMP-9 activity in the MMP-9 mAb-treated group compared with that in the IgG-treated group (Figure 8C and D). Similarly, the number of infiltrated neutrophils was significantly lower in the group treated with MMP-9 mAb than that in the group treated with IgG (4.3 ± 1.1 *vs* 9.1 ± 1.9 per hpf, $P < 0.05$) (Figure 8E-G).

We observed similar results with GM6001. Treatment with GM6001 showed significant suppression of liver necrosis compared with the DMSO vehicle (necrotic area: $0.19\% \pm 0.13\%$ *vs* $1.04\% \pm 0.36\%$, $P < 0.05$; number

of necrotic foci: 0.35 ± 0.19 *vs* 1.12 ± 0.31, $P < 0.05$). Neutrophil infiltration was significantly suppressed in the GM6001 group compared with that in the DMSO group (5.5 ± 1.0 *vs* 9.2 ± 1.3 per hpf, $P < 0.05$). In situ zymographic analysis showed a significant reduction in gelatinolytic activity in the GM6001 group compared with that in the DMSO group (data not shown). Collectively, these results demonstrate that MMP-9 inhibition plays an important role in protecting mice from developing parenchymal hemorrhage and necrosis after 80%-PH.

DISCUSSION

IHR after extended liver resection or a SFSG after SOLT is prone to develop parenchymal hemorrhage and necrosis. Uncontrolled progression of the foci of hemorrhage and necrosis leads to liver failure. The role of MMP-9 in liver injury in the hepatic remnant has not been investigated. In this study, we investigated the role of MMP-9 in the development of hemorrhage and necrosis in IHR

Figure 5 Histological analysis in each strain. Histological analysis between wild-type (WT, *n* = 15) (A), matrix metalloproteinase (MMP)-9(-/-) (*n* = 15) (B), and tissue inhibitors of metalloproteinases (TIMP)-1 (-/-) mice (*n* = 14) (C) at 6 h after 80%-partial hepatectomy (PH). Representative images of remnant liver histology at 6 h after 80%-PH in WT, MMP-9(-/-), and TIMP-1(-/-) mice. Foci of hemorrhage and necrosis are denoted by white arrows. The percentage of the necrotic area (D) and the number of necrotic foci per mm^2 (E) in remnant livers of study mice are shown. Significantly smaller and fewer necrotic foci in the remnant liver were observed in MMP-9(-/-) mice compared with WT and TIMP-1(-/-) mice ($^a P < 0.05$, $^b P < 0.01$).

Figure 6 Expression and activity of matrix metalloproteinase-9. Expression and activity of matrix metalloproteinase (MMP)-9 were determined using (A) western blotting analysis for MMP-9 with glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as a control, (B) polyacrylamide gel electrophoresis gelatin zymography with human MMP-9 and -2 standards (S), and *in situ* fluorescence gelatin zymography in the remnant livers of wild-type (WT), MMP-9(-/-), and tissue inhibitors of metalloproteinases (TIMP)-1(-/-) mice at 6 h after 80%-partial hepatectomy. We observed MMP-9 protein expression and activity in WT mice (C), but they were absent in MMP-9(-/-) mice (D). Enhancement of MMP-9 protein expression and activity in TIMP-1(-/-) mice was observed (E).

Figure 7 Immunohistochemical analysis of accumulated neutrophils with myeloperoxidase staining in remnant livers of wild-type, matrix metalloproteinase-9(-/-), and tissue inhibitors of metalloproteinases-1(-/-) mice at 6 h after 80%-partial hepatectomy. Representative images of myeloperoxidase staining, labeled in green (Alexa Fluor 488), of cytoplasmic azurophilic granules in neutrophils (arrows) in wild-type (WT) mice in remnant liver sections in (A) WT, (B) matrix metalloproteinase (MMP)-9(-/-), and (C) tissue inhibitors of metalloproteinases (TIMP)-1(-/-) mice. A histogram shows the number of accumulated neutrophils in the remnant liver (D). Significantly fewer neutrophils were observed in the remnant liver in MMP-9(-/-) mice than in WT and TIMP-1(-/-) mice ($^aP < 0.05$, $^bP < 0.01$).

after 80%-PH in mice. We demonstrated that in IHR 6 h postoperatively, MMP-9 was upregulated in infiltrating neutrophils associated with the foci of hemorrhage and necrosis. Blocking MMP-9 expression by using a synthetic inhibitor, a specific monoclonal antibody, or gene deletion significantly ameliorated the formation of parenchymal hemorrhage and necrosis.

In the current study, we found that the number and percentage of necrotic foci were decreased in MMP-9(-/-) mice compared with WT mice. While TIMP-1(-/-) mice appeared to show slightly increased necrosis, there were no statistical differences between WT and TIMP-1(-/-) mice. TIMP-1 is a physiological tissue inhibitor of MMP-9[36,37], and therefore, MMP-9 activity is increased under the absence of TIMP-1[36,37]. Our results demonstrated that a decrease or absence of MMP-9 prevented liver injury, and that a physiological inhibitor of MMP-9, i.e., TIMP-1, caused similar liver damage in WT mice with IHR after 80%-PH. One possible explanation for the similar damage between WT and TIMP-1(-/-) mice is that liver injury after 80%-PH is very severe in these mice.

In our study of IHR after 80%-PH in mice, we found that infiltrating neutrophils carry MMP-9, which appears to be responsible for the development of hemorrhage and necrosis. This is consistent with previous reports[14,28,35]. Wielockx and colleagues showed that MMPs, including MMP-9, play a central role in the destruction of sinusoidal integrity, resulting in hemorrhage and necrosis[28]. They speculated that MMPs could be derived from infiltrating neutrophils, resident hepatic stellate cells, and Kupffer cells. Recently, hepatic stellate cells have been shown to play a critical role in acute liver failure induced by lipopolysaccharide and beta-galactosamine or carbon tetrachloride by releasing MMP-9, which disrupts sinusoid integrity leading to sinusoidal collapse and liver failure[29]. Similarly, in hepatic warm ischemia-reperfusion injury, hepatic MMP-9 and MMP-2 induce sinusoidal injury in a manner that is independent of neutrophil cytotoxicity[35]. Together, these data suggest that decreasing MMP-9 expression is useful to reduce early sinusoidal injury in IHR and SFSGs.

Inhibition of MMP-9 appears to be a potential therapeutic option in ischemic liver injury. In a previous study in rats, 70% of the liver was rendered ischemic for 90 minutes followed by reperfusion; a phosphinic MMP inhibitor attenuated the liver injury and necrosis[49]. Gene deletion of MMP-9 mitigates liver injury after 90 minutes of warm ischemia and reperfusion in mice[34,35]. Inhibition of MMP-9 has been shown to protect rat livers from cold preservation-warm reperfusion injury[34,35]. Interestingly, after cold ischemic preservation and warm reperfusion, it was found that MMP-9 and MMP-2 were not of hepatocellular origin but from an extrahepatic source[34,35]. Therefore, collectively, these data support MMP-9 reduction as a potential pathway to improve parenchymal integrity and function in IHR after extended liver resection or a SFSG after SOLT.

Figure 8 Effect of matrix metalloproteinase-9 monoclonal antibody on 80%-partial hepatectomy. A, B: Treatment with matrix metalloproteinase-9 monoclonal antibody (MMP-9 mAb) in mice with 80%-partial hepatectomy (PH) resulted in a significant reduction in the size (percent area) and number of hemorrhagic and necrotic foci 6 h after 80%-PH compared with treatment using control IgG ([a]$P < 0.05$); C, D: Suppression of MMP-9 activity as determined by *in situ* fluorescence gelatin zymography compared with control IgG-treated mice; E, F: There was significantly less myeloperoxidase staining (arrows) in remnant liver sections in mice treated with MMP-9 mAb compared with that in control IgG-treated mice; G: A histogram shows the number of accumulated neutrophils in the remnant liver 6 h after 80%-PH. Significantly fewer neutrophils were observed in MMP-9 mAb-treated mice than in control IgG-treated animals ([a]$P < 0.05$).

Although MMP-9 can cause liver injury in IHR after extended liver resection or SFSGs after SOLT, MMP-9 is also essential for liver regeneration[50]. It has been shown that MMP-9 releases hepatic growth factor from the hepatic extracellular matrix during the priming phase of liver regeneration[51,52]. Together with its physiological tissue inhibitor, TIMP-1, MMP-9 participates in regulating the hepatocellular cell cycle and proliferation[51]. MMP-9 is temporally correlated to angiogenesis and regeneration in the liver. Therefore, prolonged inhibition of MMP-9 might be clinically undesirable. Recent studies have suggested that inhibition of MMP-9 to ameliorate the early formation of parenchymal hemorrhage and necrosis should probably be started within and be limited to the first 2 d after extended liver resection or SOLT with SFSGs[50,52]. However, the use of MMP-9 inhibition in the clinical management of IHR or SFSGs requires further investigation and understanding to optimize its therapeutic effectiveness.

After extended liver resection or SOLT with SFSGs, portal hyperperfusion is likely to occur. Although increased portal hypertension is important in liver regeneration, uncontrolled acute portal hypertension with portal hyperperfusion can be detrimental[21,25,53]. In SOLT with SFSGs, portal hypertension and hyperperfusion are known to contribute to SFSL failure[25,54,55]. In experimental models[25,53,56] and in clinical LT with SFSGs[8,9,25,54,55], decompression of portal hyperperfusion has been shown to significantly attenuate hepatic hemorrhage and necrosis[57,58]. Evidence suggests that surgical and anatomical reduction of portal hyperperfusion is important in the management of IHR and SFSGs.

The molecular mechanisms by which portal hyperperfusion affects the outcome of IHR after extended hepatectomy and SFSGs after SOLT are poorly understood. Shear stress has been shown to induce nitric oxide production in microvascular endothelial cells[59], which might upregulate MMP-9 synthesis and production[60]. Reduction of portal hyperperfusion could thus indirectly mitigate the effect of MMP-9 production. However, it is not known how portal hyperperfusion relates to MMP-9 with respect to sinusoidal injury leading to parenchymal hemorrhage and necrosis. Other potential important mediators in the injury of IHR or SFSGs include oxidative stress[61] and tumor necrosis factor[62]. Understanding the role of MMP-9 and other signaling pathways will increase our ability to develop therapeutic options to heal and prevent liver injury associated with IHR and SFSGs.

Neutrophils have been consistently implicated in ischemia-reperfusion injury[19,35]. Neutrophils might produce and release MMPs that contribute to initiating sinusoidal injury[14]. Conversely, hepatic MMP-9 might be derived from hepatic stellate cells or sinusoidal cells, including endothelial cells and Kupffer cells[29]. Hepatic-derived MMP-9 might then attract neutrophils[30] into the liver after an injury. Neutrophils could then initiate and/or propagate sinusoidal hemorrhage and progressive necrosis[35]. Therefore, targeting neutrophils for treatment could be important in some diseases and conditions.

The limitations of this study include the following. Although MMP-9 is implicated in the formation of parenchymal hemorrhage and necrosis in IHR after 80%-PH, our study did not address how and where MMP-9 acts on the sinusoidal elements. The cascade of nitric oxide synthetase, which is important in upregulating MMP-9, was not examined[59,60]. Even though we did not observe constitutive MMP-9 in association with parenchymal hemorrhage and necrosis, we could not rule out the possibility that hepatic cells, including sinusoidal endothelial cells, Kupffer cells, and hepatic stellate cells[30], produced MMP-9 at a minute level that was adequate to initiate liver injury with subsequent recruitment of circulating neutrophils. The potential role of T cells was not evaluated[63]. The possibility of myeloperoxidase-associated oxidative inactivation of TIMP-1, thus activating MMP-9, was not considered in this study[64]. We consider that the effects of upregulation of MMP-9 on sinusoidal and endothelial cells should be investigated in detail.

Initially, we hypothesized that MMP-9 plays an important role in parenchymal hemorrhage and necrosis in the small remnant liver. We found significantly less hemorrhagic and necrotic lesions in MMP-9(-/-) remnant livers than in WT and TIMP-1(-/-) remnant livers. Similar results were observed with MMP-9 monoclonal antibody or the synthetic inhibitor GM6001. In conclusion, we demonstrated that MMP-9 plays an important role in the development of hepatic hemorrhage and necrosis in the small liver remnant 6 h after extensive partial hepatectomy. Moreover, we showed that infiltrating neutrophils are critical to the process of liver injury. Targeting MMP-9 could provide a clinically useful tool to optimize the function of a small liver volume, i.e., IHR after extended hepatectomy or SFSGs after SOLT.

ACKNOWLEDGMENTS

COMMENTS

Background

In the field of hepatobiliary surgery, liver resection is considered the standard treatment for primary liver tumors and colorectal liver metastases. Major liver resections have been associated with an increased morbidity and mortality compared with more limited resections. In particular, the outcomes are worsened when a chronic underlying liver disease is present. Recent studies have shown that the volume of the remnant liver is correlated with perioperative morbidity and mortality, and an insufficient hepatic remnant (IHR) after extended hepatectomy is a critical issue.

Research frontiers

Matrix metalloproteinases (MMPs) comprise a family of zinc-dependent neutral proteases that can degrade the extracellular matrix and basement membrane.

MMPs play significant roles in cellular regulation, cell-cell communication, and tumor progression. MMP-2 and MMP-9 have been implicated in liver injury and remodeling. Knocking out MMP-9 and other MMPs attenuates liver injury associated with interferon treatments. MMP-9 contributes to the pathogenesis of experimental acute liver failure. Specifically, MMP-9 has been implicated in sinusoidal breakdown leading to extravasation of circulating cells and hemorrhage. MMP-9 plays a pivotal role in ischemia-reperfusion injury. When MMP-9 is blocked with a synthetic inhibitor or by MMP-9 gene deletion, it successfully reverses ischemia-reperfusion injury. Collectively, these data show that MMP-9 is involved in sinusoidal injury in liver failure. However, the role of MMP-9 in the pathogenesis of failure in IHR is not well understood.

Innovations and breakthroughs

Initially, the authors hypothesized that MMP-9 plays an important role in parenchymal hemorrhage and necrosis in the small remnant liver. In this study, the authors found significantly less hemorrhagic and necrotic lesions in MMP-9(-/-) remnant livers than in wild-type and tissue inhibitors of metalloproteinases (TIMP)-1(-/-) remnant livers. Similar results were observed with a MMP-9 monoclonal antibody or synthetic inhibitor GM6001.

Applications

The authors demonstrated that MMP-9 plays an important role in the development of hepatic hemorrhage and necrosis in the small remnant liver 6 h after extensive partial hepatectomy. Moreover, the authors showed that infiltrating neutrophils are critical to the process of liver injury.

Terminology

Targeting MMP-9 could provide a clinically useful tool to optimize the function of a small liver volume, i.e., IHR after extended hepatectomy.

Peer review

Using MMP-9(-/-), wild type, and TIMP-1(-/-) mice, the authors demonstrated that in IHR at 6 h postoperatively MMP-9 is upregulated in the infiltrating neutrophils associated with the foci of hemorrhage and necrosis. Blocking MMP-9 expression by using a synthetic inhibitor, specific monoclonal antibodies, or gene deletion significantly ameliorated the formation of parenchymal hemorrhage and necrosis. The authors finally proposed that MMP is tightly associated with liver parenchymal hemorrhage and necrosis for insufficient liver remnant, which always leads a lethal outcome clinically.

Abstract

AIM: To investigate the effect of the demethylating reagent 5-aza-2'-deoxycitidine (DAC) on telomerase activity in hepatocellular carcinoma (HCC) cell lines, SMMC-7721 and HepG2.

METHODS: The related gene expression in cell lines was examined by real-time reverse transcription-polymerase chain reaction and Western blotting analysis. The telomerase activity was examined by telomeric repeat amplification protocol-enzyme-linked immunosorbent assay and DNA methylation was determined by methylation-specific polymerase chain reaction.

RESULTS: The telomerase activity was significantly reduced in both cell lines treated with DAC, accompanied by downregulation of telomerase reverse transcriptase (hTERT). We also observed the effect of DAC on the methylation status of hTERT promoter and the expression of regulatory genes, such as c-myc, p15, p16, p21, E2F1, and WT1. The methylation status of hTERT promoter could be reversed in SMMC-7721 by DAC, but not in HepG2 cells. However, p16 expression could be reactivated by demethylation of its promoter, and c-Myc expression was repressed in both cell lines. Moreover, DAC could enhance the sensitivity to the chemotherapeutic agents, such as cisplatin, by induction of apoptosis of HCC cells.

CONCLUSION: The DAC exerts its anti-tumor effects in HCC cells by inhibiting the telomerase activity.

INTRODUCTION

The demethylating reagent 5-aza-2'-deoxycitidine (DAC) inhibits DNA methyltransferases and reverses DNA me-

thylation[1]. It has been found that DAC can inhibit cancer cell growth, particularly the leukemia cells, and it has been applied for the treatment of myelodysplastic syndromes. A phase 1 study was finished using DAC as an antineoplastic drug for hematopoietic malignancies[2,3]. However, the mechanisms underlying its anticancer activity and other biological effects are not fully understood. It is believed to reactivate genes, including the tumor suppressor genes p16, E-cadherin, and hMLH1 in cancer cells. Reactivation of these genes is associated with cell cycle arrest and apoptosis, which leads to inhibition of tumor cell growth[4]. However, the mechanisms of telomerase activity and telomerase reverse transcriptase (hTERT) down-regulated by DAC remain unclear. Telomerase is an RNA-dependent DNA polymerase that synthesizes telomeric DNA sequences and almost universally provides the molecular basis for tumor cell proliferative capacity[5]. Telomerase reactivation is a critical step in cellular immortality and carcinogenesis[6,7]. The enzyme consists of three major components: hTERT, telomerase associated protein (TEP1), and telomerase RNA (TERC)[8]. Transcriptional regulation of hTERT is believed to be the major mechanism of telomerase regulation in human cells. Transient transfection experiments with hTERT promoter-luciferase reporters showed that the hTERT promoter is inactive in normal and transformed preimmortal cells but, like telomerase, is activated in immortal cells[9]. Expression of hTERT was observed at high levels in malignant tumors and cancer cell lines, but not in normal tissues or telomerase-negative cell lines, and a strong correlation has been found between hTERT expression and telomerase activity in a variety of tumors[10,11]. These findings suggest that expression of hTERT might be a critical event in carcinogenesis. Thus, the mechanisms of hTERT activation are essential for understanding the molecular basis of telomerase activation and carcinogenesis. The hTERT promoter contains binding sites for many transcription factors that could be involved in its regulation. The abundance of these potential transcription factor binding sites was subjected to various factors in different cellular contexts[12,13]. Several transcription factors are known to participate in hTERT gene expression, including positive regulators: c-Myc, Sp1, human papillomavirus 16 E6, and steroid hormones; and negative regulators: Mad1, p53, p15, p16, p21, E2F, pRB, WT1, interferon-α, tumor growth factor-β and myeloid cell-specific zinc finger protein[14,15]. Our previous studies revealed that methylation status of P21, P15, P16, WTI and E2F-1 was significantly associated with cancer tissues in hepatocellular carcinoma (HCC)[16]. In the present study, we observed the effect of DAC on telomerase activity and hTERT expression in HCC cell lines, and found that DAC down-regulated the telomerase activity and hTERT expression by p16 promoter demethylation.

MATERIALS AND METHODS

Cell lines and cell culture

Human hepatoma cell lines SMMC-7721 and HepG2 were maintained in Dulbecco's modified Eagle's medium (high glucose) (Gibco, Invitrogen, United States) and supplemented with 10% fetal bovine serum (GIBCO, Invitrogen, United States), 100 units/mL penicillin, and 100 mg/mL streptomycin in a humidified incubator under 95% air and 5% CO_2 at 37 ℃. Cells from exponentially growing cultures were used in all the experiments. This study was approved by the Institutional Ethics Committee of the Second Military Medical University, China.

DAC

Human hepatoma cell lines (SMMC-7721 and HepG2) were seeded at a density of 5×10^5 cells per well in 6-well tissue culture plates and were allowed to attach over a 24-h period. The demethylating reagent DAC (Merk, Calbiochem, United States) was added to a final concentration of 1 μmol/L, 2 μmol/L and 4 μmol/L and the cells grew for 1 d, 3 d and 5 d. At indicated time intervals, cells were harvested by trypsinization and washed with phosphate-buffered saline.

Assay of telomerase activity by telomeric repeat amplification protocol-enzyme-linked immunosorbent assay

Telomeric repeat amplification protocol-enzyme-linked immunosorbent assay (TRAP-ELISA) was performed using the telomerase kit Telo TAGGG Telomerase PCR ELISA PLUS (Roche Diagnostics, Mannheim, Germany) according to the manufacturer's instructions. Extracts from HEK293 cells were used as positive controls for the assay, and cell lysates heat-inactivated for 10 min at 85 ℃ were used as negative controls. Absorbance values were reported as the $A_{450 nm}$ reading.

Real-time reverse transcription-polymerase chain reaction

RNA was extracted from cells using Trizol (Invitrogen, Carlsbad, CA, United States). cDNA was synthesized using 2 μg total RNA and a moloney murine leukemia virus-reverse transcriptase kit with random hexamer primers and an RNase inhibitor (Takara Biotechnology Co. Ltd., Dalian, China). Polymerase chain reaction (PCR) amplifications of the respective genes were carried out with 40 ng complementary DNA, 500 nmol/L forward and reverse primer, and iTaqSYBRGreen Supermix (Bio-Rad Laboratories, Hercules, CA) in a final volume of 20 μL. Primer sequences and annealing temperature are summarized in Table 1. Real-time RT-PCR was performed on a Mastercycler cycler (Eppendorf, Hamburg, Germany), and all experiments were performed twice. Amplification of the housekeeping gene β-actin was performed to standardize the amount of sample RNA. Relative quantification of gene expression was performed by the -ΔΔct method.

Methylation-specific polymerase chain reaction

The bisulfite modification of DNA was done as described previously[17]. DNA methylation was determined

by methylation-specific PCR (MSP). Forty ng of bisulfite-modified DNA was subjected to PCR amplification. The PCR reaction mixture contained 2.5 µL of 10 × PCR buffer, 100 pmol of each primer, 2 mmol/L of each dNTPs, and 1 U of Hotstart Taq DNA polymerase (Takara Biotechnology Co. Ltd., Dalian, China) at a final volume of 25 µL. The PCR was performed in a thermal cycler. Primer sequences and reaction conditions are summarized in Table 1. DNA methylated by SssI methylase (Sss DNA) was used as positive control for methylated alleles.

Western blotting analysis

HepG2 and SMMC-7721 cells were lysed in RIPA lysis buffer (Beyotime, China) with 1 mmol/L phenylmethanesulfonyl fluoride (PMSF). An equal amount of protein was separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and transferred onto the nitrocellulose membrane. After blocking with 5% nonfat milk, the membrane was probed with anti-hTERT (Santa Cruz, United States), developed with the BeyoECL Plus substrate system (Beyotime, China). Blots were stripped and re-probed with β-actin antibody (Santa Cruz, United States) to confirm equal protein loading.

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide colorimetric assay and cell apoptosis analysis

The SMMC-7721 and HepG2 cells were seeded in 96-well plates and cultured with chemotherapeutic drugs and DAC for 3 d. The cells were examined by a colorimetric 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bro-

mide (MTT) (5 mg/mL, Sigma) assay. The spectrophotometric absorbance was measured using a plate reader at 570 nm. The morphology of apoptosis was observed by 4',6-diamidino-2-phenylindole (DAPI) staining. The cells were analyzed using a Facial Action Coding System (FACS) Aria flow cytometer (Becton Dickinson, San Jose, CA).

Statistical analysis

All of the experiments were repeated at least three times. The data were expressed as means ± SD. Statistical analysis was performed using Student's *t* test (two tailed). $P < 0.05$ was considered statistically significant.

RESULTS

Telomerase activity in HCC cells with DAC

To investigate the effects of DAC on telomerase activity, SMMC-7721 and HepG2 were cultured with 1 µmol/L, 2 µmol/L and 4 µmol/L DAC. Telomerase activity was measured by TRAP-PCR-ELISA assay after 1 d, 3 d and 5 d of exposure to DAC. Inhibition of telomerase activity was observed in both cell lines in a dose-dependent manner, by maximal repression on day 3 at 4 µmol/L or day 5 at 2 µmol/L DAC (Figure 1). There was a 52.7% reduction of telomerase activity in SMMC-7721 cells treated with 4 µmol/L DAC for 3 d, and a 45.6% reduction of telomerase activity in HepG2 cells. The results revealed that the effect of DAC on telomerase activity varied in different cell lines.

Effect of DAC on telomerase reverse transcriptase expression in HCC cells

Since the expression of hTERT is closely associated with telomerase activity, we examined whether hTERT expression is suppressed in SMMC-7721 and HepG2 cells by DAC. The expression of hTERT mRNA in SMMC-7721 cells was decreased to 82% on day 1, 34% on day 3, and 26% on day 5 after DAC treatment (2 µmol/L) (Figure 2). A decline in hTERT mRNA was also detected in HepG2 cells treated with DAC. hTERT mRNA expression was maximally down-regulated by 4 µmol/L DAC. The complete down-regulation of hTERT mRNA became apparent on day 3 of treatment and maximal on day 5 in both cell lines. Furthermore, we treated SMMC-7721 and HepG2 cells with 1 µmol/L, 2 µmol/L, 4 µmol/L DAC respectively for 3 d and 2 µmol/L for 1 d, 3 d, 5 d, respectively, then detected the hTERT expression in protein level by Western blotting analysis (Figure 3). The hTERT protein in SMMC-7721 and HepG2 cells was also down-regulated by DAC in a dose- and time-dependent manner, with maximal repression at 4 µmol/L on day 5. The hTERT protein was notably suppressed in both HepG2 and SMMC-7721 cells after treated by 2 µmol/L DAC for 3 d; however, the effect was more significant in SMMC-7721 cells. These results were in accordance with hTERT mRNA expression. The results indicated that inhibition of telomerase activity in HCC cells treated with DAC may contribute to a striking decrease in hTERT

Figure 1 Effect of 5-aza-2'-deoxycitidine on telomerase activity in human hepatocellular carcinoma cell lines SMMC-7721 (A) and HepG2 (B). Cells were incubated with DAC (1 μmol/L, 2 μmol/L or 4 μmol/L). Cell pellets were collected and subjected to telomeric repeat amplification protocol-enzyme-linked immunosorbent assay. [a]$P < 0.05$ (by unpaired Student's *t* test). Neg: Negative control; Pos: Positive control; DAC: 5-aza-2'-deoxycitidine. All studies are representative of at least three independent experiments.

Figure 2 Effect of 5-aza-2'-deoxycitidine on telomerase reverse transcriptase mRNA in hepatocellular carcinoma cell lines SMMC-7721 (A) and HepG2 (B). Cells were incubated with DAC (1 μmol/L, 2 μmol/L or 4 μmol/L). Cell pellets were collected and subjected to real-time reverse transcription-polymerase chain reaction assay. PC: Positive control; DAC: 5-aza-2'-deoxycitidine; hTERT: Human telomerase reverse transcriptase.

mRNA and protein.

Methylation of telomerase reverse transcriptase promoter in HCC cells by DAC

Since promoter methylation may be involved in hTERT repression in HCC cells, we observed the effects of DAC on promoter methylation of hTERT gene using MSP[18]. According to MSP analysis, the hTERT promoter was found to be hypermethylated in SMMC-7721, but not in HepG2 cells (Figure 4). The demethylation of hTERT was found in SMMC-7721 cells treated with DAC in a dose- and time-dependent manner, and there was complete demethylation after treatment with 5 μmol/L DAC for 3 d or 2 μmol/L for 3 d (Figure 4A). However, DAC showed no effects on hTERT methylation in HepG2 cells (Figure 4B). These data suggested that the demethylation of hTERT promoter by DAC could not play an important role in down-regulation of hTERT expression.

Expression of critical regulatory genes of telomerase reverse transcriptase transcription by DAC

We focused on some regulatory genes of hTERT transcription, such as c-myc, p15, p16, p21, E2F-1, WT1. Using real-time PCR, we examined the mRNA expression of these genes during exposure to DAC at 2 μmol/L for 1 d, 3 d and 5 d. The data showed that c-myc had high expression while p16 had low expression (SMMC-7721) or lost expression (HepG2) in hepatoma cells, and the other genes showed different levels of expression (Figure 5). The down-regulation

of c-myc and up-regulation of p16 mRNA expression were found in HCC cell lines treated with DAC. Western blotting analyses further revealed the significant levels of c-myc and p16 in both SMMC-7721 and HepG2 cells. These results suggested that c-myc and p16 could play an important role in down-regulating the hTERT expression by DAC.

Methylation of p16 promoter and reactivation of its expression by DAC

We reproduced the methylation pattern of p16 (Figure 6) using MSP. With DAC treatment, we detected increased demethylation of p16 promoter. The data suggested that promoter hypermethylation could causatively contribute to transcriptional silencing of p16, which up-regulated the hTERT transcription in HCC cells.

Human hepatoma cells sensitive to chemotherapeutic agents after DAC treatment

To determine whether DAC could effectively inhibit HCC cell growth, we treated SMMC-7721 and HepG2 cells with various doses of DAC for 72 h. We found that DAC inhibited the growth of cell lines in a dose-dependent manner (Figure 7). To determine whether the growth inhibition by DAC can be enhanced by chemotherapeutic agents, SMMC-7721 and HepG2 cells were treated with DAC in combination with cisplatin. Notably, while dramatic morphological changes were caused by combination of DAC with cisplatin, many cells revealed detachment and shrinkage. The growth inhibition was about 76% in

Figure 5 Effect of 5-aza-2'-deoxycitidine on expression of critical regulatory genes of telomerase reverse transcriptase transcription in hepatocellular carcinoma cell lines. A, B: Cells were incubated with 2 μmol/L DAC for 3-5 d, and subjected to real-time reverse transcription-polymerase chain reaction assay, [a]*P* < 0.05 (by unpaired Student's *t* test); C: Western blotting analysis of c-myc and p16 in hepatocellular carcinoma cell lines by DAC. The same blot was reprobed for β-actin as a loading control. DAC: 5-aza-2'-deoxycitidine.

the cells treated with DAC in combination with cisplatin (20 μmol/L) as compared with 54% in the cells treated with cisplatin alone, or 48% treated with DAC alone. These data suggested that DAC could enhance the sensitivity of HCC cells to chemotherapeutic agents such as cisplatin. With the administration of cisplatin and DAC, more cells revealed nuclear condensation and fragmentation of apoptotic cell death. These results were confirmed by Annexin-V and propidium iodide staining and FACS analysis (Figure 8). The cell apoptosis was significantly enhanced by the combined administration of 2 μmol/L DAC and 20 μmol/L cisplatin. These results suggested

that the enhanced effects of the combined treatment on cell death were attributed to the augmented induction of apoptosis.

DISCUSSION

The most widely used demethylating agent, DAC, was first characterized 30 years ago and it functions as a mechanism-dependent suicide inhibitor of DNA methyltransferases, with which genes silenced by hypermethylation can be reactivated[19]. It has been found that telomerase activity in cancer cells was inhibited by differ-

Figure 6 Demethylation of p16 promoter region and reactivation of p16 expression after 5-aza-2'-deoxycitidine treatment. Cells were incubated with 2 μmol/L DAC for 3-5 d and subjected to methylation-specific polymerase chain reaction (MSP) and real-time reverse transcription-polymerase chain reaction assay, respectively. M: Methylation; U: Unmethylation; Pos: Positive control. [a]$P < 0.05$ (by unpaired Student's *t* test). DAC: 5-aza-2'-deoxycitidine.

Figure 7 Sensitivity of SMMC-7721 and HepG2 cells to cisplatin enhanced by 5-aza-2'-deoxycitidine. A: Effects of DAC on growth inhibition. The hepatocellular carcinoma cell lines SMMC-7721 and HepG2 were treated with various doses of DAC for 72 h. Cell viability was determined by cell proliferation assay kit; B: The morphology of the cells was captured under a light microscope; C, D: SMMC-7721 (C) and HepG2 cells (D) cells were treated with 2 μmol/L DAC, 20 μmol/L cisplatin, or in combination for 72 h. Cell viability was determined by MTT assays. DAC: 5-aza-2'-deoxycitidine; Con: Control; CDDP: Cisplatin.

entiation, inducing demethylating agent DAC. We demonstrated that telomerase activity could be inhibited by DAC in HCC cells (HepG2 and SMMC-7721), and the demethylation of p16 promoter could play an important role.

Telomerase reactivation is a critical step in cellular immortality and carcinogenesis and is considered as a target for cancer treatment[8]. Our lab revealed that more than 85% HCC had much stronger telomerase activity than cirrhosis[16]. Drug-induced cell killing of tumor cells is as-

sociated with a decline in detectable telomerase activity[20]. In the present study, DAC inhibited telomerase activity and down-regulated hTERT expression in both human hepatoma cell lines SMMC-7721 and HepG2, and DAC suppressed the transcriptional activity of hTERT genes. Targeting telomerase activity is one of the mechanisms responsible for this reagent's inhibition of cancer cell growth.

On one hand, promoter methylation was associated with transcriptional silencing of the hTERT gene, as treat-

Figure 8 Apoptosis induced by 5-aza-2'-deoxycitidine. SMMC-7721 and HepG2 cells were treated with 2 μmol/L DAC, 20 μmol/L cisplatin, or in combination for 72 h. A: The fluorescent microscopic pictures of apoptotic cells were captured by 4',6-diamidino-2-phenylindole staining of the condensed and fragmented nuclei; B, C: Annexin V-fluorescein isothiocyanate (FITC) staining following facial action coding system analysis was shown for SMMC-7721 (B) or HepG2 cells (C). DAC: 5-aza-2'-deoxycitidine; Con: Control; CDDP: Cisplatin.

ment of cells with demethylating agent DAC resulted in an increase in hTERT transcription in an immortal fibroblast line SUSM-1[21]. On the other hand, DNA hypermethylation was implicated in the positive regulation of the hTERT promoter because demethylation in several telomerase-positive tumor cell lines reduced hTERT expression and telomerase activity accompanied by telomere shortening[22,23]. Our present study showed that hTERT promoter was methylated in SMMC-7721 cells, but not in HepG2 cells, and almost complete demethylation of hTERT promoter only occurred in the former cell line after DAC treatment. The explanation that CpG methylation likely interfered with the binding of transcriptional repressors, thereby positively regulating the hTERT promoter, may be reasonable for SMMC-7721 but not for HepG2. These findings suggested that hTERT promoter methylation is not the sole regulator of hTERT gene expression in HCC cells treated with DAC.

Several transcription factors are known to be responsible for the regulation of hTERT expression, including c-myc, p21, p16, p15, E2F-1 and Wilms' Tumor 1 suppressor gene[24]. This evidence prompted us to examine the effect of DAC on the expression of these genes. The c-myc was over-expressed while p16 expression was low or lost in hepatoma cell lines, and DAC repressed c-myc expression while reactivating p16. c-myc plays a critical role in telomerase activation through up-regulating the hTERT transcription, and this could be one mechanism by which 5-aza-CR represses hTERT transcription. Inactivation of p16-dependent pathways possibly in conjunction with telomerase activation might be a critical step for immortalization[25]. Our findings indicated that up-regulation of p16 and subsequent down-regulation of c-myc could be major pathways for hTERT repression by DAC.

Several evidences indicated that p16 expression could be transcriptionally silenced by CpG island hypermethylation in HCC[26]. The absence of expression and promoter methylation of p16 suggested that aberrant methylation is a major mechanism of the inactivation of p16 expression in HCC. Our data showed that DAC reversed p16 promoter methylation status and reactivated its expression, suggesting that p16 plays an important role in the down-regulation of telomerase activity by DAC.

In conclusion, the demethylating reagent 5-aza-CR represses telomerase activity and down-regulates hTERT expression. p16 could play a key role in this regulation. Our findings may provide insights into one of the mechanisms through which 5-aza-CR exerts growth-inhibitory effects on HCC cells.

COMMENTS

Background
The inactivation of tumor suppressor genes by aberrant DNA methylation plays an important role in the development of malignancies. An inhibitor of DNA methylation, 5-aza-2'-deoxycitidine (DAC), could inhibit telomerase activity in some cancer cell lines, but the molecular mechanism remains unclear.

Research frontiers
DAC can inhibit cancer cell growth, particularly leukemia cells, and it has been

applied for the treatment of myelodysplastic syndromes. Targeting telomerase activity is one of the mechanisms responsible for this reagent's inhibition of cancer cell growth.

Innovations and breakthroughs
The authors demonstrated that the demethylating reagent DAC represses telomerase activity and down-regulates telomerase reverse transcriptase (hTERT) expression. p16 could play a key role in this regulation.

Applications
By understanding the mechanism of DAC repressing telomerase activity, this study may represent a future strategy for the treatment of patients with hepatocellular carcinoma (HCC).

Terminology
Telomerase and hTERT is a critical step in cellular immortality and carcinogenesis and is considered as a target for cancer treatment. And several transcription factors such as c-myc and p16 were responsible for the regulation of hTERT expression. The DNA methylation could play an important role in telomerase activity.

Peer review
This is a nice paper that describes the role of an inhibitor of DNA methylation DAC on telomerase expression and activity in HCC cell lines. Work has been well designed, effects have been proved in more than one HCC cell lines and in general terms, conclusions are supported by the presented results.

Abstract

AIM: To investigate the role of *Lactobacillus crispatus* (*L. crispatus*) strain China Center for Type Culture Collection (CCTCC) M206119 in intestinal inflammation.

METHODS: Forty 8-wk-old Balb/c mice (20 ± 2 g) were divided into four groups of 10 mice each. Three groups that had received dextran sulfate sodium (DSS) were administered normal saline, sulfasalazine or CCTCC M206119 strain, and the fourth group received none of these. We assessed the severity of colitis using a disease activity index, measured the colon length and weight, collected stools and mesenteric lymph nodes for bacterial microflora analysis. One centimeter of the proximal colon, middle colon and distal colon were collected and fixed in 10% buffered formalin, dehydrated in ethanol, and embedded in paraffin. Interleukin (IL)-1β, IL-6 and tumor necrosis factor (TNF)-α expression was detected using reverse transcription polymerase chain reaction. Protective factors zonula occludens (ZO)-1 and β-defensin 2 were detected by immunoblot-

ting. The features of CCTCC M206119 strain were identified based on morphology, biochemical profile, and 16S RNA sequencing.

RESULTS: DSS-colitis animals treated with CCTCC M206119 had markedly more severe disease, with greater weight loss, diarrhea, fecal bleeding, and shortened colon length. In addition, the CCTCC-M206119-treated group had comparatively higher histological scores and more neutrophil infiltration than the controls. Expression of protective factors ZO-1 and β-defensin 2 was downregulated due to destruction of the mucosal barrier after CCTCC M206119 strain treatment. An *in vitro* assay demonstrated that CCTCC M206119 strain increased the nuclear translocation of nuclear factor-κB in epithelial cells. Intestinal proinflammatory or anti-inflammatory cytokine responses were evaluated. Proinflammatory colonic cytokine (IL-1β, IL-6 and TNF-α) levels were clearly increased in CCTCC-M206119-treated animals, whereas anti-inflammatory colonic cytokine (IL-10) level was lowered compared with saline or 5-aminosalicylic-acid-treated DSS-colitis mice. Next, CCTCC M206119 strain was characterized as *L. crispatus* by microscopic morphology, biochemical tests and 16S rRNA gene level.

CONCLUSION: Not all lactobacilli are beneficial for intestinal inflammation, and *L. crispatus* CCTCC M206119 strain is involved in exacerbation of intestinal inflammation in DSS-colitis mice.

INTRODUCTION

Inflammatory bowel diseases (IBD), including Crohn's disease and ulcerative colitis (UC), are characterized by an abnormal activation of the gut-associated immune system resulting in a chronic inflammation of the digestive tract[1]. It is widely accepted that a combination of genetic factors, immune disorders and environmental factors could be involved in the etiology of IBD[2]. Recent research has shown that some commensal and pathogenic bacteria are closely related to these diseases[3,4].

In acute dextran sulfate sodium (DSS)-induced colitis, bacteria and/or bacterial products play a major role in the initiation of inflammation but not in chronic DSS-colitis[5]. In the neonatal period, *IL-10* gene-deficient mice have decreased levels of colonic *Lactobacillus spp.* and an increase in colonic mucosal adherent and translocated bacteria. Normalizing *Lactobacillus spp.* levels reduces colonic mucosal adherent and translocated bacteria and prevents colitis[6]. Also, it is widely accepted that antibiotic treatment can definitely alleviate the clinical manifestation of UC. Various antibiotics have been shown to exhibit varying abilities to prevent and treat colitis in HLA-B27 rats and IL-$10^{-/-}$ mice[7,8]. Some authors recommended that where there are no bacteria, there is no colitis. Various IBD models in rodents reared under germ-free conditions are free of intestinal inflammation[6]. Increasing evidence supports that luminal microflora, or their products, are probably an important initiating factor in the pathogenesis of IBD[9].

Interestingly, facultative anaerobic Gram-positive bacteria and *Lactobacillus spp.* are decreased in patients with active UC, whereas bifidobacteria are decreased in fecal extracts from patients with Crohn's disease (CD)[10]. Another group has shown that bifidobacteria are reported to be deficient in rectal biopsies from patients with IBD and studies of fecal flora in patients with CD suggest a deficiency in both lactobacilli and bifidobacteria[11]. Furthermore, a marked decrease in intestinal *Lactobacillus spp.* precede the onset of colitis in *IL-10* gene deficient mice, and specific lactobacilli are relevant to disease induction or progression in the IL-10-deficient mouse model of colitis[12]. These studies offer strong evidence to support the view that an imbalance in the intestinal microflora triggers intestinal inflammation.

Microflora considered beneficial to the host includes the genera *Bifidobacterium* and *Lactobacillus*, whereas species potentially pathogenic include Enterobacteriacae and clostridia[4]. Therefore, maintaining or recovering the intestinal microflora or mucosa-associated bacteria in specific compartments has been proposed as a potential therapy to treat IBD[13]. For example, the administration of the VSL#3 probiotic cocktail delays relapse of pouchitis after surgical resection[14,15]. Probiotics have undergone investigation for their capacity to reduce the severity of a number of inflammatory conditions including pouchitis and UC. Also, some natural anti-inflammatory effects have recently been shown for *Lactobacillus salivarius*, *Lactobacillus crispatus* (*L. crispatus*), *Bifidobacterium* and *Lactobacillus plantarum* and *Lactobacillus casei* Shirota based on experimental colitis models[16-18].

Despite the wide usage of probiotics in controlling IBD, their efficacy is still controversial[19,20]. Thus, it is very difficult to draw a definitive conclusion in evaluating the role of microflora in pathogenesis of IBD, and subsequently, the efficacy of controlling IBD. Some published data have also questioned the safety of probiotics. The possibilities include possible adverse effects of probiotics in diseased or debilitated patients, rational bacterial selection, bacterial translocation, and microflora shift among individuals. Some published data have shown that lactobacilli isolated from IL-10-deficient mice failed to decrease tumor necrosis factor (TNF)-α production, whereas six lactobacillus isolates from mice without colitis significantly inhibited TNF-α production. This indicates that multiple strains of lactobacteria may be capable of probiotic activity but, conversely, that not all strains of lactobacteria have *in vitro* immunomodulatory activity[12]. Interestingly, it has been reported that *Lactobacillus rhamnosus* GG exacerbated acute DSS-induced colitis, demonstrated by increased colitic disease activity and histological damage score, however, in a chronic colitis model, a protective effect was observed[21].

In a previous study, we investigated and compared the effect of different *Lactobacillus* and *Bifidobacterium* strains, in a model of DSS-induced colitis[22]. When we screened to find some probiotics that can be potentially therapeutic, we came across a strain *L. crispatus* China Center for Type Culture Collection (CCTCC) M206119 that is capable of aggravating murine DSS-colitis. What was the possible mechanism? Does it mean that probiotics safety should be reconsidered?

In the present study, the promotive effects of strain CCTCC M206119 on the development of the inflammation were analyzed using a DSS-colitis model in BALB/c mice. We compared the effect of CCTCC M206119 administration, saline, and 5-aminosalicylic acid (5-ASA) treatment on DSS-colitis in mice. Thus, we tested *in vivo* and *in vitro* whether and how the CCTCC M206119 strain could aggravate epithelial damage of the colon, and indentified the features of CCTCC M206119 strain based on morphology, biochemical profiles, and 16S RNA sequencing.

MATERIALS AND METHODS

Bacterial strains and growth conditions

L. crispatus strain CCTCC M206119 was isolated from

Table 1 Experimental protocol for induction of dextran sulfate sodium-colitis

Groups	Experimental design
Healthy control	No DSS treatments
Negative control (saline)	5% (w/v) DSS dissolved in drinking water for 7 d
	Saline administered intragastrically once daily for 9 d
Positive control (5-ASA)	5% (w/v) DSS dissolved in drinking water for 7 d
	5-ASA administered intragastrically once daily for 9 d
Investigating group (CCTCC M206119)	5% (w/v) DSS dissolved in drinking water for 7 d
	CCTCC M206119 administered intragastrically once daily for 9 d

DSS: Dextran sulfate sodium; 5-ASA: 5-aminosalicylic acid.

Table 2 Scoring of disease activity index

Score	Weight loss (%)	Stool consistency	Occult/gross fecal bleeding
0	0	Normal	Negative
1	1-5		
2	5-10	Loose stool	Hemoccult
3	10-15		
4	> 15	Diarrhea	Gross bleeding

DAI = (combined score of weight loss, stool consistency, and bleeding)/3. Normal stool, well-formed pellets; Loose stool, pasty and semi-formed stool that does not adhere to the anus; Diarrhea, liquid stool that adheres to the anus.

Table 3 Histological score to quantify the degree of colitis

Score	Inflammation	Depth of lesions	Destruction of crypt	Width of lesions (%)
0	None	None	None	
1	Mild	Submucosa	1/3 basal crypt	1-25
2	Severe	Muscularis	2/3 basal crypt	26-50
3		Sera	Intact epithelium only	51-75
4			Total crypt and epithelium	76-100

human feces in the Division of Digestive Disease of the Second XiangYa Hospital (Changsha, Hunan, China), and kept at China Center for Type Culture Collection (CCTCC, Wuhan, China). *Lactobacillus* strains were grown at 37 ℃ in de Man, Rogosa and Sharpe (MRS) medium (Difco, MD, United States) without shaking.

Animals

Eight-week-old BALB/c mice of either sex were purchased from Hunan Agricultural University [SCXK (Xiang 2002-003)], and then bred under specific pathogen-free conditions. Mice were kept in ventilated and filtered cages, fed an irradiated diet, and housed on irradiated bedding. Food and water were supplied *ad libitum*. All animal experiments were performed in compliance with the guidelines of the Chinese government approved by the College BioResources ethical review board.

Preparation of bacterial strains and administration to mice

Bacterial strains were grown to an optical density at 600 nm of 3 to 4 (early stationary phase) at 37 ℃ in MRS medium anaerobically, harvested by centrifugation, washed with sterile neutral saline, and resuspended at 10^9 colony forming units (CFU)/mL in neutral saline. Three hundred microliters of this daily-prepared suspension was fed daily to the mice *via* intragastric gavage, whereas the controls (both UC-induced and healthy mice) received 300 μL neutral saline *via* the same procedure.

DSS-induced colitis model and experimental design

Eight-week-old Balb/c mice (20 ± 2 g) were divided into a healthy control group, negative control (normal saline) group, positive control (5-ASA, 6 mg/20 g) group, and investigation (CCTCC M206119 strain) group, with 10 mice in each. Normal saline (300 μL), sulfasalazine, CCTCC M206119 strain were administered intragastrically once daily for 2 d before starting DSS and continued for 7 d after DSS induction. Colitis was induced

by 5% (w/v) DSS (molecular weight 35 000-50 000; MP Biomedicals, Solon, OH, United States) dissolved in drinking water for 7 d (Table 1). The healthy control group received no DSS. Severity of colitis was assessed daily using a disease activity index (DAI). After the seventh day of induction of colitis, animals were euthanized by CO_2 asphyxiation. The colon lengths and weight were measured. Under aseptic technique, 300 mg stools and mesenteric lymph nodes (MLNs) were collected for bacterial microflora analysis. All the samples were placed immediately in sterile tubes containing 5 mL of transport medium. One centimeter of the proximal colon, middle colon and distal colon was collected and fixed in 10% buffered formalin, dehydrated in ethanol, and embedded in paraffin. The remaining tissues were immediately snap-frozen and stored at -80 ℃ [23,24].

Assessment of colitis DAI

The severity of colitis was assessed daily using a DAI based on the scoring system of Hamamoto *et al*[25], which scores body weight loss, stool consistency and occult/gross fecal bleeding (Table 2). Occult blood in feces was evaluated by means of Hemoccult II test (Beckman Coulter, Palo Alto, CA, United States).

Histology and histological grading

Tissue fixed with 4% (w/v) paraformaldehyde in phosphate buffered solution (PBS) was prepared for light microscopy, and 5-μm-thick sections were stained with hematoxylin and eosin to study histological changes. Grading of intestinal inflammation was determined as follows (Table 3)[26]. All scores were obtained in a blinded fashion by two independent investigators.

Table 4 Primers used to detect gene expression at mRNA level

Genes		Sequence of primers
GAPDH	Sense	5′-ATCACCATCTTCCAGGAGCG-3′
	Anti-sense	5′-CCTGCTTCACCACCTTCTTG-3′
IL-1β	Sense	5′-TTTTAATCAGCTATCCGGAC-3′
	Anti-sense	5′-TAATGGGAACGTCACACACC-3′
IL-6	Sense	5′-ATGAAGTTCCTCTCTGCAAGAGACT3′
	Antisense	5′-CACTAGGTTTGTTTAATCTC-3′
TNF-α	Sense	5′-ACGTGGAACTGGCAGAAGAG-3′
	Antisense	5′-GGTTGTCTTTGAGATCCATGC-3′

Analysis of colon microflora

Three-hundred-microgram fecal samples were dispersed in 2 mL PBS. Each pooled sample (0.1 mL) was serially diluted *via* 10-fold dilutions (from 10^{-1} to 10^{-10}). Eosin methylene blue agar, KULB agar, TTC azide dextrose agar and mannitol salt agar were used for the enumeration of *Enterobacteriaceae*, *Bacteroides*, *Enterococcus* and *Staphylococcus spp.*, respectively. Standard Nutrient Agar was used for the enumeration of total aerobic bacteria. All the plates were incubated at 37 ℃, aerobically, for 24-48 h and the number of colonies were counted. Brain-heart infusion agar and LAMVAB agar were used to enumerate bifidobacteria and lactobacteria, respectively. Anaerobic incubation was carried out in anaerobic jars (Oxoid, Basingstoke, Hants, United Kingdom) at 37 ℃ for 48-72 h. Anaerobic conditions were obtained using Anaerogen (Oxoid) and were checked using methyl blue strips as oxidation reduction indicator. CFUs were counted and expressed per gram of sample[27,28].

Myeloperoxidase activity

The extent of neutrophil infiltration was determined by myeloperoxidase (MPO) assay[29]. Briefly, 500 mg colon was homogenized in 1 mL iced 0.5% hexadecyltrimethylammonium bromide buffer. The aliquot was centrifuged (4000 *g*, 15 min) and the supernatant was diluted into 5% homogenates. A mixture of 0.1 mL 0.05% hydrogen peroxide and 0.9 mL 5% homogenates was vortexed to release MPO from the tissue. After incubation in 37 ℃ for 15 min, 0.2 mL mixture was added to 3 mL O-dianisidine reaction mixture and incubated for 30 min at 37 ℃. Sodium azide (50 μL, 2.0%) was added and incubated at 60 ℃ for 10 min. Absorbance of the reaction mixture was measured at 460 nm by spectrophotometer. Saline was used as a control. MPO activity was expressed as U/g tissue.

Nuclear translocation of nuclear factor-κB in CCTCC-M206119-stimulated HT-29 cells

HT-29 cells (purchased from Y-Y Chemical Reagent Co. Ltd., Shanghai, China) were cultured in RPMI 1640 medium (Gibco, Rockville, MD, United States) supplemented with 10% fetal calf serum under 5% CO_2 at 37 ℃ and divided into negative control, TNF-α (10 ng/mL) and CCTCC M206119 groups. CCTCC M206119 was diluted

to 10^9 CFU/mL with RPMI 1640 medium. HT-29 (3 × 10^6 cells) were cultured in 24-well tissue culture plates for 72 h and TNF-α or CCTCC M206119 was added. After 4 h of incubation, HT-29 cells were fixed in cold methanol for 5-15 min. The fixed cells were blocked in 5% bovine serum albumin (BSA)/PBS for 1 h on ice. We remove the blocking buffer and added primary antibody anti-nuclear factor (NF)-κB p65 (10 μg/mL) (MBL, Woods Hole, MA, United States; clone 8F11, rat IgG2a) diluted in PBS/0.3% Triton X100/1%BSA/1% serum overnight at 4 ℃ in a humidified chamber. After washing three times for 10 min with PBS on ice, the cells were incubated with anti-rabbit Cy3 (10 μg/mL) (Abcam, Cambridge, United Kingdom; polyclonal rabbit IgG) for 1 h at room temperature. The cells were mounted in Vectashield mounting medium (Vector Laboratories, Burlingame, CA, United States) with 4′,6′-diamidino-2-phenylindole hydrochloride after three washes in PBS at room temperature, and analyzed by a Nikon ECLIPSE E600 fluorescent microscope. The ratio of positive nuclear cells to total cells represented the nuclear translocation of NF-κB. The average number of positive stained cells within at least nine independent high power fields (400 × magnification) were determined microscopically and subjected to statistical analysis as indicated.

Reverse transcription polymerase chain reaction

Total tissue RNA was isolated using TRIzol reagent following the manufacturer's instructions For each sample, first-strand cDNA was synthesized using 1.0 μg total RNA with oligo dT23VN primer and M-MuLVuLV reverse transcriptase (Gibco). Five milliliters cDNA samples were amplified in 25 μL of a reaction mixture containing 10 × Taq buffer, 1.5 mmol $MgCl_2$, 5 μmol dNTPs (each), 10 μmol of each 5′ and 3′ primers, and 2 U TaqGold polymerase (Perkin-Elmer Cetus, Waltham, MA, United States). Polymerase chain reaction (PCR) was performed in a thermal cycler (GeneAmp Model 2400; Perkin-Elmer Cetus) for 22 cycles (94 ℃ for 30 s, 55 ℃ for 30 s, and 72 ℃ for 1 min), followed by a 10-min extension at 72 ℃. The PCR products (5 μL) were subjected to electrophoresis on 1.5% agarose gels and stained with 0.5 μg/mL ethidium bromide. Primers used in this paper are illustrated in Table 4.

Immunoblotting

Colon extracts (40 μg total protein) from each group of mice were resolved by SDS-PAGE under reducing conditions and transferred to a nitrocellulose membrane (Bio-Rad Laboratories, Hercules, CA, United States). The membrane was blocked with 5% nonfat dry milk overnight and incubated with a rabbit polyclonal antibody to zonula occludens (ZO)-1, β-defensin 2 (Lab Version, Fremont, CA, United States), with a rabbit polyclonal antibody to IL-1β, IL-6 or TNF-α (Santa Cruz Biotechnology, Santa Cruz, CA, United States), with a mouse monoclonal antibody to IL-10 (BD Biosciences, Franklin

Lakes, NJ, United States), or with an anti β-actin or glyceraldehyde-3-phosphate dehydrogenase (GAPDH) antibody (Affinity BioRegents, Golden, CO, United States) for loading control. Antigen-antibody binding was detected with horseradish-peroxidase-conjugated anti-rabbit or mouse IgG (Vector Laboratories) using enhanced chemiluminescence (Amersham Biosciences, Piscataway, NJ, United States).

Scanning electron microscopy
To investigate the characterization of CCTCC M206119 strain, 10^8 CFU/mL bacteria were grown for 18 h in MRS (Difco), washed with PBS and fixed with 2.5% glutaraldehyde. After two washings with PBS, samples were dehydrated with ethanol to the critical point, coated with 20 nm of gold in the scanning electron microscopy (SEM) coating unit, and examined by a XL30 ESEM scanning electron microscope (Philips, Eindhoven, Netherlands).

Biochemical profiling
CCTCC M206119 strain were grown on MRS agar and incubated under anaerobic conditions at 37 ℃ for 24-48 h. All isolates were visualized by Gram staining. Biochemical testing was performed with API 20A strips (BioMerieux, Hazelwood, MO, United States) according to the manufacturer's instructions. Catalase and SPOR tests were performed according to the supplier's recommendations (Becton Dickinson). G + C percentage was determined using high-performance liquid chromatography (HPLC) method in the Chemistry College of Central South University (China). Ten microliters base standard and 10 μL DNA hydrolase were injected into the HPLC sample injector and analyzed three times. The separating conditions used were as follows: 250 mm Zonbax-C18 column, 0.05 mol/L $NH_4H_2PO_4$ (pH 4.0) and acetonitrile mixture (20:1) as washing solution, 1 mL/min, moving phase: 2% acetonitrile, 98% 50 mmol/L NaH_2PO_4 buffered solution (pH 3.94), room temperature, detecting wavelength 254 nm and 270 nm, 0.1 mg/mL dA, dT, dG, dC solution used as external standard.

16S rRNA gene sequencing
Approximately 700 bp of the *16S rRNA* gene were amplified with primers 16S-F (5'-AGA GTT TGA TCA TGG CTC AG-3') and 16S-R (5'-CAC CGC TAC ACA TGG AG-3') under the following PCR conditions: 95 ℃ for 5 min; 10 cycles of 94 ℃ for 30 s, 70 ℃ for 30 s, and 72 ℃ for 40 s; 26 cycles of 94 ℃ for 30 s, 60 ℃ for 30 s, and 72 ℃ for 1 min; and 72 ℃ for 10 min. 16S rDNA amplicons were gel purified by using SDS-PAGE and a gel band purification kit (Amersham Biosciences). The 5' terminus of the *16S rRNA* gene was sequenced with primers 16S-F and 16S-R by using an ABI Prism 3100 (Applied Biosystems) sequencing system and an ABI Prism BigDye Terminator cycle sequencing ready reaction kit (version 2.0, Applied Biosystems). Sequencing traces of amplicons containing ambiguous signals were resubmitted for sequencing. rDNA sequences were ana-

lyzed by using Lasergene (version 5.0, DNAStar, Madison, WI, United States). Contigs were generated by using SeqMan. Isolates were identified by using the nucleotide-nucleotide Basic Local Alignment Search Tool (BLASTn) (www.ncbi.nlm.nih.gov/BLAST).

Statistical analysis
Data were analyzed by Student's *t* test or analysis of variance (ANOVA). The Wilcoxon signed-rank test was used to compare data that did not satisfy Student's *t* test. *P* < 0.05 was considered significant.

RESULTS

Colonic inflammation was aggravated in DSS-colitis mice after CCTCC M206119 treatment
Survival rate of DSS-colitis mice reduced to 80% from day 5 after CCTCC M206119 treatment changes, which differed from other groups significantly (Figure 1A). Body weight loss, stool consistency, and occult/gross fecal bleeding were evaluated and scored individually for each animal according (Table 2). The scores were evaluated statistically by χ^2 test and Monte Carlo exact test. CCTCC-M206119-treated DSS-colitis animals showed much higher DAI scores compared with 5-ASA- and saline-treated DSS-colitis mice, starting from day 3 after 5% DSS treatment (Figure 1B).

After 7 d of treatment, all DSS-colitis mice showed a significant reduction in their colon length compared with the healthy controls. CCTCC-M206119-strain-treated DSS-colitis mice had the shortest length (8.2 ± 0.68 cm), followed by saline- (9.8 ± 0.56 cm) or 5-ASA- (10.0 ± 0.89 cm) treated DSS-colitis mice (*P* < 0.05, Figure 1C). CCTCC-M206119-treated DSS-colitis mice had markedly more severe disease, with greater weight loss, diarrhea, fecal bleeding, and shortened colon length.

The histological lesions were examined blindly and the average scores were evaluated statistically by ANOVA. In the acute study, CCTCC-M206119-treated DSS-colitis mice presented scores of 10.9 ± 0.5 that differed statistically from those in the 5-ASA-treated DSS-colitis mice. It became evident that the CCTCC-M206119-treated DSS-colitis group had comparatively higher DAI scores than the saline controls (*P* < 0.01, Figure 1D and E).

Furthermore, there was significant difference in MPO enzymatic activity detected in the colons control mice (1.038 ± 0.012 U/g tissue), DSS plus saline group (18.368 ± 1.226 U/g tissue), DSS plus 5-ASA group (8.369 ± 0.652 U/g tissue), and DSS plus CCTCC M206119 group (24.565 ± 2.006 U/g tissue) (Figure 1F). This indicated that more neutrophils infiltrated DSS-colitis mice after CCTCC M206119 treatment.

CCTCC M206119 administration changed the fecal microflora in DSS-colitis mice
To characterize the role of CCTCC M206119 strain on potential gut flora shifts during DSS-induced barrier damage, we performed a bacterial-culture-based survey

Figure 1 Colonic inflammation was aggravated in dextran sulfate sodium-colitis mice after China Center for Type Culture Collection M206119 treatment. A: Survival rate changes of four age- and sex-matched BALB/c mouse groups (n = 10) [○ : Healthy controls; ● : 5% dextran sulfate sodium (DSS) plus saline treatment; △ : 5% DSS plus 5-aminosalicylic acid (5-ASA) treatment; ▲ : 5% DSS plus China Center for Type Culture Collection M206119] at the indicated time points; B: Disease activity index (DAI) changes among groups in (A) after 7 d 5% DSS treatment at the indicated time points. Each point represents the mean ± SE (n = 10); C: Mean colon length (cm) for the mice in (A); D: Histological analysis of representative colons from the mice in (A) (original magnification, hematoxylin and eosin staining, 100 ×); E: Summarized histological scores from colons of (D); F: Summarized myeloperoxidase (MPO) activities of colons from mice in (D).

of the gut flora in DSS-colitis mice treated with saline, 5-ASA, or CCTCC M206119 strain. No significant differences in total aerobic bacteria or *Enterococcus* were obtained for any of the groups. Bacterial counts of all fecal aerobic [*Escherichia coli* (*E. coli*), *Staphylococcus*, *Bacteroides*, or total aerobic bacteria] cultured in DSS-colitis mice increased significantly compared to the healthy group. Also, both *E. coli* and *Staphylococcus* increased in the saline group, whereas 5-ASA rebalanced the bacterial counts of *Staphylococcus* to normal levels (Figure 2A). In contrast, *Lactobacillus* in the colon lumen was reduced significantly in all DSS-colitis groups, with no significant changes in *Bifidobacterium* or *Enterococcus spp.* (Figure 2B).

To determine whether the changes in gut flora after

CCTCC M206119 treatment were due to alteration of the epithelial junction or antagonistic agents, we measured the expression levels of ZO-1 and β-defensin 2 from colons of DSS-colitis mice treated with saline or CCTCC M206119 and healthy mice, by western blotting. Expression of ZO-1 in healthy mice remained at an abundant level compared to all DSS-colitis mice. Treatment of mice for 5 d with 5% DSS plus saline reduced ZO-1 expression significantly compared to healthy mice, whereas 5% DSS plus CCTCC M206119 strain reduced ZO-1 expression dramatically at day 3. In contrast, no β-defensin 2 expression was detected in the healthy mice, with relatively high expression of β-defensin 2 detected in the colons in mice that were treated with 5 d of either

Figure 2 Alteration of fecal microflora in DSS-colitis mice after China Center for Type Culture Collection M206119 treatment. Bacterial counts of (A) aerobic (*Escherichia coli*, *Staphylococcus*, *Bacteroides*, total aerobic bacteria) and (B) anaerobic (*Bifidobacterium*, *Lactobacillus*, *Enterococcus spp.*) in colon luminal contents from healthy animals and dextran sulfate sodium (DSS)-colitis mice treated by saline, 5-aminosalicylic acid (5-ASA), or China Center for Type Culture Collection (CCTCC) M206119 strain at day 2 and day 7 after DSS-treatment, as determined by culture. The data sets were pooled from two independent experiments. Significance levels were determined by *U* test. Underlined *P* values shown in black were calculated from comparisons of healthy *vs* diseased animals; C: Zonula occludens (ZO)-1 and defensin 2 expression from colons of DSS-colitis mice treated with saline or CCTCC M206119 and healthy mice was measured by western blotting at indicated time points; GAPDH was used as a loading control. The data represent at least three experiments. [a]*P* < 0.05 *vs* healthy group. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

5% DSS plus saline or 5% plus CCTCC M206119. After 5 d exposure to 5% DSS plus CCTCC M206119, there was a significant (*P* < 0.05) decrease in β-defensin 2 level in the colons of mice relative to 5% DSS plus saline treatment (Figure 2C).

Effects of CCTCC M206119 strain on epithelial injury and translocation of NF-κB *in vitro*

Nuclear translocation of NF-κB p65 represents increased inflammation at the initiation stage. To investigate whether the aggravation of DSS-colitis after CCTCC M206119 strain treatment was due to the initiation of inflammation-related transcription, we detected the translocation of NF-κB p65 in HT-29 cells inoculated with CCTCC M206119 strain. TNF-α was used as a control. In the blank control, no positive staining for NF-κB p65 was detected. Both TNF-α and CCTCC M206119 strain upregulated the translocation of NF-κB p65 *in vitro*, with more positively stained cells in the latter group (*P* < 0.05, Figure 3A and B).

Colonic cytokines in CCTCC-M206119- or vehicle-treated DSS-colitis mice

To investigate if CCTCC M206119 administration affected the expression of colonic cytokines, we first screened the mRNA levels of the major colonic proinflammatory cytokines by semi-quantitative reverse transcription polymerase chain reaction (RT-PCR). We observed increased mRNA levels for IL-1 β, IL-6 and TNF-α from the colons of DSS-colitis mice treated with CCTCC M206119 strain or saline for 3 d. Also, it was evident that mRNA levels of IL-1 β, IL-6 and TNF-α from colons of CCTCC-M206119-treated DSS-colitis mice were significantly higher than those from colons of saline-treated DSS-colitis mice (Figure 4A). Next, we confirmed the changes in expression of the above cytokines at the protein level, suggesting that DSS treatment resulted in increased expression of proinflammatory cytokines, whereas DSS plus CCTCC M206119 strain treatment resulted in significantly higher expression of the cytokines mentioned above (Figure 4B).

Anti-inflammatory cytokine IL-10 expression from colons of DSS-colitis mice treated with saline, 5-ASA, or CCTCC M206119 was measured by western blotting. IL-10 expression was dramatically downregulated in saline- and CCTCC-M206119-treated DSS-colitis mice, with more significant changes in the latter group. In contrast, 5-ASA upregulated IL-10 expression compared to saline-treated DSS-colitis mice (Figure 4C). It indicated that CCTCC M206119 treatment inhibited the expression of anti-inflammatory cytokine in DSS-colitis mice.

Characteristics of CCTCC M206119 strain

Distinct microscopic morphological features were observed after Gram staining of broth-grown CCTCC M206119 strain. Gram-positive, rod-shaped morphology could be distinguished (Figure 5A). Under SEM, CCTCC M206119 strain showed exclusively smooth rod-

Figure 3 Effects of China Center for Type Culture Collection M206119 strain on epithelial injury and translocation of nuclear factor-κB *in vitro*. Immunofluorescence staining for nuclear factor (NF)-κB p65 (red) and 4',6'-diamidino-2-phenylindole hydrochloride (DAPI) (blue) in HT-29 cells treated either by tumor necrosis factor (TNF)-α or China Center for Type Culture Collection (CCTCC) M206119 (scale bars, 10 mm). Error bars indicate mean ± SD (n = 3).

or fork-shaped morphology, without spores, flagella or capsules (Figure 5A). Based on analysis of the peak and data of base C, G, T and A, G + C mol% of CCTCC M206119 strain was determined as 58.64% (Figure 5B). All CCTCC M206119 strains tested were unable to utilize indepamide, urea enzymes and gelatin. All strains tested were able to utilize glucose, mannitol, lactose, saccharose, maltose, salicin, L-xylose, arabitol, esculin, glycerol, cellobiose, MNC, melezitose, D-raffinose, sorbitol, rhamnose, and trehalose. All strains were found to be catalase negative [at 3% (v/v) H_2O_2]. With discriminant and factorial analyses of data from all biochemical tests, a presumptive identification scheme for CCTCC M206119 strain was formulated based on biochemical properties. In conjunction with Gram stain morphology, biochemical profiling can be used to differentiate among major groups of lactobacilli (up to 95% confidence interval). In our abbreviated identification scheme, CCTCC M206119 strain can be presumptively grouped into lactobacilli when biochemical tests are combined with microscopic morphology (Figure 5C). To verify the identities of the reference strains used in this study, 16S rRNA genes were amplified and sequenced. With BLASTn, CCTCC M206119 strain was determined as *L. crispatus* at the *16S rRNA* gene level (Figure 5D).

DISCUSSION

IBD, including CD and UC, are chronic immune-mediated diseases in which endogenous bacteria are thought to play an important role, as suggested by many clinical observations and experimental studies summarized in recent reviews[1]. Recent studies have also shown that some bacterial strains or mixtures may have the capacity to promote or reduce intestinal inflammation[4].

Although the pathogenesis of IBD remains elusive, the relevance of intestinal luminal bacteria in the initiation and progression of chronic intestinal inflammatory disorders is gaining support[30]. However, no specific microorganism has been associated with the pathogenesis of IBD, suggesting that qualitative/quantitative differences in the intestinal microbiota may play some role in the initiation or perpetuation of intestinal inflammation.

In the current study, we compared the phenotypes of DSS-colitis mice treated by saline, 5-ASA, and CCTCC M206119 strain, trying to determine the role of the probiotic bacterium. We demonstrated that CCTCC M206119 treatment reduced survival rate of DSS-colitis mice. CCTCC-M206119-treated DSS-colitis animals had markedly more severe disease, with greater weight loss, diarrhea, fecal bleeding, and shortened colon length. In addition, the CCTCC-M206119-treated DSS-colitis group had comparatively higher histological scores and more neutrophil infiltration than the controls. To our surprise, CCTCC M206119 strain could be characterized as *L. crispatus* by microscopic morphology, biochemical tests and *16S rRNA* gene level. Hence, our study suggested that not all probiotics are safe for treatment of colitis. Instead, probiotics safety should be carefully evaluated before their application.

Other recent studies also have shown supporting evidence. A strain of *Lactobacillus salivarius* was isolated from blood and bile pus cultures of a 70-year-old man with bacteremic acute cholecystitis[31]. Administration of different lactobacilli and a *Bifidobacterium* strain in an acute liver injury rat model has shown different effects on bacterial translocation and hepatocellular damage. *Bifidobacterium animalis* NM2 increases bacterial translocation to the MLNs but does not affect hepatocellular damage[32]. Together with our data, some probiotics could act as op-

portunistic pathogens and result in endogenous infection unexpectedly. Also, some researchers have demonstrated that the activities to promote endogenous infections are strain specific.

As we know, most lactobacilli have a remarkable record of safety and have been consumed by humans for decades. However, the possible involvement of certain strains has been described in cases of sepsis, endocarditis, or bacteremia; mostly in association with a severe underlying disease

or detrimental condition[33]. In view of these facts, the safety of potential probiotic microorganisms in these conditions should be assessed individually. Bacterial translocation (BT) is most likely the first step in the possible passage of viable (indigenous) bacteria to sterile body sites and is thus important for sepsis, endocarditis, and bacteremia caused by the commensal flora. In animal studies, mono association experiments have shown that the type of colitis is dependent on the bacterial species[12,34].

Based on our research, *E. coli* and staphylococci were increased in DSS-colitis mice, whereas lactobacilli in the colon luminal contents were reduced significantly in all DSS-colitis groups, with no significant changes in *Bifidobacterium* or *Enterococcus spp*. Furthermore, our data indicated that changes in gut flora after *L. crispatus* CCTCC M206119 treatment were related to reduced ZO-1 expression and increased β-defensin 2 expression. Our *in vitro* experiment showed that both TNF-α and CCTCC M206119 strain upregulated the nuclear translocation of NF-κB p65, with more positively stained cells in the latter group. Other studies have found that NF-κB can be activated in both intestinal epithelium and intestinal lamina propria mononuclear cells (LPMCs) in acute DSS-colitis mice[35,36]. Intrarectal administration of a*ntisense* oligonucleotides to NF-κB P65 could alleviate the in-

flammation[24,37]. Thus, it is reasonable to conclude that *L. crispatus* CCTCC M206119 strain exacerbated the imbalance of gut flora; changed the pathogen species or colonies adhered to the colonic mucosa; subsequently altered the expression of tight junction proteins and antibacterial molecules; and activated nuclear translocation of NF-κB p65 in epithelium or inflammatory response cells.

It is thought that IBD might be due to complex mucosal immune responses to antigens of resident enteric bacteria[38-40]. IL-1 and IL-6 have been shown to be the major cytokines secreted by lamina propria cells and play a critical role in the development of Th1-cell-mediated chronic colitis[41]. Recombined IL-1 receptor antagonist can alleviate the mucosal inflammation and necrosis in DSS-coltis mice[42]. DSS-induced colitis was less severe in *IL-6* gene knockout mice, whereas transgenic mice with a mutant *CIS/SOCS3* gene, encoding a negative regulator for the IL-6/STAT3 (signal transducer and activator of transcription) signaling pathway, had increased susceptibility to DSS-induced colitis[43]. In our study, we found that both mRNA and protein levels of IL-1 β, IL-6 and TNF-α from colons of CCTCC-M206119-treated DSS-colitis mice were significantly higher and earlier than those from colons of saline-treated DSS-colitis mice. In contrast, we found that expression of anti-inflammatory

cytokine IL-10 was dramatically downregulated in saline- and CCTCC-M206119-treated DSS-colitis mice, with more significant change in the latter group. This indicated that DSS treatment resulted in increased expression of proinflammatory cytokines and decreased anti-inflammatory cytokines, whereas DSS plus CCTCC M206119 treatment resulted in significantly higher and earlier expression of the proinflammatory cytokines and inhibited the expression of anti-inflammatory cytokine in DSS-colitis mice.

IL-10 can inhibit the expression of IL-1α, IL-1β, IL-6, IL-12, IL-18, granulocyte-macrophage colony-stimulating factor (GM-CSF), G-CSF, M-CSF, TNF, leukemia inhibitory factor and platelet activating factor produced by activated monocytes or macrophages. It exerts strong immune inhibitory function[8] and plays a major role in the immune tolerance of intestinal mucosa[9,10]. Thus, it is possible that administration of *L. crispatus* CCTCC M206119 strain interrupts the balance between anti-inflammatory and proinflammatory responses in colonic mucosa or lamina propria after DSS treatment, and leads to subsequently aggravated colonic inflammation. These processes are similar to those observed in UC patients[11].

Thus, our hypothesis in this study is as follows: some bacteria or bacterial products, such as *L. crispatus* CCTCC M206119, may interact directly with colonic epithelial cells or LPMCs after disruption of the mucosal barrier and balance of gut flora by DSS administration. Then neutrophils and mononuclear cells infiltrate the lamina propria and activate NF-κB translocation, which in turn increases proinflammatory cytokines such as IL-1β, IL-6 and TNF-α. Furthermore, TNF-α can augment NF-κB activation in various cell types, and inhibit the production of anti-inflammatory cytokines such as IL-10 (Figure 6).

Overall, human IBD trials to date have suggested that probiotics display no overt side effects, but conflicting reports on probiotic efficacy highlight the importance of selecting well-characterized probiotic strains and in delivering intact pharmaceutical formulations at an appropriate dose level to the inflamed regions of the intestine. These studies have emphasized that certain probiotic strains need to be thoroughly investigated *in vitro* and *in vivo* using appropriate disease models. Also, some probiotics such as *L. crispatus* CCTCC M206119 might act as aggravating factors in the pathogenesis of UC. Future studies to identify associations between microorganisms (and or their genes and gene products) and human physiological or disease processes will lead to the development and testing of hypotheses that address causality as well as a myriad of specific host-microbe interactions.

COMMENTS

Background

It is widely accepted that a combination of genetic factors, immune disorders and environmental factors could be involved in the etiology of inflammatory bowel disease (IBD). Recent research has illustrated that some commensal and pathogenic bacteria are closely related to IBD. However, to date, the role of bacteria in the pathogenesis of IBD, or the efficacy of probiotics is still controversial.

Research frontiers

The efficiency of probiotics in controlling IBD is still controversial. Thus, it is difficult to draw a definitive conclusion in evaluating the role of microflora in the pathogenesis of IBD, and subsequently, the efficacy in controlling IBD. Some published data have also questioned the safety of probiotics.

Innovations and breakthroughs

Microflora considered beneficial to the host include the genera *Bifidobacterium* and *Lactobacillus*. In this context, several candidate strains were screened to find some probiotics as therapeutics using dextran sodium sulfate (DSS)-induced colitis in mice, and China Center for Type Culture Collection (CCTCC) M206119 strain led to an exacerbated phenotype of DSS-colitis mice. Expression of protective factors zonula occludens-1 and β-defensin 2 was downregulated after CCTCC M206119 treatment. There was an increase in the nuclear translocation of nuclear factor-κB in epithelial cells. Then, intestinal proinflammatory and anti-inflammatory cytokine responses were evaluated. Proinflammatory colonic cytokines [interleukin (IL)-1β, IL-6 and tumor necrosis factor-α] levels were clearly increased in CCTCC-M206119-treated animals, whereas anti-inflammatory colonic cytokine (IL-10) level was lowered compared with saline- or 5-ASA-treated DSS-colitis mice. Next, CCTCC M206119 strain was identified as *Lactobacillus crispatus*, so it was concluded that not all lactobacilli strains have beneficial effects on intestinal inflammation and that *Lactobacillus crispatus* (*L. crispatus*) CCTCC M206119 is involved in exacerbation of intestinal inflammation in DSS-colitis mice.

Applications

The study results suggest that some probiotics such as *L. crispatus* CCTCC M206119 strain might act as an aggravating factor in the pathogenesis of ulcerative colitis (UC). They also highlight the importance of selecting well-characterized probiotic strains and in delivering intact pharmaceutical formulations at an appropriate dose level to the inflamed regions of the intestine.

Terminology

IBD is a group of inflammatory conditions of the colon and small intestine, including Crohn's disease and UC, which are characterized by abnormal activation of the gut-associated immune system, resulting in chronic inflammation of the digestive tract. *Lactobacillus* is a genus of Gram-positive facultative anaerobic or microaerophilic rod-shaped bacteria. They are a major part of the lactic acid bacteria group, named as such because most of its members convert lactose and other sugars to lactic acid. They are common and usually benign.

Peer review

In this study, the authors investigated the role of CCTCC M206119 strain on intestinal inflammation using a DSS-induced colitis mice model. They showed that CCTCC M206119 strain was identified as *L. crispatus*, but this strain was involved in the exacerbation of intestinal inflammation in DSS-colitis mice. From these results, the authors concluded that not all lactobacilli strains have beneficial effects on intestinal inflammation. This paper has been well written and the results are interesting.

Abstract

AIM: To assess the characteristics and quality of endoscopic ultrasonography-guided fine needle aspiration (EUS-FNA) in a large panel of endosonographers.

METHODS: A survey was conducted during the 13th annual live course of endoscopic ultrasonography (EUS) held in Amsterdam, Netherlands. A 2-page questionnaire was developed for the study. Content validity of the questionnaire was determined based on input by experts in the field and a review of the relevant literature. It contained 30 questions that pertained to demographics and the current practice for EUS-FNA of responders, including sampling technique, sample processing, cytopathological diagnosis and sensitivity of EUS-FNA for the diagnosis of solid mass lesions. One hundred and sixty-one endosonographers who attended the course were asked to answer the survey. This allowed assessing the current practice of EUS-FNA as well as the self-reported sensitivity of EUS-FNA for the diagnosis of solid mass lesions. We also examined which factors were associated with a self-reported sensitivity of EUS-FNA for the diagnosis of solid mass lesions > 80%.

RESULTS: Completed surveys were collected from 92 (57.1%) of 161 endosonographers who attended the conference. The endosonographers had been practicing endoscopy and EUS for 12.5 ± 7.8 years and 4.8 ± 4.1 years, respectively; one third of them worked in a hospital with an annual caseload > 100 EUS-FNA. Endoscopy practices were located in 29 countries, including 13 countries in Western Europe that totaled 75.3% of the responses. Only one third of endosonographers reported a sensitivity for the diagnosis of solid mass lesions > 80% (interquartile range of sensitivities, 25.0%-75.0%). Factors independently associated with a sensitivity > 80% were (1) > 7 needle passes for pancreatic lesions or rapid on-site cytopathological evaluation (ROSE) ($P < 0.0001$), (2) a high annual hospital caseload ($P = 0.024$) and (3) routine isolation of microcores from EUS-FNA samples ($P = 0.042$). ROSE was routinely available to 27.9% of respondents. For lymph nodes and pancreatic masses, a maximum of three needle passes was performed by approximately two thirds of those who did not have ROSE. Microcores were routinely harvested from EUS-FNA samples by approximately one third (37.2%) of survey respondents.

CONCLUSION: EUS-FNA sensitivity was considerably lower than reported in the literature. Low EUS-FNA sensitivity was associated with unavailability of ROSE, few needle passes, absence of microcore isolation and low hospital caseload.

thology; Endoscopic ultrasonography; Histopathology; Quality improvement

INTRODUCTION

Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) has become widely available in a variety of endoscopy settings. Due to its high diagnostic accuracy, EUS-FNA plays an important role in the management of masses located in or close to the gastrointestinal tract. For example, median sensitivity of EUS-FNA to differentiate between benign and malignant masses of the pancreas (technically the most difficult location)[1], is reported to be greater than 80%[2]. Such a high sensitivity for malignancy diagnosis has allowed EUS-FNA to significantly impact patient management in various clinical situations, including pancreatic cancer[3], mediastinal lesions[4,5], lung cancer[6], and solid liver lesions[7,8].

Excellent results of EUS-FNA such as those cited above have mostly been reported by dedicated endoscopists, many of them working in academic centers. The quality of EUS-FNA in the endosonographer population is poorly known, despite the fact that the quality of endoscopic procedures has become a central concern for the American and European Societies of Gastrointestinal Endoscopy[9-11].

To characterize the situation of EUS-FNA in the community, we performed a survey in a large audience of endosonographers to assess (1) current modalities of EUS-FNA; (2) self-reported sensitivity of EUS-FNA for the diagnosis of solid masses; and (3) factors associated with a diagnostic yield similar to that reported in the literature.

MATERIALS AND METHODS

Survey design and administration

A 2-page, 30-item, questionnaire (Appendix 1) was developed for the study. Content validity of the survey was determined based on input by experts in the field and a review of the relevant literature. Participants were asked to answer questions pertaining to demographics (6 items), their own current practice for EUS-FNA (16 items), sample processing (3 items), cytopathological diagnosis (3 items) and sensitivity of EUS-FNA for the diagnosis of solid mass lesions.

The survey was conducted during the 13th annual live EUS course held in Amsterdam, Netherlands, June 3rd and 4th 2010, as previously described[12,13]. Briefly, questionnaires were placed in bags distributed to course participants, and attendees were asked to deposit completed surveys in a dedicated box at the registration desk. Consent to participate in this study was inferred from voluntary completion of the survey. Efforts to increase response rates included reminders by the course director and moderators, projection of a reminder slide during breaks, and collection of surveys by staff members. No gift or financial incentive was granted to attendees.

Statistical analysis

Results are expressed as mean ± SD or as a percentage. Answers for each individual question were obtained from all survey respondents except when otherwise stated (each response was included in the analysis, regardless of the completeness of the survey); therefore, the number of respondents for each individual question (i.e., the denominator for percentage calculations) is indicated.

Comparisons between groups were performed with the Pearson χ^2 test or Fisher's exact test (Freeman-Halton extension where applicable) for categorical data and the Wilcoxon signed rank test for continuous variables. We also examined, by using multiple logistic regression analysis, which factors-including years of EUS practice, EUS-FNA annual hospital caseload, availability of rapid onsite cytopathological evaluation (ROSE) of EUS-FNA samples, number of needle passes > 7 or based on ROSE for three lesion types (lymph node, pancreas mass < 25 mm, pancreas mass > 25 mm), method of EUS-FNA sample preservation and routine isolation of microcores from EUS-FNA samples-were associated with a sensitivity of EUS-FNA for the diagnosis of solid mass lesions > 80%. All tests were 2-sided and P values < 0.05 were considered statistically significant. All analyses were performed with JMP software (version 9.0.0; SAS, Cary, NC, United States).

RESULTS

Study population

Completed surveys were collected from 92 (57.1%) of 161 endosonographers who attended the conference (excluding international faculty members, local faculty, fellows, and industry delegates). Survey respondents had been practicing endoscopy and EUS for 12.5 ± 7.8 years and 4.8 ± 4.1 years, respectively; 38 (42%) of them had been performing EUS for more than 5 years (Table 1). Approximately one third of respondents were practicing in a center with an annual caseload > 100 EUS-FNA. Endoscopy practices were located in 29 countries, including 13 countries in Western Europe (Austria, Belgium, Denmark, Germany, France, Greece, Italy, Netherland, Portugal, Spain, Sweden, Switzerland and the United Kingdom) that totaled 75.3% (67 out of 89) of the responses. Most (77.1%) survey respondents were performing FNA or drainage in fewer than 40% of EUS procedures. For patients subjected to both endoscopic biliary drainage

Table 1 Characteristics of survey respondents *n* (%)

Male gender (Nr = 92)	66 (71.7)
Age (yr) (Nr = 92)	43.1 ± 8.0

and EUS-FNA, only 27% of survey respondents were performing both procedures during a single endoscopy session. Staging of pulmonary cancer was performed by approximately one third of survey respondents (27 of 86; 31.4%).

Practice of EUS-FNA

A 22G needle was used for all lesion types by the majority of endosonographers; a 25G needle was used by 19.8% of survey respondents for EUS-FNA of the pancreas head (as compared to 6.8% for esophagogastric lesions; *P* = 0.009) (Table 2). ROSE of EUS-FNA samples was available to less than half of survey respondents, routinely (27.9% of answers) or in selected cases (15.1% of answers). Most endosonographers who had ROSE routinely available used it to determine the number of needle passes during EUS-FNA, while a maximum of three needle passes was performed by approximately two thirds of those who did not have ROSE routinely available. Samples were prepared using liquid-based methods plus smearing by approximately half of survey respondents (46.5%); microcores were routinely harvested from EUS-FNA samples by approximately one third (37.2%) of survey respondents. Paraffin-embedded blocks were prepared for histopathological examination of EUS-FNA samples in the laboratory of approximately half of survey respondents (55.8%). Forty-five (52.9%) of 85 survey respondents had regular meetings with the pathologist examining EUS-FNA samples.

If EUS-FNA was repeated after a first inconclusive procedure, survey respondents repeated an identical procedure or referred the patient to another endosonog-

Referral to another endosonographer	7 (8.2)

Nr: Number of respondents for each question; EUS-FNA: Endoscopic ultrasonography-guided fine needle aspiration; G: Gauge; ROSE: Rapid on-site cytopathological evaluation.

rapher in 35.3% and 8.2% of cases, respectively. Those who modified the procedure performed more needle passes, used a larger needle and, in 25% of cases, added ROSE of the EUS-FNA sample. The vast majority of survey respondents performed Doppler examination before EUS-FNA (79 of 88 responses; 89.7%) and administered antibiotic prophylaxis before EUS-FNA of pancreatic fluid collections (82 of 86 responses; 95.3%); antibiotic prophylaxis was less consistently administered in other indications of EUS-FNA (perirectal lesions, 43 (58.1%) of 74 responses; pancreas solid lesions, 10 (11.6%) of 86 responses). For sampling of pancreatic cysts, EUS-guided cyst wall brushing was rarely used (5 of 86 responses, 5.8%).

Table 3 Univariate analysis of variables potentially associated with an endoscopic ultrasonography-guided fine needle aspiration sensitivity > 80% for the diagnosis of solid mass lesions

	P value
Number of needle passes based on ROSE or > 7 (small pancreatic lesions)	< 0.0001
Number of needle passes based on ROSE or > 7 (large pancreatic lesions)	0.0002
ROSE available	0.0017
Number of needle passes based on ROSE or > 7 (lymphadenopathy)	0.0019
High annual hospital caseload	0.0242
Routine isolation of microcores	0.0422
Method of sample preservation	0.1198
Years of EUS practice	0.6475

EUS: Endoscopic ultrasonography; ROSE: Rapid on-site cytopathological evaluation.

Figure 1 Percentages of respondents with sensitivity > 80% according to availability of rapid on-site cytopathology evaluation (rapid on-site cytopathological evaluation) of endoscopic ultrasonography-guided fine needle aspiration samples. The number above each bar represents the total number of respondents in each category. For example, among 10 respondents who had ROSE available in selected cases, five (50%) self-reported a sensitivity > 80% for the diagnosis of solid mass lesions. EUS-FNA: Endoscopic ultrasonography-guided fine needle aspiration; ROSE: Rapid on-site cytopathological evaluation.

Sensitivity of EUS-FNA

Only one third of endosonographers (37.7%) reported a sensitivity > 80% for the diagnosis of solid mass lesions; the interquartile range of self-reported sensitivities (that represents 50% of the answers, centered on the median value) was 25.0%-75.0%. Factors associated in univariate analysis with a sensitivity greater than 80% are shown in Table 3 and specific associations (availability of ROSE and annual hospital caseload of EUS-FNA) are illustrated in Figures 1 and 2. In multivariate analysis, the only independent factors associated with a sensitivity greater than 80% were (1) the usage of ROSE to determine the number of needle passes or, if no ROSE was available, > 7 passes; (2) a high annual hospital caseload of EUS-FNA; and (3) routine isolation of microcores from EUS-FNA samples. The other associations listed in Table 3 became non-significant after including the number of needle passes for small pancreatic lesions based on ROSE or >

Figure 2 Percentages of respondents with sensitivity > 80% according to annual hospital caseload. The number above each bar represents the total number of respondents in each category. For example, among 20 respondents with an annual hospital caseload < 50 EUS-FNA, three (15.0%) self-reported a sensitivity > 80% for the diagnosis of solid mass lesions. EUS-FNA: Endoscopic ultrasonography-guided fine needle aspiration.

7 passes in the stepwise analysis.

DISCUSSION

The main finding of our survey is that the sensitivity of EUS-FNA for the diagnosis of solid mass lesions was strikingly lower than that reported in the literature. Only one third of endosonographers reported a sensitivity > 80% and one fourth of them reported a sensitivity < 60%. For comparison, a median sensitivity of 83% was reported in a large review of 28 studies that reported the performance of EUS-FNA to differentiate benign *vs* malignant pancreatic masses, technically the most difficult location; only one of these 28 studies reported a sensitivity < 60%[1,2]. The relatively poor performance of EUS-FNA reported by endosonographers in this survey is unlikely to be due to reporting bias as respondents would likely have over-, not under-, estimated their sensitivity for the diagnosis of solid mass lesions.

Quality has become a central concern in endoscopy. The large variability in sensitivities reported by endosonographers (interquartile range of 25%-75%) suggests that there is much more room for quality improvement in EUS-FNA compared to other procedures that have long been scrutinized such as colonoscopy and endoscopic retrograde cholangio-pancreatography (ERCP). For comparison, (1) in the case of ERCP for instance, deep cannulation of the desired duct was validated as a measure of quality; it was achieved in 83.6% of 3210 patients undergoing their first ever ERCP in an audit of 76 endoscopy units[14]; and (2) regarding colonoscopy, cecal intubation rates ranged between 88% and 97% for 9 of 10 endoscopists investigated over a 6-year period[15]. No quality indicator has been recommended by the Societies of Gastrointestinal Endoscopy to assess the diagnostic accuracy of EUS-FNA[16]. Recently, the overall yield of malignancy for pancreatic masses was proposed as a benchmark for EUS-FNA[17].

Factors independently associated with a high sensitivity of EUS-FNA in our study included (1) the usage of ROSE to determine the number of needle passes or, if no ROSE was available, > 7 passes; (2) a high annual hospital caseload of EUS-FNA; and (3) routine isolation of microcores from EUS-FNA samples. The number of needle passes reported by approximately half of endosonographers was ≤ 3 for lymph nodes as well as for pancreatic masses, although a minimum of 5 or even 7 passes have been recommended for the pancreas when ROSE is not available (for lymph nodes, three needle passes are sufficient)[18-20]. In a study of pancreas EUS-FNA, sensitivity for malignant diagnoses increased from 16.7% with one needle pass to 86.7% if more than 7 passes were performed and another study showed that tumor differentiation was the single factor associated with the number of needle passes required to make a diagnosis[18,19]. The low number of needle passes performed by many endosonographers in the pancreas could be related to procedure duration (approximately five minutes are required per needle pass). To shorten procedure duration, Möller *et al*[21] have proposed to perform only two needle passes for solid pancreatic masses, to harvest microcores for histopathological examination and to subject the residual sample to cytopathological examination. Using this technique, they obtained a sensitivity of 82.9% in a multicenter retrospective study that included 192 patients. A new EUS-FNA needle could also facilitate acquisition of samples adequate for histopathological evaluation[22].

Of note, routine isolation of microcores was another independent factor associated with a high sensitivity in our survey. Microcores adequate for histopathological evaluation can be obtained in 83.9%-90.9% of EUS-FNA of pancreatic masses performed using a standard 22G needle (the model used by most of our survey respondents)[21,23,24]. Several nonrandomized studies have suggested that microcores are useful: (1) in the study by Möller *et al*[21], combined cytopathological and histopathological examination was more sensitive than cytopathological or histopathological examination alone for discriminating malignant *vs* benign pancreatic lesions using two needle passes (82.9% *vs* 68.1% *vs* 60.0%, respectively; *P* < 0.01); and (2) in a prospective series of 50 patients with lymphoma, a diagnostic accuracy of 96% was reached by examining microcores obtained using a 19G needle as compared with 57% in another series when cytopathological examination alone was considered[25,26]. Paraffin-embedded cell blocks might represent an alternative to microcore isolation, however, cell blocks are made in the laboratory, not in the endoscopy room, and thus out of the control of the endosonographer (one third of survey respondents did not know if cell blocks were made with the samples that they provided to the laboratory); furthermore cell blocks have not been as well studied as microcores.

ROSE was routinely available to 28% of endosonographers only, compared to 90% in a study performed among 21 centers in the United States, of which 81% were academic[17]. Anecdotal evidence suggests that low ROSE availability in EUS-FNA facilities may be related to logistical issues, lack of perceived benefit and cost even though ROSE has been shown to be cost-effective during EUS- and percutaneous-guided FNA in some settings[27-29]. Studies about the usefulness of ROSE to reach a high diagnostic yield are contradictory. A retrospective comparison of EUS-FNA performed by a single endosonographer in two university hospitals, one with ROSE available and the other without ROSE, is traditionally cited to support the usefulness of ROSE, but differences in patient populations and indications for EUS-FNA between the two hospitals preclude definitive conclusion[30]. In another, more recent, retrospective study of EUS-FNA for pancreatic masses with ROSE available for 43.8% of 520 procedures, ROSE was associated with a higher diagnostic yield in multivariate analysis (odds ratio, 3.1; *P* = 0.0001)[31]. Nevertheless, in a multicenter prospective study that evaluated 409 patients with 474 lesions[32], a similarly high diagnostic accuracy was achieved in centers regardless of ROSE availability and, in a prospective series of 108 consecutive EUS-FNAs performed without ROSE by a single endosonographer[29], diagnostic accuracy of EUS-FNA for pancreatic lesions was 97%. The authors of the latest study attributed their results to high caseload, dedicated endosonography and cytopathology. Our finding that a high sensitivity of EUS-FNA was independently associated with ROSE and the annual hospital caseload supports that view.

A significant relationship between hospital caseload and quality has been demonstrated for few endoscopy procedures. For ERCP, a large administrative study showed that procedural failure rates were lower for inpatients undergoing ERCP at high- compared to low-volume US hospitals but the difference, albeit statistically significant because of the large sample size (> 2500 hospitals), was small (4.7% *vs* 6.0% in hospitals with an annual caseload ≥ 300 *vs* < 50 procedures, respectively)[33]. The difference in sensitivities reported by endosonographers in our study was much larger, with 15.0% *vs* 80.0% of endosonographers reporting a sensitivity greater than 80% depending if they worked in a hospital with an annual caseload < 50 *vs* > 200 EUS-FNAs, respectively (*P* = 0.024), as illustrated in Figure 2. This supports the view that centralization should be discussed for at least some of the EUS-FNA procedures, as has recently been proposed for ERCP[34]. Such a change would be important as only 8.2% of our survey respondents were referring patients to another endosonographer after a first inconclusive EUS-FNA.

Limitations of our survey include selection and recall bias: (1) surveyed endosonographers were working mostly in Western Europe and our findings may not apply to other locations; and (2) self-reported data are exposed to recall and goodwill biases because surveyed professionals tend to give the expected answer more than the real one, which indeed strengthens our main conclusion that the performance of EUS-FNA is significantly lower than

assumed from published studies. In particular, sensitivity for the diagnosis of solid mass lesions was reported by 61 (37.8%) of 161 participants in the EUS course. Because of these limitations (recruitment of participants from a course, response rate), our conclusion that sensitivity for the diagnosis of solid mass lesions is strikingly lower in the community than reported in the literature should be confirmed by larger studies.

In conclusion, the quality of EUS-FNA, as assessed in this survey by its most crucial result, *i.e.*, sensitivity for cancer diagnosis, was relatively low. Low quality was associated with unavailability of ROSE, low number of needle passes for pancreatic EUS-FNA, absence of routine microcore isolation and low annual hospital caseload. Efforts should be made to improve the quality of EUS-FNA amongst endosonographers; we suggest that endoscopists review their sensitivity for cancer diagnosis and, if this is < 80%, then they should modify their practice taking into account the factors cited above. These recommendations may be particularly valuable for endoscopists working in hospitals with a low annual caseload of EUS-FNA.

ACKNOWLEDGMENTS

COMMENTS

Background
Endoscopic ultrasonography-guided fine needle aspiration (EUS-FNA) has become widely available and is known for its high diagnostic accuracy in academic centers.

Research frontiers
The quality of several endoscopic procedures (e.g., colonoscopy) has become an area of active improvement. However, for EUS-FNA, simple quality parameters (e.g., diagnostic accuracy) are poorly known in the community. Recently, the overall yield of malignancy for pancreatic masses was proposed as a benchmark for EUS-FNA. This parameter is relatively easy to collect but it does not take into account the prevalence of malignant diseases among pancreatic masses subjected to EUS-FNA by a particular endosonographer.

Innovations and breakthroughs
The authors performed a survey of the current practice of EUS-FNA. The self-reported sensitivity of EUS-FNA for the diagnosis of solid mass lesions was considerably lower than commonly reported in the literature. A high sensitivity for the diagnosis of solid mass lesions was associated with the availability of rapid on-site cytopathological evaluation (ROSE), a high number of needle passes, microcore isolation and a high hospital caseload. The data suggest that there is ample room for improvement of the quality of EUS-FNA and provides several clues for improvement.

Applications
Scientific societies play an important role in helping to improve the quality of endoscopic procedures; particular attention in that field could be paid to EUS-FNA. Centralization of some of the EUS-FNA procedures could be explored as a means of achieving that aim.

Terminology
ROSE of material sampled by EUS-FNA is performed by a cytopathologist or a cytotechnician; preliminary diagnoses resulting from ROSE are highly reliable.

ROSE allows a reduction in the number of needle passes but its cost-efficacy is debated. Microcore isolation consists of examining the sample obtained by EUS-FNA for the presence of small tissue core samples, transferring them into a preservative (e.g., formalin) for histopathological examination and sending the rest of the material collected for cytopathological analysis.

Peer review
This is an interesting paper on a survey study performed during the 13th annual live EUS course in Amsterdam in June 2010.

Abstract

AIM: To determine the efficacy of external beam radiotherapy (EBRT), with or without intraluminal brachytherapy (ILBT), in patients with non-resected locally advanced hilar cholangiocarcinoma.

METHODS: We analyzed 64 patients with locally advanced hilar cholangiocarcinoma, including 25 who underwent resection (17 curative and 8 non-curative), 28 treated with radiotherapy, and 11 who received best supportive care (BSC). The radiotherapy group received EBRT (50 Gy, 30 fractions), with 11 receiving an additional 24 Gy (4 fractions) ILBT by iridium-192 with remote after loading. ILBT was performed using percutaneous transhepatic biliary drainage (PTBD) route. Uncovered metallic stents (UMS) were inserted into non-resected patients with obstructive jaundice, with the exception of four patients who received percutaneous transhepatic biliary drainage only. UMS were placed endoscopically or percutaneously, depending on the initial drainage procedure. The primary endpoints were patient death or stent occlusion. Survival time of patients in the radiotherapy group was compared with that of patients in the resection and BSC groups. Stent patency was compared in the radiotherapy and BSC groups.

RESULTS: No statistically significant differences in patient characteristics were found among the resection, radiotherapy, and BSC groups. Three patients in the radiotherapy group and one in the BSC group did not receive UMS insertion but received PTBD alone; cholangitis occurred after endoscopic stenting, and patients were treated with PTBD. A total of 16 patients were administered additional systemic chemotherapy (5-fluorouracil-based regimen in 9, S-1 in 6, and gemcitabine in 1). Overall survival varied significantly among groups, with median survival times of 48.7 mo in the surgery group, 22.1 mo in the radiotherapy group, and 5.7 mo in the BSC group. Patients who underwent curative resection survived significantly longer than those who were not candidates for surgery ($P = 0.0076$). Cumulative survival in the radiotherapy group was significantly longer than in the BSC group ($P = 0.0031$), but did not differ significantly from those in the non-resection group. Furthermore, the median survival time of patients in the radiotherapy group who were considered for possible resection (excluding the seven patients who were not candidates for surgery due to comorbid disease or age) was 25.9 mo. Stent patency was evaluated only in the 24 patients who received a metallic stent. Stent patency was significantly longer in the radiotherapy than in the BSC group ($P = 0.0165$). Biliary drainage was not eliminated in any patient. To determine the efficacy of ILBT, we compared

survival time and stent patency in the EBRT alone and EBRT plus ILBT groups. However, we found no significant difference in survival time between groups or for stent patencies. Hemorrhagic gastroduodenal ulcers were observed in 5 patients (17.9%), three in the EBRT plus ILBT group and two in the EBRT alone group. Ulcers occurred 5 mo, 7 mo, 8 mo, 16 mo, and 29 mo following radiotherapy. All patients required hospitalization, but blood transfusions were unnecessary. All 5 patients recovered following the administration of anti-ulcer medication.

CONCLUSION: Radiotherapy improved patient prognosis and the patency of uncovered metallic stents in patients with locally advanced hilar cholangiocarcinoma, but ILBT provided no additional benefits.

INTRODUCTION

Hilar cholangiocarcinoma is a relatively rare, slow-growing, late-metastasizing tumor associated with poor patient prognosis[1-7]. The only known effective treatment is surgery, but only a small proportion of patients are suitable candidates. The operation is technically demanding and may be too invasive for high-risk elderly patients.

External beam radiotherapy (EBRT), with or without intraluminal brachytherapy (ILBT), is widely used to treat patients with hilar cholangiocarcinoma. A randomized trial comparing stenting alone with stenting plus radiotherapy showed that both procedures significantly prolonged patient survival and stent patency[8]. However, the relatively long survival time of untreated patients (median, 298 d) suggests that some of these patients may have been resectable. Thus, the effects of radiotherapy alone, and the benefits of ILBT, are not known.

Biliary stenting is a widely-accepted palliative procedure used to treat patients with unresectable hilar cholangiocarcinoma and obstructive jaundice. Patient prognosis, however, is poor, even with the absence of metastasis. A randomized trial showed that uncovered metallic stents remained patent longer than plastic stents in patients with hilar cholangiocarcinoma[9]. The primary cause of uncov-

ered metallic stent occlusion is tumor ingrowth into the mesh[10]. Covered metallic stents prevent tumor ingrowth in patients with distal biliary obstruction and have a longer patency than uncovered metallic stents[11-16]. Although covered metallic stents are not feasible for treating hilar cancer patients because of the complex anatomy of the hilar duct, radiotherapy may be used to prevent tumor ingrowth after placement of an uncovered metallic stent[17].

The aims of this study were therefore twofold: to test the effects of radiotherapy, with or without ILBT, on the survival of hilar cholangiocarcinoma patients who did not undergo surgical resection; and to evaluate whether radiotherapy prolongs stent patency and thus improves patient quality of life.

MATERIALS AND METHODS

Patients

Between 1986 and 2008, 84 patients with hilar cholangiocarcinoma were admitted to the Department of Gastroenterology of Tokyo University Hospital. Of these 84 patients, 20 had metastatic and 64 had locally advanced disease (Figure 1 and Table 1). Of those with locally advanced tumors, 34 fulfilled our resectability criteria, and 25 underwent surgical resection. The remaining 9 patients were not candidates for surgery due to comorbid disease or advanced age. Bile duct cancer was diagnosed by pathological examination, clinical course, or imaging results. Cholangiocarcinoma staging was based on computed tomography, magnetic resonance cholangiopancreatography, or direct cholangiogram using endoscopic retrograde cholangiopancreatography or percutaneous transhepatic biliary drainage (PTBD). In addition, Bismuth's classification was applied[6].

Criteria for resectability

The resectability of each tumor was determined after consultation with the hepato-biliary surgeon. Surgical contraindications included: invasion of the celiac and super mesenteric arteries, biliary invasion of the third branch of the future remnant liver, and invasion of the both hepatic artery and portal vein of the future remnant liver.

Biliary stenting

All patients with locally advanced tumors underwent endoscopic or percutaneous biliary drainage (Table 2). Prophylactic antibiotics were administered intravenously prior to the endoscopic procedure and for 3 d afterwards. An Amsterdam-type plastic stent (7 or 8.5 Fr; Flexima stent, Microvasive, Boston Scientific, Natick, MA, United States) or a nasobiliary drainage tube (Cook Medical Company) was inserted into patients. PTBD using 8 Fr balloon catheters was performed under ultrasonographic and fluoroscopic guidance. Additional stents were inserted or PTBD was performed if jaundice did not improve.

Radiation therapy

Radiotherapy was recommended for patients whose jaun-

dice did not improve and who were not candidates for surgery. A total of 28 patients agreed to undergo EBRT (54 Gy, 30 fractions); of these, 11 also underwent percutaneous ILBT (24 Gy, 4 fractions) using a high-dose iridium-192 remote after loading system (Table 2). A metallic stent was inserted into the 11 patients who refused EBRT after their jaundice improved; these patients constituted the best supportive care (BSC) group.

After radiotherapy, a metallic stent was inserted endoscopically or percutaneously, depending on the initial drainage procedure. Some patients received bilateral metallic stents because multiple insertion routes were necessary for internal brachytherapy and unilateral stents produced insufficient drainage.

Follow up
Patient symptoms were assessed and blood tests were performed at monthly intervals in the outpatient clinic. Computed tomography scans were taken every 6 mo (every 2 mo during chemotherapy), with additional scans taken when patients were symptomatic or showed an increase in hepatic-biliary enzymes and bilirubin. Patients received chemotherapy every 2 mo.

Endpoints
The primary endpoints were patient death or stent occlusion through November 2008. Stents were considered patent if the jaundice did not worsen, with or without cholangitis. Patient survival time was measured from the date of diagnosis to the date of death, and stent patency was measured from placement to occlusion or to patient death if the stent remained patent. Survival time of patients in the radiotherapy group was compared with that of patients in the resection and BSC groups. Stent patency was compared in the radiotherapy and BSC groups.

Statistical analysis
Cumulative patient survival and stent patency were ana-

lyzed using the Kaplan-Meier method and compared using the log rank test. Patients whose stents were not obstructed were excluded from stent patency analysis. The Mann-Whitney U-test was used to compare quantitative variables, and Fisher's exact test was used to analyze qualitative variables. All analyses were performed using StatView 5.0 software (SAS Institute Inc., Cary, NC, United States).

RESULTS

Patient survival
Overall survival varied significantly among groups, with median survival times of 48.7 mo in the surgery group, 22.1 mo in the radiotherapy group, and 5.7 mo in the BSC group (Figure 2). Patients who underwent curative resection survived significantly longer than those who were not candidates for surgery ($P = 0.0076$). Cumulative survival in the radiotherapy group was significantly longer than in the BSC group ($P = 0.0031$), but did not differ significantly from those in the non-resection group (Figure 2). Furthermore, the median survival time of patients in the radiotherapy group who were considered for possible resection (excluding the seven patients who were not candidates for surgery due to comorbid disease or age) was 25.9 mo.

Stent patency
Stent patency was evaluated only in the 24 patients who received a metallic stent (Table 3). Stent patency was significantly longer in the radiotherapy than in the BSC

group (*P* = 0.0165; Figure 3). Biliary drainage was not eliminated in any patient.

Figure 3 Cumulative metallic stent patency. Stents were patent significantly longer in the radiotherapy than in the BSC group (*P* = 0.0165). BSC: Best supportive care.

Figure 4 Cumulative survival times of patients who received external beam radiotherapy alone and those who received external beam radiotherapy plus intra bile ductal radiotherapy (intraluminal brachytherapy). There was no significant difference in survival between groups. EBRT: External beam radiotherapy; ILBT: Intraluminal brachytherapy.

Additive effect of ILBT to EBRT

To determine the efficacy of ILBT, we compared survival time and stent patency in the EBRT alone and EBRT plus ILBT groups. However, we found no significant difference in survival time between groups (Figure 4) or for stent patencies.

Complications of radiotherapy

Hemorrhagic gastroduodenal ulcers were observed in 5 patients (17.9%), three in the EBRT plus ILBT group and two in the EBRT alone group. Ulcers occurred 5 mo, 7 mo, 8 mo, 16 mo, and 29 mo following radiotherapy. All patients required hospitalization, but blood transfusions were unnecessary. All 5 patients recovered follow-

Mean patent period was longer in the radiotherapy than in the BSC group, but the difference was not significant. BSC: Best supportive care.

ing the administration of anti-ulcer medication.

DISCUSSION

Surgical resection is the only known cure for hilar cholangiocarcinoma. The surgery is highly invasive and recommended for only a small percentage of patients; thus, alternative treatments are necessary. Our results suggest that radiotherapy prolongs survival in patients who cannot undergo resection. Survival was significantly longer in patients who received radiotherapy than in those who received BSC, but was similar to that of patients who underwent non-curative resection.

Radiotherapy has been shown to improve survival times of patients with locally advanced hilar cholangiocarcinoma who cannot undergo curative resection. For example, a randomized trial reported that median survival times were 12.9 mo in patients who received both EBRT and ILBT and 9.3 mo in patients did not receive radiotherapy[8]. A second study found that median survival in patients who received chemoradiotherapy (EBRT plus 5-fluorouracil) was 22 mo, but that study did not include an untreated control group[18]. A retrospective analysis found that the median survival time in patients with extrahepatic cholangiocarcinoma who received EBRT plus ILBT was 9 mo, compared with 5 mo in patients treated with EBRT alone[19]. This wide range in survival times may reflect differences in patient backgrounds. Most reports did not describe the percentage of patients with resectable tumors, the reasons that they were not resected, or the resection criteria; thus, it is difficult to generalize from these results. In contrast, we have stated the inclusion criteria for non-surgical treatment. Moreover, in our radiotherapy group, the median survival of non-resected patients considered for possible resection was 25.9 mo, longer than previously reported survival times.

We observed no significant differences between the radiotherapy and BSC groups in patient background, including the reasons for not undergoing resection and

performance score. We expected that selection bias may have resulted in longer median survival of the radiotherapy than of the BSC group, but we found no significant difference in background between these two groups. Our results therefore provide additional evidence suggesting that radiotherapy increases survival time in patients with locally advanced hilar cholangiocarcinoma.

Although surgery is the only known cure for cholangiocarcinoma, we found that median survival of the radiotherapy group did not differ significantly from that of the non-curative resection group. This finding supports the survival benefits of radiotherapy for patients with locally advanced hilar cholangiocarcinoma. Thus, radiotherapy is a treatment option for patients in poor condition or those with highly invasive tumors.

Biliary stenting is a widely accepted palliative treatment for non-resected patients with biliary obstruction, with uncovered metallic stents maintaining patency longer than plastic stents[9]. The primary cause of obstruction in patients who receive an uncovered metallic stent is tumor ingrowth into the stent mesh. In a previous randomized trial, we prevented distal biliary obstruction by inhibiting tumor ingrowth and found that a covered metallic stent was patent longer than an uncovered stent[11]. However, covered metallic stents cannot be used in patients with hilar obstruction, and it is necessary to develop strategies to prevent tumor ingrowth of hilar lesions. Stents remained patent significantly longer in the radiotherapy group than in the BSC group (stenting alone); suggesting that local tumor control using radiotherapy prolongs stent patency. Previous studies of the efficacy of metallic stents in the treatment of hilar cholangiocarcinoma did not use radiotherapy, and studies investigating the survival benefits of radiotherapy have not reported results of metallic stenting. Thus, no evidence was available to determine the efficacy of radiotherapy in improving stent patency.

Multiple laser-cut-type Nitinol stents were found to have a mean patency of 150 d[20], with Wallstents having a median patency of 169 d[21]. A comparison of the patency of metallic stents inserted endoscopically and percutaneously showed that the median stent patency of these two groups was 9.8 mo and 11.0 mo, respectively[22]. In comparison, we found that median and mean stent patency in our radiotherapy group were 557 d and 604 d, respectively. The length of time the stents remained patent suggests that radiotherapy had a significant effect on patency.

We found that the addition of ILBT to EBRT did not improve patient survival or stent patency. Stent patency is a surrogate indicator of local anti-tumor effectiveness, because the main cause of stent occlusion is tumor ingrowth through the stent mesh. ILBT requires an additional treatment period and multiple PTBD insertions. Since it did not improve patient survival or stent patency, we do not recommend this additional treatment. A retrospective study of 31 patients found that, although additional ILBT improved the 2-year survival rate, it had no effect on cumulative survival time[20]. No randomized studies to date

have compared the effect on survival of radiotherapy with and without ILBT. Thus, the efficacy of additional ILBT remains unclear.

Photodynamic therapy is a promising local anti-tumor therapy for patients with non-resectable hilar cholangiocarcinoma, with median survival times of patients who did and not receive photodynamic therapy of 493 d and 98 d, respectively, a difference that was statistically significant[23]. Although photodynamic therapy can be used to treat local tumors extending along the bile duct, it cannot be used to treat large tumors that have invaded other organs, and it cannot be used to treat loco-regional lymph node metastasis because it is performed in the bile duct. The combination of photodynamic therapy with EBRT may be a more feasible treatment option.

The major limitation of this study was its retrospective design. Moreover, despite all included patients having unresectable, locally advanced tumors, the characteristics of the radiation and BSC groups differed. Since there were no selection criteria for the BSC group, the differences in outcomes between this group and the radiation group may be due not only to the effects of radiation, but to patient condition as well.

In conclusion, radiotherapy may improve the prognosis of patients with non-resected, locally advanced hilar cholangiocarcinoma and may increase the patency of uncovered metallic stents. ILBT provides no benefit for these patients.

COMMENTS

Background
Hilar cholangiocarcinoma is a relatively rare, slow-growing and late-metastasizing tumor associated with poor patient prognosis. Surgery is the only known curative treatment, but it may be technically difficult and too invasive for high-risk elderly patients. The treatment of patients with unresectable tumors has not been established.

Research frontiers
Biliary stenting and radiotherapy, including external beam radiotherapy (EBRT) with or without intraluminal brachytherapy (ILBT), are widely used to treat patients with locally advanced hilar cholangiocarcinoma. These treatments, however, are not well established, although a recent randomized study showed good results for photodynamic therapy.

Innovations and breakthroughs
Several recent studies have shown the efficacy of radiation therapy in patients with locally advanced hilar cholangiocarcinoma. In many of those patients, however, the tumors may have been resectable. The authors clarified the reasons for non-resection of the patients and compared outcomes with resected patients. The authors found that radiation therapy effectively prolonged patient survival and stent patency. They also showed that additional ILBT did not affect survival or stent patency.

Applications
EBRT is indicated for patients with locally advanced hilar cholangiocarcinoma, with similar survival times as patients who underwent non-curative resection. Patients who undergo uncovered metallic stent placement should be considered for EBRT to prolong stent patency and survival.

Terminology
EBRT is a conventional radiation method, and ILBT is performed with iridium wire through a PTBD catheter using an after loading system. A metallic stent is a braided metallic wire or tubular nitinol cut with a laser. Metallic stents have self-expandability and are mounted onto a thin delivery system (6-9Fr). This type of stent, however, tends to be occluded by tumor ingrowth into the stent mesh.

Peer review
As stated by the authors, the limitation of the study is that it is a retrospective study and that the groups are not the results of a randomization but the consequence of different situations such not being suitable for surgery. In any case, the paper is a well presented study on a very difficult subject and is worthy of publication.

Abstract

AIM: To compare the effect of percutaneous transhepatic portal vein embolization (PTPE) and unilateral portal vein ligation (PVL) on hepatic hemodynamics and right hepatic lobe (RHL) atrophy.

METHODS: Between March 2005 and March 2009, 13 cases were selected for PTPE ($n = 9$) and PVL ($n = 4$) in the RHL. The PTPE group included hilar bile duct carcinoma ($n = 2$), intrahepatic cholangiocarcinoma ($n = 2$), hepatocellular carcinoma ($n = 2$) and liver metastasis ($n = 3$). The PVL group included hepatocellular carcinoma ($n = 2$) and liver metastasis ($n = 2$). In addition, observation of postoperative hepatic hemodynamics obtained from computed tomography and Doppler ultrasonography was compared between the two groups.

RESULTS: Mean ages in the two groups were 58.9 ± 2.9 years (PVL group) *vs* 69.7 ± 3.2 years (PTPE group), which was a significant difference ($P = 0.0002$). Among the indicators of liver function, including serum albumin, serum bilirubin, aspartate aminotransferase, alanine aminotransferase, platelets and indocyanine green retention rate at 15 min, no significant differences were observed between the two groups. Preoperative RHL volumes in the PTPE and PVL groups were estimated to be 804.9 ± 181.1 mL and 813.3 ± 129.7 mL, respectively, with volume rates of 68.9% ± 2.8% and 69.2% ± 4.2%, respectively. There were no significant differences in RHL volumes ($P = 0.83$) and RHL volume rates ($P = 0.94$), respectively. At 1 mo after PTPE or PVL, postoperative RHL volumes in the PTPE and PVL groups were estimated to be 638.4 ± 153.6 mL and 749.8 ± 121.9 mL, respectively, with no significant difference ($P = 0.14$). Postoperative RHL volume rates in the PTPE and PVL groups were estimated to be 54.6% ± 4.2% and 63.7% ± 3.9%, respectively, which was a significant difference ($P = 0.0056$). At 1 mo after the operation, the liver volume atrophy rate was 14.3% ± 2.3% in the PTPE group and 5.4% ± 1.6% in the PVL group, which was a significant difference ($P = 0.0061$).

CONCLUSION: PTPE is a more effective procedure than PVL because PTPE is able to occlude completely the portal branch throughout the right peripheral vein.

Iida H, Aihara T, Ikuta S, Yoshie H, Yamanaka N. Comparative study of percutaneous transhepatic portal vein embolization and unilateral portal vein ligation. *World J Gastroenterol* 2012; 18(19): 2371-2376 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i19/2371.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i19.2371

INTRODUCTION

Postoperative liver failure may be induced by major hepatectomy, whereby more than 60%-70% of total liver volume is planned for resection in cases such as hilar bile duct carcinoma, hepatocellular carcinoma and liver metastasis. To reduce the risk of postoperative liver failure due to an insufficient volume of functional liver, the well-established percutaneous transhepatic portal vein embolization (PTPE) procedure can be performed prior to major hepatectomy[1-6]. Unilateral portal vein ligation (PVL) is an alternative method that requires laparotomy[7,8]. Although PTPE has since its introduction become the more popular procedure of the two, PVL remains a viable option during the initial stage of a two-stage hepatectomy procedure (TSHP) for cases such as bilobar multiple liver metastases[9-11]. Both of these techniques occlude the unilateral portal vein, with the aim of inducing atrophy of the ipsilateral liver and thus inducing hypertrophy of the future liver remnant (FLR). In the present study, we retrospectively compared the effectiveness of the two techniques by evaluating the postoperative atrophy rate and hemodynamics of the right hepatic lobe (RHL).

MATERIALS AND METHODS

Patient characteristics of the PTPE and PVL groups

Between March 2005 and March 2009, nine patients were selected for PTPE and four for PVL. The mean patient age was 69.7 ± 3.2 years for the PTPE group and 58.9 ± 2.9 years for the PVL group (*P* = 0.0002). The clinical characteristics of the patients included hilar bile duct carcinoma (*n* = 2), intrahepatic cholangiocarcinoma (*n* = 2), hepatocellular carcinoma (*n* = 2) and liver metastasis (*n* = 3) in the PTPE group, and the PVL group had hepatocellular carcinoma (*n* = 2) and liver metastasis (*n* = 2). The PTPE group included one patient with hepatitis C, one with hepatitis B, and seven positive for hepatitis B virus (HBV) antigen but negative for hepatitis C virus (HCV) antibody. The PVL group included one patient with hepatitis C, one with hepatitis B, and two positive for HBV antigen and negative for HCV antibody.

PTPE cases

Two patients were diagnosed with hilar bile duct carcinoma, based on findings of obstructive jaundice. Endoscopic nasobiliary drainage was first performed. Before conducting an extended right lobectomy, PTPE was performed because the liver volumes to be resected were 70.8% and 70.2% in the two patients.

In the two cases of intrahepatic cholangiocarcinoma, the tumors were 10 cm and 8 cm in diameter, and both were adjacent to the hilar plate. These two patients also underwent a preoperative PTPE because of planned liver resection volumes of 74.2% and 70.5% respectively.

In the two patients with hepatocellular carcinoma, the tumors were 4.0 cm and 3.5 cm in diameter and adjacent to the right Glisson's capsule. In addition, both

the tumors recurred after the transarterial embolization procedure. The liver volume to be resected in these cases was 68.3% and 66.1%, respectively. In addition, indocyanine green retention rate at 15 min (ICG R15) was 17% and 18%, respectively, indicating functional liver impairment. Because of these factors, PTPE was performed prior to resection.

In the three patients with liver metastases, multiple lesions in the right lobes were noted after the initial round of chemotherapy. Preoperative PTPE was scheduled because the liver volumes to be resected in the three patients were 65.2%, 66.6% and 68.8%.

PVL cases

Patients with hepatocellular carcinoma in the PVL group presented with lymph node metastasis. The tumors adjacent to the right Glisson's capsule were 5 cm and 4 cm in diameter with ICG R15 of 38.8% and 15.2%, respectively. The planned liver resection volumes were 65.1% and 69.8%, respectively. Thus, PVL was performed on the right portal branch only during the implementation of lymphadenectomy.

Regarding the two liver metastasis cases, the patients had undergone chemotherapy and developed multiple synchronous liver metastases to both lobes, disseminated from ascending colon cancer. Because the liver resection volumes were 66.9% and 74.8%, the right portal vein was ligated. In addition, right colectomy and partial resection of the left hepatic lobe were also performed in both patients.

Indications for resection

Resectability criteria included an FLR of ≤ 30% of the total liver volume, whereas this criterion was ≤ 35% for the patients who had liver cirrhosis or underwent neoadjuvant chemotherapy. In addition, the following equation established by Yamanaka *et al*[12,13] and Okamoto *et al*[14] was used to predict posthepatectomy liver failure: Y = -110 + 0.942 × resection rate (%) + 1.36 × ICG retention rate (%) + 1.17 × patient's age + 5.94 × ICG maximal removal rate (mg/kg per minute). With this equation, the patients who had a calculated Y value > 50 points were deemed unresectable.

PVL and PTPE techniques

For all patients, PTPE or PVL was performed on the RHL. PVL was indicated for patients who were to undergo laparotomy for lymphadenectomy or right colectomy. In PTPE, the umbilical portion of the portal vein was punctured, and the right branch of the portal vein was embolized using a mixture of fibrin glue (Beriplast P; CSL Behring, Tokyo, Japan) and iodized oil (Lipiodol; Guerbet, Aulnay-sous-Bois, France). In the PVL cases, preoperative multidetector row computed tomography (CT) was routinely performed to check for the presence of anatomical variants of the right portal vein. The right branch of the portal vein was intraoperatively isolated and ligated. After each method, Doppler ultrasonography was used to confirm that portal blood flow had

been occluded in the ligated lobe and that it had been sustained in the FLR.

Follow-up
No patients had any postoperative complications. Although a slight postoperative decline in liver function was noted in some patients, all improved with conservative treatments.

Statistical analysis
Each patient underwent CT volumetry 1 mo before and after each procedure to evaluate volume changes in the RHL, and the values were compared between the two groups. The RHL atrophy rate was estimated by subtracting the RHL volume rate at 1 mo after PTPE or PVL from the preoperative RHL volume rate. The values in each group were compared using the Mann-Whitney test. All analyses were performed using statistical software (JMP 8.0.2 Macintosh; SAS Institute, Japan). Differences were considered statistically significant at $P < 0.05$.

RESULTS

Clinical characteristics of the study population
The mean age of patients was significantly higher in the PTPE group (58.9 ± 2.9 years *vs* 69.7 ± 3.2 years in the PTPE group), which was a significant difference ($P = 0.0002$). Among the indicators of liver function, including serum albumin, serum bilirubin, asparate aminotransferase, alanine aminotransferase, platelets and ICG R15, no significant differences were observed between the two groups (Table 1).

Volume change of RHL
Preoperative RHL volumes in the PTPE and PVL groups were estimated to be 804.9 ± 181.1 mL and 813.3 ±

Table 2 Right hepatic lobe atrophy rate 1 mo after percutaneous transhepatic portal vein embolization or portal vein ligation (mean ± SD)			
Variables	PTPE group (*n* = 9)	PVL group (*n* = 4)	*P* value
Preoperative RHL volume (mL)	804.9 ± 181.1	813.3 ± 129.7	0.83
Preoperative RHL volume rate (%)	68.9 ± 2.8	69.2 ± 4.2	0.94
Postoperative RHL volume (mL)	638.4 ± 153.6	749.8 ± 121.9	0.14
Postoperative RHL volume rate (%)	54.6 ± 4.2	63.7 ± 3.9	0.0056
RHL atrophy rate 1 mo postoperation (%)	14.3 ± 2.3	5.4 ± 1.6	0.0061

PTPE: Percutaneous transhepatic portal vein embolization; PVL: Portal vein ligation; RHL: Right hepatic lobe.

129.7 mL, respectively, with volume rates of 68.9% ± 2.8% and 69.2% ± 4.2%, respectively. There were no significant statistical differences in RHL volumes ($P = 0.83$) and RHL volume rates ($P = 0.94$).

At 1 mo after PTPE or PVL, postoperative RHL volumes in the PTPE and PVL groups were estimated to be 638.4 ± 153.6 mL and 749.8 ± 121.9 mL, respectively, which was not a significant difference ($P = 0.14$). Postoperative RHL volume rates in the PTPE and PVL groups were estimated to be 54.6% ± 4.2% and 63.7% ± 3.9%, respectively, which was a significant difference ($P = 0.0056$). At 1 mo postoperatively, the liver volume atrophy rate was 14.3% ± 2.3% in the PTPE group and 5.4% ± 1.6% in the PVL group, which was a significant difference ($P = 0.0061$) (Table 2).

With respect to the findings from imaging, postoperative CT and Doppler ultrasonography data confirmed residual peripheral portal inflow in the right branch of the ligated portal vein in two cases in the PVL group. In contrast, portal venous flow was confirmed as completely occluded in the PTPE group.

Liver resection and postoperative course
PTPE successfully facilitated liver resection for all nine patients, whereas among the four patients who underwent PVL, two with hepatocellular carcinoma remained unresectable after the procedure. An extended right lobectomy was performed for two hilar bile duct carcinomas and two intrahepatic cholangiocellular carcinomas. A right lobectomy was performed in all the other resectable cases. The 11 patients showed no postoperative complications.

DISCUSSION

Through experimentation on rabbits in 1920, Rous *et al*[15] proved that PVL could induce atrophy of the ipsilateral hepatic lobe and hypertrophy of the FLR lobe. Since then, this technique has been clinically applied by Honjo *et al*[16] and has recently been adopted for TSHP for bilobar multiple liver metastases. In the first stage, partial resec-

Figure 1 Computed tomography showing a case of hilar bile duct carcinoma where the right hepatic lobe volume rate decreased from 68.3% to 50.0% at 1 mo after percutaneous transhepatic portal vein embolization. A: Before percutaneous transhepatic portal vein embolization (PTPE) [right hepatic lobe (RHL) volume rate: 68.3%]; B: After PTPE (RHL volume rate: 50.0%); C: The portal vein in the RHL was completely occluded after PTPE.

Ligation point

tion or ablation is performed on the FRL, and PVL is subsequently performed to induce atrophy in the hemiliver to be resected, in preparation for the planned major hepatectomy[17-20]. PTPE has been advocated as a technique for inducing atrophy of the ipsilateral liver without the need for a laparotomy, and is commonly performed for cases such as hilar bile duct carcinoma and hepatocellular carcinoma, in which a substantial liver volume is planned for resection[21-23]. Although PVL and PTPE are both techniques that occlude the portal vein, they differ in approach. PTPE is performed by percutaneously injecting embolic materials, whereas PVL is performed by a laparotomy to ligate the first-order branch of the portal vein. To date, several studies have demonstrated the safety and effectiveness of the two techniques individually; however, there are not enough data available from comparative studies reporting the relative efficacies of

the two techniques. In the present study, we compared the atrophic effect and postoperative hepatic hemodynamics associated with PTPE and PVL.

In our study, the PTPE group demonstrated a significantly higher rate of postoperative liver volume atrophy than the PVL group 1 mo after hepatectomy. The mean liver volume atrophy rate was 14.3% ± 2.3% in the PTPE group and 5.4% ± 1.6% in the PVL group (Figures 1 and 2). The CT and Doppler ultrasound findings may explain the reason for this difference. It was confirmed that portal venous flow was completely occluded due to the use of embolic materials acting throughout the peripheral portal vein in the PTPE group. However, portal vein venous flow continued at peripheral sites away from the ligation point in two cases in the PVL group (Figure 3). Residual flow was observed from the anterior to the posterior branch (Figure 4).

Figure 4 Doppler ultrasound findings on hemodynamics. A: Color Doppler ultrasound confirming portal venous flow from the anterior to the posterior branch (arrow); B: Pulse Doppler ultrasound confirming hepatofugal venous flow in the anterior branch (arrow); C: Pulse Doppler ultrasound confirming hepatopetal venous flow in the posterior branch (arrow).

Figure 5 Hemodynamics during portal vein ligation procedure. A: The residual portal venous flow may be explained as backflow from the hepatic vein; B: The presence of an arterioportal shunt may be another reason for the residual portal venous flow.

Two explanations can be proposed for the peripheral portal blood flow observed despite the portal vein being ligated at its central site. First, the observed peripheral portal blood flow could be backflow from the ipsilateral hepatic vein (Figure 5A). Normally, portal vein pressure and hepatic venous pressure are approximately equal at 100-150 mmH$_2$O. However, ligating the first-order branch of the portal vein may decrease peripheral portal vein pressure, causing a relative pressure elevation in the hepatic vein and resulting in backflow from the hepatic vein. This backflow was significant for cases where tumors had compressed or obstructed hepatic veins in the presence of high hepatic venous pressure. A second possible explanation for the observed peripheral portal blood flow is related to the arterioportal shunt (AP shunt) (Figure 5B). Blood inflow *via* the AP shunt diminishes the effectiveness of the technique by allowing some blood to flow in the first-order branch of the portal vein. Consequently, when the AP shunt is preoperatively observed, PVL should not be the preferred treatment option.

In contrast to the PVL group, postoperative CT data confirmed the presence of embolic materials in the peripheral portal vein in all PTPE patients. In addition, postoperative Doppler ultrasound showed no residual blood in the portal vein, leading us to conclude the superiority of PTPE over PVL. However, PVL is currently more often performed in TSHP cases requiring portal vein occlusion. Time between the first stage and PTPE should be minimized because of possible cancer progression[24,25]. Therefore, we recommend PTPE for the first part of TSHP.

In conclusion, the small sample size and the retrospective nature of this study are limitations towards obtaining more conclusive results, compared to a prospective study with a larger population. However, our results show that PTPE can more effectively and rapidly achieve atrophy of ipsilateral liver volume and consequently induce compensatory FLR volume hypertrophy, compared with PVL.

COMMENTS

Background
Postoperative liver failure may be induced because of the insufficient remnant liver volume after major hepatectomy where more than 60%-70% of the total liver volume is resected in such cases as hilar bile duct carcinoma or liver metastasis. To achieve safer major hepatectomy, ligation or embolization of the portal vein is preliminarily performed to induce atrophy of the ipsilateral liver and hypertrophy of the future remnant liver.

Research frontiers
To occlude unilateral portal vein, either portal vein ligation (PVL) ligating the unilateral portal vein or percutaneous transhepatic portal vein embolization (PTPE) injecting embolic agent to the unilateral portal vein through catheter is performed. PTPE is a procedure advocated after PVL, and PVL cases have decreased in number since the introduction of PTPE. However, as two-stage hepatectomy procedure (TSHP) for liver metastasis has recently become a more popular procedure, PVL has been again increasingly performed in combination with the first resection of TSHP.

Innovations and breakthroughs
The liver atrophy rate of unilateral lobe was compared between the PTPE (n = 9) and PVL groups (n = 4) 1 mo after each procedure. The liver atrophy rate was 14.3% ± 2.3% (PTPE) and 5.4% ± 1.6% (PVL), which was a significant difference (P = 0.0061). To date, the two procedures have been regarded equivalent in effectiveness, however, the results suggest the superiority of PTPE over PVL, and to the best of knowledge, this is the first report to demonstrate such difference.

Terminology
PVL is a procedure to ligate the unilateral portal vein to induce ipsilateral liver atrophy and consequent hypertrophy of the contralateral liver. PTPE is a procedure to occlude the unilateral portal vein by percutaneously injecting embolic agent to induce ipsilateral liver atrophy and consequent hypertrophy of the contralateral liver. TSHP is a surgical strategy adopted for severe metastatic liver cases where it is impossible to remove all malignant lesions in a single procedure. In the first procedure, resectable tumors are removed and after a period of time for liver regeneration, the second procedure is performed to remove the remaining tumors.

Peer review
The current study compared PTPE and unilateral PVL. Using small cohorts, the authors concluded that PTPE is a more effective procedure than PVL as the postoperative liver volume atrophy rate was significantly greater in the PTPE group than the PVL group. This study was novel, well written, technically well conducted, and highly clinically important.

Abstract

AIM: To compare the effectiveness of sequential therapy for *Helicobacter pylori* (*H. pylori*) infection with that of triple therapy of varying durations.

METHODS: The 460 patients enrolled in this study had *H. pylori*-associated gastritis or a gastric or duodenal ulcer. After screening, *H. pylori*-infected patients were randomly assigned to receive either conventional triple therapy for 7, 10 or 14 d, or a new 10-d sequential therapy. Each of the 4 treatment groups included 115 patients. The outcomes of eradication therapy were assessed 4 wk after treatment by the urea breath test and histology.

RESULTS: The overall eradication rate was 81.0%, and eradication rates were 75.7% for 7-d conventional triple therapy, 81.9% for 10-d conventional triple therapy, 84.4% for 14-d conventional triple therapy, and 82.0% for 10-d sequential therapy. Neither intention-to-treat analysis nor per protocol analysis showed significant differences in eradication rates using sequential therapy or the standard triple therapy ($P = 0.416$ and $P = 0.405$, respectively).

CONCLUSION: There are no significant differences between 10-d sequential eradication therapy for *H. pylori* and any duration of standard triple treatment in Korean patients.

INTRODUCTION

Helicobacter pylori (*H. pylori*), first identified in 1982, is recognized as a risk factor for gastrointestinal ulcers, chronic gastritis, gastric adenocarcinoma, and mucosa-associated lymphoid tissue lymphoma. The most widely used eradication therapy at this time combines a proton pump inhibitor (PPI) with 2 antibiotics, amoxicillin and clarithro-

mycin. However, the failure rate of this triple therapy is 10%-20%[1-4] and has increased with the emergence of clarithromycin resistance[5-7]. When first-line triple therapy fails, a quadruple regimen of PPI, bismuth, tetracycline, and metronidazole is usually applied. The failure rate of this second-line therapy (20%-30%) is also high, which may stem from metronidazole resistance[6,8,9].

To address an increase in antibiotic resistance in *H. pylori* in Western countries, a 10-d sequential therapy was proposed. This new regimen includes a PPI plus 1 g of amoxicillin twice daily for the first 5 d followed by a PPI, 500 mg of clarithromycin and 500 mg of tinidazole twice daily for the remaining 5 d. Since Zullo *et al*[10]. first developed this therapy, it has produced higher eradication rates than triple therapy in several studies[11-15]. However, few studies have reported outcomes of sequential therapy in East Asian countries. Since antibiotic-resistant strains differ in geographical distribution, an *H. pylori* eradication therapy may vary in effectiveness between regions[16,17].

Furthermore, no universal evidence-based guidelines have been established for the optimal duration of triple therapy. Some countries prefer a 7-d therapy, and in other countries treatment longer than 7-d is deemed mandatory[1,18,19]. Most previous comparative studies tested the sequential regimen against 7-d or 10-d triple therapy.

We conducted this study to prospectively compare the *H. pylori* eradication rate obtained with a 10-d sequential regimen to the rates achieved with the conventional 7-d, 10-d and 14-d triple regimens in a Korean cohort of *H. pylori*-infected patients.

MATERIALS AND METHODS

Study population
From March 2008 to August 2011, we interviewed and enrolled patients who visited Korea University Anam Hospital with *H. pylori*-positive gastritis or peptic ulcer (gastric and/or duodenal ulcer) identified in gastroduodenoscopy. *H. pylori* infection was detected using a urea breath test, rapid urease test, or histopathological investigation. This was a prospective randomized controlled study.

Four hundred and sixty patients tested positive for *H. pylori* during this time. Study inclusion criteria were *H. pylori*-associated gastritis, or gastric or duodenal ulcer, and age 18 years or older. Criteria for exclusion from the study were: (1) serious kidney disease that required drug dosage adjustment; (2) previous treatment with antibiotics within the past 4 wk; (3) PPI treatment during the previous 8 wk; (4) previous *H. pylori* eradication failure; (5) significant cardiopulmonary, endocrine or hepatic disease, or a hematologic disorder; (6) previous surgery of the upper gastrointestinal tract; (7) history of malignancy; (8) history of drug or alcohol misuse; (9) antiulcer medication treatment within previous 4 wk; (10) systemic glucocorticoid or anticoagulation treatment; (11) severe psychiatric or neurological disease; and (12) current pregnancy or lactation. After screening, participants were randomly

assigned to treatment groups using a computer generated list. Patients provided written consent to participate, and the Institutional Review Board of Korea University Hospital approved this study. We conducted the study in agreement with the principles of the Declaration of Helsinki, the International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use and Guidelines for Good Clinical Practice.

Treatment protocol
Eligible patients who had no documented contraindications were randomly assigned to one of four treatments: (1) standard triple therapy (rabeprazole 20 mg + amoxicillin 1.0 g + clarithromycin 500 mg twice daily) for 7 d; (2) standard triple therapy for 10 d; (3) standard triple therapy for 14 d; and (4) a 10-d sequential treatment (amoxicillin 1.0 g + rabeprazole 20 mg twice daily for the first 5 d, followed by rabeprazole 20 mg + clarithromycin 500 mg + tinidazole 500 mg twice daily for the remaining 5 d).

Confirmation of eradication
At least 4 wk after completion of treatment, a urea breath test and histopathological diagnosis were performed to determine if *H. pylori* had been successfully eradicated. Drug side effects were assessed with a questionnaire.

Statistical analysis
Statistical analyses were performed using Statistical Package for the Social Sciences (SPSS 18.0 for Windows; SPSS Inc., Chicago, IL, United States). Power calculations to determine sample size based on previously published data[20] showed that 420 patients would be required to detect a treatment difference at the 5% level of significance with a power of 80%. Hence the sample size was set at 460 patients to allow for a possible 10% dropout rate.

Univariate analysis, with age, gender, endoscopic diagnosis, smoking, alcohol habits, and medications (NSAID) as variables, was performed using the χ^2 test. The *H. pylori* eradication rate was determined using intention-to-treat (ITT) and per protocol (PP) analyses using the χ^2 test. $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics
The mean age of the 460 patients enrolled in this study was 46.8 years. Two hundred and thirty-nine patients were male and 221 were female. Each of the 4 treatment groups included 115 patients. The groups did not differ significantly in gender, previous disease history, endoscopic diagnosis, smoking, alcohol consumption, NSAID and aspirin use, or use of previous medications (Table 1).

Eradication rates
Twenty-five of the 460 patients did not return to hospital for eradication testing and 8 patients discontinued the

medication due to side effects. Eradication results were confirmed in 427 patients; eradication was confirmed in 408 of the 427 patients by the urea breath test and in 19 patients by histopathological examination for *H. pylori*.

Among the 427 patients, 107 patients received the 7-d conventional triple therapy, 105 received the 10-d conventional triple therapy, 109 received the 14-d conventional triple therapy, and 106 received the 10-d sequential therapy (Figure 1).

The overall eradication rate among the 427 patients was 81.0%. The eradication rates according to group were as follows: 70.4%/75.7% (ITT/PP) for the 7-d conventional triple therapy group, 74.7%/81.9% for the 10-d conventional triple therapy group, 80.0%/84.4% for the 14-d conventional triple therapy group, and 75.6%/82.0% for the 10-d sequential therapy group. Neither the ITT nor the PP analysis showed a significant difference in eradication rates between the new 10-d sequential therapy and the standard triple therapy (*P* = 0.416 and *P* = 0.405, respectively) (Table 2).

Compliance and side-effects
The compliance was greater than 95% for all of the triple conventional groups and the 10-d sequential therapy group.

In the latter group, 15 patients showed side effects including problems with taste (*n* = 1), loose stools (*n* = 3), nausea/vomiting (*n* = 4), epigastric discomfort (*n* = 3), abdominal distention (*n* = 3) and itching (*n* = 1) (Table 3). For the triple therapy, reported side effects included problems with taste, loose stools, abdominal discomfort, nausea, vomiting, epigastric discomfort, and itching. Most side effects were not severe (Table 3).

DISCUSSION
We compared the *H. pylori* eradication rates obtained after 10-d sequential therapy with those achieved after 7-, 10- and 14-d conventional triple therapy and found no significant differences.

Triple therapy, which is currently used most widely, combines a PPI with 2 antibiotics such as clarithromycin and amoxicillin[2]. However, resistance to clarithromycin now stands at 13.8%-16.7%[5,21], and recent reports place the rate of *H. pylori* eradication at 74%-83.6%[18,22].

The Maastricht III consensus report published in 2005 recommends a quadruple therapy, which includes a PPI, bismuth, tetracycline, and metronidazole, as a second-line eradication therapy[1]. The effectiveness of

Table 2 *Helicobacter pylori* eradication rates according to treatment group

	7-d eradication	10-d eradication	14-d eradication	10-d sequential eradication	Total	*P* value
ITT	70.4%	74.7%	80.0%	75.6%	75.2%	0.416
	81/115	86/115	92/115	87/115	346/460	
PP	75.7%	81.9%	84.4%	82.0%	81.0%	0.405
	81/107	86/105	92/109	87/106	346/427	

ITT: Intention-to-treat; PP: Per protocol.

Table 3 Adverse events

	7-d eradication	10-d eradication	14-d eradication	10-d sequential eradication
Taste alterations	1	1	1	1
Loose stools	3	3	2	3
Abdominal distention	2	3	3	3
Nausea/vomiting	2	4	3	4
Epigastric discomfort	3	2	3	3
Itching	0	1	0	1
Total	11	14	12	15

quadruple therapy is compromised, however, by resistance to metronidazole in *H. pylori*[8,23,24]. The prevalence of metronidazole resistance in Korea has increased from 33.3% in 1994, to 47.7% in 1999, to 66.2% in 2003[25].

In Western countries, increased resistance to triple therapy fosters much discussion. Notably, an increase in clarithromycin resistance found through large-scale studies in several European countries is linked to extensive use of this antibiotic in both children and adults, and to an increasing rate of failure to eradicate *H. pylori* using conventional therapy[20,26-28]. Nevertheless, European guidelines for *H. pylori* treatment specify triple therapy with a PPI, amoxicillin, and clarithromycin or metronidazole for 14 d, or quadruple therapy with a PPI, amoxicillin, clarithromycin, and metronidazole for 10-14 d[1,29].

Zullo *et al*[10] reported a new 10-d sequential therapy for *H. pylori* in 2000. This regimen includes a PPI plus 1 g of amoxicillin for the first 5 d followed by a PPI, 500 mg of clarithromycin, and 500 mg of tinidazole for the remaining 5 d. Some studies report that this regimen yields a higher *H. pylori* eradication rate than triple therapy[11,30,31] and improves the rate in children as well as in adults[32,33]. The mechanisms underlying the effects of the 10-d sequential treatment are not known; however, the early administration of amoxicillin appears to weaken the cell walls of *H. pylori*, reducing resistance to clarithromycin and enhancing the treatment effects[28,34]. The 5-d PPI and amoxicillin regimen may reduce the numbers of *H. pylori* by 50%, which when followed by 5 d of triple therapy, is thought to improve the overall effectiveness of the regimen[35,36]. In addition, the use of 3 or more antibiotics improves the treatment effects[20].

In our patient cohort, the 10-d sequential therapy did not achieve a higher eradication rate than the standard triple therapy. This discrepancy may reflect in part genetic differences in *H. pylori* strains in the East and West[37]. In addition, the high rate of antibiotic resistance in Korea, in particular to metronidazole, may contribute to geographical variations in treatment effectiveness. Factors in addition to location and antibiotic resistance that may affect *H. pylori* eradication include patient age and compliance, gastric acid concentration, individual response to PPI, and differences in prevalence of *H. pylori* Cag A genotype[38]. We did not investigate gastric acid concentration, antibiotic resistance (or minimal inhibitory concentrations), or *H. pylori* genotypes; and as all subjects were recruited at a single center, geographical differences in *H. pylori* sensitivity and in treatment protocol did not emerge in this study.

The optimal treatment duration using triple therapy is not established. A meta-analysis performed by Fuccio *et al*[39] concluded that extending triple therapy beyond 7 d does not significantly improve outcome compared to the standard 7-d regimen. However, individual studies report higher eradication rates using 10 or 14 d of triple therapy as compared to 7 d[40,41]. Guidelines in the United States and Europe favor longer durations of triple therapy[1,19]. Previous comparative studies of the sequential regimen involved the 7-d and 10-d triple therapy. The present study aimed to clarify the relationship of treatment duration to the *H. pylori* eradication rate.

Data from East Asian countries on use of sequential therapy are limited, and further study is needed to determine the optimal duration of treatment for the triple therapy in Asian populations. Several comparative studies of sequential therapy conducted in Korea differed in outcome. Three of these studies produced higher eradication rates for sequential therapy and another failed to detect a significant difference[38,42-45]. This lack of concordance may be related to known regional variations in prevalence of *H. pylori* resistance to antibiotics, especially clarithromycin, in Korea[17].

In conclusion, we detected no significant differences between the 10-d sequential eradication therapy for *H. pylori* and any duration of the standard triple treatment tested (7-, 10- and 14-d regimens) in a group of Korean patients. More research is needed to determine whether this finding also holds true for patients from other East Asian countries.

COMMENTS

Background

Helicobacter pylori (*H. pylori*), first identified in 1982, has been identified as a risk factor for gastrointestinal ulcer, chronic gastritis, gastric adenocarcinoma, and mucosa-associated lymphoid tissue lymphoma. To date, the most widely used eradication therapy is administration of a proton pump inhibitor (PPI) and 2 types of antibiotics; amoxicillin and clarithromycin. However, the success rate of these multiple antibiotics to eradicate *H. pylori* has decreased in recent years. An increase in the antibiotic resistance of *H. pylori* has been reported in Western countries, and a 10 d sequential eradication therapy was proposed to address this problem.

Research frontiers

The 10-d sequential therapy includes a PPI plus 1 g amoxicillin for the first 5 d

followed by a PPI, clarithromycin 500 mg, and tinidazole 500 mg for the remaining 5 d. There is no established evidence about the duration of triple therapy. Guidelines for the duration of triple therapy varies according to region. So, a Korean research team evaluated whether *H. pylori* eradication with 10 d of sequential therapy is better than the conventional 7-, 10- and 14-d triple therapy in a Korean cohort.

Applications
The researchers concluded that there was no significant difference between 7-, 10-, 14-d standard triple treatment and 10-d sequential therapy in eradication of *H. pylori* in a Korean cohort of patients. Data from East Asian countries on use of sequential therapy are limited, and further study is needed to determine the optimal duration of treatment for triple therapy in Asian populations.

Terminology
Sequential therapy is a new regimen to eradicate *H. pylori* includes a PPI plus 1 g of amoxicillin twice daily for the first 5 d followed by a PPI, 500 mg of clarithromycin and 500 mg of tinidazole twice daily for the remaining 5 d.

Peer review
This is an interesting study aimed at comparing the eradication rate of a 7, 10 and 14 d triple therapy *vs* sequential therapy in Korean patients. Interestingly, the authors found that the eradication rate provided by sequential therapy is similar to that of standard therapy of the same duration. Therefore, the final message is that the most important factor in the eradication of *H. pylori* is the duration of the therapy instead of the way of administration of antibiotics and PPI.

Abstract

AIM: To investigate the ability of hexahydrocurcumin (HHC) to enhance 5-fluorouracil (5-FU) in inhibiting the growth of HT-29 cells by focusing on cyclooxygenase (COX)-2 expression.

METHODS: Antiproliferative effects of HHC and 5-FU, alone and in combination, on growth of HT-29 human colon cancer cells were assessed using 5-diphenyltetrazolium bromide (MTT) reduction assay. In combination treatment, low doses of 5-FU were used combined with various concentrations of HHC to minimize the toxicity and side effects of 5-FU. The therapeutic effects of these drugs on down-regulation of COX-2 mRNA and protein expression were examined using semi-quantitative reverse transcription–polymerase chain reaction (RT-PCR) and Western blotting analysis.

RESULTS: MTT reduction assay indicated that HHC alone markedly decreased the viability of HT-29 human colon cancer cells compared to control. Semi-quantitative RT-PCR analysis indicated that HHC is a selective COX-2 inhibitor. This finding was supported by the observation that HHC significantly down-regulates COX-2 mRNA expression compared to the control (control: $100.05\% \pm 0.03\%$ *vs* HHC: $61.01\% \pm 0.35\%$, $P < 0.05$) but does not alter COX-1 mRNA. In combined treatment, addition of HHC to a low dose of 5-FU exerts a synergistic effect against the growth of HT-29 cells by markedly reducing cell viability to a greater degree than monotherapy. Semi-quantitative RT-PCR indicated that 5-FU at the concentration of 5 μmol/L in combination with HHC at the concentration of 25 μmol/L significantly down-regulates COX-2 mRNA expression when compared with values in cells treated with 5-FU or HHC alone (HHC + 5-FU: $31.93\% \pm 5.69\%$, 5-FU: $100.66\% \pm 4.52\%$ *vs* HHC: $61.01\% \pm 0.35\%$, $P < 0.05$).

CONCLUSION: HHC together with 5-FU exerts a synergistic effect and may prove chemotherapeutically useful in treating human colon cancer.

Medicine, 3-25-8, Nishi-Shinbashi, Minato-ku, Tokyo 105-8461, Japan

Figure 1 Chemical structures of curcumin (A) and hexahydrocurcumin (B).

INTRODUCTION

Colorectal cancer is a major cause of cancer death in many countries. 5-Fluorouracil (5-FU) is a chemotherapy drug widely used in treating colorectal cancer. However, the toxicity of 5-FU towards normal cells and resistance to this drug are major barriers to successful cancer chemotherapy. Therefore, the combination of 5-FU and other regimens is often practiced to enhance the efficacy of 5-FU and also to reduce its toxicity. Previous *in vitro* and *in vivo* studies of colon cancer have reported that 5-FU combined with other regimens, such as genistein[1] and geraniol[2], are more effective than 5-FU treatment alone.

Curcumin (diferuloylmethane, Figure 1), the major yellow pigment in turmeric which is obtained from the rhizome of *Curcuma longa L.*[3], has been traditionally used in cooking in India and Southeast Asia. It has also been used in both *in vitro* and *in vivo* studies as a naturally occurring substance to treat a wide variety of cancers, including ovarian[4], lung[5], skin[6] and colon cancer[7-9]. Curcumin specifically inhibits mRNA and protein expression of cyclooxygenase (COX)-2, which is highly expressed in a variety of human cancers[10-12] including colon cancer, but it does not alter the expression of COX-1, the enzyme that maintains normal gastric mucosa and influences kidney function[13,14]. All these results seem to suggest that curcumin might have minimal toxicity and is safe for the treatment of human colon cancer compared with other traditional chemopreventive agents such as nonsteroidal anti-inflammatory drugs. Although curcumin is a very important agent in preventing and treating colon cancer, its disadvantages include poor solubility and poor absorption in the gastrointestinal tract. Previous reports have indicated that after oral administration of curcumin, about 60% of the dose was absorbed and 38% remained in the large intestine of rats[15] and it is rapidly decomposed in human blood[16]. Curcumin metabolites were synthesized to solve these problems[17].

Hexahydrocurcumin (HHC, Figure 1) is one of the major metabolites of curcumin. Previous studies revealed that this compound exhibits stronger antioxidant activity than curcumin[18]. Moreover, this compound inhibits the biosynthesis of prostaglandin (PGE2) in LPS-stimulated macrophages[19]. PGE2 is a major product of COX-2 enzymes implicated in colorectal carcinogenesis and has been shown to stimulate the growth of human colorectal carcinoma cells. In addition, HHC decreases the level of phorbol ester-induced PGE2 production in human colonic epithelial cells (HCECs) but weakly inhibits COX-2 protein[20].

All these results suggest that HHC down-regulates COX-2 expression, leading us to hypothesize that the HHC-induced suppression of COX-2 expression may improve the effectiveness of the 5-FU conventional chemotherapy drug. The synergistic effect of using 5-FU in combination with curcumin to inhibit the growth of HT-29 human colon cancer cell line has already been demonstrated[21]. The present study aims to evaluate the ability of HHC to enhance 5-FU in inhibiting the growth of HT-29 human colon cancer cells by focusing on the expression of COX-2.

MATERIALS AND METHODS

Materials

The HT-29 human colon adenocarcinoma cell lines were obtained from the American Type Culture Collection. McCoy's 5A Media Modified medium, fetal bovine serum (FBS), trypsin, penicillin and streptomycin were purchased from GIBCO-BRL (Gaitherburg, MD). 5-FU and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) were purchased from Sigma-Aldrich (St. Louis, MO, United States). TRIzol® Reagent was purchased from Invitrogen (Carlsbad, CA). InProm-Ⅱ™ reverse transcriptase and GoTaq® Flexi DNA polymerase were obtained from Promega (Madison, United States). COX-1 monoclonal antibody (1:1000 dilutions) and COX-2 polyclonal antibody (1:500 dilutions) were obtained from Cayman Chemical (Ann Arbor, MI, United States).

Preparation of hexahydrocurcumin

Curcumin was obtained from *Curcuma longa* as described previously[22]. HHC was synthesized from curcumin by catalytic hydrogenation reaction in ethanol for 5 h, with palladium on charcoal as a catalyst. The product was isolated from tetrahydrocurcumin and octahydrocurcumin by silica gel column chromatography, followed by recrystallization with dichloromethane-*n*-hexane to give 45% yield of HHC as a white amorphous solid, m.p. 81-82 ℃. Tetrahydrocurcumin and octahydrocurcumin were obtained in 28% and 11% yields, respectively, after repeated column chromatography. The spectroscopic

(IR, ^{1}H-NMR and mass spectra) data of all the synthesized compounds were identical with those obtained from the previous report[22].

Cell culture and treatment

HT-29 cells were cultured in McCoy's 5A Media Modified containing 10% FBS at 37 ℃ in 5% CO_2 and 90% relative humidity. In all experiments, cells were seeded at 1×10^4 cells per well in 96-well plates for cell viability assay, or 1.5×10^5 cells per well in 6-well plates for RNA extraction and Western blotting analysis. After plating, combinations of 5-FU with HHC were added concurrently to the culture medium. Cells were harvested after various times.

Cell viability assay

HT-29 cells were plated in 96-well plates with 100 μL medium and were exposed to various concentrations of HHC, 5FU or combination of 5FU and HHC for 24 and 48 h. After incubation, cells were treated with 100 μL MTT solution (final concentration, 0.5 mg/mL) at 37 ℃ for an additional 4 h. The formazan crystals were solubilized with 100 μL DMSO and then the absorbance was measured at wavelength 540 nm using a microplate reader (Bio-Tek, Instruments, Winooski, VT, United States).

Analysis of combined effects of 5-FU with HHC

The effectiveness of 5-FU and HHC, alone or in combination, to inhibit growth of HT-29 cells was evaluated by measurement of the combination index (CI)[23], adapted from the method described by Chou *et al*[24]. The fractional inhibitory concentrations were calculated by dividing the concentration of the drug in the combination at IC_{50} by the IC_{50} of the individual drugs. In the following equation, the sum of the dose of 5-FU and the dose of HHC give 50% inhibition of cell growth. CI < 1 indicates a synergistic effect; CI = 1, additive effect; and CI > 1, antagonistic effect. CI = (Dose of 5-FU)/[IC_{50} (5-FU)] + (Dose of HHC)/[IC_{50} (HHC)].

RNA extraction and reverse transcription-polymerase chain reaction

After the HT-29 cells were treated for 24 h, total RNA was extracted using TRIzol reagent (Life Technologies, Carlbad, CA, United States). A volume of 1 μg total RNA from each sample was subjected to reverse transcription using ImProm-II™ Reverse Transcription system (Promega Madison, WI, United States). PCR amplification was performed in a reaction volume of 20 μL containing 2 μL of cDNA product and GoTag® DNA polymerase (Promega, United States) using a PerkinElmer 9600 thermal cycler. Amplification of the constitutively-expressed enzyme d-glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal control. The oligonucleotide primers used were: human COX-1, 5'-TGCCCAGCTCCTGGCCCGCCGCTT-3' (sense), 5'-GT-GCATCAACACAGGCGCCTCTTC-3' (antisense); human COX-2, 5'-TTCAAATGAGATTGTGGAAAAT-3' (sense), 5'-AGATCATCTCTGCCTGAGTATCTT-3' (antisense); GAPDH, 5'-TCCCTCAAGATTGTGAGCAA-3' (sense), and 5'-AAATGAGCCCCAGCCTTCTCC-3' (antisense). The temperature cycling conditions of amplification were as follows: 15 min at 95 ℃, then 25 cycles at 95 ℃ for 1 min, 55 ℃ for 1 min, 72 ℃ for 1 min, and a final extension at 72 ℃ for 10 min. The amplification products were electrophoresed on a 1.0% agarose gel, visualized by ethidium bromide staining, and photographed gel images were scanned using an image analysis system (Gel Doc 1000; Bio-Rad, Hercules, CA, United States). The intensities of specific COX-1 or COX-2 bands were quantitated in relation to GAPDH bands amplified from the same cDNA using Gene Tools analysis software (Syngene, Cambridge, United Kingdom).

Western blotting analysis

Western blotting analysis was performed to measure protein expression of COX-1, COX-2 or β-actin. Cell lysates were prepared by treating the HT-29 cells in RIPA lysis buffer (1 × PBS, 1% Nonidet P-40, 0.5% sodium deoxycholate and 0.1% SDS) for 30 min. The lysates were sonicated twice for 20 s on ice and then were centrifuged at 10 000 × *g* for 10 min to sediment the particulate material. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis was performed under reducing conditions on 8% polyacrylamide gels. The resolved proteins were transferred to PVDF (Millipore, Bedford, MA, United States) and the membranes were incubated with antibodies against human COX-1 or COX-2 (Cayman Chemical Co.) protein in blocking solution. After washing with PBS plus 0.5% Tween-20, the membranes were then incubated with the secondary antibody goat anti-mouse IgG HRP in blocking solution for 2 h at room temperature. After washing, membrane blots were developed using the Immobilon Western (Millipore) chemiluminescence kit and finally exposed to X-ray film.

Statistical analysis

All values are represented as mean ± SE. Statistical comparisons between different treatment results were analyzed by one-way analysis of variance followed by the Dunnett test. The significance was taken when *P*-values were less than 0.05.

RESULTS

Antiproliferative effect of 5-FU, HHC alone and their combination on HT-29 colon cancer cells

After the HT-29 colon cancer cells were exposed to various concentrations of HHC or 5-FU alone for 24 and 48 h, HHC significantly decreased the viability of HT-29 colon cancer cells as compared to control (Figure 2A, upper panel). The growth inhibition ability of HHC on HT-29 cells was time- and concentration-dependent. A similar result was also observed in the 5-FU-treated group (Figure 2B, lower panel). The half-maximal inhibitory concentration of HHC and 5-FU for inhibiting the growth of HT-29 colon cancer cells at 24 and 48 h exposure was

Figure 2 Antiproliferative effect of hexahydrocurcumin and 5-fluorouracil on HT-29 human colon cancer cells. HT-29 cells were exposed to different concentrations of 5-fluorouracil (5-FU) (A) and hexahydrocurcumin (HHC) (B) for 24-48 h and then cell viability was measured by 5-diphenyltetrazolium bromide assay. 5-FU or HHC significantly decreased cell viability concentration-dependently. Data are expressed as mean ± SE. $^aP < 0.05$ *vs* control ($n = 3$).

represented by IC_{50}. The respective IC_{50} values for 24 and 48 h of HHC exposure were 77.05 ± 1.53 and 56.95 ± 2.75, and for 5-FU were 39.13 ± 2.32 and 38 ± 2.21.

To determine the antiproliferative effect of HHC combined with 5-FU, the HT-29 colon cancer cells were exposed to 5-FU at 5 or 25 μmol/L in combination with HHC at 5 or 25 μmol/L concurrently for 24 h and 48 h and then evaluated by MTT assay. After 24 and 48 h of exposure to two doses of HHC (5 and 25 μmol/L) and high dose of 5-FU (25 μmol/L), marked inhibition of the growth of HT-29 colon cancer cells was observed when compared with those treated with 5-FU or HHC alone. Furthermore, exposure to low dose of 5-FU (5 μmol/L) together with high dose of HHC (25 μmol/L) for 24 and 48 h markedly inhibited the viability of HT-29 colon cancer cells when compared with those treated with HHC or 5-FU alone (Figure 3). It was noteworthy that the inhibitory effect of HHC at 25 μmol/L with a low dose of 5-FU was not different from its effect in combination with a high dose of 5-FU. These results indicated that a low dose of 5-FU could effectively be used in combination with high dose of HHC to inhibit the growth of HT-29 colon cancer cells. In addition, the interactions of these two drugs at 25 μmol/L HHC and 5 μmol/L 5-FU for 24 and 48 h were evaluated by the CI at the IC_{50} level as described in materials and methods. The combination of

25 μmol/L HHC with 5 μmol/L 5-FU for 24 and 48 h resulted in a synergistic effect (CI < 1) on the inhibition of the growth of HT-29 colon cancer cells when CI = 0.46 ± 0.01 and 0.57 ± 0.02, respectively.

Combination therapy down-regulation of COX-2 mRNA expression

The MTT results showed that a low dose of 5-FU (5 μmol/L) together with HHC at 25 μmol/L decreased the viability of HT-29 colon cancer cells to a markedly greater extent than 5-FU or HHC exposure alone. Moreover, this treatment showed the quantitative synergistic inhibitory effect; therefore, this combination was chosen to further investigate the effects on COX-2 mRNA expression in HT-29 cells. In this study, we observed that 5-FU alone did not decrease the COX-2 mRNA. However, 5-FU combined with HHC markedly reduced the COX-2 expression compared to HHC or 5-FU alone ($P < 0.05$) (Figure 4). Furthermore, we also observed the combination's effects on the expression of COX-1 mRNA. The result indicated that the level of COX-1 was not altered by treatment with 5-FU or HHC alone, or their combination.

Inhibition of COX-2 protein by the combination of 5-FU with HHC

To investigate the combination's effect on the level of COX-2 protein, HT-29 colon cancer cells were treated with 5-FU (5 μmol/L) together with HHC (25 μmol/L). The results are shown in Figure 5. It is evident that the combination treatment of 5-FU and HHC reduced the COX-2 protein level to a markedly greater degree than did 5-FU or HHC alone ($P < 0.05$). We further examined the combination's effect on the level of COX-1 protein. The results show that 5-FU alone, HHC alone or 5-FU together with HHC did not alter the level of COX-1 protein.

DISCUSSION

The toxicity and the resistance to 5-FU have been major obstacles in successful colorectal cancer chemotherapy. In addition, COX-2 up-regulation is directly involved in colorectal carcinogenesis[25,26]. Therefore, a combined treatment of 5-FU with non-toxic agents that can inhibit COX-2 activity might be useful for treating colon carcinogenesis.

Curcumin, a specific COX-2 inhibitor, is usually used in combination with traditional chemotherapy or other regimens both *in vitro*, *in vivo* and also in clinical studies of colon cancer. Many reports have indicated that curcumin enhanced the cytotoxic effect of celecoxib in several human colon cancer cell lines[27]. This effect has also been observed in colorectal cancer models[28]. Moreover, curcumin enhances the cytotoxic effect of 5-FU and decreases the COX-2 protein expression better than single agent treatment[21]. However, several studies over the past three decades have reported that curcumin exhibits

Figure 3 Combination effects of 5-fluorouracil and hexahydrocurcumin on proliferation of HT-29 colon cancer cells. The HT-29 cells were exposed to 5-fluorouracil (5-FU) (5 and 25 μmol/L), hexahydrocurcumin (HHC) (5 and 25 μmol/L) and their combination for 24 h (A) and 48 h (B) and then harvested for 5-diphe-nyltetrazolium bromide assay. Combination treatment of 5-FU and HHC significantly decreased cell viability compared to the 5-FU or HHC monotherapy. Data are expressed as mean ± SE. [a]*P* < 0.05 *vs* 5-FU or HHC monotherapy (*n* = 3).

poor bioavailability due to poor absorption, low serum levels and rapid metabolism. Therefore, the pharmacological activity of curcumin may be mediated in part by its metabolites[29,30].

In the present study, we investigated the anti-carcinogenic effects of HHC on growth of HT-29 human colon cancer cells. We found that HHC was sufficient for inhibiting the growth of human colon cancer cells by decreasing the viability of HT-29 cells through down-regulation of COX-2 mRNA and protein expression. Moreover, HHC did not alter COX-1 mRNA and protein expression. These results agreed with previous study, which suggested that HHC could sensitize the cancer cells to chemotherapeutic drugs by decreasing phorbol ester-induced PGE$_2$ production in HCECs[20]. PGE$_2$ is a major

product of COX-2 enzymes. Moreover, it has been demonstrated that HHC exhibited higher antioxidant activity than its curcumin progenitor[18] and it has been suggested that the hydrogenation at the conjugated double bonds of the central seven-carbon chain and a keto group of the β-diketone of curcumin to HHC markedly enhances antioxidant activity.

Based on these results, it is reasonable to assume that HHC is a safe and effective agent for the treatment of colon cancer, and that this compound is more stable than curcumin. The present investigation deals with the study of the combination effect of HHC with 5-FU chemotherapy drug. Our results indicated that HHC in combination with even a low concentration of 5-FU (5 μmol/L) was sufficient to decrease the viability of HT-29 colon

Figure 5 Combination effects of hexahydrocurcumin and 5-fluorouracil on cyclooxygenase-2 protein expression in HT-29 colon cancer cells. A: Western blotting with polyclonal anti-cyclooxygenase (COX) 1 (70 kDa) and anti-COX2 (72 kDa), and anti-β actin (43 kDa) antibodies; B: Fold changes of proteins as represented below, each band was measured by Lab Image software. Combination treatment of 5-fluorouracil (5-FU) and hexahydrocurcumin (HHC) significantly decreased the expression of COX-2 protein with no effect on the expression of COX-1 protein. Values are expressed as percentage of control (mean ± SE), [a]$P < 0.05$ *vs* control; [c]$P < 0.05$ *vs* 5-FU or HHC monotherapy ($n = 3$).

cancer cells. Moreover, this combination showed a synergistic effect on antiproliferation against colon cancer cells (CI < 1) and down-regulated the expression of COX-2 mRNA and protein, compared to either 5-FU or HHC monotherapy. Based on these results, we suggest that the addition of HHC could enhance the inhibiting effects of 5-FU on the growth of HT-29 human colon cancer cells. Moreover, the combination of these drugs that are different in their modes of action could prove much safer and more effective than cancer monotherapy[27]. In addition, this combination did not alter the COX-1 mRNA and protein levels. It is thus reasonable to assume that this therapeutic approach may have no toxic effect and enables the use of 5-FU chemotherapy drug at a lower and safer concentration, which would be highly desirable for long-term treatment of colon cancer.

In conclusion, this study illustrates that HHC is a specific COX-2 inhibitor that plays an important role in carcinogenesis. It has been demonstrated for the first time in this study that the addition of HHC to 5-FU standard chemotherapy in HT-29 human colon cancer cells can enhance the growth inhibition and down-regulation of COX-2. Thus, the combination of these two drugs should have a great potential to be used to treat human colon cancer.

COMMENTS

Background
Colorectal cancer is a major cause of cancer death in many countries. The toxicity of 5-fluorouracil (5-FU) chemotherapeutic drug for normal cells and resistance to this drug are major barriers to successful cancer chemotherapy.

Research frontiers
Combining 5-FU with other regimens and agents, such as curcumin, is a strategy to enhance the efficacy of 5-FU and also to reduce its toxicity. Curcumin down-regulates cyclooxygenase (COX)-2, which is highly expressed in human colon cancer, but it does not alter the level of COX-1, a housekeeping enzyme. However, curcumin is only slightly absorbed in the gastrointestinal tract due to its poor solubility in water. Therefore, hexahydrocurcumin (HHC), one of the major curcumin metabolites, was synthesized to solve these problems.

Innovations and breakthroughs
This report has highlighted the importance of HHC which could improve the effectiveness of the 5-FU chemotherapeutic drug. In this study, the authors demonstrate that HHC is a specific COX-2 inhibitor. HHC down-regulates COX-2 expression, but it does not alter the level of COX-1. This is the first study to report the anti-carcinogenic effects of HHC on growth of human colon cancer cells. Furthermore, HHC has ability to enhance 5-FU in inhibiting the growth of HT-29 human colon cancer cells and down-regulates the expression of COX-2 mRNA and protein.

Applications
This report illustrates the action of HHC combined with 5-FU, and this study may represent a future strategy to provide much safer and more effective treatment for patients with colon cancer.

Terminology
HHC is one of the major curcumin metabolites. Curcumin is the major yellow pigment in turmeric which is obtained from the rhizome of *Curcuma longa* L, traditionally used in cooking in India and Southeast Asia.

Peer review
This is a good descriptive study in which authors investigate ability of HHC to enhance 5-FU in inhibiting the growth of HT-29 cells by focusing on COX-2 expression. The results are interesting and suggest that HHC together with 5-FU exerted a synergistic effect and may prove chemotherapeutically useful in treating human colon cancer.

Abstract

AIM: To compare the efficacy of the proton-pump inhibitor, rabeprazole, with that of the H$_2$-receptor antagonist, ranitidine, as on-demand therapy for relieving symptoms associated with non-erosive reflux disease (NERD).

METHODS: This is a single center, prospective, randomized, open-label trial of on-demand therapy with rabeprazole (group A) *vs* ranitidine (group B) for 4 wk. Eighty-three patients who presented to the American University of Beirut Medical Center with persistent gastroesophageal reflux disease (GERD) symptoms and a normal upper gastrointestinal endoscopy were eligible for the study. Patients in group A (n = 44) were al-lowed a maximum rabeprazole dose of 20 mg twice daily, while those in group B (n = 39) were allowed a maximum ranitidine dose of 300 mg twice daily. Efficacy was assessed by patient evaluation of global symptom relief, scores of the SF-36 quality of life (QoL) questionnaires, total number of pills used, and number of medication-free days.

RESULTS: Among the 83 patients who were enrolled in the study, 76 patients (40 in the rabeprazole group and 36 in the ranitidine group) completed the 4-wk trial. Baseline characteristics were comparable between both groups. After 4 wk, there was no significant difference in the subjective global symptom relief between the rabeprazole and the ranitidine groups (71.4% *vs* 65.4%, respectively; P = 0.9). There were no statistically significant differences between mean cumulative scores of the SF-36 QoL questionnaire for the two study groups (rabeprazole 22.40 ± 27.53 *vs* ranitidine 17.28 ± 37.06; P = 0.582). There was no significant difference in the mean number of pills used (rabeprazole 35.70 ± 29.75 *vs* ranitidine 32.86 ± 26.98; P = 0.66). There was also no statistically significant difference in the mean number of medication-free days between both groups.

CONCLUSION: Rabeprazole has a comparable efficacy compared to ranitidine when given on-demand for the treatment of NERD. Both medications were associated with improved quality of life.

Jordan; Florencia Georgina Que, MD, Department of Surgery, Mayo Clinic, 200 First Street Southwest, Rochester, MN 55905, United States

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a chronic, remitting-relapsing medical condition that involves the reflux of gastric contents into the esophagus causing a multitude of unpleasant symptoms including heartburn, sore throat, chest pain, cough, and regurgitation. GERD has been shown to have a significant negative impact on the quality of life (QoL) of affected patients and may even impair their daily activities[1]. The prevalence of GERD has markedly increased over the past two decades affecting 20%-40% of the western population[2-5]. This prevalence is predicted to rise further with time[6].

Non-erosive reflux disease (NERD) has been defined by the Vevey NERD Consensus Group as a subcategory of GERD that is characterized by reflux-related symptoms with the absence of esophageal mucosal erosions or breaks at conventional endoscopy and without recent acid-suppressive therapy[7]. About two-thirds of patients with typical GERD symptoms, such as heartburn, belching, cough, nausea, sore throat and voice changes, have no erosive changes on upper gastrointestinal endoscopic evaluation[2]. The complex pathophysiology of NERD and the exact mechanisms by which the associated symptoms are caused remain unclear[7]. It is highly evident, however, that the degree of acidity and duration of esophageal acid exposure play an essential role in NERD symptomatology. These factors are not different from the precipitants of moderate erosive reflux disease (ERD)[7-11].

The majority of GERD patients use acid-suppressive medications to control their symptoms. Unlike ERD, symptoms of NERD are more difficult to control, and tend to have a lower response rate, even to the most potent proton-pump inhibitors (PPIs)[12,13]. Nonetheless, initial management of NERD is similar to that of GERD, and includes the use of a PPI or H_2-receptor antagonist (H2RA). Around 75% of patients with NERD report a relapse of their symptoms after cessation of the initial therapy. Therefore, long-term management is often needed to maintain symptom control[1]. The preferred maintenance therapeutic strategy is supposed to utilize the least amount of medication. Hence, on-demand therapy should be a reasonable therapeutic mode for managing patients with NERD symptoms. By convention, medications for on-demand therapy should ensure a rapid onset of action in order to give instantaneous relief.

To our knowledge, and after reviewing the literature, no clinical studies have compared a PPI to an H2RA as on-demand therapy for NERD. The objective of our trial is to compare the efficacy of a PPI, rabeprazole, to that of a standard H2RA, ranitidine, as an on-demand therapy for treating patients with NERD. We selected rabeprazole among the various currently available PPIs because it results in a faster and a more prompt acid suppression and has the advantage of a first-dose symptom relief[14-16]. H2RAs including ranitidine are widely used on-demand for the management of GERD symptoms.

MATERIALS AND METHODS

The study was a 4-wk prospective, randomized, single center, open-label trial of on-demand therapy with rabeprazole *vs* ranitidine for patients with NERD. Patients who were considered eligible for enrollment had to be older than 18 years of age, had persistent GERD symptoms (typical or atypical), and a negative upper gastrointestinal endoscopy exam. Exclusion criteria were age below 18 years and older than 75 years, allergy to rabeprazole or ranitidine, any degree of esophagitis or mucosal damage on upper gastrointestinal endoscopy, pregnancy, and any use of PPI or H2RA within 2 wk of enrollment into the study.

Patients who presented to the American University of Beirut Medical Center with persistent GERD symptoms and a normal upper gastrointestinal endoscopy were considered candidates for the study. After signing a written informed consent, patients were asked to complete a baseline SF-36 QoL questionnaire. They were randomized by an independent investigator using a computer-generated random number table to one of two groups: those to receive rabeprazole (group A) and those to receive ranitidine (group B). Patients in group A were allowed a maximum oral rabeprazole dose of 20 mg (10 mg tablets, twice daily), while those in group B were allowed a maximum oral ranitidine dose of 300 mg (150 mg tablets, twice daily). A research fellow was responsible for contacting patients by phone on a daily basis over the 4-wk study period to assess for the number of pills taken, the need for a rescue medication, as well as the occurrence of any side effects. At the end of the 4 wk, patients were asked about their global symptom relief and were also requested to answer the post-treatment QoL questionnaire.

Primary efficacy endpoints were assessed by the subjective global symptom relief, total number of pills used, number of medication-free days, and the need for rescue medications. Secondary endpoints included the scores of the QoL questionnaires and the occurrence of side effects. The study protocol and informed consent were approved by the Institutional Review Board at the American University of Beirut Medical Center.

Statistical analysis

Analysis of the primary end-point (global symptom relief) was done according to intent-to-treat (ITT) basis.

Table 1 Patient baseline characteristics *n* (%)

	Group A (*n* = 44)	Group B (*n* = 39)	*P* value
Age (mean ± SD) (yr)	45.4 ± 15.2	45.1 ± 15.3	0.916
Gender M:F	16:28	16:23	0.663
Duration of symptoms (yr)	4.68 ± 7.79	3.85 ± 4.21	0.552
Esophageal manifestations	28 (63.6)	29 (74.4)	0.293
Regurgitation and heartburn	21 (47.7)	23 (59.0)	0.306
Epigastric pain	8 (18.2)	9 (23.1)	0.581
Nausea	7 (15.9)	6 (15.4)	0.948
Vomiting	0 (0)	1 (2.6)	0.285
Extra-esophageal manifestations	38 (86.4)	33 (84.6)	0.821
Chest pain	16 (36.4)	10 (25.6)	0.293
Globus	24 (54.5)	16 (41.0)	0.219
Hoarseness	15 (34.1)	10 (25.6)	0.402
Metallic taste	22 (50.0)	16 (41.0)	0.413
Nocturnal cough	17 (38.6)	09 (23.1)	0.127
Dyspnea	21 (47.7)	20 (51.3)	0.746
Sore throat	20 (45.5)	13 (33.3)	0.260
Thick sputum production	24 (54.5)	13 (33.3)	0.052
Mixed symptoms	25 (56.8)	24 (61.5)	0.663

Group A, rabeprazole; Group B, ranitidine. M: Male; F: Female.

The association between the drug group and response for binary measures was assessed using the Fischer's Exact test. For continuous measures, either a two sample *t*-test or Wilcoxon two sample rank sum test were used depending on whether normality held or not. Frequency tables and cross-tabulations were derived in order to depict any associations between the different variables. The paired samples *t*-test and the independent-samples *t*-test were used to compare the QoL score before and after treatment. A *P*-value at or below 0.05 was significant. The data were entered and analyzed using SPSS for Microsoft version 18.0 (SPSS Inc, United States).

Sample size calculation: The sample size was estimated based on an expected response rate of 80% for rabeprazole and 50% for ranitidine. Therefore, we had to include 42 patients in each arm of the study to detect a statistical significance using a power of 80% and a margin of error of 5%.

RESULTS

A total of 83 patients with symptoms consistent with GERD and a negative upper gastrointestinal endoscopy were enrolled in the study. The random assignment of patients into two arms resulted in 44 patients (53%) in group A assigned to receive rabeprazole, and 39 patients (47%) in group B assigned to receive ranitidine. Overall, seven patients dropped out of the study; two patients because of mild medication side effects (both of whom were receiving rabeprazole) and five were lost to follow-up. Seventy-six patients completed the 4-wk trial per-protocol, 40 of whom were assigned to the rabeprazole group and 36 to the ranitidine group. The ITT population consisted of 83 patients.

Baseline characteristics between both groups were

Table 2 Subjective global symptom assessment *n* (%)

	Better	Same	Worse	Total
Group A	20 (71.4)	7 (25.0)	1 (3.6)	28
Group B	17 (65.4)	8 (30.8)	1 (3.8)	26
Total	37	15	2	54

P = 0.9; Group A, rabeprazole; Group B, ranitidine.

comparable (Table 1). The mean age of individuals in group A was 45.43 ± 15.16 years *vs* 45.08 ± 15.29 years for those in group B. There was a slight female predominance in both groups: 63.6% in group A and 59% in group B. Most patients had been symptomatic for more than 1 year, with duration ranging from 3 mo to 20 years. The majority of patients (85.5%) suffered from extra-esophageal manifestations, with globus sensation, metallic taste, shortness of breath, as well as thick sputum production being the commonest among these manifestations. Esophageal manifestations were encountered in approximately 69% of patients.

Global symptom improvement was subjectively assessed at the end of the 4-wk treatment phase. Improvement was reported in 71.4% (20 out of 28) of patients in group A and 65.4% (17 out of 26) of patients in group B, while worsening of symptoms was noted in 3.6% and 3.8 % of patients in group A and B, respectively (Table 2). Of the patients in group A, 25% experienced no change in symptoms compared to 30.8% of group B patients (*P* = 0.889). There was no difference in gender distribution between responders and non-responders in either group. However, the mean age of responders to rabeprazole was significantly lower than that of patients who did not respond to this drug (38.90 ± 13.15 years *vs* 53.14 ± 17.68 years; *P* = 0.033). This difference was not noted in patients who received ranitidine.

Regarding the mean number of pills consumed, patients in group A used a mean number of 35.70 ± 29.75 pills of rabeprazole 10 mg, while group B patients consumed a mean number of 32.86 ± 26.98 pills of ranitidine 150 mg, (*P* = 0.66). The mean number of medication-free days was 13.08 ± 9.73 in group A, and 10.78 ± 10.14 in group B (*P* = 0.32).

The SF-36 QoL questionnaire was completed by a total of 65 patients at baseline: 37 in group A (84.1%) and 28 in group B (71.8%). Mean cumulative scores at baseline were comparable between groups A and B, 106.38 ± 30.30 *vs* 104.43 ± 29.82, respectively (*P* = 0.797) (Figure 1). A follow-up SF-36 QoL questionnaire was obtained from 50 patients immediately after the 4-wk treatment phase: 25 were in group A (62.5%) and 25 in group B (69.4%). Mean cumulative scores at follow-up were 135.32 ± 32.19 for group A and 122.76 ± 37.48 for group B (*P* = 0.210). Mean scores of both groups increased significantly (*P* < 0.01 for group A and *P* = 0.028 for group B, compared to respective baseline scores). However, the absolute score differences between baseline and 4 wk for groups A and B were (22.40 ± 27.53

Figure 1 Mean quality of life scores at baseline and immediately after treatment (*n* = 25 at baseline). Group A, rabeprazole; Group B, ranitidine.

vs 17.28 ± 37.06, respectively; *P* = 0.582), indicating that both drugs improve patient QoL to the same extent.

DISCUSSION

The present study compares the efficacy of the PPI rabeprazole to that of the H2RA ranitidine, as an on-demand option in the management of patients with NERD. The impact on QoL was also evaluated as a secondary outcome with both drug regimens.

Analysis of our data showed that rabeprazole is as effective as the routinely and commonly used ranitidine in controlling both the typical and atypical symptoms in patients with NERD. Evidence from several previous studies supports our findings regarding the efficacy of anti-secretory (H2RA and PPI) therapy in patients with NERD[17-24]. However, no head-to-head comparison between any H2RA and PPI had been carried out in the setting of on-demand therapy for NERD.

Our PubMed® search identified a number of clinical trials[14,21-25] that assessed the efficacy of various PPIs (rabeprazole, omeprazole, esomeprazole, lansoprazole) when given as on-demand in patients with NERD. Almost all of these studies were conducted over a period of time ranging from 3 mo to 6 mo and preceded by initial short periods (around 4-8 wk) of daily treatment with the designated PPI to achieve complete symptom resolution. A study by Lind *et al*[21] randomized 424 patients with NERD to one of three groups: omeprazole 20 mg, omeprazole 10 mg, or placebo. After 6 mo of on-demand therapy, it was concluded that omeprazole was effective in the majority of NERD patients. In another placebo-controlled study, Talley *et al*[22] assigned 342 patients to either esomeprazole 20 mg or placebo. On-demand therapy with esomeprazole 20 mg was found suitable for the long-term symptom management of NERD patients. In a separate placebo-controlled trial, Talley *et al*[23] assessed the efficacy of on-demand therapy with esomeprazole 40 mg or 20 mg in patients with NERD and showed that both dosages were superior to placebo in controlling heartburn in those patients. Bytzer *et al*[24] achieved favorable results in

a 6-mo trial of on-demand rabeprazole 10 mg in patients with NERD. Five hundred and twenty-three patients with NERD were given 4 wk of rabeprazole 10 mg once daily. The 432 patients who had complete resolution of their symptoms were then randomized for the on-demand phase of the study to two groups: rabeprazole 10 mg and placebo. Symptom relief was significantly better in the rabeprazole group compared to the placebo group.

Rabeprazole was also investigated as on-demand treatment by Ponce *et al*[25] in patients with NERD and low-grade esophagitis. Symptom control was maintained in over 85% of patients during six months of on-demand rabeprazole 20 mg therapy, following a 4-wk daily run-in period with rabeprazole 20 mg per day. During the study period, PPI consumption was found to be low and patient satisfaction with the treatment was high.

Rabeprazole appeared to be ideal for our study given its rapid onset of action and powerful acid suppression[14-16]. Studies involving NERD patients have documented its superiority over placebo. In addition, on-demand use of rabeprazole for the management of NERD incurs the least cost in comparison with other PPIs[26].

H2RAs have been widely used on-demand for patients with GERD. Clinical studies have demonstrated that, when given on-demand, they are superior to placebo in controlling heartburn in this group of patients[18,19,27]. These findings may be extrapolated to NERD patients who constitute the majority of patients with GERD. H2RAs are known to have a rapid onset, but a short duration of action. They suppress acid for approximately 4 to 8 h and produce incomplete inhibition of post-prandial gastric acid secretion. They inhibit acid secretion by up to 70% over a 24-h period. A major disadvantage of using these drugs is the development of tolerance that occurs within two weeks of uninterrupted daily intake[28]. Thus, tolerance would be less concerning if they are to be used on an on-demand basis[29]. PPIs have the advantage over H2RA in controlling both basal and food-stimulated acid secretion producing a longer-lasting acid suppression in addition to the fact that tolerance has not been observed with PPIs.

Our pilot study has a few limitations. One is the open-label nature of the study. Although patients were randomized to different arms, they were aware of the arm they were randomized to. This may have created some bias especially if those patients were previously treated with the same medication class that they were assigned to. The sample size was also relatively small and further investigation based on a larger number of patients is necessary to corroborate our data. Our study duration was short, then again the purpose of our study was not to prove the efficacy of either of the two drugs, but rather to compare them.

The advantages of our study include the fact that it is the first to compare an H2RA to a PPI in the setting of on-demand therapy for NERD. We also showed response to on-demand therapy for both typical and atypical reflux symptoms. Finally, this is a "pure" on-demand study, in

the sense that it was performed without a preceding continuous anti-secretory treatment period.

In conclusion, rabeprazole and ranitidine have been shown to be comparable in efficacy when given on-demand for the treatment of NERD. Both medications were associated with a statistically significant improved quality of life.

COMMENTS

Background
Non-erosive reflux disease (NERD) is the most prevalent of the subcategories of gastroesophageal reflux diseases (GERD). It is a chronic condition with a significant impact on patients' quality of life. On-demand acid-suppressive agents constitute the mainstay in the management of NERD. The most favorable of such agents should be fast-acting, long-lasting, potent, and safe, in order to reach an effective and timely symptom control.

Research frontiers
Acid-suppressive medications differ in terms of power of acid inhibition, onset and duration of action, and drug interactions. Identification of the ideal agent in the context of chronic and on-demand therapy is of utmost interest to patients and researchers alike.

Innovations and breakthroughs
The authors compared the efficacy of the proton-pump inhibitor (PPI) rabeprazole, to that of the H2-receptor antagonist ranitidine, as on-demand therapy for relieving symptoms associated with NERD. They concluded that both possessed comparable efficacy and were associated with an improved quality of life. Thus, a fast-acting PPI, rabeprazole, is an effective on-demand option for the management of NERD.

Applications
In conditions where an acid-suppressive medication is to be prescribed for a long period of time, recognizing the agent that has the best efficacy and safety profiles would have a prompt and significant clinical impact.

Terminology
NERD is a non-erosive reflux disease, commonly defined as the presence of classic GERD symptoms in the absence of esophageal mucosal injury during upper endoscopy. The majority of patients with GERD fall into the NERD subcategory.

Peer review
The article is novel and interesting. It answers an important research question, which might result in changing clinical practice of NERD management. The design is appropriate, and the manuscript is well written.

in Chang Gung Memorial Hospital. Patients with characteristic PE bile duct on ERC were identified from the database. Data of the patients as well as the safety and technical success of therapeutic ERC were collected and analyzed retrospectively.

RESULTS: A total of 30 patients with CBD stones and characteristic PE segments were enrolled in this study. The median patient age was 45 years (range, 20 to 92 years); 66.7% of the patients were men. The diameters of the widest non-PE CBD segment, the PE segment, and the largest stone were 14.3 ± 4.9 mm, 5.8 ± 1.6 mm, and 11.2 ± 4.7 mm, respectively. The length of the PE segment was 39.7 ± 15.4 mm (range, 12.3 mm to 70.9 mm). To remove the CBD stone(s) completely, mechanical lithotripsy was required in 25 (83.3%) patients even though the stone size was not as large as were the difficult stones that have been described in the literature. The stone size and stone/PE segment diameter ratio were associated with the need for lithotripsy. Post-ERC complications occurred in 4 cases: pancreatitis in 1, cholangitis in 2, and an impacted Dormia basket with cholangitis in 1. Two (6.7%) of the 28 patients developed recurrent CBD stones at follow-up (50 ± 14 mo) and were successfully managed with therapeutic ERC.

CONCLUSION: Patients with a PE duct frequently require mechanical lithotripsy for stones extraction. To retrieve stones successfully and avoid complications, these patients should be identified during ERC.

Abstract

AIM: To describe characteristics of a poorly expandable (PE) common bile duct (CBD) with stones on endoscopic retrograde cholangiography.

METHODS: A PE bile duct was characterized by a rigid and relatively narrowed distal CBD with retrograde dilatation of the non-PE segment. Between 2003 and 2006, endoscopic retrograde cholangiography (ERC) images and chart reviews of 1213 patients with newly diagnosed CBD stones were obtained from the computer database of Therapeutic Endoscopic Center

of Gothenburg, MagTarm lab, Bla straket 3, Sahlgrenska University Hospital, 41345 Gothenburg, Sweden; Jon Arne Soreide, Professor, Department of Surgery, Stavanger University Hospital, N-4068 Stavanger, Norway; Thiruvengadam Muniraj, University of Pittsburgh Medical Center, 11123 Avalon Gates, Trumbull, CT 06611, United States

INTRODUCTION

Endoscopic retrograde cholangiography (ERC) with endoscopic sphincterotomy (ES) and stone extraction are considered standard therapies for the treatment of common bile duct (CBD) stones[1-3]. After ES, 85% to 90% of CBD stones can be removed with a Dormia basket or balloon catheter[4,5]. However, removal of CBD stones can be challenging in certain cases, such as those involving large stones (> 15 mm), stones above strictures, and impacted stones[6]. In cases involving such difficult stones, fragmentation using mechanical lithotripsy or shock wave lithotripsy is required to facilitate stone extraction[6-8]. However, mechanical lithotripsy for extraction of CBD stones can be unsuccessful in the presence of bile duct stricture, when the size of the stone is large, and when the ratio of stone size to bile duct diameter is greater than 1[9-11]. Impaction of an extraction basket and an entrapped stone in the distal CBD may complicate stone clearance in some cases[12-14].

In contrast, anatomic abnormality of the CBD has been considered to be a contributing factor to difficult stones[15]. Kim *et al*[16] recently reported that complete clearance of CBD stones was technically difficult in patients with acute distal CBD angulation ($\leqslant$ 135 degrees) and a short distal CBD arm ($\leqslant$ 36 mm). However, the current definition of large (or difficult) CBD stone does not include the factor of distal CBD diameter[17]. In our clinical experience, we have encountered a subgroup of patients whose CBD stones were particularly difficult to extract. Further, in some cases, the extraction basket containing the entrapped stone was impacted in the bile duct if mechanical lithotripsy was not applied. The common characteristic feature of these patients was a relatively narrowed distal CBD on ERC: the distal CBD was almost normal in diameter, but it was poorly expandable (PE), as the upstream CBD was disproportionately dilated. The aim of this study was to describe the clinical and imaging features and to examine the safety and technical success of ERC in patients with both CBD stones and a PE bile duct.

MATERIALS AND METHODS

Description of poorly expandable bile duct

A PE bile duct was characterized by a rigid distal CBD with an almost normal diameter on ERC. The non-PE segment of CBD was often more dilated than the PE segment (Figure 1). The rigid characteristic of the PE segment was usually confirmed by increased resistance when the balloon or basket catheter with the stone was pulled from the non-PE segment across the PE segment.

Patients

During the 4-year period between 2003 and 2006, we retrospectively collected data from 1213 patients with CBD stones from the endoscopic computer database of Change Gung Memorial Hospital, Taipei (China). Endoscopic retrograde cholangiopancreatography (ERCP) images of patients with newly diagnosed CBD stones were reviewed, and 30 (2.5%) of the patients with the characteristics of a PE bile duct were enrolled in this study. The subjects included 20 men and 10 women. The median patient age was 45 years (range, 20 to 92 years). Chart records and the safety and technical success of ERC in these patients were reviewed. None of the patients had a medical history of chronic pancreatitis or biliary stricture prior to ERCP. The clinical diagnoses were obstructive jaundice in 13 cases, acute cholangitis in 10 cases, acute cholecystitis in 3 cases, acute pancreatitis in 1 case, and others in 3 cases. The gallbladder status of the patients was as follows: previously resected in 6 (20%) cases, intact with stone(s) in 23 (76.7%) cases, and intact without stones in 1 (3.3%) case. There were 2 (6.7%) patients with low insertion of the cystic duct and 6 (20%) patients with juxtapapillary diverticulum.

Endoscopic procedures

Endoscopic procedures were performed by endoscopists with an ERCP case volume of at least 2 per week, using a duodenoscope (JF-240 or TJF-240; Olympus). The ES procedure was performed as mentioned in our previous study[18]. After ES, a retrieval balloon catheter ($n = 9$), Dormia basket ($n = 5$), or lithotripter (BML-202Q.B or BML-203Q.B, Olympus Corporation, Tokyo, Japan, $n = 16$) was used to extract the CBD stone(s). When the balloon catheter or Dormia basket failed to retrieve the stone(s), a lithotripter was used to crush and extract the stones. After stone removal, a contrast medium was injected, and the inflated balloon catheter was withdrawn along the CBD to the duodenum to confirm bile duct clearance.

Measurements of parameters on cholangiograms

The maximum transverse diameter of the PE segment, non-PE CBD, and largest stones as well as the length of PE segment and the distal CBD angle were assessed on the cholangiography. The length of the PE segment was defined as the length between the duodenal wall and the tapering end of the non-PE CBD (Figure 1). The distal CBD angle was defined as the angle between the axis of the non-PE CBD and the PE segment (Figure 1A). These factors were measured from the ERC scan, which was obtained under the condition of full contrast injection

Figure 1 Endoscopic retrograde cholangiogram showing the poorly expandable distal common bile duct (arrows) and the more dilated upstream bile duct. A: The arrowhead indicates the stone. Line a and line b indicate the length of the non-poorly expandable bile duct and the poorly expandable segment. The actual lengths were measured after correction for the magnification with the known diameter of the duodenoscope on the endoscopic retrograde cholangiography (line c). The distal common bile duct angle was defined as the angle formed by line a and line b; B: The stone (arrowhead) is floating in the non-poorly expandable bile duct.

with the patient in a prone position and the duodenoscope in a shortened configuration. The parameters were measured after correction for the magnification using the known diameter of the duodenoscope on the ERC.

Statistical analysis

Data in the text and tables are expressed as the mean ± SD values. The difference in the ratio of the diameters of the non-PE segment to the PE segment and the stone size to the PE segment were compared using the Mann-Whitney U test. Further, the difference was compared with the two-sample t test for continuous variables and Fisher's exact test for categorical variables. The analyses were performed with SPSS version 17.0 statistical software for Windows. A P value of < 0.05 was considered statistically significant.

RESULTS

A total of 30 patients with PE bile ducts who underwent a combined total of 52 ERC procedures were analyzed. The baseline characteristics of these patients are listed in Table 1. The serum total bilirubin level before ERC was 6.5 ± 3.6 mg/dL (range, 0.6 to 15 mg/dL). The maximal diameter

of the non-PE CBD was 14.3 ± 4.9 mm (range, 7 mm to 26 mm). The diameter and the length of the PE segment were 5.8 ± 1.6 mm (range, 4 mm to 10 mm) and 39.7 ± 15.4 mm (range, 12.3 mm to 70.9 mm), respectively. The distal CBD angle was 159.3 ± 13.9 degree (range, 130 degree to 175 degree). The number of stones was one in 18 cases, two in 4 cases, three in 7 cases, and five in 1 case. The average diameter of the largest stone from each case was 11.3 ± 4.7 mm (range, 6 mm to 24 mm). Five patients had stones > 15 mm in diameter. Cholesterol stones were found in 16 cases, black stones in 11 cases, and brown stones in 3 cases. The ratio of the maximal diameter of the non-PE CBD to the PE segment was 2.4 (range, 1.4 to 3.5). The ratio of the diameter of the largest stone to the PE segment was 1.8 (range, 0.9 to 4).

In all patients, the CBD stones were eventually retrieved successfully. The number of ERC procedures needed to completely remove the CBD stone(s) was one in 16 (53.3%) cases, two in 8 (26.7%) cases, three in 5 (16.7%) cases, and five in 1 (3.3%) case. The reasons for performing more than one ERC procedure to completely extract the CBD stones were as follows: incomplete clearance of the CBD stones during the first ERC procedure (n = 8), referral from other institutions due to failure to extract the CBD stones (n = 3), recurrent CBD stones due to migration of the cystic duct stones (n = 2), and occurrence of Mirizzi syndrome (n = 1).

Overall, mechanical lithotripsy was performed in 25 (83.3%) patients, including 12 out of the 16 patients undergoing a single session of ERC and 13 out of the 14 patients undergoing multiple (≥ 2) sessions of ERC (4 of the 13 patients did not undergo lithotripsy during the first ERC procedure). Five patients did not require mechanical lithotripsy. Comparative data for the patients with and without lithotripsy for CBD stone clearance are given in Table 1. The factors used for analysis were age; gender; total serum level of bilirubin; stone size, number, and characteristics; history of cholecystectomy; presence of juxtapapillary diverticulum; diameter of the non-PE segment and the PE segment; length of the PE segment; distal CBD angle; and the diameter ratio of the non-PE segment to the PE segment and of the stone to the PE segment. Of the various factors analyzed, the stone size and the ratio of the diameter of the stone to the PE segment were significantly greater in patients who needed lithotripsy (P = 0.04 and 0.02, respectively).

Post-ERC complications occurred in 4 (13.3%) cases, including pancreatitis in 1 (3.3%), cholangitis in 2 (6.7%), and impacted Dormia basket with cholangitis in 1 (3.3%). One patient died of acute myocardial infarction 2 d after ERCP. Twenty-eight patients had long-term follow-up with a mean period of 50 ± 14 mo (range, 29 mo to 80 mo). Two (6.7%) patients developed recurrent CBD stones and were successfully managed with therapeutic ERC.

DISCUSSION

In this study, we describe the ERC findings of patients with concomitant CBD stones and a PE bile duct and the

Table 1 Characteristics of patients with a poorly expandable bile duct and comparisons between the patients with and without mechanical lithotripsy

Parameters	Overall (*n* = 30)	Need lithotripsy (*n* = 25)	Without lithotripsy (*n* = 5)	[1]*P* value
Age (yr)	47.4 ± 19.4 (20-92)	45.0 ± 19.3 (20-92)	59.0 ± 19.4 (29-76)	0.15
Gender (men) *n* (%)	20 (66.7)	17 (68)	3 (60)	1
Serum total bilirubin (mg/dL)	6.5 ± 3.6 (0.6-15)	6.7 ± 3.8 (1.1-15)	5.5 ± 3.6 (0.6-10.1)	0.55
History of cholecystectomy *n* (%)	6 (20)	5 (20)	1 (20)	1
Juxtapapillary diverticulum *n* (%)	7 (23.3)	5 (20)	2 (40)	0.57
CBD stones				
Size of the largest stone (mm)	11.3 ± 4.7 (6-24)	12.0 ± 4.8 (6-24)	7.2 ± 1.6 (6-10)	0.04
Characteristic (cholesterol/black/brown)	16/11/3	13/9/3	3/2/0	0.72
Number (≥ 2) *n* (%)	12 (40)	11 (44)	1 (20)	0.62
Bile duct diameter (mm)				
Non-PE CBD	14.3 ± 4.9 (7-26)	14.8 ± 4.9 (7-26)	11.4 ± 5.0 (7-20)	0.17
PE segment	5.8 ± 1.6 (4-10)	5.9 ± 1.6 (4-10)	5.6 ± 1.8 (4-8)	0.73
Length of the PE segment (mm)	39.7 ± 15.4 (12.3-70.9)	38.0 ± 14.8 (12.3-70.9)	45.1 ± 17.5 (22.5-70.2)	0.44
Distal CBD angle (degree)	159.3 ± 13.9 (130-175)	160 ± 12.1 (135-175)	157 ± 18.9 (130-175)	0.75
Diameter ratio of non-PE segment to PE segment	2.4 ± 0.6 (1.4-3.5)	2.5 ± 0.6 (1.5-3.5)	2.2 ± 0.4 (1.4-2.5)	0.05
Stone to PE segment	1.8 ± 0.7 (0.9-4)	2.1 ± 0.7 (1.2-4)	1.4 ± 0.4 (0.9-1.8)	0.02

CBD: Common bile duct; PE: Poorly expandable. [1]*P* value was the basis of comparison between patients with and without lithotripsy. A *P* value of < 0.05 indicated a significant difference.

impact of these findings on the retrieval of the stones. This series showed that 2.5% of patients with CBD stones had PE bile ducts. The mean diameter and length of the PE duct were 5.8 mm and 39.7 mm, respectively. The non-PE CBD was more dilated than the PE segment, with a mean diameter ratio of 2.4. Post-ERC complications occurred in 4 (13.3%) of the patients.

After ES, CBD stones up to 15 mm in diameter can usually be completely extracted with a basket or a retrieval balloon catheter[8,15]. In this study, the average diameter of the largest CBD stones was 11.3 mm, and there were only five patients (16.7%) with stones > 15 mm in diameter. However, mechanical lithotripsy was frequently performed (overall, 83.3%) to clean the CBD stones for patients with a PE bile duct. This rate was much higher compared with the rate reported in the literature (9.4% to 21.7%) for patients with CBD stones who needed lithotripsy[9,10]. In the subsequent analysis, we found that stone size or the ratio of stone size to the PE segment diameter were associated with the need of lithotripsy. Since the stones were relatively small, the major factor associated with the need of lithotripsy was the ratio of stone size to the PE segment diameter. Sharma and Jain reported that 6 of 304 patients (2%) with small CBD stones (7-9 mm) had stones extraction with mechanical lithotripsy due to a narrowed distal CBD (3-4 mm)[19]. These 6 patients might also have the PE bile duct.

The endoscopists frequently chose a lithotripter as the first tool to extract the CBD stones (16/30 or 53.3%), which might be one of the reasons for the high rate of lithotripsy in this study. This practice was adopted because of several cases in our early experience that featured an impaction of the extraction basket and an entrapped stone in the PE segment. Since then, we have often used a lithotripter rather than a Dormia basket to entrap the stone, even when the stone was small. Hence, the authors had only 1 case of biliary-basket impaction in this study.

Biliary-basket impaction often occurred upstream of the PE segment. Therefore, we suggest using Conquest through the channel lithotriptor cable for emergency lithotripsy when this complication occurs. In our experience, the Soehendra lithotripter cable is more difficult to pass through the relatively narrowed PE segment.

An impacted CBD stone or a large stone (≥ 30 mm) poses a high risk of mechanical lithotripsy failure[11]. In this series, CBD stones were successfully removed in all patients for whom mechanical lithotripsy was indicated, although some patients needed more than one endoscopic session. This high success rate was probably due to the small stone size, and there was no case in which the stone was impacted in the bile duct. The non-PE segment was dilated to a greater extent than the PE segment, providing the space for the opening of the lithotripter to capture the stone(s).

Eight (26.7%) of the 30 patients had incomplete clearance of the CBD stones during the first procedure of ERC; therefore, they needed multiple sessions of ERC to clean the stones completely. There might be 2 possible reasons for performing multiple sessions. First, a high proportion of patients underwent mechanical lithotripsy. After lithotripsy, small stone fragments may be left undetected after completion of the ERC procedure with bile duct clearance[20-22]. Second, the distal end of the non-PE segment tapered abruptly at its point of attachment to the PE segment. Similar to the bile duct stricture, some stone fragments might be left in the junction of the non-PE segment and the PE segment during extraction[11].

The cause of PE bile duct remains unknown. Physiologically, the intrapancreatic CBD can be entirely free within the pancreatic capsule, or less commonly, it is partially or completely enclosed by a strip of pancreatic tissue up to 20 mm wide and 3 to 5 mm thick, i.e., the lingula pancreatic[23]. The diameter of the PE segment was 5.8 ±

1.6 mm (range, 4 mm to 10 mm), which was compatible with the reported duct widths for an intrapancreatic portion of CBD[24]. Therefore, the PE bile duct may result from an intrapancreatic CBD that is entirely enclosed by the lingula pancreatis, resulting in the rigid characteristic. However, the length of PE segment had a wide range in this study (12.3 mm to 70.9 mm; mean 39.7 mm), which was not compatible with the length of the lingula pancreatis (range, 10 mm to 25 mm)[23]. Further study may be needed to investigate the nature of the PE bile duct.

The PE bile duct might not increase the risk of the recurrence of CBD stones. Tsuchiya *et al*[20] reported a recurrence rate of 13.2% in patients with CBD stones during a 3-year follow-up study. In a study conducted in Taiwan, the recurrence rate of CBD stones was 18%[25]. In the present series, CBD stone recurred in 7.8% of the patients during the 3-year follow-up period. This rate is no higher than that reported in the literature.

In conclusion, PE bile duct occurred in a small proportion of patients with CBD stones. Lithotripsy or multiple ERC procedures were frequently needed in patients with a PE bile duct. To avoid the complication of biliary-basket impaction, we suggest the use of a lithotripter rather than a Dormia basket to entrap and extract the stone when a PE bile duct is noted on ERC during the initial procedure.

COMMENTS

Background
There were several cases in early experience that featured an impaction of the extraction basket and an entrapped stone in the distal common bile duct (CBD) rather than in the papillary orifice after endoscopic sphincterotomy. Since then, the authors found that the common characteristic of these patients was a poorly expandable (PE) distal CBD on endoscopic retrograde cholangiography (ERC). Therefore, the authors conducted this study to describe the ERC findings of patients with CBD stones and a PE bile duct and evaluate the impact of these findings on the retrieval of the stones.

Research frontiers
CBD stones in the PE bile duct have not been reported in the literature. To the knowledge, this is the first study to describe the clinical and imaging features and to examine the safety and technical success of ERC in patients with both CBD stones and a PE bile duct.

Innovations and breakthroughs
The study showed that the diameters of the PE segment and the widest non-PE CBD segment were 5.8 ± 1.6 mm and 14.3 ± 4.9 mm, respectively. The length of the PE segment was 39.7 ± 15.4 mm (range, 12.3 mm to 70.9 mm). To remove the CBD stone(s) completely, mechanical lithotripsy was required in 83.3% of the patients, even though the stone size was not as large (11.2 ± 4.7 mm). The stone size and stone/PE segment diameter ratio were associated with the need for lithotripsy.

Applications
Patients with CBD stones and a PE duct frequently require mechanical lithotripsy during therapeutic ERC, especially when the ratio of the stone diameter to the PE segment diameter is high. To achieve successful stone retrieval and avoid complications, the authors suggest the use of a lithotripter rather than a Dormia basket to entrap and extract the stone when a PE bile duct is noted on ERC during the initial procedure.

Terminology
A PE bile duct was characterized by a rigid distal CBD with an almost normal diameter on ERC. The non-PE segment of CBD was often more dilated than the PE segment. The rigid characteristic of the PE segment was usually confirmed by increased resistance when the balloon or basket catheter with the stone was pulled from the non-PE segment across the PE segment.

Peer review
The authors have performed a study in which they identified all patients with CBD stones and a poorly expandable bile duct by means of a retrospective search in a computerized database. A total of 30 patients were found and the authors attempted to describe their characteristics. They concluded that the majority of these patients needed mechanical lithotripsy, especially those with a high ratio of stone diameter to the poorly-expandable CBD segment diameter. This a well-written paper and an interesting contribution to the understanding of factors related to difficult CBD stone extraction.

Abstract

AIM: To study the risk factors for liver metastasis and the prognosis in patients with human epidermal growth factor receptor 2 (HER2) over-expressing gastric cancer (GC).

METHODS: A total of 84 GC patients recruited from the General Hospital of the People's Liberation Army (PLA) between 2003 and 2010 were randomly enrolled in this study. HER2 expression was detected by immunohistochemistry in 84 GC patients with liver metastases. The study group consisted of 66 men and 18 women, with an average age of 54 years (range: 19-74 years). Liver metastasis was diagnosed by magnetic resonance imaging or computed tomography. Patients were followed-up and predictive factors of liver metastasis were evaluated.
