Rat DRG segments of T10-12 spinal cord were taken at the peak of inflammation and processed for gene expression profiling with a microarray biased for rat brain-specific genes. An average of 3 animals/each group was used for the microarray analysis and the study repeated at least twice. The genes were normalized with sham controls and average greater than or equal 2 fold changes in gene expressions were demonstrated in the Table 2. Modified genes were classified into groups according to their functionality (Table 3). The identified genes included: circulatory/acute phase, extracellular matrix, signaling transduction, transcription/translation-related, antioxidants/chaperones/heat shock and pancreatic and other enzymes. Candidate genes are among those modified in comparison to normals and are involved in different signaling pathways in DBTC induced pancreatic inflammation as shown in the Table 2.

Acute pancreatitis regulates gene expression in spinal cord

Subtraction of overlapping normal genes revealed 321 unique genes that were classified into 9 different functional groups (Table 3). The candidate genes included 261 that were up-regulated and 60 downregulated genes in this model. Amongst these, fifty-two distinct genes that were upregulated greater than 2-fold were chosen as candidates for the pancreatitis, visceral pain and pancreatic cancer pathway specific and listed in Table 2. Additionally, 53 selected genes which were down regulated in this pancreatitis model are shown in Table 2.

Pain related behavioral activity

¹52 selected genes ($n = 3/\text{group}$, study repeated $\times 2$). Dibutyltin dichloride induced pancreatitis regulated genes (up or down-regulated) expression normalized with sham controls. Group 1: Circulatory/acute phase/immunomodulatory; Group 2: Extracellular Matrix; Group 3: Structural; Group 4: Channel/receptor/transporter; Group 5: Signaling transduction; Group 6: Transcription/translation-related; Group 7: Antioxidants/chaperones/heat shock; Group 8: Pancreatic and other enzymes; Group 9: Unidentified genes. Total genes = 321; up-regulated = 261, down-regulated = 60.

related cutaneous mechanical hypersensitivity. Abdominal mechanical testing with von Frey microfilament demonstrated statistically significant increases in withdrawal events on day 6 post DBTC injection in pancreatitis animals and are presented as % number of events ($n = 5$) (Figure 3). In contrast, no changes were detected in the sham control rats. Data obtained were consistent for 2 different microfilaments except more intense responses were detected with the larger microfilament (3.52 mN *vs* 10.78 mN) as expected, demonstrating consistency for abdominal response with the von Frey mechanical test (Figure 3A and B).

On day 7 after induction of pancreatitis, groups of animals were simultaneously treated (i.p. injection) with 3 different doses of ET-A antagonist (BQ123, 33, 100 and 300 $\mu\text{mol/L}$). Animals with pancreatitis had dose dependent responses in contrast to control animals that were not affected by the antagonists. While 33 $\mu\text{mol/L}$ BQ123 did not provide a statistically significant effect (Figure 4), 300 $\mu\text{mol/L}$ provided significant protection against inflammatory pain related behaviors in pancreatic animals tested at 75 min after drug administration. Therefore, studies continued only with the 300 $\mu\text{mol/L}$ dose (Figure 4).

Next we compared efficacy of BQ123 (ET-A receptor antagonist) to the BQ788, an ET-B antagonist (Figure 5). Both drugs were effective in normalizing mechanical hypersensitivity response. However, ET-A receptor antagonist had a longer lasting effect compared to ET-B receptor antagonist, with a more robust response. The ET-A receptor antagonist (BQ123) and the ET-B receptor antagonist (BQ788) abolished abdominal mechanical hypersensitivity as early as 20 min (Figure 5A). The reduced events using BQ123 demonstrated more vigorous response persisting through 75 min post treatment ($n = 5$), while the number of withdrawal events increased again at 75 min for the ET-B receptor antagonist demonstrating less efficacy and persistence of effect for this agent than for the ET-A receptor antagonist in management of pain related behavioral modifications in this model.

Hotplate whole-body thermal responses: Rats with pancreatitis reacted to the hotplate with reduced response times compared to naïve rats indicating increased thermal hypersensitivity (Figure 5B). Both ET-A receptor antagonist (BQ123) and ET-B receptor antagonist (BQ788) significantly increased response latencies, rein-

Table 3 Modified genes were classified into 9 different groups according to their functions, while some genes' functionality may overlap¹

¹52 selected genes ($n = 3/\text{group}$, study repeated $\times 2$).

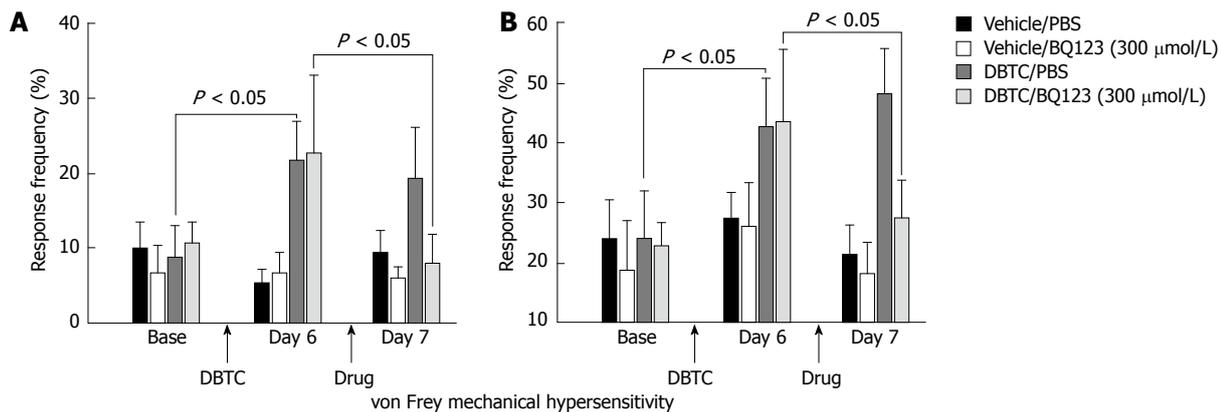

Figure 3 Behavioral responses to mechanical stimuli using 2 von Frey microfilaments of different strengths (g-Force). A: 3.52 mN; B: 10.78 mN, at baseline and on day 6 (dibutyltin dichloride-induced pancreatitis) and day 7 (drug treatment). BQ123 (300 $\mu\text{mol/L}$) abolishes abdominal hypersensitivity 75 min post treatment with no effect in naïve animals ($n = 5$). PBS: Phosphate buffered saline; DBTC: Dibutyltin dichloride.

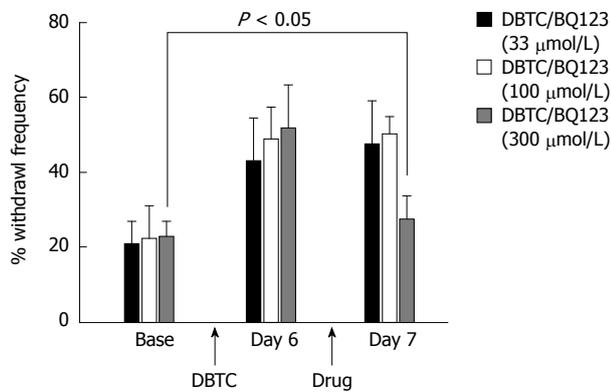

Figure 4 Response to von Frey monofilaments for rats at baseline, after induction of pancreatitis with dibutyltin dichloride which promotes mechanical hypersensitivity (day 6), and responses 75 min (day 7) after the three doses of BQ123 ($n = 5$). DBTC: Dibutyltin dichloride.

stating response times back to the levels of the vehicle control animals.

Additionally as expected abdominal hypersensitivity to von Frey mechanical stimulation and hyperalgesia (data not shown) were attenuated by the i.p. administration of the morphine in a cumulative, dose dependent manner in rats on day 7 ($n = 6$). As systemic administration of morphine is currently a gold standard therapy in different experimental pain models, data for the endothelin receptor antagonists used in this study correlated well to those obtained with morphine administration (correlation

not shown).

Open field exploration: Spontaneous behavioral activity was conducted before induction of pancreatitis (baseline), 6 d after induction of pancreatitis, as well as 30 min after drug treatments (BQ123, BQ788) for comparison to sham control animals. The overall stable activity levels indicate that the drugs produced no undesirable effects on normal exploratory behaviors (data not shown). No changes were noted in the six behavioral measures except a trend toward reduction of the active time and an increase in resting time measured at the highest dose (300 $\mu\text{mol/L}$). These data indicate that the agents do not interfere with normal exploratory behaviors.

Pancreatic pathology

Pancreatic sections stained with HE from naïve animals receiving sham treatment showed normal histological architecture and islets. In contrast DBTC treated rats develop persistent pancreatitis demonstrated as edema in parenchyma, loss of pancreatic architecture, infiltration of inflammatory cells including neutrophil and mononuclear cells, degeneration vacuolization and necrosis of acinar cells (not shown).

Endothelin-A and B receptor expression in pancreas

Endothelin-A and B receptor expression in naïve or pancreatitis DBTC rats was observed in the vascular endothelia (Figure 6). ET-A receptor appeared to be more

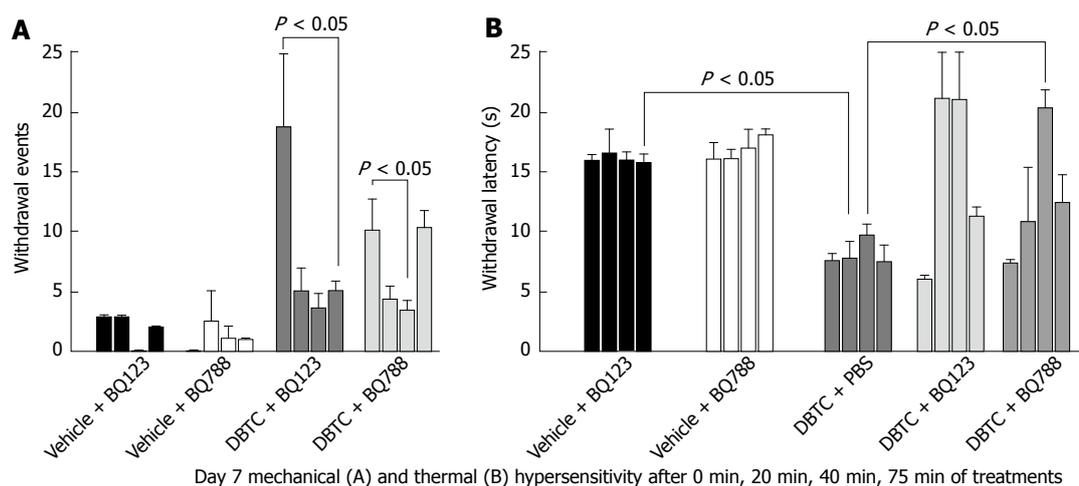

Figure 5 Mechanical and thermal hypersensitivity. A: Rats with pancreatitis demonstrate fewer withdrawal events in response to mechanical stimuli at time points after treatment with BQ123 [endothelin (ET)-A receptor antagonist, 300 $\mu\text{mol/L}$] and BQ788 (ET-B receptor antagonist, 300 $\mu\text{mol/L}$). The response to BQ788 persisted for a shortened amount of time compared to the longer lasting to BQ123. Data is presented as actual number of events ($n = 5$); B: Endothelin-A receptor antagonist (BQ123) normalized secondary thermal hypersensitivity that was shortened after induction of pancreatitis. The effect persisted longer for BQ123 compared to shorter response to BQ788 antagonist ($n = 5$). PBS: Phosphate buffered saline; DBTC: Dibutyltin dichloride.

condensed around constricted vessels in pancreatic compared to naïve control animals. However, no quantitation was done since overall, minor detectable differences were evident in ET-A and ET-B receptors expression in the pancreas in comparisons between naïve and pancreatitis animals.

Endothelin A and B in DRG

Based on immunocytochemical localization, ET-A and ET-B receptors were increased in DRG (T10-12) from pancreatitis compared to naïve rats (Figure 7). ET-A receptor expression was observed in all sizes of primary sensory neurons of the DRG. In contrast, ET-B receptors were primarily localized on the Schwann cells (myelin sheaths) surrounding the axons that were passing through the DRG from naïve or pancreatitis rats.

Endothelin receptor localization was combined in dual NeuN and GFAP (Figure 8). ET-A was expressed in the cell bodies and occasional nuclei of neurons of different sizes in the DRG in naïve animals. However, phenotypic expression of ET-A receptor was greatly increased in neurons of all sizes in rats with DBTC induced pancreatitis. Similarly, ET-B receptor was also localized in neurons of all sizes, in the satellite glia, as well as in the Schwann cell glial myelin sheaths surrounding the axons passing through the DRG and satellite glia.

DISCUSSION

In this investigation, DBTC-treated animals developed persistent pancreatic inflammation detected in pathological analysis and secondary pain-related hypersensitivity. The DRG and spinal cord from 10th-12th thoracic segments were selected for gene microarray analysis, as they portray the major source of sensory neuronal fibers in the pancreas. Amongst the 52 candidate genes upregulated in three animals in each experimental group (run

in duplicate) was ET-1. ET-1 was upregulated greater than 2-fold in the animals with pancreatic inflammation and visceral pain-related behavior. This finding illustrates the benefits of gene array analysis in identifying relevant genes with possible direct roles in mediating pain in visceral inflammatory states. Visceral mechanical testing with von Frey microfilaments demonstrated functional significance showing increases in abdominal withdrawals on day 6-7 post DBTC insult in pancreatitis animals. In contrast, no changes were detected in normal rats receiving sham vehicle alone. Similarly, spontaneous pain related behaviors were unchanged in naïve rats treated with endothelin antagonists indicating that the agent had no effect on normal exploratory behaviors. Single highest dose treatment with ET-A antagonist (BQ123) provided significant protection against inflammatory pain related behaviors in animals with pancreatitis, while the ET-B antagonist (BQ788) had a short lasting effect.

In the current study, ET-A and ET-B receptors were both detected in DRG. ET-A receptors trigger vascular constriction and ET-B receptors act as vasodilators, but their role in neurons is not defined.

Although, ET-A and ET-B receptors are both present in the thoracic spinal segment, and DRG, ET-B receptors are primarily expressed in DRG satellite cells and ensheathing Schwann cells^[27] where they can stimulate the synthesis and release of prostaglandin E₂, an active compound in inflammatory pain^[16]. In addition, ET-B receptors present on keratinocytes mediate the release of β -endorphin from these cells with a local analgesic effect^[18]. ET-1 has a mitogenic effect, promoting cancer cell growth in colon and pancreas in which there is also upregulation of ET-A receptors and moderate down-regulation of ET-B receptors^[28].

In our hands, ET-A receptors appeared to be more localized around constricted vasculature in pancreatic tissues of animals with DBTC-induced pancreatitis. While,

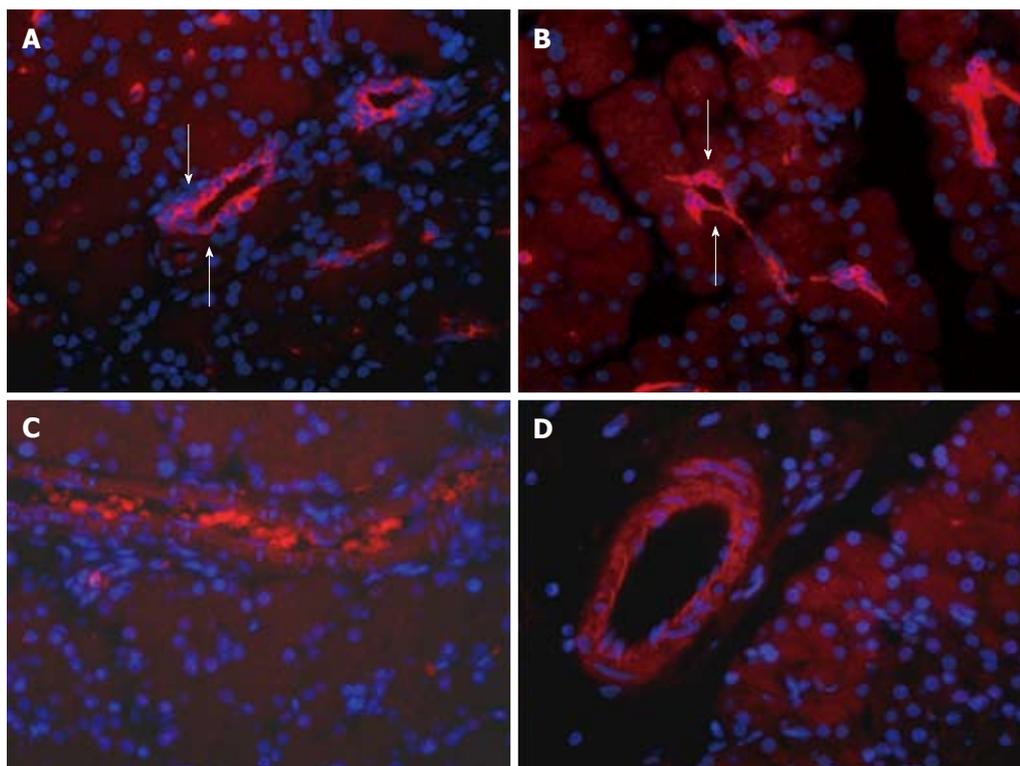

Figure 6 Pancreatic tissues from naïve and pancreatitis animals. A: Naïve endothelin (ET)-AR; B: Dibutyltin dichloride (DBTC) ET-A receptor; C: Naïve ET-B receptor; D: DBTC ET-B receptor. ET-A receptors are expressed in ducts (arrows) which appear more constricted in pancreatitis animals (B: DBTC ET-A receptor). ET-B receptors were expressed on the vasculature (4',6-diamidino-2-phenylindole, nuclear blue counterstaining) 40× magnification ($n = 5$).

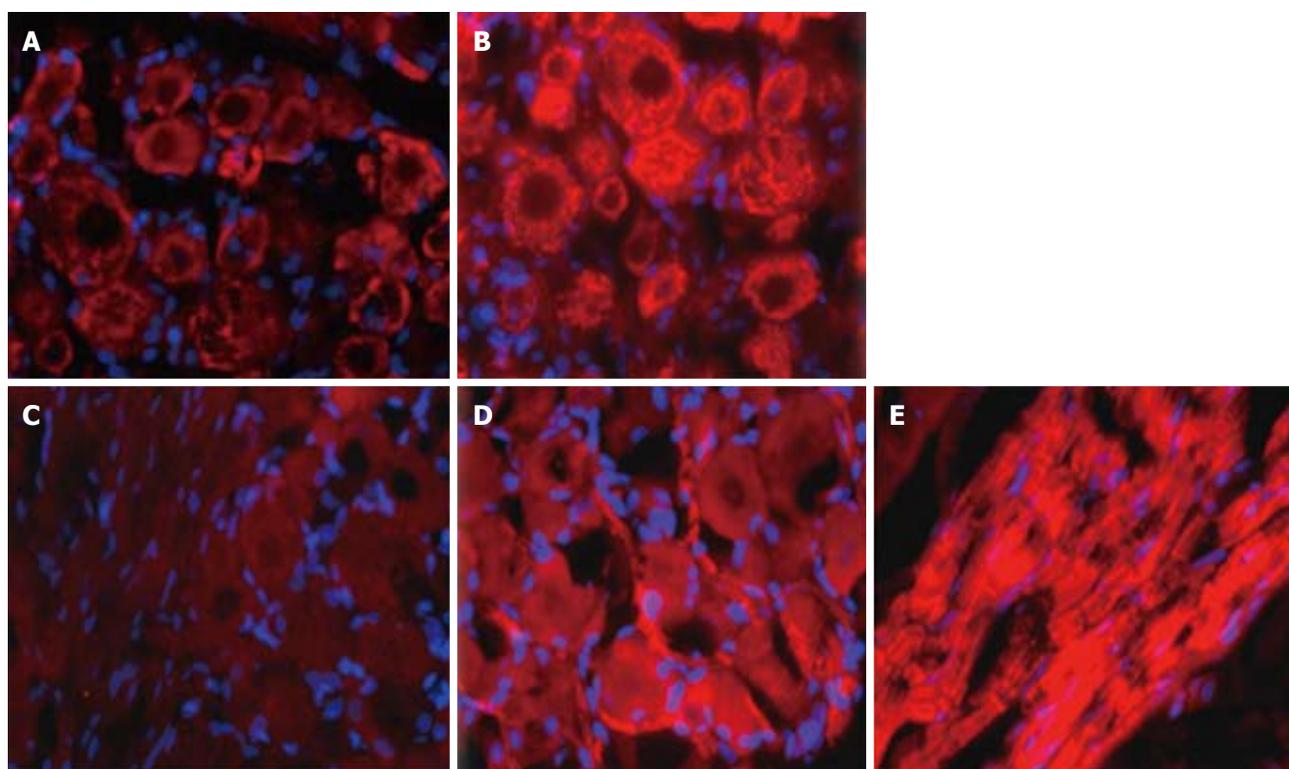

Figure 7 Immunohistochemical analysis of the localization of endothelin-A and endothelin-B receptors in dorsal root ganglia from naïve or pancreatitis rats. A: Naïve endothelin (ET)-A; B: Dibutyltin dichloride (DBTC) ET-A; C: Naïve ET-B; D, E: DBTC ET-B ($n = 5$). ET-A receptor expression is shown in primary sensory neurons (A, B). In contrast, ET-B receptors (B-E) are primarily localized on the Schwann cells (myelin sheaths) surrounding the axons passing through the dorsal root ganglia from naïve or pancreatitis rats (4',6-diamidino-2-phenylindole nuclear blue staining and Alexa Fluor 568, red).

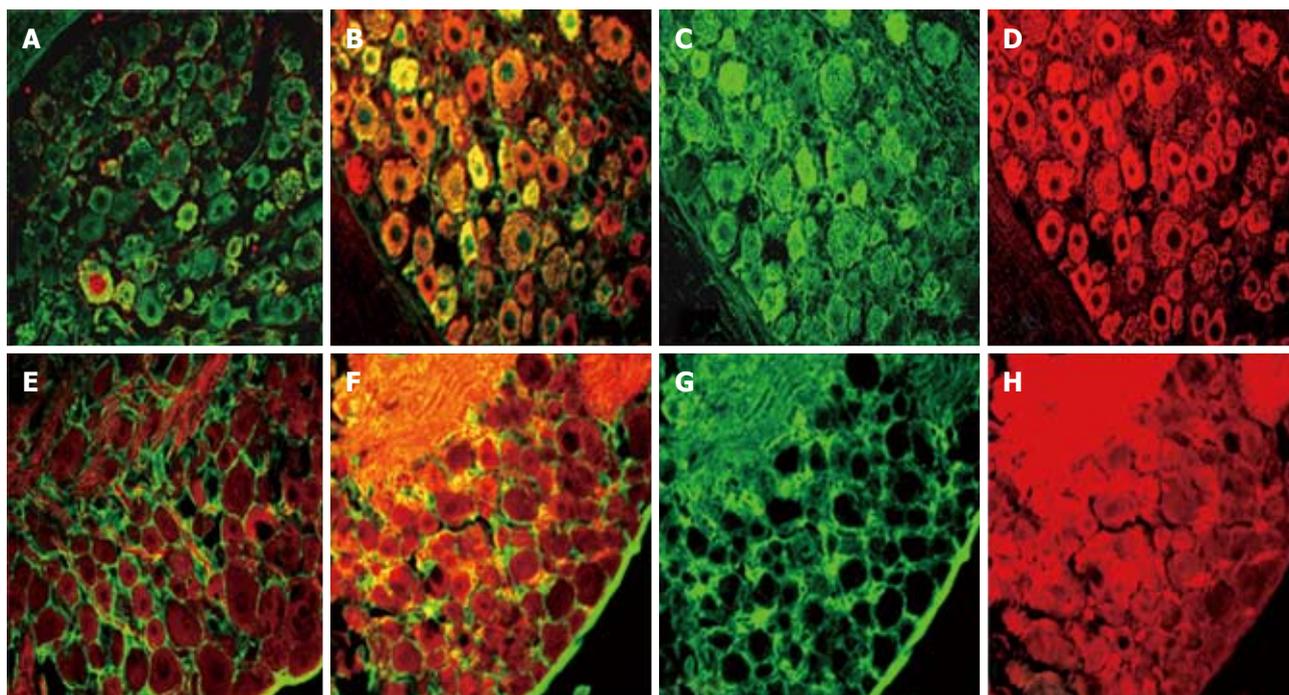

Figure 8 Endothelin receptor A and B in dorsal root ganglia (T10-12). Significant increases in the endothelin (ET)-A are noted in dorsal root ganglia (DRG) neurons of all sizes on day 7 after induction of pancreatitis; E: Dual staining for Endothelin B and GFAP in a naïve animal; F: Dual staining for Endothelin B and GFAP in a pancreatic animal; G: GFAP in a pancreatic animal; H: Endothelin receptor B in a pancreatic animal; Significant increases in the ET-B receptor are noted localized in satellite glia and Schwann cell myelin in thoracic DRG on day 7 after induction of pancreatitis. Alexa Fluor 568, red; Alexa Fluor 488, green ($n = 5$).

modest detectable differences were evident in the ET-B expression of the pancreatic tissues in comparisons of animals with pancreatitis to naïve controls.

Animals with pancreatitis demonstrated trend toward a reduction in active time and an increase in resting time. Immunohistological analysis revealed increased ET-A in DRG neurons of all sizes and ET-B in myelin sheath and satellite glia. The changes in spontaneous behaviors induced by pancreatitis were normalized by application of the ET-A antagonist (BQ123), suggesting that this receptor has a role in pancreatitis-induced behavioral changes.

Injection of ET-1 is reported to cause severe pain *via* activation of ET-A receptors, in the sciatic nerve chronic constriction injury model^[29]. In the present study, both the endothelin-A (BQ-123) and B (BQ-788) receptor antagonists significantly reversed the thermal hypersensitivity assessed using the hot plate method at 20 min, 40 min after injection. However, the ET-B antagonist was ineffective at the 75 min time point while the efficacy for the endothelin-A receptor antagonist persisted. Neither agents affected vehicle injected animals. Additionally, we demonstrated that the thermal and mechanical hyperalgesia induced in pancreatitis animals were equally well normalized by the administration of morphine (10 mg/kg) with a dose dependent response, whereas a lower dose of BQ-123 and BQ-788 were required to reverse the nocifensive responses in the pancreatic rats. Similarly, administration of the ET-A receptor antagonist reversed the attenuation of spontaneous exploratory behaviors

observed in pancreatic animals.

These data reveal that nocifensive responses invoked by the persistent pancreatitis in animals can be ameliorated by systemic post-treatment with endothelin-A receptor and to a lesser degree endothelin-B antagonist similar to conventional morphine administration. As has been suggested for neuropathic pain^[29], ET-A receptor antagonists deserve future study as potential novel therapy including against inflammatory pain.

Previous studies indicate that treatment with non-selective ET-A and ET-B (LU 302872) and selective ET-A (LU 302146) antagonists had no effect on the pancreatic pathological (edema and inflammatory infiltration) nor on trypsinogen activation 4h after caerulein-induced acute pancreatitis model. A slight increase in the pathological necrosis and vacuolization suggested the possible undesired effects of these compounds in the model^[30]. In contrast ET-1 at the high dose was found to be beneficial on morphological changes and trypsinogen activation in that model^[31]. In our hands we did not detect any undesirable pathological effects or any histological improvement in treated animals after single dose i.p. administration of endothelin-1 receptor antagonists (BQ123, BQ788).

In severe acute pancreatitis, microcirculatory disorders and increased capillary permeability contribute to multiple organ dysfunction syndrome, while, ET-A receptors stabilize capillary leakage and improved organ function^[32]. Of interest, upregulated genes reported here substantiate this finding. For example, multifunction pro-inflamma-

tory cytokine IL-6 levels were significantly upregulated in DRG of rats with pancreatitis on day 6 after DBTC injection^[20]. Relative quantification of target cDNA levels in primary stellate cultures using real-time polymerase chain reaction revealed a dose-dependent reduction of endothelin-1 after treatment with inhibitors of histone deacetylases^[33]. This is relevant to anti-cancer activities and, therefore, of growing clinical interest^[34-36]. It is well established that diabetes can occur in acute pancreatitis as well as chronic pancreatitis. Insufficient pancreatic enzyme activity and dosing is treated in pancreatic steatorrhea with administration of lipase with meals in patients^[37]. In this model we detected modulation of genes for the inflammatory markers of pancreatitis, including upregulated lipase, α enolase and α trypsinase, while insulin precursor, glucose transporter type 5, and glycogen phosphorylase were down regulated. In accordance with these findings the increased levels of the serum amylase and lipase were reported on day 3 and peaked on day 7 in this DBTC induced pancreatitis model, consistent with pancreatitis in patients^[22]. Finally, amongst those genes found to be downregulated were peripheral myelin protein 22, α platelet-derived growth factor receptor, dopamine receptor, and neuropeptide Y receptor. Further studies are warranted to investigate the role of these candidate genes as novel targeted therapeutic modalities in patients. ET-A receptor antagonists deserve future study as a potential novel therapy against inflammatory and neuropathic pain.

In conclusion, we report 8 different groups of genes modified in this model of pancreatitis. These candidate genes may be useful as future biomarkers for diagnostic and/or targeted gene therapy. As an example, endothelin-1 gene was upregulated and subsequently, ET-A and ET-B receptor antagonists were found to reverse inflammatory pain responses. These results demonstrate the potential utility of the gene microarray analysis to identify candidate genes for analgesic development.

COMMENTS

Background

Abdominal pain ranging from mild to severe pain is the chief symptom of patients with pancreatic disorders. Neural innervation of the pancreas is important in the initiation and maintenance of inflammation. Activation of pancreatic sensory neurons causes release of neurotransmitters in the spinal cord and neurogenic activation signals in the pancreas itself producing plasma extravasation and neutrophil infiltration. Endothelins (ET) cascade is implicated as a major contributing factor in pancreatic pain in both pancreatitis and pancreatic cancer.

Research frontiers

Multifunctional ETs comprise a family of peptides which interact with their receptors that are involved in regulation of blood flow, cell proliferation, muscle contraction or relaxation, secretion and ion transport. The ETs are expressed by endothelial cells, macrophages, astrocytes and neurons. ETs activate the peripheral sensory nervous system and may directly be involved in signaling nociceptive events in peripheral tissues. ETs are increased in inflammatory conditions. ETs produce their biological effects via activation of the ET-A receptor and the ET-B receptor.

Innovations and breakthroughs

The ET-1 was amongst the 52 candidate genes upregulated (average of 3 animals/group and study repeated X2) greater than 2-fold in an experimental pancreatitis model. ET receptor antagonists were safe and effective in ameliorating mechanical and thermal hypersensitivity in doses lower than the gold standard

morphine with exception of no detectable side effects.

Applications

The candidate genes reported in this investigation may be useful as future diagnostic tool and targeted gene therapies. ET-A and to a lesser extent ET-B receptor antagonists can reverse pancreatic inflammatory pain responses. The results demonstrate the possible utility of the gene array analysis to identify candidate genes for analgesic development.

Terminology

The pain systems are comprised of peripheral neurons and their receptors, the nociceptors, central neuronal transmitting pathways and neurons with excitatory or inhibitory effects on nociceptive information. Nociceptors are specialized receptors on nerve endings that respond to noxious to mechanical and thermal stimuli interpreted as pain. Dorsal root ganglia are the cell bodies of peripheral nerves and are located adjacent to the spinal cord in the vertebral column. ET interacts with its receptors and regulates blood flow, cell proliferation, muscle contraction or relaxation, secretion and ion transport.

Peer review

This paper reports a potentially interesting approach to an important problem, pain in pancreatitis. The paper is an original report focusing on the gene profiling to provide rationale for potential casual mechanisms and pharmacological block of functional pain related behaviors with specific antagonists. The agent dose response data present important information for potential future human translational studies.

Abstract

AIM: To investigate the performance of a new software-based colonoscopy quality assessment system.

METHODS: The software-based system employs a novel image processing algorithm which detects the levels of image clarity, withdrawal velocity, and level of the bowel preparation in a real-time fashion from live video signal. Threshold levels of image blurriness and the withdrawal velocity below which the visualization could be considered adequate have initially been determined arbitrarily by review of sample colonoscopy videos by two experienced endoscopists. Subsequently, an overall colonoscopy quality rating was computed based on the percentage of the withdrawal time with adequate

visualization (scored 1-5; 1, when the percentage was 1%-20%; 2, when the percentage was 21%-40%, *etc.*). In order to test the proposed velocity and blurriness thresholds, screening colonoscopy withdrawal videos from a specialized ambulatory colon cancer screening center were collected, automatically processed and rated. Quality ratings on the withdrawal were compared to the insertion in the same patients. Then, 3 experienced endoscopists reviewed the collected videos in a blinded fashion and rated the overall quality of each withdrawal (scored 1-5; 1, poor; 3, average; 5, excellent) based on 3 major aspects: image quality, colon preparation, and withdrawal velocity. The automated quality ratings were compared to the averaged endoscopist quality ratings using Spearman correlation coefficient.

RESULTS: Fourteen screening colonoscopies were assessed. Adenomatous polyps were detected in 4/14 (29%) of the collected colonoscopy video samples. As a proof of concept, the Colometer software rated colonoscopy withdrawal as having better visualization than the insertion in the 10 videos which did not have any polyps (average percent time with adequate visualization: 79% \pm 5% for withdrawal and 50% \pm 14% for insertion, $P < 0.01$). Withdrawal times during which no polyps were removed ranged from 4-12 min. The median quality rating from the automated system and the reviewers was 3.45 [interquartile range (IQR), 3.1-3.68] and 3.00 (IQR, 2.33-3.67) respectively for all colonoscopy video samples. The automated rating revealed a strong correlation with the reviewer's rating (ρ coefficient= 0.65, $P = 0.01$). There was good correlation of the automated overall quality rating and the mean endoscopist withdrawal speed rating (Spearman r coefficient= 0.59, $P = 0.03$). There was no correlation of automated overall quality rating with mean endoscopists image quality rating (Spearman r coefficient= 0.41, $P = 0.15$).

CONCLUSION: The results from a novel automated real-time colonoscopy quality feedback system strongly

agreed with the endoscopists' quality assessments. Further study is required to validate this approach.

INTRODUCTION

Colorectal cancer (CRC) is a major cause of cancer mortality worldwide, with more than one million new cases diagnosed annually^[1]. CRC screening reduces CRC incidence and mortality^[2-4]. Currently, colonoscopy is widely accepted as the most accurate method of screening the colon for CRC^[5-7]. Although there is good evidence for its positive impact in the reduction of CRC, it is also recognized that its effectiveness is dependent on the quality of the procedure^[8] which, may be highly variable in clinical practice. Several studies have highlighted important limitations in the accuracy of colonoscopy. Ineffective bowel preparation, an inability to consistently intubate the caecum, and rapid withdrawal times are significant contributors to missed lesions during colonoscopy^[9-11].

It has been suggested that a high-quality examination that ensures the detection and removal of all neoplastic lesions is key to screening efficacy^[12]. In response, professional societies have proposed the use of various quality-assessment indicators. Crucial quality indicators for colonoscopy were published in 2002 by the American Society for Gastrointestinal Endoscopy/American College of Gastroenterology^[13,14]. The assurance that colonoscopy procedures are completed with adherence to these quality standards has become important^[15,16] in the quest for high quality and effective CRC screening. Current quality indicators for colonoscopy such as mean withdrawal times and bowel preparation are endoscopist-based^[17,18]. Therefore, the quality of a colonoscopy for an individual patient may vary even when performed by an experienced endoscopist^[19,20]. The effectiveness of colonoscopy depends on adequate visualization of the entire colon and diligence during examination of the mucosa. Many colon segments can have low diagnostic yield caused by transiently rapid withdrawal, for example, when passing acute angulations of the organ^[21]. A quality indicator that

is only based on the total withdrawal time cannot recover information about colon segments which have been poorly visualized due to rapid withdrawal. In addition, the effectiveness of any colorectal cancer screening program is critically dependent on adequate bowel preparation^[22]. Poor bowel preparation contributes to inadequate visualization of the colonic mucosa. A universal, automated, real-time, feedback-based, and non-operator dependent method which could provide information about the dynamics and the level of the bowel preparation of the procedure would be particularly useful in this regard.

We propose a colometer system^[23]; a software-based, automated image analysis tool to improve the quality of the screening colonoscopy thus providing three major outputs: (1) real-time visual feedback indication of image changing velocity and image blurriness to the endoscopist; (2) automated summative statistics report provided immediately following the colonoscopy, including withdrawal time, % time of adequate visualization, and a novel graph of dynamics over time; and (3) automated stool coverage analysis for the documentation of bowel preparation. All of these outputs can be obtained automatically. Hence, this method could allow future colonoscopy quality control in the day-to-day medical practice setting.

The goal of our study was to comparatively validate the performance of the real-time feedback system for screening colonoscopy against expert opinion in clinical practice.

MATERIALS AND METHODS

System overview

The conceptual block diagram of the entire colometer system is shown in Figure 1. Initially, a high-speed analog video acquisition device (VCE-Express, Imperx, Boca Raton, FL, United States) was connected to an EPX-1 colonoscope (Pentax Canada, Mississauga, Ontario) through its S-video port before a standard colonoscopic procedure to enable a real-time video acquisition. A high-performance laptop workstation (Thinkpad W520, Lenovo Canada, North York, Ontario) equipped with Matlab 7.14 (The Mathworks, Inc., MA, United States) was employed to interface with the video acquisition unit and to allow a real-time video processing of the colonoscopy video stream at sampling frequency of 30 frames per second.

A real-time visual feedback of the colonoscopy image changing velocity and image blurriness was embedded within this video utilizing Matlab (Image Processing Toolbox™). A custom-design user control interface was developed on the workstation using Matlab (MathWorks, Natick, MA, United States) to allow the user to control the real-time feedback indicator and to provide an offline summative report.

Real-time visual feedback system

In this study, a total of 14 screening colonoscopy videos from a single endoscopy unit (Foothills Medical Campus, Calgary Zone, Alberta Health Services), Calgary, Canada) were collected, processed, and rated in a real-

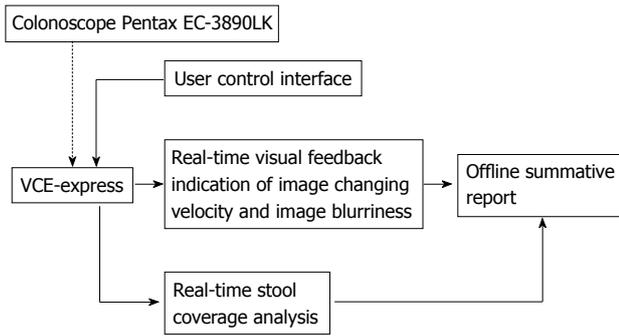

Figure 1 Conceptual block diagram of the proposed colometer system.

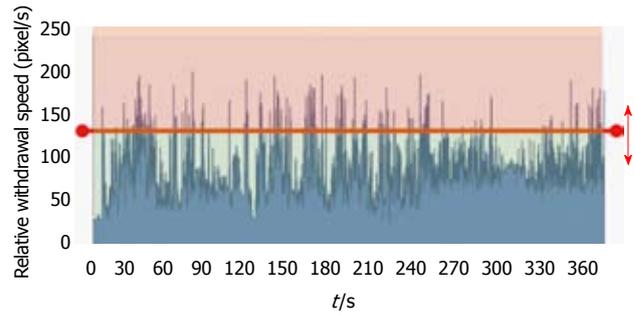

Figure 2 Relative withdrawal speed over time. Red line is the speed threshold configured by the endoscopists.

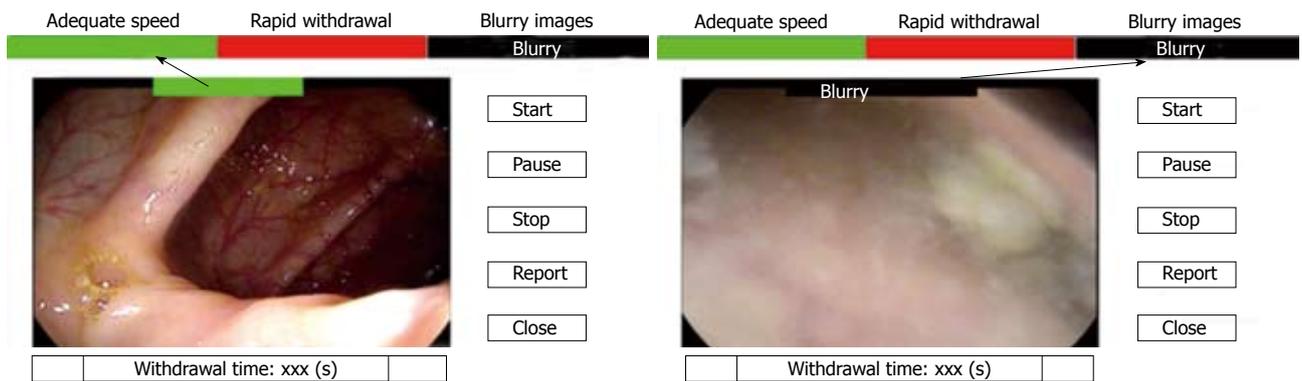

Figure 3 A sample frame with focused (left) and poor image clarity. Text indicators “adequate speed”, “rapid withdrawal”, “blurry”, were embedded into the video in a real-time to provide a visual feedback to the endoscopist.

time fashion. The colonoscopy videos were completely anonymized videos without any patient or endoscopist information on the images, filenames, or in the file meta-data. The videos were acquired for a quality assurance exercise (practice audit), for maintenance of certification purposes (for Andrews CN) and was thus exempt from consent requirements. Three other experienced gastroenterologists reviewed these videos in a blinded fashion and rated the withdrawal velocity, image quality, and colon preparation of each (scored 1-5; 1, poor; 3, average; 5, excellent) as well as overall quality on the same scale. The automated quality ratings were compared to the averaged endoscopist quality ratings.

Image changing velocity measurement: In general, the dynamics of moving objects in a video sequence can be assessed by frame differencing technique. If the temporal changes of pixel intensity have changed in a successive sequence of frames, it had to be due to the changing dynamics of objects within the image^[24]. Most frame differencing methods offer low computational complexity, which was the main constraint when designing the system to operate in real-time^[25]. Since the frame differencing technique is contrast-based and the colonoscopic image contrast can be manually adjusted according to endoscopist’s preference, a normalized approach was chosen to eliminate this problem.

Initially, an overall minimum and maximum values of velocity changes for all 14 videos were determined in real

time with 30 ms time delay. Subsequently, two different threshold ranges between these values were selected corresponding to an adequate and rapid withdrawal speeds. These ranges were further optimized to achieve agreement with the average rating from the gastroenterologists (Figure 2).

Image blurriness measurement: Colonoscopy videos also contain many blurry (out-of-focus) frames due to frequent shifts of camera positions while moving along the colon. Current endoscopes are equipped with a single, wide-angle lens that cannot be focused^[26]. Sharpness, brightness and contrast of the image are optimized using the endoscopist’s skills. In addition, the tip of the colonoscope during the procedure can be temporally buried in mucosa or closely face the colonic wall, which also results in blurry images. It is estimated that the average number of blurry frames in a colonoscopy video is 37%. However, that number can range as high as 60%, depending on endoscopists, patients and colon preparation^[27]. Numerous methods have been proposed to assess blurriness in colonoscopy videos. However, a real-time algorithm for blurriness measurement for the colonoscopy video has not yet been implemented. A variance metric calculated as the variance of the whole image was utilized to measure the blurriness of the video frames in our real-time application^[28]. During blurry video sequence, information about the image changing velocity is not important and thus was not calculated. Figure 3 shows comparison

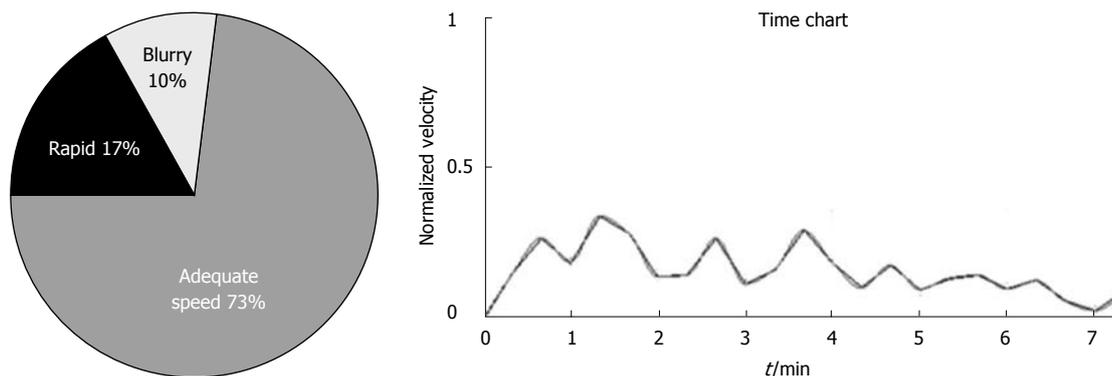

Figure 4 An automatically generated chart providing % of time of adequate speed in a colonoscopy procedure (left) and chart showing filtered velocity over time (right).

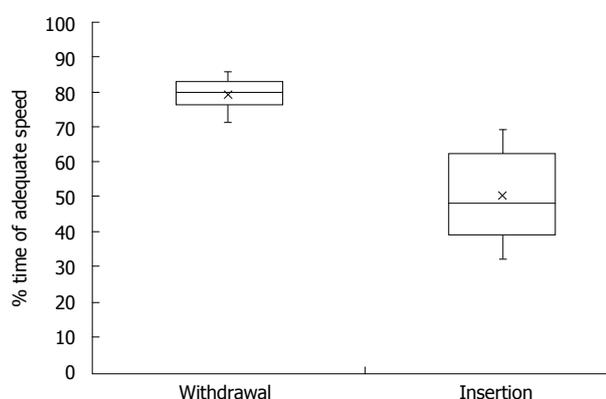

Figure 5 Comparative results (withdrawal vs insertion) for 10 colonoscopy procedures. The output mean values are marked with a cross.

between focused and blurred snapshots from a colonoscopy withdrawal video.

Stool coverage analysis: The core factor to be detected in the stool coverage analysis is the level of cleanliness in the colon. A previously reported color recognition algorithm was used for measuring this feature based on recorded colonoscopy videos^[23]. In this study, the stool coverage analysis was successfully integrated within the withdrawal and blurriness algorithm in real-time with reasonable correlation to Ottawa stool scores^[29,30]; these results are reported elsewhere^[31].

Statistical analysis

Based on these thresholds, a summative statistics report following each colonoscopy could be provided, including withdrawal time, % time with adequate visualization, and a novel graph of image changing dynamics over time. This graph may allow endoscopists to see through which portion of the colon the withdrawal was too fast. An example of a summative colometer report is given as an example in Figure 4. Moving average filter was used to smooth the velocity data for every 20 s. The peaks in the image changing dynamics graph indicate the period with frequent abrupt image changes during scoping. The slope of the line on this dynamics-time graph reveals

useful information about the acceleration of the scoping sequences. Using this information missed colonic segments could be estimated. Comparisons of continuous variables used Student's *t* test and correlations of ordinal data used Spearman coefficient. Free-margin multirater Kappa statistics were calculated for inter-rater variability^[32]. A level of *P* < 0.05 was used to determine statistical significance.

RESULTS

Proof of concept

For a colonoscopy procedure, it is widely known that the visualization quality during withdrawal is higher than the visualization quality during insertion process. Based on this assumption, a comparative study was performed to validate the functionality of the proposed algorithm by comparing the system outputs (% of time of adequate speed in a colonoscopy) between the insertion and withdrawal for 10 colonoscopy procedures. The 10 videos, which were used for validation of the functionality of the proposed algorithm, were different from the videos used to validate the automated scores against expert endoscopist. The average percentage for the colonoscope withdrawals was 79.3% ± 4.96% and it was 50.3% ± 13.95% for the insertion procedures. In a total of 10 collected videos, there was a significant difference of 29.1% ± 11% (*P* < 0.01) between both procedures. Comparative results are shown in Figure 5.

Correlation between the system output and the subjective endoscopist evaluation

Subsequently, an overall colonoscopy quality rating was computed based on the percentage of the withdrawal time with adequate visualization (scored 1-5; 1, when the percentage was 1%-20%; 2, when the percentage was 21%-40%, *etc.*). Adenomatous polyps were detected in 4/14 (29%) of the collected colonoscopy video samples. There were large differences in the withdrawal times during which no polyp was removed (range: 4-12 min). The percentage time with adequate visualization in the videos (*i.e.*, not blurry and not over the velocity

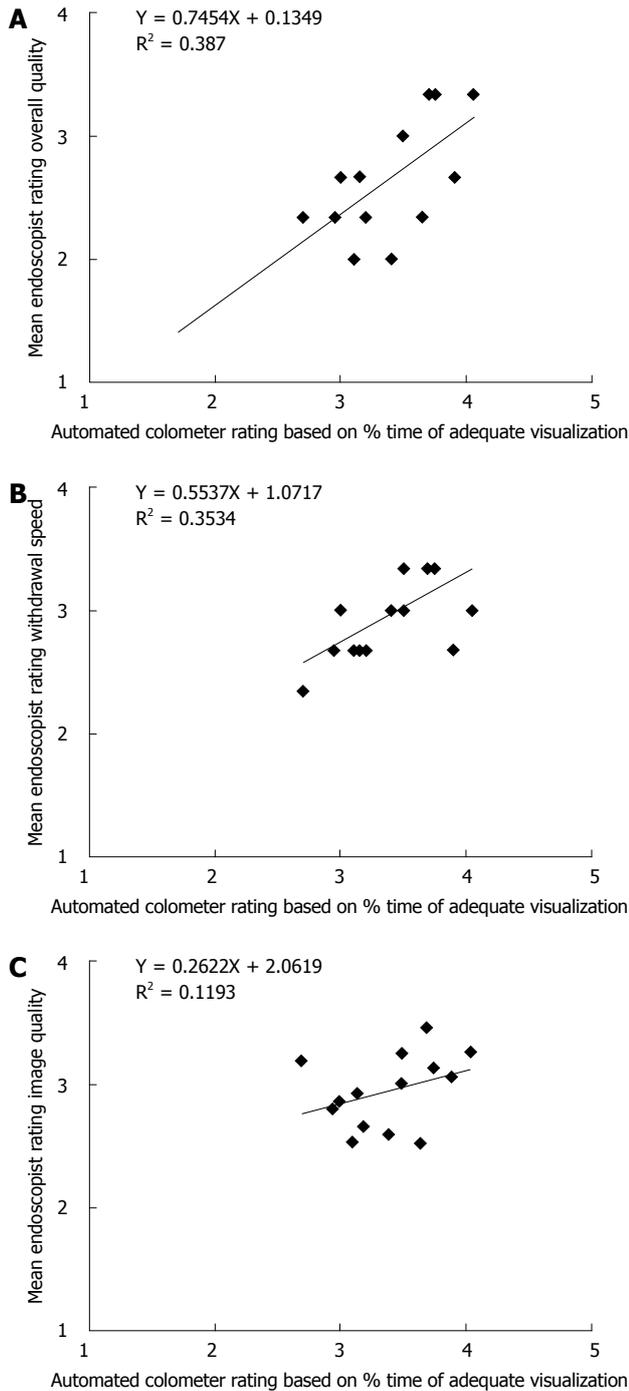

Figure 6 Correlation between the overall quality ratings from the Colometer system. A: Mean endoscopist overall quality rating ($\rho = 0.65, P < 0.01$); B: Mean endoscopist withdrawal speed rating ($\rho = 0.59, P < 0.01$); C: Mean endoscopist image quality rating ($\rho = 0.41, P = 0.15$).

threshold) ranged from 54% to 81% (mean $68\% \pm 2\%$). The median quality rating from the automated system and the reviewers was 3.45 [interquartile range (IQR), 3.10-3.68] and 2.67 (IQR, 2.33-3.00), respectively, for all colonoscopy video samples. However, there was significant variability in the endoscopist ratings (free-margin kappa statistic = 0.20).

The automated overall quality rating revealed a strong correlation with the reviewers overall quality rating

(Spearman r coefficient = 0.65, $P = 0.01$) as can be seen in Figure 6A. Similarly, there was good correlation of the automated overall quality rating and the mean endoscopist withdrawal speed rating (Spearman r coefficient = 0.59, $P = 0.03$) (Figure 6B). There was no correlation of automated overall quality rating with mean endoscopists image quality rating (Spearman r coefficient = 0.41, $P = 0.15$) (Figure 6C). There was also no correlation of the automated blurriness or excessive velocity metrics and mean endoscopists ratings (data not shown).

Comparative analysis between the withdrawal standard and the proposed algorithm

The mean withdrawal time of the videos was 5.8 min (± 0.4 min SE, range 4-10 min). Out of the 14 colonoscopy withdrawal videos, 2 videos with 6 min withdrawal time were rated as poor quality with low diagnostic yield by 3 endoscopists and confirmed with the colometer. There was no correlation of automated overall quality rating and withdrawal time (Spearman r coefficient = 0.11, $P = 0.70$).

DISCUSSION

Colonoscopy is widely used for CRC screening^[33-35] and its miss rate for advanced adenomas, neoplastic lesions or adenomas remains a concern^[36,37]. Obviously, the rate of adenoma detection is closely related to the quality of the colonoscopy^[38]. Quality assurance initiatives have been adopted by most national gastroenterology societies, with the mean withdrawal time for colonoscopy strongly correlating with adenoma detection rate. It has been accepted that endoscopists who use withdrawal times longer than 6 min detected significantly more adenomas. In this study, we present a novel, real-time colonoscopy video quality indication system for evaluating the adequacy of image clarity, the withdrawal velocity, and the bowel preparation quality.

The colometer system is a user-friendly method for evaluating the quality of individual screening colonoscopies. This is in contrast to many endoscopist-based quality indicators, such as mean withdrawal time^[39]. For example if an endoscopist has a 6 min mean withdrawal rate, many of that endoscopist's colonoscopies will presumably have a withdrawal time below 6 min^[40] and may have lower adenoma detection rates. The individuals with the more rapid withdrawals will not likely be aware of this fact. Further, calculation of mean withdrawal rates is labor-intensive, and even if published, will not likely affect patient choice of endoscopist. Thus a simple and immediate objective quality summary that can be integrated into the patient's colonoscopy report would be ideal. This is especially so in areas where reimbursement may be tied to procedure quality, as has been proposed in the United States^[41].

In our study, widely recommended criteria for colonoscopy procedures were analyzed, including withdrawal time, quality of the bowel preparation and the video qual-

ity. Quality indicators for colonoscopy have been selected to establish competence in performing colonoscopy procedures and to help define areas for continuous quality improvement^[42,43]. The Colometer quality measurements appear to correlate well with these outcomes in this small study.

This new computer-based method is based on image processing analysis of the live video feed from the colonoscope processor, and just as easily can be run on digitized video files for retrospective review. The method uses widely available video processing technology and can be retrofitted onto any endoscope processor with digital video output. No remote processing of video is required, which will prevent any privacy breach risks. Output of summative metrics is immediate, and could be added to individual endoscopy reports, as well as database recording for simple collection of quality control data in the practice setting on a large scale.

This study was designed to show the proof of the Colometer concept and compare it to subjective quality assessments based on retrospective video recordings of colonoscopy. The software however is designed to provide real-time visual feedback to the endoscopist during the withdrawal itself. We did not evaluate the actual feedback to endoscopists during the colonoscopy to determine whether this type of output (like a speedometer for the scope driver) affects withdrawal speed or other quality measures, but studies in this regard are underway. Further uses could be used in the education and (re)credentialing fields.

This study has some limitations. First, it was a small pilot-study looking at mostly good quality colonoscopies. The performance characteristics of Colometer may change with a broader spectrum of colonoscopy withdrawals. Second, overall quality of a screening colonoscopy is a multi-dimensional concept, which may not be completely captured by a small number of quality metrics. However, the established metrics are certainly not perfect (as shown by the fact that 2 of the videos with a 6 min withdrawal time were in fact of poor quality). The advantage of an automated system however removes the variability and subjectivity of current quality metrics. Third, the small numbers in this study may have led to underpowering of the correlations. Additionally, the inter-rater variability was high. This is due to a number of factors, including the fact that the rating scale used was unvalidated, despite its simplicity and face validity. Moreover, the raters were not trained prior to the study to “anchor” their responses, which we admit is a limitation of this study. Interestingly, the rater with the most experience in colonoscopy quality assessments had outstanding correlation with colometer (data not shown), and thus inter-rater correlation will likely be tighter in future anticipated studies. Finally, some endoscopists may resist the concept of real-time constant scrutiny of their screening colonoscopies. However, it is clear that high-quality screening colonoscopy requires skill and attention, in addition to expensive infrastructure and has measurable

(although small) patient risk. We therefore should strive for continuous quality improvement of this procedure, and if heightened, non-punitive, scrutiny improves it (i.e., the Hawthorne effect) this is likely a positive direction for patients.

In conclusion, a new real-time feedback system for screening colonoscopy procedures was proposed. The results from this system based on the withdrawal dynamics and image quality strongly agreed with the endoscopists’ quality ratings. The colometer system could facilitate a real-time colonoscopy quality feedback for clinical practice, with easily accessible, in depth colonoscopy quality assessment for individual patients. Such a device could also be a potential training tool for new endoscopists. Further study is required in order to better define the optimal quality thresholds and to validate this approach in a larger clinical trial.

COMMENTS

Background

Colonoscopy is widely accepted as the most accurate method of screening the colon for colorectal cancer (CRC) however its effectiveness is dependent on the quality of the procedure which may be highly variable in clinical practice. Image quality and withdrawal time or velocity are important determinants of quality. A novel automated computer-based assessment tool was described and tested.

Research frontiers

It has become clear that colonoscopy quality is a major determinant of the detection of polyps in CRC screening, and there has been significant recent interest in the creation and evaluation of quality metrics for colonoscopy.

Innovations and breakthroughs

To date, there has been limited research on computerized colonoscopy video quality assessment in the published literature. The Colometer software represents an advance by using simple algorithms to characterize a complex procedure, with the added advantages of offering a real-time feedback tool to the endoscopist, immediately available patient-level quality metrics, and with minimal hardware or software requirements.

Applications

The colometer could be potentially applied to clinical screening colonoscopy practice to assess and ultimately improve colonoscopy quality.

Terminology

Colonoscopy quality: A multi-dimensional concept that affects the ability to identify and remove pre-cancerous polyps from the colon in screening colonoscopy for CRC. It incorporates many factors, including the effectiveness of the bowel preparation, the withdrawal speed of the scope, and the skill and care taken to thoroughly assess all surfaces of the colon.

Peer review

The manuscript is well written and has useful information that would be of interest to the readers.

Abstract

AIM: To investigate whether butyrate or glutamine enemas could diminish inflammation in experimental diversion colitis.

METHODS: Wistar specific pathogen-free rats were submitted to a Hartmann's end colostomy and treated with enemas containing glutamine, butyrate, or saline. Enemas were administered twice a week in the excluded segment of the colon from 4 to 12 wk after the surgical procedure. Follow-up colonoscopy was performed every 4 wk for 12 wk. The effect of treatment was evaluated using video-endoscopic and histologic scores and measuring interleukin-1 β , tumor necrosis factor-alpha, and transforming growth factor beta production in organ cultures by enzyme linked immunosorbent assay.

RESULTS: Colonoscopies of the diverted segment showed mucosa with hyperemia, increased number of vessels, bleeding and mucus discharge. Treatment with either glutamine or butyrate induced significant reductions in both colonoscopic ($P < 0.02$) and histological scores ($P < 0.01$) and restored the densities of collagen fibers in tissue ($P = 0.015$; $P = 0.001$), the number of goblet cells ($P = 0.021$; $P = 0.029$), and the rate of apoptosis within the epithelium ($P = 0.043$; $P = 0.011$) to normal values. The high levels of cytokines in colon explants from rats with diversion colitis significantly decreased to normal values after treatment with butyrate or glutamine.

CONCLUSION: The improvement of experimental diversion colitis following glutamine or butyrate enemas highlights the importance of specific luminal nutrients in the homeostasis of the colonic mucosa and supports their utilization for the treatment of human diversion colitis.

INTRODUCTION

Diversion colitis is a complex, nonspecific inflammatory disease that occurs in an excluded colonic segment in almost all patients submitted to a fecal diversion, such as loop colostomy or Hartmann's procedure (end colostomy with closure of the distal colon's segment)^[1,2]. Clinical manifestations typically include tenesmus with abundant rectal discharge of mucus or blood and abdominal pain. The inflammatory process and the severity of symptoms are highly variable, and occasionally, areas of erosions and ulcerations spread throughout the segment and may cause severe colonic hemorrhage^[3,4]. In some cases, it may be difficult to distinguish diversion colitis from other diseases that mimic not only the clinical manifestations but also the colonoscopic appearance. It is essential that diversion colitis not be mistaken for other diseases, especially ulcerative colitis or Crohn's disease, for this may delay the initiation of appropriate treatment. Reestablishment of the fecal stream is the ideal therapy for diversion colitis, but the best outcomes are directly related to the correct diagnosis^[5]. However, many patients need to remain with the colostomy for long periods, and some will never attain the reconstruction of intestinal continuity. As a consequence, it is expected that diversion colitis will impair the quality of life in a significant number of patients.

The diagnosis and follow-up of diversion colitis usually require endoscopic and histologic analyses, but none of these are specific^[6]. The endoscopic appearance ranges from absent to severe inflammatory features, including mucus discharge, luminal narrowing, friability, erythema, ulceration and a distorted mucosal vascular pattern^[7,8]. Mucosal biopsy of the diverted segment is an important auxiliary tool for the clinical or surgical management. Histological findings usually include mucosal edema, inflammatory infiltration with follicular lymphoid hyperplasia, vascular congestion, decreased number and depth of crypts, expansion of cellular elements and edema of the lamina propria^[9,10].

Bacterial proliferation^[11,12], overproduction of free

oxygen radicals^[13], impairment of butyrate oxidation^[14,15], defective transport of short-chain fatty acids (SCFAs)^[16], and immunological factors^[17] are some of the pathogenic mechanisms proposed for explaining the intestinal inflammation after a surgical fecal diversion. Nevertheless, the exact etiopathogenesis of diversion colitis remains unclear. Although an imbalance in the mucosal production of proinflammatory and immunoregulatory cytokines has been implicated in the etiopathogenesis of inflammatory bowel disease (IBD)^[18,19], this mechanism has not been well characterized in diversion colitis, and its potential pathogenic role is yet to be determined.

Some new data suggest that the lack of luminal nutrients may be crucial in the development of diversion colitis. SCFAs, in particular butyrate, are considered the major energy source for colonocytes and have been associated with a mucosal trophic effect^[16,20,21]. Therefore, it seems that dietetic supplementation with SCFAs or glutamine increases the function and repair of the intestinal mucosa under several conditions, such as radiotherapy, chemotherapy, inflammation, trauma and sepsis^[22-24]. In animal models, butyrate and glutamine administered through the oral route or enemas reduce inflammatory processes of the intestinal colonic mucosa^[25-29]. However, the available data concerning the treatment of human diversion colitis are still not clear.

Hence, the aim of this study was to investigate whether administering essential nutrients for colonocytes, such as butyrate and glutamine, could alleviate mucosal inflammation and minimize scarring lesions in a model of diversion colitis.

MATERIALS AND METHODS

Animals

The present study was carried out at the Center of Experimental Surgery of the School of Medicine of the Federal University of Rio de Janeiro (UFRJ). The care and use of animals and the procedures reported in this study were approved by the Ethical Committee for Laboratory Animals of the UFRJ and were in accordance with the guidelines of the International Care and Use Committee of the National Institutes of Health and the Guide for the Care and Use of Laboratory Animals.

Sixty adults Wistar rats (*Rattus norvegicus*) of both sexes, specific pathogen-free and five months old, with mean body weight 250 g, were maintained on a 12 h/12 h light/dark cycle in a temperature-controlled room (24 °C). Animals were fed standard rat chow and submitted to fasting for 24 h prior to the surgical procedure. Water was offered *ad libitum* during the whole experiment.

Experimental groups

Animals were randomly assigned to four groups of 12 animals each: the control group consisted of rats without any intervention (no surgery) but subjected to a colonoscopy and to the extraction of the distal segment of the colon. The treatment groups were submitted to a

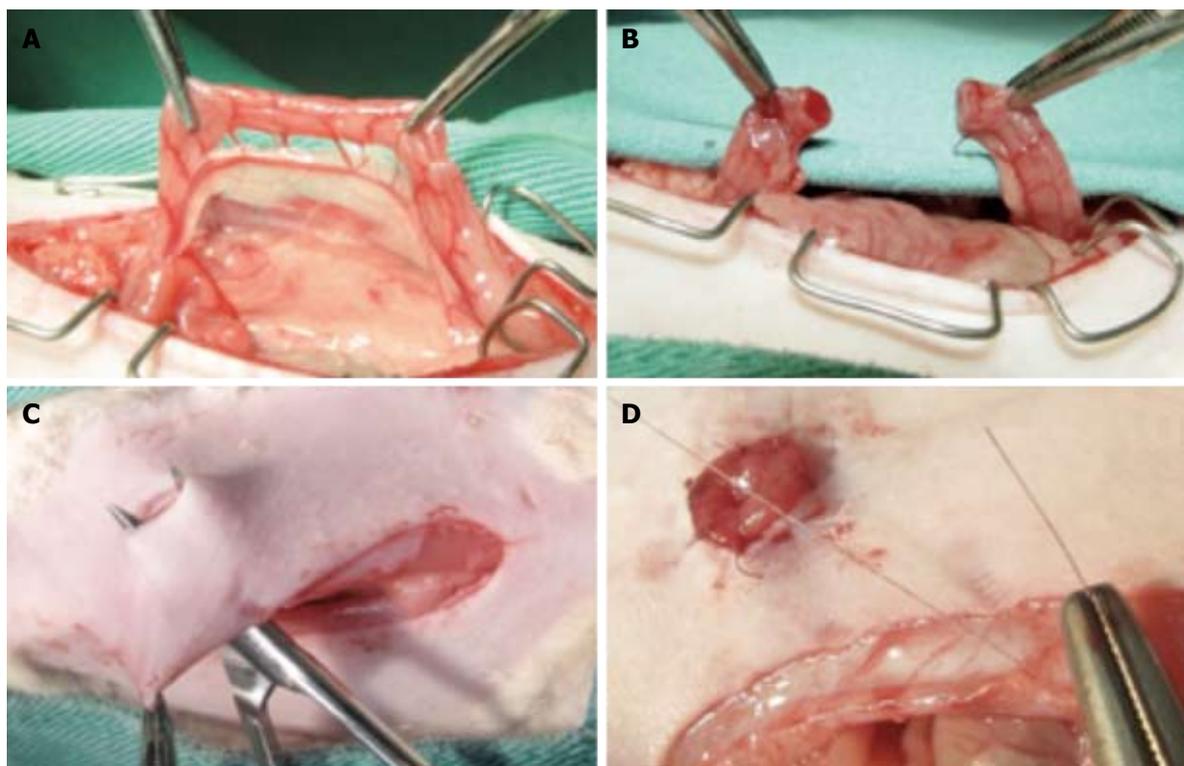

Figure 1 Steps of the surgical procedure. A: Isolation of the distal colon exposing the vascular arcade; B: Section of distal colon; C: Confection of colostomy; D: Completion of colostomy.

Hartmann's colostomy (standardized surgical procedure) followed by treatment with enemas containing saline, butyrate, or glutamine.

Surgical procedure

The anesthetic procedure consisted of the intraperitoneal administration of ketamine (1 mg/kg) associated with xylazine (0.1 mg/kg). Immediately after anesthetic administration, animals were immobilized in the dorsal decubitus position, and the skin was cleaned with an antiseptic surgical scrub solution after shaving the surgical site.

After a midline abdominal incision, animals were subjected to a Hartmann's colostomy. With the exception of the control group, all animals had the left colon transected transversally and the proximal segment brought out as an end colostomy, while the distal segment was sewn over and left within the abdomen as a blind rectal pouch. After the surgical manipulation, the laparotomy was closed by two layers of continuous suture (Figure 1). In the first two postoperative days, animals received analgesia with dipyrone (1 g/L) in the drinking water. A caloric supplement with glucose was also provided because they had been deprived of solid food for the 24 h before surgery.

Treatment protocols

A standard volume of 1 mL containing saline (placebo), butyrate (40 mmol) or glutamine (50 g/L) was instilled into the distal excluded segment of the colon through a rubber cannula (4 cm long), under light anesthesia. Ani-

mals were maintained in the Trendelenburg position for 2 min after the procedure. Enemas were administered twice a week beginning at week 4 after surgery and going through week 12.

Colonoscopies

Colonoscopies were performed under light anesthesia before the surgical procedure and thereafter every 4 wk, starting at 4 wk and going through the total follow-up of 12 wk. In addition to the real-time evaluation of mucosal appearance, video-endoscopic recorded movies were also used to confirm the results before and after the different treatments. Criteria for the endoscopic analysis were based on four parameters: hyperemia, number and size of vessels, bleeding, and mucous secretion, as previously described^[7]. Each parameter was assigned 0 to 4 points, and the sum of all parameters was used to generate a final endoscopic score.

After the 8th-week colonoscopic procedure, half of the animals from each group ($n = 6$) were euthanized by anesthetic overdose, without any pain or suffering. Three samples were excised from the colon for histological assessment and for organ cultures. The other animals from all groups ($n = 6$) were euthanized after the last colonoscopic procedure.

Histologic examination

Specimens were fixed in 40 g/L formaldehyde saline, embedded in paraffin, cut into serial sections of 5 μ m, and submitted to the different staining procedures. His-

tomorphological analysis were performed under light microscopy by two independent observers who were unaware of the experimental data and who examined all tissue sections and captured images (Leica Microsystems Ltd, Switzerland).

The following histological parameters involving inflammatory and trophic alterations were studied in hematoxylin-eosin-stained slides: mucosal edema, lymphoplasmacytic inflammatory infiltrate, lymphoid follicular hyperplasia, vascular congestion, number and depth of crypts, and the density of cellular elements in the lamina propria. Each parameter was assigned 0 to 2 points, and a total score was obtained by the sum of all parameters, as previously described^[30].

Assessment of collagen deposition in the colon wall

The phosphomolybdic acid-picro-sirius red dye was used to stain collagen fibers in the tissue of serial paraffin sections obtained as described above. At least 10 different areas per tissue section were analyzed under light microscopy at $\times 100$ magnification. The density of collagen fibers was calculated as the area positively stained for collagen in relation to total intestinal tissue using an imaging analysis system (Leica QWin Plus V 3.5.1, Leica Microsystems Ltd, Switzerland).

Assessment of goblet cells in the colonic mucosa

The periodic acid of Schiff (PAS) was used to stain goblet cells within the intestinal epithelium. The density of goblet cells was defined as the percentage of PAS-positive cells within at least 500 epithelial cells in the crypts and in the surface epithelium of longitudinally sectioned colonic pits.

Assessment of apoptosis in the colonic mucosa

To analyze apoptosis within the colon, fragmented DNA was stained by the terminal deoxynucleotidyltransferase (TdT)-mediated dUTP-biotin nick end labeling (TUNEL) assay, with the Apoptag[®] Plus Peroxidase In Situ Apoptosis Kit (Millipore, Billerica, MA, United States). Paraffin sections were first deparaffinized, incubated with proteinase K solution for 15 min at room temperature, and then immersed in hydrogen peroxide to block endogenous peroxidase activity. After rinsing with phosphate buffered saline (PBS), slides were incubated with equilibration buffer for at least 1 min, followed by incubation with a solution containing TdT enzyme. Sections were incubated at 37 °C for 1 h. A second section from each sample, incubated without TdT enzyme, constituted the negative controls. Positive controls were prepared by treating samples with DNase I (Sigma, Deisenhofen, Germany). The reaction was terminated by washing the slides with pre-warmed stop/wash buffer solution for 10 min. Specimens were subsequently incubated with non-immune horse serum for 20 min and subsequently with an anti-digoxigenin peroxidase conjugate for 30 min at room temperature. After being rinsed in PBS, all sections were developed with a solution containing hydrogen peroxide

and diaminobenzidine. Preparations were lightly counterstained in Harris's hematoxylin, dehydrated, and mounted in Permout (Fisher Scientific, Pittsburgh, PA, United States). Morphologically preserved TUNEL-positive cells and apoptotic bodies were referred to as apoptotic cells and identified by using pre-defined measurements in the computer-assisted image analyzer in conjunction with careful evaluation of morphologic criteria. Percentages of apoptotic cells were defined by the number of immunoreactive cells in relation to total cells (immunoreactive and nonimmunoreactive cells; $\times 400$ magnification), counted among at least 500 epithelial cells in the crypts and in the surface epithelium of longitudinally sectioned colonic crypts. Two independent observers who were unaware of the experimental data examined all tissue sections and captured images.

Organ culture and cytokine measurements

Colonic mucosal explants were cultured in RPMI 1640 medium supplemented with 10% fetal calf serum (Life Technologies, United States), 10 mmol HEPES (Pro-mega, United States), penicillin (100 kU/L) and streptomycin (100 mg/L) (Sigma-Aldrich, St. Louis, MO, United States) for 24 h at 37 °C in a 50 mL/L CO₂ humidified incubator. After incubation for 24 h, the supernatant was collected and stocked at -20 °C. Samples were centrifuged and the supernatants used to measure the concentrations of the cytokines tumor necrosis factor-alpha (TNF- α), interleukin (IL)-1 β and transforming growth factor beta (TGF- β) by enzyme-linked immunosorbent assay (ELISA) (R and D Systems, MN, United States). The total protein content of the biopsy specimens was estimated by the bicinchoninic acid method, and values were used to normalize ELISA results. The minimum detectable concentrations of rat TNF- α , IL-1 β , and TGF- β were typically less than 5.0 ng/L.

Statistical analysis

Statistical analyses were performed using the statistical software SPSS for Windows (version 10.0.1, SPSS Inc., 1989-1999, United States). Significant differences among the experimental groups were evaluated by one-way ANOVA followed by pairwise multiple comparisons using Dunnett's T3 test. Colonoscopic score changes before and after treatment were compared by the Wilcoxon matched-pair signed-rank test. Values are expressed as medians (1st quartile, 3rd quartile). The level of significance was set at $P < 0.05$.

RESULTS

An inflammatory process similar to human diversion colitis was well reproduced in the experimental model, and the peak inflammation was observed at 8 wk after induction.

Endoscopic changes in the colon

Diversion colitis manifested predominantly as patchy inflammatory lesions in the excluded distal colon. Colo-

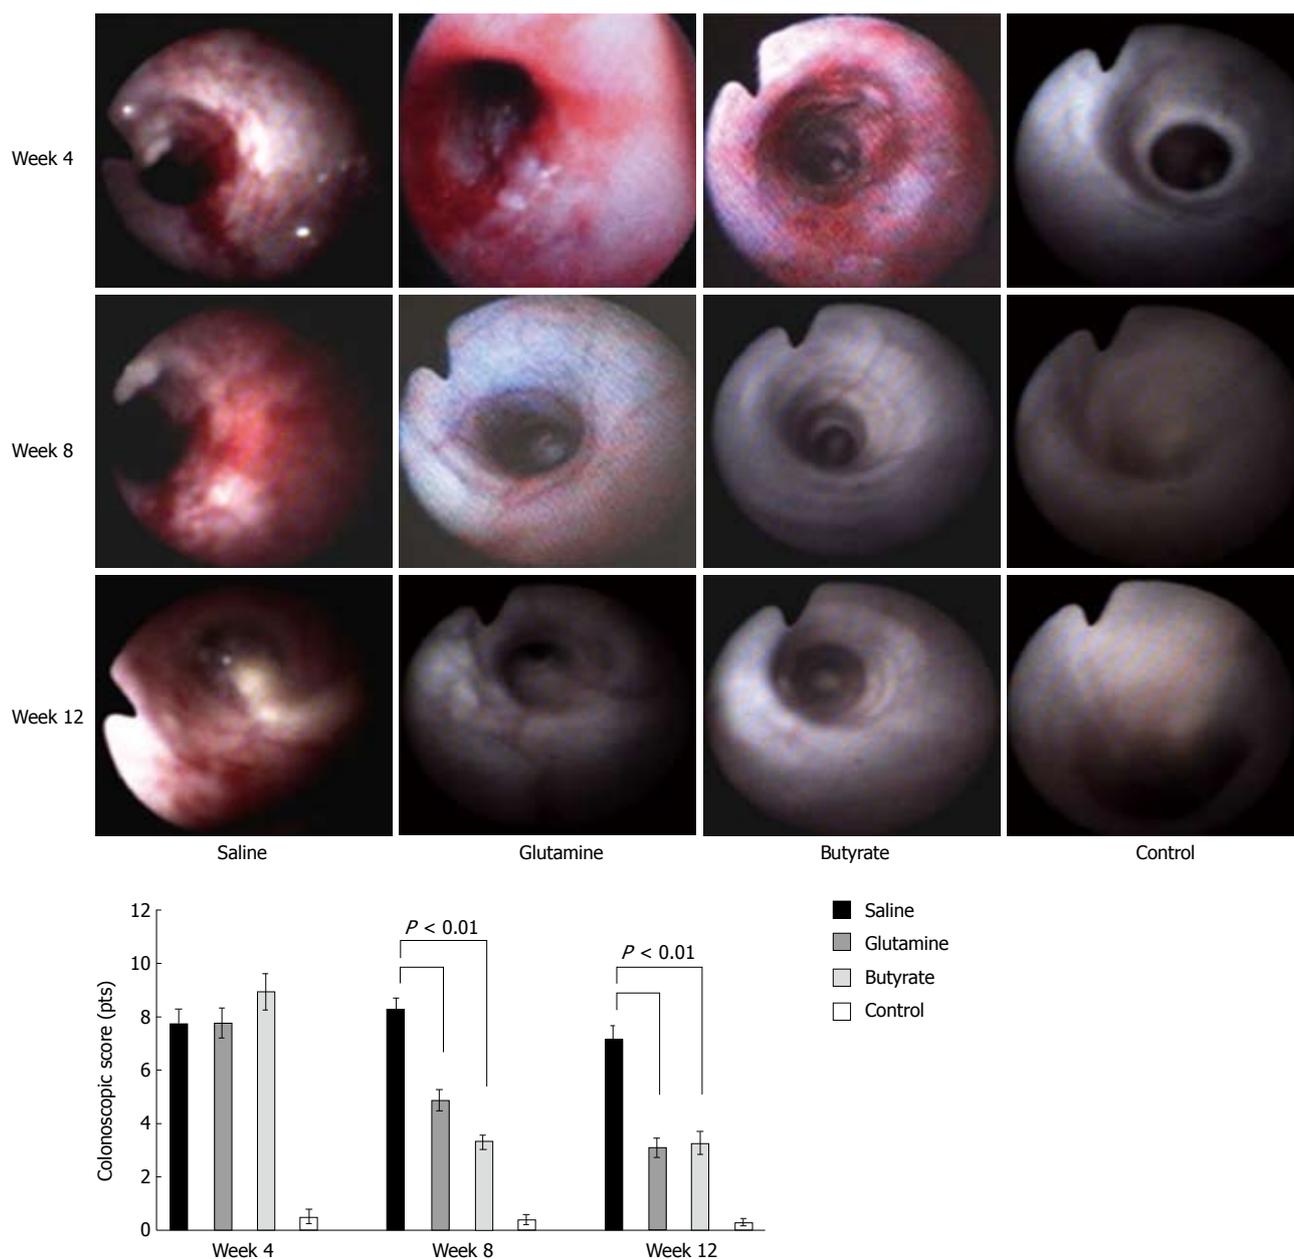

Figure 2 Endoscopic images of the diverted segments of the colon treated with different protocols at 4 wk, before treatment, and at 8 wk, the peak of inflammation in this experimental model. Diversion colitis is characterized by the presence of a fragile mucosa, hyperemia, spontaneous bleeding, and increased number of vessels and mucous secretion (at 8 wk). Colonoscopic images were semi-quantitatively analyzed with an endoscopic score. Animals treated with either glutamine or butyrate showed significantly reduced colonoscopic scores compared to animals without any treatment at 8 and 12 wk. Significant differences are noted ($n = 6$ in each group).

noscopy images of the diverted segment with colitis displayed a fragile mucosa, with hyperemia, increased number of vessels, spontaneous bleeding, and increased mucous secretion (Figure 2). Animals treated with either butyrate or glutamine showed a significant reduction in the endoscopic scores compared to saline-treated animals at both 8 and 12 wk (Figure 2).

Histological changes in the colon

Four weeks after surgery, the histological evaluation of the involved areas of the colon showed mucosal edema, inflammatory infiltration with follicular lymphoid hyperplasia, vascular congestion, decreased number and depth

of crypts, expansion of lamina propria cellular elements, and evidence of transmural inflammation (Figure 3A-F). Significantly higher histologic inflammatory scores were found in the intestinal mucosa of all animals submitted to colitis induction through colostomy compared to the normal mucosa of controls. Butyrate- or glutamine-treated animals presented significantly reduced histologic scores of the colon compared to those of the saline-treated group at 8 and 12 wk (Figure 3G).

Number of goblet cells in the colonic lamina propria

The number of goblet cells in the colonic mucosa was significantly lower in saline-treated rats, compared with

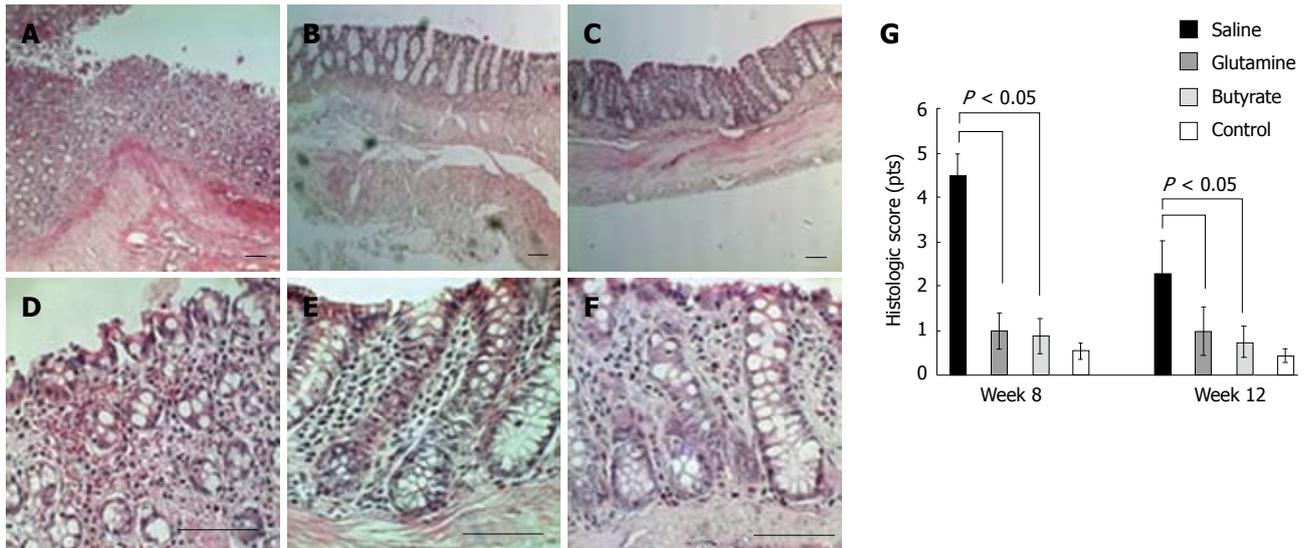

Figure 3 Hematoxylin-eosin-stained slides of diverted colon samples obtained at 8 wk. A, B: Images were captured at $\times 100$ and $\times 400$ magnifications, respectively. Diversion colitis is characterized by a predominantly mononuclear cell infiltration, hyperemia, vasodilatation, and associated atrophic changes; C, D: Glutamine-treated animals show a slightly inflamed colon; E, F: Butyrate-treated animals show an almost normal colon ($n = 6$ in each group). Bars represent $50 \mu\text{m}$.

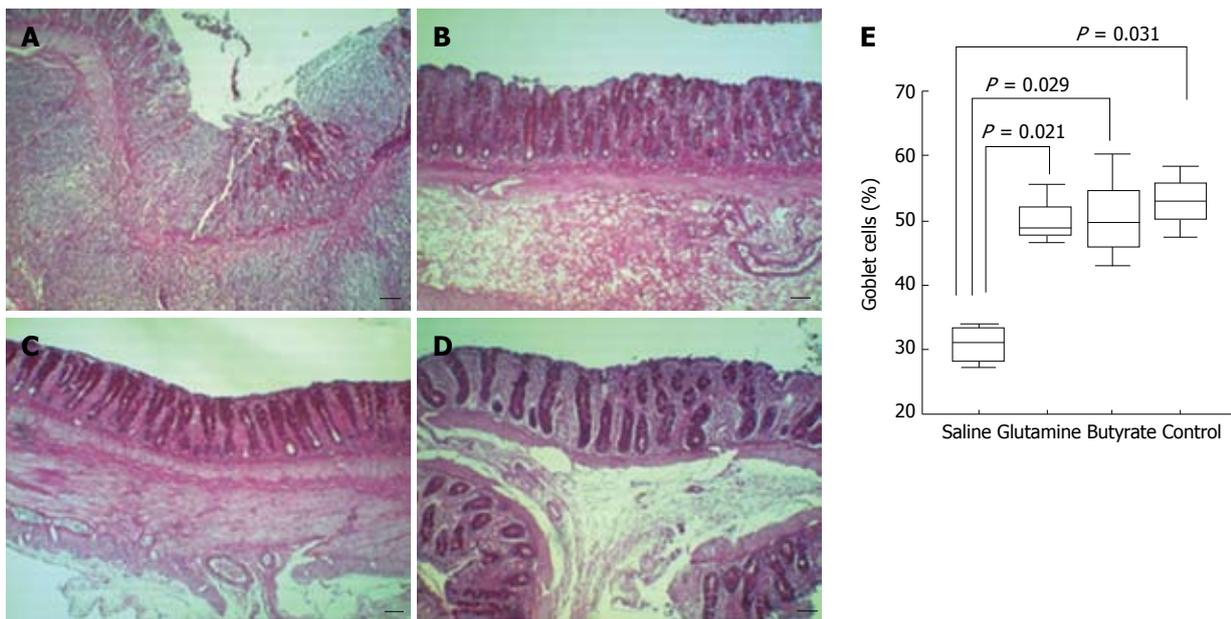

Figure 4 Quantitative analysis of goblet cells using periodic acid-schiff-stained slides of diverted colon samples obtained at 8 wk. Images show a significant reduction in the number of goblet cells in slides from animals with placebo-treated (A) colitis compared to (B) glutamine-treated, butyrate-treated (C) and control animals (D). Images were captured at $\times 100$ magnification. In the slides, bars represent $50 \mu\text{m}$. In the graph (E), horizontal bars represent medians, boxes represent the 25th and 75th percentiles, and vertical bars represent ranges. Significant differences are noted ($n = 6$ in each group).

the higher numbers found in the therapeutic glutamine or butyrate groups, which were similar to those of the normal control group (Figure 4).

Deposition of collagen fibers in the colon wall

Increased densities of collagen fibers were found in saline-treated animals, with a diffuse distribution throughout the colon wall. In contrast, rats treated with glutamine or butyrate enemas showed a significant reduction in collagen deposition, with levels similar to those observed in control animals (Figure 5).

Apoptotic rates in the colonic mucosa

In this diversion colitis model, significantly reduced rates of apoptotic TUNEL-positive cells were observed in the epithelium of glutamine- ($P = 0.042$) and butyrate-treated colitic animals ($P = 0.011$) compared to saline-treated animals. No significant difference was detected between glutamine- and butyrate-treated animals (Figure 6).

Cytokine production by the colonic mucosa

TNF- α , IL-1 β , and TGF- β production by the colonic mucosa of the diverted segment obtained at 8 wk was

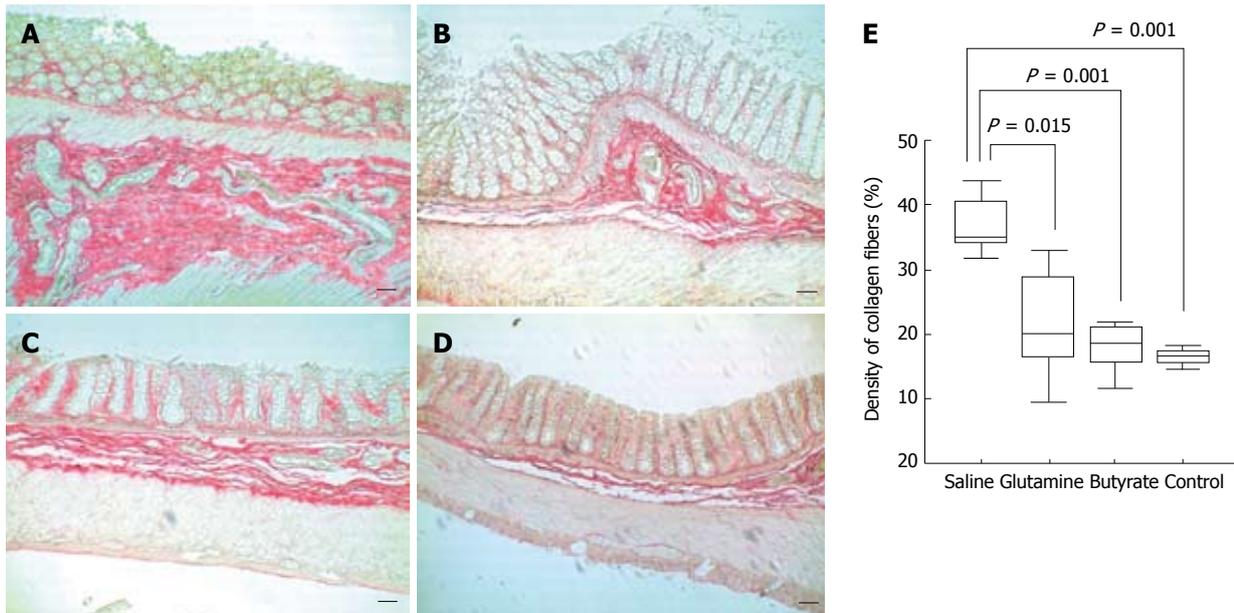

Figure 5 Quantitative analysis of collagen fiber deposition in picric acid-stained slides and apoptotic terminal deoxynucleotidyl transferase dUTP nick end labeling-positive cells of diverted colon samples obtained at 8 wk. Images show a significant increase of collagen density in slides from animals with placebo-treated (A) colitis compared to (B) glutamine-treated, butyrate-treated (C) and control animals (D). Images were captured at $\times 100$ magnification. In the slides, bars represent 50 μm . In the graph (E), horizontal bars represent medians, boxes represent the 25th and 75th percentiles, and vertical bars represent ranges. Significant differences are noted ($n = 6$ in each group).

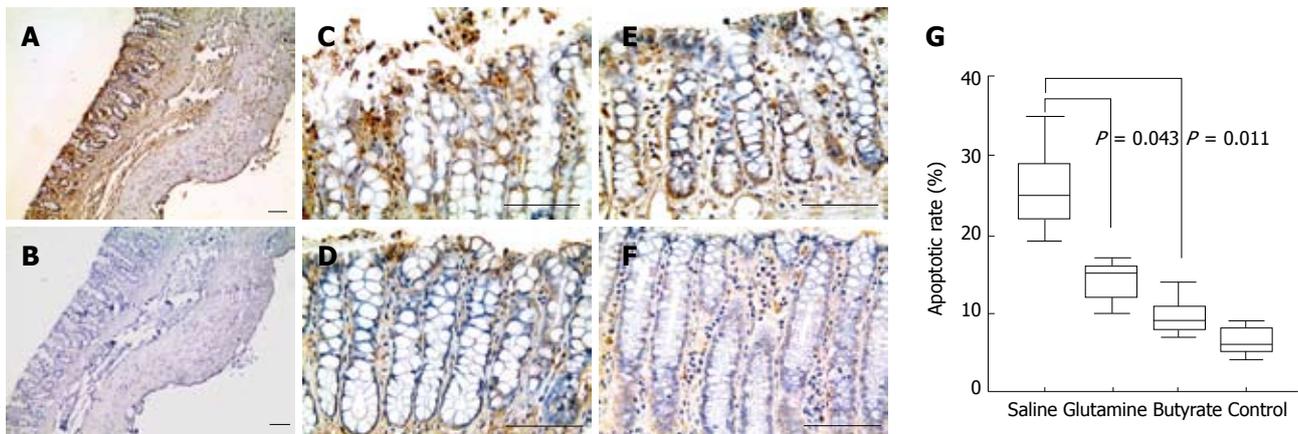

Figure 6 Quantitative analysis of apoptotic terminal deoxynucleotidyl transferase dUTP nick end labeling-positive cells of diverted colon samples obtained at 8 wk. Images show a significant reduction in the number of apoptotic cells in slides from animals with placebo-treated (A) colitis compared to (B) glutamine-treated, butyrate-treated (C) and control animals (D). Images were captured at $\times 100$ magnification. In the slides, bars represent 50 μm . In the graph (G), horizontal bars represent medians, boxes represent the 25th and 75th percentiles, and vertical bars represent ranges. Significant differences are noted ($n = 6$ in each group).

evaluated by ELISA in the supernatants of 24 h organ cultures. High levels of TNF- α (Figure 7A), IL-1 β (Figure 7B), and TGF- β (Figure 7C) were detected in the supernatants of saline-treated colitis, and significantly lowered to normal values following treatment with glutamine (Figure 7A) or butyrate (Figure 7A-C).

DISCUSSION

The experimental model presented in this study demonstrates that the simple deviation of the fecal stream through a colostomy is capable of inducing inflammation similar to human diversion colitis, even in specific

pathogen-free animals. Both glutamine and butyrate treatments significantly attenuated the inflammatory process, supporting a crucial role for specific luminal nutrients in intestinal homeostasis. We show that the inflammatory process is characterized by inflammatory cell infiltration, collagen fiber deposition, and atrophic changes in the colon, with loss of terminally differentiated goblet cells and increased local apoptotic rates, resulting in colonic remodeling. In addition, we show that a Th1-type of immune response is likely to be responsible for the inflammatory process and that the simple feeding of glutamine or butyrate can downregulate pro-inflammatory cytokines, reducing colonic inflammation.

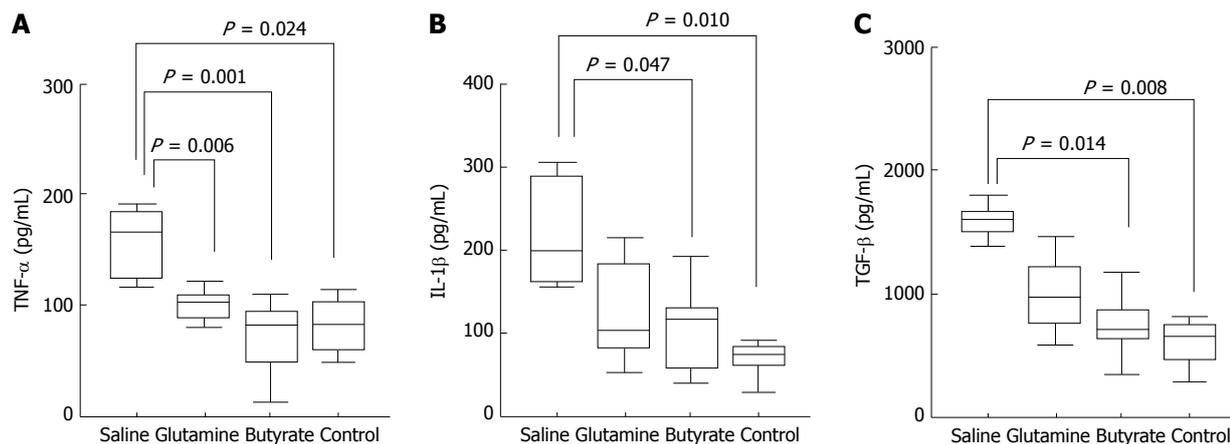

Figure 7 Cytokine production by the colonic mucosa of the diverted segment, obtained at 8 wk. Cytokines in 24 h organ cultures were measured by enzyme-linked immunosorbent assay and presented in pg/mL of culture supernatant, normalized to the protein content of tissues. A: High levels of tumor necrosis factor- α (TNF- α) measured in saline-treated colitis were restored to normal values following treatment with glutamine or butyrate; B, C: The high levels of interleukin (IL)-1 β and of transforming growth factor beta (TGF- β) detected in supernatants of saline-treated colitis decreased significantly after treatment with butyrate. Horizontal bars represent medians, boxes represent the 25th and 75th percentiles, and vertical bars represent ranges. Significant differences are noted ($n = 6$ in each group).

Diversion colitis constitutes an inflammatory process that develops within a colon segment following surgical deviation of the bowel traffic, and it usually includes the whole excluded segment, with findings common to other inflammatory conditions of the colon^[1,2]. Hence, it would be expected that the human disease could be reproducible in animal models^[30,31]. In accordance with our results, another study in rats demonstrated that inflammatory abnormalities can be detected after the fourth week following colostomy, reaching their peak between week 8 and 12^[32]. In the present study, we aimed to establish an inflammatory curve for diversion colitis. To accomplish this, we performed serial colonoscopies every two weeks from week 4 to week 20 in a pilot study, testing loop colostomy *vs* Hartmann's surgery. We confirmed that the inflammatory process appears after week four, peaking at week 8, and that the best results were obtained with Hartmann's colostomy. In addition, we showed that at sixteen week, most animals displayed a spontaneous attenuation of the inflammation. Because of these findings, we determined the best period of time for the study of inflammation and treatment outcomes in the experimental model.

In humans, diversion colitis typically occurs between three and thirty-six months after surgery, and once developed, the pathologic process and clinical manifestations can persist for decades^[10,33]. Nevertheless, it seems important to note that the biologic cycle of rats is faster compared with humans, and as a consequence, the timing of the establishment of colitis and the response to treatment are also expected to be different. Regarding the severity of diversion colitis, there appears to be considerable variation among individuals submitted to colostomy^[7,10]. This fact can be explained, at least in part, by the type of surgical procedure. For example, the loop colostomy technique allows the passage of some fecal residues to the excluded segment, sufficient to nourish colonocytes and most likely preserving their viability and function.

Although the exact mechanism underlying the pathogenesis of diversion colitis is yet to be determined, the deficiency of SCFAs is thought to play an important role in the inflammatory process^[34,35]. Because SCFAs constitute the major source of energy for human colonocytes^[36,37], SCFA depletion in the defunctionalized colon segment would most likely result in a homeostatic imbalance of a rapid-turnover tissue. Energy deprivation can limit cell restoration or induce colonocyte apoptosis, consequently disrupting the epithelial barrier. In this work, the reduction of goblet cells together with increased apoptotic rates within the colonic mucosa reflects the characteristic atrophic changes of the inflammatory process. Once the mucosal barrier is disrupted, the lamina propria is overexposed to luminal antigens, thus exacerbating the inflammatory response. Of note, some studies suggest that SCFA deprivation may constitute an additional factor for the development or the exacerbation of IBD^[35,38,39]. In addition, enemas containing SCFAs have been utilized with relative success in subsets of patients with IBD^[40,41].

Among the SCFAs, butyrate is the preferential nutrient for colonocytes. *In vitro* in both rat and human colonocytes, most oxygen consumption is due to butyrate oxidation^[14,15]. Therefore, in this work we chose to work with butyrate in its isolated form, devoid of other SCFAs, in contrast to previous works^[35,42,43].

Although the etiopathogenesis of IBD is complex and multifactorial, the chronic inflammatory process involves the excessive production of proinflammatory cytokines by the intestinal mucosa^[44]. In particular, in Crohn's disease, the disruption of the intestinal epithelial barrier and increased apoptosis are paralleled by a predominant local Th1/Th17-type of immune response^[18,45,46]. In our model, we observed a remarkable mononuclear cell accumulation within the lamina propria and atrophic changes in the epithelial layer, together with overproduction of IL-1 β and TNF- α . Most interesting, butyrate and to a lesser

extent glutamine significantly reduced the production of these Th1-type pro-inflammatory cytokines. In addition, the high levels of cytokines were correlated with the other macroscopic and histologic parameters used to analyze diversion colitis.

The highest levels of TGF- β were also detected in samples from animals with diversion colitis, in conjunction with the increased densities of collagen fibers. TGF- β is a multifunctional cytokine with potentially high anti-inflammatory activity, but it is also critical in extra-cellular remodeling in chronic inflammatory bowel diseases^[47,48]. Here, we showed that treatment with topical butyrate significantly reduced the levels of TGF- β and collagen deposition in the colon. Although the mechanism responsible for the reduction of TGF- β is not clear, it is likely that the immunomodulatory actions of butyrate, including suppression of pro-inflammatory cytokines, could indirectly downregulate TGF- β ^[49,50]. Independently of the exact mechanism responsible for the downregulation of TGF- β , it is relevant to highlight the anti-fibrotic effect of butyrate in this model. This finding seems to indicate a potential influence of butyrate counteracting fibrogenesis, an end-point consequence of many different diseases in which chronic inflammation is the dominant pathological process.

In conclusion, the successful treatment of this experimental model with either glutamine or butyrate supports the hypothesis of luminal nutrient deprivation as a major etiopathogenic mechanism underlying diversion colitis. In particular, butyrate, with its remarkable anti-inflammatory and regenerative effects, appears as a potential new alternative to topical therapy for human diversion colitis.

COMMENTS

Background

The lack of luminal nutrients has been suggested to play a crucial role in the pathogenesis of diversion colitis. The aim of this study was to test whether butyrate or glutamine enemas could diminish inflammation in a model of diversion colitis.

Research frontiers

Investigating the effects of topical administration of specific nutrients in an experimental model of diversion colitis may be relevant to mechanisms of chronicity and new therapeutic approaches in human diversion colitis.

Innovations and breakthroughs

The novelty of the work is not exclusively related to the use of topical butyrate or glutamine to treat experimental diversion colitis or other inflammatory conditions but rather to the new mechanistic observation of the anti-inflammatory action and intestinal mucosal repair of specific luminal nutrients. Furthermore, authors clearly show that the therapeutic agents proposed, in particular butyrate, actively regenerate the mucosa and influence colonic remodeling, resulting in colitis amelioration. Another fundamental and unique point of this work is the successful real-time demonstration of the anti-inflammatory effect of butyrate or glutamine in diversion colitis by a video-colonoscopy imaging system. To the knowledge, this *in vivo* observation of the benefit of topical therapy has never been presented in the field of intestinal inflammatory disorders.

Applications

The findings in experimental diversion colitis appear to be shared with other inflammatory disorders and offer a conceptually new approach to the treatment of chronic inflammatory diseases. In particular, butyrate, with its remarkable anti-inflammatory and regenerative effects, appears as a potential new alternative to

topical therapy for human diversion colitis.

Peer review

This experimental study shows the improvement of experimental diversion colitis following glutamine or butyrate enemas. The results obtained in this study clearly highlight the importance of specific luminal nutrients in the homeostasis of the colonic mucosa and support the utilization of these nutrients for the treatment of human diversion colitis.

adeno-associated virus-mediated delivery of Tregitope 167 in an experimental colitis model.

METHODS: The trinitrobenzene sulfonate (TNBS) model of induced colitis was used in Balb/c mice. Subsequently after intravenous adeno-associated virus-mediated regulatory T-cell epitopes (Tregitope) delivery, acute colitis was initiated by intra-rectal administration of 1.5 mg TNBS in 40% ethanol followed by a second treatment with TNBS (0.75 mg in 20% ethanol) 8 d later. Control groups included mice not treated with TNBS (healthy control group) and mice treated by TNBS only (diseased group). At the time of sacrifice colon weight, the disease activity index and histology damage score were determined. Immunohistochemical staining of the colonic tissues was performed to assess the cellular infiltrate and the presence of transcription factor forkhead Box-P3 (Foxp3). Thymus, mesenteric lymph nodes, liver and spleen tissue were collected and the corresponding lymphocyte populations were further assessed by flow cytometry analysis for the expression of CD4+ T cell and regulatory T cell associated markers.

RESULTS: The Tregitope 167 treated mice gained an average of 4% over their initial body weight at the time of sacrifice. In contrast, the mice treated with TNBS alone (no Tregitope) developed colitis, and lost 4% of their initial body weight at the time of sacrifice ($P < 0.01$). The body weight increase that had been observed in the mice pre-treated with Tregitope 167 was substantiated by a lower disease activity index and a decreased colon weight as compared to the diseased control group ($P < 0.01$ and $P < 0.001$, respectively). Immunohistochemical staining of the colonic tissues for CD4+ showed that inflammatory cell infiltrates were present in TNBS treated mice with or without administration with tregitope 167 and that these cellular infiltrates consisted mainly of CD4+ cells. For both TNBS treated groups CD4+ T cell infiltrates were observed in the sub-epithelial layer and the lamina

Abstract

AIM: To explore the anti-inflammatory potential of

propria. CD4+ T cell infiltrates were also present in the muscularis mucosa layer of the diseased control mice, but were absent in the Tregitope 167 treated group. Numerous Foxp3 positive cells were detected in the lamina propria and sub-epithelium of the colon sections from mice treated with Tregitope 167. Furthermore, the Foxp3 and glycoprotein A repetitions predominant markers were significantly increased in the CD4+ T lymphocyte population in the thymus of the mice pre-treated with adeno-associated virus serotype 5 (cytomegalovirus promoter-Tregitope 167), as cytomegalovirus promoter compared to lymphocyte populations in the thymus of diseased and the healthy control mice ($P < 0.05$ and $P < 0.001$, respectively).

CONCLUSION: This study identifies adeno-associated virus-mediated delivery of regulatory T-cell epitope 167 as a novel anti-inflammatory approach with the capacity to decrease intestinal inflammation and induce long-term remission in inflammatory bowel disease.

INTRODUCTION

Inflammatory bowel diseases (IBD) are inflammatory diseases that affect mostly young adults^[1,2]. Although the precise pathogenesis has not been identified, it is generally accepted that IBD result from inappropriate mucosal immune system responses against intestinal flora and other luminal antigens^[3-5]. IBD are associated with a reduction in quality of life^[6-8] and no curative treatments are available.

Despite the fact that novel treatment strategies, including tumor necrosis factor (TNF)-neutralizing antibodies, have greatly expanded the therapeutic armamentarium, these therapeutics do not prevent complications in IBD and many patients still have to undergo surgery^[9]. New treatment strategies that would prevent the initiation of inflammation and enable long-term remission would improve the lives of millions of individuals who are af-

ected by IBD world-wide^[10,11].

Recently, biological therapies that target immune pathways have emerged as a new therapeutic approach for the treatment of immune-mediated diseases. They include administration of monoclonal antibodies against inflammatory cytokines^[12] and those that influence immune responses such as certain small molecules, Helminths and stem cells^[10,13,14]. Since IBD are immune-mediated diseases, these biological therapies are highly promising treatment approaches and have the potential to achieve mucosal tolerance and long-term remission in IBD^[10,12-14]. Here, we introduce regulatory T-cell epitopes (Tregitopes)^[15,16] as novel biological agents that could create new possibilities for the regulation of inflammation and postulate that Tregitopes, delivered by adeno-associated virus (AAV), could be developed as a new therapeutic modality for the treatment of IBD.

Tregitopes are a set of putative regulatory T cell epitopes present in the immunoglobulin G molecule, which have been identified by using computational epitope mapping^[15,16]. Tregitope sequence 167 (Tregitope 167) and an additional sequence (Tregitope 289) were synthesized and shown to bind to multiple Major Histocompatibility complex (MHC) class II molecules and to suppress immune response when co-administered with an antigen. Tregitopes 167 and 289 were also shown to expand natural occurring regulatory T (nTreg) cells and to induce a regulatory phenotype and function in peripheral T (iTreg) cells^[15,16]. Harnessing the potential of Treg cells activated or induced by Tregitopes to regulate pathological immune responses in IBD may reduce the requirement for systemic immunosuppressive therapies. However, the use of immunomodulatory peptides in clinical applications for IBD so far have shown that the *in vivo* delivery of these peptides for therapeutic purposes is hindered by difficulties in obtaining sufficient and stable peptide concentrations^[17-19]. Therefore, novel means for stable delivery of regulatory peptides have to be explored. AAV present a good safety profile and have been shown to be effective as gene delivery vectors in the clinic for the treatment of a broad range of diseases^[20-22]. Therefore, AAV-mediated delivery represents an attractive approach to deliver the immuno-modulatory Tregitope peptides.

In the present study, the potential of AAV-mediated gene therapy for the therapeutic delivery of Tregitope 167 was explored. Systemic AAV-mediated administration of Tregitope 167 was shown to ameliorate the clinical and histo-pathological severity of trinitrobenzene sulfonate (TNBS) induced inflammatory colitis in mice. Hence, AAV-mediated delivery of regulatory T-cell epitopes appears to be a promising novel therapeutic approach for the treatment of IBD and could represent an alternative or adjunct to the use of immunosuppressive drugs.

MATERIALS AND METHODS

AAV vector production and characterization

Mouse Tregitope cDNA was synthesized (Integrated

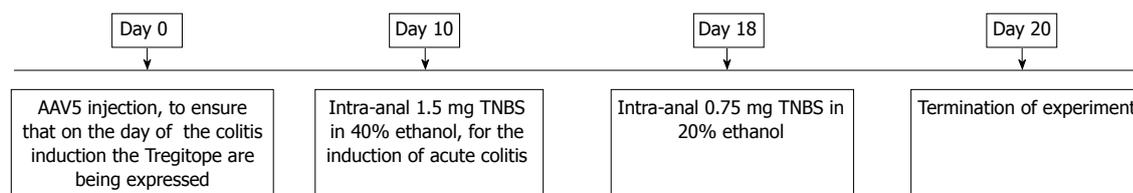

Figure 1 Schematic overview of the trinitrobenzene sulfonate induced colitis model. Mice were injected intravenously with either phosphate-buffered saline (PBS) or adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes (Tregitope) 167]. Ten days after AAV-mediated Tregitope delivery acute colitis was initiated by intra-rectal administration of 1.5 mg trinitrobenzene sulfonate (TNBS) in 40% ethanol followed by a second TNBS treatment (0.75 mg in 20% ethanol) 8 d later. Control groups consisted of mice not treated by TNBS (healthy control group) and mice treated by TNBS only (diseased control group).

DNA Technologies, IDT, Inc) according to the published corresponding sequence^[15,16] and cloned into the plasmid pPSC10^[23] under the control of the cytomegalovirus (CMV) promoter. The Woodchuck hepatitis virus post-transcriptional enhancer was incorporated behind the Tregitope 167 cDNA to further optimize gene expression^[24]. The AAV vector, AAV5 (CMV-Tregitope 167) was produced according to a technology adapted from Negrete *et al.*^[23]. The AAV vector was purified with an anion column using the ÄKTA explorer system (GE-Healthcare). After purification, the concentration of AAV vector genomes copies (genome copies/mL) was determined at 9×10^{13} genome copies/mL by Taqman qPCR amplification. The biological infectivity of AAV5 (CMV-Tregitope 167) was demonstrated *in vitro* by PCR amplification of the “CMV-Tregitope 167” DNA fragment (product size 402 bp) on DNA isolated from HEK293T transduced with AAV5 (CMV-Tregitope 167). Primers designed and synthesized for Tregitope 167 and the CMV promoter were used.

Induction of colitis and study design

Balb/c mice (males, age 6–8 wk) were obtained from Harlan Laboratories, the Netherlands. The experimental protocol was approved by the ethical committee for animal welfare of the AMC (Academic Medical Center, Amsterdam, the Netherlands). Colitis was induced in mice by administration of TNBS (TNBS, Sigma-Aldrich), as described previously^[25]. The general procedure is summarized in Figure 1.

Mice were injected intravenously with either phosphate-buffered saline or AAV5 (CMV-Tregitope) 10 d before acute colitis was initiated by intra-rectal administration of 1.5 mg TNBS in 40% ethanol. Consecutively, a second TNBS treatment (0.75 mg in 20% ethanol) was done 8 d after the first TNBS treatment as described previously^[25]. Mice not treated with TNBS (healthy control group) and mice treated with TNBS only (diseased control group) were used as references to monitor colitis development. A concomitant sham AAV control vector was not used in this study as this control has been shown to be equivalent to saline control^[26,27]. Even though AAV-mediated gene transfer leads to the development of neutralizing antibodies against the vector capsid^[28], preventing vector re-administration, no inflammatory responses against the AAV capsid were documented in *in vivo* gene

transfer mice models using AAV vectors^[27,29].

Assessment of inflammation

The body weights of the mice were recorded daily, and wasting disease progression was expressed by the percentage of weight loss as compared to body weight at the day of initiation of TNBS treatment (day 10, Figure 1). Animals were withdrawn from the study when their weight loss was > 25% of their original body weight. At the time of sacrifice, colons were collected and presence of loose stool and visible fecal blood was assessed.

At the time of sacrifice, a composite score [disease activity index (DAI)] was established as described previously^[25]. Body weight loss was scored on a scale of 0–4 (0, < 1%; 1, 1%–5%; 2, 5%–10%; 3, 10%–15%; 4, > 15%). Loose stool was scored on a scale of 0–4 (0, normal; 1, loose droppings; 2, loose stools, colon filled with feces; 3, loose stool, feces only near cecum; 4, empty bowel). Visible fecal blood was scored on a scale of 0–4 (0, negative; 2, positive; 4, gross bleeding). The DAI consists of a combination of body weight loss, loose stool and visible fecal blood scores divided by 3 as described previously^[25].

Colon tissue weights were recorded and used as an indicator of disease-related intestinal wall thickening. Increased colon weight has been shown to correlate with increased colon inflammation^[25]. Colons were first divided longitudinally into two parts: one part was immediately frozen in liquid nitrogen for protein extraction and cytokine determination, while the second part was stored in formalin and embedded in paraffin for (immuno-) histological evaluation. Blood was collected by orbital puncture immediately following sacrifice and plasma was separated by centrifugation (5000 r/min for 5 min). Plasma samples were stored at -80 °C until analysis.

Histological analysis

Colonic segments were fixed in 10% formalin overnight and thereafter stored in 70% ethanol before embedding in paraffin. Tissues sections (7 µm thick) were stained with haematoxylin and eosin (HE) for histology scoring. The histology damage score was calculated using the following criteria: percentage of area involved, number of follicle aggregates, edema, fibrosis, erosion/ulceration, crypt loss, and infiltration of mononuclear and polymorphonuclear cells, as described previously^[30]. The percentage of area involved and crypt loss were scored on a scale

of 0-4 (0, normal; 1, < 10%; 2, 10%; 3, 10%-50%; and 4, > 50%). Erosions were defined as 0 if the epithelium was intact, 1 if the lamina propria was involved, 2 if ulcerations involved the submucosa, and 3 when ulcerations were transmural. The severity of the other parameters was scored on a scale of 0-3 (0, absent; 1, weak; 2, moderate; and 3, severe)^[30]. A certified pathologist scored all the tissue sections (blinded analysis).

Immunohistochemistry

Colon tissues sections of 7 μ m were acetone-fixed and stained with rat-anti-mouse (ram) CD4 (1:100, BD550278), ram CD8a (1:50, BD550281), ram CD19 (1:50, BD550284), ram Foxp3 (1:100, eBiosciences14-5773-82) and ram F4/80 (1:500). Prior to anti-rat biotin conjugated secondary antibody (1:50, BD51-7605kc) and Streptavidin-HRP (BD) incubations, endogenous peroxidases were blocked by incubation with 0.3% H₂O₂ for 20 min. After 5 min of diaminobenzidine staining (BD), the sections were counter-stained with Haematoxylin, dehydrated and mounted in Entellan.

Flow cytometry

Thymus, mesenteric lymphoid nodes, liver and spleen tissue were collected upon sacrifice. Cell suspensions obtained from each of the tissue samples were prepared using 40 μ m cell strainers (BD Biosciences) and stained for T cell surface markers CD4 (clone RM4-5, eBioscience), CD8 (Clone 53-6.7, Miltenyi) and Treg cell surface markers glycoprotein A repetitions predominant (GARP) and CD25 (clone YGIC86 and clone PC61.5 respectively, both eBioscience) as well as for the intracellular Treg cell marker Foxp3 (clone FJK16, eBioscience). The analysis was performed by flow cytometry (FACSCalibur, BD Biosciences).

Statistical analysis

The results are presented as mean \pm SD or SE, where appropriate. Statistical analyses were performed using Prism 5.0 (GraphPad). Data were analyzed using a 1 way analysis of variance, followed by Dunn's post hoc test for multiple comparisons.

RESULTS

We investigated the potential for AAV5-mediated delivery of regulatory T-cell epitopes to prevent the development of TNBS induced colitis. Mice treated intra-rectally with TNBS in ethanol developed a severe illness as reflected in the progressive body weight loss over time and an increase in disease activity index, histology damage score and mucosal inflammatory parameters at the time of sacrifice.

Tregitope 167 delivery protects against TNBS colitis development

Development of colitis in the TNBS mice model is strongly associated with wasting disease^[31]. Daily weight determination is therefore important to determine colitis

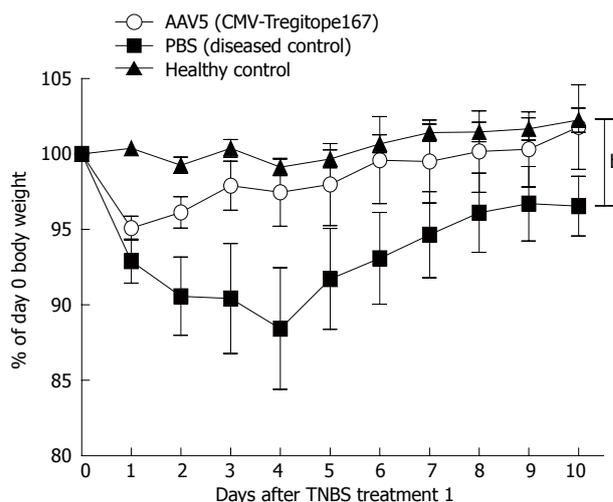

Figure 2 Adeno associated virus serotype 5 mediated delivery of regulatory T-cell epitope 167 ameliorates trinitrobenzene sulfonate induced colitis development over time. Mice were injected intravenously with either phosphate-buffered saline (PBS) or adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes (Tregitope) 167]. 10 d after AAV-mediated Tregitope delivery, acute colitis was initiated by intra-rectal administration of 1.5 mg trinitrobenzene sulfonate (TNBS) in 40% ethanol followed by a second TNBS treatment (0.75 mg in 20% ethanol) 8 d later. Control groups consisted of mice not treated by TNBS (healthy control group) and mice treated by TNBS only (diseased control group). Disease progression was assessed by changes in daily body weight. Animals were withdrawn from the study when their weight loss was > 25% of their original body weight. Overall for the healthy controls, $n = 9$; adeno associated virus (AAV) 5 (CMV-Tregitope 167) treated, $n = 7$; diseased controls, $n = 6$, were included in the analysis. The data were analyzed using a 1 way analysis of variance, followed by Dunn's post hoc test for multiple comparisons. Data are presented as mean \pm SE of all the mice. ^b P value < 0.01 between PBS (diseased control group) and both AAV5 (CMV-Tregitope 167) treated and the healthy control group.

severity and is indicative of differences in colitis development between experimental groups^[31]. Animals were withdrawn from the study when their weight loss was > 25% of their original body weight.

The body weight of the mice was monitored daily after the first TNBS treatment as an indication of the severity in the colitis development between experimental groups (Figure 2). TNBS treated mice that were pre-administered with Tregitope 167, showed a body weight that increased over time and was comparable to the weight gain of untreated healthy control mice (Figure 2). The Tregitope 167 treated mice gained an average of 4% over their initial body weight at the time of sacrifice (Figure 3A). In contrast, the mice treated with TNBS alone (no Tregitope) developed colitis, and lost 4% of their initial body weight at the time of sacrifice (Figure 3A).

Increases in colon weight, as well as in the disease activity index are both indicative of colonic inflammation and were determined at the time of sacrifice (Figure 3). The body weight increase that had been observed in the mice pre-treated with Tregitope 167 was substantiated by a lower disease activity index (Figure 3B) and a decreased colon weight (Figure 3C) as compared to the diseased control group ($P < 0.01$ and $P < 0.001$ respectively).

The histology damage score was performed on HE

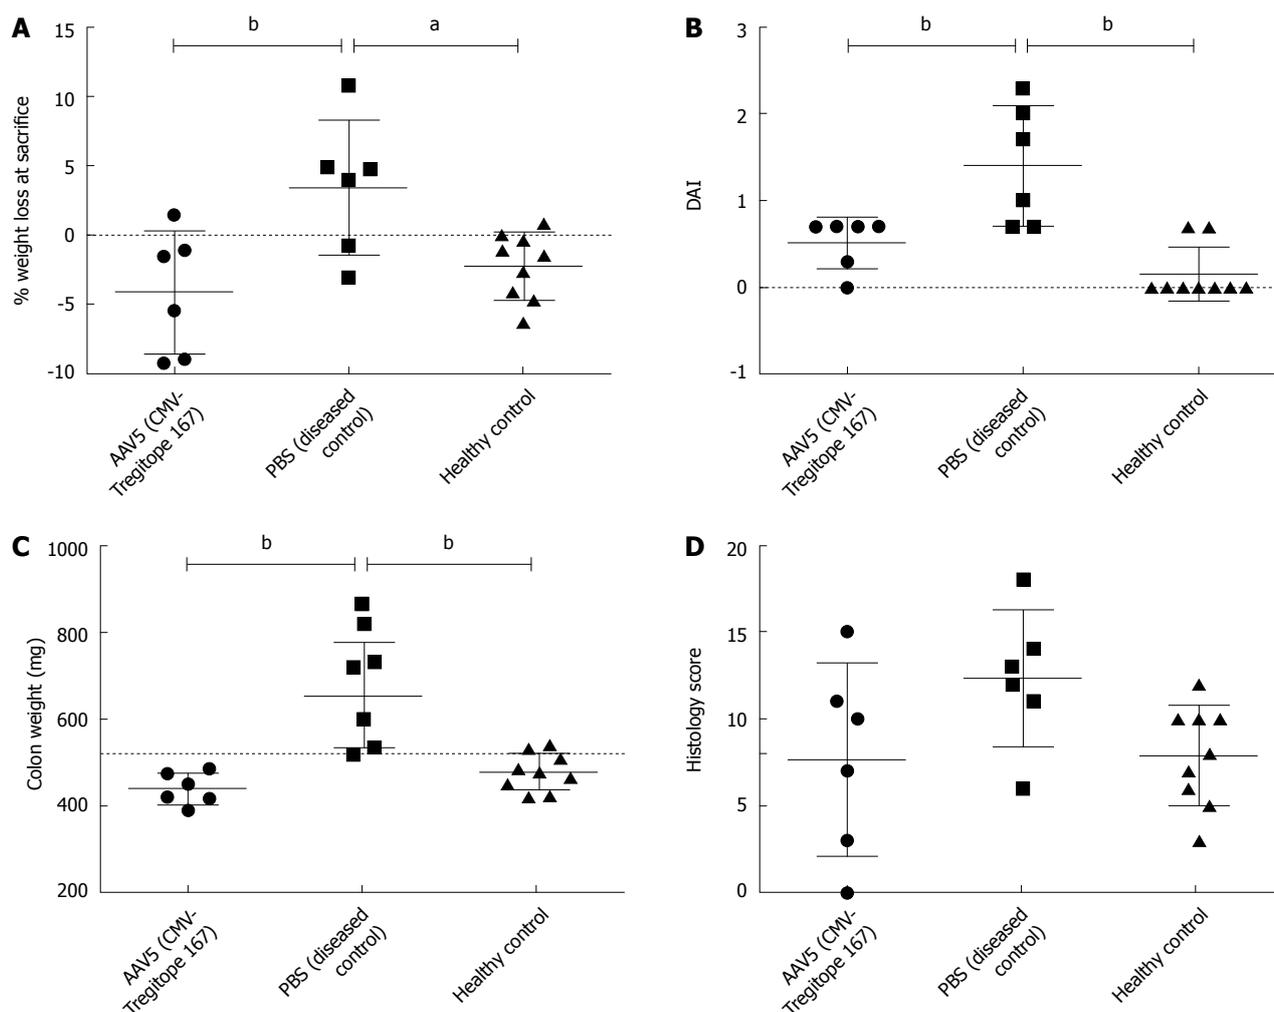

Figure 3 Adeno associated virus serotype 5 mediated delivery of regulatory T-cell epitope 167 alleviates colonic inflammation as determined at the day of sacrifice. Mice were injected intravenously with either phosphate-buffered saline (PBS) or adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes (Tregitope) 167]. Ten days after AAV-mediated Tregitope delivery acute colitis was initiated by intra-rectal administration of 1.5 mg trinitrobenzene sulfonate (TNBS) in 40% ethanol followed by a second treatment with TNBS (0.75 mg in 20% ethanol) 8 d later. Control groups consisted of mice not treated by TNBS (healthy control group) and mice treated by TNBS only (diseased control group). Disease progression was assessed by changes in daily body weight as well as macroscopic and microscopic scores on the day of sacrifice. A: Animal body weight change on day 20 upon sacrifice. The values of body weight are expressed as a percentage of body weight on the day of the first TNBS treatment; B: Macroscopic disease score. The disease activity index consist of a combination of body weight loss, loose stool and visible fecal blood scores divided by 3 at the day of sacrifice; C: Assessment of colonic weight upon sacrifice as an index of disease-related intestinal wall thickening; D: Histological grading of colonic colitis scores. The histology damage score was calculated using the following criteria: percentage of area involved, number of follicle aggregates, edema, fibrosis, erosion/ulceration, crypt loss, and infiltration of mononuclear and polymorphonuclear cells. Individual mice are depicted; from the AAV5 (CMV-Tregitope 167) pre-treated group an outlier was removed. Animals were withdrawn from the study when their weight loss was > 25% of their original body weight. Overall for the healthy controls, $n = 9$; AAV5 (CMV-Tregitope 167) treated, $n = 6$; diseased controls, $n = 6$, were included in the analysis. The data were analyzed using a 1 way analysis of variance, followed by Dunn's post hoc test for multiple comparisons. Data are presented as mean \pm SD of all the mice. ^a $P < 0.05$, ^b $P < 0.01$ vs PBS (diseased control group).

stained tissue sections. The score was calculated using the following criteria: percentage of area involved, number of follicle aggregates, edema, fibrosis, erosion/ulceration, crypt loss, and infiltration of mononuclear and polymorphonuclear cells. The histological scoring showed that the AAV5 (CMV-Tregitope 167) pre-treated mice presented a decreased severity of colitis as compared to the diseased control group (Figure 3D) as a result of lower levels of inflammation, namely decreased cellular infiltrations, little crypt loss and the absence of erosions and ulceration (Figure 4).

The TNBS induced colitis model is characterized by

the local infiltration of CD4+ T cells in the intestinal mucosa^[32]. Immunohistochemical staining of the colonic tissues for CD4+ showed that, at the day of sacrifice, inflammatory cell infiltrates were present in TNBS treated mice with or without administration with Tregitope 167 and that these cellular infiltrates consisted mainly of CD4+ cells. For both TNBS treated groups CD4+ T cell infiltrates were observed in the sub-epithelial layer and the lamina propria. CD4+ T cell infiltrates were also present in the muscularis mucosa layer of the diseased control mice, but were absent in the AAV5 (CMV-Tregitope 167) pre-treated group (Figure 5).

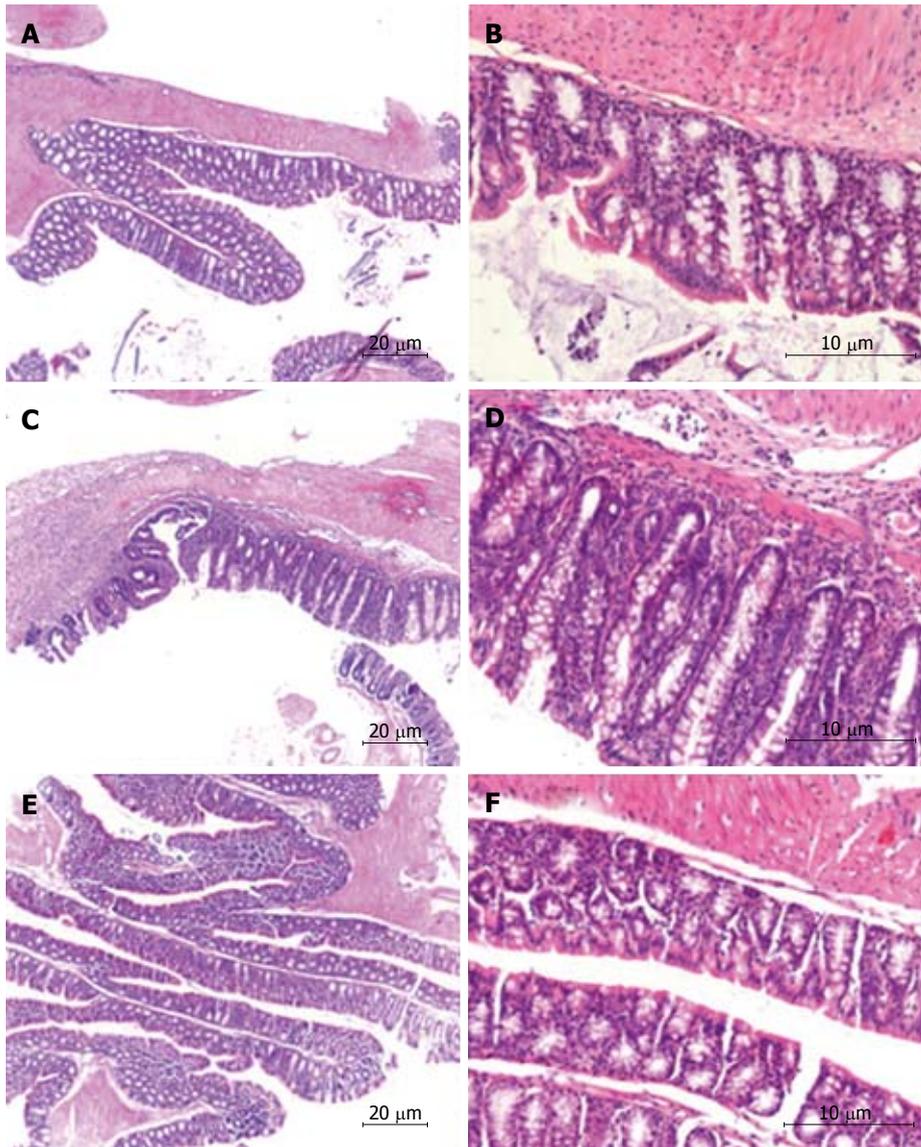

Figure 4 Hematoxylin and eosin-stained paraffin section from colon tissue. A, B: Healthy control mice; C, D: Diseased control mice; E, F: Adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes (Tregitope) 167] pre-treated mice. Histological evidence that AAV5 (CMV-Tregitope 167) ameliorates trinitrobenzene sulfonate (TNBS)-induced pathology. Images depicted of an HE-stained paraffin section of a representative mouse colon from each group at the moment of sacrifice. The images of the diseased control (C, D) demonstrated acute inflammation: elongated villi, abundant transmurular cellular infiltrate, erosions and crypt loss as compared to both the AAV5 (CMV-Tregitope 167) pre-treated and healthy control mice.

Increase of regulatory markers expression in the intestinal mucosa and thymus of mice administered with Tregitope 167

The reported ability of Tregitopes to both activate and induce Treg cells led us to further assess the presence of Treg-cell associated markers in the colonic tissues.

Colon tissues were prepared and the presence of transcription factor Foxp3 was assessed by immunohistochemistry, so as to determine whether regulatory T cells were present in the peri-colonic infiltrates^[33]. Numerous Foxp3 positive cells were detected in the lamina propria and sub-epithelium of the colon sections from mice treated with Tregitope 167 (Figure 6). Foxp3 positive cells were absent or sporadic in the colon of healthy and diseased control mice (Figure 6).

Thymus, mesenteric lymph nodes, liver and spleen tissue were collected at the time of sacrifice and the corresponding lymphocyte populations were further assessed by flow cytometry analysis for the expression of the CD4 T cell surface marker and the Treg cell associated markers Foxp3^[34], CD25^[35] and GARP^[36,37] (Figure 7A-F). The Foxp3 and GARP markers were significantly increased in the CD4+ T lymphocyte population in the thymus of the mice pre-treated with AAV5 (CMV-Tregitope 167), as compared to lymphocyte populations in the thymus of diseased and the healthy control mice ($P < 0.05$ and $P < 0.001$ respectively, Figure 7G). CD4+ thymic lymphocyte population (mean \pm SD, 11% \pm 2%, $n = 6$) co-expressed Foxp3 and GARP in the thymus of AAV5 (CMV-Tregitope 167) pre-treated mice as compared to the

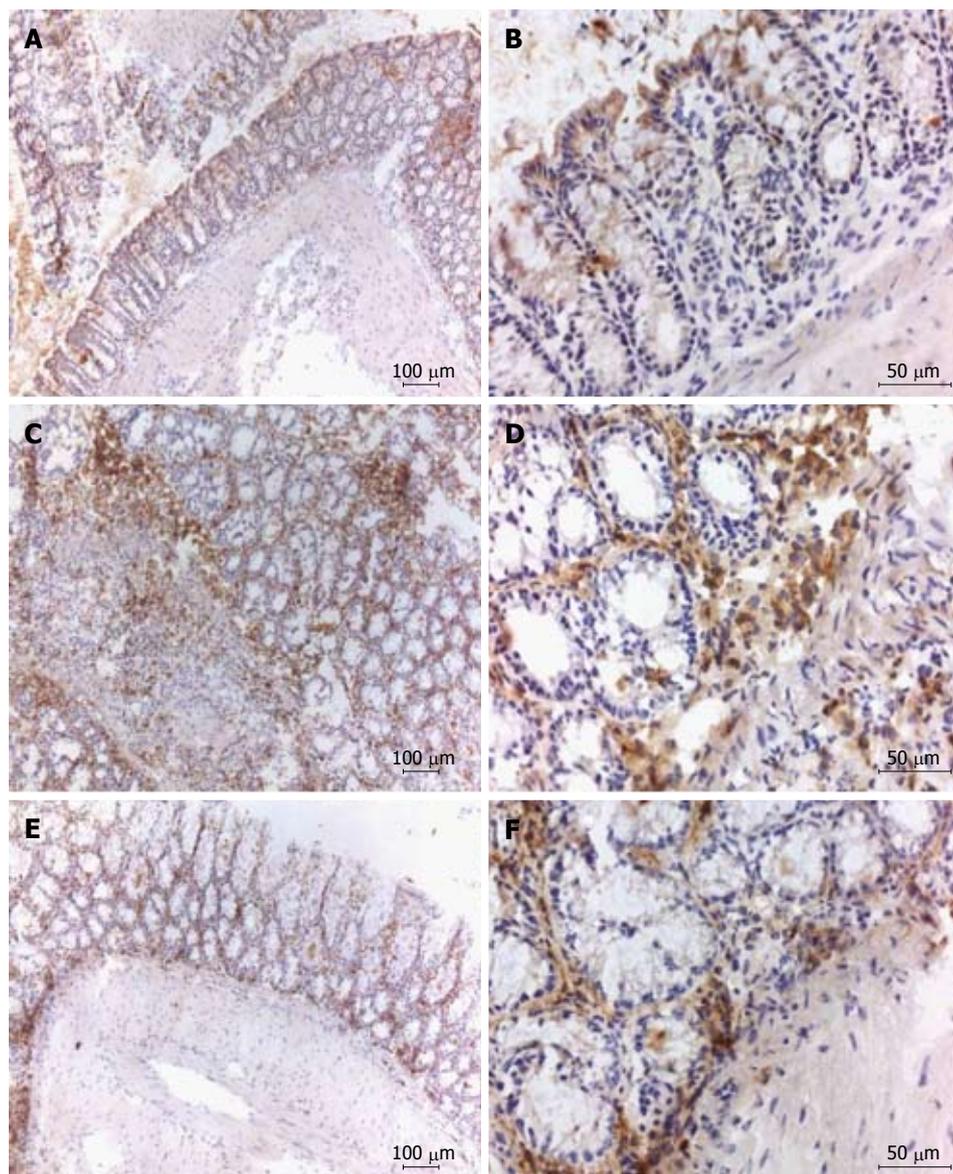

Figure 5 Immunohistochemistry pictures depicting CD4 staining colon tissue. A, B: Healthy control mice; C, D: Diseased control mice; E, F: Adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes (Tregitope) 167] pre-treated mice. Specific immunohistochemical staining showed inflammatory cell infiltrates present in trinitrobenzene sulfonate (TNBS) treated mice with or without administration with Tregitope 167 consisted of CD4 positive cells, localized in the sub-epithelial layer, in the lamina propria (C-F) and for the diseased control also in the muscular layer (C,D). Depicted are representative data from a single mouse.

thymic lymphocyte population of diseased (mean \pm SD, 7% \pm 3%, $n = 6$) and the healthy control groups (mean \pm SD, 6% \pm 2%, $n = 9$), respectively (Figure 7G). Both the relative and absolute number of Foxp3 expressing T cells were expanded in the thymus after AAV5 (CMV-Tregitope 167) pre-treatment (Figure 7H). No significant differences in the expression of Foxp3 and GARP in the lymphocyte populations of the mesenteric lymph nodes, liver and spleen were identified.

DISCUSSION

Curative treatment approaches for Crohn's disease and ulcerative colitis represent a significant unmet medical need. Regulatory T (Treg) cells are key players in maintaining

peripheral tolerance, preventing autoimmune diseases and limiting chronic inflammation^[33,38]. Therefore, novel strategies that aim for therapeutic tolerance induction and leverage Treg cells are currently being explored^[39]. In the present study, the potential for AAV-mediated delivery of an immunomodulatory peptide (Tregitope 167) was investigated.

In this study, we demonstrate that the systemic AAV-based delivery of Tregitope 167 has the potential to prevent the development of fulminant colitis in a TNBS-induced model of IBD. Tregitope 167 was used in our study as its binding affinity for the MHC molecule in Balb/c mice is superior to Tregitope 289 (De Groot, manuscript submitted for publication). The significant decrease of colonic inflammation in the Tregitope 167

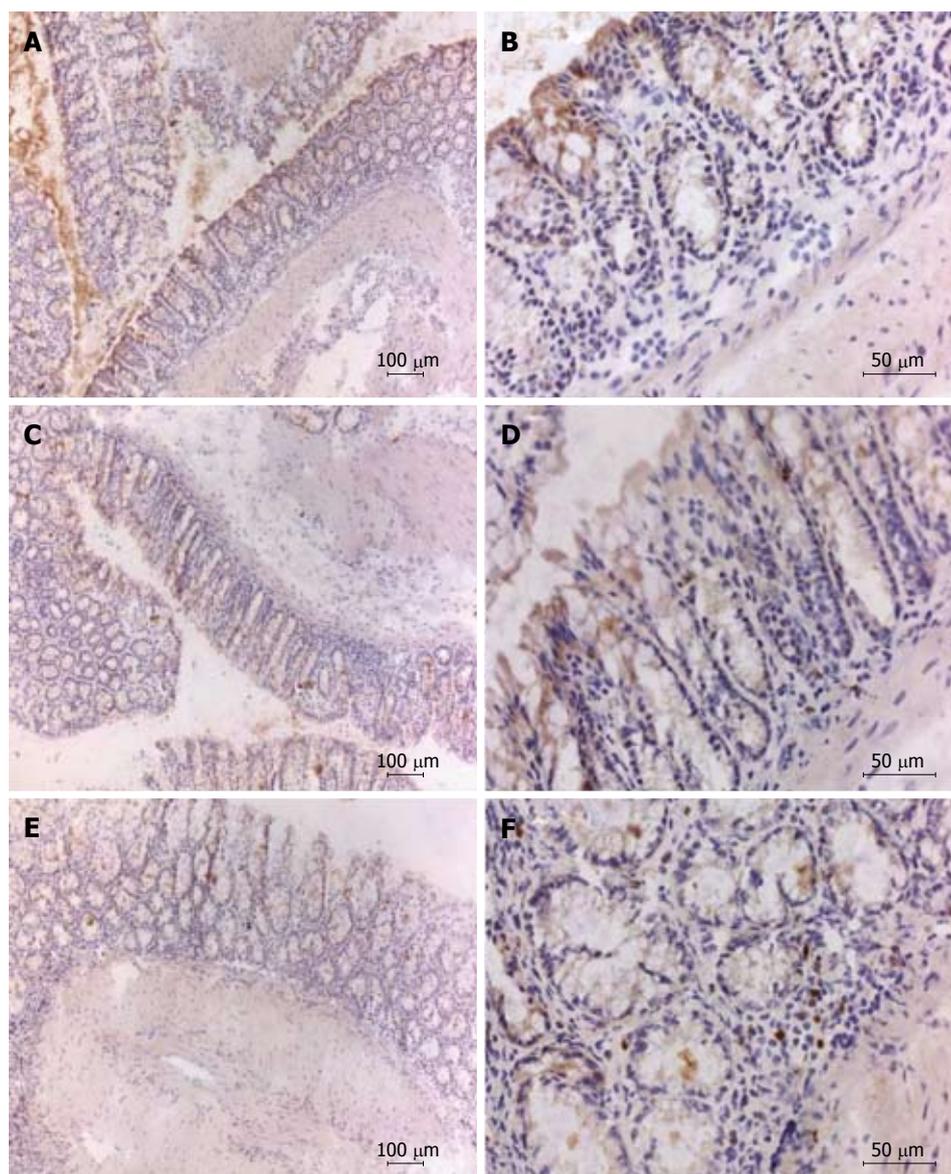

Figure 6 Immunohistochemistry pictures depicting forkhead Box-P3 staining colon tissue. A, B: Healthy control mice; C, D: Diseased control mice; E, F: Adeno associated virus (AAV) 5 [cytomegalovirus-regulatory (CMV) promoter T-cell epitopes (Tregitope) 167] pre-treated mice. Colon tissue were prepared and assessed by immunohistochemistry for the expression of the transcription factor forkhead Box-P3 (Foxp3) as a marker for regulatory T cells. Numerous Foxp3 positive cells were detected in the lamina propria and sub-epithelium of the colon sections from mice treated with Tregitope 167 (E, F). Foxp3 positive cells were rarely present in the colon of healthy and diseased control mice (A-D). Depicted are representative data from a single mouse.

pre-treated mice was reflected in an overall weight gain and substantiated by a decreased disease activity index, colon weight and histology damage score at the time of sacrifice. Additionally, there was less mucosal inflammation in the AAV (CMV-Tregitope 167) pre-treated mice. This therapeutic benefit corresponded with increases in the relative number of T cells expressing regulatory T cell markers in the colon tissues and among thymic lymphocytes of the Tregitope 167-treated mice.

IBD patients do not present defects in regulatory T cell function or phenotype^[40-42] and by consequence are more likely to benefit from therapies aiming at inducing and expanding Treg cells than patients affected by other autoimmune diseases. Tregitope 167 has the potential to both activate nTreg cells and induce iTreg cells^[15,16] and

may be suitable as a novel therapeutic agent for IBD. However, the use of immunomodulatory peptides in clinical applications for IBD has been hindered by difficulties associated with the systemic delivery of the therapeutic peptides in sufficient quantity and concentration to the target tissues^[17-19]. AAV has proven to be both effective and safe as a gene therapy delivery vector in the clinic^[20-22]. Therefore, AAV-mediated delivery of Tregitopes was explored in this study. The AAV serotype 5 (AAV5) was used since pre-existing immunity to AAV5 in humans has been shown to be low^[28,43]. Our data demonstrate that AAV5-mediated delivery may be an efficient approach for stable administration of Tregitopes *in vivo*. Further studies will need to be performed to determine the duration of the immunological tolerance that is evoked by induction

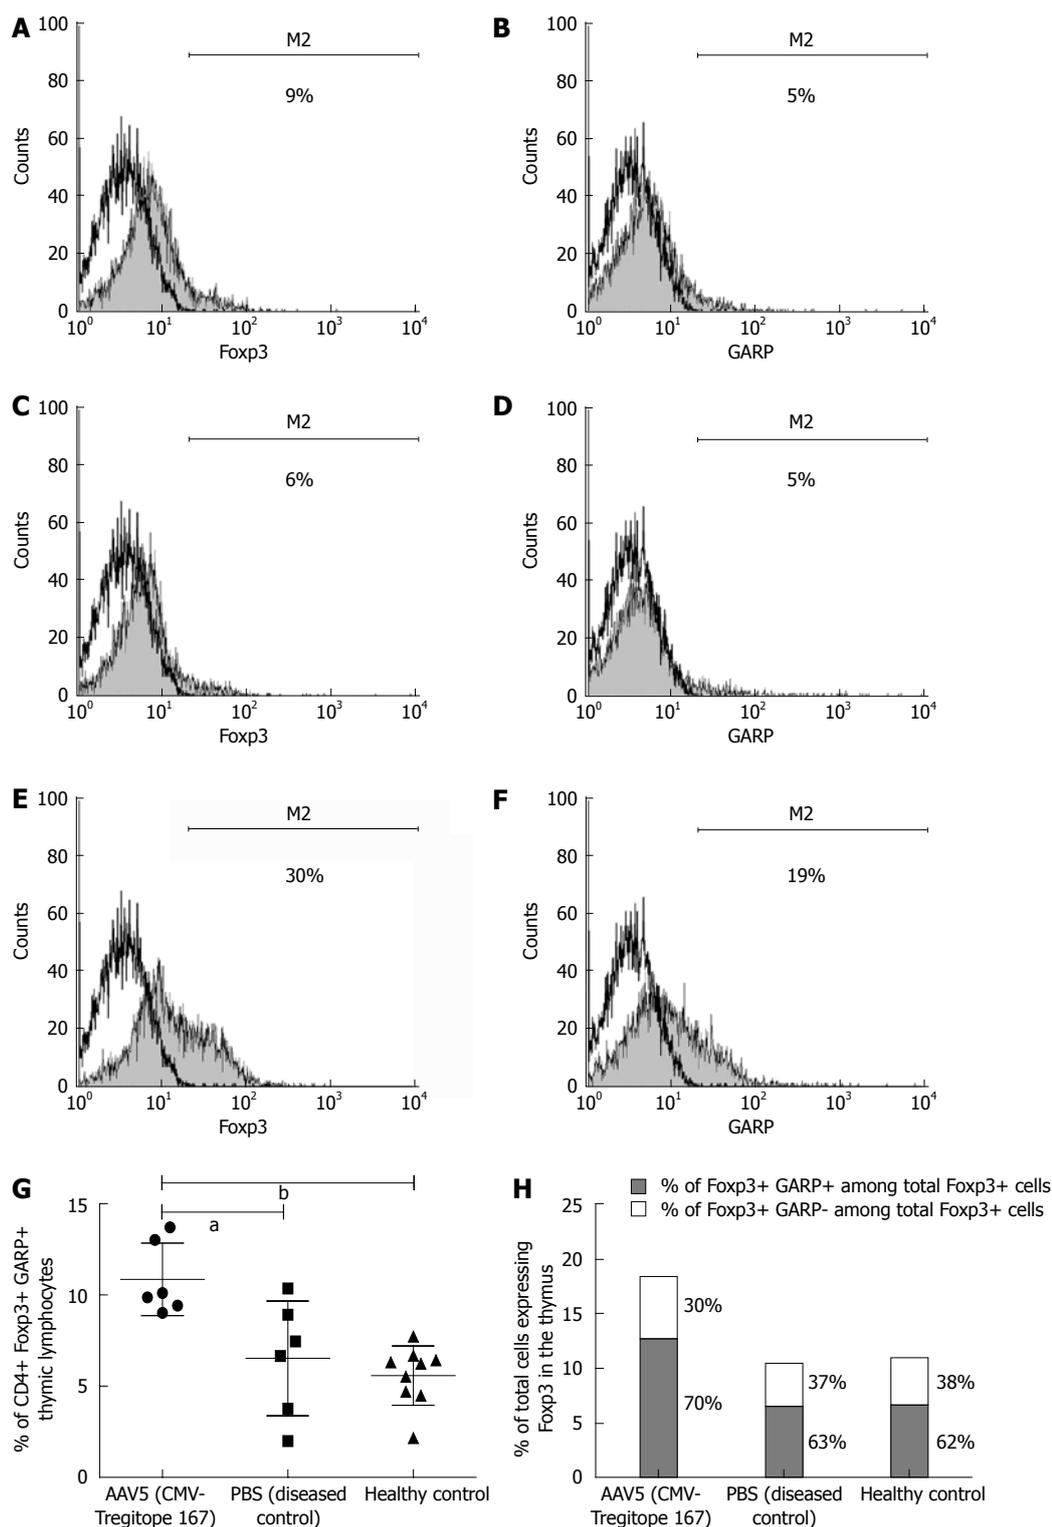

Figure 7 Adeno associated virus serotype 5 mediated delivery of regulatory T-cell epitope 167 induces forkhead Box-P3 and glycoprotein A repetitions predominant expression in the CD4 positive thymic lymphocyte population. Thymus tissue was collected upon sacrifice. Cells suspensions were prepared and stained for the following markers: CD4, glycoprotein A repetitions predominant (GARP) and forkhead Box-P3 (Foxp3) before analysis by flow cytometry (FACSCalibur, BD Biosciences). A: Histogram Foxp3 cell count: healthy control; B: Histogram GARP cell count: healthy control; C: Histogram Foxp3 cell count: diseased control; D: Histogram GARP cell count: diseased control; E: Histogram Foxp3 cell count: adeno associated virus (AAV) 5 [cytomegalovirus (CMV) promoter T-cell epitopes 167] pre-treated group (grey, filled in) vs unstained control (black continuous line). Gating was done on the CD4 positive thymic lymphocyte population. Depicted are representative data from a single mouse; F: Histogram GARP cell count: AAV5 (CMV-Tregitope 167) pre-treated group (grey, filled in) vs unstained control (black continuous line). Gating was done on the CD4 positive thymic lymphocyte population. Depicted are representative data from a single mouse; G: Depicted are percentages of CD4 positive, Foxp3 positive and GARP positive thymic lymphocytes. Individual mice are depicted; for the a AAV5 (CMV-Tregitope 167) pre-treated group one mouse did not have a thymus and therefore $n = 6$ mice were included in this analysis. The data were analyzed using a 1 way analysis of variance, followed by Dunn's post hoc test for multiple comparisons. Data are presented as mean \pm SD of all the mice. ^a $P < 0.05$, ^b $P < 0.01$ vs phosphate-buffered saline (PBS) (diseased control group) or healthy control; H: Both the relative and absolute number of Foxp3 expressing T cells were expanded in the thymus after AAV5 (CMV-Tregitope 167) pre-treatment. Mean % of lymphocytes expressing Foxp3 in the thymus of the three groups are depicted; for the AAV5 (CMV-Tregitope 167) pre-treated group one mouse did not have a thymus and therefore $n = 6$ mice were included in this analysis.

and activation of Treg cells.

Regulatory T (Treg) cells are considered to be essential in the counter-regulation of inflammatory reactions and Foxp3 is considered as a marker of the regulatory phenotype^[34,44,45]. Staining for Foxp3 in mice pre-treated with Tregitope 167 revealed the presence of Foxp3 positive cells in the lamina propria and sub-epithelium of the colon sections. Additionally, expression of both Foxp3 and GARP were increased in the thymic CD4+ T lymphocyte population in mice pre-treated with AAV5 (CMV-Tregitope 167), indicating an increase in activated regulatory T-cells^[34,36,37,44,45]. The presence of higher numbers of activated regulatory T cells corresponded with the prevention of fulminant intestinal inflammation *in vivo* in this TNBS model of IBD.

No increase in the Treg cell populations was observed in the mesenteric lymph nodes, liver and spleen in the current study. We hypothesize that this could be due to the duration of the experiment and the timing of the Treg cell evaluation. In other mouse models such as the model of spontaneous encephalomyelitis, the *de novo* generation of Treg cells was initiated intrathymically, and was followed by Foxp3 induction in peripheral tissue at later time points^[46].

Tregitopes are T cell epitopes naturally located in immunoglobulins that bind to multiple MHC class II alleles and induce Treg cell responses. We have demonstrated that antigen presenting cells (APCs) present Tregitopes to nTreg cells, engage feedback mechanisms promoting a tolerogenic APC phenotype, induce Treg cell expansion, and modulate antigen-specific effector T cell responses (Cousens and De Groot, manuscript submitted for publication). Proportions of APC expressing MHC II, CD80, and CD86 are suppressed, consistent with reported effects of intravenous immunoglobulin^[47] and of the immunoglobulin (Ig) G-derived peptide hCDR1^[48]. The basic mechanism of Tregitope tolerance induction is currently proposed to be as follows: (1) APC present Tregitopes to nTreg cells; (2) nTreg cells are activated to proliferate; (3) nTreg cells provide tolerogenic feedback signals to APC, modulating the APC phenotype; and (4) nTreg cells and tolerogenic APC together suppress antigen-specific T cell responses (Cousens and De Groot, manuscript submitted for publication).

A limitation of the colitis model used in this study was the acute necrotizing enterocolitis, occurring in the first 3 d after the first TNBS treatment, a presentation of disease which is unrelated to IBD^[25]. Therefore the surviving number of mice, included in the analysis was lower than anticipated, which, for some analysis, conflicted with statistical analysis of the data. As a consequence, a large variability in the colon mucosa cytokines levels was observed after TNBS induced experimental colitis and prevented an accurate analysis of those parameters. Therefore, further development of AAV mediated delivery of Tregitope 167 in different experimental models of inflammatory disease will be necessary to confirm the obtained results.

In summary, our data provide preliminary evidence supporting the potential use of AAV-based Tregitope delivery as a therapy for the treatment of IBD. Further investigations will permit to define the mechanism by which Tregitope exert their immune regulatory properties, the duration of the effect, the ability of Tregitopes to reduce disease that has already been established and their eventual impact on systemic immunity.

Overall, this study identifies AAV-mediated delivery of regulatory T-cell epitope 167 as a novel anti-inflammatory approach with the capacity to decrease intestinal inflammation and induce long-term remission in IBD.

ACKNOWLEDGMENTS

We would like to thank Daalhuisen JB (AMC, Amsterdam, The Netherlands) for his excellent technical expertise and the staff of the Central Animal Facility of the AMC for animal care. We would like to thank Dr. Cornelis FM Sier (LUMC, Leiden, The Netherlands) for carefully reviewing the manuscript and for statistical advice.

COMMENTS

Background

The focal point in the search for novel treatment options in inflammatory bowel diseases (IBD) is tolerance induction. In other words, exploring different mechanisms by which the immune system could maintain unresponsiveness to the antigens in the mucosal environment which cause destructive immune responses and thereby disease activity in IBD patients.

Research frontiers

The recently discovered regulatory T cell epitopes (Tregitopes) are highly promising peptides that were demonstrated to both activate and induce regulatory T cells *in vitro* and *in vivo*. Modulation of T cell responses with Tregitopes may contribute to the regulation of pathological inflammatory responses in IBD. However, the use of immunomodulatory peptides in clinical applications for IBD so far have shown that the *in vivo* delivery of these peptides for therapeutic purposes is hindered by difficulties in obtaining sufficient and stable peptide concentrations.

Innovations and breakthroughs

This study identifies adeno-associated virus (AAV)-mediated delivery of regulatory T-cell epitope as a novel anti-inflammatory approach with the capacity to decrease intestinal inflammation and induce long-term remission in IBD.

Applications

The significance of the achievements to IBD relate to possible novel therapeutic approaches, which could aim at long term tolerance induction. The described study identifies a novel anti-inflammatory strategy with the capacity to ameliorate the intestinal inflammatory response and restore mucosal immune tolerance.

Terminology

Tregitopes are T cell epitopes naturally located in immunoglobulins that bind to multiple major histocompatibility complex class II alleles and induce regulatory T cell responses. The non-pathogenic, replication-deficient AAV holds promise for gene therapy. The AAV vector has a good safety profile as it remains predominantly episomal. The therapeutic potential of AAV as a vector in gene therapy has also been demonstrated in a clinical setting in recent studies.

Peer review

This interesting paper is investigating the possibility of AAV mediated delivery of regulatory trinitrobenzene sulfonate (TNBS) colitis. The major finding of the study was that systemic administration of AAV was associated with a marked decrease in the clinical and histological severity of the TNBS induced inflammatory colitis parallel with an increase of the T lymphocytes expressing regulatory markers in the colon and thymus. Overall, this manuscript presents an interesting approach opening new possibilities.

Abstract

AIM: To study the epidemiologic indicators of uptake and characteristic colonoscopic findings in the Croatian National Colorectal Cancer Screening Program.

METHODS: Colorectal cancer (CRC) was the sec-

ond leading cause of cancer mortality in men ($n = 1063$, 49.77/100 000), as well as women ($n = 803$, 34.89/100 000) in Croatia in 2009. The Croatian National CRC Screening Program was established by the Ministry of Health and Social Welfare, and its implementation started in September, 2007. The coordinators were recruited in each county institute of public health with an obligation to provide fecal occult blood testing (FOBT) to the participants, followed by colonoscopy in all positive cases. The FOBT was performed by hypersensitive guaiac-based Hemognost card test (Biognost, Zagreb). The test and short questionnaire were delivered to the home addresses of all citizens aged 50-74 years consecutively during a 3-year period. Each participant was required to complete the questionnaire and send it together with the stool specimen on three test cards back to the institute for further analysis. About 4% FOBT positive cases are expected in normal risk populations. A descriptive analysis was performed.

RESULTS: A total of 1 056 694 individuals (born between 1933-1945 and 1952-1957) were invited to screening by the end of September 2011. In total, 210 239 (19.9%) persons returned the envelope with a completed questionnaire, and 181 102 of them returned it with a correctly placed stool specimen on FOBT cards. Until now, 12 477 (6.9%), FOBT-positive patients have been found, which is at the upper limit of the expected values in European Guidelines for Quality Assurance in CRC Screening and Diagnosis [European Union (EU) Guidelines]. Colonoscopy was performed in 8541 cases (uptake 66%). Screening has identified CRC in 472 patients (5.5% of colonoscoped, 3.8% of FOBT-positive, and 0.26% of all screened individuals). This is also in the expected range according to EU Guidelines. Polyps were found and removed in 3329 (39% of colonoscoped) patients. The largest number of polyps were found in the left half of the colon: 64% (19%, 37% and 8% in the rectum, sigma, and descendens, respectively). The other 36% were

detected in the proximal part (17% in the transverse colon and 19% in ceco-ascending colon). Small polyps in the rectum (5-10 mm in diameter), sigmoid and descending colon were histologically found to be tubular adenomas in 60% of cases, with a low degree of dysplasia, and 40% were classified as hyperplastic. Polyps of this size in the transverse or ceco-ascending colon in almost 20% had a histologically villous component, but still had a low degree of dysplasia. Polyps sized 10-20 mm in diameter were in 43% cases tubulovillous, and among them, 32% had areas with a high degree of dysplasia, especially those polyps in the ceco-ascending or transverse part. The characteristics of the Croatian CRC Screening National Program in the first 3 years were as follows: relatively low percentage of returned FOBT, higher number of FOBT-positive persons but still in the range for population-based programs, and higher number of pathologic findings (polyps and cancers).

CONCLUSION: These results suggest a need for intervention strategies that include organizational changes and educational activities to improve awareness of CRC screening usefulness and increase participation rates.

INTRODUCTION

The incidence of colorectal cancer (CRC) has been increasing during recent decades, and the lifetime risk for CRC in industrialized countries is about 5%^[1]. CRC is the one of major global public health problems, with approximately 950 000 newly diagnosed cases each year^[2]. CRC is a good candidate for screening, because it is a disease with high prevalence, has recognized precursor lesions, and early treatment is beneficial. Reducing the number of deaths from CRC depends on detecting and removing precancerous colorectal polyps, as well as detecting and treating the cancer in its early stages^[3]. Approximately 3000 new cases of CRC are diagnosed annually in Croatia and around 1900 people die of CRC each year. According to the Croatian Cancer Registry, in 2008 there were 1255 (54.5/100 000) women and 1819

(85.1/100 000) men with newly diagnosed CRC^[4]. The incidence and crude mortality rates from CRC have increased since the 1970s (Figure 1), and the incidence and mortality increase considerably after the age of 50 years. In Croatia it was the second leading cause of cancer mortality in men ($n = 1063$, 49.77/100 000), as well as in women ($n = 803$, 34.89/100 000) in 2009^[5]. CRC constitutes 12.9% of all newly diagnosed carcinomas in the European population (men 12.8%, women 13.1%) and accounts for 12.2% of deaths caused by malignancy^[6]. Compared to other European Union (EU) members where organized population screening programs have existed for several years, in Croatia the standardized mortality rates of CRC are higher, but still lower than those in some western countries (Figure 2). The joint-point analysis showed that CRC in men in Croatia has increasing trends of both incidence calculated as estimated annual percent change (EAPC 2.9%) and mortality (EAPC 2.1%), while in women, the increase in incidence was not significant, but mortality rates in the last 15 years showed a significant increase (EAPC 1.1%)^[7].

A number of randomized trials and one Cochrane review provided strong evidence that fecal occult blood test (FOBT) followed by colonoscopy, if offered every 2 years, reduced mortality rates associated with CRC by 16%^[8,9]. In the Czech Republic the rates were higher in a previous period, but, owing to the implementation of organized screening, in 2007 they became lower than in Croatia (Figure 3)^[10,11]. Hungary is one of the transitional countries with higher mortality than that in Croatia, and a pilot program has now been completed there and preparations for a nation-wide program are ongoing^[12,13]. The EU council recommendation of December 2003, stated that screening for CRC by FOBT in men and women aged 50-74 years met the requirements of the public health program.

The Croatian Cancer Registry is a nation wide population-based registry, covering over 90% of cancer cases in the country. The existence of cancer registry allows us to evaluate effects of screening on changes in CRC incidence, which is expected to be higher for the first few years. CRC is also expected to be increasingly detected at an earlier stage owing to the screening program. Therefore, after 5 years, it is expected that our national mortality data will show a reduction in CRC mortality. The aim of this paper is to describe the population-based screening program for CRC whose implementation started during 2008. The political decision to launch it was made by the Ministry of Health and Social Welfare at the end of 2007 according to the previously published proposal^[14]. Due to some unexpected organizational difficulties, it is planned that first round will be finished during 2011.

MATERIALS AND METHODS

Program organization: the Republic of Croatia is divided in 20 counties plus the capital city of Zagreb and there is one public health institute in each county and city. In

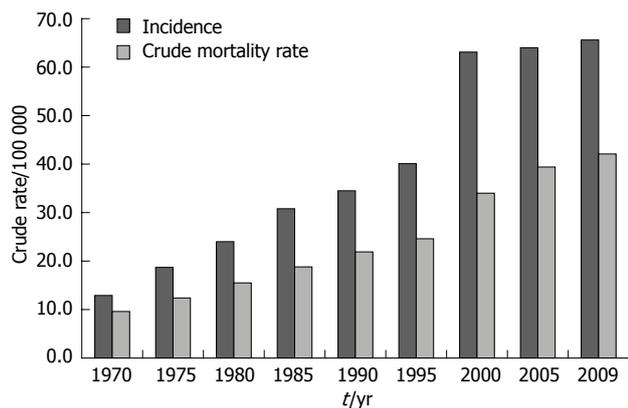

Figure 1 Incidence and crude mortality rate of colorectal cancer in Croatia from 1970 to 2009 year.

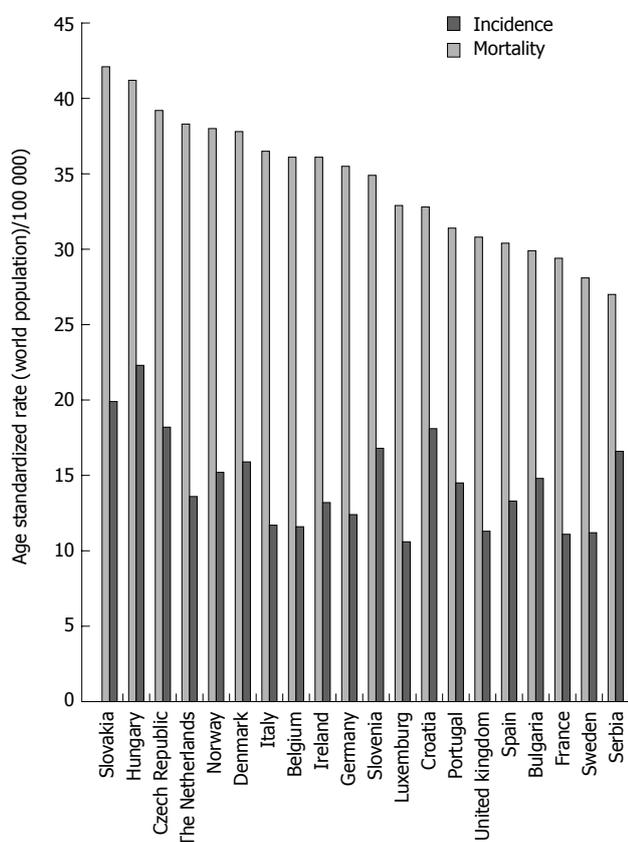

Figure 2 Incidence and mortality rates of colorectal cancer in European countries^[40].

each local public health institute there is a coordinator nominated for the National Screening Program. At the national level, a coordinator from the Croatian National Public Health Institute has been nominated, and all 22 coordinators are members of the Committee for Program Performance. An Expert Committee has also been nominated by the Minister of Health and Social Welfare with the main task to evaluate professional qualification of colonoscopists included in the National Program and to attend to other issues during the program performance. The Committee consists of project co-ordinators

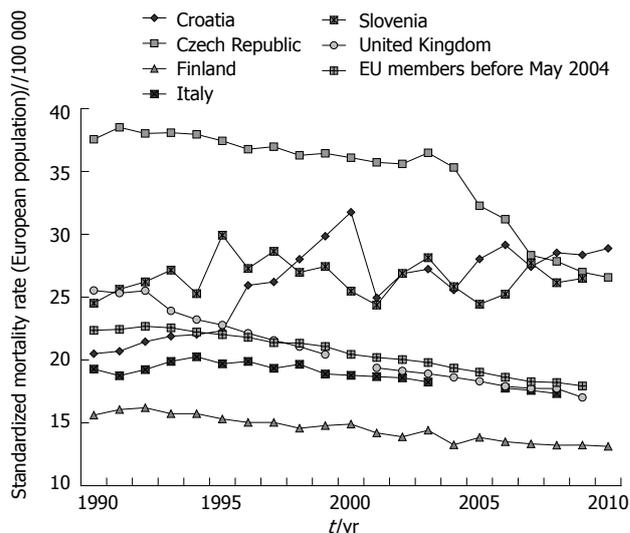

Figure 3 Comparison of standardized mortality rate of colorectal cancer in Croatia and some other European Union countries (source: World Health Organization, European Mortality Database, Health for All 2011).

from the Ministry of Health and Social Welfare, the National Co-ordinator from the Croatian National Public Health Institute, three members of the Croatian Gastroenterology Society, and representatives of oncologists and primary care physicians. The co-ordinators (medical specialists in epidemiology or in public health) in each local institute of public health are obliged to ensure performance of FOBT, followed by colonoscopy in all positive cases. They also ensure the collection of data on colonoscopic diagnosis, histopathologic findings, cancers and polyps, and to keep records about tests performed in each person. If a patient is diagnosed with CRC, the co-ordinator's obligation is to inform the patient's primary care physician. The co-ordinator also has to provide the answers to the questionnaire for each person tested in a web-based database, and to send the report with cumulative data about diagnostic findings to the national co-ordinator. Upon the receipt of the data, the national co-ordinator compiles all data and, according to results, controls the performance in each county. A national report is sent twice monthly to all members of the Expert Committee and to the member in the Ministry of Health and Social Welfare. The main indicators available from these reports include: uptake (compliance), number of persons who correctly applied specimens on cards, number of persons with positive FOBT, number of patients invited to colonoscopy, number of colonoscopies performed, number of patients in whom CRC was diagnosed, number of patients where polyp (polyps) was detected, number of patients where other disease was found (e.g., diverticula, inflammatory bowel diseases, hemorrhoids). The test and short questionnaire were planned to be delivered at the home addresses of all citizens aged 50-74 years consecutively during 3 years. So far, the population born between 1933-1945 and 1952-1957 has been invited. Each participant was re-

Table 1 Epidemiologic indicators of colorectal cancer screening uptake and diagnostic findings

Indicator	n (%)	Relative to issue
Invited	1 056 694 (84.0)	Eligible
Returned envelopes	210 239 (19.9)	Invited
Returned with specimen	181 102 (17.1)	Invited
Positive FOBT	12 477 (6.9)	Returned with specimen and examined
Colonoscopy done	8541 (66.0)	Positive FOBT
Hp confirmed Ca	472 (5.5)	Colonoscoped
Patients with polyp(s)	3329 (39.0)	Colonoscoped
Diverticula	1238 (14.6)	Colonoscoped
IBD and other findings	320 (3.7)	Colonoscoped
Hemorrhoids	2345 (27.5)	Colonoscoped

FOBT: Fecal occult blood test; Hp: Histopathologically; Ca: Carcinoma; IBD: Inflammatory bowel disease.

quired to complete the questionnaire, and send it together with the stool specimen on three test cards (each with four windows) by prepaid mail to the institute for further analysis. Most current FOBT methods are guaiac-based tests, as established more than a century ago. The pseudoperoxidase activity of heme converts colorless guaiac to a blue color in the presence of hydrogen peroxide. The FOBT is performed by guaiac-based HemoGnost card (Biognost, Zagreb, Savica-Šanci) test with a detection limit of 0.252-0.348 mg hemoglobin/g stool. Cards were designed for easy mailing, with a space to write the name of the participant and the date of fecal sampling. Each card had four windows for stool specimens. A leak proof storage and a return envelope were included. The manufacturer's instructions were closely followed concerning dietary restrictions and advice about taking samples. Dietary restrictions 3 d before and during sampling include avoiding raw meat, liver or blood dishes and large amounts of supplemental vitamin C (> 250 mg/d). Last year, in order to encourage people to take the test, printing the strip-form instruction on the back of the manufacturer's instructions was arranged. Colonoscopies were done in colonoscopic units (38 of them in Croatia) by well-trained and experienced colonoscopists.

Statistical analysis

A descriptive analysis of epidemiologic indicators was done. Results were compared with the reference range in European Guidelines for Quality Assurance in Colorectal Cancer Screening and Diagnosis^[15].

RESULTS

By the end of 2011 a total of 1 056 694 (84% of eligible) individuals (born between 1933-1945 and 1952-1957) were invited to screening. Among them, 210 239 persons (19.9%) returned the envelope with the completed questionnaire and 181 102 of them returned correctly completed FOBT cards. Until now, 12 477 positive FOBT patients have been found (6.9%). Colonoscopy was performed in 8541 cases (uptake 66%). Screening has identi-

fied CRC in 472 patients (3.6% of FOBT-positive and 0.26% of all individuals screened through the program). Polyps have been found and removed in 3329 (39% of FOBT-positive) patients (Table 1).

Unfortunately, there were great differences in the percentage of returned FOBTs between Croatian counties as well as in the number of pathologic findings (Table 2). Generally, people from continental counties returned FOBT more frequently (13.8%-30.7%), then those from the coastal areas (10.7%-21.7%). The number of CRCs identified varied from 1.0% to 12.2% of all colonoscopy participants (Table 2). There are several reasons for such differences; only partially this depends on variation in CRC and polyp incidence. Probably, the main reason can be attributed to the unequal experience and skills of the endoscopic teams, as well as the inadequate number of endoscopic instruments and equipment in some counties. An additional cause can be found in the greater response of people who had some symptoms of disease (e.g., pain, discomfort, irregular stool evacuation). Some data support this thesis because among false-positive FOBT results for CRC detection, hemorrhoids, inflammatory bowel disease and diverticula in 27.5%, 3.7% and 14.6% of cases, respectively, were found, as well as other changes which can cause positive FOBT results.

We found some differences in characteristics of polyps according to localization and size (Table 3). The largest number of polyps were found in the left half of the colon: 64% (19%, 37% and 8% in the rectum, sigmoid, and descending, respectively). The other 36% were detected in the proximal part (17% in the transverse colon, and 19% in the ceco-ascending). During screening colonoscopy, all polyps up to 15 mm in diameter were removed; 80% of those up to 20 mm in diameter, and 50% of those larger than 20 mm, were later removed by endoscopy or surgery.

Small polyps in the rectum (5-10 mm in diameter), sigmoid and descending colon were histologically tubular adenomas in 60% of cases, with a low degree of dysplasia, and 40% were classified as hyperplastic. Polyps of this size in the transverse or ceco-ascending part in almost 20% had a histologically villous component, but still were at a low degree of dysplasia. Forty-three percent of polyps 10-20 mm in diameter were tubulovillous, and among these 32% had areas with a high degree of dysplasia, especially those polyps in the ceco-ascending or transverse part.

Polyps over 20 mm in the rectum and sigmoid were tubular adenomas in 48% of cases, while others, as well as all the larger polyps in transverse or coecoascendent part were tubulovillous, villous or in 41% with high grade dysplasia, and 8% intramucosal carcinoma.

DISCUSSION

In order to ensure health-care equality, we covered 100% of the available population aged 50-74 years, and 84% of them received the test package at their home address.

FOBT: Fecal occult blood test; CRC: Colorectal cancer; pos.: Positive.

Table 3 Characteristics of polyps detected through colorectal cancer screening program in Croatia

Part of colon	Localization	Percent (%)	Size 5-10 mm	Size 10-20 mm	Size ≥ 20 mm
Left	Rectum	19	60% tubular adenoma, low degree of dysplasia	43% tubulovillous, among them 32% had areas with a high degree of dysplasia, especially in the ceco-ascending or transverse part	48% tubular adenomas
	Sigmoid	37	40% hyperplastic		
Right	Descending	8			Tubulovillous and villous
	Transverse	17	20% villous component, low degree of dysplasia		41% with high grade dysplasia
	Ceco-ascending	19			8% intramucosal carcinoma

Sometimes in our program, we were faced with problems such as a lack of educated colonoscopists and/or equipment in some counties. However, this also makes it possible for us to test feasibility in this part of the national health-care system and to plan program costs and the additional resources needed in leading time (mainly colonoscopies and education of population). This study of Croatian colonoscopic practice indicates that there are centers with practice of the highest quality, but considerable effort is required to improve the overall quality of colonoscopy. High quality of endoscopic service, early training, regular refresher courses, and continuous audit of standards at local and national levels must be a priority for all endoscopists performing colonoscopy^[16].

Additional efforts must be made to improve the quality of FOBT performance in public health institutes in order to avoid false positives.

Another problem is increasing the uptake, which is in our country significantly lower for CRC than for breast cancer (the uptake for mammography is up to 70%). On one hand, this issue results from unwillingness to take stool specimens and, on the other hand, from non-

compliance with avoiding complicated food and therapy restriction before testing. In order to increase the uptake, newly written recommendations by the Group for Quality Control of the International CRC Network support the decision that the procedure and prescriptions have to be simplified, so that they can be changed for the next cycle immediately^[15]. We are aware that guaiac FOBT shows notable variations in the performance characteristics between different studies^[17]. These differences most likely reflect the different populations tested and the methods for identifying neoplasia. Indeed, from the first results by Allison *et al*^[17] and Greenberg *et al*^[18] to meta-analysis by Soares-Weiser *et al*^[19], different sensitivities for the same tests in different populations or conditions have been reported^[20]. In the same reports, some advantages and disadvantages of immuno-FOBT are discussed. In the process of decision making on which test to choose for the Croatian Program, we considered the arrangement of mailing the tests, time from taking specimens to testing, and relatively high surrounding temperatures in almost half a year which all can influence the accuracy of immuno-FOBT^[21]. So, we have decided that

guaiac card-based tests are more convenient for screening in Croatia. Data about higher percentage of FOBT-positive persons indicated that the population screened so far was not really asymptomatic; people who returned tests most frequently had evident symptoms; mostly blood in stool or impairment of bowel discharge, constipation or diarrhea, with or without pain in the distal abdomen. Thus, there is a need actively to include the individuals who are in the “normal and healthy” population. This is frequently seen at the start of every screening program^[22,23]. It is well known that the effectiveness of any screening program depends not only on the diagnostic performance of the screening, but also on the uptake and general acceptance of the test by the public^[23,24]. In a field trial, urban-rural differences in the screening uptake were detected^[25]. Among some other issues, one of the important problems is to find how to improve uptake. There is clear evidence in our national program of early diagnosis of breast cancer, where we reached a 70% uptake level, that education of a focused population group can increase uptake^[25]. We must continue to improve awareness that screening for CRC can reduce the mortality associated with the disease. According to other studies, compliers with CRC screening are less deprived; they have higher education than non-compliers. There is also a need to advance knowledge and promote engagement of primary care physicians, according to other data^[21]. However, the Croatian Adult Health Survey showed that self-reported compliance for CRC screening was 4.5% for females and 6.1% for males included in study^[26]. It is obvious that the response in the National Screening Program was higher and it depended on the age group of the invited population and county. The results of a control field trial showed a significantly higher response rate to FOBT when given by primary care physicians^[27], but, unfortunately, in that study a small number of physicians was voluntarily included, precluding us from achieving conclusive results on the whole population. In addition, this experience cannot be easily implemented to the whole country due to organizational difficulties and presence or absence of willingness of physicians to be included in organized national screening. The results of a population study from Italy confirmed that there is a higher response if the FOBT kit was sent by mail, but in non-responders it incurred higher costs^[28]. Response to screening depends on population education but also on willingness of all included in the program, and it has to be carefully planned^[29-34]. We still do not have a detailed analysis of costs and possible differences if the test kit is not sent by mail, so this remains to be done for the next cycle.

There are some other reasons for nonparticipation which could be targeted in interventions aimed at increasing participation rates in Croatia. For example, it may be difficult to make arrangements for colonoscopy for people who live on islands and must travel to hospitals in the nearest city on the coast; they feel uncomfortable traveling by ferry while prepared for colonoscopy

and must be near the toilet during that journey. Hence, in that case, it might be reasonable to provide a mobile colonoscopy service.

Another problem of CRC screening is people with false-positive FOBT results, who occupy time in colonoscopic units and represent unnecessary procedures. According to our data, most false positive FOBT persons (false-positive to CRC but not to bleeding) had hemorrhoids or anal fissures, which is consistent with the other data^[35]. This can be avoided with adequate education of the population and active inclusion of primary care physicians^[36].

Successful intervention strategies include organizational changes, such as providing reminders to healthcare providers or users about screening opportunities, better financial support and educational strategies to improve awareness and attitudes toward CRC screening^[37,38]. In our future work we also must think about reducing inequalities related to socio economic position and ethnicity in the uptake of screening (e.g., Roma population).

In conclusion, the main characteristics of the Croatian CRC National Program are as follows: low percentage of returned FOBTs, a relatively higher number of FOBT-positive persons, but still in the range for population-based program; and a higher number of pathologic findings (CRC at the upper range and polyps above the upper range)^[39].

There are many possible strengthening mechanisms for this activity, which include multifactorial interventions that target more than one level of the screening process and likely can have greater effects. Firstly, much effort must be given to population education and mass campaign with whole society inclusion.

ACKNOWLEDGMENTS

The authors thank all persons included in the implementation and performance of this National Program.

COMMENTS

Background

Colorectal cancer (CRC) screening by either guaiac or immuno fecal occult blood test (FOBT) followed by colonoscopy of all positive patients is recommended worldwide. The main purpose of this screening is to detect CRC in early phase, or in pre-cancer phase when polyps can be easily removed by colonoscopy. This type of cancer can be prevented and/or diagnosed early, and patients can have a better quality of life, and mortality of CRC can be reduced.

Research frontiers

The implementation of the National CRC Screening Program in Croatia gives opportunity for better monitoring uptake of screening and to explore characteristic colonoscopic findings.

Innovations and breakthroughs

The CRC screening program in Croatia is organized through a network of public health institutes and represents good co-operation between public health and clinicians. But, there is still a place for improvement.

Applications

Epidemiologic data of screening uptake and characteristic colonoscopic findings compared with other data and also with expected ranges in European Guidelines for Quality Assurance in Colorectal Cancer Screening and Diagnosis

showed similar values in Croatia, but authors found some differences between counties.

Terminology

FOBT can detect very small amounts of blood in stools, which cannot be seen visually without this laboratory test. Patients who have polyps or CRC can be detected by this test. Colonoscopy is still the gold standard to make the final diagnosis and to remove polyps in order to prevent CRC.

Peer review

This study reported data on the CRC Screening Program in Croatia performed with FOBT followed by colonoscopy in positive cases. CRC detection rates widely ranged from 2.5% to 12.2% (mean 5.5%). There are several possible causes for these differences. Data on the histology of polyps removed at endoscopy showed differences between location in colon and size of polyps.

Abstract

AIM: To elucidate the colonoscopic features of serrated lesions of the colorectum using magnifying colonoscopy.

METHODS: Broad division of serrated lesions of the colorectum into hyperplastic polyps (HPs), traditional

serrated adenomas (TSAs), and sessile serrated adenomas/polyps (SSA/Ps) has been proposed on the basis of recent molecular biological studies. However, few reports have examined the colonoscopic features of these divisions, including magnified colonoscopic findings. This study examined 118 lesions excised in our hospital as suspected serrated lesions after magnified observation between January 2008 and September 2011. Patient characteristics (sex, age), conventional colonoscopic findings (location, size, morphology, color, mucin) and magnified colonoscopic findings (pit pattern diagnosis) were interpreted by five colonoscopists with experience in over 1000 colonoscopies, and were compared with histopathological diagnoses. The pit patterns were categorized according to Kudo's classification, but a more detailed investigation was also performed using the subclassification [type II-Open (type II-O), type II-Long (type II-L), or type IV-Serrated (type IV-S)] proposed by Kimura T and Yamano H.

RESULTS: Lesions comprised 23 HPs (23/118: 19.5%), 39 TSAs (39/118: 33.1%: with cancer in one case), 50 SSA/Ps (50/118: 42.4%: complicated with cancer in three cases), and six others (6/118: 5.1%). We excluded six others, including three regular adenomas, one hamartoma, one inflammatory polyp, and one juvenile polyp for further analysis. Conventional colonoscopy showed that SSA/Ps were characterized as larger in diameter than TSAs and HPs (SSA/P vs HP, 13.62 ± 8.62 mm vs 7.74 ± 3.24 mm, $P < 0.001$; SSA/Ps vs TSA, 13.62 ± 8.62 mm vs 9.89 ± 5.73 mm, $P < 0.01$); common in the right side of the colon [HPs, 30.4% (7/23): TSAs, 20.5% (8/39): SSA/P, 84.0% (42/50), $P < 0.001$]; flat-elevated lesion [HPs, 30.4% (7/23): TSAs, 5.1% (2/39): SSA/Ps, 90.0% (45/50), $P < 0.001$]; normal-colored or pale mucosa [HPs, 34.8% (8/23): TSAs, 10.3% (4/39): SSA/Ps, 80% (40/50), $P < 0.001$]; and with large amounts of mucin [HPs, 21.7% (5/23): TSAs, 17.9% (7/39): SSA/Ps, 72.0% (36/50), $P < 0.001$]. In magnified colono-

scopic findings, 17 lesions showed either type II pit pattern alone or partial type II pit pattern as the basic architecture, with 14 HPs (14/17, 70.0%) and 3 SSA/Ps. Magnified colonoscopy showed the type II-O pit pattern as characteristic of SSA/Ps [sensitivity 83.7% (41/49), specificity 85.7% (54/63)]. Cancer was also present in three lesions, in all of which a type VI pit pattern was also present within the same lesion. There were four HPs and four TSAs each. The type IV-S pit pattern was characteristic of TSAs [sensitivity 96.7% (30/31), specificity 89.9% (72/81)]. Cancer was present in one lesion, in which a type VI pit pattern was also present within the same lesion. In our study, serrated lesions of the colorectum also possessed the features described in previous reports of conventional colonoscopic findings. The pit pattern diagnosis using magnifying colonoscopy, particularly magnified colonoscopic findings using subclassifications of surface architecture, reflected the pathological characteristics of SSA/Ps and TSAs, and will be useful for colonoscopic diagnosis.

CONCLUSION: We suggest that this system could be a good diagnostic tool for SSA/Ps using magnifying colonoscopy.

INTRODUCTION

In addition to the previously known oncogenic pathways of adenoma-carcinoma sequence and *de novo* cancer^[1], the so-called serrated neoplastic pathway has been proposed in recent years as a new oncogenic pathway from serrated lesions of the colorectum^[2-6]. Sessile serrated adenomas/polyps (SSA/Ps) are a particular focus of attention as one type of precursor lesion for the microsatellite deficiency (MSI-H) cancers that comprise around 15% of sporadic colorectal cancers^[7-11]. The low risk subtype of serrated adenocarcinomas is characterized by proximal location, BRAF-mutation, high CpG-island methylation with loss of MLH1 expression, and MSI-H phenotype^[10,12-14]. Identifying

serrated lesions of the colorectum during colorectal cancer surveillance is thus important, but few reports have described the colonoscopic characteristics of these lesions, particularly in terms of magnified colonoscopic findings, and a unified consensus has yet to be reached. We report herein our investigation of the colonoscopic characteristics of serrated lesions of the colorectum, using the surface architecture subclassification proposed by Kimura *et al*^[15] in addition to conventional pit pattern diagnosis.

MATERIALS AND METHODS

Patient characteristics

From among all suspected serrated lesions that were endoscopically resected in our hospital between January 2008 and September 2011, this study examined the 118 lesions for which magnified colonoscopic findings and histopathological specimens could be compared. The study was conducted in accordance with all rules and regulations of the St. Marianna University School of Medicine Institutional Review Board, and informed consent was obtained from each patient.

Endoscopic resection and magnifying colonoscopy

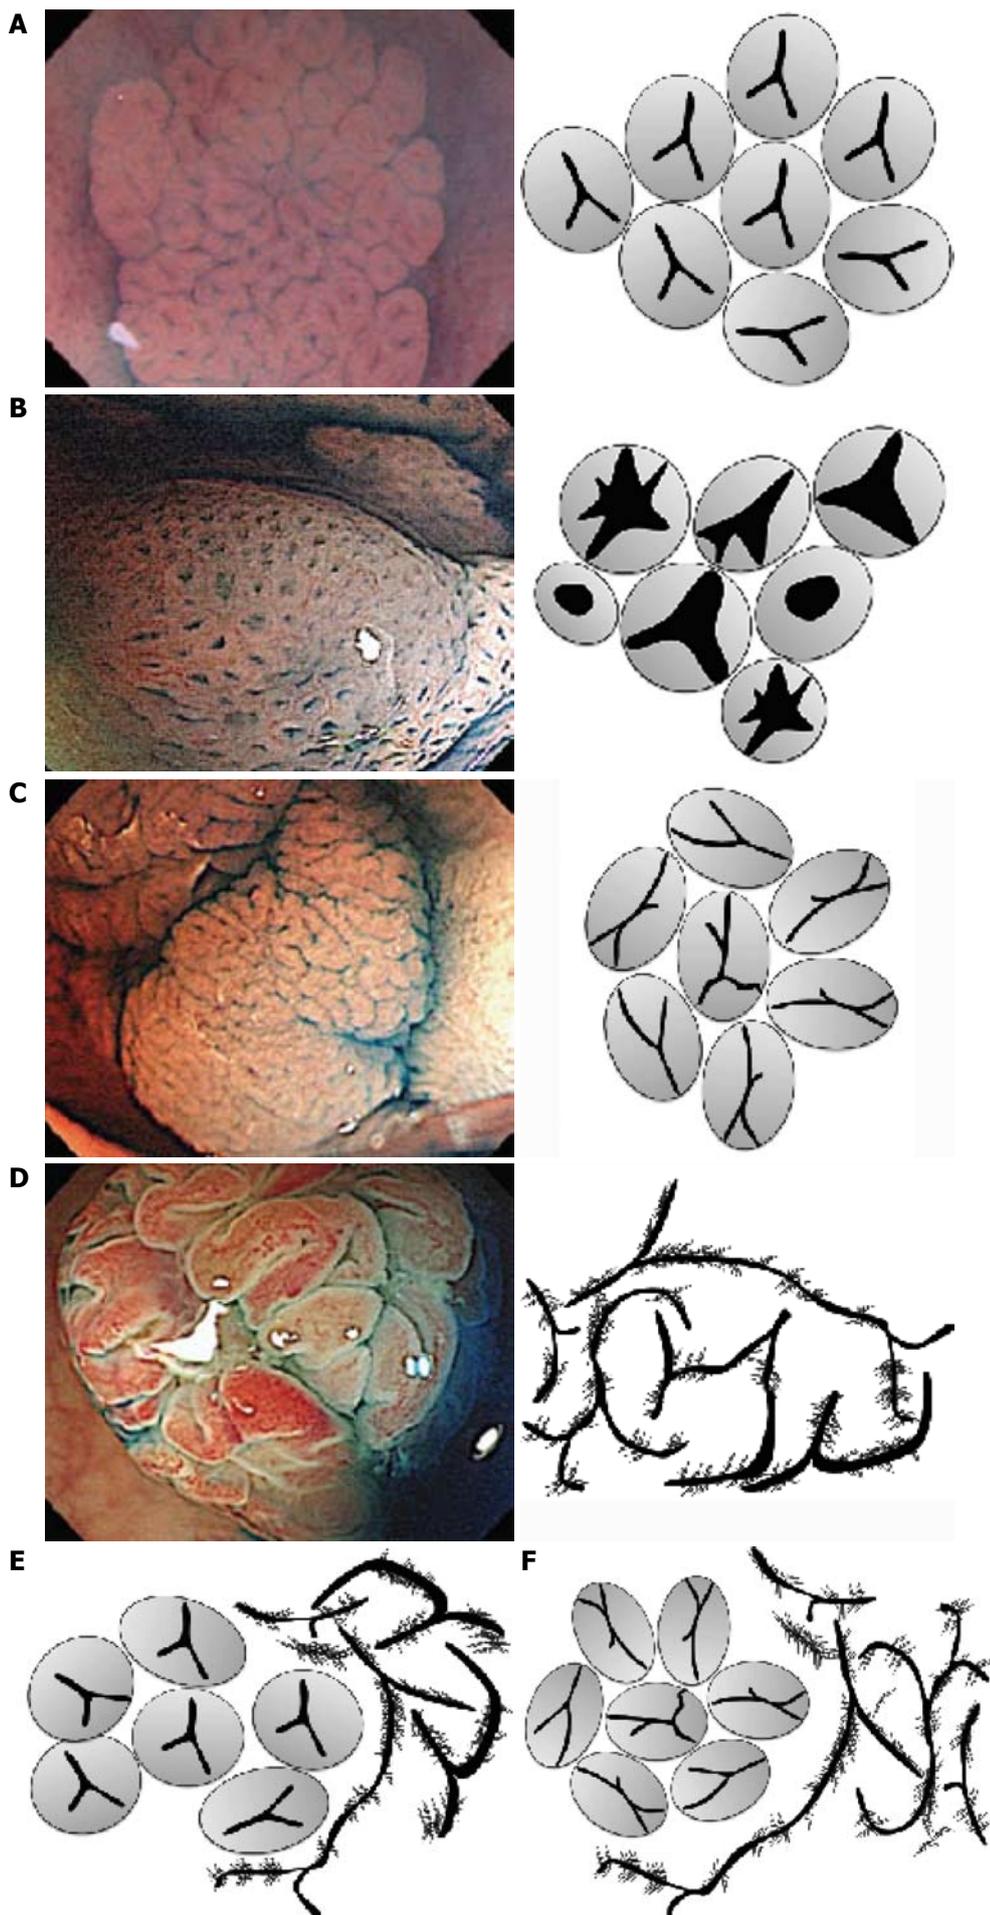

All lesions were sprayed with indigo carmine and observed under endoscopic guidance with a CF-H260AZI endoscope using the EVIS LUCERA system (Olympus, Inc., Tokyo, Japan).

Five categories of conventional colonoscopic findings (location, size, shape, color, and presence or absence of mucin) and magnifying colonoscopic findings (pit pattern diagnosis) for these lesions were interpreted by five colonoscopists with experience in over 1000 colonoscopies, and compared with histopathological diagnoses. In addition to Kudo's classification, the pit pattern was diagnosed in accordance with the subclassification proposed by Kimura *et al*^[15] and Kudo *et al*^[16] (Figure 1A-I). The endoscope was washed with an automatic washing machine and disinfectant (DISOPA Solution 0.55%, Johnson and Johnson, Langhorne, PA, United States) after each patient, according to the guidelines^[17-19].

In addition to conventional type II pit pattern according to Kudo's classification, surface architecture of the lesions was also broadly categorized as type II-Open (type II-O), type II-Long (type II-L), or type IV-Serrated (type IV-S) according to the provisional naming proposed by Kimura *et al*^[15]. If several pit patterns were present in a single lesion, the pit pattern that occupied the greatest area was regarded as the basic architecture. We categorized into two groups as SSA/Ps or others on histopathological findings. Lesions that included a diagnosis other than that of serrated lesion of the colon are indicated as "others", SSA/P, or SSA/P plus if adenoma was also present together with "SSA/Ps".

Histopathological diagnosis

Histopathological diagnosis followed conventional diagnostic criteria for regular adenomas, the diagnostic

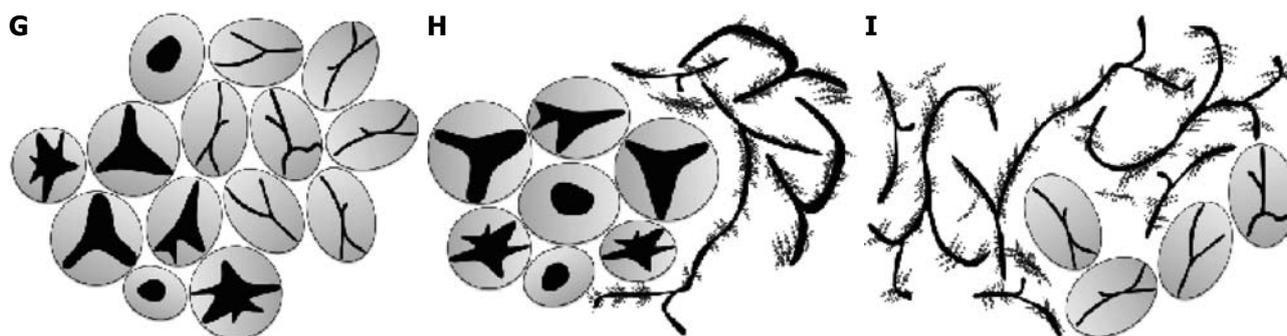

Figure 1 Type II pit patterns and subclassification of surface architectures of serrated lesions of the colon and rectum. A: Conventional type II pit pattern. Regular array of star-shaped, uniform pits with serrated architecture; B: Type II-Open pit pattern. Star-shaped pits similar to conventional type II pits, but with dilated openings of the glandular crypts; C: Type II-Long pit pattern. Similar to type II pits, but elongated without dilation; D: Type IV-Serrated pit pattern. Also called "pine cone-shaped." Villiform with a serrated architecture; E-I: Mixture of example pit patterns (E: Type II with IV-S; F: Type II-L with IV-S; G: Type II-O with II-L; H: Type II-O with IV-S; I: Type IV-S with II-L).

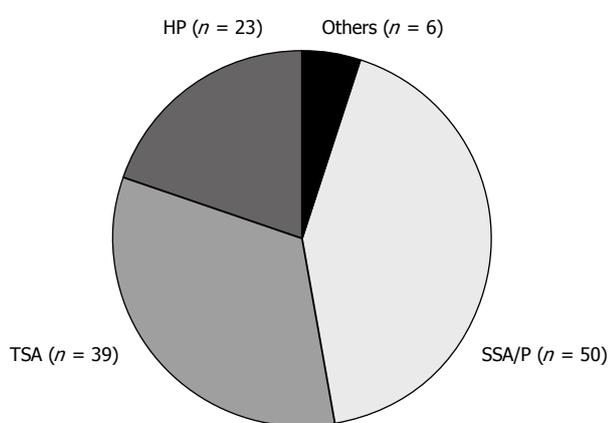

Figure 2 Classification of 118 subject lesions. Ratio of each lesions [traditional serrated adenomas (TSAs), and sessile serrated adenomas/polyps (SSA/Ps) and others].

criteria of Torlakovic *et al.*^[20] for hyperplastic polyps (HPs) and traditional serrated adenomas (TSAs). For practical purposes, according to the 2010 WHO classification, the diagnostic criteria for SSA/Ps was established by the research project "Potential of Cancerization of Colorectal Serrated Lesions" led by the Japanese Society for Cancer of the Colon and Rectum (JSCCR)^[20,21].

According to these criteria, SSA/Ps are composed of serrated cryptal epithelium with aberrant compartmentalization, essentially characterized by the architectural abnormalities listed below. If the serrated lesions had more than two findings [crypt dilation; irregularly branching crypts; horizontally arranged basal crypts (inverted T- and/or L- shaped crypts)], it can be diagnosed as SSA/Ps^[21].

Statistical analysis

Statistical testing comprised *t* tests, χ^2 tests, and Fisher's exact test, with values of $P < 0.05$ regarded as significant. All statistical analysis were performed using PRISM software for Windows, Version 4 (GraphPad Prism, Inc., San Diego, CA).

HPs: Hyperplastic polyps; TSAs: Traditional serrated adenomas; SSA/Ps: Sessile serrated adenoma/polyps; NC: Normal-colored or pale in color of mucosa; RC: Reddish change in color.

RESULTS

Patient characteristics

Lesions comprised 23 HPs, 39 TSAs (complicated with cancer in one case), 50 SSA/Ps (complicated with cancer in three cases), and six others, including regular adenomas and juvenile polyps. We excluded these six other lesions for further analysis. Patient characteristics and conventional colonoscopic findings are shown in Table 1 and Figure 2. Mean age and sex (percentage of females) were 58.9 years/13% for HPs, 61.9 years/33.3% for TSAs, and 63.7 years/32% for SSA/Ps. No characteristic trends were evident in patient backgrounds (Table 1).

Conventional colonoscopic findings

We categorized the location of lesions as either right side of the colon (on the oral side of the transverse colon) or left side of the colon (on the anal side of the transverse colon). Results showed that HPs tended to locate on the

left side of the colon 69.6% (16/23) rather than the right side 30.4% (7/23). TSAs were more frequently located on the left side 79.5% (31/39) rather than the right side 20.5% (8/39). 84.0% (42/50) of SSA/Ps were on the right and 16% (8/50) were on the left (Table 1). SSA/Ps were found significantly more often on the right, compared with TSAs and HPs ($P < 0.001$) (Table 1).

Macroscopic morphology was categorized as either flat type (includes 0-IIa, superficial flat/elevated tumors: LST, lateral spreading tumor) or protruded type (0-Ip, protruded/pedunculated: 0-Isp, protruded/mixed sessile and pedunculated) based on JSCCR Guidelines 2010 for the treatment of colorectal cancer^[22]. Results were as follows: 30.4% (7/23) of HPs were flat type and 69.6% (16/23) were protruded type; 5.1% (2/39) of TSAs were flat type and 94.9% (37/39) were protruded type; and 90.0% (45/50) of SSA/Ps were flat type and 10.0% (5/50) were protruded type. Significantly more SSA/Ps were identified as flat surface lesions compared with TSAs and HPs ($P < 0.001$) (Table 1).

We categorized as either reddish change (RC) or normal-colored (NC) or pale mucosa. The results were as follows: 65.2% (15/23) of HPs were RC and 34.8% (8/23) were NC; 89.7% (35/39) of TSAs were RC and 10.3% (4/39) were NC; and 20.0% (10/50) of SSA/Ps were RC and 80.0% (40/50) were NC. Significantly more SSA/Ps were same to whitish change in color compared with TSAs and HPs ($P < 0.001$) (Table 1).

We categorized lesions as without mucin if they could be observed without washing or with only regular washing, or with mucin if they required several repeated washings before they could be observed. Results were as follows: 78.3% (18/23) of HPs were without mucin and 21.7% (5/23) were with mucin; 82.1% (32/39) of TSAs were without mucin and 17.9% (7/39) were with mucin; and 28% (14/50) of SSA/Ps were without mucin and 72% (36/50) were with mucin. Significantly more SSA/Ps showed abundant mucin compared with TSAs and HPs ($P < 0.001$) (Table 1).

According to the tumor size, mean lesion size was 7.74 ± 3.24 mm for HPs, 9.89 ± 5.73 mm for TSAs, and 13.62 ± 8.62 mm for SSA/Ps. SSA/Ps were significantly larger in mean size compared with TSAs and HPs (SSA/P *vs* HP, $P < 0.001$; SSA/P *vs* TSA, $P < 0.01$) (Table 1).

Magnified colonoscopic findings

A comparison of magnified colonoscopic findings and histopathological diagnoses is given in Table 2. Seventeen lesions showed either type II pit pattern alone or partial type II pit pattern as the basic architecture, with 14 HPs (82.4%) and 3 SSA/Ps (Table 2).

Fifteen lesions showed either type II-L alone or partial type II-L as the basic architecture, of which 6 were SSA/Ps, 5 were TSAs, 4 were HPs. Forty-nine lesions showed either type II-O alone or partial type II-O as the basic architecture, with SSA/Ps histology evident in 41 (83.7%) (Figure 1, Table 2). Cancer was also present in 3 lesions, in all of which a type VI pit pattern was also present within the same lesion (Figure 3C and F). There were

4 HPs and 4 TSAs.

Thirty-one lesions showed either type IV-S alone or partial type IV-S as the basic architecture, including 30 TSAs (96.8%). Cancer was present in one lesion, in which a type V₁ pit pattern was also present within the same lesion.

DISCUSSION

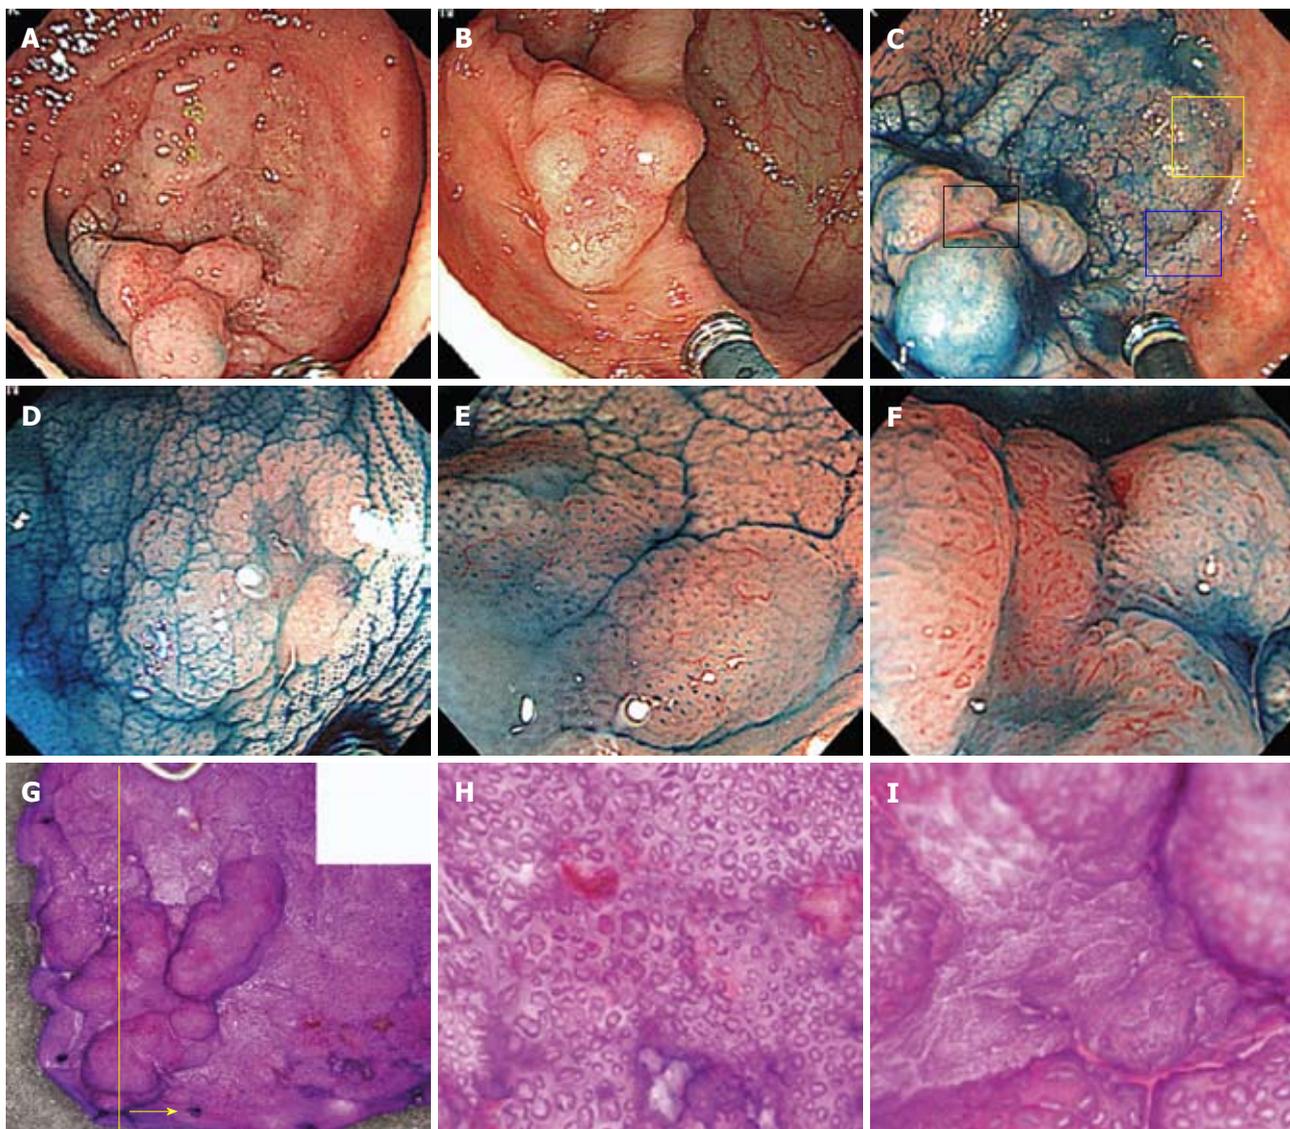

Epithelial polyps, a serrated architecture without atypical cells, were previously called HPs. Such lesions were believed not to possess cancerous potential. In 1990, Longacre *et al.*^[23] proposed that lesions with a serrated architecture and atypicalities should be known as SAs. Torlakovic *et al.*^[20,24] subsequently suggested the existence of a subtype comprising atypia admixed within HPs, for which the name SSAs was proposed. Some, however, consider the term adenoma inappropriate, because these lesions cannot be recognized as tumorous. The latest 2010 WHO classification uses the term SSA/Ps, incorporating both adenoma and polyp^[21,25]. The concept of serrated lesions, particularly SSA/Ps, is therefore comparatively new, with terminology and classifications that have only recently been standardized. Although this transition has yet to be fully adopted, the fact that it is widely recognized that there is no risk of cancer developing from HPs is one reason for the lack of detailed reports on the colonoscopic characteristics of these lesions.

Based on the WHO classification, serrated lesions of the colorectum can be broadly divided into HPs, TSAs, and SSA/Ps^[25]. The present study investigated the characteristics of these three types from conventional colonoscopic findings and magnified colonoscopic findings (pit pattern diagnosis), which are routinely used in everyday colonoscopic evaluation^[25]. To start with conventional colonoscopic findings, the characteristics of HPs are that they tend to occur in the left side of the colon, particularly in the rectum, are commonly less than 5 mm in size, and are NC or pale in color and flat^[26]. In this study, HPs did not necessarily fit these characteristics. This may have been because the lesions investigated in the present study had been removed colonoscopically, and HPs that exhibited typical characteristics were not indicated for resection. HPs thus included many atypical lesions. The characteristics of TSAs are that they are Isp or Ip protruded lesions that tend to occur on the left side of the colon, vary in size from less than 5 mm to over 10 mm (although most are less than 10 mm)^[23], and are often reddish in color. A further characteristic that was not included in this study is that some flat lesions show a surface architecture that can be described as highly protruding double elevation, pinecone-shaped, or coral-shaped^[15,27,28]. In the present study, TSAs mostly satisfied these characteristics. SSA/Ps have been reported as a subclassification of HPs^[20,24], and the colonoscopic findings are mostly similar. However, SSA/Ps tend to occur more often in the right colon compared with HPs; many are large, with a diameter exceeding 10 mm, and coloration may be yellowish due to mucin^[29]. Our findings in the present study were similar.

Table 2 Comparison of the magnified colonoscopic findings and pathological diagnoses

Pit pattern	<i>n</i>	HPs (<i>n</i> = 23)	TSAs (<i>n</i> = 38)	TSAs + cancer (<i>n</i> = 1)	SSA/Ps + α (<i>n</i> = 47)	SSA/Ps + cancer (<i>n</i> = 3)
Type II	17	14			3	
Alone	16	13			3	
With IV-S	1	1				
Type II-L	15	4	5		6	
Alone	10	4	1		5	
With IV-S	5		4		1	
Type II-O	49	4	4		38	3
Alone	30	3			27	
With II-L	9		1		8	
With IV-S	7	1	3		3	
With V ₁	3					3
Type IV-S	31	1	29	1		
Alone	28	1	27			
With II-L	2		2			
With V ₁	1			1		

HPs: Hyperplastic polyp; TSAs: Traditional serrated adenoma; SSA/Ps: Sessile serrated adenoma/polyp; SSA/Ps + α : SSA/Ps or SSA/Ps + adenoma, others except serrated lesions.

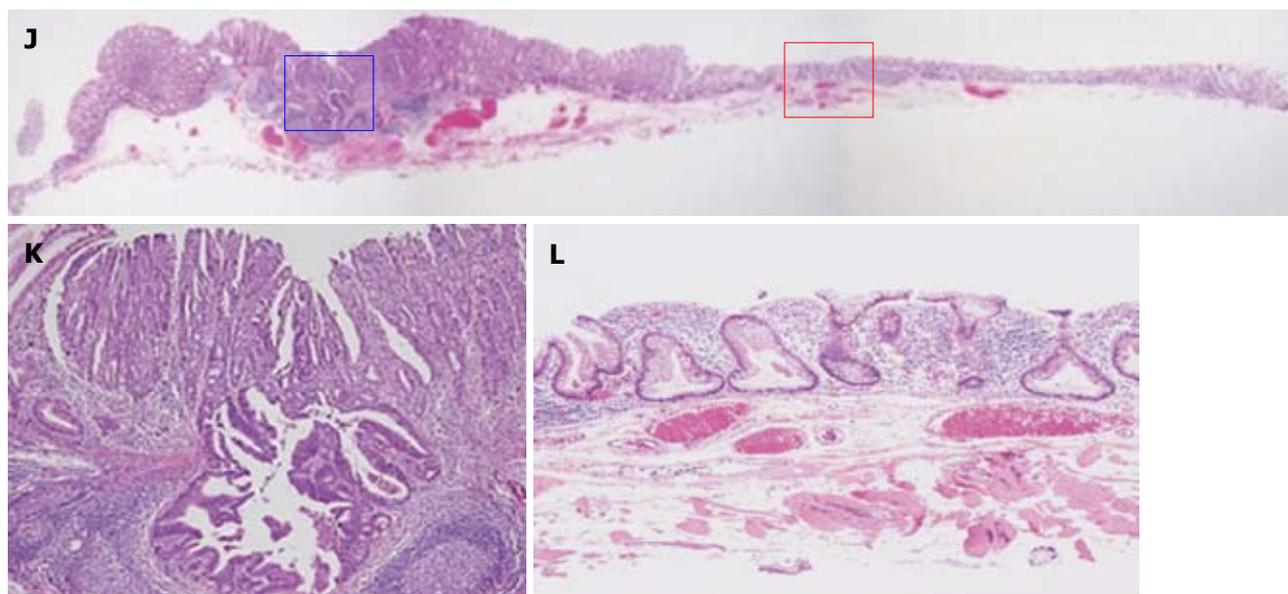

Figure 3 Adenocarcinoma (tub1) in sessile serrated adenomas/polyps case. A 60-year-old woman had a tumor lesion in the cecum, which was flat and elevated, that is a so-called lateral spreading tumor (LST), 45 mm in diameter. A, B: Standard view. A 45-mm LST lesion with large amounts of mucin is evident in the cecum. The flat portion is somewhat discolored compared with the surrounding mucosa. The protruded portion on the anal side is reddish in the center; C: Indigo carmine staining. The center of the protruded portion on the anal side is flat; D: Indigo carmine staining, enlarged image (yellow square in 3C). Type II-Long pit pattern is evident; E: Indigo carmine staining, enlarged image (blue square in 3C). Type II-Open pit pattern is evident; F: Indigo carmine staining, enlarged image (black square in 3C). We diagnosed as type VI pit pattern, because high density of crypts and irregular pit pattern were evident; G: Comparison of stereomicroscopic and colonoscopic images; H: Enlarged image of flat portion. Although basically type II, dilated duct openings are evident; I: Enlarged image of protruded portion on the anal side. An irregular surface architecture is evident; J: HE magnifying glass image (yellow line in Figure 3G). We examined HE staining (Figure 3J-L) using the yellow cutting line of endoscopically resected tissue (yellow arrow side tissue); K: Central part of the protrusion on the anal side (blue square in Figure 3J). Highly differentiated ductal cancer corresponding to type VI pits is evident; L: Dilatation of crypts and deformation in the horizontal direction at the bottom of the crypts are evident in the flat portion (red square in Figure 3J). Sessile serrated adenomas/polyps was diagnosed.

In magnified colonoscopic findings, Rembacken *et al*^[30] reported the value of SA diagnosis of lesions with serrated architecture with type III_L tubiform pit pattern as type III_H pits, and type IV villiform pit pattern enlarged to resemble pine cones as type IV_H pit pattern. These pits may be considered to correspond to the type IV-S pits of the present study. In this study, TSAs accounted for 76.9% (30/39) of lesions with a basic architecture of type IV-S pit pattern, and lesions without type IV-S pit pattern could be classified as non-TSAs with 96.7% sensitivity and 88.9% specificity. Lesions previously regarded as SAs are now considered to be TSAs, and type IV-S pit pattern can be considered a characteristic finding of TSAs.

Pit patterns reflect the pathological characteristics of lesions, and if the characteristics differ, different pit patterns should also be apparent. HPs are characterized histologically by serrated crypts, with straight crypts evenly distributed throughout^[31]. There should thus be no argument that the type II pit pattern of Kudo's classification reflect this characteristic. Diagnostic criteria for SSA/Ps, however, have yet to be standardized, and the classifications of Higuchi *et al*^[32,33] have mainly been used in Japan. The JSCCR diagnostic criteria used in the present study have extracted three categories from among those defined by Higuchi *et al*^[32,33] that can be regarded as important expressions of the nature of SSA/Ps. Figure 3 shows a typical case of SSA/Ps complicated with cancer treated in our hospital. In terms of serrated crypt, as in HPs, "dilatation of crypts" can be named as an observ-

able colonoscopic finding. This finding may be considered to correspond to the type II-O pit pattern proposed by Kimura *et al*^[15]. The present study also found SSA/P histology in 41 of 50 lesions (82.0%) with type II-O pit pattern as the basic architecture. Lesions without type II-O pit pattern could be classified as non-SSA/Ps with 83.7% sensitivity and 85.7% specificity. We could not deny that we diagnosed as HPs some lesions that even had a tiny SSA/P component at the glandular base. Although it is therefore not possible to diagnose all SSA/Ps solely on the basis of type II-O pit pattern, at least this finding is useful for the diagnosis of SSA/Ps with dilatation of crypts. Even if not diagnosed as SSA/Ps according to current diagnostic criteria, lesions with type II-O pit pattern reportedly possess molecular biological commonalities and regarding these as a single population may be preferable^[9,15].

TSAs show a greater number of characteristic findings compared with HPs and SSA/Ps, facilitating colonoscopic diagnosis. Magnified colonoscopic assessment of the histological characteristics of SSA/Ps is difficult when they do not exhibit dilatation of the crypts, and distinguishing them from HPs is difficult at this point. Our findings suggest, however, that type II-O pit pattern may be of assistance in the colonoscopic diagnosis of lesions with dilatation of crypts.

The concept of serrated lesions of the colorectum is relatively recent, and criteria for pathological diagnosis have yet to be standardized. As TSAs and SSA/Ps are

undoubtedly precursor lesions of colon cancer, however, colonoscopists are faced with the task of establishing colonoscopic diagnoses and elucidating lesions for which treatment is indicated. Identifying serrated lesions of the colorectum during colorectal cancer surveillance is thus important. Rex *et al* recommend that all serrated lesions proximal to the sigmoid colon and all serrated lesions in the rectosigmoid > 5 mm in size, be completely removed^[34-37]. However, many issues still remain, including whether all TSAs and SSA/Ps should be indicated for treatment as precursor lesions for colon cancer and the probability of progression to a cancerous state. We hope that the present findings will be useful as a reference for the accumulation of larger numbers of cases in further studies to elucidate the oncogenic pathways in serrated lesions of the colon and rectum.

COMMENTS

Background

Broad division of serrated lesions of the colorectum into hyperplastic polyps, traditional serrated adenomas (TSAs), and sessile serrated adenomas/polyps (SSA/Ps) has been proposed on the basis of recent molecular biological studies. However, few reports have examined the colonoscopic features of these divisions, including magnified colonoscopic findings. In this article, the authors verified the diagnostic potency for SSA/Ps using the pit pattern classifications by magnifying colonoscopy.

Research frontiers

The pit patterns were categorized according to Kudo's classification, but a more detailed investigation was also performed using the subclassification [type II-Open (type II-O), type II-Long (type II-L), or type IV-Serrated (type IV-S)] proposed by Kimura T and Yamano H. However, it has yet to be standardized. In this study, the authors performed herein the investigation of the colonoscopic characteristics of serrated lesions of the colorectum, using the surface architecture subclassification proposed by Kimura T and Yamano H in addition to conventional pit pattern diagnosis

Innovations and breakthroughs

The authors successfully confirmed that the pit pattern diagnosis using magnifying colonoscopy, particularly magnified colonoscopic findings using subclassifications of surface architecture, reflected the pathological characteristics of SSA/Ps and TSAs.

Applications

This study offers a better understanding of pathological characteristics of SSA/Ps and TSAs using subclassifications of surface architecture by magnified colonoscopy.

Terminology

Pit patterns reflect the pathological characteristics of lesions, and if the characteristics differ, different pit patterns should also be apparent. Hyperplastic polyps are characterized histologically by serrated crypts, with straight crypts evenly distributed throughout. There should thus be no argument that the type II pit pattern of Kudo's classification reflect this characteristic.

Peer review

In magnified colonoscopic findings, lesions without type II-O pit pattern could be classified as non-SSA/Ps with high sensitivity and specificity. It is therefore not possible to diagnose all SSA/Ps solely on the basis of type II-O pit pattern, at least this finding is useful for the diagnosis of SSA/Ps with dilatation of crypts.

Abstract

AIM: To study the angle between the circular smooth muscle (CSM) and longitudinal smooth muscle (LSM) fibers in the distal esophagus.

METHODS: In order to identify possible mechanisms for greater shortening in the distal compared to proximal esophagus during peristalsis, the angles between the LSM and CSM layers were measured in 9 cadavers. The outer longitudinal layer of the muscularis propria was exposed after stripping the outer serosa. The inner circular layer of the muscularis propria was then revealed after dissection of the esophageal mucosa and the underlying muscularis mucosa. Photographs of each specimen were taken with half of the open esophagus folded back showing both the outer longitudinal and inner circular muscle layers. Angles were measured every one cm for 10 cm proximal to the squamocolumnar junction (SCJ) by two independent investigators. Two human esophagi were obtained from organ transplant donors and the angles between the circular and longitudinal smooth muscle layers were measured using micro-computed tomography (micro CT) and Image J software.

RESULTS: All data are presented as mean \pm SE. The CSM to LSM angle at the SCJ and 1 cm proximal to SCJ on the autopsy specimens was 69.3 ± 4.62 degrees vs 74.9 ± 3.09 degrees, $P = 0.32$. The CSM to LSM angle at SCJ were statistically significantly lower than at 2, 3, 4 and 5 cm proximal to the SCJ, 69.3 ± 4.62 degrees vs 82.58 ± 1.34 degrees, 84.04 ± 1.64 degrees, 84.87 ± 1.04 degrees and 83.72 ± 1.42 degrees, $P = 0.013$, $P = 0.008$, $P = 0.004$, $P = 0.009$ respectively. The CSM to LSM angle at SCJ was also statistically significantly lower than the angles at 6, 7 and 8 cm proximal to the SCJ, 69.3 ± 4.62 degrees vs 80.18 ± 2.09 degrees, 81.81 ± 1.75 degrees and 80.96 ± 2.04 degrees, $P = 0.05$, $P = 0.02$, $P = 0.03$ respectively. The CSM to LSM angle at 1 cm proximal to SCJ was statistically significantly lower than at 3, 4 and 5 cm proximal to the SCJ, 74.94 ± 3.09 degrees vs 84.04 ± 1.64 degrees, 84.87 ± 1.04 degrees and 83.72 ± 1.42 degrees, $P = 0.019$, $P = 0.008$, $P = 0.02$ respectively. At 10 cm above SCJ the angle was 80.06 ± 2.13 degrees which is close to

being perpendicular but less than 90 degrees. The CSM to LSM angles measured on virtual dissection of the esophagus and the stomach on micro CT at the SCJ and 1 cm proximal to the SCJ were 48.39 ± 0.72 degrees and 50.81 ± 1.59 degrees. Rather than the angle of the CSM and LSM being perpendicular in the esophagus we found an acute angulation between these two muscle groups throughout the lower 10 cm of the esophagus.

CONCLUSION: The oblique angulation of the CSM may contribute to the significantly greater shortening of distal esophagus when compared to the mid and proximal esophagus during peristalsis.

Circular smooth muscle contributes to esophageal shortening during peristalsis. *World J Gastroenterol* 2012; 18(32): 4317-4322 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i32/4317.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i32.4317>

INTRODUCTION

The mechanisms of contraction and bolus transportation of the esophagus have been of great interest^[1]. Peristalsis in the smooth muscle portion of the esophagus involves the interaction of central and peripheral neural mechanisms and the interaction between these neural mechanisms and the smooth muscle^[2,3]. Different instruments have been devised to measure the motions of esophageal peristalsis^[4,5]. The longitudinal muscle contraction of the human esophagus has been inferred from longitudinal shortening measured using widely spaced metal clips attached to the esophageal mucosa. The measured degrees of shortening vary depending upon how widely the clips are placed. The more widely spaced the clips, the more the measurement will under predict true longitudinal shortening. Furthermore, the relative motion between a clip on the mucosal surface and the underlying muscle layer introduces additional unknown errors into the estimate of longitudinal shortening^[6-8]. We recently demonstrated that the mucosa shortens independent of the muscularis propria, upon cholinergic stimulation and with peristaltic contraction^[9,10]. Nicosia *et al*^[11] avoided this variability associated with mucosal clips, by developing a procedure to accurately measure local longitudinal shortening of the esophageal wall using simultaneous

high-resolution endoluminal ultrasound and manometry during peristaltic contraction.

In a follow-up study we measured cross sectional area and manometry at four levels in the esophagus: 5 cm, 10 cm, 15 cm and 20 cm above the upper border of the distal esophageal high-pressure zone. We found that (1) the shortening of the circular smooth muscle (CSM) and longitudinal smooth muscle (LSM), at 5 cm was significantly greater than at 20 cm above the distal esophageal high pressure zone; and (2) the CSM and LSM both shortened in the longitudinal direction but the CSM contribution towards longitudinal esophageal shortening at the distal esophagus was greater than at the proximal esophagus^[12]. This was surprising, as it was commonly assumed that the LSM of the esophagus was completely responsible for esophageal shortening, while the CSM was responsible for the narrowing of the lumen and the pressure generated within the esophageal lumen. Before this finding it was assumed that CSM contraction did not actively contribute to the longitudinal esophageal shortening and that any shortening within the CSM occurred by longitudinal smooth muscle drag.

We proposed several hypotheses to explain this physiologic phenomenon: (1) the LSM dragged the CSM with it during shortening causing the CSM to shorten. While this could account for some of the CSM shortening it could not account for the CSM shortening more than what is accounted for by the LSM. This also cannot explain the regional differences in shortening along the length of the esophagus; (2) the entire esophagus is tonically stretched at rest (under axial tension) and during swallowing there is a decrease in this tension due to deglutitive inhibition causing the circular smooth muscle to shorten, as a spring would shorten when the tension was released. Once again this could account for some of the CSM shortening but could not account for the differences in CSM shortening along the length of the esophagus; and (3) the CSM fibers actually spiral down the esophagus at an angle other than perpendicular to the longitudinal axis leading to subsequent shortening of the CSM during peristaltic contraction. This seemed the most likely explanation for the CSM shortening more than that contributed by LSM in the distal esophagus. In addition we hypothesized that if this was the case, one would observe that the distal spiral angle would be greater than the proximal spiral angle.

The aim of this study was to provide an explanation to the functional observation obtained by Dai *et al*^[12], that the CSM shortens more than can be explained by longitudinal drag of the LSM alone during peristaltic contraction, especially in the distal esophagus.

MATERIALS AND METHODS

Study design and conduct

This research study was approved by the Temple University Institutional review board. Data management, analysis and interpretation and preparation of the manuscript

were performed by the authors who had full access to all the study data. All authors had responsibility for the decision to submit the manuscript for publication, and vouch for the accuracy, integrity, and completeness of the data as reported.

Assessments and outcome measurements

In the current study, we used fine dissection of cadaveric esophagi to define the LSM and CSM layers in detail. Angles of the CSM fibers relative to the axial direction (longitudinal muscle fibers) of the esophagus were measured. In addition, we used micro-computed tomography (micro CT) scan to virtually dissect the human esophagi obtained from organ transplant donors to evaluate the angle of the CSM relative to LSM.

Cadaveric esophageal measurements

Nine human esophagi were procured from formaldehyde preserved cadavers previously used for medical education purposes. Each esophagus was removed from the pharyngo-esophageal junction to the cardia of the stomach. The outer longitudinal layer of the muscularis propria was exposed after carefully stripping the outer serosa. Minimal tension was applied to straighten the esophagus and the esophagus was then longitudinally cut open in a straight line following the orientation of the longitudinal muscles. The squamocolumnar junction (SCJ) was identified on the mucosa and its location was marked on the specimen. The inner circular layer of the muscularis propria was then revealed after careful dissection of the esophageal mucosa and the underlying muscularis mucosa. Photographs of each specimen were taken with half of the open esophagus folded back showing both the outer longitudinal and inner circular muscle layers. Although the entire esophagus is much longer only the distal 10 cm of the esophagus was used to make measurements. A ruler was also included in the pictures with a mark placed at the SCJ, which was identified earlier. The ruler was also used to mark the esophagus at every centimeter proximal to the SCJ. Special attention was given to ensure that the folded-back longitudinal layer was in its *in vivo* position relative to the circular layer by carefully aligning the marks made along the incision line on the esophagus before it was cut open (Figure 1).

Image Pro Plus (version 6.1, Media Cybernetics, Inc. MD) was used to analyze each digital image. Angles between the longitudinal and the circular muscles were measured by two independent investigators, blinded to the other investigators measurements. Measurements were made starting at the SCJ and moving proximally measuring every 1 cm for 10 cm.

High-resolution micro-computed tomography scan of the gastroesophageal junction

Two human esophagi and stomachs were obtained from organ transplant donors (National Disease Research Institute and the International Institute for the Advancement of Medicine). The specimens were fixed by sub-

mersion in 4% paraformaldehyde for 10 d, followed by immersion in a 2% phosphotungstic acid, 0.02% potassium permanganate, 0.1% hematoxylin (PTAH) solution for 48 h after fixative wash out using running tap water for several hours. The specimen was removed carefully, washed and then dissected down in size so that a region of 5 cm diameter \times 5 cm in height remained. This block of tissue was supported by a piece of Styrofoam that was shaped to match the shape of the specimen and wrapped in Parafilm and sealed closed to maintain hydration.

SkyScan 1172 high-resolution cone-beam micro-CT scanner (SkyScan, Ltd, Kontich, Belgium), with a Hamamatsu C9300 11Mp camera, was used to scan the specimens using the double-size and oversize sample options. The following settings were used: a camera pixel size of 8.76 μm , an image pixel size of 11.89 μm , voltage of 80 kV, current of 124 μA , aluminum 0.5 mm as well as copper filters, rotation step of 0.50 degrees, 180 degrees of rotation, a frame averaging of 11 335 rows, 3872 columns, and a scan duration of 3 h and 45 min. The image slices were reconstructed using cone-beam reconstruction software (SkyScan NRecon) based on the Feldkamp algorithm, on 3 linked servers, a process that yielded 3492 tomographic sections, each with a thickness of 11.89 μm in thickness, in the axial (transverse) plane, for each sample. A ring artifact correction of 10, and a beam hardening correction of 40% was applied to both samples.

Three dimensional (3D) image constructs were made using 3D imaging software (SkyScan CTvox). Virtual dissection of these 3D constructs was performed in order to image the circular smooth muscle and the longitudinal smooth muscle in the same plane, using sphere-shaped and cylinder-shaped virtual “cutting boxes” (Figure 2). Image J software was used to measure the angle between the muscle fibers of the LSM and the CSM. Although the entire esophagus is much longer only the distal 5 cm of the esophagus was used due to the limitations of the micro-CT scanner.

Statistical analysis

All data are presented as mean \pm SE. Statistical analysis was performed using one way analysis of variance with post hoc pair wise comparisons using the Bonferroni method.

RESULTS

All data are presented as mean \pm SE. The CSM to LSM angle at the SCJ and 1 cm proximal to SCJ on the autopsy specimens was 69.3 ± 4.62 degrees *vs* 74.9 ± 3.09 degrees, $P = 0.32$. The CSM to LSM angle at SCJ were statistically significantly lower than at 2 cm, 3 cm, 4 cm and 5 cm proximal to the SCJ, 69.3 ± 4.62 degrees *vs* 82.58 ± 1.34 degrees, 84.04 ± 1.64 degrees, 84.87 ± 1.04 degrees and 83.72 ± 1.42 degrees, $P = 0.013$, $P = 0.008$, $P = 0.004$, $P = 0.009$ respectively. The CSM to LSM angle at SCJ was also statistically significantly lower than the angles at

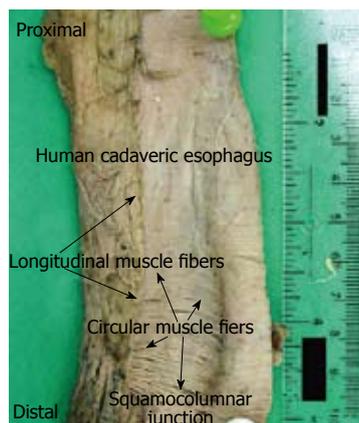

Figure 1 A photograph of a dissected cadaveric esophagus. The esophagus is cut longitudinally along the longitudinal muscle fibers after dissecting the serosa. The mucosa and sub mucosa were later dissected. The esophagus was later folded back so that the longitudinal fibers were on top of the circular muscle fibers. Measurements of the angle of the circular smooth muscle fibers with respect to the longitudinal smooth muscle fibers were made starting from the squamocolumnar junction.

6, 7 and 8 cm proximal to the SCJ, 69.3 ± 4.62 degrees *vs* 80.18 ± 2.09 degrees, 81.81 ± 1.75 degrees and 80.96 ± 2.04 degrees, $P = 0.05$, $P = 0.02$, $P = 0.03$ respectively. The CSM to LSM angle at 1 cm proximal to SCJ was statistically significantly lower than at 3 cm, 4 cm and 5 cm proximal to the SCJ, 74.94 ± 3.09 degrees *vs* 84.04 ± 1.64 degrees, 84.87 ± 1.04 degrees and 83.72 ± 1.42 degrees, $P = 0.019$, $P = 0.008$, $P = 0.02$ respectively. At 10 cm above SCJ the angle was 80.06 ± 2.13 degrees which is close to being perpendicular but less than 90 degrees (Figure 3A). The CSM to LSM angles measured on virtual dissection of the esophagus and the stomach on micro CT at the SCJ and 1 cm proximal to the SCJ were 48.39 ± 0.72 degrees and 50.81 ± 1.59 degrees. Rather than the angle of the CSM and LSM being perpendicular in the esophagus we found an acute angulation between these two muscle groups throughout the lower 10 cm of the esophagus. (Figure 3B).

DISCUSSION

A number of prior studies looking at longitudinal shortening were performed using metallic clips or wires. Dodds *et al*^[6] measured the axial motion of four tantalum wires inserted into the cat esophageal mucosa in vivo. Their results suggested the progression of a wave of longitudinal shortening into the lower esophagus roughly coincident with the bolus tail. Pouderoux *et al*^[8] placed three clips at 4-cm intervals in the distal 8-10 cm of the human esophagus and concluded: “contracting longitudinal segment was advancing ahead of the contracting circular muscle segment.” An earlier study with mucosal clips by Edmundowicz *et al*^[7] measured the change in length of upper and lower halves of the human esophagus and observed that early in the swallow the lower half lengthened while the upper half shortened, consistent with the clip motions in the cat esophagus measured by Dodds *et al*^[6]. Their measurements were also consistent with the later

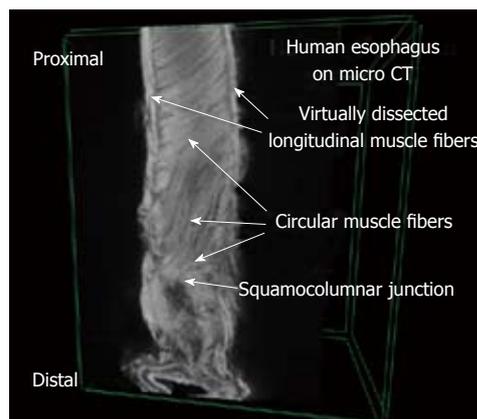

Figure 2 A human esophagus obtained using micro-computed tomography. The longitudinal muscle fibers were virtually dissected to expose the underlying circular muscle fibers. Measurements were made starting from the squamocolumnar junction.

clip data of Pouderoux *et al*^[8], who observed that two adjacent 4-cm segments of the distal esophagus initially lengthen and later shorten in peristalsis-like fashion. Dai *et al*^[13], Liu *et al*^[14] and Miller *et al*^[15-19] pioneered the use of endoluminal ultrasound to evaluate esophageal motility. Miller *et al*^[20-22] combined the use of endoluminal ultrasound with manometry to study peristaltic contraction. Nicosia *et al*^[11] used this new method to measure local longitudinal esophageal shortening in which we calculated shortening for both the circular CSM and LSM using the equation $\text{Cross Sectional Area}_{\text{rest}} / \text{Cross Sectional Area}_{\text{contract}} = \text{Length}_{\text{contract}} / \text{Length}_{\text{rest}}$. It is thought that there is a mechanical advantage of local longitudinal shortening on peristaltic transport in the human esophagus. The peristaltic wave of local longitudinal muscle contraction coordinated with the circular muscle contraction wave has both a physiological advantage (concentrating circular muscle fibers), and a mechanical advantage (reducing the level of contractile force required to transport the bolus), which combine to greatly reduce circular muscle tone during esophageal peristalsis^[23].

In a follow-up study evaluating local longitudinal shortening in different regions of the esophagus, we identified regional differences in local longitudinal shortening. The distal esophagus shortened more than the proximal esophagus. In addition the local longitudinal shortening of the CSM and total muscularis propria at 5 cm above the LES were significantly greater than at 20 cm. The shortening of LSM at 5 cm *vs* 20 cm was not statistically significant. These surprising results imply that the CSM was actually responsible for the greater shortening of the distal esophagus. We hypothesized that the increase in shortening of the CSM was due to the spiral nature of the muscle fibers within the distal CSM^[12].

An extensive literature search yielded only a handful of publications that suggested the oblique/spiral nature of the CSM in the body of the esophagus. Netter illustrated in his atlas a distal circular smooth muscle layer oriented in a spiral fashion^[24]. Floch in Netter’s Gastroenterology textbook described, “In the upper esophagus, the circular muscle closely approximates the encircling lower

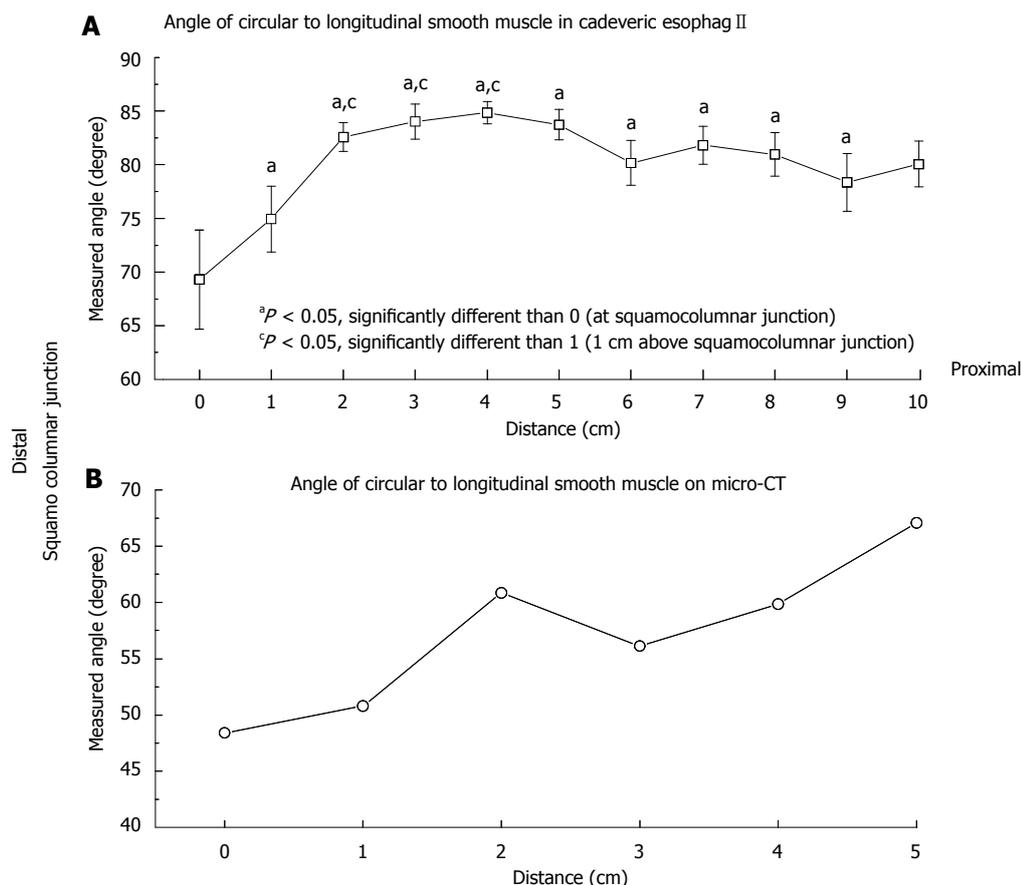

Figure 3 The average angle of the circular smooth muscle with respect to the longitudinal smooth muscle. A: On cadaveric esophagi. The x-axis represents the distance from the squamocolumnar junction with 0 being the squamocolumnar junction. At 90 degrees the circular smooth muscle and longitudinal smooth muscle are perpendicular to each other. Therefore the smaller the angle the greater the deviation from the perpendicular and the greater the resulting shortening during peristaltic contraction; B: Measured using micro computed tomography. The x-axis represents the distance from the squamocolumnar junction with 0 being the squamocolumnar junction. CT: Computed tomography.

fibers of the cricopharyngeus muscle. The upper esophageal fibers are not circular but elliptical, with the anterior part of the ellipse at a lower level to the posterior part. The ellipses become more circular as the esophagus descends, until the start of its middle third, where the fibers run in a horizontal plane. In a 1-cm segment, the fibers are truly circular. Below this point, the fibers become elliptical once again, but they now have a reverse inclination - that is, the posterior part of the ellipse is located at a lower level than the anterior part. In the lower third of the esophagus, the fibers follow a spiral course down the esophagus²⁵. Gray's anatomy text also mentioned the oblique nature of the CSM²⁶.

The study used formalin fixed specimens. The measurements might have been somewhat different if fresh non-contracted tissues were used. Formalin fixation can cause shortening in the length of the esophagus and the shortening associated with formalin fixation will change the angle measured between the CSM vs LSM. However, this does not change the validity of the comparisons between angles in different parts of the esophagus, but may alter the absolute numbers measured.

In the current study we found that rather than the angle of the circular smooth muscle and longitudinal

smooth muscle being perpendicular to each other in the esophagus, a significant difference was found in the angle of the muscle fibers between these two smooth muscle groups. We also found a significant difference between the muscle angles of the CSM at and 1 cm above the SCJ when compared with the muscle angles further above the SCJ. In conclusion, we believe that this spiral or oblique angulation of the CSM to LSM along with drag from the LSM causes shortening of the esophagus which is greater than can be explained by shortening due to the LSM alone. Furthermore we believe that acute angulation of the CSM at the SCJ may be responsible for the greater distal esophageal shortening compared to the proximal esophagus during peristaltic contraction.

COMMENTS

Background

In a previous study, the distal esophagus shortened more than the proximal

esophagus. In addition the local longitudinal shortening of the circular smooth muscle (CSM) and total muscularis propria at 5 cm above the lower esophageal sphincter were significantly greater than at 20 cm. It was concluded that the CSM shortened longitudinally more than that which was accounted for by the longitudinal smooth muscle (LSM) shortening. These surprising results implied that the CSM was actually responsible for the greater shortening of the distal esophagus. Authors hypothesized that the increase in shortening of the CSM was due to the spiral nature of the muscle fibers within the distal CSM.

Research frontiers

It is thought that the LSM of the esophagus is completely responsible for esophageal shortening during peristaltic contraction. The role of CSM in esophageal shortening has not adequately been evaluated. In this study, the authors demonstrate that the CSM, which is at an oblique angle to the LSM, contributes to esophageal shortening.

Innovations and breakthroughs

Recent reports have highlighted the importance of longitudinal shortening of the esophagus in peristaltic contraction. This is the first study to evaluate the role of the CSM in longitudinal shortening due to the orientation of the CSM fibers.

Applications

By understanding how the CSM is oriented in the esophagus this study may increase the readers' knowledge of the anatomy, physiology of peristaltic contraction. In the future, understanding of the mechanism of esophageal shortening may help in the explanation of peristaltic contractile dysfunction.

Terminology

The esophageal wall consists of multiple layers. The main muscular component of the distal esophagus is the muscularis propria which is composed to two smooth muscle layers, the CSM and LSM. The CSM is the inner layer of muscularis propria which is closest to the lumen of the esophagus. The CSM is thought to generate the luminal pressure during peristaltic contraction. The LSM is the layer of muscularis propria which is separated from the CSM by an intramuscular connective tissue layer which contains neural tissue. The LSM is the outer layer of the muscularis propria which is thought to be responsible for esophageal shortening during peristaltic contraction.

Peer review

The authors examined the relative angles of the CSM and LSM in the distal esophagus to explain how the CSM contributes to shortening of the distal esophagus. The authors found that the CSM in the distal esophagus is oriented at an oblique angle to the LSM, thus contributing to distal esophageal shortening. The results are interesting and may have a role in the pathophysiology of esophageal peristalsis.

Abstract

AIM: To investigate the effect of *in vivo* environment on gene expression in *Helicobacter pylori* (*H. pylori*) as it relates to its survival in the host.

METHODS: *In vivo* expression technology (IVET) systems are used to identify microbial virulence genes. We modified the IVET-transcriptional fusion vector, pIVET8, which uses antibiotic resistance as the basis for selec-

tion of candidate genes in host tissues to develop two unique IVET-promoter-screening vectors, pIVET11 and pIVET12. Our novel IVET systems were developed by the fusion of random Sau3A DNA fragments of *H. pylori* and a tandem-reporter system of chloramphenicol acetyltransferase and beta-galactosidase. Additionally, each vector contains a kanamycin resistance gene. We used a mouse macrophage cell line, RAW 264.7 and mice, as selective media to identify specific genes that *H. pylori* expresses *in vivo*. Gene expression studies were conducted by infecting RAW 264.7 cells with *H. pylori*. This was followed by real time polymerase chain reaction (PCR) analysis to determine the relative expression levels of *in vivo* induced genes.

RESULTS: In this study, we have identified 31 *in vivo* induced (*ivi*) genes in the initial screens. These 31 genes belong to several functional gene families, including several well-known virulence factors that are expressed by the bacterium in infected mouse stomachs. Virulence factors, *vacA* and *cagA*, were found in this screen and are known to play important roles in *H. pylori* infection, colonization and pathogenesis. Their detection validates the efficacy of these screening systems. Some of the identified *ivi* genes have already been implicated to play an important role in the pathogenesis of *H. pylori* and other bacterial pathogens such as *Escherichia coli* and *Vibrio cholerae*. Transcription profiles of all *ivi* genes were confirmed by real time PCR analysis of *H. pylori* RNA isolated from *H. pylori* infected RAW 264.7 macrophages. We compared the expression profile of *H. pylori* and RAW 264.7 coculture with that of *H. pylori* only. Some genes such as *cagA*, *vacA*, *lpxC*, *murI*, *tlpC*, *trxB*, *sodB*, *tnpB*, *pgi*, *rbfA* and *infB* showed a 2-20 fold upregulation. Statistically significant upregulation was obtained for all the above mentioned genes ($P < 0.05$). *tlpC*, *cagA*, *vacA*, *sodB*, *rbfA*, *infB*, *tnpB*, *lpxC* and *murI* were also significantly upregulated ($P < 0.01$). These data suggest a strong correlation between results obtained *in vitro* in the macrophage cell

line and in the intact animal.

CONCLUSION: The positive identification of these genes demonstrates that our IVET systems are powerful tools for studying *H. pylori* gene expression in the host environment.

Screening *Helicobacter pylori* genes induced during infection of mouse stomachs. *World J Gastroenterol* 2012; 18(32): 4323-4334 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i32/4323.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i32.4323>

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a gram-negative bacterium that infects a large percentage (50% to 90%) of the world's population and is a causative agent for gastritis, ulcer disease and some gastric cancers. To date, the mechanism of *H. pylori* pathogenesis is not completely understood. *H. pylori* can infect and survive in the stomachs of mice and macrophages. *H. pylori* infection can last for a lifetime, suggesting that the microbes successfully evade the host immune response to infection. Although previously considered an extracellular organism, several recent *in vitro* studies suggest that *H. pylori* may be a facultative intracellular bacterium^[1]. The intracellular habitation offers a plausible explanation for the evasion of host immune response and thus a life-long persistence in the host.

Characterization of microbial genes that are specifically induced during infection is critical to the understanding of the mechanism by which microbial pathogens cause disease. Many different techniques have been developed to study bacterial genes that are expressed during growth in specific niches^[2-4]. A useful tool for identifying genes involved in virulence is *in vivo* expression technology (IVET)^[5,6]. IVET was designed to identify genes of pathogens that are preferentially expressed during infection and has been used extensively^[7,8]. It is a promoter trapping strategy used for identifying bacterial promoters that are upregulated in the host by using an auxotrophic mutant strain or with various reporter systems. This technique allows the identification of genes that may be expressed only under *in vivo* conditions. Such genes are difficult to identify during growth under laboratory conditions, but are likely to play an important role

in survival inside the host. This technology has not been exhaustively utilized in *H. pylori* because of limitations imposed by the genetic intractability of this bacterium. Recently, recombination-based IVET has been utilized to identify *H. pylori* genes important for host colonization^[9]. In this study, we developed an antibiotic-based IVET tool (a variant of IVET^[10]) that is specific for screening *H. pylori* genes that are specifically expressed *in vivo* in mice and macrophage hosts.

MATERIALS AND METHODS

Bacterial strains and growth media

All bacterial strains used in this study are listed in Table 1. The *H. pylori* strains used in this study were: Sydney strain 1 (SS1)^[11] and strain HP1061^[12]. The strains were grown for 16 h to 18 h at 37 °C in a microaerophilic atmosphere in bisulfiteless Brucella broth (BLBB)^[13] containing 5% fetal bovine serum (Hyclone, Logan, UT). For BLBB solid medium, 1.7% agar was added. Unless stated otherwise, the antibiotics used in BLBB solid or liquid medium were: kanamycin (kan) 15 mg/L, Glaxo Selective Supplement A (GSSA) (5 mg/L of Amphotericin-B, 20 mg/L of Bacitracin, 1.07 mg/L of Nalidixic acid, 0.33 mg/L of Polymyxin-B, and 10 mg/L of Vancomycin)^[14]. BLBB 5-Bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-gal) plates were supplemented with X-gal at 40 mg/L. *Escherichia coli* (*E. coli*) strains, TAM1λ pir and DH5α λ pir were grown in L broth (LB) medium^[15].

Animal housing and diet

Mice were maintained in a National Institutes of Health (NIH) animal facility accredited by the Association for Assessment and Accreditation of Laboratory Animal Care International (Rockville, MD).

They were maintained in a specific-pathogen-free animal care holding room and were confirmed to be free of the following microorganisms: cilium-associated respiratory bacillus, ectromelia, mouse rotavirus, mouse encephalomyelitis virus, lymphocytic choriomeningitis virus, murine cytomegalovirus, mouse hepatitis virus, mouse adenovirus, minute virus of mice, *Mycoplasma pulmonis*, parvovirus, polyomavirus, pneumonia virus of mice, reovirus, and Sendai virus. Mice were housed in 7.5- by 11.5- by 5-in. sterilized ventilated Thoren cages (Thoren Caging System, Inc., Hazleton, PA) on Tek Fresh bedding (Harlan Teklad, Madison, WI). Cages were changed weekly. The animal holding room was maintained under environmental conditions of 20 °C, 40% to 70% relative humidity, 15 air changes/h and a 12-h/12-h light-dark cycle. Mice were fed an autoclaved pelleted rodent diet (rodent NIH-31 autoclavable NA; Zeigler Brothers, Inc., Gardners, PA) ad libitum and provided sterilized individual water bottles for an ad libitum water source. Upon arrival, the mice were acclimated for a minimum of 7 d prior to being used in the experiments. Mice were identified by numerical stainless steel rodent ear tags (National Band and Tag Co., Newport, KY). This study was

reviewed and approved by the NIH Institutional Animal Care and Use Committee. All procedures and use of animals were in compliance with the Public Health Service Guide for the Care and Use of Laboratory Animals^[16].

Isolation of DNA from bacterial strains

Plasmid DNA was isolated from *E. coli* using the QIAprep Miniprep or QIAfilter plasmid maxi kit (QIAGEN, United States) in accordance with manufacturer's recommended protocols. Genomic DNA was extracted from *H. pylori* strains, SS1 and 1061 using the Wizard Genomic DNA Purification Kit (Promega, United States) as described by the manufacturer.

Plasmid construction

Two novel *H. pylori* specific plasmids, pIVET11 and pIVET12 (Figure 1.) were constructed by modifying plasmid pIVET8^[10]. pIVET8 is a suicide vector containing *oriR6K* origin that requires, in trans, a host-encoded Pi protein for replication^[17-19]. It also contains an ampicillin resistance gene and a promoterless *cat* and *lacZY* gene fusion. The gene encoding kanamycin resistance was amplified by PCR from pCR II (Stratagene), with primers KanF and KanR (Table 2). The amplified fragment was cloned at the *Aat*II site of pIVET9. A *Bgl*II restriction site in the kanamycin sequence was removed by Quick change site-directed mutagenesis kit (Stratagene). In so doing, we produced pIVET 10 which contained the unique *Bgl*II cloning site immediately upstream of promoterless *cat* and *lacZY* genes. We produced pIVET11 by removing the mob RP4 sequence which accounted for the conjugal transfer functions necessary for mobilization. Finally, pIVET12 plasmid was generated by the removal of ampicillin gene by *Bsp*BI restriction and the transfer of the kanamycin gene from the *Aat*II site to a unique *Bam*HI

site in pIVET11. The kanamycin gene sequence, inserted at the *Aat*II site in pIVET11, disrupts *lacZ* gene without affecting its activity. *H. pylori* is sensitive to ampicillin and therefore we could not use this antibiotic in our system.

Construction of genomic library

H. pylori Sydney strain 1 (SS1) genomic DNA was isolated using the Wizard Genomic DNA purification kit (Promega, United States). The genomic DNA was partially digested with *Sau*3AI. After agarose gel electrophoresis, fragments of 1-3kb were purified using QIAquick Gel Extraction Kit (Qiagen, United States) and ligated into *Bgl*II digested and dephosphorylated pIVET11 or pIVET12 using the Rapid DNA Ligation kit (Roche, United States). Ligation samples were transformed into DH5 α λ pir competent cells which provided the Pi protein, in trans, for plasmid replication. Transformants were replica plated in a 6 \times 8 pattern on LB agar plates containing kanamycin. Forty eight colonies from the replica plates were pooled in TE buffer, pH 8.0 and plasmid DNA purification was carried out using the QIAprep Miniprep kit (QIAGEN, United States).

Preparation of electro-competent *H. pylori*

An overnight-grown 100 mL *H. pylori* culture was chilled for 10 min on ice. The cells were pelleted at 4360 \times g for 5 min. The centrifugations and all subsequent procedures were done at 4 $^{\circ}$ C. The pellets were washed three times, twice with 40 mL ice cold water and finally with 40 mL ice cold water containing 5% glycerol. The washed pellets were placed on ice, covered with 2 mL ice cold 10% glycerol, incubated for 10 min and later resuspended in the same solution. 200 μ L samples were placed in cold screw capped tubes and after quickly freezing on dry ice samples were stored at -80 $^{\circ}$ C.

Electrotransformation of *H. pylori* and merodiploid selection

Electro-competent *H. pylori* strain 1061 was transformed with 0.5-2 μ g recombinant plasmid DNA pools by electroporation (12.5 ms, 2.5 kV, 25 μ F, 600 ohm, 0.4 cm gap, Bio-Rad gene pulser, United States). Electrotransformed *H. pylori* were screened for kanamycin resistance on BLBB GSSA Kan agar plates. Selection for kanamycin resistance requires the integration of the recombinant plasmids into the chromosome by homologous recombination, using the cloned *Helicobacter* DNA as the source of homology (wild type *H. pylori* does not have *cat* and *lacZY* genes). This integration event duplicates a small portion of the *H. pylori* genomic DNA leading to the generation of a merodiploid. Kanamycin resistant colonies/merodiploids were replica plated in a 6 \times 8 pattern on BLBB GSSA Kan agar plates. After 72 h of microaerophilic incubation, forty eight colonies from the replica plates were pooled in 1 mL of BLBB, GSSA, and Kan. This suspension was inoculated in 10 mL BLBB, GSSA, Kan and grown under microaerophilic conditions. After 24 h of incubation, cultures were subcultured 1:100 in 10 mL of BLBB, GSSA,

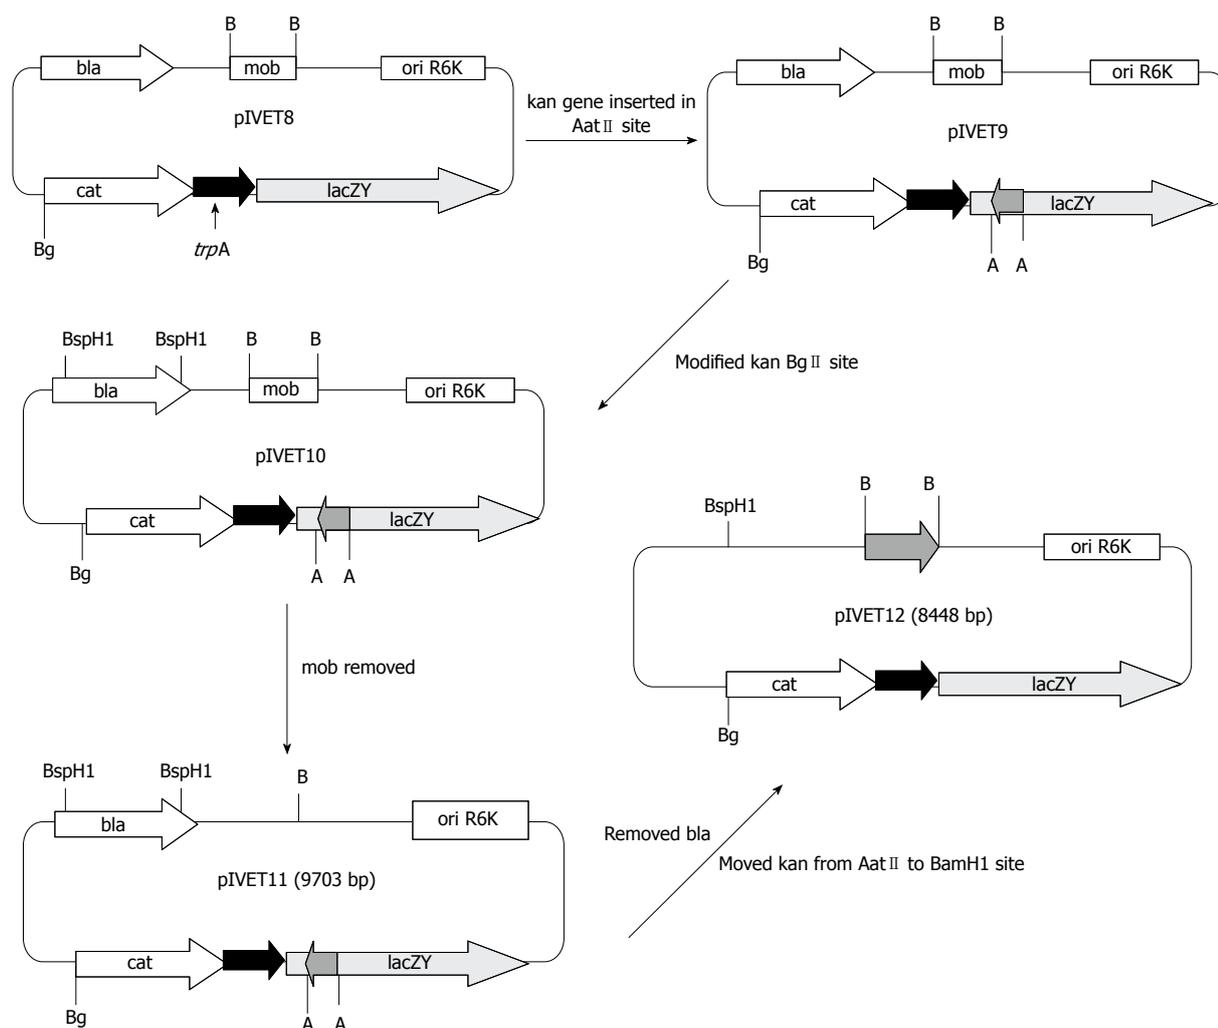

Figure 1 Construction of *Helicobacter pylori* specific antibiotic-based *in vivo* expression technology plasmids, pIVET11 and pIVET12. These plasmids are derivatives of plasmid pIVET8^[10]. Kan and grown for 16-18 h under microaerophilic conditions. These resulting merodiploids were used to infect mice or macrophage cultures (see below).

Inoculation of mice with *H. pylori* merodiploids

Six to eight week old *Helicobacter* and pathogen-free female C57BL/6 mice (Jackson Laboratory Maine, United States) were used, in compliance with guidelines and protocol approved by the Animal Care and Use Committee of the National Institutes of Health, United States. Using a 20-gauge ball-point metal feeding tube (Harvard Apparatus, Inc., Holliston, MA), mice were inoculated intragastrically with 0.1 mL of *H. pylori* merodiploid pooled cultures (10^8 colony-forming-units per milliliter-CFU/mL) once a day every other day for a total of three inoculations. Each pair of mice was inoculated with a fresh 18 h culture. Control mice were inoculated with BLBB medium.

Isolation and analysis of DNA from fecal pellets

Five days post-infection, fecal pellets were collected from

the infected and control mice. DNA was isolated from fecal pellets (2 pellets per mouse) by using the QIAamp DNA stool mini kit (QIAGEN, United States). DNA samples extracted from the fecal pellets were analyzed by PCR as done previously^[20].

Selection for chloramphenicol resistant *H. pylori* in mice

Seven days post-infection, mice were treated with chloramphenicol. 100 μL chloramphenicol (0.9 g/L, apple flavored, Foer's Pharmacy, United States) was given to each mouse by oral gavage twice a day for three days. Chloramphenicol was also added to the water in the mouse cages to a concentration of 0.1 g/L. Following the last chloramphenicol treatment, the mice were sacrificed, and the stomachs were excised.

H. pylori IVET selection in mouse stomachs

The excised stomach was cut into two longitudinal sections. One half was added to 1 mL BLBB medium containing 20% glycerol and frozen at -80 °C. The other half of the stomach was added to 1 mL BLBB Kan medium

and homogenized with a sterile motorized Polytron homogenizer (Kinematica AG, United States). The resulting homogenate was spread on BLBB, GSSA, Kan plates at 10, 100 and 1000 fold dilutions. The plates were incubated under microaerophilic conditions at 37 °C for 3-4 d. Kanamycin resistant colonies were replica plated in a 6 × 8 pattern on BLBB GSSA Kan agar plates. Forty eight colonies from the replica plates were pooled and grown overnight for the second round of mice infections.

H. pylori IVET selection in macrophages

The IVET selection in macrophage was performed as described previously with some modifications^[10]. The mouse macrophage cell line, RAW 264.7 was grown in Dulbecco's modified Eagle medium (DMEM; Gibco-BRL) supplemented with 10 % heat-inactivated fetal calf serum (FCS; Gibco-BRL) and GSSA antibiotics at 37 °C in a 50 mL/L CO₂ humidified atmosphere. The day before each *in vivo* selection assay RAW 264.7 cells were seeded in 24-well tissue culture plates to 2 × 10⁵ cells per well. *H. pylori* merodiploid pools were grown for 16 h to 18 h under microaerophilic conditions at 37 °C in BLBB Kan medium. 30 µL of the bacterial cultures were added per 1 mL of DMEM medium. The monolayers were infected with 1 mL of the bacteria suspension and centrifuged for 5 min at 600 r/min to synchronize bacterial contact with the monolayers^[21,22]. The infected macrophage monolayers were incubated for 2 h at 37 °C in a microaerophilic atmosphere. The monolayers were washed three times with phosphate buffered saline (PBS) and then were incubated with 2 mL of DMEM containing 100 mg/L gentamicin for 2 h at 37 °C in a microaerophilic atmosphere to kill extracellular bacteria. Following extracellular killing, the monolayers were washed three times with 2 mL of PBS and then the infected cells were incubated overnight in DMEM containing 1 mg gentamicin/L and 20 mg chloramphenicol/L. After the incubation period the macrophage-monolayers were washed three times with PBS and then lysed by adding 1 mL of sterile water per well. The resulting lysate was spread on BLBB, GSSA, Kan plates at 10, 100 and 1000 fold dilutions. The plates were incubated under microaerophilic conditions at 37 °C for 3-4 d and the kanamycin resistant colonies were pooled and grown

overnight for the second round of infections.

Screening of chloramphenicol resistant *H. pylori* for β -galactosidase expression *in vitro*

Kanamycin resistant colonies recovered from the stomach homogenates and RAW 264.7 cell lysates were replica plated in a 6 × 8 pattern on BLBB GSSA Kan X-gal plates. These plates were then incubated under microaerophilic conditions at 37 °C for 24 h, and screened for blue or white color. White colonies were used to inoculate BLBB, GSSA medium for preparing genomic DNA.

Identification of *ivi* gene fusions

The genomic DNA samples prepared from white colonies were tested for the presence of *H. pylori* 16S DNA^[20]. The presence of pIVET11/pIVET12 in the genome of co-integrate strains was confirmed by PCR analysis using KanF and KanR primers. To sequence regions of genomic DNA flanking the inserted plasmid, we performed Vectorette PCR according to the manufacturer's instructions (Sigma-Genosys). Genomic DNA from the co-integrate strains was digested separately with *Eco*RI, *Bam*HI and *Hin*DIII. Following this, compatible vectorette linkers were ligated to the ends of the genomic DNA fragments and PCR was then performed using a primer (MCAT) homologous to the 5' end of *cat* gene in pIVET11/pIVET12 and a primer unique to the vectorette linker. The resulting PCR products were sequenced using MCAT primer or cloned into pSC-A-amp/kan, PCR AU cloning vector (Stratagene, United States) and sequenced subsequently.

RNA isolation

RAW 264.7 macrophages were infected with *H. pylori* as described above and incubated for 2 h at 37 °C in a microaerophilic atmosphere. An identical amount of *H. pylori* was added to a flask without RAW 264.7 cells and incubated in the same way as the *H. pylori*-RAW 264.7 cell coculture. A non-infected flask of RAW 264.7 cells served as a negative control for RNA isolation to ensure that no contaminating signals derived from eukaryotic RNA were present. After 2 h of incubation, the *H. pylori*-RAW cell coculture was washed three times with 2 mL of PBS to remove extracellular *H. pylori* cells. Finally, the *H. pylori* infected RAW cell cultures were incubated in 2 mL of medium containing 100 mg/L gentamicin for 2 h at 37 °C in a microaerophilic atmosphere to kill extracellular bacteria. Following extracellular killing, the coculture was washed three times with 2 mL of PBS and then the infected cells were treated with the TRIzol reagent for RNA isolation as described by the manufacturer (Invitrogen, United States). Further RNA purification was performed with an RNeasy mini kit (Qiagen, United States). The culture containing only *H. pylori* was centrifuged and washed twice with phosphate buffered saline, and TRIzol was directly applied to the pellet and the preparation was subsequently treated in the same fashion as *H. pylori* and RAW cells coculture described above for RNA purification.

Separation of eukaryotic and prokaryotic mRNA

H. pylori RNA from coculture was enriched by removal of the eukaryotic 18S and 28S rRNAs and polyadenylated mRNAs using the MICROBEnrich kit (Ambion) according to manufacturer's instructions.

Real time PCR

Primers were designed for 100-150 bp regions of *in vivo* induced genes obtained after sequencing (Table 3). Primer design was aided by Primer Express 3.0 software (Applied Biosystems, United States). Standard PCR was performed with *H. pylori* SS1 genomic DNA as the template to check that all the primer pairs resulted in the amplification of a single product. RNA was reverse transcribed using Superscript III first strand synthesis system for RT-PCR (Invitrogen, United States). Real-time PCR was done using Power SYBR Green PCR Master mix (Applied Biosystems, United States). 16S RNA was used in each set of reaction for normalization. Each reaction was repeated thrice with three independent RNA samples in an Applied Biosystems 7500 real time PCR system. Melt curve analysis was done to confirm the specificity of the amplified product. Relative expression levels were determined using the 2-delta-delta Ct method^[23]. Results were expressed as fold induction of expression in *H. pylori* and RAW 264.7 coculture as compared to *H. pylori* only.

Statistical analysis

Data were presented as mean ± SE in Microsoft Excel. Differences between the *H. pylori* alone, and *H. pylori* and RAW 264.7 co-culture group means were analyzed by the Student's *t* test. The threshold significance level for the mean difference between groups was $P < 0.05$.

RESULTS

Construction of *H. pylori* specific IVET vectors and vector validation with known *H. pylori* promoter

As a means to identify Helicobacter promoters specifically expressed under defined conditions, we have successfully developed two promoter trap vectors, pIVET11 and pIVET12 (Figure 1). These vectors are suicide vectors containing *oriR6K* origin that requires a host-encoded Pi protein, in trans, for replication. They contain two promoterless reporter genes, one encoding the *cat* gene and the other *lacZY* genes. These two genes are organized into a single transcription unit located immediately downstream from a unique *Bgl*/II site, allowing for the cloning of promoter libraries. In Figure 2, we summarized an overview of the IVET strategy used in these studies. To validate the *H. pylori* specific promoter trap vector system, we placed the *cat-lacZY* fusion of pIVET11 under the control of the *H. pylori vacA* promoter. We transformed the resulting plasmid, pIVET11/*vacA*, through electroporation into electro-competent *H. pylori* strain 1061. Transformed *H. pylori* were screened

H. pylori: *Helicobacter pylori*.

for kanamycin resistance (See materials and Methods). Selection for kanamycin resistance requires the integration of the recombinant plasmid into the chromosome by homologous recombination, where the source of homology is the cloned helicobacter DNA *vacA* promoter sequence. The integrated sequences partially duplicate the *H. pylori* genomic DNA, leading to the generation of a merodiploid. With this merodiploid, one copy of the promoter drives the expression of *cat-lacZY* fusion, while the other promoter copy drives the expression of a wild-type *ivi* gene. Kanamycin resistant merodiploids were used to infect mice and macrophages. After infection, chloramphenicol resistant colonies were recovered and subjected to blue or white screening to analyze β -galactosidase expression *in vitro*. We identified 728 cm^R white colonies and analyzed their genomic DNA. The region of genomic DNA flanking the inserted plasmid was identified using the universal vectorette system as described by Sigma-Genosys. Sequence analysis of the PCR product showed the presence of the *vacA* promoter upstream of *cat-lacZY* fusion. These results indicate that the *vacA* promoter is capable of driving the expression of promoterless *cat-lacZY* genes *in vivo*. The expression results also serve to validate the efficacy of our promoter trap systems to detect and identify *H. pylori* promoters expressed *in vivo*.

IVET selection in mouse model

We generated IVET vectors that contained a library of *Sau3AI* digested *H. pylori* chromosomal DNA. These IVET vectors were transformed into *H. pylori* 1061 to generate a library of merodiploid (co-integrated) strains. These strains are plasmid recombinants characterized by integration into different loci of the *H. pylori* genome through homologous recombination. The recombinant strains along with wild type *H. pylori* strain were used to infect mice. Infected mice were then subjected to chloramphenicol treatment. Chloramphenicol effectively kills the intragastric wild type *H. pylori* strain. The surviving chloramphenicol resistant *H. pylori* are merodiploid which were recovered from the stomachs of mice infected with these strains. We pooled the resistant colonies and repeated the second round of infection in mice. Of a total of 702 merodiploid strains that survived chloramphenicol challenge, 38 (approximately 6%) were found to be negative for β -galactosidase activity during *in vitro* screens. In the pre-selection pool, 15% (86/596) of the *H. pylori* genomic DNA *cat-lacZY* fusions were LacZ⁺ *in vitro* (light blue) and 85% (510/596) were LacZ⁻ (white). In contrast, after two rounds of the antibiotic selection, 94% (664/702) were LacZ⁺, and 6% (38/702) were LacZ⁻. These LacZ⁺ strains presumably carried gene fusions that expressed chloramphenicol transacetylase *in vivo* in order

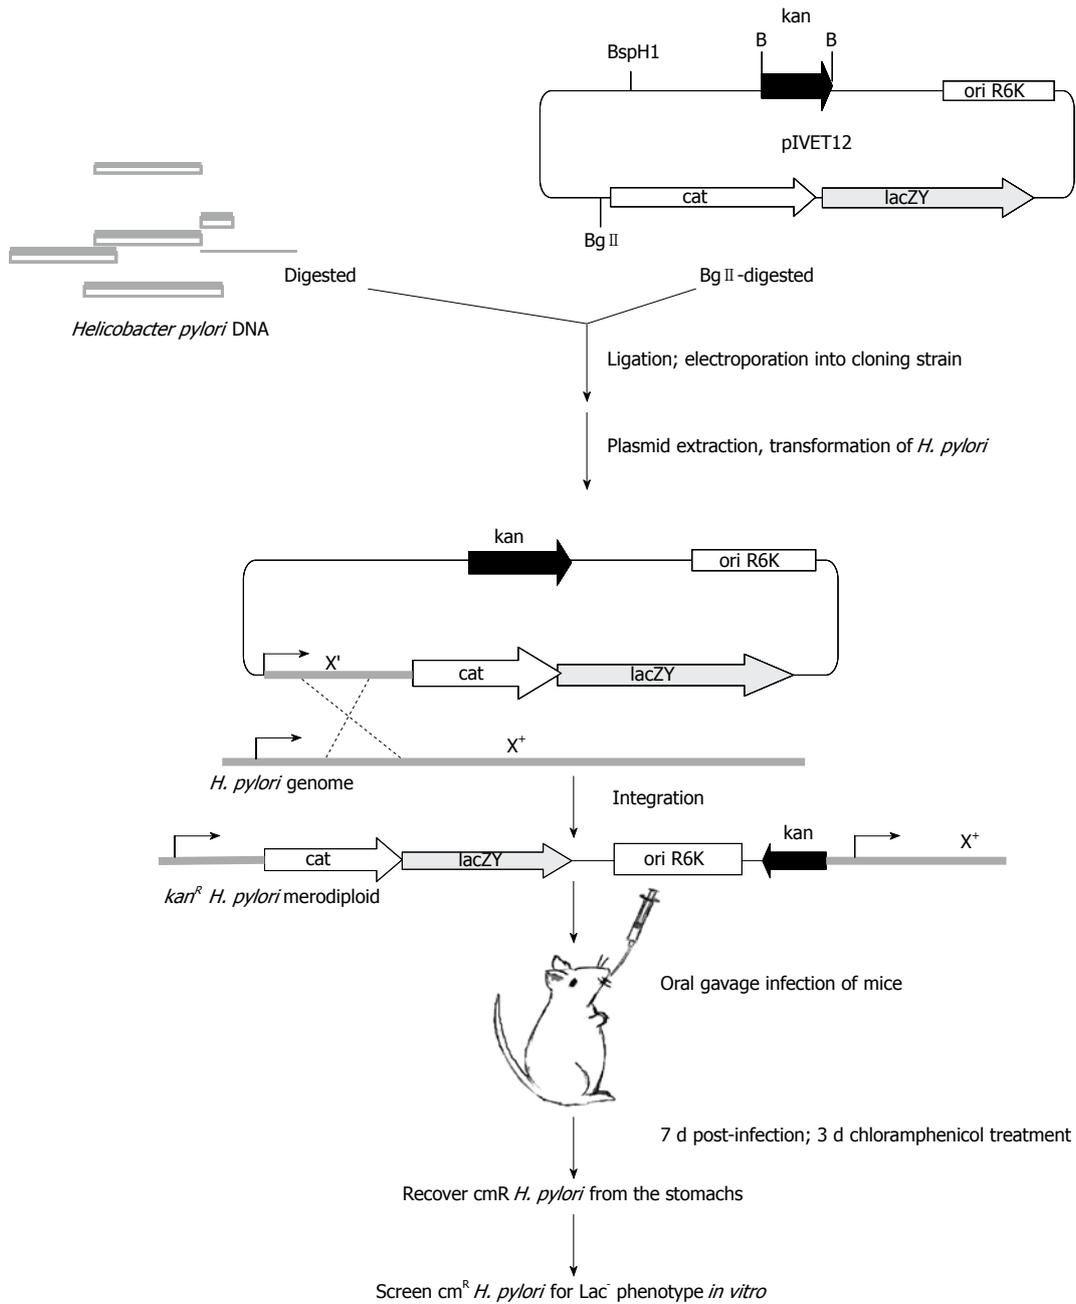

Figure 2 *Helicobacter pylori* specific *in vivo* expression technology strategy. *H. pylori*: *Helicobacter pylori*; B: *Bam*HI; Bg: *Bgl*II ; kan: Kanamycin gene.

to survive the systemic antibiotic treatment. However, the enzyme was expressed poorly when these strains were grown *in vitro* on BLBB Kan X-gal medium. Operating on this premise, we focused our efforts on the characterization of these gene fusions because they may represent genes that are specifically induced *in vivo* (*ivi* genes).

IVET selection in cultured macrophages

RAW 264.7 macrophages were infected with *H. pylori* as described in the methods section. Chloramphenicol resistant bacteria were recovered from the lysates of RAW cells infected with merodiploid strains, but not from those infected with the wild type *H. pylori*. Chloramphenicol resistant colonies were pooled and the pools were used for the second round of infection of RAW 264.7

cells. Of a total of 231 merodiploid strains that survived chloramphenicol challenge, 15 (approximately 7%) were found to be inactive in β -galactosidase *in vitro* screens. In the pre-selection pool, 20% (41/206) of the *cat-lacZY* fusions were $LacZ^+$ *in vitro* (light blue) and 80% (165/206) were $LacZ^-$ (white). In contrast, after two rounds of chloramphenicol selection, 93% (216/231) were $LacZ^+$ and 7% (15/231) were $LacZ^-$. These strains likely contain fusions of *cat-lacZY* to *H. pylori* promoters which are active in macrophages but were not induced during *in vitro* growth.

Functional validation of IVET

To validate that the *in vivo* expressed pIVET11 and 12 proteins were under the control of *H. pylori* promoters,

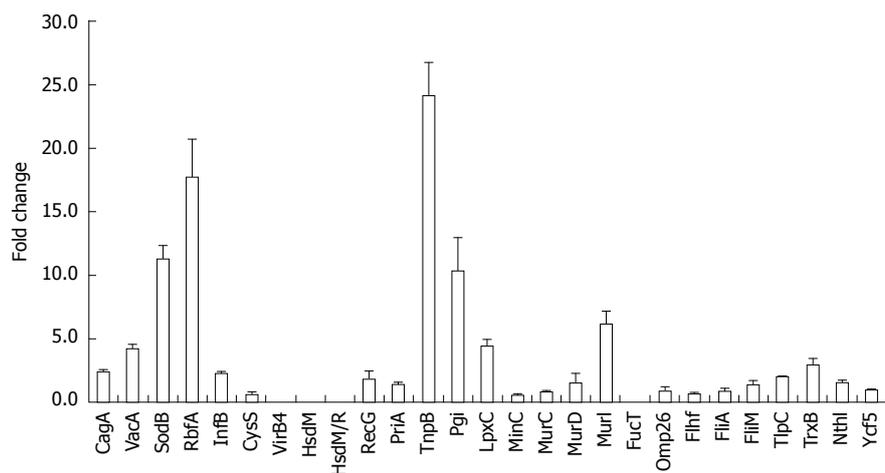

Figure 3 Gene expression of *Helicobacter pylori* induced by phagocytosis. Up-regulation and down-regulation of *Helicobacter pylori* *in vivo* induced genes expressed by macrophage engulfed bacteria.

we analyzed the nucleotide sequences and real time PCR results from infected mice (38 clones) and from infected RAW cells (15 clones). These clones contain the *cat-lacZY* reporter genes that are fused with genes in the *H. pylori* genome. The reporter genes should express in the host but not *in vitro*. Genomic DNA isolated from these clones was digested with *EcoRI*, *BamHI* and *HinDIII* and ligated to the compatible vectorette linkers. To sequence regions of genomic DNA flanking the inserted plasmid, we performed PCR using a primer homologous to the 5' end of *cat* gene in the IVET vectors and a primer unique to the vectorette linker. The resulting PCR products were sequenced directly or cloned and then sequenced.

Based on analysis of the nucleotide sequences of the individual inserts and comparison with the annotated genes of *H. pylori* in the GenBank database, we identified 31 genes. The list of the genes is shown in Table 3. The 31 genes included genes for virulence, cell envelope structures, motility, oxidative stress, nucleic acid and sugar metabolism, translation, protein synthesis and type IV secretion system. Four *ivi* conserved gene sequences did not show significant homology with any known genes in the Genbank database.

The real time PCR primers used to screen for *ivi* genes were tested using standard PCR conditions. Using *H. pylori* SS1 genomic DNA as the template, we found that only single PCR products resulted from each primer set. RNA was isolated from: (1) RAW 264.7 and *H. pylori* coculture; (2) *H. pylori* only; and (3) RAW 264.7 cells only. No product was obtained with the RNA of RAW 264.7 cells alone, confirming that there was no cross-reactivity that might have confounded the interpretation of data. Using 16s RNA as an internal control, we compared the expression profile of *H. pylori* and RAW 264.7 coculture with that of *H. pylori* only. The expression levels of genes differed from those observed in mice. We observed a 2-20 fold upregulation in *cagA*, *vacA*, *lpxC*, *murI*, *tlpC*, *trxB*, *sodB*, *tnpB*, *pgi*, *rbfA* and *infB* (Figure 3). In contrast, *hsdM*, *hsdM/R*, *fucT*, *virB4*, HP0426 and HP0427 were not

upregulated. The expression levels of the remaining *ivi* genes remained the same.

DISCUSSION

Characterization of microbial genes that are specifically induced during infection is important to the understanding of the mechanisms by which microbial pathogens cause disease. Intracellular pathogens have to evolve strategies to overcome the unfavorable environment met inside the host, which is very different in a culture broth outside the host. *H. pylori* colonizes the gastric mucosa during infection and synthesizes defense molecules to survive in the acidic gastric environment. Therefore, it is important to identify the genes of *H. pylori* that are up-regulated in the intracellular environment of the host.

IVET has previously been attempted in *Salmonella typhimurium*, *Vibrio cholerae* and *Pseudomonas aeruginosa*^[5,10,24-27]. In the present investigation, an antibiotic-based IVET has been applied in *H. pylori* for the first time. Novel *H. pylori* specific plasmids, pIVET11 and pIVET12 (Figure 1), were constructed by modifying the plasmid pIVET8^[10] and then used to construct the *H. pylori* library. Although this library does not contain the entire *H. pylori* genome, it will likely give insight into the type of genes up-regulated and hence necessary for the bacterium to evade host immune defenses. On the basis of chloramphenicol selection, 31 genes were identified (Table 3). These include genes responsible for a broad and varied group of cellular structures and functions: virulence, cell envelope structures, motility, oxidative stress, nucleic acid and sugar metabolism, translation, protein synthesis, type IV secretion system and few conserved and hypothetical proteins. Virulence genes such as *cagA* and *vacA* were induced and upregulated *in vivo*. *CagA* is translocated into gastric epithelial cells and induces numerous alterations in cellular signaling^[28-30]. Several *H. pylori* factors are known to interact directly with immune cells and modulate immune responses to *H. pylori*. One of these factors is *vacA* which

alters the function of T lymphocytes, B cells, macrophages and mast cells^[31,32].

H. pylori null mutant strains defective in the production of flagella are unable to colonize animal models^[33]. Flagella facilitate bacterial motility resulting in bacterial penetration of the mucus layer. Hence, upregulation of *flhF*, a global regulator of flagella biosynthesis and *fliA*, *fliM*, flagella motor switch proteins and *tlpC*, a methyl accepting chemotaxis protein is significant.

During host infection, animal pathogens are exposed to reactive oxygen species, such as superoxides, hydrogen peroxides, or organic peroxides, as a result of the release of lysosomal contents within inflammatory cells^[34]. In our IVET screen, proteins involved in oxidative stress protection, *trxB*, thioredoxin reductase, *sodB*, iron-dependent superoxide dismutase, *nth1*, endonuclease III and *ycf5*, cytochrome c biogenesis were upregulated. Thioredoxins have been implicated in a variety of physiological processes and biological pathways. In addition, they play a role in defense against oxidative stress, either by reducing protein disulfide bonds produced by various oxidants or by scavenging reactive oxygen species^[35]. Superoxide dismutase has been demonstrated to play an important role in oxidative stress defense mechanisms to counter iron-promoted DNA damage in *H. pylori*^[27].

Bacterial surface structures (adhesins, pilins, lipopolysaccharide, capsules) are often involved in direct contact with host cells, signaling molecules, and/or immune defenses (e.g., antibody). Hence the production and/or modification of many of these surface structures *in vivo* is often hypervariable in order to facilitate dissemination and to avoid immune defense mechanisms^[36]. In our system, several cell envelope structure-related proteins were identified. These included *fucT*, *lpxC*, *minC*, *murD*, *murC*, *murI*, and *omp26*.

Our IVET screening revealed the host-induced expression of several genes involved in nucleic acid metabolism, including *hsdM/R*, *hsdM*, *recG*, *priA* and *tnpB* (encodes the *H. pylori* IS606 transposase). This class of host-induced genes is involved in DNA synthesis and modification. Bacterial type II restriction-modification systems involve a restriction endonuclease and, a methyltransferase^[37,38]. The coordinated action of these enzymes mimics primitive immune defense mechanisms and protects bacterial cells from foreign DNA invasion^[39,40]. In addition, DNA methylation may play a role in gene regulation by inhibiting the interaction between regulatory proteins and their target DNA sequences^[41]. It may also be involved in the regulation of chromosomal DNA replication and gene expression^[42], transposon movement^[43], or DNA mismatch repair^[44]. A potential role for *recG* in recombination and in the rescue of stalled replication forks has been suggested^[45-47]. Additionally, recent studies suggest that *recG* provides a more general defense against pathological DNA replication^[19]. Cells lacking *priA* show a reduced viability and an increased sensitivity to DNA damage, phenotypes that are generally attributed to the deficiency in rescuing stalled or damaged forks^[48]. Genes involved in transposition have been upregulated in mi-

croorganisms during interaction with a eukaryotic host. *IS600* and *tnpF* genes were upregulated during interaction of *S. flexneri* with epithelial cells and HeLa monolayer respectively^[49,50].

Our IVET screens showed that genes involved in sugar metabolism (*pgi*), translation and regulation (*rbfA* and *infB*), as well as, protein and peptide synthesis (*cysS*) were also upregulated. We also detected upregulation of four hypothetical proteins: HP0426, HO0427, HP0423 and HP0424. These genes encode putative proteins with unknown functions and do not show significant homology to known proteins. This finding has been observed in most genome-wide analyses, including IVET studies^[7]. In a recent IVET study of *V. cholerae*, the largest class of *ivi* genes was found to encode hypothetical proteins^[51]. These results indicate that the function of many genes required for growth and survival in complex niches remain uncharacterized and additional functional analyses of these genes are needed.

Transcription profiles of all *ivi* genes were confirmed by real time PCR of *H. pylori* RNA isolated from *H. pylori* infected RAW 264.7 macrophages. These experiments were conducted to determine how well *in vitro* *ivi* genes in macrophages mirror *in vivo* *ivi* genes inside the host. The expression levels of several *ivi* genes in macrophages varied from the levels observed in mice. For example, *cagA*, *vacA*, *lpxC*, *murI*, *tlpC*, *trxB*, *sodB*, *tnpB*, *pgi*, *rbfA* and *infB* showed a 2-20 fold upregulation (Figure 3). However, *hsdM*, *hsdM/R*, *fucT*, *virB4*, HP0426 and HP0427 were not upregulated in the macrophage cell line, and there was no change in the expression of the remaining *ivi* genes. These data suggest a strong correlation between results obtained *in vitro* in the macrophage cell line and in the intact animal. Thus, the macrophages are suitable for the study of initial stages of host cell and bacterium interaction. However, the *in vivo* animal IVET screenings provide a broader and more comprehensive picture of *ivi* genes necessary for infection and colonization. In this study, we identified novel *H. pylori* *in vivo* induced genes that belonged to several functional gene families, including several well known virulence factors that are expressed by bacterium in infected mouse stomachs. The positive identification of these genes demonstrates that our IVET systems are powerful tools for studying *H. pylori* gene expression in the host environment, and points to potential *H. pylori* specific targets that allow *H. pylori* to circumvent host immune defenses.

ACKNOWLEDGMENTS

We would like to acknowledge Stephanie Marshall for her contribution in the construction of pIVET9 and pIVET10 plasmids.

COMMENTS

Background

Helicobacter pylori (*H. pylori*) chronically infect 50% to 90% of the world's population. Gastritis and ulcers are seen in 15% to 20% of the infected popula-

tion and gastric cancers occur in 1% to 2% of the same group. Identification of bacterial genes (virulence factors) accounting for *H. pylori* survival in the host is fundamental to understanding the mechanisms of pathogenesis.

Research frontiers

Several methods such as signature-tagged mutagenesis, selective capture of transcribed sequences, differential fluorescence induction and microarray analyses have been used to study bacterial genes that are expressed during infection of animal hosts. These strategies are often limited by their inability to reproduce the complex environments encountered by pathogens in their hosts. To overcome these limitations, *in vivo* expression technology (IVET) has been developed. IVET has resulted in the identification of bacterial genes involved in infection, survival and pathogenesis.

Innovations and breakthroughs

IVET has been utilized extensively in *Salmonella typhimurium*, *Vibrio cholerae* and *Pseudomonas aeruginosa* to identify potential virulence factors. This technology has not been exhaustively utilized in *H. pylori* because of limitations imposed by the genetic intractability of this bacterium. Recombination-based *in vivo* expression technology (RIVET) approach has been used with *Vibrio cholerae*, *Lactobacillus plantarum*, *Staphylococcus aureus*, *Mycobacterium tuberculosis*, and *Bordetella pertussis*. RIVET is a variant of the original IVET in which a promoter transcriptional event is captured permanently as a conversion of the infecting strain from antibiotic resistant to antibiotic sensitive. Recently, RIVET has been utilized to identify *H. pylori* genes important for host colonization. In this study, authors have developed IVET approach for screening *H. pylori* genes that are specifically expressed *in vivo*.

Applications

The study results suggest that this IVET approach may provide powerful tools for studying *H. pylori* gene expression in the host environment. Identification of *H. pylori in vivo* induced genes will provide an improved understanding of metabolic, physiological, and genetic factors that contribute to survival and virulence of this pathogen. It may also lead to the identification of possible vaccine targets.

Terminology

IVET is a genetic method used to determine which bacterial genes are upregulated when bacteria invade the stomach of a host.

Peer review

This study demonstrated the efficacy of *in vivo* expression technology for screening *H. pylori* genes that are expressed *in vivo* in mice and macrophage hosts. In this study, genes responsible for a broad group of functions were identified. Although no screen of this type can provide an exhaustive account of all genes induced *in vivo*, it will likely give insight into the type of genes upregulated and hence necessary for the survival of *H. pylori* in gastric mucosa.

Abstract

AIM: To examine the relative prevalence and temporal variation of dysphagia etiologies in patients undergoing upper endoscopy (EGD) over the past decade.

METHODS: EGDs with the indication of dysphagia at an urban, university medical center in 1999, 2004 and 2009 were retrospectively identified from the electronic medical record. The entire patient chart, including EGD, pathology, manometry, radiographic and clinician reports, was reviewed for demographic and clinical data and to determine the etiology of dysphagia. The number of EGDs in which an esophageal biopsy was performed was also noted. Gastroesophageal reflux disease (GERD) as a cause of dysphagia independent of peptic stricture was defined by symptoms with erosive esophagitis or symptom response to proton pump inhibition (PPI). Cases of eosinophilic esophagitis (EoE) were defined by an appropriate clinical history and his-

tological criteria of ≥ 15 eosinophils per high powered field. PPI-responsive esophageal eosinophilia was not routinely reported prior to 2008. Statistical analysis was performed using one-way analysis of variance to analyze for trends between 1999, 2004 and 2009 and a post-hoc Tukey analysis was performed following a significant main effect.

RESULTS: A total of 1371 cases (mean age 54 years, 43% male) met pre-specified inclusion criteria with 191, 504 and 675 cases in 1999, 2004 and 2009, respectively. Patients were older in 2004 compared to 2009 (mean \pm SD, 54.0 \pm 15.7 years *vs* 52.3 \pm 16.8 years, $P = 0.02$) and there were more males in 1999 compared to 2004 (57.5% *vs* 40.8%, $P = 0.005$). Overall, GERD (27.6%) and EoE (7.7%) were the most common identifiable causes of dysphagia. An unspecified diagnosis accounted for 21% of overall cases. There were no significant differences in the relative prevalence of achalasia or other motility disorders, peptic stricture, Schatzki's ring, esophageal cancer or unspecified diagnoses over the 10-year time period. There was, however, a decrease in the relative prevalence of GERD (39.3% *vs* 24.1%, $P < 0.001$) and increases in the relative prevalence of EoE (1.6% *vs* 11.2%, $P < 0.001$) and oropharyngeal disorders (1.6% *vs* 4.2%, $P = 0.02$) from 1999 to 2009. Post-hoc analyses determined that the increase in relative prevalence of EoE was significant between 1999 and 2009 as well as 2004 and 2009 (5.4% *vs* 11.6%, $P < 0.001$), but not between 1999 and 2004 (1.6% *vs* 5.4%, $P = 0.21$). On the other hand, the decrease in relative prevalence of GERD was significant between 1999 and 2009 and 1999 and 2004 (39.3% *vs* 27.7%, $P = 0.006$), but not between 2004 and 2009 (27.7% *vs* 24.1%, $P = 0.36$). There were also significantly more EGDs in which a biopsy was obtained in 1999 compared to 2009 (36.7% *vs* 68.7%, $P < 0.001$) as well as between 2004 and 2009 (37.5% *vs* 68.7%, $P < 0.001$). While total EGD volume did increase over the 10-year time period, the percentage of EGDs for the indication of dysphagia remained stable making increasing

upper endoscopy an unlikely reason for the observed increased prevalence of EoE.

CONCLUSION: EoE has emerged as a dominant cause of dysphagia in adults. Whether this was due to a rise in disease incidence or increased recognition is unclear.

Kidambi T, Toto E, Ho N, Taft T, Hirano I. Temporal trends in the relative prevalence of dysphagia etiologies from 1999-2009. *World J Gastroenterol* 2012; 18(32): 4335-4341 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i32/4335.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i32.4335>

INTRODUCTION

Dysphagia is a common indication for referral to a gastroenterology specialist, and is classified based on location as either oropharyngeal or esophageal^[1,2]. Common causes of oropharyngeal dysphagia include cerebrovascular accidents (CVA), radiation injury, and Parkinson's disease^[2]. Frequently identified etiologies of esophageal dysphagia include structural lesions such as peptic strictures, Schatzki's rings, and neoplasm as well as non-obstructive disorders such as gastroesophageal reflux disease (GERD) and esophageal motility disorders^[1,2]. Upper endoscopy (EGD) has largely supplanted upper gastrointestinal radiologic examination for the initial evaluation of dysphagia^[1]. Little published data exists reporting the frequency of the various dysphagia etiologies for patients undergoing EGD.

Recent cross-sectional studies have demonstrated that eosinophilic esophagitis (EoE) is an important and emerging cause of dysphagia^[3-6]. These studies, examining patients undergoing an EGD in the evaluation of dysphagia, report an EoE prevalence between 6.5% and 15%^[3-5]. The studies did not report the frequency of additional etiologies of dysphagia nor whether the prevalence of EoE has changed over time. A histologic analysis of 296 esophageal biopsies from children in Australia demonstrated an 18 fold increase in the prevalence of EoE from 1995 to 2004, but did not include analysis of clinical or endoscopic data^[7]. A population based study from Olten County, Switzerland recently reported a 12 fold increase in the prevalence of EoE from 1989 to 2009^[8].

The aims of this study were to examine the prevalence of various etiologies of dysphagia amongst patients undergoing EGD and to determine the relative prevalence of EoE over the past decade.

MATERIALS AND METHODS

We performed a retrospective review of patients undergoing EGD for the indication of dysphagia at a single, urban, academic medical center, with the goal of determining the relative prevalence of dysphagia-related diagnoses. Endoscopy at this medical center is performed by both academic and private practice gastroenterologists (approximately two-thirds academic faculty and one-third private practice).

Patient population

Patients were identified by a query of the electronic medical record (EMR) for all adult inpatients and outpatients who had an EGD ordered with an associated ICD-9 code for dysphagia (787.2) from 1999 through 2010. For ease of data analysis, our search was narrowed to the years of 1999, 2004 and 2009. The total number of EGDs performed for all indications was extracted to assess endoscopy volume. Clinician office and EGD reports were reviewed to confirm that dysphagia was the actual indication for the EGD and that an EGD was, in fact, performed. Cases were excluded if the indication for the EGD was found not to be dysphagia, if a scheduled EGD was never performed, or if the EGD report was absent from the EMR. If a particular patient had multiple EGDs during this time period, that patient was included in the earliest year but final diagnosis was still determined based on the entirety of their medical record. The medical center completed its transition to an EMR in 2003 and medical records prior to this date were uploaded retrospectively to the database, leading to numerous absences of reports prior to 2003.

Data collection

Pertinent demographic data were collected for the patients who met inclusion criteria. EGD, pathology, manometry, radiographic, and clinician consultation notes were reviewed to determine the etiology of dysphagia. When necessary and available, records from subsequent years were reviewed to determine the final diagnosis. The number of EGDs in which an esophageal biopsy was performed was also noted.

Non-obstructive dysphagia related to GERD was diagnosed by the exclusion of esophageal stricture and response of dysphagia to treatment of acid reflux with proton pump inhibition (PPI)^[9]. All-GERD related dysphagia was the sum of non-obstructive GERD and peptic strictures. Non-obstructive dysphagia related to GERD was diagnosed by the exclusion of esophageal stricture and response of dysphagia to treatment of acid reflux. Cases of EoE were defined by an appropriate clinical history (i.e., dysphagia) and ≥ 15 eosinophils per high powered field (EOS/HPF) on histological review. PPI-responsive esophageal eosinophilia was not routinely reported prior to 2008 and was therefore not analyzed separately from GERD as recommended by the 2007 and 2011 consensus statements on EoE^[10,11]. Achalasia was defined by

characteristic manometric features as well as supportive endoscopic and radiologic abnormalities. Additional abnormal esophageal dysmotility assessed by manometry, such as nutcracker esophagus, diffuse esophageal spasm, or aperistalsis, was grouped as “other motility disorder” and considered the etiology of dysphagia only if subsequent clinician notes specifically attributed dysphagia to esophageal dysmotility. Schatzki’s rings were considered the etiology of dysphagia only if the EGD report explicitly stated that they contributed to the dysphagia; in cases where the EGD or clinician report specifically stated that the Schatzki’s ring was widely open, non-obstructing, or not likely to be contributing to the dysphagia, an alternative diagnosis was considered. Post-operative and iatrogenic etiologies included anastomotic strictures, marginal ulcers, and symptomatic type III paraesophageal hernias. Oropharyngeal disorders included CVA, traumatic brain injury, and neurologic disorders such as amyotrophic lateral sclerosis or multiple sclerosis in which patients had an unremarkable endoscopic exam along with either an abnormal radiologic swallow study and, or an abnormal swallow evaluation by a speech and language pathologist. Functional dysphagia was deemed the final diagnosis after all other organic causes were ruled out based on negative EGD, pathology reports, and motility studies, and if the clinician’s reports indicated that the patient’s dysphagia was functional. Given its low prevalence, it was included in the “other” category. In cases where review of the chart was unable to determine an etiology, the diagnosis was considered “unspecified”.

Statistical analysis

Data were analyzed using statistical software, SPSS version 20 (IBM SPSS Inc, Chicago, IL). The number of excluded EGDs was expressed as a percentage of the total number of EGDs for dysphagia in that year. The total number of included EGDs for dysphagia was the difference between the total number of EGDs for dysphagia and the excluded EGDs for dysphagia. The number of EGDs in which an esophageal biopsy was performed and the relative prevalence of the various etiologies for dysphagia were expressed as a percentage of the included EGDs for dysphagia in the given year.

One-way analysis of variance was used to analyze for trends between 1999, 2004 and 2009. Following the significant main effect, a Tukey *post-hoc* analysis was performed. A *P* value of less than 0.05 was considered statistically significant. The study was approved by the Northwestern University Institutional Review Board.

RESULTS

A total of 1478 patients were identified who had an EGD ordered for dysphagia, with 237, 513 and 728 cases in 1999, 2004 and 2009, respectively. A total of 1371 cases met inclusion criteria with 191, 504 and 675 cases in 1999, 2004 and 2009, respectively (Table 1). In 1999, 46 cases (19.4%) were excluded because EGD reports were

¹Including: Cricopharyngeal bar, globus, functional dysphagia, diverticulum, scleroderma and epidermolysis bullosa with proximal stricture. Statistical analysis performed using one-way analysis of variance. GERD: Gastroesophageal reflux disease; EGDs: Upper endoscopies; NS: Non-significant.

unavailable in the EMR (44 cases) or the indication for EGD was found to be upper gastrointestinal bleeding. In 2004, 9 cases (1.8%) were excluded because review of the EMR revealed the indication for EGD was either an upper gastrointestinal bleed or iron-deficiency anemia. In 2009, 53 cases (7.3%) were excluded because an EGD was not performed (46 cases) or because the indication was found not be dysphagia on review of the chart. There was a significant difference in the number of excluded EGDs between 1999, 2004, and 2009 (*P* < 0.001).

The mean age of the patients included in the study was 53.5 years (SD = 16.3 years) with 43% of the patients being men (*n* = 591). Patients were older in 2004 compared to 2009 (*P* = 0.04) and there were more men in 1999 compared to 2004 (*P* = 0.003).

Overall, non-obstructive GERD (27.6%) and EoE (7.7%) were the most common identifiable causes of dysphagia over the ten year period. An unspecified diagnosis accounted for 21.0% of cases. Other motility disorders (4.7%), achalasia (4.5%) and dysphagia secondary to a post-operative/miscellaneous etiology (4.5%) were other important identifiable causes.

The relative prevalence of the various etiologies for dysphagia over the ten year time period is shown in Table 1 and Figure 1. When analyzing for temporal trends, there was a decrease in the relative prevalence of non-obstructive GERD (39.3% in 1999 and 24.1% in 2009; *P* < 0.001), and increases in the relative prevalence of EoE (1.6% in 1999 and 11.2% in 2009, *P* < 0.001) and

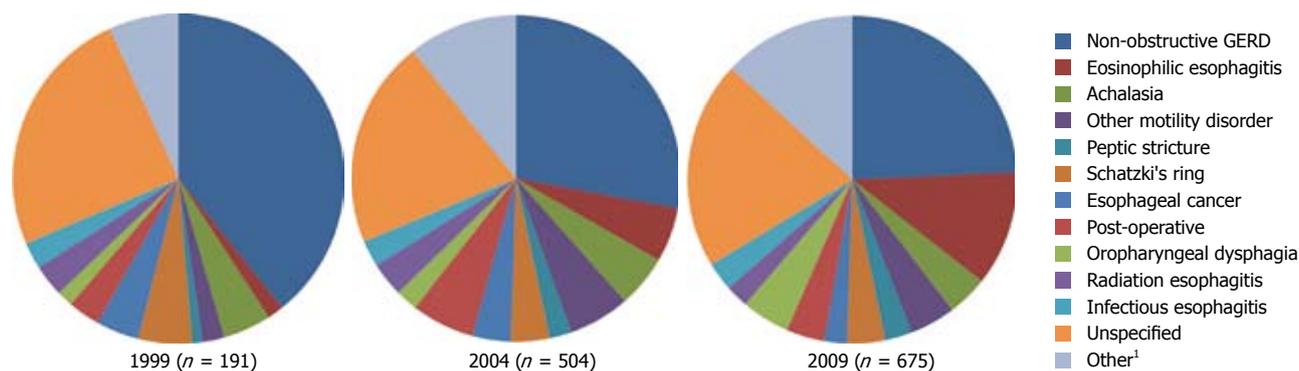

Figure 1 Trends in relative prevalence of dysphagia etiologies from 1999-2009. GERD: Gastroesophageal reflux disease. ¹Including cricopharyngeal bar, globus, functional dysphagia, diverticulum, scleroderma, and epidermolysis bullosa with proximal stricture.

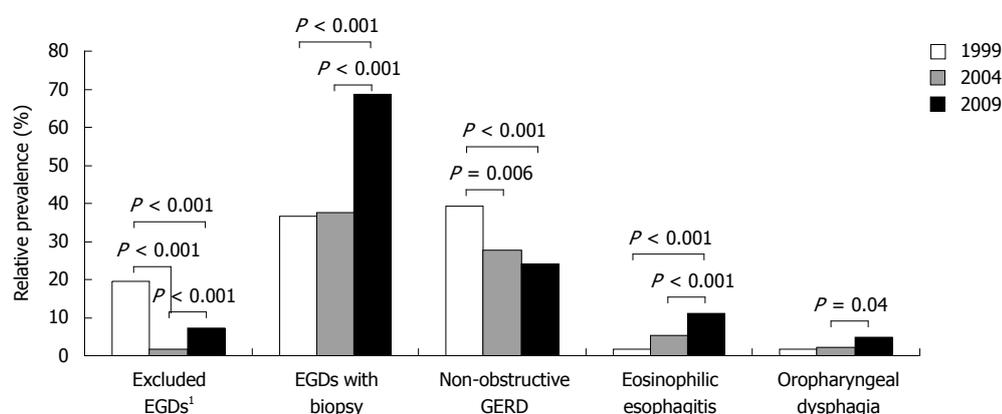

Figure 2 Selected post-hoc Tukey analysis. ¹Expressed as percentage of total upper endoscopies for dysphagia in the given year. GERD: Gastroesophageal reflux disease; EGD: Upper endoscopy.

oropharyngeal disorders (1.6% in 1999 and 4.7% in 2009; $P = 0.02$). There was no significant difference in the relative prevalence of all-GERD related dysphagia (non-obstructive GERD and peptic strictures) over the 10-year time period ($P = 0.07$).

Select post-hoc Tukey analyses are shown graphically in Figure 2. There was a decrease in the relative prevalence of non-obstructive GERD from 1999 to 2004 ($P = 0.006$) as well as from 1999 to 2009 ($P < 0.001$). The increase in the relative prevalence of EoE between 1999 and 2009 was significant ($P < 0.001$) as was the increase between 2004 and 2009 ($P < 0.001$). Of the three patients in 1999 ultimately diagnosed with EoE who had an EGD for dysphagia, one patient was actually diagnosed with EoE in 2003 and another patient was diagnosed in 2005. As specified in the methods section, these patients were included in the 1999 cohort. The increase in relative prevalence of oropharyngeal disorders was significant between 2004 and 2009 ($P = 0.04$). There was no significant difference in the relative prevalence of achalasia, other esophageal motility disorders, peptic strictures, Schatzki's rings, esophageal cancer, or unspecified diagnosis over the ten year time period (Table 1 and Figure 1).

The percentage of EGDs in which an esophageal biopsy was obtained increased over the time period ($P < 0.001$). As shown in Figure 2, this increase was significant

between 1999 and 2009 ($P < 0.001$) as well as between 2004 and 2009 ($P < 0.001$); there was no significant difference in the proportion of EGDs in which a biopsy was performed in 1999 compared to 2004 ($P = 0.98$). Total EGD volume at the medical center also increased in the ten year time period with 2456 EGDs performed in 1999, 5944 in 2004 and 9071 in 2009. The percentage of EGDs performed for the indication of dysphagia remained stable at 8%-9%.

DISCUSSION

This is the first study to describe the relative prevalence of distinct etiologies of dysphagia in an adult patient population undergoing EGD. In our cohort, non-obstructive GERD was the most common, identifiable cause of dysphagia but its relative prevalence decreased over the past decade while EoE was the second most common identifiable cause and its relative prevalence increased from 1.6% in 1999 to 11.2% in 2009. Interestingly, the relative prevalence of all-GERD related dysphagia remained constant. The number of EGDs performed for the indication of dysphagia as a percentage of total EGD volume remained stable at 8%-9%. However, the proportion of EGDs with esophageal biopsies obtained did increase from 36.7% in 1999 to 68.7% in 2009.

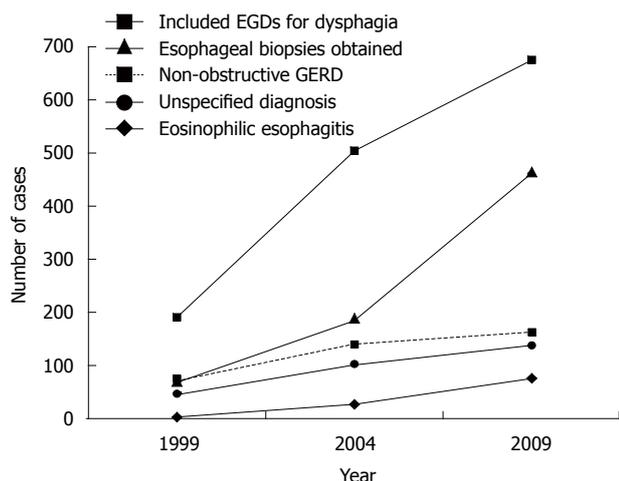

Figure 3 Trends in upper endoscopy volume, esophageal biopsies, and dysphagia diagnoses. GERD: Gastroesophageal reflux disease; EGDs: Upper endoscopies.

The emergence of EoE as a leading cause of dysphagia is of interest and supports earlier studies. The relative prevalence of EoE in 2009 of 11.2% is consistent with the results of recent prospective, short-term, cross-sectional studies^[3-5] that reported an EoE prevalence ranging from 10%-15% in patients with dysphagia undergoing EGD. While these studies reported EoE prevalence, they did not report the other etiologies of dysphagia in the non-EoE patients. In these studies, EoE was defined by histological criterion of ≥ 20 EOS/HPF, which was more stringent than our definition of ≥ 15 EOS/HPF. In two of the studies^[4,5], all patients underwent esophageal biopsies regardless of endoscopic findings while 59% of the patients in the other study^[3] underwent esophageal biopsy. In all of the studies, a specific protocol for obtaining multiple biopsies along the length of the esophagus (midesophagus *vs* proximal and distal) was employed; in our retrospective study, a standardized biopsy strategy could not be used. Regardless of the differences in study designs, it is interesting to note that the high prevalence of EoE in our study was similar to that reported in other prospective studies of patients with dysphagia undergoing EGD.

The rise in the relative prevalence of EoE over the past decade is another interesting finding of this study. In a retrospective epidemiological study of Olmsted County, Prasad *et al*^[6] reviewed pathology specimens that mentioned “eosinophils” and/or “esophagitis” from 1976 to 2005 and found that there was an increase in the incidence of EoE over time ($P < 0.001$). The histological criterion used in that study was ≥ 15 EOS/HPF and esophageal symptoms were assessed by review of the medical record. However, the authors noted a parallel increase in endoscopy utilization over the three decades and raised the possibility that recognition bias from increased endoscopy volume contributed to the rise in EoE diagnoses. In contrast to our cohort, the absolute number of just 78 EoE cases in the Olmsted County population

was quite small. Additionally, the population in the study was not limited to patients with dysphagia.

The largest EoE prevalence study to date utilized a national pathology database to identify 363 cases of EoE from biopsy specimens taken between January 2002 and May 2006 with “eosinophilic” in the diagnosis and/or comment text^[12]. In their subset analyses of pathology specimens from 12 465 patients who underwent an EGD for the indication of dysphagia, they found an increasing prevalence of EoE from 2002 to 2005 ($P < 0.001$), with a prevalence of 0.1% in 2002 and 1.9% in 2005. This study had many important differences from ours. Cases were identified from a pathology database and the timeframe studied was shorter. Additionally, dysphagia as the indication for EGD was not confirmed by review of the medical chart, which, as seen in our study, would have potentially excluded a number of cases. Lastly, only EGDs for dysphagia in which a biopsy was obtained were included in their study, which is only a subset of the total number of EGDs performed for dysphagia although it is surprising that the reported prevalence was much lower than that of the present study.

It is difficult to ascertain whether the increase in relative prevalence of EoE seen in our study is due to a true rise in population prevalence or secondary to heightened recognition from increased numbers of biopsies or increased clinician awareness of the disorder. Interestingly, the prevalence of an “unspecified” cause of dysphagia remained constant at 20%-24% over the measured time period implying that EoE was not simply misclassified as “unknown” a decade ago. It is possible that EoE was initially misclassified as non-obstructive GERD and then properly classified as EoE with increased awareness of the disease, although each patient’s entire EMR was reviewed so that if a subsequent diagnosis of EoE was made at our medical center it would have been detected. However, another plausible explanation for the decrease in prevalence of non-obstructive GERD is the increasing utilization of PPIs by both patients (over-the-counter) and primary care physicians so that only a smaller percentage of PPI-refractory patients are undergoing EGDs.

Increased recognition of EoE may explain the rise in prevalence given the increase in esophageal biopsies obtained, as shown in Figure 3. Lending credibility to this theory is the fact that as the number of biopsies increased between 1999 and 2009 as well as between 2004 and 2009, the prevalence of EoE also increased (Figure 2). On the other hand, when there was not a significant increase in biopsies, such as between 1999 and 2004, the relative prevalence of EoE also did not significantly increase. In contrast to the study by Prasad *et al*^[6] which suggested that increased endoscopy volume may have contributed to increased recognition of EoE, our study provides more specific insight into the issue of increased recognition by identifying trends in the number of biopsies taken.

The stable and relatively low overall prevalence of esophageal cancer (3.1%) was surprising given the rise

in esophageal adenocarcinoma seen in the past five decades^[13,14]. One possible explanation for the low prevalence of esophageal cancer seen in our study is that our medical center is a tertiary care center and patients with esophageal cancer causing dysphagia were being diagnosed in the community and referred directly to oncology and surgery.

The mechanism for non-obstructive dysphagia in GERD is not clear. Several studies have demonstrated that non-obstructive dysphagia in GERD is common and improves with therapy directed at acid reflux^[15,16]. Manometric abnormalities are commonly cited as explanations for this entity^[17], but the role of altered visceral sensation as well as diminished esophageal wall compliance owing to inflammation have not been adequately examined. In a study by Triadafilopoulos^[18], dysphagia was more commonly associated with severity of acid reflux on pH monitoring or erosive esophagitis with only a minority having abnormal motility.

The primary mechanism for dysphagia in EoE is esophageal remodeling secondary to subepithelial fibrosis that is identified in over 90% of patients^[11]. Additionally, structural alterations of the esophageal luminal diameter in the form of focal strictures, esophageal rings or narrow caliber esophagus can be identified in most adults with EoE. In fact, the impact of these structural alterations in EoE have been verified and shown to decrease esophageal mural compliance and lead to significantly reduced esophageal distensibility in EoE patients compared to normal controls^[19]. Furthermore, there is indirect evidence of the role of fibrostenotic complications in the pathogenesis of dysphagia in EoE given the effectiveness of esophageal dilation in the treatment of dysphagia in EoE^[20,21].

There were several important limitations to this study. The large number of excluded cases in 1999 was due to unavailable data in the EMR (given the transition from paper charting in 2003) while the excluded cases in 2009 were because the EGDs were not performed; both of these pitfalls were largely attributable to the retrospective nature of this study. The large number of excluded cases and the difference in age of the patients in 2004 compared to 2009 raise the question of whether the groups being analyzed were subsets of the same larger population. The retrospective nature of the study did not allow for a standardized protocol for esophageal biopsies, which may have led to confounding by indication since biopsies were more likely to be obtained when the EGD showed the classic EoE features^[3,11] of rings, linear furrows, and exudates. The setting of the study was a single, urban, tertiary care center with active esophageal motility and EoE research, so there was the potential for loss to follow-up outside of the medical center in addition to referral bias that limits the generalizability of the results to other practice settings. The utilization of EGD as the primary modality for the evaluation of dysphagia may affect the generalizability of the results to populations where dysphagia may be assessed with barium esophagrams. In addition, many referred patients may have had

a diagnostic endoscopy for dysphagia performed at an outside facility that already established the etiology. When undergoing a follow up EGD at our medical center, such patients may have had listed indications for EGD such as “GERD” or “unspecified esophagitis” and would have been potentially excluded in our analysis.

Another potential problem with this study was how EoE was defined. It is likely that PPI-responsive esophageal eosinophilia was included in the EoE cohort^[11]. Our definition of EoE did not require the exclusion of GERD with a trial of PPI therapy or a normal pH monitoring study as suggested by the 2007 consensus definition^[10] and its 2011 update^[11], since this criterion was not applied widely prior to 2008. The understanding of interactions between GERD and EoE has become increasingly complex and remains controversial^[22,23]. However, significant esophageal eosinophilia (≥ 15 EOS/HPF) is uncommon in GERD, being demonstrated in less than 2% of patients in one large study^[24]. While a significant proportion of patients with suspected EoE respond to PPI therapy, this response may not be specific for acid reflux^[25] and may occur with an allergic pattern of inflammation^[26].

In summary, the relative prevalence of EoE in patients undergoing EGD for dysphagia increased from 1.6% to 11.2% over the past decade. EoE has emerged as one of the dominant, identifiable causes of dysphagia in adults, second only to GERD. Prospective, long-term studies are needed to discern whether this is due to a true increase in disease prevalence or increased recognition.

COMMENTS

Background

Dysphagia is a commonly encountered clinical problem and limited data exist regarding the prevalence of dysphagia etiologies. Recently, cross-sectional studies have demonstrated that eosinophilic esophagitis (EoE) is an important cause of dysphagia.

Research frontiers

Upper endoscopy (EGD) is critical in the evaluation and management of patients with dysphagia. To the knowledge, this is the first study to integrate clinical, pathological, EGD, manometry, and imaging reports in order to systematically report the relative prevalence of all dysphagia-related diagnoses in a large series of patients undergoing EGD, which provides an evidence-based differential diagnosis for the practicing gastroenterologist. Cross-sectional studies have reported on the prevalence of EoE in patients with dysphagia, however these studies have not looked at EoE prevalence over time and with relation to other dysphagia diagnoses. This study demonstrated that between 1999 and 2009, the relative prevalence of gastroesophageal reflux disease (GERD) decreased while the relative prevalence of EoE increased.

Innovations and breakthroughs

Recent studies have reported an EoE relative prevalence between 10%-15% amongst patients undergoing EGD for dysphagia. This study shows that the relative prevalence of EoE has risen significantly from 1.6% to 11.2% over the past decade making it the second most common identifiable cause of dysphagia. Furthermore, the authors' *post-hoc* analysis show that in contrast to previous studies, the proportion of EGDs for dysphagia remained stable over the measured time, but the percentage of EGDs in which a biopsy was performed did increase significantly, providing a plausible mechanism for increased recognition of EoE.

Applications

By providing an evidence based differential diagnosis, this study informs clinicians' decision making in the evaluation of dysphagia. Given the possible inclu-

sion of proton pump inhibition (PPI)-responsive esophageal eosinophilia in the EoE cohort and the increasing proportion of EGDs with biopsies, prospective, long-term studies would be beneficial to discern whether the findings were due to a true increase in EoE prevalence or increased recognition.

Terminology

EoE is a chronic, immune/antigen driven inflammatory disease of the esophagus defined by clinical symptoms of esophageal dysfunction as well as pathological criteria of ≥ 15 eosinophils per high powered field. Current guideline recommendations require exclusion of other causes of esophageal eosinophilia, such as GERD, to make the diagnosis of EoE. By acknowledging the accumulating body of evidence showing that PPIs have effects beyond acid suppression alone, a new disease entity termed "PPI-responsive esophageal eosinophilia", which is distinct from GERD, has been recognized.

Peer review

The authors examined the relative prevalence and temporal variation of dysphagia etiologies in patients undergoing EGD over the past decade and found a decrease in the prevalence of GERD and increases in the prevalence of EoE and oropharyngeal disorders. This is an interesting research.

Abstract

AIM: To investigate national trends in distal pancreatectomy (DP) through query of three national patient care databases.

METHODS: From the Nationwide Inpatient Sample (NIS, 2003-2009), the National Surgical Quality Improvement Project (NSQIP, 2005-2010), and the Surveillance Epidemiology and End Results (SEER, 2003-2009) databases using appropriate diagnostic and procedural codes we identified all patients with a diagnosis of a benign or malignant lesion of the body and/or tail of the pancreas that had undergone a partial or distal pancreatectomy. Utilization of laparoscopy was defined in NIS by the International Classification of Diseases, Ninth Revision correspondent procedure code; and in NSQIP by the exploratory laparoscopy or unlisted procedure current procedural terminology

codes. In SEER, patients were identified by the International Classification of Diseases for Oncology, Third Edition diagnosis codes and the SEER Program Code Manual, third edition procedure codes. We analyzed the databases with respect to trends of inpatient outcome metrics, oncologic outcomes, and hospital volumes in patients with lesions of the neck and body of the pancreas that underwent operative resection.

RESULTS: NIS, NSQIP and SEER identified 4242, 2681 and 11 082 DP resections, respectively. Overall, laparoscopy was utilized in 15% (NIS) and 27% (NSQIP). No significant increase was seen over the course of the study. Resection was performed for malignancy in 59% (NIS) and 66% (NSQIP). Neither patient Body mass index nor comorbidities were associated with operative approach ($P = 0.95$ and $P = 0.96$, respectively). Mortality (3% vs 2%, $P = 0.05$) and reoperation (4% vs 4%, $P = 1.0$) was not different between laparoscopy and open groups. Overall complications (10% vs 15%, $P < 0.001$), hospital costs [44 741 dollars, interquartile range (IQR) 28 347-74 114 dollars vs 49 792 dollars, IQR 13 299-73 463, $P = 0.02$] and hospital length of stay (7 d, IQR 4-11 d vs 7 d, IQR 6-10, $P < 0.001$) were less when laparoscopy was utilized. One and two year survival after resection for malignancy were unchanged over the course of the study (ductal adenocarcinoma 1-year 63.6% and 2-year 35.1%, $P = 0.53$; intraductal papillary mucinous neoplasm and neuroendocrine 1-year 90% and 2-year 84%, $P = 0.25$). The majority of resections were performed in teaching hospitals (77% NIS and 85% NSQIP), but minimally invasive surgery (MIS) was not more likely to be used in teaching hospitals (15% vs 14%, $P = 0.26$). Hospitals in the top decile for volume were more likely to be teaching hospitals than lower volume deciles (88% vs 43%, $P < 0.001$), but were no more likely to utilize MIS at resection. Complication rate in teaching and the top decile hospitals was not significantly decreased when compared to non-teaching (15% vs 14%, $P = 0.72$) and lower volume hospitals (14% vs 15%, $P = 0.99$).

No difference was seen in the median number of lymph nodes and lymph node ratio in N1 disease when compared by year ($P = 0.17$ and $P = 0.96$, respectively).

CONCLUSION: There appears to be an overall underutilization of laparoscopy for DP. Centralization does not appear to be occurring. Survival and lymph node harvest have not changed.

INTRODUCTION

The first open distal pancreatectomy was reported by Billroth in 1884^[1,2]. In the early 1900s, Finney^[1] and Mayo^[3] reported the first open case series and description of their respective techniques. The laparoscopic approach was first introduced to general surgery in the 1980s for gallbladder resection, and quickly adopted as an operative approach for resection of other solid organs. This adoption of laparoscopy has been slower in pancreatic surgery due to the complexity of the procedure, low number of cases, the level of technical skills required by the surgeon in manipulating the important vascular structures, and the lower acceptance of this approach in the resection of malignant lesions.

The use of laparoscopy in distal pancreatectomy was first described in a porcine model by Soper *et al*^[4] in 1994. Soon after this reports of laparoscopy in human patients were reported^[5], though for many years laparoscopy was used principally for staging of malignancy. Multiple reports have shown that laparoscopic pancreatic resection is safe and feasible for benign and malignant pancreas lesions^[6-9]. The known benefits of laparoscopic approach such as lower intraoperative blood loss, less pain and analgesic requirements, earlier return of bowel function, shorter recovery and hospital stay have also been shown in pancreas surgery, including high quality clinical trials^[9-13]. Importantly, it has been reported that complication rates are lower after laparoscopic resection^[9,14].

There has been recent interest in improving the oncologic aspects of distal pancreas resection with attention

to margins and lymph node harvest, oncological surrogate markers for oncological resection. During open or laparoscopic distal pancreatectomy in patients with peripancreatic and retropancreatic invasion, negative surgical margins and appropriate lymph node harvest can be accomplished if wider and deeper dissection techniques are used^[15,16]. It is unclear if this attention to a more radical resection has affected the practice of oncological surgical resection. Strasberg *et al*^[16] reported that after open radical antegrade modular pancreatectomy procedure for patients with adenocarcinoma of the body and tail of the pancreas outside the capsule, a negative tangential margin was accomplished in 91% of the patients.

Recent reports have not shown any difference between open and laparoscopic operations in regards to these oncological surrogate markers^[8,10,11,15,16].

Due to the association of higher hospital procedure volumes and improved clinical outcomes in complex oncologic operations, there has been interest in centralizing pancreas resections to high-volume hospitals. Current reports have documented the trend towards centralization of pancreatic procedures in the last decade, and report an improvement in perioperative mortality when these procedures are performed in high-volume hospitals^[17-20]. It has not been determined whether this centralization has occurred with distal pancreas resection.

We sought to determine whether these concepts have gained any traction and are reflected in the trends of distal pancreas resections in the United States. Therefore we analyzed three major national databases with respect to inpatient outcome metrics, oncologic outcomes, and volume trends of patients with lesions of the neck and body of the pancreas that underwent a surgical resection.

MATERIALS AND METHODS

From the Nationwide Inpatient Sample (NIS, 2003-2009) and the National Surgical Quality Improvement Project (NSQIP, 2005-2010) databases we identified all patients with a diagnosis of a benign or malignant lesion of the body and/or tail of the pancreas that had undergone a partial or distal pancreatectomy. From the Surveillance Epidemiology and End Results (SEER, 2003-2009) database we identified patients with diagnosis of a malignant lesion in the body and tail of the pancreas that underwent an operative resection. Patients from the NIS database were identified by the correspondent International Classification of Diseases, ninth revision (ICD-9) diagnosis and procedure codes (Table 1). In the NSQIP database patients were identified by a combination of ICD-9 diagnosis codes and current procedural terminology (CPT) codes. Utilization of laparoscopy was defined in NIS by the ICD-9 correspondent procedure code; and in NSQIP by the exploratory laparoscopy or unlisted procedure CPT codes. In SEER patients were identified by the International Classification of Diseases for Oncology, third edition (ICD-O-3) diagnosis codes and the SEER Program Code Manual, Third Edition procedure

Table 1 International classification of diseases, ninth revision, and current procedural terminology codes used

ICD-9 codes	Description
Diagnosis	
Malignant neoplasms	
157.1	Body of pancreas
157.2	Tail of pancreas
157.3	Pancreas duct (Santorini and Wirsung)
157.4	Islets of Langerhans
157.8	Other specified sites of the pancreas (ectopic pancreatic tissue, malignant neoplasms of contiguous or overlapping sites of pancreas)
157.9	Pancreas, part unspecified
Benign neoplasms	
211.6	Benign neoplasms of pancreas except Langerhans
211.7	Benign neoplasm of islets of Langerhans
Procedure	
52.5	Partial pancreatectomy
52.52	Distal pancreatectomy
52.53	Radical subtotal pancreatectomy
52.59	Other partial pancreatectomy
54.21	Laparoscopy utilization
CPT codes	
48140	Pancreatectomy, distal subtotal, with or without splenectomy; without pancreaticojejunostomy
48145	Pancreatectomy, distal subtotal, with or without splenectomy; with pancreaticojejunostomy
48999	Unlisted procedure
49320	Exploratory laparoscopy
ICD-O-3 codes	
25.1	Body of the pancreas
25.2	Tail of the pancreas
SEER codes	
30	Partial pancreatectomy, NOS (distal pancreatectomy)
80	Pancreatectomy, NOS
90	Surgery, NOS

ICD-9: International Classification of Diseases, ninth revision; CPT: Current procedural terminology; ICD-O-3: International Classification of Diseases for Oncology, third edition; SEER: Surveillance Epidemiology and End Results; NOS: Not otherwise specified.

codes. Diagnoses and procedures codes are summarized in Table 1. Neither database enabled differentiation of whether laparoscopy was utilized for resection or diagnosis, and if diagnostic laparoscopy was followed by an open resection.

Patients' demographic characteristics included age, gender and body mass index. The comorbidities considered in NIS were acquired immune deficiency, alcohol abuse, iron deficiency anemia, rheumatoid arthritis, collagen vascular diseases, chronic blood loss anemia, congestive heart failure, chronic pulmonary disease, coagulopathy, uncomplicated diabetes, diabetes with chronic complications, hypertension, liver disease, fluid and electrolyte disorders, obesity, peripheral vascular disorders, renal failure and cardiac valve disease. Postoperative complications of interest in NSQIP were superficial surgical site infection, deep incisional surgical site infection, organ space surgical site infection, pneumonia, unplanned intu-

bation, pulmonary embolism, renal insufficiency, stroke with neurological deficit, coma, peripheral nerve injury, cardiac arrest requiring CPR, myocardial infarction, intra-operative or postoperative transfusions, deep vein thrombosis requiring therapy, sepsis and septic shock. The type of hospital (teaching or non-teaching) was assessed by a specific variable in the NIS database. We defined high volume hospitals as the top decile for volume (with ≥ 11 cases per year) over the course of this study (NIS).

Statistical analysis

In SEER, patient identification was performed using the Surveillance Research Program, National Cancer Institute SEER Stat software (seer.cancer.gov/seerstat) version 7.0.5.

In NIS and NSQIP patient identification and data analysis were performed with SAS software version 9.2. Statistical analysis of categorical variables was done with Fischer's exact test. Continuous variables were analyzed with Wilcoxon test as data distribution for non-parametric data. Kendall correlation was done to assess for significance between body mass index (BMI) and year of operation. Linear regression was used to analyze for correlation between mortality and morbidity with operation approach. Logistic regression was used to analyze for trend significance of laparoscopy utilization and pancreas procedures performed in high volume hospitals or teaching hospitals during the course of the study. Survival was analyzed through Kaplan-Meier method.

RESULTS

Demographics

From the NIS database 4242 patients were identified of which 2618 (62%) were female and 1612 (38%) were male; from NSQIP 2681 total patients were identified, 1581 (62%) female and 1093 (41%) male, and from SEER 1090 were identified, 599 (55%) female and 491 (45%) male. The mean age was 60.8 ± 15.1 years in NIS, 61.9 ± 13.8 years in NSQIP and 63.4 ± 13.3 years in SEER (mean \pm SD). In NSQIP the BMI was 28 ± 6.6 kg/m² (mean \pm SD), and 335 (13%) of the patients had a BMI ≥ 35 kg/m². The overall BMI increased significantly during the course of the study (NSQIP, $P = 0.04$). There were 72% patients in NIS that had one or more comorbidities.

Pathology of primary tumor and lymph nodes

In NIS there were 2486 (59%) malignant lesions and 1756 (41%) benign lesions, whereas in NSQIP 1759 (66%) were malignant and 922 (34%) benign. In SEER, when compared by year of operation, no difference was seen in the median number of lymph nodes resected and the lymph node ratio in N1 disease ($P = 0.17$ and $P = 0.96$, respectively). Results by year are summarized in Table 2. Overall, when grouped by lymph node ratio, 45% were $> 0-0.20$ LNR, 28% were $> 0.20-0.40$ LNR and 27% with LNR > 0.40 . The most common neoplasm types in patients that underwent an operation were adenocarcinoma

Table 2 Number of patients and lymph nodes resected per year from 2003 to 2008 (Surveillance Epidemiology and End Results database)

Year	Number of lymph nodes resected				Lymph node ratio in N1 disease			
	<i>n</i>	Median	1QR	3QR	<i>n</i>	Median	1QR	3QR
2003	88	8	2	14	31	0.27	0.14	0.50
2004	133	7	4	13	66	0.23	0.13	0.50
2005	133	7	3	14	62	0.23	0.10	0.50
2006	160	8	5	13	71	0.21	0.14	0.45
2007	179	8	4	15	85	0.25	0.13	0.36
2008	315	9	5	16	94	0.21	0.13	0.40

QR: Quartile range.

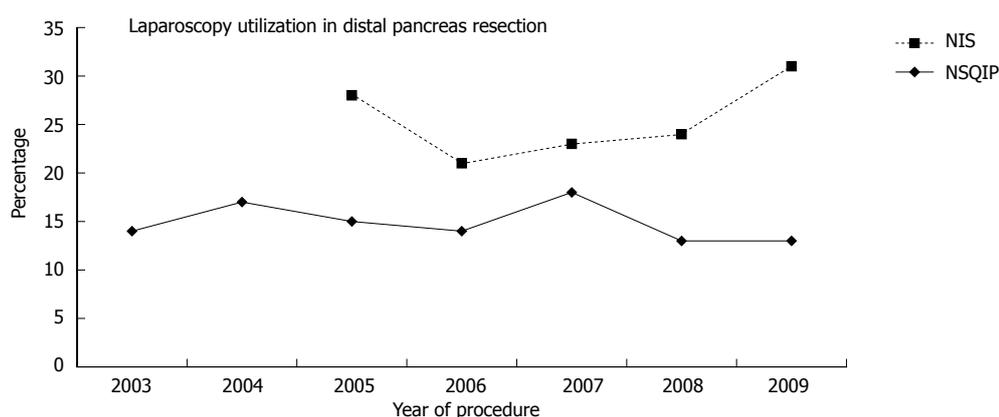

Figure 1 Yearly percentage of laparoscopic utilization in distal pancreas resection by both Nationwide Inpatient Sample and National Surgical Quality Improvement Project. NIS: Nationwide Inpatient Sample; NSQIP: National Surgical Quality Improvement Project.

in 52%, neuroendocrine (NE) in 27% and intraductal papillary mucinous neoplasm (IPMN) in 12% (SEER). Survival at 1 and 2 years was unchanged for resected patients with ductal adenocarcinoma of the pancreas (1-year 63.6% and 2-year 35.1%, $P = 0.53$ and $P = 0.21$, SEER). Over the time covered in the study neither the IPMN nor NE 1 and 2 year survival changed (1-year 90%, and 2-year 84%, $P = 0.15$ and $P = 0.25$, SEER).

Operative approach

Overall, laparoscopy was utilized in 15% (NIS) and 27% (NSQIP) patients and 85% NIS and 73% NSQIP patients were performed through an open approach. During the course of the study the overall use of laparoscopy did not increase in either NIS ($P = 0.51$) or NSQIP ($P = 0.54$) datasets (Figure 1).

In patients with a comorbidity there was no difference in the utilization of laparoscopy (15%) in comparison to patients without any medical comorbidities (NIS, $P = 0.96$). Patients' BMI was not associated with an operative approach (NSQIP, $P = 0.95$). Laparoscopy was utilized significantly more frequently in malignant lesions (21%) in comparison to benign lesions (8%; NIS, $P < 0.001$). In patients with malignant lesions spleen resection was performed more commonly (75%) in comparison to spleen preservation (25%; NIS, $P < 0.001$).

Utilization of laparoscopy did not correlate with type of hospital; utilization of laparoscopy occurs in 15% of

resection in teaching hospitals and 14% were performed in non-teaching hospitals (NIS, $P = 0.26$).

Outcome metrics

The rate of reoperation was not different between laparoscopy utilization (4%) and open approach (4%, NIS, $P = 1.0$).

Overall, postoperative complications were less frequent after laparoscopy utilization (10%) in comparison to open approach (15%, NIS, $P < 0.001$). Postoperative complications occurred more commonly after resection of malignant lesions (12% *vs* 8%, NIS, $P < 0.001$). After resection of a malignant lesion complications were less frequent after laparoscopy utilization when compared to open approach (9% *vs* 18%, NIS, $P < 0.001$). Overall, the most frequent complications were intra-abdominal infection in 9%, sepsis in 7% and superficial site infection in 4% (NSQIP).

The overall length of stay was shorter when laparoscopy was utilized in comparison to open approach both in NIS [laparoscopy: 7 d, interquartile range (IQR) 4-11 *vs* open: 7 d, IQR 6-10, $P < 0.001$] and NSQIP (laparoscopy: 6 d, IQR 4-8 *vs* open: 7 d, IQR 5-9, $P < 0.001$; Figure 2). In both NIS and NSQIP the overall median length of stay was shorter after resection of a benign lesions (NIS, 7 d, IQR 5-9 *vs* NSQIP, 6 d, IQR 5-8) in comparison to malignant lesion (NIS, 8 d, IQR 6-11 *vs* NSQIP, 7 d, IQR 5-9, $P < 0.001$), irrespective of approach.

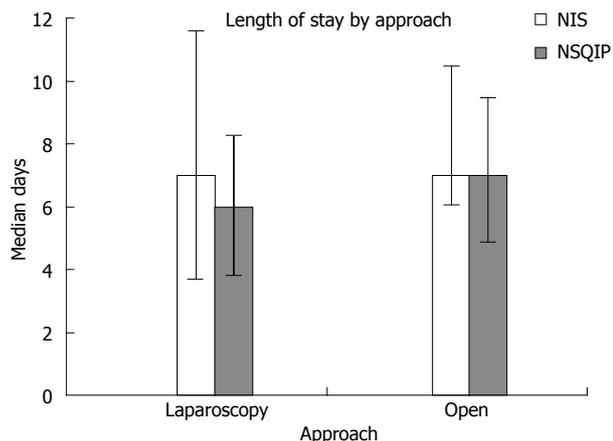

Figure 2 Median length of stay by approach. Bars represent interquartile ranges. NIS: Nationwide Inpatient Sample; NSQIP: National Surgical Quality Improvement Project.

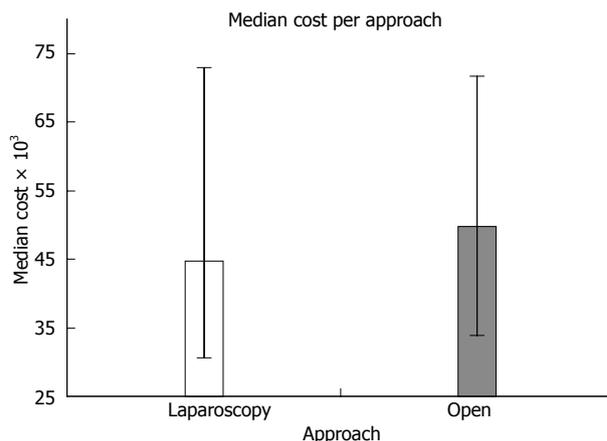

Figure 3 Median cost of procedures by approach (Nationwide Inpatient Sample, $P = 0.02$). Bars represent interquartile ranges.

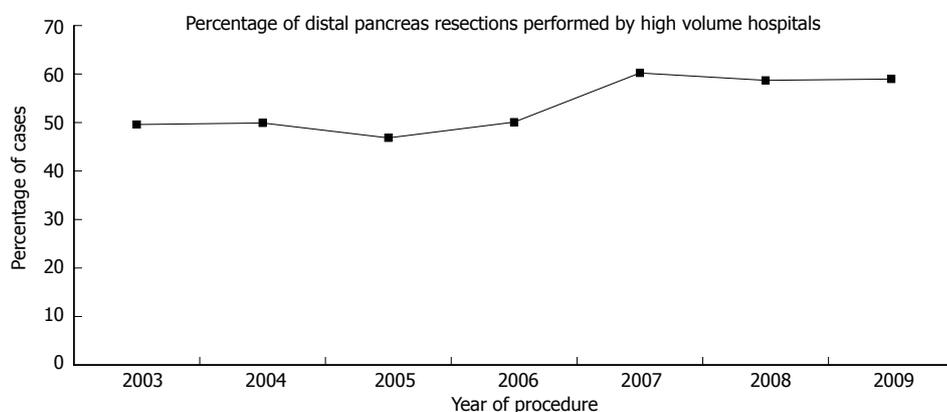

Figure 4 Percentage of distal pancreas procedures performed by high volume hospitals.

Regarding cost of care, there was a significantly lower total charge with laparoscopy utilization (median cost was 44 741 dollars, IQR 28 347-74 114 dollars) when compared to open approach (median cost was 49 792 dollars, IQR 13 299-73 463, NIS, $P = 0.02$) (Figure 3).

The hospital mortality rate was not different between laparoscopy utilization and open approach respectively (3% *vs* 2%, NIS, $P = 0.05$).

Hospital volume

Of the 903 hospitals included in NIS, the top decile for volume included hospitals that performed greater than 11 cases per year. Overall, the fraction of total procedures of the distal pancreas performed by high volume hospitals did not increase significantly during the course of the study (NIS, $P = 0.43$) (Figure 4). A significant majority of the teaching hospitals (88%) were in the top decile of hospitals for volume (NIS, $P < 0.001$).

No significant difference was seen in the frequency of postoperative complications when analyzed by deciles of hospital volume; the complication rate for resection in the top decile hospitals was 14% and 15% in the lower decile hospitals (NIS, $P = 0.99$). Neither was a significant

difference seen when analyzed by type of hospital; teaching hospitals and non-teaching hospitals had similar complication rate (15% *vs* 14% respectively, NIS, $P = 0.72$).

DISCUSSION

The NIS database is directed to determine health care utilization, access, charges, quality and outcomes^[21]. NSQIP focuses on perioperative complications, with a mandate to determine the quality of surgical care^[22] and SEER focuses on the incidence, prevalence and survival of cancer^[23]. Taking into consideration the goal of each database, we amalgamated the available information from these respected datasets to obtain an integrated and broad nationwide analysis of distal pancreas resection. Specifically we found NIS useful to assess laparoscopy utilization and comorbidities, comparison of costs and analysis by hospital type (teaching and non-teaching). On the other hand, the NSQIP database is more appropriate for detailed analysis of perioperative complications and patient risk factors. Oncological metrics and outcomes are best assessed by the SEER database. All of these have limitations, but we believe that the nationwide databases

are complementary to each other and it is helpful to present an analysis of them together. The limiting factor we encounter in both NIS and NSQIP is that procedures are grouped in broad categories, limiting the ability to distinguish the role of laparoscopy in each procedure. Though using the current coding system allowed for a general procedure analysis, an improvement in coding system that further categorizes procedures will facilitate a more detailed analysis.

Overall, we found that in patients where laparoscopy was utilized, the median length of stay was shorter. This reinforces the findings of single center studies^[8,12,15,24]. Recently, Venkat *et al*^[9] in a meta-analysis reported that patients that underwent a laparoscopic distal pancreatectomy had not just a lower blood loss and hospital length of stay, but also had fewer complications and surgical site infections. Importantly, no difference was found in operative time, margin positivity, incidence of postoperative pancreatic fistula or mortality. Additionally, we found that utilization of laparoscopy reduced overall expenses; this finding is likely secondary to the shorter length of stay and lower complication rate.

Other recent reports have confirmed the advantages of laparoscopic distal pancreatectomy over open approach, in terms of lower intraoperative blood loss, pain and analgesic requirements, earlier return of bowel function, shorter recovery and hospital stay^[9,10,14,25,26]. Therefore, the subset of patients with medical comorbidities could potentially benefit more than healthier patients, but we did not find that patient morbidity was associated with use of minimally invasive surgery.

Despite the known and reported benefits, overall laparoscopy was utilized in 15% (NIS) and 27% (NSQIP) of the distal pancreas resection cases. This represents all patients that had laparoscopy performed for diagnosis, staging, resection or a combination of these procedures. The rate of utilization of laparoscopy has remained stable over most of the past decade, although we could not determine in each case the specific technique of laparoscopy used. The finding of no increase in utilization of laparoscopy could be explained by the low number of pancreas surgeons that perform laparoscopic pancreatic resection. Also, another potential explanation for this stable rate could be that more laparoscopic resections and fewer diagnostic staging procedures are being performed over the study course, but these changes could not be detected by our analysis.

In our analysis, we showed that laparoscopy was utilized more frequently in malignant lesions, which could be due to utilization of laparoscopy for diagnosis and/or staging purposes. Interestingly, we did not find that laparoscopy was utilized and performed more frequently in teaching or high volume hospitals, though we expected that teaching hospitals and specialized medical centers would perform more MIS resection cases. It is not surprising that NSQIP hospitals have a higher rate of laparoscopy utilization than NIS hospitals, because NSQIP hospitals have volunteered for the program in an effort

to improve quality. But it would not be appropriate to further compare data across different databases.

No consensus exists for or against the use of laparoscopic approach for distal pancreatectomy in malignant lesions, though recent publications support this approach in selected patients^[7]. It has also been reported that after laparoscopic distal pancreatectomy in patients with invasion, a resection to negative margins and adequate lymph node harvest can be accomplished^[15]. We also found that postoperative complications were more common after resection of malignant lesions, but even in malignant lesions use of laparoscopy was associated with a decrease in complications. The reported laparoscopic distal pancreatectomy morbidity ranges from 20% to 47% and the reported mortality rate ranges from 3% to 5%^[14,27,28]. Our study shows that nationwide mortality is at or below the benchmark reported data. The most common reported complications after laparoscopic distal pancreatectomy are pancreatic fistula, intra-abdominal abscesses, wound infection, sepsis, malabsorption, electrolyte disturbance and hemorrhage^[14,27,28]. The rate of intra-abdominal infection we report (9%) is also at or below reported benchmarks. This may reflect inaccuracy of coding.

Regarding oncological outcomes, no increase was seen in the number of lymph nodes harvested and lymph node ratio in N1 disease. More importantly the 1-year and 2-year survival did not increase during the course of this study.

The oncological surrogate markers associated with survival in pancreas cancer such as tumor size, tumor differentiation, surgical margins, lymph node status and lymph node ratio have been well documented^[8,10,11,15,29]. We speculate that surgeons might opt for open operation to enable a more radical oncologic resection. This however, does not appear to be the case, as survival and oncologic surrogate markers were unchanged over the course of the study. We believe that published data support using MIS to perform a more radical oncologic resection, but these data show this is not a common practice across the country^[8,15,16,30].

Multiple reports support centralization of oncological pancreas procedures towards high-volume hospitals, and as a result of this, a decrease in mortality has also been reported^[17-20]. Stitzenberg *et al*^[18] analyzed the NIS database to assess cancer surgery centralization for pancreas, esophagus and colon cancer. Interestingly, during the course of the study there was a decrease in total number of hospitals performing pancreas procedures, but a statistical significant increase in the number of high-volume hospitals and a decrease in low-volume hospitals performing pancreatectomy procedures. All the high-volume centers were teaching hospitals. A total of 8.3% patients with a diagnosis of pancreas malignancy were admitted through an emergency room, and were more likely to have surgery done in a low-volume hospital.

Forces opposing the trend for centralization include the technological advances in imaging, resulting in diagnosis of pancreas lesions at earlier stages. Smaller le-

sions could potentially be managed in a non-specialized hospital, and only complicated cases referred to specialized hospitals. On the other hand, recent reports and guidelines support the use of endoscopic ultrasound with guided fine-needle aspiration for diagnosis and staging of body and tail pancreatic neoplasms^[31,32]. This procedure is usually performed in specialized medical centers, which would support the concept of centralization. In our analysis, centralization of distal pancreas procedures over the last decade has not occurred.

Even though the definition of utilization of laparoscopy in our analysis was broad, it appears that at a nationwide level, laparoscopy is underutilized for distal pancreas resection despite sufficient evidence of its benefit. Centralization of distal pancreas resections to high volume centers does not appear to be occurring in the United States, but this does not appear to affect overall quality. During the course of this study survival and extent of lymph node harvest has not changed.

We can conclude that there is room for improvement in distal pancreas resection in the United States.

COMMENTS

Background

Laparoscopy utilization in pancreas operations has progressed at a slower pace when compared to procedures for other solid organs. Current reports have documented the trend towards centralization of proximal pancreatic procedures in the last decade, and improvement in perioperative mortality when performed in high-volume hospitals.

Research frontiers

Database analysis allows assessment of trends across the spectrum of surgical practice in a country. Trends of distal pancreas resections in the United States were studied with respect to concepts of centralization of care, surgical technique, and clinical and oncological outcome metrics.

Innovations and breakthroughs

In patients where laparoscopy was utilized, there were fewer complications and surgical site infections, and decreased length of stay. Additionally, utilization of laparoscopy reduced overall expenses. The rate of utilization of laparoscopy has remained stable over most of the past decade. Interestingly, they did not find that laparoscopy was utilized and performed more frequently in teaching or high volume hospitals. Postoperative complications were more common after resection of malignant lesions. Regarding oncological outcomes, no increase was seen in the number of lymph nodes harvested and lymph node ratio in N1 disease. More importantly, the 1-year and 2-year survival did not increase during the course of this study. There was no trend for centralization of care for resection of lesions of the distal pancreas.

Applications

Utilization of laparoscopy during distal pancreas resection is associated with improved outcomes at a national level, when compared to open resection. These findings confirm results of recent multi-center studies.

Terminology

From the Health Care Cost and Utilization Project, the Nationwide Inpatient Sample database is directed to determine health care utilization, access, charges, quality and outcomes. The National Surgical Quality Improvement Project is a database from the American College of Surgery that focuses on perioperative complications, with a mandate to determine the quality of surgical care. The Surveillance Epidemiology and End Results by the National Cancer Institute focuses on the incidence, prevalence and survival of cancer.

Peer review

Each database shows unique aspects of the trends in distal pancreatectomy, demonstrating their individual advantages and weaknesses. There appears to be an overall underutilization of laparoscopy for distal pancreatectomy across the United States despite the benefits demonstrated on multiple published series.

Abstract

AIM: To examine effects of chronic methadone usage on bowel visualization, preparation, and repeat colonoscopy.

METHODS: In-patient colonoscopy reports from October, 2004 to May, 2009 for methadone dependent (MD) patients were retrospectively evaluated and compared to matched opioid naive controls (C). Strict criteria were applied to exclude patients with risk factors known to cause constipation or gastric dysmotility. Colonoscopy reports of all eligible patients were analyzed for degree

of bowel visualization, assessment of bowel preparation (good, fair, or poor), and whether a repeat colonoscopy was required. Bowel visualization was scored on a 4 point scale based on multiple prior studies: excellent = 1, good = 2, fair = 3, or poor = 4. Analysis of variance (ANOVA) and Pearson χ^2 test were used for data analyses. Subgroup analysis included correlation between methadone dose and colonoscopy outcomes. All variables significantly differing between MD and C groups were included in both univariate and multivariate logistic regression analyses. *P* values were two sided, and < 0.05 were considered statistically significant.

RESULTS: After applying exclusionary criteria, a total of 178 MD patients and 115 C patients underwent a colonoscopy during the designated study period. A total of 67 colonoscopy reports for MD patients and 72 for C were included for data analysis. Age and gender matched controls were randomly selected from this population to serve as controls in a numerically comparable group. The average age for MD patients was 52.2 ± 9.2 years (range: 32-72 years) compared to 54.6 ± 15.5 years (range: 20-81 years) for C ($P = 0.27$). Sixty nine percent of patients in MD and 65% in C group were males ($P = 0.67$). When evaluating colonoscopy reports for bowel visualization, MD patients had significantly greater percentage of solid stool (i.e., poor visualization) compared to C (40.3% vs 6.9%, $P < 0.001$). Poor bowel preparation (35.8% vs 9.7%, $P < 0.001$) and need for repeat colonoscopy (32.8% vs 12.5%, $P = 0.004$) were significantly higher in MD group compared to C, respectively. Under univariate analysis, factors significantly associated with MD group were presence of fecal particulate [odds ratio (OR), 3.89, 95% CI: 1.33-11.36, $P = 0.01$] and solid stool (OR, 13.5, 95% CI: 4.21-43.31, $P < 0.001$). Fair (OR, 3.82, 95% CI: 1.63-8.96, $P = 0.002$) and poor (OR, 8.10, 95% CI: 3.05-21.56, $P < 0.001$) assessment of bowel preparation were more likely to be associated with MD patients. Requirement for repeat colonoscopy was also significant higher in MD group (OR, 3.42, 95%

CI: 1.44-8.13, $P = 0.01$). In the multivariate analyses, the only variable independently associated with MD group was presence of solid stool (OR, 7.77, 95% CI: 1.66-36.47, $P = 0.01$). Subgroup analysis demonstrated a general trend towards poorer bowel visualization with higher methadone dosage. ANOVA analysis demonstrated that mean methadone dose associated with presence of solid stool (poor visualization) was significantly higher compared to mean dosage for clean colon (excellent visualization, $P = 0.02$) or for those with liquid stool only (good visualization, $P = 0.01$).

CONCLUSION: Methadone dependence is a risk factor for poor bowel visualization and leads to more repeat colonoscopies. More aggressive bowel preparation may be needed in MD patients.

INTRODUCTION

Approximately 7 million colonoscopies are performed annually in the United States^[1,2]. It is the preferred modality for colorectal cancer screening^[3,4]. A successful colonoscopy requires adequate pre-colonoscopy bowel preparation^[5]. The adequacy of the preparation depends on its ability to reliably empty the colon of fecal material without altering the colonic mucosa^[2,6]. Inability to properly visualize the lumen due to retained fecal material may result in missed pathologies, diagnostic delays and repeat procedures, with potentially adverse medical, legal, and economic implications. It has been reported that over 20% of all colonoscopies performed in the United States fail due to suboptimal bowel preparation or poor colonic visualization^[7,8], leading to an estimated 12%-22% increase in long term costs related to the procedure^[9].

Concurrently, opioid use in the United States has increased sharply over the last decade^[10-13]. An estimated 3% of all adult population in the United States is on long term opioid treatment for chronic pain management^[10,14]. Methadone, a synthetic opioid, is commonly used for analgesia in patients with malignancy^[15], and intractable neuropathy^[16]. It is also standard therapy for the treatment

of opioid addiction^[17]. However, methadone can cause constipation due to its anti-peristaltic effects on the entire gastrointestinal (GI) tract^[18]. Therefore, it is reasonable to postulate that adequate colonic visualization may be difficult to accomplish in patients on chronic methadone therapy due to excessive fecal retention.

Although studies have demonstrated a variety of risk factors for suboptimal preparation and poor bowel visualization^[19,20], the effects of opioids on the quality of bowel visualization has not been evaluated. Our aim was to examine the quality of colonoscopic bowel visualization in methadone dependent patients.

MATERIALS AND METHODS

Patient selection

This was a retrospective cohort study of patients selected from Beth Israel Medical Center (BIMC) at Albert Einstein College of Medicine endoscopy database who had an in-patient colonoscopy performed between October, 2004 and May, 2009. The study was approved by BIMC Institutional Review Board. Patients were cross referenced using BIMC's computerized medical records, out-patient records, and discharge summaries to obtain demographic, clinical, medications and laboratory data. Search filters for "methadone" were applied to select for patients. Patients with risk factors known to cause constipation or gastric dysmotility were excluded (Table 1). Eligible patients were divided into two groups: (1) methadone dependent (MD); and (2) those without any history of opioid usage (C). MD patients and their dosages were verified from their respective institutional methadone maintenance treatment program. Patients whose methadone dose was not verified or those who received methadone on an as needed basis were also excluded. The colonoscopy reports of all eligible patients were analyzed for degree of bowel visualization, assessment of the bowel preparation (good, fair, or poor), and whether a repeat colonoscopy was required. Age and gender matched controls who were free of any opioid exposure for at least 4 wk before colonoscopy were selected from our database as controls.

Evaluation of bowel visualization

Bowel visualization was scored on a 4 point scale utilized in multiple prior studies examining quality of bowel visualization^[20-22]. Points were assigned as following: excellent = 1, good = 2, fair = 3, or poor = 4^[20-22]. Excellent visualization was defined as a clean bowel without presence of any stool and small to moderate amount of clear liquid. Good was defined as presence of small amount of liquid fecal material able to be easily suctioned. Fair was defined as semisolid stool (fecal particulate), able to be washed out with more than 90% of the colon visualized. Poor was defined as presence of large amounts of solid stool obscuring more than 90% of the colonic mucosa.

Statistical analysis

were used to describe the continuous variables. Percent-age and frequency were used to describe the categorical variables. Analysis of variance (ANOVA) compared for differences in the continuous variables. Pearson χ^2 test compared for differences in the categorical variables. *P* values were two sided, and < 0.05 were considered statistically significant. All variables significantly differing between MD and C groups were included in both univariate and multivariate logistic regression analyses. ANOVA was used to compare methadone dose to bowel visualization level. Least significant difference post-hoc comparisons were performed. All analysis were performed with IBM SPSS Statistics Version 19.

RESULTS

Demographics and clinical characteristics

A total of 178 MD patients underwent colonoscopy during the designated study period, out of which 57 were excluded for concomitant use of other opioids or prescribed methadone on an as needed basis, 48 were excluded for unverifiable methadone dosage and 17 for either incomplete colonoscopy reports, colonoscopies performed urgently, or for prematurely terminated examinations for unknown reasons. A total of 115 colo-

Table 3 Comparisons of bowel visualization, preparation assessment, and rate of repeat colonoscopy between methadone and control patients *n* (%)

Variables	Methadone patients (<i>n</i> = 67)	Control (<i>n</i> = 72)	<i>P</i> value
Bowel visualization			< 0.001
Excellent	12 (17.9)	30 (41.7)	
Good	14 (20.9)	28 (38.9)	
Fair	14 (20.9)	9 (12.5)	
Poor	27 (40.3)	5 (6.9)	
Bowel preparation assessment			< 0.001
Good	22 (32.8)	52 (72.2)	
Fair	21 (31.3)	13 (18.1)	
Poor	24 (35.8)	7 (9.7)	
Repeat colonoscopy	22 (32.8)	9 (12.5)	0.004

noscopies were performed during the same study period on opioid naïve patients who passed the exclusion criteria for the study. Age and gender matched patients were randomly selected from this population to serve as controls in a numerically comparable group. In the final analysis, 56 patients were included in the MD group and 68 in control group. This yielded a total of 67 colonoscopy reports for MD patients and 72 for C, as some patients underwent repeat examinations. Baseline characteristics of all patients are listed in Table 2. The average age for MD patients was 52.2 ± 9.2 years (range: 32-72 years) years compared to 54.6 ± 15.5 years (range: 20-81 years) for C ($P = 0.27$). Sixty nine percent of patients in MD and 65% in C group were males ($P = 0.67$).

Colonoscopy evaluation

Table 3 compares bowel visualization, overall assessment of bowel preparation, and need for repeat colonoscopies between MD and C groups. Bowel visualization quality significantly differed between the two groups, with data suggesting greater percentages of solid stool (poor visualization) for MD compared to C (40.3% *vs* 6.9%, $P < 0.001$). Poor bowel preparation (35.8% *vs* 9.7%, $P < 0.001$) and need for repeat colonoscopy (32.8% *vs* 12.5%, $P = 0.004$) were significantly higher in MD group compared to C.

Results for univariate and multivariate analysis are listed in Table 4. In the univariate analysis, factors significantly associated with MD group were presence of fecal particulate [odds ratio (OR), 3.89, 95% CI: 1.33-11.36, $P = 0.01$] and solid stool (OR, 13.5, 95% CI: 4.21-43.31, $P < 0.001$). Bowel preparation assessment had significantly greater odds ratios for fair and poor status in the MD group (Table 4). Requirement for repeat colonoscopy was also significant in the MD group (OR, 3.42, 95% CI: 1.44-8.13, $P = 0.01$). However, in the multivariate analyses, the only significant variable independently associated with MD group was presence of solid stool (OR, 7.77, 95% CI: 1.66-36.47, $P = 0.01$).

Methadone dosage and bowel visualization

A subgroup analysis limited to MD patients was per-

Table 4 Univariate and multivariate analysis in methadone dependent patients

OR: Odds ratio.

formed to evaluate the relationship between methadone dosage and quality of bowel visualization. There was a general trend towards poorer visualization with higher dosage (Figure 1). Mean methadone doses for quality of bowel visualization levels were: 76.7 ± 54.3 mg for clean bowel, 75.4 ± 45.8 mg for liquid stool, 108.6 ± 46.1 mg for fecal particulate, and 116.5 ± 42.3 mg for presence of solid stool (Figure 2). ANOVA analysis demonstrated statistically significant differences in mean methadone dosage between the quality of bowel visualization ($P = 0.02$). Least significant difference post-hoc comparisons showed that mean methadone dose associated with the presence of solid stool (poor visualization) was significantly higher compared to mean dosage for clean colon (excellent visualization, $P = 0.02$) or for those with liquid stool only (good visualization, $P = 0.01$).

DISCUSSION

To our knowledge, this is the first study to examine the effects of methadone on bowel visualization. After applying strict exclusionary criteria eliminating many known causes of GI dysmotility, our results show that chronic methadone use is an independent risk factor for poor bowel visualization due to higher incidence of retained solid stool. Bowel visualization may also be dose dependent since mean methadone dose for colonoscopies containing solid stool was significantly higher compared to the clean colonoscopies or those with only liquid stool.

Prior studies on bowel visualization have used a scoring system to evaluate for the degree of colonic stool retention^[20-22]. We used the identical scoring system to examine bowel visualization in methadone dependent patients. Compared to opioid naïve patients, methadone dependent patients had a significantly higher rate of retained solid stool (poor visualization) and fecal particulate (fair visualization). Even under multivariate analysis, methadone patients had approximately an 8-fold higher occurrence for presence of solid stool compared to controls. Methadone, as with other opioids, binds to μ receptors in the central nervous system^[23], and periph-

**Figure 1** Bowel visualization according to methadone dose.**Figure 2** Mean methadone dose for quality of bowel visualization. ^a $P < 0.05$ vs solid stool.

eral sensory nerve fibers terminals^[24], including enteric neurons^[10,25]. Opioids inhibit both gastric emptying and intestinal propulsive motor activity^[17] throughout the entire GI tract while stimulating contraction of the pyloric and ileo-cecal sphincters^[10,26]. The densest concentrations of mu receptors are found in the stomach and colon^[27], therefore decreased colonic propulsion is also likely. Furthermore, it is well known that one of the major functions of a normal colon includes water absorption^[28]. Opioids stimulate fluid and water absorption mainly due to delayed transit time and increased luminal contact time^[10]. The combination of multiple effects of methadone throughout the GI tract in conjunction with increased colonic fluid resorption from decreased propulsion most likely explains the significantly higher presence of solid stool in methadone dependent patients.

We further examined whether there was a relationship between methadone dosage and bowel visualization. Our results show that methadone patients whose colonoscopies contained solid stool were consuming a significantly higher dose compared to methadone patients with clean bowel or liquid stool. Methadone pharmacokinetics has demonstrated a strong linear relationship between plasma concentration and methadone dose^[29,30]. Therefore, it might be possible that consuming higher methadone dose led to higher plasma concentration and subsequently more side effects, including

decreased transit time and increased water absorption, leading to higher presence of solid stool. Unfortunately, studies on the relationship between opioid dosage and GI motor function are limited. A study by Delgado-Aros *et al*^[31] examined the effects of asimadoline, a κ receptor opioid agonist, in patients with irritable bowel syndrome and found no difference in GI motor function with increasing dosage. However, κ receptors are involved in visceral pain perception^[32,33] and do not affect GI motility. A study by Ness *et al*^[19] on factors affecting colonic preparation demonstrated no association between narcotics use and inadequate bowel preparation. However, it is unclear whether their study population had other comorbidities which may have confounded the results^[19]. Furthermore, information on the type of narcotics (opioid *vs* non-opioid), dosage, and duration of usage were lacking, and the number of patients on narcotics were small ($n = 14$)^[19].

The presence of solid stool may also have factored into the requirement for repeat colonoscopies. Methadone dependent patients were significantly more likely to require repeat colonoscopies compared to non-opioid patients under univariate analysis. However, results were non-significant when controlling for other variables under multivariate analysis. Therefore, the requirement for a repeat colonoscopy in methadone patients is dependent on other factors, most likely the presence of solid stool obscuring proper luminal visualization. Another explanation for the lack of significant results under multivariate analysis may be due to the relatively small sample size, since the range of the odds ratio was large under univariate analysis. Further studies using a larger sample size are needed to validate these results. Nonetheless, our study underscores the importance of proper bowel visualization and the substantial costs associated with repeat colonoscopies. According to a cost analysis study by Rex *et al*^[9], the economic impact of repeat colonoscopies resulted in a 12%-22% increase in potential long term costs due to decreased time interval for subsequent colonoscopies and associated charges for polypectomy and histological examinations.

Lastly, we evaluated the overall assessment of the adequacy of bowel preparation. The American Society of Gastrointestinal Endoscopy and the American College of Gastroenterology Taskforce on Quality in Endoscopy suggest that every colonoscopy report should include an overall assessment, although acknowledge that it lacks standardized definitions due to endoscopist subjectivity^[54]. Multiple prior studies have evaluated the adequacy of bowel preparation based on the endoscopist's overall assessment of the colonoscopy^[8,19,35]. Harewood *et al*^[8] demonstrated that approximately 25% of colonoscopies examining bowel preparation and detection of colonic neoplasia were considered "inadequate," defined as "fair" or "poor". Standardized definitions for preparation quality were not provided to the endoscopists^[8]. Similar criteria for bowel assessment were applied in the study by Kazarian *et al*^[35] examining adequacy of bowel

preparation in urban populations. In our study, a significantly higher percentage of colonoscopies performed on methadone patients were assessed as "poor" compared to opioid naive patients. While the assessment of poor preparation was not independently associated with methadone patients, the results were significant under univariate analysis. This suggests that the significantly higher presence of solid stool in the methadone patients most likely contributed to the overall poor bowel assessment. Inter-observer variability in the assessment of the bowel preparation quality between endoscopists may also have contributed to the lack of significant results under multivariate analysis. Colonoscopy reports from multiple endoscopists were evaluated, which represents a limiting factor in our study. However, other studies on the quality of bowel preparations have also been limited by similar inter-observer bias due to multiple endoscopists^[7,8]. Further studies on methadone's effect on quality of bowel assessment based on a single endoscopist are needed to validate our results.

Due to the retrospective nature of our study, there were several other limitations. Information on the time elapsed between bowel preparation to procedure, and type of purgative ingested were not available. Therefore, bowel preparation may not have been standardized. Our study was also limited due to potential inter-observer bias since there were multiple endoscopists whose colonoscopy evaluations were utilized. This raises the concern that one endoscopist may have a more stringent assessment of the quality of bowel preparation than others. However, these limitations applied to both methadone and control groups equally, thereby reducing their confounding effects. Data on colonoscopic findings and need for therapeutic interventions were not available since it was outside the scope of our investigation into bowel visualization and preparation. We were also unable to apply the Ottawa^[56] or Boston Bowel Preparation^[57] Scales. These scales utilize a cumulative scoring system based on a combination of fluid quality and bowel location to determinate the quality of bowel preparation. While it is a validated system, the aims of our study were to examine the need for repeat colonoscopies and the presence of retained fecal matter instead of its location. Another limitation is the small sample size, including the number of controls, in our study. Although this is a preliminary study, the most likely explanation for the limited number of patients, specifically the controls, is due to the extensive exclusionary criteria applied. We excluded all individuals with any pathology that may affect GI motility, including many common diseases, such as diabetes and thyroid dysfunction, surgical interventions, and medications. We also excluded all partial colonoscopy reports that did not contain information on bowel assessment or those without images. Lastly, our study was performed at a single institution, thereby limiting a broad generalization of the results. Nevertheless, these limitations underscore the importance of the effects of methadone, and other opioids, on bowel visualiza-

tion. Currently, studies in this area are lacking. Further prospective studies in methadone and other opioids on colonoscopic outcomes are needed to validate the results of our preliminary study.

In conclusion, methadone dependent patients may require more repeat colonoscopies due to poor bowel visualization and retained stool. Poor bowel visualization may also be dose dependent. Methadone and other opioid use has risen drastically over the last decade in the United States, and an estimated 3% of all adults are currently on chronic opioid treatment^[10,14]. Considering the high numbers of colonoscopies performed annually in the United States, it is reasonable to conclude that clinicians will encounter a significant number of patients on chronic opioid therapy awaiting a colonoscopy. In fact, the average age for methadone dependent patients in our study was in the range where a screening colonoscopy should be performed on all individuals. Our results also suggest that a more aggressive approach to bowel preparation may be needed in methadone, or other opioid dependent patients. Current bowel cleansing practices may need to be revisited in these patients to not only improve the purgative effects, but also decrease the need for repeat colonoscopies. Recent investigations on peripherally acting μ -opioid receptor antagonists, such as methylnaltrexone or alvimopan^[38], have shown benefit in treating opioid induced constipation, and may aid in improved bowel preparations in these patients. The utility of these antagonists in the setting of pre-colonoscopy bowel preparation for opioid dependent patients are lacking and is an area of potential future research.

COMMENTS

Background

While approximately 7 million colonoscopies are performed in the United States annually, over 20% of all colonoscopies fail due to suboptimal bowel preparation or poor colonic visualization. This has led to an estimated 12%-22% increase in long term costs associated with colonoscopy. Concurrently, opioid use has increased sharply over the last decade in the United States. It is estimated that 3% of all adults are currently opioid dependent.

Research frontiers

Opioids, such as methadone, both inhibit intestinal propulsive motor activity throughout the entire gastrointestinal (GI) tract and stimulate fluid and water absorption in the colon. These effects lead to constipation and fecal retention. Fecal retention can obscure proper bowel visualization, thus potentially resulting in missed pathologies, diagnostic delays and repeat procedures. Studies on colonoscopy outcomes and bowel visualization in methadone dependent patients are lacking. In this study, the authors suggest that chronic methadone usage is a risk factor for poor bowel visualization and preparation, thereby leading to more repeat colonoscopies. These effects appear to be dose dependent.

Innovations and breakthroughs

Studies on the relationship between opioids and colonoscopy outcomes are limited. A prior study demonstrated no association between narcotics use and inadequate bowel preparation. However, there were several limitations, including small number of patients on unspecified narcotics without information on

dosage and duration of narcotic use. This is the first and largest study to examine the effects of methadone dependence on bowel visualization and need for repeat colonoscopies. Furthermore, they examined whether there was a relationship between methadone dosage and colonoscopy outcomes.

Applications

By demonstrating that methadone is another risk factor for failure of colonoscopies, pre-colonoscopy bowel preparation methods may need to be re-evaluated in methadone dependent patients to improve bowel visualization and reduce the need for repeat colonoscopies. Mu-receptor antagonists used to treat opioid induced constipation may serve a role in pre-colonoscopy bowel preparation to improve visualization and reduced rates of repeat colonoscopies in methadone dependent patients.

Terminology

Methadone, a synthetic mu receptor agonist, is a commonly used opioid for analgesia in patients with malignancy, and intractable neuropathy. It is also standard therapy for the treatment of opioid addiction. In addition to slowing GI motility and increased fluid resorption in the colon, methadone pharmacokinetics has demonstrated a strong linear relationship between methadone dose and plasma concentrations.

Peer review

In this novel study, the authors retrospectively examined bowel visualization and preparation assessment, and need for repeat colonoscopies in a small cohort of methadone dependent patients. The study revealed that chronic methadone usage may be an additional risk factor for failure of colonoscopy due to poorer visualization and bowel preparation, and leads to a higher need for repeat colonoscopies. This association may also be dose dependent. Larger, prospective studies are needed to affirm these findings.

Abstract

AIM: To determine which features of history and demographics predict a diagnosis of malignancy or peptic stricture in patients presenting with dysphagia.

METHODS: A prospective case-control study of 2000 consecutive referrals (1031 female, age range: 17-103 years) to a rapid access service for dysphagia, based in a teaching hospital within the United Kingdom, over 7 years. The service consists of a nurse-led telephone triage followed by investigation (barium swallow or gastroscopy), if appropriate, within 2 wk. Logistic regression analysis of demographic and clinical variables was performed. This includes age, sex, duration of dysphagia, whether to liquids or solids, and whether there are associated features (reflux, odynophagia, weight loss, regurgitation). We determined odds ratio (OR) for these variables for the diagnoses of malignancy and peptic stricture. We determined the value of the Edinburgh Dysphagia Score (EDS) in predicting cancer in our cohort. Multivariate logistic regression

was performed and $P < 0.05$ considered significant. The local ethics committee confirmed ethics approval was not required (audit).

RESULTS: The commonest diagnosis is gastro-esophageal reflux disease (41.3%). Malignancy (11.0%) and peptic stricture (10.0%) were also relatively common. Malignancies were diagnosed by histology (97%) or on radiological criteria, either sequential barium swallows showing progression of disease or unequivocal evidence of malignancy on computed tomography. The majority of malignancies were esophago-gastric in origin but ear, nose and throat tumors, pancreatic cancer and extrinsic compression from lung or mediastinal metastatic cancer were also found. Malignancy was statistically more frequent in older patients (aged >73 years, OR 1.1-3.3, age < 60 years 6.5%, 60-73 years 11.2%, > 73 years 11.8%, $P < 0.05$), males (OR 2.2-4.8, males 14.5%, females 5.6%, $P < 0.0005$), short duration of dysphagia (≤ 8 wk, OR 4.5-20.7, 16.6%, 8-26 wk 14.5%, > 26 wk 2.5%, $P < 0.0005$), progressive symptoms (OR 1.3-2.6: progressive 14.8%, intermittent 9.3%, $P < 0.001$), with weight loss of ≥ 2 kg (OR 2.5-5.1, weight loss 22.1%, without weight loss 6.4%, $P < 0.0005$) and without reflux (OR 1.2-2.5, reflux 7.2%, no reflux 15.5%, $P < 0.0005$). The likelihood of malignancy was greater in those who described true dysphagia (food or drink sticking within 5 s of swallowing than those who did not (15.1% vs 5.2% respectively, $P < 0.001$). The sensitivity, specificity, positive predictive value and negative predictive value of the EDS were 98.4%, 9.3%, 11.8% and 98.0% respectively. Three patients with an EDS of 3 (high risk EDS ≥ 3.5) had malignancy. Unlike the original validation cohort, there was no difference in likelihood of malignancy based on level of dysphagia (pharyngeal level dysphagia 11.9% vs mid sternal or lower sternal dysphagia 12.4%). Peptic stricture was statistically more frequent in those with longer duration of symptoms (> 6 mo, OR 1.2-2.9, ≤ 8 wk 9.8%, 8-26 wk 10.6%, > 26 wk 15.7%, $P < 0.05$) and over

60 s (OR 1.2-3.0, age < 60 years 6.2%, 60-73 years 10.2%, > 73 years 10.6%, $P < 0.05$).

CONCLUSION: Malignancy and peptic stricture are frequent findings in those referred with dysphagia. The predictive value for associated features could help determine need for fast track investigation whilst reducing service pressures.

INTRODUCTION

Esophageal cancer accounts for 3% of all cancer diagnoses in the United Kingdom (an annual incidence of nearly 8000) and has poor prognosis^[1-4]. The Department of Health in the United Kingdom has produced guidelines to identify patients with dyspepsia at higher risk of upper gastro-intestinal malignancy and requiring rapid referral and investigation^[5]. Dysphagia is an alarm symptom with a high predictive value for finding significant pathology [odds ratio (OR) 2.0-3.1 for malignancy in 3600 referrals to a rapid access upper gastro-intestinal cancer service]^[6].

However, dysphagia is common, occurring in 5%-8% of those over 50^[7]. It can be due to many different underlying conditions, including malignancy.

Many patients referred to secondary care with “dysphagia” do not actually have any swallowing difficulties^[8]. Despite it being a relatively good predictive symptom for cancer diagnosis, even in those with true dysphagia, less than 10% have cancer^[8]. Patients presenting with dysphagia require rapid assessment, diagnosis and treatment. An accurate diagnosis is dependent upon history and appropriate investigations, which may include barium swallow, gastroscopy or esophageal manometry^[9-13].

If it were possible to predict which patient demographics and symptoms were most highly predictive of serious pathology, especially malignancy or peptic stricture and which predicted a non-serious problem, it would allow health resources to be targeted towards rapid investigation in the high risk group. A scoring system, the Edinburgh Dysphagia Score (EDS) has been devised to

predict which patients require fast track investigations^[14].

The aim of our study is to identify which factors are strongest predictors of malignancy or peptic stricture in patients referred to a rapid access service with dysphagia. We use our data to validate the EDS on a larger patient cohort.

MATERIALS AND METHODS

The Royal Cornwall Hospital serves a largely rural population of 450 000, more than 99% of whom are white. The county is one of the poorest in the United Kingdom.

The dysphagia hotline (DHL) service consists of an initial telephone triage by our nurse endoscopist with barium swallow or endoscopy within one week. The radiology department hot report DHL barium swallow examinations and if the examination is abnormal, the patient is given diet Cola and metoclopramide and undergoes gastroscopy after 2 h^[15].

We prospectively collect data on patient demographics and final diagnosis following gastroscopy or barium swallow based on test results and clinical opinion. Duration of dysphagia, whether for both liquids and solids, and whether there are associated features (reflux, odynophagia, weight loss, regurgitation) are all prospectively recorded. Review of demographics, patient presentation and final diagnosis showed highly predictive variables for each major diagnosis, so these were formally analysed.

The EDS was determined for each patient (determined by scores for age, weight loss (> 3 kg), duration of symptoms, sex, location of dysphagia and presence of acid reflux)^[14].

Statistical analysis

Statistical analysis of the data was performed using IBM SPSS 19 software. The relationship between the variables and the diagnosis was explored using Pearson's χ^2 Independence test. The predictive value of each variable in diagnosing malignancy and in diagnosing peptic stricture was explored using logistic regression. In both analysis, a P value less than 0.05 was considered statistically significant.

The South West Regional Ethics committee determined that formal ethics approval was not required as the study fell within the category of audit.

RESULTS

From April 2004 to January 2011, 2000 patients were referred, 48.5% male, age range 17-103 years, mean 68.1 years (SD 14.1 years). Of these, 225 (11.2%) did not undergo investigation through the dysphagia hotline, mainly because they refused any investigations but also because we were unable to contact them by telephone, or they were admitted prior to test. Two patients' data could not be interpreted for clerical reasons. Three hundred and thirty-five patients (20% of those investigated) denied true dysphagia, defined as the feeling of food or

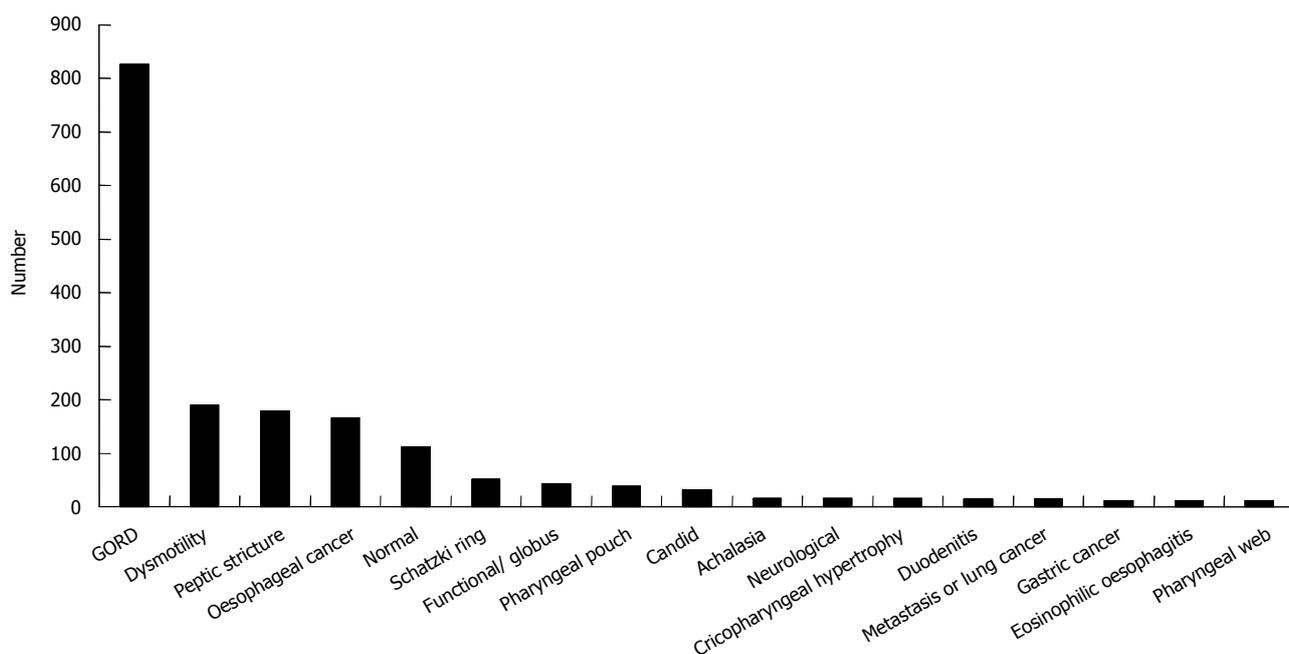

Figure 1 The outcome following investigation of 2000 consecutive patients referred with dysphagia. Some patients had more than one diagnosis and some had a diagnosis endoscopically which was unlikely to be the cause of the dysphagia. Only outcomes with an occurrence of 10 or more are shown. Other diagnoses with lower frequency were gastric (7), esophageal (5) and duodenal ulcers (4), compression from vascular structures including left atrium (4), pancreatic cancer (3), ear, nose and throat cancers (2), esophageal gastrointestinal stromal tumors (2), drug reaction (2), esophageal spasm (2) or diverticulum (2) and 1 each of respiratory infection, celiac disease, small intestinal stricture, goitre, post-operative stricture, pseudomembranous esophagitis, varices, pyloric ulcer, scleroderma, thyroglossal cyst and pharyngitis. Oesophageal cancer includes adenocarcinoma (98), squamous cancer (46), unspecified oesophageal cancers (4) and junctional cancers (18). GORD: Gastro-oesophageal reflux disease.

drink sticking within 5 s of swallowing, the majority describing globus although some presented with dyspepsia or weight loss.

Of those having investigations, 259 (14.6%) had barium swallow only, 1341 (75.5%) gastroscopy only and 175 (9.9%) had both procedures. Twenty patients failed to attend an appointment for procedures (7 barium swallows, 9 gastroscopies, the remainder unspecified) giving a DNA (did not attend) rate of 1.1% for patients referred for procedures.

The most common diagnosis was gastro-oesophageal reflux disease 826 (41.3%) with the more serious diagnoses of malignancy [199 (11.0%), 183 of gastrointestinal origin], peptic stricture 179 (10.0%), pharyngeal pouch 38 (2.1%) and achalasia 16 (0.9%). All outcomes are shown in Figure 1.

We investigated the likelihood of various significant pathologies based on patient demographics and presenting symptoms, including age (divided empirically into three similar sized groups of under 60 years, 60-73 years and over 73 years), sex, the type of dysphagia (to liquids, solids or both), whether the symptoms were progressive, whether “true dysphagia” or globus, and associated features including weight loss (defined as > 2 kg loss of weight in preceding 3 mo, the Department of Health criterion for a 2 wk wait referral), duration of dysphagia and presence or absence of reflux (percentages of each are shown on Table 1).

A diagnosis of malignancy or of peptic stricture was significantly associated with a history of true dysphagia

(feeling of food or drink sticking within 5 s of swallowing) than in those who did not ($P < 0.001$).

Logistic regression was performed using the Enter method to assess the impact of a number of factors on the likelihood of someone presenting with dysphagia having malignancy. The model contained seven independent variables (sex, age, duration of symptoms, nutrition, progressive symptoms, reflux and weight loss) however, the type of dysphagia was found to be highly non-significant ($P = 0.727$) and so the model was run again with removal of this variable.

The strongest predictor of a cancer diagnosis was the duration of symptoms (Table 2). If a patient reported symptom duration of less than eight weeks, the OR of having cancer was 9.6 higher than for symptoms more than twenty six weeks (95% CI: 4.5-20.7). The OR was 6 (95% CI: 2.8-12.8) for symptom duration between eight and twenty six weeks. The next strongest predictor was the presence of weight loss greater than 2 kg where the OR of 3.6 (95% CI: 2.5-5.1). Being male increased the likelihood of malignancy 3.3 fold (95% CI: 2.2-4.8) compared to females. Being less than sixty years old reduced the likelihood of a cancer diagnosis by 47.1% compared to being over 73 (OR 0.53, 95% CI: 0.3-0.9). If the patient had reflux, the OR of 0.54 (95% CI: 0.4-0.8) showed the likelihood of malignancy was significantly reduced and if symptoms were progressive then the OR of a cancer diagnosis was 1.8 (95% CI: 1.3-2.6). The sensitivity and specificity values are 97.6% and 31.1% respectively.

Table 1 Demographics and clinical features of the first 2000 patients referred to the dysphagia hotline (%)

Demographics			
Age	< 60 yr	60-73 yr	> 73 yr
	26.4	34.9	38.7
Sex	Male	Female	
	48.5	51.5	
Clinical features			
Nature of dysphagia	Solids	Liquids	Both
	79.6	0.7	19.7
Symptoms progressive	Yes	No	
	40	60	
"True" dysphagia	Dysphagia	Globus	
	81.3	18.7	
Weight loss \geq 2 kg in past 3 mo	Yes	No	
	28.5	71.5	
Presence of reflux	Yes	No	
	60.6	39.4	
Duration of dysphagia	< 8 wk	8-26 wk	> 26 wk
	34.5	42	23.5

Using an EDS $>$ 3.5 (10) to predict likelihood of cancer gave sensitivity, specificity, positive and negative predictive values of 98.4%, 9.3%, 11.8% and 98.0%. The three cancer cases that did not fall into the high risk group as defined in the original paper, had an EDS of 3.

Of patients with pharyngeal level dysphagia, 11.9% had malignancy, compared to 12.4% of patients with dysphagia affecting mid or lower chest ($P = \text{NS}$), i.e., in our cohort, the level of dysphagia was not significant for a diagnosis of malignancy.

Logistic regression was also used to assess the impact of a number of factors on the likelihood of someone presenting with dysphagia of having peptic stricture. The model originally contained seven independent variables. However five of these variables were not statistically significant and therefore were removed from the model [reflux ($P = 0.703$), sex ($P = 0.247$), progressive symptoms ($P = 0.196$), type of dysphagia ($P = 0.156$) and weight loss ($P = 0.069$). The only significant factors were age ($P = 0.012$) and duration of symptoms ($P = 0.008$)].

The OR of having a peptic stricture diagnosis is reduced by 48.9% for patients under 60 years old (OR 0.51, 95% CI: 0.33-0.80), and by 24.5% for patients between 60-73 years old (OR 0.76, 95% CI: 0.52-1.1) compared to those older than 73 years. The OR of having a peptic stricture diagnosis is reduced by 47.9% in patients presenting with symptoms of duration less than 8 wk (0.52, 95% CI: 0.34-0.81) and 37% in patients with symptoms of duration of between 8-26 wk (0.63, 95% CI: 0.43-0.92) compared to patients with symptom duration greater than 26 wk. The sensitivity and specificity values were 95.2% and 8.1% respectively.

In summary, in patients presenting with dysphagia, the likelihood of a diagnosis of cancer is increased by being male, over the age of 60 years, experiencing weight loss of $>$ 2 kg with progressive symptoms but without reflux and a symptom duration of less than eight weeks. Patients who have had their symptoms for greater than twenty six weeks and are over the age of 73

Table 2 Demographics and clinical features suggestive of malignancy in a dysphagic population

	Odds ratio	95% CI		Significance
		Lower	Upper	
Sex (male)	3.358	2.273	4.961	0.000
Progressive	1.807	1.259	2.593	0.001
Weight loss \geq 2 kg	3.572	2.501	5.104	0.000
Reflux	0.528	0.369	0.754	0.000
Age				
< 60 yr	0.529	0.320	0.872	0.013
60-73 yr	1.170	0.788	1.737	0.437
Duration				
< 8 wk	11.019	4.897	24.794	0.000
8-26 wk	6.936	3.124	15.398	0.000

Logistic regression analysis by the Enter method of 1400 patients investigated for dysphagia showing odds ratio with 95% CI and significance level compared to female patients, without progressive symptoms, without 2 kg or more weight loss, without reflux symptoms, aged over 73 years and with symptom duration of greater than 26 wk. The level of dysphagia (pharyngeal, mid chest or lower retrosternal) and the type of dysphagia (to liquids, solids or both) were removed as these were not statistically significant.

years are more likely to have a peptic stricture diagnosis than those presenting with the same symptoms that are younger and have symptoms for less than 26 wk.

DISCUSSION

For the past 7 years we have offered a telephone triage and one stop procedure service for dysphagia and have been referred 2000 patients. The commonest underlying cause for dysphagia is reflux disease but we have found malignancy in 10% of those referred and peptic stricture in 9%. We have prospectively collected data on patient demographics and symptoms at time of referral. Logistic regression analysis has enabled us to determine which symptoms and features make the diagnosis of malignancy or peptic stricture more likely.

Previous studies have found an incidence of cancer in 4%-15% of those referred with dysphagia^[6,16-19] making this an alarm symptom with a relatively high positive predictive value. We have confirmed this and also shown that in those referred to the DHL without dysphagia, the likelihood of malignancy is considerably lower.

Malignancy is more common in older men with a shorter duration of symptoms (less than 8 wk), with weight loss and without associated reflux. The negative association with reflux and positive association with weight loss has been noted previously^[8,14] as has the negative association with long duration of symptoms (greater than either 6 mo^[14] or 1 year^[8]). Because of the size of our cohort we have been able to demonstrate that those with particularly short duration of symptoms (less than 8 wk) have a markedly increased likelihood of malignancy (increased 11 fold) compared to those with symptoms from 8 wk to 6 mo (nearly 7 fold increase from those with symptoms of more than 6 mo).

Our findings are similar to those of Rhatigan *et al*^[14]

who have produced the “Edinburgh dysphagia score” to triage patients referred with dysphagia into low or high risk for malignancy. They have also found an increased likelihood of malignancy in patients who were male, older, with shorter duration of symptoms and have noted a negative association with symptoms of reflux. They found a significant relationship between type of dysphagia and the likelihood of cancer in univariate but not in multivariate analysis and hence they do not include it in their final calculation. In our study, the relationship was not statistically significant. Conventionally it is thought that dysphagia to solids is most likely due to organic obstruction whilst that to liquids is due to neuromuscular incoordination so it is interesting that both studies failed to demonstrate a significant relationship. It is possible in our own study that this was due to few patients having dysphagia to liquids alone.

There are several differences between their study and this one however. We failed to confirm a positive association of a malignant diagnosis with localisation of disease (in study of Rhatigan *et al.*^[14], dysphagia below the pharyngeal level was more likely to be associated with malignancy) or with progressive nature of symptoms (found to be an independent risk for malignancy but not included in their final scoring system). The reasons for this are not clear, although we did have 10 fold more patients with pharyngeal level dysphagia making it possible that the difference found previously had been a type 1 error due to a relatively small sample size. Alternatively there may be some unrecognised difference in referral patterns between the 2 hospitals.

We chose to group patients into three age ranges rather than investigating age as a continual variable but confirmed a strong association with older patients more likely to have malignancy and we chose 2 kg weight loss cut-off for weight loss as this is the weight chosen by the Department of Health in their guidelines for referral under the suspected cancer pathway. Only 8.4% of our patients fell into the low-risk group compared to 30.0% in study of Rhatigan *et al.*^[14]. This may have been because of the older age of our patients (mean age 68.1 years against 61.4 years in the original development cohort).

The high specificity and positive predictive value of the EDS was confirmed although again concerningly there were 3 patients who had malignancy but an EDS of less than 3.5. This figure is comparable to the study of Rhatigan *et al.*^[14] where the EDS failed to detect one malignancy in a cohort of 574 patients investigated, compared to 3 patients with malignancy in 1775 investigated. Clearly, whilst high risk patients with scores of 3.5 and above require urgent investigation, those with scores below this also require still to be investigated, albeit with a lower incidence of malignancy.

Further studies are required to determine whether the ORs are generalizable in other populations and in particular in non-whites. It would also be useful to record the effect of smoking and alcohol consumption on likelihood of both diagnoses.

As with malignancy, the likelihood of peptic stricture is greater in older patients but in contrast to a diagnosis of malignancy which is associated with a shorter duration of symptoms, a longer duration of symptoms (greater than 26 wk) is considered a feature of a peptic stricture diagnosis. No other clinical features were significantly associated with a diagnosis of peptic stricture. The associated with long duration of symptoms in older patients was recognized nearly 20 years ago but is worth re-iterating^[20-22].

Interestingly type of dysphagia (to solids rather than liquids), was not significant for neither malignancy nor peptic stricture. It is recognized that a history of dysphagia to solids progressing to both solids and liquids is indicative of mechanical obstruction whereas dysphagia to both at the onset is likely to be functional in origin^[23]. Relatively few of our patients had dysphagia to liquids only or both and we did not ask about the nature of the dysphagia at the onset which might explain this.

Likewise a history of reflux did not predict peptic stricture and appeared protective against a diagnosis of malignancy. Reflux is a known risk factor for esophageal adenocarcinoma and cardiac tumors (OR 7.7 and 2.0 respectively^[24]. In this and study of Rhatigan *et al.*^[14] it may simply have been more strongly associated with a final alternative diagnosis, namely reflux esophagitis^[21].

Future studies could focus on other factors which are recognized as risk factors for esophageal malignancy such as alcohol intake and smoking^[25-29] and this could improve the model of malignancy prediction.

We have prospectively obtained history from patients undergoing investigation for dysphagia and have demonstrated which factors are most likely to be indicative of malignancy or peptic stricture disease and hence which necessitate urgent investigation. We have confirmed the value of the EDS in recognising a smaller group of patients with dysphagia who require less urgent investigation.

COMMENTS

Background

Dysphagia can be the presenting symptom of a serious pathology, namely malignancy or peptic stricture. Determining which patients are more likely to have malignancy or stricture could help determine which patients need urgent investigation.

Research frontiers

A previous study from Scotland has shown malignancy to be more common in older males, with short duration of progressive symptoms, no reflux, weight loss and dysphagia not at the pharyngeal level and produced the Edinburgh Dysphagia Score (EDS).

Innovations and breakthroughs

The authors investigated 1775 patients with dysphagia and confirmed earlier findings malignancy to be more common in older men with progressive symptoms of less than 8 wk duration and weight loss of at least 2 kg. Malignancy was more common in those without reflux but level of dysphagia did not predict malignancy. An EDS of less than three predicted no malignancy. Peptic stricture was more common in older patients with longer duration of symptoms.

Applications

The authors confirmed the value of the EDS but caution that a score of 3 may still predict malignancy (contrary to the original article). Authors also defined

predictors of peptic stricture. Where resources are limited these predictors could be used to expedite investigations in high risk patients.

Peer review

It is larger scale cohort of validation study for the EDS than ever before. EDS is useful for primarily diagnosing esophageal malignancy associated with dysphagia.

Abstract

AIM: To investigate the prevalence of gastroesophageal reflux disease (GERD) in patients with a laryngoscopic diagnosis of laryngopharyngeal reflux (LPR).

METHODS: Between May 2011 and October 2011, 41 consecutive patients with laryngopharyngeal symptoms (LPS) and laryngoscopic diagnosis of LPR were empirically treated with proton pump inhibitors (PPIs) for at least 8 wk, and the therapeutic outcome was assessed through validated questionnaires (GERD impact scale,

GIS; visual analogue scale, VAS). LPR diagnosis was performed by ear, nose and throat specialists using the reflux finding score (RFS) and reflux symptom index (RSI). After a 16-d wash-out from PPIs, all patients underwent an upper endoscopy, stationary esophageal manometry, 24-h multichannel intraluminal impedance and pH (MII-pH) esophageal monitoring. A positive correlation between LPR diagnosis and GERD was supposed based on the presence of esophagitis (ERD), pathological acid exposure time (AET) in the absence of esophageal erosions (NERD), and a positive correlation between symptoms and refluxes (hypersensitive esophagus, HE).

RESULTS: The male/female ratio was 0.52 (14/27), the mean age \pm SD was 51.5 ± 12.7 years, and the mean body mass index was 25.7 ± 3.4 kg/m². All subjects reported one or more LPS. Twenty-five out of 41 patients also had typical GERD symptoms (heartburn and/or regurgitation). The most frequent laryngoscopic findings were posterior laryngeal hyperemia (38/41), linear indentation in the medial edge of the vocal fold (31/41), vocal fold nodules (6/41) and diffuse infraglottic oedema (25/41). The GIS analysis showed that 10/41 patients reported symptom relief with PPI therapy ($P < 0.05$); conversely, 23/41 did not report any clinical improvement. At the same time, the VAS analysis showed a significant reduction in typical GERD symptoms after PPI therapy ($P < 0.001$). A significant reduction in LPS symptoms. On the other hand, such result was not recorded for LPS. Esophagitis was detected in 2/41 patients, and ineffective esophageal motility was found in 3/41 patients. The MII-pH analysis showed an abnormal AET in 5/41 patients (2 ERD and 3 NERD); 11/41 patients had a normal AET and a positive association between symptoms and refluxes (HE), and 25/41 patients had a normal AET and a negative association between symptoms and refluxes (no GERD patients). It is noteworthy that HE patients had a posi-

tive association with typical GERD-related symptoms. Gas refluxes were found more frequently in patients with globus (29.7 ± 3.6) and hoarseness (21.5 ± 7.4) than in patients with heartburn or regurgitation (7.8 ± 6.2). Gas refluxes were positively associated with extra-esophageal symptoms ($P < 0.05$). Overall, no differences were found among the three groups of patients in terms of the frequency of laryngeal signs. The proximal reflux was abnormal in patients with ERD/NERD only. The differences observed by means of MII-pH analysis among the three subgroups of patients (ERD/NERD, HE, no GERD) were not demonstrated with the RSI and RFS. Moreover, only the number of gas refluxes was found to have a significant association with the RFS ($P = 0.028$ and $P = 0.026$, nominal and numerical correlation, respectively).

CONCLUSION: MII-pH analysis confirmed GERD diagnosis in less than 40% of patients with previous diagnosis of LPR, most likely because of the low specificity of the laryngoscopic findings.

How many cases of laryngopharyngeal reflux suspected by laryngoscopy are gastroesophageal reflux disease-related? *World J Gastroenterol* 2012; 18(32): 4363-4370 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i32/4363.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i32.4363>

INTRODUCTION

Gastroesophageal reflux disease (GERD) is one of the most common gastrointestinal disorders in Western countries^[1]. The manifestations of GERD have been recently classified into either esophageal or extra-esophageal syndromes (EES)^[1]. Among the latter, Vakil *et al*^[1] have included the atypical manifestations of GERD such as chronic cough and laryngopharyngeal symptoms (LPS) (i.e., laryngitis, globus, throat discomfort), which are increasingly recognised by general physicians, lung specialists and ear, nose and throat (ENT) surgeons^[2,3]. In particular, there is a large number of data on the growing prevalence of LPS in GERD patients^[4-6].

Despite the recognition that GERD can provoke laryngeal symptoms, the diagnosis of laryngopharyngeal reflux (LPR) remains a very difficult task. Initially, pa-

tients with laryngeal symptoms undergo a laryngoscopy and a chest X-ray to rule out malignancies. Once cancer is excluded, a diagnosis of LPR is suspected. The diagnosis of LPR is usually performed by ENT surgeons in case of detection of the following laryngoscopic findings: erythema, oedema, ventricular obliteration, post-cricoid hyperplasia and pseudosulcus^[7]. However, these laryngoscopic findings are also common in healthy volunteers, and this largely limits their diagnostic value^[7]. Moreover, there are several controversies regarding how to confirm LPR diagnosis and, more generally, EES diagnosis. Upper gastrointestinal endoscopy has been demonstrated to have low sensitivity^[8,9], the proton pump inhibitor test has been shown to have low specificity^[10], and radiologic studies have limited sensitivity and specificity^[8]. Moreover, the sensitivity and specificity of ambulatory pH monitoring as a means for diagnosing reflux in patients with extra-esophageal GERD symptoms have been challenged^[1]. Recently, the availability of multichannel intraluminal impedance and pH monitoring (MII-pH) has modified the diagnostic approach towards atypical manifestations of GERD^[11-14]. MII-pH is able to detect not only acid but also non-acid reflux and proximal migration of the refluxate and can correlate symptoms with both types of reflux^[15-17]; additionally, there is a rising consensus that this technique should be considered as the gold standard for GERD diagnosis^[18]. At present, few data are available on the prevalence of LPR in patients with or without GERD symptoms and on the characteristics of overall reflux episodes in those patients.

The aim of this study was to evaluate the prevalence of GERD in patients with a recent laryngoscopic diagnosis of LPR by means of MII-pH. The second endpoint was to assess the effectiveness of an empirical treatment with proton pump inhibitors (PPIs) in patients with both GERD-related and non-GERD-related LPR.

MATERIALS AND METHODS

Study subjects

Between May 2011 and October 2011, 41 consecutive patients with LPS and an ENT diagnosis of LPR were prospectively enrolled in the study. During the first visit, a distinct investigator completed a structured interview on the patients, recording a careful medical history (with recording of height and weight), current medications, tobacco use and alcohol consumption. All patients signed a written informed consent form before entering into the study. The study was designed and carried out in accordance with the Helsinki Declaration (Sixth revision, Seul 2008).

Inclusion criteria were as follows: LPS for at least three consecutive months during the last year, previous history of dysphonia, cough, hoarseness, throat globe and/or dysphagia and an ENT diagnosis of LPR. In particular, such a diagnosis was performed after an accurate phoniatric and otorhinolaryngoiatric anamnesis and a general ENT examination with a flexible rhino-pharyn-

go-laryngoscope with an optical fibre. The reflux findings score (RFS) was completed by the otolaryngologist (RFS > 7), suggestive value for LPR), and all patients were asked to complete the reflux symptom index (RSI) (RSI > 13, suggestive value for LPR)^[19]. Patients with a RFS > 7 and a RSI > 13 were considered affected by LPR.

Exclusion criteria were as follows: Previous surgery in the upper digestive tract, pregnancy and/or breastfeeding, eating disorders with vomiting, underlying psychiatric illness, use of non-steroidal anti-inflammatory drugs and aspirin, and peptic ulcer at a previous endoscopy.

All the enrolled patients were allowed an empirical treatment with PPIs for at least 8 wk, and the therapeutic outcome was recorded through a validated questionnaire (GERD impact scale, GIS), which was completed before and after therapy^[20]. The GIS comprises eight questions about the frequency, over the previous 2 wk, of the following items: acid-related symptoms; chest pain; extra-esophageal symptoms; impact of symptoms on sleep, work, meals and social occasions; and the use of additional non-prescription medications. A 4-point rating Likert scale was used to describe the frequency of the symptoms over the previous 2 wk: 0 = none (absence of symptoms), 1 = mild (symptoms present for a little of the time), 2 = moderate (symptoms present for some of the time), and 3 = severe (symptoms present all of the time). Patients who responded with a score of 2 or 3 were considered as non-responders to PPI therapy.

The patients were also asked to rate their satisfaction with the symptom control on a global visual analogue scale (VAS) from 0 (no relief at all) to 10 (complete symptom relief). The VAS score has been used as a self-assessment tool for symptom measurement, which has been used in many other trials for evaluation of ENT symptoms and typical and atypical GERD symptoms^[21,22].

After 8 wk of PPI therapy, all patients underwent upper endoscopy, stationary esophageal manometry and 24-h MII-pH esophageal monitoring. All patients discontinued PPI therapy at least 16 d before undergoing the planned esophageal investigations. The patients were only allowed to take alginates, on an as-needed basis, as rescue therapy. During upper gastrointestinal endoscopy, biopsies were taken from the gastric antrum and corpus to assess the presence of *Helicobacter pylori* and atrophic gastritis. Stationary manometry and MII-pH were performed after an overnight fast.

Stationary esophageal manometry

All subjects underwent stationary esophageal manometry to determine the distance of the proximal border of the lower esophageal sphincter (LES) from the nostrils and to evaluate the esophageal peristaltic wave. This study was performed by means of an eight-channel water-perfused manometric catheter with an external diameter of 4.5 mm (Dyno 2000[®] Menfis, BioMedica, Bologna Italy), equipped with computer-based data recording and storage. Esophageal body motility and LES relaxation

were tested by at least 10 wet swallows of 5 mL of water. Wave amplitude and duration were measured by means of four openings located at 5, 10, 15 and 20 cm above the LES. A stationary pull-through technique was then used to accurately locate the position of the LES.

Esophageal MII-pH

MII-pH was performed using a polyvinyl catheter (diameter: 2.3 mm), equipped with an antimony pH electrode and several cylindrical electrodes, with a length of 4 mm, placed at intervals of approximately 2 cm (Sandhill Scientific Inc., Highland Ranch, CO). Each pair of adjacent electrodes represented an impedance-measuring segment corresponding to one recording channel. The single-use MII-pH catheter was positioned with the pH electrode 5 cm above the LES and the six impedance recording channels positioned at 3, 5, 7, 9, 15 and 17 cm above the LES.

The methodology of probe calibration, catheter placement, patient instruction and performance has been previously described^[23].

MII-pH data analysis

At the end of the recording period, MII-pH tracings were reviewed manually to ensure accurate detection and classification of reflux episodes. Meal periods were excluded from the analysis. Impedance and pH data were used to determine the number and type of reflux episodes as well as the acid exposure time (AET) (reflux percent time) in each patient. In particular, the distal esophageal AET was defined as the total time with a pH measurement below 4 divided by the total time of monitoring. A percent time lower than 4.2% with pH < 4, over 24-h, was considered normal^[23,24]. Reflux events were characterised according to previously reported criteria^[25]. Total reflux number, esophageal AET and correlation between symptoms and reflux using the symptom index (SI) and symptom association probability (SAP) were evaluated for each patient as previously described^[26]. The symptoms were considered to be related to reflux if they occurred within a 2-min time window after the onset of the reflux episode^[27]. For symptom analysis, weakly acidic and weakly alkaline refluxes were pooled as non-acid reflux episodes (nadir pH > 4).

Statistical analysis

MII-pH data were matched with the ENT diagnosis. Statistical analysis was performed with the Chi-squared test and the Fisher exact test to evaluate nominal values, and Pearson's correlation was performed to explore numerical values. The results were considered statistically significant for *P* values < 0.05.

RESULTS

Demographic and clinical characteristics

The study evaluated 14 males and 27 females (M/F ratio 0.52), with a mean age \pm SD of 51.5 \pm 12.7 years and a

Table 1 Results of the gastroesophageal reflux disease impact scale questionnaire before and after proton pump inhibitor therapy

How often have you had the following symptoms: (GIS questionnaire)	Before PPI therapy				After PPI therapy				P value

Cough	7.9 ± 2.6	6.8 ± 2.8	0.069
Throat discomfort	8.1 ± 3.4	6.9 ± 2.1	0.058
Dysphonia	6.5 ± 2.1	5.5 ± 3.5	0.121

¹Statistically significant differences. PPI: Proton pump inhibitor.

mean body mass index of 25.7 ± 3.4 kg/m². Eight patients out of 41 (19.5%) were current smokers (5-10 cigarettes/d); 11/41 (28.8%) reported 2 to 3 units of alcohol consumption per day, and 33/41 (73.3%) drank two cups of coffee daily.

Symptoms

All subjects reported one or more LPS, and 25/41 patients also had typical GERD symptoms (heartburn and/or regurgitation). In particular, they described the predominant symptom (the most troublesome/frequent symptom during the day) and the overall most frequent symptoms in the last 6 mo. The predominant symptoms were globus 13 (31.7%), heartburn 10 (24.4%), hoarseness 9 (22%), sore throat 6 (14.6%), regurgitation 2 (4.9%) and epigastric pain 1 (2.4%). The overall most frequent symptoms were globus 21 (51.2%), heartburn 15 (36.6%), hoarseness 14 (34.1%), sore throat 13 (31.7%), regurgitation 9 (22%), dysphonia 9 (22%), belch 7 (17.1%), epigastric pain 5 (12.2%), and chronic cough 3 (7.3%).

The prevalence of symptom relief after PPI therapy, evaluated with the GIS questionnaire, showed that 10/41 (24.4%) patients reported at least one typical GERD symptom with “well controlled symptoms” (0) and that 23/41 (56.1%) patients reported only LPS without any symptom relief. All the details regarding the prevalence of symptom relief are described in Table 1.

The VAS analysis showed a significant reduction in typical GERD symptoms after PPI therapy. This reduction was not recorded for LPS. All details are presented in Table 2.

Upper gastrointestinal endoscopy

Upper endoscopy showed esophagitis (ERD) in 2/41 (4.9%) patients. None of the patients were diagnosed with complications of GERD (i.e., Barrett's esophagus, stenosis, adenocarcinoma). No other lesion or mucosal abnormality was detected during the examination.

Endoscopic hiatal hernia was found in 17/41 (41.5%) patients. With regard to the histological findings of the corpus and antrum biopsies, 4 out of 41 (9.75%) patients had *Helicobacter pylori* infection, and no one had atrophic gastritis or intestinal metaplasia.

Pathophysiological esophageal investigations

Two out of 41 (4.9%) patients presented with ineffective esophageal motility at the stationary manometry. Thirty-nine out of 41 (95.1%) patients did not present with abnormal esophageal motility.

The MII-pH analysis showed an abnormal AET in 5/41 (12.2%) patients [2 ERD and 3 non erosive esophagitis (NERD)]; 11/41 (26.8%) patients had a normal AET and a positive SAP (hypersensitive esophagus, HE), and; 25/41 patients had a normal AET and a negative association between symptoms and refluxes (no GERD patients). HE patients presented with a positive SAP for typical GERD-related symptoms (7 heartburn and 4 regurgitation).

The percentage of proximal reflux was abnormal (up more than 33%) in 4 cases with ERD/NERD (9.8%).

Gas refluxes were found more frequently in patients with globus (29.7 ± 3.6) and hoarseness (21.5 ± 7.4) than in patients with heartburn or regurgitation (7.8 ± 6.2). The SAP analysis for gas refluxes was positive for extra-esophageal symptoms.

Laryngoscopic examination

The most frequent laryngoscopic findings in our selected patients, classified by our MII-pH results, are shown in Table 3. Overall, no differences were found among the three groups of patients in terms of the frequency of the laryngeal signs. In particular, both ERD and NERD patients did not show severe findings of laryngeal disease.

The differences observed among the three subgroups of patients (ERD/NERD, HE, no GERD) with esophageal pathophysiological analysis (MII-pH) were not demonstrated with the ENT symptom questionnaire (RSI) or with the laryngoscopic findings (RFS), as shown in Table 4.

was confirmed ($P = 0.026$). All detailed results are shown in Table 5.

DISCUSSION

GERD is considered an important cause of laryngeal inflammation^[28]. The most common symptoms of this condition, termed LPS by ENT physicians, include hoarseness, throat pain, sensation of a lump in the throat, cough and repetitive throat clearing. However, these symptoms

are nonspecific and can also be seen in other diseases such as post-nasal drip syndrome or environmental exposure to allergens and other irritants^[29]. Lundell *et al*^[30] showed that acid is an uncommon cause of LPS in the absence of typical reflux symptoms or endoscopic features of reflux esophagitis. A similar finding was demonstrated in a more recent study by Ang *et al*^[31] where 14% of patients investigated for suspected EES showed an abnormal AET, suggesting that acid and non-acid refluxes do not play different roles in the genesis of extra-esophageal symptoms. Likewise, signs of laryngeal inflammation (i.e., hyperemia, oedema) are not specific to GERD. In 2007, Vavricka *et al*^[32] evaluated the prevalence of specific laryngopharyngeal changes thought to be GERD-related in patients with known reflux disease ($n = 132$) *vs* normal subjects ($n = 132$). Ten specific hypopharyngeal and laryngeal sites were evaluated: the posterior pharyngeal wall, the interarytenoid bar, the posterior commissure, the posterior cricoid wall, the arytenoids complex, the true vocal folds, the false vocal folds, the anterior commissure, the epiglottis and the aryepiglottic fold. Investigators found that the prevalence of laryngeal lesions was the same in both groups. Moreover, most signs identified in patients suspected of having LPR were also present in healthy subjects without any symptoms^[33]. Milstein *et al*^[34] performed a laryngoscopic evaluation of 52 non-smoking volunteers without any history of ENT disease or GERD-related symptoms and observed the presence of one or more signs of tissue irritation in 93% of the subjects. Laryngoscopic or laryngostroboscopic examinations are determinant for excluding laryngeal nodules or neoplastic lesions but are not specific for diagnosing LPR^[35]. Thus, in keeping with these considerations, the utility of laryngoscopy in detecting GERD-associated laryngitis remains uncertain^[33,34]. The use of MII-pH technology has provided new insights into the complex pathogenesis underlying atypical GERD symptoms. Based on our findings, LPS are not always due to GERD and RFS. Although RFS is a useful score for ENT, it is not able to accurately identify patients with LPR due to GERD. Nevertheless, in clinical practice, GERD is often considered as the underlying cause of laryngeal symptoms even in those patients who have a negative MII-pH or in those undergoing twice daily PPI therapy without any efficacy. At present, different causes that might be involved in the genesis of GERD-unrelated LPS are not known, highlighting the need for future studies in this field. We should focus our efforts on searching for these other causes; reflux might be the easy answer, but we must look for difficult answers when logic suggests that direction. Chronic laryngitis is a heterogeneous disease, and GERD may be just one of the causes or an aggravating factor. Patients with and without troublesome reflux symptoms may have different pathophysiological mechanisms and may therefore require different therapies.

Notably, one study demonstrated that gas refluxes with weak acidity were more common in patients with reflux-attributed laryngitis compared to GERD patients and controls^[36]. In keeping with this finding, our results

showed that the only characteristic of refluxes associated with LPR was the presence of gas refluxes. The mechanisms by which gas refluxes may develop into LPS are far from being clarified. It has been hypothesised that gas refluxes carry aerosolised droplets containing hydrogen and pepsin that are able to generate troublesome symptoms into the proximal esophagus and pharyngeal/laryngeal mucosa. Indeed, microaspiration of acid aerosolised droplets is considered one of the most important mechanisms for laryngeal inflammation. Hydrochloric acid vaporises easily and can result in a concentrated cloud of acidic vapour entering the airways^[37].

An increasing number of studies are using the presence of pepsin in clinical samples as a marker for gastroesophageal reflux because it is produced exclusively by the stomach. Indeed, reflux has been documented by detection of pepsin in the trachea, lung, sinus, middle ear, combined sputum and saliva, and breath condensate. Of note, pepsin is stable up to pH 7 and regains activity after reacidification^[38]. In this regard, two recent review articles have highlighted that an immunologic pepsin assay is a rapid, sensitive, and specific tool for correlation of reflux with airway disease and is a reliable diagnostic marker of EES^[39,40]. In particular, extra-esophageal reflux can now be detected by recognising pharyngeal acidification using a miniaturised pH probe and by the non-invasive identification of pepsin in saliva and in exhaled breath condensate using the pepsin immunoassay^[40].

Recently, a new technology able to detect aerosols of acid and gaseous clouds of acid has been described: the Dx-pH measurement system (Dx-pH) (Respiratory Technology Corp., San Diego, CA). Dx-pH is a highly sensitive and minimally invasive device for the detection of acid reflux in the posterior oropharynx. It uses a nasopharyngeal catheter with a sensor that is able to measure pH in either liquid or aerosolised droplets^[41]. A number of preliminary studies have suggested that this technique may have a role in identifying patients with extra-esophageal symptoms caused by reflux disease^[40].

PPI therapy is considered to be the standard of care in patients with LPS when GERD is the underlying suspected aetiology. In clinical practice, it is believed that patients with reflux-related laryngitis require more aggressive and prolonged PPI treatments to achieve an improvement of laryngeal symptoms than those with typical GERD symptoms^[42]. Conversely, several placebo-controlled trials and meta-analyses have failed to demonstrate any therapeutic benefit of PPIs^[43-47]. Some studies have shown that the proportion of patients with marked improvement in laryngeal symptoms after PPI therapy is higher in GERD patients than in those without GERD^[48,49]. On the other hand, the most recent multicenter study, with 145 patients suspected of having LPR, did not show any benefit in patients treated with esomeprazole 40 mg *bid* for 4 mo *vs* placebo^[43].

In the present study, patients with typical GERD symptoms and an abnormal AET had increased symptom relief after PPI therapy. Atypical/extra-esophageal

GERD-suspected symptoms are less responsive to antisecretive therapy.

In conclusion, current knowledge on LPR diagnosis and management needs to be expanded with new diagnostic techniques to better understand the underlying pathophysiological mechanisms. In this respect, the present study underscores the importance of MII-pH monitoring to assess the presence of an established association between GERD and suspected LPR.

COMMENTS

Background

Laryngopharyngeal reflux is defined as the reflux of gastric contents into the larynx and pharynx, and it is the most extensively investigated extra-esophageal syndrome with an established association with gastroesophageal reflux disease (GERD). It may be manifested as laryngeal symptoms as well as laryngoscopic findings. However, laryngoscopic findings are not specific, and this largely limits their diagnostic value. Moreover, there are currently several controversies regarding accurate confirmation of such a diagnosis.

Research frontiers

In the area of chronic laryngitis, the research hotspot is how to diagnose and manage laryngopharyngeal reflux (LPR). In particular, new diagnostic techniques to better understand the underlying pathophysiological mechanisms are necessary. Indeed, GERD may represent just one of the causes or an aggravating factor of laryngopharyngeal symptoms (LPS).

Innovations and breakthroughs

The use of esophageal multichannel impedance and pH technology has provided new insights into the complex pathogenesis underlying atypical reflux symptoms. In clinical practice, GERD is often considered to be the underlying cause of laryngeal symptoms, even in those patients who have a negative impedance and pH study or in those undergoing twice daily proton pump inhibitor therapy without any efficacy. In the present study, LPS were not always due to GERD, and laryngoscopic findings were not able to accurately identify patients with LPR due to GERD. Based on the findings, the only characteristic of refluxes associated with LPR was the presence of gas refluxes, although the mechanisms by which gas refluxes may contribute to LPR are far from being clarified. Overall, patients with typical reflux symptoms and abnormal acid exposure time had increased symptom relief after proton pump inhibitor therapy. Conversely, extra-esophageal reflux-suspected symptoms were less responsive to antisecretive therapy.

Applications

The present study underscores the importance of impedance and pH monitoring to assess the presence of an established association between GERD and suspected LPR.

Terminology

Extra-esophageal syndromes: The manifestations of GERD have been recently classified into either esophageal or extra-esophageal syndromes. Among the latter, the atypical manifestations of GERD such as chronic cough and LPS (i.e., laryngitis, globus, throat discomfort) have been included; Laryngopharyngeal reflux: Laryngopharyngeal reflux is a condition with an established association with GERD and is defined as the reflux of gastric contents into the larynx and pharynx; Multichannel intraluminal impedance and pH monitoring: This is a technique that is able to detect both acid and non-acid reflux and proximal migration of the refluxate, to physically characterise the refluxate (i.e., liquid, gas, mixed), and to correlate symptoms with each type of reflux.

Peer review

This is an interesting and well-structured study aimed to evaluate the diagnostic capacity of laryngoscopic findings suspected to be related to GERD, as performed by ear, nose and throat physicians. The LPR definition is based on the symptoms, although the criteria for LPR symptoms have not been established by many papers. The entry number is relatively small. The authors use multichannel intraluminal impedance and pH monitoring and many questionnaires as the diagnostic gold standard. Of note, they found that laryngoscopic findings had a poor sensitivity and were not related to the multichannel intraluminal impedance and pH results. From their data, the authors suggested that another reason for LPR besides acid reflux was gas reflux.

Abstract

AIM: To evaluate the effect of a novel alginate-based compound, Faringel, in modifying reflux characteristics and controlling symptoms.

METHODS: In this prospective, open-label study, 40 patients reporting heartburn and regurgitation with proven reflux disease (i.e., positive impedance-pH test/evidence of erosive esophagitis at upper endoscopy) underwent 2 h impedance-pH testing after eating a refluxogenic meal. They were studied for 1 h under basal conditions and 1 h after taking 10 mL Faringel. In both sessions, measurements were obtained in right lateral and supine decubitus positions. Patients also com-

pleted a validated questionnaire consisting of a 2-item 5-point (0-4) Likert scale and a 10-cm visual analogue scale (VAS) in order to evaluate the efficacy of Faringel in symptom relief. Tolerability of the treatment was assessed using a 6-point Likert scale ranging from very good (1) to very poor (6).

RESULTS: Faringel decreased significantly ($P < 0.001$), in both the right lateral and supine decubitus positions, esophageal acid exposure time [median 10 (25th-75th percentil 6-16) *vs* 5.8 (4-10) and 16 (11-19) *vs* 7.5 (5-11), respectively] and acid refluxes [5 (3-8) *vs* 1 (1-1) and 6 (4-8) *vs* 2 (1-2), respectively], but increased significantly ($P < 0.01$) the number of nonacid reflux events compared with baseline [2 (1-3) *vs* 3 (2-5) and 3 (2-4) *vs* 6 (3-8), respectively]. Percentage of proximal migration decreased in both decubitus positions (60% *vs* 32% and 64% *vs* 35%, respectively; $P < 0.001$). Faringel was significantly effective in controlling heartburn, based on both the Likert scale [3.1 (range 1-4) *vs* 0.9 (0-2); $P < 0.001$] and VAS score [7.1 (3-9.8) *vs* 2 (0.1-4.8); $P < 0.001$], but it had less success against regurgitation, based on both the Likert scale [2.6 (1-4) *vs* 2.2 (1-4); $P =$ not significant (NS)] and VAS score [5.6 (2-9.6) *vs* 3.9 (1-8.8); $P =$ NS]. Overall, the tolerability of Faringel was very good 5 (2-6), with only two patients reporting modest adverse events (i.e., nausea and bloating).

CONCLUSION: Our findings demonstrate that Faringel is well-tolerated and effective in reducing heartburn by modifying esophageal acid exposure time, number of acid refluxes and their proximal migration.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a common problem affecting about 20% of the population in western countries^[1]. Nonerosive reflux disease (NERD) and erosive reflux disease (ERD) represent the most common phenotypic presentations of GERD, accounting for 90%-95% of the overall GERD patients^[2]. Previous studies have documented that patients with ERD and NERD present the same clinical picture in terms of frequency and severity of reflux symptoms^[2,3].

To date, the use of proton pump inhibitors (PPIs) has been considered the best therapeutic option for GERD patients, given their high efficacy in determining symptom relief and in inducing esophageal mucosal healing^[4,5]. On the other hand, there is increasing evidence that not all patients respond satisfactorily to this kind of treatment and that about 30%-35% of the patients require additional intervention to control symptoms^[6-8]. Thus, traditional antacids are frequently used as add-on therapy in order to neutralize gastric acidity and to help control of heartburn^[7,9,10]. However, there are limited data regarding the mechanisms by which they are able to modify the determinants of reflux symptom perception^[11]. Moreover, despite their utility, the majority of current antacid formulations are not well tolerated by patients and this limits their widespread use and efficacy.

Recently, a novel compound, Faringel (CADIGroup, Rome, Italy), containing sodium bicarbonate and alginate with the addition of herbal components (i.e., honey, chamomille or *Matricaria recutita* L., *Calendula officinalis*, *Aloe vera*, Propolis gel) has been introduced to the market. The first two elements are well known to have an antireflux effect due to their ability to neutralize gastric acidity and to create an alginate-based raft that remains in the upper part of the stomach as a physical barrier capable of preventing reflux episodes^[12-15], while the latter components have been recently associated with mild anti-inflammatory and analgesic effects, and it has been suggested that they may favor the healing of human mucosa^[16-22].

In recent years, multichannel intraluminal impedance combined with pH-metry (MII-pH) has been applied to assess the effectiveness of drugs or endoscopic devices proposed for the therapy of GERD, particularly if we want to know whether they can affect both acid and

nonacid reflux or are able to reduce the proximal migration of the refluxate^[23-26].

The aim of the present study was to evaluate the anti-reflux properties of an alginate antacid formulation (Faringel) on both acid and nonacid reflux episodes, and the height of the proximal extent of reflux events by means of MII-pH monitoring in patients with documented mild to moderate GERD. As a secondary aim, we assessed the therapeutic efficacy of this novel compound as well as its tolerability using validated questionnaires.

MATERIALS AND METHODS

Subjects

This was a prospective, open-label study, enrolling consecutive patients with typical reflux symptoms (i.e., heartburn and regurgitation) lasting for > 6 mo and occurring at least three times weekly, presenting to the University Hospital of Genova and to the University Hospital of Pisa, Italy. They were referred to our units because they were undergoing upper endoscopy, preoperative surgical evaluation, or being investigated for PPI refractoriness. Exclusion criteria were: history of thoracic, esophageal or gastric surgery; primary or secondary severe esophageal motility disorders (e.g., achalasia, scleroderma, diabetes mellitus, autonomic or peripheral neuropathy, myopathy); or history of alcohol or drug abuse. In women of childbearing age, pregnancy was excluded by urine analysis.

For comparison, normal values were obtained from a group of 48 healthy volunteers [HV; 22 male; mean age 44 years, range 22-77 years; mean body mass index (BMI) 23 kg/m², range 16-34 kg/m²] without any type of digestive and systemic symptoms, and previously studied in our laboratory^[27].

The study protocol was approved by the local Ethics Committee and performed according to the Declaration of Helsinki. All patients provided written informed consent to take part.

Study protocol

All subjects who agreed to undergo both upper gastrointestinal (GI) endoscopy and 24-h esophageal impedance pH, underwent physical and clinical examination and a detailed medical history was recorded. The medical history included information on their symptomatic response to previous PPI therapy taken for at least 8 wk at double dose. Patients reporting < 50% heartburn improvement were considered nonresponders to PPIs (i.e., heartburn more than twice weekly for at least 2 mo). Patients taking antisecretory or prokinetic drugs were asked to stop any medication at least 30 and 15 d before endoscopy, respectively. Antacids or alginate preparations were suggested in case of frequent symptoms. The frequency and intensity of symptoms and impact on quality of life were registered using a structured and validated questionnaire for the diagnosis of GERD^[28].

Thereafter, within 1-5 d (median 3 d) from the up-

per GI endoscopy, every patient underwent esophageal impedance-pH testing off-therapy using an ambulatory multichannel intraluminal impedance and pH (MII-pH) monitoring system (Sleuth, Sandhill Scientific, Highland Ranch, CO, United States), according to our methodology^[27]. During the test day, meal time and composition were standardized^[29]. Stationary esophageal manometry was performed before MII-pH in order to locate with accuracy the lower esophageal sphincter (LES). Other features regarding the variables of reflux measurement by MII-pH and data analysis have been previously reported^[30,31].

After the 24-h monitoring period, patients returned to our hospital service. Based on the results of endoscopy and impedance-pH testing, patients were classified as NERD, in case of absence of esophageal mucosal breaks in combination with an abnormal esophageal acid exposure time and/or a positive symptom association probability (> 95%) to acid and/or nonacid reflux during impedance-pH monitoring^[3,27], and as ERD, in case of presence of esophageal mucosal injury according to international criteria^[32]. Furthermore, patients with hypersensitive esophagus (i.e., normal upper endoscopy, normal MII-pH testing, and positivity for symptom association analysis) were ruled out from the whole group of NERD in order to include patients with well-documented GERD. Then, they were asked to ingest a refluxogenic meal consisting of a continental breakfast [one cappuccino, two brioches containing chocolate cream (450 kcal, 60%) fat and orange juice], at least 4 h after the breakfast, and completed two questionnaires including questions on the presence and intensity of heartburn and regurgitation after the meal, as well as a 10-cm visual analogue scale (VAS) scale for each one of the two symptoms (see below). Patients underwent an additional 2-h period of recording; 1 h under basal conditions and another 1 h after a single dose (10 mL) of Faringel. Studies were performed while patients laid in the right lateral decubitus position for 30 min and in the supine decubitus position for another 30 min; both under basal conditions and after Faringel treatment. In particular, the right lateral decubitus position was chosen because it has been shown to be associated with an increased esophageal acid exposure^[33]. Afterward, data recording was concluded. Between the two sections and at the end of the test, patients filled out both symptomatic questionnaires.

Symptom assessment

The primary efficacy parameter was the change in the sum score of the validated Likert scale^[34,35] filled in by the investigator. Intensity of heartburn (defined as a retrosternal burning sensation occurring in waves and tending to rise upward toward the neck) and regurgitation (return of partially digested food from the stomach to the mouth) during the test was recorded by interviewing the patient, using a 5-point Likert rating scale as follows: 0 = none (absence of symptoms); 1 = mild (minimal awareness of symptoms, which is easily tolerated); 2 = moderate (awareness of symptoms, which is bothersome

but tolerable); 3 = severe (symptoms hard to tolerate); 4 = very severe (symptom impossible to tolerate). The score was used for the outcome measurement as a sum score, with its highest value of 8 points representing the most severe symptom intensity.

Patients were also asked to rate their satisfaction with symptom control on a global VAS of 0 (no relief at all) to 100 (complete symptom relief). The VAS score has been used as a self-assessment tool for symptom measure, which has been adopted in many other trials for evaluation of visceral symptoms^[36,37].

The secondary target variable comprised the overall tolerability of the treatment, assessed by investigator and patient using a 6-point Likert scale ranging from very poor (1) to very good (6). Together with the exploratory target variables, the number of responders and patients free of symptoms were also studied. Responders were defined as patients for whom a 40% improvement in the Likert scale was achieved, whereas patients free of symptoms were defined as subjects showing an overall sum score of 0 or 1 point when treatment stopped.

Statistical analysis

Differences in proportions were compared using the χ^2 or Fisher's exact test, depending on the sample size. Unless otherwise specified, data were presented as median and percentile values (25th, 75th, 95th percentile). In case of non-normally distributed data, differences between patients were compared using the Kruskal-Wallis and/or Mann-Whitney tests. Differences were considered statistically significant at $P < 0.05$.

RESULTS

Patients

Forty patients with heartburn (20 female/20 male, mean age 48 years, range 18-76 years) reporting at least one symptom during the testing day were included in the study. Detailed demographic and clinical features of GERD patients and HVs are shown in Table 1. There was no difference among them and HVs in terms of sex and age. The prevalence of hiatal hernia as well as mean BMI was significantly higher in patients with GERD compared to the HVs ($P < 0.01$). All subjects tolerated well the examination and the test meal. No important technical failure occurred.

24-h impedance-pH data

Detailed impedance-pH characteristics of our patients and HVs are reported in Table 2. Patients with GERD had significantly greater distal esophageal acid exposure time compared to HVs (5.5 *vs* 0.7, $P < 0.0001$). The median total number of reflux episodes was 65 and the median number of acid reflux events was 53, and both were significantly higher in GERD patients compared to HVs (32 and 17, respectively; $P < 0.0001$). Patients with GERD and HVs had a similar number of nonacid reflux episodes (20 *vs* 18, $P < 0.0615$). The percentage of total

reflux episodes reaching the proximal measuring site (15 cm above the LES) was higher in GERD patients than in HVs (46% *vs* 33%, *P* < 0.0001).

2-h impedance-pH data before and after treatment

As shown in Figures 1 and 2A, Faringel decreased significantly (*P* < 0.001), in both the right lateral and supine decubitus positions, esophageal acid exposure time [10 (6-16; 23) *vs* 5.8 (4-10; 16) and 16 (11-19; 32) *vs* 7.5 (5-11; 15), respectively], acid reflux events [5 (3-8; 11) *vs* 1 (1-1; 2) and 6 (4-8; 11) *vs* 2 (1-2; 5), respectively], and proximal reflux episodes [4 (3-6; 11) *vs* 1 (1-2; 3) and 5 (4-7; 11) *vs* 3 (2-3; 4), respectively]. Also, the percentage of proximal migration of reflux events decreased significantly in both the right lateral and supine decubitus positions (60% *vs* 32% and 64% *vs* 35%) compared with baseline. In contrast, Faringel increased significantly (*P* < 0.01) the number of nonacid reflux events compared with baseline [2 (1-3; 5) *vs* 3 (2-5; 7) and 3 (2-4; 7) *vs* 6 (3-8; 13); Figure 2B]. The number of total reflux episodes slightly significantly decreased in the right lateral decubitus position, before and after Faringel treatment, while no difference was found in the supine decubitus position [7 (5-10; 15) *vs* 4 (3-5; 10) and 8.5 (7-11; 16) *vs* 7 (5-10; 17), *P* = 0.0001 and *P* = 0.1321, respectively].

Table 2 Impedance-pH features in gastro-esophageal reflux disease patients and healthy volunteers

Impedance-pH features	GERD patients	HVs	<i>P</i> value
% pH < 4 upright	6.9 (5.5-12; 28)	1 (0.2-1.9; 5)	< 0.0001
% pH < 4 recumbent	3.5 (1.2-7; 18)	0 (0-0.1; 2.1)	< 0.0001
% pH < 4 total	5.5 (4.3-9; 22)	0.7 (0.2-1.4; 4.2)	< 0.0001
GER total	65 (54-108; 177)	32 (18-43; 54)	< 0.0001
GER acid	53 (34-72; 95)	17 (8-31; 45)	< 0.0001
GER nonacid	20 (15-37; 116)	18 (14-26; 45)	0.0615
Prox. extension	31 (20-48; 86)	9 (4-17; 30)	< 0.0001

GER: Gastroesophageal reflux; GERD: Gastroesophageal reflux disease; HV: Healthy volunteer.

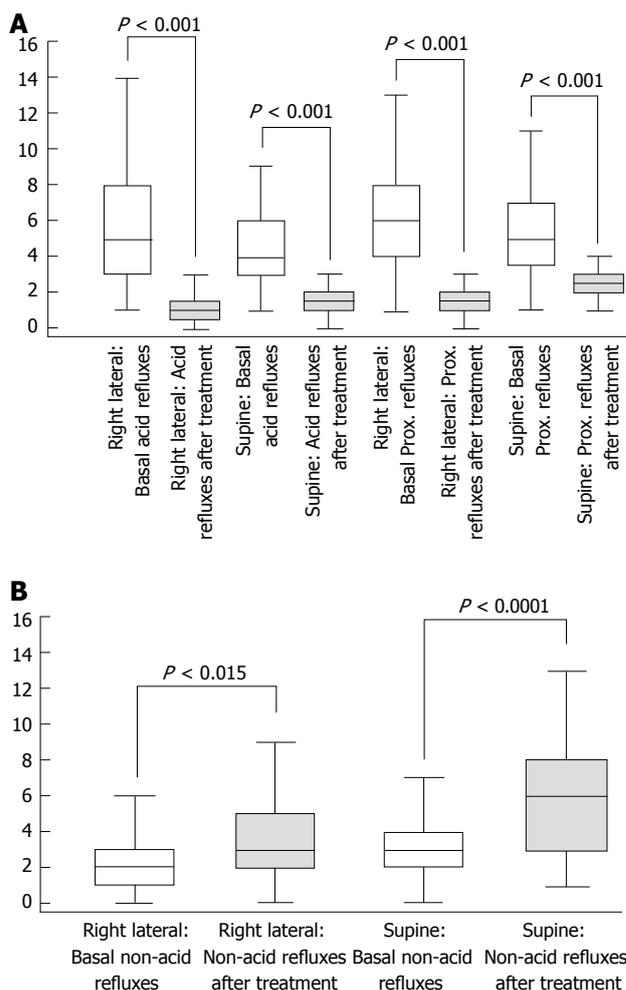

Figure 2 Number of acid reflux (A) and non-acid reflux (B) episodes under basal conditions and after Faringel intake in the two decubitus positions.

Symptom relief and drug tolerability

Patients reported a greater mean (range) number of symptoms before than after treatment and this included both heartburn [2.5 (1-9) *vs* 1 (0-2)] and regurgitation [2 (1-5) *vs* 1 (0-2)]. Faringel was found to be significantly effective in controlling heartburn, based on the both Likert scale [3.1 (range 1-4) *vs* 0.9 (0-2); *P* < 0.001] and

VAS score [7.1 (3-9.8) *vs* 2 (0.1-4.8); $P < 0.001$], while it had less success against the symptom regurgitation based on both the Likert scale [2.6 (1-4) *vs* 2.2 (1-4); $P =$ not significant (NS)] and VAS score [5.6 (2-9.6) *vs* 3.9 (1-8.8); $P =$ NS]. Overall, the tolerability of Faringel was very good [5 (2-6)], with only two patients reporting modest adverse events (i.e., nausea and bloating).

DISCUSSION

Alginates are neutral polysaccharide polymers isolated from brown seaweed (*Phacophyceae*) and are classified as dietary fiber. They are constituted by a proportion of D-mannuroic and L-glucuronic acids. In the presence of gastric acid, alginates precipitate and form a gel. One of the most interesting characteristics is due to the presence of sodium or potassium bicarbonate that, in the presence of gastric acid is converted to a dioxide which, when entrapped in the gel, converts it into a foam that floats on the surface of the gastric contents^[12]. Thus, thanks to their unique mechanism, alginate-based raft-forming formulations have been marketed worldwide for > 40 years under various brand names for the symptomatic treatment of GERD, and many studies have reported their efficacy^[12,38,39]. However, the majority of these studies have assessed only the control of symptoms without objective evaluation of the effect of these drugs on abnormal reflux by means of pH-monitoring, and even less using impedance-pH testing that is available in the clinical setting since few years.

Therefore, in our prospective study we evaluated the effect of a new alginate raft-forming formulation, Faringel, in a group of 40 patients with GERD who underwent 24 h MII-pH testing after a reflux-provocative meal. Our results showed that this alginate-based formulation is able to reduce the number of acid refluxes and the esophageal exposure time below pH 4.0. Moreover, it is able to decrease significantly, in both the right lateral and supine decubitus position, the number of acid reflux events and their proximal migration. Finally, all patients also reported a lower number of symptoms after treatment, including both heartburn and regurgitation, although the effect on the latter was less evident.

The patients evaluated in the present study were truly representative of the GERD population. Indeed, they had typical reflux symptoms (i.e., heartburn and regurgitation), abnormal acid exposure time, and/or evidence of mucosal breaks at upper GI endoscopy. We opted to include patients with these characteristics in order to be sure of excluding those with functional heartburn. Moreover, we preferred not to enroll patients with normal acid exposure and positive symptom association (i.e., hypersensitive esophagus) for reducing possible confounding factors such as visceral hyperalgesia, overlap with functional disease, autonomic dysfunction and concomitant psychiatric illness that have been more associated with the above condition^[40-43]. Finally, a recent report has suggested caution about overinterpretation

of symptom indexes in reflux monitoring, thus supporting our decision to exclude patients with hypersensitive esophagus in order to avoid confusion^[44].

Previously, Chatfield has reported a comparison of alginate preparation with placebo for the symptomatic relief of reflux esophagitis^[39]. In this multicenter randomized double-blind study, alginate was superior to placebo in reducing symptom severity and increasing symptom-free days. Interestingly, the placebo group recorded a larger number of dropouts due to side effects. This means that alginate is safe and provides better relief of symptoms. An older study that simultaneously used pH-telemetry and X-rays demonstrated that pH within the raft is approximately neutral, while the pH of the gastric contents beneath the raft remains acidic (pH 1-2)^[45]. These data are important because they explain why the alginate formulation is effective in controlling heartburn in the supine decubitus position, as observed in this study, and probably also during the night-time. More recently, using impedance-pH monitoring, we showed a reduction of acid reflux episodes and proximal migration of the refluxate and thereby a relevant decrease of GERD-related symptoms compared with baseline after sodium alginate administration^[7]. However, the results of the latter study were less marked than those of the current investigation, probably because patients were enrolled only on the basis of symptoms without objective documentation of GERD, either by endoscopy or pH monitoring. Moreover, in the previous study, tolerability was not evaluated.

The good control of acid reflux confirms the results obtained in previous studies performed with pH-metry^[7,14,46,47] or scintigraphic methods^[48,49], and represents the main mechanism of the quick and effective relief of heartburn in reflux patients. In a recent study, the positive effect of sodium alginate in reducing acid refluxes has been confirmed using simultaneously stepwise pH pull-throughs, high-resolution manometry and fluoroscopy^[15]. In fact, Kwiatek *et al*^[15] have shown that alginate can also eliminate or displace the “acid-pocket”, which is a phenomenon seen in the proximity of the esophago-gastric junction and is the likely origin of postprandial acid reflux in GERD patients.

Another interesting characteristic of sodium alginate has been emphasized by Manabe *et al*^[50] in NERD patients, who are known to have a lower response rate to PPIs than patients with ERD when gauged by relief of heartburn. In this study, patients who received omeprazole combined with sodium alginate recorded longer symptom relief compared with those receiving omeprazole alone. They concluded that sodium alginate is useful in combination with PPI therapy and has to be considered for treating NERD patients who do not respond completely to PPIs. Also, in our investigation, we evaluated NERD patients and found similar results on symptom relief in this particular group of GERD patients, although we did not study Faringel as an add-on therapy.

It is likely that the positive effect of sodium algi-

nate in controlling GERD-related symptoms is due to a whole equilibrium between raft-forming alginate and antacid substances. Faringel is constituted from sodium alginate and sodium carbonate. A previously published study has shown that, if two different antacid substances are present (e.g., Algicon Liquid), an effective reflux suppressing raft cannot form because a large amount of antacid prevents the raft formation by neutralizing the gastric acid required to react with alginate. Faringel and Gaviscon formulation consist of sodium alginate and sodium carbonate, and they have a lower acid-neutralizing capacity and a complete raft-forming gel reaction^[13,47,49]. These studies have shown that a large amount of antacids is not required for strong raft formation and effective reflux suppression.

On the contrary, various findings suggest that alginate is less effective in reducing nonacid than acid reflux. In our study alginate increased significantly the number of nonacid reflux events compared with baseline. The number of total reflux episodes decreased slightly but significantly in the right lateral decubitus position, whereas no difference was found in the supine decubitus position. Similarly, Zentilin *et al*^[7] have shown no action of alginate on nonacid reflux events. Surprisingly, in our study, the number of nonacid reflux episodes almost doubled after drug intake in 50% of patients. Probably the antacid effect of sodium alginate reduces acid reflux, but seems to increase nonacidic reflux.

Finally, our study shows that the percentage of proximal migration of reflux events decreased significantly both in the right lateral and supine decubitus positions compared with baseline, thus stopping one of the main determinants by which reflux causes symptoms^[51-53]. These results confirm our previous findings with a different sodium alginate formulation, although the study was performed in a smaller sample of patients and without a clear documentation of GERD^[7]. These investigations performed with impedance-pH monitoring technique permitted us to assess the ability of sodium alginate to reduce the proximal extension of refluxed material. The raft obtained with alginate represents a cork in the zone of the LES that prevents any gastric material migration into the esophagus independently of the patient decubitus. This beneficial effect could help in controlling not only typical, but especially extraesophageal symptoms. In particular, the Faringel formulation adds to alginate able to control GERD related typical symptoms a large number of vegetal extracts, which have the potential to promote healing of pharyngo-esophageal mucosal lesions. The anti-flogistic properties of Faringel are due to herbs such as Propolis, *A. vera*, and *Calendula*. Eamlamnam *et al*^[54] have observed that *A. vera* treatment induces a complete reduction in leukocyte adherence and tumor necrosis factor- α levels combined with elevated interleukin-10 levels, which are able to promote healing of gastric ulcers in male Sprague-Dawley rats. Propolis and *A. vera* have also demonstrated pain-killing effects^[55]. Moreover, experimental studies have shown that *C. officinalis* has anti-inflammatory and antibacterial activities as well as angiogenic and fibroblastic

properties acting in a positive way on the inflammatory and proliferative phase of the healing process^[20]. Thus, we can speculate that all these data on the anti-inflammatory properties of the herbal components of Faringel may be relevant for extraesophageal reflux-related symptoms in which a flogistic component seems to be more evident^[56].

In conclusion, our findings demonstrated that Faringel formulation is well tolerated and highly effective in controlling, or at least reducing, heartburn in GERD patients by modifying the number of acid reflux episodes and lowering the proximal migration of reflux events. It was less effective in controlling nonacid reflux and regurgitation. Its action in reducing the proximal extension of reflux events and the combined presence of natural substances (*Calendula*, *Aloe*, honey) that favor mucosal healing could be useful to improve GERD-related extraesophageal symptoms.

COMMENTS

Background

The use of proton pump inhibitors (PPIs) has been considered the best therapeutic option for gastroesophageal reflux disease (GERD), given their high efficacy in inducing symptom relief and esophageal mucosal healing. On the other hand, there is increasing evidence that not all patients (30%-35%) respond satisfactorily to this treatment. Thus, traditional antacids as alginate-based raft-forming formulations are used worldwide as add-on therapy to neutralize gastric acidity and help control heartburn. In recent years, multichannel intraluminal impedance combined with pH-metry (MII-pH) has been applied to assess the effectiveness of drugs or endoscopic devices proposed for the therapy of GERD, particularly if people want to know whether they can affect both acid and nonacid reflux or reduce the proximal migration of the refluxate.

Research frontiers

There are few data available regarding the mechanisms by which antacids as alginate-based raft-forming formulations are able to modify the determinants of reflux symptom perception, therefore, this study tried to evaluate the antireflux properties of an alginate antacid formulation (Faringel) on both acid and nonacid reflux episodes, and the height of proximal extent of reflux events by means of MII-pH monitoring in patients with documented mild to moderate GERD. As a secondary aim, authors assessed the therapeutic efficacy of this novel compound as well as its tolerability using validated questionnaires.

Innovations and breakthroughs

In this prospective, open-label study, 40 patients reporting heartburn and regurgitation with proven reflux disease (i.e., positive impedance-pH test/evidence of erosive esophagitis at upper endoscopy) underwent 2-h impedance-pH test after eating a refluxogenic meal. They were studied for 1 h under basal conditions and 1 h after taking 10 mL Faringel. Patients also completed validated questionnaires in order to evaluate the efficacy of Faringel for symptom relief. Tolerability of the treatment was also assessed.

Applications

The results suggest that Faringel is able to reduce the esophageal acid exposure time, the number of acid reflux events and their proximal migration, thus stopping two of the main determinants by which reflux causes symptoms (i.e., abnormal esophageal acid exposure time and proximal extension of the refluxate). Moreover, Faringel was very well-tolerated and effective in reducing heartburn and regurgitation, although the efficacy on the latter symptom was less evident.

Terminology

GERD is a condition that develops when the reflux of stomach contents causes troublesome symptoms and/or complications; Faringel is an antacid formulation, containing sodium bicarbonate and alginate with the addition of herbal components (i.e., honey, *Chamomille* or *Matricaria recutita* L., *Calendula officinalis*, *Aloe vera*, Propolis gel) that have been recently associated with mild anti-inflammatory and analgesic effects; MII-pH is a novel technique for pH-

independent detection of GER.

Peer review

The study is interesting, well conducted, with a clear statistical analysis and a comprehensive discussion.

Abstract

AIM: To study the prevalence of functional dyspepsia (FD) (Rome III criteria) across eating disorders (ED), obese patients, constitutional thinner and healthy volunteers.

METHODS: Twenty patients affected by anorexia nervosa, 6 affected by bulimia nervosa, 10 affected by ED not otherwise specified according to diagnostic and statistical manual of mental disorders, 4th edition, nine constitutional thinner subjects and, thirty-two obese patients were recruited from an outpatients clinic devoted to eating behavior disorders. Twenty-two healthy volunteers matched for age and gender were enrolled as healthy controls. All participants underwent a careful clinical examination. *Demographic* and *anthropometric characteristics* were obtained from a structured *questionnaires*. The presence of FD and, its subgroups, epigastric pain syndrome and

postprandial distress syndrome (PDS) were diagnosed according to Rome III criteria. The intensity-frequency score of broader dyspeptic symptoms such as early satiety, epigastric fullness, epigastric pain, epigastric burning, epigastric pressure, belching, nausea and vomiting were studied by a standardized questionnaire (0-6). Analysis of variance and *post-hoc* Sheffè tests were used for comparisons.

RESULTS: 90% of patients affected by anorexia nervosa, 83.3% of patients affected by bulimia nervosa, 90% of patients affected by ED not otherwise specified, 55.6% of constitutionally thin subjects and 18.2% healthy volunteers met the Postprandial Distress Syndrome Criteria (χ^2 , $P < 0.001$). Only one bulimic patient met the epigastric pain syndrome diagnosis. Postprandial fullness intensity-frequency score was significantly higher in anorexia nervosa, bulimia nervosa and ED not otherwise specified groups compared to the score calculated in the constitutional thinner group (4.15 ± 2.08 vs 1.44 ± 2.35 , $P = 0.003$; 5.00 ± 2.45 vs 1.44 ± 2.35 , $P = 0.003$; 4.10 ± 2.23 vs 1.44 ± 2.35 , $P = 0.002$, respectively), the obese group (4.15 ± 2.08 vs 0.00 ± 0.00 , $P < 0.001$; 5.00 ± 2.45 vs 0.00 ± 0.00 , $P < 0.001$; 4.10 ± 2.23 vs 0.00 ± 0.00 , $P < 0.001$, respectively) and healthy volunteers (4.15 ± 2.08 vs 0.36 ± 0.79 , $P < 0.001$; 5.00 ± 2.45 vs 0.36 ± 0.79 , $P < 0.001$; 4.10 ± 2.23 vs 0.36 ± 0.79 , $P < 0.001$, respectively). Early satiety intensity-frequency score was prominent in anorectic patients compared to bulimic patients (3.85 ± 2.23 vs 1.17 ± 1.83 , $P = 0.015$), obese patients (3.85 ± 2.23 vs 0.00 ± 0.00 , $P < 0.001$) and healthy volunteers (3.85 ± 2.23 vs 0.05 ± 0.21 , $P < 0.001$). Nausea and epigastric pressure were increased in bulimic and ED not otherwise specified patients. Specifically, nausea intensity-frequency score was significantly higher in bulimia nervosa and ED not otherwise specified patients compared to anorectic patients (3.17 ± 2.56 vs 0.89 ± 1.66 , $P = 0.04$; 2.70 ± 2.91 vs 0.89 ± 1.66 , $P = 0.05$, respectively), constitutional thinner subjects (3.17 ± 2.56 vs $0.00 \pm$

0.00, $P = 0.004$; 2.70 ± 2.91 vs 0.00 ± 0.00 , $P = 0.005$, respectively), obese patients (3.17 ± 2.56 vs 0.00 ± 0.00 , $P < 0.001$; 3.17 ± 2.56 vs 0.00 ± 0.00 , $P < 0.001$ respectively) and, healthy volunteers (3.17 ± 2.56 vs 0.17 ± 0.71 , $P = 0.002$; 3.17 ± 2.56 vs 0.17 ± 0.71 , $P = 0.001$, respectively). Epigastric pressure intensity-frequency score was significantly higher in bulimic and ED not otherwise specified patients compared to constitutional thin subjects (4.67 ± 2.42 vs 1.22 ± 1.72 , $P = 0.03$; 4.20 ± 2.21 vs 1.22 ± 1.72 , $P = 0.03$, respectively), obese patients (4.67 ± 2.42 vs 0.75 ± 1.32 , $P = 0.001$; 4.20 ± 2.21 vs 0.75 ± 1.32 , $P < 0.001$, respectively) and, healthy volunteers (4.67 ± 2.42 vs 0.67 ± 1.46 , $P = 0.001$; 4.20 ± 2.21 vs 0.67 ± 1.46 , $P = 0.001$, respectively). Vomiting was referred in 100% of bulimia nervosa patients, in 20% of ED not otherwise specified patients, in 15% of anorexia nervosa patients, in 22% of constitutional thinner subjects, and, in 5.6% healthy volunteers (χ^2 , $P < 0.001$).

CONCLUSION: PDS is common in eating disorders. Is it mandatory in outpatient gastroenterological clinics to investigate eating disorders in patients with PDS?

INTRODUCTION

Eating disorders (ED) are highly prevalent health problems in Western countries, especially in young women^[1]. Although no consensus has been yet achieved in the definition of eating disorders^[2], three main ED categories have been identified according to the diagnostic and statistical manual of mental disorders, 4th edition (DSM-IV)^[3]: anorexia nervosa (AN), bulimia nervosa (BN), and eating disorders not otherwise specified (EDNOS). In ED patients there is a significant impairment of both physical health and psychosocial functioning^[4]. Gastrointestinal (GI) symptoms are a common complaint in these patients. Boyd *et al*^[5] interviewed 101 ED patients

(44% AN, 22% BN, 34% EDNOS), using a standardized questionnaire to assess the presence of functional gastrointestinal disorders (FGIDs) such as irritable bowel syndrome (IBS), functional heartburn, functional abdominal bloating, functional constipation, functional dysphagia and functional anorectal pain disorder, showing that 98% of ED patients fulfilled the criteria for at least one FGID. A recent study demonstrated that 68.8% of ED patients met the Manning criteria for IBS^[6]. However, it was suggested that the wide range of FGIDs found in ED were the result of the behavior-associated ED. In fact, these GI symptoms may persist even after the recovery from ED, especially in psychologically distressed patients^[7]. However, the underlying mechanisms that link ED and GI symptoms remain to be elucidated^[8].

It is a common occurrence that patients, before presenting to healthcare services with an ED, seek treatment for GI symptoms^[9]. FGIDs induce high healthcare utilization and negative impact on quality of life^[10]. Dyspeptic symptoms are very common in the general population, with prevalence estimates ranging between 10% and 45%^[11,12]. The results of prevalence studies are strongly influenced by the criteria used to define dyspepsia. Well-performed epidemiological studies have reported a prevalence of approximately 20%-25% in western countries^[13,14], slightly higher in women, with a variable influence of age across studies.

Currently, an internationally accepted clinical standard (Rome III criteria) is extensively used to diagnose FGIDs^[15]. The Rome III Criteria were developed by a Committee that recommended the following pragmatic description of functional dyspepsia (FD) defined as the presence of symptoms thought to originate in the gastroduodenal region, in the absence of any organic, systemic, or metabolic disease that is likely to explain the symptoms. The specific symptoms needed to diagnose FD are: epigastric pain, epigastric burning, post-prandial fullness and early satiation. In addition, the Rome III consensus offers an umbrella definition for FD, and, furthermore, helps to distinguish whether patients report symptom aggravation after ingestion of a meal, meal-related dyspeptic symptoms, the so called postprandial distress syndrome (PDS) characterized by postprandial fullness and early satiation or meal-unrelated dyspeptic symptoms, the so called epigastric pain syndrome (EPS), characterized by epigastric pain and epigastric burning^[16]. A distinction between meal-related and meal-unrelated symptoms might be pathophysiologically and clinically relevant to disclose differences across ED, and other groups of patients with different patterns of abnormal eating behavior such as obese patients (OB) and constitutional thinness subjects (CT) in comparison to healthy volunteers (HV).

Our primary aim was to study the prevalence of FD and its subgroups according to the Rome III criteria across ED in comparison to OB patients, CT subjects and HV. Secondary aims were the evaluation of the frequency-intensity score of broader dyspeptic symptoms

such as early satiety, epigastric fullness, epigastric pain, epigastric burning, epigastric pressure, belching, nausea and vomiting in ED patients compared to the other groups of patients with different patterns of abnormal eating behavior.

MATERIALS AND METHODS

Participants

Five groups of patients matched for age and gender were recruited from an outpatients clinic devoted to eating behavior disorders. The first group consisted of 20 patients (AN-group), the second group of 6 BN patients (BN-group), the third group of 10 EDNOS patients (EDNOS-group), the fourth group of 9 CT subjects (CT-group) and the last group of 32 OB patients (OB-group). Twenty-two HV were recruited among administrative and/or paramedical staff members and patients' friends as the control healthy group (HV-group).

All patients and HV were interviewed to detect lifetime eating disorders in accordance with the criteria of the DSM-IV^[3]. The DSM-IV criteria define anorexia nervosa as self-induced weight loss or refusal to maintain or gain weight normally, with resulting weight more than 15% below normal; intense fear of fatness or gaining weight, even though underweight; deep disturbance in body image; and reproductive hormone abnormality (for example, at least 3 mo of amenorrhea).

Bulimia nervosa is defined as recurrent episodes of binge eating (a large amount of food eaten quickly and privately with lack of control over eating) and recurrent inappropriate compensatory behaviour to prevent weight gain (self-induced vomiting; misuse of laxatives, diuretics, enemas, or other medications; fasting; excessive exercise) at least twice a week for at least 3 mo, and self-evaluation unduly influenced by body shape and weight.

EDNOS represents the third category of ED and involves milder versions of anorexia and bulimia nervosa that do not satisfy all the criteria (for example, a binge episode once a week or for less than 3 mo for bulimia nervosa; weight loss less than 15% for anorexia nervosa).

CT subjects were recruited among the patients evaluated for leanness, using the following inclusion criteria: severely underweight, but stable throughout the post-pubertal period, presence of physiological menstruations without estroprogestative treatment, and the desire for weight gain as the main reason for medical consultation, together with the exclusion of celiac disease, infectious diseases, cancer, or other consumptive diseases^[17].

Obesity is defined if the body mass index (BMI) was ≥ 30 kg/m² according to the National Institute of Health guidelines^[18].

For each patient, demographic (age, smoking habits, alcohol intake) and anthropometric characteristics (weight, height and BMI) were collected.

All patients gave their written consent to participate into the study. The study, fully complied with the Declaration of Helsinki, and was approved by the Ethics Com-

mittee of the Ruggi d'Aragona Hospital AOU University of Salerno.

Questionnaire

All participants underwent a standardized questionnaire testing the presence of FD according to Rome III criteria. The Rome III symptom questionnaire consisted of 18 questions and allowed the diagnosis of FD and its subgroups (PDS and EPS). The characteristic symptoms of PDS were bothersome postprandial fullness or early satiation and those of EPS were unexplained epigastric pain or burning^[16]. The frequency for early satiety, epigastric fullness, epigastric pain and burning (the 4 cardinal symptoms pragmatically described by the Rome III Committee)^[16] and other dyspeptic symptoms such as epigastric pressure, belching, nausea and vomiting was scored from 0 to 3 (0 = absent, 1 = 2 d/wk; 2 = 3-5 d/wk; and 3 = 6 d or 7 d/wk); the intensity for the same symptoms was scored from 0 to 3 (0 = absent; 1 = not very bothersome, not interfering with daily activities; 2 = bothersome, but not interfering with daily activities; and 3 = interfering with daily activities). A frequency-intensity score from 0 up to a maximum of 6 was obtained for each symptom^[19].

Statistical analysis

Data are expressed as mean \pm SE, unless otherwise specified. χ^2 test and, analysis of variance (ANOVA) followed by one way ANOVA for multiple comparisons (Scheffé) were used to compare categorical and continuous data, respectively. The significance level was set at 0.05. The statistical program used was SPSS version 12.0 for Windows.

RESULTS

Anthropometric characteristics of the studied population were shown in Table 1. Eighteen/20 (90%) AN, 5/6 (83.3%) BN, 9/10 (90%) EDNOS, 5/9 (55.6%) CT, and 4/22 (18.2%) HV met Rome III criteria for PDS (χ^2 , $P < 0.001$). Figure 1 shows the distribution of PDS diagnosis in ED, CT and HV. Only one BN patient met the EPS Criteria. None of the patients with ED, CT, OB or HV had both PDS and EPS.

Table 1 shows the intensity-frequency score calculated for each symptom in the studied population. Postprandial fullness intensity-frequency score was significantly higher in AN, BN and EDNOS groups compared to the score calculated in the CT group (4.15 ± 2.08 vs 1.44 ± 2.35 , $P = 0.003$; 5.00 ± 2.45 vs 1.44 ± 2.35 , $P = 0.003$; 4.10 ± 2.23 vs 1.44 ± 2.35 , $P = 0.002$, respectively), OB group (4.15 ± 2.08 vs 0.00 ± 0.00 , $P < 0.001$; 5.00 ± 2.45 vs 0.00 ± 0.00 , $P < 0.001$; 4.10 ± 2.23 vs 0.00 ± 0.00 , $P < 0.001$, respectively) and, HV (4.15 ± 2.08 vs 0.36 ± 0.79 , $P < 0.001$; 5.00 ± 2.45 vs 0.36 ± 0.79 , $P < 0.001$; 4.10 ± 2.23 vs 0.36 ± 0.79 , $P < 0.001$, respectively). Early satiety intensity-frequency score was prominent in anorectic patients compared to bulimic patients (3.85 ± 2.23 vs 1.17 ± 1.83 ,

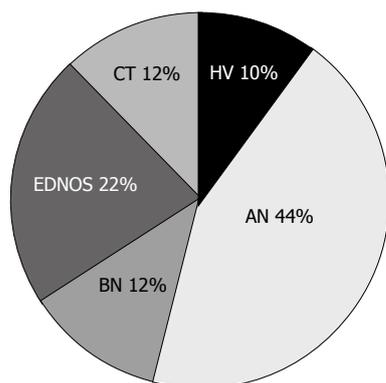

Figure 1 Distribution of the postprandial distress syndrome diagnosis in anorexia nervosa, bulimia nervosa, eating disorders not otherwise specified, constitutional thinners and healthy volunteers ($n = 41$). AN: Anorexia nervosa; BN: Bulimia nervosa; EDNOS: Eating disorders not otherwise specified; CT: Constitutional thinners; HV: Healthy volunteers.

$P = 0.015$), obese patients (3.85 ± 2.23 vs 0.00 ± 0.00 , $P < 0.001$) and, HV (3.85 ± 2.23 vs 0.05 ± 0.21 , $P < 0.001$). Nausea and epigastric pressure were increased in bulimic and EDNOS patients. Specifically, nausea intensity-frequency score was significantly higher in BN and EDNOS patients compared to the score calculated in anorectic patients (3.17 ± 2.56 vs 0.89 ± 1.66 , $P = 0.04$; 2.70 ± 2.91 vs 0.89 ± 1.66 , $P = 0.05$, respectively), Constitutional Thinner subjects (3.17 ± 2.56 vs 0.00 ± 0.00 , $P = 0.004$; 2.70 ± 2.91 vs 0.00 ± 0.00 , $P = 0.005$, respectively), obese patients (3.17 ± 2.56 vs 0.00 ± 0.00 , $P < 0.001$; 3.17 ± 2.56 vs 0.00 ± 0.00 , $P < 0.001$, respectively) and, HV (3.17 ± 2.56 vs 0.17 ± 0.71 , $P = 0.002$; 3.17 ± 2.56 vs 0.17 ± 0.71 , $P = 0.001$, respectively). Epigastric pressure intensity-frequency score was significantly higher in bulimic and EDNOS patients compared to the score calculated in CT subjects (4.67 ± 2.42 vs 1.22 ± 1.72 , $P = 0.03$; 4.20 ± 2.21 vs 1.22 ± 1.72 , $P = 0.03$, respectively), obese patients (4.67 ± 2.42 vs 0.75 ± 1.32 , $P = 0.001$; 4.20 ± 2.21 vs 0.75 ± 1.32 , $P < 0.001$, respectively) and, HV (4.67 ± 2.42 vs 0.67 ± 1.46 , $P = 0.001$; 4.20 ± 2.21 vs 0.67 ± 1.46 , $P = 0.001$, respectively). Vomiting was referred in 100% of BN patients, in 20% of EDNOS patients, in 15% of AN patients, in 22% of CT subjects and, in 5.6% of HV (χ^2 , $P < 0.001$). Epigastric pain intensity-frequency score just failed to reach significance in EDNOS compared to HV ($P = 0.05$), whereas it was significantly higher in EDNOS compared to OB patients ($P = 0.02$). Figure 2 shows the pattern of dyspeptic symptoms that reached the statistical significance in all groups.

DISCUSSION

The novel result of our study was that the diagnosis of PDS according to Rome III Criteria was very common in AN, BN and EDNOS, the three main categories of ED, whilst EPS is incredibly rare. Moreover, BN and EDNOS showed high postprandial fullness, epigastric pressure and nausea intensity-frequency scores, whereas AN patients shared with BN an increase in postprandial fullness

score, but conversely demonstrated a prominent early satiety. OB patients were almost asymptomatic regarding FD symptoms.

The hallmarks of ED are clinical disturbances in body image and eating behavior resulting in physical and psychological impairment. These clinical entities are diagnosed according to DSM-IV criteria. Among them disorders such as AN, BN and EDNOS are more common in women and can result in long-term health consequences even in increased mortality. The core presentation of Anorexia nervosa is characterized by the inability or refusal to maintain a minimally normal weight, a profoundly distorted perception of body weight and shape, and amenorrhea. Under the definition of BN are included individuals who engage in recurrent binge-eating episodes and recurrent inappropriate compensatory behaviours that are intended to rid calories that they voraciously ingested. EDNOS involves milder versions of anorexia and bulimia nervosa that do not satisfy all the criteria. Previous studies have suggested that anorectic patients frequently complain of gastrointestinal symptoms hinting at a disordered gastric motility, especially when they are in a refeeding phase^[20]. Dyspeptic symptoms such as epigastric fullness and distension were found to be significantly more prevalent and intense than in healthy subjects^[21-23] and may serve as an argument for food refusal^[24]. However, they are often overlooked or misinterpreted. In this study the more prevalent and intense dyspeptic symptoms scored by a standardized questionnaire were epigastric fullness and early satiety. In bulimic patients the large quantities eaten during a binge not only lead to a feeling of loss of control but also to a sensation of epigastric distension. The latter as well as the often associated epigastric pain are terminated by self-induced vomiting, which allows either continuation or termination of the binge^[20]. Our findings demonstrated that BN and EDNOS referred postprandial fullness, epigastric pressure and nausea as their most prevalent and intense dyspeptic symptoms. The mechanisms underlying these dyspeptic symptoms in ED are still unclear, although malnutrition and the resultant metabolic myopathy, along with electrolyte depletion seem to play the crucial role in determining the demonstrated abnormalities in gastric emptying^[22], gastric capacity^[25] and, blunted endocrine control^[26]. Conversely, irrespective of the pathophysiology and mechanisms involved, it is intriguing that the association of higher body mass index alone with dyspeptic symptoms was relatively modest also contrary to the study expectation. It is noteworthy that in our OB group no binge behavior has been diagnosed, suggesting that eating patterns are more closely linked to symptom generation in the GI tract^[27]. In addition, to our knowledge this is the first study that demonstrated in ED a high prevalence of PDS using the Rome III criteria, an international accepted instrument. Another novel finding of this study was that 55% of CT subjects met the Rome III criteria for PDS and referred a higher intensity-frequency score for early satiety than healthy volunteers. Individuals with CT belong to a non

pathological state, poorly described^[28]. They are often young women, severely thin that continue to have a close to normal fat mass percentage, normal physiological menstrual cycles, no detectable abnormalities of cortisol, insulin-like growth factor 1, or free T₃ secretory patterns and normal energy metabolism^[17,28]. The mechanism behind low-weight steadiness in CT was not yet elucidated. Multifactorial etiology involves a combination of genetics in addition to as yet unrecognized pathophysiological factors^[29]. CT subjects display an equilibrated energy metabolism similar to that of control subjects. CT subjects attempt to gain weight, often overeating. To assess whether this eating pattern is related to GI symptom generation, further dynamic studies are needed.

Our findings leave room for speculation on the mechanisms underlying FD in patients with an ED. It has been suggested that FD results from a closed interaction of biological, psychosocial and social factors^[30]. The altered eating behavior seen in EDs is strongly associated with disturbed gastrointestinal sensitivity and motor physiology^[8]. ED and FD patients shared a high prevalence of psychiatric comorbidities^[31]. These latter together with the motor and sensitivity disturbances can lay the foundation of an FGID. Once established the psychological and

physiological disturbances can perpetuate and strengthen each other resulting in an FGID that can persist independently of the ED that originally caused the motor and sensitivity disturbances^[7]

It is also conceivable that a large number of individuals presenting for medical treatment for GI symptoms in gastroenterologic outpatient clinics could be better managed by firstly the identification and, secondly by receiving adequate treatment for concurrent ED. This is an important issue given that the ultimate goal of therapy in suspected ED patients is the normalization of gastric motor function with the resumption of normal eating behavior enabling the patient's social reintegration and restoration to an appearance acceptable to the social environment.

We acknowledge the limitations of this study. Firstly, the overall sample size was small. Furthermore, the study was limited by the failure to screen for organic GI disorder which, although quite rare in patients with EDs^[32], could falsely inflate estimates of FD incidence.

In conclusion, the high prevalence of meal-related symptoms in ED patients should encourage in gastroenterology outpatient clinics the routine screening for ED. In addition to perhaps helping design more efficacious

interventions for FD if patterns of food ingestion contribute to the development of unexplained GI symptoms, further studies are necessary to demonstrate whether patterns of food ingestion contribute to the development of unexplained GI symptoms. This attention to eating patterns might provide a simple, safe and potentially effective method to better manage FD patients too.

COMMENTS

Background

Eating disorders (ED) are highly prevalent health problems in Western countries, especially in young women. Three main ED categories have been identified on the basis of the diagnostic and statistical manual of mental disorders, 4th edition: anorexia nervosa (AN), bulimia nervosa (BN), and eating disorders not otherwise specified (EDNOS). Gastrointestinal (GI) symptoms are a common complaint in ED patients. It is a common occurrence that patients, before presenting to healthcare services with an ED, seek treatment for GI symptoms.

Research frontiers

A previous study demonstrated that 98% of ED patients fulfilled the criteria for at least one functional gastrointestinal disorder (FGIDs) such as irritable bowel syndrome, functional heartburn, functional abdominal bloating, functional constipation, functional dysphagia and functional anorectal pain disorder. Recently, a high prevalence of irritable bowel symptoms was confirmed in patients already affected by ED. However, it was suggested that FGIDs were the result of the behaviour-associated ED and that, these GI symptoms may persist even after the recovery from ED, especially in psychologically distressed patients. Currently, the underlying mechanisms that link ED and GI symptoms remain to be elucidated.

Innovations and breakthroughs

The novel result of the study was that AN, BN and EDNOS, the three main categories of ED, had a high prevalence of dyspeptic symptoms fulfilling the Rome III criteria to positively diagnose postprandial distress syndrome (PDS), not epigastric pain syndrome (EPS). Moreover, BN and EDNOS showed high postprandial fullness, epigastric pressure and nausea intensity-frequency scores, whereas AN patients shared with BN an increase in postprandial fullness score, but conversely demonstrated a prominent early satiety. Irrespective of the pathophysiology and mechanisms involved, it is intriguing that the association of higher body mass index alone with dyspeptic symptoms was relatively modest, also contrary to the study expectations. In addition, to the knowledge, this is the first study that demonstrated in ED a high prevalence of PDS using the Rome III criteria, an internationally accepted instrument. Another interesting finding of the study was that 55% of constitutional thinness subjects (CT) met the Rome III criteria for PDS and, referred a higher intensity-frequency score for early satiety than healthy volunteers.

Applications

It is conceivable that a large number of individuals presenting for medical treatment for GI symptoms in gastroenterologic outpatient clinics could be better managed by the identification of a concurrent ED. Their findings leave room for speculation on the mechanisms underlying functional dyspepsia (FD) in patients with an ED. The altered eating behavior seen in EDs is strongly associated with impairment in gastrointestinal sensitivity and motor physiology. ED and FD patients shared a high prevalence of psychiatric comorbidities. These latter together with the motor and sensitivity disturbances can lay the foundation of an FGID. Once established the psychological and physiological disturbances can perpetuate and strengthen each other resulting in an FGID that can persist independently of the ED that originally caused the motor and sensitivity disturbances. Further studies are needed in the future to demonstrate these hypotheses.

Terminology

ED are clinical disturbances in body image and eating behavior resulting in physical and psychological impairment. These clinical entities are diagnosed according to diagnostic and statistical manual of mental disorders, 4th edition criteria; AN is characterized by the inability or refusal to maintain a minimally normal weight, a profoundly distorted perception of body weight and shape, and amenorrhea; BN is a clinical entity that includes individuals who engage in recurrent binge-eating episodes and recurrent inappropriate compensatory behaviours that are intended to rid calories that they voraciously ingested; EDNOS involves milder versions of anorexia and bulimia nervosa that do not satisfy all the criteria; CT is a non

pathological state, poorly described. Subjects constitutionally thin are often young women, severely thin that continue to have a close to normal fat mass percentage and, normal physiological menstrual cycles; Rome III criteria to diagnose FD are defined as the presence of symptoms thought to originate in the gastroduodenal region, in the absence of any organic, systemic, or metabolic disease that is likely to explain the symptoms. The specific symptoms needed to diagnose FD are: epigastric pain, epigastric burning, post-prandial fullness and early satiety; PDS is characterized by bothersome postprandial fullness or early satiety; EPS is characterized by bothersome unexplained epigastric pain or burning.

Peer review

This is a good descriptive study. The results are interesting and suggest that due to the high prevalence of dyspepsia symptoms in patients already diagnosed for ED, it could be recommended to gastroenterologists to evaluate patients seeking treatment for the post-prandial distress syndrome to rule out a possible coexistence of any ED.

Abstract

AIM: To compare triple therapy vs quadruple therapy for 10 d as first-line treatment of *Helicobacter pylori* (*H. pylori*) infection.

METHODS: Consecutive *H. pylori* positive patients never treated in the past for this infection were randomly treated with triple therapy of pantoprazole (PAN) 20 mg bid, amoxicillin (AMO) 1 g bid and moxifloxacin (MOX) 400 mg bid for 10 d (PAM) or with quadruple therapy of PAN 20 mg bid, AMO 1 g bid, MOX 400 mg bid and bismuth subcitrate 240 mg bid for 10 d (PAMB). All patients were found positive at 13 C-Urea breath test (UBT) performed within ten days prior to the start of the study. A successful outcome was confirmed with an UBT performed 8 wk after the end of treatment. χ^2 analysis was used for statistical comparison. Per protocol (PP) and intention-to-treat (ITT) values were also calculated.

RESULTS: Fifty-seven patients were enrolled in the PAM group and 50 in the PAMB group. One patient in each group did not return for further assessment. Eradication was higher in the PAMB group (negative: 46 and positive: 3) vs the PAM group (negative: 44 and positive: 12). The *H. pylori* eradication rate was statistically significantly higher in the PAMB group vs the PAM group, both with the PP and ITT analyses (PP: PAMB 93.8%, PAM 78.5%, $P < 0.02$; ITT: PAMB 92%, PAM 77.1 %, $P < 0.03$).

CONCLUSION: The addition of bismuth subcitrate can be considered a valuable adjuvant to triple therapy in those areas where *H. pylori* shows a high resistance to fluoroquinolones.

INTRODUCTION

Helicobacter pylori (*H. pylori*) has an important role in the

development of chronic gastritis and peptic ulcer disease and has been linked to the pathogenesis of gastric lymphoma and gastric cancer^[1-3], hence it is recommended that this infection be cured whenever it is diagnosed. *H. pylori* is susceptible to several antibiotics including clarithromycin, amoxicillin (AMO), metronidazole, tinidazole, tetracycline, rifabutin and fluoroquinolones [levofloxacin and moxifloxacin (MOX)]^[4,5], and is inherently resistant to many other antibiotics such as bacitracin, vancomycin, trimethoprim, polymyxins and nalidixic acid^[6,7]. This bacterial infection, however, has proven challenging to cure. There are several reasons for the loss of eradication efficacy, and antibiotic resistance is the key factor for treatment failure^[8]. Resistance rates vary in different geographic areas and therefore the selection of therapeutic regimes needs adjustments according to local resistance pattern^[9,10]. The prevalence of antibiotic resistance in various regions is correlated with general use of antibiotics in the region^[11,12].

Classical triple therapies with proton pump inhibitors (PPI) clarithromycin and AMO or metronidazole are the mainstay of current treatment, but resistance to clarithromycin has been reducing its effectiveness in recent years, with an eradication rate below 80% of treated cases^[13,14]. In geographic areas with high clarithromycin resistance, bismuth-containing quadruple therapy is superior to standard triple therapy. The original quadruple therapy based on omeprazole, bismuth subcitrate, metronidazole and tetracycline achieves higher eradication rates compared with the standard triple therapy^[15,16]. In a recent randomized, open-label, phase 3 trial, a quadruple regimen with a capsule containing bismuth citrate potassium, metronidazole, and tetracycline given with omeprazole was found more efficacious than a clarithromycin-based triple therapy in patients never treated in the past for the infection^[17].

MOX-based triple therapy has been suggested as an alternative first-line therapy for *H. pylori* infection in geographical areas with clarithromycin resistance exceeding 30% of strains. Eradication rates of up to 92% in the MOX-based triple regimens compared to 79% in the clarithromycin-based regimens were demonstrated^[18]. Primary resistance of *H. pylori* strains collected from patients who have never been treated in the past for *H. pylori* infection to fluoroquinolones has been reported to be lower than that of clarithromycin in several geographic areas^[19]. Resistance to fluoroquinolones, however, rapidly develops in areas where these antibiotics are widely used. In our region in fact, the resistance rate of *H. pylori* to MOX has increased in the last two years from 12% in 2009 to 25% in 2011, while resistance to clarithromycin is stable, ranging from 40% to 59% (unpublished results). Similar results have been registered in other areas of the world. A recent study from Korea reports a steady increase of MOX resistance from 5.6% in 2004 up to 28.2% in 2008 with the need to optimize dosage and duration of treatment^[20]. Treatment with MOX-based triple therapy for 10 d should be preferred over a 7-d course, and there is

evidence that a dose of 800 mg/d is superior to the 400 mg standard dose^[21,22].

The aim of the study was to compare MOX containing triple therapy *vs* MOX and bismuth-containing quadruple therapy for first-line treatment of *H. pylori* infection.

MATERIALS AND METHODS

Eligibility criteria

Patients were enrolled among those with a positive ¹³C urea breath test (UBT) performed with citric acid and 75 mg of ¹³C urea performed within ten days prior to the start of the study. Exclusion criteria included: age <18 years or > 80 years; any previous treatment for *H. pylori* infection, treatment with PPI (omeprazole, lansoprazole, pantoprazole (PAN), rabeprazole, esomeprazole), H₂-blockers (ranitidine, nizatidine, cimetidine, famotidine, roxatidine), and/or antibiotics during the 4 wk before the study; gastrointestinal malignancy, severe concomitant diseases, previous gastric surgery. Further exclusion criteria were a prolongation of the QT interval, defined as the interval between the beginning of the QRS complex and the end of the T wave. QT interval was computed using an electrocardiogram (ECG) performed in all patients within 10 d prior to the beginning of the study.

Study protocol

Consecutive *H. pylori* positive patients never treated in their past for the infection were randomly treated with a triple therapy with PAN, AMO, MOX (PAM) or with a quadruple therapy with PAN, AMO, MOX and bismuth subcitrate (PAMB) for 10 d.

While PAN, AMO and MOX were administered before breakfast and supper, bismuth salts were administered 3 h after the administration of PAN, AMO, MOX, since it may bind in some patients with MOX and prevent its full absorption^[23].

Dosages and time of administration of the studied drugs are summarized in Table 1. Patients were informed that bismuth renders the stools a black dark colour. Successful outcome was confirmed with an UBT performed 8 wk after the end of treatment with a Delta Over Baseline value equal or less than 5.

Determination of sample size

Sample size was predetermined taking the following parameters into consideration: $\alpha = 0.05$; $\beta = 0.20$; lost to follow-up = 5%; expected eradication rate in the PAM group = 72%; expected eradication rate in the PAMB group = 95% (23% increase). With these parameters, the required sample size was equal to 90 patients per group.

Statistical analysis

Statistical evaluation was carried out using the χ^2 analysis. A *P*-value of 0.05 or less was considered statistically significant. Per protocol (PP), in which only data from adherent subjects are analyzed, and intention-to-treat (ITT), in

Table 1 Summary of study data

Triple therapy regimen (PAM)	Quadruple therapy regimen (PAMB)
Pantoprazole 20 mg <i>bid</i> (8.00 am-8.00 pm)	Pantoprazole 20 mg <i>bid</i> (8.00 am-8.00 pm)
Amoxicillin 1 g <i>bid</i> (8.00 am-8.00 pm)	Amoxicillin 1 g <i>bid</i> (8.00 am-8.00 pm)

UBT positive: 12	UBT positive: 3
Per protocol: 44/56 (78.5%)	Per protocol: 46/49 (93.8%) ^a
Intention to treat: 44/57 (77.1%)	Intention to treat: 46/50 (92%) ^a

^a $P < 0.05$ vs pantoprazole, amoxicillin and moxifloxacin (PAM). PAMB: Pantoprazole, amoxicillin, moxifloxacin and bismuth subcitrate; UBT: Urea breath test.

which all subjects are followed regardless of adherence, evaluations were calculated.

RESULTS

Patient characteristics are summarized in Table 1. Fifty-seven patients were enrolled in the PAM group and 50 in the PAMB group. One patient in each group did not return for further assessment (Table 1). Results of UBT performed 8 wk after the end of treatment are shown in Table 1.

The eradication rate was the following for PP and ITT analysis: PAM group PP: 44/56 (78.5%), PAMB group PP: 46/49 (93.8%); PAM group ITT: 44/57 (77.1%), PAMB group ITT: 46/50 (92%). *H. pylori* eradication rate was statistically significantly higher in the PAMB group vs the PAM group, both with the PP ($P < 0.02$) or ITT analysis ($P < 0.03$) (Table 1).

Adverse effects

Both treatments were well tolerated with no reported side effects.

DISCUSSION

Triple therapy based on a PPI combined with clarithromycin and AMO and/or metronidazole has been the established first-line therapy for *H. pylori* infection over the past years around the world^[24,25]. However, the efficacy of standard triple therapy needs to be reconsidered in areas with a high prevalence of clarithromycin or metronidazole resistant *H. pylori* strains. The geographical prevalence of antibiotic resistance should influence the choice of a first-line regimen for the treatment of infection by *H. pylori*. Alternatively, new regimens with high eradication rates should be identified. Quadruple therapies have been used as second-line therapy, and have also been proven effective as first-line treatment in areas with a high prevalence of clarithromycin-resistant *H. pylori* strains. Quadruple therapy containing bismuth has been used in the first-line therapy of *H. pylori* infection with variable results. Ching *et al.*^[26], from North Wales, United King-

dom, randomized patients to bismuth quadruple therapy or clarithromycin triple therapy. A total of 91% of patients receiving bismuth quadruple therapy and 92% of patients receiving clarithromycin triple therapy achieved successful *H. pylori* eradication. Calvet *et al.*^[27] performed a study in which patients were randomized to receive bismuth quadruple therapy or receive clarithromycin triple therapy. Eradication was achieved in 83% of the bismuth quadruple therapy group and 77% of the clarithromycin triple therapy group. In conclusion, in these two studies, first-line quadruple and triple therapies yielded similar eradication rates in the treatment of *H. pylori* infection.

Other studies have shown that the addition of bismuth to a first-line triple therapy produces high eradication rates despite the presence of high antibiotic-resistant strains. Malfertheiner *et al.*^[17] have recently shown that a quadruple therapy with omeprazole and a single three-in-one capsule containing bismuth citrate potassium, metronidazole and tetracycline for 10 d when compared with a triple therapy for 7 d with omeprazole, AMO, and clarithromycin produces an eradication rate of 80% vs 55% in the standard therapy group. The authors concluded that quadruple therapy needs to be considered as first-line therapy in areas with a high prevalence of clarithromycin-resistant *H. pylori* strains. These data are supported by results from a study from China in which bismuth was added to standard triple-therapy including PPI, clarithromycin and AMO and the *H. pylori* eradication rate was above 90%. This treatment showed a higher efficiency than standard triple-therapy, and the addition of bismuth and prolongation of the treatment from 7 to 14 d helped to overcome clarithromycin resistance in 84% of the patients^[28].

Our study shows that the addition of bismuth subcitrate to a triple therapy that includes PAN, AMO and MOX for first-line treatment of *H. pylori* infection significantly increases the eradication rate of the same therapy without bismuth. With bismuth included, eradication was 93.8% in PP and 92% in ITT analysis, but without bismuth the eradication rate was 78.5% in PP and 71.8% in ITT analysis. Indeed the same triple therapy used three years before the present study, induced a higher eradica-

tion rate^[22]; this change is probably due to an increase in resistance to MOX in our region from 2009-2011 (increase from 12% to 25%). Unfortunately, the absence of a preliminary susceptibility test in our patients does not allow us to understand whether the low rate of eradication in PAM group is effectively due to increased resistance to MOX or if patients infected by *H. pylori* resistant to MOX were equally distributed in the two therapeutic groups. Therefore, a periodic surveillance of antibiotic resistance is necessary since some antibiotics may develop resistance much more easily than others, such as in the case of MOX^[20]. The resistance against fluoroquinolones is mainly generated by mutations in the *gyrA* gene that encodes DNA gyrase^[29,30]. The consequence of such a mutation is the inability of fluoroquinolones to inhibit DNA replication^[31,32].

In our study the addition of bismuth to triple therapy has provided a therapeutic gain of 15% to a standard therapy. Bismuth exerts its antibacterial action by decreasing mucin viscosity, by binding toxins produced by *H. pylori*, and by preventing bacterial colonization and adherence to gastric epithelium^[33,34]. In addition bismuth reduces the bacterial load and has a synergistic effect with antibiotics^[35], particularly with the nitroimidazole family^[36].

The use of bismuth has raised some concerns about its side effects. A meta-analysis of 35 randomized controlled trials was published to assess the safety of bismuth. It showed that no serious adverse events occurred with bismuth therapy, and bismuth for the treatment of *H. pylori* was safe and well-tolerated^[37]. In our study, there have been no side effects reported.

Criticism for our study might include the absence of a preliminary susceptibility test in our patients. In fact, treatment failure in 12 patients in the PAM group was probably due to MOX resistance. However, the addition of bismuth to triple therapy helps to overcome *H. pylori* resistance to MOX: only 3 patients had a positive ¹³C UBT after treatment with quadruple therapy. The addition of bismuth to standard therapy results in an improved eradication rate, therefore, bismuth may be considered as a valuable adjuvant to triple therapy in those areas *H. pylori* shows a high resistance to fluoroquinolones.

The 10-d quadruple therapy consisting of a PPI, bismuth, AMO, and MOX achieved ITT success of 93.8% and can be recommended as the first-line treatment of *H. pylori* infection in regions of high fluoroquinolones resistance.

ACKNOWLEDGMENTS

The authors thank Mrs. Catherine Hlywka for reviewing the English style of the manuscript.

COMMENTS

Background

The standard treatment of *Helicobacter pylori* (*H. pylori*) infection is carried out by using a drug that inhibits gastric acid secretion associated with two antibiot-

ics represented by amoxicillin and clarithromycin or metronidazole. The success rate of this triple therapy varies from region to region worldwide, mainly due to a variation in antibiotic resistance. There is, therefore, a continuous search for new antibiotics that show low resistance against *H. pylori* or other substances that, when added to triple therapy, may overcome the obstacle of resistance.

Research frontiers

Fluoroquinolones are a relatively new class of antibiotics that may be highly efficacious against *H. pylori* infection. However, bacterial resistance to fluoroquinolones may rapidly increase over time due to their widespread use, especially for pulmonary and urinary tract infections. Recent studies have shown that the addition of bismuth subcitrate to a standard triple therapy may at least in part overcome the antibiotic resistance and improve the success rate of a standard triple therapy. In this study, the authors showed the adjunction of bismuth subcitrate to a triple therapy that includes the fluoroquinolone derivative, moxifloxacin, improved the success rate of the same therapy given without bismuth in a group of patients with *H. pylori* infection never treated in the past. The *H. pylori* infection had been diagnosed by means of urea breath test (UBT). To verify the effectiveness of the therapy, UBT was repeated in all patients 2 mo after the end of therapy.

Innovations and breakthroughs

To the knowledge, this is the first study that shows that bismuth improves the therapeutic effect of moxifloxacin for the treatment of *H. pylori* infection in patients never treated in the past for this infection.

Applications

The study offers an alternative therapeutic option for all who are involved in the treatment of *H. pylori* infection.

Terminology

UBT is the most accurate non-invasive test for the diagnosis of *H. pylori* infection and does not necessitate endoscopic intervention. The main limit of the test is that it results in false negative results if performed while the patient is taking drugs that may inhibit gastric secretion or antibiotics.

Peer review

The study is an important contribution to the growing body of literature on alternative therapies to treat the increasingly drug-resistant *H. pylori* isolates.

Abstract

AIM: To evaluate the effectiveness of adalimumab in preventing recurrence after intestinal resection for Crohn's disease in high-risk patients.

METHODS: A multicenter, prospective, observational study was conducted from June 2009 until June 2010. We consecutively included high-risk Crohn's disease patients who had undergone an ileal/ileocolonic resection. High-risk patients were defined as two or more criteria: smokers, penetrating pattern, one or more

previous surgical resections or prior extensive resection. Subcutaneous adalimumab was administered 2 wk (\pm 5 d) after surgery at a dose of 40 mg eow, with an initial induction dose of 160/80 mg at weeks 0 and 2. Demographic data, previous and concomitant treatments (antibiotics, 5-aminosalicylates, corticosteroids, immunomodulators or biologic therapies), smoking status at the time of diagnosis and after the index operation and number of previous resections (type and reason for surgery) were all recorded. Biological status was assessed with C-reactive protein, erythrocyte sedimentation rate and fecal calprotectin. One year (\pm 3 mo) after surgery, an ileocolonoscopy and/or magnetic resonance enterography was performed. Endoscopic recurrence was defined as Rutgeerts score \geq i2. Morphological recurrence was based on magnetic resonance (MR) score \geq MR1.

RESULTS: Twenty-nine patients (55.2% males, 48.3% smokers at diagnosis and 13.8% after the index operation), mean age 42.3 years and mean duration of the disease 13.8 years were included in the study. A mean of 1.76 (range: 1-4) resections previous to adalimumab administration and in 37.9% was considered extensive resection. 51.7% had previously received infliximab. Immunomodulators were given concomitantly to 17.2% of patients. Four of the 29 (13.7%) developed clinical recurrence, 6/29 (20.7%) endoscopic recurrence and 7/19 (36.8%) morphological recurrence after 1-year. All patients with clinical recurrence showed endoscopic and morphological recurrence. A high degree of concordance was found between clinical-endoscopic recurrence ($\kappa = 0.76$, $P < 0.001$) and clinical-morphological recurrence ($\kappa = 0.63$, $P = 0.003$). Correlation between endoscopic and radiological findings was good (comparing the 5-point Rutgeerts score with the 4-point MR score, a score of i4 was classified as MR3, i3 as MR2, and i2-i1 as MR1) ($P < 0.001$, $r_s = 0.825$). During follow-up, five (17.2%) patients needed adalimumab dose intensification (40 mg/wk); Mean time to intensi-

fication after the introduction of adalimumab treatment was 8 mo (range: 5 to 11 mo). In three cases (10.3%), a biological change was needed due to a worsening of the disease after the dose intensification to 40 mg/wk. One patient suffered an adverse event.

CONCLUSION: Adalimumab seems to be effective and safe in preventing postoperative recurrence in a selected group of patients who had undergone an intestinal resection for their CD.

INTRODUCTION

Crohn's disease (CD) is a complex chronic inflammatory bowel disease with an unpredictable course, in most cases accompanied by periodic recurrence and exacerbations^[1]. Up to 70% of patients with CD have to undergo surgery due to complications of the disease at least once in their lifetime, frequently resulting in ileocolonic anastomosis^[2,3]. Unfortunately, postsurgical recurrence, defined as the appearance of new lesions detected endoscopically, radiologically or pathologically, is common after surgery. One year after intestinal resection, 70%-90% of patients have endoscopic evidence of recurrent disease in the neo-terminal ileum. Despite the high endoscopic recurrence rate, symptomatic recurrence is delayed, with only 20% of patients having symptoms within the first year, increasing to one third after 3 years^[4].

Ileocolonoscopy was considered the gold standard in the evaluation of postoperative recurrence, being a useful tool to predict clinical recurrence, CD-related complications and the need for repeat surgery in the future. Rutgeerts *et al*^[4] devised a 5-point score ranging from i0 to i4 to measure the presence and severity of endoscopic lesions in the neoterminal ileum and anastomosis and reported a correlation between endoscopic recurrence and the likelihood of clinical recurrence, especially in those patients with more severe (i3-i4) endoscopic score.

The main limitations of ileocolonoscopy are its restriction to the level of intestinal mucosa and to the co-

lon and neoterminal ileum area due to stenosis at the ileocolonic anastomosis site. Recently, magnetic resonance (MR) enteroclysis, a safe and non-invasive new imaging technique for small bowel, has proven to be a useful tool for detecting unsuspected penetrating disease, reaching areas restricted to ileocolonoscopy. A 4-point MR-enteroclysis-based score (MR0-MR3) has been validated by Sailer *et al*^[5] and studies comparing ileocolonoscopy and MR enteroclysis suggest that they are of similar value in terms of predicting the risk of clinical recurrence in postoperative CD patients^[6].

Different studies have assessed the efficacy of the available medications in the prevention of postoperative CD recurrence. Mesalamine, nitroimidazole antibiotics, azathioprine and 6-mercaptopurine have been reported to be effective treatments but have shown limited efficacy in reducing postoperative recurrence^[7-12]. Recent results from a randomized placebo-controlled trial and a prospective pilot study with the chimeric anti-tumor necrosis factor alpha (TNF- α) antibody infliximab (IFX) support the utility of biologic therapies for the prevention of postoperative CD recurrence^[13-15].

Adalimumab is a fully human anti-TNF- α monoclonal antibody that has been shown to be highly effective in inducing and maintaining remission in patients with moderate-to-severe CD. Adalimumab is effective not only in naïve patients but also in patients with loss of response or intolerance to IFX^[16-19]. However, its efficacy in preventing postoperative recurrence has yet to be assessed.

The aim of this study is to evaluate the effectiveness and safety of adalimumab in preventing endoscopic and morphological recurrence at 12 mo after intestinal resection for CD in patients at high risk of recurrence, as well as to assess the influence of different risk factors associated with recurrence in CD patients treated with adalimumab. Additionally, we investigated the effectiveness of adalimumab in preventing clinical CD recurrence 1 year after surgery and compared endoscopic and radiological findings for predicting clinical recurrence in CD patients who had undergone intestinal resection.

MATERIALS AND METHODS

Study design

A multicenter, prospective, observational study was conducted in order to assess the effectiveness and safety of adalimumab in the prevention of postoperative recurrence of CD in high-risk patients. Four Spanish referral hospitals participated in the study.

Patients

All patients undergoing intestinal resection (macroscopically normal lines of resection) for ileal or ileocolonic CD from June 2009 to June 2010 were assessed and invited to participate. Inclusion criteria were: (1) patients aged between 15 and 70 years; (2) undergoing intestinal resection for CD; (3) high risk of recurrence, defined as at least two of the following criteria: smoker; penetrating pattern; prior extensive resection (> 100 cm); or one

or more previous surgical resections; (4) monitored for at least 1 year; and (5) if on concomitant treatments, a stable dose 12 wk before surgery and constant throughout the duration of the study. Exclusion criteria included the following: (1) patients with active ileocolonic or anorectal disease at entry; (2) more than 10 years of CD requiring first respective intestinal surgery for short (< 10 cm) fibrostenotic stricture; and (3) prior adverse events related to adalimumab.

Demographic data (gender and age), previous and concomitant treatments (antibiotics, 5-aminosalicylates, corticosteroids, immunomodulators or biologic therapies), smoking status at the time of diagnosis and after the index operation and number of previous resections (type and reason for surgery) were all recorded. Clinical data and inflammatory parameters C-reactive protein (CRP) (level in milligrams per liter), erythrocyte sedimentation rate (level in millimeters per hour) and fecal calprotectin (level in micrograms per gram) were evaluated at each visit (months 0, 3, 6, 9 and 12 after surgery). Ileocolonoscopy and magnetic resonance enterography (MRE), if available at the site, were performed at one year (\pm 3 mo) after treatment initiation, or withdrawal if clinical recurrence was suspected by the clinician, with or without elevated biological parameters. Adalimumab was administered 2 wk (\pm 5 d) after surgery with an induction dose of 160/80 mg at weeks 0 and 2 and at a maintenance dose of 40 mg subcutaneous eow. During follow-up, if at the discretion of the physician, the patient required intensified treatment, the adalimumab was increased to 40 mg every week.

Definitions

Index operation was defined as the last ileal or ileocolonic resection prior to the study. Baseline data, month 0, refers to the month when the index operation was performed. Clinical postoperative recurrence was defined as the onset of symptoms (diarrhea, abdominal pain and decreased well-being) or complications that led to changes in medical or surgical management.

Endoscopic recurrence refers to the existence of new mucosal (endoscopic) lesions in the neoterminal ileum after surgery. Ileocolonoscopy was performed by an experienced endoscopist and classified according to Rutgeerts score^[4] (Table 1). Endoscopic recurrence was defined as i2-i4 classified endoscopic findings.

Morphological recurrence refers to the occurrence of new lesions assessed by imaging techniques. MRE was performed with administration of oral contrast (1500 mL of 5% mannitol solution) as described Leyendecker *et al*^[20]. The presence of irregularities in mucosal surface, enhancement of mucosal contrast, thickening of the bowel wall, stenosis and extramural abnormalities (abscesses and fistulas) were evaluated and MRE findings were classified into the four grade MR score (Table 1)^[5]. Morphological recurrence was defined as MR1-MR3 classified MRE findings. Radiologist and endoscopist were blinded to the results of each other and to the in-

flammatory marker testing to assure correct and non-biased results.

Statistical analysis

Continuous variables were summarized as mean \pm SD or range when appropriate. Test of normality was developed using the D'Agostino test. Categorical variables were summarized as frequencies and percentages. Concordance between clinical-endoscopic recurrence and clinical-morphological recurrence was calculated with the weighted kappa statistic (κ). Kappa values were interpreted as follows: 0.99-0.81 "almost perfect agreement"; 0.80-0.61 "substantial agreement"; 0.60-0.41 "moderate agreement"; 0.40-0.21 "fair agreement" and less than 0.2 "slight agreement"^[21]. Correlation between endoscopic and morphological recurrence was calculated using Spearman rank correlation. Univariate logistic regression was performed to assess the influence of variables collected on the development of recurrence. Logistic regression multivariate analysis could not be performed due to the low number of observations. Differences were considered significant if *P* value < 0.05.

RESULTS

Demographics and clinical history

Twenty-nine patients were included in the study, 16 (55.2%) of whom were male. Mean age at diagnosis of CD was 28 years (range: 13-60 years). Demographic and clinical characteristics are shown in Table 2. The mean time from diagnosis to the last resection was 166 mo (range: 7 to 365 mo). Mean age at the last resection was 42.3 \pm 11.18 years. The indication for resection was therapeutic failure in 10/29 (34.5%), stenosis in 17/29 (58.6%) and penetrating pattern in 2 (6.9%) cases. Almost all patients (28 of 29) had been treated with a course of systemic corticosteroids at some point for the disease (mean No. courses: 5.7; range: 1-10) and 12 (42.9%) had received corticosteroids prior to the index operation. In addition, 41.4% of patients were taking antibiotics at the time of the index operation. IFX had been taken previously by 15 (51.7%) patients and aminosalicylates by 13 (44.8%) patients. Concomitant treatment with thiopurines was given to five (17.2%) patients and enteral nutrition therapy (elemental and/or semi-elemental formulas) in six (20.7%) patients. Patients' smoking status, at diagnosis and after the index operation was evaluated. At diagnosis, almost half (48.3%) were smokers while after the index operation, only 4 (13.8%) continued smoking.

Adalimumab intervention

All patients were treated with an induction dose of 160/80 mg subcutaneous adalimumab at weeks 0 and 2 and at a maintenance dose of 40 mg eow after intestinal resection. During follow-up, colonoscopy and MRE were necessary to continue in five (17.2%) patients because of suspected clinical recurrence and/or elevated

Table 1 Rutgeerts and magnetic resonance score for classification of postoperative recurrence in Crohn's disease

Rutgeerts score	Description	MR score	Description
i0	No lesions	MR0	No findings
i1	Less than 5 aphthous lesions	MR1	Minor mucosal irregularities: Slight wall thickening Slight mural contrast enhancement No stenosis
i2	More than 5 aphthous lesions with normal mucosa between the lesions or skip areas or larger lesions or lesions confined to ileo-colonic anastomosis		
i3	Diffuse aphthous ileitis with diffusely-inflamed mucosa	MR2	Major mucosal abnormalities: Distinct bowel wall thickening Distinct mural contrast enhancement Low grade stenosis without prestenotic dilatation
i4	Diffuse inflammation with already large ulcers, nodules and/or narrowing	MR3	Same finding as MR 2 plus: Transmural edema with T2w signal increase and contrast enhancement of the perienteric fat High grade stenosis without prestenotic dilatation Extramural complications (fistula, abscess, conglomeration of bowel loops)

MR: Magnetic resonance; MR0-MR3: A 4-point MR-enteroclysis-based score; i0-i4: A 5-point score to measure the presence and severity of endoscopic lesions in the neoterminal ileum and anastomosis.

Table 2 Patient characteristics at baseline (n = 29) (%)

Patient characteristics	Value
Gender	
Female	13 (44.8)
Age (yr), mean (range)	42.3 (19.8-61.1)
Duration of the disease (mo), median (range)	166 (7-365)
Montreal classification:	
A1 (< 17 yr)	6 (20.7)
A2 (17-40 yr)	17 (58.6)
A3 (> 40 yr)	6 (20.7)
L1 (ileal)	15 (51.7)

L1 + L4 (ileal + upper gastrointestinal)	5 (17.2)
B1 (non-stricturing/penetrating)	9 (31.0)
B2 (stricturing)	14 (48.3)
B3 (penetrating)	6 (20.6)
Perianal disease	10 (34.4)
Extensive resection	11 (37.9)
Immunomodulators (AZA, 6-MP) concomitant to adalimumab	5 (17.2)
Concomitant enteral nutrition	6 (20.7)
Previous infliximab	15 (51.7)
Previous resections (including index operation)	
1	15 (51.7)
2	7 (24.1)
3	6 (20.7)
4	1 (3.4)
Smoking status at diagnosis	
Smokers	14 (48.3)
Ex-smokers	2 (6.9)
Non-smokers	13 (44.8)
Smoking status after the index operation	
Smokers	4 (13.8)
Ex-smokers	12 (41.4)
Non-smokers	13 (44.8)

AZA: Azathioprine; 6-MP: 6-mercaptopurine.

biological parameters. All patients had endoscopic and morphological recurrence and needed adalimumab

dose intensification (40 mg every week). Mean time to intensification after the introduction of adalimumab treatment was 8 mo (range: 5 to 11 mo). The 5 patients had received thiopurine drugs and 4 of them, biological treatment with IFX, before index surgery. Concomitant treatment with immunomodulators was given to one of the 5 patients.

In three cases (10.3%), a biological change was needed due to the persistence of symptoms and progressive elevation of acute-phase reactants after the dose had been increased to 40 mg every week. Two of the three patients had previously received IFX and changed to certolizumab, and the third had switched to IFX.

Primary endpoint: Endoscopic and morphological recurrence at 12 mo

Six of the 29 (20.7%) showed endoscopic recurrence (i2-i4). Two patients had an endoscopic grade score of i2, two patients had a score of i3 and the other two, i4. Additionally, 19 of the 29 (65.5%) patients had MRE 1 year after resection. In 7 of the 19 (36.8%), morphological recurrence (MR1-MR3) was observed. Three had an MR score of MR1, three of MR2 and the other patient, MR3 (Table 3).

Influence of clinical parameters in endoscopic recurrence:

In the univariate analysis (Table 4), two variables were found to be associated with endoscopic recurrence. Patients with extensive resection (over 100 cm) [odds ratio (OR): 14.17, 95% CI: 1.12-708.0, P = 0.026] and with more than two previous resections (OR: 13.3, 95% CI: 1.7-107.4, P = 0.015) had increased risk of endoscopic recurrence. Other variables studied, such as the disease pattern, presence of perianal disease, number of previous surgical resections, indication of surgery and IFX treatment failure had no significant influence on the endoscopic recurrence rate.

Table 3 Correlation between endoscopic and radiological findings *n* (%)

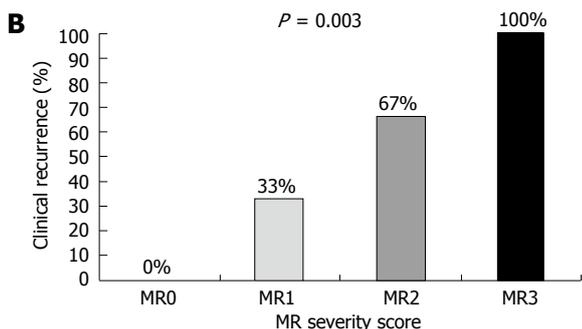

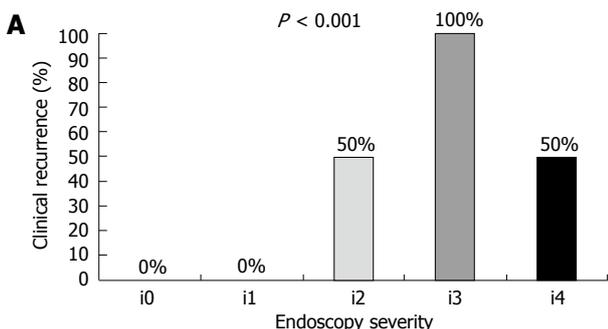

Figure 1 Concordance after ileocolonic resection for Crohn's disease. A: Between clinical-endoscopic recurrence; B: Between clinical-morphological recurrence. MR: Magnetic resonance; MR0-MR3: A 4-point MR-enteroclysis-based score; i0-i4: A 5-point score to measure the presence and severity of endoscopic lesions in the neoterminal ileum and anastomosis.

Secondary endpoints

Clinical recurrence at 12 mo: Four of the 29 (13.7%) patients developed clinical recurrence 1 year after intestinal surgery. In the univariate analysis, active smoker status after the index operation was significantly correlated with higher clinical recurrence rate (smokers *vs* non-smokers OR: 11.50; 95% CI: 1.01-131.29; *P* = 0.049). Patients with extensive resection (OR: 14.17; 95% CI: 1.12-708.0; *P* = 0.014) were significantly correlated with the development of clinical recurrence. No other significant correlations were found with the other variables.

Correlation between clinical, endoscopic and morphological recurrence: After 12 mo of follow-up, all patients with clinical recurrence (four patients) showed

endoscopic and morphological recurrence. Patients with clinical recurrence were classified into i2-i4 groups (1 in i2, 2 in i3 and 1 in i4) using the Rutgeerts score for Post-operative Endoscopic Classification of CD^[4]. There was significant concordance (substantial agreement) between the endoscopy severity and the clinical recurrence rate (κ = 0.76, *P* < 0.001) (Figure 1A).

Similarly, with the MR score, the four patients with clinical recurrence showed radiological recurrence (1 in MR1, 2 in MR2 and 1 in MR3). Also, substantial agreement between MR-score severity and the clinical recurrence rate was observed (κ = 0.63, *P* = 0.003) (Figure 1B).

Endoscopic and MRE evaluation was possible in 19 patients. Correlation between endoscopic and radiological findings was good. The Spearman rank correlation coefficient between the two techniques was r_s = 0.889 (*P* < 0.001) when dichotomous outcome “recurrence, yes or no” was correlated. To compare the 5-point Rutgeerts score with the 4-point MR score, a score of i4 was classified as an MR score of MR3, i3 was defined as equivalent to MR2, and i2-i1 were classified as MR1, consistent with the fact that MR imaging does not provide sufficient spatial resolution to differ between i1 and i2^[6]. In this case, the Spearman rank correlation coefficient was r_s = 0.825, *P* < 0.001.

Using endoscopy as the gold standard, the sensitivity of MRE for detecting moderate-to-severe endoscopic findings (Rutgeerts score i3 and i4) was 75%; specificity 93.3%, positive predictive value 75% and negative predictive value 93.3%.

Safety: One (3.4%) patient reported an adverse event during the 12 mo of follow-up: episodes of peripheral

vertigo. Although the etiology for this adverse event was not identified, adalimumab treatment was discontinued at month 6. This patient continued without treatment and remained in remission at month 12.

Ethical considerations

The study was carried out in accordance with the Declaration of Helsinki principles of good clinical practice. The study protocol was reviewed and approved by the local independent ethics committee.

DISCUSSION

In this study, we found adalimumab to be effective and safe in preventing recurrence after surgery for CD in a special subgroup of patients at high risk of recurrence. Intestinal resection is not curative and the majority of patients develop endoscopic recurrence even before clinical symptoms become apparent. Early detection and treatment of endoscopic lesions is essential to improve the long-term outcome for these patients and thus, to improve their quality of life. One year after intestinal resection, 70%-90% of patients have endoscopic recurrence and clinical recurrence occurs in nearly 20%^[4]. A number of studies have evaluated the efficacy of active treatment (mesalamine, nitroimidazole antibiotics and immunomodulators) for prevention of postoperative CD recurrence and most of them reported endoscopic recurrence to be between 40% and 60% at 12 mo after surgery^[22]. Recently, the anti-TNF- α antibody, IFX, has been associated with a significant reduction in postoperative recurrence in CD^[14,15,23,24]. However, to date, there have been no published results with adalimumab, only a case series of six patients who underwent resection for an ileocecal stricture in which adalimumab was successfully used to prevent postsurgical recurrence of CD^[25]. For this reason, we decided to evaluate the effectiveness and safety of adalimumab in preventing postoperative endoscopic and morphological recurrence as the primary study endpoint. This cohort of patients developed clinical recurrence in 13.7% of cases, endoscopic recurrence in 20.7% and MRE recurrence in 36.8%, although MRE was only evaluated in 19 patients and could be overestimated. In the clinical trial conducted by Regueiro *et al*^[14], 9.1% of patients in the IFX-treated group had endoscopic recurrence and 84.6% in the placebo group. In our study, the rate of endoscopic recurrence was higher, at 24.1%. It is important to take into account that our results refer to a special subgroup of patients with high risk factors for recurrence (two or more of: smoker, penetrating pattern, prior extensive resection and one or more previous surgical resections), so higher percentages are expected. In addition, there were several differences between the two studies in terms of design. In our cohort, only 5 of the 29 patients (17.2%) were on concomitant immunomodulator treatment whereas this applied to 4 of the 11 (36.4%) patients in the IFX-treated group in the Regueiro study. Also, in the clinical trial with IFX,

only one (9.1%) patient had previously undergone more than two intestinal resections compared to 7 (24.1%) patients in this study.

Different risk factors have been associated with postoperative CD recurrence. However, cigarette smoking is the only modifiable risk factor to be identified to date, and the most significant, with twice the risk of presenting a clinical recurrence compared with non-smokers^[26,27]. We found an increased clinical recurrence risk in patients who reported smoking at the time of the index operation compared with non-smokers. When we evaluated patients who were smokers at the time of diagnosis, no differences in risk were found. This was consistent with other studies that found no increased risk in ex-smokers^[26,27] or reported a reduction in the recurrence rate after stopping^[28,29] and suggests that the effect of smoking disappears some time after giving up the habit. These results support the fact that physicians should advise, encourage and assist CD patients to stop smoking. Another factor to consider is the length of the previous intestinal resection. In our study, the clinical and endoscopic recurrence rate was higher in patients with prior extensive resection (> 100 cm) and with more than two previous resections, consistent results with those obtained from the study about the impact of azathioprine on the prevention of postoperative CD recurrence^[9]. Other risk factors for postoperative CD recurrence, such as penetrating pattern, duration of CD or complex perianal disease, did not influence the proportion of patients with endoscopic and/or morphological recurrence.

Clinical postoperative recurrence was defined as the presence of symptoms, such as diarrhea, abdominal pain or decreased well-being, or complications which led to changes in medical or surgical management. All patients with clinical recurrence showed endoscopic and morphological recurrence 1 year after intestinal resection.

We avoided using the clinical activity index because it is difficult to perform in this setting. Some studies in which clinical postoperative recurrence was measured with the Crohn's Disease Activity Index did not correlate with endoscopic recurrence one year after ileocolonic resection, while inflammatory parameters, such as CRP values, showed good correlation with endoscopic recurrence at one year^[30,31]. We decided to use serum and fecal biological markers because they represent objective and quantifiable estimates of inflammatory activity. The main advantages are its simplicity and reproducibility; they can be repeated frequently to monitor changes in inflammatory activity, whether spontaneous or induced by treatment. We found that two or more elevated inflammatory parameters showed good correlation with endoscopic and morphological recurrence, especially in those scores indicating more severe lesions (i3-i4 or MR2-MR3). These techniques have been compared previously and our results are consistent with available data^[5,6].

The incidence of side effects (3.4%) was no different from other published series. The patient that developed

an adverse event also had to discontinue treatment with IFX previously. This is consistent with a recent study that concluded that elective switching from IFX to adalimumab may be associated with loss of tolerance within one year, and the recommendation is therefore to adhere to the first anti-TNF agent^[32].

We are aware of the potential limitations of our study. The main one is that there was no control group, so we cannot accurately compare our results with those obtained in other studies such as Regueiro *et al*^[14]. Secondly, the number of patients included in this cohort study was small, which may compromise statistical validity and not allow differences to be established in some of the variables measured. Lastly, five patients were treated concomitantly with immunomodulators, although there was no change in the dose regimen for these drugs before or during the study. It is difficult to assess the added benefit of co-treatment in preventing postoperative recurrence. In fact, in the Regueiro clinical trial, with a higher percentage of patients on immunomodulators, the concomitant use of immunomodulators did not appear to influence postoperative recurrence.

In summary, a significant percentage of CD patients require intestinal resection surgery over the course of their disease, and almost all show endoscopic recurrence one year after resection. This is the first published study on the effectiveness of adalimumab in preventing endoscopic and morphological recurrence after intestinal resection for CD. Our results strongly suggest that adalimumab is effective in patients with several risk factors associated with postoperative recurrence, such as smokers, penetrating pattern, or previous and extensive intestinal resections. Obviously, further randomized, controlled trials with better design and a larger number of patients are needed to confirm our conclusions and determine the duration of adalimumab maintenance treatment after surgery.

COMMENTS

Background

Crohn's disease (CD) is a complex chronic inflammatory bowel disease with an unpredictable course, in most cases accompanied by periodic recurrence and exacerbations. Up to 70% of patients with CD have to undergo surgery due to complications of the disease at least once in their lifetime, frequently resulting in ileocolonic anastomosis.

Research frontiers

Ileocolonoscopy was considered the gold standard in the evaluation of postoperative recurrence, being a useful tool to predict clinical recurrence, CD-related complications and the need for repeat surgery in the future.

Innovations and breakthroughs

A multicenter, prospective, observational study was conducted from June 2009 until June 2010. Authors consecutively included high-risk CD patients who had undergone an ileal/ileocolonic resection.

Applications

In this study, authors found adalimumab to be effective and safe in preventing recurrence after surgery for CD in a special subgroup of patients at high risk of recurrence. Intestinal resection is not curative and the majority of patients develop endoscopic recurrence even before clinical symptoms become apparent. Early detection and treatment of endoscopic lesions is essential to improve the long-term outcome for these patients and thus, to improve their quality of life.

Peer review

This manuscript is a prospective observational study that evaluated the effectiveness of adalimumab (ADA) for the prevention of postoperative recurrence of CD. Although this study lacks control group, this is the first prospective study on the efficacy of ADA for postoperative prevention of CD, so the presented data are important for the clinical practice and for the future controlled trial.

Abstract

AIM: To investigate whether a tissue-transglutaminase antibody (tTGA) level ≥ 100 U/mL is sufficient for the diagnosis of celiac disease (CD).

METHODS: Children suspected of having CD were prospectively included in our study between March 2009 and September 2011. All patients with immune globulin A deficiency and all patients on a gluten-free diet were excluded from the study. Anti-endomysium antibodies (EMA) were detected by means of immunofluorescence using sections of distal monkey esophagus (EUROIMMUN, Luebeck, Germany). Serum anti-tTGA were measured by means of enzyme-linked immunosorbent assay using human recombinant tissue transglutaminase (ELIA Celikey IgA kit Phadia AB, Uppsala, Sweden). The

histological slides were graded by a single experienced pathologist using the Marsh classification as modified by Oberhuber. Marsh II and III lesions were considered to be diagnostic for the disease. The positive predictive values (PPVs), negative predictive values (NPVs), sensitivity and specificity of EMA and tTGA along with their 95% CI (for the cut off values > 10 and ≥ 100 U/mL) were calculated using histology as the gold standard for CD.

RESULTS: A total of 183 children were included in the study. A total of 70 (38.3%) were male, while 113 (61.7%) were female. The age range was between 1.0 and 17.6 years, and the mean age was 6.2 years. One hundred twenty (65.6%) patients had a small intestinal biopsy diagnostic for the disease; 3 patients had a Marsh II lesion, and 117 patients had a Marsh III lesion. Of the patients without CD, only 4 patients had a Marsh I lesion. Of the 183 patients, 136 patients were positive for EMA, of whom 20 did not have CD, yielding a PPV for EMA of 85% (95% CI: 78%-90%) and a corresponding specificity of 68% (95% CI: 55%-79%). The NPV and specificity for EMA were 91% (95% CI: 79%-97%) and 97% (95% CI: 91%-99%), respectively. Increased levels of tTGA were found in 130 patients, although only 116 patients truly had histological evidence of the disease. The PPV for tTGA was 89% (95% CI: 82%-94%), and the corresponding specificity was 78% (95% CI: 65%-87%). The NPV and sensitivity were 92% (95% CI: 81%-98%) and 97% (95% CI: 91%-99%), respectively. A tTGA level ≥ 100 U/mL was found in 87 (47.5%) patients, all of whom were also positive for EMA. In all these 87 patients, epithelial lesions confirming CD were found, giving a PPV of 100% (95% CI: 95%-100%). The corresponding specificity for this cut-off value was also 100% (95% CI: 93%-100%). Within this group, a total of 83 patients had symptoms, at least gastrointestinal and/or growth retardation. Three patients were asymptomatic but were screened because they belonged to a group at risk for CD (diabetes mellitus type 1 or positive family history). The fourth patient who

lacked CD-symptoms was detected by coincidence during an endoscopy performed for gastro-intestinal bleeding.

CONCLUSION: This study confirms based on prospective data that a small intestinal biopsy is not necessary for the diagnosis of CD in symptomatic patients with tTGA \geq 100 U/mL.

INTRODUCTION

Celiac disease (CD) is an immune-mediated enteropathy affecting approximately 1% of the worldwide population^[1-3]. The immune reaction occurs when genetically susceptible individuals ingest gluten, which is a storage protein in wheat and the related grain species barley and rye, and this reaction is completely reversible upon gluten withdrawal, which is currently the only available treatment for CD^[3-5]. The gold standard for the diagnosis of CD has been considered to be a small intestinal biopsy since the histological lesions of CD were discovered in 1954^[6,7]. However, a small intestinal biopsy is not only expensive, time-consuming and stressful for children and their parents but may also provide inconclusive or even false results, due to patchy disease or to inadequate quality or orientation of the biopsy specimen^[8-10]. Therefore, there has long been research focused on finding non-invasive markers to diagnose CD. For this purpose, the disease-associated auto-antibodies, especially anti-endomysium antibodies (EMA) and anti-tissue-transglutaminase antibodies (tTGA), have proven to be highly sensitive and specific^[6,11-14]. In fact, according to the new ESPGHAN guidelines for the diagnosis of CD, a confirmatory small intestinal biopsy is no longer necessary in genetically predisposed individuals who are symptomatic and who have a tTGA of at least 10 times the upper limit of normal, a positive EMA and a good clinical response to the gluten free diet^[15]. However, these new guidelines for children are mainly based on retrospective data^[16-18]. Because such study designs are subject to selection bias, and because

the diagnosis of CD implies a lifelong gluten free diet, the diagnosis of CD should be based on serology only when the chance of a false positive result is close to zero. The aim of the present study was therefore to evaluate prospectively whether the new diagnostic approach in patients with high tTGA levels is justified.

MATERIALS AND METHODS

Study population

All patients who were referred to the Wilhelmina Children's Hospital in Utrecht, the Netherlands with the suspicion of having CD were prospectively included in the study between March 2009 and September 2011. Patients were referred to us because of symptoms associated with CD (e.g., abdominal symptoms, growth retardation) or because they belonged to a group at risk for CD, e.g., patients with Down syndrome or Diabetes Mellitus and patients with a positive family history for CD. In this patient group, serology (both EMA and tTGA) was performed, and any patient with abnormal serology was biopsied, as were patients with negative serology but a high clinical suspicion of CD. Patients with immunoglobulin A (IgA) deficiency ($n = 8$) and patients on gluten restriction during the diagnostic work-up were excluded from the study. The study was performed according to the guidelines of the local medical ethics board.

Serological assessment

IgA EMA values were detected by indirect immunofluorescence using sections of distal monkey esophagus mounted on glass slides (EUROIMMUN, Luebeck, Germany). Serum IgA tTGA values were measured using the ELiA Celikey IgA kit (Phadia AB, Uppsala, Sweden). As recommended by the manufacturer, serum samples containing an antibody titer greater than 10 U/mL were considered positive. Total IgA was measured in all patients, and a serum IgA concentration below 0.07 g/L was regarded as IgA deficiency.

Histological evaluation

Duodenal biopsies were obtained by upper gastrointestinal endoscopy. An average of 3.1 biopsies (range: 1-8 biopsies) per patient were taken from the distal duodenum. Starting at the end of 2009, duodenal bulb biopsies were also routinely obtained during endoscopy, as recent studies suggested that this region could be the only affected site in CD^[19]. On average, 1.9 biopsies per patient were taken from this location with a range of 0 to 5.

Histological diagnosis for all patients was performed by a single experienced pathologist using the Marsh classification as modified by Oberhuber^[20,21]. The pathologist had no knowledge of the serological results or of the clinical presentation of the patients. An increased number of intraepithelial lymphocytes (Marsh I) were considered not to be diagnostic for CD. By contrast, Marsh I combined with crypt hyperplasia (i.e., Marsh II) or findings with villous atrophy (Marsh III) were consid-

ered to be diagnostic for CD.

Statistical analysis

The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the screening tests, which exhibited 95% confidence intervals (CI), were calculated using the histological evaluation as the gold standard. It was subsequently determined whether a tTGA level ≥ 100 U/mL is associated with a nearly perfect PPV.

RESULTS

A total of 183 patients met the inclusion criteria of the study. Of those patients, 70 (38.3%) were male, and 113 (61.7%) female with an age range of between 1.0 and 17.6 years and a mean age of 6.2 years. A total of 120 (65.6%) patients had a biopsy diagnostic for CD, of whom only 3 patients had a Marsh II lesion. In the remaining 63 (34.4%) patients, the diagnosis of CD could be excluded. Of the patients without CD, only 4 patients had Marsh I histology.

Of the total study population, 138 patients had positive EMA and/or tTGA antibodies, while 45 patients were negative for both antibodies. The patients who were negative for both antibodies underwent a small intestinal biopsy because of a strong clinical suspicion of CD (CD-like symptoms). Three of these patients had a Marsh III lesion, and one patient had a Marsh II lesion, while the diagnosis of CD could be excluded in the remaining 41 patients.

A positive EMA was found in 136 (74.3%) patients; 20 (31.7%) of them did not meet the histological criteria for CD (Table 1), giving a specificity of only 68% (Table 2). The corresponding PPV was 85%. The specificity of tTGA was slightly better (78%), with 116 of 130 positive patients being correctly diagnosed (Table 1). The corresponding PPV was also better at 89% (Table 2).

EMA was undetectable in 47 (25.7%) patients, of whom 43 indeed showed normal histology (Table 1). Consequently, the sensitivity and NPV of EMA were high with values of 97% and 91%, respectively (Table 2). These values were equally high for tTGA, i.e., 97% and

Table 2 Sensitivity, specificity, positive predictive value and negative predictive value of anti-endomysium antibodies and anti-tissue-transglutaminase antibodies (%)

	Sensitivity	Specificity	PPV	NPV
IgA EMA	97 (91-99)	68 (55-79)	85 (78-90)	91 (79-97)
IgA tTGA >10	97 (91-99)	78 (65-87)	89 (82-94)	92 (81-98)
IgA tTGA ≥ 100	73 (63-80)	100 (93-100)	100 (95-100)	66 (55-75)

The 95% CI are given in parentheses. IgA: Immunoglobulin A; EMA: Anti-endomysium antibodies; tTGA: Anti-tissue-transglutaminase antibodies; PPV: Positive predictive value; NPV: Negative predictive value.

92%, respectively. Illustratively, 49 of the 53 patients with negative tTGA did not have CD (Table 1).

A total of 42 patients (23.0%) had tTGA levels between 10 and 100 U/mL. Of those patients, only 28 (66.7%) had CD, while the diagnosis could be histologically excluded in 14 (33.3%) patients. Of the latter group, 3 patients had a Marsh I lesion. By contrast, the 87 patients with a tTGA level ≥ 100 U/mL all met the histological criteria for CD (Table 1), yielding a PPV of 100% (Table 2). All were also positive for EMA. Among these 87 patients, only 4 patients were asymptomatic. Three patients were screened because they belonged to a group at risk for CD (diabetes mellitus type 1 or a positive family history for CD). The fourth patient who lacked CD-symptoms was detected by coincidence during an endoscopy performed for gastro-intestinal bleeding. All other patients (*n* = 83) had typical symptoms (at least gastro-intestinal symptoms and/or growth retardation). After the diagnosis of CD was made, all patients adhered to the gluten-free diet, and the vast majority showed clinical improvement.

DISCUSSION

In patients with high tTGA levels, there is increasing evidence that a small intestinal biopsy is not needed to confirm the diagnosis of CD, as these increased levels are highly suggestive of the disease. This conclusion was also stated in the new ESPGHAN guidelines for the diagnosis of CD in the pediatric population^[15]. Briefly, these guidelines suggest that in symptomatic individuals who have tTGA levels of at least 10 times the upper limit of normal and who respond well to the gluten free diet, histological confirmation is unnecessary. However, prospective studies are needed to confirm the applicability of these guidelines in clinical practice.

The sole reliance on serology for the diagnosis of CD is appropriate only if the PPV is close to 100%. In this study, it was prospectively shown that 87/87 patients with a tTGA of at least 100 U/mL did indeed suffer from CD, giving a PPV of 100%. However, in this cohort, most of the patients had typical CD symptoms and responded well to the diet, while only 4 patients lacked any CD associated symptoms. Therefore, due to the underrepresentation of asymptomatic patients in this cohort, it can be questioned whether this perfect PPV will also be

observed in asymptomatic patients.

Comparable results were found in previous retrospective studies, showing that high tTGA levels are associated with histological lesions compatible with CD^[16-18]. Barker *et al*^[22] showed that 48 of 49 mostly symptomatic children with a tTGA level ≥ 100 U/mL had at least Marsh II enteropathy. Comparably, Donaldson *et al*^[23] showed that 38 of the 38 pediatric patients with tTGA ≥ 100 U/mL had Marsh III histopathology. A subsequent retrospective study, also in a pediatric population, showed that all symptomatic patients with tTGA of at least 100 U/mL who responded well to the diet had CD ($n = 111$), thereby reaching a PPV of 100%^[24].

Similarly, in a study conducted in a mixed adult/pediatric population, it was shown that a tTGA ≥ 100 U/mL occurs almost exclusively in the setting of Marsh III (73 of 76 patients) and that the 3 patients without villous atrophy had either a Marsh II ($n = 2$) or a Marsh I ($n = 1$) lesion^[25]. Likewise, a study performed in adults showed that 91 patients with a tTGA level of at least 10 times the upper limit all had at least Marsh II enteropathy^[16]. By contrast, Freeman reported that 3 of 14 adult patients with tTGA ≥ 100 U/mL did not have CD^[26]. Notably, in the latter 3 studies, an exact description of the clinical presentation of the patients was lacking^[16,25,26].

To the best of our knowledge, only one other prospective study has been performed in a mixed pediatric and adult population. This study showed that 1 of the 72 patients with a tTGA of at least 11.4 times the upper limit of normal had a normal small intestinal biopsy, yielding a PPV of 98.6%, which the authors considered to be insufficient for omitting a biopsy^[27]. However, in this study, the presence of symptoms was not taken into consideration, which may influence the PPV. In fact, the patient with this high level of tTGA and a normal biopsy did have an excellent clinical and serological response to the diet, suggesting that CD may have been missed histologically.

In conclusion, the current study shows that 87/87 patients with tTGA ≥ 100 U/mL had CD, which confirms the new ESPGHAN guidelines and other retrospective studies. However, because almost all studied patients in this study were symptomatic, omitting a biopsy should only be considered in this group. By contrast, in asymptomatic individuals, a small intestinal biopsy should still be performed, at least until more studies become available studying this specific group.

ACKNOWLEDGMENTS

The authors would like to thank Willy de Kruijf for performing the EMA and tTGA analysis.

COMMENTS

Background

In celiac disease (CD), the ingestion of gluten leads to a typical enteropathy characterized by an increase in the number of intra-epithelial lymphocytes, hyperplasia of the crypts and, in most cases, atrophy of the villi. The detec-

tion of these lesions in small intestinal biopsy specimens obtained by upper endoscopy is used to identify CD and is considered to be the gold standard investigation for the diagnosis of the disease. Serologically, the immune reaction to gluten can be detected by measuring disease-specific antibodies, the anti-endomysium antibodies (EMA) and the anti-tissue-transglutaminase antibodies (tTGA). In clinical practice, the measurement of these antibodies is used to screen for CD, as they are highly sensitive and specific. The aim of this study is to determine to what extent serology can replace a small intestinal biopsy for the diagnosis of CD.

Research frontiers

Retrospective studies have shown that a notably high titer of tTGA is strongly associated with the degree of enteropathy. Thus, high levels of tTGA seem to be sufficient for the diagnosis of CD. Therefore, the ESPGHAN guidelines for the diagnosis of CD in children and adolescents were revised this year, recommending that the diagnosis of CD can be made without histological confirmation in genetically predisposed children who are symptomatic, have a tTGA level of at least 10 times the upper limit of normal, as well as a positive EMA, and who respond well to the diet.

Innovations and breakthroughs

Because the new guidelines are based only on retrospective data, which allow a chance of selection bias, there was need for a prospective study to evaluate the guidelines in clinical practice. The authors therefore prospectively investigated the positive predictive value of tTGA ≥ 100 U/mL (= 10 times the upper limit) and demonstrated that it indeed reached 100%; i.e., all patients with these high tTGA values showed the small intestinal lesions that are diagnostic for CD. Therefore, in these patients, histological confirmation seems to be unnecessary. Because the majority of the studied patients had typical CD-symptoms and all of them were positive for EMA, omitting a biopsy should only be considered for symptomatic patients who also have increased levels of EMA.

Applications

The results of this study show that the new ESPGHAN guidelines in patients with very high tTGA levels can be used safely without being at risk for over-diagnosing the disease. Because a significant number of patients fulfill these criteria, i.e., almost half of the patients in this study, applying this guideline will have great clinical implications. Omitting a biopsy will not only reduce the stress and inconvenience associated with the diagnosis, but will also save time and significantly reduce costs.

Terminology

tTGA: These anti-bodies are directed against the enzyme tissue-transglutaminase, which is the auto-antigen in CD. This enzyme plays an essential role in eliciting the immune response against gluten; EMA: The endomysium is the intercellular matrix, which lies between the smooth muscle cells of the muscularis mucosae throughout the gastro-intestinal tract. It is rich in the enzyme tissue-transglutaminase. Antibodies directed against the endomysium are actually directed against tissue-transglutaminase.

Peer review

The authors present data from a prospective study on application of new cut-off values for diagnosing celiac disease in a population of children with high pre-test likelihood of disease. In the presented population, the specificity reaches 100 % if cut-off is raised to 10 times the regular cut-off. The draw-back is loss of specificity, but the subgroup with high titre can be diagnosed without duodenal biopsies. Upper endoscopy is demanding for children and mostly is performed in general anaesthesia, with the implications that may have for complications *etc.* The manuscript is well written, with a clear aim and conclusion.

Abstract

AIM: To compare quantities of predominant and pathogenic bacteria in mucosal and faecal samples.

METHODS: Twenty patients undergoing diagnostic colonoscopy with endoscopically and histologically normal mucosa were recruited to the study, 14 subjects of which also supplied faecal (F) samples between 15 d to

105 d post colonoscopy. Mucosal biopsies were taken from each subject from the midportion of the ascending colon (right side samples, RM) and the sigmoid (left side samples, LM). Predominant intestinal and mucosal bacteria including clostridial 16S rRNA gene clusters IV and XIVab, *Bacteroidetes*, *Enterobacteriaceae*, *Bifidobacterium spp.*, *Akkermansia muciniphila* (*A. muciniphila*), *Veillonella spp.*, *Collinsella spp.*, *Faecalibacterium prausnitzii* (*F. prausnitzii*) and putative pathogens such as *Escherichia coli* (*E. coli*), *Clostridium difficile* (*C. difficile*), *Helicobacter pylori* (*H. pylori*) and *Staphylococcus aureus* (*S. aureus*) were analysed by quantitative polymerase chain reaction (qPCR). Host DNA was quantified from the mucosal samples with human glyceraldehyde 3-phosphate dehydrogenase gene targeting qPCR. Paired *t* tests and the Pearson correlation were applied for statistical analysis.

RESULTS: The most prominent bacterial groups were clostridial groups IV and XIVa+b and *Bacteroidetes* and bacterial species *F. prausnitzii* in both sample types. *H. pylori* and *S. aureus* were not detected and *C. difficile* was detected in only one mucosal sample and three faecal samples. *E. coli* was detected in less than half of the mucosal samples at both sites, but was present in all faecal samples. All detected bacteria, except *Enterobacteriaceae*, were present at higher levels in the faeces than in the mucosa, but the different locations in the colon presented comparable quantities (RM, LM and F followed by P_1 for RM vs F, P_2 for LM vs F and P_3 for RM vs LM: $4.17 \pm 0.60 \log_{10}/g$, $4.16 \pm 0.56 \log_{10}/g$, $5.88 \pm 1.92 \log_{10}/g$, $P_1 = 0.011$, $P_2 = 0.0069$, $P_3 = 0.9778$ for *A. muciniphila*; $6.25 \pm 1.3 \log_{10}/g$, $6.09 \pm 0.81 \log_{10}/g$, $8.84 \pm 1.38 \log_{10}/g$, $P_1 < 0.0001$, $P_2 = 0.0002$, $P_3 = 0.6893$ for *Bacteroidetes*; $5.27 \pm 1.68 \log_{10}/g$, $5.38 \pm 2.06 \log_{10}/g$, $8.20 \pm 1.14 \log_{10}/g$, $P_1 < 0.0001$, $P_2 \leq 0.0001$, $P_3 = 0.7535$ for *Bifidobacterium spp.*; $6.44 \pm 1.15 \log_{10}/g$, $6.07 \pm 1.45 \log_{10}/g$, $9.74 \pm 1.13 \log_{10}/g$, $P_1 < 0.0001$, $P_2 \leq 0.0001$, $P_3 = 0.637$ for *Clostridium* cluster IV; $6.65 \pm 1.23 \log_{10}/g$, $6.57 \pm 1.52 \log_{10}/g$, $9.13 \pm 0.96 \log_{10}/g$, $P_1 <$

0.0001, $P_2 \leq 0.0001$, $P_3 = 0.9317$ for *Clostridium* cluster XIVa; $4.57 \pm 1.44 \log_{10}/g$, $4.63 \pm 1.34 \log_{10}/g$, $7.05 \pm 2.48 \log_{10}/g$, $P_1 = 0.012$, $P_2 = 0.0357$, $P_3 = 0.7973$ for *Collinsella* spp.; $7.66 \pm 1.50 \log_{10}/g$, $7.60 \pm 1.05 \log_{10}/g$, $10.02 \pm 2.02 \log_{10}/g$, $P_1 \leq 0.0001$, $P_2 = 0.0013$, $P_3 = 0.9919$ for *F. prausnitzii*; $6.17 \pm 1.3 \log_{10}/g$, $5.85 \pm 0.93 \log_{10}/g$, $7.25 \pm 1.01 \log_{10}/g$, $P_1 = 0.0243$, $P_2 = 0.0319$, $P_3 = 0.6982$ for *Veillonella* spp.; $4.68 \pm 1.21 \log_{10}/g$, $4.71 \pm 0.83 \log_{10}/g$, $5.70 \pm 2.00 \log_{10}/g$, $P_1 = 0.1927$, $P_2 = 0.0605$, $P_3 = 0.6476$ for *Enterobacteriaceae*). The *Bifidobacterium* spp. counts correlated significantly between mucosal sites and mucosal and faecal samples (Pearson correlation coefficients 0.62, $P = 0.040$ and 0.81, $P = 0.005$ between the right mucosal sample and faeces and the left mucosal sample and faeces, respectively).

CONCLUSION: Non-invasive faecal samples do not reflect bacterial counts on the mucosa at the individual level, except for bifidobacteria often analysed in probiotic intervention studies.

Comparison of bacterial quantities in left and right colon biopsies and faeces. *World J Gastroenterol* 2012; 18(32): 4404-4411 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i32/4404.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i32.4404>

INTRODUCTION

Within the gastrointestinal tract, the bacterial community living dispersed in the luminal content differs from those living on the mucosal surface^[1] and reflects the health status of the gastrointestinal tract^[2]. The mucosal microbiota, intimately located on the host epithelium, has an active role in the host's immunity and forms an essential part of the protective mucosal barrier against invading pathogens^[3,4]. In general, the same main bacterial groups, *Firmicutes*, *Bacteroidetes* and *Proteobacteria*, dominate on the mucosa and in faeces, with the bacterial families of *Ruminococcaceae*, *Actinobacteria*, *Prevotellaceae*, *Porphyromonadaceae*, *Lachnospiraceae* and *Bacteroidaceae* being characteristic for the mucosal microbiota^[5,6].

Durban and colleagues assessed the microbial community from four randomly located, pooled mucosal biopsy samples and faecal samples retrieved from 9 volunteers between 2 wk to 8 wk post colonoscopy^[6]. They found that on family level taxonomy the mucosal microbiota was higher in richness and diversity and was presented by

a comparatively steep rarefaction curve, whereas on species level taxonomy no clear distinction between the two sample types was seen. This could imply that the mucosal environment allows for a variety of microbes to thrive with less exhaustive competition and that, in faeces, the niches are less compartmentalized and thus the most efficiently growing bacterial families dominate. Although both types of microbiota were predominant in *Firmicutes* and *Bacteroidetes*, the microbial composition was clearly more dependent on the sample type (biopsy or faeces) than the individual being sampled and the mucosal microbiota was found to be underrepresented in the faecal samples^[6].

Hong *et al.*^[5] recently published a study in which they applied an elaborate sampling schema which enabled the comparison of closely (1 cm apart) and distantly (left and right colon) located mucosal biopsies from 5 (five) subjects. Unexpectedly, the microbiota on the mucosal surface appeared to be unique, even when comparing closely situated sampling sites (1 cm distance)^[5], even though the intestinal microbiota had previously been shown to be subject-specific in several studies^[7-9]. Thus the study by Hong *et al.*^[5] raises further concerns regarding the representativeness of mucosal samples from a certain anatomical location and of faecal samples in relation to the overall mucosal microbiota. Possibly a single mucosal biopsy gives a less reliable picture of the status of the overall gastrointestinal tract than a faecal sample, as faeces represents an end-point view of the ecosystem.

Clearly, for a thorough evaluation of the species composition of the mucosa, faecal material is not a representative sample. However, in many cases the alterations in the quantities of selected bacterial groups or species in the gastrointestinal tract are of interest and, in such a setting, the alterations in bacterial quantities at different mucosal locations and in faeces may be more uniformly expressed, depending on the target species. Thus, the present study focused on the quantification of selected gastrointestinal bacterial groups or species being either dominant, potentially pathogenic, or often encountered on the mucosal surface.

MATERIALS AND METHODS

Subjects

Twenty patients (8 men and 12 women, aged 61 ± 15 years, range: 33-85 years), who underwent colonoscopy between June 2010 and Feb 2011 at the Sahlgrenska University Hospital Östra, Gothenburg, were included in the study. Colonoscopy was performed due to various abdominal complaints, such as diarrhoea, constipation and/or abdominal pain as well as lower gastrointestinal bleeding and/or iron-deficiency anaemia (Table 1). The prerequisite for inclusion into the study was normal-appearing mucosa in the entire colon, and thus patients with any significant pathology, such as colonic polyps, inflammatory bowel disease, malignancy, ischemic colitis *etc.*, were excluded. The possibility of microscopic colitis

was ruled out through light microscopic examination of biopsy specimens obtained from the mid-portion of the colon ascendens, as well as from the sigmoid. On the other hand, the presence of colonic diverticula was accepted provided there were no signs of acute diverticulitis and/or diverticulosis-associated colitis. Eight tissue specimens for analysis were obtained from the midportion of the ascending colon, as well from the sigmoid colon, using regular biopsy forceps. One of these specimens from each site was used for analysis of the microbiota. There were no complications related to the colonoscopy or biopsy procedures. In addition, faecal samples were

collected post-colonoscopy (15 d to 105 d and unknown for 6 subjects) from 14 subjects. The ethics committee of the University of Gothenburg approved the study and written informed consent was obtained from each of the patients.

Isolation of DNA and microbial quantification

Bacterial DNA was extracted from the mucosal and faecal samples with the Promega Wizard[®] Genomic DNA Purification Kit, A1125, (Promega Corporation, Madison, WI, United States) with some minor modifications applied. The mucosal samples were cut in half with scalpel knives and DNA was extracted from both pieces. Homogenisation of the samples was done by bead beating for 3 × 30 s at 6800 g in a 1.4 mL Bertin VK01 glass bead tube, before continuing according to the protocol. Extraction of bacterial DNA from faecal samples was performed as described previously^[10]. The DNA concentrations were measured with a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies, Wilmington, DE, United States) and samples were stored at -20 °C until quantitative polymerase chain reaction (qPCR) analysis.

The qPCR reactions were performed using Applied Biosystems Real-Time PCR system equipment (7500 Fast, Applied Biosystems, Foster City, CA, United States) and software applying in-house optimized assay conditions for the primer sequences presented in Table 2. Reactions were run in a 25 µL volume, except for the *Helicobacter pylori* (*H. pylori*) and *Clostridium difficile* (*C. difficile*)-targeting qPCR analysis, which were run in a 15 µL volume. Mucosal or faecal microbial DNA was applied as template in quantities of 25 ng or 5 ng respectively. All reactions were run in triplicate. For the human glyceraldehyde 3-phosphate dehydrogenase (*GAPDH*) gene assay, 5 ng of mucosal microbial DNA was used as template. In order to obtain standard curves, ten-fold serial dilutions ranging from 1 pg to 10 ng of the genomic DNA of selected bacterial species or human DNA (Table 2) were used. Results were expressed as log₁₀ genomes per gram of sample (wet weight), taking into account the size and the 16S rDNA copy number of the standard species genome.

Statistical analysis

For mucosal samples, the proportion of host DNA was estimated according to the *GAPDH* qPCR result and subtracted prior to calculations. Outlier values and target bacteria that were not normally distributed due to too low prevalence were removed from the data set. Normality of the data was checked with the D'Agostino and Pearson omnibus *K*² test and comparisons within bacterial groups between sampling sites were done using paired *t* tests. Correlations between different sample types for each qPCR assay were analysed using Pearson's correlation coefficient. Statistical analysis were performed with Prism 5 Version 5.01 (GraphPad Software, Inc., San Diego, United States).

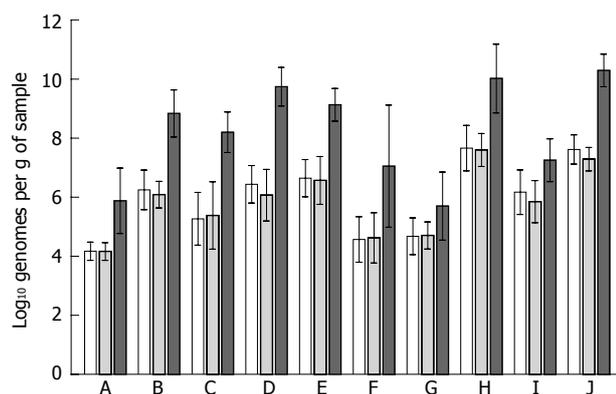

Figure 1 Quantities of bacterial groups detected on the mucosa and in faeces. The bacterial targets A: *Akkermansia muciniphila*; B: *Bacteroidetes*; C: *Bifidobacterium* spp.; D: *Clostridium* cluster IV; E: *Clostridium* cluster XIVab; F: *Collinsella aerofaciens*; G: *Enterobacteriaceae*; H: *Faecalibacterium prausnitzii*; I: *Veillonella* spp.; J: Eubacteria are represented with the three sample types side-by-side (biopsies from the right colon as white bars with pattern; biopsies from the left colon as grey bars; faecal samples with dark grey bars). The bacterial quantities between the two mucosal samples did not differ according to paired *t*-tests, whereas the faecal quantities of all analysed bacteria were significantly higher than those detected for either mucosal site ($P < 0.05$), except for *Enterobacteriaceae*. The error bars denote the 95% CI.

RESULTS

Preliminary qPCR analysis from six mucosal and three faecal samples, showed an average percentage of human DNA of $60.74\% \pm 12.26\%$ and $0.02\% \pm 0.02\%$ respectively. Thus, the proportion of bacterial DNA was not further analysed for faecal samples as they were assumed to demonstrate 100% bacterial DNA. Among the bacterial groups and species analysed in this study, no alterations were detected between the colonic samples originating from the right and left sides of the colon (Figure 1). The clostridial clusters XIVab and IV, *Bacteroidetes* and *Faecalibacterium prausnitzii* (*F. prausnitzii*) were the most abundant bacteria in all sample types.

H. pylori and *Staphylococcus aureus* were not detected in any of the samples. *C. difficile* was detected in four samples, all originating from different subjects: one mucosal sample originating from the left side of the colon and three faecal samples. The *C. difficile* positive subjects were all female, aged 47, 74, 57 and 33 and subject to colonoscopy due to diverticulitis follow-up, iron deficiency anemia, rectal bleeding and diffuse abdominal pain. All, however, had endoscopically and histologically normal appearing mucosa. *Escherichia coli* (*E. coli*) was detected in less than half of the mucosal samples at both sites, while present in all faecal samples at $\log_{10} 5.92 \pm 1.04$ genomes per gram of faeces. *H. pylori*, *Staphylococcus aureus* (*S. aureus*), *C. difficile* and *E. coli* were not included in the statistical analysis due to low prevalence.

For the whole subject group, the abundances of different bacteria appeared to follow the same trend in the mucosa and faeces (Figure 1), whereas at the individual level, only *Bifidobacterium* spp. quantities correlated significantly between the two mucosal sampling sites and faeces (Table 3). The two mucosal sites also correlated signifi-

cantly for the quantities of *Bacteroidetes*, *Clostridium* cluster XIVab and *F. prausnitzii* (Table 3).

DISCUSSION

The right and left segments of the colon show differences in physiology and motility, creating different environments for bacteria in the murine^[11] and human^[1,5] mucosa. Our aim was to analyse the quantities of predominant gastrointestinal bacteria and putative pathogenic species in relation to the site of mucosal sampling. We studied 20 patients undergoing diagnostic colonoscopy that displayed, both endoscopically and histologically, normal appearing mucosa. In addition, faecal samples were obtained from 14 subjects between 15 d to 105 d post colonoscopy to assess how well a faecal sample can represent the mucosal microbiota with a 16S rRNA gene-based qPCR. Since in whole community analysis (i.e., 16S rDNA pyrosequencing and metagenomics) the abundance data represents relative proportions of the whole with all groups affecting the result, a targeted analysis, such as qPCR, which quantifies the target independently, could allow for a less biased comparison of quantities. This possibly also results in more uniform representation between different mucosal sampling sites.

The selected bacterial quantities analysed in the present study were comparable between the two mucosal sampling sites for each individual, although previous analysis covering the overall mucosal microbiota with higher taxonomic precision have shown definite heterogeneity between different sampling sites in both humans^[5] and rodents^[11,12]. However, cleansing of the colon prior to colonoscopy may have distorted the mucosal microbiota at the genus level^[13] and possible faecal contamination of the mucosal biopsies may diminish the degree of heterogeneity between mucosal biopsy samples. In addition, the 20 subjects that were analysed, had a considerably heterogeneous background in relation to gastrointestinal health and age, possibly resulting in a wide range of detected microbial quantities reducing the sensitivity of comparative analysis. Of the analysed bacterial groups for both mucosal and faecal quantities, only *Bifidobacterium* spp. correlated significantly between the different sample types (i.e., a high abundance in faeces predicted a high abundance in mucosal samples at both sites and *vice versa*, although the faecal quantities were on average higher than the mucosal quantities). As *Bifidobacterium* spp. have previously been associated with both compromised functional gastrointestinal health^[7] and, in some studies, with aging^[14], the subjects of the present study may present a substantially wide range of abundance for gastrointestinal bifidobacteria, enabling more evident correlation: 6 of the 20 subjects had irritable bowel syndrome or abdominal pain, and the subjects' ages varied broadly. The two mucosal sites, the midportion of the ascending colon and the sigmoid, were also comparable in terms of *Bacteroidetes*, *Clostridium* cluster XIVab and *F. prausnitzii* for each subject. The wide time range between colonoscopy and faecal sampling post

Significant correlations ($P < 0.05$) are designated with bold font.

colonoscopy may bias the correlation analysis. Nevertheless, no statistically significant correlations were found for age, reason for referral to colonoscopy, or for the time that elapsed between colonoscopy and faecal sampling for any of the bacteria analysed (data not shown). Due to the invasive and burdensome nature of colonoscopy, no timely follow-up was possible.

In general, average levels of bacteria were higher in the faeces than in the mucosa and comparable with previously published 16S rRNA gene-targeting qPCR data^[15-17]. The clostridial clusters XIVab and IV and *Bacteroidetes* were the most abundant bacterial groups in both sample types, in accordance with the present view of human mucosal and faecal microbiota^[5-7,18]. For *Enterobacteriaceae* the higher abundance in faeces was not statistically significant, but a similar trend was evident between the left side mucosal and faecal samples. When analysed in relation to the eubacterial counts (i.e., as proportional values), the majority of the analysed bacteria were as prominent on the mucosa as in the faeces (data not shown), as has previously been shown with RNA-targeting fluorescent in situ hybridization for a selected set of bacterial groups^[19]. However, only non-parametric analysis of the target bacteria were possible using proportional values as the data was no longer normally distributed. Nevertheless, even though *Bifidobacterium spp.* was the only bacterial group that correlated within individuals, for the subject group as a whole the average faecal and mucosal bacterial quantities appeared to be associated, as abundant mucosal bacteria were also abundant in faeces (Figure 1). As for the prevalence of the different bacteria, only *Collinsella aerofaciens* was significantly more prevalent on the mucosa (right side of the colon) than in faeces according to Fisher's test (data not shown). *F. prausnitzii* was detected in all sample types with quantities above the eubacterial count (\log_{10} 7.6 ± 1.5 , 7.6 ± 1.1 and 10.0 ± 2.0 bacteria per gram of sample for right colon, left colon and faecal sample, respectively; Figure 1), implying technical issues related to the analysis, as it has previously been detected at the level of \log_{10} 8 to 9^[16]. The potentially pathogenic bacteria (*H. pylori*, *S. aureus*, *C. difficile*) were rarely detected even though 11 of the 20 study subjects were over 60 years of age and all had compromised gastrointestinal health prior

to colonoscopy. *E. coli*, which is a common commensal gastrointestinal species, in addition to being a potential pathogen, was more prominent.

Taken together, faecal samples did not reflect quantities of bacteria in the intestinal mucosa at the individual level, except for *Bifidobacterium spp.* which has often been analysed in pro- and prebiotic intervention studies. Although the mucosal microbiota is site-specific in terms of use of community profiling methods, selected bacterial quantities did not differ, even between distant locations in the colon and thus less exhaustive biopsy sampling may be sufficient to evaluate bacterial quantities on the mucosa. At the group level, faecal sampling may be adequate.

COMMENTS

Background

The intestinal microbiota has been recognized as an important factor in the maintenance of good health and in the prevention of disease and has thus received a steadily increasing amount of attention in research. It has been widely acknowledged that the mucosal and faecal microbiotas are not alike and that even closely situated mucosal samples differ from each other. Thus sampling schemas highly affect the outcome when analyzing intestinal bacteria and an important research focus has been to gain a better insight into the selection of the most appropriate methodologies in each setting and to understand how the techniques compare and complement one another.

Research frontiers

The aim of the present study was to test whether quantities of distinct bacterial groups, genera or species, as opposed to a whole community analysis, could be quantified in a representative manner from mucosal samples originating from different sites in the colon and from faecal samples. Comparable bacterial quantities at different mucosal sites would allow less exhaustive biopsy sampling during colonoscopy while a correlation between mucosal and faecal quantities would allow predictions to be made on the mucosal microbiota from non-invasive faecal samples.

Innovations and breakthroughs

Real-time quantitative polymerase chain reaction (qPCR) allows independent

comparison of each target bacterial group, genera and species between the different samples, whereas whole community approaches are restricted to proportional quantities. In the present study, selected gastrointestinal bacterial groups or species being either dominant, potentially pathogenic, or often encountered on the mucosal surface were quantified from three kinds of samples of up to twenty subjects. Distantly situated mucosal sites were found to have comparable bacterial quantities in an individual, whereas the faecal quantities did not reflect mucosal quantities at the individual level for most bacteria.

Applications

With quantitative analysis of selected bacteria, mucosal biopsies taken from different parts of the colon are comparable, allowing less exhaustive biopsy sampling. Faecal samples, however, poorly reflect mucosal quantities.

Terminology

Quantitative real-time PCR is based on detecting the amount of amplified product during each PCR cycle and comparing the detection threshold cycle to a standard dilution series. Primer and probe design allows a vast array of target selection and taxonomic depth to be applied.

Peer review

This study reports the analysis of several bacterial species, including resident and pathogenic bacteria present in the right and left segments of the human colon, compared with species present in faeces. The study is well conducted and the results are interesting, improving knowledge of the microbiome present in the human colon.

Abstract

AIM: To study possible decrease in prevalence of *Helicobacter pylori* (*H. pylori*) infection in the Czech Republic within a 10-year period.

METHODS: A total of 22 centres entered the study. The catchment areas of these centres covered cities and towns with more than 20 000 inhabitants, smaller towns ($\leq 20\ 000$ inhabitants) with surrounding villages and rural areas, and were spread over the

whole country, corresponding well to the geographical distribution of the Czech population. A total of 1 837 subjects (aged 5-98 years) took part in the study, randomly selected out of 38 147 people from the general population. *H. pylori* infection was investigated by means of a ^{13}C -urea breath test. Breath samples in duplicates were analysed using isotope ratio mass spectrometry. The cut-off point was 3.5. Social and demographic characteristics were based on data from self-completed questionnaires.

RESULTS: The overall prevalence of *H. pylori* infection was 23.5% (430/1826), and 4.8% (20/420) in children aged 15 or less. There was no statistically significant difference in prevalence between males (24.3%; 208/857) and females (22.9%, 222/969, $P = 0.494$). *H. pylori* infection was strongly associated with higher age, among subjects aged 55+ years, prevalence of *H. pylori* infection was 39.8% (252/633, $P < 0.001$). The highest prevalence of *H. pylori* infection was found among persons aged 55-64 years (43.9%, 97/221) and 75+ years (37.9%, 58/153). Among study subjects aged 15+ years, prevalence of *H. pylori* infection was significantly increased in those with lowest education (odds risk 3.19, 95% CI 1.87-5.47). Compared to never married (14.1%), the prevalence of *H. pylori* infection was statistically significantly higher among married (35.4%, 246/694, $P < 0.001$), divorced (36.8%, 49/133, $P < 0.001$) and widowed study subjects (40.2%, 45/112, $P < 0.001$), both in minimally and fully adjusted analysis. There was no significant difference in the prevalence of *H. pylori* infection between married and widowed subjects (35.4%, 246/694 vs 40.2%, 45/112, $P = 0.389$). There was little variation in smoking prevalence across categories of smoking and there was no evidence of an increased risk of *H. pylori* infection among current or past smokers in our data (odds risk 1.04 with 95% CI 0.78-1.40 for current smokers; odds ratio 0.83 with 95% CI 0.60-1.16 for former smokers). The current prevalence of *H. pylori*

in 2011 was significantly lower compared to the prevalence reported from identical geographical areas in 2001 (23.5% vs 41.7%, $P < 0.001$).

CONCLUSION: The overall prevalence of *H. pylori* infection in the general population has fallen substantially in the Czech Republic over the past 10 years.

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection is still the most common human infection worldwide. It is estimated that 50%-80% of the population is infected^[1-3]. The prevalence in developed countries of Europe is 10%-30% (with an increase of 1%-3% for each age decade). Up to 95% of the adult population is infected in developing countries^[4-8].

Our group accomplished a large multi-centre epidemiologic study on the prevalence of *H. pylori* and dyspepsia in the Czech Republic, a Central European country, in 2001^[9-11]. The Project was executed on a total of 2509 persons aged 5-100 years, randomly selected out of 30 012 subjects from the general population. *H. pylori* infection was investigated by means of ^{13}C -urea breath test. The overall prevalence of *H. pylori* was 41.7% in 2001^[9]. Meanwhile, several concerns have been raised about the possible decrease of *H. pylori* prevalence in developed countries. The aim of our current multi-centre prospective study was to evaluate the prevalence of *H. pylori* infection in the Czech Republic using the same methods in a representative sample of general unselected population from the same geographical areas 10 years later.

MATERIALS AND METHODS

Study population

A total of 22 centres entered the study. They included 15 centres of general practitioners for adults and 7 for children and adolescents. These centres covered cities and towns with more than 20 000 inhabitants (10 centres),

smaller towns ($\leq 20\ 000$ inhabitants) with surrounding villages (9 centres) and rural areas (3 centres), and were spread over the whole country, corresponding well to the geographical distribution of the Czech population. A total of 1837 subjects (aged 5-98 years) took part in the study, randomly selected out of 38 147 registered males and females in this age range.

Urea breath test

Urea breath tests were performed in the morning after overnight fasting by means of ^{13}C -urea breath test^[12]. Citric acid solution (3 g dissolved in 150 mL of still water) was given initially as a test drink. Five min later two baseline exhaled breath samples were collected into 20-mL vacutainers using a straw. Thereafter all persons ingested 75 mg ^{13}C -urea (*Helicobacter Test* INFAI, INFAI GmbH, Köln, Germany) dissolved in 50 mL of still water with 1 g citric acid (at time 0). Breath samples were collected in duplicates using a straw into 20-mL vacutainers after 30 min. Tubes with breath samples were sent to a single analytical centre by post and measured within a one-week period. Breath samples in duplicates were analysed using isotope ratio mass spectrometry (AP 2003, Analytical Precision Products, Cambridge, United Kingdom). The cut-off point was 3.5. Results of ^{13}C -urea breath test for *H. pylori* status were obtained for 99.4% (1826/1837) of subjects.

Questionnaires

Data were collected by self-completed questionnaires distributed to adults and parents of children aged 5-15 years. The questionnaire included information on place of residence in childhood, mother's and father's education, access to running warm water in childhood, crowding in childhood and number of siblings. Information on the study subjects' current place of residence, education, marital status, self-reported socio-economic group and smoking habits was also collected in the questionnaire and was used in the analysis of determinants of *H. pylori* positivity in subjects aged above 15 years.

Ethical approval

The study was approved by the University Ethics Committee. All participants received detailed written information about the Project in advance and signed written consent (parents on behalf of their children). For all data obtained, all personal identification information was deleted in compliance with the laws for the protection of confidentiality of the Czech Republic.

Statistical analysis

The data was analysed using STATA statistical software (StataCorp. 2011. Stata Statistical Software: Release 12, College Station, TX). Education was analysed in six categories (university, secondary, vocational higher and lower, elementary and students) and marital status in five categories (single, first time married, re-married, divorced and widowed). In the analysis, we used three categories

Table 1 Prevalence of *Helicobacter pylori* by age and gender in a representative sample of Czech population *n* (%)

Age (yr)			
5-14	188 (4.8)	197 (5.1)	385 (4.9)
15-24	124 (10.5)	151 (7.9)	275 (9.1)
25-34	97 (16.5)	107 (13.1)	204 (14.7)
35-44	84 (30.9)	79 (19.0)	163 (25.1)
45-54	73 (42.5)	93 (34.4)	166 (37.9)
55-64	94 (42.5)	127 (44.9)	221 (43.9)
65-74	122 (38.5)	137 (36.5)	259 (37.4)
≥ 75	75 (34.7)	78 (41.0)	153 (37.9)

Czech population examined in 2011 (*n* = 1826).

of smoking (never smoker, past smoker and current smoker). Proportions were compared using Chi-square test and the relative risk of *H. pylori* infection was studied in logistic regression with adjustment for age, gender and other social variables. Multivariable analyses were restricted to subjects with non-missing data on the variables studied.

RESULTS

The overall prevalence of *H. pylori* infection was 23.5% (430/1826), and 4.8% (20/420) in children aged 15 or less. There was no statistically significant difference in prevalence between males (24.3%, 208/857) and females (22.9%, 222/969, *P* = 0.494). *H. pylori* infection was strongly associated with higher age (Table 1).

Among study subjects aged above 15 years, prevalence of *H. pylori* infection was significantly increased in those with lowest education (Table 2). Compared to never married, the prevalence of *H. pylori* infection was statistically significantly higher among married and divorced study subjects, both in minimally and fully adjusted analyses (Table 2). There was little variation in smoking prevalence across categories of smoking and there was no evidence of an increased risk of *H. pylori* infection among current or past smokers in our data (Table 2).

The current prevalence of *H. pylori* in 2011 was significantly lower compared to the prevalence reported from identical geographical areas in 2001 (23.5% *vs* 41.7%, *P* < 0.001).

DISCUSSION

Our multi-centre prospective study proved that the current prevalence of *H. pylori* in 2011 is significantly lower compared to the prevalence of identical geographical areas in 2001. Both our studies were based on a representative sample of the general population, covering large and small urban population as well as rural areas and using ¹³C-urea breath test as a gold standard for *H. pylori* diagnostics. Thus our results are reliable and trustworthy. The decline of *H. pylori* was found not only in overall prevalence but also in particular age decades. Explanation of this phenomenon is not easy and unequivocal. Although

there are no strictly unimpeachable epidemiologic data available, the decrease of *H. pylori* prevalence probably already started in the Czech Republic in the late 1990s^[9]. It could be explained mostly by the relatively favourable and improving socio-economic conditions and standards of living together with falling fertility rates. In the same period, the age-standardised death rate from stomach cancer in the Czech Republic fell from 17.3/100 000 (in 1992) to 11.9/100 000 (2001) followed by further current decline to 8.7/100 000 (in 2010)^[13]. Two large Czech seroprevalence studies found decreased *H. pylori* prevalence in the mid 2000s among subjects screened for thyroid disease^[14] and in patients with peptic ulcer disease, functional dyspepsia and gastro-oesophageal reflux disease^[15].

Decrease in the prevalence of *H. pylori* infection was also reported in other former communist countries such as Estonia (in children from 42% in 1991 to 28% in 2002)^[16], Slovakia (in adults from 52% in 1992 and 41% in 2002 to 35% in 2007)^[17,18] and Russia (in children from 44% in 1995 to 13% in 2005)^[19]. This decline in *H. pylori* prevalence was explained by the profound socio-economic changes after the fall of communist regimes.

However, significant decrease of the prevalence of *H. pylori* infection was also found in stable developed European countries like the Netherlands^[20-22], Finland^[23,24], the United Kingdom^[25,26], Germany^[27], Norway^[28] and Denmark^[29]. This decrease could not be explained only by the birth-cohort phenomenon either. In developed countries, spontaneous subsequent clearance of *H. pylori* infection seems to be common^[30]. In Finland, decrease of prevalence of *H. pylori* infection is believed to be due to the "screen and treat" project^[31,32]. The main explanation for the decrease in *H. pylori* prevalence cannot merely be wide use of antibiotics for various indications.

The prevalence of *H. pylori* infection is significantly lower in patients with inflammatory bowel disease but not in those with chronic obstructive pulmonary disease (despite of extensive antibiotic use)^[33]. There was no difference in *H. pylori* prevalence in Crohn's disease with or without previous treatment with sulfasalazine or antibiotics^[34].

In our previous study, we did not find a birth-cohort phenomenon of *H. pylori* infection after the Second World War^[35], in contrast to developed countries^[8,36-41]. This could be explained by the great migration of population in former Czechoslovakia after the Second World War, forced unnatural collectivisation (in fact expropriation) of agriculture, equalisation of society and mostly low socio-economic status under the communist government^[35]. den Hoed *et al*^[42] found a new birth-cohort phenomenon of *H. pylori* infection in the Netherlands. They observed a decline in *H. pylori* prevalence in 6- to 8-year-old Dutch children from 19% in 1978 to 9% in 1993. The further prevalence of *H. pylori* in childhood has remained stable in the Netherlands from 1993 to 2005, suggesting a stabilisation of the previously decreasing trend in subsequent birth cohorts. This finding may reflect stabilisation in determinants such as family size, housing, and hygienic conditions (or offset by day care)^[42].

Several interesting data came from other studies outside Europe. Decreased prevalence of *H. pylori* was also found for instance in the United States^[43,44], China^[45,46], Japan^[47], South Korea^[48] and Singapore^[49]. After fifteen years, the prevalence of *H. pylori* infection among both children and adults in China remained significantly higher in areas with a high incidence of gastric cancer compared with that in areas with a low incidence of gastric cancer. *H. pylori* infection rates have decreased in the general Chinese population during recent years^[50].

Poor standard of living, low socio-economic status, overcrowded families, low education of parents and smoking (in adults) are still major risk factors of *H. pylori* infection. Acquisition, chronic infection and possible spontaneous clearance of *H. pylori* are influenced by several other factors like ethnicity and genetic factors. Extensive broad use of antibiotics for different indications might be less important^[9].

It is necessary to revive the so-called hygiene hypothesis^[51]. It was suggested that with the higher hygiene standards in developed countries, people (especially raising children) are less exposed to helminths and this fact modulates development of the immune system (Th1/Th2 shift of CD4+ T-lymphocytes) and thereby increases the risk of several diseases like inflammatory bowel disease, bronchial asthma, food allergy and many others. The high prevalence of *H. pylori* and low rate of gastric cancer in Africa and some parts of Asia were called the "African or Asian (Indian) Enigma" and explained merely by the high prevalence of helminth infections^[52]. Subsequent prospective studies found that no such dissociation existed^[53]. Nowadays the "African Enigma" is considered to be a myth^[54]. Nevertheless, hygiene theories should be considered in explanation of the gradual decline of *H. pylori* infection. Blaser and his group pointed out an

inverse association between *H. pylori* infection and bronchial asthma^[55-57], even though not confirmed by some others^[58]. Sonnenberg *et al*^[59] found low prevalence of *H. pylori* infection in inflammatory bowel disease.

Sýkora *et al*^[60] published an excellent study on *H. pylori* among children in the Western Bohemian region (based on *H. pylori* stool antigen testing). The overall prevalence was 7.1% among 1545 children (aged 0-15 years; in the period 2003-2005). Breast-feeding was an important protective factor, *H. pylori* was found in 12.4% children that were not breast-fed. The prevalence of *H. pylori* was 80.8% among subjects living in children's homes in this study^[60].

Smoking is another independent risk factor for *H. pylori* infection in adults^[61,62]. The lower number of current smokers in Europe might also influence the decline of *H. pylori* infection. In our previous study in 2001, smoking habits were strongly related to risk of *H. pylori* positivity in adults, men and women with lowest education and heavy smokers being at the highest risk of *H. pylori* infection^[9]. Surprisingly, there was no evidence of an increased risk of *H. pylori* infection among current or past smokers in our present study. It is necessary to mention another interesting phenomenon: the decreased prevalence of *H. pylori* represents a prominent decline of CagA positive *H. pylori* strains^[42]. Explanation for this finding still remains unclear.

However, several studies recently showed that the prevalence of *H. pylori* is also declining among children in developing countries like Uganda, Brazil and the Middle East region despite persisting poor hygiene, standard of living and low socio-economic conditions^[5,6,63-65].

On top of all those aspects mentioned above, it is necessary to admit that the reasons for decline of *H. pylori* infection have not been fully clarified yet^[66,67]. It is necessary to also consider the fundamental determinants of "modern times" that could cause gradual disappearance of *H. pylori* from the human microbiome^[68-72].

In summary, the overall prevalence of *H. pylori* infection in the general population has fallen substantially in the Czech Republic over the past 10 years. This decrease can be explained mostly by the relatively favourable and improving socio-economic status and high standard of living conditions. However, it is necessary to also consider that both environmental factors and the human host create an unfavourable milieu responsible for the decline of *H. pylori* infection.

ACKNOWLEDGMENTS

Our sincerest thanks go to all general practitioners and their staff. They performed some really great work in their respective centres. COMMENTS

Background

Helicobacter pylori (*H. pylori*) infection is still the most common human infection worldwide. It is estimated that 50%-80% of the population is infected. The prevalence in developed countries of Europe is 10%-30%. Up to 95% of the adult population is infected in developing countries.

Research frontiers

The authors accomplished a large multi-centre epidemiologic study on the prevalence of *H. pylori* and dyspepsia in the Czech Republic, a Central European country, in 2001. *H. pylori* infection was investigated by means of ¹³C-urea breath test. The overall prevalence of *H. pylori* was 41.7% in 2001. The aim of the current multi-centre prospective study was to evaluate the prevalence of *H. pylori* infection in the Czech Republic using the same methods in a representative sample of general unselected population from the same geographical areas 10 years later.

Innovations and breakthroughs

The current prevalence of *H. pylori* in 2011 was significantly lower compared to the prevalence of identical geographical areas in 2001 (23.5% vs 41.7%, *P* < 0.001).

Applications

This decrease can be explained mostly by the relatively favourable and improving socio-economic status and high standard of living conditions. However, it is necessary to also consider that both environmental factors and the human host create an unfavourable milieu responsible for the decline of *H. pylori* infection.

Peer review

The paper aims at assessing the prevalence of *H. pylori* infection based on ¹³C urea-breath test in a large random sample of Czech population. The study results show that the prevalence is declining in comparison with a similar previous study from the same group. Potential reasons for this fall are considered in the discussion. The paper is interesting, scientifically sound and well written.

Abstract

AIM: To detect of colorectal cancer (CRC) circulating tumour cells (CTCs) surface antigens, we present an assay incorporating cadmium selenide quantum dots (QDs) in these paper.

METHODS: The principle of the assay is the immunomagnetic separation of CTCs from body fluids in conjunction with QDs, using specific antibody biomarkers: epithelial cell adhesion molecule antibody, and monoclonal cytokeratin 19 antibody. The detection signal was acquired from the fluorescence signal of QDs. For the

evaluation of the performance, the method under study was used to isolate the human colon adenocarcinoma cell line (DLD-1) and CTCs from CRC patients' peripheral blood.

RESULTS: The minimum detection limit of the assay was defined to 10 DLD-1 CRC cells/mL as fluorescence was measured with a spectrofluorometer. Fluorescence-activated cell sorting analysis and Real Time RT-PCR, they both have also been used to evaluate the performance of the described method. In conclusion, we developed a simple, sensitive, efficient and of lower cost (than the existing ones) method for the detection of CRC CTCs in human samples. We have accomplished these results by using magnetic bead isolation and subsequent QD fluorescence detection.

CONCLUSION: The method described here can be easily adjusted for any other protein target of either the CTC or the host.

INTRODUCTION

Colorectal cancer (CRC) is ranked as the second most common cause of cancer-related death worldwide^[1]. Cancer-related death is most commonly caused by metastases derived from epithelial tumors like CRC^[2]. The process of metastasis requires the potential and ability of cancer cells to enter into circulation, attach to the endothelium, invade the target organ and subsequently form metastases. The concept and existence of circulating tumour cells (CTCs) and the dissemination and settlement of these cells in secondary organs have been widely accepted^[3]. Approximately 10⁶ tumour cells per gram of primary tumour are daily released into the bloodstream^[4]. However, shear forces in the physiological range can induce lethal damage in a high percentage of CTCs, thus only the 0.1% of those are viable and the 0.01% of the viable cells are responsible for the metastasis. A possible explanation why CTCs are still detectable in the blood months to years after complete removal of the primary tumour may therefore be the circulation and exchange of tumour cells between different metastatic sites and compartments^[5].

The first report with regard to the identification of CTC specific biomarker and genes in CRC was published by Smirnov *et al.*^[6]. Many studies tried to identify biomarkers for CRC-derived CTCs, but further investigations are needed to evaluate the use of these biomarkers in an automated clinical practice^[7,8]. Additionally, the potential prognostic significance of CTCs in CRC has been intensively and extensively reviewed^[9]. Rahbari *et al.*^[10] have supported that the detection of CTCs in the peripheral blood is significantly associated with poor prognosis in CRC. Therefore, the identification of CTCs would be extremely useful to clinical practice, allowing for early cancer detection, as well as, early therapeutic intervention, monitoring and detection of disease recurrence.

Identifying CTCs in peripheral blood, however, has been proven to be more difficult than expected, due to the low concentration of CTCs in blood and lack of technology with sufficiently high sensitivity and specificity^[11]. To date, the reverse transcriptase polymerase-chain reaction (RT-PCR) has been used for CTC detection in a variety of cancers. However, there are difficulties using RT-PCR for CTC detection. High RT-PCR sensitivity is associated with a susceptibility to false positive results in up to 5% of samples^[12]. In addition, RT-PCR based methods are time-consuming, expensive and difficult to standardise^[13]. Flow cytometry (FACS) has been used for CTC detection in several cancers^[14]. CTC quantification is possible with FACS, and this might provide a more accurate measure of the risk of recurrence than current RT-PCR based techniques. The introduction of immunomagnetic detection devices, such as the CellSearch[®] System (Veridex, Warren, NJ), has made possible the detection and at the same time the quantification of CTCs^[15]. How-

ever, the equipment required for FACS and CellSearch[®] System is very bulky, expensive, and difficult to operate at the point-of care. Therefore, the development of alternative sensitive, speedy, specific and low cost methods for CTC detection is important for cancer prognosis.

Quantum dots (QDs) have been developed as a new class of high-sensitivity and high-specificity probes lacking the intrinsic limitations of organic dyes and fluorescent proteins^[16,17]. In comparison with organic fluorophores, the QDs have unique optical and electronic properties, such as size- and composition-tunable fluorescence emission from visible to infrared wavelengths, large absorption coefficients across a wide spectral range and very high levels of brightness and photostability^[16]. QDs have been applied in fluorescence labelling for cancer imaging in living animals, and cellular imaging^[16,17].

The recent introduction of fluorescence detection technology using multifunctional magnetic beads and QDs has been reported^[18-20]. In the present study, we demonstrate a sensitive assay that combines magnetic beads isolation and QDs fluorescence detection for the identification of CRC CTCs surface antigens. The principle of the assay is the separation of CTCs from body fluids using magnetic beads coupled with epithelial cell adhesion molecule (EpCAM) antibody, and monoclonal cytokeratin 19 (CK19) antibody. These complexes are then tagged with streptavidin-conjugated QDs which lead to the detection of a fluorescent signal. For the evaluation of the performance, the method under study was used to isolate human colon adenocarcinoma cell line (DLD-1) human CRC cell line from and CTCs from CRC patient's peripheral blood. FACS analysis and Real Time RT-PCR have also been used to evaluate the performance of the described method. This method provides a simple, low cost and sensitive means of CTCs detection that can be easily adjusted for any other protein target, and can be directly applicable on clinical samples.

MATERIALS AND METHODS

Antibodies

The following antibodies were incorporated in the assay under study: mouse anti-human EpCAM biotin conjugated monoclonal antibody (Acris Antibodies Inc. Acris GmbH, San Diego, CA, United States), mouse anti-human CK19 biotin conjugated monoclonal antibody (Novus Biologicals, Littleton, Colorado, United States), mouse anti-human IgG (Fc specific) biotin conjugated monoclonal antibody (Acris), IgG2b negative control antibody (Santa Cruz, CA, United States), and mouse anti-human CD45 Alexa Fluor 488 conjugated monoclonal antibody (Acris).

Cell culture

The DLD-1 cell line (American Type Culture Collection: CCL-221) was used in our experiments. The DLD-1 colorectal cancer cell line was cultured in RPMI-1640 (Invitrogen), supplemented with 10% foetal bovine

serum (Invitrogen). Prior to testing, the cells were trypsinized, washed and then resuspended in Ca^{2+} and Mg^{2+} free phosphate buffered saline (PBS). Peripheral blood samples were obtained from 9 CRC patients (Table 1) and 5 healthy donors that gave informed consent to be included in this study. Concerning CRC patients, peripheral venous blood was sampled immediately after patients were anaesthetised and prior surgery's commencement. In all patients, an intravenous cannula was used to collect blood into 7-mL vacutainers containing sodium ethylenediaminetetraacetic acid (EDTA), discarding the first 7-mL aliquot of blood to reduce the risk of contamination of blood by skin epithelial cells. Three 30-mL samples were then collected at one-minute intervals (five 6-mL aliquots per 30-mL sample). Each 30-mL aliquot was thoroughly mixed and then divided into three 10-mL aliquots, one for analysis by RT-PCR, one by the proposed method and one by flow cytometry (FACS analysis). Human white blood cells were isolated from peripheral blood using Ficoll-Hypaque PLUS reagents (Amersham Biosciences, Little Chalfont, NA, United Kingdom). Cells were counted manually using a Burkert-Turk haemocytometer. Trypan blue (0.4%, Sigma, LO, United Kingdom) exclusion test was used to ensure cell viability was above 90% in experiments.

Conjugation of magnetic beads with anti-EpCAM antibody

Streptavidin coated magnetic beads (MBs) (Dynabeads M-280, Invitrogen) were functionalized with the biotinylated antibody EpCAM. For this purpose, 40 mg of antibody were added to 200 mL (10 g/L) streptavidin coated MBs and incubated at room temperature for 30 min. For the removal of unbound antibody, conjugated MBs were washed 5 times with PBS (1X) with the aid of a magnetic device (Dyna MPC-s, Invitrogen) and dis-

solved in 200 mL of PBS containing 0.1% bovine serum albumin (BSA). For negative control IgG2b antibody was used to replace EpCAM on MBs.

Functionalization of QDs with streptavidin

Cadmium selenide (CdSe) QDs (15-20 nm in size) with a maximum emission wavelength of 655 nm, shelled with ZnS and a polymer coating presenting carboxylic groups were purchased by Invitrogen. QDs were coated with streptavidin prior to testing according to the manufacturer's instructions. Briefly, 50 mL of QDs were diluted in 400 mL of borate buffer 10 mmol/L (pH 7.4), 96 mL of streptavidin solution (10 g/L) (Invitrogen) and 11.4 mL of EDC (10 g/L) (Sigma-Aldrich, MO, United States) and incubated at room temperature for 90 min. Streptavidin coated QDs were washed 5 times with 500 mL of borate buffer 50 mmol/L (pH 8.3) on an Amicon Ultra-4 Filter (Millipore, MA, United States) and dissolved into 50 mmol/L borate buffer (pH 8.3) to a final volume of 500 mL.

Limit of detection

For the assessment of the limit of detection (LOD) of the method, our team had to add DLD-1 cells and duplicate solutions of DLD-1 cells in whole blood, both obtained from healthy control individuals, in order to test them. Two series of ten-fold dilutions ranging from 10^4 to 10 cells/mL were prepared. Two negative controls were used in our experiments. The first has consisted of white blood cells from healthy donors, and the second MBs were coupled with IgG2b antibody. The LOD was defined as the lowest concentration level that could be determined to be statistically different from the negative controls (Analytical detection limit guidance 1996).

Cell detection

The principle of the assay is based upon the separation of cells using MBs coupled with anti-EpCAM (epithelial cell adhesion molecule). EpCAM is a carcinoma-associated antigen and is a member of a family that includes at least two type I membrane proteins and functions as a calcium-independent cell adhesion molecule. Like most other tumor-associated antigens, EpCAM is expressed on normal tissue. However, EpCAMs' expression on a wide variety of carcinomas, mostly in gastrointestinal carcinomas, exceeds the expression and accessibility of the antigen compared with normal cells, thereby establishing a useful therapeutic and diagnostic window for a targeted antibody approach. These complexes are then tagged with anti-CK19 biotinylated antibody that specifically recognizes CTCs and finally streptavidin-conjugated QDs leading to the detection of a fluorescent signal (Figure 1). To this purpose, 500 μL of each dilution of the cells comprising positive and negative controls or an equal volume of PBS BSA 0.1% (blank) were coupled at first with 40 mL of EpCAM antibody conjugated MBs, and then with 10 mL (0.2 g/L) of CK19 biotinylated antibody, and finally 40 mL of streptavidin coated QDs. For each hy-

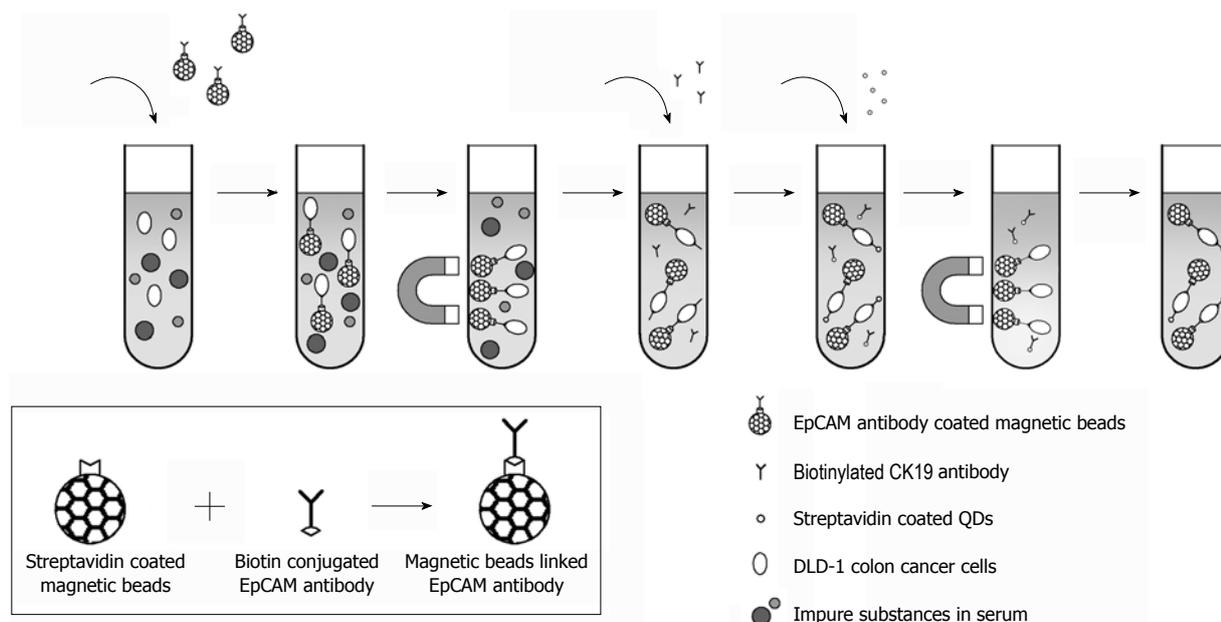

Figure 1 Circulating tumour cells are separated from the leucocytes using magnetic beads coupled with epithelial cell adhesion molecule antibody and a magnetic device. These complexes are then tagged with cytokeratin-19 (CK19) biotinylated antibody and streptavidin-conjugated quantum dots (QDs) which lead to the detection of a fluorescent signal. EpCAM: Epithelial cell adhesion molecule; DLD-1: Human colon adenocarcinoma cell line.

bridization step the dilutions were incubated at 37 °C for 20 min with gentle agitation, separated by the matrix with the aid of a magnetic device (DynaL MPC-s, Invitrogen), washed once with PBS-BSA 0.1% and then re-suspended in 200 mL PBS 0.1% BSA. For the direct visual observation of fluorescence, the samples were transferred on a UV transilluminator with UV emission at 312 nm (Vilber Loumat, France). Fluorescence was also detected with a spectrofluorometer (excitation 480 nm emission 655 nm, PMT 450V), (Infinite M200, Tecan United States).

FACS analysis

All samples were analyzed using a FACS Calibur BD Biosciences (United States) and the software BD FACStation™ System with the program Cell Quest, Mac. The antibodies used are described above and the staining of the isolated peripheral blood mononuclear cells samples was proceeded according to routine protocols. The anti-CK19 biotin conjugated monoclonal antibody with the QDs was used to evaluate the number of CTCs in the sample of interest and the CD45 Alexa Fluor 488 conjugated monoclonal antibody for the detection of non-specific interactions. Concerning the cell counting, for each sample 10 000 events were acquired. The parameter being used to describe individual samples was the % percentage of positive cells. In the first diagram (FSC/SSC) of FACS analysis the monocytes were gated, given that the CTCs are generally found in this population, in order to exclude most of the negative events. From the diagram of FSC/FL3 we have calculated the percentage of the cells that are fluorescent in FL3 (CK19+). In order to avoid non-specific binding, we have calculated at the same time the percentage of the cells that are fluorescent in FL3, but not in FL1 (CK19+/CD45-). In the FSC/FL3 diagram

the cells that are fluorescent in FL3 (CK19+) were gated, and screened them in another diagram FL1/FL3. At last, the percentage of the cells that are fluorescent in FL3, but not in FL1 was calculated and the percentage in absolute cell number was converted. We deemed that if we found > 1 positive cell/mL in a sample, this would be a CTC, considering that the mean average of the healthy samples was 1000 cell/L (Figure 2).

Reverse transcriptase and real time RT-PCR

Total RNA was isolated from DLD-1 cells, as well as RBC samples with the use of Trizol (Invitrogen, TRI Reagent) according to the manufacturer's instructions. The isolated RNA was dissolved in diethylpyrocarbonate-treated water and stored at -80 °C until used. Reverse transcription was performed by incubating 1 µg total RNA for 1 h at 42 °C in the presence of 500 mg/L of OligodT 12-18, 10 mmol/L deoxyribonucleotide triphosphates, 5 × first-strand buffer, 0.1 mol/L dithiothreitol, and 200 U/mL MMLV reverse transcriptase (Invitrogen). Assessment of the CK19 and EpCAM mRNA levels was performed by employing the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) expression levels as a reference gene. The following pair of primers were used: (1) GAPDH (Fw) 5'-GAAGGTGAAGGTCGGAGT-3' and (Rv) 5'-GAAGATGGTGTATGGGATTTTC-3' resulting in a 228-bp fragment; (2) CK19 (Fw) 5'-CCC GCGAC-TACAGCCACTA-3' and (Rv) 5'-GCTCATGCGCA-GAGCCTGTT-3' resulting in a 193-bp fragment; and (3) EpCAM (Fw) 5'-GCCAAATAATAACGGGACCTA-3' and (Rv) 5'-CCAGCTGAGAGACCAGGAGAA-3' resulting in a 130-bp fragment. Real-time PCR was performed in an ABI PRISM 7000 Sequence Detection System (Applied Biosystems, Foster City, CA, United States),

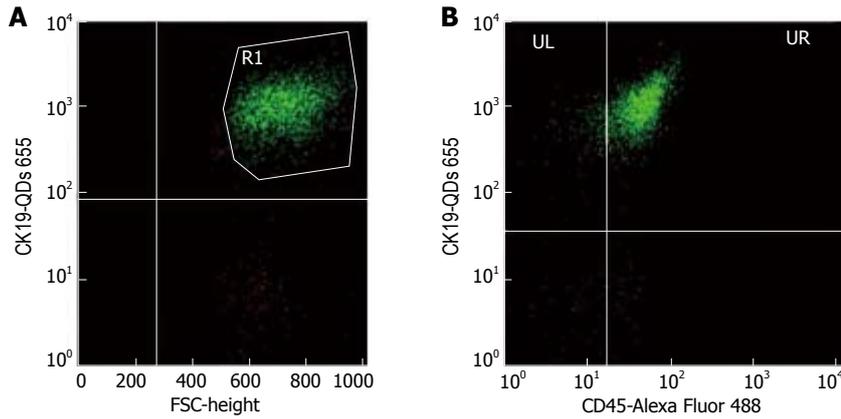

Figure 2 Representative fluorescence-activated cell sorting analysis of peripheral blood samples. A: Events which fell within region R1 are confirmed to be cytokeratin 19 (CK19)+ and fluorescent in FL3 (anti-CK19 conjugated with QDs); B: From the R1 gate, the events confirmed to be CK19+CD45+ are those in the UL region, in UR region the events represent those that are CK19+CD45+ and fluorescent in FL1 (anti-CD45 conjugated with Alexa Fluor). We deemed that the cells in the UL are those meeting the criteria for circulating tumor cells.

as follows: initial denaturation for 2 min at 50 °C and for 10 min at 95 °C, followed by 40 cycles of PCR (95 °C for 15 s; 60 °C for 1 min). Reactions were performed in duplicate, using the SYBR Green PCR Master Mix (Applied Biosystems) according to the manufacturer's instructions. Data were analyzed using the comparative CT method for the relative quantitation of results^[21]. Post-amplification denaturation curves showed that the primer pairs generated single products.

Statistical analysis

The consistency of the methods and comparison of total positive rate in the methods were analyzed using Cohen's kappa statistic and χ^2 test, respectively. All statistical analyses were carried out using GraphPad version 3.00 (GraphPad Software, San Diego, Calif). $P < 0.05$ was considered significant.

RESULTS

Our method for CTCs isolation and detection using EpCAM antibody coated MBs and CK19 antibody coated QDs is schematically illustrated in Figure 1. The assessment of the immobilization of antibodies on the surface of MBs was performed by using spectrophotometric measurement at 280 nm of the antibody solution before and after conjugation with MBs (data not shown).

For the evaluation of performance, the method under study was used to detect DLD-1 human CRC cells. The DLD-1 cells expressed EpCAM and CK19, as identified by RT-PCR. The direct visual observation of negative control did not reveal any fluorescent signal (Figure 3) as opposed to the DLD-1 cells reported above that reacted positively at or above the LOD concentration. The LOD of the methodology described in the present study was defined to 10 DLD-1 cells/mL of sample when results were assessed by visual observation of the test tubes.

In order to obtain an indication of the method's performance with clinical samples, we applied the optimized

assay to the detection of CTCs from human white blood cells that were isolated from peripheral blood of CRC patients, in comparison with real-time PCR and FACS analysis. Several studies used QDs-probes for FACS analysis^[22-24]. The concordance of the positive results recorded by the proposed assay on CRC samples with those of real-time PCR and FACS was 78.57% (11 of 14) and 85.71% (12 of 14) respectively. The relevant percentage with regard to negative results was 100% in both cases (Table 2). Despite the fact that the number of clinical samples was limited, it was noted that the samples with tumor node metastasis (TNM) stage IV had increased number of CTCs compared to those with TNM stage II and III.

The repeatability of the method was defined as 100% since the results recorded for the samples included in this type of evaluation were identical for all assessments ($n = 3$).

DISCUSSION

The spreading of tumor cells is one of the primary causes of recrudescence at distant sites and of death from cancer. Thus, the detection of circulating metastatic cells is important to predict recurrence and improve survival. In the present study, we describe a newly developed technique for the detection of CTCs, incorporating CdSe QDs for the detection of CTCs specific surface antigens. In the aforementioned method for CTCs detection, we used EpCAM antibody coated MBs and CK19 antibody coated QDs. We used EpCAM since the anti-EpCAM-based immunomagnetic enrichment technology, have showed significant better recovery rates compared to other cytometric technologies in spiking experiments. In addition, EpCAM-based enrichment methods of CTCs in CRC patients have been successfully applied in several cases^[25-27]. Regarding CK19, the later is a widely used biomarker to detect tumor cells which derive from epithelial tissues^[27].

The developed methodology does not require sample processing for DNA isolation, which facilitates its

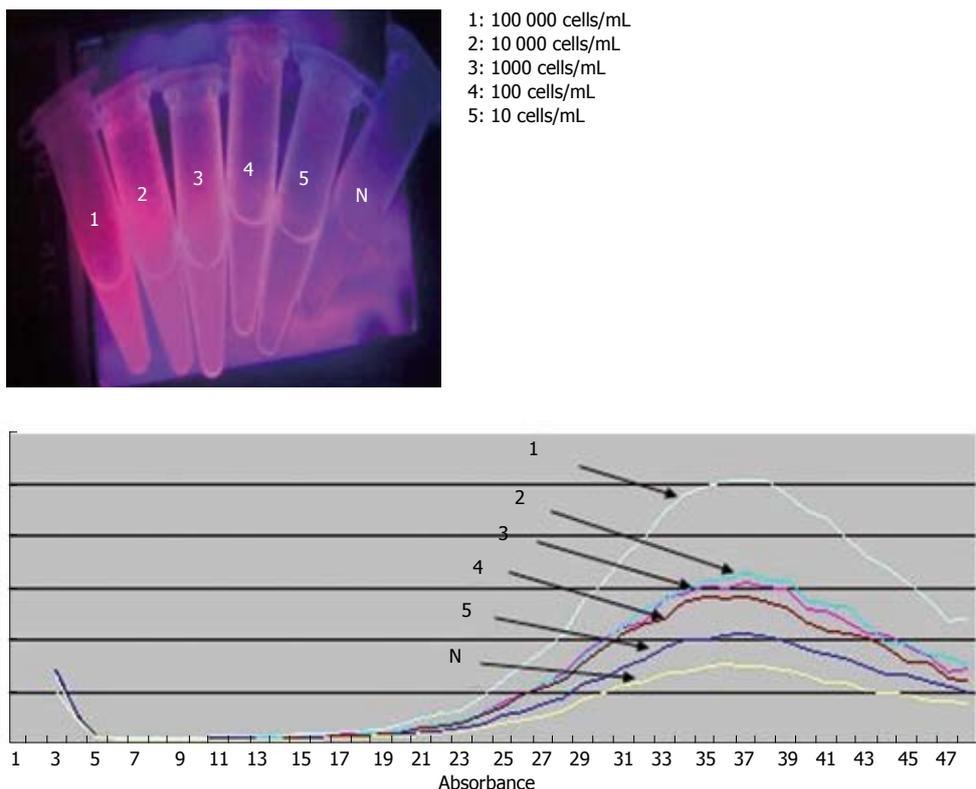

Figure 3 Representative results recorded by the proposed method for the human colon adenocarcinoma cell line serial dilutions ranging from 10^4 to 10 cells/mL (numbers 1-5) and negative controls. Fluorescence is evident in the human colon adenocarcinoma cell line samples with concentration up to 10 cells/mL, as illustrated at the fluorescent emission spectra obtained after magnetic separation.

incorporation at point-of-care. The use of QDs in the proposed approach bypasses the disadvantages of fluorescent dyes often incorporated into immuno-detection tests such as rapid photobleaching, narrow excitation spectrum and low signal intensity.

The accuracy of the QD detection system, as evaluated on clinical samples from CRC patients, compared to reverse transcriptase real-time PCR and FACS analysis applied to blood samples has ranged between 78.57% and 85.71%. Admittedly, PCR-based techniques as well as FACS analysis are among the most reliable and useful methodologies for the detection of CTCs in a variety of cancers. However, both techniques require trained personnel, dedicated space, and high-cost equipment.

It should be noted that while our method shows great promise in sensitive detection of CTCs, it is still far from achieving to detect a single CTC in the whole human circulating blood. At the present time, according to our knowledge, the most sensitive system in probably CellSearch™, whose detection limit is claimed to be 1 CTC/7.5 mL^[25]. However, this system is very expensive and partially subjective by distinguishing the CTC shapes from those of normal cells. Recently, the detection of CTC has also been achieved using surface enhanced Raman spectroscopy with a detection limit of 50 CTC/mL in whole blood^[28-30]. The method we presented here, might provide a fast and low-cost alternative way for CTC cell detection. For reasons of applicability the method described here incorporates a combination of

cancer and CTC antibodies that increases specificity and at the same time facilitates its adjustment for any other protein target, either of the tumor or the host. Evidently the method can be easily extended to the detection of any other tumor as the adaptation of the method would require only the incorporation of specific antibodies for the cancer or disease in question. Once fully developed, this method will be directly applicable on clinical samples in the context of the one reported above. This implies the potential use of the proposed methodology as a diagnostic technology platform.

COMMENTS

Background

The detection of circulating tumor cells (CTCs) is of great importance for the clinical management of patients with solid cancers like colorectal cancer (CRC), due to the fact that they have long been considered as a reflection of tumor aggressiveness. However, owing to the rarity of CTCs in peripheral blood, their detection requires methods combined with high sensitivity and specificity, which sets tremendous challenges for the implementation of these assays into clinical routine.

Research frontiers

The concept and existence of CTCs as well as the dissemination and settlement of these cells in secondary organs have been widely accepted. The development of alternative sensitive, speedy, specific and low cost methods for CTC detection is important for cancer prognosis. In the present study, authors demonstrate a sensitive assay that combines magnetic beads isolation and quantum dots (QDs) fluorescence detection for the identification of CRC CTCs surface antigens.

Innovations and breakthroughs

The developed methodology does not require sample processing for DNA isolation, which facilitates its incorporation at point-of-care. The use of QDs in the proposed approach bypasses the disadvantages of fluorescent dyes often incorporated into immuno-detection tests such as rapid photobleaching, narrow excitation spectrum and low signal intensity.

Applications

This method can be easily extended to the detection of any other tumor as the adaptation of the method would require only the incorporation of specific antibodies for the cancer or disease in question.

Peer review

The topic is of significant clinical importance as the detection of circulating cancer cells may be used for early diagnosis of the recurrence of the disease.

Abstract

AIM: To study the role of time-intensity curve (TIC) analysis parameters in a complex system of neural networks designed to classify liver tumors.

METHODS: We prospectively included 112 patients with hepatocellular carcinoma (HCC) ($n = 41$), hypervascular ($n = 20$) and hypovascular ($n = 12$) liver metastases, hepatic hemangiomas ($n = 16$) or focal fatty changes ($n = 23$) who underwent contrast-enhanced ultrasonography in the Research Center of Gastroenterology and Hepatology, Craiova, Romania. We recorded full length movies of all contrast uptake phases and post-processed them offline by selecting two areas

of interest (one for the tumor and one for the healthy surrounding parenchyma) and consecutive TIC analysis. The difference in maximum intensities, the time to reaching them and the aspect of the late/portal phase, as quantified by the neural network and a ratio between median intensities of the central and peripheral areas were analyzed by a feed forward back propagation multi-layer neural network which was trained to classify data into five distinct classes, corresponding to each type of liver lesion.

RESULTS: The neural network had 94.45% training accuracy (95% CI: 89.31%-97.21%) and 87.12% testing accuracy (95% CI: 86.83%-93.17%). The automatic classification process registered 93.2% sensitivity, 89.7% specificity, 94.42% positive predictive value and 87.57% negative predictive value. The artificial neural networks (ANN) incorrectly classified as hemangiomas three HCC cases and two hypervascular metastases, while in turn misclassifying four liver hemangiomas as HCC (one case) and hypervascular metastases (three cases). Comparatively, human interpretation of TICs showed 94.1% sensitivity, 90.7% specificity, 95.11% positive predictive value and 88.89% negative predictive value. The accuracy and specificity of the ANN diagnosis system was similar to that of human interpretation of the TICs ($P = 0.225$ and $P = 0.451$, respectively). Hepatocellular carcinoma cases showed contrast uptake during the arterial phase followed by wash-out in the portal and first seconds of the late phases. For the hypovascular metastases did not show significant contrast uptake during the arterial phase, which resulted in negative differences between the maximum intensities. We registered wash-out in the late phase for most of the hypervascular metastases. Liver hemangiomas had contrast uptake in the arterial phase without agent wash-out in the portal-late phases. The focal fatty changes did not show any differences from surrounding liver parenchyma, resulting in similar TIC patterns and extracted parameters.

CONCLUSION: Neural network analysis of contrast-enhanced ultrasonography - obtained TICs seems a promising field of development for future techniques, providing fast and reliable diagnostic aid for the clinician.

INTRODUCTION

Rapid classification of liver masses is of utmost importance, as early diagnosis drastically improves survival chances of oncologic patients, determined by the appropriate curative therapy. Hepatocellular carcinoma (HCC) is the sixth cancer as incidence worldwide, being the third cause of cancer-related mortality^[1,2].

Current guidelines include at least one dynamic imagistic method for establishing a positive HCC diagnosis^[3,4], as with the widespread use in recent years of imaging techniques, the differential diagnosis of a newly discovered liver mass became less invasive for the patient.

Contrast-enhanced ultrasonography (CEUS) with second generation blood-pool contrast agents is one of the most cost-effective methods for determining tumor vascularization patterns^[5-9]. Arterial contrast uptake followed by late portal wash-out is considered the radiological hallmark of HCC. Various other benign and malignant liver tumors show different uptake patterns, thus providing differential diagnosis. Since other tumors can sometimes mimic the filling patterns specific to HCC, different studies reported lower sensitivities for CEUS when compared to other dynamic imaging methods such as contrast-enhanced magnetic resonance imaging (CE-MRI) or 4-phase computed tomography (CT)^[9,10]. Time intensity curves (TIC) are the graphical representation of contrast intensity represented in every moment of a CEUS investigation. Comparative TIC analysis between a tumoral region of interest (ROI) and a parenchymal equivalent ROI could enhance the diagnostic accuracy of CEUS, thus establishing its role in HCC diagnosis^[11,12].

Artificial neural networks (ANN) emerged in recent

years as potent diagnostic tools for malignant lesions, mainly because of their adaptability and excellent problem solving-oriented architecture. They have been employed in complex medical image analysis tasks with various degrees of success. Computer-aided diagnosis (CAD) systems have gained a reputation for providing integrative solutions for the diagnosis of several types of malignancies^[13-15], with many applications in gastroenterology and tumor pathology associated with the digestive tract.

Our aim here was to establish the role of TIC analysis parameters in a complex system of neural networks designed to classify liver tumors.

MATERIALS AND METHODS

Patient inclusion and final diagnosis

Between September 2008 and May 2011 we prospectively included 112 patients with hepatocellular carcinoma ($n = 41$), hypervascular ($n = 20$) and hypovascular ($n = 12$) liver metastases, hepatic hemangiomas ($n = 16$) or focal fatty changes ($n = 23$) who underwent CEUS in the Research Center of Gastroenterology and Hepatology, Craiova, Romania. Positive diagnosis was reached through a combination of other imagistic methods (CT and CE-MRI), liver biopsy in uncertain cases or follow-up for a minimum period of six months. The study was performed in accordance with the Declaration of Helsinki and received necessary approval of the Ethic Committee of the University of Medicine and Pharmacy of Craiova. All patients gave informed consents on all procedures and agreed in writing so that their anonymized CEUS investigations were to be used in the ANN model. An overview of the study protocol can be observed in Figure 1.

Data collection and pre-processing

Full length CEUS recordings were retrieved in an uncompressed video for offline post-processing and subsequent TIC analysis. This ensured an optimal preservation of image features, color intensities and hues.

Digital files were transferred to a high-end graphical station where they were analyzed with in-house developed software (programmed by Ionescu M and Streba CT). At first, the team of gastroenterologists with extensive US and CEUS experience (Sandulescu L, Ciurea T, Saftoiu A, Vere CC and Rogoveanu I) supervised Streba CT in the selection of tumor and normal parenchyma ROIs at equal tissue depths, on each CEUS recording. The software recorded median color intensity values inside the ROIs for each frame and presented an accurate TIC for visual interpretation. The locations of the two ROIs were manually adjusted after a breathing motion, thus removing breathing artifacts. The team also visually analyzed the TICs and provided a diagnosis, blinded to any other patient details.

ANN design and methodology

Raw intensity values were extracted as data sequences

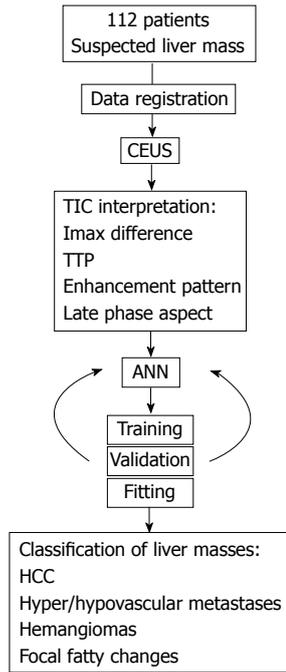

Figure 1 Study protocol. The patients were registered and contrast-enhanced ultrasonography (CEUS) was performed, with subsequent movie registration and offline time-intensity curve (TIC) analysis. Relevant parameters were fed to the artificial neural networks (ANN) which divided the dataset into training, validation and fitting lots. A back propagation and 10-fold cross-validation algorithm assured a high accuracy for the classifications obtained by the ANN system. Imax: Maximum intensities; TTP: Time to reaching peak intensities; HCC: Hepatocellular carcinoma.

and analyzed by a feed forward back propagation multi-layer ANN which was trained to classify data into distinct classes, corresponding to each type of liver lesion. Based on previous studies which concluded that the best suited ANN layout for classification tasks should be as simple as possible, the network architecture of choice contained only one hidden layer, with an input layer and one layer dedicated for the output (Figure 2A)^[14,16].

The first layer of the ANN consisted of several groups of input neurons (Figure 2B) corresponding to each imputed parameter, as follows: difference in maximum intensities, corresponding time to reaching peak intensities and the aspect of the late/portal phase, as quantified by the ANN on individual frame-by-frame differences between median intensities starting from the 45th second of the recording. As various tumors can be diagnosed by evaluating central versus peripheral enhancement, the software also calculated a ratio between median intensities of the central and peripheral areas, thus quantifying relative changes in contrast uptake.

Each neuron in an ANN was connected to every neuron of the consecutive layer hidden layer through connections called “synapses”, which are attributed different “weights”, based on strength of the connection^[14,17,18]. These weights were calculated by the ANN in a hierarchical manner (basically, the system determined the importance of each parameter in the analysis).

A hidden 2nd layer contained neurons with associ-

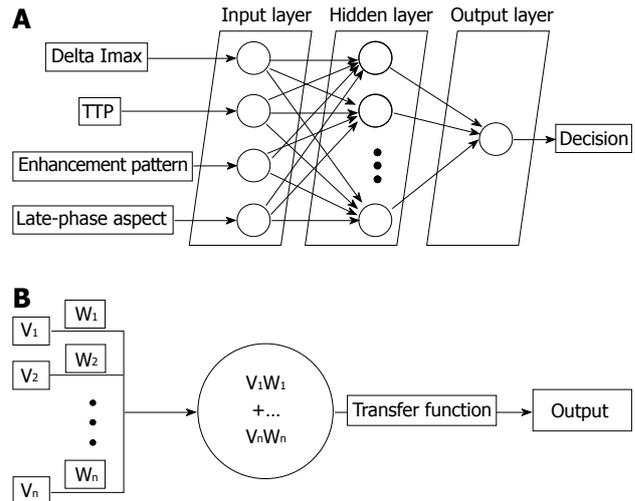

Figure 2 Graphical representation of an artificial neural networks and a neuron from the 2nd hidden layer. A: The four classes of parameters are imputed to corresponding neurons in the first layer of the artificial neural networks, which in turn establish synaptic connections with all neurons of the 2nd hidden layer. These neurons provide a value for the output layer, which in turn presents the user with a classification decision; B: Neurons in the hidden layer receive multiple inputs (V) which are attributed specific weights (W) and all products between these two values are summed. The corresponding result (output) is forwarded through a transfer function of the efferent synapse. Imax: Maximum intensities; TTP: Time to reaching peak intensities.

ated transfer and processing functions which received weighted parameters as well as activity of the previous neurons. The sum of the products between synaptic weights and neuron activity decided an output category (in this case, any real number between 1 and 5, corresponding to the five distinctive tumor classes), similar to information processing within a human brain^[17-20].

A final output layer was organized and provided five distinct values, one for each type of liver mass identified. This layer could have been varied in size depending on the total number of categories, if other types of tumors would have been present. This presented the user with a possible classification suggestion and probability score, calculated as a percentage from the total ideal score for the ideal value (i.e., if the total was 0.8, it would present the user with an 80% probability for the tumor to be HCC, as “1” was the assigned score for this diagnosis).

All 112 cases were randomly divided into training, validation and testing sets. The training phase represented the moment when the system learned from a selected data-set which varied in size and composition, thus determining respective weights for each synapses. The ANN was trained with the back propagation algorithm and 10-fold cross-validation was used to assess its performance, as previously described elsewhere^[18,19]. This method minimized the risk of over-fitting, which is an increasingly rigid structure that could ultra-classify cases. Operators chose the learning rate, determining the epoch (that is, the number of iterations needed for going through the training phase), as previously experience showed^[18,19]. Also, all cases were assessed by the team of experts according to the visual TIC representation, thus

Table 1 Descriptive statistics of the study lot and description of the artificial neural networks classification

	HCC	Hypervascular metastasis	Hypovascular metastasis	Hepatic hemangioma	Fatty focal change
Sex (<i>n</i>)					
Male	30	9	5	4	16
Female	11	11	7	12	7
Age (yr), median (range)					
Male	64 (52-83)	68 (45-89)	66 (42-89)	48 (32-64)	43 (31-61)
Female	66 (59-77)	62 (38-72)	62 (41-80)	50 (41-62)	44 (29-61)
Tumor size (cm), median (range)					
Male	5.08 (2-10.7)	5.09 (2-13.1)	5.11 (2.1-12.7)	3.1 (2-7)	4 (2-6.5)

Hepatic hemangioma	1	3	0	12	0
Fatty focal change	0	0	0	0	23

When accounting for multifocal tumors, only the largest median sizes was taken into the calculation. ANN: Artificial neural networks; HCC: Hepatocellular carcinoma.

enabling a direct comparison with the diagnostic accuracy of TIC analysis as a stand-alone method.

Statistical analysis

The statistical analysis was performed using GraphPad Prism 5.0 (GraphPad Software Inc, LaJolla, CA). We calculated the respective sensitivities, specificities, positive (PPV) and negative (NPV) predictive values for both human visual and computerized ANN interpretations. We evaluated the differences between the sensitivity and specificity of the ANN-guided and human TIC evaluation-based diagnosis by using the McNemar's test. A *P* value below 0.05 was considered significant. Moreover, we calculated the training and testing accuracy of the ANN and we performed a fitting analysis in order to better characterize the classification characteristics of the system.

RESULTS

The study lot consisted of 69 men and 43 women, their detailed characteristics being illustrated in Table 1.

HCC cases showed contrast uptake during the arterial phase, followed by wash-out in the portal and first seconds of the late phases (Figure 3A). For the hypovascular metastases we recorded negative peak values which resulted in negative differences being imputed in the ANN (Figure 3B). For hypervascular metastases, wash-out in the late phase was registered in the majority of cases. Hemangiomas showed contrast uptake in the arterial phase, followed by the absence of wash-out during the portal-late phases (Figure 3C). Focal fatty changes registered similar TIC patterns to the surrounding parenchyma (Figure 3D).

The ANN containing TIC parameters showed similar diagnostic capabilities to human interpretation of TICs. The automatic classification process registered 93.2% sensitivity, 89.7% specificity, 94.42% PPV and 87.57% NPV. Comparatively, human visual interpreta-

tion of TICs showed 94.1% sensitivity, 90.7% specificity, 95.11% PPV and 88.89% NPV. The ANN incorrectly classified as hemangiomas three HCC cases and two hypervascular metastases, while in turn misclassifying four liver hemangiomas as HCC (one case) and hypervascular metastases (three cases) (Table 1). Overall, the ANN correctly identified 67/72 (93%) malignant lesions and 36/40 (90%) of all benign focal liver lesions. In turn, human evaluation based solely on TIC parameters misclassified four hypervascular metastases as hemangiomas and four hemangiomas as either HCC (two cases) or hypervascular metastases (two cases). The differences between the automatic ANN classification and human interpretation of TIC data were not statistically significant in terms of specificity (*P* = 0.225) and sensitivity (*P* = 0.451).

The neural network had 94.45% training accuracy (95% CI: 89.31%-97.21%) and 87.12% testing accuracy (95% CI: 86.83%-93.17%). Fitting coefficients demonstrated the overall classification capabilities of the ANN, with *r* = 0.989 (training); 0.991 (validation); 0.984 (testing) and 0.993 (overall).

DISCUSSION

We present here the first report on using an ANN-driven computer aided diagnostic system in conjunction with CEUS TIC analysis for the correct classification of liver masses. Our pilot study on an initial lot of 112 patients compared the diagnostic capability of such a system with visual TIC analysis by a team of gastroenterologists blinded to any other patient data. We obtained similar results, the ANN scoring 93.2% sensitivity and 89.7% specificity, compared to 94.1% sensitivity and 90.7% specificity for human visual interpretation, respectively.

Early correct diagnosis and appropriate staging of liver malignancies is of utmost importance for patient survival, as curative surgical interventions have narrow indications and are extremely specific to certain types

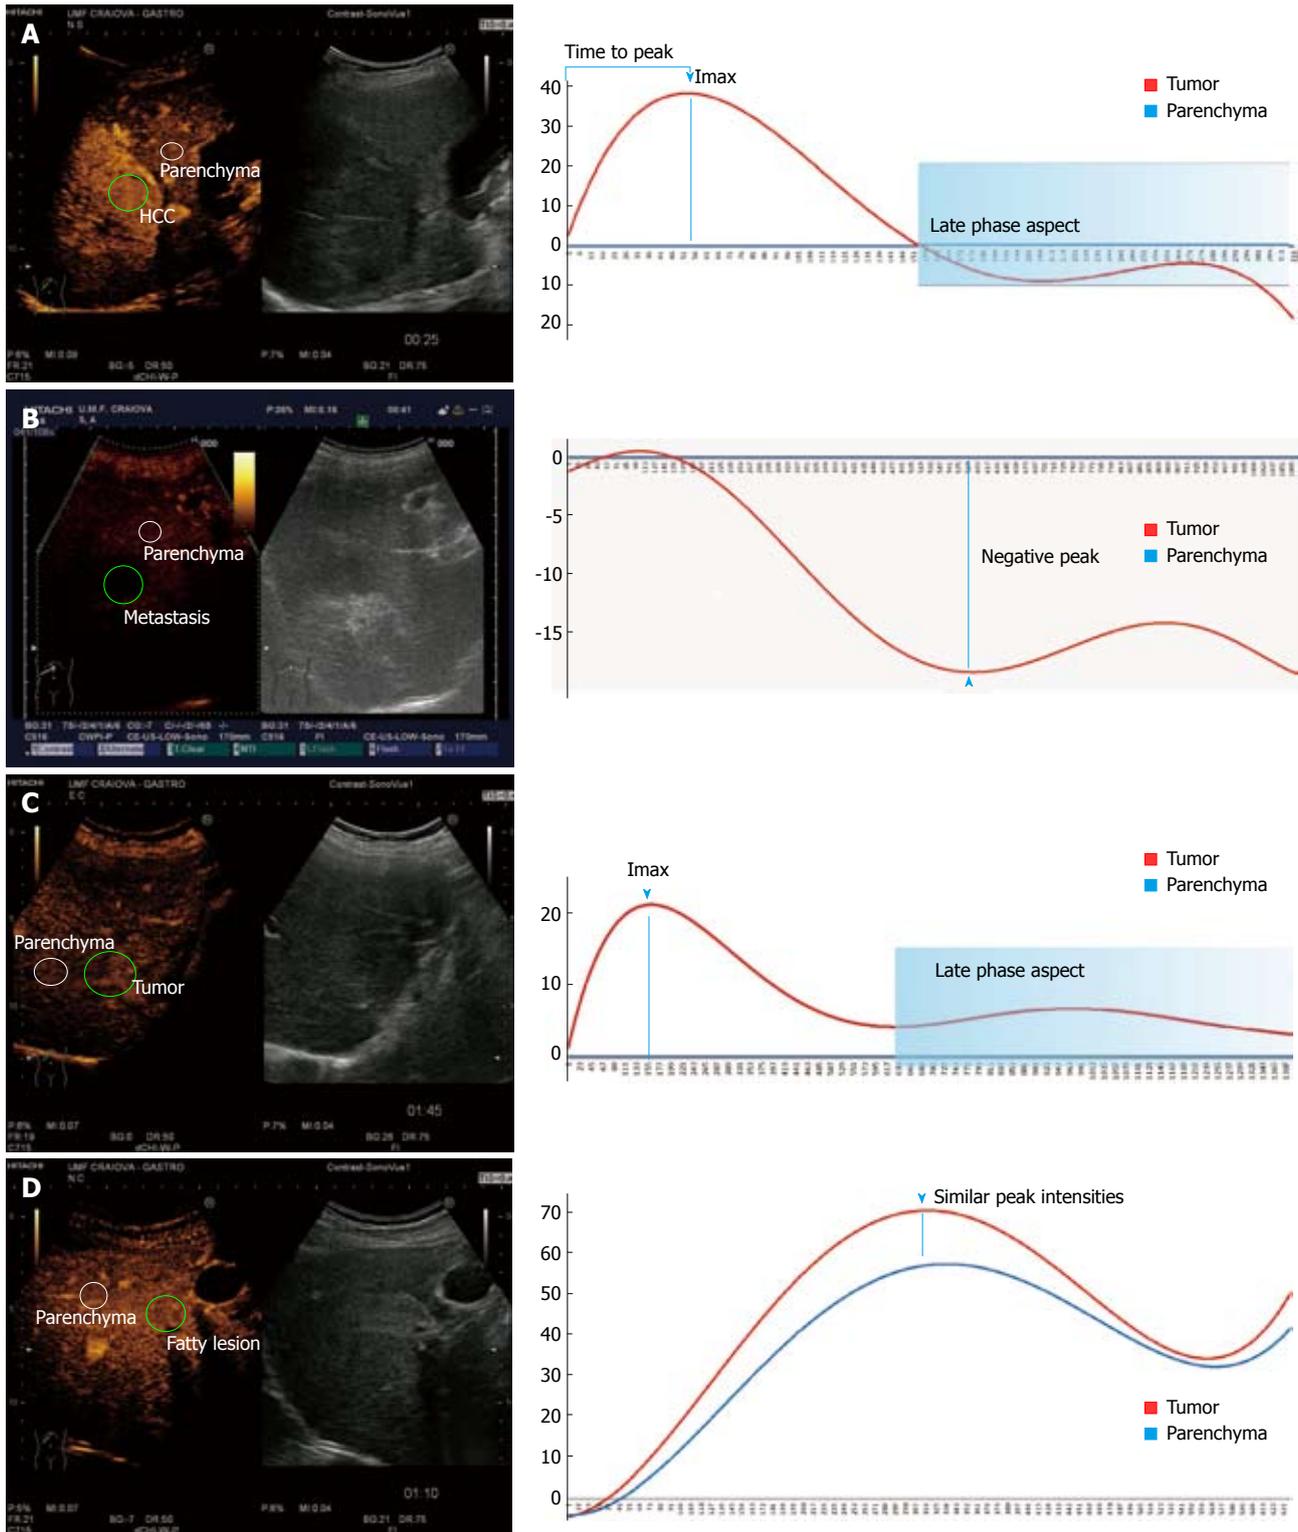

Figure 3 Examples of contrast-enhanced ultrasonography aspects and the selection of the two regions of interest, corresponding to the liver tumor and normal parenchyma, respectively. Graphical representation of the time-intensity curve (TIC) and the most important parameters extracted and later fed to the artificial neural networks. A: Hepatocellular carcinoma (HCC)-positive contrast uptake in the early arterial phase followed by wash-out in the portal/late phase; B: Hypovascular metastasis-hypo-enhancement of the tumor compared to normal parenchyma; C: Hepatic hemangioma-absence of the wash-out and positive peak intensity; D: Focal fatty change-similar TIC parameters for the two selected areas of interest.

of tumors^[1-4]. HCC currently ranks third in terms of mortality worldwide and fifth in incidence with almost 750 000 new cases diagnosed each year, while being second in mortality among digestive cancers^[5]. The diag-

nostic criteria for HCC, the most common primary liver malignancy worldwide, rely primarily on imagistic methods^[3,4]. Current accepted guidelines worldwide are those proposed by the American Association for the Study of

Liver Disease (revised in 2010)^[3] and those of the association between the European Society for the Study of Liver and the European Organization for Research and Treatment of Cancer (EASL-EORTC, recently revised in April 2012)^[4]. The introduction of new generations of contrast agents marked the adoption of a generally accepted radiological hallmark for positive HCC diagnosis, namely contrast up-take in the arterial phase followed by washout in the venous/late phase. The American Association for the Study of Liver Diseases guidelines stipulate that only one imaging technique with contrast uptake, either CT or MRI, showing the radiological hallmark, is sufficient for positive diagnosis of tumors between 1 and 2 cm in diameter (this being the optimum tumor size for curative surgery)^[3,4]. Their European counterparts, however, are more cautious in applying a single imaging method, and recommend two coincidental techniques in suboptimal settings due to technical limitations^[4].

The use of CEUS is regarded as controversial in the latest EASL guideline^[4]. Second generation contrast agents use gas bubbles between 2 and 7 microns in diameter which resonate under the US probe, the amplified signal being registered by the US machine through the same probe^[5,6]. While the radiological hallmark can be clearly identified in this technique, the contrast microbubbles are bound to the intravascular space, as opposed to iodinated contrast-CT or gadolinium-based MR imaging in which the contrast agents are rapidly cleared from the bloodstream into the surrounding parenchymal space^[4,9,10]. According to some studies, intrahepatic cholangiocarcinoma or even some highly vascularized liver metastases can display uptake patterns similar to HCC during CEUS or gadolinium-based MRI, thus providing an important source of error^[9]. Currently, efforts are being made to overcome the inherited issues with CEUS investigations and diminish the rate of false interpretations^[11,12]. The use of TICs in the interpretation of CEUS movies seems a feasible method of increasing the specificity of this investigation^[12,13]. The method relies on plotting and comparing on a time scale the median intensities of two user-defined areas, one within the suspected tumor and one in a parenchymal area with no major vessels, thus producing two curves which depict contrast uptake during CEUS^[12]. The usual graphical representation show contrast uptake in the first 30-60 s, followed by tumor wash-out in portal and venous phases, when the maximum intensity are similar to those of the parenchymal-selected area of interest. While TIC quantification does add more precision to the investigation, several user-dependent and technique-dependent limitations have been identified, such as different depths of the analyzed tumor/parenchyma areas of interest, moving artifacts due to patient breathing or the interference of large blood vessels in the selected areas of interest^[12]. Our system showed good capabilities in selecting the appropriate ROIs, as it allowed for breathing compensation to be applied during post processing.

The neural network developed and tested consisted

of an input layer containing four classes of neurons corresponding to TIC-dependent parameters, one hidden layer for data processing and a variable output layer which classified the data into five categories. This model, the perceptron feed-forward multi-layered ANN with back-propagation algorithms is the preferred embodiment of a CAD system for medical diagnosis, as it provides rapid diagnosis with minimal over-fitting (the artificial increase of certain rules of inclusion, leading to incorrect classifications)^[13-19]. Automated quantitative image analysis techniques have been introduced in medical practice for a number of years^[21-25]. The use of ANNs or other adaptive, machine-based learning systems, can substantially improve the accuracy of any quantitative-based image analysis method^[25,26]. Moreover, current image analysis methods employed with US or CEUS are heavily dependent on the expertise of the medical operator^[22-26]. The neural network approach showed excellent training and validation characteristics, with fast and reliable cycles. The usage of ANNs proved adequate, having promising results compared to human interpretation of the data. Using an independent CAD system proved beneficial and can considerably reduce user-dependent bias from CEUS interpretation, perhaps improving its ability to correctly diagnose liver malignancy, further enhancing its role in current medical guidelines.

One possible limitation of our study is represented by the relatively low number of cases included in the analysis. This was resolved by applying specific training algorithms with a long history of success in small patient lots^[14,18,19]. Patients presented some of the most masses most commonly encountered by the physician in daily practice, therefore the system showed good promise in providing an independent diagnostic aid based solely on accurate quantification of imaging data. The system has promising telemedicine application, as it can be accessed from small tertiary referral centers, with limited experience in diagnosing liver malignancies. It can provide an independent expert diagnosis and verification system for physicians who do not routinely encounter liver-related pathology. Another indication for the system would be in medical training, as an independent help for training gastroenterologists. The self-improving model specific to the architecture of any ANN will only benefit from an extended number of cases, a greater training set further improving its diagnosis performances. Future directions should include other intelligent artificial systems, such as support vector machines, genetic algorithms, Bayesian classifiers and so on, with perhaps even better results.

We previously presented preliminary results of introducing an ANN analysis of CEUS parameters in a cascade ANN system for the diagnosis of HCC and other liver malignancies, with good prospects in terms of accuracy and efficiency^[27]. Therefore, we strongly believe that the merger between clinical data and imagistic parameters represent a necessary direction in future aiding clinicians in their therapeutic decisions.

In conclusion, neural network analysis of CEUS

TICs seems a promising field of development for future techniques, providing fast and reliable diagnostic aid for the clinician. A multi-layer perceptron ANN proved sufficient for the classification of liver masses based on TIC analysis data, producing the most rapid and accurate results. Future studies are needed in order to validate the system in larger cohorts and perhaps improving the architecture of the proposed ANN. The system can ultimately become an independent objective quantifier of clinical and imagistic data which can improve the diagnostic accuracy of CEUS regarding liver malignancies.

COMMENTS

Background

An early diagnosis of liver malignancies represent a major concern, as the therapeutic options become increasingly limited as the disease progresses. The imagistic diagnosis based on contrast agents is the preferred method for hepatocellular carcinomas (HCC), the most important primary malignant tumor of the liver. The role of contrast-enhanced ultrasonography (CEUS) in the differential diagnosis of liver tumors is currently subject to international debate, while time-intensity curve (TIC) analysis provides a rapid method to quantify perfusion parameters. Several computer-aided diagnosis (CAD) systems are currently employed in the diagnosis of various malignancies, specifically artificial neural network (ANN) systems being employed in image-recognition tasks.

Research frontiers

CEUS was found to provide limited data when differentiating hepatocellular carcinomas from other liver malignancies; however, the introduction of TIC analysis provides important parameters that can objectify the vascular particularities of liver masses. ANN systems designed for differential diagnosis of malignancies are employed in various areas of medicine, including gastroenterology, with various degrees of success.

Innovations and breakthroughs

This is, to the knowledge, the first report on an ANN-based diagnosis and classification system based on imagistic data, designed to differentiate between several types of liver tumors, both malignant and benign. The CAD system presented here relies on TIC parameters extracted from CEUS investigations which are imputed in a feed forward back propagation single-layer neural network trained to classify liver tumors.

Applications

This system can successfully be applied in telemedicine settings, where smaller referral centers or gastroenterologists with limited experience in CEUS-based diagnosis of liver tumors and especially HCC, may benefit from an independent, objective diagnosis suggestion. Another preferred application is in medical training of gastroenterologists who can fully benefit from the growing experience such a system can provide.

Terminology

CEUS: Ultrasonography (US) using 2nd generation contrast agents containing micro bubbles which resonate under the US probe, the amplified signal being registered by the US machine; TIC analysis: Method to visualize the parallel dispersion of the contrast agent between the tumor and an area selected from the surrounding parenchyma; ANN: Decision making artificial intelligent systems designed to mimic the operating principles of the human central nervous system and their key components - neurons and synapses.

Peer review

This is a high quality research in which authors analyze the role of TIC analysis parameters in a complex system of neural networks designed to classify liver tumors. The results are interesting and suggest that neural network analysis of CEUS-obtained TICs seems a promising field of development for future techniques, providing fast and reliable diagnostic aid for the clinician.

Abstract

AIM: To investigate the long-term outcomes of endoscopic ultrasound-guided choledochoduodenostomy (EUS-CDS) with a fully covered self-expandable metallic stent (FCSEMS).

METHODS: From April 2009 to August 2010, 15 patients with distal malignant biliary obstructions who were candidates for alternative techniques for biliary decompression due to a failed endoscopic retrograde cholangiopancreatography (ERCP) were included. These 15 patients consisted of 8 men and 7 women and had a median age of 61 years (range: 30-91 years). The un-

derlying causes of the distal malignant biliary obstruction were pancreatic cancer ($n = 9$), ampulla of Vater cancer ($n = 2$), renal cell carcinoma ($n = 1$), advanced gastric cancer ($n = 1$), lymphoma ($n = 1$), and duodenal cancer ($n = 1$).

RESULTS: The technical success rate of EUS-CDS with an FCSEMS was 86.7% (13/15), and functional success was achieved in 100% (13/13) of those cases. In two patients, the EUS-CDS failed because an FCSEMS with a delivery device could not be passed into the common bile duct. The mean duration of stent patency was 264 d. Early adverse events developed in three patients (3/13, 23.1%), including self-limited pneumoperitoneum in two patients and cholangitis requiring stent reposition in one patient. During the follow-up period (median: 186 d, range: 52-388 d), distal stent migration occurred in four patients (4/13, 30.8%). In 3 patients, the FCSEMS could be reinserted through the existing choledochoduodenal fistula tract.

CONCLUSION: EUS-CDS with an FCSEMS is technically feasible and can lead to effective palliation of distal malignant biliary obstructions after failed ERCP.

INTRODUCTION

A self-expandable metallic stent insertion is a well-established palliative treatment that has been verified in numerous studies for patients with inoperable malignant biliary obstructions^[1-4]. Although a self-expandable metallic stent can be inserted *via* the transpapillary route in most cases using endoscopic retrograde cholangiopancreatography (ERCP), a metallic stent insertion may be impossible due to duodenal obstruction, altered anatomy due to a previous operation (e.g., Roux-en-Y anastomosis), or tumor invasion of the major duodenal papilla^[5,6]. Until recently, percutaneous transhepatic biliary drainage (PTBD) has mainly been used in these cases. PTBD, however, is often accompanied by procedure-related adverse events and by many issues related to external drainage, such as pain, catheter dislodgement, and cosmetic problems. Thus, PTBD may cause a serious decline in the quality of life^[7,8].

Since the endoscopic ultrasound (EUS)-guided bile duct puncture was first reported in 1996, sporadic case reports on EUS-guided biliary drainage (EUS-BD) suggested that it was a feasible and effective alternative in patients with failed conventional ERCP stenting^[9-13]. Currently, three types of EUS-BD have been described, depending on the route of intervention [e.g., EUS-guided choledochoduodenostomy (EUS-CDS), EUS-guided hepaticogastrostomy, and EUS-guided gallbladder drainage]^[5,14,15]. Plastic stents usually have been used in the EUS-BD procedure, but several studies suggested that EUS-BD with a fully covered self-expandable metallic stent (FCSEMS) might be a feasible and useful alternative to PTBD^[6,16]. Although EUS-CDS with an FCSEMS is expected to show longer patency duration and fewer adverse events in patients with malignant biliary obstructions, to the best of our knowledge there have been no studies that address the long-term follow-up results of such a procedure. Therefore, we studied the long-term outcomes of EUS-CDS with an FCSEMS after failed conventional ERCP.

MATERIALS AND METHODS

Study population

From April 2009 to August 2010, a total of 2844 ERCPs were performed in a 2680-bed tertiary referral hospital; of these, 926 ERCPs were performed to relieve biliary obstruction. Endoscopic transpapillary biliary drainage failed in 115 (12.4%) patients, with 69 patients undergoing PTBD and 46 patients undergoing EUS-BD. EUS-CDS with an FCSEMS was attempted in 15 patients.

These 15 patients included 8 men and 7 women and had a median age of 61 years (range: 30-91 years). The causes of distal malignant biliary obstruction were 9 pancreatic cancers, 2 ampulla of Vater cancers, 1 renal cell carcinoma, 1 advanced gastric cancer, 1 lymphoma, and 1 duodenal cancer. The inclusion criteria were the presence of a distal malignant biliary obstruction and failed conventional ERCP stenting, and the exclusion criteria were

an inability to sedate the patient due to advanced heart or pulmonary diseases and a lack of informed consent. Finally, we excluded any patients who had been included in previous publications^[6].

Five experienced endoscopists (Lee SS, Park DH, Seo DW, Lee SK and Kim MH) performed the ERCP procedures, and two of them (Lee SS and Park DH) performed the EUS-CDS. These two endosonographers perform more than 500 EUS procedures for pancreaticobiliary diseases annually. This study was approved by the Institutional Review Board of our center. All patients provided written informed consent.

Techniques for EUS-CDS

We administered broad-spectrum, prophylactic antibiotics directed against gram-positive and gram-negative organisms before the procedure to minimize the risk of infection. Initially, ERCP was performed using a therapeutic duodenoscope (TJF-260, Olympus Optical, Tokyo, Japan). When the ERCP was unsuccessful, the EUS-CDS was performed using a linear-array echoendoscope (GF-UCT 240-AL 5) during the same endoscopy session or 1-2 d later.

The dilated extrahepatic duct was usually accessed with the echoendoscope placed at the duodenal bulb. The initial puncture was performed under real-time ultrasound and color Doppler guidance with a 19-gauge aspiration needle (EUSN-19-T, Cook Endoscopy, Winston-Salem, NC). After the puncture, the aspiration of bile and cholangiography was performed to confirm that there was an adequate puncture. Next, a 0.0889 cm guidewire was inserted through the needle and coiled in the bile duct lumen. The needle was exchanged for a 6F and a 7F tapered biliary dilator catheter (catheter tip, 4F; Cook Endoscopy, Winston-Salem, NC) to dilate the tract. If there was resistance to the advance of the dilator catheter, a triple-lumen needle-knife (Microtome, Boston Scientific, Natick, MA) with a 7F shaft diameter was gently inserted over the guidewire to dilate the tract using a brief burst of pure cutting current. Finally, an FCSEMS with an 8F deployment system (nitinol stent, 8 to 10 mm in diameter, 4 to 6 cm in length, and flared at both ends to prevent distal or proximal migration; BONASTENT, Standard Sci Tech, Seoul, South Korea) was inserted under echoendoscopic and fluoroscopic guidance (Figure 1).

Definition of events

Technical success was defined as the passage of a metallic stent across the duodenum, along with the flow of contrast medium and/or bile through the stent. Functional success was defined as a decrease in serum total bilirubin to < 75% of the pretreatment value within 4 wk. An early adverse event was defined as any stent-related adverse event within 4 wk, including pneumoperitoneum, bleeding, biloma, bile peritonitis, and stent migration. A late adverse event was defined as any stent-related adverse event occurring > 4 wk after the stent placement, such as stent migration or stent occlusion. Biliary re-intervention was defined as any type of endoscopic, percutaneous, or

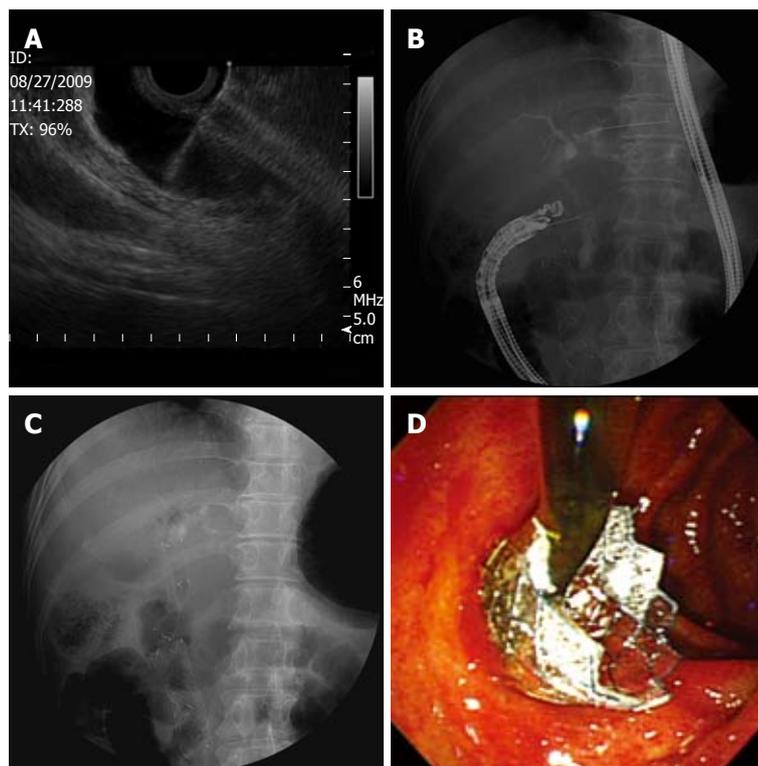

Figure 1 Technique for endoscopic ultrasound-guided choledochoduodenostomy with a fully covered self-expandable metallic stent. A: The bile duct was punctured with a 19-gauge needle under linear-array echoendoscopic guidance; B: A guidewire was introduced through the needle; C: A fully covered self-expandable metallic stent was inserted under fluoroscopic guidance; D: Illustration of a biliary stent extending from the first portion of the duodenum to the extrahepatic bile duct.

surgical procedure that was required to improve biliary drainage after the stent placement. The duration of stent patency was defined as the time between functionally successful EUS-CDS and the occurrence of stent occlusion, stent revision, or patient death.

Follow-up

Follow-up data were prospectively collected after the procedure until September 2011. Biochemical parameters and a simple abdominal X-ray were assessed on the day following the procedure, 1 wk after stent placement, and every month thereafter. The follow-up results of the patients were based on the findings from outpatient examinations.

Statistical analysis

The cumulative patency duration of the EUS-CD with an FCSEMS was estimated using the Kaplan-Meier technique. All statistical analyses were performed using SPSS software (version 12.0; SPSS Inc., Chicago, IL).

RESULTS

Technical and functional success

EUS-CDS with an FCSEMS was performed in 15 patients with a technical success rate of 86.7% (13/15). In two patients, the FCSEMS with a delivery device could not be passed into the CBD through the guidewire even after dilatation of the fistula tract with a needle knife and use of a 4-mm dilatation balloon because of the acute angulation of the scope. A 7F plastic stent, which is more flexible than an FCSEMS, was successfully inserted in one of these two patients, and PTBD was performed in

the other patient as a rescue method.

The functional success rate of EUS-CDS with an FCSEMS was 100% (13/13). The baseline demographic characteristics of the 13 patients who underwent successful EUS-CDS with an FCSEMS are shown in Table 1.

Adverse events

Early adverse events developed in 3 patients (3/13, 23.1%), including 2 cases of self-limited pneumoperitoneum and 1 case of cholangitis. In 1 patient, the proximal tip of the stent was placed in the left intrahepatic duct, impairing drainage of the right intrahepatic duct and leading to cholangitis of the right intrahepatic duct. The cholangitis improved after the tip of the stent was repositioned below the hilar region.

During the follow-up period, distal stent migration occurred in 4 patients (4/13, 30.8%) as a late adverse event. Among them, 2 patients presented with cholangitis, and 1 patient presented with jaundice. In these patients, an FCSEMS could be reinserted through the existing choledochoduodenal fistula tract (Figure 2). In another patient, distal stent migration was observed during a routine, follow-up X-ray without the patient experiencing adverse symptoms: additional stent insertion was not considered because his life expectancy was less than a month and bile was draining through his matured fistula tract.

Duration of stent patency

All patients were followed up until their time of death, with a median follow-up period of 186 d (range: 52-388 d). Stent patency was maintained until death in 9 patients, while distal stent migration occurred in 4 patients during

Table 1 Patients' characteristics and technical features of endoscopic ultrasound-guided choledochoduodenostomy with fully covered self-expandable metallic stents

No.	Age/sex	Diagnosis	Reason for failed ERCP	Diameter/length of FCSEMS (mm/mm)	Early adverse events	Late adverse events	Re-intervention

the follow-up period (range: 68-185 d). The mean patency duration of the stents was 264 d (Figure 3).

DISCUSSION

Previous studies on EUS-CDS have shown favorable technical success rates, with resolution of obstructive jaundice observed in all patients after stent placement. To date, EUS-CDS with a metallic stent insertion has been reported in 11 patients, including covered metallic stents in 6 patients, partially covered metallic stents in 3, and uncovered metallic stents in 2^[6,17-20]. However, there have not yet been any long-term, follow-up results of stent

patency in patients who have undergone EUS-CDS with a metallic stent, making this study the first long-term follow-up evaluation of EUS-CDS with an FCSEMS.

Until recently, there has been only one study to our knowledge that has reported on the long-term results of EUS-CDS with plastic stents. Yamao *et al*^[11] reported that the mean duration of stent patency of EUS-CDS with plastic stents was 211.8 d. Usually, the diameter of metallic stents is 8-10 mm, which is larger than that of plastic stents (7-10F). Thus, theoretically, metallic stents have an advantage in terms of stent patency over plastic stents. In transpapillary drainage through the ERCP, metallic stents have been shown to have a longer

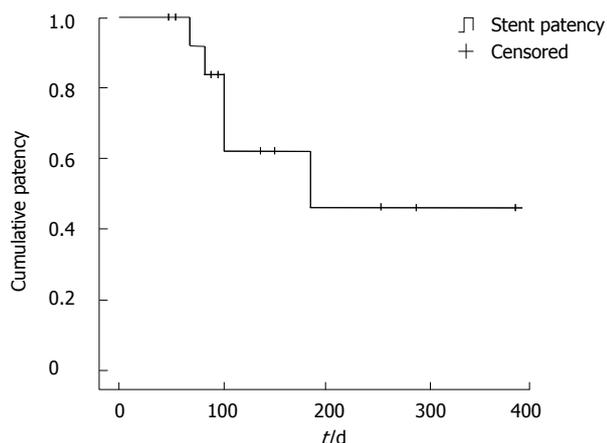

Figure 3 Kaplan-Meier survival curve showing stent patency.

patency duration compared with plastic stents, and the mean patency duration of a metallic stent inserted *via* the transpapillary route was 234–506 d^[4,21]. In our study, the mean duration of stent patency was 264 d, which is comparable with that observed in transpapillary drainage with an FCSEMS.

We found that the technical success rate of EUS-CDS with an FCSEMS was 86.7% (13/15). Although this rate is acceptable, it also indicates that EUS-CDS may not be simple to perform and that careful consideration and adequate experience in EUS-related intervention are mandatory. In this study, EUS-CDS with an FCSEMS was unsuccessful in 2 patients. Because of the acute angulation of the echoendoscope in the duodenal bulb in these patients, the force exerted on the FCSEMS resulted in the echoendoscope being pushed away from the duodenal wall, thereby leading to technical failure. This finding indicates that despite the creation of a fistula with an adequate diameter for FCSEMS insertion, stent insertion may fail if the echoendoscope has an acute angulation because an undeployed metallic stent is rigid.

In previous studies, early adverse events of EUS-CDS included bile peritonitis, pneumoperitoneum, and hemobilia, all of which are self-limiting^[10,14,17,22,23]. In EUS-CDS, the puncture site is selected to bypass the tumor around the distal bile duct, and thus, the puncture may be located close to the hepatic hilum. If the puncture is made near the hepatic hilum, then the proximal end of the stent can be inserted into the right or left intrahepatic duct. In this case, a fully covered metallic stent may block the opposite duct because its diameter is larger than that of a plastic stent. With uncovered metallic stents, although the drainage of the opposite duct is possible through the open mesh, its use is restricted because the risk of a bile leak through the fistula tract from the duodenum into the bile duct exists^[24]. In our study, 1 case showed cholangitis caused by the obstruction of the right intrahepatic duct, which resulted from the insertion of the proximal end of the stent into the left intrahepatic duct. Therefore, the puncture should be made while avoiding the hepatic hilum if possible, and the

insertion of a plastic stent is suggested to be better than a metallic stent in cases where the puncture site is close to the hepatic hilum. In addition, the development of a partially covered metallic stent-in which the proximal end is specially designed to lack a covered membrane-is required to overcome these disadvantages.

In this study, the stent patency of 9 patients was maintained until their death, but distal stent migration occurred in 4 patients during the follow-up period. These results indicate that the most important factor in maintaining stent patency in patients undergoing EUS-CDS with an FCSEMS may be the prevention of stent migration. Because the FCSEMS has a large bore diameter, it may theoretically have advantages over the conventional plastic stents in terms of stent revision. In patients with an FCSEMS insertion, stent revision was relatively easy because the opening of the fistula tract was large enough to be able to easily find, even after stent migration. In an FCSEMS inserted *via* the transpapillary method, tumor ingrowth due to a crack in the covered membrane or tumor overgrowth can be observed^[25,26]. EUS-CDS, however, has advantages in that it reduces the risk of tumor ingrowth or tumor overgrowth because it bypasses the tumor instead of directly passing through the tumor. Stent obstruction by tumor ingrowth or overgrowth was not found in this study.

This study has several limitations. First, the study population was not sufficiently large to allow for a decisive conclusion regarding our results. Second, standard techniques and devices for the EUS-guided drainage procedure have not yet been established. Each endosonographer used a slightly different technique, which may have affected the results of the study. A prospective multicenter evaluation may be valuable to overcome this limitation. Third, this study is an observational study. Thus, a prospective randomized study comparing EUS-CDS with an FCSEMS and other alternative drainage methods, such as percutaneous metallic stent insertion, is necessary.

In conclusion, we have prospectively assessed the long-term outcomes of EUS-CDS with an FCSEMS. EUS-CDS with an FCSEMS was a safe and effective method in patients with distal malignant biliary obstructions and had a comparatively long patency duration. Nevertheless, the significant rate of distal stent migration cannot be ignored, suggesting the need for a newly designed metallic stent for EUS-CDS.

COMMENTS

Background

Endoscopic ultrasound-guided choledochoduodenostomy (EUS-CDS) may be a feasible and useful alternative in patients with distal malignant biliary obstructions after failed endoscopic retrograde cholangiopancreatography (ERCP). Little is known, however, about the long-term outcomes of EUS-CDS with a fully covered self-expandable metallic stent (FCSEMS).

Research frontiers

This is the first study that addresses the long-term follow-up results of patients who underwent EUS-CDS with an FCSEMS.

Innovations and breakthroughs

The technical and functional success rates of EUS-CDS with an FCSEMS were 13 (86.7%) and 13 (100%), respectively. EUS-CDS with an FCSEMS is technically feasible and can lead to effective palliation of distal malignant biliary obstructions after failed ERCP. EUS-CDS with an FCSEMS showed a comparatively long patency duration (264 d).

Applications

Although EUS-CDS with an FCSEMS showed a high success rate and comparatively long patency duration, the significant rate (30.8%) of distal stent migration suggests the need for a newly designed metallic stent for EUS-CDS.

Terminology

EUS-CDS is a new technique for biliary drainage using EUS-guided puncture of the common bile duct from the duodenal bulb and is usually performed as a rescue drainage method when endoscopic transpapillary stenting fails.

Peer review

The authors examined the usefulness and long-term outcomes of EUS-CDS with an FCSEMS. It revealed that EUS-CDS with an FCSEMS is technically feasible and can lead to effective palliation of distal malignant biliary obstructions after failed ERCP. However, it also showed a significant rate of distal stent migration. Therefore, a prospective randomized study on EUS-CDS with newly developed stents is needed.

Abstract

AIM: To determine long-term outcomes of surgical treatments for patients with constipation and features of colonic pseudo-obstruction.

METHODS: Consecutive 42 patients who underwent surgery for chronic constipation within the last 13 years were prospectively collected. We identified a subgroup with colonic pseudo-obstruction (CPO) features, with dilatation of the colon proximal to the narrowed transitional zone, in contrast to typical slow-transit constipation (STC), without any dilated colonic segments. The outcomes of surgical treatments for chronic constipation with features of CPO were analyzed and compared with outcomes for STC.

RESULTS: Of the 42 patients who underwent surgery for constipation, 33 patients had CPO with dilatation of the colon proximal to the narrowed transitional zone.

There were 16 males and 17 females with a mean age of 51.2 ± 16.1 years. All had symptoms of chronic intestinal obstruction, including abdominal distension, pain, nausea, or vomiting, and the mean duration of symptoms was 67 mo (range: 6-252 mo). Preoperative defecation frequency was 1.5 ± 0.6 times/wk (range: 1-2 times/wk). Thirty-two patients underwent total colectomy, and one patient underwent diverting transverse colostomy. There was no surgery-related mortality. Postoperative histologic examination showed hypoganglionosis or aganglionosis in 23 patients and hypoganglionosis combined with visceral neuropathy or myopathy in 10 patients. In contrast, histology of STC group revealed intestinal neuronal dysplasia type B ($n = 6$) and visceral myopathy ($n = 3$). Early postoperative complications developed in six patients with CPO; wound infection ($n = 3$), paralytic ileus ($n = 2$), and intraabdominal abscess ($n = 1$). Defecation frequencies 3 mo after surgery improved to 4.2 ± 3.2 times/d (range: 1-15 times/d). Long-term follow-up (median: 39.7 mo) was available in 32 patients; all patients had improvements in constipation symptoms, but two patients needed intermittent medication for management of diarrhea. All 32 patients had distinct improvements in constipation symptoms (with a mean bowel frequency of 3.3 ± 1.3 times/d), social activities, and body mass index (20.5 kg/m^2 to 22.1 kg/m^2) and were satisfied with the results of their surgical treatment. In comparison with nine patients who underwent colectomy for STC without colon dilatation, those in the CPO group had a lower incidence of small bowel obstructions (0% vs 55.6%, $P < 0.01$) and less difficulty with long-distance travel (6.7% vs 66.7%, $P = 0.007$) on long-term follow-up.

CONCLUSION: Chronic constipation patients with features of CPO caused by narrowed transitional zone in the left colon had favorable outcomes after total colectomy.

INTRODUCTION

Constipation is a common clinical problem with multiple etiologies, affecting approximately 16.5% of the population in South Korea^[1] and 5%-20% of the Western world^[2]. Most patients with constipation have various symptoms, representing different pathologic processes^[3,4] and including infrequent or difficult evacuation, abdominal pain, and bloating, which are often resistant to medical therapy or dietary manipulation. Constipation is believed to be frequently observed in women, elderly people, and those of low socioeconomic status^[5-7]. When chronic idiopathic constipation is diagnosed, a conservative treatment is generally conducted as a first-line treatment. If such a conservative treatment fails, surgical treatment is then considered^[8-12]. The British surgeon Lane^[13] first performed surgery for constipation in 1908. Since then, total colectomy (TC) with ileorectal anastomosis has been suggested as a standard option for the management of refractory chronic constipation. In our previous report, we demonstrated favorable surgical outcomes for patients with features of chronic pseudo-obstruction (CPO) with distinct transitional zone (TZ)^[14]. The purpose of this study was to analyze the long-term surgical outcomes of patients with chronic idiopathic constipation and features of CPO, and compare these results with treatment of patients with slow-transit constipation (STC).

MATERIALS AND METHODS

Patients

Between 1998 and 2011, 47 consecutive patients with chronic intractable constipation underwent surgery by a single surgeon at the Department of Surgery, Seoul National University Hospital. Two patients were excluded from this study because they had secondary constipation due to amyloidosis, and three patients were excluded because they had Hirschsprung's disease (HD). The remaining 42 patients with chronic idiopathic constipation were enrolled in our study. All patients were subjected to a full history taking and physical examination. Prior to surgery, 40 (95.2%) patients were treated with various medications, such as bulking agents, stimulant laxa-

tives, and probiotics, specifically, 24 patients (57.1%) were treated with prokinetic agents (e.g., mosapride and itopride) and eight patients (19.0%) were treated with pyridostigmine. Suppositories or enemas were used in 40 patients (95.2%). Anorectal manometry and colon transit-time studies were selectively conducted as preoperative functional tests. Plain abdominal X-ray, abdominal computed tomography scan, and colonoscopy were selectively conducted when necessary. The preoperative and postoperative clinical symptoms, postoperative complications, defecation frequency after surgery, results of postoperative histologic examination, postoperative satisfaction, and postoperative activities were retrospectively analyzed by a medical chart review and phone survey. Postoperative satisfaction after surgery was divided into five grades: poor, unhappy, good/satisfied, improved, and very good, and was scored from 1 to 5 points. Surgery was considered successful if the score was 3 points or higher^[15].

Statistical analysis

Analysis were performed using the SPSS statistical software package (version 18.0; SPSS Inc, Chicago, IL). Comparisons were made between groups using the χ^2 and Mann-Whitney tests. *P* values of less than 0.05 were considered statistically significant.

RESULTS

The patient group included 21 women and 21 men, with a mean age of 51.2 ± 16.1 years (range: 18-75 years) and a median follow-up duration of 39.7 mo (range: 3-147 mo). Thirty-three patients (78.6%) presented with features of CPO with distinct TZ (the CPO group), whereas the remaining nine patients (21.4%) had STC without colon dilatation (the STC group; Figure 1). The preoperative characteristics of the CPO and STC groups are shown in Table 1. The patients complained of symptoms including abdominal pain, abdominal distension, vomiting, and weight loss before surgery. The mean duration of symptoms was 67.1 ± 72.8 mo (range: 6-252 mo). Of the 42 patients, 26 (61.9%) experienced abdominal pain preoperatively, 21 (50.0%) complained of abdominal distention, and 15 (35.7%) experienced inadequate defecation. Nausea or vomiting was a chronic problem in six patients (14.3%), and three patients (7.1%) experienced weight loss preoperatively. Among the 42 patients, 40 patients (95.2%) received laxatives or enemas for treatment of chronic constipation. Three patients had a previous history of abdominal surgery in other hospitals; one patient underwent colostomy; one patient had ileostomy because of persistent intestinal obstruction after right hemicolectomy; and one patient underwent biopsy after exploration.

The surgical procedures performed in this study were as follows: 39 patients underwent TC with ileorectal anastomosis (92.9%); two patients underwent TC with end ileostomy (4.8%); and one patient underwent

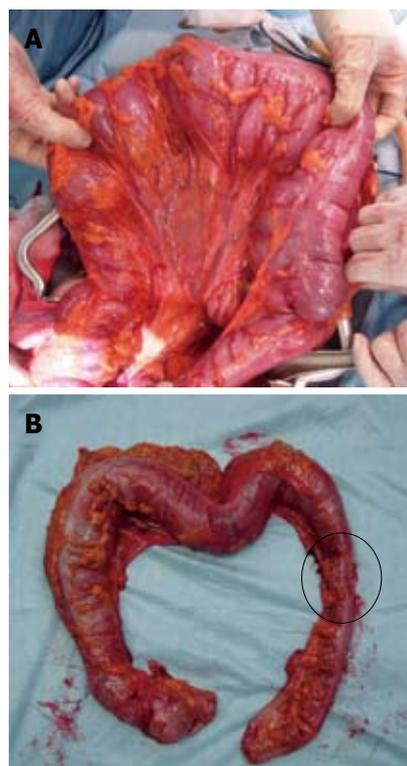

Figure 1 Operative findings and colectomy specimen from a 70-year-old female with chronic constipation. A: Operative findings; B: Colectomy specimen. A definite transitional zone (marked with a circle) with proximal dilatation and distal collapse can be seen.

transverse colostomy (2.3%). The patient who underwent transverse colostomy instead of TC was initially treated for severe bowel distension but refused further surgery. In 13 patients (30.9%), emergency surgery was performed because of impending perforation or toxic symptoms such as tachycardia, fever, hypotension, and marked dilatation of both the small intestine and colon.

In the entire CPO group, intraoperative findings manifested as marked colonic dilatation proximally within the TZ and a normal or collapsed distal bowel lumen. The location of the TZ was near the left side of the descending colon in 20 patients (60.6%) and of the sigmoid colon in nine patients (27.3%) patients; four patients (12.1%) had TZ in the distal transverse colon.

Postoperative histologic examination in the CPO group showed hypoganglionosis (HG) or agangliosis (AG) in 23 patients, and HG combined with visceral neuropathy or myopathy in 10 patients. In contrast, histology in STC group revealed visceral neuropathy [intestinal neuronal dysplasia (IND) type B, $n = 6$] and visceral myopathy ($n = 3$) (Table 2).

Postoperative results are shown in Table 1. The patients in the CPO group passed the first flatus significantly earlier than did patients in the STC group, and their hospital stay tended to be shorter. Early postoperative complications developed in seven patients (16.7%): paralytic ileus ($n = 3$), wound infection ($n = 3$), and intraabdominal abscess ($n = 1$). The incidence of early postoperative complications did not differ significantly

Table 1 Preoperative clinical characteristics and postoperative results of patients with constipation

	CPO ($n = 33$)	STC ($n = 9$)	<i>P</i> value	
Preoperative clinical characteristics				
Sex (male/female)	21/21	16/17	5/4	0.43

CPO: Colonic pseudo-obstruction; STC: Slow-transit constipation.

between the CPO and STC groups (Table 3). All of these early complications resolved after conservative care, and there was neither anastomotic leakage nor mortality.

In long-term follow-up (median: 40 mo), recurrent small bowel obstruction requiring hospitalization occurred in five patients (11.9%). The incidence of small bowel obstruction was significantly higher in the STC group (0% in CPO *vs* 55.6% in STC, $P < 0.01$), and all patients in whom small bowel obstruction occurred had pathologic features of IND type B. These five patients in the STC group responded to conservative management. Postoperative diarrhea requiring intermittent medication occurred in four patients (9.5%); two in the CPO group and two in the STC group).

Preoperatively, the mean defecation frequency was 1.6 times/wk. The defecation frequencies were 1.5 ± 0.3 times/wk (range: 1-2 times/wk) and 1.6 ± 0.6 times/wk (range: 1-2 times/wk) in the CPO and STC groups, respectively (Table 1). At 3 mo after surgery, defecation

Table 4 Quality of life scoring (questionnaire) and postoperative satisfaction *n* (%)

Scores	Quality of life scoring	CPO	STC
1	Poor	0 (0)	0 (0)
2	Unhappy	0 (0)	1 (11.1)
3	Good/satisfied	5 (15.6)	2 (22.2)
4	Improved	25 (78.1)	5 (55.6)
5	Very good	2 (6.3)	1 (11.1)
Scores of ≥ 3		32/32 (100)	8/9 (89)

CPO: Colonic pseudo-obstruction; STC: Slow-transit constipation.

frequency increased in both groups (Table 1) but did not differ significantly between the two groups ($P = 0.56$).

Informed consent for the questionnaire on satisfaction and quality of life after surgery was received from 41 of the 42 patients (97.6%) who were alive at the time of the review. Overall, 97.6% of the patients (40/41) were satisfied with the results of their surgery (Table 4). All 32 patients in the CPO group responded that they were satisfied with the results of the surgery. In comparison, one patient in the STC group gave 2 points and was not satisfied with the surgery because she had treatments for intermittent obstructive symptoms. Thirty-three patients (80.5%) indicated that they had no problems in their daily or leisure activities, housework, travel, and social activities. However, eight patients (19.5%) complained of difficulty with long-distance travel because of increased bowel frequency. In the CPO group, only two patients (6.7%) had difficulty with long-distance travel in contrast to six patients (66.7%) in the STC group ($P = 0.007$). Body mass index increased from 20.5 kg/m² to 22.1 kg/m² in the CPO group, and from 19.9 kg/m² to 22.0 kg/m² in the STC group, which did not significantly differ between the two groups.

DISCUSSION

Surgical treatment may be considered in patients with intractable constipation who are poorly responsive to conventional medical treatments. TC with ileorectal anastomosis is the most commonly performed surgical procedure for constipation^[16-18]. The reasons for primarily performing TC in patients with chronic constipation are that it is difficult to precisely distinguish between normal bowel segments and pathologic lesions and that symptoms may recur if segmental resection alone is performed^[19-21]. In our series of patients, one of the patients in CPO group had undergone right hemicolectomy at another hospital for chronic constipation as well as two more operations because of persistent symptoms within the previous 2 years. Subsequently, the patient visited our hospital and underwent TC. As a result, the patient enjoys good nutritional status without any evidence of recurrence to date. This case illustrates the importance of appropriate resection with pathologic lesions, using TC as a favorable example.

When evaluating the results of surgical treatments

for chronic constipation, it is important to assess patient satisfaction after surgical treatment, complications, and improvement in quality of life. All the patients in this study experienced difficulty in their daily lives due to symptoms of intestinal obstruction preoperatively. In severe cases, these symptoms prevented the patient from sufficient nutritional intake. However, almost all of the patients were satisfied with their surgery and had no problems in their daily lives afterwards.

Our study suggests that defecation frequency improved significantly after surgery. Postoperative diarrhea, when it occurred, was present for only a short time and did not require long-term therapy. Constipation symptoms in the preoperative period, such as abdominal distention or pain, disappeared in both groups. There were no serious early postoperative complications and late complications, especially recurrent small bowel obstruction, were more common in the STC group. All five patients with small bowel obstruction had pathologic findings of IND type B and were successfully managed with conservative therapy. In the STC group of patients with pathologic features of IND type B, the pathology may not be localized to the colon; thus, the possibility of small bowel involvement exists. This may account for intestinal obstructions after the surgery in the STC group of patients with IND type B pathology. None of the three patients with visceral myopathy in the STC group had a small bowel obstruction episode. On the other hand, pathologic changes of AG or HG associated with features of CPO are limited to a relatively short segment of the colon and probably account for the low rate of small bowel obstruction after TC.

HG, a disease associated with a limited number of intestinal ganglion cells, is an intestinal neuronal dysganglionosis arising in the gastrointestinal tract^[17]. HG is typified by a decreased number of ganglion cells, a reduced size of ganglia, and a wider distance between myenteric ganglia. The diagnostic criteria used for diagnosis of HG and IND type B have been previously discussed^[14]. IND type B has also been described as one of the causes of chronic idiopathic constipation^[22]. In the CPO group, HG and AG were confined to a short segment of the colon in most patients, resulting in a failure of segment relaxation and dilatation of the proximal colon, as is the case for HD in which the region of the colon proximal to the aganglionic segment becomes dilated. Segmental HG or AG may be considered a variant of HD. A finding similar to our study was recently described by Do *et al.*^[23] in which the term adult-onset HD was used. However, clinically, radiologically, and histologically, there may be differences^[24,25]. Clinically, HG shows later symptom onset and a better prognosis than HD. In addition, in abdominal computed tomography and barium enema studies, TZ ratio (the transverse diameter ratio of the most dilated colonic segment proximal to the TZ to the narrowed colonic segment distal to the TZ) was higher in HD than in HG^[26]. Since our patients had symptom onset during adulthood, we suggest that our

patients with features of CPO have an acquired form of AG or HG, in contrast to typical HD, which manifests in early childhood. Additionally, various mechanisms for ganglion cell loss have been described^[27-32], and acquired loss of myenteric nerves may occur secondary to Chagas disease, multiple sclerosis, scleroderma, diabetes, amyloid disease, advanced malignancy, Crohn's disease, and in response to certain medications^[8,33].

In our STC patients, since there was no TZ, pathologic examinations were performed at random sites throughout the colon, thus reflecting the diffuse nature of the pathologic changes. As such, it is assumed that the CPO patients in our study have a zonal pathology that is responsible for their constipation compared to the diffuse pathologic changes observed in the STC patients. The persistent abdominal symptoms that include small bowel obstruction episodes after surgery may result from diffuse neurologic abnormalities of the gastrointestinal tract in IND type B patients. In the case of gastrointestinal dysmotility involving the small bowel, a careful approach is required for selecting surgical treatment because the role of surgery may be limited and recurrence is possible^[34,35].

In our study, the CPO group had better early postoperative results regarding gas passing and shortened hospital stays compared to the STC group. On long-term follow-up, all of the CPO patients had distinct improvements in constipation symptoms and were satisfied with the results of their surgical treatment. In comparison with the STC group, the CPO group had a lower incidence of small bowel obstructions and fewer difficulties with long-distance travel on long-term follow-up.

CPO in patients with chronic constipation is characterized by a narrowed TZ in the left side of the colon. Its pathologic features suggest that CPO is caused by acquired segmental HG or AG. Pathologic findings in the CPO group were quite different from patients in the STC group without a dilated colon, and the CPO group had outcomes that were more favorable after TC compared to those of STC patients.

COMMENTS

Background

Constipation is a common clinical problem with multiple etiologies and affects. When chronic idiopathic constipation is diagnosed, a conservative treatment is conducted as the first line treatment. If the conservative treatment has failed, surgical treatment is then considered

Research frontiers

Because of diagnostic difficulty, hypoganglionosis (HG) is often considered to be a variant of Hirschsprung's disease (HD) or a subtype of intestinal neuronal dysplasia type B. But clinically, radiologically and histologically, there are differences between them. Clinically, HG shows later onset of symptoms and a better prognosis than HD. In abdominal computed tomography and barium enema studies, transition zone ratio (the transverse diameter ratio of the most dilated colonic segment proximal to the transitional zone (TZ) to the narrowed colonic segment distal to the TZ) is higher in HD than in HG.

Innovations and breakthroughs

In the series of patients operated for intractable constipation, patients were divided into two groups; features of chronic pseudo-obstruction (CPO) with distinct transitional zone and slow-transit constipation (STC) without colonic dilata-

tion. Authors suggested that CPO group had more favorable outcome after total colectomy as compared to STC patients.

Applications

By understanding pathophysiology of CPO, this study may represent a future strategy for surgical procedure in the treatment of patients with chronic idiopathic constipation.

Terminology

HG has been associated with fewer intestinal ganglion cells. HG is one of an intestinal neuronal dysganglionosis arising in the gastrointestinal tract.

Peer review

The authors provide evidence that patients with chronic constipation with CPO do have a better outcome from surgical resection than patients with slow transit dysmotility. Distinguishing the two groups of patients is not difficult and the article suggests that if CPO is identified with a normal caliber distal colon, that these patients have better outcome. While that authors suggest the aganglionosis in this segment of bowel is acquired, others believe that this disease is still a variant of HD. Nevertheless, it seems reasonable that such patients tend to have better outcomes with surgery than patients who have dysmotility.

Abstract

Histiocytes have a pivotal role in wound repair and intestinal epithelial recovery - the most important goal to sustain gut functionality. Yet, an *in vivo* description of colonic histiocytes by confocal laser endomicroscopy (CLE) is missing. Here, we report the case of a 45-years-old male patient who was referred to our clinic with

weight loss and a history of two consecutive *Clostridium difficile* colitis episodes, the latter cured 3 wk before present admission. Stool microbiology was negative. Conventional colonoscopy showed atrophy and a light mucosal oedema in the distal colon. During on-going endoscopy, we performed a fluorescein-aided CLE which revealed large polygonal (histiocytes-like) cells with copious cytoplasm and large nuclei in the lamina propria of the sigmoid colon as well as regenerative epithelial changes. Histopathological assessment of biopsies from the same areas confirmed the endomicroscopical findings: Periodic acid-Schiff- and CD68-positive foamy histiocytes in the colonic lamina propria and an advanced epithelial recovery. Since stool microbiology was repeatedly negative and polymerase chain reaction-analysis from colonic biopsies could not detect any mRNA for *Thropheryma whipplei* and common pathogens, we interpreted this particular setting as a mucosal healing process after consecutive *Clostridium difficile* infections. In conclusion, by describing these colonic histiocytes, we highlight the clinical usefulness of CLE in describing the entity of histiocytes *in vivo* and in real-time during the process of post-infectious mucosal healing in the colon.

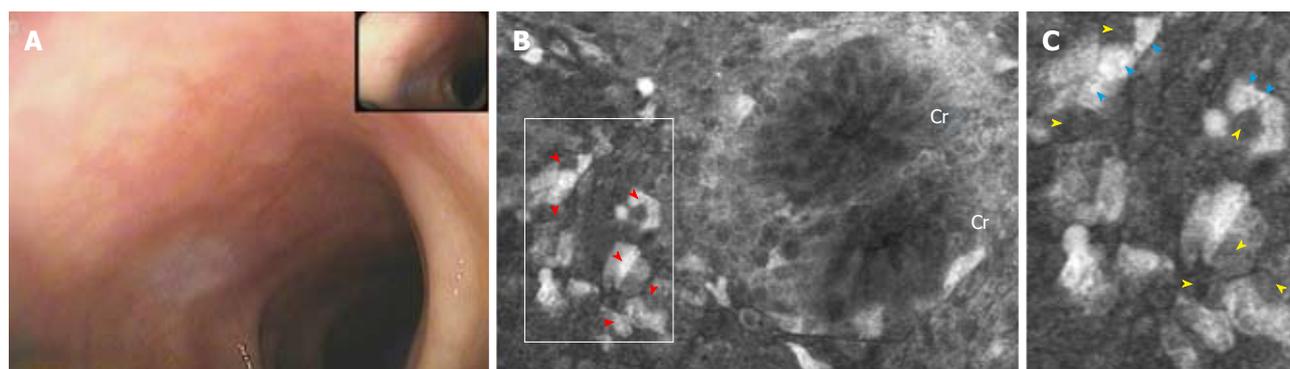

Figure 1 Endoscopic and endomicroscopic characterization of the sigmoid colon in the context of a post-infectious mucosal healing process. A: White light colonoscopy shows mild atrophy and reduced vascular pattern in the sigmoid colon; B: Fluorescence-guided confocal laser endomicroscopy reveals large polyclonal cells (red arrowheads) with copious cytoplasm in the lamina propria - near two crypts (Cr) - corresponding morphologically to foamy histiocytes; C: In an enlarged manner the aggregated histiocytes with large fluorescence-negative nuclei (yellow arrowheads) and foamy cytoplasm (blue arrowheads) defining their appearance and nomenclature.

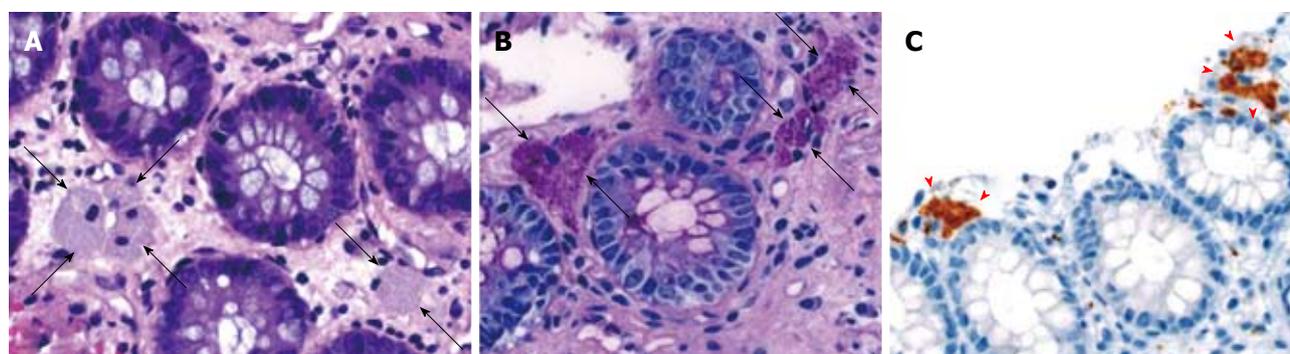

Figure 2 Histopathologic confirmation of the endomicroscopic findings. A-C: Large polyclonal histiocytes between mucosal crypts (arrows) are highlighted in the hematoxylin-eosin stain (A) as well as in Periodic acid-Schiff stain after diastase predigestion (B) and image (C) (CD68 immunostaining) with a CD68-positive cytosol, overall confirming the endomicroscopical findings.

INTRODUCTION

A subset of macrophages differentiating to histiocytes were proved to have a pivotal role in wound repair processes^[1] and intestinal epithelial recovery. This is the most important goal to sustain functionality of the gut and it was also defined as therapeutic goal in order to achieve mucosal healing in chronic inflammatory bowel disease^[2]. So far, two reports have described histiocytes in the duodenum^[3,4] using confocal laser endomicroscopy (CLE)^[5]. Yet, the *in vivo* description of histiocytes within the colon by confocal endomicroscopy has not been published so far.

CASE REPORT

Here, we report the case of a 45-year-old male patient who was referred to our endoscopy unit with anaemia and weight loss. In the last three months he had a history of 2 consecutive *Clostridium difficile* (*C. difficile*) colitis episodes, the latter resolved completely after appropriate treatment 3 wk before the present admission. Microbiological analysis of stool samples was repeatedly negative for *C. difficile* and other intestinal pathogens (Salmonella, Shigella, Yers-

inia, Campylobacter). White light colonoscopy showed signs of atrophy, mild mucosal oedema and reduced vasculature pattern in the distal colon (Figure 1A). During on-going endoscopy, we performed a fluorescein-aided confocal endomicroscopy of the colonic mucosa which revealed large polygonal (histiocytes-like) cells with copious cytoplasm and large nuclei in the lamina propria of the sigmoid colon (Figure 1B, C). By taking biopsies from the areas analysed by confocal imaging, we were able to correlate and verify the endomicroscopical findings with histopathology. These were Periodic acid-Schiff-positive and CD68-positive foamy histiocytes in the colonic lamina propria between basal mucosal crypts (Figure 2A-C).

DISCUSSION

Since stool microbiology was repeatedly negative and PCR-analysis could not detect any intestinal pathogens (incl. *Tropheryma whippelii* that causes Whipple's disease), we interpreted this particular setting as a mucosal healing process after two consecutive *C. difficile* infections^[6].

In conclusion, by describing these colonic histiocytes *in vivo* and real-time, we highlight the clinical usefulness of confocal laser endomicroscopy in characterizing the

cell entity of colonic histiocytes and the context of a post-infectious mucosal healing process in the colon, for the first time. Confocal laser endomicroscopy was used previously for the detection of architectural changes, vascularity changes like leakage but not for the differentiation of a specific cell entity. Our report provides the morphological criteria and exemplifies the differentiation and characterization of a particular cell entity, namely the foamy histiocytes, involved in the post-infectious mucosal healing.

In this histopathological and clinical setting, our report is also the first non-invasive and real-time description of human foamy histiocytes in the colon.

Abstract

An 87-year-old, Japanese woman was shown to have a submucosal tumor-like lesion with a deep, central ulceration covered with thick, whitish exudate in the stomach. Biopsy showed Candida tropicalis but not *Helicobacter pylori* (*H. pylori*). She had no predisposing factors or history of peptic ulcers nor had taken non-steroidal anti-inflammatory drugs (NSAIDs), diagnosed with Candida-associated gastric ulcer. Though cured of the lesion, she developed another ulcer in a different position, in which Candida was demonstrated but *H. pylori* was undetectable. This is the first case of recurrent Candida-associated gastric ulcer in the world. Detected in both the original and recurrent lesions in an *H. pylori*-negative patient with no antecedent ulcers who had not taken NSAIDs, Candida is considered, contrary to the prevailing opinion, to play an etiologic role in ulcer formation.

INTRODUCTION

Candida is ubiquitously indigenous to the normal human gastrointestinal tract throughout^[1] but infection with the fungus of the tract is more widespread than previously recognized^[2,3]. The most frequently involved organ is the esophagus followed by the stomach^[2]. Gastric candidiasis is classified into thrush, nodular and ulcerated types^[4]. Though usually seen in immunocompromized hosts^[2,3], Candida-associated gastric ulcer also occurs in apparently healthy individuals^[5-9] and its frequency is widely different contingent on authors^[8-12]. The clinical significance of the fungus in and the natural history of Candida-associated gastric ulcer remain to be clarified^[2] so that the treatment of the disease has not yet been established. The fungus has been reported to be no longer detected once the ulcers were healed and no recurrence of the disease has been described, so far^[9,11].

Presented is a hitherto unreported case of the disease relapsing in a different site with a different shape in a *Helicobacter pylori* (*H. pylori*)-negative patient with no antecedent peptic ulcers who had not taken non-steroidal anti-inflammatory drugs (NSAIDs).

CASE REPORT

Complaining of anorexia after succumbing to the summer heat, an 87-year-old, Japanese housewife was shown

Figure 1 Endoscopic photograph showing the deep ulcer with the submucosal tumor-like margin on the greater curvature of the upper gastric body.

to have a medium-sized, submucosal tumor (SMT)-like elevation covered with the erythematous mucosa with an oval, deep, central ulceration covered with thick whitish exudate on the greater curvature of the upper gastric body (Figure 1). Biopsy showed no malignancy or *H. pylori* but a large number of hyphae in the ulcer slough (Figure 2A). No signs of candidiasis were detected in the oropharynx through esophagus or in the duodenal bulb through descending part of the duodenum.

Though suffered from adhesion ileus 2 mo ago, when no such lesions or any scars in the upper or any signs of candidiasis in the lower gastrointestinal tract were endoscopically detected, in the wake of ovariectomy and concomitant appendectomy she underwent when younger and had been given steroid inhaler for bronchial asthma for the past several years, she had no past history of peptic ulcers. Neither had she taken NSAIDs or antibiotics then. She was not diabetic. The ulceration was found much diminished in size spontaneously 2 wk after the first endoscopic examination and the organism was proven to be *Candida tropicalis* by culture. No circulating *Candida* antigens or β -D-glucan was detected, however. Though diagnosed as having *Candida*-associated gastric ulcer, she refused to undergo further endoscopic examination, not given any proton pump inhibitors (PPIs), H_2 receptor antagonists, or antifungal agents.

She complained of heartburn 10 mo later, when the lesion was shown to have turned into a white scar (Figure 3A) but another large, oval, deep ulcer was detected covered with thick, whitish exudate surrounded by the markedly swollen margin on the lesser curvature of the lower gastric body (Figure 3B). Biopsy demonstrated no malignancy but numerous hyphae of *Candida* again (Figure 2B). No findings of candidiasis were recognized in the oropharynx through other parts of the upper gastrointestinal tract. *H. pylori* was not detected by histopathologic examination or rapid urease test. Though had not taken any NSAIDs or antibiotics then, either, she had been given risedronate by an orthopedist under the diagnosis of osteoporosis once a week for the past 9 mo. She was diagnosed with *Candida*-associated gastric ulcer recurrent in a different location with a different appearance.

The lesion was proven to have turned into a red scar in 6 wk with administration of a PPI without antifungal agents (Figure 3C). The original lesion was shown to have remained to be a white scar. The follow-up endoscopy performed 3 mo later showed the red scar to have turned into white (Figure 3D) and the original scar to have remained unchanged. She has kept an uneventful course ever since, even though she has kept taking risedronate. No further recurrence has been detected, so far.

DISCUSSION

Candida is a fungus indigenous to the entire human gastrointestinal tract^[1] and the demonstration of infiltration of the tissue or ulcer slough by the hyphae is proposed as the diagnostic criterion of gastrointestinal candidiasis^[5,8]. The present case was diagnosed according to the criterion. *Candida*-associated gastric ulcer is more widespread than previously considered, seen not only in patients with predisposing conditions but in apparently healthy individuals^[5-9]. The present case was also lacking in conspicuous predisposing factors.

While endoscopic features of *Candida*-associated gastric ulcer have been asserted to be nonspecific^[4,9,11], an SMT-like lesion with a deep, central ulceration has been regarded as specific by some Japanese authors^[13,14]. In the present case, the original lesion did indeed assume such a form but the recurrent one appeared to be an ordinary, large ulcer. Since an SMT-like lesion with a central ulceration has been detected only in Japanese patients^[13,14], it may be peculiar to the race and considered suggestive of *Candida*-associated gastric ulcer, though not all ulcers associated with the fungus take on such an appearance.

Whereas *Candida*-associated gastric ulcer has been reported to have low healing rate^[6,11], some cases of the disease have been reported to have spontaneously healed^[12]. In the present case, the original lesion was found to have spontaneously healed and the recurrent one was in no way intractable. The intractability of the disease may be affected by other factors than the fungus, such as *H. pylori* or NSAIDs because such factors were not inspected in the cases reported to be intractable^[6,11].

Candida has been reported to be no longer detected once the ulcers were healed even without antifungal treatment and no recurrence of the lesions has been described, so far^[9,11]. The natural history of *Candida*-associated gastric ulcer is yet to be elucidated and the disease was reported to engender no specific symptoms^[8]. Presenting no specific symptoms, either, the present patient developed the disease without any antecedent peptic ulcers or their vestiges, which healed spontaneously at the first time and recurred 10 mo later. This is the first case of *Candida*-associated gastric ulcer in the world, which was demonstrated to have recurred not only in a different site but with a different appearance and followed up from before development of the original ulcer till complete cicatrization of the recurrent, disclosing the natural history of the disease.

Bisphosphonates are known to be ulcerogenic, consid-

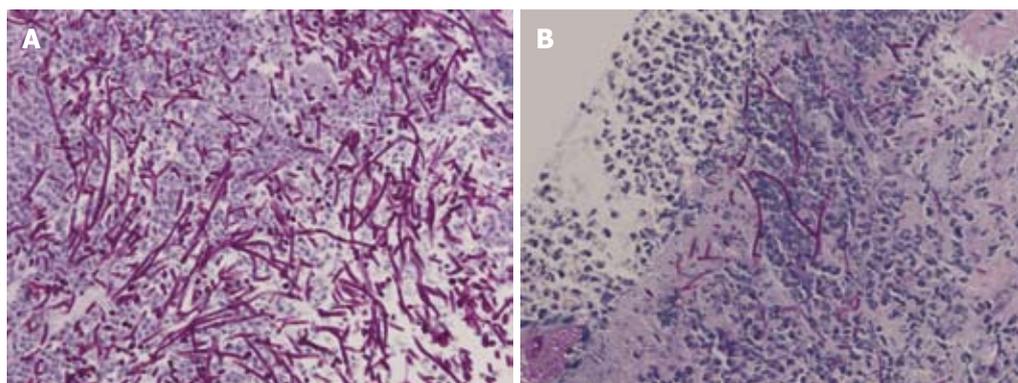

Figure 2 Biopsy demonstrated no malignancy but numerous hyphae. A: Light micrograph of the specimen biopsied from the original ulcer demonstrating hyphae in the ulcer slough [Periodic acid-Schiff (PAS)/diastase, original magnification $\times 400$]; B: Biopsy from the recurrent ulcer illustrating hyphae of *Candida* on the ulcer edge (PAS/diastase, original magnification $\times 400$).

ered to disrupt the protective hydrophobic phospholipid barrier of the gastric mucosa to trigger ulceration^[15,16]. But they are reported to greatly differ in potential to damage the mucosa^[15,16], risedronate having by far the weakest potential^[15]: the drug has been shown to have a gastrointestinal safety profile similar to that of placebo^[17-19]. It was not until 9 mo after the treatment with the drug was instituted when the recurrent ulcer was developed in the present case and, after it was healed, no recurrence has been detected even under the regimen. Sufficient ground is, therefore, lacking to suspect the drug to be the culprit in development of the recurrent ulcer. Though the clinical significance of the fungus has not yet been elucidated, it has not been regarded as directly etiologic in develop-

ment of ulcer, possibly as the presence of the fungus aggravates or perpetuates ulceration^[5,6,8]. Contrary to the prevailing opinion, the fungus is considered, by analogy with *H. pylori*, to play an etiologic role in ulcer formation in the present case on the basis of the circumstantial evidences, since it was detected not only in the original but also in recurrent lesion in an *H. pylori*-negative patient with no antecedent peptic ulcers who had not taken NSAIDs.

Abstract

Colonoscopy sometimes causes pain during insertion, especially in difficult cases. Over-insufflation of air causes elongation or acute angulations of the colon, making passage of the scope difficult and causing pain. We previously reported a sedative-risk-free colonoscopy insertion technique, namely, "Water Navigation Colonoscopy". Complete air suction after water infusion not only improves the vision, but also makes water flow down to the descending colon, while the sigmoid colon collapses and shortens. While non-sedative colonoscopy can be carried out without pain in most cases, some patients do complain of pain. Most of these patients have abnormal colon morphology, and the pain is caused while negotiating the "hairpin" bends of the colon. The "hairpin" bends of the colon should be negotiated by gently pushing the full-angled colonoscope. The proximal 10-20 cm from the angulated part of the conventional colonoscope is stiff, with a wide turning radius, therefore, a conventional colonoscope cannot be negotiated through the "hairpin" bends of the colon without stretching them and causing pain. The "passive-bending colonoscope" has a flexible tip with a narrow turning radius, so that the scope can be

negotiated through the "hairpin" bends of the colon with a minimum turning radius and minimal discomfort. Therefore, the intubation and pain-reducing performance of the "passive-bending colonoscope" was assessed in difficult cases.

INTRODUCTION

Colonoscopy sometimes causes pain during insertion, especially in difficult cases. Over-insufflation of air causes elongation or acute angulations of the colon, making passage of the scope difficult and causing pain.

Administration of sedatives masks pain, which is a warning sign of perforation. Therefore, we developed a sedative-risk-free colonoscopy insertion technique, namely, "Water Navigation Colonoscopy"^[1,2] (Figure 1). Complete air suction after water infusion not only improves the visibility, but also makes the water flow down to the descending colon, while the sigmoid colon collapses and shortens. The Water Methods were reported to reduce pain and make it possible to perform colonoscopy without the use of sedatives^[3]. While non-sedative

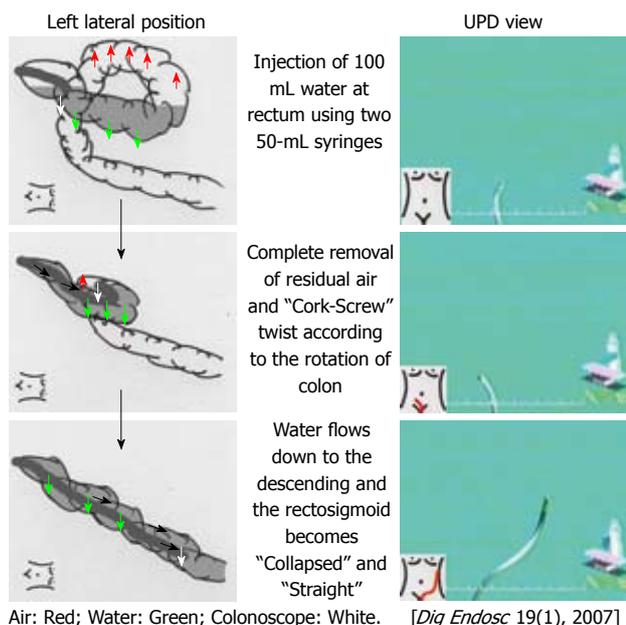

Figure 1 Water Navigation Colonoscopy. Red arrows mean buoyancy; Green arrows mean gravity of water; White arrows mean gravity of endoscope. UPD: Endoscope position detecting unit.

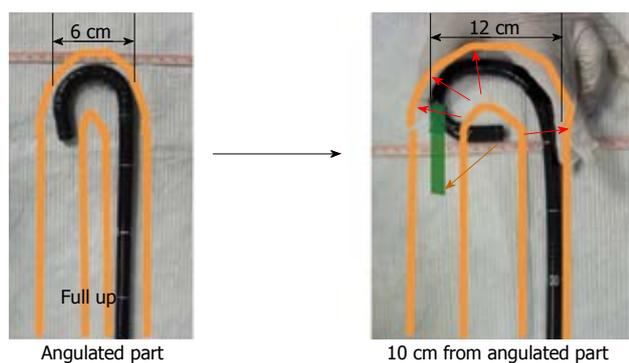

Figure 2 Conventional scope stretches the "hairpin" bend and causes pain. Red arrows mean the tension of colonoscope; Brown arrow shows that the tip of colonoscope stretches in the colonic lumen after passing the hairpin bend.

"Water Navigation Colonoscopy" can be carried out without pain in most cases, some patients do complain of pain. Most of these patients have abnormal colon morphology, and the pain is caused while negotiating the "hairpin" bends of the colon^[4,5]. The "hairpin" bends of the colon should be negotiated by gently pushing the full-angled colonoscope. The proximal 10-20 cm from the angulated part of the conventional colonoscope is stiff, with a wide turning radius, therefore, a conventional colonoscope cannot be negotiated easily through the "hairpin" bends of the colon without stretching them or causing pain (Figure 2).

"Passive-bending colonoscope," PCF-PQ260 (Olympus Co, Tokyo, Japan), has a flexible tip with a narrow turning radius, so that the scope can be easily negotiated through the "hairpin" bends of the colon, with minimal discomfort^[6,7] (Figure 3).

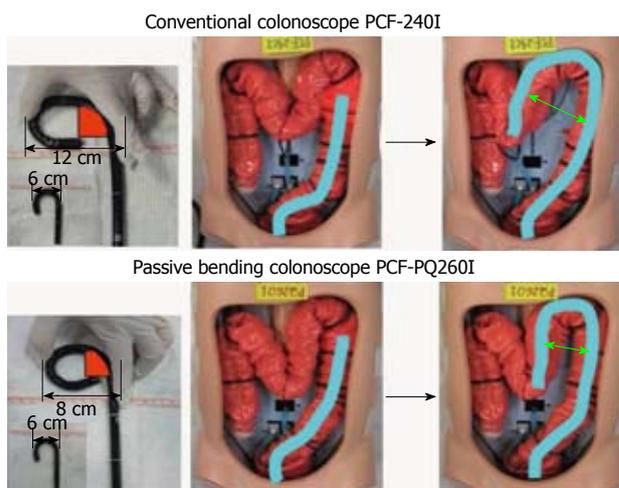

Figure 3 During negotiation of "hairpin" bend of the splenic flexure, "passive-bending colonoscope" does not stretch the bend. Green arrow shows the radius of colonoscope. Passive bending colonoscope has smaller one.

CASE REPORT

The subjects were 11 patients, including 2 cases of cecal intubation failure and 9 cases of difficult colonoscopy with the "conventional colonoscope," PCF-240Z Olympus, who underwent a second colonoscopy with the "passive-bending colonoscope," PCF-PQ260, more than 7 d after the first procedure. All colonoscopies were performed by the same physician, Mizukami T. Colonoscopy was performed according to the method of "Water Navigation Colonoscopy". The cecal intubation time was measured and the patients were asked to report their level of discomfort after the colonoscopy on a visual analog scale of 1 to 5, as follows: grade 1, no discomfort; grade 2, strange feeling; grade 3, distension of the abdomen; grade 4, tolerable pain; grade 5, intolerable pain. Computed tomographic colonography (CTC) was performed for morphological evaluation. Cecal intubation was accomplished successfully in all cases and the intubation time was significantly shortened with the use of the "passive-bending colonoscope" ($n = 9$) (10.1 ± 3.2 min *vs* 5.1 ± 2.8 min, $P < 0.05$). The average self-reported pain score was also significantly lower in the "passive-bending colonoscope" group (3.7 ± 0.6 *vs* 2.3 ± 0.9 , $P < 0.01$). CTC showed that every patient had "hairpin" bends of the colon. PCF-PQ260 significantly shortened the cecal intubation time and reduced the pain score in difficult cases, and CTC showed that every case had "hairpin" bends of the colon. This showed that the "passive-bending colonoscope" can be negotiated more easily through the "hairpin" bends of the colon, with its minimum turning radius. Use of the "passive-bending colonoscope" shortens the cecal intubation time and reduces pain in difficult cases.

Case 1

This patient (78-year-old female) had sigmoid malrotation

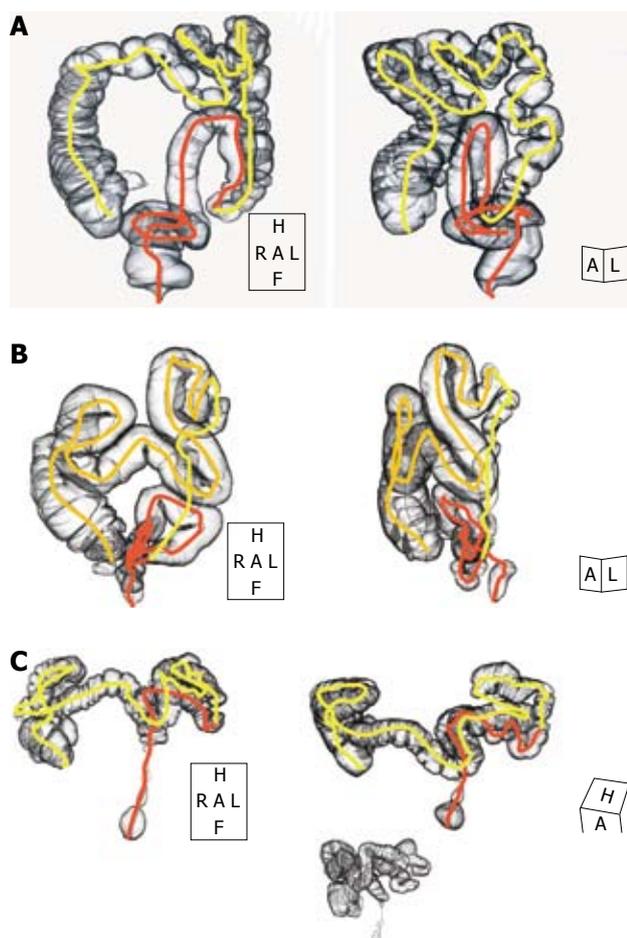

Figure 4 Sigmoid malrotation and loops, malrotation and mesocolon descendens, ascendens of patients. A: 78 years old female has sigmoid malrotation and loops at splenic flexure; B: 70 years old female has sigmoid malrotation and mesocolon descendens and ascendens; C: 70 years old male has mesocolon descendens and ascendens.

and loops at the splenic flexure. The cecal intubation time was 11 min (conventional), and 6 min (passive bending). The level of discomfort was 4 (conventional), and 2 (passive bending, Figure 4A).

Case 2

This patient (70-year-old female) had sigmoid malrotation and mesocolon descendens. The 1st cecal intubation (conventional) failed because of the "hairpin" bends at the splenic flexure. The 2nd cecal intubation (passive bending) was accomplished in 11 min. The level of discomfort was 4 (conventional), and 2 (passive bending, Figure 4B).

Case 3

This patient (70-year-old female) had mesocolon descendens and ascendens. The 1st cecal intubation (conventional) failed because of the "hairpin" bends in the descend-

ing colon. The 2nd cecal intubation (passive bending) was accomplished in 11 min. The level of discomfort was 4 (conventional), and 2 (passive bending) (Figure 4C).

DISCUSSION

Cases with difficult cecal intubation have looping and "hairpin" bends of the colon^[4,5]. There are some reports suggesting that the use of a variable-stiffness colonoscope or a pediatric colonoscope can reduce pain and facilitate intubation^[8,9].

In conventional colonoscopes, the 10-20 cm segment proximal to the angulated part is stiff, which causes stretching and pain during negotiation of the scope through the "hairpin" bends of the colon. The "passive-bending colonoscope" has a flexible tip with a narrow turning radius and can be more easily negotiated through the "hairpin" bends of the colon, with its minimum turning radius. Use of this scope in difficult cases was associated with a significantly shortened cecal intubation time and reduced pain score. CTC showed that every case had "hairpin" bends and loops of the colon, indicating that the "passive-bending colonoscope" could be negotiated through the "hairpin" bends of the colon relatively easily, with its minimum turning radius. In conclusion, use of the "passive-bending colonoscope" with "Water Navigation Colonoscopy" significantly shortens the cecal intubation time and reduces pain in difficult cases.

Acknowledgments to reviewers of World Journal of Gastroenterology

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

Takaaki Arigami, MD, PhD, Department of Surgical Oncology and Digestive Surgery, Field of Oncology, Kagoshima University Graduate School of Medical and Dental Sciences, 8-35-1 Sakuragaoka, Kagoshima 891-0175, Japan

Anupam Bishayee, PhD, Assistant Professor of Pharmaceutical Sciences, Research Assistant Professor of Internal Medicine, Northeastern Ohio Universities Colleges of Medicine and Pharmacy, 4209 State Route 44, PO Box 95, Rootstown, OH 44272-0095, United States

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/ study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of *P* values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]”. If references are cited directly in the text, they should be put together within the text, for example, “From references^[19,22-24], we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/esps/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
