Weekly Volume 18 Number 25 July 7, 2012

EDITORIAL

- 3183 Ghrelin's second life: From appetite stimulator to glucose regulator
Verhulst PJ, Depoortere I

TOPIC HIGHLIGHT

- 3196 Can zinc enhance response interferon therapy for patients with HCV-related liver disease?
Ishikawa T

REVIEW

- 3201 Gastroenterostoma after Billroth antrectomy as a premalignant condition
Sitarz R, Maciejewski R, Polkowski WP, Offerhaus GJA

ORIGINAL ARTICLE

- 3207 Mangiferin, a natural xanthone, accelerates gastrointestinal transit in mice involving cholinergic mechanism
Morais TC, Lopes SC, Carvalho KMMB, Arruda BR, de Souza FTC, Trevisan MTS, Rao VS, Santos FA

- 3215 Predictive value of ¹⁸F-fluorodeoxyglucose PET/CT for transarterial chemolipiodolization of hepatocellular carcinoma
Song MJ, Bae SH, Yoo IR, Park CH, Jang JW, Chun HJ, Choi BG, Lee HG, Choi JY, Yoon SK

- 3223 Effect of biologically active fraction of *Nardostachys jatamansi* on cerulein-induced acute pancreatitis
Bae GS, Kim MS, Park KC, Koo BS, Jo IJ, Choi SB, Lee DS, Kim YC, Kim TH, Seo SW, Shin YK, Song HJ, Park SJ

- 3235 Effect of Yiguanjian decoction on cell differentiation and proliferation in CCl₄-treated mice
Wang XL, Jia DW, Liu HY, Yan XF, Ye TJ, Hu XD, Li BQ, Chen YL, Liu P

BRIEF ARTICLE

- 3250 Carbon dioxide insufflation during colonoscopy in deeply sedated patients
Singh R, Neo EN, Nordeen N, Shanmuganathan G, Ashby A, Drummond S, Nind G, Murphy E, Luck A, Tucker G, Tam W

- 3254 Intestinal alkaline phosphatase in the colonic mucosa of children with inflammatory bowel disease
Molnár K, Vannay Á, Szebeni B, Bánki NF, Sziksz E, Cseh Á, Györffy H, Lakatos PL, Papp M, Arató A, Veres G

- 3260** Incidence and clinical features of endoscopic ulcers developing after gastrectomy
Chung WC, Jeon EJ, Lee KM, Paik CN, Jung SH, Oh JH, Kim JH, Jun KH, Chin HM
- 3267** Two-stage resection for malignant colonic obstructions: The timing of early resection and possible predictive factors
Yang HY, Wu CC, Jao SW, Hsu KF, Mai CM, Hsiao KCW
- 3272** Preoperative predictors of short-term survival after hepatectomy for multinodular hepatocellular carcinoma
Zhao WC, Zhang HB, Yang N, Fu Y, Qian W, Chen BD, Fan LF, Yang GS
- 3282** Electrical bioimpedance gastric motility measurement based on an electrical-mechanical composite mechanism
Zhao S, Sha H, Li ZY, Ren CS
- 3288** Omega-3 polyunsaturated fatty acids promote liver regeneration after 90% hepatectomy in rats
Qiu YD, Wang S, Yang Y, Yan XP
- 3296** Expression and significance of homeodomain protein Cdx2 in gastric carcinoma and precancerous lesions
Qin R, Wang NN, Chu J, Wang W
- 3303** Increased frequency and clinical significance of myeloid-derived suppressor cells in human colorectal carcinoma
Sun HL, Zhou X, Xue YF, Wang K, Shen YF, Mao JJ, Guo HF, Miao ZN
- 3310** Protective effect of nitric oxide on hepatopulmonary syndrome from ischemia-reperfusion injury
Diao TJ, Chen X, Deng LH, Chen HX, Liang Y, Zhao XD, Wang QH, Yuan WS, Gao BC, Ye Y

CASE REPORT

- 3317** Lymphogranuloma venereum proctosigmoiditis is a mimicker of inflammatory bowel disease
Gallegos M, Bradley D, Jakate S, Keshavarzian A
- 3322** Diagnosis in bile acid-CoA: Amino acid N-acyltransferase deficiency
Hadžić N, Bull LN, Clayton PT, Knisely AS
- 3327** Giant choledocholithiasis treated by mechanical lithotripsy using a gastric bezoar basket
Chung HJ, Jeong S, Lee DH, Lee JI, Lee JW, Bang BW, Kwon KS, Kim HK, Shin YW, Kim YS

World Journal of Gastroenterology
Volume 18 Number 25 July 7, 2012

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-VI Instructions to authors

ABOUT COVER Editorial Board Member of *World Journal of Gastroenterology*, Dr. Assy Nimer, MD, Assistant Professor, Liver Unit, Ziv Medical Centre, PO Box 1008, Safed 13100, Israel

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.
The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Ghrelin, a 28 amino acid peptide hormone produced by the stomach, was the first orexigenic hormone to be discovered from the periphery. The octanoyl modification at Ser³, mediated by ghrelin O-acyltransferase (GOAT), is essential for ghrelin's biological activity. Ghrelin stimulates food intake through binding to its receptor (GRLN-R) on neurons in the arcuate nucleus of the hypothalamus. Ghrelin is widely expressed throughout the body; accordingly, it is implicated in several other physiological functions, which include growth hormone release, gastric emptying, and body weight regulation. Ghrelin and GRLN-R expression are also found in the pancreas, suggesting a local physiological role. Accordingly, several recent studies now point towards an important role for ghrelin and its receptor in the regulation of blood glucose homeostasis, which is the main focus of this review. Several mechanisms of this regulation by ghrelin have been proposed, and one possibility is through the regulation of insulin secretion. Despite some controversy, most studies suggest that ghrelin exerts an inhibitory effect on insulin secretion, resulting in increased circulating glucose levels. Ghrelin may thus be a diabetogenic factor. Obesity-related type

2 diabetes has become an increasingly important health problem, almost reaching epidemic proportions in the world; therefore, antagonists of the ghrelin-GOAT signaling pathway, which will tackle both energy- and glucose homeostasis, may be considered as promising new therapies for this disease.

INTRODUCTION

Ghrelin, a 28 amino acid peptide hormone predominantly produced by the stomach^[1], is the endogenous ligand of the growth hormone secretagogue receptor 1a isoform (GHS-R1a), presently renamed ghrelin receptor (GRLN-R)^[2]. Soon after the identification of ghrelin^[3], it became clear that ghrelin's effect extends beyond the stimulation of growth hormone (GH) secretion. Ghrelin's involvement in appetite stimulation was discovered as a side-effect in a study investigating the effect of ghrelin injection on GH-release in healthy humans^[4]. Ghrelin was soon identified to be the only known orexigenic hormone from the periphery, which stimulates food intake in a dose-dependent manner in rodents^[5-8] and humans^[9,10]. Many papers have been dedicated to ghrelin's orexigenic

effect, which has long been considered its main physiological function. More recent research now supports the idea that ghrelin may play an equally or even more important role in the regulation of blood glucose homeostasis. This review will give a summary of research data pointing out the importance of ghrelin in the regulation of blood glucose homeostasis. We will start with a general introduction about ghrelin and its expression throughout the body, including the pancreas. The relation with insulin will be discussed, followed by an overview of possible therapeutic implications resulting from these findings. The main goal of this review is not to provide an integral overview of previous research, but to indicate the importance of ghrelin in the regulation of blood glucose and implications for the treatment of disorders like diabetes.

GHRELIN AND THE GHRELIN RECEPTOR

Ghrelin is mainly produced by the X/A like cells, a distinct endocrine cell type found in the mucosal layer of the stomach and, to a lesser extent, in the small and large intestines^[1]. Smaller amounts are also detected in the pancreas, hypothalamus, heart, kidneys, lungs, testes, liver, and thyroid^[11,12].

Active ghrelin contains a unique posttranslational modification, an n-octanoyl group on the third serine residue, performed by ghrelin O-acyltransferase (GOAT), the 4th and highly conserved member of the membrane-bound O-acyltransferases superfamily (MBOAT4)^[13,14]. GOAT is localized to the gastric ghrelin cells, suggesting that ghrelin becomes octanoylated at its production site^[15]. GOAT transcripts predominantly occur in the stomach and pancreas in humans, while in mice they are found in the stomach, small intestine, colon, and, to a lesser extent, in the testis^[13,14]. According to the latest reports, acyl ghrelin makes up only 25% of the total amount of circulating ghrelin^[16]. The amount of circulating acylated ghrelin does not always parallel total ghrelin concentrations, suggesting that ghrelin acylation and secretion are regulated separately^[17,18]. In addition to n-octanoyl ghrelin, other acyl groups can be transferred to ghrelin, giving rise to other forms, such as decanoylated ghrelin, the second most abundant form of acylated ghrelin in circulation. The acyl groups added to ghrelin reflect the fatty acid content of the diet^[18], as enrichment of the diet with heptanoic acid causes ghrelin to be preferentially acylated with heptanoate, rather than with octanoic acid^[19]. The non-modified, unacylated form of ghrelin, which is the most abundant form of circulating ghrelin, does not bind to the ghrelin receptor and was first believed to be biologically inactive. Several studies have since established a physiological role for unacylated ghrelin^[20-22], probably through binding to a distinct, but unidentified, receptor^[22,23].

Alternative splicing of the *GRLN-R* gene results in the formation of two receptor forms, the full length *GRLN-R1a*, which is believed to be the biologically active form, and the truncated *GRLN-R1b*^[24,25]. *GRLN-R1a* is activated by octanoyl ghrelin and synthetic growth

hormone secretagogues while the *GRLN-R1b* is not activated by ghrelin and its physiological function remains unknown, despite its wide expression. *GRLN-R1a* is also widely expressed throughout the body. The highest expression levels of *GRLN-R1a* have been found in the hypothalamus^[26], where *GRLN-R1a* is expressed on growth hormone releasing hormone-expressing neurons^[27,28] and NPY/AgRP neurons in the arcuate nucleus^[29], consistent with its role in growth hormone release and appetite stimulation. Other expression sites of *GRLN-R1a* mRNA include the pituitary, thyroid, pancreas, spleen, myocardium, the adrenal gland, and the intestinal myenteric plexus^[11,30]. *GRLN-R* immunoreactivity was also observed within neuronal cell bodies and fibers in the human stomach and colon^[31].

The variety of ghrelin and *GRLN-R* expression sites already suggests a broad range of different physiological functions. In addition to its stimulatory effects on food intake in humans^[9,10] and rodents^[6,32,33], ghrelin also stimulates body weight gain, not only by promoting food intake, but also through an increased adipogenesis^[8,34]. Ghrelin also has prokinetic properties in the gastrointestinal tract. Peripheral ghrelin administration accelerates gastric emptying in conscious rats^[35,36] and mice^[37,38]. Ghrelin infusion stimulates gastric emptying in healthy volunteers^[39] and in patients with idiopathic^[40], diabetic^[41] and neurogenic^[42] gastroparesis, and induces hunger contractions in the fasting state^[43]. In addition, ghrelin has many other physiological functions, including cardiovascular effects^[44] and stimulatory effects on learning and memory^[45,46]. Recently, more and more attention has been given to the regulatory effects of ghrelin on glucose homeostasis^[47,48].

To unravel the physiological functions of ghrelin signaling, different transgenic and knockout mice models have been developed. Mice with a genetic deletion of ghrelin^[49,51], the ghrelin receptor^[52,53], or GOAT^[19] display only subtle phenotypic changes on a standard laboratory diet and a lower body weight compared to wild-type mice on a high fat diet, probably due to less accumulation of body fat^[19,53,54]. Ablation of ghrelin in *ob/ob* mice markedly improved glucose tolerance by increasing serum insulin levels, but did not result in a reduced body weight^[55]. Another study reported that ghrelin or ghrelin receptor ablation did not prevent diet-induced obesity in adult mice, but increased insulin sensitivity^[56]. When these mice were subjected to 50% caloric restriction, ghrelin and *GRLN-R* knockout mice had lower blood glucose levels than their wild-type littermates, as also observed in a recent study using GOAT knockout mice^[57], suggesting that ghrelin is involved in the counterregulatory glucose response during negative energy balance. While several compensatory mechanisms on food intake and body weight may have evolved in these knockout mice, these studies support the hypothesis that ghrelin and the *GRLN-R* may be non-essential regulators of appetite. It seems that ghrelin and its receptor have an important role in the regulation of blood glucose ho-

meostasis, which may represent a more important physiological function than the earlier reported effects on food intake regulation.

EXPRESSION OF GHRELIN AND THE GHRELIN RECEPTOR IN THE PANCREAS

The endocrine cells of the pancreas are assembled in dispersed islets containing traditionally four different types of cells, the insulin releasing β -cells, which make up the major cell population within an islet, the glucagon producing α -cells, the somatostatin producing δ -cells, and the pancreatic polypeptide containing PP cells. Moreover, the pancreas is an important source of ghrelin. Release of ghrelin by the pancreas was assessed by comparing the ghrelin concentration in the pancreatic vein with that in the pancreatic artery in rats. Acylated and unacylated ghrelin levels were found to be significantly higher in the pancreatic vein, indicating that the pancreas not only produces ghrelin^[58], but also expresses GOAT, the enzyme responsible for its acylation^[14].

The exact location and cellular origin of pancreatic ghrelin has been a matter of debate, and conflicting results have appeared. The first study to report that the pancreas is an important production site for ghrelin^[59] also stated that ghrelin production is restricted to the insulin producing β -cells of the human pancreas. In contrast, Date *et al.*^[47] reported that ghrelin is exclusively expressed in the glucagon producing α -cells in rats and humans, supported by the overlapping immunohistological stainings for ghrelin and glucagon observed in another study^[58]. The existence of a fifth separate islet cell population in the human pancreas, producing ghrelin and devoid of any other islet hormones, was postulated for the first time by Wierup *et al.*^[60] and is no longer debated. These pancreatic cells were found to be quite numerous (up to 10% of the endocrine cells) from midgestation to early postnatally, sometimes forming an almost continuous layer at the islet periphery^[60]. Only a few ghrelin cells remain visible on the mantle of the islets in adult pancreata of humans^[60,61] and rats^[62]. Therefore, the major source of ghrelin in fetal circulation is probably the pancreas, not the stomach^[63]. Normal mouse pancreas also contains a small population of ghrelin-producing cells, which were named “epsilon” cells. In the neonatal mouse pancreas, about 30% of the ghrelin cells were found to coexpress glucagon, whereas two-thirds (67%) of the ghrelin cells represented a unique islet cell population^[64].

Deletion of Nkx2.2 or Pax4 in mice, two transcription factors involved in the differentiation of insulin-producing cells, leads to an enormous increase in ghrelin-producing ϵ cells^[64]. Based on these results, it has been postulated that insulin-producing β -cells and ghrelin-producing ϵ cells share a common precursor^[64].

Guan *et al.*^[26] first demonstrated a weak GRLN-R mRNA signal in the rat pancreas during *in situ* hybridization. Indeed, not only transcripts for ghrelin, but also for its receptor are expressed in pancreatic tissue of both

humans^[11,59,65] and rats^[3,47]. Immuno-histochemical studies in rat pancreatic tissue revealed that the GRLN-R is localized to most of the α -cells and to some, but not all, β -cells^[66]. The latter was confirmed in human pancreatic islets^[67], supporting the idea of an autocrine/paracrine response of both β - and α -cells to ghrelin.

EFFECTS OF GHRELIN ON INSULIN SECRETION AND VICE VERSA

Glucose homeostasis is controlled by two key processes: insulin secretion by the pancreatic β -cells and insulin sensitivity of the peripheral tissues. The presence of the GRLN-R on pancreatic β -cells already suggested a role for ghrelin in the function of the β -cell, leading to the hypothesis that ghrelin also has a regulatory role in insulin secretion.

The observed inverse relationship between the circulating levels of ghrelin and insulin in healthy humans^[68] suggested inhibitory feedback between ghrelin and insulin. Indeed, insulin is able to suppress circulating ghrelin concentrations, independent from changes in glucose concentrations^[69]. The decrease of plasma ghrelin is induced by hyperinsulinemia and not by the resulting plasma glucose decrease, because plasma ghrelin was similarly suppressed when glucose was kept constant in a euglycemic study^[70]. A direct effect of physiological insulin concentrations on ghrelin secretion was also shown in the isolated perfused rat stomach^[71]. The inhibitory effect of insulin on ghrelin secretion was confirmed in several other studies^[72,73], while some reports did not confirm this observation, probably because of the different experimental conditions^[74,75].

Ghrelin, in turn, has been proven to affect insulin secretion, which was first demonstrated by Broglio *et al.*^[76], who showed that acute ghrelin administration in healthy volunteers resulted in prompt increases in blood glucose levels, followed by a decrease in insulin levels, independent from GH. Numerous other studies have investigated ghrelin's (acylated, unless otherwise indicated) effects on glucose and insulin metabolism, sometimes showing ambiguous results. An overview is given in the following paragraphs.

In vitro studies

Exogenous ghrelin: Studies on the effect of exogenous ghrelin on insulin release *in vitro* are summarized in Table 1.

Studies with β -cell lines, isolated β -cells, and pancreatic perfusion experiments considerably contributed to the understanding of the basic mechanisms governing the role of ghrelin in glucose and insulin metabolism. Date *et al.*^[47] reported an increased cytosolic Ca^{2+} concentration and stimulated insulin release in isolated rat islets treated with ghrelin (1 pmoL/L) in the presence of a stimulatory (8.3 mmol/L), but not basal (2.8 mmol/L) glucose concentration^[47]. Ghrelin at 1 pmoL/L modestly potentiated glucose-induced Ca^{2+} responses in a small portion of β -cells, but ghrelin had a clear inhibitory ef-

Table 1 Summary of *in vitro* and *in vivo* studies investigating the effect of exogenous ghrelin on insulin release

Study	Species	Dose	Effect on insulin
<i>In vitro</i> studies			
Isolated rat islets			
Date <i>et al</i> ^[47] , 2002	Rat	1 pmol/L ghrelin +2.8 mmol/L glucose	No effect
		1 pmol/L ghrelin +8.3 mmol/L glucose	Increase

iv: Intravenous; *ip*: Intraperitoneal; GH: Growth hormone.

fect at relatively high concentrations (10 nmol/L)^[58,77], which is consistent with the majority of literature reports. Although this concentration is higher than that of circulating ghrelin, ranging from 100 pmol/L to 3 nmol/L^[78], it is generally conceived that the level of hormone working in a paracrine or autocrine manner is higher than that working in an endocrine manner. Acylated ghrelin could also dose-dependently suppress glucose-induced insulin secretion in isolated adult rat and mouse islets^[79-81], in isolated islets from rat neonates^[82], and in β -cell lines^[62,83,84]. In a pancreas perfusion study, an *in vitro* system that retains the intact circulation in pancreatic islets excluding the influence of other organs, the infusion of ghrelin into the isolated pancreas also inhibited the insulin response to increasing glucose concentrations, arginine, and carbachol^[77,85].

Only a few studies reported a stimulatory effect of ghrelin on insulin secretion. Ghrelin could stimulate insulin release in pancreatic tissue fragments from normal and diabetic rats^[86]. Accordingly, both acylated (AG) and unacylated ghrelin (UAG) could exert an insulinotropic effect in the INS-1E rat^[67,87] and HIT-T15 hamster^[67] insulinoma derived β -cell lines in the presence of a static glucose concentration.

In addition its effect on insulin secretion, both acylated and unacylated ghrelin promote cell proliferation and counteract apoptosis of pancreatic β -cells in INS-1E β cell lines and in human islets independent from the GRLN-R^[67].

In vitro studies

Endogenous ghrelin: To examine the effects of endogenous ghrelin produced in the islets, isolated rat islets and pancreata were treated or perfused, respectively, with GRLN-R antagonists or an antiserum against active ghrelin, both resulting in increased glucose-induced insulin re-

lease in the absence of exogenous ghrelin^[77]. In the same study, glucose-induced insulin release from isolated islets of ghrelin knockout mice was significantly greater than that of wild-type mice, despite the similar density and size of the islets. These results indicate an insulinostatic effect of endogenous ghrelin in the islets. In contrast, the GRLN-R antagonist YIL-781 only blocked the inhibitory effect of ghrelin on glucose-induced insulin secretion in dispersed pancreatic islets, but had no effect in the absence of ghrelin^[88].

In vivo studies

Exogenous ghrelin: Studies on the effect of exogenous ghrelin on insulin release *in vivo* are summarized in Table 1.

Systemic administration of exogenous ghrelin decreases glucose-induced insulin secretion in mice^[58,81] and rats^[89]. In mice fasted for 3 h, intraperitoneal (*ip*) injection of ghrelin diminished the 1-min insulin response after administration of an intravenous glucose load (1g/kg)^[81], which was confirmed in overnight fasted mice^[58]. When ghrelin was simultaneously injected with glucose, the glucose levels at 30 min and 60 min were higher and the insulin levels at 5 min and 10 min were markedly attenuated in comparison to control values. Overnight fasted mice also displayed significantly elevated glucose levels at 30 min after *ip* administration of ghrelin, an effect that could be blocked completely by simultaneous administration of the GRLN-R antagonist, [D-Lys³]GHRP-6, indicating that ghrelin increases blood glucose *via* specific interaction with the GRLN-R^[58]. Accordingly, ghrelin infusion into the hepatic portal vein inhibited glucose-induced insulin secretion in rats^[89]. In contrast, UAG infusion at pharmacological doses enhanced the insulin response to an intravenous glucose load potently and dose-dependently, an effect that was abolished by co-administration of AG^[90].

There is little and inconsistent information concerning the effect of ghrelin on insulin release in humans. The first study with exogenous ghrelin administration in healthy humans confirmed that acute administration of ghrelin (1 µg/kg) after an overnight fast resulted in prompt increases in blood glucose concentrations, followed by a slight, but significant, decrease in insulin levels, which may further increase blood glucose^[76]. A decrease in insulin levels was also observed in a study from Akamizu *et al.*^[91]. However, Lucidi *et al.*^[92] could not confirm these changes in insulin and glucose levels when physiological increases (two to three-fold increments) in plasma ghrelin levels were reached, indicating that ghrelin only affects glucose metabolism at pharmacological doses.

Until now, only a few studies investigated the effect of exogenous ghrelin administration on glucose-stimulated insulin secretion. A recent study reported a reduction in glucose-induced insulin in an intravenous glucose tolerance test after exogenous ghrelin administration^[48] in healthy humans. However, because ghrelin infusion raised ghrelin levels by about 4.5, 15.4, and 22.6 fold, the clinical relevance of the latter study can be questioned.

Administration of ghrelin not only affects insulin release, but also insulin sensitivity. In adult-onset GH-deficient patients, ghrelin reduced insulin sensitivity up to 6 h after administration, whereas co-administration of AG ghrelin and UAG ghrelin neutralized the insulin desensitizing effects of AG administration and even improved insulin sensitivity^[93]. Broglio *et al.*^[94] also showed that administration of UAG alone did not affect insulin and glucose levels, but antagonized the effects of AG on insulin secretion and glucose levels in humans. That the relationship between AG and UAG may have an impact on metabolism has been suggested from clinical studies, which show an indirect relationship between circulating AG/UAG ratio and insulin resistance^[95], and a decreased AG/UAG ratio in fasting, relatively insulin sensitive, subjects^[17].

In vivo studies

Endogenous ghrelin: Intraperitoneal injection of the GRLN-R antagonist, [D-Lys³]GHRP-6, in mice markedly decreased fasting glucose concentrations, and resulted in an attenuated glucose elevation and enhanced insulin response after an *ip* glucose challenge^[58]. Similarly, injection of [D-Lys³]GHRP-6 in overnight fasted rats resulted in an enhanced insulin response during an intravenous glucose tolerance test (GTT)^[90]. In gastrectomized rats, which have dramatically lower acylated ghrelin levels (around 16% of control animals), [D-Lys³]GHRP-6 increased plasma insulin concentrations to a similar extent as in normal rats, indicating that locally produced ghrelin in the pancreas is the major regulator of insulin release^[77].

Numerous studies were performed in ghrelin, ghrelin receptor and recently also in GOAT knockout mice, to investigate whether endogenous ghrelin can influence blood glucose homeostasis. Ghrelin knockout mice presented normal blood glucose and plasma insulin levels in

the fed and fasted state on a standard laboratory diet^[49,50]. However, during a GTT, ghrelin knockouts had reduced blood glucose and increased insulin levels compared to the wild-types. In addition, an insulin tolerance test showed a more pronounced decrease in glucose levels occurring 30 min after insulin injection in the ghrelin knockout animals on a standard diet, pointing towards increased insulin sensitivity compared to the wild-types. The latter was confirmed by an increased performance in euglycemic hyperinsulinemic clamp studies^[55]. When placed on a high fat diet immediately after weaning, wild-type mice became glucose intolerant and insulin resistant, while ghrelin knockout animals were able to maintain normal glucose levels because of a markedly enhanced insulin secretion^[54,77]. Their body weight and body fat percentage were lower.

Similar results were obtained in GRLN-R knockout mice, which showed resistance to diet-induced obesity and enhanced insulin sensitivity when exposed to a high fat diet immediately after weaning^[53,96]. In addition, RQ values were found to be higher in GRLN-R knockout mice indicating a preference for carbohydrates as fuel, regardless of the diet^[96].

Whereas one study found no difference in glucose tolerance during an *ip* GTT in GOAT knockout mice^[19], Zhao *et al.*^[57] showed that GOAT knockout mice, during caloric restriction (fasted for 16 h), experience an improved glucose tolerance and an increased insulin secretion during an oral GTT. Accordingly, mice that were pretreated during an *ip* glucose challenge with the bisubstrate analog, GO-CoA-Tat, which antagonizes GOAT, showed a significant increase in insulin response that was accompanied by a reduction in blood glucose^[97]. This effect was not observed in ghrelin knockout mice, indicating that the effect on glucose regulation is mediated by acyl ghrelin.

MECHANISMS INVOLVED IN THE INHIBITORY EFFECT OF GHRELIN ON INSULIN SECRETION

Insulinoma-associated protein 2β (IA-2β), a membrane glycoprotein localized to secretory granules, is a β cell autoantigen for type 1 diabetes, and about 50% of newly diagnosed patients have autoantibodies against IA-2β^[98,99]. Administration of ghrelin increased IA-2β mRNA expression in mouse pancreas, brain, and insulinoma (MIN6 and βTC3) cell lines. Moreover, both ghrelin administration and stable overexpression of IA-2β could attenuate glucose-induced insulin secretion. These findings strongly suggest that ghrelin exerts its inhibitory effects on insulin secretion at least partly through enhancement of IA-2β expression^[83]. Another recently identified pathway implicated in the effect of ghrelin on glucose-stimulated insulin secretion (GSIS) and independent from IA-2β, is the AMPK-uncoupling protein 2 (UCP2) pathway^[84], which is also involved in the control of food intake in

the hypothalamus^[100]. UCP2, which uncouples oxidative phosphorylation from ATP synthesis, diminishes the glucose-stimulated insulin secretion in β cells^[101]. The link between ghrelin and UCP2 was hypothesized based on the observation that ghrelin knockout mice, which have an enhanced glucose-induced insulin secretion, also displayed reduced expression of UCP2 mRNA in the pancreas^[55]. Conclusive evidence was provided by down-regulating UCP2 with the siRNA technique in MIN6 cells, which enhanced GSIS and blocked ghrelin's inhibitory effect on GSIS^[84].

GHRELIN RECEPTOR AS A THERAPEUTIC TARGET FOR THE TREATMENT OF DIABETES

Diabetes mellitus (DM) is a chronic disease with increasing worldwide prevalence. In 2000, 171 million individuals were estimated to have diabetes and this is expected to increase to 366 million by 2030^[102]. Currently, more than 220 million people worldwide have diabetes. There are two main types of DM: type 2 diabetes or non insulin-dependent diabetes mellitus (NIDDM) accounts for 90% of patients, whereas type 1 or insulin-dependent diabetes mellitus (IDDM) accounts for most other diabetic patients and generally appears before the age of 40 years. Both types of diabetes are characterized by fasting hyperglycemia and abnormal glucose excursion after administration of a glucose load. In the following paragraphs, the role of GRLN-R as a therapeutic target for type 1 and 2 diabetes will be discussed. For both types of diabetes, it is important to preserve and protect viable β -cells. Type 2 diabetes is also characterized by insulin resistance, which means that improving insulin sensitivity is important for the outcome of this disease.

DM type 1

Type 1 diabetes results from autoimmune destruction of the β -cells, leading to a dependency of exogenous insulin administration for maintaining blood glucose homeostasis in these patients. Inverse patterns of plasma ghrelin and insulin concentrations have been described in a 24 h observation period in normal subjects^[68]. Likewise, fasting insulin and ghrelin concentrations were found to be negatively correlated in both lean and obese subjects^[103]. However, plasma ghrelin data obtained from type 1 diabetic patients are often conflicting, probably dependent on whether these patients are treated or not with insulin in addition to the timing of sampling. In newly diagnosed children with type 1 diabetes, ghrelin levels were low prior to insulin treatment and did not respond to meal tests^[104]. This was confirmed in another study, which reported that total and acylated ghrelin concentrations were decreased, compared to healthy children^[105]. Another study observed higher plasma total ghrelin concentrations in type 1 diabetic patients and these levels declined by 29% after insulin treatment^[106]. Murdolo *et al.*^[107] showed

that the lack of insulin in untreated type 1 diabetic patients prevented post-prandial ghrelin suppression, which may contribute to the hyperphagia that is often observed in these patients. Accordingly, gastric and plasma ghrelin concentrations were reported to be increased in untreated streptozotocin (STZ)-induced diabetic rats, an animal model of type 1 diabetes^[108-110]. Conclusive evidence for the contribution of ghrelin signaling pathway to the development of STZ-induced diabetic hyperphagia has been provided in two studies with ghrelin^[111] and ghrelin-receptor knockout mice^[112].

Therapeutic applications of ghrelin receptor antagonists in type 1 diabetes

Treatment of mice, five days after the induction of STZ-induced diabetes, with a GRLN-R antagonist reduced blood glucose levels and normalized plasma glucagon levels^[111]. In addition, daily food intake was reduced. However, in STZ-induced diabetic GHS-R or ghrelin knockout mice hyperphagia was reduced, but no differences in blood glucose levels were observed compared with wild-type mice^[111,112]. These data suggest that ghrelin receptor antagonists may only be efficient in the treatment of type 1 diabetes when a small percentage of insulin-producing β -cells remain intact, particularly at early onset.

Therapeutic applications of ghrelin receptor agonists in type 1 diabetes

Growing evidence exists for a potential therapeutic role for ghrelin receptor agonists during type 1 diabetes, at least at an early stage. Ghrelin administration for 7 d was able to promote β -cell regeneration in newborn rats treated with STZ, thereby preventing the development of hyperglycemia at an adult age^[113]. Surprisingly, similar protective effects were observed after treatment with unacylated ghrelin, which resulted in an increased area and number of pancreatic islets in STZ-treated rats^[114]. Likewise, daily exogenous ghrelin injections in 90% pancreatectomized rats enhanced endocrine and exocrine pancreatic regeneration. Acylated ghrelin treatment increased the number of β -cells, resulting in increased insulin production and an improved glucose tolerance^[115]. However, twice daily ghrelin administration for 4 wk, in adult mice 8 wk after STZ-diabetes induction, did not change body weight, food intake, blood glucose levels, or plasma insulin levels, indicating that ghrelin did not improve or worsen diabetic conditions^[116]. This strongly suggests that ghrelin may only affect diabetes type 1 in its earliest stage, when some viable β -cells remain. Ghrelin administration may then be able to prevent further progression of the disease, while later administration may have the opposite effect and may further inhibit insulin secretion. This indicates that the timing of administration is very important. Long-term treatment may further impair the function of the remaining β -cells; therefore, it is also important to take the duration of treatment into account.

In *in vitro* studies, both acylated and unacylated ghrelin have been demonstrated to promote proliferation and to

inhibit apoptosis (induced by serum-starvation or cytokines) of HIT-T15 and INS-1E β cell lines and human islets of Langerhans^[67,117]. Acylated ghrelin prevents lipotoxicity-induced apoptosis in MIN6 β -cells^[118]. The comparable effects of both acylated and unacylated ghrelin on β -cell survival may be mediated *via* an as yet unidentified receptor, because high-affinity binding sites for both peptides were identified on the cell membrane of HIT-T15 cells, which do not express the ghrelin receptor^[67].

Ghrelin also stimulates the expression of islet associated protein 2 β (IA-2 β) mRNA, a major auto-antigen for type 1 diabetes, in mouse pancreas, brain and insulinoma (MIN6 and β TC3) cell lines^[83].

DM type 2

The key pathogenic feature of type 2 DM is insulin resistance leading to a compensatory hypersecretion of insulin, ultimately leading to β -cell dysfunction. Type 2 diabetes, which is far more common than type 1 diabetes, is tightly associated with obesity, making it difficult to distinguish between the effects of diabetes alone, or in conjunction with obesity. Obese subjects have decreased circulating ghrelin levels^[103] and several studies have found that low ghrelin levels are associated with elevated fasting insulin concentrations and the prevalence of type 2 diabetes and insulin resistance^[119]. Indeed, total plasma ghrelin, as well as unacylated ghrelin, concentrations were found to be lower in insulin-resistant obese adults relative to equally obese insulin-sensitive controls^[120], indicating a link between ghrelin and insulin sensitivity.

Therapeutic applications of ghrelin receptor antagonists in type 2 diabetes

Although inconclusive data about the effects of ghrelin on insulin secretion were reported, most studies observed an inhibitory effect of ghrelin on glucose-induced insulin secretion *in vitro* using isolated pancreatic islets, β -cell lines, or perfused pancreata, which was confirmed *in vivo* in rodents and humans (Table 1). Transgenic mice over-expressing ghrelin showed glucose intolerance caused by decreased insulin secretion^[121]. Another study revealed that MK-677, a ghrelin mimetic, decreased insulin sensitivity and increased fasting blood glucose in aged healthy volunteers in a 1 year study^[122].

Accordingly, improved insulin sensitivity was observed in ghrelin-receptor knockout mice^[53,96,123] and the high fat diet-induced glucose intolerance is largely prevented by an enhanced insulin release in ghrelin knockout mice^[77]. Ghrelin deletion in ob/ob mice also promoted insulin sensitivity and insulin release in response to a glucose challenge^[55], by decreasing pancreatic UCP2 expression. By deleting the insulinostatic effect of ghrelin, the maximum capacity of glucose-induced insulin release may be increased enabling the β -cells to secrete more insulin to meet the increased insulin demand during obesity. Oral glucose tolerance testing in GOAT knockout mice, which lack the active form of ghrelin, showed a markedly better glucose tolerance and enhanced insulin secretion

on a regular and a high fat diet, compared to their wild-type littermates^[57].

Immunoneutralization of endogenous ghrelin with anti-ghrelin antiserum, or by GRLN-R antagonism, resulted in an enhanced glucose-induced insulin release in perfused pancreas^[77] and in isolated islets^[58]. *In vivo*, the ghrelin receptor antagonist, YIL-781 improved body weight and glucose tolerance in rats with insulin resistant diet-induced obesity^[88]. The GOAT-inhibitor, GO-CoA-Tat improved glucose tolerance and reduced weight gain in wild-type mice, but it remains to be investigated whether this compound is also effective in animal models of type 2 diabetes^[97]. The first non-peptidic, small molecule antagonists of GOAT, have recently been discovered^[124].

Unacylated ghrelin prevented the ghrelin-induced decrease in insulin secretion and insulin sensitivity, but did not induce any changes in these parameters when it was given alone^[94]. It is therefore unlikely that this compound will find any application in patients with type 2 diabetes, who have low plasma ghrelin levels.

All these results indicate that ghrelin is a diabetogenic factor and that counteraction of ghrelin augments glucose-dependent insulin secretion in pancreatic β -cells and improves insulin sensitivity in peripheral tissues, with beneficial effects on body weight. This reinforces the concept that ghrelin antagonists and/or GOAT inhibitors may provide a good therapeutic option for the treatment of type 2 diabetes and obesity.

Table 2 gives an overview of the ghrelin receptor antagonists that are currently under development. It is intriguing to observe that, despite 10 years of ghrelin research, the development of ghrelin antagonists is still in its infancy. One of the problems may be the discrepancy obtained with ghrelin antagonists *in vivo* and *in vitro*^[125] or the restraint of pharmaceutical companies to develop drugs which target a multifactorial disease such as obesity related type 2 diabetes, where the redundancy in orexigenic signals may lead to unpredictable results.

CONCLUSION

Besides ghrelin's well-described effects on food intake and growth hormone secretion, more attention has been given recently to its contribution to the regulation of blood glucose levels in the body. Although this effect may be mediated by direct mechanisms, most evidence suggests indirect regulation through insulin. Despite controversial results, many studies point out that ghrelin is able to inhibit insulin secretion *in vitro* and *in vivo*, which provides excellent therapeutic perspectives for type 2 diabetes. Ghrelin receptor antagonists for example, could be used to improve insulin release and insulin sensitivity. However, only a few antagonists are currently under investigation in clinical studies and the development of new potent and selective antagonists of the ghrelin receptor are warranted. Moreover, antagonists of ghrelin-O-acyltransferase have recently been discovered and their development may provide new perspectives.

Table 2 Ghrelin antagonists under development for the treatment of obesity and type 2 diabetes

Ghrelin antagonists Drug	Company	Target	Status
TZP-301	Tranzyme Pharma	Obesity, metabolic syndrome	Lead optimization
Two families of ghrelin antagonists	Helsinn Pharmaceuticals	Obesity, metabolic syndrome	Lead optimization
AEZS-123	Aeterna Zenartis	Obesity, alcohol abuse	Preclinical
Ghrelin antagonist	Novartis (Elixir)	Type 2 diabetes, obesity	Preclinical

Ghrelin agonists may be a promising therapeutic avenue to preserve and improve the function of the remaining β -cells in both type 1 and type 2 diabetes, by promoting β cell regeneration at an early stage of the disease. In addition, ghrelin agonists are useful to accelerate diabetic gastroparesis, which often impairs quality of life in diabetic patients. Long-term studies will be needed to investigate whether the developed ghrelin agonists do not induce desensitization of the ghrelin receptor. To prevent this issue, the half-life of these agonists should not be too long. Moreover, ghrelin has a wide range of other physiological functions, such as cardiovascular effects, anxiety, sleep, memory, and mood, which may lead to unwanted side effects. Additional research is needed to further address these issues.

Ishikawa T. Can zinc enhance response interferon therapy for patients with HCV-related liver disease? *World J Gastroenterol* 2012; 18(25): 3196-3200 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i25/3196.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i25.3196>

Abstract

Patients with liver disease may be at risk of zinc depletion. Zinc supplementation has been shown to contribute to inhibition of liver fibrosis and improvement in hepatic encephalopathy. However, little is known about the anti-inflammatory effect of zinc on hepatitis C virus (HCV)-related chronic liver disease. The standard of care for chronic HCV has improved markedly since the approval of interferon (IFN) therapy more than a decade ago. Over the past 20 years, IFN therapy has improved to more effectively eliminate the virus, progressing from single IFN therapy to combination therapy with ribavirin (RBV) and finally to pegylated IFN (PEG-IFN) therapy. However, even combined therapy with PEG-IFN and RBV for 48 wk is unable to eliminate the virus in some 40% of hepatitis C cases, particularly those with genotype 1b and high viral load. Treatment options for patients who have relapsed or are refractory to treatment with PEG-IFN and RBV therefore need to be critically assessed. This paper overviews the relationship between chronic liver disease and zinc metabolism.

Key words: Chronic hepatitis C; Zinc; Interferon therapy

LIVER DISEASE AND ABNORMAL METAL METABOLISM

Abnormal metal metabolism, which is related to liver disease, has long been a subject of pathological study, particularly storage diseases such as iron metabolism in hemochromatosis^[1] and copper metabolism in Wilson's disease^[2].

As nutrition science has advanced, it has recently been pointed out that trace metallic elements in blood play essential roles, and abnormal metal metabolism involving metal deficiency in various diseases has been studied.

Zinc is an essential trace element in the human body, with approximately 2 g distributed throughout the body of a healthy adult, including many organs^[3-5]. *In vivo*, this element stimulates the activity of as many as 300 metal enzymes and metal-activated enzymes, and is crucial for nucleic acids and protein metabolism. Zinc plays an important role in the activity of many enzyme proteins, and a deficiency of zinc causes various pathologic disorders in the human body.

Regarding zinc metabolism abnormality in liver disease, in 1951 Vikbladh pointed out that the zinc content in serum was low in the case of various liver diseases^[6], and conjectured that serum contains albumin loosely

bound to zinc and globulin firmly bound to zinc, and that the albumin is associated with a lower zinc content. In 1957, Bartholomay *et al*^[7] claimed that hypozincemia in liver disease might be associated with increased urinary zinc excretion. In 1979, Sullivan *et al*^[8] pointed out that decreased zinc absorption was observed in cases of alcoholic cirrhosis, and in 1988, Grüngreiff *et al*^[9,10] reported that poor zinc absorption was observed in cases of non-alcoholic cirrhosis.

It is known that among liver disease cases, those with chronic hepatitis C show lower zinc concentrations in blood as their pathologic condition worsens from chronic hepatitis, to compensated cirrhosis, to decompensated cirrhosis, to hepatocellular carcinoma (HCC). Serum and hepatic zinc concentrations are decreased in chronic liver diseases, and zinc depletion has been suggested to be a cause of liver fibrosis^[11,12]. Particularly, cases with liver failure^[13] or cases of HCC^[14,15] are known to show conspicuous hypozincemia, and zinc supplementation therapy improves liver disease.

CORRELATION OF HEPATITIS C VIRUS WITH ZINC

A study of the relationship of the existence of hepatitis C virus (HCV) with zinc concentration in serum suggested that zinc concentration was not related to HCV genotypes or HCV-RNA values, and thus the existence of HCV did not affect the serum zinc concentration. However, it was reported that the serum zinc concentrations of untreated asymptomatic carrier (ASC) cases were significantly lower than those of healthy people^[16]. From this report, it can be inferred that the existence of HCV may be related to the serum zinc concentration even if the former does not directly affect the latter.

It has recently been reported that nonstructural 3 proteinase^[17-20], which is involved in the replication of HCV, is a zinc-containing enzyme, and that the nonstructural 5A protein is a zinc metalloprotein^[21]. Accordingly, it is necessary to examine and control the serum zinc concentration when treating cases of refractory chronic hepatitis C. In addition, in ASC cases, their progress may need to be observed by monitoring the serum zinc concentration and other means.

It has been reported that zinc in blood is closely related to hepatic fibrosis in cases of liver disease. It has also been reported that drug therapy or gene therapy that increases the serum zinc concentration can inhibit the progress of hepatic fibrosis^[22]. Many studies, including those noted above, suggest that pathologic conditions of the liver are closely related to zinc in blood. However, although there have been basic researches, its relationship with hepatic fibrosis has not been clinically studied.

CHRONIC HEPATITIS C AND ZINC

Some 60% to 70% of cases of hepatitis C progress to

chronic hepatitis, and then to cirrhosis and hepatocellular carcinoma over 20 years to 30 years. Following the 1986 report of Hoofnagle *et al*^[23] on the effects of interferon (IFN) on HCV infection in patients with chronic hepatitis, IFN therapy has been employed throughout the world to treat chronic hepatitis C. The treatment of choice for chronic hepatitis C is antiviral therapy using IFN^[24,25].

In Japan, many cases of hepatitis C have been treated with IFN since 1992, when treatment using IFN drugs became covered by the public health insurance system. IFN monotherapy, which was used initially, successfully resulted in low sustained HCV-negative condition of all cases treated^[26]. Sustained virological response (SVR) was gained in merely 6% of patients with HCV-1b in high viral loads when the practice of administering a 6-mo regimen of natural IFN was started in 1992; it increased to 20% with the 6-mo regimen of standard IFN combined with ribavirin (RBV) implemented in 2001^[27,28]. Finally, the introduction of the 12-mo regimen of pegylated IFN (PEG-IFN) and RBV approved in 2004 achieved SVR in 50%^[29,30].

The viral factors that affect the effectiveness of IFN therapy include HCV genotype and HCV-RNA quantity, and the host factors that do so include the histological condition of the liver, age and degree of fatness.

Generally, genotype I b virus is more resistant to IFN than genotype II a or II b viruses. In Japan, genotype I b in high viral loads accounts for more than 70% of HCV infections, making it difficult to treat patients with chronic hepatitis C^[27,28].

With regard to the effect of the combination therapy of oral administration of zinc with IFN for chronic hepatitis C, Nagamine *et al*^[31] reported on the roles of zinc and metallothionein in IFN- α therapy for hepatitis C in 1997. Takagi *et al*^[32] treated 68 cases of chronic hepatitis C with genotype I b virus of an HCV-RNA quantity of at least 100 Kcopy/mL with a dose of 10 million units of IFN- α once daily for four weeks, and then the same dose three times weekly for the subsequent 20 wk, by intramuscular injection. They combined the IFN administration with an oral dose of 150 mg of polaprezinc (Promac; Zeria Pharmaceutical, Company Ltd., Tokyo, Japan) daily (equivalent to 34 mg of zinc) in 32 of the 68 cases. The effects of the treatment were evaluated six months after completion, with the criteria of complete response (CR) for disappearance of HCV-RNA and normal alanine aminotransferase (ALT) levels; incomplete response (IR) for HCV-RNA that did not disappear, but normal ALT levels; and non-responder for other cases. The IFN monotherapy group (IFN) was compared with the IFN and zinc combination group (IFN + Zn) in terms of those criteria, with the following results. The IFN group showed CR: 11.1% (4/36) and IR: 11.1% (4/36), totaling 22.2% (8/36), while the IFN + Zn group showed CR: 37.5% (12/32) and IR: 18.8% (6/32), totaling 56.3% (18/32). Thus, they concluded that the zinc combination group had a significantly higher effective rate^[32].

Murakami *et al*^[33] treated cases of chronic hepatitis C with a high virus quantity of genotype I b with the PEG-IFN/RBV therapy, and analyzed the proportion of cases that became HCV-RNA negative after eight weeks of treatment by using groups with and without combination with zinc administration with an oral dose of 150 mg of polaprezinc (containing 34 mg of zinc) daily. They reported that the proportion of cases in whom ALT lowered to 35 U/L or less by the eighth week was 91% (10/11) in the zinc combination group and 58% (7/12) in the non-zinc administration group; however, the proportions of cases that became HCV-RNA negative were 18% (2/11) and 25% (3/12) respectively, showing no significant difference. Furthermore, they continued to observe the cases, and reported that all the cases (9/9) in the group with combination with zinc administration and 67% (8/12) of the cases in the group without combination with zinc administration showed normal ALT levels after 24 wk, and that all the cases (7/7) in the group with zinc and 60% (6/10) of the cases in the group without zinc did so after 48 wk. Interferon therapy for chronic hepatitis C has improved in many ways such as combination with ribavirin, and the rate of virus disappearance resulting from such therapy has increased conspicuously in comparison with the initial results. This therapy now achieves an SVR of approximately 50% even for cases with a high virus quantity of genotype I b, and a viral clearance rate of nearly 90% for other cases. However, this therapy has shown poor results for cases with severe hepatic histological fibrosis or thrombocytopenia, or for elderly patients, so its combination with zinc administration should be attempted in refractory cases.

HEPATIC FIBROSIS AND ZINC

In cirrhosis, the quantity of hydroxyproline in liver tissues increases while that of zinc decreases. Boyett *et al*^[34] reported that the concentration of zinc per unit nitrogen not derived from collagen was correlated with the concentration of zinc in liver tissues. Himoto *et al*^[35] examined the effects of zinc administration on inflammatory activity and fibrosis of the liver in patients with HCV-related chronic liver disease (CLD). Treatment with polaprezinc significantly decreased serum aminotransferase levels (aspartate aminotransferase: 92 ± 33 IU/L *vs* 63 ± 23 IU/L, $P = 0.0004$; ALT: 106 ± 43 IU/L *vs* 65 ± 32 IU/L, $P = 0.0002$), whereas alkaline phosphatase levels were significantly increased (305 ± 117 IU/L *vs* 337 ± 118 U/L, $P = 0.0020$). There was a tendency toward a decrease in serum type IV collagen 7S levels after treatment with polaprezinc. However, administration of polaprezinc did not affect peripheral blood cell counts, other liver function tests, or HCV-RNA loads. These findings suggest that polaprezinc exerts an anti-inflammatory effect on the liver in patients with HCV-related CLD by reducing iron overload.

Furthermore, Matsuoka *et al*^[36] reported that zinc supplementation improves the outcome of chronic hep-

atitis C and liver cirrhosis. Takahashi *et al*^[37] investigated the effect of oral zinc supplementation on liver fibrosis in patients with advanced chronic liver disease. The serum levels of type IV collagen and the activity of tissue inhibitors of metalloproteinase-1 were significantly reduced. This suggests that oral zinc supplement therapy is safe and may be a novel and useful strategy for antifibrosis therapy in patients with early liver cirrhosis.

Generally, the oxidative stress is high in hepatitis patients, and significant correlations among HCV-RNA. Oxidant stress is a significant feature of hepatitis C infection^[38]. There is evidence that the production of free radicals increases while anti-oxidant defense decreases significantly in all types of liver damage. Alongside the direct effect of the HCV core protein, hepatocellular iron accumulation and the production of reactive oxygen species associated with the immune response are considered to be of crucial significance for the creation of oxidative stress in chronic HCV. Mitochondrial effects may contribute to liver injury and oxidative stress seen in chronic hepatitis C^[39]. Zinc plays an important role in the redox process as a signal molecule and second messenger.

Decrease of supportive nutrients such as zinc have been documented in patients with viral or alcoholic liver disease. These markers may contribute to the monitoring the degree of liver damage, the response to antiviral therapies and to the design of new therapeutic strategies^[40]. Effects of zinc in the treatment of chronic hepatitis C are produced *via* immunological reactions, antiviral defence mechanisms and the role of zinc as an antioxidant^[41]. Furthermore, Yuasa *et al*^[42] have shown that zinc substitution negatively influences HCV replication. Zinc supplementation thus appears to offer a novel approach to the development of future strategies for the treatment of intractable chronic hepatitis C.

TREATMENT FOR CHRONIC HEPATITIS C BY ADMINISTERING ZINC

Leucopenia or thrombocytopenia is often found in elderly patients with chronic hepatitis C with severe fibrosis, and in many such cases, the IFN therapy must be discontinued due to side effects.

According to the results of a study in which zinc was administered in applying IFN and RBV therapy to cases of chronic hepatitis C with a tendency toward zinc deficiency to assess its effects on cytopenia, zinc served to protect against a reduction in white blood cells or platelets and thus effectively inhibited side effects.

The reduction in the number of peripheral blood cells due to IFN therapy seems to be caused by inhibition of the hematopoietic function of bone marrow. When RBV is combined with IFN therapy, hemolytic anemia due to the accumulation of RBV in red blood cells also seems to cause such a reduction. In cases of chronic hepatitis C with severe fibrosis, the number of blood cells tends to be already low before the adminis-

tration of IFN or RBV, and therefore how to prevent the reduction in blood cells as a side effect is important.

Nagamine *et al*^{43]} conducted a basic study on the activity of IFN- α in U937 cells in order to elucidate whether zinc would enhance the action of interferon. They found that zinc chloride and polaprezinc increased IFNAR mRNA by 30% to 40%, whereas monotherapy of L-carnosine had no such effect, suggesting that zinc enhanced the action of interferon and induced the production of anti-viral proteins. Hence, many cases of liver disease are accompanied by complaints of symptoms in the mouth such as dysgeusia, dry mouth and stomatitis when treated with PEG-IFN/RBV. Zinc supplement seems to be effective against oral mucosa disorders in IFN therapy treatment.

A new antiviral drug called DAA became covered by the public health insurance system in Japan. Hence, the treatment of choice for cases with a high quantity of genotype 1 virus is likely to be DAA + PEG-IFN α -2b + RBV combination therapy (the "3-drug therapy"). However, it has been reported that this therapy causes side effects such as severe hemoglobin reduction or severe rash, and many side effects in elderly patients.

Zinc supplementation to reduce such side effects may be the key to developing more effective anti-viral therapies. As this paper has suggested, the administration of zinc in many clinical cases requires further study. Prospective double-blind studies with large sample sizes are necessary.

Abstract

Gastric stump carcinoma (GSC) following remote gastric surgery is widely recognized as a separate entity within the group of various types of gastric cancer. Gastrectomy is a well established risk factor for the development of GSC at a long time after the initial surgery. Both exo- as well as endogenous factors appear to be involved in the etiopathogenesis of GSC, such as achlorhydria, hypergastrinemia and biliary reflux, Epstein-Barr virus and *Helicobacter pylori* infection, atrophic gastritis, and also some polymorphisms in interleukin-1 β and maybe cyclo-oxygenase-2. This review summarizes the literature of GSC, with special reference to reliable early diagnostics. In particular, dysplasia can be considered as a dependable morphological marker. Therefore, close endoscopic surveillance with multiple biopsies of the gastroenterostomy is recommended. Screening starting at 15 years after the initial ulcer surgery can detect tumors at a curable stage. This approach can be of

INTRODUCTION

The first partial gastrectomy with gastroduodenostomy was performed by Billroth in 1881 and was followed by the first gastrojejunostomy 3 years later. Both procedures became known as Billroth I and II, respectively^[1]. Although the famous Viennese surgeon Theodor Billroth is credited for the first gastric resection, known as the Billroth I procedure, the less well-known Ludwik Rydygier from Poland, performed and described the procedure several months earlier^[2]. Particularly in Europe, the Billroth II resection became the most popular treatment for peptic ulcer disease until the mid 1970s^[3]. Since then, a significant decrease of peptic ulcer surgery was seen due to the introduction of H₂-receptor antagonists^[4], and later the proton pump inhibitors^[5]. In the early 1980s, the discovery of *Helicobacter pylori* (*H. pylori*)^[6] as the main cause of peptic ulcer disease further diminished the role of surgery in the treatment of this disease^[7-12]. Surgical

treatment for uncomplicated peptic ulcer disease became rare, but operations for complications of peptic ulcer disease such as perforation, bleeding or gastric outlet obstruction are still regularly performed. The rise of the use of nonsteroidal anti-inflammatory drugs explains part of this occurrence^[13-16]. In Eastern Europe, the prevalence of surgery for benign gastroduodenal ulcers remained higher for a longer time than in Western Europe. In Poland for example, several thousand complicated as well as chronic peptic ulcer patients were still operated upon^[17-20], and there, the introduction of antisecretory drugs occurred in the late 1980s^[21]. Nevertheless, complications of peptic ulcer surgery will presumably become less important there as a public health problem^[22].

HISTOPATHOLOGY

Billroth antrectomy and its various modifications remove the part where the ulcer is located and that contains the gastrin-producing antral mucosa responsible for the stimulation of acid production through the oxyntic mucosa. It also induces biliary reflux, felt to be beneficial for healing due to its alkaline contents. The majority of patients with peptic ulcer disease will have an antrum-predominant *H. pylori* gastritis^[23,24]. The biliary reflux creates a microenvironment that is not suitable for *H. pylori* and it will eradicate the microorganisms from the anastomosis after surgery. The microscopy of the anastomosis will therefore change from the chronic active *H. pylori* gastritis picture into that of the typical reflux gastritis. The most important features of reflux gastritis are foveolar hyperplasia, congestion, paucity of inflammatory infiltrate, reactive epithelial change and smooth muscle fiber proliferation. These changes are already apparent shortly after surgery; less so when a Roux-en-Y conversion is carried out to avoid reflux^[25,26]. The picture is therefore directly related to the reflux of bile, as is the eradication of *H. pylori* from the anastomosis.

In the long run, other microscopic features are encountered in the operated stomach^[27]. Loss of parietal cells with the subsequent disappearance of the chief cells introduces an accelerated mucosal atrophy that is caused by the lack of the trophic hormone gastrin and the vagotomy that is mostly done simultaneously. The specialized glandular mucosa is replaced by intestinal metaplasia and pseudopyloric metaplasia^[28-31]. Atrophy of the gastric mucosa may lead to vitamin B12 deficiency. At the site of the anastomosis, the glands often become cystically dilated, and sometimes these cystically dilated glands herniate through the muscularis mucosae. This provides a nodular aspect to the anastomosis and gives rise to a microscopic picture known as gastritis polyposis cystica or gastritis cystica profunda^[32-34]. Erosions may occur as a result of compromised vasculature due to the surgery, but in the case of persistent ulceration after surgery, Zollinger-Ellison-like syndrome or a retained antrum needs consideration and these conditions are accompanied by high gastrin levels. The retained antrum is caused

by resection that is too limited and G-cell hyperplasia in the stretch of antral mucosa left behind^[35,36].

Xanthelasma, also known as gastric xanthomas or gastric lipid islands, are aggregates of foamy macrophages filled with lipids that can be seen in the stomach and more often after partial gastrectomy^[37,38]. At endoscopy, they appear as grossly visible whitish nodules or plaques, well circumscribed, with a size varying from 1 to 10 mm in diameter^[39,40]. They typically occur along the lesser curve^[41], the so-called "magenstrasse" where generally reflux is most severe. It is felt that these aggregates phagocytose remnants of cellular debris after degradation due to chemical injury, and they are harmless. Their importance lies in the fact that these should not be confused with signet ring cell carcinoma, because the microscopy of xanthelasma can resemble signet ring cells. Special stains for mucin or immunohistochemistry for cytokeratins versus histiocytic macrophages makes this differentiation easy^[42,43]. Xanthelasma occur more frequently in stomachs harboring other pathological changes such as chronic gastritis, atrophic gastritis and intestinal metaplasia^[39,44]. The significance of these lesions remains unknown.

PREMALIGNANT CONDITION

The stump of the stomach after remote gastric resection because of benign ulcer disease is a well-defined premalignant condition. Many studies in the past have confirmed that, after remote partial gastrectomy, there is an increased risk for stomach cancer^[3,45-49]. GSC is defined as a malignancy of the stomach occurring > 5 years after initial partial gastrectomy, to confusion with cancer recurrence after initial misdiagnosis. The risk for stump cancer is remarkable because most of these patients suffer from peptic ulcer disease prior to surgery. The relation between peptic ulcer disease and gastric cancer is not fully understood. Gastric cancer and peptic ulcer disease are inversely associated and they are accompanied by distinct patterns of acid secretion^[50]; by contrast, gastric ulcers, non-peptic gastric ulcers, and gastric cancer partly share pathophysiological features^[51-53]. The part of the stomach that is at the highest risk for gastric cancer is removed by surgery. Nevertheless, with an increasing postoperative interval, there is a steadily increasing risk for stomach cancer in the gastric remnant. After more than 15-20 years postoperatively, the risk is higher than can be expected for an age- and sex-matched general population, and it rapidly increases thereafter^[45,48,54]. In line with the increased risk for stomach cancer, the post-gastrectomy stomach also harbors dysplasia relatively frequently^[29,55,56]. The dysplasia is typically encountered around the gastric anastomosis, and similarly the cancers are almost exclusively found there. Both the dysplasia and the cancers can be multifocal and extensive mapping of the mucosa with endoscopic biopsies is warranted. Unlike primary gastric cancer, which is frequently resectable (resectability rate in Poland: 66%), gastric stump carcinoma once detected be-

Table 1 IL-1 β -31T>C genotype in gastric stump cancer and in conventional gastric cancer *n* (%)

Genotype of IL-1 β -31T>C ¹	Gastric stump cancer	Conventional gastric cancer
CC	8/30 (27)	21/96 (22)
TC	19/30 (63)	36/96 (37)
TT	3/30 (10)	39/96 (41)
Presence of C allele	90	59

cause of symptoms is virtually unresectable in the majority of patients. In view of the increased risk, surveillance of post-gastrectomy patients has been advocated and it can indeed detect cancer at an early and operable stage^[57]. Whether or not large-scale screening would be indicated is however questionable. In a screening program carried out in Amsterdam among > 500 patients > 15 years post-operatively, 10 cancers were found; six of which turned out to be early cancers^[56]. Mortality of stomach cancer among these screened individuals was, however, only marginally different from that among the patients who did not participate in the screening program, after an observation period of 10 years. Moreover, a similar difference in mortality was observed in lung cancer, suggestive of selection bias among the screened patients^[58].

ETIOLOGY

It is thought that after partial gastrectomy, an environment is created that is favorable for the development of cancer. Patients enter an accelerated neoplastic process due to the altered microenvironment. The stump carcinomas evolve as the end result of a series of mutagenic cell transformations, leading to stepwise tumor progression from atrophic gastritis with metaplasia *via* dysplasia to invasive carcinoma. During tumor progression an increased proliferation and expansion of the proliferative compartment towards the luminal surface is observed. This is accompanied by an increasing concomitant chance of mutations, because the proliferating cells are particularly vulnerable to mutation. Biliary reflux, achlorhydria, atrophic gastritis and formation of N-nitroso compounds are considered factors that contribute to carcinogenesis in the gastric stump^[3,59,60]. It has been shown that the changes in the quantity of the nitrate-reducing bacteria and in the N-nitrosamine concentration depend on the type of

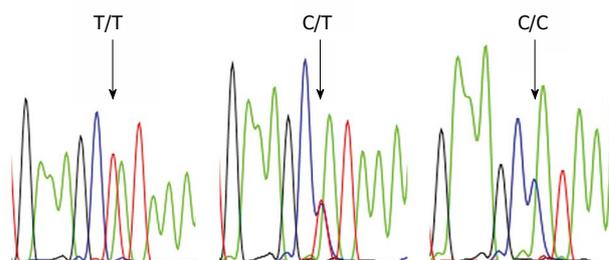

Figure 1 An example of the sequence analysis of the T/T, C/T and C/C interleukin-1 β -polymorphism.

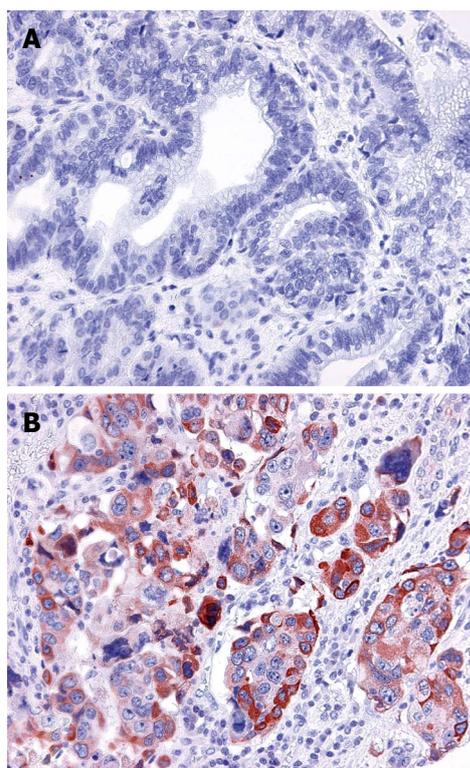

Figure 2 An example of cyclo-oxygenase-2 immunohistochemistry. A: Cyclo-oxygenase (COX)-2 low staining; B: COX-2 high staining.

surgical intervention performed. The highest content of nitrate-reducing bacteria and the N-nitrosamine concentration were found in the gastric juice of patients after Billroth II antrectomy, and the lowest values after highly selective vagotomy^[61].

Epstein-Barr virus (EBV) positivity by RNA *in situ* hybridization is seen more often in carcinomas in the gastric remnant than in the intact stomach^[62]. In contrast, *H. pylori* is less frequently observed^[63]. Interestingly, there is an inverse relationship between positivity for EBV and positive immunohistochemistry for TP53; also loss of heterozygosity of 17p at the locus of TP53 is less frequently observed in EBV-positive stump carcinomas^[64]. It has been reported that the EBV-encoded EBNA-5 protein can form a complex with TP53 and retinoblastoma proteins, and it is conceivable that this may lead to accel-

erated degradation of either one of these proteins^[65].

Endogenous factors may also play a role. The interleukin (IL)-1 β 31T>C polymorphism is associated with higher gastric cancer risk. This allele confers hypoacidity to the oxyntic mucosa of the *H. pylori*-infected intact stomach and it thereby induces a corpus-predominant inflammatory gastritis^[66,67]. The IL-1 β -31T>C polymorphism is also associated with GSC (Table 1 and Figure 1)^[68]. Apparently, the relatively few peptic ulcer disease patients carrying this genotype are at particularly high risk for the development of stomach cancer, after operation. Surgery has a similar effect as pharmacologically induced acid suppression; a fact that is known to lead from an antrum- to a corpus-predominant inflammatory picture in the gastric mucosa.

Cyclo-oxygenase (COX)-2 expression is increased in gastric stump cancer and the 765 G allele of COX-2 is associated with higher gastric cancer risk (Table 2 and Figure 2)^[69]. There is however no direct relationship between expression of COX-2 and the -765 C>G polymorphism in gastric stump cancer. This finding contrasts with observations in the duodenum of familial adenomatous polyposis patients, in whom this polymorphism is associated with increased COX-2 expression in the normal mucosa^[70].

CONCLUSION

Partial gastrectomy for benign peptic ulcer disease is a well-established premalignant condition. With increasing postoperative interval since the initial surgery, the risk steadily increases and after more than 15-20 years postoperatively, gastric cancer risk is higher than that of age and sex-matched controls with intact stomachs. The surgery itself and the resulting biliary reflux seem responsible for the risk. Endogenous factors such as polymorphisms in IL-1 β and COX-2 may contribute. EBV infection is more prevalent than in the intact stomach, and *H. pylori* infection less frequent. EBV may interact with the *TP53* gene. Stump cancer is preceded by well-defined preinvasive precursor lesions, most notably dysplasia. Dysplasia can be considered a dependable morphological marker, amenable for early detection by endoscopic surveillance.

Abstract

AIM: To investigate the effects of mangiferin on gastrointestinal transit (GIT) in normal and constipated mice, together with the possible mechanism.

METHODS: Intragastrically-administered charcoal meal

was used to measure GIT in overnight starved Swiss mice. In the first experiments, mangiferin (3 mg/kg, 10 mg/kg, 30 mg/kg, and 100 mg/kg, *po*) or tegaserod (1 mg/kg, *ip*) were administered 30 min before the charcoal meal to study their effects on normal transit. In the second series, mangiferin (30 mg/kg) was tested on delayed GIT induced by several different pharmacological agonists (morphine, clonidine, capsaicin) or antagonists (ondansetron, verapamil, and atropine) whereas in the third series, mangiferin (30 mg/kg, 100 mg/kg and 300 mg/kg) or tegaserod (1 mg/kg) were tested on 6 h fecal pellets outputted by freely fed mice. The ratio of wet to dry weight was calculated and used as a marker of fecal water content.

RESULTS: Mangiferin administered orally significantly ($P < 0.05$) accelerated GIT at 30 mg/kg and 100 mg/kg (89% and 93%, respectively), similarly to 5-hydroxytryptamine₄ (5-HT₄) agonist tegaserod (81%) when compared to vehicle-treated control (63%). Co-administered mangiferin (30 mg/kg) totally reversed the inhibitory effect of opioid agonist morphine, 5-HT₃-receptor antagonist ondansetron and transient receptor potential vanilloid-1 receptor agonist capsaicin on GIT, but only to a partial extent with the GIT-delay induced by α_2 -adrenoceptor agonist clonidine, and calcium antagonist verapamil. However, co-administered atropine completely blocked the stimulant effect of mangiferin on GIT, suggesting the involvement of muscarinic acetylcholine receptor activation. Although mangiferin significantly enhanced the 6 h fecal output at higher doses (245.5 ± 10.43 mg vs 161.9 ± 10.82 mg and 227.1 ± 20.11 mg vs 161.9 ± 10.82 mg of vehicle-treated control, at 30 and 100 mg/kg, $P < 0.05$, respectively), the effect of tegaserod was more potent (297.4 ± 7.42 mg vs 161.9 ± 10.82 mg of vehicle-treated control, $P < 0.05$). Unlike tegaserod, which showed an enhanced water content in fecal pellets ($59.20\% \pm 1.09\%$ vs $51.44\% \pm 1.19\%$ of control, $P < 0.05$), mangiferin evidenced no such effect, indi-

cating that it has only a motor and not a secretomotor effect.

CONCLUSION: Our data indicate the prokinetic action of mangiferin. It can stimulate the normal GIT and also overcome the drug-induced transit delay, *via* a cholinergic physiological mechanism.

Mangiferin, a natural xanthone, accelerates gastrointestinal transit in mice involving cholinergic mechanism. *World J Gastroenterol* 2012; 18(25): 3207-3214 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i25/3207.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i25.3207>

INTRODUCTION

Dyspepsia and constipation are common gastrointestinal disorders of ageing populations, irritable bowel syndrome, and in chronic users of narcotic and non-narcotic analgesics^[1-5]. The high prevalence, economic consequences and decrement in health-related quality of life make these disorders a major public issue. Constipation remains a major gastrointestinal ailment with multiple symptoms and a diverse etiology. To get relief from chronic constipation, conventional treatments include the use of fiber supplements and laxatives, but the clinical data do not support the efficacy of these therapies^[6]. Even recently introduced drugs such as tegaserod [a 5-hydroxytryptamine₄ (5-HT₄) partial agonist] and lubiprostone (a chloride channel activator approved by the Food and Drug Administration) were not found to be clinically useful, due to intolerable side effects^[7,8]. Erythromycin, a non-peptide motilin receptor agonist, has been shown to induce phase 3 of the migrating motor complex in the antro-duodenum and cause an improvement in clinical symptoms of constipation^[9], but there was a report that it lacks colon prokinetic effect in children with chronic constipation^[10]. Although advances have been made in understanding gastrointestinal motility, visceral pain, mucosal inflammation, and tissue repair, the major gastrointestinal disorders like constipation remain significant therapeutic challenges^[11]. Therefore, there is a need for intense research to develop newer, well-tolerated and effective drugs to cure or to alleviate the symptoms of chronic constipation.

Dyspepsia is a highly prevalent condition characterized by symptoms originating in the gastroduodenal

region. Patients experience postprandial fullness, early satiation, epigastric pain, or burning in the absence of causative structural disease. These symptoms may coexist with irritable bowel syndrome, in which patients frequently complain of occasional bowel movement disorders, associated with abdominal pain or discomfort, but they are rarely due to an underlying organ involvement^[12]. Treatment options that may be beneficial for functional dyspepsia include histamine H₂ blockers, proton pump inhibitors, and prokinetic agents. However, most of the available treatments have only limited efficacy^[13,14]. Recent reports described the prokinetic and laxative effects of *Lepidium sativum* (garden cress) and *Aquilaria sinensis* (agarwood) in mice, which were partially mediated through a cholinergic pathway^[15,16]. Developing drugs from natural sources (plant extracts or plant-derived substances) may be a treatment option to combat symptoms associated with dyspepsia and constipation.

Mangiferin is a naturally occurring glucosylxanthone commonly encountered in several traditionally used medicinal plants^[17] that has been shown to exhibit multiple pharmacological effects that include antioxidant, anti-inflammatory^[18-20], and immunomodulatory activities^[21]. Diminutions in glutamate-induced neurotoxicity and memory enhancement effects of mangiferin have also been reported^[22,23]. Mango fruit is rich in mangiferin^[24] and, according to Nadkarni^[25], the ripe fruit is very wholesome, nourishing, and useful in nervous and atonic dyspepsia and constipation. We previously demonstrated that mangiferin affords gastroprotection against absolute ethanol or indomethacin-induced gastric ulceration through an antioxidant mechanism^[26]. Mangiferin also attenuated acidified ethanol-induced gastric damage in mice and this gastroprotective effect was accompanied by enhanced gastric emptying (unpublished observations from our laboratory) suggesting a likely prokinetic effect. In the light of these observations, the present study was aimed to verify a possible prokinetic effect of mangiferin on normal and delayed gastrointestinal transit, evoked by several different pharmacological agents in mice, and to analyze the underlying mechanism.

MATERIALS AND METHODS

Plant material and isolation of mangiferin

Mangiferin (Figure 1) used in this study was extracted and isolated from the bark of *Mangifera indica* L. (Anacardiaceae) as per procedures reported earlier^[26]. A voucher specimen (No. 32628) of the plant material authenticated by Dr. Francisco Edson de Paula has been deposited at the Herbário Prisco Bezerra of the Federal University of Ceará. The isolated mangiferin (MGF) was approximately of 95% purity^[20] having the molecular weight 422.5 and melting point (mp) 27 °C.

Animals and animal procedures

Swiss albino male mice (20-25 g) obtained from the Central Animal House of the Federal University of Ceará

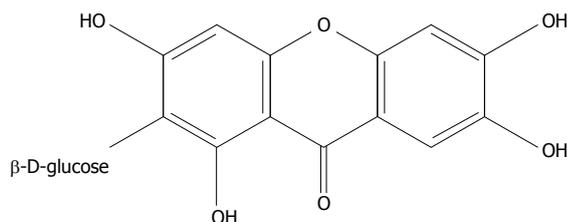

Figure 1 Chemical structure of mangiferin.

were used. They were housed in environmentally-controlled conditions ($23\text{ }^{\circ}\text{C} \pm 2\text{ }^{\circ}\text{C}$, 12-h light-dark cycle), with free access to a standard diet (Purina Chow) and water *ad libitum*. They were kept in wire-mesh cages to prevent coprophagy. Mice were fasted for 15 h prior to the experiments, but allowed free access to water.

The experimental protocols were approved by the Animal Care and Use Committee of the Federal University of Ceará in accordance with the ethical guidelines of the International Association for the Study of Pain.

Chemicals

Capsazepine (Calbiochem, San Diego, California, United States), indomethacin, capsaicin, clonidine hydrochloride (Sigma Aldrich Co., St. Louis, MO, United States), and morphine (Cristália, Brazil) were used. All other chemicals used were of analytical grade. MGF was dissolved in 2% dimethylsulfoxide (DMSO) and further dilutions were made in distilled water. Drug concentrations were adjusted for treatment to give a volume of 10 mL/kg.

Gastrointestinal transit in mice

Gastrointestinal transit was measured using the charcoal propulsion test^[27]. In the first series of experiments, overnight fasted mice were used to establish the dose-response of mangiferin on gastrointestinal transit (GIT). These animals were distributed into 6 groups (eight in each): group 1 received 10 mL/kg vehicle (the diluent of mangiferin, 2% DMSO in distilled water) whereas groups 2, 3, 4 and 5 were treated orally with mangiferin in doses of 3 mg/kg, 10 mg/kg, 30 mg/kg or 100 mg/kg. The 6th group served as the positive control and was treated with tegaserod (1 mg/kg, *ip*). Thirty minutes following the treatments, each mouse was orally given 0.1 mL of charcoal meal (5% activated charcoal suspended in 10% aqueous gum Arabic). The animals were killed 20 min later by cervical dislocation, and the intestines were removed from the pylorus through the ileocecal junction. The extent of charcoal propulsion in the small intestine was measured (distance travelled by the charcoal (from pylorus to the most distal part of the small intestine) and expressed as follows:

Gastrointestinal transit (%) = distance travelled by the charcoal/total length of the small intestine \times 100.

In the second series of experiments, mice in groups (eight/group) were used to study the effect of mangiferin (30 mg/kg, *po*) on gastrointestinal transit delay caused by the opioid agonist morphine (2.5 mg/kg, *sc*), 5-HT₃-

receptor antagonist ondansetron (3 mg/kg, *ip*), transient receptor potential vanilloid 1 (TRPV1) agonist capsaicin (0.3 mg/kg, *po*), α_2 -adrenoceptor agonist clonidine (0.1 mg/kg, *ip*), calcium antagonist verapamil (5 mg/kg, *ip*), and cholinergic muscarinic antagonist atropine (3 mg/kg, *sc*). The effects of these drugs on GIT (administered 30 min before the charcoal meal test) alone, or their co-administration with mangiferin were established. To verify the specificity of the above drugs that cause transit delay, the effects of their corresponding agonists (serotonin 3 mg/kg, *sc*; calcium chloride 50 mg/kg, *ip*; and bethanechol 3 mg/kg, *ip*) or antagonists (naloxone 1 mg/kg, *ip*; yohimbine 2 mg/kg, *sc*; and capsazepine 5 mg/kg, *ip*) alone or in their combination (administered 15 min before) were observed on GIT. The dose selection of test drugs was based on our pilot studies and literature reports.

Fecal pellets output and water content

The third series of experiments were performed to determine whether the prokinetic action of mangiferin or 5-HT₄ agonist tegaserod was capable of propagating a prokinetic signal along the entire length of the gastrointestinal tract. With this aim, the treatment effects of mangiferin or tegaserod were verified on 6 h fecal pellets output and fluidity (water content) as per the method described earlier, with little modification^[28]. Briefly, mice in groups (eight in each) were treated with vehicle, mangiferin at oral doses of 30 mg/kg, 100 mg/kg and 300 mg/kg or tegaserod (1 mg/kg, *ip*) and then transferred to individual cages (19 cm \times 31 cm, lined with bright non-absorbent white paper) and monitored constantly over six hours. To prevent water absorption, no bedding was included in the observation cages; also, to minimize the risk of water evaporation and coprophagia, fecal pellets were collected at 1 h intervals. Fecal pellets were then weighed (wet weight, in mg), desiccated in an oven (50 $^{\circ}\text{C}$, 6 h), and weighed again (dry weight, in mg). Fecal water content was calculated according to the equation:

$$\text{Water content (\%)} = 100 (\text{wet weight} - \text{dry weight}) / \text{wet weight}.$$

Statistical analysis

Statistical analysis was performed by analysis of variance followed by Student Newman Keuls as *post-hoc* tests using GraphPadPrisma 4.0 (GraphPad Software, San Diego, CA, United States). The parametric data was expressed as mean \pm SEM. Differences were considered to be statistically significant when $P < 0.05$.

RESULTS

Effect of mangiferin on gastrointestinal transit

Mangiferin significantly ($P < 0.05$) accelerated GIT at oral doses of 30 mg/kg and 100 mg/kg by 89% and 93%, respectively, compared with the vehicle control which showed 63% GIT (Figure 2). However, mangiferin response was not dose-related. On the other hand, tegas-

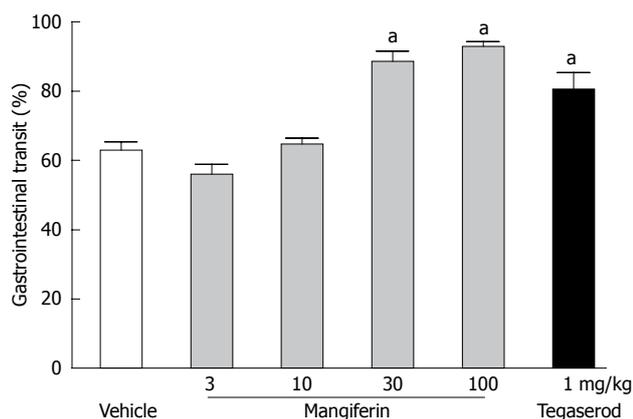

Figure 2 Effects of mangiferin and tegaserod on normal gastrointestinal transit. Each column represents mean \pm SEM ($n = 8$). ^a $P < 0.05$ vs vehicle control group.

erod, a known prokinetic included in the study as a positive control, stimulated GIT by 81%. We observed from pilot experiments that the vehicle (2% DMSO, 10 mL/kg, *po*) itself does not influence the GIT. Therefore, test drug responses on GIT were compared with the vehicle-treated control.

Effect of mangiferin on drug-induced gastrointestinal transit-delay

The opioid agonist morphine (2.5 mg/kg, *sc*), α_2 -adrenoceptor agonist clonidine (0.1 mg/kg, *ip*), 5-HT₃-receptor antagonist ondansetron (3 mg/kg, *ip*), calcium antagonist verapamil (5 mg/kg, *ip*), TRPV1 agonist capsaicin (0.3 mg/kg, *po*), and cholinergic muscarinic antagonist atropine (3 mg/kg, *sc*), all significantly ($P < 0.05$) delayed GIT by 42.4%, 63.2%, 32.9%, 50.7%, 28.7%, and 31%, respectively, when compared to corresponding vehicle-treated control transit values (Figures 3 and 4). These delayed transits were found to be effectively reversed in mice pretreated with respective antagonists (naloxone 1 mg/kg, *ip*; yohimbine 2 mg/kg, *sc*; and capsazepine 5 mg/kg, *ip*) or agonists (serotonin 3 mg/kg, *sc*; calcium chloride 50 mg/kg, *ip*; and bethanechol 3 mg/kg, *ip*). While co-administered mangiferin totally reversed the inhibitory effects of morphine, ondansetron and capsaicin on GIT, the transit delays caused by clonidine and verapamil were only partially reversed. However, co-administered atropine completely blocked the stimulant effect of mangiferin on GIT (Figure 5), suggesting the involvement of muscarinic acetylcholine receptor activation.

Effect of mangiferin on 6 h fecal pellets weight and water content

Table 1 shows the 6 h fecal pellets output and water content from freely fed mice treated with vehicle, mangiferin (30 mg/kg, 100 mg/kg and 300 mg/kg) or tegaserod (1 mg/kg). Six hours cumulative measurement of fecal mass output and water content in the vehicle-treated group was not significantly different from the normal control group.

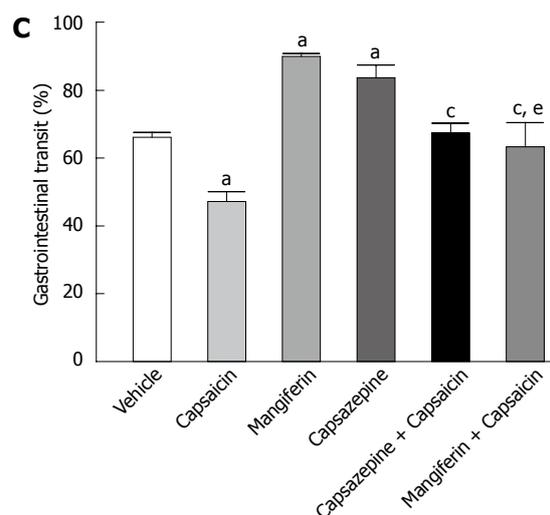

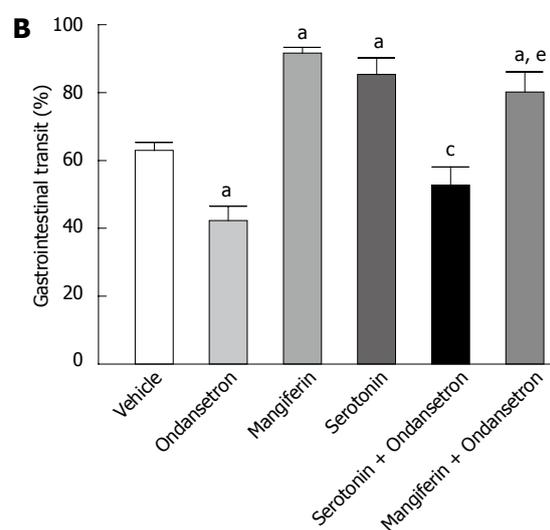

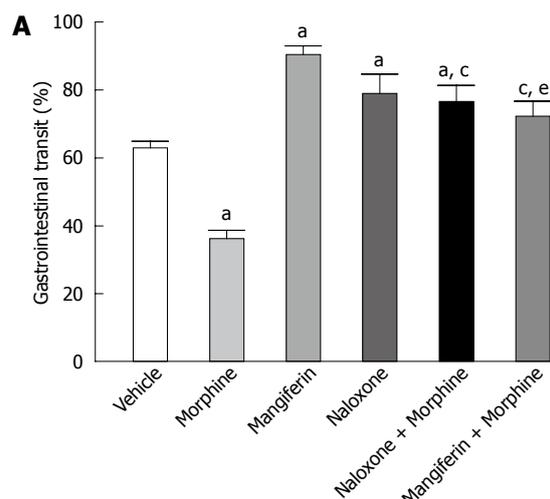

Figure 3 Effect of co-administered mangiferin on delayed gastrointestinal transit induced by morphine, ondansetron, and capsaicin in mice. A: Morphine (2.5 mg/kg, *sc*); B: Ondansetron (3 mg/kg, *ip*); C: Capsaicin (0.3 mg/kg, *po*) induced gastrointestinal transit-delay. Each column represents mean \pm SEM ($n = 8$). ^a $P < 0.05$ vs vehicle control group; ^c $P < 0.05$ vs respective morphine/ondansetron/capsaicin; ^e $P < 0.05$ vs mangiferin alone group.

However, mangiferin at doses of 100 mg/kg and 300

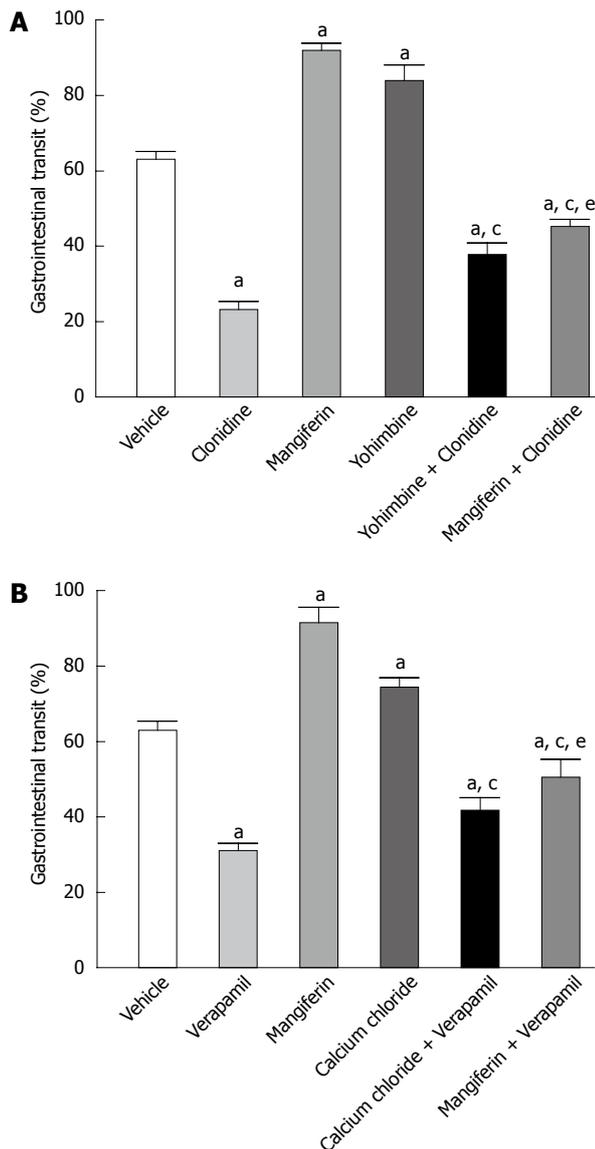

Figure 4 Effect of co-administered mangiferin on delayed gastrointestinal transit induced by clonidine and verapamil in mice. A: Clonidine (0.1 mg/kg, ip); B: Verapamil (5 mg/kg, ip) induced gastrointestinal transit-delay. Each column represents mean \pm SEM ($n = 8$). ^a $P < 0.05$ vs vehicle control group; ^c $P < 0.05$ vs respective clonidine/verapamil group; ^e $P < 0.05$ vs mangiferin alone group.

mg/kg, and tegaserod at 1 mg/kg significantly ($P < 0.05$) enhanced the fecal pellets output by 52%, 40%, and 80%, respectively, when compared to fecal output in vehicle-treated mice (161.9 mg). Fecal mass analysis from different treatment groups revealed that only the tegaserod-treated group evidenced significantly ($P < 0.05$) elevated water content (59%) relative to the vehicle-treated control (51%), suggesting that, unlike mangiferin, tegaserod possibly promotes ionic secretion.

DISCUSSION

In this study, we demonstrated the stimulant effect of mangiferin, a glucosylxanthone on GIT in mice using the charcoal meal test, a suitable preclinical model for quanti-

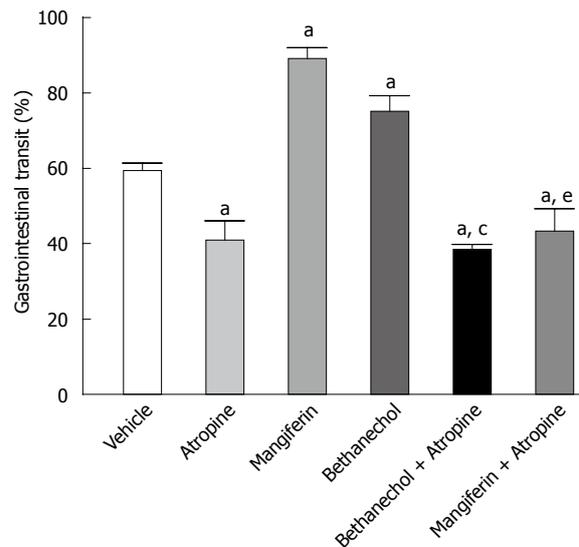

Figure 5 Effect of co-administered mangiferin on atropine-induced delayed gastrointestinal transit in mice. Each column represents mean \pm SEM ($n = 8$). ^a $P < 0.05$ vs vehicle control group; ^c $P < 0.05$ vs bethanechol alone group; ^e $P < 0.05$ vs mangiferin alone group.

Table 1 Effects of mangiferin and tegaserod on 6 h cumulative fecal pellet wet weight and water content in freely fed mice

Group	Dose	Fecal pellets wet weight (mg)	Water content (%)
Control (normal)	-	156.8 \pm 20.98	50.46 \pm 2.28
Control (vehicle)	-	161.9 \pm 10.82	51.44 \pm 1.19
Mangiferin	30 mg/kg, po	205.7 \pm 12.69	50.31 \pm 1.61
	100 mg/kg, po	245.5 \pm 10.43 ^{a,c}	49.76 \pm 3.25
	300 mg/kg, po	227.1 \pm 20.11 ^{a,c}	49.11 \pm 3.01
Tegaserod	1 mg/kg, ip	297.4 \pm 7.42 ^{a,c}	59.20 \pm 1.09 ^{a,c}

The results are expressed as mean \pm SEM of 8 animals per group. Statistical comparison was performed using analysis of variance followed by Student Newman Keuls test. ^a $P < 0.05$ vs control (normal) group; ^c $P < 0.05$ vs control (vehicle) group.

fication of changes in GIT and to analyze the effects of test drugs on gastro-intestinal motility^[28,29]. However, the present experiment is not completely suitable to demonstrate the effect on constipation, because the charcoal test measures gastric emptying and small intestinal transit, rather than the colonic transit, that is important for constipation. Mangiferin accelerated normal GIT and showed an oral efficacy at doses of 30 mg/kg and 100 mg/kg. Our principal aim in this study was to verify whether mangiferin can exert a prokinetic action that could help to alleviate constipation, a major gastrointestinal functional disorder affecting 12%-17% of the general population in North America and elsewhere^[30,31]. Prokinetic drugs share the common characteristic of accelerating GI motility and they appear to be more effective than a placebo in the treatment of functional dyspepsia^[32], wherein constipation is a common feature.

Prokinetics exert their physiological actions through effects on a variety of neurotransmitter receptors in-

cluding acetylcholine, dopamine, motilin and serotonin. Therefore, to characterize mangiferin as a prokinetic, we tested its ability to revert the delayed GIT induced by several pharmacological agents which act by different action mechanisms. The results show that mangiferin accelerates normal GIT as well as the delayed GIT promoted by different pharmacological agents, indicating its prokinetic action *in vivo*. Co-administered mangiferin (30 mg/kg) effectively suppressed the GIT-delay induced by opioid receptor agonist morphine, 5-HT₃-receptor antagonist ondansetron, or TRPV1-receptor agonist capsaicin. This implies that mangiferin's action is non-specific and likely to combat constipation associated with therapeutic or surgical interventions. Patients with chronic pain during daily opioid therapy are frequently burdened with symptoms of constipation^[5]. It is estimated that up to 81% of patients still report constipation despite regular use of laxatives. Studies by Iwata *et al*^[33] reveal that morphine inhibits small intestinal transit, causing tonic contraction of the ileal circular muscle *via* inhibition of the nitrenergic pathway in mice in a naloxone reversible manner. Also, mangiferin administered orally at a similar dose (30 mg/kg) significantly prevented morphine-induced delay in gastric emptying in Wistar rats (unpublished observations from our laboratory).

In the present study we found that systemic administration of clonidine in mice inhibits GIT in mice, consistent with earlier reports^[34,35]. This inhibitory effect of clonidine was significantly inhibited by pre-administration of yohimbine, an α_2 -adrenoceptor antagonist, or by co-administration of mangiferin. However, the reversal of clonidine's effect on GIT delay was incomplete and did not attain the levels of normal transit. Clonidine by its central sedative effect might have contributed to greater depression of GIT.

Prokinetic drugs either directly or indirectly stimulate smooth muscle function, activating intrinsic primary afferent neurons (IPANs) located in the myenteric plexus that play important roles in controlling gastric emptying and small- and large-intestinal transit^[36]. The release of acetylcholine from these neurons is amplified by presynaptic serotonin 5-HT₄ receptor activation or blockade of 5-HT₃ receptors^[37]. Thus, prokinetic drugs like cisapride, mosapride and tegaserod, which have dual action (i.e., induce both 5-HT₄ receptor agonistic and 5-HT₃ receptor blockade effects), have gained clinical importance for the treatment of functional dyspepsia and chronic constipation^[38]. Although the greatest interest has been focused on the development of serotonergic drugs as prokinetics^[39], conflicting data currently exists on the efficacy of mixed 5-HT₄ agonist and 5-HT₃ antagonist drugs, like cisapride, mosapride and tegaserod, for the treatment of constipation^[7], attention has been now drawn to discover alternatives for the treatment of constipation. Interestingly, mangiferin was able to overcome the delayed GIT induced by several pharmacological agents suggesting an action similar to mosapride, a commonly used prokinetic drug and recently described prokinetic,

and the laxative effects of lepidium sativum in mice, which act *via* a mechanism that facilitates cholinergic neurotransmission^[40].

In rodents, the cholinergic stimulant bethanechol acts not only in the enterocytes, but also in submucosal nerves^[41], and since the effects on ion transport were nerve-dependent we decided to investigate the GIT stimulating effect of mangiferin in comparison with bethanechol in atropinized animals. The results show that atropine, the cholinergic antagonist, blocks the stimulatory effects of both mangiferin and bethanechol suggesting that these drugs, by specifically activating cholinergic muscarinic receptors, could induce Ca²⁺ mobilization in the submucosal neurons, thereby stimulating gut motility and secretion. The part played by calcium in mangiferin's effect is further supported by our results with verapamil, a calcium channel blocker that could also produce an effective blockade. In this study, while atropine totally blocked the prokinetic action of mangiferin, only a partial blockade was observed with clonidine, an α_2 -adrenoceptor agonist, and verapamil, a voltage dependent calcium channel blocker, suggesting that participation of muscarinic cholinergic receptors could play a major role in the stimulant effect of mangiferin on GIT.

Interestingly, mangiferin, besides accelerating GIT in normal as well as in constipated mice, could enhance the fecal output (but not the water content) in fecal mass. In contrast, fecal pellets produced by tegaserod-treated mice had higher water content than vehicle- or mangiferin-treated mice, presumably due to its greater secretomotor action on the colon. The increase in water content is indicative of augmented secretory activity, which might be the reason for its diarrhea-inducing side effect when used to control constipation^[42]. Thus mangiferin appears to have a safer prokinetic profile than tegaserod, since it has no diarrhea inducing effect.

In conclusion, this study has shown that mangiferin, a glucosyl xanthone ameliorate, delayed gastrointestinal transit induced by several pharmacologic agents *via* cholinergic mechanism, an action similar to that of some prokinetic drugs. Our study suggests that mangiferin could be an alternative to available prokinetic drugs for the treatment of functional gastrointestinal disturbances such as dyspepsia and postoperative ileus.

COMMENTS

Background

Dyspepsia and constipation are functional gastrointestinal ailments with diverse etiology and symptoms which adversely influence the health-related quality of life. Treatment modalities include the use of fiber supplements, laxatives and prokinetic agents, but the clinical data do not support the efficacy of these therapies. Therefore, there is a need for intense research to develop newer well-tolerated and effective drugs for a cure or symptom-alleviation for dyspepsia

and constipation.

Research frontiers

Mangiferin is a natural polyphenolic compound found in several traditional medicinal plants, including *Mangifera indica* (mango). The mango fruit contains mangiferin and is very wholesome, nourishing and useful in nervous and atonic dyspepsia and constipation. Mangiferin may be a treatment option to combat symptoms associated with dyspepsia and mild to moderate constipation.

Innovations and breakthroughs

In the present study, the authors showed that mangiferin is remarkably effective as a prokinetic agent *via* a cholinergic mechanism in the upper gastrointestinal tract. Mangiferin could enhance gastrointestinal transit and also increase fecal output in normal and physiological situations.

Applications

The study results suggest that mangiferin is a promising lead compound for the treatment of functional gastrointestinal disturbances such as dyspepsia and light to moderate constipation.

Terminology

Dyspepsia: a functional gastrointestinal disorder wherein patients experience postprandial fullness, early satiation, epigastric pain, or burning in the absence of causative structural disease; Constipation: a functional problem of the gastrointestinal tract, with symptoms including hard stools, straining during defecation, and a sense of incomplete evacuation. Treatment options include use of fiber supplements, and prokinetics/laxatives to relieve these functional disorders; Prokinetics: an important class of medicinal products for the treatment of all clinical forms of dyspepsia/moderate constipation that promote gastric emptying and intestinal transit; Mangiferin: a naturally-occurring xanthone glucoside present in many medicinal plants, which has antioxidant and anti-inflammatory actions.

Peer review

The authors performed an experimental study aimed at evaluating the effects of mangiferin in comparison with tegaserod on normal and pharmacologically constipated mice, along with investigating the possible mechanism, and found that mangiferin has a prokinetic action *via* a cholinergic mechanism. This paper is sufficiently well done and most interesting.

Abstract

AIM: To investigate the correlation of ^{18}F -fluorodeoxyglucose (^{18}F -FDG) positron emission tomography (PET) with clinical features and the prediction of treatment response.

METHODS: A total of 83 hepatocellular carcinoma (HCC) patients undergoing ^{18}F -FDG PET before transarterial chemolipiodolization with systemic chemo-infusion between October, 2006 and May, 2009 were retrospec-

tively enrolled. The patients included 68 men and 15 women (mean age, 60 ± 10.7 years). The effect of ^{18}F -FDG-monitored PET uptake on clinical features and on the evaluated treatment response was ascertained with modified Response Evaluation Criteria in Solid Tumors. The PET parameters of maximal standardized uptake value of the tumor (T_{SUVmax}), the ratio of the tumor maximal standardized uptake value (SUV) to the liver maximal SUV ($T_{\text{SUVmax}}/L_{\text{SUVmax}}$) and the ratio of tumor maximal SUV to the liver mean SUV ($T_{\text{SUVmax}}/L_{\text{SUVmean}}$) were tested as predictive factors.

RESULTS: Among the 3 SUV parameters, the $T_{\text{SUVmax}}/L_{\text{SUVmean}}$ ratio (cutoff value of 1.90) was significantly associated with tumor burden including tumor size, tumor number, α -fetoprotein levels and tumor stage ($P < 0.001$, $P = 0.008$, $P = 0.011$, $P < 0.001$, respectively). The objective response rates in patients with a high SUV ratio (≥ 1.90) were significantly better than those with a low SUV ratio (< 1.90) ($P = 0.020$). The overall survival rates of patients exhibiting a low $T_{\text{SUVmax}}/L_{\text{SUVmean}}$ ratio (< 1.90) and those with a high SUV ratio (≥ 1.90) was 38.2 and 10.3 mo, respectively ($P < 0.01$). However, the time to progression showed no significant difference between the groups ($P = 0.15$).

CONCLUSION: ^{18}F -FDG PET can be an important predictor of HCC treatment. In particular, the $T_{\text{SUVmax}}/L_{\text{SUVmean}}$ ratio (cutoff value of 1.90) can provide useful information in treatment prognosis for HCC patients treated with locoregional therapy.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common malignancy, with an increasing incidence worldwide^[1], and the third most common cause of cancer related death^[2]. Surveillance programs have been implemented for cirrhotic patients. However, curative therapies such as resection or transplantation can be applied to fewer than 30% of HCC patients^[3], because most are diagnosed at an intermediate-to-advanced stage of the disease. The prognosis of HCC patients remains poor, and life expectancy is difficult to predict because of variable factors that include tumor burden and liver reserve function^[4]. Thus, it is important to assess the aggressive nature and metabolic change in HCC because this information is valuable in predicting the treatment response and in aiding in the selection of treatment modalities. One approach used to assess the biological activity of a tumor is positron emission tomography (PET).

^{18}F -fluorodeoxyglucose (FDG) PET is an imaging modality that can gauge the glucose metabolism of tumors, which has been established as a useful diagnostic tool for evaluating extrahepatic metastasis^[5]. However, ^{18}F -FDG PET has limitations in its ability to detect primary HCC because of variable F-FDG uptake in HCC^[6]. Nonetheless, PET monitored FDG uptake has the potential to be an additional tool for assessing biological behavior in HCC^[7,8]. The difference in uptake between a tumor and the liver can be expressed as a standardized uptake value (SUV) ratio ($\Gamma/\text{L}_{\text{SUV}}$), which is associated with prognostic aspects of tumor aggressiveness such as differentiation grade, tumor size/number and tumor recurrence in liver transplantation^[8]. It is feasible that FDG uptake, similar to tumor size/number and vascular invasion, may be of value in the prognosis of the treatment response in HCC^[9,10]. However, the usefulness of ^{18}F -FDG PET has not been investigated in the prediction of treatment response for HCC by transarterial chemolipiodolization (TACL) with systemic chemo-infusion.

The present study was undertaken to evaluate whether FDG uptake in HCC correlated with tumor characteristics and to determine, which PET/computed tomography (CT) parameter is especially important as a

predictor of treatment response. Finally, the probability of prognostic ability of ^{18}F -FDG PET for the prediction of treatment response in HCC was assessed.

MATERIALS AND METHODS

Patients

A total of 83 HCC patients, who were aged > 18 years were retrospectively selected and analyzed. Patients included 68 men and 15 women (mean age, 60 ± 10.7 years). All patients had undergone ^{18}F -FDG PET within 3 d before treatment between October, 2006 and May, 2009. The median duration of follow-up was 10.3 mo (range, 1.8-35.7 mo). The eligibility criteria were as follows: no previous transarterial chemo embolization, chemotherapy or radiotherapy; a confirmed diagnosis of HCC according to the American Association for the Study of Liver Disease criteria; an Eastern Cooperative Oncology Group performance status of 0 or 1; and preserved liver function (Child-Pugh class A or B). Patients with potentially resectable or ablative lesions who were high risk for surgery and radiofrequency ablation were also enrolled. Exclusion criteria included any extrahepatic metastasis, another primary tumor, advanced liver disease (bilirubin levels > 3 mg/dL, and a level of aspartate aminotransferase (AST) or alanine transaminase (ALT) > 5 \times the upper limit of normal). The study was approved by the institutional Ethics Review Board and was in compliance with the Declaration of Helsinki.

Treatment methods

The treatment regimen was a combination of intra-arterial epirubicin (50 mg/m^2) and/or cisplatin (60 mg/m^2) in a mixture of lipiodol (5-10 mL) without gelform embolization, and received an additional systemic infusion of 5-fluorouracil (200 mg/m^2) after completing the transarterial chemolipiodolization^[11,12]. The dose or treatment interval was modified whenever any treatment-related toxicity was encountered. Based on our previous report, the following formula for dosage modification was derived: administration dosage = $D \times \text{body surface area (BSA)} \times M$ where D is initial dosage of each agent, BSA is body surface area, and M is the modification rate = $(\text{white blood cell count}/4000) \times [1 - (\text{age} - 45)/100] \times [1 - (\text{Child-Pugh score} - 5)/10]$. According to this formula, the administration dosage of each chemotherapeutic agent was modified. Only the Child-Pugh score was calculated using this formula if the patient's white blood cell count was > $4000/\text{mm}^3$ or the patient's age was < 45 years^[13].

Follow-up imaging and laboratory tests including α -fetoprotein, albumin, bilirubin, AST, ALT and prothrombin time, were performed 4 wk after treatment. Repeat treatment was scheduled within 4 wk after follow-up imaging if there was residual viable tumor.

All CTs were performed with a 64-slice multidetector CT (Siemen Somatom Sensation 64, Munich, Germany). CT examination was performed using a 4-phase protocol

including a non-enhanced acquisition. Arterial phase (delay 20-30 s), portal venous phase (delay 60 s) and delayed venous phase (delay 80 s) were obtained using 120 mL of contrast (Iopromide 300 mg I/L, Schering, Germany) at a rate of 4 mL/s. The images were acquired with a slice thickness of 5 mm.

Treatment response

Treatment response was evaluated at 1 mo after receiving 3 sessions of TACL by modified Response Evaluation Criteria in Solid Tumors^[14]. In the modified criteria of the tumor response for HCC, complete response (CR) is the disappearance of any intratumoral arterial enhancement in all lesions; partial response (PR) is at least a 30% decrease in the sum of the diameters of viable (contrast enhancement in the arterial phase) lesions; progressive disease (PD) is an increase of at least 20% in the sum of the diameters of viable lesions; stable disease (SD) denotes any cases that do not qualify for either PR or PD^[15]. Objective response (OR) included CR and PR.

Evaluation of tumor characteristics according to treatment response

For the analysis of treatment response, all images were retrospectively assessed based on consensus by two attending radiologists. The imaging parameters including tumor size and number, portal vein thrombosis and Barcelona Liver Clinic Cancer (BCLC) stage was also evaluated. According to OR, HCC patients were categorized into an objective response group and a non-response group. The clinical features including the $T_{suvmax}/L_{suvmean}$ ratio were evaluated in both groups. Treatment response according to SUV ratio was analyzed based on stage.

¹⁸F-fluorodeoxyglucose- PET/CT

All patients fasted for at least 6 h prior to the PET/CT study. ¹⁸F-FDG (370-555 MBq) was injected intravenously, and scanning began 60 min later. None of the patients had blood glucose levels > 130 mg/dL before the injection. No intravenous contrast agent was administered. Data were acquired using a combined PET/CT in-line system, Biograph Turepoint (Siemens Medical Solutions, Knoxville, TN). The acquisition time was 2-3 min per bed position during PET/CT scanning. Precontrast CT began at the orbitomeatal line and progressed to the proximal thigh (130 kVp, 80 mAs, and 5 mm slice thickness; 120 kVp, 50 mAs, and 5 mm slice thickness). The PET scan followed immediately over the same body region. The CT data were used for attenuation correction, and images were reconstructed using a standard ordered-subset expectation maximization algorithm. The axial spatial resolution was 4.5 mm or 6.5 mm at the center of the field of view.

To evaluate ¹⁸F-FDG uptake, the region of interest (ROI) was drawn for each tumor, and the normal liver and measured standardized uptake value in each ROI were determined. The ROI was drawn to encircle the highest activity of each tumor. For normal liver regions, two cir-

cular 1.5 cm-diameter ROIs were drawn in both lobes. All tumor and non-tumor regions were defined by correlation with diagnostic CT undergone within 3 d. The maximum SUV (SUV_{max}) was measured in each ROI, and mean SUV (SUV_{mean}) was measured in each normal-liver ROI.

Statistical analysis

To evaluate the usefulness of ¹⁸F-FDG PET, calculated parameters included the following: the SUV_{max} of tumor (T_{suvmax}), the ratio of tumor SUV_{max} to liver maximal SUV (T_{suvmax}/L_{suvmax}), and the ratio of tumor SUV_{max} to liver mean SUV ($T_{suvmax}/L_{suvmean}$). The predictive value of each factor for the treatment response was analyzed based on analysis of the area under the receiver-operating-characteristic curve. After determination of the most effective ¹⁸F-FDG PET predictive factor, this parameter was compared with other prognostic factors, including tumor size and number, portal vein thrombosis, serum α -fetoprotein (AFP) and BCLC stage. The significance of the prognostic value was analyzed with Mann-Whitney and Fisher's exact tests in a univariate analysis and by logistic regression testing in a multivariate analysis. A value of $P < 0.05$ was considered significant (SPSS 16, IL, Chicago).

RESULTS

Clinical characteristics of the HCC patients

The patients included 68 men and 15 women. The average age was 60 ± 10.7 years and hepatitis B virus infected patients were 78%. 85.5% of the patients had Child-Pugh class A liver function. The mean values of tumor number and size were 2.2 ± 1.6 cm and 7.5 ± 5.0 cm, respectively. The BCLC stage of the patients consisted of stage A ($n = 26, 31.3\%$), B ($n = 20, 24.0\%$) and C ($n = 37, 44.5\%$).

Predictive values of ¹⁸F-fluorodeoxyglucose-PET parameters of objective response

The median values of T_{suvmax} , T_{suvmax}/L_{suvmax} and $T_{suvmax}/L_{suvmean}$ were 4.03 (1.5-20.8), 1.36 (0.77-7.64) and 1.82 (0.96-10.79), respectively. The area under the curve of $T_{suvmax}/L_{suvmean}$ was the highest on the receiver-operating-characteristic curve (Figure 1). The cutoff value of T_{suvmax} , T_{suvmax}/L_{suvmax} and $T_{suvmax}/L_{suvmean}$ was 4.0, 1.45 and 1.90, respectively. The cutoff level of $T_{suvmax}/L_{suvmean}$ was used as the effective parameter of ¹⁸F-FDG PET in the prediction of an objective response to HCC treatment. The tumor characteristics of the 83 patients according to the cutoff value of the $T_{suvmax}/L_{suvmean}$ ratio are summarized in Table 1. Forty patients displayed a $T_{suvmax}/L_{suvmean} \geq 1.90$, and the other 43 patients showed a $T_{suvmax}/L_{suvmean} < 1.90$. Two examples of FDG uptake according to $T_{suvmax}/L_{suvmean}$ ratio are shown in Figure 2. The number and size of the tumors, portal vein thrombosis, serum AFP, and BCLC stage in patients with $T_{suvmax}/L_{suvmean} (\geq 1.90)$ indicated significantly more poor prognostic characteristics than in the other patient group.

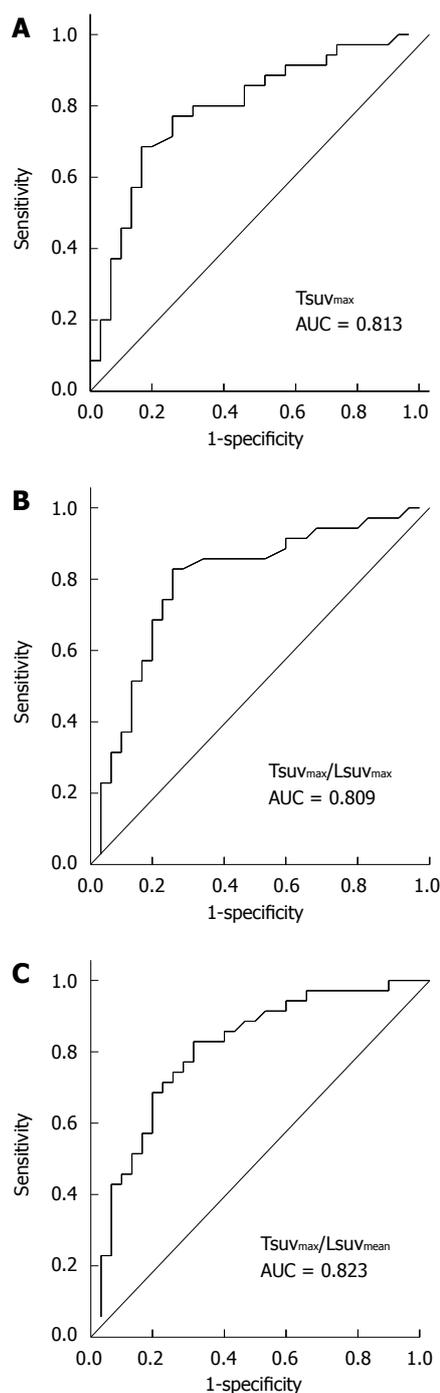

Figure 1 Predictive value of parameters on ¹⁸F-fluorodeoxyglucose positron emission tomography. $TsuV_{max}/LsuV_{mean}$ (C) demonstrated the highest area under curve based on the receiver-operating-characteristic curve analysis compared to $TsuV_{max}$ (A), and $TsuV_{max}/LsuV_{max}$ (B). AUC: Area under curve.

Tumor characteristics according to objective response

CR was observed in 29 (34.9%) of the 83 patients; PR, SD and PD was observed in 16 (19.3%), 20 (24.1%) and 18 (21.7%) patients, respectively. Objective response rates were different above (77.7%) and below (23.6%) the 1.90 cutoff value of $TsuV_{max}/LsuV_{mean}$ ($P < 0.001$).

According to treatment response, HCC patients were categorized into an objective response group and a non-response group. The clinical features associated with ob-

jective response are shown in Table 2. Tumor size, portal vein thrombosis, BCLC stage and $TsuV_{max}/LsuV_{mean}$ ratio showed significant differences and were also determined as prognostic factors in univariate analysis. However, in the multivariate analysis, $TsuV_{max}/LsuV_{mean}$ was the only significant factor for objective response (Table 3).

The treatment response according to the $TsuV_{max}/LsuV_{mean}$ ratio was analyzed based on BCLC stage (Table 4). Treatment response showed a significant difference on BCLC stage B and C ($P = 0.048$ and $P < 0.001$, respectively). These data implicated the $TsuV_{max}/LsuV_{mean}$ ratio as being associated with HCC in more than the intermediate stage.

Overall survival rates and $TsuV_{max}/LsuV_{mean}$ ratio

During follow-up, 31 of the 83 patients (37.3%) died. The median survival time was 416 d (range, 55-1221 d). The overall survival rates of patients exhibiting a low $TsuV_{max}/LsuV_{mean}$ ratio (< 1.90) and those with a high SUV ratio (≥ 1.90) was 38.2 mo and 10.3 mo, respectively. The survival curve is shown in Figure 3. The cumulative survival rates at 6 mo, 12 mo, and 24 mo were 91%, 88%, and 75% in patients with low SUV ratio and 63%, 42%, and 33% in those with high SUV ratio. The patients exhibiting a low SUV ratio (< 1.90) survived significantly longer than those with a high SUV ratio (≥ 1.90). In addition, tumor size ($P = 0.006$), number ($P < 0.001$), portal vein thrombosis ($P < 0.001$), AFP ($P = 0.016$) and BCLC stage ($P < 0.001$) were related to overall survival rates. In the multivariate analysis, the tumor-to-liver ratio of SUV significantly increased survival rate (Table 5). These results suggest that this ¹⁸F-FDG PET parameter was associated with survival in HCC patients.

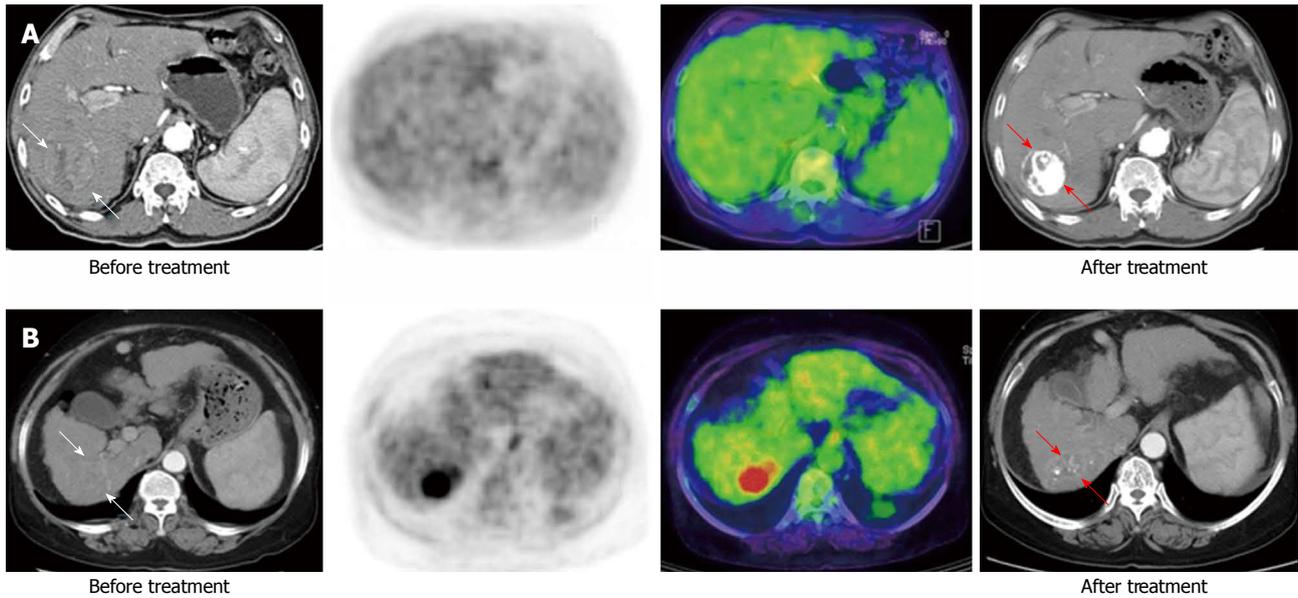

Figure 2 Baseline and follow-up images after treatment of fluorodeoxyglucose uptake according to the $Tsuv_{max}/Lsuv_{mean}$ ratio. A: Patient with nodular hepatocellular carcinoma (HCC) (white arrow) based on liver dynamic computed tomography (CT) showed fluorodeoxyglucose (FDG) uptake with a low $Tsuv_{max}/Lsuv_{mean}$ ratio (< 1.90) in ^{18}F -FDG positron emission tomography/CT. After transarterial chemo embolization, this patient showed compact lipiodol uptake (red arrow) on follow-up liver CT; B: Patient with infiltrative type HCC (white arrow) in liver dynamic CT showed FDG uptake with a high $Tsuv_{max}/Lsuv_{mean}$ ratio (≥ 1.90). This patient showed faint lipiodol uptake (red arrow) in a follow-up liver CT. The patient with a low standardized uptake value (SUV) ratio showed improved treatment response and survival over the patient with a high SUV ratio (complete response vs stable disease, 782 d vs 167 d, respectively).

Time to progression and $Tsuv_{max}/Lsuv_{mean}$ ratio

Progression of HCC after objective response was observed in 13 of 39 patients (32.5%) with a low $Tsuv_{max}/Lsuv_{mean}$ ratio (< 1.90) and 13 of 24 patients (56.5%) with a high SUV ratio (≥ 1.90). Although progression of low ratio patients was slower than that of high ratio patients, no significant difference was found between both groups (Figure 3B, $P = 0.15$).

DISCUSSION

^{18}F -FDG PET is an imaging modality that can be used to assess glucose metabolism of tumors. PET detects high ^{18}F -FDG uptake in rapidly growing tumors in which the rate of glycolysis increases^[8,16]. PET CT has been widely utilized for detection of extrahepatic metastasis from HCC^[5,17]. Recent quantitative studies of glucose utilization in liver tumors have shown that PET uptake is useful for tumor characterization and assessment of therapeutic response^[18-21]. ^{18}F -FDG uptake in HCC depends on the difference in the activity of glucose-6-phosphatase, which is responsible for the conversion of FDG-G-phosphate to FDG^[20]. Increased uptake of ^{18}F -FDG is associated with poorly differentiated HCC and poor outcome indi-

cating that ¹⁸F-FDG uptake in HCC is closely related to tumor progression and prognosis^[7].

The present study demonstrates that ¹⁸F-FDG PET is a feasible tool for assessing biological behavior in HCC. The increase of FDG uptake in HCC was significantly associated with tumor burdens such as size, number of tumors and portal vein thrombosis. Because these tumor burdens are regarded as predictive factors of the aggressiveness of HCC, glucose metabolism on ¹⁸F-FDG PET may be a factor that is related to the aggressive character of tumors. FDG uptake is increased in more advanced HCC stages. The results suggest that PET might be useful as a modality for assessing biologic activity in HCC.

This study focused on the predictive value of FDG PET uptake for evaluating the treatment response in HCC patients. Transarterial chemoembolization is the main treatment that is indicated for unresectable HCC in intermediate stage based on the BCLC guideline^[22,23], but there are limited data on managing these patients^[24-27]. Still, the homogeneity of the treatment modality was important for more reliable analysis. We previously reported promising results with combination treatment

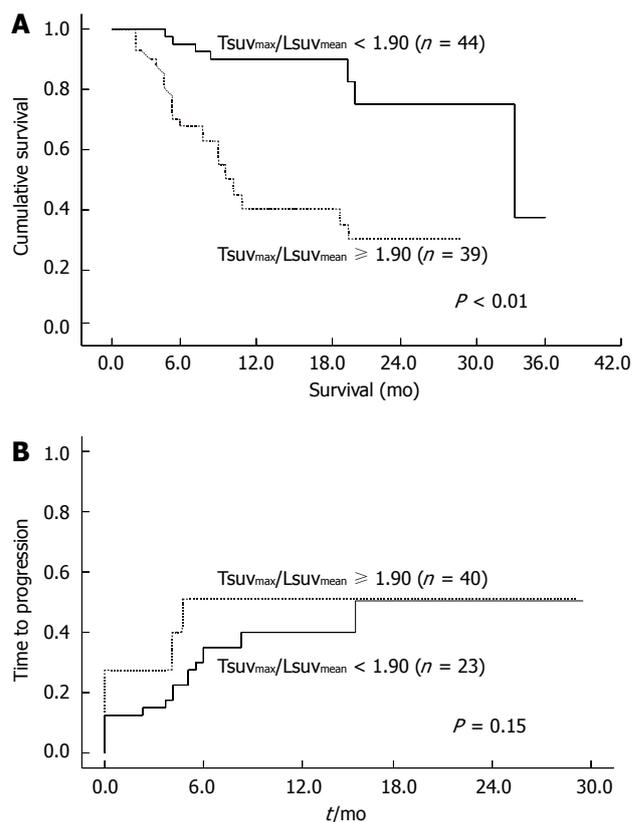

Figure 3 Overall survival and time to progression rates according to TsuV_{max}/LsuV_{mean} level. A: Patients exhibiting low TsuV_{max}/LsuV_{mean} (< 1.90) survived longer than those with high TsuV_{max}/LsuV_{mean} (≥ 1.90); B: No significant difference of progression was evident between patients exhibiting low TsuV_{max}/LsuV_{mean} and those with high TsuV_{max}/LsuV_{mean}. SUV: Standardized uptake value.

using TACL and systemic chemo-infusion therapy for advanced HCC with portal vein invasion^[12]. This combination therapy could be applied for treating advanced HCC. At this point, the present study determined the predictive factors for treatment response of the combination therapy in deciding on a management strategy for HCC. Tumor burdens such as tumor size and the reserved liver function have been previously reported to be predictive factors for treatment response^[24]. However, these factors are unable to exactly predict the degree of tumor malignancy, and there is a need for considering PET CT in assessing the biological activity of HCC as an additional predictive factor.

¹⁸F-FDG uptake showed the potential to predict the TACL with systemic chemo-infusion treatment response for HCC, with a cutoff TsuV_{max}/LsuV_{mean} value of 1.90. Objective response rates were significantly different above (77.7%) and below (23.6%) the cutoff value (P < 0.001). According to stage, the prediction of treatment response after three cycles of TACL was significantly better in the B and C stage than in the A stage (P = 0.048, P = 0.000, respectively). These facts demonstrate the predictive value for ¹⁸F-FDG uptake in HCC.

Presently, the SUV ratio correlated with treatment response suggesting that this ratio may be a useful index of HCC aggressiveness^[28-30]. Previous reports have dem-

onstrated comparative SUV ratio between tumors and non-tumors is a more useful parameter than the SUV of tumors^[28,31,32]. Because ¹⁸F-FDG uptake is affected by underlying liver cirrhosis, the ratio reflects more the underlying variation of glucose metabolism in the liver than SUV of tumor itself^[33,34]. This SUV ratio correlates with tumor volume doubling time and the differentiation of HCC^[5]. The tumor-to-non tumor ratio of SUV may be an effective parameter of progression or aggressiveness in HCC.

Furthermore, our principal finding is that the SUV ratio in FDG PET diagnosis before treatment is an independent predictor of survival in unresectable HCC patients. This finding is compatible with previous studies performed in other treatments such as LT and liver resection^[28,35]. In the univariate analysis, tumor size, portal vein thrombosis and BCLC stage were determined to be as significant as the $T_{suvmax}/L_{suvmean}$ ratio. The increase in FDG uptake ratio in HCC was significantly associated with the aggressive character of the tumor burden such as size, number of tumors and portal vein thrombosis. However, in the multivariate analysis, $T_{suvmax}/L_{suvmean}$ was a significant prognostic factor with BCLC stage. This result suggests the ratio of ¹⁸F-FDG uptake might provide additional information to staging system.

The BCLC staging system has been used to predict outcome and inform decision about treatment strategy in HCC^[36]. Although this system includes variables such as tumor burden and liver function reserve, according to Child-Pugh class and performance status, this stage does not adequately consider the biological activity of HCC. FDG-PET permits the evaluation of glucose metabolism in HCC and the detection of extrahepatic metastasis^[37]. The determination of the SUV ratio might contribute to the clinical management of HCC patients and compensate for the drawbacks of this staging system for the prediction of treatment response and prognosis in HCC.

This study has some limitations inherent to a retrospective study. First, the number of HCC cases for each stage was relatively small, although PET/CT was performed to detect extrahepatic metastasis and to evaluate the treatment response. Second, sorafenib is considered to be the standard treatment in advanced HCC. Sorafenib was not applicable in the advanced HCC cases in our study. However, we showed beneficial results with combination treatment using TACL and systemic chemo-infusion therapy for advanced HCC and the homogeneity of treatment would rather allow a more reliable analysis. We intended to analyze the correlation of tumor characteristics and treatment response according to ¹⁸F-FDG uptake. Prospective studies are needed to confirm these results in the future.

In summary, this study shows that ¹⁸F-FDG PET is a significant predictor of treatment response with TACL and systemic chemo-infusion therapy in HCC. The $T_{suvmax}/L_{suvmean}$, can be a significant way of distinguishing, overall survival. Therefore, ¹⁸F-FDG PET could provide effective information on the prognosis of the treatment response in the evaluation of HCC cases.

COMMENTS

Background

¹⁸F-fluorodeoxyglucose positron emission tomography (¹⁸F-FDG PET) is an imaging modality that can assess the glucose metabolism of tumors. PET monitoring of FDG uptake may be an additional tool to assess biological behavior of hepatocellular carcinoma (HCC). The present study evaluated the correlation of ¹⁸F-FDG PET with clinical features and prediction of treatment response.

Research frontiers

This study showed that the standardized uptake value ratio of FDG uptake could be used to predict the treatment response and overall survival of HCC patients treated with transarterial chemo embolization (TACE).

Innovations and breakthroughs

¹⁸F-FDG PET is a significant predictor of treatment response with transarterial chemolipiodolization (TACL) and systemic chemo-infusion therapy in HCC. The $T_{suvmax}/L_{suvmean}$ (cutoff value of 1.90) was significantly associated with overall survival of HCC patients.

Applications

The study results suggest that the FDG PET is a potential modality that could be used in predicting treatment prognosis for HCC patients treated with locoregional therapy.

Terminology

TACL refers to transarterial treatment with chemotherapeutic agents and lipiodol without embolic materials such as gelatin or polyvinyl alcohol particles. Systemic chemo-infusion is a type of systemic chemotherapy that is administered after TACE.

Peer review

In this study, the authors have studied the role of FDG PET in the evaluation of treatment response in patient undergoing the TACL procedure for treatment of HCC. Based on a retrospective review of 83 patients, the authors find that FDG PET can be used to predict the treatment response to HCC. This study is interesting and well performed, and the authors need to be lauded for their efforts. The findings of this study will definitely contribute to the scientific literature and improve our understanding of the biological behavior of HCC.

Abstract

AIM: To determine if the fraction of *Nardostachys jatamansi* (NJ) has the potential to ameliorate the severity of acute pancreatitis (AP).

METHODS: Mice were administered the biologically active fraction of NJ, i.e., the 4th fraction (NJ4), intraperitoneally, and then injected with the stable cholecystokinin analogue cerulein hourly for 6 h. Six hours after the last cerulein injection, the pancreas, lung, and blood were harvested for morphological examination,

measurement of cytokine expression, and examination of neutrophil infiltration.

RESULTS: NJ4 administration attenuated the severity of AP and lung injury associated with AP. It also reduced cytokine production and neutrophil infiltration and resulted in the *in vivo* up-regulation of heme oxygenase-1 (HO-1). Furthermore, NJ4 and its biologically active fraction, NJ4-2 inhibited the cerulein-induced death of acinar cells by inducing HO-1 in isolated pancreatic acinar cells.

CONCLUSION: These results suggest that NJ4 may be a candidate fraction offering protection in AP and NJ4 might ameliorate the severity of pancreatitis by inducing HO-1 expression.

INTRODUCTION

Acute pancreatitis (AP) refers to inflammation of the pancreas and is caused by an imbalance in the factors that maintain cellular homeostasis^[1]. AP could lead to distant

organ damage and multiple organ dysfunction, the primary cause of morbidity and mortality in this condition^[2]. The AP cascade is complex. An unknown trigger within the pancreas converts digestive pro-enzymes into their active form, initiating auto-digestion of the gland, causing necrosis, edema, and destruction of the pancreatic parenchyma^[2].

Nardostachys jatamansi (NJ) is widely used in several Asian countries to treat mental disorders, insomnia, and disorders of the circulatory system^[3]. It has protective effects against diabetes and sepsis^[4,5]. We have previously reported that NJ protects against cerulein-induced AP^[6]. Further, several studies have reported on the protective effects afforded by compounds from NJ^[3,7] such as jatamansic acid and nardosinone. However, the compound in NJ that protects against AP remains to be identified.

This study aimed to identify the candidate fraction of NJ that protects against cerulein-induced AP in a mouse model. To achieve this, we fractionated NJ by using RP C-18 column chromatography and the 4th fraction (NJ4) showed more potent effects than the aqueous extract of NJ. Our results suggest that NJ4 may be a candidate fraction for reducing the severity of AP.

MATERIALS AND METHODS

Materials

Avidin peroxidase and 3,3',5,5'-tetramethylbenzidine (TMB), cerulein, Tris-HCl, NaCl, Triton X-100, curcumin, ZnPP, and hexadecyltrimethyl ammonium bromide were purchased from Sigma-Aldrich (St. Louis, MO). Anti-mouse interleukin (IL)-1 β , IL-6, and tumor necrosis factor (TNF)- α antibodies and recombinant IL-1 β , IL-6, and TNF- α were purchased from R and D Systems (Minneapolis). Phosphospecific mitogen-activated protein kinases (MAPKs), extracellular signal-regulated kinases (ERK)1/2, c-Jun NH₂-terminal kinases (JNK), and p38 were purchased from Cell Signaling Technology (Beverly, MA). ERK1/2, JNK, p38, inhibitory kappa-B α heme oxygenase-1 (HO-1), and β -actin were purchased from Santa Cruz Biotechnology (Santa Cruz, CA).

Plant materials

The roots of NJ were purchased from a standard commercial source (Omni Herb, Seoul, South Korea). The herb's identity was confirmed at Wonkwang University. Voucher specimens were deposited at the College of Oriental Medicine Herbarium of Wonkwang University. The NJ roots were prepared by decocting the dried prescription of herbs (100 g) with boiling distilled water (1 L). The decoction time was approximately 2 h. The water extract was frozen at -80 °C and then freeze-dried to be powdered (7.35 g, 7.35 w/w%).

Preparation of NJ4 fraction

The water extract (3.8 g) was subjected to octadecyl functionalized silica gel flash column (5 cm \times 20 cm; 63-200 μ m particle size) chromatography (Figure 1). The

column was eluted with a stepwise gradient with 500 mL aliquots of MeOH in H₂O (starting from 10% and followed by 20%, up to 100% at 20% increments), affording 6 fractions (NJ1: 1.24 g; NJ2: 79.1 mg; NJ3: 490.7 mg; NJ4: 416.2 mg; NJ5: 273.1 mg; NJ6: 67.8 mg). NJ4 (60% MeOH) in saline was used as the main fraction (Figure 1).

Preparation of NJ4 fraction

A portion (9.0 mg) of the fraction eluted with 60% MeOH in H₂O (NJ4-2) was then purified by semi-preparative reversed-phase high-performance liquid chromatography (HPLC) [Shiseido Capcell Pak C₁₈ column (10 mm \times 250 mm; 5 μ m particle size); 2 mL/min; detection at 254 nm] eluting with a gradient from 40% to 70% MeOH in H₂O (0.1% formic acid) over 30 min to yield NJ4-2 (3.0 mg, *t_R* = 28.0 min) (Figure 1).

HPLC sample preparation and HPLC conditions

For HPLC analysis, the chromatographic system consisted of a pump (3000 HPLC pump; Dionex Association, United States), a ultraviolet detector (Photodiode array detector; Dionex Association), and an autosampler (Waters Association, United States). A hydrosphere C₁₈ column (4.6 mm \times 250 mm, 5 μ m) was used. Water-methanol glacial (50:50) was used as the mobile phase. Detection of the peaks was made at 254 nm and the sensitivity was set at 0.5 absorbance units full scales. The injection volume was 10 μ L and the flow rate was 1.0 mL/min. A standard solution was prepared by dissolving in distilled methanol (10 μ g/10 mL). The solution was filtered through a 0.45 μ m membrane filter and applied to HPLC (Figure 2).

Animals

Protocols approved by the Animal Care Committee of Wonkwang University were used for all experiments. Female 6- to 8-wk-old C57BL/6 mice weighing 15-20 g were purchased from Orient Bio (Sungnam, KyungKiDo, South Korea). All animals were bred and housed in standard shoebox cages in a climate-controlled room with an ambient temperature of 23 \pm 2 °C under a 12-h light-dark cycle for 7 d. The animals were fed standard laboratory chow, allowed water *ad libitum*, and randomly assigned to control or experimental groups. The mice were fasted for 18 h before AP was induced.

Experimental design

AP was induced by intraperitoneal injections of supra-maximal concentrations of the stable cholecystokinin analogue cerulein (50 μ g/kg) or saline, hourly for 6 h^[6]. Prior to injecting the NJ4 treatment group with cerulein, NJ4 (1 μ g/kg, 5 μ g/kg, or 10 μ g/kg, *n* = 6) or saline (control group, *n* = 6) were intraperitoneally administered (1 h before the first cerulein injection). Mice were killed 6 h after the last cerulein injection was administered. Blood samples were taken to determine serum amylase, lipase, and cytokine levels. For histological examination and scoring, the entire pancreas and lungs were rapidly re-

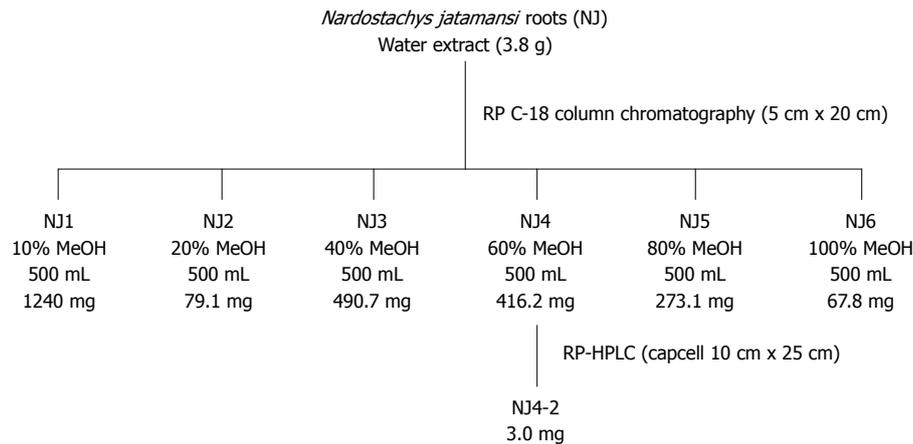

Figure 1 Fractionation of the aqueous extract of *Nardostachys jatamansi*. NJ: *Nardostachys jatamansi*; HPLC: High-performance liquid chromatography.

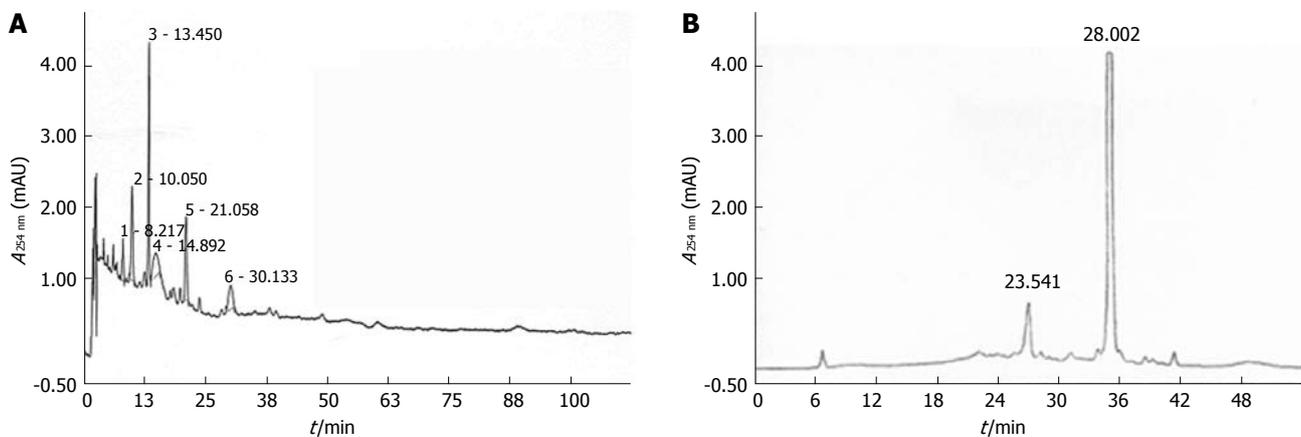

Figure 2 High-performance liquid chromatography findings of the aqueous extract of *Nardostachys jatamansi* (A) and the 4th fraction of *Nardostachys jatamansi* (B).

moved from each mouse and fixed in formalin. To measure tissue myeloperoxidase (MPO) activity, an indicator of neutrophil sequestration, and for real-time reverse transcriptase polymerase chain reaction (RT-PCR) studies, the pancreas and lungs were stored at -80°C .

Histological analysis

The pancreases from each treatment group were examined and semi-quantitatively described in terms of necrosis, vacuolization, inflammation, and edema. A tissue section representing a minimum of 100 fields was examined for each sample and scored on a scale of 0-3 (0 being normal and 3 being severe disease) on the basis of the number of necrotic acinar cells and the presence of interstitial edema and interstitial inflammation.

Measurement of serum amylase and lipase

Blood samples to determine serum amylase and lipase were obtained 6 h after inducing pancreatitis. Mice were anesthetized with an intraperitoneal injection of ketamine (80 mg/kg) and xylazine (4 mg/kg). After anesthetization, blood was withdrawn from the heart of each mouse into a syringe. Serum amylase and lipase were measured using an assay kit from BioAssay Systems (CA).

Enzyme-linked immunosorbent assay

Enzyme-linked immunosorbent assay (ELISA) for IL-1 β , IL-6, and TNF- α were carried out in duplicate in 96-well plates coated with 100 μL aliquots of anti-mouse IL-1 β , IL-6, and TNF- α monoclonal antibodies in phosphate buffered saline (PBS) at pH 7.4 during an overnight incubation at 4°C . The plates were washed in PBS containing 0.05% Tween-20 and blocked with PBS containing 10% FBS for 2 h. After additional washes, standards and samples were added and incubated at room temperature for 2 h. Subsequently, the wells were washed, and biotinylated anti-mouse IL-1 β , IL-6, and TNF- α were added and incubated at room temperature for 1 h. The wells were washed, avidin-peroxidase was added, and the plates were incubated for 30 min at room temperature before washing again and adding the TMB substrate. Color development was measured at 450 nm by using an automated microplate ELISA reader. Standard samples were run on each assay plate using serial dilutions of recombinant IL-1 β , IL-6, and TNF- α .

Messenger RNA expression

Transcription of target cytokines in mouse pancreatic tissues and acini was analyzed using RT-PCR. Total RNA was isolated from the mouse pancreas using TriZol (In-

vitrogen, Carlsbad, CA) and subjected to reverse transcription using SuperScript II RT (Invitrogen). TaqMan quantitative RT-PCR using the LightCycler 2.0 detection system was performed according to the manufacturer's instructions (Roche, Basel, Switzerland). For each sample, triplicate test reactions and a control reaction lacking reverse transcriptase were analyzed for the expression of the gene of interest, and the results were normalized to those of "housekeeping" hypoxanthine-guanine phosphoribosyltransferase (HPRT) mRNA. Arbitrary expression units were calculated by dividing the expression of the gene of interest by ribosomal protein HPRT mRNA expression. The sequences of forward, reverse, and probe oligonucleotide primers for multiplex real-time TaqMan PCR were as follows: for mouse IL-1 β (forward, 5'-TTG ACG GAC CCC AAA AGA T-3'; reverse, 5'-GAA GCT GGA TGC TCT CAT CTG-3'; universal probe, M15131.1, Roche Applied Science), for mouse IL-6 (forward, 5'-TTC ATT CTC TTT GCT CTT GAA TTA GA-3'; reverse, 5'-GTC TGA CCT TTA GCT TCA AAT CCT-3'; universal probe, M20572.1, Roche Applied Science), and for mouse TNF- α (forward, 5'-TCT CTT CAA GGG ACA AGG CTG-3'; reverse, 5'-ATA GCA AAT CGG CTG ACG GT-3'; probe, 5'-CCC GAC TAC GTG CTC CTC ACC CA-3'). For mouse HO-1, we purchased a custom primer from Applied Biosystems (CA).

MPO estimation

Neutrophil sequestration in the pancreas was quantified by measuring tissue MPO activity. Tissue samples were thawed, homogenized in 20 mmol/L phosphate buffer (pH 7.4), and centrifuged (13 000 rpm, 10 min, 4 °C). The pellet was resuspended in 50 mmol/L phosphate buffer (pH 6.0) containing 0.5% hexadecyltrimethylammonium bromide (Sigma-Aldrich). The suspension was subjected to 4 cycles of freezing and thawing and further disrupted by sonication for 40 s. The sample was then centrifuged (13 000 rpm, 5 min, 4 °C), and the supernatant was used for the MPO assay. The reaction mixture consisted of the supernatant, 1.6 mmol/L TMB, 80 mmol/L sodium phosphate buffer (pH 5.4), and 0.3 mmol/L hydrogen peroxide. This mixture was incubated at 37 °C for 110 s, the reaction was terminated with 2 mol/L H₂SO₄, and the absorbance was measured at 450 nm.

Western blotting

Pancreatic tissues and pancreatic acini were homogenized, following which the lysates were boiled in a sample buffer (62.5 mmol/L Tris-HCl, pH 6.8, 2% sodium dodecyl sulfate (SDS), 20% glycerol, and 10% 2-mercaptoethanol). Proteins in the cell lysates were then separated using 10% SDS-polyacrylamide gel electrophoresis and transferred to a nitrocellulose membrane. Then, the membrane was blocked with 5% skim milk in PBS-Tween-20 for 2 h at RT and then incubated with primary antibodies overnight. After washing 3 times, each blot was incubated with peroxidase-conjugated secondary antibody for 1 h, and antibody-specific proteins were visualized using an

enhanced chemiluminescence detection system (Amersham, Piscataway, NJ) according to the manufacturer's recommended protocol.

Acinar cell isolation

Pancreatic acini were isolated from C57BL/6 mice using collagenase digestion. All experiments were performed according to protocols approved by the Animal Care Committee of Wonkwang University. Briefly, pancreatic tissue was minced with scissors and digested for 15 min in solution Q (120 mmol/L NaCl, 20 mmol/L HEPES, 5 mmol/L KCl, 1 mmol/L MgCl₂, 1 mmol/L CaCl₂, 10 mmol/L sodium pyruvate, 10 mmol/L ascorbate, 10 mmol/L glucose, 0.1% BSA, 0.01% soybean trypsinogen inhibitor, and 150 units of collagenase/mL). Cells were continuously shaken and gassed with 100% O₂ in a 37 °C water bath and subsequently washed in fresh isolation medium. After collagenase digestion, the tissue was gently pipetted. Dispersed acini were filtered through a 150- μ m nylon mesh, centrifuged 3 times (each for 90 s at 720 rpm), resuspended in Waymouth medium (Invitrogen, Gibco, CA) and incubated with 95% O₂ and 5% CO₂ for 4 h.

Cell viability assay

Cell viability was assayed using a modified colorimetric technique that is based on the ability of live cells to convert the tetrazolium compound 3-(4,5-dimethylthiazol)-2,5-diphenyltetrazolium bromide (MTT) into purple formazan crystals. MTT (5 mg/mL) was dissolved in Krebs-Henseleit buffer (115 mmol/L NaCl, 3.6 mmol/L KCl, 1.3 mmol/L KH₂PO₄, 25 mmol/L NaHCO₃, 1 mol/L CaCl₂, and 1 mol/L MgCl₂), and 50 μ L was added to each well. After incubating for 30 min at 37 °C, the suspension was removed, and the formazan crystals formed were dissolved in 200 μ L dimethyl sulfoxide. Aliquots from each well were seeded in the wells of a 96-well plate in duplicate and assayed at 540 nm using a microplate ELISA reader. The number of viable cells was expressed as a percentage of the control.

Statistical analysis

Results were expressed as means \pm SE. The significance of differences was evaluated using a two-way analysis of variance (ANOVA) with time and dose parameters. Differences between the experimental groups were evaluated using ANOVA. *P* values < 0.05 were considered statistically significant.

RESULTS

Effect of NJ4 on cerulein-induced AP

To examine the effect of NJ4 on the development and severity of AP, mice pretreated with saline or NJ4 were injected intraperitoneally with a supramaximal dose (50 μ g/kg) of cerulein. Intraperitoneal injection of cerulein resulted in significant pancreatic parenchyma destruction, inflammation, edema, and necrosis. However, NJ4-treated

Histological sections of the lung were scored from 0 (normal) to 3 (severe) for inflammation, and edema. ^a*P* < 0.05 vs the saline treatment; ^c*P* < 0.05 vs cerulein treatment alone. AP: Acute pancreatitis; NJ: *Nardostachys jatamansi*.

mice showed reductions in damage of the pancreas and severity of AP (Table 1 and Figure 3A). As an additional assessment of the severity of the inflammatory response, we measured MPO activity, which is an indicator of neutrophil infiltration in the pancreas. Cerulein-induced MPO activity in the pancreas of NJ-treated mice was lower than that in the pancreas of saline-injected mice (Figure 3B).

Effect of NJ4 on lung injury associated with AP

Acute lung injury in AP still represents a substantial problem, with a mortality rate in the range of 30%-40%^[8]. The cytokines and inflammatory mediators from pancreatic acini regulate the migration and pulmonary infiltration of neutrophils to the interstitial tissue, where they cause injury and breakdown of pulmonary parenchyma^[9]. As shown in Figure 4, cerulein injection resulted in lung injury, which is characterized by destruction of the lung parenchyma, edema, and inflammatory cell infiltration. However, NJ4 treatment reduced lung damage, inflammation, and edema and inhibited MPO activity in the lung in cerulein-induced AP (Table 2 and Figure 4A and B).

Effect of NJ4 on pancreatic weight/body weight ratio and serum digestive enzymes in cerulein-induced AP

In order to assess the effect of NJ4 on pancreatic edema, the pancreatic weight/body weight (PW/BW) was measured. As shown in Figure 5A, NJ4 administration inhibited the PW/BW ratio in a dose-dependent manner during cerulein-induced AP. When acinar cells are challenged with inflammatory responses, pro-enzymes in the pan-

creatic zymogen are converted to active enzymes such as amylase and lipase. Therefore, serum amylase and lipase

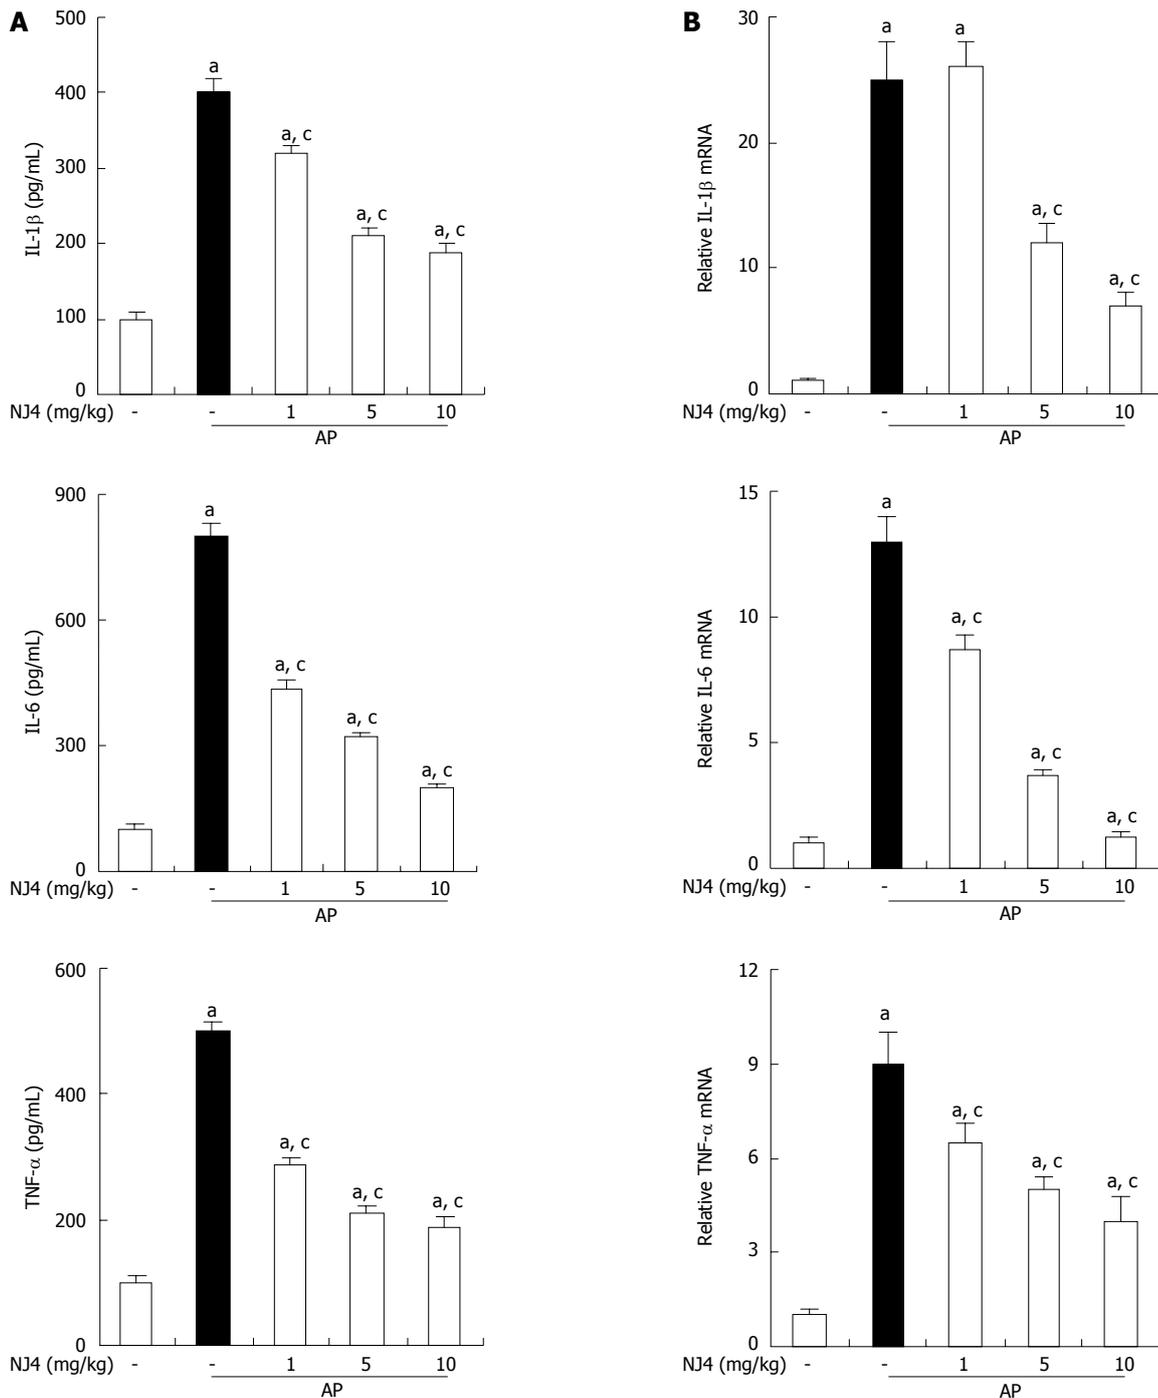

Figure 6 Effects of the 4th fraction of *Nardostachys jatamansi* on interleukin 1, interleukin 6, and tumor necrosis factor during cerulein-induced pancreatitis. Mice pretreated with *Nardostachys jatamansi* (NJ) were challenged with intraperitoneal injections of cerulein at a supramaximal dose (50 μg/kg). Mice were killed at 6 h after the last cerulein injection. Levels of serum cytokines were measured by enzyme-linked immunosorbent assay (A). Levels of pancreatic mRNA for interleukin (IL)-1, IL-6, and tumor necrosis factor (TNF)-α were quantified using real-time reverse transcriptase polymerase chain reaction (B). Data show the mean ± SE for 6 mice in 1 group. The results were similar in 3 additional experiments. ^a*P* < 0.05 vs the saline treatment; ^c*P* < 0.05 vs cerulein treatment alone. AP: Acute pancreatitis.

activity were used to assess the severity of AP. The activities of amylase and lipase were up-regulated by cerulein injection. However, these activities were inhibited by NJ4 treatment (Figure 5B and C).

Effect of NJ4 on pro-inflammatory cytokine production

Several inflammatory mediators such as ILs and TNFs have been shown to increase in AP^[10]. Therefore, the levels of cytokines were examined in the serum and pan-

creas. Substantial increases in IL-1β, IL-6, and TNF-α were found in the serum and pancreas at 6 h after the final administration of cerulein. However, the levels of IL-1β, IL-6, and TNF-α in the serum and pancreas were significantly reduced with NJ4 treatment (Figure 6A and B).

Effect of NJ4 on in vivo HO-1 induction

To evaluate the protective mechanisms of NJ4, we determined the levels of HO-1, which exhibits certain bio-

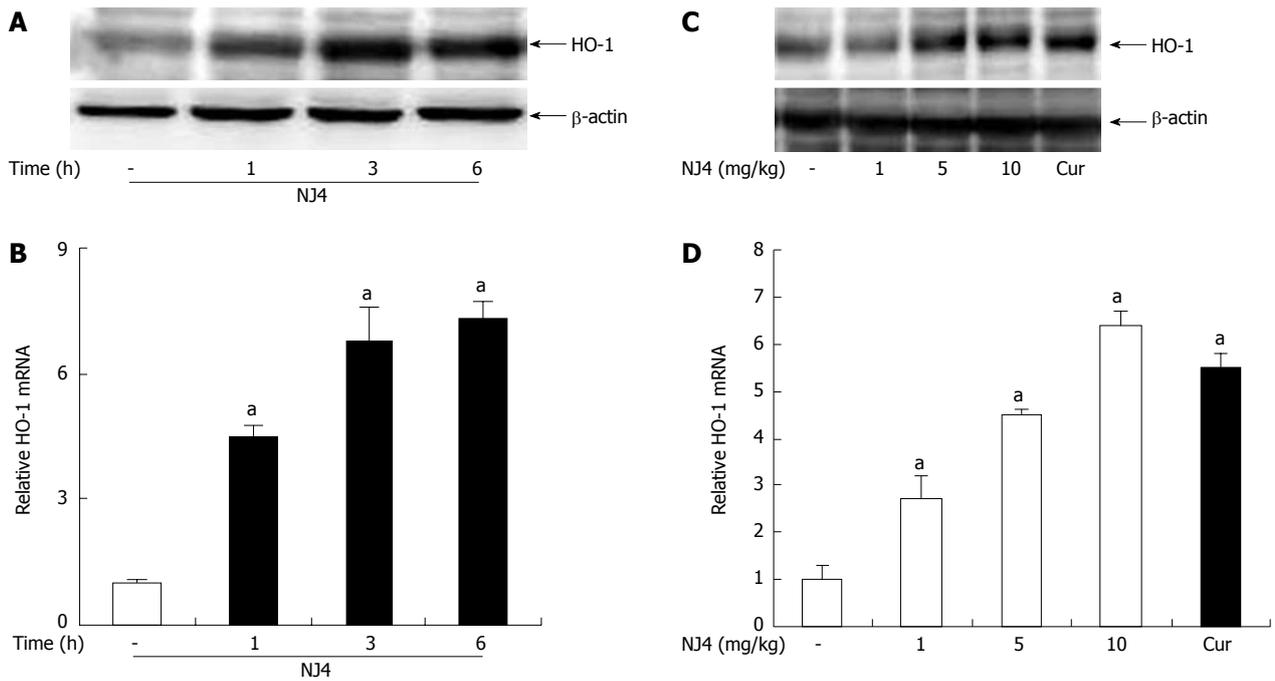

Figure 7 Effects of the 4th fraction of *Nardostachys jatamansi* on heme oxygenase-1 expression in the pancreas. Mice were treated with saline, or *Nardostachys jatamansi* (NJ) (10 mg/kg). Then, the pancreas was harvested at the indicated time. A: The protein level of heme oxygenase-1 (HO-1) in the pancreas was measured using Western blotting. β -actin was used as the loading control; B: The mRNA expression of HO-1 was measured using real-time reverse transcriptase polymerase chain reaction (RT-PCR). Mice were treated with the indicated dose of NJ4. At 6 h after NJ4 injection, the pancreas was harvested; C: The protein level of HO-1 in the pancreas was measured using Western blotting. β -actin was used as the loading control; D: The mRNA expression of HO-1 was measured using real-time RT-PCR. The results were similar in 3 additional experiments. ^a $P < 0.05$ vs the saline treatment. Cur: Curcumin.

logical properties, including anti-inflammatory^[11,12] and antioxidant^[13,14] properties. Therefore, NJ4 (10 mg/kg) was administered intraperitoneally at the indicated time point. Administration of NJ4 was followed by significant up-regulation of pancreatic HO-1 after 1 h (Figure 7A and B). Pancreatic HO-1 induction also occurred in a dose-dependent manner at 6 h after the injection of NJ4 (Figure 7C). Curcumin, an HO-1 inducer, was loaded as the positive control. The pancreatic mRNA levels of HO-1 were correlated with the pancreatic protein levels of HO-1 (Figure 7D).

Effect of NJ4 on in vitro HO-1 induction and acinar cell death

To examine the effect of NJ4 on HO-1 expression in isolated pancreatic acinar cells, HO-1 expression was measured. As shown in Figure 8A and B, NJ4 treatment increased the HO-1 expression after 1 h, but significantly at 3 h. The expression was increased in time dependant manner. HO-1 induction in pancreatic acinar cells occurred in a dose-dependent manner at 6 h after NJ4 treatment (Figure 8C and D).

AP is characterized by acinar cell death in the pancreas. Therefore, we examined the effect of NJ4 on pancreatic acinar cell death. The cells were pretreated with NJ4 for 1 h and then stimulated with cerulein for 6 h. NJ4 significantly increased the viability of pancreatic acinar cells in a dose-dependent manner (Figure 8E). We also investigated whether NJ4 could regulate cerulein-induced acinar cell death through the induction of HO-1. The HO-1

inhibitor ZnPP inhibited the effect of NJ4 on cerulein-induced acinar cells (Figure 8F). Furthermore, the HO-1 inducer curcumin also inhibited cerulein-induced acinar cell death (Figure 8F).

Effect of NJ4-2 on in vitro acinar cell death

To examine the effect of NJ4-2 on HO-1 expression in isolated pancreatic acinar cells, HO-1 expression was measured. As shown in Figure 9A and B, NJ4-2 treatment increased the HO-1 expression after 1 h. The expression was increased in time dependant manner. HO-1 induction in pancreatic acinar cells occurred in a dose-dependent manner at 6 h after NJ4-2 treatment (Figure 9C and D).

The cells were pretreated with NJ4-2 for 1 h and then stimulated with cerulein for 6 h. NJ4-2 significantly increased the viability of pancreatic acinar cells in a dose-dependent manner (Figure 9E).

DISCUSSION

Various studies have investigated candidates that could treat AP^[6,15-18]. However, specific and effective candidates to treat AP remain unknown. Our previous report showed that the total extract of NJ reduces the severity of mild acute pancreatitis^[6]. In this study, we report that the biological main fraction of NJ, i.e., NJ4, has a protective effect against cerulein-induced AP. To identify the fraction responsible for the main effect of NJ, we fractionated NJ and obtained 6 fractions. The effects of the 6

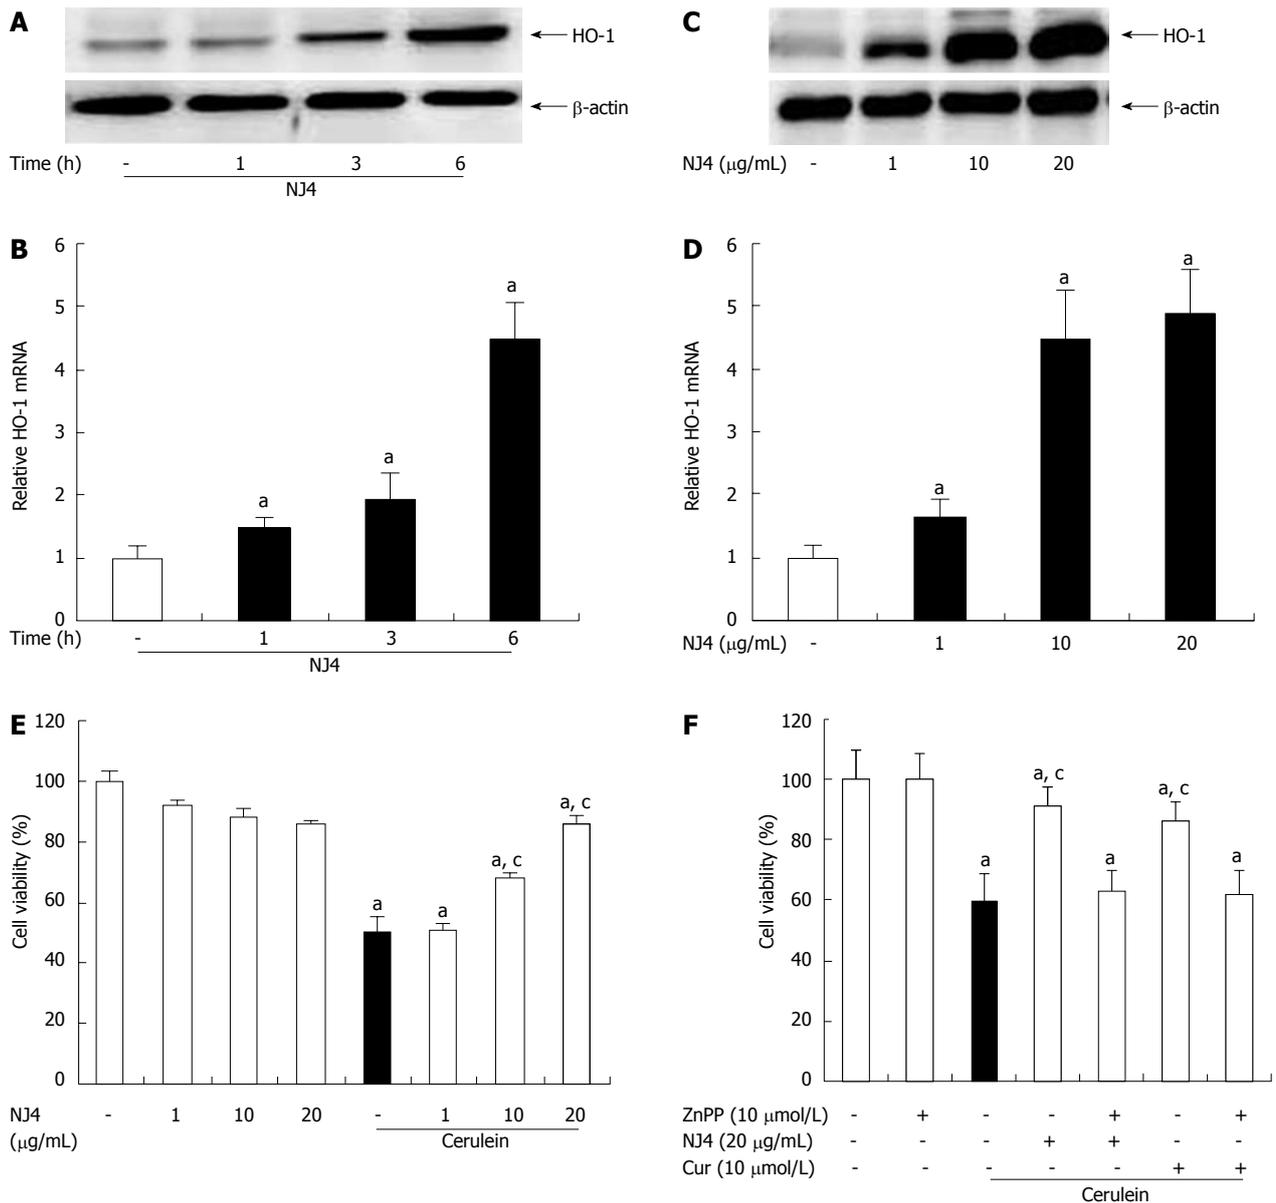

Figure 8 Effects of the 4th fraction of *Nardostachys jatamansi* on heme oxygenase-1 expression in acinar cells and cerulein-induced acinar cell death. Pancreatic acinar cells were pretreated with *Nardostachys jatamansi* (NJ) (20 $\mu\text{g/mL}$), and then the cells were harvested at the indicated time. A, B: The protein level (A) and mRNA level (B) of heme oxygenase-1 (HO-1) in pancreatic acini were measured. Pancreatic acinar cells were pretreated with the indicated dose of NJ4. Then, the cells were harvested at 6 h; C, D: The protein level (C) and mRNA level (D) of HO-1 in the pancreatic acini were detected. The pancreatic acinar cells were pretreated with the indicated dose of NJ4 and then stimulated with cerulein (10 nmol/L); E: After 6 h of cerulein stimulation, cell viability was measured as described in the experimental protocol. Pancreatic acinar cells were pretreated with ZnPP (10 $\mu\text{mol/L}$), an HO-1 inhibitor, for 1 h and then treated with NJ4 (20 $\mu\text{g/mL}$), curcumin (10 $\mu\text{mol/L}$); F: At 1 h after treatment, cerulein (10 nmol/L) was added; After 6 h of cerulein stimulation, cell viability was measured. The results were similar in 3 additional experiments. ^a $P < 0.05$ vs the saline treatment; ^c $P < 0.05$ vs cerulein treatment alone. Cur: Curcumin.

fractions on lipopolysaccharide (LPS)-induced inflammatory responses were examined in peritoneal macrophages. NJ4 significantly inhibited the LPS-induced production of inflammatory mediators such as nitric oxide (NO), IL-1, IL-6, and TNF- α (unpublished data). Therefore, NJ4 was chosen to examine its effect on pancreatitis. Also among the 3 fractions from NJ4, NJ4-2 inhibited the inflammatory mediators significantly. Thus, we also choose NJ4-2 as NJ4's candidate. NJ4 ameliorated the severity of AP and AP associated with lung injury and inhibited neutrophil infiltration, digestive enzymes, and cytokines. NJ4 also increased cell viability against cerulein

challenge. In the present study, we showed that the effect of NJ4 on pancreatitis was comparable with the effect of the total aqueous extract of NJ.

AP remains a challenging clinical problem in which mortality is significantly increased depending on its severity^[19]. Despite a few clinical trials with pharmacological agents, no effective treatment exists for AP. AP is commonly caused by excessive alcohol consumption, biliary tract disease, hereditary factors, certain medications, and invasive procedures of the biliary and pancreatic ducts^[20-23]. In this experiment, we used a well-established murine model. Mice with AP showed destruction in acinar

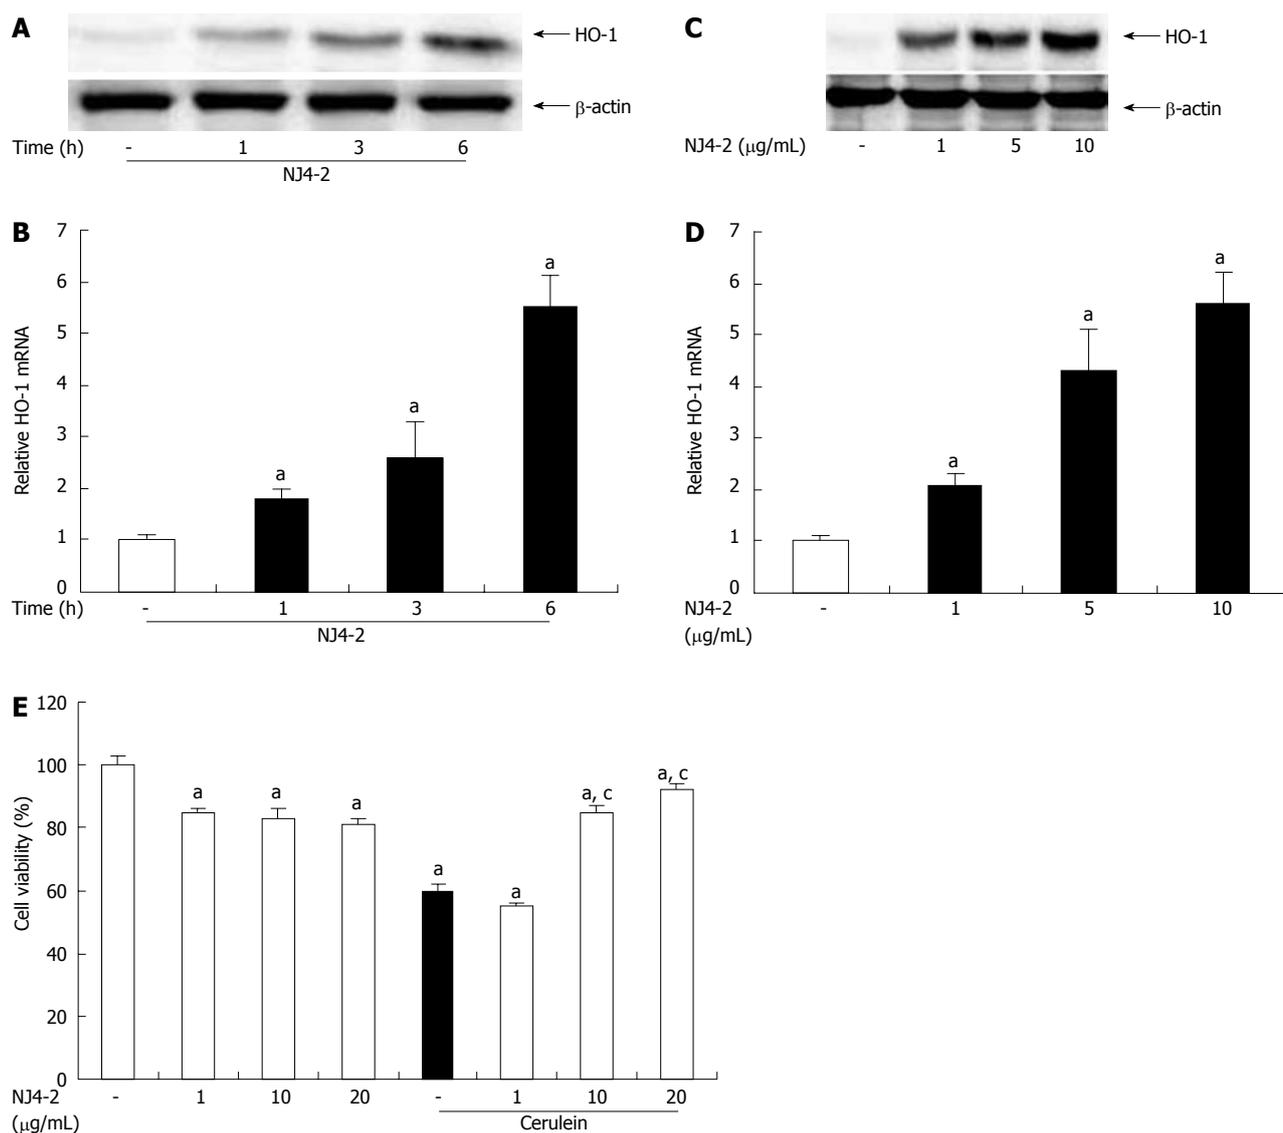

Figure 9 Effects of *Nardostachys jatamansi*-2 on heme oxygenase-1 expression in acinar cells and cerulein-induced acinar cell death. Pancreatic acinar cells were pretreated with *Nardostachys jatamansi* (NJ4)-2 (10 μg/mL), and then the cells were harvested at the indicated time. A, B: The protein level (A) and mRNA level (B) of heme oxygenase-1 (HO-1) in pancreatic acini were measured. Pancreatic acinar cells were pretreated with the indicated dose of NJ4-2; C, D: Then, the cells were harvested at 6 h, the protein level (C) and mRNA level (D) of HO-1 in the pancreatic acini were detected. The pancreatic acinar cells were pretreated with the indicated dose of NJ4 and then stimulated with cerulein (10 nmol/L); E: After 6 h of cerulein stimulation, cell viability was measured as described in the experimental protocol. The results were similar in 3 additional experiments. ^a*P* < 0.05 vs the saline treatment; ^c*P* < 0.05 vs cerulein treatment alone.

cell structure and increased neutrophil infiltration. The NJ4-pretreated mice with AP showed reduced acinar cell destruction and neutrophil infiltration (Figure 3).

The mortality rate in AP is approximately 20%-30%, and the major cause of AP-induced death is acute lung injury, referred to as acute respiratory distress syndrome. After cytokines, or the digestive enzymes from the pancreas, attack the lung alveolar cells, inflammation and vascular injury occurs in the lung^[8]. Cells that have infiltrated the pulmonary tissues cause breakdown of the pulmonary parenchyma^[24]. This lung attack is particularly damaging in the elderly, and if they survive an attack, their quality of life is impaired^[25-27]. Therefore, it is important to protect against lung injury caused by AP. In the present study, we showed that NJ4 treatment reduces lung injury and inflammation in AP (Figure 4).

Experimental pancreatitis models and pancreatitis patients showed increased IL and TNF-α levels^[28-30]. IL-1β, IL-6, and TNF-α play a pivotal role in AP, acting early in the disease course in addition to transitioning the acute inflammatory response to a chronic response^[31,32]. We have previously reported that the total aqueous extract of NJ could inhibit cytokine production in mice with AP and LPS-induced cytokine production in macrophages^[5,6]. Similar to the total aqueous extract of NJ, NJ4 inhibited serum and pancreatic cytokine production in mice with AP.

HO-1 is a stress-inducible enzyme, whereas its isoform HO-2 is constitutively expressed^[33]. HO-1 catabolizes heme into a free iron, carbon monoxide, and bilirubin/biliverdin^[34]. Studies have shown that HO-1 has protective and anti-inflammatory effects on AP^[35,36]. In the above

experiment, the administration of HO-1 inducers resulted in significant induction of HO-1 in a specific target organ, the pancreas, and reduction in pro-inflammatory cytokines, a major factor in AP regulation. We have already reported that the protective mechanism of the total water extract of NJ on AP involves the inhibition of MAPKs. Similarly, NJ4 inhibited the activation of MAPKs, but the inhibition was not significant (data not shown). Therefore, we hypothesize that the main protective mechanism of NJ4 is *via* HO-1 upregulation. HO-1 was up-regulated 1 h after NJ4 injection, and the upregulation was dose-dependent. The HO-1 up-regulation by NJ4 was comparable with that observed with curcumin. Furthermore, NJ4 induced expression of HO-1 in isolated pancreatic acinar cells at 3 h significantly; this finding is different from that of the *in vivo* experiment. In the *in vivo* experiment, NJ4 induced pancreatic HO-1 expression at 1 h significantly; however, in the *in vitro* experiment, NJ4 treatment led to the significant up-regulation of HO-1 at 3 h. We speculate that differences in metabolism between tissues and cells might be the reason for the difference in the expression time of HO-1 in the *in vivo* and *in vitro* experiments.

In this study, we suggest and evaluate the possible protective effect of NJ4 against AP. NJ4 treatment attenuated the severity of AP and lung injury associated with AP *via* the up-regulation of HO-1. The biological fraction of the total aqueous extract of NJ (NJ4) showed similar effects to those obtained with the total extract, which means that NJ4 might contain a compound useful for treating AP. Further fractionation and analyses are needed to identify this novel compound from NJ4.

COMMENTS

Background

Acute pancreatitis (AP) is a serious, unpredictable clinical problem, whose pathophysiology remains poorly understood. Therefore, drugs and therapies need to be developed.

Research frontiers

The paper previously reported that the total water extract of *Nardostachys jatamansi* (NJ) could protect against AP. This study aimed to determine if the fraction of NJ has the potential to ameliorate the severity of AP.

Innovations and breakthroughs

Nowadays, the treatment of acute pancreatitis is limited to protease inhibitors, and the pathogenesis is not well-understood. In this paper, the authors studied a possible candidate to develop as drug treatment for acute pancreatitis, in line with the previous report. Also the authors provided the regulating mechanisms in AP. This finding could strengthen up further studies of acute pancreatitis.

Applications

The papers, here, firstly provided the possible candidate of NJ. These results could provide the clinical basis for development of a drug or compound to treat acute pancreatitis.

Terminology

Acute pancreatitis: a sudden inflammation of the pancreas. It can have severe complications and high mortality despite treatment. While mild cases are often successfully treated with conservative measures and aggressive intravenous fluid rehydration, severe cases may require admission to the intensive care unit or even surgery to deal with complications of the disease process.

Peer review

This submission shows interesting results.

Abstract

AIM: To investigate the cellular mechanisms of action of Yiguanjian (YGJ) decoction in treatment of chronic hepatic injury.

METHODS: One group of mice was irradiated, and received enhanced green fluorescent protein (EGFP)-positive bone marrow transplants followed by 13 wk of CCl₄ injection and 6 wk of oral YGJ administration. A second group of Institute for Cancer Research mice was treated with 13 wk of CCl₄ injection and 6 wk of oral YGJ

administration. Liver function, histological changes in the liver, and Hyp content were analyzed. The expression of α -smooth muscle actin (α -SMA), F4/80, albumin (Alb), EGFP, mitogen-activated protein kinase-2 (PKM2), Ki-67, α fetoprotein (AFP), monocyte chemotaxis protein-1 and CC chemokine receptor 2 were assayed.

RESULTS: As hepatic damage progressed, EGFP-positive marrow cells migrated into the liver and were mainly distributed along the fibrous septa. They showed a conspicuous coexpression of EGFP with α -SMA and F4/80 but no coexpression with Alb. Moreover, the expression of PKM2, AFP and Ki-67 was enhanced dynamically and steadily over the course of liver injury. YGJ abrogated the increases in the number of bone marrow-derived fibrogenic cells in the liver, inhibited expression of both progenitor and mature hepatocyte markers, and reduced fibrogenesis.

CONCLUSION: YGJ decoction improves liver fibrosis by inhibiting the migration of bone marrow cells into the liver as well as inhibiting their differentiation and suppressing the proliferation of both progenitors and hepatocytes in the injured liver.

INTRODUCTION

Yiguanjian (YGJ) decoction, containing 6 herbs: *radices glehniae*, *radices ophiopogonis*, *radix angelicae sinensis*, *dried rehmannia root*, *lycium barbarum L* and *fructus meliae toosendan*, was first described in an ancient book which was printed in about the 18th century. The decoction has been used clinically for almost 3 centuries for the treatment of liver diseases in China. It is reported that the decoction is effective for various hepatic diseases of different etiologies^[1-3]. We previously reported that YGJ exerts significant therapeutic effects on CCl₄-induced chronic liver injury in rats, through mechanisms which inhibit hepatocyte apoptosis and activation of hepatic stellate cells, as well as regulating the function of Kupffer cells^[4]. Modified YGJ could also induce apoptosis in hepatic stellate cells, preventing liver fibrosis^[5]. However, little is known about the molecular and cellular mechanisms of YGJ which are responsible for chronic hepatic injury. This has also limited the use of YGJ in the clinic. In this study, we aimed to investigate the cellular and molecular mechanisms of action of this decoction in suppression of hepatic fibrosis, using a CCl₄-induced enhanced green fluorescent protein (EGFP) transgenic mouse model of chronic liver injury.

Liver fibrosis is a repair reaction to chronic liver injuries of varying etiologies. Many investigations have shown that bone marrow (BM) plays an important role in the progression of liver fibrosis. However it remains controversial whether the BM contributes to the promotion^[6] or regression of liver fibrosis^[7]. The cells in the liver derived from BM are also varied, and both parenchymal^[8] and nonparenchymal cells^[9-12] have been reported.

Upon liver injury, activated hepatic stellate cells (HSCs) expressing their marker protein α -smooth muscle actin (α -SMA) play a key role in the progression of hepatic fibrosis. However, the origins of HSCs are still obscure. In many studies, BM cells have been confirmed to differentiate into myofibroblasts both *in vitro* and *in vivo*. Besides liver, BM cells can contribute to the procession of many organs such as the lung, skin and kidney by virtue of differentiating into myofibroblasts in response to injury^[13]. Hepatocytes are the most abundant cells in liver and are always the initial target attacked by any injury factor which contributes to their loss in number. Some reports have shown that BM cells can differentiate into hepatocytes^[14] while others have shown that bone marrow-derived mesenchymal stromal cells support hepatocyte growth and proliferation^[15]. Kupffer cells in liver have diverse activities, and their role in the pathogenesis of liver injury remains controversial, as it has been demonstrated that these cells display pro-toxicant and hepato-protective functions. Two major classes of Kupffer cells have been identified, but only the BM-derived class is recruited into inflammatory foci^[12]. In the present study, we investigated the possibility of BM derivation of these cells in liver and the influence of YGJ on this process.

MATERIALS AND METHODS

Preparation of YGJ

All six herbs were chosen according to the Pharmacopoeia of the People's Republic of China (2000), and authenticated by a pharmacologist. The YGJ was prepared by the Shanghai Shuguang Hospital affiliated to the Shanghai University of Traditional Chinese Medicine. Briefly, YGJ herbs, including 2000 g *radices glehniae*, 2000 g *radices ophiopogonis*, 2000 g *radix angelicae sinensis*, 3600 g *dried rehmannia root*, 2400 g *lycium barbarum L* and 900 g *fructus meliae toosendan* were ground into a powder, and then decocted with boiling water. The filtrate was concentrated with a rotary vacuum evaporator, and freeze-dried to 4270 g, and stored at 4 °C. Before use, the filtrate was diluted with normal saline to a final concentration of 0.2682 g/mL.

Animals

Fifty-two male 5- to 6-wk-old Institute for Cancer Research (ICR) mice and 26 EGFP⁺ transgenic ICR mice (license number: SCXK, 2003-0003, Shanghai, China) were purchased from the Shanghai Animal Center of the Chinese Academy of Sciences. All mice were housed in the animal center of Shanghai University of Traditional Chinese Medicine and fed a standard pelleted diet and water *ad libitum*.

Bone marrow transplantation plus hepatic fibrosis model

EGFP transgenic ICR 5- to 6-wk-old mice were killed by dislocation of the cervical vertebrae and used as BM donors. Approximately 0.5×10^7 whole BM cells were isolated by flushing the bones of all four limbs of EGFP donors with a gauge needle containing Roswell Park Memorial Institute 1640 medium with 2% fetal bovine serum. Normal male 5- to 6-wk-old ICR mice served as recipients, after receiving whole body irradiation of 6.2 Gy in a divided dose 2 h apart. The recipient mice received a tail vein injection of BM cells immediately after the second session of radiation.

Five weeks after transplantation, peripheral blood samples were collected and analyzed to verify successful engraftment and reconstitution of BM in transplanted mice. Twenty-four recipient mice were then injected with CCl₄ as above and randomly divided into three groups: control group ($n = 9$), CCl₄ only ($n = 9$) and CCl₄ plus YGJ gavages for 6 wk ($n = 6$).

Mouse hepatic fibrosis model

Hepatic fibrosis was induced in 92 mice by subcutaneously injecting a 1:1 solution of CCl₄ and olive oil (CCl₄ and oil, supplied by the Chemical Agent Company of Shanghai, Shanghai, China) three times a week for 13 wk. At the end of the 7th week, CCl₄-injected mice were divided into two groups: CCl₄ injection only and CCl₄ injection plus YGJ gavages at a dose of 0.2682 g/100 g body weight. Some mice were sacrificed at the end of the 7th, 8th, 9th,

10th, and 13th week of the experiment to dynamically observe the damage. Twelve mice served as normal controls. Blood was collected from postcaval veins for measurement of serum alanine aminotransferase (ALT) activity and albumin (Alb) content. After weighing the entire livers, liver tissue specimens were taken from the right lobe of the liver and fixed in 10% phosphate-buffered formaldehyde, then routinely processed and embedded in paraffin for histopathology, while another two samples from each mouse were embedded in optimum cutting temperature compound and snap-frozen in liquid nitrogen for immunofluorescence. The rest of the livers were stored at -80°C .

Morphological analysis

Paraffin sections ($4\ \mu\text{m}$) were hydrated and stained for 20 min in Sirius red to identify interstitial collagen. Immunohistochemical staining was performed on liver tissue sections. After deparaffinizing in xylene and dehydrating through serial alcohol solutions, we processed the sections by microwave antigen retrieval and then incubated them with monoclonal primary antibodies against α -SMA (Sigma A2547), mitogen-activated protein kinase-2 (PKM2) (Cell signaling No. 3198) and Ki-67 (Abcam ab15580) at 4°C overnight. After washing, peroxidase-conjugated secondary antibody was added and incubated for 30 min. As a negative control, the primary antibody was replaced with phosphate buffered saline (PBS). All sections were stained with diaminobenzidine.

Immunofluorescence

After fixation in ice-cold acetone for 10 min and blocking with 10% goat serum (for Alb without serum block) for 30 min at room temperature (RT), $8\ \mu\text{m}$ cryostat sections were incubated for 1.5 h at RT with a polyclonal primary antibody against green fluorescence protein (GFP) (Cell Signaling, No. 2555). After rinsing with PBS, the secondary antibody, Alexa Fluor 488 goat anti-rabbit IgG (H + L) (Invitrogen A11008) was added and sections were incubated for 1 h at 37°C .

For detection of α -SMA, the GFP-conjugated sections were blocked with 10% goat serum and incubated with monoclonal α -SMA (sigma A2547) at a dilution of 1:200 overnight at 4°C . The secondary antibody Alexa Fluor 633 goat anti-mouse (Invitrogen A21050) was used at a dilution of 1:200 for 1 h at 37°C .

For detection of Alb, $8\ \mu\text{m}$ cryostat sections were fixed in ice-cold acetone for 10 min, then incubated with the primary antibody, a goat polyclonal antibody (Santa Cruz Biotechnology, INC sc-46293), at 1:50 overnight at 4°C . After rinsing, the secondary antibody, donkey anti-goat 633 (Invitrogen A21082) was added at 1:200 for 1 h at 37°C . Following blocking with 5% BSA, the antibody to GFP and the Alexa Fluor 488-labeled secondary antibody described above were used as primary and secondary antibodies, respectively.

All the slides were washed 3 times for 5 min each in PBS between primary and secondary antibodies. The

slides were mounted in a mixture of PBS and glycerol.

Microscopy and image capture

For light microscopy, an Olympus IX70 microscope was used with Image-Pro Plus 6.1 image analysis software. For fluorescent microscopy, slides were visualized under an Olympus CKX41 fluorescent microscope. For confocal microscopy, a Leica laser confocal microscope equipped with a triple bandpass filter was used. The images were analyzed with ScnImage and quantified using the control group as the baseline.

Liver function and hydroxyproline

Liver Hyp content, serum ALT activity and Alb content were determined according to the protocols provided with the kits, which were supplied by the Institute of Biological Products Nanjing Jiancheng (Nanjing, China).

RNA isolation and real-time polymerase chain reaction

Total RNA was isolated with Trizol Reagent (Invitrogen lot: 1401902) and the quality was checked by spectroscopy. The A260/A280 ratio was between 1.9 and 2.1 for all samples.

For the reverse transcription reaction, cDNA was produced using a Revert Aid™ First Strand cDNA Synthesis Kit (Ferments Life Sciences, No. K1 621). Real-time polymerase chain reaction (PCR) was performed using a real-time PCR machine (Rotor-Gene RG-3000, Corbett Research) in quantitative mode. Initial denaturation was performed at 95°C for 10 s, followed by 40 cycles of 95°C denaturing for 5 s, primer annealing, and extension at 62°C for 20 s. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used for normalization. The templates and primers were as follows: mouse monocyte chemotaxis protein (MCP)-1 (Forward: 5'-TCAGCCAGATGCAGTTAACGC-3' and Reverse: 5'-TCTGGACCCATTCCTTCTTGG-3', 185 bp); CC chemokine receptor 2 (CCR2) (Forward: 5'-CACGAAGTATCCAAGAGCTT-3', and Reverse: 5'-CATGCTCTTCAGCTTTTAC-3', 199 bp) and they were normalized to GAPDH (Forward: 5'-GAGCGAGACCCACTAACAT-3' and Reverse: 5'-TCTCCATGGTGGTGAAGACA-3', 86 bp). The SYBR Green fluorescence intensity of the specific double-strand reflecting the amount of amplicon formed was read after each elongation step at an additional acquisition temperature using Rotor-Gene Analysis Software V6.0. To verify the specificity of the amplification reaction, melting curve analysis was performed. For quantification analysis, all samples were analyzed in triplicate, and cycle threshold values for target genes and the housekeeping gene were determined for each sample. Relative gene expression was presented using the $2^{-\Delta\Delta\text{CT}}$ method.

Western blotting

Liver samples were homogenized and the supernatants were collected after centrifugation at $12\ 000 \times g$ at 4°C for 10 min. Protein concentrations were determined us-

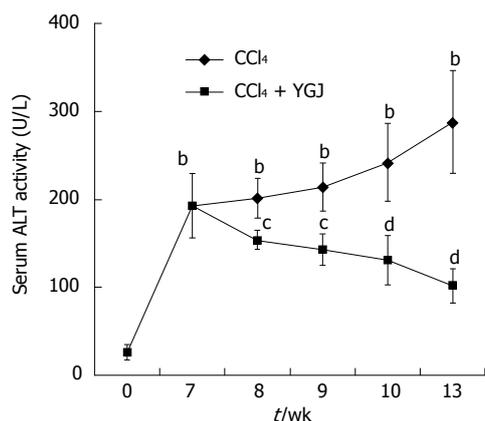

Figure 1 Serum alanine aminotransferase activity in mice. ALT activities in CCl₄ groups increased continuously but declined in YGJ + CCl₄ groups over the entire period. ^b*P* < 0.01 vs the week 0 control group; ^c*P* < 0.05, ^d*P* < 0.01 vs the same time-point CCl₄ group. Results are presented as mean ± SD. ALT: Alanine aminotransferase; CCl₄: Carbon tetrachloride; YGJ: Yiguanjian.

ing a protein assay kit II (BIO-RAD, No. 500-0 122), and 50 µg proteins were loaded and separated on 12% sulfate dodecyl sodium-polyacrylamide gels. The proteins were electrotransferred to a nitrocellulose membrane (Amersham Biosciences, Piscataway, NJ, United States) in transfer buffer at 4 °C for 1 h. Nonspecific binding to the membrane was blocked for 1 h at room temperature with 5% nonfat milk in Tween-80 Tris-buffered saline. The membranes were then incubated overnight at 4 °C with various primary antibodies in blocking buffer containing 5% nonfat milk, followed by incubation with horseradish peroxidase-conjugated secondary antibody (Chemicon Co) for 1 h in 5% nonfat milk dissolved in Tris-buffered saline. Membranes were then washed with Tris-buffered saline, signals were visualized using the enhanced chemiluminescence system (Amersham Biosciences) and the intensity of the bands was determined by scanning video-densitometry and normalized to the control group.

Statistical analysis

All results were expressed as mean ± SD. Data were analyzed using one-way analysis of variance. Student's *t* test was employed for the comparison of parameters and correlation analysis, respectively.

RESULTS

YGJ decoction dynamically protects against carbone tetrachloride-induced chronic liver fibrosis

Changes in serum ALT activity in the mice receiving CCl₄ which developed chronic liver injury were evaluated at several distinct time points. From week 7 to week 13, serum ALT activity in the CCl₄-injected mice increased continually and significantly compared with that in the control group (*P* < 0.01), but YGJ markedly reduced serum ALT activity even after just one week of administration (*P* < 0.05), and ALT was reduced to 50% of that in the control CCl₄-injected group (*P* < 0.01) after 6 wk of

YGJ administration (Figure 1).

The results of Sirius red staining showed that only a little collagen was present in the area of the portal and central veins in normal mice, while over the course of the study, bridging collagen connecting the central veins and neighboring portal areas increased continually, deposition of collagen fibers was steadily enhanced in livers throughout the entire experimental period, and pseudonodules were formed by the end of the study. In contrast, in the YGJ-treated group, collagen deposition in the livers was significantly attenuated. Semi-quantification of the collagen staining showed that collagen levels increased sharply after CCl₄ injection, reaching 3.5-fold above basal values by week 7, and peaking 6.5-fold above basal values by week 13. YGJ treatment maintained and significantly reduced the increase in collagen. For example, after 6 wk of YGJ treatment, the level of collagen was about 50% lower in YGJ-treated mice than in controls at the same time point (Figure 2A and B).

The results of Sirius red staining also showed that Hyp concentration in livers was significantly increased from week 8 and increased steadily up to week 13. However, in the YGJ-treated group, the content of Hyp in livers significantly decreased as compared with that at the same time-point in the CCl₄-injected group (Figure 2C). These findings support our previous results showing that YGJ protected hepatic function and attenuated collagen deposition during chronic liver injury in rats^[4].

YGJ decoction continuously inhibits α-smooth muscle actin (+) cells in chronically-injured liver

During development of chronic liver injury, accumulation of myofibroblastic cells and increased production of extracellular matrix were the main characteristics. It is clear that α-SMA-positive activated HSCs, the main source of extracellular matrix, play a key role in this pathological process. Our studies of immunohistochemical staining showed that the accumulation in livers of the myofibroblast marker α-SMA increased steadily and then remained at this level until the end of the study, peaking at the 13th week when it was distributed along fibrotic areas (Figure 3A and B). This change was consistent with the expression of α-SMA protein analyzed by Western blotting, which also increased after CCl₄ injection and peaked at the end of the study (Figure 3C and D). The progressive expression of α-SMA in this study is consistent with earlier reports which demonstrated that early increases in the number of activated HSCs, followed by enhanced collagen synthesis and decreased collagen degradation, combined to cause accumulation of collagen matrix following liver injury. YGJ treatment significantly attenuated the induction of α-SMA, even after only 1 wk of YGJ administration (*P* < 0.01) and it continually declined up to 6 wk of YGJ gavages (*P* < 0.01) (Figure 3A and B), a result which was similar to that obtained from the Western blotting of α-SMA in livers (*P* < 0.01) (Figure 3C and D).

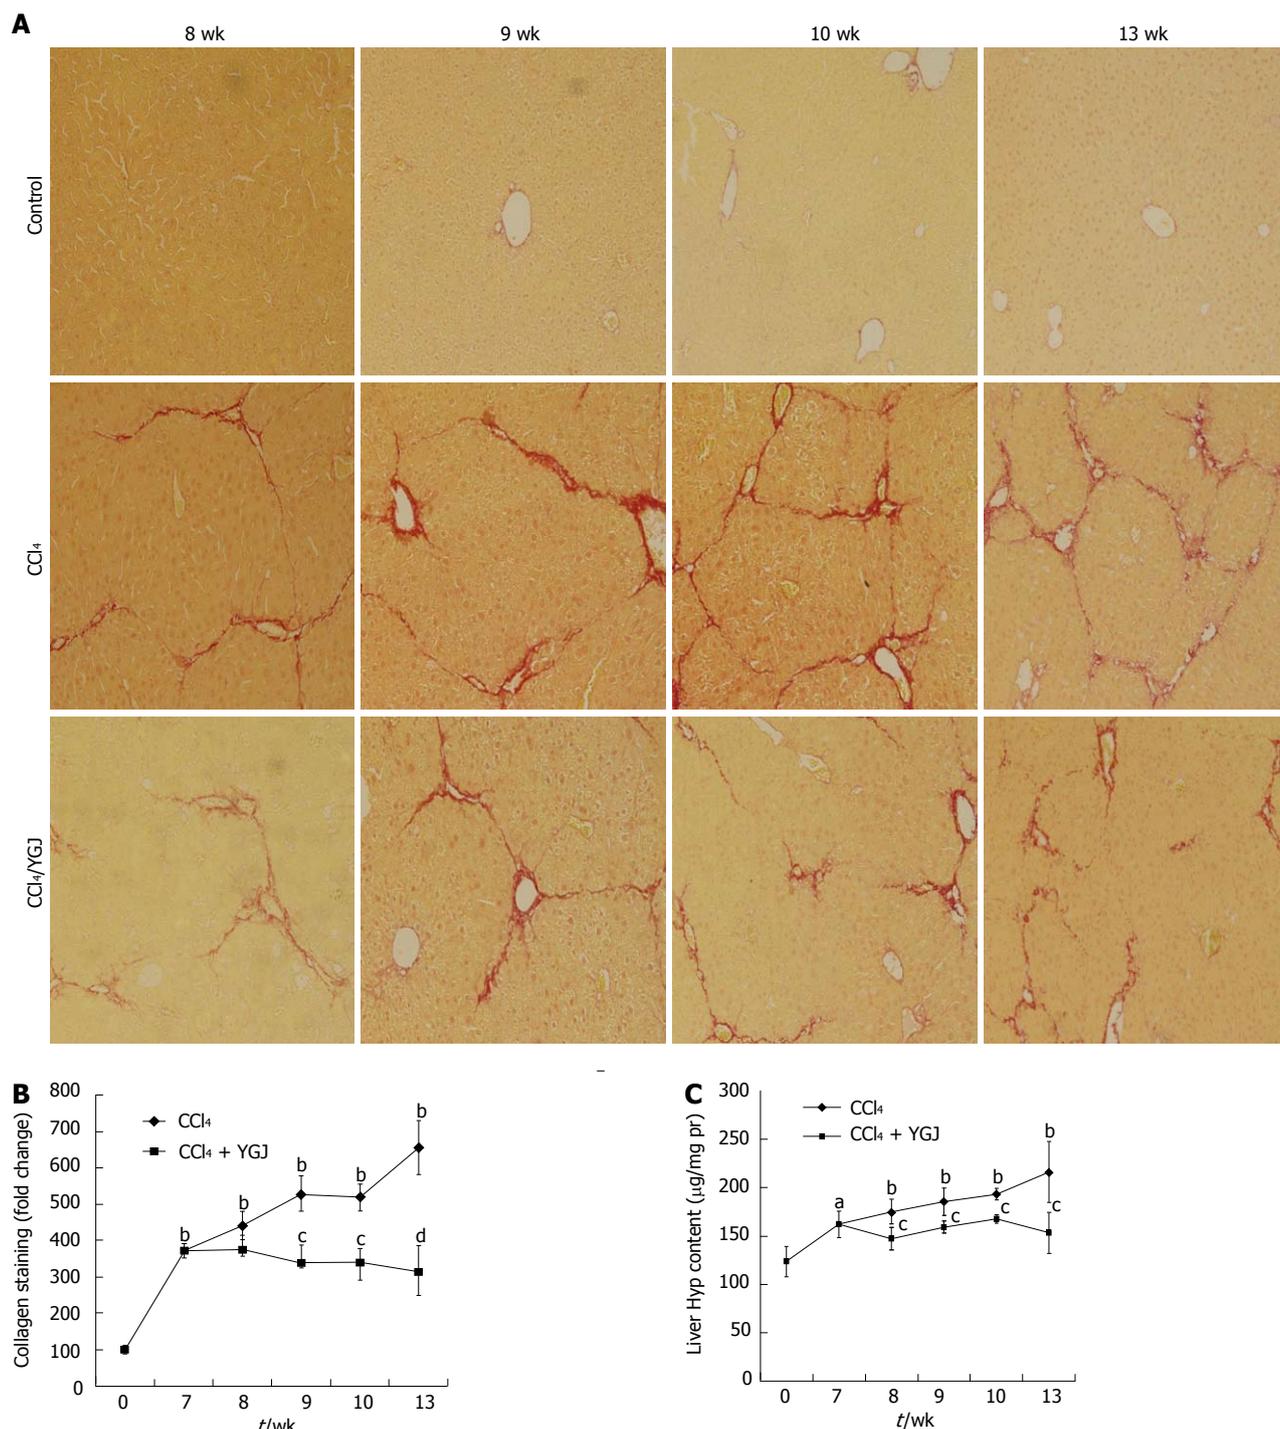

Figure 2 Collagen staining with Sirius red and Hyp content. A: Collagen staining. Week 0 control mice have limited collagen in the portal area, but fibrous septa bridging the portal tracts were found in the livers of CCl₄-treated mice, and this was significantly attenuated in YGJ-treated mice, × 200; B: Semi-quantification of collagen staining, the week 0 control group level was set as the basal level; C: Hyp content in the liver. Results of collagen staining and Hyp content show that they both continuously increased in the CCl₄ group but declined in the YGJ + CCl₄ group over the entire period. ^aP < 0.05, ^bP < 0.01 vs week 0 control group; ^cP < 0.05, ^dP < 0.01 vs the same time-point CCl₄ group. Results are presented as mean ± SD. CCl₄: Carbone tetrachloride; YGJ: Yiguanjian; Hyp: Hydroxyproline.

YGJ decoction inhibits the migration of bone marrow cells into chronically injured liver

It has been reported that bone marrow cells or their progeny can circulate into various damaged organs and differentiate into myofibroblasts or fibrocytes^[13]. In the liver, several studies have suggested that bone marrow contributes to scar forming cells of various types, such as the HSCs^[10].

Our results further confirmed these reports. Following CCl₄ injection into the mice which received bone marrow transplantation, the number of EGFP⁺ cells also increased steadily in injured livers, which were mainly distributed in the fibrotic areas. In contrast, only a few EGFP⁺ cells were found in the vehicle-treated control mice, who received only olive oil but no CCl₄ injection after bone marrow re-

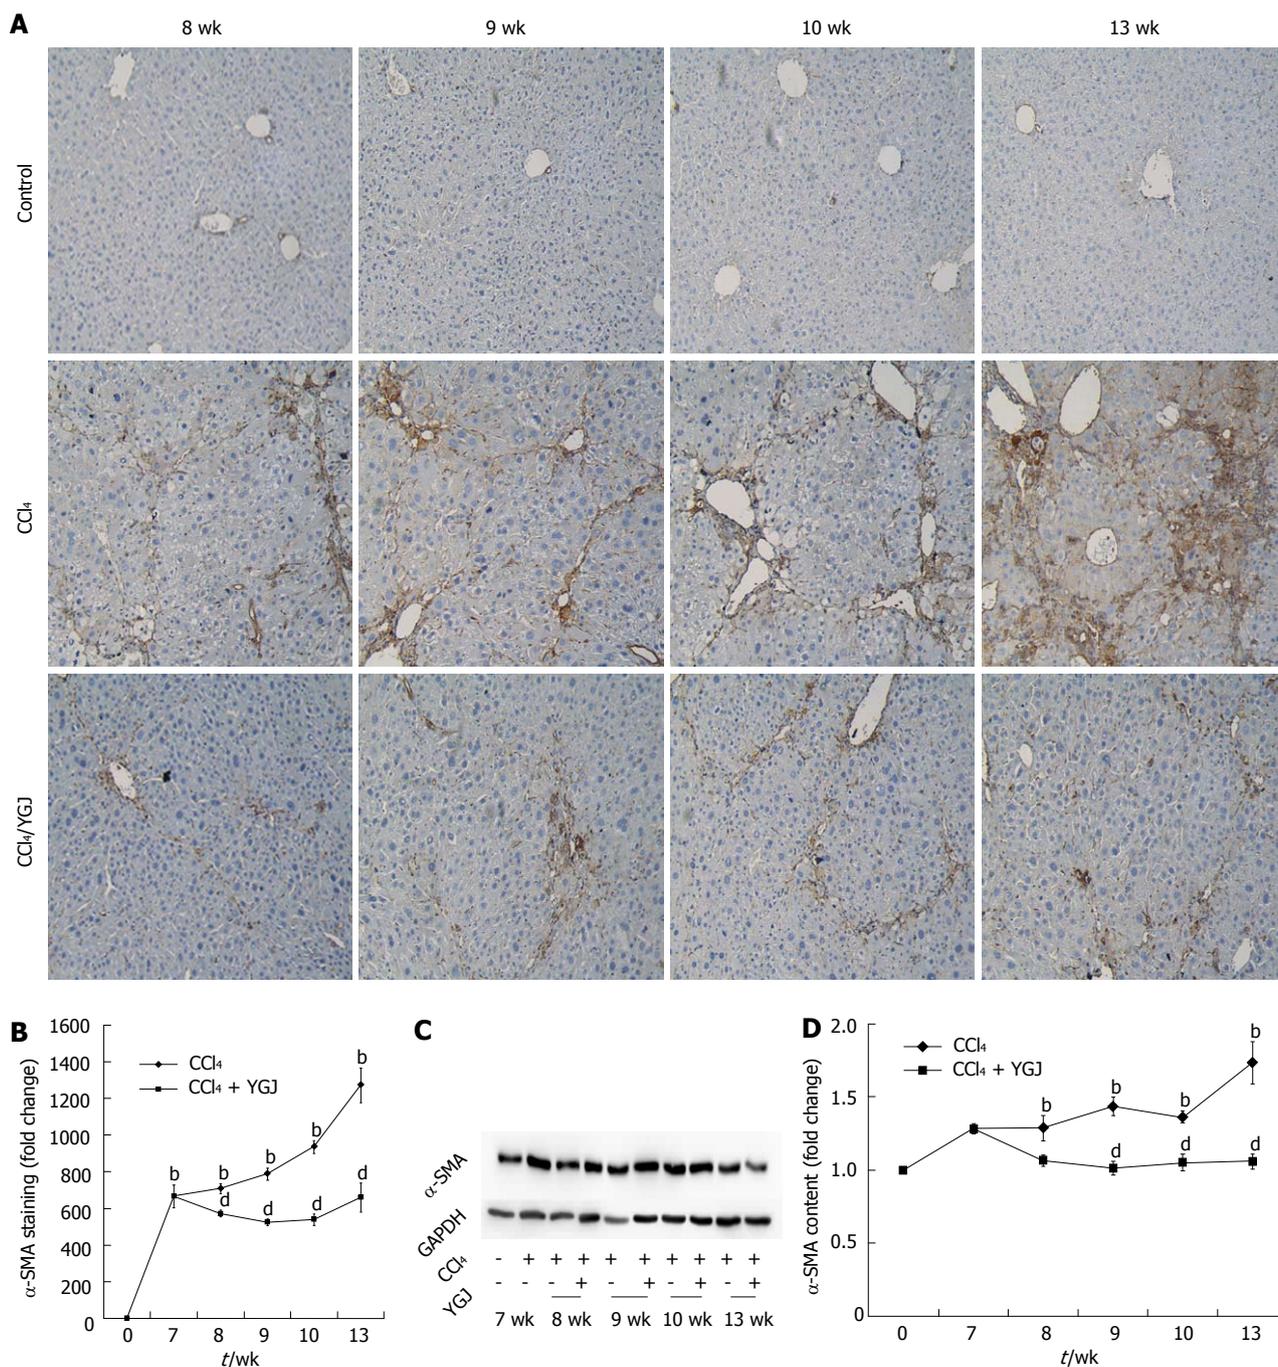

Figure 3 Immunostaining and Western blot analysis of α -smooth muscle actin in liver tissues. A: α -smooth muscle actin (α -SMA) immunostaining, $\times 200$; B: Semi-quantification of α -SMA positive area, with the level in the week 0 control group set as the basal level; C: Western blotting of α -SMA; D: Semi-quantification of the α -SMA Western blot results, with the week 0 control group level set as the basal level. ^b $P < 0.01$ vs week 0 control group; ^d $P < 0.01$ vs the same time-point CCl₄ group. Results are mean \pm SD. CCl₄: Carbone tetrachloride; YGJ: Yiguanjian; GAPDH: Glycerlaldehydes-3-phosphate dehydrogenase.

constitution. In YGJ-treated mice, the number of EGFP⁺ cells decreased markedly as compared with the CCl₄-injected mice at the same time point. Moreover, unlike the distribution of EGFP⁺ cells which were mainly found in the fibrotic area in CCl₄-injected mice, the EGFP⁺ cells were distributed not only in mesenchymal but also in parenchymal areas in YGJ-treated mice (Figures 4-6).

YGJ decoction-mediated bone marrow-derived cell differentiation in chronically injured liver

In accordance with the results of the dynamic CCl₄ injec-

tion model without BM transplantation, both the number and distribution of α -SMA⁺ cells increased constantly over the course of liver injury in mice with bone marrow reconstitution. Treatment with YGJ reduced the number of α -SMA⁺ cells in fibrotic livers. The results of EGFP/ α -SMA double staining showed that there were almost no double positive cells in the vehicle control mice. In contrast, the number of the EGFP⁺/ α -SMA⁺ cells increased over time in all mice after receiving CCl₄ injections for 7 wk ($P < 0.01$) and remained high to the final time-point ($P < 0.01$); moreover, the EGFP⁺/ α -SMA⁺ cells were mainly

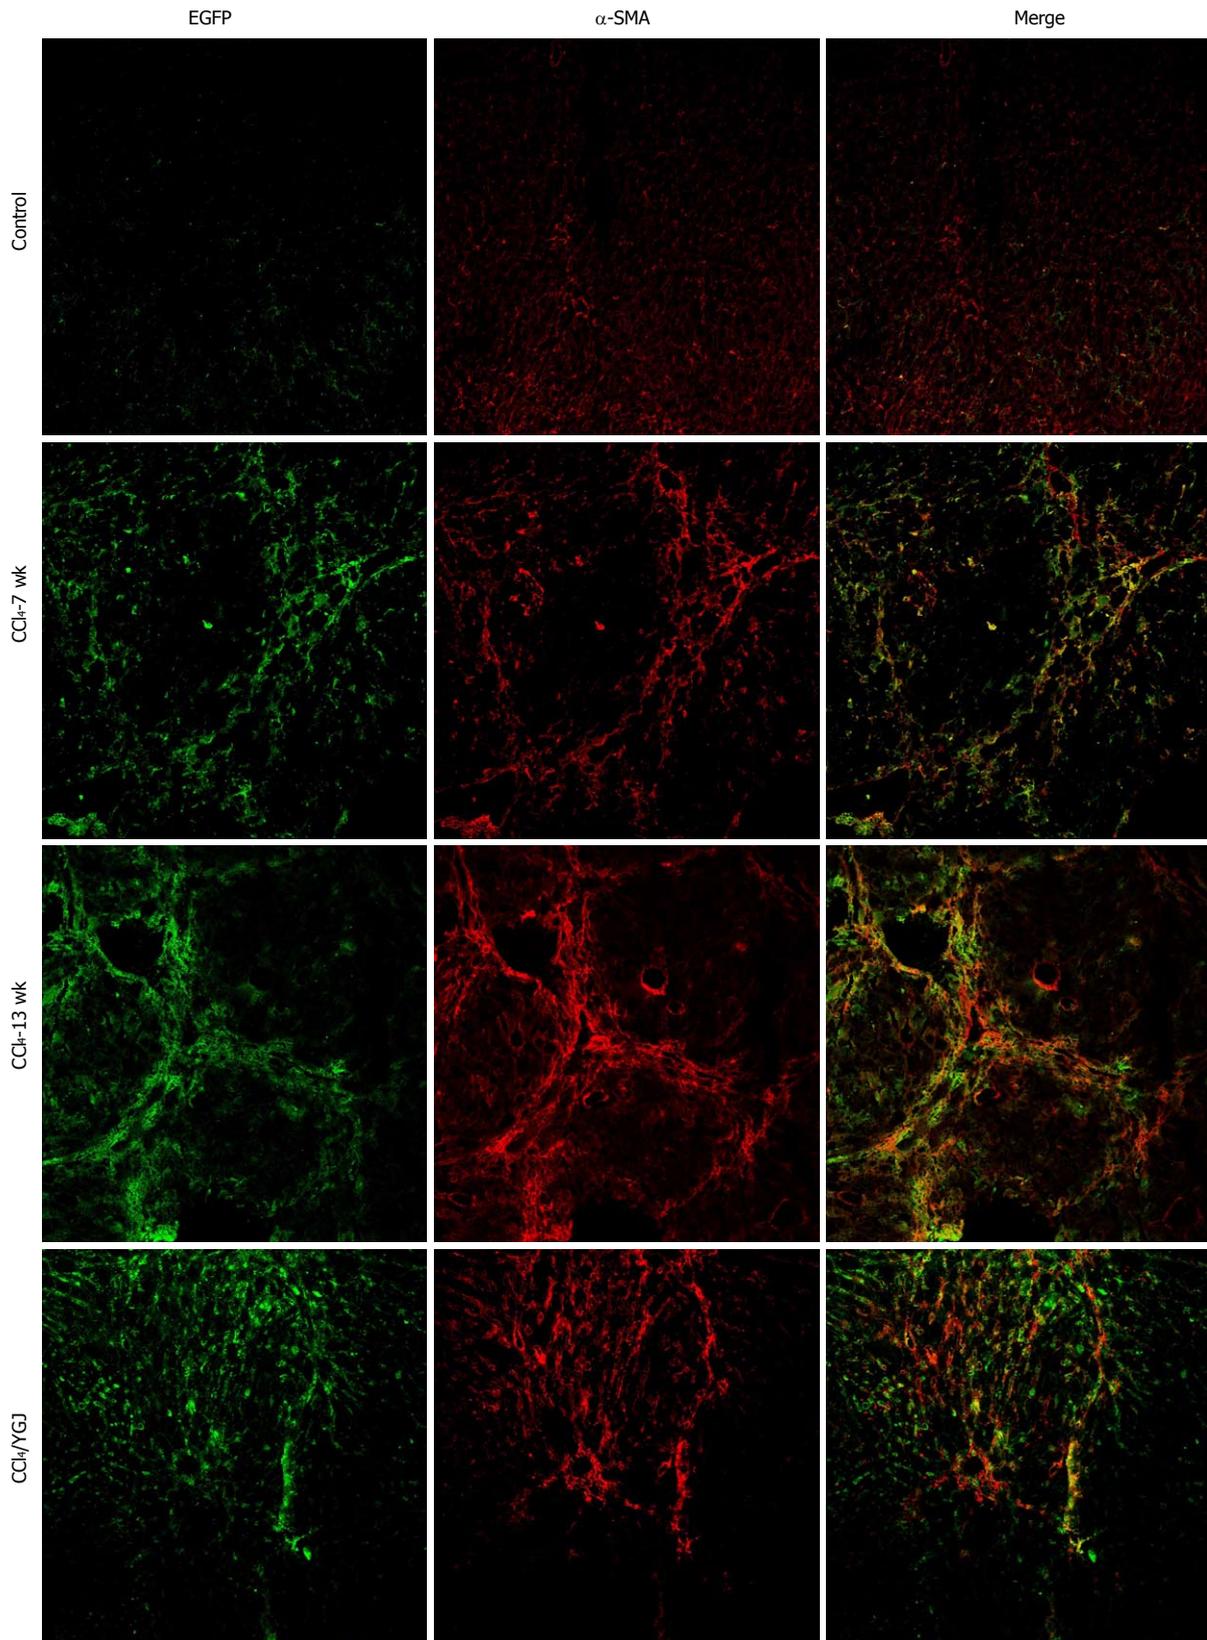

Figure 4 Immunofluorescent colocalization of enhanced green fluorescent protein and α -smooth muscle actin in CCl_4 -induced chronic liver injury in bone marrow chimera mice, $\times 200$. EGFP is shown in green and α -smooth muscle actin (α -SMA) in red. A yellow color confirms colocalization in the merged images. The number of EGFP/ α -SMA double positive cells was found to increase in all mice after receiving CCl_4 injection and they were mainly found in the areas of scarring. In contrast, the number of EGFP⁺/ α -SMA⁺ cells decreased in the YGJ treatment group. EGFP: Enhanced green fluorescent protein; YGJ: Yiguanjian.

found in the areas of scarring. However, YGJ treatment significantly decreased the number of EGFP⁺/ α -SMA⁺

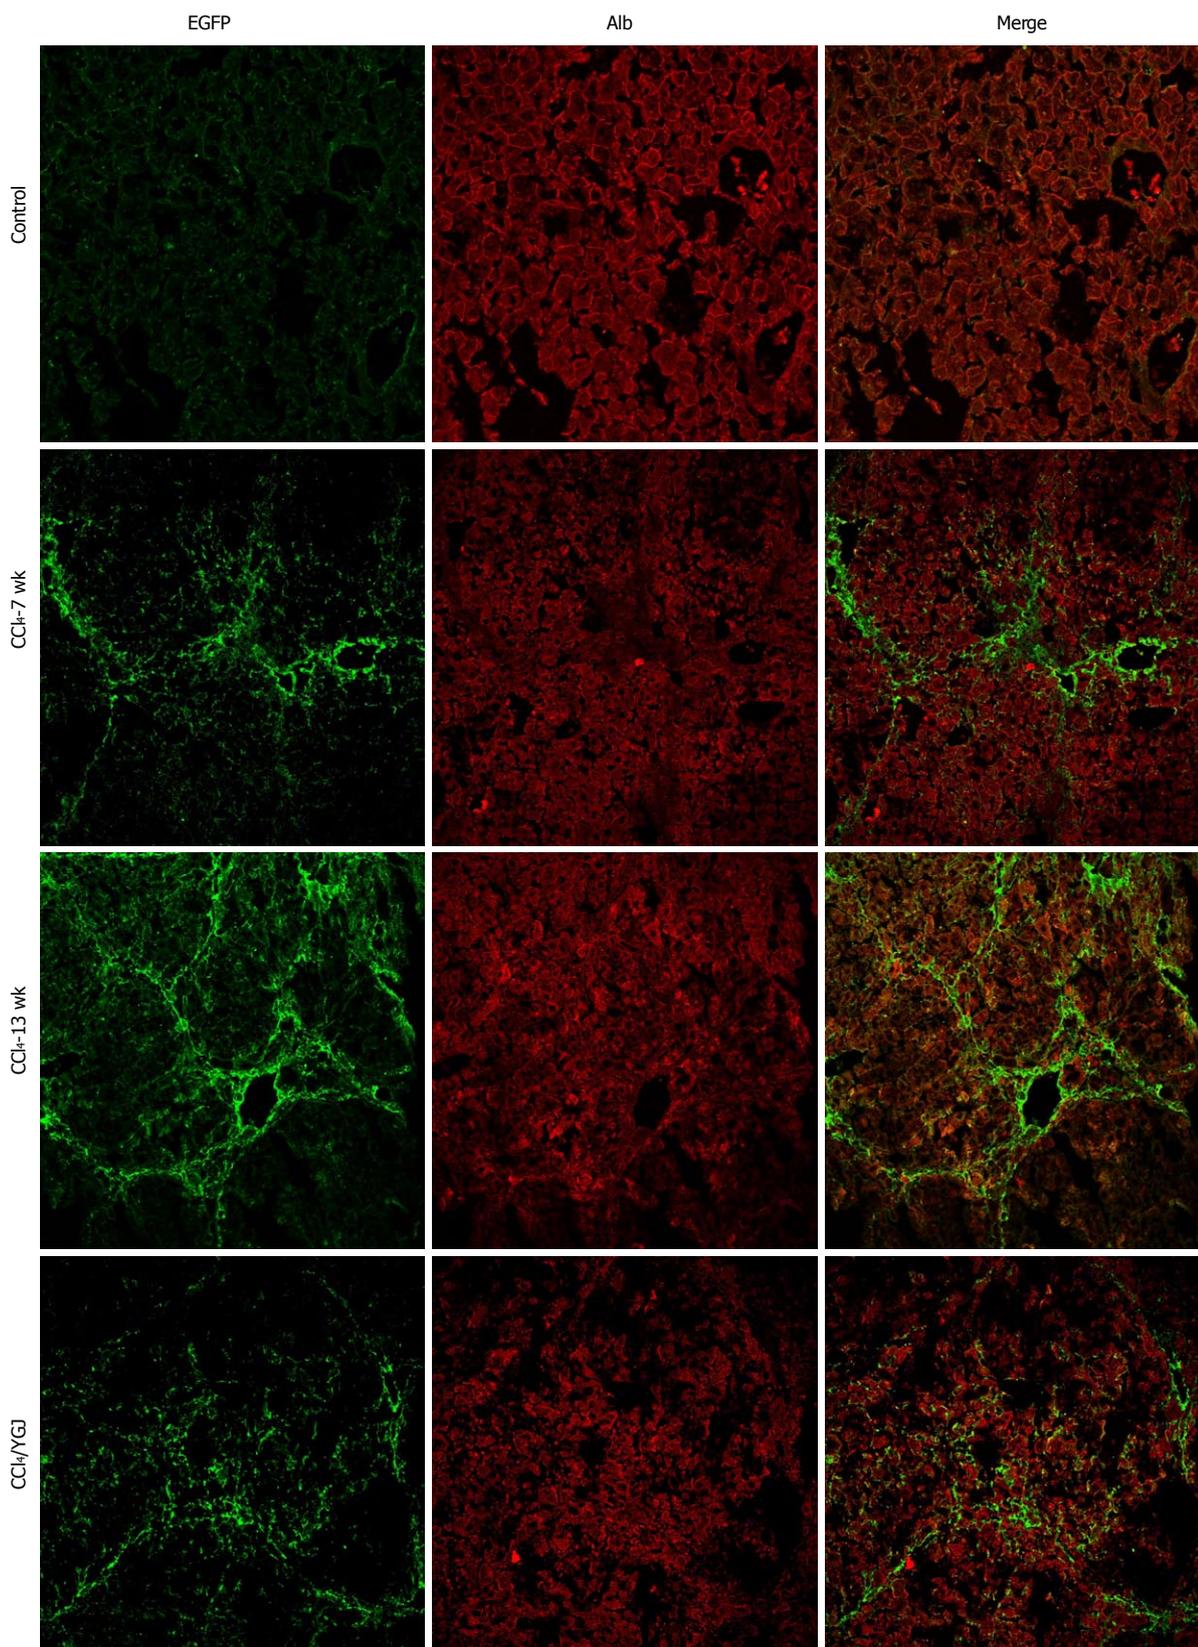

Figure 5 Immunofluorescent colocalization of enhanced green fluorescent protein and albumin in CCl₄-induced chronic liver injured bone marrow chimera mice, × 200. EGFP is shown in green and Alb in red. No yellow color is visible in the merged images in control, CCl₄ or CCl₄ + YGJ groups. EGFP: Enhanced green fluorescent protein; YGJ: Yiguanjian; Alb: Albumin.

cells as compared with the CCl₄-injected controls at the same time-points ($P < 0.01$) (Figure 4).

Because of the apparent increase in the number of EGFP⁺ cells in parenchymal areas in YGJ-treated mice

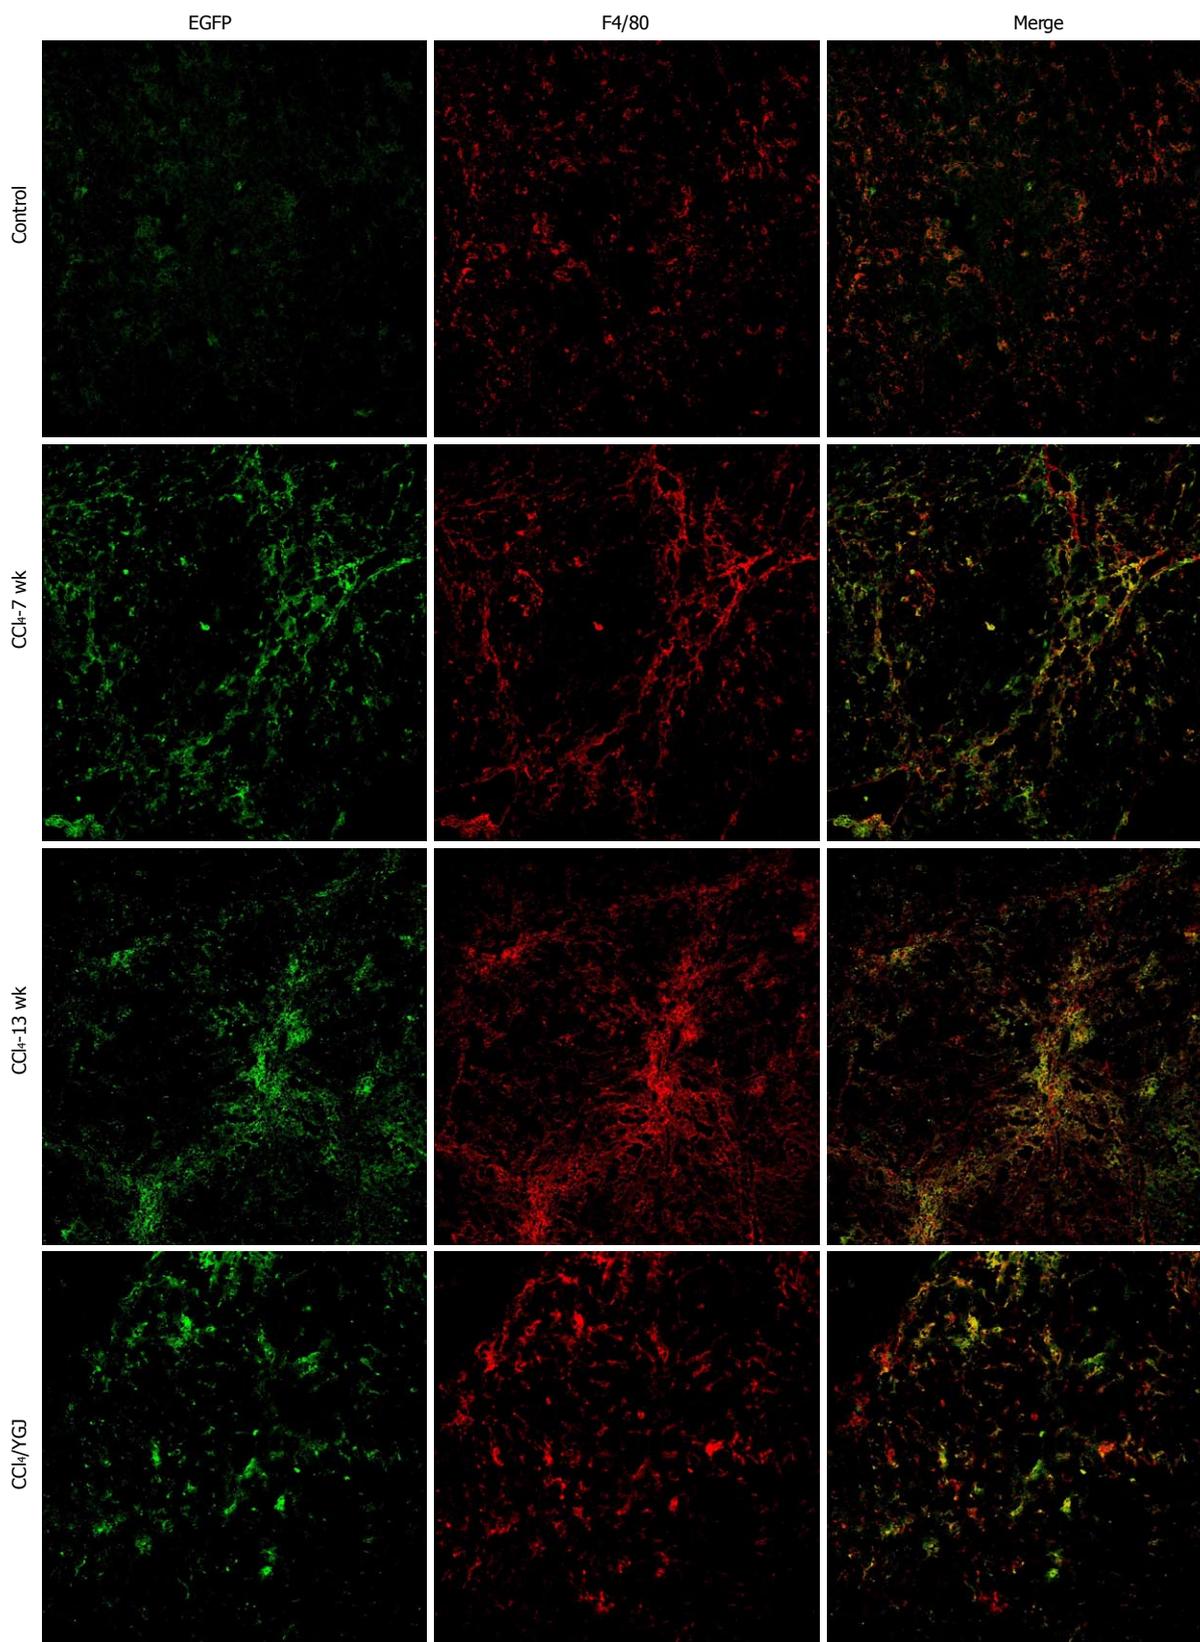

Figure 6 Immunofluorescent colocalization of enhanced green fluorescent protein and F4/80 in CCl₄-induced chronic liver injured bone marrow chimera mice, × 200. EGFP is shown in green and F4/80 in red. A yellow color confirms colocalization in the merged images. The number of EGFP/F4/80 double positive cells was found to increase in all mice after receiving CCl₄ injection. In contrast, the number of EGFP⁺/F4/80⁺ cells decreased in the YGJ treatment group. EGFP: Enhanced green fluorescent protein; YGJ: Yiguanjian.

compared with CCl₄-injected mice, we hypothesized that YGJ could stimulate the EGFP⁺ cells from bone

For both genes the relative expression is quantified using the control group as the basal level; **B:** MCP-1 and CCR2 bands by Western blotting. Band 1, control group; band 2, CCl₄ 7 wk group; band 3, CCl₄ 13 wk group; and band 4, CCl₄ + Yiguanjian (YGJ) group; **C:** CCR2 gene and protein expression. For both genes the relative expression is quantified using the control group as the basal level. MCP-1: Monocyte chemotaxis protein-1; CCR2: CC chemokine receptor 2; GAPDH: Glyceraldehydes-3- phosphate dehydrogenase. ^a*P* < 0.05, ^b*P* < 0.01 vs week 0 control group; ^c*P* < 0.05 vs the same time-point CCl₄ group.

marrow to differentiate into hepatocytes. To assess the possibility of YGJ stimulating bone marrow cells to differentiate into hepatocytes, we investigated the presence of EGFP⁺/Alb⁺ cells by double staining. In the CCl₄-injected control mice, the number of EGFP⁺ cells increased steadily over time and the cells were distributed mainly in mesenchymal areas, but Alb⁺ cells were mainly distributed in parenchymal areas, and there was no

overlap between EGFP⁺ cells and Alb⁺ cells, indicating that no EGFP⁺/Alb⁺ cells were present in chronically injured liver. No EGFP⁺/Alb⁺ cells were present in the vehicle control mice or in the YGJ-treated mice (Figure 5). These results seemingly suggest that no hepatocytes were derived from bone marrow in our study.

To further investigate the mechanisms of YGJ mediation of bone marrow cell differentiation in chronic liver injury, we explored the possibility that BM cells differentiated into other main types of cells in the liver, such as Kupffer cells. The EGFP⁺/F4/80⁺ cells represented BM-derived Kupffer cells in our experiments. In the vehicle control mice, despite of a little F4/80 expression, virtually no EGFP⁺/F4/80⁺ cells were present in the liver. However, after 7 wk of CCl₄ injection, coexpression of EGFP and F4/80 increased significantly (*P* < 0.01) and remained at a high level up to 13 wk. These results indicated that some Kupffer cells differentiated from BM cells as the hepatic injury progressed. With YGJ treatment, both EGFP and F4/80 were expressed in parenchymal areas, and some of the areas were overlapped (Figure 6). However, there were fewer EGFP⁺/F4/80⁺ cells in the YGJ-treated mice than in the CCl₄-injected mice (*P* < 0.01).

YGJ decoction suppresses monocyte chemotaxis protein-1 and CCR2 expression in fibrotic liver

MCP-1 was identified as a factor likely to be responsible for stem/progenitor cell recruitment. Therefore, we analyzed the expression of MCP-1 during CCl₄-induced fibrogenesis. For the gene and protein expression, results were normalized to expression in the liver at the time of CCl₄ injection (0 wk), for example the control group mRNA level of MCP-1 reached 2.8-fold after 7 wk (*P* < 0.05) and 6.7-fold after 13 wk of CCl₄ injection (*P* < 0.05) (Figure 7A). Western blotting showed that MCP-1 protein was increased markedly (approximately 4 fold) after 13 wk of CCl₄ injection (Figure 7A and B). YGJ treatment significantly reduced the expression of both MCP-1 gene and protein (Figure 7A and B). CCR2 is the specific receptor of MCP-1, and both Kupffer cells and HSCs, but not hepatocytes, have been shown to express CCR2 in liver^[16]. In our study, the gene expression of CCR2 continuously increased over the course of the experiment (*P* < 0.05), which was in accordance with its protein expression (*P* < 0.01), and treatment with YGJ only suppressed expression at the protein level (*P* < 0.05) but not at the gene level (Figure 7B and C). These data demonstrate that more exogenous stem/progenitor cells were recruited into chronically injured livers compared with the controls, but that YGJ treatment decreased the number of exogenous stem/progenitor cells in the liver.

YGJ decoction decreases proliferation of liver epithelial progenitor cells and mature hepatocytes

It is important to determine whether the proliferative activity of hepatocytes increased during hepatic injury since the hepatocytes are the most numerous cells in

liver and have potent proliferative activity. Ki-67 nuclear accumulation increased constantly in hepatocytes after liver injury, reaching 23-fold as compared with the basal level of controls at week 13, the end point of the study (Figure 8A and B). This finding means that the number of mature hepatocytes increased steadily and significantly after CCl₄ injury, and indicates that mature hepatocytes also play a part in responding to CCl₄-induced liver injury by increasing their proliferative activity. However, even after 1 wk of YGJ treatment, the number of Ki-67 positive hepatocytes was dramatically reduced ($P < 0.01$), and by the 13th wk, the number accounted for only 12.6% of those in the CCl₄ injection group at the same time point, which is a reduction of approximately 87% compared with the CCl₄-treated group (Figure 8A and B). These findings suggest that YGJ treatment significantly reduced the number of hepatocytes accumulated after CCl₄ injury.

Serum Alb concentration (34.5 ± 6.9 g/L, control group) decreased by week 7 after hepatic injury (29.4 ± 3.5 g/L), and continued to decrease steadily at week 8 (26.4 ± 4.5 g/L, $P < 0.05$), week 9 (25.3 ± 3.2 g/L, $P < 0.01$), week 10 (28.9 ± 2.2 g/L) and week 13 (25.5 ± 2.40 g/L, $P < 0.01$). However, in YGJ-treated mice, the serum Alb concentration increased markedly compared with that at week 9 ($P < 0.05$) and week 13 ($P < 0.01$) (Figure 8). Similarly, Western blotting results of Alb also showed that Alb protein expression in injured livers continually declined and reached its lowest level by the end of the experiment, at only 64% of the basal level. In contrast, treatment with YGJ steadily enhanced its protein level so that it reached 90% of the basal level by the end of the experiment.

During the process of liver regeneration after injury, liver epithelial progenitor cells were induced to proliferate to compensate for the missing number of parenchymal hepatocytes. Hence, hepatic expression of progenitor markers, such as AFP and PKM2^[17,18], were used in our experiment to assess the proliferation of hepatic progenitor cells after liver injury. PKM2 expression increased steadily after CCl₄ injection as shown by immunostaining and Western blotting analysis, spanning 6 time points over 13 wk. Our data revealed that after 7 wk of CCl₄ injection, PKM2 expression increased significantly ($P < 0.01$) and thereafter remained at a high level throughout the entire experimental period (Figure 9A, B and D). These enhancements were accompanied by an increase in AFP expression (Figure 9C and E). Treatment with YGJ significantly attenuated the increase in the progenitor markers PKM2 and AFP (Figure 9). These findings support the concept that after CCl₄ injection, hepatic injury promotes accumulation of liver progenitor cells.

DISCUSSION

YGJ can ameliorate chronic liver injury in some animal models of CCl₄-induced liver damage in mice. In the course of the experiment, serum ALT activity, deposi-

tion of collagen fibers and Hyp content were continuously increased, and had formed pseudo-nodules by the end of the study. In contrast, all these markers decreased significantly after YGJ treatment. These results strongly suggest that YGJ can block CCl₄-induced chronic liver injury and exhibit a favorable therapeutic effect in mice.

Any etiologically chronic liver injury could result in activation of myofibroblasts, which are the main source of extracellular matrix (ECM) and finally lead to fibrosis or cirrhosis. We consider myofibroblasts to be a target of therapeutic liver fibrosis because they play such a key role in liver fibrogenesis. In our mouse model, α -SMA expression in mice increased in a dynamic manner after CCl₄ injection, and reached a peak at week 13. In contrast, α -SMA expression was remarkably and constantly suppressed after YGJ treatment.

Because myofibroblasts are thought to be heterogeneous in origin, both intrahepatic and BM-derived sources are important in the development of fibrosis^[19]. To assess the function of the BM in supplying myofibroblasts in cases of chronic liver injury, we examined the formation of BM-derived myofibroblasts and found that BM-derived EGFP-positive cells time-dependently increased over the course of the study, reaching a peak at week 13, and they were mainly localized along the fibrous septa, in accordance with the course of fibrogenesis. Furthermore, the number of EGFP and α -SMA double positive cells increased time-dependently and they were scattered at the fibrous septa. Therefore, we concluded that the EGFP and α -SMA positive cells are of BM origin and that BM cells can migrate and differentiate into myofibroblasts in the damaged liver. On the other hand, the number of both EGFP-positive cells and the EGFP- α -SMA positive cells decreased steadily after YGJ treatment, which suggested that YGJ inhibited the migration and differentiation of BM cells into myofibroblasts.

Kupffer cells facilitate liver fibrogenic processes either by secreting fibrotic factors or by increasing the production of tissue inhibitor of metalloproteinases to reduce ECM degradation^[20]. The origin of Kupffer cells was thought to be recruitment from the bone marrow to the liver^[21] or from intrahepatic precursor cells that exist in the liver^[21]. However, only the former population can be recruited into inflammatory foci in response to inflammation^[22]. Our results indicate that the number of EGFP and F4/80 double positive cells begins to increase after CCl₄ injection, reaching a peak at week 13, and that the cells are distributed along the fibrotic septa. The number of EGFP and F4/80 double positive cells decreased significantly after YGJ treatment. This revealed that YGJ inhibited liver fibrogenesis by mediating BM differentiation into Kupffer cells in the liver.

It has also been reported that various components of the bone marrow can differentiate into hepatocyte-like cells, causing a decrease in liver fibrosis^[23,24]. The results from previously published reports concerning whether hepatocytes were BM-derived or not were conflicting.

Our results revealed virtually no EGFP-Alb double positive cells in any of the mice, whether they were in the control, CCl₄-damaged or YGJ treatment group.

Chemokines and their receptors play a central role in the regulation of cell migration. MCP-1 and its receptor CCR2 not only contribute to the recruitment of BM cells to liver but also have been identified as profibrotic mediators^[25,26]. Increased MCP-1 is associated with HSCs and macrophage recruitment^[27,28]. In the present study, MCP-1 increased constantly over the course of fibrogenesis. Bone marrow F4/80⁺ cells are the major producers of MCP-1^[29], and we observed that the number of bone marrow F4/80⁺ cells increased following liver injury. These results revealed that production of MCP-1 by bone marrow F4/80⁺ cells recruited into liver was one of the mechanisms underlying CCl₄-induced liver fibrosis. YGJ treatment significantly decreased the number of bone marrow F4/80⁺ cells and the level of MCP-1 expression in accordance with the improvement of liver fibrosis.

CCR2 promotes fibrosis^[30,31] and is expressed on resident liver cells including hepatic stellate cells and Kupffer cells, but not hepatocytes^[16]. CCR2 expression increased over the time-course of CCl₄ injection, similarly to MCP-1 expression. YGJ treatment markedly inhibited CCR2 expression.

In order to further investigate the mechanisms of YGJ antifibrotic function in CCl₄ injury, we took into account the role of mature hepatocytes. Because various etiologies of liver injury involve hepatocytes as the target, mature hepatocytes have stem cell functions, giving them the ability to re-enter the cell cycle rapidly after liver injury has occurred^[32]. The number of proliferative hepatocytes increased constantly after CCl₄ injection, reaching a peak at week 13. Unlike the proliferative behavior of mature hepatocytes during injury, both the serum content and expression of Alb protein, which is uniquely synthesized by hepatocytes, in the liver declined continuously over the time course of liver injury. It would be reasonable to assume that the proliferation of hepatocytes in injured liver is a kind of compensatory response to their reduction in number. In contrast, hepatocyte proliferation was suppressed steadily after YGJ administration, but the Alb content in both serum and liver increased continuously. It seems unnecessary to initiate mature hepatocyte proliferation after YGJ treatment, since YGJ works as an inhibitor of hepatocyte apoptosis in CCl₄-induced liver fibrosis^[4]. Together with the ALT results, these findings infer that the improvement in hepatocyte function in the YGJ group may result from attenuation of hepatocyte necrosis or apoptosis.

Hepatic progenitor cells (or oval cells) are activated in response to persistent liver injury when the hepatocytes are unable to mount a proliferative response to injury^[32]. In the present study, AFP and PKM2 protein expression increased continuously with time after CCl₄ injection, reaching a peak at the 13th week of CCl₄ injury. The results demonstrated that hepatic progenitor cells were

activated in the CCl₄-injured liver, but reduced steadily after oral YGJ administration. These results suggest that hepatic progenitor cells are activated by persistent CCl₄-induced liver injury, but the hepatic progenitor cells are not activated after YGJ treatment.

In summary, our results revealed that YGJ improves CCl₄-induced liver injury by inhibiting BM migration into injured liver and suppressing the proliferation of hepatic progenitor cells and hepatocytes.

COMMENTS

Background

Liver fibrosis is usually progressive and reversible, but up to now, the molecular and cellular mechanisms responsible for the reversibility of liver fibrosis have been poorly understood. Yiguanjian (YGJ) decoction has been employed clinically in China for centuries to treat various chronic hepatic injuries, but its mechanisms of action remain unclear.

Research frontiers

YGJ decoction is a traditional Chinese medicine complex containing six herbs which has a long history of clinical use. In the search for therapies for chronic liver diseases, the research hotspot focuses on its mechanisms of eliminating liver fibrosis.

Innovations and breakthroughs

In previous published papers, research focuses on how YGJ improves liver fibrosis, and especially how it induces apoptosis of hepatic stellate cells while exerting anti-apoptotic effects in hepatocytes. In the present study, the authors not only investigated the homing of bone marrow cells to the liver and their differentiation, but also investigated the behavior of intrahepatic progenitors and mature hepatocytes during liver injury. The number of bone marrow cells which differentiate into fibrogenic cells increased in the liver following injury, but was decreased by YGJ treatment. Furthermore, the proliferation of intrahepatic progenitors and mature hepatocytes was stimulated during CCl₄-induced liver injury, and YGJ also suppressed their proliferation.

Applications

The study results suggest that oral administration of YGJ decoction is a potential therapy for the prevention of chronic liver injury of varying etiologies.

Terminology

Liver fibrosis is a pathological progress characterized by an excessive deposition of extracellular matrix especially collagen; YGJ is a traditional Chinese medicine containing six herbs, which has a long history of clinical use in China.

Peer review

This is a good descriptive study in which authors analyze the effects of Yiguanjian decoction in liver fibrosis, induced by CCl₄. The results are interesting and suggest that YGJ decoction improved liver fibrosis by inhibiting the migration of bone marrow cells into the liver as well as inhibiting their differentiation and suppressing the proliferation of both progenitors and hepatocytes in the injured liver. The paper is interesting and deserves to be published.

Abstract

AIM: To compare the impact of carbon dioxide (CO₂) and air insufflation on patient tolerance/safety in deeply sedated patients undergoing colonoscopy.

METHODS: Patients referred for colonoscopy were randomized to receive either CO₂ or air insufflation during the procedure. Both the colonoscopist and patient were blinded to the type of gas used. During the procedure, insertion and withdrawal times, caecal intubation

rates, total sedation given and capnography readings were recorded. The level of sedation and magnitude of patient discomfort during the procedure was assessed by a nurse using a visual analogue scale (VAS) (0-3). Patients then graded their level of discomfort and abdominal bloating using a similar VAS. Complications during and after the procedure were recorded.

RESULTS: A total of 142 patients were randomized with 72 in the air arm and 70 in the CO₂ arm. Mean age between the two study groups were similar. Insertion time to the caecum was quicker in the CO₂ group at 7.3 min vs 9.9 min with air ($P = 0.0083$). The average withdrawal times were not significantly different between the two groups. Caecal intubation rates were 94.4% and 100% in the air and CO₂ groups respectively ($P = 0.012$). The level of discomfort assessed by the nurse was 0.69 (air) and 0.39 (CO₂) ($P = 0.0155$) and by the patient 0.82 (air) and 0.46 (CO₂) ($P = 0.0228$). The level of abdominal bloating was 0.97 (air) and 0.36 (CO₂) ($P = 0.001$). Capnography readings trended to be higher in the CO₂ group at the commencement, caecal intubation, and conclusion of the procedure, even though this was not significantly different when compared to readings obtained during air insufflation. There were no complications in both arms.

CONCLUSION: CO₂ insufflation during colonoscopy is more efficacious than air, allowing quicker and better caecal intubation rates. Abdominal discomfort and bloating were significantly less with CO₂ insufflation.

INTRODUCTION

Colonoscopy is now widely used as a screening tool for colorectal neoplasia screening. It is generally necessary to distend the colon adequately during colonoscopy to allow safe navigation and permit thorough inspection of the mucosa. Abdominal discomfort attributed to gas insufflation during the procedure can occasionally lead to significant patient discomfort. The perception of the procedure being relatively painless is hence of paramount importance. In order to make the procedure more comfortable, deep sedation with Propofol have been used^[1]. Patients given Propofol had a more rapid onset of sedation and recovery. The use of carbon dioxide (CO₂) instead of air has also been shown to reduce abdominal discomfort and pain in several randomized controlled trials^[2-8]. These studies however utilized no or only minimal sedation when assessing the efficacy and safety of CO₂ in colonoscopy. The additional benefit of CO₂, if any, in patients who are deeply sedated has not been gauged. We therefore embarked on this study to assess the true impact of CO₂ in deeply sedated patients undergoing colonoscopy.

MATERIALS AND METHODS

This was a randomized, double blind study conducted over a period of 10 mo from May 2008 to March 2009. All patients undergoing screening and surveillance colonoscopy were invited to participate. Patients with previous colonic resections were excluded. Randomization was performed by whole sessions rather than individually by a clinical research coordinator. Sealed envelopes marked with either CO₂ or air insufflation was used. If the first patient on a given list was randomized to receive CO₂, the air insufflation button was switched off and the CO₂ delivery system was activated by depressing a lever which was set up just above the CO₂ tank. The whole gas delivery system was intentionally located out of the view of the colonoscopist, the nurse assigned to grade the level of sedation and patient discomfort during the procedure as well as the patient. Air insufflation was delivered through standard means whereas CO₂ was delivered at a rate of 4 L/min with a pressure of 50 kilopascals using a standard CO₂ delivery system.

All colonoscopies were performed by experienced gastroenterologists or colorectal surgeons whom had each individually performed more than 5000 procedures. Patients received sedation in combinations of Propo-

fol, Midazolam and Fentanyl. This was administered by a trained nurse sedationist under the direction of the proceduralist. The total amount of sedation given was recorded at the end of each procedure. During the procedure, insertion and withdrawal times were recorded. Insertion time was defined as the time taken from the commencement of colonoscopy until the caecum was reached whilst the withdrawal time, time from the caecum up to the anus. The stopwatch was stopped during biopsies and polypectomies. Cecal intubation rates were also recorded.

End tidal CO₂ measurements were used to measure the CO₂ levels. Continuous measurement was possible using a nasal cannula which was connected to a capnograph. Capnography readings were charted at the 3 different time frames: at the commencement of colonoscopy, upon intubation of the caecum and at the conclusion of the procedure. The level of sedation during the procedure was assessed by the nurse sedationist using a visual analogue scale (VAS) (0-wide awake, 1-mild sedation/easy to rouse, 2-moderate sedation/unable to stay awake, 3-difficult to rouse) while the magnitude of patient discomfort was also assessed using a similar VAS (0-nil, 1-mild, 2-moderate, 3-severe).

At the conclusion of each procedure, the colonoscopists were asked to determine whether they thought the gas used was CO₂ or air. The patients were then observed in the recovery bay using a standardized post procedure recovery protocol. Prior to discharge from the unit, patients graded their level of discomfort and abdominal bloating using a similar VAS as described above.

Statistical analysis was performed using the Stata V10 Statistical software (StataCorp. 2007 College Station, TX, United States). *P* value < 0.05 was used to indicate statistical significance.

RESULTS

A total of 150 patients participated in the study. Eight patients were excluded due to failure to give consent (3), history of previous colonic resection (3) and poor bowel preparation (2) leaving a total of 142 patients of which 72 were randomized in the air arm and 70 in the CO₂ arm. The two patient groups were of similar age with a mean of 59.97 (range: 22-88 years) in the air group and 58.26 (range: 22-84 years) in the CO₂ group. Of the 72 patients in the air group, 33 were male and 39 female whilst in the CO₂ group, 45 were male and 25 female (*P* < 0.05). The average insertion time was 9.88 min in the air group and 7.29 min in the CO₂ group (*P* = 0.0083). The average withdrawal times were 6.69 min and 7.29 min in the air and CO₂ groups respectively (*P* > 0.05). The caecal intubation rates were 94.4% in the air group and 100% in the CO₂ group (Table 1).

The amount of sedation given to patients during the procedure was similar in both groups. The level of sedation as assessed by a nurse during the procedure was 1.0 in the air group and 1.09 in the CO₂ group (*P* > 0.05).

Table 1 Patient characteristics, procedure duration, sedation parameters, and capnographic readings with air and CO₂ insufflation during colonoscopy

	Air	CO ₂	P value
Total procedures	72	70	NS
Age (mean) (yr)	59.97	58.26	NS
Male:female ratio	33:39	45:25	NS
Insertion time (min)	9.88	7.29	0.0083
Withdrawal time (min)	6.69	7.29	NS
Cecal intubation rate (%)	94.4	100	0.012
Sedation used			
Propofol (mg)	185.97	184.14	NS
Midazolam (mg)	0.78	0.66	NS
Fentanyl (mg)	32.64	34.93	NS
Sedation (nurse assessment)	1.00	1.09	NS
Discomfort (nurse assessment)	0.69	0.39	0.0155
Pain (patient assessment)	0.82	0.46	0.0228
Bloating (patient assessment)	0.97	0.36	0.001
Capnography at commencement	18.53	20.21	NS
Capnography at caecum	15.1	19.28	NS

NS: Not significant.

Conversely, the discomfort level as assessed by the nurse (during the procedure) was 0.69 (air) and 0.39 (CO₂) ($P = 0.0155$) and post procedure by the patient 0.82 (air) and 0.46 (CO₂) ($P = 0.0228$). The level of abdominal bloating as assessed by the patient prior to discharge from the endoscopy unit was 0.97 (air) and 0.36 (CO₂) ($P = 0.001$) (Table 1).

Capnography readings were higher in the CO₂ group at commencement of colonoscopy, upon reaching the caecum and at the conclusion of the procedure (Table 1). This, however, was not statistically significant. There were 2 patients with Chronic Obstructive Airway Disease (COPD) in the air arm and 3 in the CO₂ arm ($P > 0.05$). There were no complications observed with both the use of CO₂ or air. The accuracy of the colonoscopists in predicting the type of gas insufflation used was 73.6% in the air group and 54.7% in the CO₂ group.

DISCUSSION

This prospective, randomized study has shown that insufflation of CO₂ during colonoscopy resulted in significantly reduced abdominal discomfort in deeply sedated patients. The rapid absorption of CO₂ from the colon resulted in less distension of the colon and therefore shorter procedural times. This was demonstrated with the quicker caecal insertion times in the CO₂ group compared to patients who were randomized to receive air insufflation. The caecal intubation rate in the CO₂ group was also better.

There have been numerous studies looking at the efficacy and safety of CO₂ in the gastrointestinal tract leading to a recently published systematic review on this subject by Dellon *et al*⁹¹. The authors concluded that CO₂ insufflation was associated with decreased post procedural pain and distension. One of the major drawbacks of this review which the authors concurred with is that 6 of the

9 randomized controlled trials were from the same group. None of the studies however looked at patients who were deeply sedated. With an increasing number of patients opting for a painless procedure especially with deep sedation, we attempted to address this question here.

The different colonoscopists performing the procedure may have arguably influenced the results as the more experienced practitioners would be expected to be more skilled. However, all colonoscopists involved in the study were experienced consultants with recognition in the practice of colonoscopy. No trainees/registrar were involved in performing the procedure. The insufflation of gas during colonoscopy was determined by sealed envelopes and several methods were employed in this study to ensure blinding of all parties involved. The gas coupling was hidden from view during the colonoscopic session thereby eliminating the possibility of unblinding if the changing of gas coupling was done after each patient. The usage of CO₂ or air was also silent further reducing the possibility of any audible sound from either the air or CO₂ delivery systems being heard by the colonoscopist or the nurse sedationist during the procedure. In addition, the possibility of the colonoscopist being able to determine the gas used by observing the distension of the colon during insufflation was not found to be a problem as seen in the accuracy of gauging the type of gas used at the procedure being 73.6% in the air group and 54.7% in the CO₂ group.

There have been concerns expressed with regards to use of CO₂ causing interference with metabolic homeostasis and respiratory complications in certain patient groups. Several studies have confirmed the safety of CO₂ insufflation although patients with COPD were excluded. We specifically did not exclude patients with COPD in this study (air: 2 *vs* CO₂: 3). Although this study showed an increased level of capnography readings in the CO₂ group compared to air, this was not statistically significant. Moreover the baseline CO₂ was slightly higher than the air group (18.53 mmHg *vs* 20.21 mmHg). There were no respiratory complications seen. One of the major limitations though is that the measurement of CO₂ levels by capnography is not performed in a closed system and may have therefore not been very accurate. The level of CO₂ should ideally be measured by performing arterial blood gases. However, this was not thought to be appropriate given that the patients would have to undergo multiple arterial punctures during the procedure. We were also vigilant with the continuous monitoring of the CO₂ levels during the procedure although actual documentation was only done at 3 set time frames. Another drawback of the study is that there were a higher number of male patients compared to female patients in the CO₂ group which may have affected the result of bloating and pain level. However, the patient gender was found to not have any statistically significant difference.

In conclusion, the use of CO₂ insufflation during colonoscopy in deeply sedated patients was more efficacious than air, resulting in a quicker procedural time and

better patient tolerance with regards to less abdominal bloating and pain. It was also safe with no complications observed. It is recommended that CO₂ be considered for routine use in colonoscopy in deeply sedated patients to further increase patient comfort.

COMMENTS

Background

Colonic distention with gas during colonoscopy allows thorough inspection of the mucosa, at the expense of causing abdominal discomfort. In order to make the procedure more comfortable, apart from anaesthetic agents, the use of carbon dioxide (CO₂) instead of air has also been shown to reduce abdominal discomfort and pain in several randomized controlled trials.

Research frontiers

Previous studies however utilized no or only minimal sedation when assessing the efficacy and safety of CO₂ in colonoscopy. This study aimed to assess the true impact of CO₂ in deeply sedated patients undergoing colonoscopy.

Innovations and breakthroughs

Use of CO₂ insufflation during colonoscopy in deeply sedated patients was not only safe, but more efficacious than air, resulting in a quicker procedural time and better patient tolerance with regards to less abdominal bloating and pain.

Applications

It is recommended that CO₂ be considered for routine use in colonoscopy in deeply sedated patients to further increase patient comfort while allowing safe adequate colonic distention.

Terminology

CO₂ insufflation is the distention of the colon with carbon dioxide gas during the performance of colonoscopy, to allow better visualization of the mucosa surface.

Peer review

It is well known that patients who are not sedated or minimally sedated have significant benefits when CO₂ is used to insufflate the bowel. This study evaluated the effect of CO₂ on deeply sedated patients and further adds to the available data in the literature with regards to the its application in colonoscopy.

Abstract

AIM: To investigate intestinal alkaline phosphatase (iAP) in the intestinal mucosa of children with inflammatory bowel disease (IBD).

METHODS: Colonic biopsy samples were taken from 15 newly diagnosed IBD patients and from 10 healthy controls. In IBD patients, specimens were obtained

both from inflamed and non-inflamed areas. The iAP mRNA and protein expression was determined by reverse transcription-polymerase chain reaction and Western blotting analysis, respectively. Tissue localization of iAP and Toll-like receptor (TLR) 4 was investigated by immunofluorescent staining.

RESULTS: The iAP protein level in the inflamed mucosa of children with Crohn's disease (CD) and ulcerative colitis (UC) was significantly decreased when compared with controls (both $P < 0.05$). Similarly, we found a significantly decreased level of iAP protein in the inflamed mucosa in CD compared with non-inflamed mucosa in CD ($P < 0.05$). In addition, the iAP protein level in inflamed colonic mucosa in patients with UC was decreased compared with non-inflamed mucosa in patients with CD ($P < 0.05$). iAP protein levels in the non-inflamed mucosa of patients with CD were similar to controls. iAP mRNA expression in inflamed colonic mucosa of children with CD and UC was not significantly different from that in non-inflamed colonic mucosa with CD. Expression of iAP mRNA in patients with non-inflamed mucosa and in controls were similar. Co-localization of iAP with TLR4 showed intense staining with a dotted-like pattern. iAP was present in the inflamed and non-inflamed mucosa of patients with CD, UC, and in control biopsy specimens, irrespective of whether it was present in the terminal ileum or in the colon. However, the fluorescent signal of TLR4 was more pronounced in the colon compared with the terminal ileum in all groups studied.

CONCLUSION: Lower than normal iAP protein levels in inflamed mucosa of IBD patients may indicate a role for iAP in inflammatory lesions in IBD. Based on our results, administration of exogenous iAP enzyme to patients with the active form of IBD may be a therapeutic option.

INTRODUCTION

The etiology of inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), remains unclear. It is hypothesized that, in genetically susceptible individuals, inappropriate and ongoing activation of a mucosal immune response against luminal antigens is a major cause of the inflammation^[1,2]. In active IBD, the tolerance towards the resident intestinal flora is decreased. The balance between protective and commensal luminal bacterial species is lost and, due to increased mucosal permeability and insufficient mucosal clearance, the commensal flora and pathogenic bacteria enter into the lamina propria and destructive inflammatory responses are unavoidable^[3-6]. This prompts an exaggerated immune response with the activation of the two arms of mucosal immune system, the innate and adaptive elements^[7,8].

The activation of the innate immune system heavily depends on the recognition of microbes by pattern recognition receptors such as Toll-like receptors (TLRs). The TLR family consists of 13 members, and each has different type of ligands. One of them is TLR4, which is responsible for recognition of lipopolysaccharide (LPS), a principal component of the bacterial outer membrane. Uncontrolled activation of TLR4 may lead to the loss of mucosal barrier integrity, aggravation of the inflammatory response within the gut epithelial mucosa, increased expression of TLR-ligands and tumorigenesis^[9-13]. Previously, we found increased TLR4 protein and mRNA levels in the inflamed mucosa of children with IBD and celiac disease^[14,15].

An increasing body of evidence also supports the regulatory role of intestinal alkaline phosphatase (iAP) in TLR activation. iAP is expressed on the apical surface of enterocytes and exists in membrane-bound and soluble forms^[16]. iAP plays an essential role in the inactivation of LPS through dephosphorylation of its lipid A moiety, thus generating a non-toxic monophosphoryl section. This dephosphorylated monophosphoryl lipid A is not able to form a complex with TLR4^[17,18].

There is only one human study where expression of iAP (mRNA) in adult IBD patients was analyzed, and lower than normal iAP mRNA expression was found

in epithelial specimens^[19]. It should be noted, however, that no data on the level of iAP protein in IBD mucosa is available. The aim of our study was to investigate iAP protein and mRNA levels in affected and non-affected colon mucosa of children with newly diagnosed IBD. In addition, our secondary aim was to determine the localization of iAP enzyme with TLR4.

MATERIALS AND METHODS

Patients and colonic biopsies

Ten children (7 boys, 3 girls; median age: 10.5 years, range: 1.5-15 years) with newly diagnosed CD, 5 children (3 boys, 2 girls; median age: 11 years, range: 6-17 years) with newly diagnosed UC, and 10 control children (5 boys, 5 girls; median age: 9.5 years, range: 1.5-16 years) were enrolled in the study (Table 1). IBD was diagnosed according to the Porto criteria^[20,21]. The presenting symptoms in CD were perianal fistula, hematochezia, abdominal pain, diarrhea-bloody diarrhea, or anemia. All of the patients later diagnosed with UC had hematochezia, and some had abdominal pain and weight loss. Colonic biopsy samples were taken from macroscopically inflamed and non-inflamed sites of the colonic mucosa in children with CD. As each UC children had pancolitis, only inflamed mucosa was obtained from UC patients (Table 1). The activity score was calculated by means of the Pediatric Crohn's Disease Activity Index (PCDAI) and Pediatric Ulcerative Colitis Activity Index (PUCAI)^[22,23]. Measuring disease activity in pediatric CD is based on disease history (abdominal pain, stools per day and general well-being), laboratory findings, weight, abdominal and perianal examination, extra-intestinal manifestations, and growth rate^[24]. PUCAI requires no laboratory measurements^[25]. The mean PCDAI of our patients was 33.75, and the mean PUCAI was 35. This means that both groups had moderate-to-severe disease activity. Control children were referred to the outpatient clinic with rectal bleeding, constipation or weight loss. Colonoscopy was part of their diagnostic procedure and the biopsy specimens showed normal macroscopic appearance and histology. Written informed consent was obtained from parents prior to the procedure, and the study was approved by the Semmelweis University Regional and Institutional Committee and Research Ethics.

RNA isolation and real-time polymerase chain reaction

Total RNA was isolated from the colonic biopsy samples by RNeasy Total RNA Isolation Kit (Qiagen GmbH, Hilden, Germany), according to the instructions of the manufacturer. One μ g of total RNA was reverse-transcribed and iAP mRNA expressions were determined by real-time polymerase chain reaction (PCR) on Light Cycler480 (Roche Diagnostics, Mannheim, Germany). PCRs were performed containing RealTime ready Catalog Assay primer (Roche Diagnostics), Light Cycler 480 Probes Master (Roche Diagnostics, Mannheim, Germany), and cDNA. Conditions for iAP mRNA measurements: one

Table 1 Clinical characteristics of newly diagnosed patients with Crohn's disease and ulcerative colitis

cycle, 95 °C, 10 min (denaturation), followed by several cycles at 95 °C, 10 s and 30 s, 72 °C 1 s (annealing and extension). The mRNA expression of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as internal control was determined using Brilliant II Fast SYBR Green quantitative polymerase chain reaction Master Mix (Stratagene, Cedar Creek, TX, United States), PCR primers (Forward: 5'-CAC CAC CAT GGA GAA GGC TG-3'; Reverse: 5'-GTG ATG GCA TGG ACT GTG-3', Invitrogen, CA, United States) and cDNA. Conditions for GAPDH: one cycle, 95 °C, 2 min, 50 cycles at 95 °C 20 s and 60 °C, 40 s. Results were analyzed by Light-Cycler software 480 (Roche Diagnostics).

Protein isolation and Western blotting

Colonic biopsy specimens were homogenized in lysing solution, and protein concentrations were determined by DC Protein Assay (Bio-Rad Laboratories, Hercules, CA, United States); 0.5 µg protein from each sample was separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (120 V, 40 mA, 120 min) (Penguin™ Dual-Gel Water Cooler Systems, Owl, NH, United States) and transferred to nitrocellulose membrane (GE Healthcare, Little Chalfont, United Kingdom) (70 V, 220 mA, 120 min) (MiniTank™ electroblotter, Owl). Membranes were blocked in 1% non-fat dry milk solution (1 h) and

incubated with iAP specific rabbit polyclonal antibody (1:1000, 1 h) (AbCam, Cambridge, United Kingdom). Equal protein loading was confirmed by β-actin specific (C-11) goat polyclonal IgG antibody (1:100) (Santa Cruz Biotechnology Inc., Santa Cruz, CA, United States). Peroxidase-conjugated secondary anti-rabbit IgG or donkey anti-goat IgG antibodies (1:2000, 30 min) (Santa Cruz Biotechnology Inc.) were used. Immunoreactive bands were visualized using the enhanced chemiluminescence Western blotting detection protocol (GE Healthcare). Bands were analyzed with software Image J. 1.42q (National Institutes of Health, United States). The values were expressed as relative optical density.

Immunofluorescent staining

Biopsy samples were snap-frozen, embedded in Shandon cryomatrix (ThermoElectron Co., Waltham, United States), cut to 3-4 µm slides and double incubated with TLR4 specific goat polyclonal antibody and iAP specific rabbit polyclonal antibody (1:100, 1 h) (Abcam Plc). Secondary antibodies were Alexa Fluor 488 donkey anti-goat and Alexa Fluor 568 goat anti-rabbit antibodies (Invitrogen). Zeiss LSM 510 Meta confocal laser scanning microscope (Carl Zeiss, Jena, Germany) was used with 20 × Plan Apochromat (NA = 0.8) and 63 × Plan Apochromat oil immersion differential interference contrast objectives (NA = 1.4).

Statistical analysis

Data were analyzed using Statistica 7.0 software (StatSoft Inc., Tulsa, OK, United States). After testing the normality with Shapiro-Wilk's test, non-parametric Mann-Whitney *U* test was used. Data were considered statistically significant if $P \leq 0.05$, and expressed as mean ± standard deviation.

RESULTS

iAP protein levels

Western blotting analysis revealed one distinct band at 60 kDa. The iAP protein level in the inflamed mucosa of children with CD and UC was lower by 22% and 20%, respectively, compared with controls ($P < 0.05$). We found a lower iAP protein level in the inflamed mucosa in CD compared with non-inflamed mucosa in CD ($P < 0.05$). The iAP protein level in the inflamed colonic mucosa in UC patients was decreased by 24% compared with non-inflamed mucosa in CD patients ($P < 0.05$) (Figure 1). iAP protein levels in the non-inflamed mucosa of patients with CD were normal.

iAP mRNA expression

iAP mRNA expression in inflamed and non-inflamed colonic mucosa in IBD was comparable with that in controls (Figure 2).

Mucosal localization of iAP and TLR4

The distribution of iAP was restricted to the epithelial

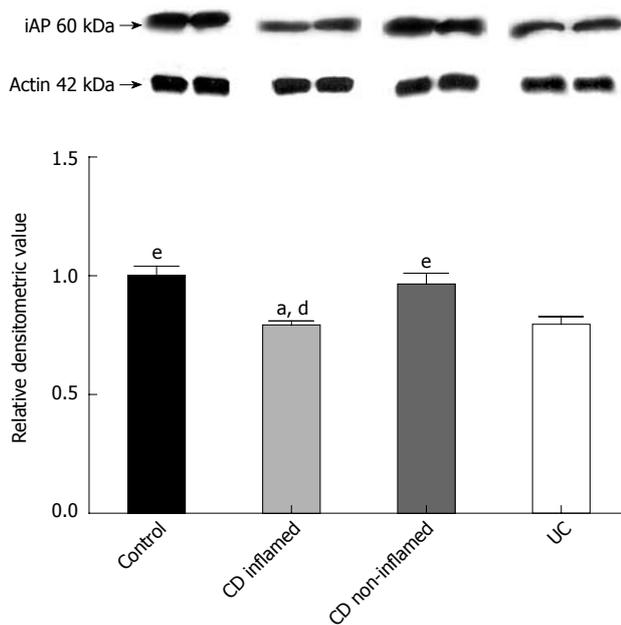

Figure 1 Protein levels of intestinal alkaline phosphatase in the colonic mucosa of children with newly diagnosed Crohn's disease, ulcerative colitis and controls. A: Western blotting analysis of the colonic biopsy specimens using intestinal alkaline phosphatase (iAP)-specific antibody reveals one distinct band at 60 kDa; B: Data for protein levels of iAP were obtained by computerized analysis of the Western blottings and expressed as median interquartile range. Analysis of significance was performed by the Mann-Whitney *U* test. ^a*P* < 0.05 vs control; ^d*P* < 0.01 vs non-inflamed CD; ^e*P* < 0.05 vs UC. CD: Crohn's disease; UC: Ulcerative colitis.

surface of the colonic and terminal ileal mucosa in each group. No fluorescent signal was detected in Lieberkühn crypt cells, in goblet cells, and in lamina propria immune cells. The co-localization of iAP with TLR4 showed intense staining with a dotted-like pattern. iAP was present in inflamed and non-inflamed mucosa of patients with CD, UC, and in control specimens irrespective of whether it was present in the terminal ileum or in the colon. However, the fluorescent TLR4 signal was more pronounced in the colon compared with the terminal ileum in all groups (Figure 3).

DISCUSSION

A dysregulated immune response, involving the innate immunity of the intestinal mucosa plays a role in the pathomechanism of IBD. The maintenance of microbiota and host is supported by the balance of microbiota and immune activation that may be disturbed in IBD^[26]. Previously we and others showed that activation of TLR4 by bacterial lipopolysaccharide contributes to disease progression^[14,27].

Recently, in connection with LPS-activated TLR4, a new enzyme, iAP has received increasing attention as a factor responsible for mucosal defense. iAP dephosphorylates and detoxifies LPS and, hence, generates an inactive, non-toxic form. This may be one of the key factors why dephosphorylated LPS is unable to bind to TLR4 and the innate immune system is not triggered. iAP may control the interaction between TLR4 in the intestinal

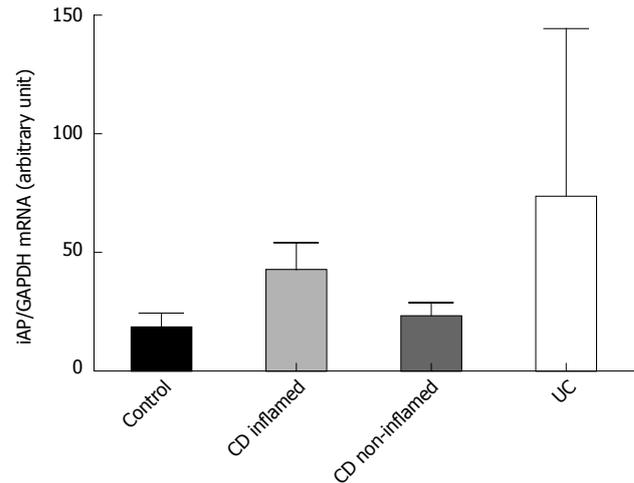

Figure 2 Intestinal alkaline phosphatase mRNA expression in the colonic mucosa of children with newly diagnosed Crohn's disease, ulcerative colitis and controls. iAP mRNA expression data were obtained by computerized analysis of PCR products. Optical density was corrected according to that of GAPDH. Data are expressed as median interquartile range. Analysis of significance was performed by Mann-Whitney *U* test. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; PCR: Polymerase chain reaction; iAP: Intestinal alkaline phosphatase; CD: Crohn's disease; UC: Ulcerative colitis.

mucosa and LPS derived from the bacterial flora^[28,29].

In the present study, we obtained data regarding the protein level, mRNA expression and localization of iAP in the intestinal mucosa of children with IBD. Lower than normal iAP levels were observed in the inflamed mucosa of CD and UC patients.

Previously it was hypothesized that the altered LPS-dephosphorylating activity may be a consequence of decreased iAP activity. We think that, in accordance with Tuin *et al*^[19], our observations also suggest that iAP has a role in the pathogenesis of IBD. Decreased iAP levels in the inflamed mucosa may be associated with decreased LPS detoxification and, consequentially, with increased TLR4 activation. On the other hand, we found no significant difference in iAP mRNA expression that may indicate a possible role of posttranscriptional regulation.

Tuin *et al*^[19] demonstrated decreased iAP mRNA expression in pretreated CD patients compared with controls. However, it should be noted that, in this study, more than half of the patients received immunosuppressive drugs such as infliximab, methotrexate, corticosteroids, and thiopurine at the time of sample collection, which may influence iAP mRNA synthesis^[30]. The unique feature of our study is the investigation of children without prior immunomodulatory therapy, hence, our results can be considered as characteristic for IBD.

Previously, we have demonstrated increased TLR4 mRNA expression and protein levels in the inflamed colonic mucosa of children with IBD^[14]. Therefore, the finding that iAP and TLR4 are co-localized, is particularly important from two aspects. First, it supports a linked role of iAP in the maintenance of mucosal integrity both in healthy and in diseased subjects. Second, the lower than normal iAP in the presence of a higher than

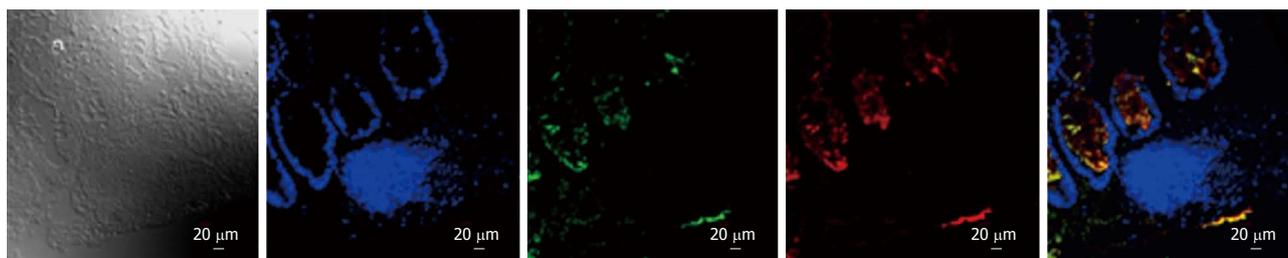

Figure 3 Localization of intestinal alkaline phosphatase and Toll-like receptor-4 in colon of Crohn's disease. Immunofluorescent staining for intestinal alkaline phosphatase (iAP) (red) and Toll-like receptor-4 (TLR4) (green) staining was performed in inflamed colon of patient with Crohn's disease. Yellow color (merge) indicates co-localization of iAP and TLR4. For the observation of non-labeled tissues, differential interference contrast was used. Nuclei are stained with blue.

normal TLR4 expression might indicate an imbalance in iAP/TLR4 that would result in an increased susceptibility of the mucosa to LPS. Indeed, this mechanism is already demonstrated in animal models of induced colitis. Our results are the first to indicate the presence of this phenomenon in man.

The current management of IBD consists of conventional therapy, but severe therapy-resistant cases require more powerful therapies, such as biological treatment^[31]. Therapeutic manipulation to restore the balance of microflora may have a strong impact on mucosal healing of IBD^[32]. In animal models of dextrane sodium sulfate (DSS)-induced colitis, exogenously administered iAP improved the signs of colitis both macroscopically and microscopically^[33]. Microscopic injury scores of DSS-induced colitis in iAP-knockout mice were much higher than in the wild-type group, which may reveal the mucosal defense role of iAP^[34]. In a human study performed in adult subjects a 7-d course of iAP products decreased the activity index of therapy-resistant UC patients^[35]. Oral administration of iAP may have a beneficial effect in the case of severe intestinal epithelial damage^[36]. Our results obtained in a pediatric population might indicate a similar approach may be of benefit in children with IBD.

In summary, to the best of our knowledge, this is the first demonstration of a decrement in the iAP enzyme in the mucosa of patients with IBD. A decreased level of iAP with reduced LPS-detoxifying capacity could be responsible for increased bacterial passage across the intestinal mucosa of patients with IBD, and this may play an important role in pathogenesis. In addition, co-localization of iAP and TLR4 was demonstrated in the epithelial compartment. Based on our results, administration of exogenous iAP enzyme to patients with active form of IBD may be a supplemental therapeutic option.

COMMENTS

Background

The level of intestinal alkaline phosphatase (iAP) protein in inflammatory bowel disease (IBD) mucosa is very important for the study of IBD. The authors have

demonstrated firstly the presence of iAP enzyme in the colonic mucosa of patients with IBD. The decreased level of iAP enzyme with reduced lipopolysaccharide-detoxifying capacity could be responsible for the increased bacterial passage across the intestinal mucosa in the inflamed mucosa of patients with IBD and this may play a role in the pathogenesis.

Research frontiers

To the best of our knowledge, this is the first demonstration of a decrement in iAP enzyme in the mucosa of patients with IBD.

Innovations and breakthroughs

A decreased level of iAP with reduced lipopolysaccharide-detoxifying capacity could be responsible for increased bacterial passage across the intestinal mucosa of patients with IBD, and this may play an important role in the pathogenesis of IBD. In addition, co-localization of iAP and Toll-like receptor-4 was demonstrated in the epithelial compartment.

Applications

Based on their results, the authors propose administration of exogenous iAP enzyme to patients with the active form of IBD as a supplemental therapeutic option. However, this hypothesis should be tested in future clinical trials.

Terminology

The importance of the mucosal barrier damage is emphasized in IBD due to its potential role in IBD pathogenesis. iAP, a potent factor to maintain or restore mucosal barrier integrity in the gut, could participate in the mucosal healing of IBD.

Peer review

This is a well-written manuscript reporting about significance of intestinal alkaline phosphatase in the colonic mucosa for the pathogenesis of inflammatory bowel disease in children. The manuscript contains clear component of novelty to the best my knowledge, the authors have firstly demonstrated the decrement of iAP enzyme in the mucosa of patients with IBD.

Abstract

AIM: To determine the precise incidence and clinical features of endoscopic ulcers following gastrectomy.

METHODS: A consecutive series of patients who underwent endoscopic examination following gastrectomy between 2005 and 2010 was retrospectively analyzed. A total of 78 patients with endoscopic ulcers and 759 without ulcers following gastrectomy were enrolled. We analyzed differences in patient age, sex, size of the lesions, method of operation, indications for gastric resection, and infection rates of *Helicobacter pylori* (*H. pylori*) between the nonulcer and ulcer groups.

RESULTS: The incidence of endoscopic ulcers after gastrectomy was 9.3% and that of marginal ulcers was 8.6%. Ulcers were more common in patients with Billroth II anastomosis and pre-existing conditions for

peptic ulcer disease (PUD). Infection rates of *H. pylori* did not differ significantly between the two groups. The patients who underwent operations to treat PUD had lower initial levels of hemoglobin and higher rates of hospital admission.

CONCLUSION: *H. pylori* was not an important factor in ulcerogenesis following gastrectomy. For patients who underwent surgery for PUD, clinical course of marginal ulcers was more severe.

INTRODUCTION

Total or partial gastrectomy is reserved for patients with peptic ulcer disease (PUD) who have failed to respond to therapy or individuals with gastric malignancies. The need to perform gastrectomy on PUD patients has decreased since the discovery of *Helicobacter pylori* (*H. pylori*) and development of proton pump inhibitors^[1,2]. Nevertheless, the total frequency of performing gastrectomy has increased due to the frequent detection of early gastric

cancer and increasing morbid obesity^[3-6]. The complications of gastrectomy are recurrent ulcers, nutritional disturbances, dumping syndrome, *de novo* cancer of the gastric remnant [so-called “gastric stump cancer” (GSC)], and alkaline reflux gastritis^[7].

During follow-up endoscopic examination, the detection of ulcerative lesions including marginal ulcers as well as cancer recurrence and development of GSC are of clinical interest. Therefore, information about the distinct features of these different ulcerative lesions will help discriminate these lesions from one another so that appropriate treatment strategies can be identified. Marginal ulcers are defined as ulceration around anastomosis following gastrectomy. It has been reported that the incidence of marginal ulcers varies from 0.6% to 16%^[8,9]. Although the etiology of marginal ulcers remains obscure, several mechanisms have been postulated. Until now, there are no convincing results, and the exact link between *H. pylori* and the development of marginal ulcers is unclear. GSC was originally defined as a gastric cancer that arises in the remnant stomach > 5 years after primary surgery for benign diseases such as PUD. A minimal latency of 5 years is included in the definition to avoid misdiagnosis^[10,11]. Until now, many features of these lesions were controversial.

The goal of this study was to determine the precise incidence of endoscopic ulcers in patients with a history of gastrectomy. Clinical features of these lesions and patients were evaluated including location, size, types of reconstruction following gastrectomy, causative disease for operation, and history of *H. pylori* infection. In addition, features of GSC were evaluated including frequency, site, time of appearance following gastrectomy, and pathological characteristics of cancer.

MATERIALS AND METHODS

Patients

This study protocol was approved by the Ethics Committee of the Catholic University of Korea. The study was conducted at St. Vincent Hospital, a teaching hospital of the Catholic University of Korea. The medical records, charts, and digitized archived images of consecutive patients who had a history of gastrectomy and underwent diagnostic esophago-gastroduodenoscopy between January 2005 and December 2010 were reviewed.

Each case was classified as *H. pylori*-positive or -negative according to the histological results [rapid urease test (CLO test[®], Kimberly-Clark, Utah, United States) or silver staining] for two biopsy specimens taken from the remnant stomach. Exclusion criteria were endoscopic evaluation within 1 year following gastrectomy and comorbidity of serious systemic disease. Individuals with conditions that might have substantial effects on our study results (e.g., serum creatinine > 2.5 mg/dL, total bilirubin > 3.0 mg/dL), pregnant women, patients with psychiatric diseases, and patients who did not sign a consent form were excluded. Patients were also excluded if they had cancer recurrence.

Study design

The endoscopic, histological, and clinical features of the ulcerative lesions were analyzed. Subsequently, the ulcerative lesions were classified as neoplastic or non-neoplastic lesions. Cases of recurrent cancer were excluded; the remaining lesions included marginal ulcer and GSC. We analyzed differences in patient age, sex, size of lesions, method of operation, indications for gastric resection, and infection rates of *H. pylori* between the non-ulcer and ulcer groups. For patients with marginal ulcers, we analyzed baseline characteristics, clinical manifestation, and rates of *H. pylori* infection according to the location of ulcers. In addition, we evaluated the clinical features of GSC.

Statistical analysis

Continuous variables were expressed as the mean \pm SD and compared using Student's *t*-test. Categorical variables were expressed as percentages and compared using a χ^2 test. Statistical analyses were conducted with SPSS version 12.0 software (SPSS, Chicago, IL, United States). *P* < 0.05 was considered to be statistically significant.

RESULTS

Demographic features

Data for a consecutive series of patients who underwent gastrectomy between 2005 and 2010 were retrospectively analyzed. A total of 2862 endoscopic examinations were performed and 918 patients were enrolled in our study. Among these, endoscopic examinations were performed for 512 patients within 1 year of gastrectomy and were excluded from our study. Each patient underwent two or three endoscopic procedures during the study period. Eighty-one patients were excluded due to underlying chronic illnesses including: liver cirrhosis, heart failure, chronic obstructive pulmonary disease, chronic renal failure (*n* = 37), simple closure (*n* = 12), gastrojejunostomy without gastrectomy (*n* = 7), and recurrence of previous cancer (*n* = 25). The remaining 837 patients were endoscopically examined and included in our study. A total of 78 patients with endoscopic ulcers and 759 without ulcers following gastrectomy were enrolled (Figure 1). Six (0.7%) out of all 837 patients who underwent gastrectomy were diagnosed with GSC.

Basal characteristics of endoscopic ulcers following gastrectomy

The clinical features of patients in both groups are shown in Table 1. There were no significant differences in age or sex ratio in the group of patients with or without ulcers following gastrectomy. Patients with Billroth II (B-II) gastrojejunal anastomosis were more prone to endoscopic ulceration (*P* < 0.01) compared to those with Billroth I (B-I) anastomosis (Figure 2). The formation of endoscopic ulcers was more frequent in patients who had undergone gastrectomy for PUD complications than

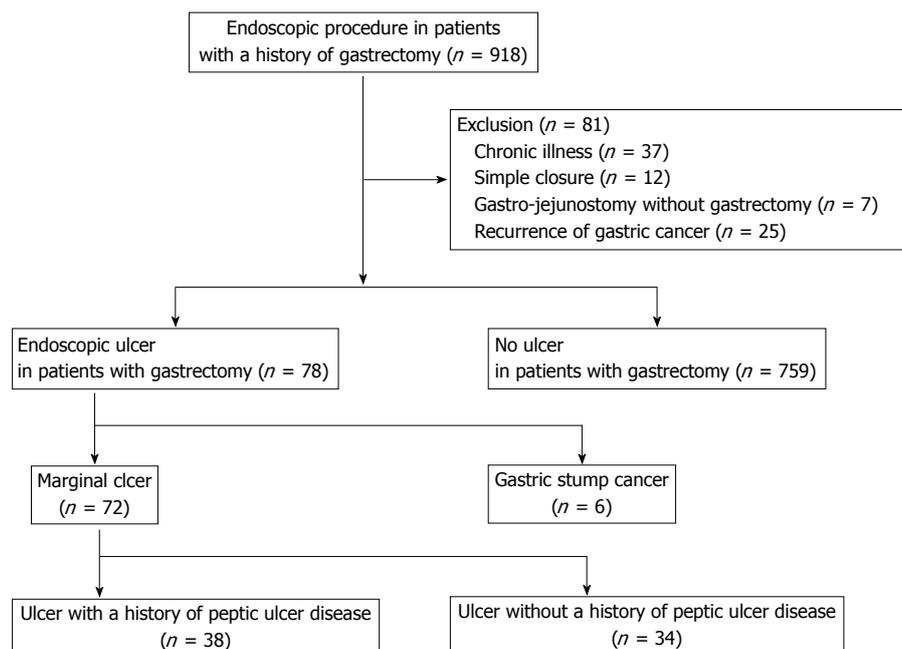

Figure 1 Study design.

	Patients with endoscopic ulcers after gastrectomy (n = 78)	Patients without endoscopic ulcers after gastrectomy (n = 759)	P value
Age (yr)	62.26 ± 12.89	61.00 ± 12.50	0.92

<i>H. pylori</i> infection (%)	20/58 (34.5)	145/397 (36.5)	0.76

H. pylori: *Helicobacter pylori*; PUD: Peptic ulcer disease.

for other reasons ($P < 0.01$). In patients treated with gastrectomy for PUD complications, the incidence of ulcers was 30.1% (44/146). When patients with GSC were excluded, the incidence of marginal ulcers was 27.1% (38/140). The incidence of ulcers in patients treated with gastrectomy for non-PUD diseases was 4.9% (34/691). The incidence of *H. pylori* infection did not differ significantly between the two groups (34.5% *vs* 36.5%, $P > 0.05$).

Clinical features of marginal ulcers

A total of 72 patients had marginal ulcers that were located on the efferent side or anastomosis. Most of these patients (86.1%, 62/72) complained of specific gastrointestinal symptoms, and 41.7% (30/72) experienced episodes of bleeding or developed anemia. The most frequent symptom was abdominal pain. However, there

were no differences of clinical manifestation according to ulcer location. The rate of patients undergoing therapeutic endoscopy to stop or prevent bleeding was 19.4% (14/72) and the rate of patients receiving admission care was 54.2% (39/72). The recurrence of marginal ulcers was observed in 29.2% (21/72) of the patients. There were no differences in the rate of patients receiving therapeutic endoscopy or recurrence of ulcers according to ulcer location (Table 2).

The patients were divided into two groups according to ulcer location: individuals with ulcers on the efferent side and ulcers at anastomosis sites. The most common location of marginal ulcers was the efferent side (55.6%, 40/72). There were no differences in patient age, sex ratio, tobacco use, alcohol consumption, types of reconstruction, causative disease, initial hemoglobin levels, recurrence rates of marginal ulcers, or *H. pylori* infection rates. Ulcers on the efferent side compared to those at anastomosis sites had a tendency of multiplicity, but a number of marginal ulcers appeared as a single lesion (69.4%, 50/72).

Comparison of marginal ulcers according to causative disease

Thirty-eight patients with marginal ulcers previously underwent an operation to control PUD, whereas 34 patients underwent operations to treat malignancies or other conditions (e.g., hemoperitoneum due to trauma). Clinical features of these two groups are shown in Table 3. There was no significant difference in the clinical characteristics including age, sex, types of reconstruction, or *H. pylori* infection rates. The patients who underwent operations to treat PUD had a higher rate of admission (25/38, 65.8%) than the other group (13/34, 38.2%; $P = 0.01$).

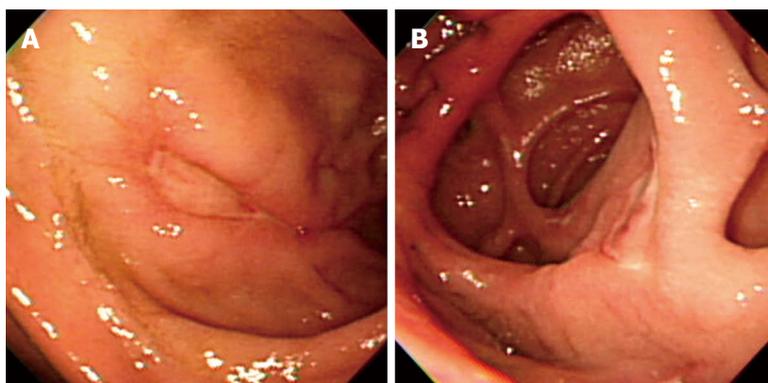

Figure 2 Endoscopic finding of marginal ulcer. In patients with B- I (A) and B- II (B) anastomosis, ovoid shaped ulcerations were observed on the efferent side.

<i>H. pylori</i> infection (%)	7/25 (28)	1/2 (50)	8/25 (32)

RY: Roux-en-Y anastomosis; *H. pylori*: *Helicobacter pylori*; PUD: Peptic ulcer disease.

Initial hemoglobin levels were significantly lower in the PUD group. However, the incidence of rebleeding after primary hemostasis and rate of ulcer recurrence were not different (Table 3).

Clinical features of GSC

GSC was found in six (0.7%) out of 837 patients who underwent gastrectomy. The clinicopathological features of GSC are shown in Table 4. All of these patients were male, and the median interval between the initial gastrectomy and treatment of GSC was 298.8 mo (range, 141-480). Half of these patients underwent gastric reconstruction by B-

I anastomosis and the remaining patients underwent reconstruction by B- II . In two-thirds of all patients, the location of the ulcerative lesion was the gastric stump (Figure 3). Most of these individuals underwent total gastrectomy and only one patient survived the operation.

DISCUSSION

The etiology of ulcer formation following gastrectomy is often multifactorial. Possible contributing factors include local ischemia, anastomotic tension, increased gastric acidity, *H. pylori* infection, tobacco use, and nonsteroidal anti-inflammatory drug (NSAID) use^[12-14]. Chronic inflammation caused by the suture materials at the anastomosis may lead to ulcer formation. Earlier studies have demonstrated that most marginal ulcers develop in the first 3 mo postoperatively due to prolonged irritation by foreign material, however, no ulcers have been found after the first postoperative year^[9,15].

In this study, we included patients who developed

Table 4 Case profile of gastric stump cancer

Case number	1	2	3	4	5	6

ulcers 1 year or more after surgery, and analyzed true marginal ulcers that appeared after gastrectomy. Our results showed that the incidence of endoscopic ulcers after gastrectomy was 9.3% and marginal ulcers was 8.6%. In particular, the incidence of marginal ulcers in patients who had undergone gastrectomy to treat PUD-associated complications was 27.1%. Furthermore, it is noteworthy that most of the patients with marginal ulcers (86.1%) complained of specific gastrointestinal symptoms. Half of these individuals experienced bleeding episodes or developed severe anemia. There was a limitation in this study and we did not consider whether vagotomy was performed. We focused on ulcer development after gastrectomy. Previously, it has been demonstrated that vagotomy prevents ulcer recurrence^[16,17], and most of the enrolled patients had gastrectomy with vagotomy as peptic ulcer surgery.

Marginal ulcer is a well-known complication of partial gastrectomy. It has been reported that marginal ulcer is

evidence of inadequate acid reduction. However, incomplete suppression of gastric acid production is not the sole cause of marginal ulcers. In our endoscopic survey, marginal ulcer was formed following total gastrectomy. On the basis of this result, impaired blood supply or use of NSAIDs can be another mechanism of ulcer development after gastrectomy. In our study, risk factors for ulcer formation after gastrectomy were B-II anastomosis and previous gastrectomy for treating PUD complications. Generally, B-I anastomosis has several advantages. This technique can be performed more easily and rapidly than a B-II anastomosis because fewer steps are required. Normal continuity of the gastrointestinal tract is maintained, thus promoting the mixture of food with bile and pancreatic secretions. The remaining duodenum offers more resistance to recurrent ulceration than does the jejunum and plays a role in preventing the recurrence of ulcers after B-I anastomosis^[18]. These factors explained why ulcerative lesions developed less frequently following

B- I anastomosis.

Infection with *H. pylori* has been shown to be a predictive marker of PUD in the general population, but the exact link between *H. pylori* and the development of marginal ulcers following gastrectomy is unclear. Previously, uncontrolled data have suggested that the frequency of symptomatic marginal ulcers can be reduced by preoperative screening and treatment of *H. pylori* infection in patients undergoing gastric bypass surgery^[19,20]. Although these studies were performed in bariatric patients who have undergone gastric bypass surgery, the results indicate that infection with *H. pylori* may promote marginal ulcer formation. On the contrary, our investigation showed that the rate of *H. pylori* infection did not differ significantly between the ulcer and non-ulcer groups. This suggests that *H. pylori* infection does not play an important role in the pathogenesis of recurrent ulceration after gastrectomy.

However, our study had several limitations associated with our investigation of *H. pylori* infection. First, we did not determine whether patients enrolled in this study were treated when *H. pylori* was diagnosed before they underwent endoscopic examination. In fact, our patients were not routinely tested nor treated for *H. pylori* before gastrectomy. Second, spontaneous clearance of *H. pylori* might occur in a certain number of patients who undergo distal gastrectomy^[21]. Third, the number of patients with B-II was more than twice that with B- I anastomosis. A previous study has shown that resection with B- I has an incidence of *H. pylori* infection of approximately 70%, followed by a significantly lower rate of infection in B- II anastomosis of 45%^[22]. The lower rate of *H. pylori* infection found in B-II may reflect the role of bile reflux, which is more common in B- II than B- I, and may interfere with colonization by *H. pylori*.

To date, many studies have shown that GSC develops after distal gastrectomy, at frequencies of 0.4-2.5%, with an increased incidence 15 years after surgery^[23-25]. Some authors have postulated that patients who have undergone B- II gastrojejunal anastomosis are more prone to developing carcinomas in the gastric remnant^[26,27]. However, GSC has been reported in patients following B- I anastomosis. Our results revealed that GSC was found in three patients after B- I and three after B- II anastomosis. GSC is often described as a tumor with a poor prognosis, with low resectability rates because of extended lymph node metastases and infiltration of adjacent organs^[24,28]. The reported 5-year disease-free overall survival ranges from 7% to 20%^[29,30]. In our study, all patients had advanced stage disease at diagnosis and surgical treatment (total gastrectomy with radical lymph node dissection) was performed in 80% of cases. However, only one patient had 5-year disease-free survival.

Although specific factors responsible for the pathogenesis of GSC have not been identified, chronic inflammation of remnant gastric mucosa is considered to be a risk factor. Enterogastric reflux of bile acids results in increased proliferation of epithelial cells, and hypochlorhydria with subsequent bacterial overgrowth promotes

this condition^[31,32]. It has been previously reported that the gastric mucosa undergoes marked morphological changes in most patients after gastrectomy^[27,33]. Other mechanisms underlying GSC development are effects of hormonal regulation following vagotomy, and *H. pylori* infection^[34-37]. Although *H. pylori* infection may also be a causative factor for GSC, it has reported that the rate of *H. pylori* infection in patients with GSC is lower than in those with primary gastric cancer. The reason is that the gastric stump may be an unsuitable environment for *H. pylori* colonization due to increased bile reflux^[38,39]. However, the exact effect of *H. pylori* is unclear in clinical practice because of the small number of studies on this subject.

In conclusion, we found that endoscopic ulcers following gastrectomy were more common in patients who have undergone B- II anastomosis and had pre-existing cases of PUD. Infection with *H. pylori* did not appear to play an important role in the formation of ulcers following gastrectomy. Patients who underwent operations to treat PUD had lower initial levels of hemoglobin and a higher frequency of admission. Our study demonstrated that patients who undergo operations to treat PUD and subsequently develop marginal ulcer are likely to have a more severe clinical course. Further prospective and detail studies are needed to confirm our findings.

COMMENTS

Background

The total frequency of performing gastrectomy has increased due to the frequent detection of early gastric cancer and increasing morbid obesity. During follow-up endoscopic examination, the detection of ulcerative lesions including marginal ulcers, as well as cancer recurrence, is of clinical interest. Until now, there are limited data currently available on the incidence of marginal ulcer, and the exact link between *Helicobacter pylori* (*H. pylori*) and the development of marginal ulcers is unclear.

Research frontiers

Earlier studies have demonstrated that most marginal ulcers develop in the first 3 mo postoperatively due to prolonged irritation by foreign material. In this study, we excluded the possibility of chronic inflammation caused by the suture materials, and included patients who developed ulcers 1 year or more after surgery. Therefore, true marginal ulcers were analyzed. It was more common in patients in who had undergone Billroth II (B- II) anastomosis and had pre-existing cases of peptic ulcer disease (PUD). It is noteworthy that the incidence of marginal ulcers in patients who had undergone gastrectomy to treat PUD-associated complications was 27.1%. This provided information about the precise incidence and clinical features of marginal ulcers.

Innovations and breakthroughs

The results showed that the incidence of endoscopic ulcers after gastrectomy was 9.3% and that of marginal ulcers was 8.6%. When the patients were divided into two groups according to the presence of ulcer, infection rates of *H. pylori* did not differ significantly between the two groups (34.5% vs 36.5%, $P > 0.05$). Ulcers were more common in patients with B- II anastomosis and pre-existing conditions for PUD. The patients who underwent operations to treat PUD had lower initial levels of hemoglobin and higher rates of hospital admission.

Applications

The researchers drew a conclusion that *H. pylori* infection did not play an important role in the formation of ulcers following gastrectomy. For the patients who underwent operations for PUD, the clinical course of marginal ulcers was more severe.

Peer review

The paper is well written and the findings are of values for gastrectomy evaluation.

Abstract

AIM: To study potential predictive factors for early radical resection in two-stage resection for left malignant colonic obstruction.

METHODS: Thirty-eight cases of left-sided obstructive colon cancer undergoing two-stage operations were reviewed between January 1998 and August 2008. Patients were classified into two groups ($n = 19$ each): early radical resection (interval ≤ 10 d) and late radical resection (interval > 10 d). Baseline demographics, post-diversion outcome, perioperative data, tumor characteristics, outcome and complications were analyzed.

RESULTS: The baseline demographics revealed no differences except for less pre-diversion sepsis in the early group ($P < 0.001$) and more obstruction days in the late group ($P = 0.009$). The mean intervals of early and late radical resections were 7.9 ± 1.3 d and 17.8 ± 5.5 d, respectively ($P < 0.001$). After diversion,

the presence of bowel sounds, flatus, removal of the nasogastric tube and the resumption of oral feeding occurred earlier in the early group. The operation time and duration of hospital stay were both significant reduced in the early group. Complication rates did not differ between groups.

CONCLUSION: The earlier recovery of bowel function seems to be predictive of early radical resection. In contrast, pre-diversion sepsis and more obstruction days were predictive of delayed radical resection.

INTRODUCTION

Bowel obstruction occurs in 7%-47% of patients with colorectal cancer (CRC)^[1-9]. This condition usually requires emergency surgical intervention and is associated with high postoperative morbidity, mortality and a poor 5-year survival rate^[4,5,8]. Surgical management for patients with obstructive CRC varies widely according to the tumor location, severity of the patient's condition and experience level of the surgeon. Resection with anastomosis in one stage is now a generally accepted practice

for primary right-sided obstructive CRC^[1,4,6,9-12]. For left-sided obstructive CRC, two types of surgical intervention have been used: primary resection and staged resection (diversion prior to resection). A randomized trial of emergency colostomy versus resection in patients with left-sided obstructive CRS demonstrated that the only advantage of primary resection was a shorter hospital stay^[13]. A Cochrane systematic review found no evidence to suggest a benefit in terms of mortality when comparing staged procedures with primary resection^[11]. Although the optimal choice of treatment for patients with left-sided obstructive CRS remains controversial^[8,11,14-17], several studies have reported better results for staged procedures^[1,2,4,9,18,19].

Two-staged resection consists of a colostomy or ileostomy to resolve the obstruction as a first step, followed by radical resection and simultaneous closure of the stoma. Corman suggested the use of a 10- to 14-d interval between diversion and radical resection^[20]. The mean interval has ranged widely from 11.5 d to 42 d^[1,9,14,19,21,22]. The appropriate interval for two-stage resection for left-sided obstructive CRC remains controversial and ranges widely. In critically ill patients, the interval should be longer than Corman's suggestion. In contrast, we supposed that in patients with early recovery of bowel function or those lacking any pre-diversion septic condition, the interval may be shorter than 10 d. This study aimed to evaluate the timing of early radical resection and possible predictive factors.

MATERIALS AND METHODS

Patients

From January 1998 to August 2008, there were 132 patients diagnosed with complete obstructive CRC who were treated with emergency surgery at the Tri-Service General Hospital in Taipei, Taiwan. These patients were admitted through the emergency department. Patients with the following criteria were excluded: (1) a tumor proximal to the splenic flexure; (2) colonic perforation with peritonitis; (3) primary resection with or without anastomosis; (4) three-stage resection; (5) palliative ileostomy or colostomy for non-resectable tumors, disseminated disease or critical illness; (6) a colonic stent; or (7) rectal cancer. Consequently, 38 cases with left-sided obstructive CRC for which the patients underwent two-staged resection were investigated.

Methods

Cases with intervals of 10 d or less between diversion and radical resection were classified as group A (early radical resection). Cases with intervals of longer than 10 d were classified as group B (late radical resection). Data collected from extensive chart reviews were recorded and compared. These included (1) baseline demographics including baseline data, comorbidities, days of obstruction (no feces passage) and the mean interval; (2) post-diversion outcomes including stoma type, the tim-

ing of oral feeding, the passage of flatus, the presence of bowel sounds, removal of the nasogastric tube and complications; (3) perioperative data and tumor characteristics including surgery type, operation time, blood loss, blood transfusion, tumor location, pathology diagnosis and tumor stage; and (4) the outcome in terms of hospital stay and complications.

The definition of sepsis was adopted from those published by the International Sepsis Definitions Conference^[23]. Significant comorbidities included hypertensive cardiovascular disease, diabetes mellitus, coronary arterial disease, cerebral vascular accidents, chronic obstructive pulmonary disease, liver cirrhosis and chronic renal insufficiency. Complete bowel obstruction was diagnosed based on clinical history, physical examination, a failure to pass flatus, decreased or absent bowel sounds and the X-ray signs of a distended, obstructed colon. Patients with partial bowel obstruction that responded to nasogastric decompression and intravenous fluid replacement were not included in this category of colonic obstruction. After fluid resuscitation, the correction of imbalanced electrolyte levels and optimization of the patient's general condition, emergency T-loop colostomy was performed within 24 h. Prophylactic antibiotic treatment was administered during the induction of anesthesia and maintained for 24 h unless the septic condition persisted. The type of radical resection depended on the tumor location and each surgeon's judgment; meanwhile, the colostomy was closed. The patient's nutrition status, such as their hemoglobin and serum albumin levels, were corrected to 10 dL/mg and 3.5 dL/mg, respectively, before definitive treatment. Tumor, node, metastasis classification was used for tumor staging^[24].

Group A (early radical resection): Nineteen cases in which the patients underwent two-staged resection with an interval of 10 d or less were classified as group A. A T-loop colostomy was performed as a first step, followed by radical resection and simultaneous closure of the colostomy.

Group B (late radical resection): Nineteen cases in which the patients underwent two-stage resection with an interval of more than 10 d were classified as group B. The surgical approach was the same as for group A.

Statistical analysis

Data were processed and analyzed using the Statistical Package for Social Sciences for Windows, Version 15.0 (SPSS, Inc., Chicago, IL, United States). Continuous variables were analyzed using independent Student's *t*-tests. Nominal data were compared using chi-squared or Fisher's exact tests. *P* < 0.05 was assumed to be statistically significant.

RESULTS

Baseline demographics

The baseline demographics of this patient population are shown in Table 1. There were no significant differences between groups A and B except for a higher inci-

Table 1 Baseline demographics

	Group A (n = 19)	Group B (n = 19)	P value

Stomal infection	1 (5)	3 (16)	0.290

Data are presented as n, n (%), mean ± SD or as noted.

dence of pre-diversion sepsis in group B (0% *vs* 53%, *P* < 0.001) and more days of obstruction in group B (3.6 ± 1 d *vs* 4.8 ± 1.6 d, *P* = 0.009). The mean intervals for early and late radical resection were 7.9 ± 1.3 d and 17.8 ± 5.5 d, respectively (*P* < 0.001). The molecular markers, such as white blood cell count and levels of hemoglobin, C-reactive protein and serum albumin, were measured and statistically analyzed. The initial white blood cell count and C-reactive protein level (before diversion) were higher in group B, but there was no significant difference in comparison to group A. The initial hemoglobin and serum albumin levels were similar in both groups.

Post-diversion outcome

Post-diversion outcomes are shown in Table 2. All 38 patients underwent T-loop colostomy for emergency diversion. Bowel sounds, the passage of flatus, removal of the nasogastric tube and oral feeding were observed earlier in group A than group B (1.6 ± 0.5 d *vs* 2.7 ± 1.2 d, 1.8 ± 0.4 d *vs* 3 ± 1.4 d, 1.8 ± 0.8 d *vs* 3.1 ± 1.5 d, 2.2 ± 0.6 d *vs* 3.5 ± 1.3 d; *P* = 0.001, 0.002, 0.001 and 0.001, respectively). There were no differences between groups in terms of the complications of diversion.

Table 3 Perioperative data and tumor characteristics

Data are presented as n, n (%), mean ± SD or as noted.

Perioperative data and tumor characteristics

The perioperative data and tumor characteristics are shown in Table 3. There was no significant difference between the two groups in terms of the type of operation, blood loss, blood transfusion, tumor location, tumor stage or stage of tumor differentiation. The pathology was adenocarcinoma in all 38 cases. Operation time was longer in group B than in group A (4.9 ± 0.4 h *vs* 5.5 ± 0.7 h, *P* = 0.003).

Outcomes and complications

The outcomes and complications are shown in Table 4. Group A had a shorter mean hospital stay than group B (21.2 ± 3.2 d *vs* 36.2 ± 17.4 d, *P* = 0.001). There were no differences between groups in terms of complications.

DISCUSSION

The study conducted on this series of 38 cases showed that early oral feeding, the passage of flatus, the presence of bowel sounds and the time to removal of the nasogastric tube could be predictive factors for early radical resection in patients undergoing a two-stage resection. Pre-diversion sepsis and longer obstruction days, in contrast, were associated with the delay of radical resection. Malignant colonic obstruction usually required emergency surgical intervention. A single-stage strategy has been suggested for patients with primary right-sided obstructive CRC^[1,4,6,9-12] Although the topic is debated, a staged procedure for left-sided obstructive

Table 4 Outcome and complications

	Group A (n = 19)	Group B (n = 19)	P value
Hospital stay	21.2 ± 3.2	36.2 ± 17.4	0.001

CRC is still considered to be the best option due to its safety^[8,15,18,19,21,25]. Corman suggested that a 10- to 14-d interval be used for two-stage procedures. The mean interval has ranged from 11.5 d to 42 d. The optimal interval has not been thoroughly investigated^[1,9,14,19,21,22]. The present study grouped patients based on the timing of radical resection. The mean intervals were 7.9 ± 1.3 d and 17.8 ± 5.5 d in the early and late radical resection groups, respectively.

Tumors cause obstruction by two major mechanisms: mechanical or adynamic obstruction^[26]. In our study, the late radical resection group had significantly more pre-diversion sepsis than the early group (0% vs 53%, P < 0.001) and a longer period of obstruction (3.6 ± 1 d vs 4.8 ± 1.6 d, P = 0.009). As is known, sepsis is associated with adynamic obstruction. We consider that pre-diversion sepsis and longer durations of obstruction-especially more than 5 d, which exacerbates mechanical obstruction-may be the predisposing factors necessitating a delay in radical resection. In contrast, the absence of pre-diversion sepsis or a shorter period of obstruction may lead to more rapid recovery of bowel function and early radical resection.

A nasogastric tube is usually placed temporarily to decompress the proximal bowel and to alleviate acute bowel obstruction symptoms^[26]. The passage of flatus and the presence of bowel sounds are generally considered to be signs of the recovery of bowel movement. In this series, the initiation of oral feeding, flatus, the presence of bowel sounds and removal of the nasogastric tube were observed sooner in the early radical resection group. These signs may imply the early elimination of edematous bowel, the early recovery of bowel movement and the early timing of any further surgical intervention required. However, more evidence is necessary to clarify the relationship between the recovery of bowel function or edematous status and the timing of the initiation of oral feeding, flatus, the presence of bowel sounds and removal of the nasogastric tube.

In our data, the operation time was significantly longer in cases that underwent delayed radical resection. This may have been caused by more severe post-inflammatory bowel adhesion in group B. Post-inflammatory bowel adhesion makes radical surgery difficult, even after a longer interval. However, further studies will be necessary to demonstrate the severity of bowel adhesion in patients with obstructive CRC.

The early radical resection group tended to stay in the hospital for less time than the late group (21.2 ± 3.2 d vs 36.2 ± 17.4 d, P = 0.001). No anastomotic leakage was noted in either group. The rates of wound infection, post-resection sepsis and complications, such as urinary tract infection, pneumonia and upper gastrointestinal bleeding, were similar between groups. The five-year disease-free survival rates were also similar between groups.

Although a 10- to 14-d interval between diversion and radical resection is generally accepted for the two-stage resection of acute left malignant colonic obstruction, early radical resection (with an interval shorter than 10 d) may be considered when the patients present with the earlier recovery of bowel function or the lack of any pre-diversion septic condition.

The present study found that earlier oral feeding, the presence of bowel sounds, the passage of flatus and removal of the nasogastric tube, all of which indicate the recovery of bowel function, seem to predict early radical resection. In contrast, pre-diversion sepsis and obstructions longer than five days may indicate the need to delay radical resection. The early radical resection group benefited from a shorter hospital stay with no difference in terms of complications compared to the late group. Further prospective or multicenter studies are recommended to clarify the relationship between such factors and the optimal timing of radical resection.

COMMENTS

Background

Surgical management for patients with obstructive colorectal cancer (CRC) varies widely according to tumor location, severity of the patient's condition and experience of the surgeon. Resection with anastomosis in one stage is now generally accepted for primary right-sided obstructive CRC. For left-sided obstructive CRC, two types of surgical intervention have been used: primary resection and staged resection (diversion prior to resection). Two-staged resection consists of colostomy or ileostomy to resolve the obstruction as a first step, followed by radical resection and closure of the stoma at the same time. Corman suggested a 10- to 14-d interval between diversion and radical resection. In critical illness patients, the interval would be longer than the Corman's suggestion. In contrast, the authors supposed that the patients with early recovery of bowel function or no pre-diversion septic condition, the interval may be earlier than 10 d.

Research frontiers

Signs of earlier oral feeding, presence of bowel sound, passage of flatus and removal of the nasogastric tube, which indicating recovery of bowel function, seem to be predictive factors for early radical resection. In contrast, pre-diversion sepsis and obstructions longer than five days might indicate a later timing for radical resection.

Innovations and breakthroughs

The present study found signs of earlier oral feeding, presence of bowel sound, passage of flatus and removal of the nasogastric tube, which indicating recovery of bowel function, seem to be predictive factors for early radical resection. In contrast, pre-diversion sepsis and obstructions longer than five days might

indicate a later timing for radical resection. The early radical resection group had an advantage of a shorter hospital stay with no difference in terms of complications comparing to the late group.

Applications

Earlier oral feeding, presence of bowel sound, passage of flatus and removal of the nasogastric tube, which indicating recovery of bowel function, seem to be predictive factors for early radical resection in two-staged resection for obstructive CRC.

Peer review

This paper describes two-stage resection for acute left-sided malignant colonic obstructions: timing of early radical resection and possible predictive factors. This work provides useful information on the early group had significantly earlier presence of bowel sounds, flatus, and removal of nasogastric tube and resumption of oral feeding.

Abstract

AIM: To investigate preoperative factors associated with poor short-term outcome after resection for multinodular hepatocellular carcinoma (HCC) and to assess the contraindication of patients for surgery.

METHODS: We retrospectively analyzed 162 multinodular HCC patients with Child-Pugh A liver function who underwent surgical resection. The prognostic significance of preoperative factors was investigated by univariate analysis using the log-rank test and by multivariate analysis using the Cox proportional hazards model. Each independent risk factor was then assigned points to construct a scoring model to evaluate the indication for surgical intervention. A receiver operating characteristics (ROC) curve was constructed to assess the predictive ability of this system.

RESULTS: The median overall survival was 38.3 mo (range: 3-80 mo), while the median disease-free survival was 18.6 mo (range: 1-79 mo). The 1-year mortality was 14%. Independent prognostic risk factors of 1-year death included prealbumin < 170 mg/L [hazard ratio (HR): 5.531, $P < 0.001$], alkaline phosphatase > 129 U/L (HR: 3.252, $P = 0.005$), α fetoprotein > 20 μ g/L (HR: 7.477, $P = 0.011$), total tumor size > 8 cm (HR: 10.543; $P < 0.001$), platelet count < $100 \times 10^9/L$ (HR: 9.937, $P < 0.001$), and γ -glutamyl transpeptidase > 64 U/L (HR: 3.791, $P < 0.001$). The scoring model had a strong ability to predict 1-year survival (area under ROC: 0.925, $P < 0.001$). Patients with a score ≥ 5 had significantly poorer short-term outcome than those with a score < 5 (1-year mortality: 62% vs 5%, $P < 0.001$; 1-year recurrence rate: 86% vs 33%, $P < 0.001$). Patients with score ≥ 5 had greater possibility of microvascular invasion ($P < 0.001$), poor tumor differentiation ($P = 0.003$), liver cirrhosis with small nodules ($P < 0.001$), and intraoperative blood transfusion ($P = 0.010$).

CONCLUSION: A composite preoperative scoring model can be used as an indication of prognosis of HCC patients after surgical resection. Resection should be considered with caution in patients with a score ≥ 5 , which indicates a contraindication for surgery.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the third leading cause of cancer deaths worldwide, with the highest incidence rates reported in East Asia^[1,2]. Multinodular HCC accounts for a large number of HCC cases. For these patients, hepatic resection may lead to an increased risk of postoperative liver failure and the recurrence rates after resection are higher than those for a single HCC. Hence, multinodular HCC have been considered a controversial indication for hepatic resection, especially for cases involving liver cirrhosis^[3].

However, the fact that patients with multinodular HCC have poorer survival than those with a single small tumor should not be considered a sufficient reason for excluding them from undergoing resection. Although liver transplantation is considered another curative treatment, its application is hampered by the lack of liver donors and high drop-out rates^[4]. The efficacy of radiofrequency ablation (RFA) is greatly limited by tumor size and location. Chemoembolization has been regarded as a palliative method with lower rates of tumor necrosis^[5,6]. With developments in surgical techniques and perioperative treatment, the safety of hepatic resection has markedly improved. Surgical mortality rates have been reduced to less than 5.0%^[7]. Many previous studies have demonstrated that resection can provide survival benefits for patients with multinodular HCC^[4,8-12]. Therefore, hepatic resection remains the widely accepted mainstay of curative treatment for multinodular HCC.

Better patient selection plays a crucial role in the improvement of postoperative outcome^[7]. Although it is widely accepted that Child-Pugh A cirrhosis can be treated safely in elective surgery, poor short-term survival still exists in these patients. It is reported that patients with multinodular HCC have a 1-year mortality ranging from 14% to 26% after hepatectomy^[4,13]. Several previous studies reported that HCC patients undergoing non-surgical therapy had a total 1-year survival rate of 40%-62%^[2,14-16], and patients without adverse factors who only received supportive care had a 1-year survival rate of 80%^[16], thus patients who die in the first year after surgery may not have gained a benefit from hepatic resection. Hepatectomy should not be indicated for these patients even though there is acceptable perioperative safety.

Several recent studies showed that traditional scoring systems of liver function such as the Child-Pugh score have limitations^[17,18], and routine parameters may not describe hepatic impairment sufficiently. Most current staging systems for HCC focus on predicting perioperative or

long-term survival but neglect the short-term outcome. The risk factors for poor short-term survival in patients with satisfactory liver function remain unclear. The present study was designed to investigate the independent predictive factors that are associated with poor short-term outcome after resection of multinodular HCC. We only focused on the preoperative clinical data that were most helpful in choosing the optimal initial treatment. The results may supplement the classical estimation system for surgical indication.

MATERIALS AND METHODS

Patients

Between January 2004 and December 2008, we retrospectively accumulated 208 consecutive patients with multinodular HCC underwent hepatic resection at the Department of Surgery, Eastern Hepatobiliary Surgery Hospital, Second Military Medical University (Shanghai, China). We regarded a tumor with a surrounding conodule(s) as a single tumor only when the co-nodule(s) was attached to the main tumor^[4,13]. Multinodular HCC was diagnosed when the tumor number was ≥ 2 . Fifteen patients with extrahepatic metastasis and 31 patients with macroscopic cancerous emboli were excluded. The remaining 162 patients (28 female, 134 male; mean age, 50.16 years; range: 27-76 years) who underwent curative hepatic resection were enrolled in this study. The baseline clinical features are listed in Table 1. All patients had liver function of Child-Pugh class A. Among them, 44 patients were Barcelona Clinic Liver Cancer (BCLC) stage A and 118 BCLC stage B. A total of 156 patients were diagnosed with hepatitis B virus (HBV) infection, which was defined as positivity of hepatitis B surface antigen (HBsAg) in the serum. No patient had a background of other chronic liver disease. The study protocol was approved by the clinical research ethics committee of the hospital. Written informed consent was obtained from all patients according to the policies of the committee.

Diagnosis of hepatocellular carcinoma and preoperative assessment

The preoperative diagnosis of multinodular HCC was based on the findings of focal lesions with signs of early hyperenhancement and delayed hypoenhancement on 2 different imaging modalities such as enhanced spiral computed tomography (CT) and magnetic resonance imaging (MRI), or on the combination of imaging findings and α fetoprotein (AFP) level^[5,13,19]. Tumor size was defined as the maximal diameter. Routine biopsy of the lesions was not performed before resection if the lesion had typical characteristics of HCC. No patient enrolled in this study received a fine-needle biopsy. The diagnoses of all patients were confirmed definitively by pathological examination after resection. Histological tumor differentiation was determined using the Edmonson-Steiner grading.

Each patient underwent a complete blood count.

Postoperative transfusion	6 (3.70%)
Death in 3 mo after operation	4 (2.47%)

HBsAg: Hepatitis B surface antigen; HBV: Hepatitis B virus; HCV: Hepatitis C virus; AFP: α fetoprotein; TBIL: Total bilirubin; DBIL: Direct bilirubin; IBIL: Indirect bilirubin; ALB: Albumin; PT: Prothrombin time; ALT: Alanine transaminase; AST: Aspartate aminotransferase; BCLC: Barcelona Clinic Liver Cancer; UCSF: University of California, San Francisco; WBC: White blood cell; RBC: Red blood cell; PLT: Platelet; HGB: Hematoglobulin; TNM: Tumor, nodes, metastasis.

Liver impairment was evaluated in all patients by liver biochemistry, including serum total bilirubin (TBIL), direct bilirubin, indirect bilirubin, albumin (ALB), globulin, prealbumin, alanine transaminase, aspartate aminotransferase (AST), alkaline phosphatase (ALP) and

γ-glutamyl transpeptidase (GGT). Prothrombin time (PT) and activated partial thromboplastin time were also determined to evaluate liver function and surgical safety. Tumor markers, including AFP, carcinoembryonic antigen, carbohydrate antigen 19-9 and α fucosidase (AFU), were used to identify the tumor origin. The parameters of HBV infection were tested. We evaluated kidney function by measuring serum urea nitrogen, creatinine, uric acid and electrolytes. All patients received an upper gastrointestinal endoscopic examination for portal hypertension and hemorrhage. Patients also underwent thoracic X-ray to examine metastasis to the lungs. Abdominal ultrasonography and enhanced CT or MRI were used to evaluate the size and location of the tumors. For patients older than 60 years or who had a relevant disease history, pulmonary function tests and cardiovascular Doppler ultrasound were performed to determine any contraindications to resection.

Hepatic resection

Hepatic resection was considered the first-line therapy for patients with Child-Pugh A liver function. The indications for hepatic resection included the technical feasibility of resection, the absence of macroscopic cancerous thrombi in vessels, absence of distant metastasis and sufficient future remnant liver volume in the preoperative evaluation. Patients with resectable multinodular HCC received resection immediately without any preoperative anti-HCC therapy. We defined curative hepatic resection as complete removal of all the detectable tumors combined with tumor-free margins confirmed by histopathology^[4,8,13]. In China, most HCC patients had underlying liver disease such as hepatitis, fibrosis and cirrhosis, which result in limited capacity for regeneration. Surgery must balance resectability with preservation of hepatic function to reduce the risk of hepatic failure^[20]. For multinodular HCC, concomitant resection may result in more blood loss, a longer Pringle time, and a significant change in blood perfusion and drainage. The limits for safe resection of multinodular HCC should be smaller than that of a single tumor. Therefore, all patients received local nonanatomic resection. The surgical procedure has been reported previously^[21]. The tumors of 44 patients were resected *en bloc* (27.16%), and 118 patients underwent multinodular hepatic resections (72.84%). Intraoperative ultrasonography was always used to detect non-visible, nonpalpable nodules and to check the resection plane. Resection margins were examined by a microscopic histological test.

Follow-up

All patients were regularly followed up for recurrence by determination of AFP, liver enzymes, complete blood count, and CT or MRI scan monthly for the first 3 mo after resection. If there was no recurrence, the frequency of routine examination was changed to once every 3 mo. Tumor recurrence was identified by new lesions on imaging with appearances typical of HCC, a rising AFP

level, or rapid enlargement of lesions without typical HCC characteristics. If tumor recurrence was diagnosed, patients received a second hepatectomy, chemoembolization and locoregional ablation, such as RFA or percutaneous ethanol resection.

Statistical analysis

Patient demographics, tumor parameters, liver function and hepatitis-associated characteristics were evaluated. Continuous data are expressed as mean \pm SD. Categorical data were compared using the χ^2 test and Fisher's exact test as appropriate. Survival analyses were performed using the Kaplan-Meier method and compared using the log-rank test. For continuous data with statistical significance in the univariate analysis, a series of receiver operating characteristics (ROC) curves were used to identify the cutoff values with optimal discriminatory ability for 1-year survival. Multivariate analysis was performed using the Cox proportional hazard ratio model to identify independent prognostic factors. The factors with a *P*-value less than 0.1 in univariate analysis were included in the multivariate Cox regression analysis. In order to estimate the clinical value of the independent factors, a prognostic scoring system was constructed. We assigned points to each independent predictor according to the value of the partial regression coefficient, because each factor had different importance in the final Cox model^[22]. Each patient's score was the total points of 6 factors. A ROC curve was constructed to estimate the prognostic ability of the new scoring model. Overall survival was the time from the day of surgery to the day of death or to the most recent follow-up visit. Disease-free survival was the time from the day of surgery to the most recent follow-up visit at which evidence of a tumor was clear. The deaths caused by non-HCC-associated factors were included in the overall survival analysis, but not in the disease-free survival analysis. A *P* value $<$ 0.05 was considered statistically significant. All statistical processing was performed by SPSS 18.0 (SPSS Inc., Chicago, IL, United States).

RESULTS

Survival, outcome and morbidity after liver resection

The mean postoperative hospitalization period was 10.6 d (range: 5-28 d). The overall morbidity was 25.31% ($n = 41$). Pleural effusion ($n = 24$) and ascites ($n = 14$), which required diuretics or paracentesis, were the most common sequelae, with both occurring in 7 patients. Two patients developed bile leakage and one developed transitory arrhythmia. The median overall survival was 38.3 mo (range: 3-80 mo); overall survival rates at 1 year, 3 years and 5 years were 86%, 51% and 35%, respectively; the median disease-free survival was 18.6 mo (range: 1-79 mo); 1-year, 3-year and 5-year disease-free survival rates were 56%, 40% and 31%, respectively. The survival outcome was similar to that in 2 previous retrospective studies^[4,8]. During the entire follow-up, a total of 100 (61.73%) patients were diagnosed with tumor recurrence during the follow-

up period. Among them, twelve patients underwent a second hepatic resection, 65 received transarterial chemoembolization (TACE) alone, 18 received TACE combined with locoregional ablation and 5 received locoregional ablation alone. A total of 32 patients died within the first year after resection. Four patients died at the 3rd month, one died of acute severe hepatitis and 3 of unrecovered liver impairment after chemoembolization for recurrence. Of the remaining 28 patients, one died of incidental hemorrhage of the upper digestive tract at the 7th month after resection, 27 died of liver failure, including 4 patients within 4-6 mo, 2 within 7-9 mo, and 9 within 10-12 mo. All 27 patients had diffuse tumor recurrence leading to liver failure.

Predictive factors for 1-year survival

In the evaluation of preoperative factors that may have potential prognostic ability for short-term outcome, we limited the endpoint of follow-up to 1 year. The univariate Kaplan-Meier analysis showed that TBIL, prealbumin, AST, AFP, HBeAg, HBV-DNA, GGT, AFU, total tumor size, largest tumor size, ALP, and platelet count were significantly associated with 1-year mortality after hepatic resection (Table 2).

For the above factors, we analyzed continuous data by ROC curves to determine cutoff values that had the optimal sensitivity and specificity (i.e., the largest sum of sensitivity and specificity). The cutoff values of platelet count, AST, TBIL, AFU, AFP, GGT and ALP ($92.5 \times 10^9/L$, 41.8 U/L, 17.25 $\mu g/L$, 36 U/L, 32.6 $\mu g/L$, 75.5 U/L, 119.5 U/L, respectively) were similar to the limits of normal values, thus we defined the normal upper or low limitations as the best cutoff points (Table 3).

Multivariate analysis showed that 6 variables were significant predictive factors for 1-year survival status after resection: prealbumin $<$ 170 mg/L [hazard ratio (HR): 5.531, $P <$ 0.001]; ALP $>$ 129 U/L (HR: 3.252, $P =$ 0.005); AFP $>$ 20 $\mu g/L$ (HR: 7.477, $P =$ 0.011); total tumor size $>$ 8 cm (HR: 10.543, $P <$ 0.001); platelet count $<$ $100 \times 10^9/L$ (HR: 9.937, $P <$ 0.001), and GGT $>$ 64 U/L (HR: 3.791, $P <$ 0.001) (Table 4). Although factors of tumor invasiveness cannot be detected before surgery, the data showed that microvascular invasion and poor tumor differentiation were associated with tumor size (Figure 1).

Construction of a scoring system to determine indication for surgery

We assigned points for each prognostic factor (Table 4). The theoretical range of the prognostic score was 0 to 9. In the total population in our study, 10 patients scored 0, 16 patients scored 1, 44 patients scored 2, 32 patients scored 3, 18 patients scored 4, 22 patients scored 5, 10 patients scored 6, 6 patients scored 7, and 4 patients scored 8. A higher score implied a lower chance of 1-year survival. We assessed the prognostic value of the score on 1-year survival using a ROC curve (Figure 2). The area under the curve was 0.925 [95% confidence interval (CI): 0.864-0.985, $P <$ 0.001]. The data indicated that,

for patients with multinodular HCC, the scoring system had a satisfactory ability to predict 1-year mortality after hepatic resection. A score of 5 was the cut-off value with optimal specificity and sensitivity. For patients with a score of 5 or more, the 1-year mortality was 62% which was similar to that of patients who received nonsurgical treatment^[2,15-17], while patients with a score of 0-4 had 1-year mortality of only 5%.

We also compared the long-term survival of patients with a score 0-4 (*n* = 120, group 1) and those with a score of 5-8 (*n* = 42, group 2). In group 1, the median survival was 53.55 mo (range: 6-80), the median disease-free survival was 37.14 mo (range: 1-79). In group 2, the median survival was 12.86 mo (range: 3-51), the median disease-free survival was 7.00 mo (range: 1-45). The 1-year and 3-year survival rates of group 1 were 95% and 60%, respectively, while the 1-year and 3-year survival rates of group 2 were 38% and 8%, respectively. The 1-year and 3-year disease-free survival rates of group 1 were 67% and 35%, respectively, while the 1-year and 3-year

disease-free survival rates of group 2 were 14% and 12%, respectively. Patients in group 2 had much poorer long-term overall and disease-free survival ($P < 0.001$ for both, Figure 3). Table 5 shows the comparison of pathological status between group 1 and group 2. Patients in group 2 had a greater possibility of microvascular invasion ($P < 0.001$) and poor tumor differentiation ($P = 0.003$). Liver cirrhosis with small nodules was more likely to be detected in group 2 ($P < 0.001$). In addition, group 2 patients were more likely to receive intraoperative blood transfusion ($P = 0.010$).

DISCUSSION

This study evaluated the short-term prognosis of patients with multinodular HCC after curative resection and developed a scoring system to determine contraindication to surgery. In patients with well-preserved liver function, hepatic resection remains the optimal and effective treatment. Although liver transplantation provides an alternative curative treatment option for small HCC, organ shortages and long waiting times have prohibited it as initial treatment^[4,5]. Several studies have proved that the benefit of resection was similar to that of transplantation. However, patients who received transplantation had undergone a natural selection process in which patients with more aggressive tumor phenotypes, such as the presence of microvascular invasion and microscopic metastasis, had been ruled out because of tumor progression^[23]. The efficacy of RFA is limited by several factors, such as sub-

capsular location, tumor size and tumor differentiation, which have been proved to be associated with increased risk of bleeding, peritoneal seeding and residual vital tumor tissue^[5,6,24]. Several studies have demonstrated that patients who underwent resection had better survival than those who received RFA^[25,26]. Chemoembolization, as a palliative treatment, results in a high incidence of residual viable tumor tissue, even after repeated treatment^[27,28]. Its poor performance on blood-deficient and larger tumors restricts its application in HCC treatment. Previous studies have demonstrated that resection brought more benefit to patients of intermediate stage than TACE^[4,10]. As surgical techniques have advanced, many studies have explored the possibility of broadening the surgical criteria for HCC. Ng *et al*^[4] demonstrated the safety and effectiveness of hepatic resection for multinodular HCC, although the survival rate was lower than for a single tumor. Ishizawa *et al*^[8] concluded that resection can provide a survival benefit for patients with multinodular HCC on the background of Child-Pugh A cirrhosis, as well as for those with portal hypertension. Torzilli *et al*^[9] confirmed that patients with BCLC stage B and stage C HCC can tolerate hepatic resection with low mortality, acceptable morbidity, and a survival benefit, if resection is performed under strict intraoperative ultrasonographic guidance.

However, the benefit of hepatic resection in the treatment of multinodular HCC remains controversial. In spite of the exciting conclusions above, we can also observe in clinical practice that there are patients who

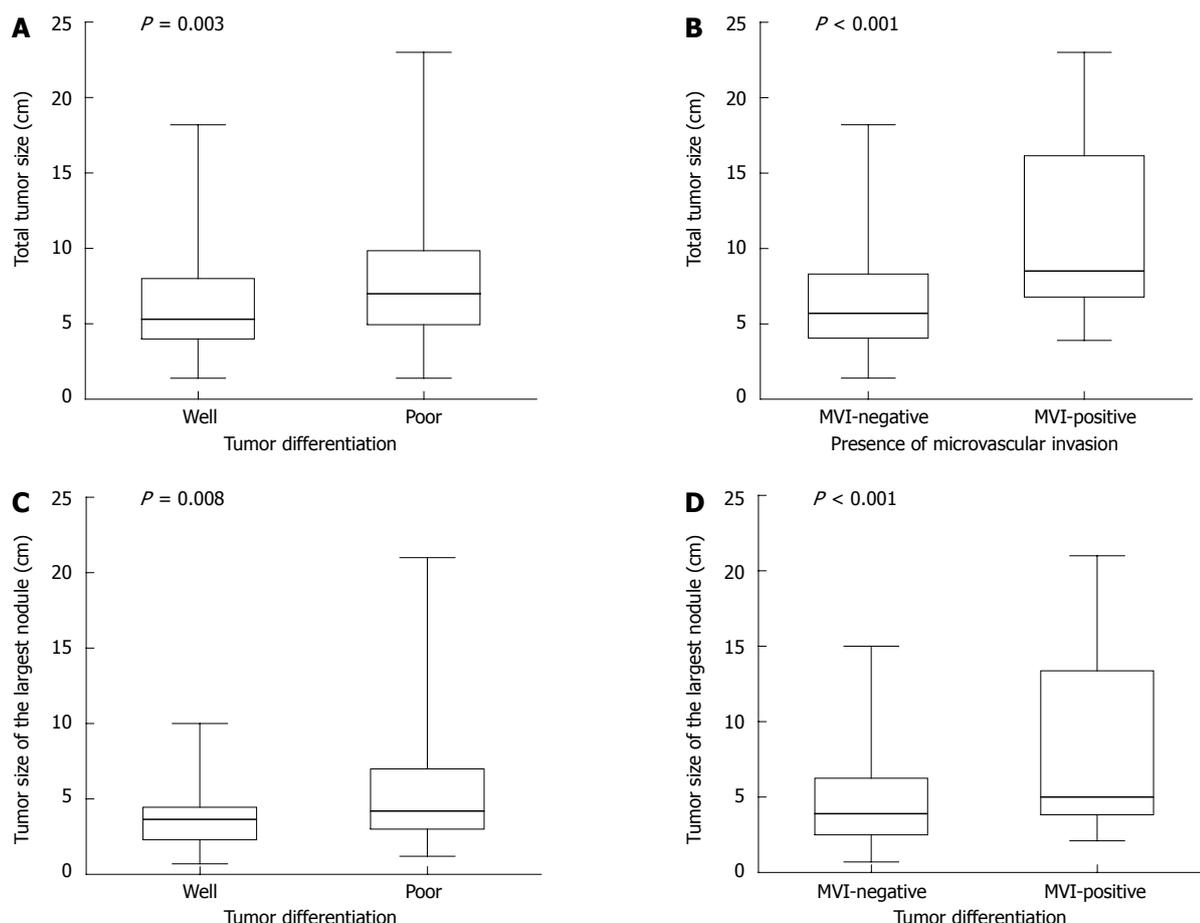

Figure 1 Distribution of tumor size according to tumor differentiation and presence of microvascular invasion, showing median, 25th-75th percentile box and complete range of measurements. A: Distribution of total tumor size according to tumor differentiation ($P = 0.003$); B: Distribution of total tumor size according to presence of microvascular invasion ($P < 0.001$); C: Distribution of the largest tumor size according to tumor differentiation ($P = 0.008$); D: Distribution of total tumor size according to tumor differentiation and presence of microvascular invasion ($P < 0.001$). The tumor size was associated with presence of microvascular invasion and poor tumor differentiation. MVI: Microvascular invasion.

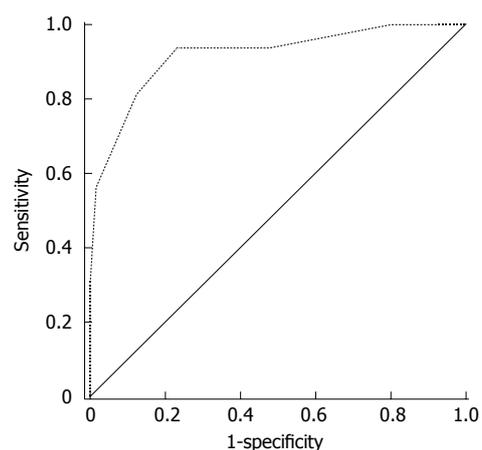

Figure 2 Receiver operating characteristics curve of the predictive scoring system. The area under the curve was 0.925, 95% confidence interval was 0.864-0.985 ($P < 0.001$). The data indicated that the scoring system had a strong ability to predict the 1-year outcome of patients with multiple hepatocellular carcinoma after hepatic resection.

have satisfactory liver function and seemingly optimistic prognosis empirically, but have poor short-term outcome

after resection. This indicates that the classical evaluation systems have their limitations, and that they cannot detect mild liver impairment, which would markedly influence outcome. In our study, no patient died during the hospital stay, and only 4 (2.47%) died in the 3 mo after resection, indicating that the preoperative safety assessment according to the established guidelines was acceptable. However, 32 of the patients died in the first year. For these patients, surgical resection brought no benefit and may even have adversely affected survival. Therefore, identification of these patients may determine that surgical treatment should be contraindicated.

Multivariate analysis showed that 6 variables were independent predictive factors for poor short-term survival. Among them, prealbumin < 170 mg/L, ALP > 129 U/L, GGT > 64 U/L and platelet count $< 100 \times 10^9/L$ were factors associated with liver impairment. Their roles as indicators of liver damage have been reported previously^[29-32]. Platelet count may also be used as a potential marker of portal hypertension^[33]. Conventional blood parameters of liver function, such as TBIL and PT, as well as scoring systems using these values (such as the Child-Pugh score and Model for End-stage Liver Disease score)

Table 5 The comparison of surgical data and tumor biological characteristics between two groups *n* (%)

have been widely accepted in clinical circles. Many staging systems also adopt them in preoperative estimation of surgical safety. However, decreased ALB and prolonged PT indicate marked liver damage^[29], while ascites and encephalopathy indicate liver failure and serious portal hypertension. Previous studies reported that most patients who underwent elective hepatic resection were classified as Child-Pugh class A, but postoperative liver failure and mortality existed even in this group of patients^[17,18]. This phenomenon indicated that most hepatic impairment in surgical candidates is slight and might not be fully evaluated by classical estimation systems. Our results disclosed that platelet count, ALP, prealbumin and GGT may be considered as supplemental factors for routine liver function scoring systems. Patients who have satisfactory liver function reserve according to the traditional estimation system, but abnormalities in these additional parameters above should be considered with caution for surgery.

Factors associated with tumor burden also have a crucial influence on the short-term survival of patients. The majority of our patients who died in the first year had tumor recurrence and metastasis. Early tumor recurrence and fast hyperplasia adversely affected liver function recovery. Our results included AFP > 20 µg/L and total tumor size > 8 cm as independent risk factors of first year death. AFP > 200 µg/L is the diagnostic level indicating HCC, but only one-third of patients with HCC have AFP levels higher than 100 µg/L, and even mild elevation predicts a worse prognosis^[14]. Hence, the 20 µg/L as cutoff point in the ROC curve was reasonable. The AFP level and total tumor size are widely accepted risk factors affecting surgical outcome^[34]. Several studies have reported that tumor size is related to the presence of microvascular invasion and poor tumor differentiation^[35,36], which are strongly associated with intrahepatic metastasis and greatly increase the risk of tumor recurrence^[5,35,36]. Our analysis observed a similar phenomenon. These results implied that clinicians could estimate tumor invasiveness by preoperative examination. Other tumor-associated fac-

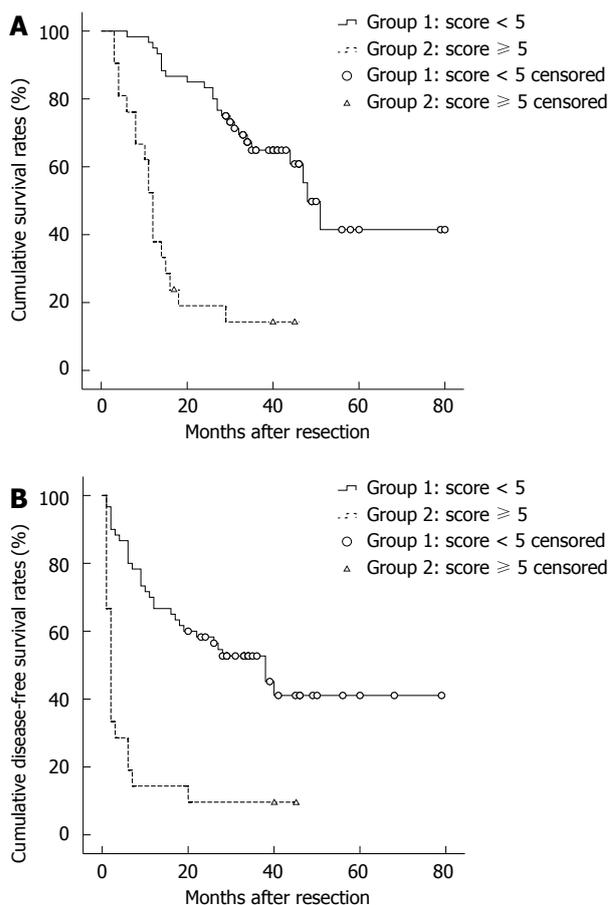

Figure 3 Results of long-term survival of group 1 (score < 5) and group 2 (score ≥ 5). The overall survival and disease-free survival in group 2 were significantly poorer than those in group 1 (both *P* < 0.001).

tors were not included in our results as our study focused on short-term (1-year) survival rather than the long-term outcome.

To apply these risk factors in clinical practice, we constructed a scoring model. A total of 42 patients with high score (≥ 5, group 2) had 1-year outcome similar to that of patients who received non-surgical treatment, and also had significantly poorer long-term overall and disease-free survival. Our analysis also showed that these patients had a greater possibility of microvascular invasion and poor tumor differentiation. They also had a higher percentage of liver cirrhosis with small nodularity, which has been proved to be an independent predictor of clinically significant portal hypertension^[37]. Intraoperative blood transfusion, which significantly influenced short-term survival^[22], was more common in patients with a score ≥ 5, indicating greater surgical difficulty. Although we resected all visible and palpable nodules and a tumor-free margin under guidance of intraoperative ultrasonography, the 3-mo recurrence rate in group 2 patients was 71.4%, indicating the greater possibility of preoperative existence of non-detectable micrometastasis. For these patients, seemingly curative resection does not achieve radical efficacy. This series of data confirmed that this group of patients may derive little benefit from resection and surgery should be

considered a contraindication in spite of satisfactory liver function estimated by classical scoring systems.

Major limitation of our study is that this study was a retrospective analysis with a small sample size in a single center. The potential selective bias that accompanied with this setup was hard to avoid. Patients with hepatitis C virus infection or other chronic liver disease were not included in the analysis. Other limitations of this study were that different types of recurrence were not taken into consideration because of the small sample size. Therefore, further study is needed before a final conclusion is made.

In summary, hepatic resection has been proved to be a safe and effective treatment for some patients with multinodular HCC. However, some patients with good liver function as estimated by traditional scoring systems have poor short-term outcome. Our study focused on these patients and indicated that other factors, namely prealbumin < 170 mg/L, ALP > 129 U/L, GGT > 64 U/L, platelet count < 100×10^9 /L, AFP > 20 μ g/L and total tumor size > 8 cm are independent risk factors for short-term mortality. For patients with these characteristics, 1-year mortality was significantly increased, and resection was associated with an adverse outcome.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the third leading cause of cancer mortality worldwide. Multiple lesions are detected in about 40% patients once HCC is diagnosed. The treatment strategies for multiple HCC remain in controversy.

Research frontiers

Several recent studies reported that surgical resection improves the survival of patients with multiple HCC. However, the indication and contraindication of surgical resection for multiple HCC remain unclear.

Innovations and breakthroughs

Patients with poor short-term (1 year) survival after surgery benefit little from hepatic resection. They should be considered surgical contraindication. The risk factors of poor short-term survival for patients with satisfactory liver function remain unclear. The authors analyzed the preoperative data of 162 multiple HCC patients received surgical resection and found that factors, namely prealbumin < 170 mg/L, alkaline phosphatase (ALP) > 129 U/L, γ -glutamyl transpeptidase (GGT) > 64 U/L, platelet count < 100×10^9 /L, α fetoprotein (AFP) > 20 μ g/L, total tumor size > 8 cm are independent risk factors of short-term mortality. The authors then assigned points to each factor according to its partial regression coefficient and construct a score system. For the patients with score ≥ 5 , 1-year mortality was 62% while only 5% for patients with score < 5.

Applications

The study results suggest that more factors namely ALP, GGT, platelet, prealbumin, AFP and total tumor size should be enrolled in preoperative estimation. Patients with score ≥ 5 should be considered with more cautious attitude towards resection.

Terminology

HCC is the most common primary malignant tumor of the liver which originated from liver parenchymal cells. Multiple HCC refers to the HCC with more than one lesion.

Peer review

The authors analyzed the clinical data of patients with multiple HCCs treated by surgery for detecting prognostic factors of 1 year survival. They determined six prognostic factors from preoperative clinical data. Based on the multivariate analysis, they proposed a prognostic scoring system. This scoring system well predicted poor short outcome after hepatic resection. The study was carefully designed and the evaluation of the results was also appropriate. The manuscript was well organized and well written.

Abstract

AIM: To introduce a bioimpedance gastric motility measurement method based on an electrical-mechanical composite concept and a preliminary clinical application.

METHODS: A noninvasive gastric motility measurement method combining electrogastrogram (EGG) and impedance gastric motility (IGM) test was used. Preliminary clinical application studies of patients with functional dyspepsia (FD) and gastritis, as well as healthy controls, were carried out. Twenty-eight FD patients (mean age 40.9 ± 9.7 years) and 40 healthy volunteers (mean age 30.9 ± 7.9 years) were involved. IGM spectrum was measured for both the healthy subjects and FD patients, and outcomes were compared in the FD patients before treatment and 1 wk and 3 wk after treatment. IGM parameters were obtained from 30 erosive gastritis patients (mean age 50.5 ± 13.0 years) and 40 healthy adults, and IGM and EGG results were compared in the gastritis patients before treatment and 1 wk after treatment.

RESULTS: There were significant differences in the IGM parameters between the FD patients and healthy subjects, and FD patients had a poorer gastric motility [percentage of normal frequency (PNF) 70.8 ± 25.5 in healthy subjects and 28.3 ± 16.9 in FD patients, $P < 0.01$]. After 1 wk administration of domperidone 10 mg, *tid*, the gastric motility of FD patients was not improved, although the EGG of the patients had returned to normal. After 3 wk of treatment, the IGM rhythm of the FD patients became normal. There was a significant difference in IGM parameters between the two groups (PNF 70.4 ± 25.5 for healthy subjects and 36.1 ± 21.8 for gastritis patients, $P < 0.05$). The EGG rhythm of the gastritis patients returned to normal (frequency instability coefficient 2.22 ± 0.43 before treatment and 1.77 ± 0.19 one wk after treatment, $P < 0.05$) after 1 wk of treatment with sodium rabeprazole tablets, 10 mg, *qd*, *po*, *qm*, while some IGM parameters showed a tendency toward improvement but had not reached statistical significance.

CONCLUSION: The electrical-mechanical composite measurement method showed an attractive clinical application prospect in gastric motility research and evaluation.

INTRODUCTION

An electrical bioimpedance technique is a method used to extract physiological and pathological information from the human body according to the electrical property of the tissue and organs. This method has the advantage of being noninvasive and convenient and can provide functional information. It is a powerful tool in clinical diagnosis and medical research^[1]. There are many applications that use bioimpedance signals for different pathological conditions, but their use in gastric motility assessment needs further exploration^[2].

Gastrointestinal motility as an interdisciplinary subject has developed rapidly in recent years. Gastric motility is one of the most critical physiological functions of the human body. Coordinated gastric motility is necessary for digestion and the absorption of dietary nutrients. Impairment of gastric motility results in delayed gastric emptying and symptoms such as nausea, vomiting, abdominal pain and discomfort^[3]. The research on gastric motility function has fallen behind as compared with the studies on gastric endocrine and exocrine secretion functions and gastric morphology. One of the important reasons for this is the absence of convenient and effective measurement methods for gastric motility function^[4].

Stomach volume distends gradually after the ingestion of food. In the period of digestion, such as contraction and peristalsis after a meal, the stomach content changes greatly and so does the impedance of the stomach. When measuring the impedance of the stomach during digestion, information reflecting the stomach volume (gastric emptying) and gastric motility can be extracted. Sutton *et al.*^[5] in 1985 reported results on extracting the signal of gastric movement by an electrical impedance method. The curve reflecting gastric emptying was obtained and, from the curve, the gastric peristaltic information was extracted showing a rhythm of 2-4 cycles per minute (cpm), which is in accordance with gastric contraction. In 1987, Familoni *et al.*^[6] presented a technique to monitor gastric electrical activity and mechanical activity as an aid in assessing gastric motor function. In 1992, Kothapalli *et al.*^[7] established a three-dimensional abdomen model to study the origin of changes in the epigastric signal, and analyzed the relationship between the gastric impedance signal and food capacity, resistivity of a test meal, and gastric contraction when the exciting current electrodes and the measuring voltage electrodes were located at different positions.

Early research using an impedance method to measure the digestion course mainly focused on gastric emptying measurement^[8-10]. There have been few researches on the extraction of gastric motility information^[11-13]. One of the primary reasons is that the rhythm of gastric motility is much lower; i.e., about 3 cpm. It is difficult to extract the gastric motility signal and eliminate respiration interference. In 1991, Chen *et al.*^[14] reported their work on obtaining an electric impedance signal, which reflected gastric contraction, and measurement devices

were subsequently developed^[15]. However, the impedance signals obtained by the devices were all sine waveforms that were similar for both healthy and diseased subjects because of an incorrect filter processing. It was difficult to differentiate normal or abnormal conditions from the signals. In 2007, we proposed a noninvasive electrical impedance method for gastric motility measurement and evaluation^[16]. Multi-resolution analysis of the wavelet was adopted to separate the gastric motility signal from the mixed impedance signal obtained on the body surface^[17].

In this paper, a gastric motility measurement method based on an electrical-mechanical composite concept was introduced and results from some preliminary clinical application studies of gastric motility measurement for patients with functional dyspepsia (FD) and gastritis, as well as normal controls, were presented.

MATERIALS AND METHODS

Electrical-mechanical composite method for gastric motility assessment

Gastric contraction is a mechanical behavior that follows electrical activity occurring on the cell membrane surface of smooth muscles. It begins with electrical activity of the smooth muscle, followed by evoked contraction of the gastric corpus and antrum, and is then transmitted to the distal pylorus. It is a composite course from electrical activity to mechanical contraction, which then leads to gastric peristalsis and transmission. Gastric contraction complies with the rhythm of electrical activity and is affected by the amplitude, time limitation, transmission direction and distance of the transmission contraction. Gastric motility is a complex electrical-mechanical composite course. It is very important to measure and evaluate gastric motility according to an electrical-mechanical composite mechanism^[18].

There are two kinds of gastric myoelectric activities: slow wave and spike potential. The gastric antrum contracts only when the slow wave occurs accompanied by the spike potential. The spike potential appears during the slow wave phase, and the rhythm of gastric contraction may be determined by the slow wave. Electrogastrogram (EGG) signals recorded from the body surface reflect the myoelectric activity of different regions of the stomach. It corresponds to the gastric slow wave accurately and, therefore, can be used to investigate the rhythm of gastric contraction. EGGs reflect myoelectric activity of the stomach and the rhythm of gastric contraction. The information from the impedance measurement of the stomach directly corresponds to gastric motility. A combined measurement of EGG and impedance gastric motility (IGM) is a new approach for evaluating gastric motility based on an electrical-mechanical composite mechanism.

IGM measurement

Based on an electrical-mechanical composite mechanism

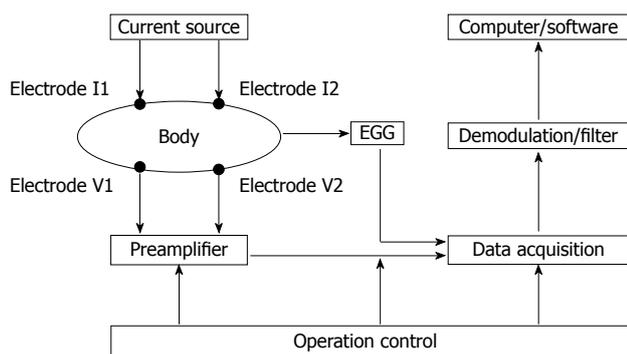

Figure 1 Diagram of gastric motility measurement. EGG: Electrogastragram.

and combined IGM and synchronous EGG measurements, a gastric motility measurement method has been developed, which was reported in our previous paper^[19]. The block diagram of the measurement system is shown in Figure 1.

The measurement system consists of a current source, electrodes, preamplifier, demodulation/filter circuit, data acquisition, operation control and an upper computer. Four electrodes (I₁, I₂, V₁ and V₂) placed on the epigastric surface of the body are used to inject measurement current and measure impedance signals. An electric current of 50 kHz and 1 mA provided by the current source injects into the epigastric area of the subject *via* excitation electrodes I₁ and I₂. The IGM signal picked up from the measurement electrodes V₁ and V₂ is put into the preamplifier and the demodulation/filter, and then goes into the data acquisition system for analog/digital (A/D) conversion and numeralization processing of the signal. The digitized data are transmitted to the computer where proprietary software performs the IGM and EGG information extraction, analysis and calculation of the gastric motility parameters.

IGM and EGG signals are classified according to their rhythm. The rhythm of 2-4 cpm is considered a normal rhythm, while that below 2 cpm is bradygastria, and above 4 cpm is tachygastria. Based on this classification, frequency spectra, energy spectra, dynamic spectra, running spectra, percentage of normal frequency (PNF), percentage of normal power (PNP), the frequency instability coefficient (FIC) and the power instability coefficient (PIC), for both IGM and EGG, were analyzed as temporal features for the subjects. FIC and PIC represent the stability of the frequency (e.g., the rhythm of the gastric motility signals) and power of the rhythm for both IGM and EGG, respectively. The higher FIC or PIC means that the stability of the rhythm and the power of gastric motility signals are worse.

Subjects

The subjects included FD patients, erosive gastritis patients and healthy volunteers. All patients with FD and erosive gastritis came from the First Affiliated Hospital of Chongqing University of Medical Sciences. Twenty-eight FD patients (mean age 40.9 ± 9.7 years) who self-

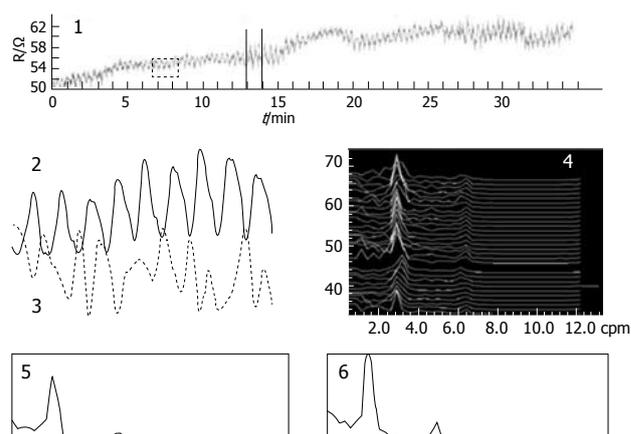

Figure 2 Results of impedance gastric motility measurement and spectra analysis for a healthy volunteer.

reported the symptoms of abdominal bloating, belching and gastric acid reflux and were diagnosed according to the Rome III criteria of FD. All selected FD patients were taking domperidone (10 mg, *tid*) for treatment. The 30 erosive gastritis patients (mean age 50.5 ± 13.0 years) were diagnosed through gastroscopy and were taking sodium rabeprazole tablets (10 mg, *qd, po, qm*) for treatment. The 40 healthy volunteers were university students and teachers (mean age 30.9 ± 7.9 years) who served as a control group.

Preliminary application of IGM measurement

In order to validate the feasibility and effects of the proposed method in this study, a preliminary clinical application study of gastric motility measurement for healthy volunteers and patients with FD and gastritis was conducted. The IGM measurement is a noninvasive method. The study was approved by the ethical committee of the institute and all subjects in the study signed a consent form. The statistical software SPSS 13.0 was used to analyze the data. The data were expressed as mean ± SD. Variance analysis between the study and control groups was undertaken and a significant difference was accepted at $P < 0.05$.

RESULTS

IGM measurement in healthy volunteers

IGM measurement results for healthy volunteers are illustrated in Figure 2. Part 1 represents the original mixed impedance signal picked up from the abdominal surface, part 2 is the IGM signal extracted from the mixed signal, part 3 is the synchronous EGG, part 4 is the dynamic spectrum of IGM, and parts 5 and 6 are the power spectrums before and after a test meal. The dominant frequency of the IGM signal was 2.8 cpm in the dynamic spectrum of part 4.

IGM measurement in FD patients

The IGM parameters for 40 healthy volunteers and 28

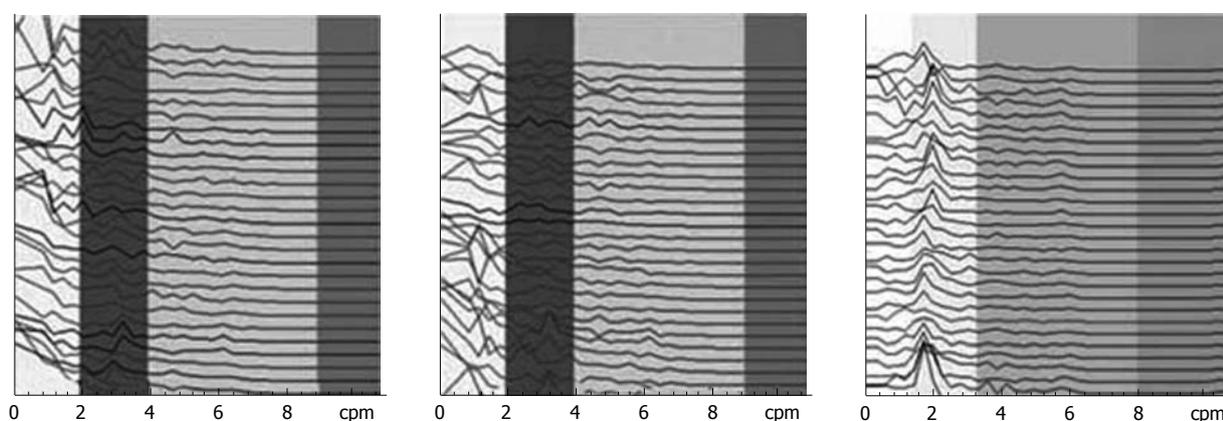

Figure 4 Impedance gastric motility dynamic spectra of functional dyspepsia patients before treatment (left) and 1 wk (middle) and 3 wk (right) after treatment.

Table 1 Impedance gastric motility measurement results in healthy controls and patients with functional dyspepsia and gastritis (mean ± SD)					
Group	Case	PNF	PNP	FIC	PIC
Healthy	40	70.8 ± 25.5	59.3 ± 4.4	1.58 ± 0.48	0.18 ± 0.06
FD	28	28.3 ± 16.9 ^b	50.8 ± 9.9 ^b	2.08 ± 0.55 ^b	0.23 ± 0.05 ^b
Gastritis	30	36.1 ± 21.8 ^a	44.6 ± 4.8 ^a	2.23 ± 0.55 ^a	0.24 ± 0.05 ^a

^a*P* < 0.05, ^b*P* < 0.01 vs healthy group. FD: Functional dyspepsia patients; PNF: Percentage of normal frequency; PNP: Percentage of normal power; FIC: Frequency instability coefficient; PIC: Power instability coefficient.

FD patients are shown in Table 1. It can be seen that PNF in the FD group was obviously lower than that in the control group (*P* < 0.01), and FIC was higher than that in the control group (*P* < 0.01). The PNP and PIC showed similar differences between the two groups (*P* < 0.01). These results suggest that FD patients have a poorer rhythm in gastric motility and energy deficiency. This result is consistent with digestion pathology and physiology in FD.

Figure 3 shows the EGG dynamic spectrum of FD patients before and 1 wk after administration of domperidone tablets, 10 mg, *tid, po*, taken half an hour before meals. The interval for each spectrum line was 1 min in

duration. In Figure 3, the EGGs of FD patients were weak and the rhythms were disordered before treatment (left). After 1 wk of treatment, the EGG improved and the rhythm returned to 2-4 cpm (right). This suggested that the GEA of FD patients tended towards normal after 1 wk of treatment.

The IGM signal spectrums of one FD patient before treatment and 1 wk and 3 wk after treatment are shown in Figure 4. Compared with the EGG dynamic spectrum in Figure 3, the IGM spectrum after 1 wk of treatment in Figure 4 showed little change and the rhythm was also disordered. After 3 wk of treatment, the IGM rhythm returned to 2-4 cpm.

IGM measurement in gastritis patients

The parameters for IGM and EGG in the gastritis patients before and 1 wk after administration of sodium rabeprazole tablets, 10 mg, *qd, po, qm* are shown in Tables 1 and 2.

It can be seen from Table 1 that there was a significant difference in IGM parameters between the gastritis patients and healthy controls. The PNF and PNP of the gastritis patients were significantly lower than that of the healthy controls (*P* < 0.05). The FIC and PIC of the gastritis patients were evidently higher than the healthy

Table 2 Electrogastrogram and impedance gastric motility parameters in 30 gastritis patients before treatment and 1 wk after treatment (mean \pm SD)

Treatment	0-2 cpm PNP	2-4 cpm PNP	> 4 cpm PNP	FIC	PIC
EGG parameters					
Before	24.0 \pm 5.6	51.5 \pm 11.1	24.4 \pm 5.5	2.22 \pm 0.43	0.34 \pm 0.03
After 1 wk	22.7 \pm 3.4	54.3 \pm 6.7	23.1 \pm 3.3	1.77 \pm 0.19 ^a	0.23 \pm 0.02 ^a
IGM parameters					
Before	27.5 \pm 2.4	44.6 \pm 4.8	27.9 \pm 2.4	2.23 \pm 0.55	0.24 \pm 0.05
After 1 wk	27.4 \pm 2.2	44.9 \pm 4.4	27.8 \pm 2.2	1.91 \pm 0.65	0.21 \pm 0.06

^a $P < 0.05$ vs EGG before treatment. PNP: Percentage of normal power; FIC: Frequency instability coefficient; PIC: Power instability coefficient; IGM: Impedance gastric motility; EGG: Electrogastrogram.

controls ($P < 0.05$). This suggests a weakening gastric motility function and disorder of stomach peristalsis in gastritis patients. Table 2 indicates that the EGG power of the normal rhythm (2-4 cpm) for the patients was raised and the power of the abnormal rhythm (0-2 cpm and > 4 cpm) declined after 1 wk of treatment, although this was not statistically significant ($P > 0.05$). It should be noted that the FIC and PIC of the patients decreased significantly ($P < 0.05$). It suggests that the EGG of gastritis patients tended to be normal and stable after 1 wk of treatment, and the rhythm of the EGG improved.

IGM parameters in Table 2 show that the power ratios of IGM signals for the patients in all frequency bands did not change much before and after treatment ($P > 0.05$), although the FIC and PIC showed a decreasing trend ($P > 0.05$).

DISCUSSION

The motility function of the stomach is regulated by nerve and body fluid and is accomplished by the coordinated movement of smooth muscle^[4,20]. It can be seen from Figures 3 and 4 that for FD patients the IGM was not improved with 1 wk of treatment, while the EGG returned to normal. After 3 wk of treatment, the regular IGM rhythm of the FD subjects became normal and the contraction function of the stomach was recovered. It is understandable that although the EGG returned to normal by nerve regulation with 1 wk of treatment, improvement of the electric activity had not coupled with or transferred to the mechanical activity of the stomach. After 3 wk of treatment, when the electrical activity had already coupled with or transferred to the mechanical activity of the stomach *via* the regulation mechanism for nerve and body fluid, the normal IGM rhythm could be seen in the spectrum, which suggests the recovery of the contraction function of the stomach.

There were significant differences in IGM parameters between the gastritis patients and healthy controls. After 1 wk of treatment, the EGG rhythm of the gastritis patients returned to normal while the IGM parameters only showed a tendency to improve, which had no statistical significance. This suggests that the influence of the GEA may not have coupled with the mechanical contraction of the stomach after only 1 wk of treatment. On the other

hand, although the patients felt some alleviation after 1 wk of treatment, the cardinal symptoms of gastritis were not completely relieved. This fact coincided with the results of Table 2, and therefore, the patients should be advised to continue the treatment.

The mixed signal acquired from the abdominal surface contains not only IGM information but also the components of impedance blood flow, breath and some other disturbances. The normal rhythm of IGM is about 3 cpm. Within the mixed signal, the rhythm of the breath impedance signal is about 12 cpm, which is close to the rhythm of the IGM. Signals of the IGM and breath both are ultra-low frequency signals and the amplitude of the breath signal is usually much higher than that of the IGM signal. It is a challenge to extract the IGM signal from the mixed signals effectively. A low-pass filter may be good enough to reduce the effect of high-frequency noise and heart activity, however, it is difficult to eliminate respiration influence and separate the IGM signal from the mixed signal. Therefore, a narrow bandpass filter and a high-order active low-pass filter are required. In the measurement system for gastric motility described in this paper, a wavelet transform was introduced and the IGM signal was separated successfully from impedance signals, including breath and blood flow.

In this study, we focused on the stomach contraction rhythm. Some events without a rhythm, such as gastric acid secretion, did not affect the measurement results.

The EGG reflects GEA of the stomach and is sensitive to regulation mechanisms from nerve and electrical activity. The improvement of the EGG after treatment is only the beginning of improvement in gastric motility function and does not indicate a cure of gastric disorder or the recovery of gastric motility. The IGM is a veritable measure of gastric contraction and peristalsis, and reflects the gastric motility function. Gastric motility measurement is based on an electrical-mechanical composite mechanism. The combined measurement of IGM and EGG is a noninvasive, convenient and effective method that extracts information that directly reflects the gastric motility state. It can be used to measure gastric contraction and peristalsis during digestion and evaluate gastric motility function in different physiological and pathological conditions.

COMMENTS

Background

Gastric motility is one of the most critical physiological functions of the human body. The research on gastric motility function has fallen behind that on gastric endocrine and exocrine secretion functions and gastric morphology. One of the important reasons for this is the absence of a convenient and effective measurement method for gastric motility function. There are many applications using bioimpedance signals for different pathological conditions, but their use in gastric motility assessment needs to be explored in detail and there are few researches on the extraction of gastric motility information.

Research frontiers

In the period of digestion, the stomach content changes greatly and so does the impedance of the stomach. When measuring the impedance of the stomach during digestion, the information reflecting the stomach volume (gastric emptying) and gastric motility can be extracted. The method combining electrical bioimpedance measurement with an electrogastragram (EGG) is one of the research frontiers for gastric motility measurement.

Innovations and breakthroughs

Gastric motility is a complex composite course from electrical gastric activity to mechanical gastric activity. The EGG reflects the myoelectric activity of the stomach and the rhythm of gastric contraction. Information from impedance measurement on the stomach directly corresponds to gastric motility. A combination of EGG and impedance gastric motility (IGM) measurements is a new approach for measuring and evaluating gastric motility based on an electrical-mechanical composite mechanism.

Applications

A combination of IGM and EGG measurement is a noninvasive, convenient and effective method that can be used to measure gastric contraction and peristalsis during digestion and evaluate gastric motility function in different physiological and pathological conditions. This method has shown an attractive application prospect in gastric motility research and evaluation.

Terminology

An electrical bioimpedance technique is a method to extract physiological and pathological information from the human body according to the electrical property of the tissue and organs by means of injecting a small current and measuring the electrical potentials from electrodes on the body surface. The method has the advantages of being noninvasive, convenient, and providing considerable functional information.

Peer review

This is a good article illustrating how technology can be used for clinical measurement. The authors have put a lot of efforts to develop and present their work.

Abstract

AIM: To evaluate the effectiveness of omega-3 polyunsaturated fatty acid (ω -3 PUFA) administration on liver regeneration after 90% partial hepatectomy (PH) in rats.

METHODS: ω -3 PUFAs were intravenously injected in the ω -3 PUFA group before PH surgery. PH, sparing only the caudate lobe, was performed in both the control and the ω -3 PUFA group. Survival rates, liver weight/body weight ratios, liver weights, HE staining, transmission electron microscope imaging, nuclear-associated antigen Ki-67, enzyme-linked immunosorbent assay and signal transduction were evaluated to analyze liver regeneration.

RESULTS: All rats in the control group died within 30 h after hepatectomy. Survival rates in the ω -3 PUFA group were 20/20 at 30 h and 4/20 1 wk after PH.

Liver weight/body weight ratios and liver weights increased significantly in the ω -3 PUFA group. The structure of sinusoidal endothelial cells and space of Disse was greatly restored in the ω -3 PUFA group compared to the control group after PH. In the ω -3 PUFA group, interleukin (IL)-4 and IL-10 levels were significantly increased whereas IL-6 and tumor necrosis factor- α levels were dramatically decreased. In addition, activation of protein kinase B (Akt) and of signal transducer and activator of transcription 3 signaling pathway were identified at an earlier time after PH in the ω -3 PUFA group.

CONCLUSION: Omega-3 polyunsaturated fatty acids may prevent acute liver failure and promote liver regeneration after 90% hepatectomy in rats.

INTRODUCTION

The liver is a unique organ with ability to regenerate and recover its original function after extended resection or injury. This occurs due to the hyperplasia of the residual lobes and mitosis of the hepatocytes which are quiescent under normal conditions^[1,2]. The development of two-

thirds partial hepatectomy (PH) in the rat liver by Higgins and Anderson represented a milestone in the exploration of liver regeneration^[3]. In this study, we found that 90% PH was lethal for rats: the cause of death may be associated with acute liver failure induced by small residual liver. Hepatocyte growth factor, platelets and 5-hydroxytryptamine were reported to promote liver regeneration and ameliorate acute liver failure after 90% hepatectomy in previous research^[4-6].

Fatty acids, as essential nutrients, have a wide range of biological functions^[7] and omega-3 polyunsaturated fatty acid (ω -3 PUFA) supplementation is also reported to be involved in modifying the organic biochemical environment^[8]. Recently, ω -3 PUFAs were found to play significantly protective roles in the liver, cardiovascular system and kidney^[9-11] and they have been widely used in clinical perioperative total parenteral nutrition^[12]. In this study, we demonstrate that ω -3 PUFA plays an important role in stimulating liver regeneration after 90% hepatectomy in rats.

MATERIALS AND METHODS

Animals

Sprague-Dawley male rats with weights ranging from 180 to 220 g were purchased from Nanjing University. Rats were maintained in a temperature-controlled room on a 12 h light-dark cycle, with free access to water and standard chow. Animals were divided into three groups ($n = 6$ in each group): the sham group; the control group (rats without ω -3 PUFA treatment); and the ω -3 PUFA group (rats with ω -3 PUFA treatment). In the ω -3 PUFA group, rats were injected intravenously (*via* rat tail vein) with ω -3 PUFA (Fresenius Kabi Corp., Germany) at a dose of 2 mL/kg body weight once 1 d for 2 d before PH surgery. Animal experiments were approved by the Institutional Animal Experiment Committee of Affiliated Drum Tower Hospital, Medical College of Nanjing University (China), in accordance with the Regulations for Animal Experiments at Nanjing University and Fundamental Guidelines for Proper Conduct of Animal Experiment and Related Activities in Academic Research Institutions under the jurisdiction of the Ministry of Education, Culture, Sports, Science and Technology.

Surgical procedure and anesthesia

Ninety percent hepatectomy was performed in the control and the ω -3 PUFA groups. The procedure is modified from the Higgins-Anderson operation by removing the left lateral, left median and right median lobes with a single ligature (70% PH), and subsequently resecting the right lateral lobe (20%) and leaving only the caudate lobe. Hepatectomy was carried out under ether anesthesia.

Liver tissue collection

Six rats from each group were sacrificed and liver tissues were collected to investigate the effect of ω -3 PUFA administration on liver regeneration. At 12 h, 18 h and 24 h

after PH, rats were sacrificed, regenerated liver samples were collected and wet remnant liver weights were measured. In addition, liver weight/body weight ratios were measured (%) for each rat. Mean value was calculated for each group at each time point. Tissues were divided into three specimens with one immediately frozen in liquid nitrogen and the second immersed into OCT compound and quickly frozen in the liquid nitrogen. The third specimen was fixed in 10% buffered formalin.

Serum parameters

Blood was collected from the peripheral vessels in the quantity of 1-1.5 mL. Blood was centrifuged for 10 min at 4 °C at 3500 rpm. Supernatants were collected and stored at -80 °C until tested by a serum multiple biochemical analyzer to measure alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase, total protein, serum albumin, total bilirubin and total bile acids.

Histology and immunohistochemistry

Liver tissues, fixed in 10% buffered formalin, were used for histological and immunohistological analyses. Samples were stained in hematoxylin-eosin (HE). Liver sections were also incubated with Ki-67 antibody. OCT compound-immersed tissue samples were used for detection of liver sinusoidal endothelial cells (SEC) in the residual liver 24 h after PH.

Transmission electron microscopy

Livers were removed 5 min after hepatectomy. The liver was cut into small pieces (approximately 1 mm) and the specimens were fixed in 2% glutaraldehyde in 0.1 mol/L phosphate buffer, pH 7.4, and post-fixed in 1% OsO₄ in 0.1 mol/L phosphate buffer. The specimens were dehydrated through a graded series of ethanol, passed through propylene oxide and embedded in EPON 812. Ultra-thin sections mounted on copper grids were stained with uranyl acetate and lead citrate, and then were observed under a Hitachi H-7000 transmission electron microscope.

Enzyme-linked immunosorbent assay

Serum samples were collected and stored at -80 °C and serum tumor necrosis factor- α (TNF- α), interleukin (IL)-4, IL-6 and IL-10 were quantified using commercially-available enzyme-linked immunosorbent assay kits (Becton, Dickinson and Company, United States). Serum TNF- α , IL-4, IL-6 and IL-10 levels were measured in the control group and the ω -3 PUFA group.

Western blotting

Liver tissue extracts were prepared from the liquid nitrogen frozen specimens as previously described. Western blotting was developed using polyclonal antibodies: phosphoserine Akt, total Akt, phosphotyrosine signal transducer and activator of transcription 3 (STAT3), total STAT3, phosphotyrosine glycogen synthase kinase (GSK) and total GSK.

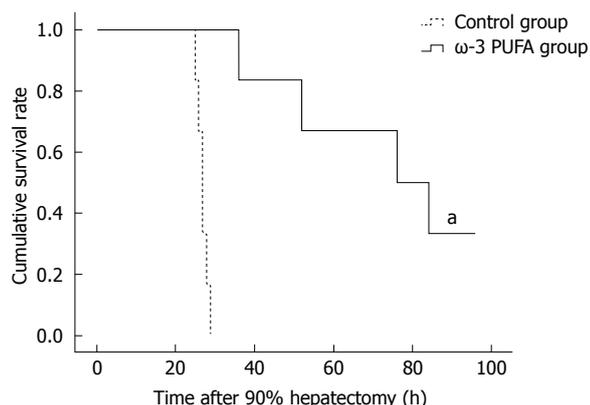

Figure 1 Survival rates in the control and the omega-3 polyunsaturated fatty acid groups. All rats from the control group died within 30 h after hepatectomy. In contrast, in the omega-3 polyunsaturated fatty acid (ω -3 PUFA) group, 20 (100%) and 4 (20%) rats were alive at 30 h and 1 wk after PH, respectively. ^a $P < 0.05$ vs normal group.

Statistical analysis

All data are expressed as the mean \pm SD of samples. Statistical analyses were carried out with the *T*-test for independent samples. In all cases, a *P* value < 0.05 was considered significant.

RESULTS

Survival rates

Twenty rats were subjected to PH surgery to examine the survival rates. All rats from the control group died within 30 h after PH. Four rats from the ω -3 PUFA group survived 1 wk after PH. According to the obtained results, the survival rates in the ω -3 PUFA group after 90% PH were 100% at 30 h after PH and 20% ($P < 0.05$) 1 wk after PH, respectively (Figure 1).

Liver weight/body weight ratios

The ratios of LW/BW and liver weights were significantly increased at 24 h after PH in the ω -3 PUFA group in comparison with the control group ($P < 0.05$) (Figure 2).

Serum parameters

Serum ALT and AST levels were increased in both control and the ω -3 PUFA groups at 24 h after PH. There was a significant difference, with higher levels in the control group ($P < 0.05$) (Figure 3A and B). Serum alkaline phosphatase levels were lower in the ω -3 PUFA group with significant differences at 12 h after PH ($P < 0.05$) in comparison with the control group (Figure 3C). Serum albumin and total protein levels were attenuated in both groups after PH with more rapidly decrease in the control group ($P < 0.05$) (Figure 3D and E). No significant differences were identified between the control and the ω -3 PUFA groups in the levels of total bilirubin, direct bilirubin and total bile acids ($P > 0.05$) (data not shown).

Histological findings

HE staining showed that the structure of liver lobules

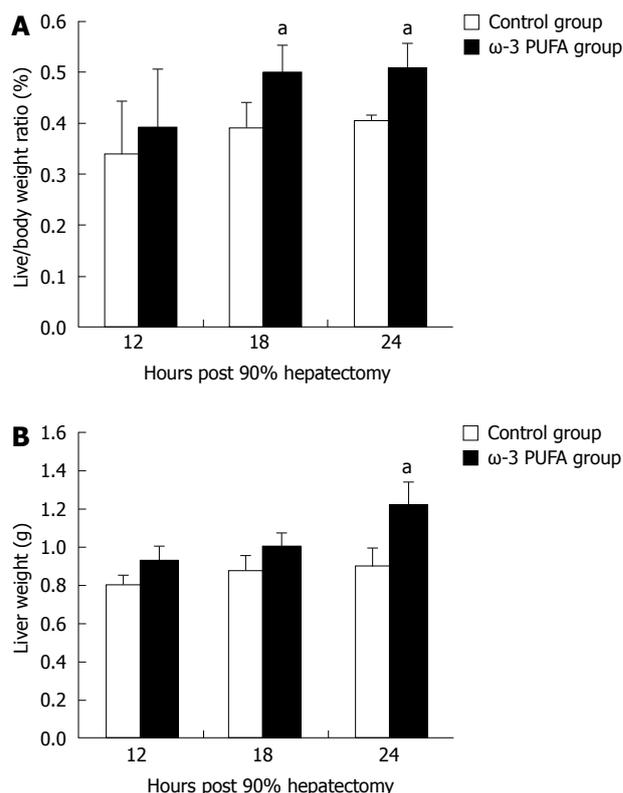

Figure 2 Change in liver weight/body weight ratios and liver weights after partial hepatectomy. Liver weight/body weight ratios (A) and liver weights (B) in the control and the omega-3 polyunsaturated fatty acid (ω -3 PUFA) group at 12 h, 18 h and 24 h post-hepatectomy. Data are expressed as mean \pm SD. $n = 6$ in each group. ^a $P < 0.05$ vs normal group.

was severely damaged; hepatocyte swelling and necrosis of hepatocytes were observed after PH at every time point in the control group. Nevertheless, hepatocytes and the structure of liver lobules were greatly restored at 24 h after PH in the ω -3 PUFA group (Figure 4). The number of Ki-67 positive cells in the liver tissue 24 h after 90% PH was much higher in the ω -3 PUFA group ($P < 0.05$) (Figure 5).

Transmission electron microscopy

In the control group, the space of Disse was enlarged and the structure of sinusoidal endothelial cells (SECs) was severely damaged at 24 h after PH. However, the SEC structure and space of Disse were greatly restored at 24 h after PH in the ω -3 PUFA group (Figure 6).

Serum cytokines

Compared with the control group, the level of pro-inflammatory cytokines IL-6 and TNF- α significantly decreased at 18 h and 24 h after PH ($P < 0.05$). The levels of anti-inflammatory cytokines IL-4 and IL-10 significantly increased in the ω -3 PUFA group at 24 h after PH ($P < 0.05$) (Figure 7).

Phosphorylation of Akt, STAT3, GSK3 β

In the ω -3 PUFA group, Akt was phosphorylated in the samples at 12 h after PH and phosphorylated Akt was

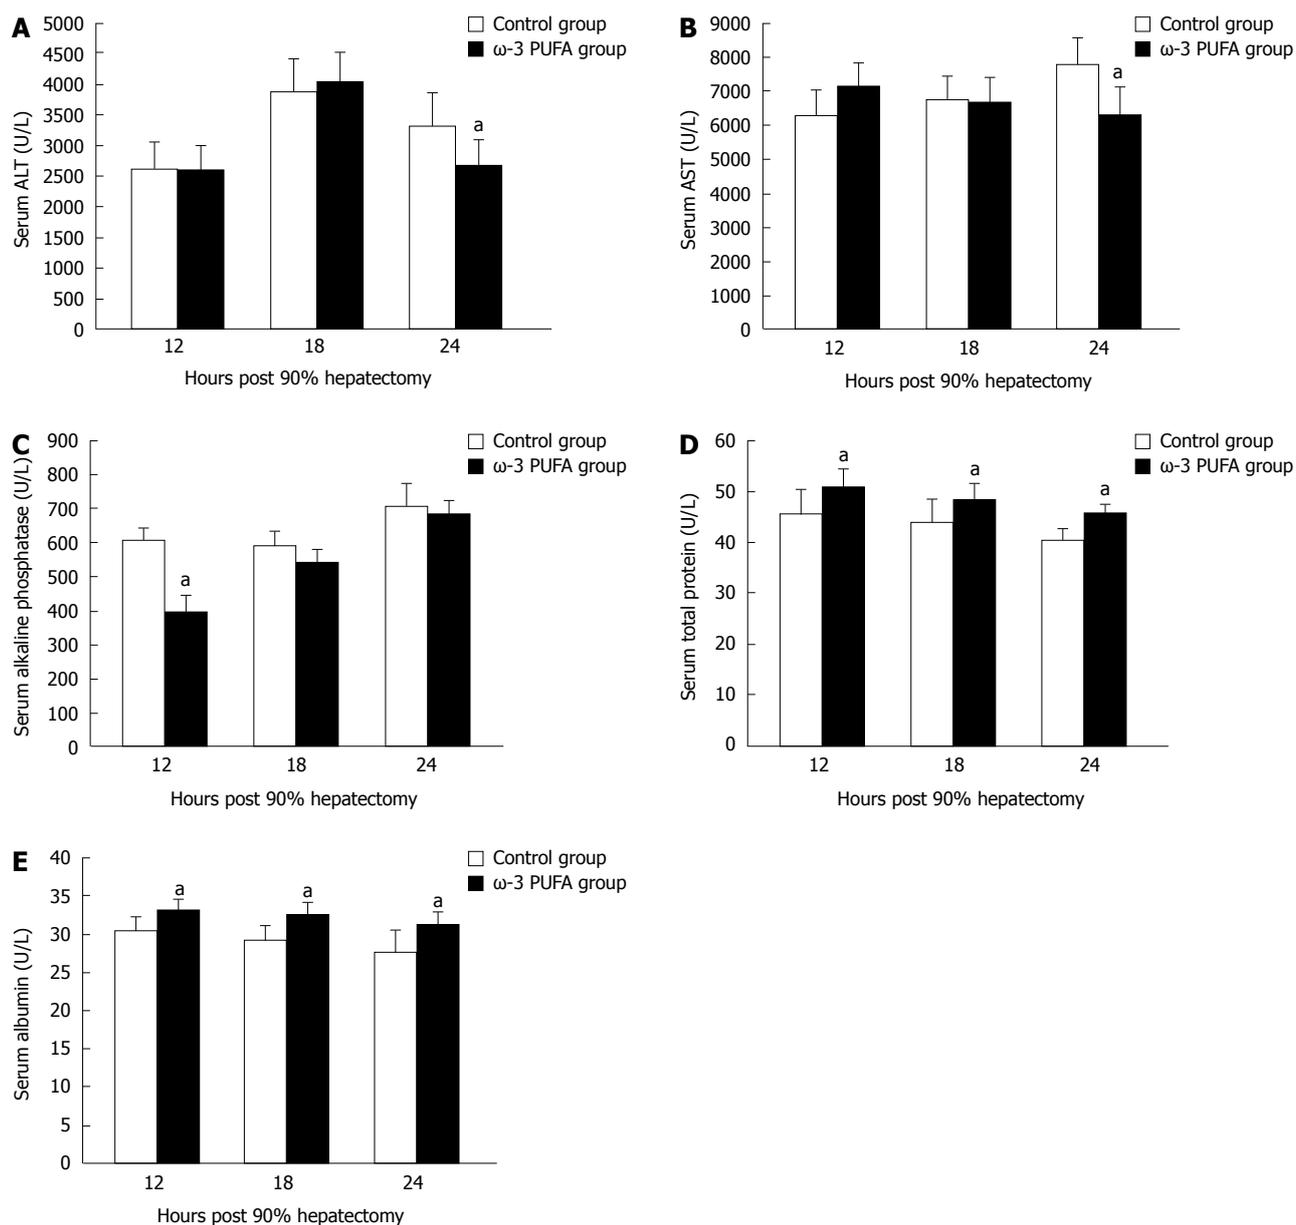

Figure 3 Serum parameters of the control and the omega-3 polyunsaturated fatty acid groups. Serum alanine aminotransferase (ALT) (A), aspartate aminotransferase (AST) (B), alkaline phosphatase (C), total protein (D) and albumin (E) levels at 12 h, 18 h and 24 h post-hepatectomy. $n = 6$ in each group. ^a $P < 0.05$ vs control group. ω-3 PUFA: Omega-3 polyunsaturated fatty acid.

increased in the samples at 18 h after PH. In contrast, phosphorylated Akt expression was much lower at 18 h after PH in the control group. In addition, GSK3 β was expressed at 12 h after PH in the ω-3 PUFA group, which was much earlier than in the normal group. Moreover, the expression of phosphorylated STAT3 was much higher and was sustained longer in the ω-3 PUFA group at 12 h, 18 h and 24 h after PH (Figure 8).

DISCUSSION

PH is the accepted gold standard of treatment for benign and malignant hepatic space-occupying lesions. The precise liver resection, which is based on preoperative evaluation, meticulous surgical procedure and postoperative

management, has been well developed. However, acute liver failure after extended hepatectomy has been shown to be a major contributor to post-operative mortality and morbidity^[13,14]. Thus, how to control post-operative liver failure remains an urgent problem to be solved. It has been shown that ω-3 PUFA plays an important role in gastrointestinal surgery; it can protect hepatocytes through inhibiting liver cell peroxidation *via* anti-oxidation and anti-inflammatory mechanisms of action after PH^[15,16]. Nevertheless, no report has shown the effects of ω-3 PUFA on liver regeneration and acute liver failure after extended hepatectomy. Our study is the first to demonstrate that ω-3 PUFA plays a beneficial role on liver regeneration after 90% hepatectomy, which may offer hope for protecting from post-operative liver failure

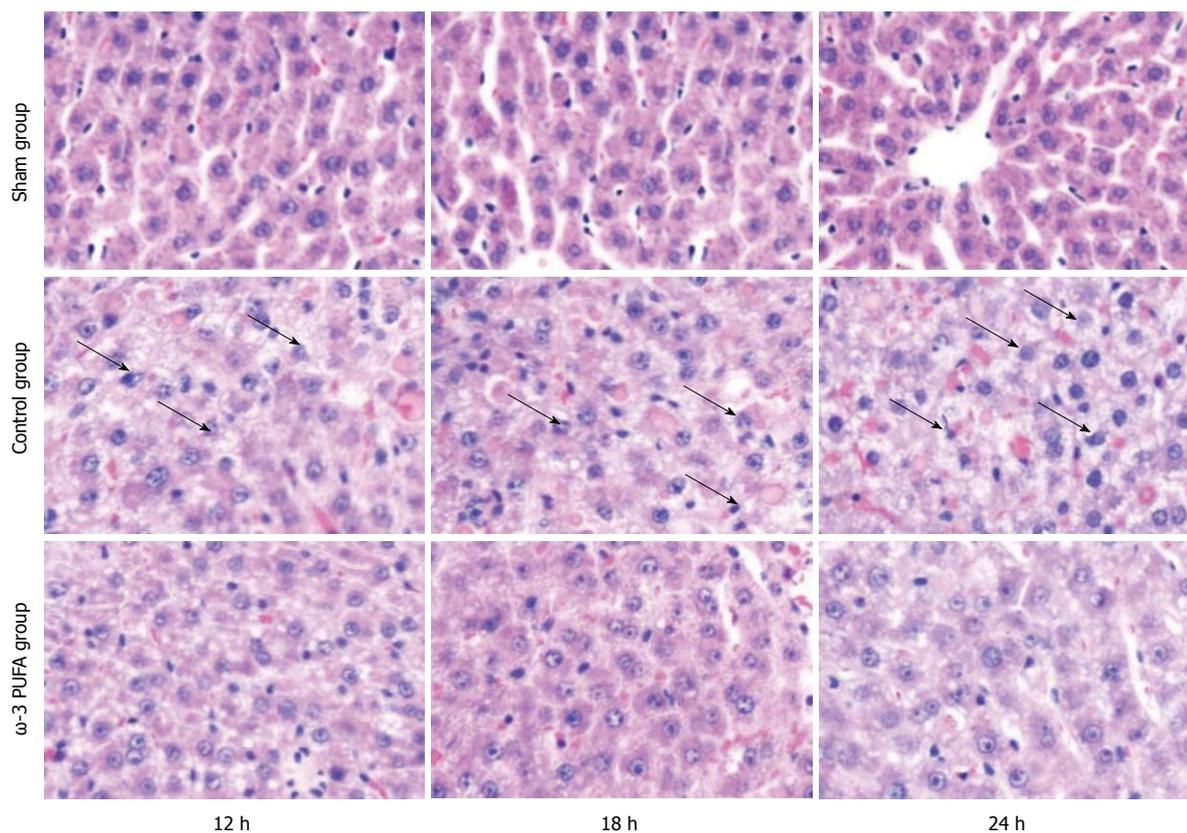

Figure 4 Histopathological examination of rats livers. Swelling and balloon degeneration of hepatocytes were observed at all time points after partial hepatectomy (PH) in the control group (hematoxylin and eosin staining, original magnification $\times 400$). By contrast, no significant hepatocyte swelling or balloon degeneration were observed at 12 h after PH in the omega-3 polyunsaturated fatty acid (ω -3 PUFA) group (arrow). Hepatocytes are normal and structure of liver lobules was obvious at 24 h after PH.

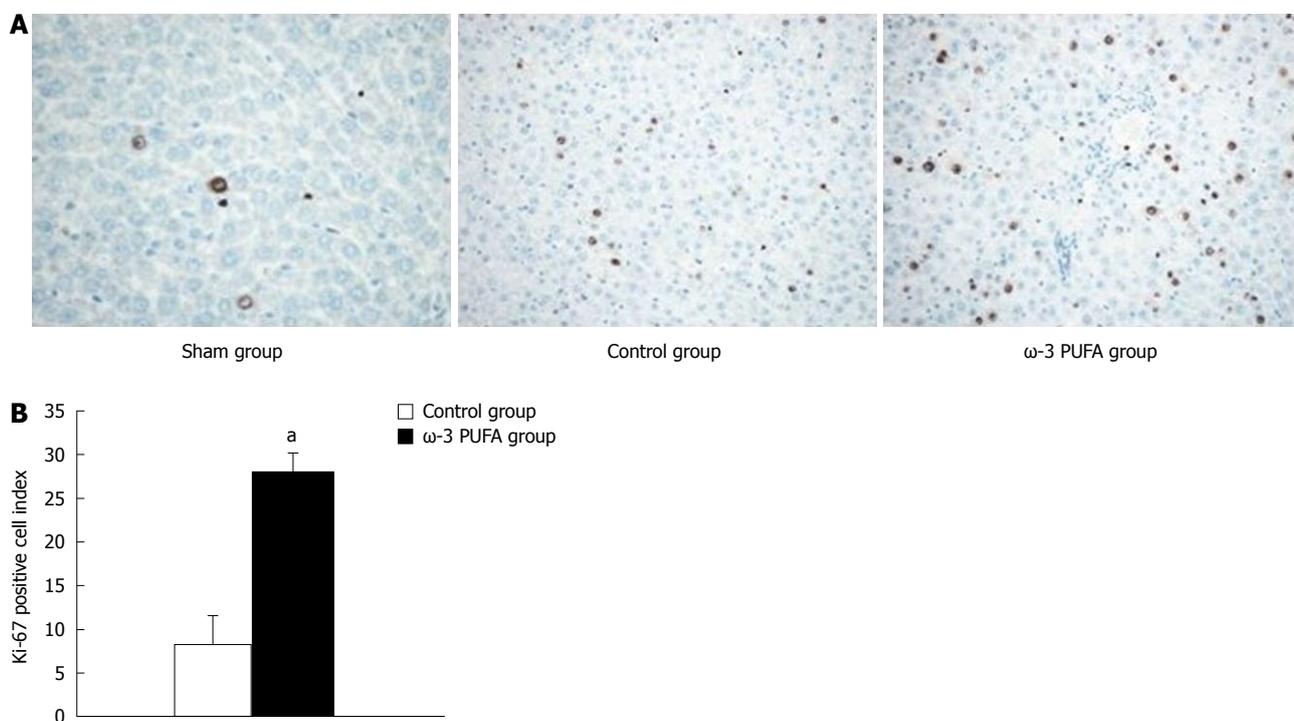

Figure 5 Change in Ki-67-positive cells after partial hepatectomy. A: The number of Ki-67-positive cells in the liver tissue 24 h after 90% partial hepatectomy (PH) was much higher in the omega-3 polyunsaturated fatty acid (ω -3 PUFA) group; B: Compared with control group, Ki-67-positive cells were significantly increased in the ω -3 PUFA group 24 h after PH. $n = 6$ in each group. ^a $P < 0.05$ vs control group.

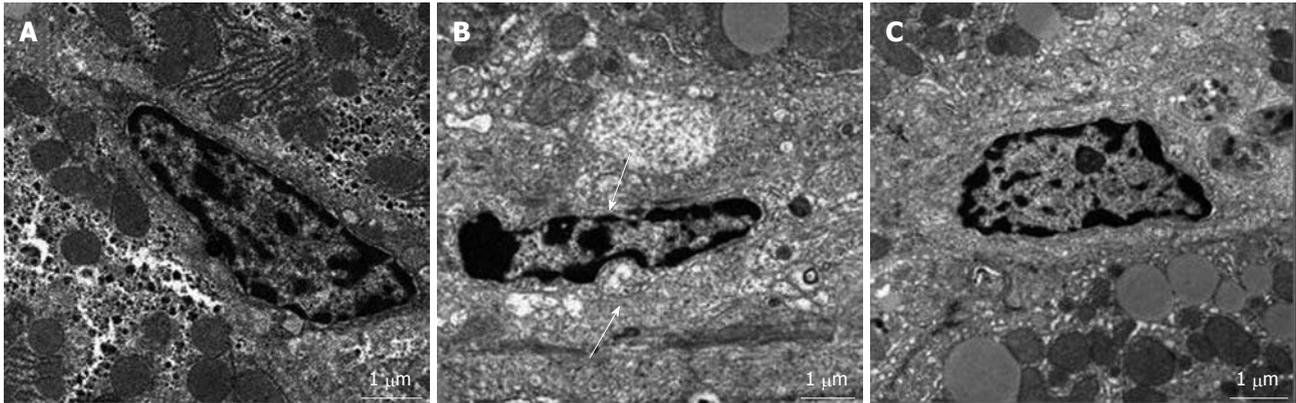

Figure 6 Change in the structure of sinusoidal endothelial cell after partial hepatectomy. A: Normal structure of liver tissue; B: Space of Disse was enlarged and the structure of sinusoidal endothelial cell (SEC) was severely damaged at 24 h after partial hepatectomy (PH) in the control group (arrow); C: Compared with control group, the SEC structure and space of Disse were greatly restored at 24 h after PH in the omega-3 polyunsaturated fatty acid group.

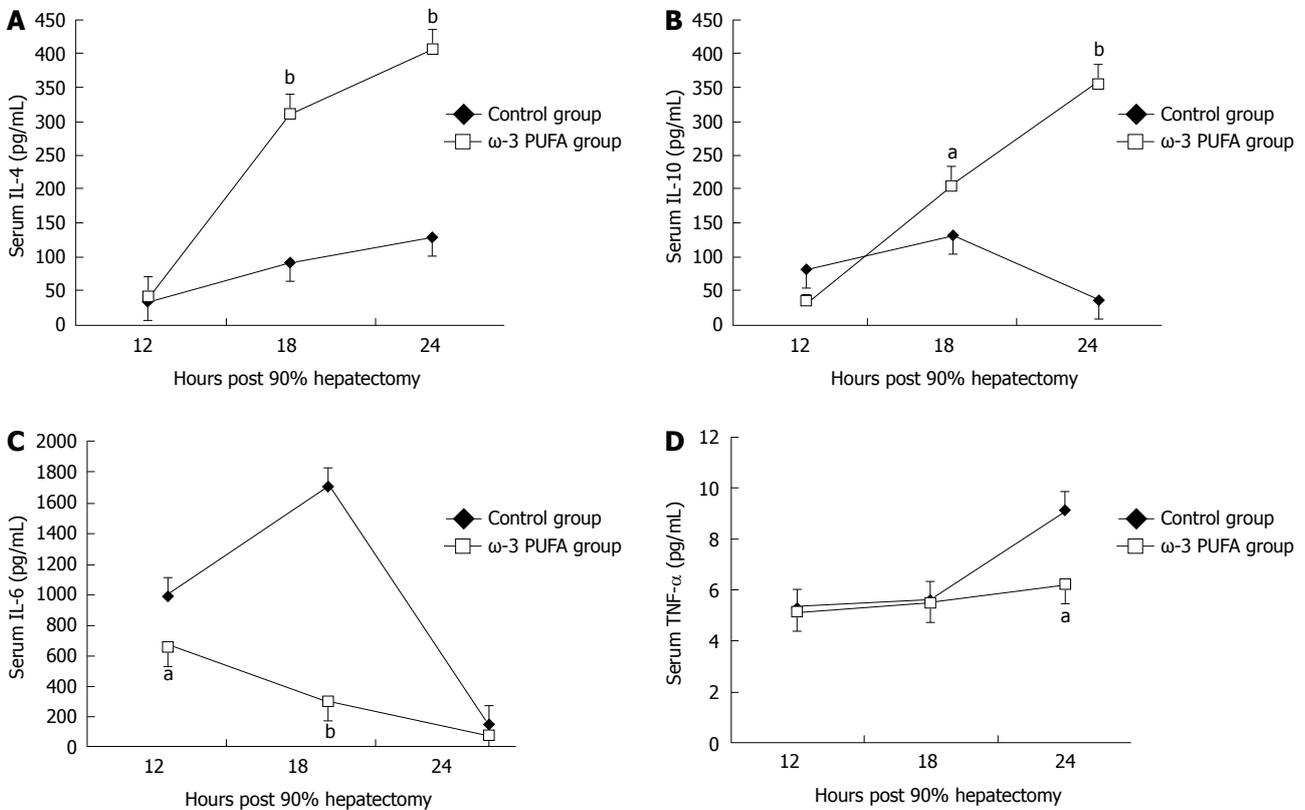

Figure 7 Change in serum cytokines. Cytokines interleukin (IL)-4 (A) and IL-10 (B) significantly increased at 24 h in the omega-3 polyunsaturated fatty acid (ω-3 PUFA) group after partial hepatectomy, while IL-6 (C), and tumor necrosis factor (TNF)-α (D) significantly decreased at 18 h and 24 h after operation in the ω-3 PUFA group. ^a*P* < 0.05, ^b*P* < 0.01 vs control group.

after clinical extended hepatectomy.

In general, serum parameters are a significant index to evaluate liver function. Serum AST and ALT concentrations are inversely related to the severity of liver damage. Albumin is a marker of synthetic function of the liver^[17,18]. In this research, both ALT and AST levels were significantly lower in the ω-3 PUFA group at 24 h after PH. In addition, total protein and albumin levels were higher in the ω-3 PUFA at 12 h, 18 h and 24 h after PH. These results strongly indicate that ω-3 PUFA plays a

protective role in liver function after 90% hepatectomy.

SECs are a type of special endothelium, which not only take part in the formation of blood vessels^[19], but also play a key role in hemodynamic changes of the liver, even physiological and metabolic functions^[20-22]. The structural feature of the SEC is a spindle type of cell with plenty of clusters of cribriform fenestrae^[23], which can accelerate the exchange of substances between hepatocytes and blood plasma^[24]. ω-3 PUFA has been reported to modulate both nitric oxide synthase

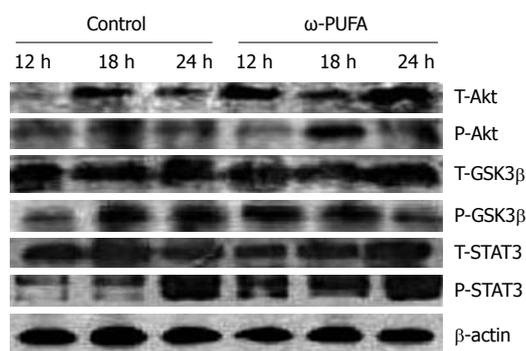

Figure 8 Phosphorylation of activation of protein kinase, signal transducer and activator of transcription 3, glycogen synthase kinase-3 β . Phosphorylation of activation of protein kinase B (Akt), signal transducer and activator of transcription 3 (STAT3), glycogen synthase kinase (GSK)-3 β in the control and the omega-3 polyunsaturated fatty acid (ω -3 PUFA) groups at 12 h, 18 h and 24 h after partial hepatectomy. Liver lysates at 12 h, 18 h and 24 h time points in the quantity of 25 μ g per lane were subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Proteins were transferred to polyvinylidene fluoride membrane and then incubated with specific antibodies. There was stronger phosphorylation of Akt at the 18 h time points and earlier phosphorylation of GSK3 β at the 12 h time points compared to the control group. Phosphorylation of STAT3 was stronger and lasted longer at all time points in the ω -3 PUFA group.

(NOS) activity and cyclooxygenase expression as antioxidants^[25,26]. Oxidative stress and the inactivation of NO by superoxide anions play an important role in disease states. NO is synthesized by three distinct NOS isoforms (neuronal, inducible, and endothelial NOS)^[27]. The endothelial NOS III plays physiologically important roles in vascular homeostasis, such as keeping the vasculature dilated, protecting the intima from platelet aggregates and leukocyte adhesion, and combining superoxide^[28]. This procedure can generate non-toxic metabolite NO₃⁻, which could circumvent oxygen-free radical damage to the integrity of the structure and function of SECs^[29]. In our study, the space of Disse was enlarged and the structure of SECs was severely damaged in the control group, in contrast to the favorable integrity of the SEC structure in the ω -3 PUFA group. These results suggest that ω -3 PUFA promotes liver regeneration through protecting the structure of the SEC in the acute phase after hepatectomy.

ω -3 PUFA is known to play a crucial role in the function of the immune system and its receptors such as Toll-like receptors (TLRs). Recently, TLRs were observed to influence the development of adaptive immune responses in T-helper-1 (Th1) and T-helper-2 (Th2) cells which are characterized by their distinct cytokine patterns including IL-4, IL-6, IL-10 and TNF- α . Jerin *et al.*^[30] suggested that the intensity of inflammation could be assessed by the ratio of IL-6/IL-10. In the present study, we showed that pro-inflammatory cytokines IL-6 and TNF- α significantly decreased, and anti-inflammatory cytokines IL-4 and IL-10 significantly increased, in the ω -3 PUFA group in comparison with the control group. TNF- α is produced mainly by resident hepatic macrophages (Kupffer cells)^[31], and the expression of IL-6 has been shown to be stimulated in hepatocytes as well as in Kupffer cells^[32]. Activa-

tion of nuclear factor- κ B induced by TNF- α is a key step in liver regeneration^[33]. IL-6 is also predominantly produced in Kupffer cells. The role of IL-6 in liver regeneration has not been clearly defined^[34]. However, it was found to be one of the strongest inducers of STAT3 in hepatocytes. After IL-6 binds to its receptor on the hepatocyte surface, signal transduction occurs by phosphorylation of cytoplasmic STAT protein 3^[35]. STAT3 is an important signal pathway in regulating cell proliferation, transformation and apoptosis of hepatocytes^[36]. A previous study has shown that a significantly higher mortality rate occurred in the early phase after 70% PH in STAT3-knockout mice^[37]. The Akt pathway is downstream of growth factor receptors^[38], and promotes cell proliferation through activation of GSK3 β to accelerate nuclear accumulation of cyclin D1^[39]. Cyclin D1 can strongly stimulate cell division and thus enhance liver regeneration. In the present study, STAT3 was strongly phosphorylated at 12 h and 18 h after PH in the ω -3 PUFA group. Phosphorylated Akt was also detected at 18 h after PH which was much earlier and stronger than that in the control group. Our results demonstrate that ω -3 PUFA is responsible for earlier and stronger phosphorylation of the STAT3 and Akt in the signaling pathway. However, IL-6 and TNF- α , key cytokines for liver regeneration, were found to decrease in the ω -3 PUFA group. The mechanism of these two opposite effects on liver regeneration is not clear in the present study and needs to be clarified in the future.

Taken together, our results provide strong evidence that intravenous injection of ω -3 PUFA could slow the progress of acute liver failure through an anti-inflammatory action and significantly promote liver regeneration after 90% hepatectomy.

COMMENTS

Background

Liver regeneration after the loss of hepatic tissue is a fundamental parameter of liver response to injury. Omega-3 polyunsaturated fatty acid (ω -3) PUFA could promote liver regeneration as an anti-inflammatory agent.

Research frontiers

Although a previous study has demonstrated that intravenous administration of ω -3 PUFA is beneficial in the treatment of fatty liver in rats, the effect of liver regeneration was not detected.

Innovations and breakthroughs

This study demonstrated that ω -3 PUFA plays a beneficial role in liver regeneration. ω -3 PUFA decreased the expression of pro-inflammatory cytokines and increased the expression of anti-inflammatory cytokines. ω -3 PUFA could slow the progress of acute liver failure through its anti-inflammation effect and promote liver regeneration.

Applications

The results of this study suggest ω -3 PUFA can promote liver regeneration in rats. Further studies are required before applying this treatment to patients with partial hepatectomy.

Terminology

The ω -3 PUFA enter human bodies mainly through consumption of cold-water fish products, and they have been widely clinically used in total parenteral nutrition treatment.

Peer review

It is of interest and importance that ω -3 PUFA may contribute to the recovery of severely damaged livers.

Abstract

AIM: To investigate the expression and significance of caudal-related homeobox transcription factor (Cdx2) in gastric carcinoma (GC) and precancerous lesions.

METHODS: The expression of Cdx2 in GC, precancerous lesions and normal gastric mucosa were detected using immunohistochemical method. Hematoxylin and eosin staining, alcian blue/periodic acid-schiff and high iron diamine/alcian blue staining were used to classify intestinal metaplasia (IM) and GC.

RESULTS: Cdx2 was not detected in normal gastric mucosa. Cdx2 expression was detected in 87.1% (101/116) of IM, 50% (36/72) of dysplasia and 48.2% (41/85) of GC. The Cdx2-expressing cells in IM were more prevalent than in dysplasia and carcinoma ($P < 0.05$). There was no relationship between Cdx2 expression and the classification of IM or the degree of dysplasia. Expression of Cdx2 was significantly higher in intestinal-type carcinoma than in diffuse and mixed-type carcinoma ($P < 0.05$). Positive expression of Cdx2

was mainly found in moderately to well differentiated GC. There was a negative association between nuclear Cdx2 expression and lymph node metastasis and tumor, nodes, metastasis stage of GC ($P < 0.05$). The patients with Cdx2-positive expression showed a higher survival rate than those with Cdx2-negative expression ($P = 0.038$). Multivariate analysis revealed that the expression of Cdx2 and lymph node metastasis were independent prognostic indicators of GC ($P < 0.05$).

CONCLUSION: Cdx2 may be closely related to IM and the intestinal-type GC and implicate better biological behavior and outcome. Cdx2 is useful for predicting the prognosis of GC.

INTRODUCTION

Gastric carcinoma (GC) is one of the most common malignant diseases and is the second most common cause of cancer-related death in China and in the world^[1]. The pathogenesis of GC is still not very clear. Despite wide acceptance of the gastritis-metaplasia-dysplasia-carcinoma sequence, the precise molecular alterations underlying this progression pathway remain to be delineated^[2].

Caudal-related homeobox transcription factor (Cdx2), which is a member of the caudal-related homeobox gene family, plays an important role in mammalian early intestinal development and the maintenance of intestinal epithelia through its regulation of intestine-specific gene transcription^[3,4]. Normally, Cdx2 is expressed in small intestinal and colonic epithelia, but not in gastric epithelium^[5]. Although Cdx2 expression is restricted to the intestinal epithelium under normal conditions, an ectopic expression has been reported in the gastric mucosa, both in intestine-like metaplasia and in a subset of GCs^[6,7]. Recently, Mutoh *et al*^[8] and Almeida *et al*^[4] reported that the ectopic expression of Cdx2 in the gastric mucosa of transgenic mice is related to the transdifferentiation of gastric mucosal glands into intestinal-like mucosa, and claimed that *Cdx2* gene causes intestinalization in the gastric mucosa. In humans, Cdx2 has been reported to be associated with intestinal metaplasia (IM) in the stomach^[6], in which ectopic expression of Cdx2 is speculated to cause the gastric epithelial cells to transdifferentiate into the intestinal phenotype. Several reports have also suggested a tumor suppressor role for Cdx2 in human colorectal carcinogenesis^[9,11], and this might also be true for gastric cancers. But the question as to whether the ectopic expression of Cdx2 has any influence on cancer initiation and/or progression in the stomach remains unanswered.

GC is a markedly heterogeneous disease in histologic feature and biological characters, especially in the advanced stages. The clinical evidence showed that the biological behavior and prognosis could be significantly different among the patients with the same stage, histological type, or differentiation grade. Therefore, searching for the biomarkers to indicate the biological characters, and predicting the outcome of patients with GC, is the major focus of research on GC. A number of biomarkers have been found to be involved in the development and progression of GC. Although expression of Cdx2 has been detected in some GCs, few studies reported the relationship between Cdx2 expression and prognosis of GC^[12,13].

To better understand the mechanisms underlying malignant transformation and its relationship with developmental processes, we studied and compared the expression of the intestine-specific homeodomain protein Cdx2 in metaplasia, dysplasia and GCs, and the morphologic appearance. Furthermore, in the present study, we analyzed the association between Cdx2 and Lauren's classification, lymph node metastasis, invasion depth, distant metastasis, vascular invasion, tumor size, as well as tumor, nodes, metastasis (TNM) stages, to evaluate the clinical significance of this marker in the histological classification and the prognosis assessment of GC.

MATERIALS AND METHODS

Patients and tissue samples

The present study consisted of 85 cases with surgically resected gastric specimens and 228 cases with endoscopic biopsies were obtained from the Department

of Pathology, the First Affiliated Hospital of Anhui Medical University of China from 2000 to 2005, under a protocol approved by the Institutional Review Board. Slides of GC were reviewed to analyze pathologic parameters, including tumor size, histological grading, depth of invasion, and the presence of nodal metastasis. The 85 patients with GCs (aged 20-87 years, mean 61.75 years; 25 females and 60 males) included 20 early cases and 65 advanced cases. Among them, 10 were classified as well-differentiated adenocarcinoma, 34 as moderately differentiated, and 30 as poorly differentiated adenocarcinoma, and 11 as mucinous cell type. Based on Lauren's classification system, all GCs were categorized into three histological types: intestinal, diffuse, and mixed^[14]. Forty-three cases were classified as intestinal, 35 as diffuse and 7 as mixed. TNM staging was assessed according to the system established by the American Joint Committee on Cancer (AJCC, 19 at pTNM stage I and II, and 66 at pTNM stage III and IV). All patients were followed up until January 2010 for a minimum of 5 years. No patient had received chemotherapy or radiation therapy before surgery. In addition, 228 cases of gastric endoscopic biopsies included 10 cases of normal gastric mucosa, 30 cases of chronic superficial gastritis, 116 cases of gastric IM, and 72 cases of gastric dysplasia (39 cases of mild dysplasia, 20 cases of moderate dysplasia and 13 cases of severe dysplasia). The study was approved by the Research Ethics Committee of Anhui Medical University, China. Informed consent was obtained from all patients. All specimens were handled anonymously according to the ethical and legal requirements.

Histochemistry

The samples were fixed with 10% neutral-buffered formalin and embedded in paraffin. Paraffin-embedded samples were serially sectioned at 4 μ m and mounted on slides. IM was classified into complete type and incomplete type, using Alcian Blue (pH 2.5)/Periodic Acid-Schiff staining and Alcian blue/high-iron diamine (AB/HID) staining (Baso Diagnostics Inc, China). After deparaffinization and rehydration, the sections were incubated with Alcian Blue pH 2.5 for 30 min, followed by 0.5% periodic acid for 10 min and Schiff solution for 10 min. The sections were then counterstained with modified Mayer's hematoxylin for 5 min, dehydrated with graded ethanols and mounted with coverslip. In complete IM, only goblet cells were stained blue, while in incomplete IM, both the goblet cells and the inter-mediate columnar cells appeared blue.

Immunohistochemistry

After routine deparaffinization and rehydration of the slides, antigen retrieval was done by incubation in modified citrate buffer at 121 $^{\circ}$ C for 20 min. The sections were treated with 0.03% hydrogen peroxide for 5min to block the endogenous peroxidase activity, followed by incubation with anti-Cdx2 monoclonal antibody (1:100, Biogenex, San Ramon, CA, United States) at 4 $^{\circ}$ C over-

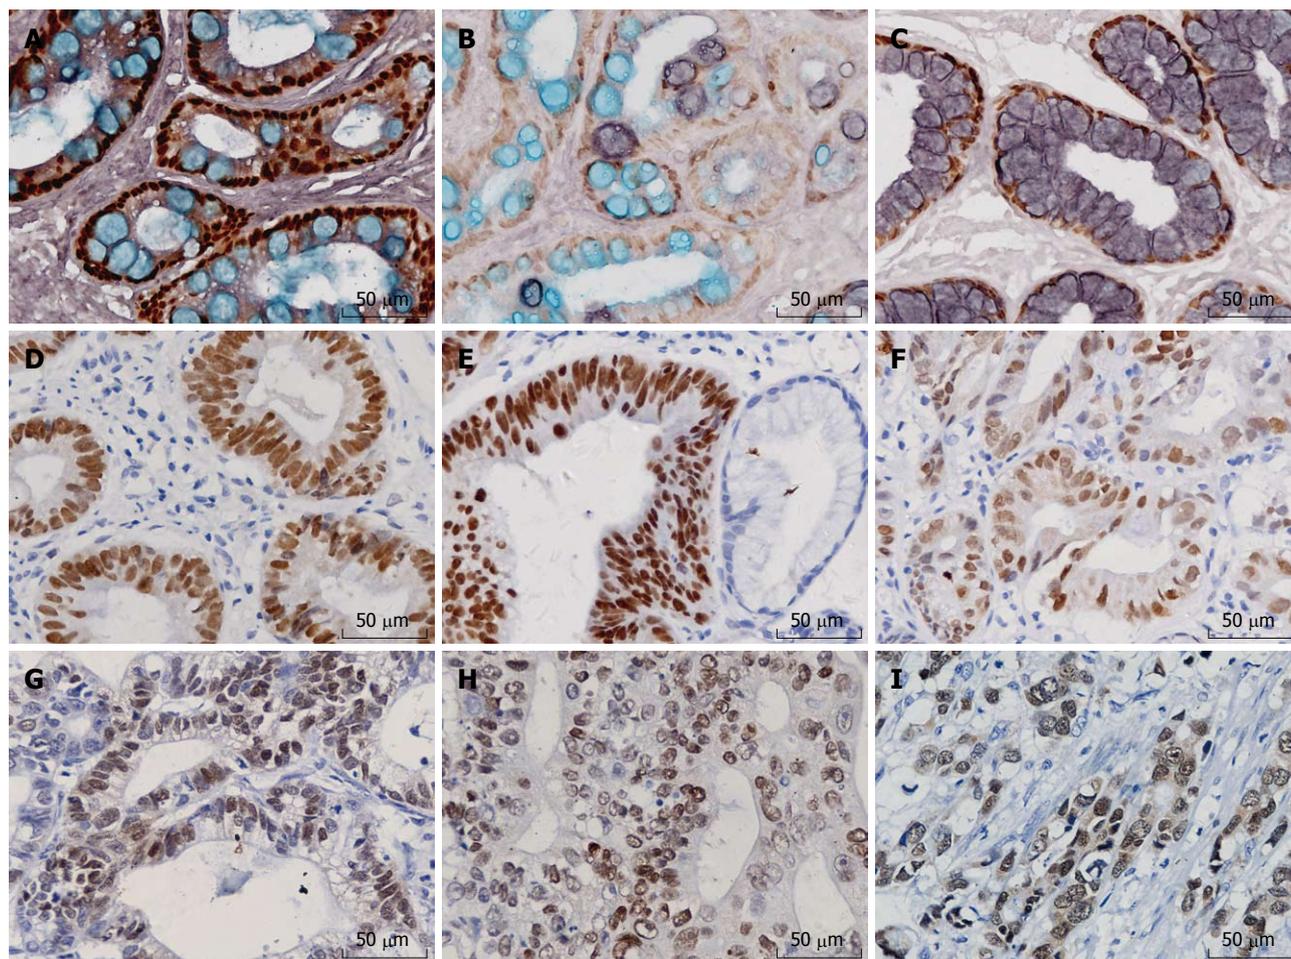

Figure 1 Positive expression of caudal-related homeobox transcription factor in intestinal metaplasia, dysplasia and differentiated gastric cancer. A: Staining of intestinal metaplasia (IM) type I ($\times 400$); B: Staining of IM type II ($\times 400$); C: Staining of IM type III ($\times 400$); D: Staining of mild dysplasia ($\times 400$); E: Staining of moderate dysplasia ($\times 400$); F: Staining of severe dysplasia ($\times 400$); G: Staining of well-differentiated gastric cancer ($\times 400$); H: Staining of moderately-differentiated gastric cancer ($\times 400$); I: Staining of poorly-differentiated gastric cancer ($\times 400$).

night. After washing with $1 \times$ phosphate buffered saline (0.01mol/L, pH 7.4), the sections were subsequently incubated with the biotinylated secondary antibody (Dako, Denmark). The sections were then stained using the Ultra-Sensitive™ Immunohistochemical Staining Kit (Maixin Bio, Fuzhou, China) according to the manufacturer's instructions. After development with 0.05% 3,3'-diaminobenzidine, the sections were counter-stained with hematoxylin, dehydrated with graded ethanols and xylene and then mounted with coverslip. In negative control samples, the primary antibody was omitted and 5% goat serum was used as the primary antibody. Known positive tissue sections served as positive control samples.

Double staining

Double staining of immunohistochemistry and AB/HID staining were applied to detect the Cdx2 expression in different subtypes of IM. Compared to either IHC or AB/HID, combination of both staining was able to detect the protein level and subtypes of IM at the same time.

Assessment of immunostaining in cancer cells

Semiquantitative scores were given as the score of the

percentage of positive cells plus the score of the staining intensity. The scoring criteria of the percentage of positive nuclei (Figure 1A-C) were: score 0: 0%-5% positive cancer cells; score 1: 6%-25% positive cancer cells; score 2: 26%-50% positive cancer cells; score 3: 51%-75% positive cancer cells; and score 4: 76%-100% positive cancer cells. The intensity was scored as follows: score 0, no staining; score 1, mild staining; score 2, moderate staining; and score 3, strong staining. The final scores were from 0 to 7. Specimens with a Cdx2 score of 0-2 were considered negative, whereas specimens with a score of 3-7 were considered positive for Cdx2 expression.

Two experienced investigators independently examined the staining who blinded to the clinicopathological data. Different scores between the two investigators were observed in 15% of the cases, and a consensus was achieved in all the cases after discussion.

Statistical analysis

All data were analyzed using SPSS 13.0 software. Fisher's exact test or χ^2 test was used to calculate the association of Cdx2 expression with various clinicopathological features. Cumulative survival was estimated by the Kaplan-

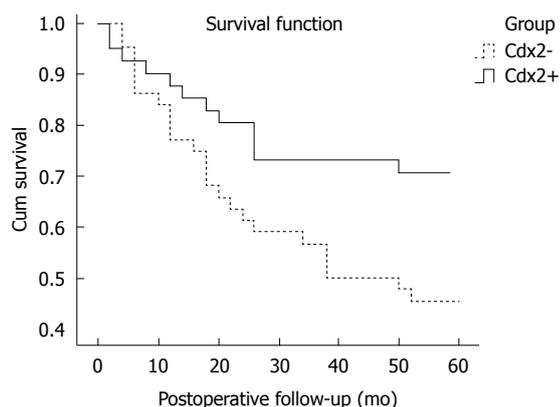

Figure 2 Survival curve of gastric cancer patients with caudal-related homeobox transcription factor positive-expression compared with negative-expression group ($P = 0.038$). Cdx2: Caudal-related homeobox transcription factor.

Meier method and differences between survival curves were analyzed by the log-rank test. The influence of each variable on survival was analyzed by the multivariate Logistic regression analysis. Differences were assumed to be statistically significant when $P < 0.05$.

RESULTS

Cdx2 expression patterns in GC and precancerous lesions

Cdx2 protein expressed in the nuclei of goblet cells of intestinal mucosa, some columnar epithelial cells and some gastric cancer cells. Representative pictures of immunohistochemical staining of Cdx2 are shown in Figure 1.

Expression of Cdx2 protein in GC and precancerous lesions

Gastric IM has been classified as complete (small intestine) or incomplete (colonic) using histochemical staining techniques and into three types based on the staining pattern of its mucins: I (complete), and II and III (incomplete). Type I is the most common type: paneth cells are present and goblet cells secrete sialomucins. Types II and III are characterized by the presence of columnar cells and goblet cells secreting sialomucins and/or sulfomucins; the columnar cells secrete sialomucins in type II and sulfomucins in type III. Cdx2 protein can not be detected in normal gastric mucosa and chronic superficial gastritis. The expression rates of Cdx2 were 87.1% in IM (101/116, Figure 1A-C), 50% in dysplasia tissues (36/72, Figure 1D-F) and 48.2% (41/85, Figure 1G-I) in gastric cancer, respectively. The positive rates of IM, dysplasia and GC were higher than that of normal mucosa ($P < 0.05$). The expression of Cdx2 in IM was much higher than that in dysplasia and carcinoma ($P < 0.05$). There was no significant difference between dysplasia and carcinoma ($P > 0.05$). The expression rates of Cdx2 were 90%, 85% and 75%, respectively in type I, II and III IM, but the difference was not statistically significant ($P > 0.05$). Cases of gastric epithelial dysplasia were graded as mild, moderate and severe dysplasia according to

Table 1 Expression of caudal-related homeobox transcription factor in gastric carcinoma and precancerous tissues

Type	Cases	Cdx2 positive cases	%	χ^2	P value
Different subtypes of intestinal metaplasia	116	101	87.1	33.826	0.000
IM (type I)	80	72	90	31.400	0.000
IM (type II)	20	17	85	7.426	0.003
IM (type III)	16	12	75	5.365	0.012
Dysplasia	72	36	50	0.004	0.873
Mild	39	17	43.5	0.083	0.700
Moderate	20	11	55	0.088	0.637
Severe	13	8	61.5	0.355	0.553
Gastric carcinoma	85	41	48.2		

Cdx2: Caudal-related homeobox transcription factor; IM: Intestinal metaplasia.

the previously established criteria that included the degree of architectural complexity and cytological atypia^[15]. The positive rates of Cdx2 were 43.5%, 55% and 61.5% in mild, moderate and severe dysplasia, showing an increasing trend. But there was no statistically significant correlation between Cdx2 expression and grade of dysplasia ($P > 0.05$, Table 1).

Correlation of Cdx2 expression with clinicopathological parameters in gastric cancer patients

The correlation of Cdx2 expression with clinicopathological parameters in gastric cancer patients is depicted in Table 2. Cdx2 expression was associated with direct Lauren classification, differentiation, lymph node metastasis and clinical stage. The positive rate of Cdx2 in intestinal gastric cancer (67.4%) was significantly higher than that in diffuse and mixed-type gastric cancer (25.7%, 42.9%, $P = 0.001$). The positive rate of Cdx2 in well and moderately differentiated adenocarcinoma (65.9%) was significantly higher than that in the poorly differentiated and mucinous adenocarcinoma (29.3%, $P = 0.001$). In addition, the positive rate of Cdx2 in the group without lymph node metastasis (63.9%) was significantly higher than that with lymph node metastasis (36.7%, $P = 0.017$). The positive rate of Cdx2 of pTNM stage III and IV (40.9%) was also reduced compared with that of pTNM stage I and II (73.7%, $P = 0.018$). Cdx2 expression was not associated with the remaining clinicopathological parameters evaluated, including depth of invasion, sex, and age of patients.

Prognostic implication of Cdx2 nuclear expression in GC

The association between the 5-year survival rate and the expression of Cdx2 was analyzed using the Kaplan Meier method. The results are shown in Figure 2. The patients with nuclear Cdx2 expression showed a significantly higher 5-year survival rate than patients without Cdx2 expression ($P = 0.038$). Based on the Cox regression analysis in the 85 patients, Cdx2 expression and lymph node metastasis seemed to be independent prognostic indicators ($P = 0.001$, $P = 0.019$, respectively, Table 3).

DISCUSSION

It was proposed by Correa^[16] that human gastric carcinogenesis is a multistep process that progresses from chronic gastritis, atrophy, IM, dysplasia and finally leads to gastric cancer. This model, although challenged by a few, is widely accepted, especially for the intestinal type of gastric cancer. IM is most frequently recognized as a pathological condition in the human stomach, where it often develops from progression of chronic gastritis, and has been extensively studied as a putative preneoplastic lesion of intestinal-type GC. Cdx2 was found to be intensively involved in intestinal metaplastic differentiation^[17]. During mouse small intestinal development, Cdx2 is expressed much earlier than Cdx1 in the hindgut^[18], and in human IM, expression of Cdx2 precedes that of Cdx1 during the progression of IM, implying that the expression of Cdx2 may trigger the initiation and devel-

opment of IM^[19,20]. Cdx2 may stimulate intestinal proliferation and differentiation by transcriptional activation of intestine-specific proteins (MUC2, sucrase-isomaltase, carbonic anhydrase I). Aberrant expression of Cdx2 is prominent in intestinal-type gastric adenocarcinoma and Cdx-2 may therefore play an important role in gastric carcinogenesis, especially in the intestinal type^[12]. In this study, we found that Cdx2 was not expressed in normal gastric mucosa and superficial gastritis, but was expressed in 87.1% of IM. The expression of Cdx2 was also higher in intestinal-type than in diffuse-type GC. Cdx2 has been shown to be a key molecule associated with IM and intestinal or differentiated type GC.

IM can be classified into different subtypes by several classification systems. The most widely accepted one is to classify IM into complete type and incomplete type, with the latter carrying a higher risk of gastric cancer. The complete type is characterized by the presence of absorptive cells, paneth cells and goblet cells secreting sialomucins, similar to the small intestinal phenotype. The incomplete type is characterized by the presence of columnar and goblet cells secreting sialomucins and/or sulphomucins, similar to the colonic phenotype. Using alcian-blue/periodic acid Schiff and high-iron diamine-alcian blue technique, Jass *et al*^[21] classified IM into three subtypes. Type I corresponded to the complete type, while type II and type III were classified as the incomplete type according to the mucins secreted by the columnar cells: sialomucins in type II and sulphomucins in type III. Several studies claimed that only type III IM is associated with an increased risk of gastric cancer, but other reports cast doubt on it. In this study, staining of both immunohistochemistry and AB/HID was applied to detect the Cdx2 protein level and subtypes of IM at the same time. The expression rates of Cdx2 were 90%, 85% and 75% respectively in type I, II and III IM. There was no difference of Cdx2 expression among type I, II and III IM. But Liu *et al*^[22] demonstrated that the expression of Cdx2 was significantly decreased in incomplete IM compared with complete IM. This may be explained by the different antibodies and different staining protocols.

So far, there have been a few reports about Cdx2 expression in gastric epithelial dysplasia. Similar to Woodland's finding^[23], we found no relationship between the grade of gastric epithelial dysplasia and Cdx2 expression. But Kim *et al*^[24] demonstrated a positive correlation between Cdx2 expression and the increasing grade of dysplasia.

Our data showed that Cdx2 expression was decreased in gastric cancers, when compared with IM and dysplasia. This collective experience may suggest a potential tumor suppressor role for Cdx2, in view of its sequential decrease in expression along with the stepwise gastric carcinogenesis (IM, epithelial dysplasia and gastric cancer). This opinion is shared by Liu *et al*^[22] and Xin *et al*^[25], who showed that Cdx2 expression is progressively decreased in gastric IM, dysplasia, and cancer. In our study, Cdx2-positive expressing tumors had tendencies towards less invasiveness and fewer lymph node metastases. The Cdx2-

positive patients were found to have a better outcome than Cdx2-negative patients. Multivariate analysis revealed that Cdx2 represents an independent prognostic indicator. The consequences are consistent with the studies by Seno *et al.*^[12] and Mizoshita *et al.*^[13]. We can speculate that, while ectopically expressed in gastric cancers, the Cdx2 gene may play a tumor suppressor role in slowing down cancer progression in the stomach, similar to what happens in the colon. Previous studies suggest that Cdx2 is a tumor-suppressor gene with regard to colorectal carcinogenesis. Several reports^[26,27] have revealed that Cdx2 could promote differentiation, inhibit proliferation, and increase sensitivity to apoptosis of intestinal epithelial cells, and colon cancer derived cells. Moreover, Cdx2 was documented to up-regulate transcription of p21/WAF1/CIP1^[28,29] and PTEN^[30], which plays a critical role in differentiation and tumor suppression, and promotes intestinal differentiation as a cyclin-dependent kinase inhibitor, leading to cell-cycle arrest. The role of Cdx2 in gastric cancer still remains unclear and Cdx2 may have different roles depending on cancer type.

In conclusion, our findings indicated that Cdx2 is a special and sensitive marker for IM. We revealed that Cdx2 might be closely related to the intestinal-type GC and implicate better biological behavior and outcome. Cdx2 might be useful in predicting the prognosis of GC. Further studies are necessary to confirm our findings.

COMMENTS

Background

Intestinal metaplasia (IM) of the stomach is a preneoplastic lesion that confers an increased risk for the development of gastric carcinoma (GC), which remains the second leading cause of cancer death worldwide. Caudal-related homeobox transcription factor (Cdx2) is an intestinal transcription factor responsible for regulating the proliferation and differentiation of intestinal epithelial cells. The role of Cdx-2 in GCs is not clearly understood.

Research frontiers

Human Cdx2 is known as a caudal-related homeodomain transcription factor that is expressed in the intestinal epithelium and is important in differentiation and maintenance of the intestinal epithelial cells. Although Cdx2 expression is restricted to the intestinal epithelium under normal conditions, an ectopic expression has been reported in the gastric mucosa, both in intestine-like metaplasia and in a subset of GCs. Although expression of Cdx2 has been detected in some GCs, few studies reported the relationship between Cdx2 expression and prognosis of GC.

Innovations and breakthroughs

This paper evaluated the immunohistochemical expression of the intestine-specific transcription factor Cdx2 in a large number of GC cases, compared with that in gastric IM, gastric dysplasia, superficial gastritis and normal gastric mucosa. The Cdx2-expressing cells in IM were more prevalent than in dysplasia and carcinoma. In GC, expression of Cdx2 was significantly higher in intestinal-type carcinoma than in diffuse and mixed-type carcinoma. Cdx2 might be closely related to IM and the intestinal-type GC and implicate better biological behavior and outcome. Cdx2 might be useful in predicting the prognosis for GC.

Applications

Cdx2 expression in GC may serve as a useful marker for diagnosis, to judge the degree of malignancy and to predict the prognosis of the patients.

Terminology

The Cdx2, located on chromosome 13 in humans and chromosome 5 in mice, is a member of the ParaHox cluster. Cdx2 is from a class of genes encoding transcription factors that constitute mammalian homologues of the Drosophila

gene Caudal. Caudal homologues have been identified in a number of organisms including humans and mice and play essential roles in intestinal development and maintenance of the epithelia. In mice and humans, there are 3 caudal homologues: Cdx1, Cdx2 and Cdx4, of which only Cdx2 plays a role in development of the gastrointestinal tract.

Peer review

This is an interesting, well written paper evaluating the immunohistochemical expression of the intestine-specific transcription factor Cdx2 in a large number of GC cases, compared with that in gastric IM, gastric dysplasia, superficial gastritis and normal gastric mucosa. It is the first study indicating a prognostic role of Cdx2 expression in GC.

Abstract

AIM: To investigate the frequency and clinical significance of the myeloid-derived suppressor cells (MDSC) in human colorectal carcinoma (CRC).

METHODS: Samples of peripheral blood and tumor tissue from 49 CRC patients were analyzed. Mononuclear cells were isolated by Ficoll-Hypaque density gradient centrifugation and were subjected to a flow cytometry-based immunophenotypic analysis.

RESULTS: A considerable increase in the percentage of CD33⁺HLA-DR⁺ MDSCs was observed in the peripheral blood (1.89% ± 0.75%) and tumor tissues (2.99% ± 1.29%) of CRC patients as compared with that in the

peripheral blood of healthy controls (0.54% ± 0.35%). This expanded CD33⁺HLA-DR⁺ subset exhibited immature myeloid cell markers, but not lineage markers, and showed up-regulation of CD18/CD11b expression as compared with the MDSCs from healthy donors. Further studies showed that the MDSC proportion in CRC peripheral blood was correlated with nodal metastasis ($P = 0.023$), whereas that in tumor tissues was correlated with nodal/distant metastasis ($P = 0.016/P = 0.047$) and tumor stage ($P = 0.028$), suggesting the involvement of MDSCs in CRC tumor development.

CONCLUSION: Characterization of MDSCs in CRC suggests the clinical significance of circulating and tumor-infiltrating MDSCs and may provide new insights into the CRC immunotherapy targeting MDSCs.

INTRODUCTION

Immune escape is not merely a passive process of immune evasion, but is rather an active one in which tumor cells, stroma cells, and immune cells present within the tumor microenvironment actively suppress the antitumor immune response. Thus, although host immune surveil-

lance may prevent tumor outgrowth during the earliest stages of tumor development, locally invasive or metastatic tumors must evade host immunity^[1]. In the tumor microenvironment, the “mission” of immune cells is to execute an antitumor function, but some of these cells are converted to act as confederates of the tumor. The inability of immune cells to mount an effective antitumor response, even following vaccination, is an immunological hallmark of cancer and represents a critical problem for the development of effective immunotherapeutic strategies. Myeloid-derived cells and lymphocytes subsets, such as regulatory T cells (Tregs), collaborate with their malignant counterparts to suppress host immunity^[2,3].

Myeloid-derived suppressor cells (MDSCs) are a large group of myeloid cells comprising immature macrophages, granulocytes, and dendritic cells (DCs) as well as myeloid cells at earlier stages of differentiation^[4-6]. In mice, MDSCs express the myeloid lineage differentiation antigens Gr-1 and CD11b, and undergo dramatic expansion during tumor development. In mouse models, MDSCs are found in tumors and lymph nodes^[2,4,5], and the proportion of MDSCs has been shown to exceed 20% in the spleen. There are some controversies about the phenotype of MDSCs in humans, but these cells are now generally defined as CD11b- and CD33-positive, but lacking mature myeloid and lymphoid cell markers and the major histocompatibility complex (MHC) class II molecule, HLA-DR^[7-9]. In the appropriate cytokine environment, MDSCs can differentiate into mature myeloid cells, but this differentiation is blocked in the presence of tumor-cell-conditioned medium or in tumor-bearing hosts, indicating that MDSC expansion can be induced in a tumor microenvironment. Recent studies have shown that MDSCs inhibit the proliferation and activation of T cells, and suppress maturation of DCs, which together contribute to the negative regulation of the immune responses and promote immune escape of tumors and pathogens^[10,11]. *In vivo* depletion of MDSCs has been shown to improve T cell-mediated immune responses and suppress tumor growth in murine models^[12]. Therefore, depletion of MDSCs in tumor-bearing hosts has been proposed as a new approach for cancer immunotherapy. Colorectal carcinoma (CRC) ranks as the third most common cancer and the fourth leading cause of cancer-related deaths worldwide^[13]. In China, the incidence of CRC is increasing due to changes in diets and lifestyle^[14]. Numerous pathological factors and transformation of multiple genes are involved in tumor genesis and progression. It has been demonstrated that an immune-escape microenvironment shaped by chronic inflammation or autoimmune diseases is clearly associated with increased risk of CRC^[15]. A variety of therapeutic strategies, including conventional surgery, chemotherapy, radiotherapy and immunotherapy, alone or in combination, are currently available for the treatment of CRC patients. However, these therapies lead to different outcomes due to the different physical situation of each patient, which also construct the different tumor microenvironment through immune suppression^[16-18].

Therefore, it is critical that clinicians perform further analyses of immune-suppression status and establish individualized therapeutic strategies for CRC patients. Several studies have described the presence of abnormalities in the immune system of patients with CRC, including defective function of natural killer cells, DCs and Tregs^[19-21], but little is known about MDSCs in CRC.

In the present study, we investigated the frequency and characterized the phenotype of MDSCs in CRC patients and evaluated the clinical significance of MDSCs in CRC clinical status and outcome. The results might suggest a new strategy for efficient, individualized treatment of CRC.

MATERIALS AND METHODS

Patients

Peripheral blood and tumor tissue samples were collected from 49 CRC patients who underwent surgery in the Third People's Hospital of Wuxi, China from January 2010 to January 2011 after the approval by the Ethics Committee of the hospital. All patients were diagnosed with CRC for the first time, and had not been previously treated. Forty age-matched healthy donors were used as controls. Clinical parameters were acquired from the medical records of patients with the permission of the hospital.

Cell isolation from fresh tumor tissues and peripheral blood

Fresh tumor specimens were gently minced over a wire mesh screen to obtain a cell suspension. The cell suspension was layered over Ficoll-Hypaque (Amersham Biosciences, Sweden) and centrifuged at $500 \times g$ for 25 min. After density gradient centrifugation, mononuclear cells were collected and washed with RPMI 1640 media (Gibco, United States) containing 5% fetal bovine serum (FBS; Hyclone, United States) and 1% penicillin/streptomycin (Sigma-Aldrich, United States). Peripheral blood mononuclear cells (PBMCs) were also isolated by Ficoll-Hypaque density gradient centrifugation. PBMCs were collected, washed, and analyzed immediately. Viable cell counts were obtained using trypan blue dye.

Immunophenotypic analysis

Antibodies against the following proteins, purchased from BD Pharmingen or eBioscience, were used for flow cytometry: CD33, HLA-DR, CD3, CD14, CD19, CD56, CD11b, CD18, and CD1a. PBMCs (1×10^5) were suspended in phosphate-buffered saline (PBS) and incubated with antibodies for 30 min at 4 °C, and then washed twice with cold PBS. Fluorochrome-conjugated antibodies were used as isotype controls. Nonspecific staining was prevented by blocking Fc receptors. A Beckman Coulter flow cytometer equipped with Expo 32 software was used to analyze the stained cells. For MDSC marker analysis, the gate was set on the CD33⁺HLA-DR⁻ cell subset.

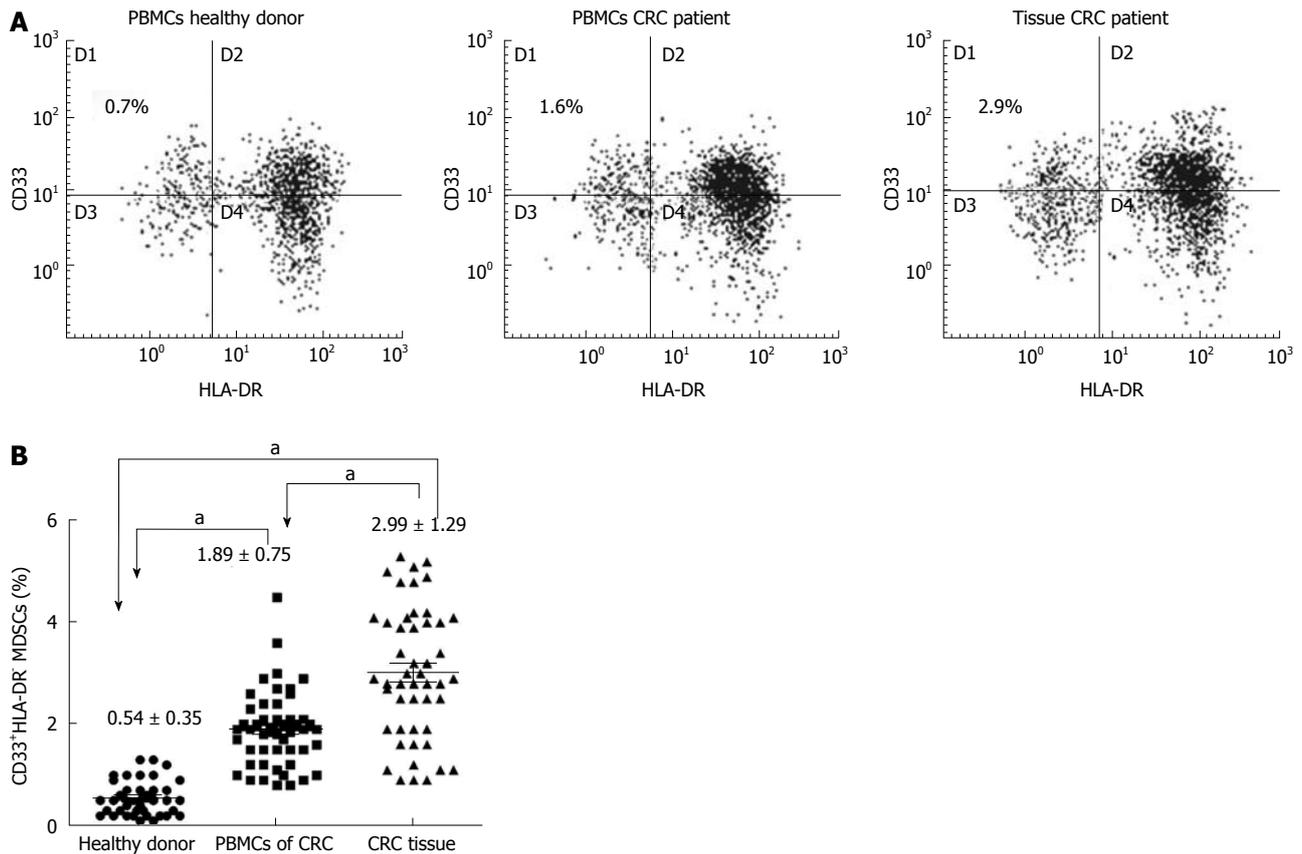

Figure 1 Circulating and tumor-infiltrating CD33⁺HLA-DR⁻ myeloid-derived suppressor cells in colorectal carcinoma patients. A: CD33⁺HLA-DR⁻ myeloid-derived suppressor cells (MDSCs) were present in the peripheral blood of colorectal carcinoma (CRC) patients and healthy donors, as well as in CRC tumor tissues; B: The percentage of CD33⁺HLA-DR⁻ MDSCs was significantly increased in the blood and tumor tissues of CRC patients ($^*P < 0.05$). PBMCs: Peripheral blood mononuclear cells.

Statistical analysis

Statistical analyses were performed using GraphPad Prism 5.0 software (GraphPad Software, United States). Paired or unpaired Student's *t* tests, Wilcoxon signed-rank tests, and Pearson χ^2 tests were used as appropriate. *P* value < 0.05 was considered statistically significant.

RESULTS

Increased frequency of myeloid-derived suppressor cells in colorectal carcinoma patients

The percentage of MDSCs was analyzed in 49 CRC patients and 40 healthy donors. Circulating and tumor-infiltrating MDSCs were defined as the CD33⁺HLA-DR⁻ double-staining cell subset (Figure 1A). As shown in Figure 1B, MDSCs were present in the peripheral blood of both healthy donors and CRC patients, but the percentages were increased in CRC patients ($1.89\% \pm 0.75\%$) as compared with healthy donors ($0.54\% \pm 0.35\%$, $P < 0.05$). Infiltrating MDSCs were also found in CRC tumor tissues, and the percentage of MDSCs among tumor-infiltrating mononuclear cells ($2.99\% \pm 1.29\%$) was remarkably elevated as compared with that among PBMCs of both healthy donors and CRC patients ($P < 0.05$).

Phenotypic analysis of CD33⁺HLA-DR⁻ MDSC subset

We analyzed the cell surface markers of the CD33⁺HLA-DR⁻ MDSC subset in each CRC patient by immunostaining and flow cytometry. Cells were gated on CD33⁺HLA-DR⁻, and cell surface expression of CD3, CD14, CD19, CD56, CD11b, CD18, and CD1a was analyzed. As shown in Figure 2A, CD33⁺HLA-DR⁻ cells exhibited high expression of CD11b, CD18 and CD1a, but low expression of CD3, CD14, CD19 and CD56. An analysis of phenotypic differences in peripheral blood MDSCs between CRC patients and healthy donors showed that CD11b and CD18 expressions were increased on MDSCs in CRC patients (Figure 2B).

Relationship between percentage of MDSCs in CRC and clinical parameters

As shown in Table 1, patients were divided into high and low MDSC groups according to the median MDSC percentages in peripheral blood and tumor tissues. A statistical analysis showed that the proportion of MDSCs in CRC patient peripheral blood was correlated with distant metastasis ($P = 0.023$): CRC patients with distant metastases showed a higher level of circulating MDSCs than CRC patients without distant metastases. The pro-

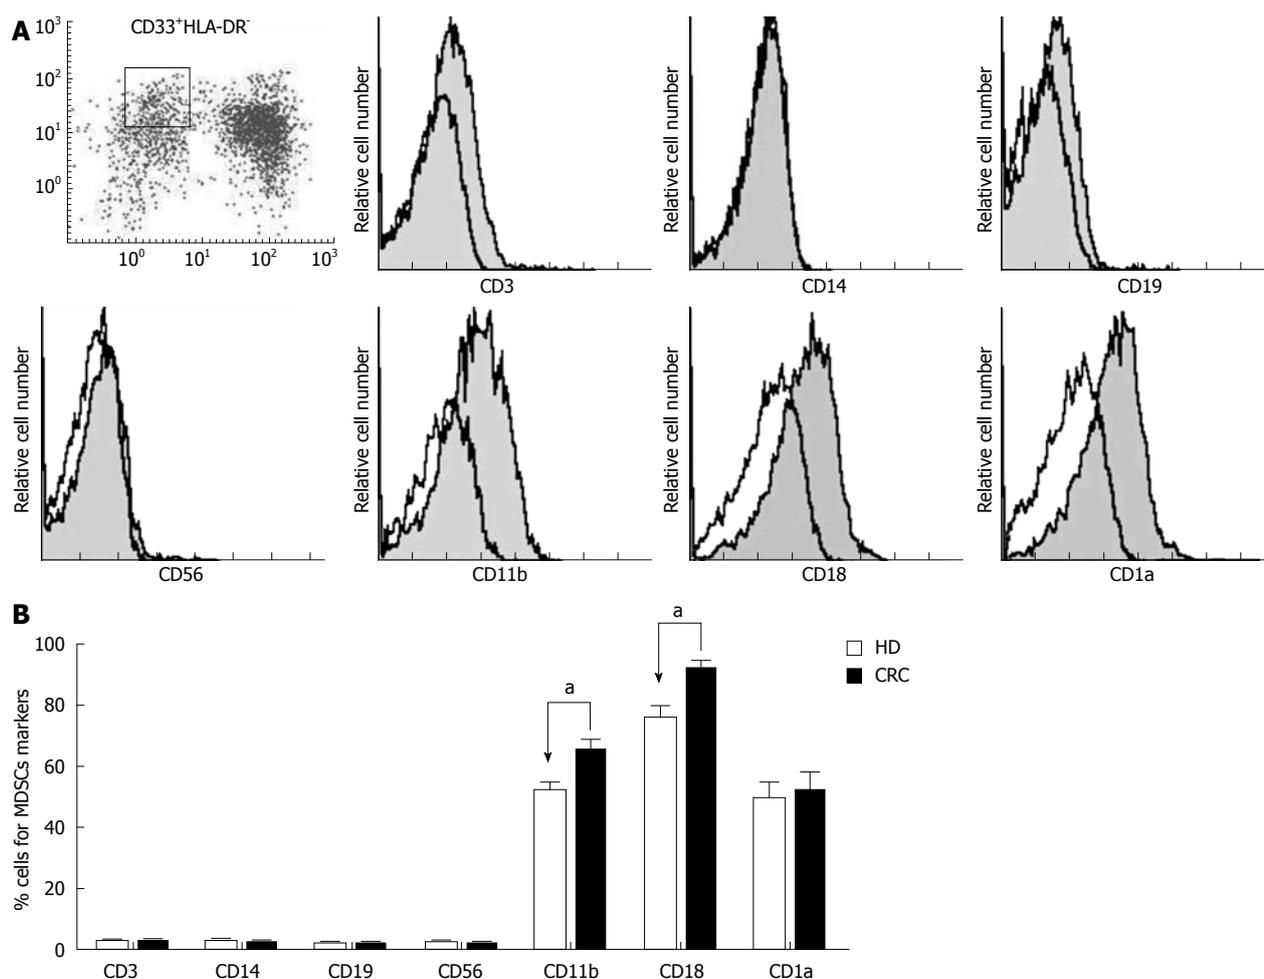

Figure 2 Phenotypic analyses of CD33⁺HLA-DR⁻ myeloid-derived suppressor cells in colorectal carcinoma patients and healthy donors. A: Cell surface markers of peripheral blood myeloid-derived suppressor cells (MDSCs), obtained by gating on the CD33⁺HLA-DR⁻ subset, were detected in colorectal carcinoma (CRC) patients; B: Percentages of cells positive for various markers on the CD33⁺HLA-DR⁻ subset in healthy donors (HD) and CRC patients (^a*P* < 0.05).

portion of MDSCs in tumor tissues was correlated with nodal metastasis, distant metastasis and tumor stages. CRC patients with metastases (nodal/distant) exhibited a higher degree of MDSC infiltration than those without metastases (*P* = 0.016/*P* = 0.047). Among stage IV CRC patients, 60% had a high-level infiltration of MDSCs in tumor tissues (*P* = 0.028), suggesting the involvement of MDSCs in tumor development.

DISCUSSION

Many studies have highlighted the role of MDSCs in cancer immune suppression^[3,4]. Infiltration of these cells in the tumor host is promoted by the tumor microenvironment, and tumor-associated expansion of MDSCs contributes to tumor escape from the immune system. The decline of immune function in the tumor leads to ineffective tumor treatment outcomes, due to the insufficient activity of antigen-specific antitumor responses and the possible extension of immune tolerance in the tumor host. Many studies have addressed MDSCs in solid tumors, but little is known about MDSCs in CRC. In this

study, we investigated circulating and tumor-infiltrating MDSCs in CRC patients, characterizing surface marker expression on MDSCs and demonstrating the clinical significance of MDSCs in CRC.

MDSCs represent 20%-30% of normal bone marrow cells and 1%-4% of all nucleated cells in the spleen^[22,23]. Our study showed that the CD33⁺HLA-DR⁻ subset was present at a very low proportion in the peripheral blood of healthy donors. CD33⁺HLA-DR⁻ MDSCs represent a homogeneous cell population that is significantly elevated in the peripheral blood of CRC patients. Furthermore, CD33⁺HLA-DR⁻ MDSCs were found at a relative high density in CRC tumor tissues compared with peripheral proportions in healthy donors or CRC patients. These data show that MDSCs expansion could be involved in CRC development, and suggest that the tumor tissue microenvironment might serve to promote MDSC expansion. Our data confirm previous studies demonstrating a dramatic expansion of MDSCs during tumor progression, infection, and even following immunization.

MDSCs are identified as a population of myeloid cells at earlier stages of differentiation^[4-6]. In CRC, these

¹Tumor status is classified as: pT₁, invasion of lamina propria or submucosa; pT₂, invasion of muscularis propria; pT₃, invasion of adventitia; pT₄, invasion of adjacent structures; ²Nodal status is classified as: N₀, no regional lymph-node metastasis; N₁, regional lymph-node metastasis; ³Distant metastasis is classified as follows: M₀, no distant metastasis; M₁, metastasis to cervical nodes, celiac nodes, and other distant metastases. ^aP < 0.05 was considered statistically significant. MDSC: Myeloid-derived suppressor cells; CRC: Colorectal carcinoma; TNM: Tumor, nodes, metastasis.

CD33⁺HLA-DR⁻ MDSCs displayed characteristics of immature myeloid cells, expressing high levels of CD33, CD11b, CD18 and CD1a, but a very low level of HLA-DR. Notably, the lineage markers CD3, CD14, CD19, and CD56 were not expressed in this subset. Thus, the phenotype of MDSCs in CRC is consistent with previous descriptions. Interestingly, however, we found that CD18/CD11b expression was considerably increased in MDSCs from CRC patients compared with those from healthy donors, indicating that the MDSCs in tumors might alter their expression of functional molecules according to the tumor microenvironment. Because CD18/CD11b (also known as Mac-1, CR-3) is critical for cell adhesion and migration^[24,25], MDSCs in CRC might contribute to invasion and metastasis.

We further explored the clinical significance of circulating and tumor-infiltrating MDSCs in CRC. We found that the percentage of MDSCs in the peripheral blood of CRC patients was correlated with distant metastasis, whereas the percentage of MDSCs in tumor tissue was correlated with nodal metastasis, distant metastasis, and tumor stage. These data revealed the clinical significance of MDSCs in CRC. Previous studies have indicated that the main action of MDSCs in tumors is suppression of antigen-specific immune responses. Our demonstration that CD18/CD11b is up-regulated on tumor-associated MDSCs is consistent

with the correlation between MDSC expansion and metastasis, indicating that MDSCs may play an important role in tumor invasion and metastasis. MDSC infiltration was also found to correlate with CRC tumor stage. Taken together, these observations suggest that MDSCs in CRC may substantially contribute to immune invasion, thereby promoting the tumor development.

In summary, we evaluated the frequency, phenotype and clinical significance of MDSCs in CRC. The increased frequency of MDSCs in CRC likely plays an important role in tumor metastasis and progression. Our study is of considerable significance for developing immunotherapeutic strategies *via* targeting and eliminating MDSCs in CRC.

ACKNOWLEDGEMENTS

We thank Professor Jian-Zhong Zhu for his advice and technical support. We especially thank Dr. Jing Sun for his valuable suggestions and critical review of the manuscript.

COMMENTS

Background

In the tumor microenvironment, the principal "mission" of immune cells is to execute an antitumor program, but a portion of such cells become confederates

of the tumor. Myeloid-derived suppressor cells (MDSCs) are a large group of myeloid cells comprising immature macrophages, granulocytes, and dendritic cells (DCs), as well as myeloid cells at earlier stages of differentiation. Recent studies have shown that MDSCs can inhibit proliferation and activation of T-cell and suppress maturation of DCs, which together contribute to the negative regulation of immune responses and the promotion of immune escape of tumors and pathogens. MDSCs have been extensively studied in solid tumors, but little is known about MDSCs in colorectal carcinoma (CRC).

Research frontiers

In humans, the phenotype of MDSCs has been a matter of some controversy, but it is now generally agreed that MDSCs are defined as CD11b- and CD33-positive cells that lack mature myeloid and lymphoid cell markers and do not express the MHC class II molecule, HLA-DR. *In vivo* depletion of MDSCs has been shown to improve T cell-mediated immune responses and suppress tumor growth in murine models. Therefore, depletion of MDSCs in tumor-bearing hosts has been proposed as a new approach for cancer immunotherapy. Several studies have described the presence of abnormalities in the immune system of patients with CRC, including defective function of natural killer cells, DCs, and Tregs, but little is known about MDSCs in CRC patients.

Innovations and breakthroughs

In this study, the authors investigated the circulating and tumor-infiltrating MDSCs in CRC patients and examined the expression of molecules characteristic of MDSCs. A considerable increase was found in the percentage of CD33⁺HLA-DR⁺ MDSCs in the peripheral blood and tumor tissues of CRC patients. The expanded CD33⁺HLA-DR⁺ subset exhibited immature myeloid cell markers, but not lineage markers, and showed up-regulation of CD18/CD11b expression as compared with MDSCs from healthy donors. These data demonstrated the existence of an MDSC population in CRC patients; further studies showed that the proportion of MDSCs in the peripheral blood and tumor tissues of CRC patients was correlated with nodal/distant metastases and tumor stage, strongly suggesting the involvement of MDSCs in CRC tumor development.

Applications

The characterization of the frequency and phenotype of MDSCs in CRC presented in this article suggests the clinical significance of circulating and tumor-infiltrating MDSCs, and it may provide new insights into the CRC immunotherapy targeting MDSCs.

Peer review

In the present paper, the authors evaluated the frequency and clinical significance of MDSCs in human CRC and they found that this population of cells was considerably increased in CRC as compared with the healthy donors. Moreover, they showed that in CRC peripheral blood, the MDSCs frequency was correlated to distant metastasis whereas, in tumor tissues the percentage was correlated to nodal and distant metastasis and tumor stages. Finally, the authors speculate that their study could have clinical implication contributing to the identification of new target for CRC immunotherapy. A major concern is related to the definition of the MDSC population. The authors have defined MDSCs as a large group of myeloid cells consisting of immature macrophages, granulocytes and dendritic cells as well as myeloid cells at earlier stages of differentiation. The description itself is not a definition but a "Pandora box". Each cell type has its own identity and specificity. Two or more cell types interact in unpredictable ways, and in the absence of a clear definition, each observation has little value. Given these premises, the attempt to clarify the confused MDSC issue by the authors is respectable, and their results, albeit flexible, are worth publication.

Abstract

AIM: To evaluate immunological protection of nitric oxide (NO) in hepatopulmonary syndrome and probable mechanisms of ischemia-reperfusion (IR) injury in rat liver transplantation.

METHODS: Sixty-six healthy male Wistar rats were randomly divided into three groups (11 donor/recipi-

ent pairs). In group II, organ preservation solution was lactated Ringer's solution with heparin 10 000/ μ L at 4 °C. In groups I and III, the preservation solution added, respectively, L-arginine or N^G-L-arginine methyl ester (L-NAME) (1 mmol/L) based on group II, and recipients were injected with L-arginine or L-NAME (50 mg/kg) in the anhepatic phase. Grafted livers in each group were stored for 6 h and implanted into recipients. Five rats were used for observation of postoperative survival in each group. The other six rats in each group were used to obtain tissue samples, and executed at 3 h and 24 h after transplantation. The levels of alanine aminotransferase (ALT), tumor necrosis factor (TNF)- α and NO metabolites (NOx) were detected, and expression of NO synthase, TNF- α and intercellular adhesion molecule 1 (ICAM-1) was examined by triphosphopyridine nucleotide diaphorase histochemical and immunohistochemical staining.

RESULTS: By supplementing L-arginine to strengthen the NO pathway, a high survival rate was achieved and hepatic function was improved. One-week survival rate of grafted liver recipients in group I was significantly increased (28.8 ± 36.6 d vs 4 ± 1.7 d, $P < 0.01$) as compared with groups II and III. Serum levels of ALT in group I were 2-7 times less than those in groups II and III ($P < 0.01$). The cyclic guanosine monophosphate (cGMP) levels in liver tissue and NOx in group I were 3-4 times higher than those of group II after 3 h and 24 h reperfusion, while in group III, they were significantly reduced as compared with those in group II ($P < 0.01$). The levels of TNF- α in group I were significantly lower than in group II after 3 h and 24 h reperfusion ($P < 0.01$), while being significantly higher in group III than group II ($P < 0.01$). Histopathology revealed more severe tissue damage in graft liver and lung tissues, and a more severe inflammatory response of the recipient after using NO synthase inhibitor, while the pathological damage to grafted liver and the recipient's lung tissues was signifi-

cantly reduced in group I after 3 h and 24 h reperfusion. A small amount of constitutive NO synthase (cNOS) was expressed in liver endothelial cells after 6 h cold storage, but there was no expression of inducible NO synthase (iNOS). Expression of cNOS was particularly significant in vascular endothelial cells and liver cells at 3 h and 24 h after reperfusion in group II, but expression of iNOS and ICAM-1 was low in group I. There was diffuse strong expression of ICAM-1 and TNF- α in group III at 3 h after reperfusion.

CONCLUSION: The NO/cGMP pathway may be critical in successful organ transplantation, especially in treating hepatopulmonary syndrome during cold IR injury in rat orthotopic liver transplantation.

INTRODUCTION

Recent research has shown that nitric oxide (NO) plays an important physiological role as a messenger in an autocrine or paracrine form. NO can influence vascular permeability, regulate vascular tone, inhibit adhesion and aggregation of leukocytes and endothelial cells, regulate platelet function, and improve graft microcirculation, thus easing vasospasm to reduce the incidence of vascular crisis^[1-5]. Therefore, in this study, we established animal models of cold ischemia-reperfusion (IR) injury in rat orthotopic liver transplantation. We were able to investigate the effect of NO on hepatopulmonary syndrome and its possible immunomodulatory mechanisms during IR injury in rat orthotopic liver transplantation by enhancing or inhibiting the NO/Cyclic guanosine monophosphate (cGMP) pathway.

MATERIALS AND METHODS

Materials

Male Wistar rats weighing 180-260 g were purchased from Shanghai Experimental Animal Centre (Chinese Academy of Sciences). L-arginine and N^G-L-arginine methyl ester (L-NAME) were from Sigma, and intercellular

adhesion molecule 1 (ICAM-1) (AT-29), mouse anti-rat single cloned antibody, tumor necrosis factor (TNF)- α , polyclonal rabbit anti-rat antibody, and the avidin-biotin complex (ABC) immune staining kit were purchased from Beijing Zhongshan Biotechnology Company.

Experimental methods

Experimental design: The 66 healthy male Wistar rats were randomly divided into three groups (11 donor/recipient pairs). Liver grafts were placed in different organ preservation solutions at 4 °C and stored for 6 h, and then implanted into recipients. In group II, organ preservation solution was lactated Ringer's solution with heparin 10 000/ μ L at 4 °C. In groups I and III, the organ preservation solution added, respectively, L-arginine or L-NAME (1 mmol/L) based on group II, and recipients were injected with L-arginine or L-NAME (50 mg/kg) through the penis dorsal vein in the anhepatic phase. The levels of alanine aminotransferase (ALT), TNF- α , and NO metabolites (NO_x) in the serum of recipients were detected, and expression of NO synthase was examined. The expression of TNF- α and ICAM-1 was observed by triphosphopyridine nucleotide (NADPH) diaphorase histochemical and immunohistochemical staining.

Orthotopic liver transplantation: All rats were anesthetized with methoxyflurane gas. All procedures described below were approved by the Committee for Animal Care and Usage for Research. Orthotopic liver transplantation was performed according to Harihara's three-cuff technique with minor modifications, as previously reported^[6-11], in which the suprahepatic vena cava was reconstructed by the Cuff method, along with the infrahepatic vena cava (IVC) and the portal vein (PV). The bile ducts were internally stented with a polyethylene stent.

Specimen measurement: The blood samples were obtained postoperatively via the tail vein at 3 h and 24 h after perfusion, or via the PV or IVC in the recipients being killed or those undergoing liver biopsy, and then centrifuged at 3000 r/min at 4 °C for 10 min. The supernatant was rapidly frozen and immediately stored at -80 °C. NO_x were determined by the improved Griess method, and TNF- α was examined according to the MTT assay. Tissue levels of cGMP were detected by radioimmunoassay, protein concentration test with application of trichloroacetic acid solution and 200 g/L SDS protein precipitation method. Samples of liver and lung tissues from rats being killed or biopsied were immediately stored in liquid nitrogen, and kept frozen at -80 °C. Histopathological sections of the grafted liver were fixed in 100 mL/L formalin and prepared with hematoxylin and eosin staining for routine light microscopy.

Triphosphopyridine nucleotide diaphorase staining: The grafted liver or lung specimens were fixed in 40 g/L paraformaldehyde, 4 g/L picric and 0.1 mol/L sodium phosphate buffer (PBS), pH 7.4, for 4 h at 4 °C. Subse-

¹During cold ischemia-reperfusion injury in the rat orthotopic liver transplantation. ^a $P < 0.05$, ^b $P < 0.01$ vs group II; ^d $P < 0.01$ vs 3 h; ^f $P < 0.01$ vs group III. cGMP: Cyclic guanosine monophosphate; ALT: Alanine aminotransferase; TNF- α : Tumor necrosis factor- α ; NOx: Nitric oxide metabolites.

quently, specimens were frozen at -80°C until section cutting. Cryostat sections were immersed for 10 min in 0.1 mol/L PBS, pH 8.0, and were incubated for 40 min at 37°C in prewarmed solution of 0.1 mol/L PBS, pH 8.0, 3 g/L Triton X-100, 0.5 mmol/L nitroblue tetrazolium, and 1.0 mol/L NADPH. After being washed in 0.1 mol/L PBS, pH 7.4, sections were dehydrated with graded alcohol. Slides were rinsed in PBS and counter stained with fast red for 2 min, and coverslips were mounted on microscopic glass slides. Areas with a positive reaction for NADPH diaphorase were stained dark blue in the cytoplasm and red in the nucleus.

Immunohistochemistry: Immunohistochemical methods were used to examine the expressions of ICAM-1 (AT-29) with mouse anti-rat single cloned antibody, and TNF- α with polyclonal rabbit anti-rat antibody by the Avidin-Biotin complex method using an ABC immunostaining kit^[12]. Areas with a positive reaction were stained pale brown.

Statistical analysis

Data are presented as mean \pm standard error (SE). Comparisons among different groups of samples were made by two-tailed χ^2 test and F test. A value of $P < 0.05$ was considered to be statistically significant.

RESULTS

Survival

One-week survival rate of grafted liver recipients in group I was significantly increased (group I vs group II, 28.8 ± 36.6 d vs 4 ± 1.7 d, 80% vs 20%, $P < 0.01$), while the survival rate in group III recipients was significantly lower, compared with that of group II (group II vs group III, 0% vs 20%, $P < 0.05$).

Biochemical parameters

Following orthotopic liver transplantation, serum and tissue samples were assayed for ALT, NOx, TNF- α and cGMP at 3 h and 24 h after reperfusion (Table 1). The serum levels of ALT in group I were 2-7 times

less than in groups II and III ($P < 0.01$). The levels of cGMP and NOx in liver tissue in group I were 3-4 times higher than in group II at 3 h and 24 h after reperfusion, while in group III, they were significantly reduced compared with group II ($P < 0.01$). The levels of TNF- α in group I were significantly lower than those in group II at 3 h and 24 h after reperfusion ($P < 0.01$), while there were significantly higher in group III than group II ($P < 0.01$, Table 1).

Histopathology

The pathological damage in grafted liver and recipient lung tissues was significantly reduced in group I, which revealed almost normal liver sinusoidal lobular architecture, and mild degeneration of grafted liver cells at 3 h and 24 h after reperfusion (Figure 1A and C). In group III, which received NOS inhibitor, there was extensive cloudy swelling of hepatocytes, vacuolar degeneration, nuclear shrinkage, chromatin concentration, and marginalized or fragmented apoptotic bodies. We sometimes saw coagulation necrosis at the center of the central vein, small areas of spotty distribution, periportal inflammatory cell infiltration, and intrahepatic vascular thrombosis (Figure 1B). Severe structural damage to the recipient's lung tissues, a large amount of inflammatory cell infiltration, and intravascular thrombosis were seen at the same time (Figure 1D).

Triphosphopyridine nucleotide diaphorase histochemistry

Cells that were positive for NOS were mainly expressed in the liver and endothelial cells, and were stained dark blue in the arteries, veins and capillaries (Figure 1E).

Immunohistochemistry

A small amount of cNOS was expressed in endothelial cells in normal liver tissue after 6 h cold storage, but there was no expression of inducible NO synthase (iNOS). Expression of cNOS was particularly significant in vascular endothelial cells and hepatocytes at 3 h and 24 h after reperfusion in group II (Figure 1F), but expression of iNOS and ICAM-1 was low in group I (Table 2, Figure 1G and H). There was diffuse strong expression of

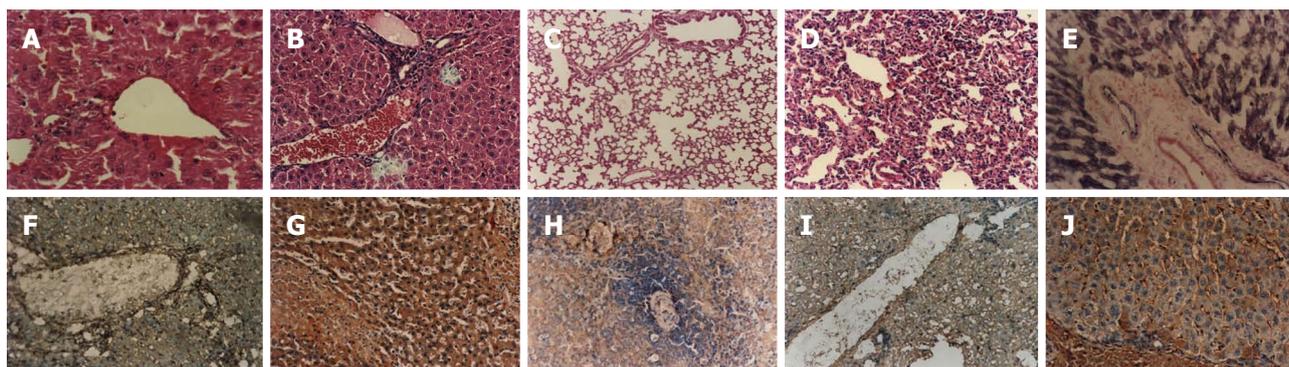

Figure 1 Hematoxylin and eosin staining and triphosphopyridine nucleotide-d staining and immunohistochemical staining for grafted liver and recipient's lung tissues. A, C: Grafted liver tissues and the recipient's lung tissues from group I of L-arginine revealed that the pathological damages of grafted liver and lung tissues significantly reduced after reperfusion 3 h (HE \times 132, \times 66); B, D: Grafted liver tissues and the recipient's lung tissues from group III of the NOS inhibitor after reperfusion 3 h showed extensive cloudy swelling of hepatocytes, vacuolar degeneration, nuclear shrinkage, chromatin concentration, and marginalized or fragmented apoptotic body and severe structural damage to the recipient's lung tissues, a large number of inflammatory cell infiltration, and intravascular thrombosis (HE \times 33, \times 66); E: NADPH diaphorase histochemistry staining of NO synthase and immunohistochemistry staining of cNOS for grafted liver tissues from group I after reperfusion 24 h (NADPH-d, \times 66); F: Expressions of cNOS in grafted liver tissues were particularly significant in vascular endothelial cells and hepatocytes after 24 h in group II [immunohistochemical staining (IH), \times 66]; G, H: Expressions of iNOS and ICAM-1 in grafted liver tissues were little in group I of L-arginine after reperfusion 24 h (IH \times 66, \times 66); I, J: Expression of ICAM-1 and TNF- α in grafted liver tissues were diffuse strong in group III of the NOS inhibitor after reperfusion 3 h (IH \times 66, \times 66). TNF- α : Tumor necrosis factor- α ; NO: Nitric oxide; NOS: Nitric oxide synthase; NADPH: Triphosphopyridine nucleotide; ICAM-1: Intercellular adhesion molecule 1; cNOS: Constitutive nitric oxide synthase; iNOS: Inducible nitric oxide synthase; HE: Hematoxylin and eosin.

Table 2 Intercellular adhesion molecule 1 expression in normal, storage and grafted livers

Groups	Portal area			Sinusoidal area		
	VE	BE	IC	HC	SLC	IC
Normal liver	±	-	-	-	-	-
Storage liver (6 h)	±	-	-	-	-	-

II	+	-	-	++	++	-
III	+++	-	-	++++	++++	-

Immunohistochemical results: "-", no significant staining; "±", a few staining; "+", focally stained; "++", diffusely stained; "+++ /++++", strongly diffusely stained. VE: Vascular Endothelium; BE: Biliary epithelium; IC: Cellular infiltrates; HC: Hepato cytes; SLC: Sinusoidal lining cell.

ICAM-1 and TNF- α in group III at 3 h after reperfusion (Table 2, Figure 1I and J).

DISCUSSION

IR injury during liver transplantation is a complex, multifactorial process in which numerous mediators and a variety of cells interact, leading to tissue damage. IR injury includes cold preservation injury, warm ischemia injury and reperfusion injury. Cold storage and warm reperfusion after restoration of blood are unavoidable steps in liver transplantation and all grafts undergo some degree of IR injury, thus leading to primary liver graft non-function or dysfunction^[13]. It is a hot issue at present and a major challenge in liver transplantation. So, which mechanisms lead to primary liver graft non-function or dysfunction? What role does the NO pathway play? How to improve quality and reduce the severity of early graft donor liver during IR injury? These are problems that need to be resolved in liver transplant surgery^[14].

NO has a modulatory function and is one of many organ-specific gaseous biological messengers newly discovered in recent decades in a variety of tissues or cells. NO modulates synthesis and secretion of a variety of immune mediators such as TNF- α , prostaglandin E₂, interleukin and interferon. It affects specific and nonspecific immune functions by mediating a variety of physiological and pathological phenomena, including endothelium-dependent vasodilatation, specific inhibition of proliferation of T lymphocytes, and adhesive accumulation of platelets. It plays an important extensive regulatory role in mammals. The immune regulation of NO is still not very clear in the physiology and pathology of solid organ transplantation.

L-arginine is an amino acid from which NO is synthesized. The NO synthesis pathway mainly refers to conversion of L-arginine to NO and L-citrulline under the action of NADPH cofactor and NOS in the endothelium. NO diffuses into both the vessel lumen and wall, thereby activating soluble guanylate cyclase to produce cGMP from GTP. NOx from the cGMP and non-cGMP pathway, either closely or remotely, directly or indirectly, play the role of second messengers on intracellular or extracellular target molecules^[15].

Our results demonstrated that early reperfusion rapidly depletes serum arginine, because of the explosive release of large amounts of arginase, thus leading to injury of liver parenchymal cells. The deletion of arginine decreases availability of tissue arginine with subsequent downregulation of endothelial NOS (eNOS). In contrast, it can protect liver graft against IR injury and improve the histopathological damage following liver transplantation by enhancement of arginine availability through arginase blockade, or by exogenous pathways to supplement NO donors or NO inhalation, or by endog-

enous pathways to induce the endogenous source downstream effector of eNOS (pharmacological treatment or ischemic preconditioning)^[16-18].

The non-cGMP pathway mainly affects the function of the substrate by acting on an iron-sulfur center protein. NO as an immune regulator mainly affects immune function through the non-cGMP pathway. Our study confirmed that ICAM-1 and TNF- α are also involved in the pathogenesis during reperfusion injury in liver transplantation^[19]. Although our previous studies demonstrated that cellular localization of NO varies according to the immunological status of liver transplantation, there are protective effects of hepatocyte-derived NO in the hyporesponsive status, but hepatic injury is probably triggered by overexpression of iNOS of the central lobule in the hyper-responsive state. NO has neither harmful nor beneficial effects, thus, it acts as a double-edged sword, mainly depending on its source and the experimental conditions^[20]. It is generally accepted that eNOS-derived NO is cell-protective by mediating vasodilatation, whereas iNOS mediates liver graft injury after transplantation^[21,22]. We showed that a small amount of eNOS was expressed in liver endothelial cells in normal liver tissue and after 6 h cold storage, but there was no expression of iNOS. Expression of cNOS was particularly significant in vascular endothelial cells and hepatocytes at 3 h and 24 h after reperfusion in group II.

We confirmed that NO plays an important protective role in organ preservation solutions by supplementing sufficient NO donors to enhance the NO/cGMP pathway. It might ameliorate function of the grafted liver and recipient's lung in hepatopulmonary syndrome, and significantly prolong the survivals of recipients after rat orthotopic liver transplantation. The levels of cGMP and serum NOx were significantly reduced after cold storage reperfusion, but there was no loss of NOS activity, suggesting that the reduction of NOx was probably the main reason for the accelerated destructive mechanism. We confirmed that NO has a significant beneficial effect on vascular function in heart and lung transplantation by strengthening NO/cGMP pathways. Therefore, by supplementing NO donors to enhance NO/cGMP pathways, it helps to balance NO/O₂ in the tendency to generate NO. The mechanisms underlying this protection involve preservation of the sinusoidal structure and maintenance of blood flow through the hepatopulmonary microcirculation^[23-26]. Our previous results demonstrated that NO of hepatocytes in the grafted liver can vary the immune status of the transplanted cells, but it is likely to have important immune protective roles for NO of hepatocytes in the hyporesponsive state^[27-30]. TNF- α is a wide range of polypeptide cytokines produced by a function of the body cells. Exogenous NO can significantly inhibit the macrophages stimulated by lipopolysaccharide to produce TNF- α ^[31]. Strengthening NO pathways significantly inhibits production and expression of TNF- α , but NOS inhibitors can contribute to increase the expression of TNF- α synthesized.

Apoptosis or programmed cell death is an active process that is controlled by specific genes without cell dissolution. Cytotoxic T lymphocytes (CTLs) leading to apoptosis can injury the target cells for lymphocyte-mediated cytotoxicity through the perforin/granzyme B and Fas/Fas-L lytic pathways^[32,33]. Apoptosis as a mechanism of cell death exists in acute rejection of liver transplantation, and it is related closely to the expression of perforin, transforming growth factor- β 1 and Fas-L^[34]. Thus, detecting expression of CTL-associated perforin and granzyme B genes provides two valuable markers to judge the effect of immunosuppression in acute rejection of liver transplantation^[35]. After reperfusion, the recipient's lymphocyte traffic to the graft is activated, and some infiltrating lymphocytes, hepatocytes, biliary endothelial and vascular endothelial cells are induced to apoptosis. We demonstrated that it can significantly reduce the expression of ICAM-1 in transplanted liver to enhance the NO pathway, and NOS inhibitors can increase the expression of ICAM-1 during cold IR in orthotopic liver transplantation. The results indicate that it is likely related to the induction of TNF- α in the expression of ICAM-1 during ischemia reperfusion after reconstruction of portal blood flow. However, we demonstrated that it was probably thrombin-induced expression of ICAM-1 in early reperfusion after liver transplantation. We confirmed the expression of ICAM-1 in liver transplantation during IR injury. It is likely to provide a more effective method for treatment of primary grafted liver dysfunction by the application of ICAM-1 monoclonal antibody 1A29F (ab)²^[36].

Hepatopulmonary syndrome is a disorder characterized by intrapulmonary vascular dilatation, leading to gas exchange abnormalities in the setting of liver disease. Hepatopulmonary syndrome is usually a progressive disease with worsening hypoxemia developing over time^[24,25,37]. The competitive inhibitor of NOS with substrate analogs such as L-NAME can reverse the local vasodilatation associated through inhibition of NOS. Administration of L-NAME abrogates the protection furnished by preconditioning^[38]. Inhibition of NO synthesis by a substance such as L-NAME leads to hypotension and an effect similar to the cytotoxic effect of endotoxins. In our study, there was both the most prominent biochemical and histological deterioration of graft liver and recipient's lung tissues, and a much higher mortality rate in the L-NAME group (group III). We observed that high survival in the L-arginine group (group I) was significantly increased, and 1-wk survival rate was 80% ($P < 0.01$), and one case showed long-term survival and was sacrificed on day 94. Survival of the recipients in group III was significantly reduced. One of the most important lethal causes in hepatopulmonary syndrome is hypoxia or hypoxemia, acute respiratory distress syndrome, or acute respiratory failure. This illustrated the remote protective effects of the NO cGMP synthesis pathway on the recipient's lungs.

In conclusion, we demonstrated the novel immuno-

modulation of NO and a crucial role of the NO/cGMP pathway during IR injury in rat orthotopic liver transplantation and the protective mechanisms of grafted liver and recipient's lung in hepatopulmonary syndrome. It is likely to be an effective way to improve postoperative antithrombotic therapy and the efficacy of liver transplantation by strengthening the NO/cGMP pathway.

COMMENTS

Background

Ischemia reperfusion (IR) injury during liver transplantation is a complex, multifactorial process in which numerous mediators and a variety of cells interact, leading to tissue damage. It is a hot issue at present and a major challenge in liver transplantation. In the field of solid organ transplantation, people do not know the immune suppression or immune stimulation of nitric oxide (NO) in acute rejection, chronic rejection, or the state of the immune response with low immune function.

Research frontiers

This research contributes to the theoretical basis of liver transplantation in clinical practice. The results improve the understanding of the molecular mechanisms of IR injury in liver transplantation.

Innovations and breakthroughs

Study results demonstrated novel immunoregulatory protective effects from IR injury in hepatopulmonary syndrome, involvement of intercellular adhesion molecule 1 and tumor necrosis factor- α in the pathogenesis after reperfusion injury in liver transplantation, and cellular localization of NO varies according to the immune status of the grafted liver. The study demonstrated the key role of the NO/cyclic guanosine monophosphate (cGMP) pathway during IR injury in liver transplantation. It is likely to be an effective way to provide a new pharmacological approach for preoperative antithrombotic therapy through strengthening the NO/cGMP pathway, which greatly improves the understanding of the molecular mechanisms of IR injury in liver transplantation.

Applications

Since 2003, the center has performed 97 cases of clinical liver transplantation. Eight cases complicated by hepatorenal syndrome were successfully reversed through enhancing the NO synthesis pathway by supplementing with an NO donor (L-arginine or alprostadil) in the early preoperative period. The authors suggest that acute renal failure might be successfully reversed to avoid further deterioration of multiorgan failure by the timely and decisive use of alprostadil, or by the repeated and sustained application of high-dose furosemide.

Terminology

IR injury is a complex, multifactorial process in which numerous mediators and a variety of cells interact, leading to tissue damage during liver transplantation. Hepatopulmonary syndrome is a disorder characterized by intrapulmonary vascular dilatation, leading to gas exchange abnormalities in the setting of liver disease.

Peer review

This is a good descriptive study in which authors evaluate immunological protections of NO in hepatopulmonary syndrome and the probable mechanisms of IR injury in rat liver transplantation. The results are interesting and suggest that the NO/cGMP pathway may be critical for successful organ transplantation, especially in treating hepatopulmonary syndrome during cold IR injury in rat orthotopic liver transplantation.

Abstract

There has been an increasing prevalence of lymphogranuloma venereum (LGV) or *Chlamydia trachomatis* (*C. trachomatis*) cases among the men who have sex with men (MSM) population, particularly in Europe and North America. These cases may present with an incomplete or undisclosed history and proctosigmoiditis without characteristic adenopathy syndrome. During the initial evaluation and colonoscopy, there is a strong clinical and endoscopic suspicion of inflammatory bowel disease (IBD) by virtue of presentation and endoscopic and histological findings. The diagnosis of IBD is subsequently modified to LGV proctosigmoiditis when one or more of the following transpire: (1) there is failure of response to IBD therapy; (2) additional components of history (MSM/travel) may be identified; (3) return of initially performed *Chlamydia* antibody test is positive; and (4) response to antibiotics effective against *Chlamydia*. We describe three such cases initially suspected

INTRODUCTION

Lymphogranuloma venereum (LGV), an ulcerative sexually transmitted infection caused by *Chlamydia trachomatis* (*C. trachomatis*), has gained recent attention as a cause of hemorrhagic proctitis among men who have sex with men (MSM) in North America, Australia, United Kingdom, and the rest of Europe^[1,2]. This infection is found most frequently in tropical and subtropical areas in the world but it is rarely reported in developed countries. However, since 2003, outbreaks have been increasingly reported in Europe and the United States in MSM^[3-5]. Human immunodeficiency virus (HIV)-1 infection is the strongest risk factor for LGV infection and it presents in more than 70% of the subjects^[6]. The patients usually have high rates of promiscuity and high risk sexual behavior, often involving international sexual networks,

which correlates with the high rate of concomitant sexually transmitted diseases (STDs) observed^[2,5]. The atypical clinical presentation, the unawareness of physicians and patients in regards to the disease, and the lack of a routine diagnostic tests for LGV serovars of *C. trachomatis* have contributed to a delay in diagnosis and have caused misdiagnosis^[5]. We report three cases of LGV proctitis in MSM patients, initially misdiagnosed or suspected to be inflammatory bowel disease (IBD).

CASE REPORT

Case 1

A 30-year-old male presented with a three week history of passing bloody mucus per rectum several times a day. A stool exam was negative for ova and parasites. A limited sigmoidoscopy showed a cobble-stoned and granular mucosa with several ulcers in the distal 5-7 cm of the rectum (Figure 1A). Rectal biopsies showed patchy severely active colitis with distorted and mucodepleted crypts and lymphohistiocytic cryptitis reminiscent of Crohn's disease (Figure 1B). Immunostains for cytomegalovirus (CMV) and herpes simplex virus and special stains for fungi and acid-fast bacilli, performed retrospectively, were negative. The patient was given mesalazine 2.4 g/d which failed to produce any response after 1 wk. Due to the lack of response to IBD therapy and the clinical need to assess the remainder of the colon, a repeat full colonoscopy was performed. Colonoscopy showed similar findings in the rectum as seen previously, but the cecum showed a bright red nodule (Figure 1C). Biopsies from the cecal nodule showed classic histological features of Kaposi's sarcoma with spindle cells, vascular proliferation and extravasated erythrocytes (Figure 1D). Immunohistochemically, the cells were positive for CD31 and HHV-8. Random colonic biopsies away from the rectum and cecum were also performed which showed incidental intestinal spirochetosis. Additional clinical history revealed that the patient had unprotected anal intercourse while traveling through Europe three months prior. Microbiological studies were then performed which confirmed the presence of *C. trachomatis* by DNA probe and serologic testing. The specimen was sent the Center for Disease Control which detected *C. trachomatis* LGV DNA by sequencing of the outer membrane protein (*omp A*). The patient was subsequently found to be HIV positive (HIV RNA: 24 177 cop/mL) and was started on antiretroviral therapy. Doxycycline 100 mg twice a day for 21 d was given for his LGV proctitis and he had resolution of symptoms after 4 d.

Case 2

A 28-year-old HIV positive male presented with rectal bleeding and dyschezia. An anoscopy revealed an ulcer at the anal verge. Biopsies showed fragments of anal skin with ulceration, lymphoid tissue, and inflammatory granulation tissue histologically suspicious for an inflammatory bowel disease. Sigmoidoscopy was recommended to

assess for Crohn's disease and it showed an erythematous mucosa in the distal rectum with small areas of white exudates and heaped folds (Figure 2A). These biopsies showed severe lymphohistiocytic proctitis and cryptitis similar to Case 1 and again were suspicious for Crohn's disease (Figure 2B). Given the history of HIV positivity, LGV was also a clinical consideration and DNA probes and serologic testing were subsequently performed and were positive for *C. trachomatis*. Retrospectively, the proctitis and anal ulceration was deemed to be LGV-related and not Crohn's disease.

Case 3

A 42-year-old male with HIV and prior anal condyloma acuminatum presented with a 3 wk history of bright red blood per rectum. Colonoscopy was performed and showed moderate colitis in the rectum with friable and erythematous mucosa (Figure 3A). The biopsies showed moderately active proctitis with focal crypt distortion and cryptitis reminiscent of Crohn's-type IBD (Figure 3B). However, the clinical profile and the short duration of symptoms raised the possibility of LGV proctitis. Serologically, IgG antibodies against *C. trachomatis* were positive and the patient responded to antibiotic therapy for LGV.

DISCUSSION

Rectal bleeding or diarrhea may be caused by a variety of etiological factors including infections, diverticular disease, inflammatory bowel disease, ischemia, and neoplasia. Acute symptoms in young patients are generally linked to infectious colitis and often associated with travel, food, antibiotic intake, or sexual transmission. Common infectious agents include bacteria such as *Escherichia coli*, *Clostridium difficile*, *Salmonella*, *Shigella* and *Campylobacter*, viruses and parasites. When an infectious agent cannot be identified and/or symptoms persist, IBD is a clinical consideration.

Patients with LGV proctitis typically present with a rectal syndrome (> 90%) with moderate to severe ulcerative proctitis or proctocolitis with mucopurulent discharge, constipation, and tenesmus. Systemic symptoms like fever, malaise, and weight loss are also relatively common^[5]. LGV is typically a disease of lymphatic tissue. When the primary inoculation is in the penis or vagina, inguinal or femoral lymphadenitis develops, with a severe inflammatory reaction that suppurates and extends to adjacent structures. However, when the rectum is the site of primary inoculation, proctitis is the most common reaction and enlarged inguinal lymphadenopathies are absent^[6]. Simultaneous penile lesions are rarely seen. The ulcerative nature of LGV proctitis could enhance the transmission and acquisition of HIV and other STDs, as well as other blood-borne diseases like Hepatitis C^[5].

LGV proctitis must be routinely ruled out in MSM with unspecific anorectal complaints. A high index of suspicion is the mainstay to its early diagnosis in order

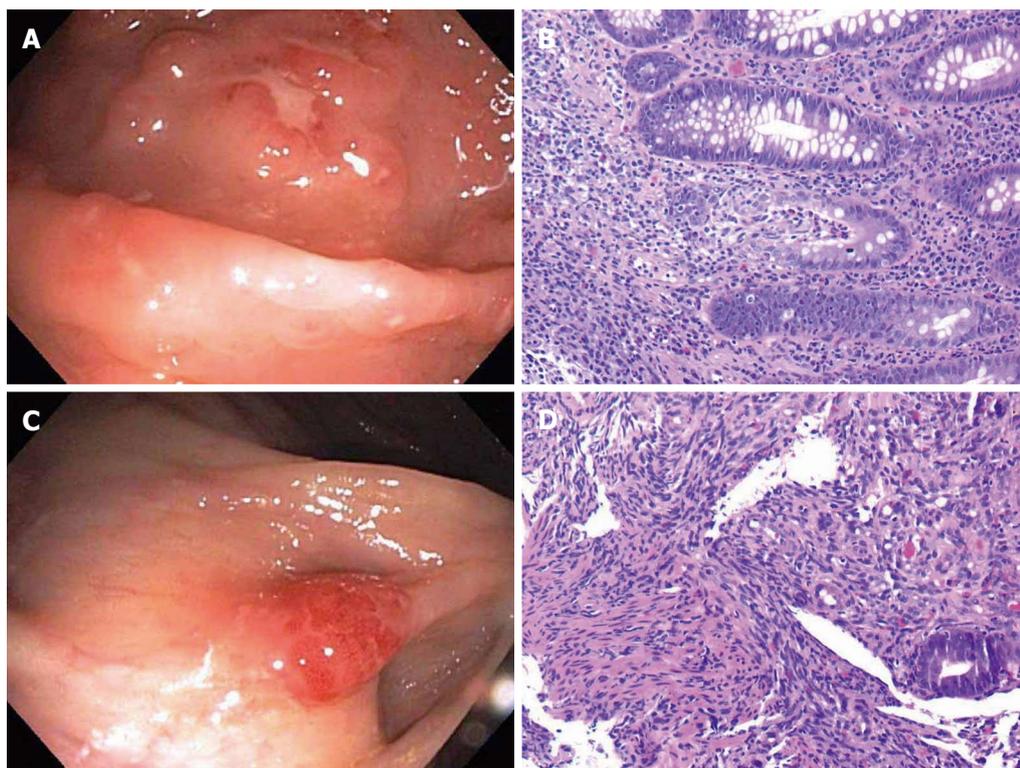

Figure 1 Endoscopic and microscopic findings (case 1).

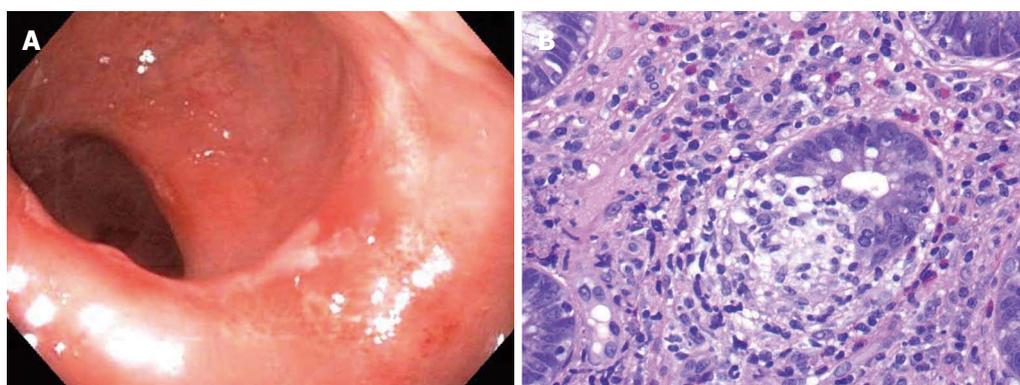

Figure 2 Endoscopic and microscopic findings (case 2).

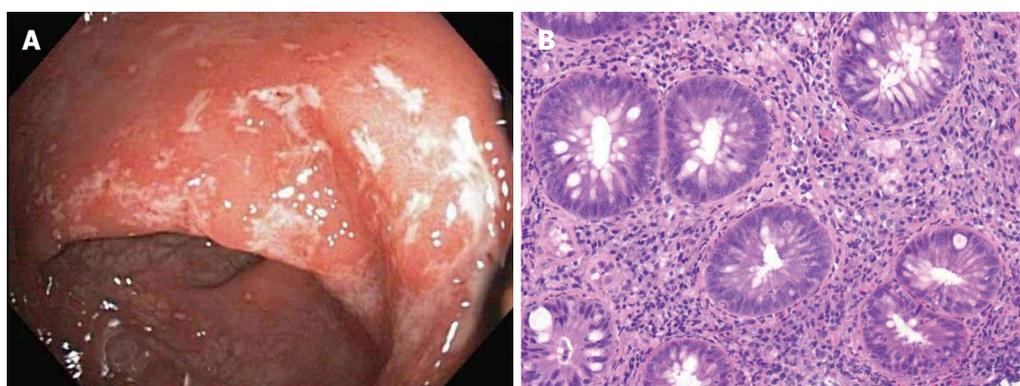

Figure 3 Endoscopic and microscopic findings (case 3).

to prevent avoidable complications. If left untreated, the disease evolves to a late stage, which is marked by fibrosis and strictures in the anogenital tract. Late complications include chronic genital ulcerations, anal fistulae, infertility, and disfiguring conditions such as genital elephantiasis and esthiomene^[4,6].

The endoscopic findings include mucopurulent exudates with a hyperemic and friable mucosa, multiple ulcers and erosions, and granulation tissue in the rectum. However, in some reports, up to 40% of men with LGV proctitis showed no anoscopic abnormalities^[5]. Also, in rare cases there were normal endoscopic findings^[7]. Hence, the endoscopic findings in LGV are nonspecific and can be easily misdiagnosed^[5].

Microscopically, the main changes are inflammatory changes, which can be easily misinterpreted even by experienced pathologists. Findings include lymphohistiocytic colitis, lymphoplasmacytic infiltrates, cryptitis, crypt abscesses, and crypt distortion.

These changes are often interpreted as IBD-type (particularly Crohn's-like) or described as non-specific inflammatory changes^[7,8].

LGV proctitis is caused by serovars L1, L2, and L3 of the obligate intracellular bacterium *C. trachomatis*, which is classified into 15 serovars based on immunogenic epitope analysis of the major outer membrane protein. Serovars A, B, Ba, and C are associated with ocular trachoma and strains D-K with genital tract disease and with inclusion conjunctivitis. Only serovars L1, L2, and L3 cause LGV, probably due to their tropism for the lymphatic system, in contrast to serovars A-K, which affect mucocutaneous tissue. The L2 serovar can be further classified into L2, L', L2a, and L2b, and the recently described L2c-L2g according to amino acid differences. The most common serovar causing LGV proctitis to date is L2b^[4,5].

A wide variation in the diagnosis and management of chlamydial infection in MSM currently exists which needs to be standardized^[9]. Historically, the laboratory diagnosis of LGV was based on culture, but this method is very tedious, has a low sensitivity (50%-80%), and cannot differentiate between different strains, therefore other detection methods have been applied. Serologic tests (complement fixation or immunofluorescence) have been used; however, these tests lack standardization, do not distinguish the different serotypes, nor do they differentiate past from present infections. Nucleic acid testing of clinical specimens has emerged as a promising technique that is both sensitive and convenient. Specialized laboratories such as the Center for Disease Control can further amplify sequences in the major outer-membrane protein and reliably distinguish among lymphogranuloma venereum serotypes^[5,6,10].

The diagnosis of LGV is challenging to clinicians because the clinical presentation may be nonspecific and specific laboratory procedures for its diagnosis require a high index of suspicion. The main pathological differential diagnosis of LGV proctitis includes other forms of infectious colitis and inflammatory bowel disease^[6].

Herpes, CMV, syphilis, and *Neisseria gonorrhoea* infections can also cause proctocolitis. Patients generally present with similar general symptoms such as anal discharge, pain, diarrhea, constipation, bloody stool, and tenesmus. Proctoscopic findings are again nonspecific and range from normal to erythema, mucosal friability, and surface erosions^[11]. Virally infected cells with herpes are histologically identified with molding and multinucleation of cells and the peripheralization of the chromatin. CMV infections have large cells with identifiable nuclear and cytoplasmic inclusions. These two viral infections are seen in a background of ulcerations with associated acute and chronic inflammation and granulation tissue and immunohistochemical markers are also helpful with identification. Syphilis is associated with a chronic inflammatory infiltrate rich in plasma cells and may also show granulomatous inflammation. With *Neisseria gonorrhoea*, as with *Chlamydia*, one may see evidence of cryptitis, crypt abscesses, and reactive epithelial changes^[12]. Since there are overlapping histological features with these two infectious processes, microbiologic studies become necessary.

There is considerable mimicry between IBD and LGV histologically^[8]. In IBD, crypt architectural distortion, the presence of a prominent increase in the cellularity of the lamina propria, and the development of well-formed granulomas can be seen. However, some of these pathologic features are often also seen in LGV proctitis. Furthermore, with more advanced LGV infection, transmural inflammation can ensue, further resembling Crohn's disease^[12]. There are no pathognomonic features of LGV, and this is why clinical suspicion along with microbiological identification in a patient with risk factors is crucial.

According to the current European and United States STD guidelines, the recommended treatment for LGV is doxycycline (100 mg orally twice a day for 21 d or as long as anorectal symptoms persist) in contrast to infection with other *Chlamydia* serovars, where only 1 wk (or a single azithromycin dose) is required. This cures the infection and prevents further tissue damage. An alternative regimen is erythromycin (500 mg orally four times daily for 21 d). However, this recommendation is not supported by randomized evidence in clinical trials, but by empirical data. Patients should be followed up until symptoms have disappeared and clinically reviewed at 3-6 wk. Likewise, sexual partners who have had unprotected contact with the patient within the previous 60 d of onset of clinical symptoms should be screened or empirically treated with an LGV regimen^[5].

In the absence of laboratory confirmation of L serovars, physicians are advised to treat possible cases presumptively for LGV and provide medical management of sexual partners^[1]. Patients should receive risk education counseling and be routinely screened for other STDs, especially HIV and hepatitis B and C^[5].

In conclusion, patients with *C. trachomatis* who present without classical history or symptoms and have isolated proctosigmoiditis may be confused clinically, endoscopically and histologically with inflammatory

bowel disease. When there is lack of response to IBD therapy and/or the clinical profile raises the potential for LGV, serological and DNA probe studies for *Chlamydia* are recommended. Awareness of its mimicry to IBD and prompt identification of *C. trachomatis* are crucial for treatment and prevention of further complications from this disease.

Abstract

Cholate-CoA ligase (CCL) and bile acid-CoA: amino acid N-acyltransferase (BAAT) sequentially mediate bile-acid amidation. Defects can cause intrahepatic cholestasis. Distinction has required gene sequencing. We assessed potential clinical utility of immunostaining of liver for CCL and BAAT. Using commercially available antibodies against BAAT and CCL, we immunostained liver from an infant with jaundice, deficiency of amidated bile acids, and transcription-terminating mutation in BAAT. CCL was normally expressed. BAAT expression was not detected. Immunostaining may facilitate diagnosis in bile-acid amidation defects.

INTRODUCTION

Conjugated bile acids are detergents essential in facilitating the enteric absorption of fats and of fat-soluble substances, among them several vitamins. They are synthesised in hepatocytes, which expel them into the lumen of the bile canaliculus *via* the transport protein bile salt export pump (BSEP). Conjugated bile acids are partially deconjugated during passage through the intestine. Bile acids are recovered from chyme and returned to the liver in portal venous blood; unconjugated bile acids are re-conjugated with glycine or taurine within hepatocytes before re-export into canalicular bile^[1]. That errors in synthesis or transport of bile acids may lead to intrahepatic cholestasis is well known^[1,2]. Errors in conjugation of bile acids with amino acids ("amidation"), a two-step process, also may cause usual cholestasis, with jaundice, but can also produce anicteric cholestasis manifest as malabsorption of fat-soluble vitamins, growth retardation, and pruritus. Few descriptions are published of children with bile-acid amidation defects and of mutations in genes that encode the enzymes responsible for amidation. Di-

agnosis can be elusive^[3]. We present our correlation of immunohistochemical, clinical-biochemistry, and genetic findings in a child with a bile-acid amidation defect and suggest approaches to diagnosis.

CASE REPORT

The first child of consanguine British parents of Pakistani heritage was born at term after an uncomplicated pregnancy. She was well until age 7 wk, when jaundice and pale stools were noted. Her liver and biliary tract were sonographically unremarkable. Clinical-laboratory findings included conjugated hyperbilirubinemia (total: direct bilirubin 106:67 $\mu\text{mol/L}$) with elevated serum alanine aminotransferase activity (378 IU/L), normal-range gamma-glutamyl transpeptidase (GGT) activity (30 IU/L), and hypercholanemia (total serum bile acids 282 $\mu\text{mol/L}$, expected < 14). Liver biopsy at age 8 wk found hepatocellular and canalicular cholestasis, with slight portal-tract fibrosis and a “neonatal hepatitis” pattern of focal giant-cell change of hepatocytes, with haemopoiesis. Canalicular-margin expression of BSEP and of ectoenzymes (alanine aminopeptidase, carcinoembryonic antigen, GGT) was normal. Transmission electron microscopy found changes of hepatocellular and canalicular cholestasis, without “Byler bile” or other abnormalities. Urine and plasma analysed by electrospray ionisation-mass spectroscopy^[1,3] contained di- and tri-hydroxy C24 bile acids, without amidated forms (Figure 1). A defect in cholate-CoA ligase (CCL) or bile acid-CoA: amino acid N-acyltransferase (glycine N-choleoyltransferase; BAAT) was hypothesised.

BAAT, encoding BAAT, was sequenced by routine techniques using DNA from peripheral-blood leucocytes^[4]. The results indicated that the patient was homozygous for the previously undescribed mutation c.415C > T/p.R139X in BAAT. Solute carrier family 27 (fatty acid transporter), member 5 (*SLC27A5*), encoding CCL, was not sequenced. Immunostaining with antibodies against CCL (HPA007292; Sigma, St Louis, MO, United States) and BAAT (ab97455; Abcam, Cambridge, United Kingdom), conducted using manufacturer-recommended protocols, found good expression of CCL and no expression of BAAT (Figure 2); controls, including liver of age-matched infants with cholestasis due to extrahepatic biliary atresia and to failure of BSEP expression, marked appropriately (reaction conditions described on request). The patient, now aged 7 years, receives ursodeoxycholic acid and fat-soluble vitamin preparations and despite slight hypercholanemia (total serum bile acids 77 $\mu\text{mol/L}$) is clinically well (height and weight 25th percentile for age, with good progress in school). Her only sibling, a sister, is without signs or symptoms of liver disease. The parents have declined genetic study of the sibling.

DISCUSSION

Bile salts within the biliary-tract and small-bowel lumina

exist principally as glyceryl or tauryl conjugates of primary bile acids. Bacteria within chyme and faeces deconjugate and dehydroxylate bile salts. The resulting secondary bile acids are taken up by the bowel and passed into venous effluent. They are then absorbed by hepatocytes and again conjugated with glycine or taurine in the process of amidation; newly synthesised bile acids also undergo amidation in the liver^[1].

Two enzymes, CCL [International Union of Biochemistry and Molecular Biology European Commission (EC) 6.2.1.7] in cytoplasm and BAAT (EC 2.3.1.65) in peroxisomes, act sequentially to amidate bile acids^[1,3]. Experimental data conflict on whether non-amidated bile acids are poorer substrates for BSEP, the protein that transports bile salts against a concentration gradient from hepatocyte cytoplasm into bile-canalicular lumen, than are amidated bile acids^[5,6]. Non-conjugated bile acids may back-diffuse from canalicular lumen into hepatocytes and into the space of Disse, impeding secretory efficiency, and excess of bile acids within hepatocytes may cause injury^[4]. Data on back-diffusion of non-amidated bile acids from bile-duct lumen into cholangiolar venous effluent, with drainage into portal-vein radicles and presentation to the liver lobule of such bile acids in excess (“cholehepatic shunting”), are not available. However, this process may conduce to hepatocellular overload with bile acids, and hence to hepatocellular injury.

Intrahepatic cholestasis has been described in association with amidation defects. Anicteric cholestasis, manifest as failure to thrive with malabsorption and fat-soluble vitamin deficiency, was found in Amish children homozygous for the mutation c.226A > G/p.M76V in BAAT^[4]. A preliminary description of children with three additional different mutations in BAAT, all in homozygous form, has appeared^[7]. Homozygous mutation in *SLC27A5* (c.1012C > T/p.H338Y) also has been associated with intrahepatic cholestasis in a prematurely born infant^[3]. To what extent exogenous factors - ontogenetic immaturity, parenteral alimentation, various drugs, or a genetic background that includes mutation in other cholestasis-associated genes^[3] - conduce to jaundice with amidation defects, expected *per se* to result in anicteric cholestasis^[8], remains to be determined. Our patient, who developed icterus, was born at term, was not subjected to parenteral alimentation, and received no drug treatment recognised as capable of precipitating cholestasis. Were intrahepatocytic concentrations of bile acids elevated (4), leading to damage to organelles and to cellular processes, with jaundice a non-specific sequela? The factors that predisposed to icterus in our patient must remain matter for speculation.

As reported in patients with defects of bile-acid amidation^[3,4], cholestasis in our patient was not associated with elevations in serum GGT activity even when conjugated hyperbilirubinemia was present. Normal-range serum GGT activity is a feature of disorders of bile-acid synthesis as well as of bile-acid amidation. It also characterises certain forms of intrahepatic cholestasis

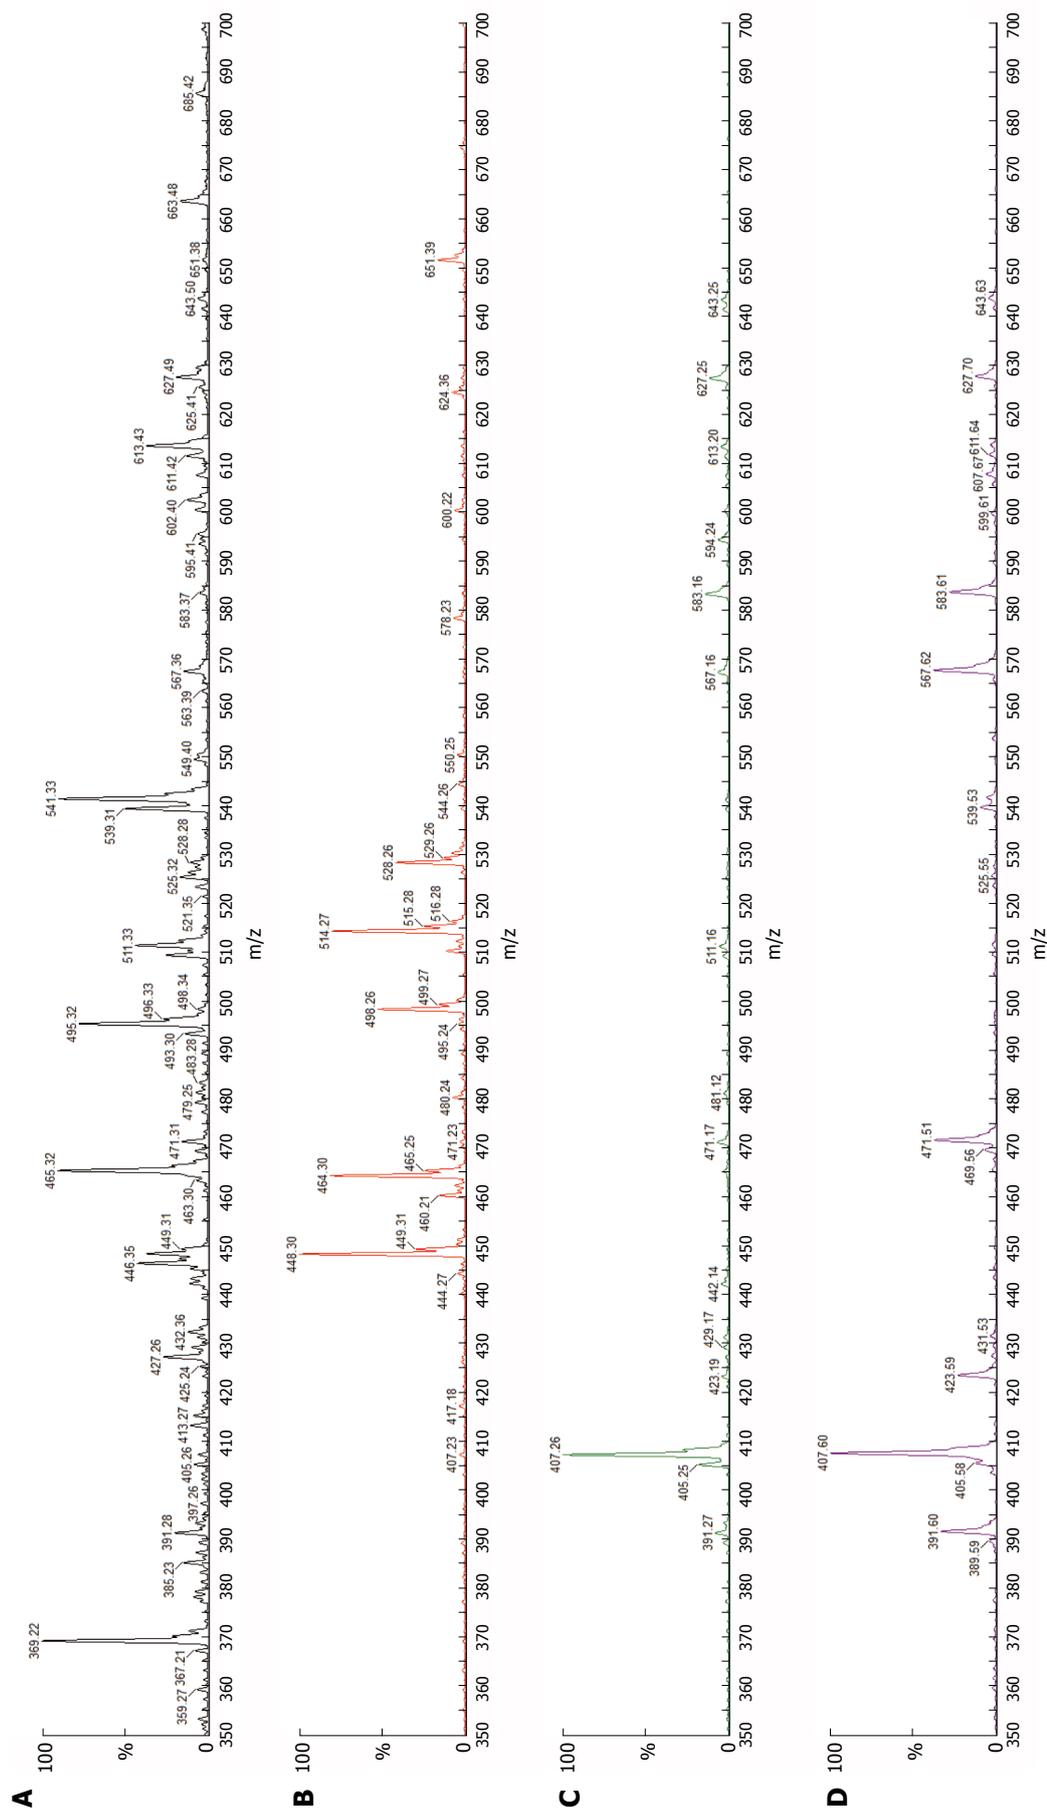

Figure 1 Bile acid mass spectra, urine. A: Normal (neither icterus nor known amidation defect); B: Deficiency of bile salt export pump (BSEP) (intrahepatic cholestasis with icterus); C: Deficiency of cholate-CoA ligase (described elsewhere³³); D: Deficiency of bile acid-CoA: amino acid N-acyltransferase (patient). Abscissa, mass-charge ratio (m/z); ordinate, intensity of ion current as percentage of most abundant peak in spectrum (%). From left to right, principal peak sites and the species represented are: 391: Unamidated chenodeoxycholic acid (CDCA); 407: Unamidated chenodeoxycholic acid (CDCA); 448: Glycine-conjugated CA; 471: Unamidated CDCA sulphate; 487: Unamidated CA sulphate; 498: Taurine-conjugated CA; 514: Taurine-conjugated CA; 528: Glycine-conjugated CDCA sulphate; 567: Unamidated CDCA glucuronide; 583: Unamidated CA glucuronide; 613: 27-Nor-cholestane pentol glucuronide; 643: Cholestane hexol glucuronide. In normal urine (A), bile-acid and bile-alcohol peaks are just detectable. In urine from a patient with BSEP deficiency (B), increased excretion of glycine- and taurine-conjugated bile acids is apparent. Large quantities of non-conjugated species are present in both cholate-CoA ligase deficiency (C) and BAAT deficiency (D); differences between the two in size and distribution of this and other peaks are not apparent.

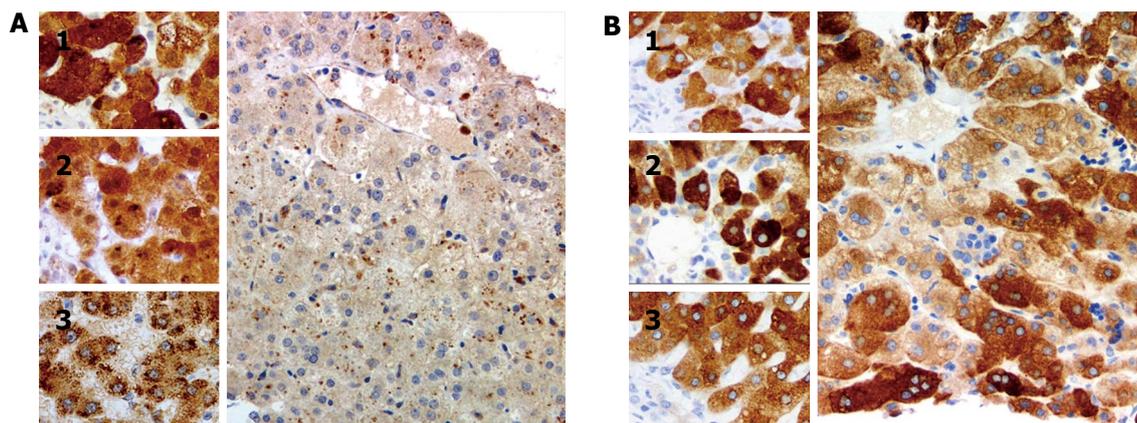

Figure 2 Photomicrographs of liver immunostained for enzymes that subserve bile-acid amidation. A: Main image: Core needle biopsy specimen, patient liver (age 57 d); inset, control livers (1, infant, matched for age with patient, with cholestasis and extrahepatic biliary atresia; 2, infant, matched for age with patient, with intrahepatic cholestasis in setting of absence of bile salt export pump (BSEP) expression; and 3, adult without cholestasis). The patient liver lacks immunohistochemically demonstrable bile acid-CoA: amino acid N-acyltransferase (BAAT). Granular cytoplasmic marking, suggestive of peroxisomal location, is found in (3); marking is more diffuse in the livers of age-matched infants; B: Tissue specimens as in (A). Diffuse cytoplasmic marking for cholate-CoA ligase (CCL) is seen in patient liver (main image) and in control livers (1, infant, matched for age with patient, with cholestasis and extrahepatic biliary atresia; 2, infant, matched for age with patient, with intrahepatic cholestasis in setting of absence of BSEP expression; and 3, adult without cholestasis). A, anti-BAAT antibody, and B, anti-CCL antibody (see principal text for sources); in all images, reaction development with EnVision proprietary technique (Dako UK, Ely, United Kingdom), haematoxylin counterstain, original magnification 200 ×.

ascribed to deficiency of BSEP expression or function, abnormalities in canalicular-membrane composition, and abnormalities of intracellular trafficking of canalicular-membrane components^[2]. Evidence indicating such disorders, either clinical or histopathologic, was not identified in our patient.

Little histopathologic information is available concerning hepatobiliary disease in bile-acid amidation deficiency. Whether the appearances of BAAT deficiency differ from those of CCL deficiency in routinely stained sections, for example, is still an open question. The same is true for differences in ultrastructural features; too few instances have been described to allow discrimination. As urine and plasma bile-acid spectra and chromatograms in amidation-deficiency disease do not vary between CCL deficiency and BAAT deficiency (personal observations, PTC; *cf.* Figure 1), screening of both *SLC27A5* and *BAAT* for variations from canonical sequence is at present necessary to distinguish between forms of amidation defect.

Our findings demonstrate that immunohistochemical study can detect absence of BAAT expression. They correlated well with genetic findings that suggested that BAAT synthesis was not to be expected in our patient. Lack of BAAT expression thus may constitute a strong indication for evaluation of *BAAT* for mutation.

We believe that immunohistochemical screening of liver tissue for CCL and BAAT expression may identify instances of bile-acid amidation deficiency disease in patients with normal-range serum GGT activity and either icteric or anicteric cholestasis. To do so admittedly may not identify all such instances; defects in protein function without defects in protein expression are to be expected, particularly with mutations that substitute one amino-acid residue for another^[3]. However, immunostaining is rou-

tinely practiced, whereas only a few laboratories speciate bile acids in plasma and urine or offer analysis of genes that encode enzymes involved in bile-acid handling. In addition, liver biopsy continues to be an approach widely used in the evaluation of neonatal cholestasis, permitting repeated interrogation of liver-biopsy material as application of diagnostic algorithms suggests candidate disorders. Results on immunostaining of liver-biopsy or hepatectomy specimens from patients with hepatobiliary disease and normal-range serum GGT activity thus may guide both clinical-biochemistry and genetic investigations, speeding definitive diagnosis.

ACKNOWLEDGMENTS

We thank Rayner A, chief biomedical scientist, and Starling C, biomedical scientist, of the histopathology laboratories at the Institute of Liver Studies, King's College Hospital, for their work in establishing and validating the immunohistochemical techniques used in this study, and Wagner B, chief biomedical scientist, Electron Microscopy Unit, Histopathology Department, Northern General Hospital, Sheffield, United Kingdom, for technical and consultative ultrastructural studies.

Abstract

Mechanical lithotripsy (ML) is usually considered as a standard treatment option for large bile duct stones. However, it is impossible to retrieve oversized stones because the conventional lithotripsy basket may not be able to grasp the stone. However, there is no established endoscopic extraction method for such giant stone removal. We describe a case of successful extraction of a 4-cm large stone using a gastric bezoar basket. A 78-year-old woman had suffered from upper abdominal pain for 20 d. Contrast-enhanced computed tomogram revealed a 4-cm single stone in the distal common bile duct (CBD). Endoscopic stone retraction was decided upon and endoscopic papillary balloon dilation was performed using a large balloon. An attempt to capture the stone using a standard lithotripsy basket failed due to the large stone size. Subsequently, we used a gastric bezoar basket to successfully capture

the stone. The stone was fragmented into small pieces and extracted. The stone was completely removed after two sessions of endoscopic retrograde cholangiopancreatography; each of which took 30 min. No complications occurred during or after the procedure. The patient was fully recovered and discharged on day 11 of hospitalization. ML using a gastric bezoar basket is a safe and effective retrieval method in select cases, and is considered as an alternative nonoperative option for the management of difficult CBD stones.

INTRODUCTION

Since endoscopic sphincterectomy (EST) was introduced for bile duct stone extraction, up to 90% of bile duct stones could be removed by using EST and standard endoscopic maneuvers^[1]. However, bile duct stone removal can be challenging in patients with large stones (> 12 mm), multiple stones, barrel-shaped stones, and tapering or tortuosity of the distal common bile duct (CBD)^[2]. Mechanical lithotripsy (ML) is an established alternative in

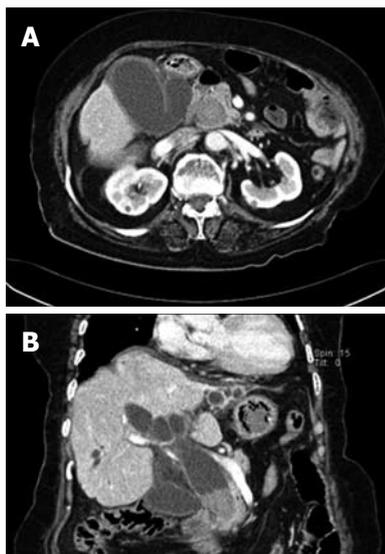

Figure 1 Computed tomogram revealed a huge stone in the distal common bile duct. Marked dilation of the gallbladder and bile duct was also seen. A: Axial view; B: Coronal view.

cases of large CBD stones that cannot be removed using standard endoscopic retrieval methods. Large and hard concretions, however, often make ML difficult. There are several nonoperative options available^[1-5], but there is no established technique for difficult large stones.

Here, we report a case of a giant CBD stone that was retrieved by ML using a gastric bezoar basket.

CASE REPORT

A 78-year-old woman was referred to our institution due to upper abdominal pain and vomiting that occurred 20 d prior to admission. Blood pressure was 100/50 mmHg, heart rate was 96 beats/min, and temperature was 36 °C. There was tenderness to palpation in the right upper quadrant of the abdomen, but rebound tenderness was not documented. Laboratory tests showed: white blood cells, 25 600/mm³; neutrophils, 97.2%; hemoglobin, 14.5 g/dL; total bilirubin, 5.5 mg/dL; aspartate aminotransferase, 104 IU/L; alanine aminotransferase, 87 IU/L; serum alkaline phosphatase, 510 IU/L; and γ -glutamyl transpeptidase, 365 IU/L.

Contrast-enhanced computed tomogram (CT) of the abdomen revealed a single 4-cm stone in the distal CBD, with marked and diffuse dilation of the entire biliary tree (Figure 1). Endoscopic retrograde cholangiopancreatography (ERCP) was urgently performed because the patient's mental state and vital signs had deteriorated on the day of admission. We identified an opening of a choledochoduodenal fistula near the ampulla of Vater where a large amount of pus was emitted. A 4.0 cm \times 3.2 cm filling defect was noted in the distal CBD on the cholangiogram (Figure 2). Nasobiliary drainage through the fistulous tract was performed endoscopically. After the first session, the signs of systemic infection improved as well as the patient's performance status, and the second session

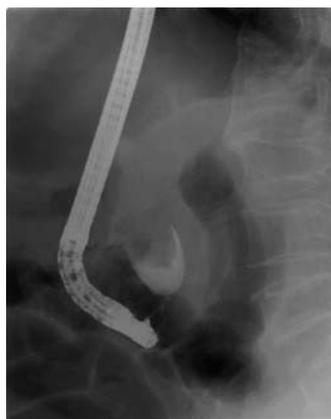

Figure 2 Endoscopic retrograde cholangiopancreatogram showed a large filling defect measuring 4.0 cm \times 3.2 cm. The proximal portion of bile duct was not opacified.

Figure 3 Basket for gastric bezoar (left) is larger than a conventional basket used for mechanical lithotripsy (right).

of ERCP was performed on day 3 in hospital, to retrieve the stone.

Instead of EST, endoscopic papillary balloon dilation was performed (for 60 s, one session) using a large balloon catheter, 15 mm in diameter (Controlled Radial Expansion balloon; CRE[®]; Boston Scientific, Natick, MA, United States) for esophageal dilation. ML using a usual lithotripter (Stonebuster[®], 40 mm-inner diameter; Medi-Globe GmbH, Achenmühle, Germany) was tried and failed to capture the stone due to its large size. Subsequently, we were able to capture the stone using a gastric bezoar basket (Stonebuster[®], 60 mm-inner diameter; Medi-Globe GmbH) that was larger than the usual basket for ML (Figure 3). The captured stone was broken into fragments with a mechanical lithotripter (Memory Eight Wire Basket 2 cm \times 4 cm (MB5-2X4-8[®]; Cook Medical Inc., Winston Salem, NC, United States) (Figure 4). Then, we performed endoscopic nasobiliary drainage to prevent cholangitis induced by the fragmented stones. On the 6th day in hospital, follow-up cholangiogram revealed multiple small filling defects within the CBD (Figure 5). All of the stone fragments were extracted with the basket, and we confirmed complete clearance of the CBD by a balloon-occluded cholangiogram (Figure 6). The patient

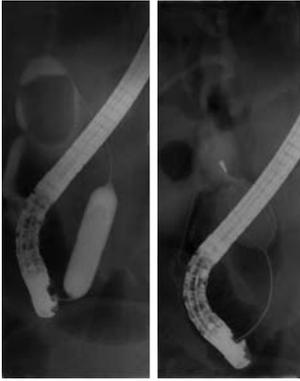

Figure 4 Endoscopic balloon dilation using a large balloon and mechanical lithotripsy. The balloon was inflated gradually to a diameter of 15 mm across the papilla and the ballooning was sustained for 60 s, and the bezoar basket captured the stone completely. The stone was fragmented by mechanical lithotripsy using a bezoar basket.

Figure 5 Follow-up endoscopic retrograde cholangiopancreatogram disclosed remnant stone fragments.

Figure 6 Remnant stone fragments were extracted by the basket and balloon occluded cholangiogram showed complete duct clearance.

was fully recovered and discharged on the 11 th day of hospitalization.

DISCUSSION

Since ML was first introduced by Riemann *et al*^[6] for the retrieval of CBD stones, ML has been the method of

choice in cases of large or impacted stones. Additionally, in cases with concomitant narrowing of the distal CBD from which it is impossible to remove stones by EST, ML is the simplest, most cost-effective, and safe procedure^[1-5]. For large stones > 1 cm, there are several therapeutic options other than ML. Endoluminal electrohydraulic lithotripsy (EHL) *via* the peroral or percutaneous route^[3,7,8], extracorporeal shockwave lithotripsy (ESWL)^[1,3], laser lithotripsy^[9], and stenting^[10,11] are nonoperative options, especially for elderly patients and patients at high surgical risk.

ESWL, EHL and laser lithotripsy yield similar success rates of 80%-95% and may be used in combination. These techniques are not available at all treatment facilities, thus, the selection of a specific treatment option may differ between institutions or physicians. There have been some studies of EHL using balloon catheters under fluoroscopy^[7] and single-operator duodenoscope-assisted cholangioscopy-guided EHL^[8]. These are complex and very labor-intensive procedures. ESWL usually requires multiple sessions and an additional endoscopic procedure for complete stone retrieval^[1]. The placement of biliary stents is used as an immediate management option to prevent cholangitis or stone impaction^[5], and for retrieval in choledocholithiasis patients who are intractable to the usual lithotripsy option, or have a high surgical risk^[6,11]. However, recent studies have shown high rates of late morbidity and mortality after long-term stenting. Temporary use of self-expandable metallic stents combined with EHL has been reported for avoiding long-term stent placement in patients with intractable CBD stones^[11].

Large stones (2.5 cm or 2.8 cm in diameter), or hard concretions, often make ML cumbersome or even impossible^[3]. Indeed, a stone size > 2.8 cm is associated with lithotripsy failure^[12]. Another study has shown that impacted stones, as well as stone size only, is a predictive factor for stone extraction failure, especially in cases where the bile duct is not dilated adequately to accommodate a large stone^[5]. In our case, the stone was oversized (4 cm) and dilation of the bile duct was not sufficient to capture the stone using a basket for ML. Other retrieval modalities, such as EHL, and laser lithotripsy, were not promptly available. Also, ESWL was not indicated because the stone was radiolucent. Therefore, we selected a 6-cm diameter bezoar basket to grasp the large stone completely for ML.

We performed endoscopic papillary large balloon dilation (EPLBD) without EST before ML for easy removal of the large stone. Several reports have shown the efficacy of EPLBD for treatment of large bile duct stones^[13-15]. Most studies have carried out EST followed by EPLBD, but some groups have attempted stone extraction by EPLBD alone without EST^[16]. The preceding EST has a lower risk of pancreatitis that the pancreatic orifice is separated from the biliary orifice after EST and it may result in balloon dilation forces away from the pancreatic duct^[15]. In our opinion, preceding EST before EPLBD may not play a role in the guidance of balloon

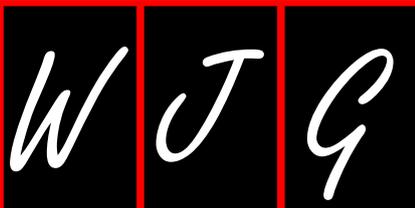

dilation because the direction of ballooning by the inflating catheter is always radial. Therefore, our case had LBS only without a previous EST.

In conclusion, ML using a gastric bezoar basket was safe and effective for the retrieval of a CBD stone, which was extraordinarily large. The bezoar basket is not a newly designed device, but an existing tool originally used for the removal of bezoars. This is believed to be the first published attempt to retrieve a giant and intractable bile duct stone and should be considered as an alternative nonoperative option for the management of difficult CBD stones.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of *P* values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]”. If references are cited directly in the text, they should be put together within the text, for example, “From references^[19,22-24], we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Contents

Weekly Volume 18 Number 26 July 14, 2012

EDITORIAL

- 3331 Time to detoxify medical literature from guideline overdose
Vyas D, Vyas AK

TOPIC HIGHLIGHT

- 3336 Recent advances in small bowel diseases: Part I
Thomson ABR, Chopra A, Clandinin MT, Freeman H
- 3353 Recent advances in small bowel diseases: Part II
Thomson ABR, Chopra A, Clandinin MT, Freeman H

GUIDELINES FOR CLINICAL PRACTICE

- 3375 How can portal vein cavernous transformation cause chronic incomplete biliary obstruction?
Harmanci O, Bayraktar Y

ORIGINAL ARTICLE

- 3379 Acute pancreatitis in aging animals: Loss of pancreatitis-associated protein protection?
Fu S, Stanek A, Mueller CM, Brown NA, Huan C, Bluth MH, Zenilman ME
- 3389 Osteopontin increases hepatocellular carcinoma cell growth in a CD44 dependant manner
Phillips RJ, Helbig KJ, Van der Hoek KH, Seth D, Beard MR

BRIEF ARTICLE

- 3400 Retrograde-viewing device improves adenoma detection rate in colonoscopies for surveillance and diagnostic workup
Siersema PD, Rastogi A, Leufkens AM, Akerman PA, Azzouzi K, Rothstein RI, Vleggaar FP, Repici A, Rando G, Okolo PI, Dewit O, Ignjatovic A, Odstrcil E, East J, Deprez PH, Saunders BP, Kalloo AN, Creel B, Singh V, Lennon AM, DeMarco DC
- 3409 Importance of early diagnosis of pancreaticobiliary maljunction without biliary dilatation
Takuma K, Kamisawa T, Tabata T, Hara S, Kuruma S, Inaba Y, Kurata M, Honda G, Tsuruta K, Horiguchi S, Igarashi Y
- 3415 Effect of sumatriptan on gastric emptying: A crossover study using the BreathID system
Sakamoto Y, Sekino Y, Yamada E, Higurashi T, Ohkubo H, Sakai E, Endo H, Iida H, Nonaka T, Fujita K, Yoneda M, Koide T, Takahashi H, Goto A, Abe Y, Gotoh E, Maeda S, Nakajima A, Inamori M

- 3420 Safety and effectiveness of propofol sedation during and after outpatient colonoscopy
Horiuchi A, Nakayama Y, Kajiyama M, Kato N, Kamijima T, Ichise Y, Tanaka N
- 3426 Efficacy of hepatic arterial infusion chemotherapy in advanced hepatocellular carcinoma
Baek YH, Kim KT, Lee SW, Jeong JS, Park BH, Nam KJ, Cho JH, Kim YH, Roh YH, Lee HS, Choi YM, Han SY
- 3435 Proteomic analysis of glutathione S-transferase isoforms in mouse liver mitochondria
Sun HD, Ru YW, Zhang DJ, Yin SY, Yin L, Xie YY, Guan YF, Liu SQ
- 3443 Anticoagulation therapy prevents portal-splenic vein thrombosis after splenectomy with gastroesophageal devascularization
Lai W, Lu SC, Li GY, Li CY, Wu JS, Guo QL, Wang ML, Li N
- 3451 Uncoupling protein 2 regulates glucagon-like peptide-1 secretion in L-cells
Chen Y, Li ZY, Yang Y, Zhang HJ
- 3458 Phosphoinositide-3-kinase, catalytic, alpha polypeptide RNA interference inhibits growth of colon cancer cell SW948
Huang WS, Wang TB, He Y, Chen YJ, Zhong SL, Tan M
- 3465 Endoscopic therapy for gastric stromal tumors originating from the muscularis propria
Huang LY, Cui J, Liu YX, Wu CR, Yi DL

CASE REPORT

- 3472 Recurrent ischemic strokes in a young celiac woman with *MTHFR* gene mutation
Fabbri E, Rustignoli L, Muscari A, Puddu GM, Guarino M, Rinaldi R, Minguzzi E, Caio G, Zoli M, Volta U

LETTERS TO THE EDITOR

- 3477 Endoscopic diagnosis of Barrett's esophagus
Akiyama T, Sekino Y, Iida H, Koyama S, Gotoh E, Maeda S, Nakajima A, Inamori M

overtreatment, inefficiency, and patient inconvenience. There is an urgent need to restrict articles with Guidelines and develop some strategy like have an intermediate stage of pre-guidelines and after 5-10 years of trials, a systematic launch of the Guidelines. There can be better ways than this for putting together guidelines as has been suggested by multiple authors and researchers.

Vyas D, Vyas AK. Time to detoxify medical literature from guideline overdose. *World J Gastroenterol* 2012; 18(26): 3331-3335 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i26/3331.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i26.3331>

Abstract

The current financial turmoil in the United States has been attributed to multiple reasons including health-care expenditure. Health care spending has increased from 5.7 percent of the gross domestic product (GDP) in 1965 to 16 percent of the GDP in 2004. Healthcare is driven with a goal to provide best possible care available at that period of time. Guidelines are generally assumed to have the high level of certainty and security as conclusions generated by the conventional scientific method leading many clinicians to use guidelines as the final arbiters of care. To provide the standard of care, physicians follow guidelines, proposed by either groups of physicians or various medical societies or government organizations like National Comprehensive Cancer Network. This has led to multiple tests for the patient and has not survived the test of time. This independence leads to lacunae in the standardization of guidelines, hence flooding of literature with multiple guidelines and confusion to patients and physicians and eventually

INTRODUCTION

A well researched guideline will reduce financial burden in United States healthcare. Increasing and excessive health care budget is affecting major industries in the United States. We know it is not the sole cause, but is one of the major reasons for the crisis. A jaw dropping fact is that health care spending has increased from 5.7 percent of the gross domestic product (GDP) in 1965 to 16 percent of the GDP in 2004^[1]. It has been estimated that in 2015, we will be spending close to 20 percent of the GDP, or an estimated \$4 trillion, up from \$1.9 trillion in 2004, on health care^[2]. There is an obvious role of guidelines in reducing healthcare expenditure.

The initial step in systemic review was in 1970 with a perinatal trial^[3]. Although guidelines are intended to assist physicians, this functionality seems frequently lost among the sea of guidelines that are available. Indeed, at any

given point there are frequently multiple guidelines available with regard to a particular disease process, forcing physicians who wish to avoid accusations of undertreatment to order more than one diagnostic study or treatment (polypharmacy) referencing various guidelines. A well researched and tested guideline reduces healthcare cost and mismanaged malpractice lawsuits, and allows for better physician and patient understanding and better parameters for quality control in medical care. Most guidelines indicate that they are not a rule and should not be construed as establishing a legal standard of care.

MULTIPLE TESTING DUE TO MULTIPLE GUIDELINES

Guidelines are generally assumed to have the high level of certainty and security as conclusions generated by the conventional scientific method leading many clinicians to use guidelines as the final arbiters of care^[4] and sense of a shield to malpractice litigation. This has led to multiple tests and it has not survived the test of the time. Fuchs suggested greater expenditures do not necessarily result in better health outcomes^[5]. Guidelines may cause higher utilization of medical tests and procedures and, in some cases, have negative consequences for patients, as in the case of false-positive screening test results^[6].

GUIDELINES AND ITS USE IN MEDICAL MALPRACTICE

Another very compelling reason for its standardization is the use of guidelines in the malpractice lawsuit. Guidelines are frequently used as evidence by expert witness against a physician. It is very hard for judge and jury to understand the quality of evidence, but it easy for them to concur with evidence coming from an expert with a guidelines document.

GUIDELINES AS A TOOL FOR QUALITY MEASURE FOR HOSPITAL AND HEALTHCARE PROVIDER

Guidelines are used as a tool for quality measures. It seems immature to use consensus statements as performance measures or other similar tools to critique the quality of a physician's care. It could be better addressed if it is derived from high-quality guidelines based on the highest level of evidence and derived in a more thoughtful manner. Protocols for quality must include guidelines, but it must have safety and patient care at its core with efficiency also as an outcome parameter. Any project without safety and efficiency is going to fail; hence we much have safecient guidelines.

ROLE OF GUIDELINES IN PATIENT AND PHYSICIAN EDUCATION

Guidelines are the basis of evidence based medicine

(EBM). Guidelines are widely perceived as evidence based, not authority based, and therefore viewed as unbiased and valid. A systematic review uses preplanned scientific protocols and methods to summarize similar but separate studies to perform a scientific investigation for a specific question^[7]. Druss *et al*^[8] are of the opinion to rely more on guidelines due to increase in the quantity of relevant information. Evidence is a very strong word, but it's important to understand how the facts are studied, and realize the biases of studies and researchers. A major responsibility of an educator is to be meticulous with the data collection and near perfect interpretation, but it can, at times, be challenging due to the size of data and variables involved. This is primarily due to an unprecedented explosion of medical knowledge in the past 50 years secondary to breakthroughs in numerous areas of medical science and information technology.

The Institute of Medicine stresses on use of guidelines for medical care to ensure high quality patient care^[9]. Its needed as even the most sophisticated health care consumer has difficulty in deciding appropriate care for his or her condition^[10,11]. Guidelines will assure the patient of adequate and appropriate treatment. Institute of Medicine stresses a need for a strong pertinent guideline for any particular disease. The providers and patients are faced not only with incongruous but also conflicting research findings.

A major reason to stress their implementation is to reduce undesirable practice variation and reduce the use of services that are of minimal or questionable value. National Guidelines Clearinghouse (NGC, established in 1998) is a national body in the United States whose responsibility is to compile a bank of guidelines either by submission or active retrieval thru bodies like National Comprehensive Cancer Network (NCCN) and American Heart Association (AHA). It has established its own submission standards and substandard guidelines are not incorporated. Even then there are at least 500 new guidelines submitted or reviewed every year (Figure 1). Similarly, National Institute of Clinical Excellence (NICE) is established in the United Kingdom, with an objective to standardize the health care by issuing its own guidelines, after studying relevant literature and guidelines available at a given time in point. NICE uses term guidance in place of guidelines.

OVERUSE OF TERM GUIDELINES AND OVERLAPPING GUIDELINES

The term guideline has been drifting far from the original intent of the Institute of Medicine. Unfortunately a major share of current articles called "guidelines" is actually expert consensus reports^[12]. There are interestingly too many guidelines, often on the same topic. For example, clinicians do not need 10 different adult pharyngitis guidelines^[13]. Our information of total guidelines, compiled by NGC, shows there are close to 25% guidelines renewed every year and a disease as localized as breast has an average of more than 30 new guidelines

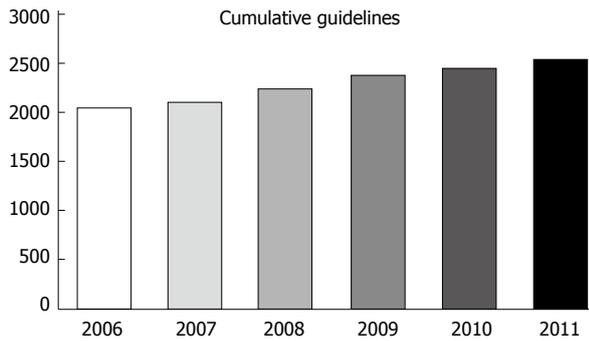

Figure 1 Cumulative number of all guideline summaries published on National Guidelines Clearing House. (Includes prior years) (Information taken from National Guidelines Clearing Annual Reports to Agency for Healthcare Research and Quality) (Source: NGC House, AHQR.com).

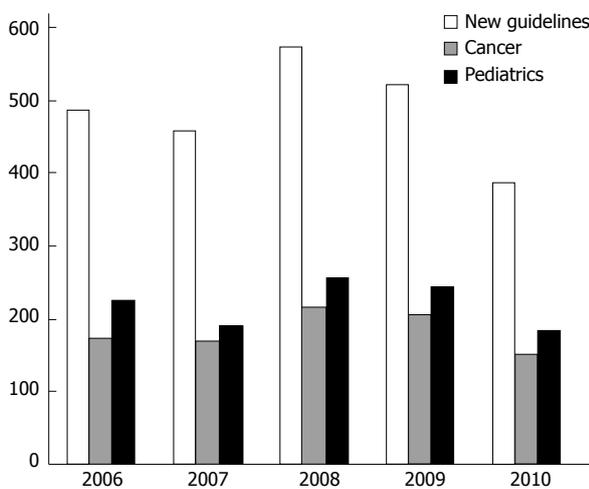

Figure 2 Total number of all new/revise, cancer and pediatrics guideline summaries organized by year of publication/revision. (Includes only that year) (Source: National Guidelines Clearing House, AHQR.com).

every year for last 5 years (Figures 1-3) (source: NGC). In 1999, after 1 year of NGC incorporation, there were total of 290 guidelines, with 82 cancers, 86 pediatrics and 21 and 7 breast and colon guidelines. The total number of guidelines, when this article is published has gone up to 2573 from 2060 in 2006 (source: NGC). This is according to the available information, the best compiled database of guidelines, by any organization internationally. According to their sources, it is possible a large number of guidelines are not even part of this pool.

CONFLICT OF INTEREST AND FACTORS INFLUENCING GUIDELINES

Personal bias has been studied by multiple researchers. In Choudhary's article, eighty-seven percent of authors had some form of interaction with the pharmaceutical industry with only seven percent admitting its influence on their inferences. Fifty-eight percent received financial support to perform research and fifty-five percent of respondents indicated that the guideline process had

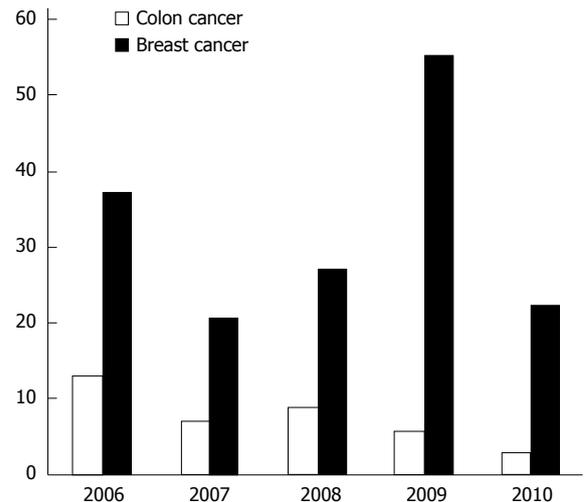

Figure 3 Total number of colon and breast cancer guideline summaries organized by year of publication/revision. (Includes only that year) (Source: National Guidelines Clearing House, AHQR.com).

no formal process for declaring these relationships^[14]. Unfortunately, all guideline committees begin with implicit biases and values affecting their worth^[15]. A very relevant question arises: affect of sponsorship by organizations, personal biases, and absence of restriction by journals, organizations and publishing bodies in using term guideline.

Another reason for the shortcomings in the guidelines is the need for resources to conduct a rigorous systematic review. The resource crunch might push guideline developers to revert to short-cuts or processes centered on expert opinion^[16]. On the contrary, a substantial investment in evidence gathering does not guarantee a sound guideline/evidence for a disease^[17]. Guideline authors often rely on research that are non rigorous, and yield conflicting results^[18]. This leads to pressure to rely more heavily on professional opinion which is problematic.

MULTIPLE GUIDELINES WITH CONFLICTING RECOMMENDATIONS AND QUALITY ISSUES

The exponential increase in guidelines is due to increasing number of research groups, societies, and associations performing analysis of a section of innumerable publications. It constitutes 40%-50% of indexed articles average annual volume. A large section of this growth is in articles on randomized trials and other types of clinical research used to guide evidence-based practice. Unfortunately, we are not seeing consistency in the guidelines issued on major areas of medicine. Contrast the guidelines with the decisions of any court of appeal in which some judgments are issued unanimously but most are not. Although unanimity is the rule in individual guidelines, it can be strikingly absent when different guidelines are compared.

Table 1 A simplistic presentation of conflicting statements in mammography and clinical breast examination by multiple authorities in last few years

Yr	Age for first mammogram	Recommending authority	Frequency	Clinical breast exam
2001	50-69 yr	Canadian Task Force	1-2 yr	1-3 yr
2003	40-49 yr (1-2 yr) > 50 yr (annually)	ACOG	As in column 2	Annually after 20 yr
2007	40-49 yr (individualize) 50-74 yr (1-2 yr)	ACP	As in column 2	No statement
2009	40-49 yr (individualize) 50-74 yr (2 yr)	USPSTF	2 yr	Insufficient evidence
2010	40 yr and above	American Cancer Society	Annually	20-40 yr every 3 yr and then annually
2011		NCCN		
2010	40 yr	NCI	1-2 yr	No statement
2011	47-73 yr	NHS, United Kingdom	3 yr	No statement

ACOG: American College of Obstetrics and Gynecology; ACP: American College of Physicians; USPSTF: United States Preventive Services Task Force; NCCN: National Comprehensive Cancer Network; NCI: National Cancer Institute; NHS: National Health Services.

EXAMPLES OF MEDICAL PRACTICE WITHOUT VALIDATION

It seems like we have come a full circle. The role of evidence-based practice, medical textbooks and editorials is to filter the literature filled with thousands of statements (based solely on the belief of the author or at best a consensus of experts)^[19].

In an article on guidelines on management of pharyngitis, review of 4 North American and 6 European guidelines were included, and recommendations were found to go tangential to each other with regard to the use of a rapid antigen test and throat culture and the indication for antibiotics^[13]. The reason for conflict is use of different data sets by different organizations. It has been suggested that guidelines are not necessary for every disease but are needed for diseases having significant practice variability and for which a valid evidence base can guide recommendations. They also suggested prioritizing individual recommendations^[12].

A simple example is commonly used guidelines issued by cardiology organization, American College of Cardiology (ACC)/AHA guidelines. It is largely developed from lower levels of evidence or expert opinion^[20]. It is flawed as it does not appear to follow the Institute of Medicine recommendations to separate the systematic review process from guideline formulation. According to the author, less than twenty percent of recommendations advocating a particular procedure or treatment in ACC/AHA practice guidelines are based on level A evidence. In another study of quality of recommendation, less than 45% recommendations in guidelines are based on high quality evidence^[21]. These studies bring a very valid question to the rational of application of evidence based medicine, when evidence itself is weak.

Another example of rapid turnover and too early update is due to the pressure of incorporating the development in technology to clinical arena without due research is inclusion of immunohistochemistry results in a sentinel lymph node specimen in cancer. This was used in tumor node metastasis staging and was withdrawn after

a short time. Situations like this make us wonder if we should make a pre-guideline of the results for a period of time and evaluate the data for its implication before incorporating the results for mass application. A similar example is withdrawal of hormone replacement therapy (HRT) in menopausal females. HRT was initially thought (1995) to have more benefits and no absolute contraindications or major risks, but after its aggressive introduction and urgency for compliance, increased incidence of hormone related side effects like lethal breast cancer, ovarian cancer and stroke persuaded clinical bodies to withdraw the major recommendations of guidelines for HRT therapy. Another example is a simplistic tabulation of guidelines on mammography. There are five guidelines from the leading medical organizations in last two years with highly conflicting recommendations, except for almost identical recommendations from NCCN and American Cancer Society. Similarly, the guidelines for colonoscopy have huge conflicts, except the frequency of every 10 years. This has not been challenged for last 40 years, even though this is based on a very flimsy theory. Clinicians and researchers are still struggling to identify appropriate intervals for colonoscopy in low risk patients, although there is some progress in identifying patients needing early colonoscopy (Table 1).

SOME OPTIONS TO MAKE GUIDELINES MORE ROBUST

Differentiating effective and ineffective health resource utilization is an important health policy objective. There are multiple articles suggesting their opinion of the subject. This awkward situation can be partially resolved by training physicians in biostatistics, a necessary tool to interpret the findings of published clinical research^[22]. At this point in time, the processes underlying guideline development is often vulnerable to bias and conflict of interest leading to sometimes poor quality. Grimshaw and group suggested a standardized and more diverse panel of physicians with competing interest with minimal bias^[23]. Another group suggested two separate grading

systems: (1) Quality of the evidence; and (2) Recommendations^[24]. We don't believe this will fix the state of affairs, but can definitely be one of the constructive steps. Another reason for streamlining the process is health quality measure reliance on guidelines. The NGC has thousands of guidelines produced by close to 300 organizations^[25] underlining the need for urgent streamlining.

A more radical thought is to reject them unless there is evidence of appropriate changes in the guideline process. Physicians will make better clinical decisions based on valid primary data^[12]. Another option is to update guideline after every 7-10 years or more if not much new data present and in areas of active research supplementing literature with pre-guidelines every 3-4 years. Also there can be a journal on guidelines where researchers can submit their opinion at the time of issues due date. And all the facts are incorporated and a final suggestion is given by the panel selected from the contributors and other established experts.

In summary, EBM is complex and incomplete. Guidelines must be directed only to the interests of patients and not to those who profit from them^[4].

Abstract

As is the case in all parts of gastroenterology and hepatology, there have been many advances in our knowledge and understanding of small intestinal diseases. Over 1000 publications were reviewed for 2008 and 2009, and the important advances in basic science as well as clinical applications were considered. In Part I of this Editorial Review, seven topics are considered: intestinal development; proliferation and repair; intestinal permeability; microbionics, infectious diarrhea and probiotics; diarrhea; salt and water absorption; necrotizing enterocolitis; and immunology/allergy. These topics were chosen because of their importance to the practicing physician.

INTESTINAL DEVELOPMENT

The development of the small intestine and its implications for nutritional support has been reviewed previously^[1]. The mucosa of the small intestine has many functions other than nutrient absorption and fluid secretion. These functions include host defense and immune responses. All of these small intestinal functions may be influenced by diet as well as by the intestinal microbionics, and may also be developmentally regulated.

At birth, there is rapid colonization of the intestinal lumen of the neonate, both with bacteria from the mother's milk, such as Gram-positive lactobacilli and bifidobacteria, and colonization with Gram-negative anaerobic bacteria. These bacteria are essential for growth and development of the gastrointestinal (GI) tract. In response to luminal microorganisms, intestinal Paneth cells produce microbicidal peptides, such as α -defensin. Paneth cells differentiate while migrating towards the crypt base, where these cells are eventually cleared by phagocytosis. In addition to the importance of Paneth cells in the innate immune defense against microorganisms, they are also involved in intestinal angiogenesis.

There is a complex interaction between bacteria in the intestinal lumen, the epithelial surface, and the underlying matrix, immune cells and enteric nervous system.

Enterocytes sense pathogenic bacteria, occupy the Toll-like receptors (TLRs) in response to their activation *via* pathogen-associated molecular patterns (PAMPs), leading to nuclear factor (NF)- κ B activation. Pattern recognition molecules (PRMs) detect any conserved bacterial products. PRMs, such as TLRs and nucleotide-binding oligomerization domain containing (NOD) receptors, are further important regulators of the intestinal barrier. TLRs are pattern-recognition receptors (PRRs) expressed by immune and nonimmune cells that signal in response to PAMPs expressed by bacteria in the intestinal lumen. Most TLR molecules signal through the adapter molecule MyD88 to interleukin (IL)-1-receptor-associated kinase. MyD88 activates the NF- κ B pathway, which is a critical regulator of tumor necrosis factor (TNF)- α and IL-1 β . Deficiency in MyD88 increases susceptibility to bowel inflammation, presumably by increasing brush border membrane (BBM) permeability. TLR ligands alter the properties of the intestinal barrier by redistributing zonula occludens (ZO)-1 and β -defensin 2. Cyclooxygenase-2-derived prostaglandin (PG)E₂ is important in TLR mucosal repair^[2].

When a child is born prematurely, its intestine is also premature, and is potentially ill-prepared for the extrauterine environment and contact with food bacteria. Microbial manipulation with antibiotic treatment or exposure of the pregnant rat dam to *Escherichia coli* (*E. coli*) results in long-lasting and potentially adverse effects on postnatal microbionics of the offspring^[3]. PAMPs produce an intestinal immune response through interaction with PRRs, including the TLRs. Transmembrane signaling may occur through TLRs^[4]. TLRs trigger signaling pathways which lead to NF- κ B activation and propagation of inflammatory responses. In addition to exogenous inflammatory mediators, TNF- α as well as IL-1 β trigger cytokine production through activation of this NF- κ B pathway. The NF- κ B proteins activate transcription, resulting in immune and inflammatory responses.

Intestinal alkaline phosphatase (AP) detoxifies lipopolysaccharide (LPS) by hydrolyzing it so that it can no longer activate TLR-dependent inflammatory responses^[5,6]. AP is involved in maintenance of homeostasis between the luminal bacterial microbionics and the body^[5,6]. About two-thirds of persons taking short or long courses of nonsteroidal anti-inflammatory drugs (NSAIDs) develop small intestinal damage. The NSAID diclofenac may induce enteropathy by way of the c-Jun-N-terminal kinase (JNK) pathway^[7]. This concept of stress-related changes in intestinal barrier and secretory function has therapeutic implications, as does the potential of JNK inhibitors to protect the GI tract from the damage of NSAIDs. For example, the NSAID indomethacin may enter the small intestine through a TLR4/MyD88-dependent pathway^[8]. In animals with stress as a result of immobilization, there will be an increase in TNF- α along with an increase in tight junction (TJ) permeability. These permeability changes are associated with alteration in the TJ proteins ZO-1, claudin-2, claudin-4, claudin-5, and β -catenin^[9].

IL-8 secretion in response to bacteria, IL-1 β and TNF- α are increased more in human fetal small intestinal epithelial cells than in older children or adults. This increased activation of NF- κ B DNA binding and transcriptional activity is due to reduced inhibition of signaling, resulting in increased phosphorylation, ubiquitination and degradation of the inhibitor of NF- κ B, in conjunction with decreased baseline expression and delayed resynthesis of this inhibitor^[10]. This represents a mechanism explaining the enhanced inflammatory response occurring in immature intestinal tissue.

The intestinal epithelial stem cells (ISCs) reside in the crypts of Lieberkuhn, giving rise to five daughter cell lines: Paneth cells, enterocytes, goblet cells, enteroendocrine cells, and M cells. In the upper third of the intestinal crypt, daughter cells differentiate into enterocytes, goblet cells, enterochromaffin cells, and Paneth cells. The Hedgehog platelet-derived growth factor and bone morphogenetic protein (BMP) signaling pathway are key mediators in morphogenesis of the intestinal villi and crypts, and maintain tenancy of ISCs. The ISCs are of two types: the fast cycling "crypt base columnar" (CBC) cells residing among the Paneth cells at the base of the crypt, and the slow cycling ISCs above the Paneth cells (+4ISC). Only one clonogenic cell is needed to regenerate a crypt and to maintain the appropriate number of crypts after injury. It is the +4ISCs that are highly sensitive to modulation and to chemotherapeutic agents such as doxorubicin^[11]. The ISCs produce progenitor cells, which form the enterocytes, goblet cells, enteroendocrine cells, and Paneth cells. Paneth cells are a major component of the innate immunity in the intestine, releasing granules containing β -defensins, matrix metalloproteinase-7, synovial phospholipase A₂, and lysozyme. Colony stimulating factor (CSF)1 acts in a direct juxtacrine/paracrine fashion, or acts indirectly through macrophages in the lamina propria, to regulate Paneth cell development^[12]. Fibroblast growth factor receptor (FGFR)-3 acts on the ISCs in the lower portion of the crypts to signal through both the β -catenin/Tcf-4 dependent and independent pathways, the expansion of the ISCs, expanding ISCs and crypt macrophages, including Paneth cells^[13]. The behavior of ISCs is regulated by canonical Wnt signals. Inhibition of Wnt signaling reduces epithelial proliferation in adult mouse intestine. In the developing intestine, the relationships among Wnt signaling, epithelial proliferation, and tissue differentiation are reversed^[14].

The intestinal epithelium is renewed through a series of programmed developmental transitions in the form and function of the intestine. For example, lactase-phlorizin hydrolase (LPH), fatty acid binding protein (Fabp1), and sucrase-isomaltase (SI) are intestinal proteins that are important for nutrition during different stages of development. LPH hydrolyzes milk lactose, SI hydrolyzes α -saccharidases, and Fabp1 is a cytoplasmic protein important for intracellular lipid transport. A member of the zinc finger transcription factor family (Gata4) and the hepatocyte nuclear factor α 1 (Hnf1 α) are essential for

LPH and Fabp1 gene expression but they do not mediate the glucocorticoid-induced precocious maturation of the intestine. Rather, specific intestinal genes have differential requirements for Gata4 and Hnf1 α , and these genes are dependent on the developmental time-frame in which each gene is expressed^[15].

Protective factors for the intestinal epithelium include secretion of mucins, as well as IgA and defensin peptides that are produced from epithelial cells. Epithelial cells also produce cytoprotective stress proteins, such as heat shock proteins (HSPs). N-formylmethionyl-leucyl-phenylalanine (fMLP) is a tripeptide produced by many enterobacteria as a by-product of protein synthesis. fMLP is a chemotactic agent from neutrophils and may be proinflammatory in nature. fMLP induces expression of HSPs and inhibits activation of the proinflammatory transcription factor NF- κ B^[16]. This finding needs to be translated to a clinical application.

Amniotic fluid and breast milk contain intestinal trophic factors that stimulate enterocyte development, and enhance various intestinal defense processes. Hydrocortisone is a trophic factor that is present in large amounts in human breast milk. Hydrocortisone reduces the cholera toxin (CT)-induced secretory response observed in fetal human small intestinal epithelial T84 cells, by inducing a pathway change from a clathrin-mediated to a caveolae-mediated endocytic process^[17]. Hydrocortisone also increases ganglioside/lipid raft association, which may also reduce intestinal secretion.

Dietary fat in mother's milk is a major modifiable environmental factor that influences intestinal growth and development of the baby. The n-6 fatty acid, linoleic acid, is the metabolic precursor for synthesis of arachidonic acid (ARA). α -linolenic acid is a precursor for synthesis of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Eicosanoids derived from ARA are proinflammatory, whereas the n-3 fatty-acid-derived metabolites are anti-inflammatory. EPA and DHA have direct effects on intestinal cells through gene expression and ion channels, as well as on G-coupled protein receptor activities. As a result of the potential for dietary substances to affect normal growth and development of neonatal intestine, the consumption of early-life non-maternal milk products must be undertaken with the greatest of care.

In adult animals, glucagon-like peptide (GLP)-2 has a trophic effect on the intestine, and enhances nutrient absorption. In contrast, in young animals, there is malabsorption of several lipids with GLP-2 or GLP-2 plus dexamethasone, but not with dexamethasone itself^[18]. The loss of body weight and jejunal atrophy induced by dexamethasone is prevented by giving GLP-2. Giving dexamethasone or GLP-2 and dexamethasone to lactating rat dams enhances glucose and lipid uptake in their suckling offspring^[19].

The premature human neonate has higher fasting levels of GLP-1 and GLP-2 compared to adults, and feeding increases these levels even further^[20]. GLP-2 levels are correlated with residual small intestinal length in the

infant with nutrient malabsorption following intestinal surgery^[21]. GLP-2 levels are directly correlated with absorption of fat, carbohydrate, and protein.

In suckling rats, GLP-2 plus dexamethasone increased the maximal transport rate (V_{MAX}) for jejunal glucose uptake, and the combination of these may be useful in stimulating glucose uptake in the developing intestine^[22]. In suckling animals, dexamethasone reduces jejunal lipid uptake to levels similar to those seen in weanling animals. Giving dams GLP-2 or dexamethasone during pregnancy and lactation reduces lipid uptake in the offspring, and this reduction persists for at least 1 mo^[23]. The impact this may have on the nutritional wellbeing of the animal in later life is unknown. This important consideration needs to be explored in terms of its long-term implications if nursing mother or child were to be exposed to steroids or GLP-2.

PROLIFERATION AND REPAIR

Homeostasis of the intestine is balanced between the process of proliferation, migration, differentiation, mitosis and apoptosis. Remodeling of the epithelium results from cell-matrix and cell-cell contacts. The proliferating regions are usually maintained by Wnt/ β -catenin signaling, whereas differentiation is regulated by BMP, transforming growth factor (TGF)- β , and Hedgehog signaling. These interact within the stem and progenitor cells in the lower regions of the intestinal crypts, and regulate the expansion and cell fate decision of the interstitial epithelial cells (IECs). Several proteins involved in the contact between cells act as the source (i.e., Notch signaling, which regulates the development of enterocytes)^[24] or the downstream effectors of signaling pathways such as E-cadherin/ β -catenin. Notch signaling regulates the formation of the Epcrin-B2-positive proliferating crypt cells, as well as the Ephrin-B1-positive differentiated cells^[25].

Homeostasis of the intestinal epithelium is a dynamic process created by a balance between proliferation, differentiation and apoptosis. This process is regulated by luminal nutrients, hormones, growth factors and cytokines. When acute damage is done to the GI tract, the usual repair process does not involve proliferation, but rather involves mucosal restitution. Restitution occurs by epithelial cell migration to reseal the superficial wound. Polyamines are involved in stimulation of intestinal epithelial cell migration during restitution. These polyamines (including spermidine, spermine, and precursor, putrescine) regulate calcium homeostasis by inducing alterations in cytosolic free Ca²⁺ concentration. Phospholipase C (PLC)- γ 1 modulates calcium store mobilization and calcium influx, thereby promoting intestinal epithelial restitution after wounding^[26].

Especially early in life, the BBM of the enterocyte is involved in the process of endocytosis, in which a tiny portion of membrane forms a bud around a luminal constituent, and breaks away from the rest of the BBM. This

hole in the remaining BBM must be quickly repaired. The subapical terminal web cytoskeleton inhibits movement of endosomes, and thereby helps to maintain permeability characteristics of the epithelium by keeping the endocytic activity occurring at the BBM under regulated control^[27].

Differential display and microarray analyses have been used to identify genes that may be involved in molecular mechanisms regulating proliferation and differentiation of the intestinal epithelium^[28]. Examples of transcription factors include the BMP expressed in the mesenchyme, Wnt which is essential for regulation of crypt stem cell proliferation and maintenance, and Notch signaling within the epithelium influencing differentiation of enterocytes, goblet cells, Paneth cells and enteroendocrine cells.

Glutamine is an amino acid that is the preferred fuel source for enterocytes. Glutamine activates extracellular signal-regulated kinase (ERK) and inhibits phosphorylated Akt, suggesting that ERK has an important role in the glutamine-mediated intestinal homeostasis^[29]. Activation of phosphoinositide 3-kinase (PI3K)/Akt during periods of glutamine deprivation limits apoptosis, and thereby may have a protective role. Glutamine-response genes influence the expression of a number of signaling pathways such as NF- κ B^[30] and peroxisome proliferator-activated receptor (PPAR) α ^[31]. This potential basis for protection with glutamine, for example, in necrotizing enterocolitis, remains to be tested.

The Notch signaling pathway is essential for the development of enterocytes, and the Wnt cascade is required for the development of Paneth, goblet and enteroendocrine cells (secretory lineage). The commitment of crypt stem cells to differentiate into enterocytes reduces the differentiation of these secretory cells. This interaction by Notch to activate the Hes1 transcription factor, which then blocks the MATH1 transcription factor, influences the Ets-domain transcription factor Spdef, thereby blocking steps in the differentiation of the stem cells into the secretory lineage^[32].

Notch, Wnt and Hedgehog signaling pathways are involved in epithelial cell proliferation and differentiation. Indian hedgehog (Ihh) is a signal sent by mature Paneth cells to their stem cell precursors, negatively regulating their differentiation. PPAR β is a nuclear hormone receptor activated by fatty acids in the intestinal lumen. PPAR β acts on Paneth cell homeostasis by downregulating expression of Ihh^[33]. Hedgehog proteins are members of a family of secreted signaling factors that orchestrate development of many organs and tissues, including those of the GI tract^[34]. In addition to epithelial differentiation being influenced by this variety of signaling cascades, amino acids and carbohydrates regulate gene expression and cellular function. For example, coenzyme A (CoA)-thioester derivatives contribute to cellular renewal along the crypt-villus axis in human small intestine^[35].

The Wnt/ β -catenin pathway involves molecules secreted by the mesenchyme, and controls proliferation and migration of enterocytes and Paneth cells. Transcription

regulators such as the CDX2 and CDX3 homeoproteins, members of the homeobox gene family of transcription factors, activate several intestine-specific genes such as SI and LPH, as well as the adhesion proteins L1-cadherin and claudin-2. Furin is a calcium-dependent serine protease which processes many proteins such as BMP-4, the insulin receptor, the Notch1 receptor, and the cell adhesion protein E-cadherin. CDX2 regulates furin expression in intestinal epithelial cells^[36]. Hepatocyte growth factor-1 α cooperates with CDX2, and regulates transcription of SI, LPH, claudin-2, calbindin 3 and liver Fabp1 gene^[37]. The crosstalk between lamina propria lymphocytes and intestinal epithelial cells may also be mediated by keratinocyte growth factor (KGF), such that lymphoepithelial interactions may both promote barrier function as well as regulate mucosal immune responses^[38].

Mitogen-activated protein kinases (MAPKs) and PI3K are activated in a cascade-like fashion by various growth factors. Three of the MAPKs that have been identified include ERK, JNK and p38 MAPK. Rac1 also mediates apoptosis irrespective of ERK1/2 and Akt activation^[39]. Signaling cascades such as the NF- κ B and MAPK pathways provide transcriptional activation of inflammatory mediators such as chemokines, adhesion molecules and antibacterial peptides. In addition, reactive oxygen species (ROS) are important mediators in cellular signal transduction cascades regulating proliferation, apoptosis and migration. TNF- α is an inducer of apoptosis that requires the small GTPase Rac1, which has a role in the control of ROS production^[40]. Protein-tyrosine kinase 6 (PTK6) is a stress-reduced kinase that promotes differentiation, and is a target of the serine threonine kinase AKT. After DNA damage, PTK6 is induced to promote apoptosis^[11].

The intestinal mucosa is constantly being deformed by peristalsis, movement of the villi, and passage of chyme along the surface of the intestine. This strain by a variety of signals stimulates the migration of epithelial cells across fibronectin [such as Scn, focal adhesion kinase (FAK), and ERKs]^[41].

INTESTINAL PERMEABILITY

The intestinal BBM of enterocytes constitutes the small intestinal epithelial barrier, which helps to protect the body against invasion by millions of luminal bacteria. This barrier function is a balance between the bacterial microbionota, and homeostasis provided by the preservation of the integrity of the BBM. TJs, innate immune cell function, and microbial peptides are important in establishing and maintaining this barrier integrity.

Modifications in NOD2 alter intestinal homeostasis, and may be associated in some individuals with chronic intestinal inflammation. PRMs, TLRs and NOD receptors are regulators of the intestinal epithelial barrier, which is essential along with innate immune cells and antimicrobial peptides, to maintain normal intestinal permeability^[42].

TJs between the intestinal epithelial cells provide a dynamic structure, altering cellular permeability. TJs are

formed by organization of a number of specific proteins including occludin, ZO-1, ZO-2, ZO-3, claudins, and junctional adhesion molecules. Mucosal hydration occurs through activation of ion channels and transporters, as well as through secretion of mucous and antibacterial protein. These are additional defense pathways against pathogens^[43]. Under some circumstances such as intestinal ischemia, there may be increased mucosal penetration and translocation of bacteria, as well as transcytotic movement of bacteria through intestinal epithelium by way of lipid rafts. This movement of bacteria across the disrupted intestinal barrier may precede cytokine-induced disruption of TJs^[44].

Adherens junctions (AJs) are a major part of the junctional complexes. The main transmembrane protein of AJ is E-cadherin. E-cadherin mediates adhesion or anchorage of the enterocytes to the matrix by a process that is Ca²⁺-dependent. Epidermal growth factor receptor (EGFR) is induced in the process by which there is deprivation of the E-cadherin-dependent junctions, and enterocytes lose their interactions with the basal lamina. This leads to anoikis, a form of apoptosis caused by the loss of cell anchorage^[45]. Symplekin is also a component of the TJ cytoskeletal plaques. Symplekin co-operates with the transcription factor ZONAB to regulate negatively the differentiation of goblet cells in the intestine^[46].

Mast cells (MCs) in the lamina propria contain both preformed bioactive mediators such as tryptases and histamine, as well as synthesized mediators like prostanoids and leukotrienes. MCs express corticotrophin-releasing factor receptor 1 (CRFr1) and CRF receptor 2 (CRFr2), G-protein-coupled corticotrophin-releasing factor receptors^[47]. In pigs, when CRFr1 is activated during early weaning stress in pigs, the epithelial barrier becomes leaky, whereas CRFr2 may be protective.

When the serotonin reuptake transporter (SERT) is lost, there is enhanced intestinal translocation of bacterial endotoxin in a murine model of chronic increased intake of fructose^[48].

The permeability of the intestinal mucosa is determined by the relative balance of uptake from the intestinal lumen, across the BBM and into the cytosol of the enterocyte, and efflux from the cytosol across the BBM and into the lumen, through transporters such as P-glycoprotein (P-gp; ABCB1), multidrug resistance-associated protein 2 (MRP2; ABCG2), and breast cancer resistance protein (BCRP; ABCG2). Changes in the activity of these efflux transporters will modify net drug absorption. For example, sulfasalazine uptake across the BBM is adequate, but sulfasalazine may be transported out of the enterocytes (efflux) by MRP2 and BCRP, contributing to the apparent low permeability of the small intestine to this drug^[49].

The transport and barrier properties of the intestinal epithelium are regulated, influenced by food and the microbionics that colonize mucus overlying the epithelium. Epithelial transport mechanisms are present to regulate the long-term adaptation of intestinal function. Specific

molecular components of TJs decrease or increase transepithelial resistance^[50]. In enterocytes in the upper portion of intestinal crypts, there are cell cycle promoting and inhibiting genes, as well as transcription/translation related genes. In the enterocytes, in the middle of the villi, there are metabolism-related genes, and vesicle/transport-related genes^[51].

Stressful events will increase intestinal permeability to macromolecules, deplete intestinal mucus, and alter interaction of bacteria in the intestinal lumen with the intestinal epithelial cells. Stress may even lead to inflammation, bacterial invasion of the mucosa, as well as T-cell activation. The disturbance of epithelial cell kinetics depends on the duration of the stress. The stress-induced increase of intestinal permeability may be related to an increased number of apoptotic cells in the epithelium^[52]. Perfusion of a jejunal segment in persons with low *vs* moderate background stress (called “pain stress”), results in an increase in chloride-related peak secretory response, as well as enhanced permeability to albumin^[53].

In addition to glucocorticoid-induced precocious maturation of the intestine, “stress” may also play a role in disease susceptibility through its actions on CRF, and subsequent activation of CRF receptors expressed locally in the intestine. It is predominantly the CRF-r1 activation that alters intestinal function in times of stress. One such type of stress in the developing animal is weaning, when the increased intestinal permeability and secretory activity are mediated by the intestinal CRF receptors. This is possibly through activation of enteric neural and PG synthesis pathways in weaned intestinal tissues^[54].

In humans, the increased intestinal permeability due to the acute effects of radiotherapy may be reflected by increased fecal excretion of DHA and calprotectin^[55]. From 50% to 70% of NSAID users have damage to the GI tract beyond the stomach. When capsule endoscopy, fecal calprotectin measurement, and urinary recovery of orally administered lactulose and mannitol are used, about half of NSAID users will have defects in the small bowel^[56].

The TJ (also known as the zonula occludens) has both a gate function (regulating the passage of molecules through the paracellular pathway), and a fence function. In some intestinal disorders, the permeability of the intestine may increase (“leaky” TJs), and endogenous PPAR β ligands may reduce the degree of TJ permeability, thereby reducing the degree of leakiness^[56]. This raises the therapeutic potential of using PPAR β ligands to correct the “leaky gut”. Adrenomedullin (AM) may also prove to be useful to reduce intestinal permeability. AM is a 52-amino-acid peptide formed in the mucosa. AM increases cAMP, activates protein kinase (PK)A, and stabilizes the barrier function of the intestine (i.e., prevents increased permeability and decreases leakiness^[57]). EGF binds to its receptor, and improves epithelial barrier function (i.e., decreases intestinal permeability). During sepsis there is barrier dysfunction, increased apoptosis, and higher levels of cytokines. Potentially all of these may lead to multiple

organ failure. Systemic EGF prevents peritonitis-induced intestinal barrier dysfunction^[58], and may thereby reduce mortality from noninfectious inflammation and intestinal injury. It remains to be established whether this modification of intestinal permeability will have any therapeutic benefits in humans.

MICROBIOTICA, INFECTIOUS DIARRHEA AND PROBIOTICS

Probiotics

The World Health Organization defines probiotics as “live microorganisms which, when consumed in adequate amounts as part of food, confer a health benefit on the host”. Probiotic therapy has been used for traveler’s diarrhea, to prevent antibiotic-associated diarrhea, and to prevent relapse of pouchitis (after colectomy and ileoanal pouch formation). *Lactobacillus rhamnosus* GG (LGG) is a probiotic bacteria that prevents cytokine-induced apoptosis by way of two LGG-produced viable proteins p75 and p40. These activate Akt and regulate intestinal epithelial cells as well as antiapoptotic responses by a PKC-MAPK-dependent mechanism^[59]. The clinically tested VSL#3 probiotic formula and its secreted components may augment the protective mucus layer through MUC2 gene expression^[60]. Treating infectious diarrhea in children with *L. rhamnosus* shortens the duration of diarrhea, and also reduces the duration of the need for parental rehydration^[61].

A meta-analysis of five randomized controlled trials of *Saccharomyces boulardii* has shown moderate effectiveness in preventing antibiotic-associated diarrhea (AAD) in children and adults. *S. boulardii* reduced the risk of AAD from 17% to 7%, with the number needed to treat to prevent one case of AAD being only 10^[62].

The probiotic bacterium *Lactobacillus casei* strain Shirota (LCS) suppresses the LPS/TLR4 signaling pathway and prevents indomethacin-induced intestinal injury, possibly by way of the production of lactic acid^[63]. The nonpathogenic yeast *S. baoulardii* inhibits EGFR and thereby also inhibits the downstream ERK1/2 MAPK pathway^[64]. This raises the possibility that *S. baoulardii* may have both anti-inflammatory and antineoplastic therapeutic potential.

It will soon be possible to target the human microbiome with antibiotics, probiotics and prebiotics. “Culture-independent strategies such as high-throughput parallel sequencing and comparative genomes, metabolic proliferating and functional genomes, fluorescence *in situ* hybridization, and phylogenetic microarrays will provide new insights into the composition, architecture and functional roles of the human microbiota”^[65].

A therapeutic approach to enteric infections is to express molecular mimics of toxin receptors on the surface of harmless bacteria, so that the toxin binds to the bacterium rather than to its natural target, the intestinal mucosa. This strategy using molecular mimicry has been used to develop recombinant probiotics for treatment and prevention of diarrheal disease caused by enterotoxigenic

E. coli^[66], and for prophylaxis and treatment of cholera^[67].

Infections

The protozoon *Giardia lamblia* is a human GI parasite that is common in Western Europe and in North America. Some 15% of infected individuals develop chronic symptomatic disease. *G. lamblia* infection increases intestinal permeability due to downregulation of TJ occludin 1, reduced sodium-dependant glucose absorption, and by increased epithelial apoptosis, as well as increased active electrogenic anion secretion^[68]. Exposure to DDT, organochlorine, reduces the efficacy of treatment of mice with experimental giardiasis^[69].

Cyclospora responds variably to albendazole^[70]. Nitazoxanide is effective in treating diarrhea and enteritis caused by *Cryptosporidium* in immunodeficient as well as non-immunodeficient patients aged ≥ 12 years^[71].

The synthesis of NO is increased in infectious diarrhea, but its physiological role is unknown. Inducible NO synthase (iNOS) is constitutively expressed by the intestinal villous cells. After acute injury of the intestinal epithelium rapidly induces iNOS and synthesizes NO. The induction of iNOS in response to neonatal piglet *Cryptosporidium parvum* is a nonspecific response^[72].

Campylobacter spp. are a common cause of diarrhea in developing countries. They causes mild to severe bloody diarrhea, chronic relapsing infection, and invasion of the mucosa. This may be associated with extraintestinal complications such as neuropathy in the peripheral nervous system, (e.g., Guillian Barré syndrome). Norepinephrine (NE) is present in high concentrations in the noradrenergic neurons in the intestine. Exposure to NE increases the virulence-associated properties of *Campylobacter*^[73]. This suggests that microorganisms may have evolved a “sense and respond” system. The evidence linking inflammatory bowel disease (IBD) and *Campylobacter jejuni* infection has been reviewed^[74].

Diarrhea in the traveler may be termed “traveler’s diarrhea,” therefore, detection of bacterial enteropathogens is not uniform. When diarrhea occurs in travelers, ciprofloxacin (500 mg *bid* for 3 d), levofloxacin (500 mg *qid* for 3 d), rifaximin (200 mg *qid* for 3 d), or azithromycin (1000 mg, single dose) should be taken in conjunction with an anti-diarrheal agent^[75]. Indeed, there is an advantage of adding loperamide to fluoroquinolone, rifaximin, and azithromycin treatment of traveler’s diarrhea. Two new antisecretory drugs that have been shown to be useful for reducing stool frequency of traveler’s diarrhea including crofelemer, a chloride channel blocker^[76], and zaldaride, a calmodulin inhibitor^[77]. Racecadotil, an enkephalinase inhibitor, may also be useful for the treatment of acute diarrhea^[78-80].

Vibrio cholerae secretes CT, which binds to mucosal enterochromaffin cells, and release large amounts of 5-hydroxytryptamine (5-HT). The sustained hyperexcitability of CT on the submucosal secretomotor neuronal pathway depends on 5-HT₃, and nicotinic receptors^[81]. The small GTP-binding proteins increase the CT-catalyzed ADP-ribosylation of the heterotrimeric guanine nucleo-

tide-binding (G) protein Gs β . There is increased susceptibility of neonates to infectious diarrhea. For example, there is increased uptake of CT by a developmentally regulated clathrin-endocytic pathway. Immature human enterocytes, DRF1, play a role in clathrin-mediated CT trafficking through the endoplasmic reticulum and Golgi, and ARF6 enhances Gs β activation by CT^[82].

Shiga toxin (Stx) 1 and 2 are virulence factors for noninvasive enterohemorrhagic *E. coli* (EHEC) infection, such as by *E. coli* 0157:H7 infection. Stx is taken up by microendocytosis in cells that lack the Stx1 receptor, mediated by Gc3 on the BBM^[83].

Clostridium difficile accounts for 15%-25% of episodes of AAD. Methicillin-resistant *Staphylococcus aureus* (MRSA), and particularly the enterotoxin-producing strains, may also cause nosocomial AAD^[84].

Rotavirus is the major cause of life-threatening diarrheal disease in infants and young children. Rotavirus-induced diarrhea can be prevented by use of a live-attenuated vaccine^[85]. Following acute mucosal injury such as from rotavirus infection, there is enterocyte migration that is proliferation-independent. This restitution or migration of cells requires NO, PGs and polyamines. Acute regulation of protein synthesis is achieved through changes in the rates of translation of mRNA, by way of alterations in peptide chain initiation. This chain initiation process is influenced by mammalian target of rapamycin (mTOR). mTOR is an amino acid-sensing mechanism that targets ribosomal p70 S6 kinase (p70^{S6K}). p70^{S6K} is activated during an active state of mucosal regeneration produced by a piglet rotavirus enteritis^[86].

The etiologic agent of Whipple's disease (WD) is *Tropheryma whipplei*, a PAS-positive, rod-shaped actinomycete. Some healthy persons harbor *T. whipplei* in their bowel, and there is no correlation between *T. whipplei* genotypes and clinical manifestations. The cumulative odds ratio (OR) for disease are 2.23 for the HLA-DRB1 X 13 allele, and 2.25 for the DBQ1*06 allele^[87]. A randomized controlled trial of 40 persons with previously untreated WD showed that daily infusions of ceftriaxone 1 \times 2 g or meropenem 3 \times 1 g for 14 d, followed by 12 mg oral trimethoprim-sulfamethoxazole, both gave an OR of 0.95 for remission for at least 3 years^[88]. One patient with asymptomatic cerebrospinal fluid infection with WD was resistant to ceftriaxone and to meropenem, but responded to chloroquine and minocycline. This compares favorably to retrospective case series with treatment of *T. whipplei* with tetracycline, penicillin, streptomycin and low trimethoprim-sulfamethoxazole, in which only about three quarters of WB patients had an initial response, and approximately a quarter of those who had an initial response subsequently relapsed.

Both Crohn's disease (CD) and intestinal tuberculosis (TB) (caused mainly by *Mycobacterium tuberculosis* or *Mycobacterium bovis*) have a predilection for the tumor ileum. An algorithm has been developed for the investigation of persons in whom the diagnosis includes CD and TB^[89].

Diarrhea is the most common GI symptom in persons

with human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS), affecting 50%-90% of those with a low CD4 lymphocyte count. However, in some 30%-40% of cases of HIV/AIDS, enteric pathogens cannot be identified. Conceptually, HIV enteropathy has been supported by the detection of HIV proteins in the intestinal epithelial cells as well in gut lymphocytes and macrophages. In a case report, a 33-year-old woman with HIV enteropathy was described with structural changes in the duodenal mucosa, regressing after triple antiviral therapy^[90].

About half of the HIV-infected persons in the United States have diarrhea. The intestinal immune system is central to the pathogenesis of AIDS (transmission, viral complication, CD4⁺ T-cell destruction), with the progression of AIDS due to a decrease in the expression of genes that maintain the mucosal barrier, and HIV translocation^[91]. Endoscopy and biopsy of the upper and lower GI tract has identified pathogens in about half of those HIV-infected persons who were initially thought to have an idiopathic disorder or AIDS enteropathy. Viral replication occurs early in HIV in the gut-associated lymphoid tissue CD4⁺ T cells and macrophages. AIDS enteropathy is "an idiopathic, pathogen-negative diarrhea, and treatment includes highly active antiretroviral therapy (HAART), fluid and electrolyte balance, and nutritional support^[92]". The opportunistic infections can still occur in HIV-positive persons taking HAART, especially in those with a high viral load and a low T-cell count. Also note that these opportunistic disorders occur even if the HIV load is low and the CD4⁺ T-cell count is near normal.

In a young patient with chronic diarrhea, bacterial rDNA (16S rDNA) has been extracted from the duodenal biopsy, and was thought to be due to *Stenotrophomonas maltophilia*^[93]. Such genomic techniques may be used for the diagnosis of chronic infections, including those with HIV enteropathy.

Matrix metalloproteinases (MMPs) are a group of enzymes that are capable of degrading all components of the extracellular matrix. Fibroblasts are the major source of MMPs in the human intestine. Fibroblasts are a potential target of IL-21, a T cell-derived cytokine that acts on the IL-21 receptor, and then interacts with the common γ chain receptor IL-21 that controls MMP secretion by fibroblasts^[94].

Enteropathogenic *E. coli* (EPEC) is a leading cause of infantile diarrhea in developing countries. The EPEC-induced inflammation is a balance between pro- and anti-inflammatory proteins^[95]. Nosocomial infections with *Pseudomonas aeruginosa* are associated with a high fatality rate. A virulence circuitry of *P. aeruginosa* is activated by both soluble and contact-mediated elements of the intestinal epithelium^[96]. *P. aeruginosa* metabolizes adenosine to inosine, which enhances virulence of the organism^[97].

Malnutrition may be associated with prolonged episodes of EPEC infection. In the human epithelial Caco-2 cell model, EPEC inhibits uptake of thiamine^[98]. EPEC also inhibits SERT, the serotonin inhibitor; reduction in

SERT by EPEC may represent an additional and new mechanism of EPEC-mediated diarrhea^[99].

Severe acute respiratory syndrome (SARS) is characterized clinically by fever, nonproductive cough, dyspnea, lymphopenia, and rapidly progressing changes on chest X-ray, however, it is not uncommon for SARS patients to have diarrhea, nausea and vomiting, as well as abdominal pain. This may be associated with atrophy of the mucosal lymphoid tissue, staining of intestinal epithelial cells and lymphocytes for corona virus (*via in situ* hybridization), and demonstration by electron microscopy of SARS-coronal virus-like particles in the mucosal epithelial cells^[100].

The total microbial population within the GI tract exceeds the total number of mammalian cells in the body by at least an order of magnitude. There is a complex environment of microbes that interfaces with the mucosal lining of the GI tract. This coexistence between eukaryotes and prokaryotes has both beneficial and unfortunately harmful interactions^[101]. The intestinal mucosa downregulates proinflammatory signaling pathways, expresses antimicrobial proteins, and initiates epithelial repair after mucosal injury. Indeed, commensal bacteria are actively involved in shaping the very barriers that confine them to the gut lumen^[102].

Lipid rafts are cholesterol-sphingolipid-rich microdomains in the enterocyte BBM. These lipid rafts contain digestion and transport enzymes that are important in trafficking and signaling of various proteins. For example, Cx43 is present on enterocyte lipid rafts, and interferon (IFN) inhibits enterocyte migration by displacing Cx43 from these lipid rafts in enterocytes^[103]. Some pathogens recognize these lipid-rich specialized areas, and modify function of the nutrient digestive and transport proteins. Anti-glycosyl antibodies are induced by a glycosyl antigen, and are associated with lipid rafts. These anti-glycosyl antibodies act as competitors to pathogens, having a protective role on the lipid rafts by preventing lactic acid pathogens from gaining access to the intestinal BBM^[104].

SMALL INTESTINAL BACTERIAL OVERGROWTH

Small intestinal bacterial overgrowth (SIBO) occurs as a result of a reduction in gastric acid secretion, a failure of mucosal and systemic barrier functions, as well as a failure of immune responses. SIBO also occurs in the presence of anatomical abnormalities such as intestinal fistulae or multiple small intestinal (not colonic) diverticulae. Gram-positive and Gram-negative bacteria, including both aerobes and anaerobes, contribute to the diarrhea and malabsorption of nutrients. While the prevalence of SIBO is increased in persons with irritable bowel syndrome (IBS), especially those with diarrhea-predominant IBS, the exact rates depend upon the method used to diagnose SIBO, with low prevalence rates of 4% using the gold standard test of a positive jejunal aspirate and culture, and a prevalence of 54% using the lactulose or glucose hydrogen breath test^[105]. The crux of this association of IBS and

SIBO is whether treatment of the positive test for SIBO will improve the patient's symptoms.

SIBO may recur after it has been successfully treated with appropriate antibiotics (e.g., metronidazole or ciprofloxacin). The recurrence rates after initially successfully treated SIBO are about 13% at 3 mo, 28% at 6 mo and 44% at 9 mo^[106]. SIBO recurrence is more likely in older persons, those treated chronically with proton pump inhibitors, and curiously, those with a previous history of appendectomy. Retreatment with the same or different antibiotics will be necessary, and some persons with recurrent SIBO require maintenance use of antibiotics.

The absorbable antibiotic metronidazole is more effective than the nonabsorbable antibiotic rifaximin for treatment of SIBO in persons with blind loop syndrome^[107]. Rifaximin may safely prevent traveler's diarrhea: in a study in travelers to Mexico, rifaximin reduced the risk of diarrhea from 54% in those taking placebo to 15% in those taking rifaximin^[108].

In persons with chronic rosacea, 46% had SIBO, vs 5% of healthy controls. After eradication of the SIBO, the cutaneous rosacea lesions cleared in 71% and greatly improved in 21%, whereas those treated with placebo remained unchanged in 90% or worsened in 10%^[109].

DIARRHEA, SALT AND WATER ABSORPTION

The topic of diagnosis and treatment of acute or persistent diarrhea has been reviewed^[110]. Host genetic polymorphisms may influence susceptibility to traveler's diarrhea. The topic of chronic diarrhea has been reviewed and can be accessed for a tutorial (BMJ Learning <http://gut.dmj.com/tutorials/collection.dtl>)^[111].

Na⁺/H⁺ exchange (NHE) is the principal exchanger isoform responsible for transepithelial Na⁺ absorption at the BBM of the intestinal epithelium. Coupled activity includes both Na⁺/H⁺ and Cl⁻/HCO₃⁻ exchangers. The Cl⁻/HCO₃⁻ exchanger, SLC26A3 [also known as down-regulated in adenoma (DRA)], also exchanges sulfate and formate. Electroneutral NaCl absorption is mediated through NHE₃ as well as DRA as the major Cl⁻/HCO₃⁻ exchanger^[112]. NHE is highly regulated by a number of second messenger systems including cAMP-dependent protein kinase (PKA), cGMP dependent kinase, Ca²⁺, PKC, PI3K, and Akt. The phosphorylation of NHE by PKA alters the clathrin-mediated cAMP-stimulated endocytosis of NHE₃, thereby reducing Na⁺ absorption. Synaptotagmin 1 (Syt1) directs NHE₃ to the adaptor protein 2-clathrin complex^[113].

There are two Cl⁻/OH⁻ exchangers, DRA (SLC26A3) and PAT-1 (putative anion transporter-1; SLC26A6). DRA is in the colon, whereas PAT-1 is in the human jejunum and ileum. Cytokines such as IL-1β, TNF-α and IFN-γ increase secretion in models of inflammatory diarrhea. IL-1β decreases DRA mRNA, as also does IFN-γ by means of the STAT1/JAK (Janus kinase) pathway^[114]. This opens the way for the development of potential antidiarrheal

agents for the treatment of persons with inflammatory bowel disease. For example, *Lactobacillus acidophilus* prevents enteroinvasive *E. coli*-mediated disruption of the BBM barrier in Caco 2 cells, and increases Cl/OH⁻ exchange by enhancing the mRNA and activity of DRA^[115].

Lysophosphatidic acid (LPA) is a glycerophospholipid present in abundance in foods such as soybeans and egg yolk. There are seven LPA receptors, and LPA^[116] acts through these receptors to inhibit the activity of the cystic fibrosis transmembrane conductance regulator (CFTR)-dependent Cl⁻ channel. LPA also stimulates BBM Cl⁻/OH⁻ exchange and levels of DRA^[117]. This combined mechanistic effect of LPA may explain its antidiarrheal effect. This raises the possibility of using LPA for the treatment of diarrhea.

Serotonin (5-HT) is a neurotransmitter and hormone that influences many physiological functions. Over 97% of the serotonin in the body is in the enterochromaffin cells. SERT is present in the human intestine^[118], and the enterochromaffin cells have apical microvilli that protrude into the intestinal lumen. Serotonin is secreted from granules at the basolateral pole of the enterochromaffin cells. Abnormalities in the release, reuptake and catabolism of serotonin may be responsible for altered secretion, motility and pain sensation in patients with IBS, inflammatory bowel disease, or in persons with diarrhea or constipation. Release of serotonin may be mediated through central and enteric nervous system regulation, or by way of the enterochromaffin cells acting as sensors in the gut luminal milieu, responding to tastants such as (caffeine, tyramine and octopamine), olfactants (thymol and eugenol), as well as glutamine, deoxycolate, 2-deoxyglucose, and the artificial sweetener, sucralose. There are 11 secretory-associated genes, including the vesicle docking inhibitor STXBP3, which may be upregulated in response to luminal glutamine or bile acids, whereas anti-sense knockdown reduces serotonin secretion^[119].

NHE₃ is regulated by cAMP, cGMP, intracellular calcium, PI3K, glucocorticoid kinase-1 and PKC. The acute regulation involves changes in both functional activity and membrane trafficking. This acute effect on NHE₃ may be mediated by the glucocorticoid receptor, which stimulates SGK-1. Membrane insertion of NHE₃ may be caused by Na⁺-K⁺-ATPase-induced changes in A⁺ translocator Na⁺ flux^[120].

NHEs help to maintain intracellular pH homeostasis, cell volume regulation, and electroneutral sodium chloride (NaCl) absorption. NHE₂, NHE₃ and NHE₈ are present in the apical membrane of enterocytes and colonocytes. Sp3 is the major activator of NHE2 gene transcription in the intestinal epithelial cells^[121]. NHE₃ is also regulated by certain growth factors, protein kinase, and IFN-γ. The Sp transcription factor is involved in cell cycle regulation, hormonal activation, and development patterning. NHE₃ facilitates intestinal neutral NaCl absorption, and thereby increases the net transmucosal absorption of bicarbonate in rat duodenal mucosa. This mechanism is similar to the proximal renal tubular bicarbonate absorption^[122].

The epithelial sodium channels (ENaCs) are a rate-limiting component for electrogenic sodium absorption in the distal colon. ENaC function is regulated by mineralocorticoid and glucocorticoid hormones. Steroid hormones act through transcriptional induction of β- and γ-ENaC subunits. In macroscopically noninflamed colon in persons with active CD, there is impaired ENaC-mediated Na⁺ absorption, which contributes to the diarrhea arising from the inflamed mucosa^[123].

Water movement across the intestinal epithelium is driven osmotically, and is therefore influenced by the balance between sodium absorption and chloride secretion. These processes, absorption and secretion, are regulated. Intestinal motor and sensory function is altered by the action of transmitters and by changes in ion channel function. CFTR is a cAMP-dependent Cl⁻ channel. CFTR is located in the intestinal epithelium, and is activated by PKA-mediated phosphorylation. A minor component of Cl⁻ transport occurs by way of intestinal and colonic epithelial cell transport, the type 2 Cl⁻ channel (ClC-2) volume-regulated channel. CFTR acts as an entry pathway for Cl⁻ into epithelial cells, in parallel with Na⁺ entry through apical ENaCs. ClC-2 promotes anion secretion, with little anion reabsorption. The properties of ClC-2 differ depending upon the conditions in the tissue in which the ClC-2 channels are studied^[124].

Diarrhea is common after pelvic radiotherapy, and this may be associated with modification in the diversity of luminal microbionota, as reflected by a drop in the similarity index of the enteric bacteria. Cluster analysis of the microbial profile 5 wk after radiotherapy displayed a dentogram which was different in patients who presented with or without diarrhea^[125]. It is not clear why there is this differential effect of radiation on the intestinal organisms.

Newer and even more effective antidiarrheal agents are needed. In the presence of malabsorption of Na⁺ and water in the small intestine, the ENaCs in the distal colon are upregulated in order to absorb more Na⁺/water, and hopefully thereby reduce diarrhea. ENaCs are responsive to mineral corticoids as well as to glucocorticoids. Glucocorticoids act through p38 MAPK to enhance the transcription of the B- and J- subunits of ENaCs, thereby rapidly increasing water absorption^[126].

DRA is a Cl⁻/HCO₃⁻ exchanger. When DRA is eliminated in mice, there is an approximately 50% reduction of basal and cAMP-stimulated HCO₃⁻ secretion^[127]. Microfluorimetry of villi shows that DRA is the major Cl⁻/HCO₃⁻ exchanger in the lower villous epithelium. In humans, loss-of-function mutations cause congenital Cl⁻ losing diarrhea^[128].

The development and control of the inflammatory reactions, which occur in food allergies, are mediated by T helper (Th)2 or regulatory responses, in which IL-4 is a factor. Allergic responses include IL-4 induction of the differentiation of committed effector Th2 lymphocytes for mRNA for TNFβ, Th1, IFNβ, IL-12p40, regulatory cytokines or Foxp3 (forkhead box P3). These may serve

as “rescue channels” for all Cl⁻ secretion, but lubiprostone activation of Cl⁻ secretion requires CFTR. The PPAR- β agonist rosiglitazone reduces cAMP-dependent Cl⁻ secretion as a result of reduced expression of the CFTR Cl⁻ channel, KCNQ, K⁺ channel, and Na⁺/K⁺/2Cl⁻ cotransporter proteins^[129].

IBS

About half of diarrhea-predominant IBS patients report an exacerbation of their symptoms within 90 min of eating. Normally, the duodenal and ileal breaks slow the passage of chyme along the intestine, and this helps to prevent exceeding the approximately 2-L composition of the colon to absorb water. Indeed, the small bowel water content initially falls, and then rises after a meal of liquids and solids^[130]. This could possibly be due to MC products being released from the small bowel mucosa, causing rapid transit of mill as intestinal fluid secretion.

IBS may aggregate in families, and twin studies demonstrate both a genetic as well as an environmental basis for IBS. Human intestinal smooth muscle cells and ICCs express SCN5 (gene encoded Na⁺ channel, expressed in interstitial cells). There may be an association between genetic defects in SCN5A and GI symptoms, and SCN5A may be a candidate gene in the pathophysiology of IBS^[131].

In a group of 62 patients with presumed idiopathic chronic watery diarrhea, HLA-DQ2/DQ8 genotyping, eHCAT abdominal retention test, small bowel follow-through, and hydrogen breath test were undertaken. In 45% of these patients, bile acid was presumed to be the cause of diarrhea. Sugar malabsorption was seen in 16%, gluten sensitive enteropathy in 16%, and both bile acid and sugar absorption in 3% of patients. It is important to note that not only was the cause of the chronic watery diarrhea not idiopathic in 81% of the patients, but it responded to specific treatment^[132].

NECROTIZING ENTEROCOLITIS

Intestinal mucus is one of the important factors protecting the intestinal epithelium. Without this well-formed gel layer, the underlying mucosa is more susceptible to attack by bacteria. Much of the oral intake of threonine is used for mucin production. A threonine-deficient diet will lead to a reduced number of acidic mucin-producing goblet cells in the small intestine. The abnormalities in mucus resulting from the impaired oral intake of threonine can be prevented through parenteral administration of this amino acid^[133].

The mucus layer over the intestinal epithelium acts as a barrier, retarding the access of bacteria and bacterial products to the BBM. Goblet cells secrete mucin 2 (MUC2), a glycoprotein with high density and viscoelasticity. MUC2 contains large amounts of threonine and proline. Studies determining the fractional synthetic rate of MUC2 in human neonates have shown rapid incorporation of systemic threonine into MUC2^[134].

Premature infants are at increased risk of developing necrotizing enterocolitis (NEC). The initial colonization of the intestine by bacteria, and the use of enteral feeds, contribute to the development of NEC. The maldigestion of carbohydrate may also be a risk factor^[135]. This is possibly because maternal diets are high in n-6/n-3 fatty acids. These dietary lipids are epigenetic factors that contribute to the increased incidence of ischemia by altering the composition of amniotic fluid and intestinal membrane structural lipid essential fatty acids^[136].

There is a wide range of mortality rates of infants with NEC, depending on the number of risk factors (e.g., prematurity, use of feeding formula, bacterial colonization of the GI tract), as well as the extent of the damage to the bowel (inflammation, necrosis, perforation, peritonitis, sepsis, and systemic inflammatory response). In the healthy child, there is high blood flow and low resting vascular resistance. One mechanism of development of NEC is reduced blood flow in the arteries penetrating the wall of the intestine, as well as the submucosal arterial plexus.

NEC is a major cause of death from GI disease in neonates. The mucosal damage and increased intestinal permeability lead to translocation of enterobacteria, activation of macrophages in the lamina propria, and initiation of a systemic inflammatory response. NO is released in a response to cytokine induction of the enzyme iNOS. Restitution is regulated in part by the Rho family of small-molecular-weight GTPases. NO inhibits enterocyte migration through protein tyrosine phosphatase (SHP-2)^[137].

Intestinal barrier function can also be altered as a result of impaired intestinal restitution. This restitution is decreased in, for example, hemorrhagic shock, sepsis, intestinal ischemia and NEC. The increase in intestinal permeability that occurs with stress and the presence of viable nonpathogenic *E. coli* is exaggerated by TNF- α release from macrophages^[138]. The proinflammatory mediators IL-18 and TNF- α are involved in the development of NEC. As noted by these authors, this raises the possibility that “...anti-TNF- α could be used as a potential therapy for human NEC”^[139]. The use of TNF- α modifiers may also be effective to normalize *E. coli*-associated increased intestinal permeability. It is unknown whether the inhibition of membrane or soluble TNF- α may be used clinically to prevent or to treat NEC.

Heparin-binding epidermal growth factor-like growth factor (HB-EGF) is produced by epithelial cells, where it decreases apoptosis, preserves the integrity of the cytoskeleton, and rebuilds depleted intracellular stores of ATP. In newborn rat pups, HB-EGF maintains the blood flow of the microcirculation that normally would be decreased in NEC^[140]. Histological abnormalities correlate with changes in blood flow, and less histological damage occurs with the use of HB-EGF. This may prove to be a useful preventive or therapeutic agent in newborn human infants who are at risk of developing NEC.

The probiotics lactobacilli and bifidobacteria may help to prevent the development of NEC. TLRs on the

intestinal BBM are PRRs that identify components of the usual intestinal microbiota. TLR4 recognizes the Gram-negative LPS, which is increased in NEC. The TLR changes occur before the histological changes, suggesting that the activator of the inflammatory response through TLRs may be causative in the development of NEC^[141].

As a result of the importance of the formation of the microbiota in the development of NEC, the possibility has been raised for the therapeutic potential of altering the bacterial contents by the use of probiotics^[142]. Feeding premature rats the probiotic *Bifidobacterium bifidum* reduced the prevalence of NEC from 57% to 17%. This dramatic protective effect was associated with reduced and indeed normalized levels of proinflammatory IL-6, trefoil factor 3 and mucin-3, as well as TJ and AJ proteins^[143].

The release of bacterial LPS from enterobacteria associated with NEC increases the enterocyte expression of integrin. Integrin leads to adhesion of the enterocyte to the underlying matrix and healing of the damaged mucosa by the migration process of restitution. Dystroglycans (DGs) are a component of the dystrophin-glycoprotein complex that are involved in integrin activation in the intestinal epithelium^[144]. With restitution, the migrating cells transiently adhere to the underlying matrix, reducing fibrillar adhesions containing a structural core of transmembrane integrins. These integrins provide anchors (adhesion complexes) and also sensors for mechanical events, as well as signal transducers. Removal of neurocytes requires disassembly of the integrin-based adhesions structures. β 1-Integrin is endocytosed *via* a dynamin-dependent lipid-raft-mediated pathway that helps to regulate intestinal epithelial cell migration and wound closure^[145].

The bacterial ligand activated TLRs signal intracellularly to upregulate both pro- and anti-inflammatory cytokines. There are several genes induced in the inflammatory process such as cytokines, chemokines and adhesion molecules. A factor that is central to the regulation of these various genes is NF- κ B. For example, NF- κ B is induced in NEC. Platelet activating factor (PAF) is an endogenous proinflammatory phospholipid that rapidly activates NF- κ B. PAF also stimulates neutrophils to produce the chemokine that used to be known as macrophage inflammatory protein (MIP)-2, now called CXCL₂. The bowel injury produced by PAF is mediated through the processing of the NF- κ B p105 into NF- κ B p50^[146].

PAF induces Cl⁻ channel activation associated with intracellular acidosis. The Cl⁻ channel activation occurs through caspase-3 activation and DNA fragmentation, as well as by apoptosis^[147]. In NEC, PAF and accelerated apoptosis of enterocytes results in tissue necrosis. Inhibition of caspase activation prevents the progression of disease in a neonatal rat model of NEC. Palmitoylation is a post-translational modification that is necessary for efficient signal transduction by many G protein-coupled receptors (GPCRs). Nutrients in the intestinal lumen may be sensed. For example, free fatty acids lead to release

of peptide YY. This affects GPCRs, thereby modifying cell proliferation and differentiation as well as hormonal secretion^[148]. Inhibition of the PI3K/Akt signaling pathway is the main mechanism of PAF-induced apoptosis in enterocytes. Polyunsaturated fatty acids block this mechanism early in the signaling cascade, probably by way of an effect on protein palmitoylation^[149].

After a period of bowel ischemia, the reperfusion of blood actually increases damage to the tissue. As oxygenation of the reperfused tissue occurs, free radicals are produced, MCs degranulate, leukocytes adhere to the endothelial wall, and thus ischemia/reperfusion (I/R) damages especially the mucosal cell layer and villous structure, as well as mucosal permeability and mitochondrial activity. 3,4-Dihydroxy-phenyl lactic acid reduces the production of peroxide and the expression of adhesion molecules in neutrophils and thereby minimizes the disturbance in the microcirculation^[150]. If the initial period of ischemia is short (about 15 min in mice), these adverse effects may reverse, but in longer periods of ischemia, the changes in structure and function are irreversible^[151].

During hypoxia-associated inflammation, endogenous adenosine is protective. In hypoxia, the levels of equilibrative nucleoside transporter-2 (ENT2) falls in human epithelial cells^[148], whereas hypoxia-inducible-factor-12-dependent repression of ENT2 increases mucosal adenosine signaling, thereby reducing the hypoxia-associated inflammation of the intestine. During hypoxia, the actin cytoskeleton is aggregated in endothelial, epithelial and vascular smooth muscle cells. This aggregation results from the disposition of IgM and complement (C3), causing further tissue injury^[152].

IMMUNOLOGY/ALLERGY

Immune-associated disease is of epidemic nature in postindustrial society. For example, adverse reactions to food are common, and true food allergies are believed to affect about 7% of children under the age of 10 years, and 2% of the adult population. These immune reactions are mediated by IgE-dependent or -independent mechanisms involving MCs, eosinophils, and other immune cells^[153].

The intestinal immune system includes Peyer's patches, isolated lymphoid follicles, mesentery lymph nodes, lamina propria mononuclear cells, and intraepithelial lymphocytes. The human intestine has unique natural killer (NK) cells derived from hemopoietic stem cells in the bone marrow. These NK cells contribute to maintenance of immune homeostasis in the intestine^[154].

Chemokines and their receptors control the influx of T and B cells into the Peyer's patches of the intestine. There is different expression of chemokines along the length of the small intestine^[155].

The M (microfold) cells are a clonal population derived from a single stem cell in the small intestinal crypts, within the follicle-associated epithelium of the Peyer's patches. M cells transport antigens and microorganisms

into the underlying lymphoid tissues. Mature enterocytes may convert to the M cell phenotype under the influence of either T and B lymphocytes or microorganisms^[156].

Macrophages in the intestinal tract are important to host defense by way of recognizing, phagocytizing and killing microorganisms. Classically, activated Th1 immune response macrophages are major effector cells in the Th1 immune responses. These mediate the production of NO by inducing NOS-2. Alternatively, activated macrophages are induced by T helper (Th)2 cytokines, including IL-4 and IL-13, as well as signal transducer and activator of transcription 6^[157].

Under normal circumstances, the gut immune system is poorly responsive to food allergens and to commensal bacteria. This hyporesponsiveness occurs through a process of immune tolerance. The Th2 phenotype is involved in development of allergic disease through release of IL-4, IL-5 and IL-13. These cytokines play a role in antigen-specific IgE production by B cells. IL-4, IL-5 and IL-13 are also important in mucous secretion, muscle contraction and eosinophilia.

IL-4 is the key Th2 cytokine involved in switching antibody responses to IgE. IL-4 induces the expression of IgE receptors on MCs, as well as on other cell types. IL-4 gene transfer to the small bowel serosa leads both to intestinal inflammation and smooth muscle hyperresponsiveness^[158]. Sensitization induces expression of CD23 on intestinal epithelial cells. This CD23 enhances IgE-dependant transepithelial antigen uptake by encoding a functional IgE receptor on human intestinal epithelial cells^[159].

A localized Th2 milieu has been observed in the intestine of subjects with food allergic disorders. A gut-homing phenotype is induced by mesenteric lymph node, with selective upregulation of the Th2 chemoattractants^[160]. TGF β is an immunoregulatory cytokine that is constitutively expressed in the intestine by epithelial cells, fibroblasts and lamina propria mononuclear cells. As noted by Di Sabatino *et al.*^[161], “one of the paradoxes of human mucosal T-cell responses in health is the dominant Th1 profile and interferon γ (IFN γ) secretion of normal human gut T cells”.

It is of interest that there is a link between intestinal immunology and motility. The Th2 cytokines are implicated in intestinal muscle dysfunction following tissue injury. Products of the innate and adaptive immune responses contribute to the activation and sensitization of primary sensory neurons. T lymphocytes are an important determinant of visceral nociception, and may provide an important opioid-mediated antinociceptive influence in the gut^[162].

Cell surface molecules are required for development of intestinal allergy^[163]. Disruption of the enteric glial cell (EGC) network is associated with intestinal and mesenteric T-cell infiltration, leading to Th1 cytokine-associated bowel inflammation. EGCs express major histocompatibility complex (MHC) class I, and regulate MHC class II in persons with bowel inflammation. CD8 and CD4 T

cells trigger autoimmunity. Direct presentation of antigen by lymph node stromal cells protects against CD8 T-cell-mediated intestinal autoimmunity^[164].

CD23 is a tight II intercoil membrane glycoprotein with a carboxy terminal C-type lectin head that binds its ligand, IgE, in a calcium-dependent manner. CD23a is expressed constitutively on mature activated B cells, whereas CD23b is induced by IL-4 or IL-23. CD23a is increased in food-allergic patients, and CD23a is expressed by primary human IECs. The increase in antigen uptake by specific IgE is through the process of diverting antigen from delivery to lysosomes. Delivery of antigen-IgE complexes across the intestinal epithelial barrier may induce deactivation of MCs, and contribute to food-induced pathophysiology of the GI tract^[165].

The *in vitro* treatment of smooth muscle tissue with IL-1 β decreases expression of CPI-17. Smooth muscle serine-threonine protein phosphorylases are endogenous inhibitory proteins. This TNF- α -mediated process inhibits muscle contraction in the small intestine^[166]. It is not yet known whether intestinal motility may be modulated for therapeutic purposes by immune alterations.

The vagus nerve regulates GI motor and digestive functions through the release of acetylcholine (ACh). This parasympathetic neurotransmitter activates mAChRs, the nicotinic ACh receptors. The afferent vagal nerve, working through the hypothalamic pituitary adrenal axis, acts to inhibit the activation of NF- κ B. This reduces proinflammatory cytokine secretion by macrophages, as well as modifying macrophage endocytosis and phagocytosis. Thus, “vagus nerve efferent activity may stimulate surveillance in the intestinal mucosa and peritoneal compartment^[167]. This role of the vagus nerve awaits study as a potential therapeutic target in persons with allergies.

Abstract

As is the case in all areas of gastroenterology and hepatology, in 2009 and 2010 there were many advances in our knowledge and understanding of small intestinal diseases. Over 1000 publications were reviewed, and the important advances in basic science as well as clinical applications were considered. In Part II we review six topics: absorption, short bowel syndrome, smooth muscle function and intestinal motility, tumors, diagnostic imaging, and cystic fibrosis.

ABSORPTION

Triglycerides

For triglycerides (TG), it has been traditionally considered that lipid uptake is by way of passive permeation through the lipophilic portion of the intestinal brush border membrane (BBM). However, enterocyte-binding or transport proteins have been identified as also being important in this process^[1]. Gata4 is a zinc-containing transcription factor, expressed in the epithelium of the upper small intestine, and functions to assist in fat and cholesterol absorption^[2]. Lipid micelles at the BBM modulate a large number of genes, and this transcriptome responding to dietary lipids has an impact on cell architecture, signaling and metabolism genes^[3]. Most lipids are in the enterocyte, and may be bound to the liver and the intestinal fatty acid (FA) binding proteins (L-FABP and I-FABP). L-/I-FABP function to translocate long chain FAs and monoacylglycerol from the BBM to the endoplasmic reticulum (ER). These long FAs are then used in the resynthesis of diacylglycerol and then triacylglycerol.

The absorption of dietary TG in the small intestine is accompanied by a rise of intestinal alkaline phosphatase (IAP) in the serum, and by the secretion of IAP-containing surfactant-like particles (SLPs) from the enterocytes. IAP is a membrane-bound protein that hydrolyses monophosphate esters at high pH optimum, and limits fat absorption by enterocytes by way of its action as a SLP^[4]. Translocation of IAP across the enterocyte BBM occurs within 5 min of lipid intake by way

of induction of endocytosis *via* clathrin-coated pits^[5]. After fat has been taken up into the enterocyte, IAP is incorporated into membranes surrounding intracellular lipid droplets, and is also incorporated into basolaterally secreted SLPs. IAP is not associated with chylomicron formation, but rather with chylomicron secretion. Serum IAP levels are correlated with levels of apolipoprotein B-48 (apoB48), a protein exclusive to intestinal chylomicrons in humans^[6].

After ingestion of a meal rich in TG, the small intestine continues to form very low density lipoprotein (VLDL), but the predominant TG-rich lipoprotein particles secreted in this postprandial condition are the larger chylomicron particles^[7]. In the liver, TG is synthesized and packaged with apoB100 to form VLDL particles, whereas chylomicrons produced by the human gut contain apoB48. ApoB48 provides efficient chylomicron formation and lipid absorption. Apolipoprotein A-IV synthesis in the small intestine is regulated by lipid absorption, and plays a role in the regulation of chylomicron assembly and secretion.

Hepatocyte nuclear factor-4 α (HNF-4 α) is a nuclear receptor that regulates gene expression during enterocyte differentiation. HNF-4 α is also involved with the transcription of genes involved in lipid metabolism, such as *Apo-IV*^[8]. In newborn swine intestine, dietary lipid causes ligand-independent transactivation of HNF-4 α to induce Apo-A IV and microsomal triglyceride transfer protein (MTP).

The uptake of FAs across the BBM may be partially passive and partially facilitated, mediated by the multiligand scavenger protein CD36. CD36 also participates in the orosensory detection of lipids and the production of the sensation of satiety. Thus, CD36 may play a role in lipid preferences and feeding behaviour^[9]. Monoglyceride and free FAs in the cytoplasm reform TG by the successive actions of monoacylglycerol acyltransferase and diacylglycerol acyltransferase at the membrane of the smooth ER. After transfer in the ER lumen, TG droplets associate with primordial lipoprotein comprising apoB48 and phospholipids through the actions of MTP, to form TG-rich lipoproteins (TRL). The lipid droplets fuse with apoB48 plus a resident ER chaperone, MTP. MTP-dependent fusion of lipid droplets with apoB48 in the ER is the crucial restriction point in the formation of chylomicrons. The lipoprotein particle enlarges as more TG is added to the droplet. The maturing lipoprotein particles (prechylomicrons) undergo vectorial vesicular transport through the Golgi membranes. Chylomicrons cross the basolateral membrane (BLM) and into the lacteals.

Glucagon-like peptide-2 (GLP-2) increases lipid absorption, but how does this occur, when enterocytes have no GLP-2 receptors? Perhaps the GLP-2 acts on the enteroendocrine L cells, releasing insulin-like growth factor (IGF-1). GLP-2 increases the glycosylation of CD36 and increases the number of chylomicrons.

After 1 wk of feeding with a high fat diet (HFD) in mice, there is repression of genes involved in FA syn-

thesis, and an increased expression of genes involved in lipoprotein assembly (*apoB*, *MTP*, *apoA-IV*). This process may be coordinated by an increase in the transcription factor SREBP-IC^[10]. The number of secreted chylomicrons falls, but there are larger chylomicrons containing increased associated TG, as well as increased amounts and activity of MTP. These changes result in postprandial hypertriglyceridemia, but normal fasting levels of TGs. This postprandial hypertriglyceridemia in the absence of changes in fasting levels may explain some of the risk factors for the development atherosclerosis and cardiovascular diseases.

Cholesterol

Dietary and biliary cholesterol are solubilized by bile acid micelles in the upper intestinal lumen. These are large negatively-charged unilamellar vesicles, smaller mixed micelles or monomeric bile acids. Bile acids promote cholesterol absorption and reduce cholesterol synthesis^[11].

It is now recognized that intestinal absorption of cholesterol is a complex process, involving both BBM permeation and cotransporters^[12,13]. Uptake of cholesterol from the intestinal lumen across the enterocyte BBM is also mediated by at least five proteins: Niemann-Pick C1-like 1 (NPC1L1), the scavenger receptor B-1 (SR-B1), CD36, the ATP-binding cassette protein 5 (ABCG5) and ATP-binding cassette protein 8 (ABCG8) ATP-binding cassette transporters^[14,15]. NPC1L1 protein is predominantly expressed in the liver and in the proximal intestine^[16]. Modulation of NPC1L1 expression is by cholesterol, as well as by the involvement of several nuclear receptors, such as liver X receptor (LXR), peroxisome proliferator-activated receptor (PPAR)- α , and by sterol regulatory element (SRE) binding proteins (SREBPs). SREBPs are transcription factors which regulate cholesterol synthesis and metabolism^[17]. SREBP-2 activates the NPC1L1 promoter, which has two sterol regulatory elements.

The ATP-binding cassette transporter ABCG1 promotes cholesterol efflux across the BLM and out of the enterocyte. In contrast, ABCG5/G8 facilitates cholesterol efflux back across the enterocyte BBM and into the intestinal lumen^[18]. The ATP-binding cassette transporters are target genes of the nuclear receptor LXR. Mice on a high-fat cholesterol free diet have reduced or downregulated NPC1L1, ABCA1, ABCG5, and ABC8, reduced fractional cholesterol absorption, and a posttranslational increase in 3-hydroxy-3methylgluteral-coenzyme A reductase activity. Downregulation of cholesterol transporters is independent of LXR A^[19].

NPC1L1 also occurs in intracellular compartments, and is involved as well in the absorption of dietary saturated FAs such as steric and palmitic acids^[20]. The drug ezetimibe binds NPC1L1, reduces intestinal absorption of cholesterol as well as saturated FAs, and reduces weight gain in animals fed a diabetogenic diet. In this way, the drug may protect against diet-induced hyperglycemia and insulin resistance^[20]. NPC1L1 and the FA translocase (FAT/CD36), as well as scavenger receptor class B type 1 (SR/B1)

transporter protein, have been shown to be influenced by 5 mmol/L glucose in the intestinal lumen; enhancing protein expression of NPC1L1 and CD36, decreasing SR/B1 protein, but having no effect on the protein expression of ABCA1 and ABCG8^[21]. Higher intraluminal glucose concentration increases 3-hydroxy-3-methylglutaryl-coenzyme A reductase activity, increasing the transcription factors LXR- α and LXR- β , PPAR- β and PPAR- γ , as well as SREBP2. Thus, reducing the luminal concentration of glucose will also reduce uptake of cholesterol.

Aging enhances cholesterol absorption by suppressing expression of the sterol efflux transporters ABCG5/G8. In contrast, estrogen enhances cholesterol absorption due to upregulated expression of NPC1L1, ABCG5 and ABCG8^[22]. Cholesterol absorption is also enhanced in diabetes; medium levels of glucose concentration in Caco-2 cells in culture increase cholesterol uptake as well as the expression of NPC1L1 and CD36 proteins^[21].

Liver FA binding protein (L-FABP) increases FA uptake, intracellular transport, esterification, and oxidation in transfected transformed cells, and gene-ablated mice with no L-FABP show reductions in these steps of FA metabolism^[23]. L-FABP may also play a role in hepatic cholesterol metabolism^[24].

Phytosterols are cholesterol-like compounds found in plants, which reduce cholesterol absorption and plasma concentrations of low density lipoprotein cholesterol. Natural phytosterol glycosides purified from lecithin are bioactive in humans^[25].

Two Na⁺-coupled (SMIT1 and SMIT2) and one H⁺-coupled (HMIT) secondary active intestinal transporters for myo-inositol have been identified^[26].

One hypothesis suggests that cholesterol is absorbed by an energy independent passive diffusion process regulated *via* a concentration gradient^[14]. The second hypothesis proposes that cholesterol is absorbed through an energy-dependent, protein-mediated process^[27].

NPC1L1: NPC1L1 is the main cholesterol transporter in the jejunal BBM^[16]. NPC1L1 shares 42% amino acid homology with Niemann-Pick type C1 protein (NPC1), a protein involved in the intracellular transport of cholesterol^[28]. Post-translationally, NPC1L1 moves from internal membranes to the mucosal membrane during cellular cholesterol depletion, facilitating absorption^[29]. Other studies suggest that NPC1L1 is located at the BBM of enterocytes^[30]. NPC1L1 mRNA expression appears to be positively correlated with plasma apoB48 and chylomicron cholesterol content^[31].

Scavenger receptor B1: Scavenger receptor B1 (SRB1) is highly expressed in the BBM of the proximal small intestine^[32]. Intestinal SRB1 overexpression in transgenic mice has been associated with increased cholesterol absorption^[33]. Moreover, antibodies against SRB1 demonstrate abolishment of high affinity binding of cholesterol to BBM vesicles that would normally be observed in *NPC1L1*^{-/-} mice^[32]. SRB1 may play a role in the initial step of cho-

lesterol absorption by facilitating high affinity cholesterol binding to the mucosal BBM, but alternative cholesterol transporters may compensate for the absence of SRB1 in mediating cholesterol absorption in KO models^[32].

FAT/CD36: FAT/CD36 (translocase), a human analogue of SRB1, is expressed along the BBM of the duodenum and jejunum. CD36 deficiency correlates with abnormal lipid processing in enterocytes^[14].

ABCG5/8: ABCG5 and ABCG8 are located at the enterocyte BBM^[14]. Their expression is greatest in the duodenum and jejunum, where they work in tandem to efflux cholesterol (mainly plant sterols) from the enterocyte back into the lumen for excretion^[34]. A negative correlation exists between ABCG5/8 and chylomicron cholesterol content^[31]. Mutations of *ABCG5* and *ABCG8* in humans enhance intestinal cholesterol absorption, and predisposes these individuals to atherosclerosis^[35].

ATP-binding cassette protein 1: ATP-binding cassette protein 1 (ABCA1) not only mediates cholesterol efflux from the basolateral surface of enterocytes to high-density lipoprotein^[36], but it also contributes to the efflux of cholesterol out of the enterocyte and back into the intestinal lumen^[37].

Bile acids

Bile acids are synthesized from cholesterol in the liver, secreted into the bile ducts, stored in the gallbladder, and intermittently released into the duodenum in response to a meal, where bile acids solubilize lipids in the intestinal lumen by formation of micelles^[38]. Bile acids dissociate from the lipids which they stabilize prior to the uptake of the lipids across the BBM of the proximal intestine. The bile acids are absorbed passively along the length of the small intestine. In the ileum, enterocyte BBM sodium-dependent bile acid transporters (ASBTs) also mediate bile acid uptake and bile acids are returned to the portal circulation. This is known as the “enterohepatic” circulation of bile acids. ASBT is, in effect, a salvage mechanism for luminal bile acids, providing for maintenance of cholesterol homeostasis, as well as for efficient lipid absorption.

The apical ASBT in the lipid rafts of the ileal BBM functions in concert with hepatic bile acid efflux transporters to regulate hepatic bile acid synthesis from cholesterol. One of the green tea catechins decreases the maximal transport rate (V_{max}) of ASBT, without altering its content in the BBM. This reduction in V_{max} is achieved by moving the transporter out of the lipid rafts^[39]. This suggests a role for lipid rafts in the modulation of the function of this transporter, reducing the size of the bile acid pool, stimulating the hepatic synthesis of bile acids from cholesterol, and thereby reducing the serum concentration of cholesterol.

Initially, ASBT in the enterocyte cytosol undergoes vesicular trafficking to microdomains in the BBM. These

ASBT lipid rafts are enriched with sphingolipids and cholesterol. Alterations in cholesterol content of the BBM lead to rapid modulation of the activity of ASBT^[40]. Obstructive cholestasis leads to downregulation of ASBT mRNA expression. Thus, luminal bile acid levels may be involved in regulation of ASBT gene regulation^[41]. In patients with ileal inflammation, such as Crohn's disease, reduced bile acid transport may be due to diminished ASBT protein expression, as the result of ASBT inhibition by inflammatory cytokines *via* direct interactions of c-fos with the ASBT promoter^[42].

Once bile acids are in the ileal enterocytes, they bind to ileal bile acid-binding protein (I-BABP). Organic solute transporters (Ost) α and β are located in the BLM of the ileocytes. Ost α /Ost β expression is induced by bile acids through ligand-dependent transactivation of both *Ost* genes by the nuclear bile acid receptor/farnesoid X receptor (FXR)^[43]. "By coordinated control of Ost α /Ost β expression, bile acids adjust the rate of efflux from enterocytes in response to changes in intracellular bile acid levels". Ost α is a seven transmembrane domain protein, and Ost β is a single transmembrane domain polypeptide. Ost α -Ost β is the major BLM transporter of bile acids and conjugated steroids in the intestine, as well as in the kidney and liver^[44]. Ost α and Ost β promoters harbor both FXR and liver receptor homolog-1 (LRH-1) elements. FXR and LRH-1 mediate positive- and negative-feedback regulation, respectively^[45].

When the BBM uptake of bile acids is impaired, excess bile acids spill into the large intestine, where bile acids stimulate cAMP and cause a secretory diarrhea. The locally-acting steroid budesonide is beneficial for the symptoms of collagenous colitis, which in turn is associated with bile acid malabsorption. This clinical benefit may be due in part to stimulation of bile acid absorption, with decreased bile acids entering the colon, less stimulation of cAMP, and less secretory diarrhea^[46].

Glucose-dependent insulinotropic polypeptide (GIP) is a potent insulin secretagogue. GIP is an incretin, a gut factor released after intestinal transport of hexoses, long-chain FAs and TG, and GIP stimulates insulin secretion at physiological concentrations. GIP is secreted by enteroendocrine K cells in the proximal small intestine. Intestinal lymph contains high concentrations of GIP that respond to both enteral carbohydrate and to fat absorption. The combination of glucose and lipid has a potentiating effect on stimulation of GIP secretion in lymph fistula rats^[47].

Approximately 25% of individuals with irritable bowel syndrome (IBS) have a previous history of enteric infection, such as with *Campylobacter* or *Salmonella*. Persistent chronic diarrhea is more frequently associated with infectious IBS, and bile acid malabsorption may be observed in as many as a third of patients with diarrhea-predominant IBS. In a mouse model of IBS, it was shown that ileal uptake of bile acids was reduced. Surprisingly, this was associated not with a decrease but rather with an unexpected increase in expression of the

BBM Na⁺-dependent bile acid transporter (ASBT)^[48].

Bile acids act as detergents to solubilize lipids, but also act as signaling hormones: bile acids activate the G-protein-coupled receptor TGR5, resulting in changes in energy expenditure and glucose homeostasis, as well as having an anti-inflammatory role. Novel patent and selective bile acid derivatives are being developed as TGR5 agonists for possible therapeutic enhancers^[49].

Bile acids are synthesized from cholesterol. In the neutral pathway, the rate-limiting enzyme β hydroxylase (Cyp7a7) converts cholesterol to 7-hydroxycholesterol. In the attenuated acidic pathway in mitochondria, sterol 25-hydroxylase or 27-hydroxylase hydroxylates the cholesterol, and a 7 β hydroxyl group is added from catalysis by oxysterol 7 β hydroxylase (Cyp7b1). The ring structure is then modified, and the side chain is oxidized and shortened, and further hydroxylation occurs to form the primary bile acids, cholic and chenodeoxycholic (chenic) acid. Bile acids regulate their own synthesis by way of negative feedback on the transcription of the rate-limiting enzyme, Cyp7a1. When bile acid concentrations are high, there is activation of the nuclear FXR, which leads to increased transcription of short heterodimeric partner (SHP). Cyp7a1 is activated by the SHP-dependent as well as by the SHP-independent pathway.

The small size of the bile acid pool in neonates is increased as the result of elevated mRNA levels of FXR and SHP, and later by an increase in mRNA and protein levels of Cyp7a1^[50]. The increase in Cyp7a1 levels and therefore the increased synthesis of bile acids occurs independently of FXR and SHP, and is not influenced by the administration of sterols^[50].

Gangliosides

Gangliosides are sialic acid-containing glycosphingolipids which are found in lipid rafts in outer plasma membranes, such as the BBM of the small intestine. The oligosaccharide portion of the ganglioside faces the cell surface, whereas the lymphatic ceramide portion is anchored into the inner (cytosolic side) layer of the BBM. In the rat intestine, 34% of the glycosphingolipids are gangliosides. The amount of ganglioside in the membranes varies along the intestine, being higher distally than proximally. Gangliosides differ depending upon whether ingested in micelles or unilamellar vesicles. GM3 is localized on the BBM whereas GD3 is mainly localized on the BLM. GD3 uptake into Caco-2 cells is greater across BLM than BBM, and gangliosides taken up by the BLM are largely metabolized by these enterocyte-like cells^[51]. In contrast, GD3 uptake across the BBM is time- and concentration-dependent, reaches a plateau, and the GD3 is metabolized, stored, or transported out of the cell across the BLM. GD3 is found in milk and colostrum, and feeding GD3 increases its content in the intestinal lipid rafts, and in the blood membrane: the main ganglioside in the BBM is GM3, whereas GD3 is the main ganglioside in the BLM. This raises the possibility of the oral use of gangliosides to modify or to enhance some of their functions,

such as regulating cell signaling, protein functions, as well as the recognition of microbes and macromolecules.

Sugars

SGLT1, the Na⁺-glucose cotransporter in the enterocyte BBM, is a secondary active transport process which requires a favorable intracellular Na⁺ gradient. This gradient is provided by Na⁺-K⁺-ATPase on the BLM of enterocytes. Constitutive nitric oxide (cNO) has opposite effects on the two primary Na⁺-absorptive pathways in the mammalian small intestine: reducing cNO inhibits SGLT1 and stimulates the Na⁺/H⁺ hydrogen exchanger NHE3^[52]. cNO also regulates mucosal blood flow, mucous secretion, and intestinal motility. The glucocorticoid-inducible kinase-1 (SGK1) stimulates SGLT1 as well as NHE3. The effects of glucocorticoid on SGLT1 are fully dependant on SGK1, whereas for NHE3 the effects of glucocorticoids also involve some additional processes^[53].

During chronic intestinal inflammation, there is a transcription-mediated decrease in the number of glucose transporters. This is possibly due to altered binding of Sp1 and Hnf1, transcription binding sites for the SGLT1 promoter regions^[54].

When glucose is taken by mouth, there is a fast rise in expression of SGLT1. Intestinal sugar uptake is increased in diabetes and in obesity. Roux-en-Y gastric bypass (RYGB) is a successful form of bariatric surgery. RYGB reduces glucose absorption in the Roux limb, as well as in the remaining intestine^[55].

Fructose is prevalent in the diet either as a free hexose, as the disaccharide sucrose, and in the polymerized form, fructans. About 50% of adults are unable to absorb a 25 g load of fructose. Fructans are neither hydrolyzed nor absorbed in the small intestine. This osmotic load may alter intestinal motility and change the microbiota by producing a mucosal biofilm. Restricting dietary intake free of fructose and/or fructan has symptomatic benefits in some persons with diarrhea and bloating^[56].

The revised SLC Transporter Gene Tables are available online at <http://www.bioparadigms.org/slc/intro.htm>.

Carbohydrate malabsorption, as assessed by hydrogen breath testing, is common in persons with Crohn's disease (CD) and celiac disease (CeD)^[57]. The absolute increase in the rate of fructose malabsorption is about 20% higher in Crohn's disease, and lactose malabsorption is 30% higher.

The BBM hydrolysis of carbohydrates takes place by the BBM-bound glycoproteins sucrase-isomaltase (SI), maltase-glucoamylase, and lactase-phlorizin hydrolase (LPH). The pro-SI passes from the ER to the Golgi apparatus. With glycosylation it becomes targeted to the BBM, where it is cleaved by trypsin to form sucrase and isomaltase. Compound heterozygous mutation defects in the protein folding, the direct interaction between sucrase and isomaltase, and an intermolecular chaperone included in the intracellular transport of SI, all have a role in the development of congenital sucrase-isomaltase

deficiency^[58]. Congenital lactase deficiency results from mutations in the coding region of LPH, with misfolding of LPH which prevents the mutant protein from exiting the ER^[59].

Amino acids and proteins

The numerous BBM transporters for amino acids are differentiated functionally by their substrate specificity and driving forces. Neutral amino acids are transported by the system B0+ (Na⁺-dependent transporter for neutral and cationic amino acids), as well as by the ASC system (Na⁺-dependent transporter for mid-size neutral amino acids).

Glutamine comprises approximately 20% of the total amino acid content in the human blood stream, and as such is an important amino acid. Glutamine is the preferred substrate for enterocytes, and is also important for mucosal integrity and the intestinal permeability barrier. The Na⁺-glutamine cotransporter in the BBM of the enterocyte is B0AT1 (SLC6A19)^[60]. Glutamine is converted to citrulline in the enterocytes. A citrulline generation test has been developed to assess enterocyte function, and the value of the slope from baseline to peak plasma citrulline concentrations is reduced in persons with celiac disease^[61].

Under the influence of cholecystokinin (CCK), bile and pancreatic enzymes are secreted into the duodenal lumen where the pancreatic proteolytic enzymes (trypsin, chymotrypsin, elastase, carboxypeptidase A and carboxypeptidase D) digest proteins and polypeptides into peptides, which are usually 2-6 residues in length. Conjugated bile acids accelerate protein hydrolysis by pancreatic proteases^[62].

During chronic intestinal inflammation, there is a decrease in the activity of several transporters such as the short-chain FA-bicarbonate exchanger, H⁺-dipeptide cotransporter, Na⁺-amino acid transporter, Na⁺-glucose cotransporter 1 (SGLT-1), and Na⁺-bile acid transporter. There may be a decreased number of SGLT -1 transporters in villus cells (lowering the value of the maximal transport rate, Vmax), and decreased affinity of the cotransporter for Na⁺-neutral amino acid transport (increasing the value of the affinity constant, Km).

For amino acids, the reduction in transport during chronic inflammation arises from a decrease in the affinity of the transport systems, and may be mediated through an increase in leukotriene D4 (an eicosanoid pathway product), which is released in chronic inflammation^[63].

The proton-amino acid transporter 1 (PEPT1) transports small neutral amino acids as well as small peptides, through mediation of an inwardly directed H⁺ gradient across the enterocyte BBM. PEPT1 also transports drugs such as β -lactam and angiotensin-converting enzyme inhibitors. PEPT1 is under diurnal variation, relating to food intake. It is also influenced by transcription factors, such as Sp1, Cdx2, and PPAR- α . Leptin treatment increases enterocyte uptake of di- and tripeptides *via* the PepT1 transporter, through transcription activation of

the MAPK pathway as well as translational activation *via* ribosomal protein S6^[64].

The albumin D site-binding protein (DBP) expression is regulated in a circadian manner by oscillators called “circadian clocks”. These circadian clocks reside in the suprachiasmatic nuclei (SCN) of the anterior hypothalamus. This clock system consists of single-cell circadian oscillators that are composed of several clock genes. The expression of DBP is in phase with that of PEPT1. DBP binds to the DBP binding site in the distal promoter region of the *PEPT1* gene, and thereby induces transcriptional activity^[65].

The *SLC6A19* gene encodes the main sodium-independent BBM transporter for neutral amino acids, B0AT1. The expression of B0AT1 requires angiotensin-converting enzyme 2 (ACE2)^[66]. It is unknown whether the use of inhibitors of ACE2 in humans alters the protein homeostasis of the body by way of inhibiting the intestinal uptake of neutral amino acids in the small intestine (as well as in the proximal tubule of the kidney).

Small peptides are absorbed predominantly in the proximal small intestine, and free amino acids in the distal intestine. The uptake of sugars is increased by a high carbohydrate diet by upregulation of the Na⁺-dependent BBM glucose transporter SGLT, and the amino acid alanine also controls its own absorption, through capsaicin-sensitive primary afferent neuronal fibers as well as by the peptide calcitonin gene-related peptide, CGRP^[67].

Glutamines become conditionally essential during metabolic stress. Glutamine prevents apoptosis and also plays a role in regulating glucose metabolism. For example, during fasting as well as in diabetes, the intestine by way of its glucose-6 phosphatase (G6Pase) contributes about a quarter of endogenous glucose production through gluconeogenesis.

After a RYGB, used to treat severe obesity, the glucose sensing vagal afferents in the portal vein influence glucose homeostasis. After RYGB, the absorption of glutamine by B0AT is increased in both the biliopancreatic (3.8-fold increase) and the Roux limbs (1.4-fold increase), but not in the common channel. The levels of glutaminase are also increased, but the levels of GEPase (intestinal gluconeogenesis) and PEPCK-C (cytosolic phosphoenolpyruvate carboxykinase, a measure of glutamine metabolism) were not seen to be affected^[68].

Biotin

Biotin is a coenzyme for the “carboxylases” which catalyze essential steps in FA biosynthesis, gluconeogenesis, and catabolism of several amino acids and FAs. Biotin is essential for cellular functions including growth and development. The human intestine utilizes the sodium-dependent multivitamin transporter (hSMVT) for biotin uptake across the enterocyte BBM^[69]. The uptake process is adaptively regulated during biotin deficiency, by induction of protein and mRNA levels of hSMVT, mediated by transcriptional regulatory mechanisms.

Two other functionally unrelated nutrients, the water-

soluble vitamin pantothenic acid and the metabolically important antioxidant lipoate, share the biotin transport system (hSMVT).

Iron

Dietary non-heme ferric (Fe³⁺) iron in the intestinal lumen is reduced to the ferrous (Fe²⁺) form by cytochrome b reductase1 (Cybrd1) in the BBM of the mature villus enterocytes of the proximal small intestine. Iron is transported across the BBM by the divalent-metal ion transporter 1 (DMT1). DMT1 is also known as solute carrier family 11, member 2, (SLC11A2). Fe²⁺ is transported through the cytoplasm of the enterocyte, and is then transferred across the BLM of the enterocyte and into the body by the BLM exporter ferroportin (solute carrier family 40, 1, Slc40a1). There is coordinated expression of ferroportin in enterocytes as well as in tissue macrophages^[70].

Ferroxidase (hephaestin) in the BLM promotes the conversion of Fe²⁺ to Fe³⁺. Once the Fe³⁺ is in the vascular system, it binds to transferrin (Tf). There are two mechanisms by which mRNA levels of iron homeostasis-related genes are regulated; firstly, by post-transcriptional mechanisms mediated by the iron response element/iron regulatory protein system, and secondly, by mechanisms related to transcriptional regulation. In peripheral tissues, the Tf-Tf receptor (TfR) system delivers iron in the Tf-Fe loaded TfR by way of endocytosis. Unlike TfR1, TfR2 mRNA does not contain an Fe-responsive element, and TfR2 mRNA expression is not regulated by intracellular Fe levels. Instead, hepatic TfR2 protein is regulated post-translationally by diferric (Fe²⁺) transferrin. In this way, TfR2 is a sensor of body iron status, and regulates duodenal Fe²⁺ absorption and liver Fe³⁺ uptake^[71]. Hephaestin expression also occurs in gastric antrum, enteric nervous system and pancreatic β -cells^[72].

Fe²⁺ uptake across the enterocyte BBM responds to body iron stores, whereas transport across the BLM is regulated by the enterocyte iron status. When the enterocyte intracellular ferritin level is increased, iron will be transferred across the BLM and into the portal blood. In addition to a potential cytoplasmic route for iron across the enterocyte, there is evidence of vesicular transport or transcytosis of apotransferrin (apoTf). Approximately half of iron transfer across the enterocyte BLM is by way of apoTf and non-apoTf-dependent vesicular pathways^[73].

Factors that affect hepcidin have recently been reviewed and include body iron stores, rate of erythropoiesis, hypoxia and inflammation^[74]. The amount of iron absorbed is regulated by the hepatic synthesis of hepcidin. The most common inheritable form of iron overload is an autosomal recessive disorder caused by mutation in the *HFE* gene, HFE-associated hereditary hemochromatosis (HH). *HFE* codes for a major histocompatibility complex class I (MHC-I)-like molecule. HFE also needs to be associated with a β 2 microglobulin for its appropriate expression of the cell surface.

HFE modulates the expression of hepcidin in the liver. HFE may influence iron status by acting on hepatocytes and/or Kupffer cells, as well as on duodenocytes^[75]. Hepcidin inhibits cellular efflux of iron by binding to and inducing degradation of ferroportin^[76]. Hepcidin causes ferroportin on the BLM to be internalized and degraded^[77]. In macrophages, hepcidin inhibits iron export by inducing ferroportin degradation, whereas in enterocytes hepcidin inhibits DMT1 transcription and thereby reduces BBM iron uptake^[76,78]. Other critical regulators of systemic iron homeostasis are intestinal hypoxia-inducible transcription factors (HIFs)^[79]. HIFs (HIF-1 and HIF-2) are critical mediators of cellular adaptation to hypoxia. HIF-2 α , but not HIF-1 α , promotes iron absorption in mice^[80].

The normal decline in intestinal iron absorption which occurs from neonatal to adult animals is due to loss of the iron transporters (particularly ferroportin) from the distal small intestine and colon^[81]. Curiously, in iron deficiency there is altered intestinal lipid metabolism resulting in production of biologically active lipid molecules (12-HETE, 13-HODE and 13-HOTE), arising as a result of changes in arachidonate 12-lipoxygenase (Alox15)^[82]. It is unknown if this has any clinical significance.

The cytochrome b reductase in the BBM of the duodenal enterocytes (Dcyt6) reduces dietary iron from Fe³⁺ to Fe²⁺. Fe²⁺ is transported across the BBM by divalent metal transporter (DMT). The Fe²⁺ is transported into vesicles containing either ferroportin (FPN1) or hephaestin (Heph). These Fe²⁺-containing FPN1 and Heph-containing vesicles cross the enterocyte cytoplasm to the BLM. The Heph oxidizes the Fe²⁺ to Fe³⁺. Fe³⁺ binds to transferrin and is released into the circulation^[83]. Hepcidin is secreted from the liver in response to the body iron stores: increased body iron stores result in increased hepcidin, decreased FPN1 mRNA expression and increased FPN1 internalization and degradation. The end result of this repositioning of the FPN1 from the BLM is to reduce iron efflux from across the BLM of the duodenocyte, and thereby decrease iron absorption.

Heph, therefore, is a protein in the BLM of the duodenum which has ferroxidase activity to oxidize dietary Fe²⁺ to Fe³⁺. Heph is also found by immunocytochemistry to extend from the gastric antrum along the length of the entire GI tract, and to be present in both the submucosa and the myenteric plexi of the entire nervous system^[72].

In HH, the variable phenotypic expression of the homozygous HFE C282Y genotype has been attributed to possible disease-modifying genes which affect the iron transporters. In HH “expressors” and “nonexpressors”, there is a significant difference in the expression of DMT1 and DMT1 (IRE), such that HFE C282Y homozygotes without phenotypic expression do not have significantly decreased duodenal gene expression of non-transport genes compared with HH subjects with iron overload^[84]. Also, regardless of phenotype, “...there is coordinated regulation between duodenal expression of

FPN1 [ferroportin] and DMT1 [divalent metal transporter 1], FPN1 and DCYTB [ferriductase duodenal cytochrome b] and FPN1 and HEPH [ferroxidase hephaestin] and also DCYTB and HEPH...”.

Calcium

Canonical transient receptor potential (TRPC)1 acts as a calcium channel, with the total calcium effect being mediated by calcium influx through calcium-permeable channels in the plasma membrane, as well as calcium release from intracellular stores such as the ER and cytoplasmic reticulum^[85].

Much of our understanding of calcium (Ca²⁺) absorption has come from studies in animals. Ca²⁺ enters the enterocyte across the BBM using TRPV₆ (aka CAT, or ECAC₂), a Ca²⁺ channel. Intracellular Ca²⁺ is bound to calbindin-D9K, maintaining a low intracellular concentration of free Ca²⁺. PMCA (a Ca²⁺ ATPase) pumps Ca²⁺ across the BLM. The major storage form of vitamin D is 25-hydroxy vitamin D (25OHD). In humans, 25OHD is metabolized by the gene product of CYP27B1 [25-hydroxy vitamin D 1 α -hydroxylase (1 α OHase)] to the biologically active 1 α , 25-dihydroxycholecalciferol [1,25(OH)₂O₃]. 1 α OHase forms 25OHD, which increases the transcription of TRPV₆, PMCA, and CYP₂₄, thereby enhancing Ca²⁺ absorption^[86].

The active hormonal form of vitamin D is 1.25 dihydroxyvitamin D₃ [1,25(OH)₂D]. 1,25(OH)₂D activates the vitamin D receptor (VDR) which heterodimerizes with the retinoid X receptor to interact on response units such as the apical membrane Ca²⁺ channel, TRPV₆ (the transient receptor potential cation channel, subfamily V, member 6), and the Ca²⁺ binding protein calcium binding protein D9k (calbindin D9k). VDR and 1,25(OH)₂D, acting on TRDV₆ and calbindin D9k, maintain high rates of Ca²⁺ absorption^[87].

Copper

Copper is a mineral essential for normal growth and development. The level of copper in the body is regulated, because excessive amounts may be toxic. The copper transporter (Ctr1) is copper-specific; its transport function is energy-independent and saturable. Copper efflux from enterocytes across the BLM is mediated by ATP7A. The ability of suckling rat pups to tolerate varying amounts of dietary copper may be due to changes in copper transporters, Ctr1 and ATP7A, facilitated by transcriptional and post translational mechanisms^[88].

The Steap proteins on the BBM reduce copper to the cuprous form, which is then transported by Ctr1 across the BBM. In the enterocyte, copper is bound to chaperone Atox1, and reaches ATP7A for export across the BLM^[89]. When copper intake is high, Ctr1 is endocytosed into the enterocyte, where there is induction of the copper-binding protein metallothionein, and ATP7A moves to a more basal lateral location. Maturation of small intestinal copper transport occurs by way of increased abundance and local alteration of Ctr1, ATP7A

and ATP7B.

Zinc

The intestinal absorption of zinc is regulated to meet zinc requirements in the body. ZIP4 is a major intestinal zinc transporter; absorptive upregulation of ZIP4 enhances the uptake of zinc from the intestinal lumen, replenishing any deficiency. When the zinc content of the diet is low, there is induction of the transcription factor Kruppel-like factor 4 (KLF4)^[90], which leads to increased intestinal zinc uptake, thereby preventing disease manifestations of zinc deficiency such as acrodermatitis enteropathica.

SHORT BOWEL SYNDROME AND TRANSPLANTATION

“Intestinal failure” refers to a condition in which inadequate digestion and/or absorption of nutrients leads to malnutrition and/or dehydration. The most common condition resulting in intestinal failure is the short bowel syndrome (SBS). The SBS occurs following massive resection of the small intestine^[91]. SBS may be defined anatomically as less than 30% of the normal intestinal length (less than 200 cm in adults). In the United States, the estimated annual prevalence of SBS in patients who have non-malignant intestinal disease, and who require home parenteral nutrition, is at least 4 per 10⁵. The point prevalence is reported to be between 0.6 and 12.7 per 10⁵. The commonest cause of SBS is surgical resection of small intestine for Crohn’s disease. Other common causes include mesenteric infarction, congenital abnormalities, and multiple strictures due to adhesions or abdominal irradiation.

Early in the adaptive response after an intestinal resection, there is an increase in proliferation of intestinal epithelium, with increased depth of crypts, increased villous height, and increased microvillous surface area. The process of adaptation involves the presence of luminal nutrients, gastrointestinal secretions, the mesenchyme, as well as neuronal and hormonal factors. Expansion of the number of intestinal stem cells (ISC) occurs following intestinal resection. This increases the number of intestinal crypts, through the process of intestinal dilation^[92]. These ISCs are located deep in the crypts of Lieberkuhn. Isolation of ISCs has been simplified by the use of side population sorting of viable fractions of cell progenitor characteristics^[93].

Wnt proteins are regulators of cell proliferation, differentiation and adhesion. Mutation in mice of the adenomatous polyposis coli (*APC*) gene, together with augmented Wnt signaling in the intestine, results in an enhanced adaptive response to extensive small bowel resection^[94]. The increased mucosal surface area occurring following resection is due to sustained increases in crypt depth and villus height. This arises from resetting of proliferative responses, with increases in expression of mRNAs associated with proliferation (c-MYC) and dif-

ferentiation of goblet cells and Paneth cells^[95]. This raises the possibility that early expansion of intestinal secretory lineages within the epithelium may serve to amplify the signal(s) for initiating and sustaining intestinal adaptation. Further proof of concept studies are needed.

The Hedgehog (Hh) signaling pathway plays an important role in epithelial-mesenchymal interactions in gut morphogenesis and in epithelial cell proliferation. Hh proteins are produced in epithelial cells, and interact with underlying mesenchymal/stromal cell receptors. Blocking Hh signaling in the fetus or neonate leads to increased crypt cell proliferation, crypt-villus axis structural abnormalities, and alterations in enterocyte morphology. In Hh antibody-treated mice following intestinal resection, enterocyte migration from the crypt to the villus tip is increased, and apoptosis is also increased^[96].

The epidermal growth factor receptor (EGFR) is important in the pathogenesis of intestinal adaptation. This EGFR-mediated induction of enterocyte proliferation requires induced expression of the cyclin-dependent kinase inhibitor p21 to transcribe *waf1/cip1*, as well as mitogen-activated protein kinase (MAPK)^[97]. The cyclin-dependent kinase inhibitor (CDK1) p21*waf1/cip1* may be necessary for induction of enterocyte proliferation following initiation of intestinal adaptation^[98]. To maintain the new homeostasis achieved with adaptation, the high cell production rate must be matched by an equivalent rate of cell loss. EGFR signaling regulates specific Dcl-2 (Dax and Dcl-w) in the intestinal crypts, and this regulation of Dcl-2 influences apoptosis following extensive small bowel resection^[99].

The vascular endothelial growth factor (VEGF) enhances angiogenesis (the growth of new blood vessels from pre-existing blood channels). Angiogenesis is a requirement for successful healing or adaptation. As expected, VEGF is important in the intestinal adaptive response^[100].

The bcl-2 family of intracellular proteins has apoptotic properties. An increase in the ratio between pro- and anti-apoptotic members of these pathways occurs after massive small bowel resection, with upregulation of inducers of apoptosis including Fas and TNF- α by way of the death receptor pathway. Angiotensin converting enzyme (ACE) also promotes apoptosis in association with a reduced bax-bcl-2 protein ratio^[101]. Thus, ACE may play an important role in epithelial cell adaptive responses.

GLP-2 is released from the ileum and colon in response to nutrients in the intestinal lumen. GLP-2 enhances morphologic and proliferative indices of intestinal adaptation, and this adaptation is inhibited by GLP-2 immunoneutralization^[102]. GLP-2 administration enhances intestinal crypt cell proliferation and villus height, and increases expression of glucose transporters. Basal and postprandial GLP-2 levels are correlated with the magnitude of intestinal resection in experimental SBS^[103].

A number of hormones and peptides act on the intestinal tract^[104]. For example, glucagon-like peptide-1 (GLP-1) stimulates glucose-dependent insulin secretion, pancreatic B-cell proliferation, and reduces lipid absorp-

tion, food intake and the rate of gastric emptying^[105]. GLP-2 may reduce Ach release from the enteric nervous system, and thereby reduce neuronally evoked intestinal crypt epithelial Cl⁻ secretion^[106]. GLP-2 enhances the absorption of sugars and lipids^[107] and has a therapeutic potential in patients with the SBS^[108].

SBS patients with an end jejunostomy and no colon have limited meal-stimulated GLP-2 secretion. This is due to the removal of GLP-2 secreting L cells which are located primarily in the terminal ileum and colon. Teduglutide (ALX-0600), a dipeptidyl peptidase IV resistant GLP-2 analog, has been administered to enhance the adaptive process in patients with SBS, and to aid intestinal absorption^[109]. Thus, there is a therapeutic role for GLP-2 analogs in SBS.

Long-term parenteral nutritional (PN) support may be necessary in persons with SBS. Because of the potential complications of PN, such as infection or cholestatic liver disease, efforts have been undertaken to understand and to improve the intestinal adaptive process, and to thereby enhance nutrient absorption and to possibly reduce the need for PN^[110]. The success of surgical procedures designed to optimize intestinal absorptive function, such as bowel tapering or lengthening, has only been modest.

Small intestinal transplantation is an accepted treatment for severe intestinal failure. Over the past 50 years, more than a thousand children have received small bowel transplantation (SBT), alone or with liver and other organs. The one- and five-year graft survival routinely exceeds 90% and 80%, respectively^[111]. However, transplantation is usually used only in those persons who have SBS with complications from home PN. With good control of acute rejection and infections, patient and graft survival after small intestinal transplantation is approximately 77% and 65%, respectively. Patient and graft survivals of 60% and 59% are seen in those with combined liver and small bowel transplantation. Unfortunately, almost half of these transplanted patients require enteral nutrition again within two years after transplantation^[112]. Thus, small bowel transplantation has its risks and limitations for the SBS patient.

NOD2 is an intercellular microbial sensor present in macrophages, dendritic cells and Paneth cells. *NOD2* polymorphisms may be associated with impaired expression of certain Paneth cell-derived antimicrobial peptides. The likelihood of allograft failure is about one hundred-fold higher in small bowel transplantation recipients with mutant *NOD2* alleles, as compared with recipients with wild-type *NOD2* loci^[113].

While intestinal stem cell transplantation may play a role in refractory patients with Crohn's disease (CD) or celiac disease, the role of stem cells in treatment of other intestinal disorders remains at an early stage of consideration^[114,115].

Patients with short bowel syndrome from other non-CD causes were recently reported to develop CD in the residual intestine. The authors suggested that this shortened intestine may be a predisposing factor because of

alterations in the motility of the intestine as well as alterations in the intestinal flora^[116]. In persons with a short bowel syndrome, continuous tube feeding alone or with oral feeding enhances nutrient absorption, as compared with oral intake alone^[117]. "SBS results from surgical resection, congenital defect, a disease-associated loss of absorption and is characterized by the inability to maintain protein-energy, fluid, electrolyte, or micronutrient balances when on a conveniently accepted, normal diet"^[118].

SMOOTH MUSCLE FUNCTION AND INTESTINAL MOTILITY

Segmentation in the intestine consists of rhythmic contractions of the inner circular muscle and occurs after meals. These rhythmic contractions are regulated by slow waves, with the enteric nervous system (ENS) having a permissive role. These stationary contractions are independent of slow-wave activity, while simultaneously activating surrounding inhibitory motor neurons^[119].

The ENS "...coordinates the peristaltic and secretory activity of the gut and is also involved in the regulation of blood flow and modulation of the immune system"^[120]. ENS and enteric glial cells (EGCs) are in the submucosal plexus and the myenteric plexus. The ENS is composed of two ganglionated plexuses, the submucosal and the myenteric plexus, as well as the mucosal plexus. This extends within the lamina muscularis mucosae and the lamina propria mucosae beneath the epithelial lining of the intestine. Activation of human submucosal neurons decreases cellular permeability, and also decreases intestinal epithelial cell proliferation. Neurons respond to changes in intracellular calcium levels or to the expression of activation markers such as c-FOS. TTF- β 1 mRNA is expressed and TGF- β 1 is secreted by EGCs and they have anti-proliferative effects on intestinal epithelial cells^[121]. EGCs promote neuronal survival by regulating substrate supply, and thereby help to maintain neuronal homeostasis. EGCs also synthesize cytokines, and in inflammatory conditions may modulate glia proliferation. Glial disruption alters neurochemical coding of the enteric neurons, and leads to dysmotility^[122].

A method has been described for isolation and culture of primary enteric neurons. These cell lines have neuronal characteristics similar to those of primary enteric neurons^[123]. It is possible to isolate and expand enteric progenitor cells from human adult tissue^[120], thereby providing a potential future role for cell-based therapies for disorders of the ENS.

Patients with IBS may have abnormal colonic transit, as well as increased or decreased rectal sensation. The β 3-adrenoceptor (β 3-AR) is a member of the family of G-protein-coupled receptors. β 3-ARs are co-localized with choline acetyltransferase in human neurons in the cholinergic myenteric and submucosal plexus. Selective β 3-AR agonists inhibit cholinergic contractions, and enhance the release of somatostatin without altering carbachol-induced contractions. β 3-ARs inhibit cholinergic

contractions and inhibit spontaneous contraction of the human colon, as well as relaxing pre-contracted colonic longitudinal and circular muscle. Somatostatin may act as an endogenous analgesic substance, and a β -adrenergic agonist may modify visceral sensitivity. Solabegron is a β 3-AR agonist which has been studied in healthy human volunteers, where it is well tolerated^[124]. This raises the possibility that β 3-ARs may be useful for the pain suffered by persons with IBS.

The IGF system influences cell development, growth, and apoptosis. IGF-binding proteins (IGFBP-1 to -6) transport IGFs in the blood. IGFBP-3 to -5 are present in human smooth muscle, and modify the interaction of IGF-I with its receptor, IGF-IR. IGFBP-5 has a role in regulating smooth muscle growth independent of IGF-1, by activating the G protein G_i3 ^[125].

Acetylcholine (ACh) is released from cholinergic neurons in the myenteric plexus, and activates M2 and M3 receptors on the smooth muscles of the gastrointestinal tract. This results in smooth muscle contraction. The M2 and M3 receptors are expressed in the ratio of approximately 75%/25%, respectively, and are coupled to TRPC4 and TRPC6 (transient receptor potential channels), which depolarize the intestinal smooth muscle cells^[126]. Cholinergic nerves contain substance P, and there are also nitrergic nerves and nerves which release ATP as well as other mediators in the deep muscular plexus.

Substance P (SP)-mediated sustained contraction of the small intestine is negatively regulated at a pre-synaptic level by the M2 receptor, whereas the atropine-sensitive phasic contraction is positively regulated at the M2 receptor^[127]. Cytokines exert differential effects on the muscarinic receptors of intestinal longitudinal smooth muscle^[128]. Corticotropin-releasing-factor (CRF) acts through both central and peripheral mechanisms. CRF induces Ca^{2+} transients in myenteric neurons *via* a CRF-1 receptor-dependent mechanism^[129]. Calcium influx through voltage-operated Ca^{2+} channels, and in particular the R-type channels, causes the calcium transients necessary for muscle contraction.

Nonselective cationic channels in the smooth muscle cells generate muscarinic receptor-induced nonselective cation currents (MICAT), with increased Ca^{2+} influx by way of voltage-dependent Ca^{2+} channels. The Ca^{2+} leads to smooth muscle contraction, and peristalsis.

The gastrointestinal tract contains most of the serotonin (5-hydroxytryptamine, 5-HT) in the body, where it acts as a neurotransmitter, neuromodulator, and a paracrine factor. 5-HT is produced and released by enterochromaffin cells and by enteric nerves of the intestine. In addition to 5-HT having an effect on motility, it also regulates cell survival and proliferation. The 5-HT_{2D} receptors are expressed on the interstitial cells of Cajal (ICC). Exogenous 5-HT regulates the number of ICC through the 5-HT_{2B} receptor, in part by increasing ICC proliferation^[130].

The sensory intrinsic primary afferent neurons (IPANs) from an ENS network modify enteric reflexes,

which in turn alter gastrointestinal functions. The sensory terminals of IPANs are close to the enterochromaffin cells, which contain serotonin (5-HT). Extrinsic afferents (vagus and spinal afferents) have similar innervation territories, and both respond to chemical and to mechanical stimulation. In response to mechanical stimuli, extrinsic afferent neurons do not crosstalk with the IPANs. 5-HT activates the extrinsic afferents by a Ca^{2+} -dependent pathway which is different from the N-type Ca^{2+} channels in IPANs^[131].

The topic of the role of the ICC in gastrointestinal motility has been reviewed^[132]. It has become controversial with regard to the way nerves transmit their signals to regulate activity of intestinal smooth muscle^[133]: the c-kit receptor may be of importance^[134]. ICC help in maintaining the gradient of resting membrane potential, rather than by pacing the slow waves or assisting in their propagation^[135]. It is by volume transmission rather than wire transmission *via* the ICC that there is communication between the enteric neuronal varicosities and muscle cells. While the ICC may be impaired in numerous motility disorders, "...a cause-and-effect relationship between ICC impairment and motility dysfunction is not established". In the small intestine, ICC in the deep muscular plexus mediate neurotransmission, whereas ICC surrounding the myenteric plexus generate slow waves. The slow waves are transferred to the adjacent smooth muscles, and can be recorded as straight "...spontaneous, rhythmic, electrical oscillations of the resting membrane potential"^[136].

The ICC occur in the myenteric plexus, within either the circular (CM) or longitudinal (LM) muscles, contributing to pacing these muscle slow waves. ICC also line the septa (ICC-SEP) separating circular muscle bundles, and ICC-SEP form an important conduction pathway for spreading excitation deep into muscle bundles in the human jejunum^[137]. The $Na^+/K^+/2Cl^-$ cotransporter (NKCC1) is involved in generation of slow waves in the jejunal musculature. ICC at the deep muscular plexus (ICC-DMP) are closely associated with the enteric nerve endings. Varicosities of nitrergic and other nerves are found on ICC-DMP or on CD34-positive, c-kit-negative fibroblast-like cells. The gap junction coupling is necessary for pacing or nerve transmission to the circuit or muscle of the mouse intestine^[138].

The ICC act as pacemakers, producing slow waves of depolarization along the intestinal muscle. A transient outward K^+ current may moderate the uptake of the pacemaker potential, resulting in motility arising from the waves of depolarization^[139].

Bone morphogenetic protein 2 (BMP-2) is a regulatory molecule which induces the phosphorylation of the Smad1 signaling cascade, and thereby increases the differentiation of the neurons of the ENS^[140].

Endogenous adenosine (eADO) is a metabolite of ATP that acts on A1, A2A and A2B receptors on enteric neurons to suppress coordinated responses triggered by immune-histamine H₂ receptor activation^[141].

Extracellular adenosine levels control adenosine re-

ceptor signaling. Enzymes that produce CD73 or degrade adenosine deaminase (adenosine), and thereby alter activity of transport systems in the plasma membrane, influence these extracellular adenosine levels, thereby affecting adenosine receptor signaling, which in turn alters intestinal motility^[142]. β -Adrenoceptors are G-protein-coupled receptors which, when activated by an agonist, stimulate adenylyl cyclase to produce the second messenger, cAMP. cAMP activates cAMP-dependent protein kinase (PKA). There is compartmentalization of the process by which these proteins form an interaction.

Caveolae are non-clathrin-coded plasma membrane invaginations which are present in a variety of cells, including monocytes. These caveoli are present in microdomains, also known as lipid rafts, an area of the plasma membrane which is rich in cholesterol and sphingolipid. The caveolae are coated on their cytoplasmic side by caveolins, a family of integral membrane proteins including adenylyl cyclase, which are involved in signal transduction. In knockout mice depleted of caveolin-1, there is reduced PKA activity and thereby reduced function of the β -adrenoceptors^[143].

Adenosine is generally accepted to be the ligand for the P1 receptor, and ATP is the ligand for P2 receptors. Adenosine A2A receptors on neuronal cells are excitatory in nature, but A1 receptors in the submucosal plexus have inhibitory actions^[144]. In the murine enteric nervous system, adenosine "... suppresses synaptic transmission, efferent function of extrinsic capsaicin-sensitive sensory nerves, mucosal reflexes, neuroeffector transmission, and morphine withdrawal diarrhea". Purinergic signaling pathways are important in sensory signaling in enterochromaffin cells and secretomotor reflexes in the intestinal tract; purinergic modulation of synaptic transmission also occurs in human intestine^[145].

Intestinal motor activity and secretion are linked, and are changed cyclically in a rhythm called the migrating motor complex (MMC). Submucous neurons are both directly and indirectly mechanosensitive, and myenteric neurons can be activated by stretch. There are both rapid and slow components to the potential difference (PD) response to intestinal stretching or distension. The rapid component operates *via* nicotinic transmission and NK1 receptors; the slow component operates by way of VIP-ergic transmission and involves both NK1 and NK3 receptors^[146].

Intestinal inflammation causes hyperplasia of smooth muscle, and this thickening of the smooth muscle layer results in dysmotility. IL-1 β is a proinflammatory cytokine which results in production of PGE2 and NO from macrophages within the ileal smooth muscle tissue, and IL-1 β acts as an anti-proliferative mediator^[147]. Nematode infection in the small intestine induces a smooth muscle hypercontractility that depends on IL-4 and IL-3 (Th-2 cytokines) activation of the signal transducer and activator of transcription (STAT) 6. 5-HT_{2A} is one of the molecules downstream from STAT6 activation that mediates changes in smooth muscle function^[148].

Integrins are a family of transmembrane proteins, and the expression of integrins and their preferred ligands is tissue specific. In the small intestine, occupancy of a specific integrin receptor acts in concert with IGF-I-stimulated receptor tyrosine kinase activity on muscle cell growth^[149]. Both insulin and IGF-I prevent apoptosis through the activation of phosphatidylinositol 3-kinase (PIK3-kinase). Through the subsequent activation of the downstream protein serine/3 kinase, Akt IGF-I stimulates proliferation and inhibits apoptosis in intestinal smooth muscle^[150].

Mechanisms underlying the sustained tonic contraction of the intestinal smooth muscle include prolonged myosin-like chain phosphorylation, phosphorylation of cytoskeleton filaments and associated proteins, alterations in Ca²⁺ influx, and increased sensitivity of contractile elements to Ca²⁺^[151]. Muscarinic agonists acting through M3 receptors contract gastrointestinal smooth muscle by a protein kinase C (PKC)-dependent mechanism in the guinea pig ileum; this is thought to be through a novel PKC, PKC- δ ^[151].

Electrical stimulation may be synchronized with the intrinsic intestinal smooth muscle slow waves [synchronized intestinal electrical stimulation (SIES)]. SIES induces small intestinal contractions during phase I of the MMC in the fed state, and improves postprandial small intestinal hypomotility^[152]. SIES remains to be of proven clinical use.

There are olfactory receptors in human mucosal enterochromaffin cells. Odorants present in the luminal environment of the gut may stimulate serotonin release by way of olfactory receptors present in these EC cells^[153].

The "ileal break" describes the process by which high concentrations of lipids in the terminal ileum will slow gastric emptying and intestinal transit. High intra-ileal carbohydrate and lipid loads induce phase III motility, probably through release of neurohormonal mediators, glucagon-like peptide (GLP-1) and peptideYY (PYY). Physiological postprandial ileal lipid concentrations inhibit human digestive pancreatic protease and bile acid output, but do not influence intestinal motor activity^[154].

Acute radiation exposure of the abdomen is associated with accelerated small intestinal transit through involvement of cholinergic receptors. This raises the possibility that M3 receptors "...may provide specific therapeutic targets in acute radiation enteritis"^[155]. The mucosal damage in the small intestine produced by abdominal radiation may occur independently of intestinal dysmotility, and may result in diarrhea and nutrient malabsorption. Interestingly, the high molecular weight polyethylene glycol-based copolymer PEG 15-20 prevents radiation-induced intestinal injury in rats, prevents apoptosis and lethal sepsis due to *Pseudomonas aeruginosa* in mice, and protects cultured intestinal epithelial cells from apoptosis and microbial adherence, possibly by binding characteristic lipid raft coalescence during the development of intestinal radiation damage^[156].

The mechanisms of drug-associated changes in intes-

tinal motility have been reviewed^[157]. Chronic intestinal dysmotility or chronic intestinal pseudo-obstruction may be primary, or secondary to disorders such as diabetes mellitus or scleroderma. These disorders may affect isolated components of the GI tract, or the entire GI tract. There may be absence of the phase III component of the MMC, postprandial low amplitude contractions, bursts of sustained uncoordinated phasic contractions, and clusters of contractions. All of these mechanisms contribute to the pathophysiology and the high morbidity of these dysmotility syndromes^[158].

Cannabis (CB) and cannabinoid receptors inhibit intestinal motility. The CB1 receptor is present in the central and peripheral nervous system, including the enteric nervous system, as well as in non-neural tissues such as liver and adipose tissue. CB2 receptor expression is present in cells of the immune system as well as in the brain. Lipopolysaccharide (LPS) enhances intestinal transit, and this effect is reversed by cannabinoid CB2 receptor agonists^[159].

Lubiprostone is a bicyclic FA compound, a prostone derived from a metabolite of prostaglandin E1. Prostones have highly selective activity on ClC-2 chloride channels, enhancing intestinal fluid secretion, but also accelerating small intestinal and colonic transit^[160]. These compounds may be used clinically for the treatment of constipation.

Bowel inflammation may lead to abnormalities in intestinal motor and secretory pattern, through changes in enterochromaffin cell activity, as well as through changes in the excitability of primary afferent neurons of the enteric nervous system. Inflammation at one site of the intestine also alters the cellular components of enteric reflex circuits in non-inflamed regions^[161]. Intestinal inflammation is a key event in the pathogenesis of post-operative ileus, and in rats the degree of intestinal paralysis is directly proportional to the degree of intestinal handling and inflammation which occurs at the time of surgery. Intestinal handling triggers mast cell activation and prolongs post-operative ileus^[162]. The therapeutic role of this observation in preventing or treating post-operative ileus remains to be proven.

There are three endogenously-produced biologically-active gases, carbon monoxide, hydrogen sulfide and nitric oxide. Methane is also produced by enteric bacteria in one- to two-thirds of humans, and may slow intestinal transit by augmenting small bowel contractile activity^[163]. Excess methane production has been recognized in a proportion of persons with constipation-predominant IBS.

Substance P and neurokinin A are the main endogenous tachykinins in the enteric neurons. Stimulation of the NK3R receptor in the GI tract activates protein kinase C, then protein kinase D, leading to noncholinergic slow excitatory postsynaptic potentials in the myenteric intrinsic primary afferent neurons of the guinea pig ileum^[164].

The ICC generate pacemaker potentials which drive the electric slow waves that contribute to neuromuscular

signaling leading to motor neurotransmission in the GI tract. ICC express receptor tyrosine kinase c-kit. *Kit* gain-of-function mutations lead to hyperplasia of ICC, with maintenance of both pacemaker function and normal enteric neural responses^[165]. This is in contrast to the association between fewer ICC and the development of disturbances in GI motility. *Ano1* is part of a family of 10 gene products, and labels ICC around ganglia in the deep muscular plexus^[166]. Because *Ano1* does not label mast cells, it may prove to be a better marker than c-kit for ICC and for mesenchymal tumors.

C-kit immunohistochemistry is used to diagnose gastrointestinal stromal tumors (GIST), since about 94% of mesenchymal tumors are positive for c-kit receptors. Between 80% and 90% of GIST tumors have gain-of-function mutations in *Kit*.

Stimulation of the myenteric plexus of the ENS by food in the intestinal lumen or by stretching of the intestine activates mucosal pathways to produce three different types of slow excitatory post-synaptic potentials (EPSPs) which are mediated by tachykinin or purine nucleotide neurons^[167]. The predominant cell type in the ENS, the glial cells, provide functional purinergic neuron-glia communication in the ENS^[168].

Myofibroblasts are an intermediate cell type between smooth muscle cells and fibroblasts. In persons with Crohn's disease, there is disruption of the subepithelial myofibroblasts of the epithelial sheath, adding to the suggestion that myofibroblasts may be involved in the pathogenesis of inflammatory bowel disease^[169]. This role of myofibroblasts is likely because they serve as a component of the innate immune system, and respond to luminal bacterial adjuvants such as LPS^[170].

Manipulation of the intestine rapidly causes activation of the p38 nitrogen-activated protein kinase (MAPK), a stress-activated protein kinase. There is liberation of NO and prostaglandins from the macrophages in the muscularis external to the intestine, and the extravasation of immunocompetent white blood cells^[171]. In turn, this leads to postoperative ileus, which can be prevented by giving mice a single preoperative dose of semapimod, which inhibits p38-MAPK and NO production in macrophages. This is an exciting development for its possible future application to humans undergoing abdominal surgery.

An increase in the intracellular concentration of Ca^{2+} in the smooth muscle of the intestine results from the release of Ca^{2+} from intracellular stores, as well as from the entry of Ca^{2+} into the cell through L-type Ca^{2+} channels. With stretching of the wall of the intestine there develops tension in the plasmalemmal membrane. This tension is transmitted to the mechanosensitive L-type Ca^{2+} channels, thereby leading to increased intracellular Ca^{2+} and the possibility for smooth muscle contraction^[172].

The peristaltic reflex is mediated by IPANs (intestine sensory efferent neurons), interneurons, as well as excitatory and inhibitory motor neurons. The antipropulsive effect of cannabinoids on the small and large intestine result from the inhibition of the calcitonin gene-related

peptide (CGRP)-containing neurons that begin the peristaltic reflex, as well as the inhibition of both the excitatory cholinergic/tachykinergic and inhibitory VIPergic motor neurons responsible for ascending contraction and descending relaxation, respectively^[173].

The balance between myosin light chain kinase (MLCK) and myosin light chain phosphatase (MLCP) controls the overall phosphorylation of the 20-kDa regulatory light chains of myosin III. Ca²⁺-independent contraction of longitudinal ileal smooth muscle is potentiated by a zipper-interacting protein kinase pseudosubstrate peptide^[174]. This raises the possibility of developing synthetic peptides from the autoinhibitory region of the smooth muscle myosin light chain kinase to treat hypomotility disorders of the GI tract.

TUMORS

Small bowel cancers represent a heterogeneous group of rare tumors, and the prognosis depends upon the cell type. The standardized incidence rate for primary malignant small bowel cancer is 1.2/10⁵ men and 0.8/10⁵ women^[175]. The four main histological types are adenocarcinoma (40%), carcinoid (31%), lymphoma (20%) and sarcoma (9%). The five-year survival rate is about 37%, and varies between 57% for neuroendocrine tumors and 18% for sarcomas.

The gastrointestinal tract is the most common extranodal site for non-Hodgkin's lymphoma (NHL). GI NHL may be primary or secondary, the latter usually representing involvement from diffuse nodal disease. GI NHL used to be increased in the HIV-positive population, but with HAART therapy, GI NHL has virtually disappeared^[176]. One intestinal nuclear receptor map has been developed, which "...indicates that the localization pattern of a receptor in normal intestine (signature) predicts the modulation of its expression in tumors"^[177].

DIAGNOSTIC IMAGING

Imaging techniques for the small intestine include the classic small bowel series, enteroclysis, CT enterography, MR enterography, and more recently capsule endoscopy (CE), push enteroscopy (PE), and double balloon enteroscopy (DBE)^[178]. The topic of recent developments in CE has been reviewed^[179-182]. Optimal bowel preparation for CE is a PEG solution plus simethicone^[183]. Using duodenal histology as the gold standard, the performance characteristics of CE for the diagnosis of celiac disease are: sensitivity 88% (95% CI: 76%-99%), specificity 91% (95% CI: 81%-100%), positive predictive value 97% (95% CI: 90%-100%), negative predictive value 71% (95% CI: 56%-87%), as well as positive and negative likelihood ratios of 9.6 and 0.14, respectively^[184]. Of 43 celiac patients, 42% had mucosal changes extending beyond the duodenum, and in 7% the alterations involved the entire small intestine. Interobserver agreement for the diagnosis of celiac disease by CE ranges between 79% and 94%; and κ

values range between 0.6 and 0.9. Murray *et al.*^[185] reported a sensitivity of CE for the detection of small intestinal mucosal atrophy, as compared with upper endoscopy, to be 92% *vs* 55% ($P = 0.0005$), with a specificity of 100%. Other authors have agreed with this high sensitivity of CE (over 90%), but reported a much lower specificity of approximately 64%^[186].

The topic of small bowel enteroscopy has been reviewed^[187]. CE is contraindicated under a number of circumstances^[188]: (1) Swallowing disorder; (2) Known or suspected intestinal obstruction, strictures, or fistulae; (3) Pregnancy; (4) Children less than 10 years old; and (5) Persons with implanted electromedical devices.

In 120 persons on long-term NSAIDs or COX-2 selective agents, CE demonstrated that the 62% with abnormal CE had denuded areas (39%), mucosal breaks (29%), or reddened folds (13%)^[189]. CE demonstrated small intestinal polyps in 60% of subjects with familial adenomatous polyposis (FAP) and in 75% of subjects with Peutz-Jeghers Syndrome^[190].

A meta-analysis of nine studies compared CE *vs* other diagnostic methods for Crohn's disease. The diagnostic yield for CE *vs* barium radiography was 63% and 23%, respectively. The yield for CE *vs* ileoscopy was 61% and 46%, respectively, and the yield of CE compared to computed tomography (CT) enterography/CT enteroclysis was 69% and 30%, respectively. A meta-analysis of the yield of CE *vs* other modality examinations of the small intestine in patients with non-stricturing Crohn's disease showed that CE was superior to small bowel barium radiography, ileoscopy, CT enterography, CT enteroclysis and PE, as well as small bowel magnetic resonance imaging (MRI)^[191]. In patients with previous surgical resection for Crohn's disease, CE is inferior to ileocolonoscopy, but does detect about two-thirds of lesions outside the reach of the colonoscope^[192]. These authors suggest that CE "...cannot systematically replace ileocolonoscopy in the regular management of patients after surgery" (for Crohn's disease). The CE findings have an impact on patient management: physicians change post-CE diagnostic strategy in 61% of patients^[193]. Clearly, CE has proven its diagnostic potential.

There is an incremental diagnostic yield (yield of CE minus yield of comparative modality) of 38% comparing CE to PE, and 22% compared to small bowel MRI. As compared with PE, CE provides superior identification of obscure bleeding sites in the small intestine (50% *vs* 24%). While CE missed 8% of lesions, these sites were accessible to standard endoscopy; in contrast, PE missed lesions in 26% of patients^[194].

DBE may be used from the oral or anal route, or from both. The overall detection rate of small bowel diseases using CE is superior to that with DBE (72% *vs* 41%, respectively), and is also superior for the detection of small bowel diseases in patients with obscure gastrointestinal bleeding (88% *vs* 60%, respectively)^[195]. In another study, for detection of causes of obscure gastrointestinal bleeding, 80% of small bowel abnormalities were detected by

CE vs 60% with DBE^[196]. PE may be inferior to push-and-pull enteroscopy to find lesions in patients with suspected small bowel bleeding^[197]. DBE performance has also been evaluated in patients with refractory CD who had circumferential, discreet, or confluent ulcerations^[196].

When patients with acute intestinal symptoms after allogeneic stem cell transplantation underwent esophago-gastroduodenoscopy (EGD) with duodenal biopsies, as well as CE within 24 h of the onset of their symptoms, acute intestinal graft-vs-host disease (GVHD) was diagnosed by EGD with biopsies in 7 out of 13 patients, 3 of whom would have been missed by EGD alone but were detected by CE. In all 7 patients with histologically confirmed acute intestinal GVHD, CE revealed the typical lesions of GVHD^[198]. The authors concluded that CE showed comparable sensitivity with EGD plus biopsies, and CE also demonstrated a high negative predictive value for diagnosing acute intestinal GVHD.

After the formation of an ileal pouch anal anastomosis (IPAA) in patients having a colectomy for ulcerative colitis, development of pouchitis is common. It is unknown how frequently lesions occur elsewhere in the small intestine. At small bowel follow-through of persons with pouchitis, 13% showed a focal ectasia of the middle ileum and a stenosis of the pouch, whereas CE performed in patients with chronic pouchitis after IPAA showed diffuse lesions from the duodenum to the ileum in all evaluable patients^[199]. These lesions included aphthous ulcers, erosions, redness, atrophy, cobblestoning, and deep ulcers or fissures.

A retrospective analysis of the charts of 562 patients who underwent CE at the Mount Sinai Medical Centre (NYC) for a variety of indications showed small bowel tumors in 9%^[200]. In a report of the largest series of patients with small bowel tumors detected by CE, half were identified in the jejunum and approximately a quarter were in the ileum or in the mid to distal small bowel^[201]. The most common malignant small bowel tumors were adenocarcinoma, carcinoids, melanomas, lymphomas and sarcomas. The most common benign tumors were GIST, hemangiomas, hamartomas, adenomas, and granulation tissue polyps. In a three-center report of Australian experiences with CE, the usefulness of CE was also confirmed, and the authors suggested that “in many patients, detection of a tumor alters management and improves outcomes”^[202].

CE found a median of four small bowel polyps greater than 1 cm in size in persons with Peutz-Jeghers syndrome, while barium follow-through detected a median of only one polyp^[203]. In persons with known familial adenomatous polyposis (FAP), regular examination of the small intestine for small intestinal tumors is part of the recommended management. CE detected ileal or jejunal polyps in 30% of patients, and all polyps were less than 5 mm in size. Upper gastrointestinal endoscopy detected duodenal polyps in 11 of 23 patients, and only four of these patients were identified as having duodenal polyps on CE. Thus, CE underestimated the number of polyps

and did not visualize the ampulla of Vater. This suggests that CE is useful for detection of jejunal and ileal polyps in patients with FAP, but standard forward- and side-viewing endoscopic procedures are advised for detection of duodenal polyps^[204].

While duodenal biopsy represents the gold standard for the diagnosis of celiac disease, CE has shown that over a third of celiac patients have mucosal changes extending beyond the duodenum, and in approximately 7% the entire small bowel is involved^[184]. As compared with duodenal biopsy for detecting celiac disease, the sensitivity of CE was 88%, specificity 91%, positive predictive value 97%, and negative predictive value 71%.

Although CE provides excellent visualization of the small intestinal epithelium, if a small bowel lesion is identified, it cannot be biopsied. DBE is clinically useful to identify and biopsy such lesions^[205-210].

Because of the varying values of the sensitivity and specificity of the various diagnostic methods available to diagnose small bowel disease (such as capsule endoscopy, CT- or MRI- enteroscopy, ileocolonoscopy, small bowel follow-through), it is suggested that except for CE, “...a combination of two of the other available imaging methods is the best diagnostic option for small-bowel Crohn’s disease...”^[211,212]. While CE gives a diagnostic yield in about two-thirds of patients with obscure gastrointestinal bleeding, DBE (when used within 1 mo after the last episode of overt bleeding) reveals positive findings in 84% and provides a means to control bleeding in 64%^[213].

CYSTIC FIBROSIS

Meconium ileus occurs in approximately 20% of newborns with cystic fibrosis (CF). The distal intestinal obstruction syndrome (DIOS) occurs in about 25% of CF adults. Mucus accumulation in the CF intestine is partly due to the dehydrated, acidic environment, as well as to the altered glycosylation of mucins. Mucin glycoprotein levels are increased, due to reduced mucus clearance rather than an enhanced synthesis. This is suggested by the lack of increase in the levels of expression of the major intestinal mucin genes (*Muc2*, *Muc3*). Interestingly, *Muc1* is not a major component of the accumulated mucus of CF mice^[214]. Mucin binds bacteria, both by nonspecific trapping as well as by binding to specific glycans, which help to carry bacteria aborally for efficient clearance from the small intestine.

In human CF, there are mutations in the *CFTR* gene that result in little or no cystic fibrosis transmembrane conductance regulator (CFTR) activity. Some 30%-50% of CF patients have small intestinal bacterial overgrowth (SIBO), thought to be due to slow small intestinal transit^[215]. This SIBO may be due to impaired migrating motor complexes, which lead to less removal of mucus and bacteria from the small intestine. Laxatives and N-acetylcysteine (NAC) reduce bacterial overgrowth in the CF intestine of mice, and this eradication is associated with normalized intestinal transit and a reduction in the innate

immune response^[215].

Exogenous pancreatic replacement enzyme therapy improves, but does not normalize, steatorrhea in CF patients. In CF mice, the crypt-villus axis height is decreased, there are fewer apoptotic cells in the intestinal crypts; there is also goblet cell hyperplasia and inflammatory cell infiltration^[216]. In humans with CF, there is more than just defective lipolytic enzyme activity leading to the malabsorption of lipids. Indeed, there is evidence for abnormal enterocyte intracellular lipid processing in intestinal biopsies from CF subjects, such as decreased lipid esterification and lipid secretion, decreased output of triglyceride-rich lipoproteins, as well as diminished synthesis of apoB48 and apoA-1^[217].

Factors that may contribute to the incomplete normalization of fat malabsorption in CF patients who are compliant with their intake of adequate amounts of pancreatic replacement enzymes include the use of outdated or inactivated enzymes, incorrect timing of the intake of the supplements with regards to meals, excessive duodenal acid inactivation of the enzymes, or reduced duodenal and pancreatic bicarbonate secretion leading to high intraduodenal acid concentrations, impaired formation of mixed micelles, altered composition of the BBM [decreased linoleic acid (18:2n-6) and docosahexaenoic acid (26:6n-3), as well as increased arachidonic acid (20:4n-6) and elevated (20:3n-9) to (20:4n-6) ES] with changes in its permeability and absorptive function, impaired esterification of lipids in the enterocytes, reduced apolipoprotein synthesis, chylomicron formation or secretion across the BLM. CFTR knockdown in Caco-2 cells stimulates both the synthesis and transport of fat but not cholesterol^[218].

Approaches are needed to prevent the CF-associated increased viscosity of the intestinal luminal contents, and hopefully reduce the frequency of meconium ileus in CF newborns, or DIOS in CF adults. The activation of proteinase-activated receptors on the BLM of enterocytes by EGFR activation, MAP kinase signaling, Ca²⁺, PKA (and possibly PKC), causes chloride secretion. PKC enhances the activation of PKA, or increases BLM NKCCI, thereby enhancing the phosphorylation of CFTR, and thus Cl⁻ and water secretion. Basolateral PAR2-induced Cl⁻ secretion induces the activation of PKC β 1 and PKC δ *via* a phospholipase C mechanism, which results in the stimulation of cRaf and ERK 1/2 signaling^[219]. Reduction of NHE3-mediated Na⁺ and water absorption helps to increase the fluidity of the intestinal contents that would otherwise be very thick and dehydrated if NHE3 activity remained normal in the presence of reduced CFTR activity^[220]. Lubiprostone activates ClC-2 chloride channels, causing Cl⁻ and water secretion^[221].

Abstract

Biliary disease in the setting of non-cirrhotic portal vein thrombosis (and similarly in portal vein cavernous transformation) can become a serious problem during the evolution of disease. This is mostly due to portal biliary ductopathy. There are several mechanisms that play a role in the development of portal biliary ductopathy, such as induction of fibrosis in the biliary tract (due to direct action of dilated peribiliary collaterals and/or recurrent cholangitis), loss of biliary motility, chronic cholestasis (due to fibrosis or choledocholithiasis) and increased formation of cholelithiasis (due to various factors). The management of cholelithiasis in cases with portal vein cavernous transformation merits special attention. Because of a heterogeneous clinical presentation and concomitant pathophysiological changes that take place in biliary anatomy, diagnosis and therapy can become very complicated. Due to increased incidence and complications of cholelithiasis, standard treatment modalities like sphincterotomy or balloon sweeping of bile ducts can cause serious problems. Cholangitis, biliary strictures and hemobilia are the most common complications that occur during management of these patients. In this review, we specifically discuss important issues about bile stones related to bile duct

obstruction in non-cirrhotic portal vein thrombosis and present evidence in the current literature.

Harmanci O, Bayraktar Y. How can portal vein cavernous transformation cause chronic incomplete biliary obstruction? *World J Gastroenterol* 2012; 18(26): 3375-3378 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i26/3375.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i26.3375>

INTRODUCTION

The thrombosis occurring secondary to various causes results in acute and generally asymptomatic thrombosis in an extra-hepatic portion of portal vein transformation (PVT). Eventually, portal vein cavernomatous transformation (PVCT) forms as a compensatory reaction 3 wk to 3 mo after the initial event at the hilum of the liver. However, this salvage also results in inevitable anatomical or functional changes at surrounding structures including the biliary tree, gallbladder and pancreas^[1-4]. These changes are secondary to perfusion changes, neovascularization, fibrosis reaction or compression of ducts by newly formed but highly perfused vessels.

Recent terminology uses the term "portal biliopathy" to denote overall anatomical, morphological and functional changes in the biliary tree^[5]. The manufactured term "biliopathy" originates from a combination of the Latin word "bilis" (meaning bile) and the Greek word "pathos" (meaning disease) suggesting a disease of liq-

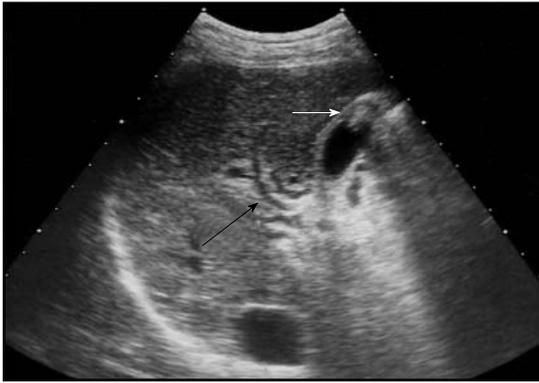

Figure 1 Liver ultrasound image showing stone (white arrow) and portal vein cavernomatous transformation (black arrow) in gallbladder.

uid bile or its constituents. However, current knowledge lacks compelling evidence of formation of diseased bile in patients with PVCT. Therefore in this review, the term “portal ductopathy” (PD) will be used instead of portal biliopathy as suggested by our group previously^[6].

The changes that take place in the biliary ducts during the course of PVCT can be summarized as strictures, dilatations and varicose veins located at the ductular walls and gallbladder. In the long term, these changes result in biliary stasis, jaundice, cholangitis and cholelithiasis adding more to morbidity and even resulting in mortality (Figures 1 and 2). The superimposition of cholelithiasis observed in the setting of PD is very important since these patients are prone to secondary biliary cirrhosis, a complication observed in 4% of patients^[7]. The clinical problem of cholelithiasis observed in chronic, non-cirrhotic PVCT patients is an under-mentioned topic and forms the basis of this compact review. Other clinical problems such as cirrhotic patients, biliary strictures or surgical management related to PD are beyond the scope of this paper.

PATHOGENESIS OF CHOLELITHIASIS IN PORTAL VEIN CAVERNOMATOUS TRANSFORMATION

Theoretically, cholelithiasis in the setting of PD and PVCT may be secondary to chronic cholestasis, changes in the constituents of bile or other factors such as reduced portal flow and associated liver atrophy.

Cholestasis and gallbladder functions

Cholestasis and related clinical findings such as jaundice, pruritus and cholangitis are the most common presenting symptoms in the setting of symptomatic PD and occurs in 5%-30% of all patients^[8,9]. Chronic biliary stasis (due to compression in the biliary outflow and loss of bile duct contractility due to either fibrosis or ischemia^[8]) may eventually result in stones formed *de novo* located in biliary ducts and/or gallbladder. The evidence for the proof of this hypothesis is obtained from clinical studies which generally observed pigment stones, located

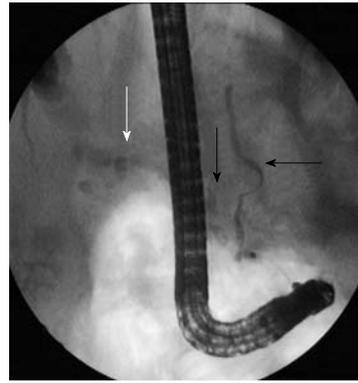

Figure 2 “Portal double ductopathy” sign with stones. Endoscopic retrograde cholangiopancreatography image of a patient with chronic portal vein cavernomatous transformation showing irregular pancreatic duct and biliary ducts (black arrows). Main bile duct shows local stricture and dilations with cholelithiasis (white arrow).

just proximal to the site of ductular stenosis without associated stones in the gallbladder^[10,11]. The reduced contractile function of the gallbladder may also contribute to development of stones due to the presence of varicose veins in the gallbladder wall, but in one study the contractile function of gallbladder has been found to be unchanged^[12]. Thus, cholestasis is believed to develop at later stages of PD secondary to fibrosis and compression of newly formed vessels, which are a major factors for development of stones. Once formed, stones further contribute to cholestasis and stricture formation by initiating recurrent cholangitis attacks.

Change in the constituents of bile

There is a small amount of evidence in the literature to indicate a change in the composition of bile resulting in a tendency for development of cholelithiasis. Previous studies investigating the contribution of reduced portal flow for development of cholelithiasis found that there is an increased tendency towards formation of stones after selective portal vein ligation in dogs^[13]. Also, temporary interruption of portal flow leads to decreased bile acid synthesis and biliary flow^[14]. There is no human study in the literature to indicate definitive changes in biliary composition take place during PVCT. Hypothetically speaking, presence of abnormal portal inflow might contribute to formation of lithogenic bile either by causing hypersplenism and increased pigment load in bile or abnormal enterohepatic circulation of bile acids due to portal hypertension.

FREQUENCY AND CLINICAL FINDINGS OF CHOLELITHIASIS IN PORTAL VEIN CAVERNOMATOUS TRANSFORMATION

The findings obtained from key studies concerning cholelithiasis observed in PVT-PVCT (in adult and pediatric populations) are summarized in Table 1. The frequency of cholelithiasis is highly variable (0%-84%). Probably, this variability is secondary to the problem of potential

Table 1 Cholelithiasis and important findings from selected studies

Author	Patient population	Frequency and location of cholelithiasis (%)	Notes
Bayraktar <i>et al</i> ^[1]	47 PVT patients evaluated by ERCP	8 (19) located in CBD	Unselected PVCT patients irrespective of symptoms, had a control group of 22 patients with other causes of portal hypertension
Condat <i>et al</i> ^[11]	25 consecutive patients in 2 yr evaluated by MRCP	4 (16)	Cholelithiasis associated with abrupt elevation of transaminase level, obstructive jaundice and cholangitis (2 patients)
Khare <i>et al</i> ^[27]	13 patients with obstructive jaundice evaluated by ultrasound	4 (31) located in GB, 4 (31) located in CBD	Retrospective selection of patients with obstructive jaundice
Sezgin <i>et al</i> ^[19]	10 consecutive patients in 6 yr presenting with jaundice and/or cholangitis evaluated by ERCP	0	Only patients with biliary symptoms are evaluated; Total number of patients or prevalence of cholelithiasis is not mentioned
Oo <i>et al</i> ^[16]	13 patients with symptoms related to PD in 13 yr	11 (84) located in GB, 9 (69) located both in GB and CBD	Symptomatic patients selected
Dumortier <i>et al</i> ^[28]	6 consecutive patients presented as case series	4 (66) located in GB, 2 also had stones in CBD	Upon follow up 3 patients suffered from cholecystitis and cholangitis requiring cholecystectomy
Chaudhary <i>et al</i> ^[20]	9 symptomatic PD patients managed surgically	2 (22) located in CBD	Selected patients with indications for surgery; Bile aspirates during surgery revealed <i>Escherichia coli</i> in patients with stones
Agarwal <i>et al</i> ^[29]	39 symptomatic PD patients managed surgically	12 (30) located in GB, 7 (18) located in CBD	Selected patients with indications for surgery
Dhiman <i>et al</i> ^[17]	53 symptomatic and asymptomatic patients	11 (20) (7 located in GB while 4 in CBD)	Stones were found more frequently in patients with symptoms than asymptomatic patients
Ozkavukcu <i>et al</i> ^[30]	16 patients diagnosed with PVT evaluated by MRCP	0 (there are 3 patients with history of cholecystectomy but the reasons are not given)	Patients with history of, chronic liver diseases, liver abscess and hydatid cyst were not eliminated with potential interference with findings of biliary system
Chiu <i>et al</i> ^[31]	29 children with PVT diagnosis evaluated for Rex shunt	5 (17) located in GB, 4 (14) had biliary sludge	Only children evaluated for possible surgery included
Yamada <i>et al</i> ^[32]	21 children with PVT	3 (14) located in GB	21 patients selected out of 35, selection criteria not mentioned

PVT: Portal vein transformation; ERCP: Endoscopic retrograde cholangiopancreatography; MRCP: Magnetic resonance cholangiopancreatography; PD: Portal ductopathy; CBD: Common bile duct; GB: Gallbladder; PVCT: Portal vein cavernomatous transformation.

bias in patient selection criteria. Most of the studies only included patients with symptoms in a retrospective design or included patients with chronic liver disease-cirrhosis or with mass-occupying lesions. In most of these studies, investigation methods [endoscopic retrograde cholangiopancreatography (ERCP), magnetic resonance cholangiopancreatography or ultrasound] were not uniform so it was not possible to make a definitive conclusion about incidence and prevalence of stones. The choice of investigation method has been found to have a clear impact on the results of anatomical location of cholelithiasis found in the biliary system. Therefore, current literature lacks prospective and well-designed studies to reveal the exact prevalence and incidence of cholelithiasis in a group of well selected PVCT patients irrespective of presence of symptoms.

The clinical findings related to cholelithiasis in PVCT patients are not different from patients who do not have PVCT, but it is evident that it results in a high frequency of PD symptoms. Cholelithiasis is found more commonly in patients with biliary findings such as jaundice, biliary colic, cholangitis and elevated liver enzymes compared with asymptomatic patients^[7,15].

TREATMENT

The management of stones in patients with PVCT merits special attention since concomitant changes in the biliary system may jeopardize standard therapeutic proce-

dures. The collaterals of Petren and Saint around major bile ducts enlarge in response to PVCT and they form the basis of collateral vessel compression to major bile ducts in PD^[6,7]. Also, secondary to ischemic injury and development of fibrous tissue in the major biliary ducts, biliary interventions should be performed with caution. Since these varicose collaterals and fibrous strictures may result in detrimental complications like hemobilia or recurrent cholangitis, clinicians should follow special management strategies being aware of these potential risks. Otherwise, therapeutic strategies for cholelithiasis in PD are not different from other patient groups.

In previous studies focusing on treatment of PD, the major concern and attention was given to the problem of biliary strictures. The treatment of strictures and associated cholestasis is important since resolving these factors also reduces the risk of formation or recurrence of cholelithiasis. Biliary stricture and associated jaundice can be managed by medical treatment with ursodeoxycholic acid^[11,16] or by interventions like biliary stenting^[16-18], balloon dilatation^[19] or portosystemic shunting^[20]. If present, cholelithiasis should first be managed by evaluation of varicose veins around the common bile duct, either by magnetic resonance angiography or endoscopic ultrasonography^[17]. After elimination of varicose veins, standard sphincterotomy and balloon trawl for extraction of common bile duct stones and/or sludge should be employed^[10]. The presence of any collateral varicose vein is very important since inadvertent interventions

like basket removal of stones or biliary stenting might result in bothersome hemobilia^[21-25] requiring massive transfusions, injection sclerotherapy^[26], terlipressin^[25] or urgent portosystemic shunting^[21]. In our personal experience, we propose that papillotomy should be performed at earlier stages of disease as a prophylactic measure to make future ERCP procedures safer and easier. If not performed earlier, varices and fibrosis in the distal main bile duct can preclude or complicate safe papillotomy.

In conclusion, cholelithiasis and choledocholithiasis in the setting of PVCT and PD is a specific problem that needs special attention. Stones can become very problematic and interventions may result in severe hemobilia. Stone extraction by balloon or basket trawl can be grueling due to strictures and fibrosis in biliary system. If present, biliary strictures and severe vascular compression should be treated by medical or interventional treatments in order to facilitate stone extraction and reduce recurrence. Further well designed prospective studies are required to clearly understand the exact natural history of cholelithiasis in PVCT patients.

Abstract

AIM: To investigate the effect of age on severity of acute pancreatitis (AP) using biochemical markers, histology and expression of the protective pancreatitis-associated proteins (PAPs).

METHODS: AP was induced *via* intraductal injection of 4% sodium taurocholate in young and old rats. Sera and pancreata were assayed at 24 h for the parameters listed above; we also employed a novel molecular technique to assess bacterial infiltration using polymerase chain reaction to measure bacterial genomic ribosomal RNA.

RESULTS: At 24 h after induction of AP, the pancreata of older animals had less edema (mean \pm SE histologic score of young *vs* old: 3.11 ± 0.16 *vs* 2.50 ± 0.11 , $P < 0.05$), decreased local inflammatory response (histologic score of stromal infiltrate: 3.11 ± 0.27 *vs* 2.00 ± 0.17 ,

$P < 0.05$) and increased bacterial infiltration ($174\% \pm 52\%$ increase from sham *vs* $377\% \pm 4\%$, $P < 0.05$). A decreased expression of PAP1 and PAP2 was demonstrated by Western blotting analysis and immunohistochemical staining. There were no differences in serum amylase and lipase activity, or tissue myeloperoxidase or monocyte chemoattractant protein-1 levels. However, in the most-aged group, serum C-reactive protein levels were higher (young *vs* old: 0.249 ± 0.04 mg/dL *vs* 2.45 ± 0.68 mg/dL, $P < 0.05$).

CONCLUSION: In older animals, there is depressed PAP expression related to a blunted inflammatory response in AP which is associated with worsened bacterial infiltration and higher C-reactive protein level; this may explain the more aggressive clinical course.

INTRODUCTION

Acute pancreatitis (AP) is a disease with significant impact in the United States. In 2003 there were about 226 000 admissions for this diagnosis, at a cost of over \$2.2 billion^[1]. The incidence of pancreatitis is higher^[2], and its severity is

worse^[3] in the older patient. While Frey *et al*^[3] showed that the increased comorbidities associated with age account, in part, for the worsened severity, he and others also showed that age is an independent prognostic indicator of survival, specifically in patients over the age of 70 years^[3-5].

The mechanism that puts the aged pancreas, and aged patient, at risk for severity in pancreatitis is unknown. Possibilities include: the immune response of the organism to the injury is impaired; the host organ response to the injury (e.g., lung or renal) is worsened; or protective mechanisms from the pancreas are depressed. The latter two concepts are supported by the observation that the aged patient with pancreatitis has a higher incidence of systemic complications, while there is a decreased local complication rate^[4].

We have recently defined that pancreatitis-associated proteins (PAPs) are proteins innate to the pancreas which are induced during AP. PAPs are members of the pancreatic regenerating (Reg) family of proteins, which are calcium-dependant lectins; all are secretory proteins^[6-8]. PAPs are homologues of pancreatic reg I, and in rats, mice and man, localize to the same chromosome^[7,9-12]. However, while reg I is constitutively expressed in normal pancreas, PAP mRNA expression is very low. PAPs are highly induced during AP^[7,13].

PAPs are endogenous protectors against pancreatic injury. We have shown that targeted inhibition of the three rat PAP isoforms, PAP1, 2 and 3, exacerbated AP^[14,15]. They likely protect by immunomodulation^[16-18]. In particular, PAP2 protects by inducing macrophages, and PAP1 has other anti-inflammatory and anti-apoptotic effects^[19].

Loss of protection by PAP with aging may put patients at risk for pancreatitis. The normal expression of the PAP homologue pancreatic regeneration gene I (*reg I*), decreases in aging^[20], resulting in impairment of its function in the aged animal. We postulate that PAP levels are also depressed in aging, resulting in less protection in AP and more severe disease. However, since baseline PAP levels are minimal in the normal pancreas, we needed to measure the extent of its induction after stimulation.

In this study, we used sodium taurocholate (NaT) to induce AP and determined: (1) the extent of pancreatitis in young and old rats; (2) the extent of PAP expression in young and old animals with pancreatitis; and (3) how PAP expression relates to severity of pancreatitis in the older animals. We employed a novel molecular method to measure bacterial infiltration.

MATERIALS AND METHODS

Animals

Sprague Dawley male rats weighing 260-1000 mg (Charles River, Wilmington, MA) were divided follows: animals in the young group had an average age of 91.9 ± 3.7 d (range 82-111 d, $n = 10$), and those in the older group averaged 339 ± 17.9 d (range 291-546 d, $n = 21$). Each group had 10 unoperated and 10 sham-operated animals as controls.

Animals were fed standard laboratory chow, given

water *ad libitum*, and were randomly assigned to control or experimental groups. All animal studies were approved by the Division of Animal and Laboratory Resources, SUNY Downstate Medical Center.

Pancreatitis

AP was induced with 4% NaT, by retrograde injection into the pancreatic duct as previously described^[14]. Briefly, under nembutal anesthesia (50 mg/kg intraperitoneally, Abbott Laboratories, North Chicago, IL), a midline incision was performed. The common bile duct was identified and cannulated in a retrograde direction with PE-10 tubing (Fisher Scientific, Pittsburgh, PA) through the ampulla of Vater *via* small needle puncture of the duodenum. The bile duct was ligated to prevent the flow of bile, and NaT was infused into the pancreatic duct at a rate of 1 mL/kg over 30 min. The abdomen was then closed with monofilament suture, and the animals allowed to recover.

Animals assigned to the sham group were anesthetized under the same protocol as the sodium taurocholate group. They were then subjected to a midline incision, pancreaticoduodenal manipulation, and then similarly closed and recovered.

Post-operative analysis

The animals were sacrificed 24 h after surgery. Swab cultures of the pancreata were taken, after which whole blood was taken *via* an 18-Gauge syringe in the inferior vena cava. The pancreas was then subdivided into 30 mg portions for pathology (10% formalin), RNA isolation (liquid nitrogen and rapid isolation), and protein isolation.

Qualitative cultures were performed in the clinical microbiology laboratory at SUNY Downstate, for which samples were plated on agar plates for 48-72 h.

To calculate edema, a pancreatic sample was immediately weighed on a coverslip and placed in a 37 °C dry oven. These samples were then re-weighed at 72 h on the same scale. The wet-to-dry ratio was then calculated.

Other pancreas samples were homogenized in 25 mmol/L Tris/0.5% Triton (Sigma, St. Louis, MO) in a glass homogenizer and centrifuged at 12 000 *g* for 10 min at 4 °C. After aspiration of the lipid layer, the supernatant was poured into a 1.5 mL tube and the pellet discarded. Proteins were assessed by the Bradford Assay (Bio-Rad Laboratories, Inc., Richmond, CA) and all samples were diluted to 2 mg/mL in phosphate buffered saline (PBS) (Lonza, Walkersville, MD), treated with protease inhibitor cocktail (Sigma) and stored at -20 °C until analyzed.

Ribonucleic acid isolation

Pancreas samples were flash frozen in liquid nitrogen and immediately processed using 600 μ L Trizol reagent (Fisher Scientific, Piscataway, NJ). The samples were homogenized and mixed with 75% ethanol. The tubes were centrifuged at 10 000 *g*, and the clear lysate was applied to an RNeasy column (Qiagen, Valencia, CA). They were

centrifuged at 10 000 *g* for 15 s and then rinsed with wash buffer, and subjected to DNase digestion.

Blood

Whole blood was collected in red-top tubes without anti-coagulant (Fisher, Piscataway, NJ) and allowed to clot for 30 min at room temperature. Tubes were centrifuged at 1800 rpm for 20 min. Sera were collected and stored at -80 °C until analyzed.

Serum amylase activity was measured using 4,6-ethylidene (G7)-p-nitrophenyl (G1)- α -D-maltoheptaoside as the substrate. Serum lipase was measured by the Clinical Laboratories, SUNY Downstate Medical Center. Similarly, C-reactive protein (CRP) levels were determined in the clinical laboratory using a conventional immunoassay system and Beckman nephelometer (Beckman Coulter, Inc., Galway, Ireland).

Myeloperoxidase, monocyte chemotactic protein-1 analysis

Pancreatic protein was assessed for rat monocyte chemo-tactic protein-1 (MCP-1) using the Rat MCP-1 ELISA Kit for tissue lysate (RayBiotech, Inc., Norcross, GA) and myeloperoxidase (MPO) by the rat MPO ELISA kit (Cell Sciences, Canton, MA) according to the manufacturer's protocol.

Polymerase chain reaction

One-step real-time quantitative reverse-transcriptase-polymerase chain reaction (PCR) for PAP 1, 2, 3, and *reg I* was performed as previously described^[13,14] using the LightCycler 480 (Roche, Indianapolis, IN) with β -actin as an endogenous control to standardize the amount of sample RNA added to a reaction. Primers and probes were designed as previously for PAP 1, 2, and 3^[13,14]; the primers for *reg I* were 5'-TACAGCTGCCAATGTCT-GGATT-3' (forward), 5'-CAGTGTCCAGGATTT-GTAGAGA-3' (reverse), and 5'-ATCCCAAAAATA-ATCGCCGCTGGC-3' (probe) (Applied Biosystems, Bedford MA). One hundred nanograms of total RNA was used to set up 20 μ L real-time quantitative PCRs that consisted of 1 \times Master Mix, 500 nmol/L forward and reverse primers, and 250 nmol/L TaqMan probe (Roche). Polymerase chain reaction amplification was performed with the temperature profile of: 3 min at 45 °C, 7 min at 95 °C, and 45 cycles of 5 s at 95 °C and 30 s at 60 °C. Assays were performed in triplicate. Data were analyzed with the relative standard curve method. Standard curves of the genes of interest and β -actin were prepared with six ten-fold dilutions of total RNA from the sample that was expected to have the highest amount of mRNA for the gene of interest. For each reaction tube, the amount of target or endogenous reference was determined from the standard curves. The mean amount of each sample was calculated from the triplicate data and was normalized by division by the mean quantity of β -actin RNA for the same sample. The mean and standard error of each

treated group were calculated from the normalized value for each rat in the group.

Bacterial 16s ribosomal DNA from pancreatic tissue was amplified by PCR as described^[21], using probes specific for gram-positive cocci (GPC) and gram-negative rods (GNR). The primers are specific for bacterial 16sRNA, a gene highly conserved in bacterial strains. Briefly, 0.2 μ g of total DNA extracted from each pancreas tissue isolated above was added to pre-decontaminated PCR cocktail for PCR amplification with the primers. The product is a 370 bp fragment.

Western blotting analysis

After SDS-polyacrylamide gel electrophoresis (15%), 15 μ g and 30 μ g protein/well was electrophoretically transferred to nitrocellulose (Nytan; Schleicher and Schuell, Keene, NH) and monoclonal antibody to *reg I*^[22] was used at 1:10 000 dilution, polyclonal antibodies to PAP 1, and PAP 2^[22] were used at 1:1000 dilution. Secondary antibody to IgG at 1:100 000 dilution was used for detection of primary antibody.

Densitometry was performed using the Bio-Rad Gel Documentation System with Quantity One software. Units are presented as Intensity (INT) \times area (mm²).

Histopathological analysis

The head of the pancreas from each rat was fixed in 10% buffered formaldehyde solution (Fisher Scientific, Pittsburgh, PA). Four to six micron section slides were generated for each pancreas, collected and stained with hematoxylin and eosin (H and E). Using previously described criteria, the histological severity of pancreatitis was examined in a blinded fashion by our pathologist. Using a scale ranging from zero (representing the least), to four (representing the greatest) severity, the degree of leukocytic infiltration (acinar and stromal) and tissue necrosis (acinar and stromal), edema and hemorrhage were determined for each specimen.

Immunohistochemical analysis was done as described in^[23] using PAP1 and 2 antibodies at 1:1500 dilution.

RESULTS

NaT experiments

There were three mortalities after surgery to induce pancreatitis; 2 in the young and one in the old group. Where appropriate, we show data from shams and unoperated controls for clarity and comparisons. Where noted, we performed subgroup analysis of the older animals, dividing them into: subgroup (a) aged, whose average age was 256.3 \pm 2.1 d (*n* = 10); subgroup (b) very aged, 372.5 \pm 0.4 d (*n* = 9); and subgroup (c) most aged, 544 \pm 2.8 d (*n* = 3). The latter group had the single mortality of the older group.

Twenty four hours after induction of NaT pancreatitis, older animals had slightly less edema, as measured by ratio of wet to dry weight, when compared to younger ones (1.35 \pm 0.04 *vs* 1.52 \pm 0.08, *P* = 0.07). By compari-

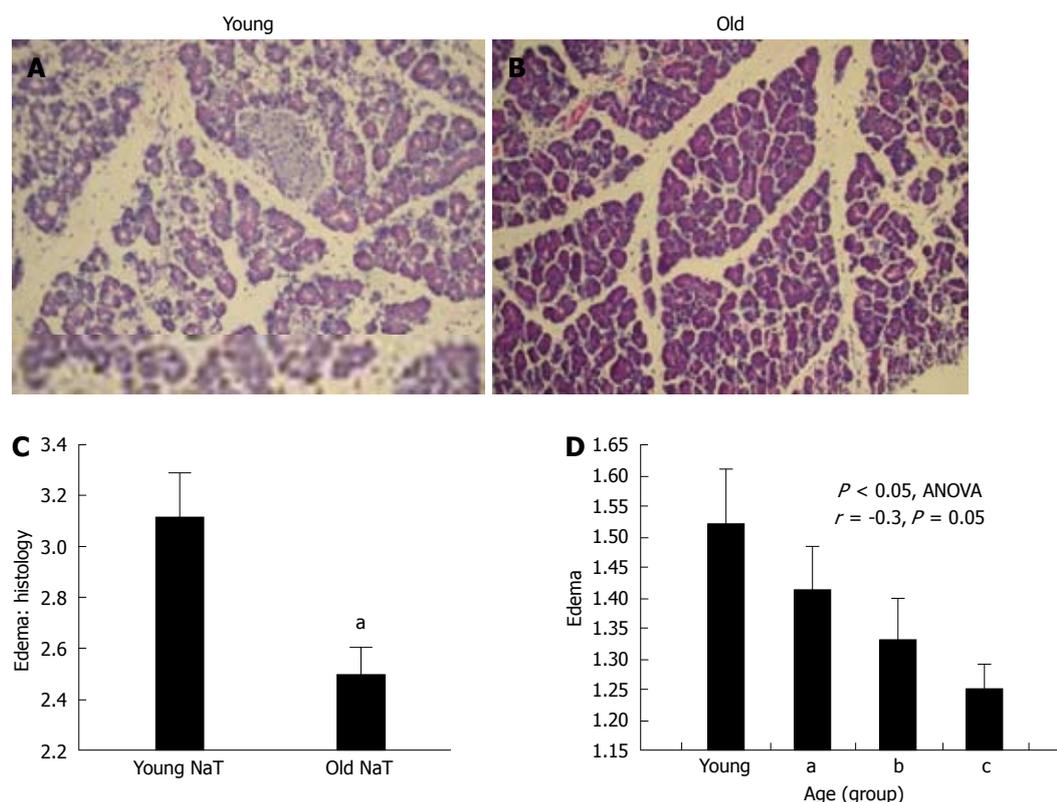

Figure 1 Effect of age on pancreatic edema 24 h after induction of sodium taurocholate pancreatitis. A: A young rat with severe, grade 4 edema [hematoxylin and eosin (H and E), 40×]; B: An old rat with moderate, grade 3 edema (H and E, 40×); C: Mean ± SE histologic scoring of edema for both groups; D: Edema data calculated by wet:dry ratio of pancreatic tissue. While young vs old ratios are discussed in the text, when animals were sorted into young, aged (group a), very aged (group b) and most aged (group c) groups, a progressive decrease in edema was seen with age. A significant negative correlation was also noted ($^{\#}P < 0.05$, Student's *t* test). NaT: Sodium taurocholate; ANOVA: Analysis of variance.

son, sham-operated animals had 1.12 ± 0.03 wet to dry ratios; unoperated controls had 1.01 ± 0.08 (all statistically significantly lower than the NaT group).

Histopathologic examination also showed that the extent of edema was significantly depressed in the older group (Figure 1A-C, $P < 0.05$) When subgroups of age (subgroups A-C), were subjected to analysis of variance (ANOVA), there was a statistically significant decrease (Figure 1D, $P = 0.02$), and significant negative correlation ($r = -0.3$, $P = 0.05$) with aging.

Histopathologic examination also showed that the extent of parenchymal and stromal inflammatory cell infiltrates was depressed in aging (Figures 2A and B, 3B and C). The extent of necrosis (acinar, peripheral acinar or fat necrosis), cellular vacuolization and hemorrhage was not different in the older animals (Figure 3A).

Markers of pancreatitis

When compared to sham-operated controls, animals with NaT pancreatitis showed significant increases in amylase ($628 \pm 63 \mu\text{g/L}$ vs $7919 \pm 2022 \mu\text{g/L}$, respectively, $P < 0.05$), and lipase ($37.7 \pm 16 \mu\text{g/L}$ vs $864 \pm 260 \mu\text{g/L}$, respectively, $P < 0.05$). Also, pancreatic levels of MPO were very high ($202 \pm 49 \text{ ng/mL}$ vs $2014 \pm 628 \text{ ng/mL}$, respectively, $P < 0.05$), as were levels of MCP-1 ($2172 \pm 463 \text{ pg/mL}$ vs $4508 \pm 251 \text{ pg/mL}$, respectively, $P < 0.05$). However, when values from old and young NaT animals

Table 1 Effect of age on biochemical markers of sodium taurocholate pancreatitis

	Young rats	Old rats
Amylase ($\mu\text{g/L}$)	$12\ 536 \pm 6141$	5941 ± 1162
Lipase ($\mu\text{g/L}$)	1288 ± 755	682 ± 194
MPO (ng/mL)	1962 ± 538	2066 ± 1219
MCP-1 (pg/mL)	4312 ± 350	4730 ± 376
CRP (mg/dL)	0.25 ± 0.04	0.61 ± 0.19

All serum levels were higher than sham and unoperated controls. No differences were seen between young and old animals. However, subgroup analysis of CRP levels revealed that the most-aged subgroup (c) had significantly higher levels (Figure 3). MPO: Myeloperoxidase; MCP-1: Monocyte chemoattractant protein-1; CRP: C-reactive protein.

were compared, no differences were noted (Table 1).

Serum CRP levels in control, unoperated animals were $0.17 \pm 0.07 \text{ mg/dL}$. A significant increase in CRP was seen after NaT ($0.25 \pm 0.04 \text{ mg/dL}$, respectively, $P = 0.05$ compared to unoperated controls); but when young and old NaT animals were directly compared, no difference was seen between younger and older groups (Table 1). However, subgroup analysis of age groups showed that serum CRP was statistically higher in the most-aged (subgroup c) (Figure 4) ($2.45 \pm 0.69 \text{ mg/dL}$, $P < 0.001$ ANOVA compared to all groups, $P < 0.001$ compared to young, Student's *t* test). This phenomenon was noted only for

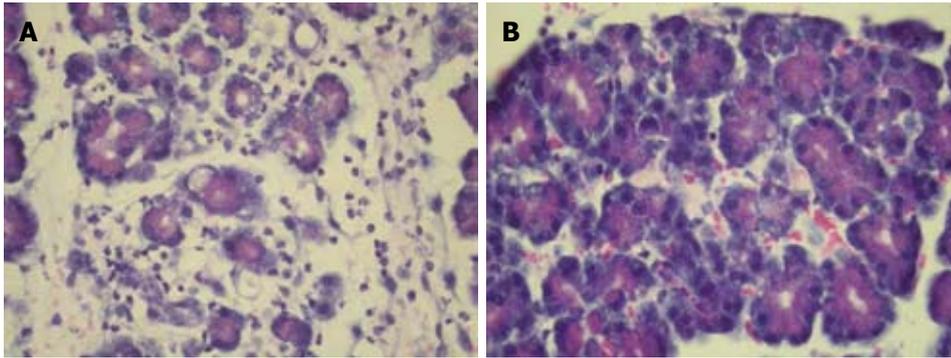

Figure 2 Histology (hematoxylin and eosin, 100 \times) of young (panel A) and old (panel B) inflammatory infiltrates 24 h after induction of sodium taurocholate pancreatitis. A: Severe, grade 4 parenchymal inflammation in the young animal; B: Mild, grade 2 inflammation in an older one.

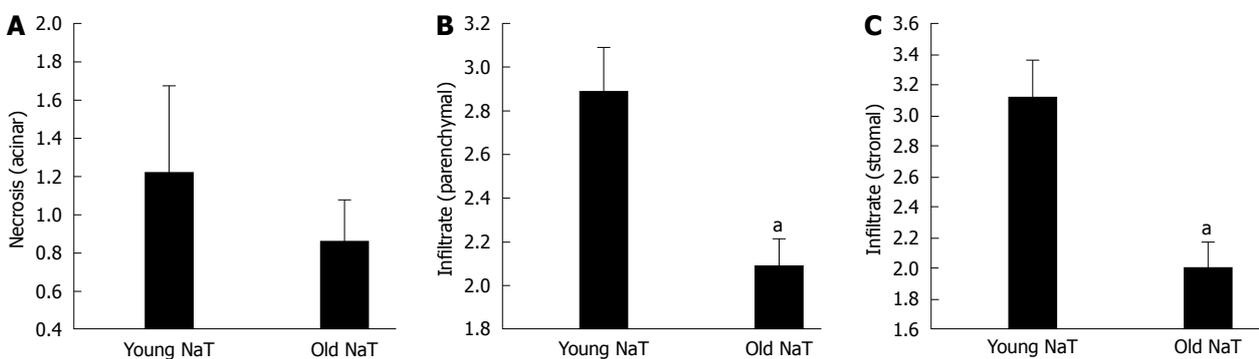

Figure 3 Histologic scores. There was no difference in necrosis scores between young and old (C), but significant decreases were observed in inflammatory infiltrates of the parenchymal (D) and stromal (E) tissue ($^aP < 0.05$, Student's *t* test). NaT: Sodium taurocholate.

CRP, not for any of the other markers measured above (amylase, lipase, MPO, MCP-1).

Real time PCR of mRNA isolated from rats with pancreatitis showed that *reg I*, PAP1, PAP2 and PAP3 all increased when compared to controls (not shown). The increase was similar to that which we have observed previously^[13,14] with *reg I* increasing twofold, and PAP1, 2, and 3 increasing 50-100 fold (not shown). Western analysis showed that protein levels increased but only minimally for *reg I* and by a factor of 3-8 fold for PAP1 and 2.

When young and old NaT animal mRNAs were compared, no differences were noted for pancreatic *reg I*, PAP1 and PAP2 mRNA (Table 2); and only PAP3 levels were significantly decreased. Conversely, when protein levels were compared, older animals had lower levels of PAP1 ($P < 0.05$); PAP2 proteins were depressed as well ($P = 0.07$) (Figure 5). PAP3 proteins were not measured since antibodies were not readily available.

Since we have previously shown *in vitro* that PAP2 directly activates leukocytes^[17], we postulated that its expression would correlate with MPO or MCP-1 activity. While there were no correlations between mRNAs or proteins and MCP-1 levels, a significant positive correlation of PAP2 mRNA levels with MPO protein was observed ($r = 0.81$, $P = 0.004$).

Immunohistochemistry

PAP1 and 2 immunohistochemistry showed no staining in normal pancreas, and positive staining pattern in the acinar cells (Figure 6A-C) after induction of NaT pancreatitis. Similar to our observation in the Western analysis, both PAP1 and 2 immunohistochemistry showed more intensity in the younger animals when compared to older (Figure 7); preparation of the slides was done side by side.

In young animals, PAP1 staining in AP was typically intracellular, uniform, and oriented in a base-to-apical intensity (Figures 6B, 7A). In contrast, PAP2 staining in AP was heterogeneous (Figures 6C, 7C): it too was intracellular, but was occasionally visible as dense, clumped proteins towards the base of the cells.

In older animals the staining patterns reversed: PAP1 staining became more heterogeneous (Figure 7B), and the pattern for PAP2 became more homogenous (Figure 7C).

Interestingly, in many sections, PAP2 staining was found in areas which corresponded to parenchymal and stromal inflammatory infiltrates (Figure 8).

Bacteriology

Qualitative cultures of the pancreata from almost all the animals showed colonization by GPC and GNR, with no difference between old and young animals. For example,

Table 2 Effect of age on pancreatic Reg1 and pancreatitis-associated protein mRNA levels

	Young rats	Old rats
Reg1	0.727 ± 0.19	1.27 ± 0.22
PAP1	119 ± 46	116 ± 18
PAP2	690 ± 267	475 ± 142
PAP3	57.8 ± 19	26.4 ± 4.3 ^a

Real time polymerase chain reaction analysis of RNA isolated from pancreata from young and old rats 24 h after induction of pancreatitis by sodium taurocholate. All were done against a β-actin control. No difference in RNAs were found except for pancreatitis-associated protein (PAP)3 (^a*P* < 0.05, Mann Whitney *U* test).

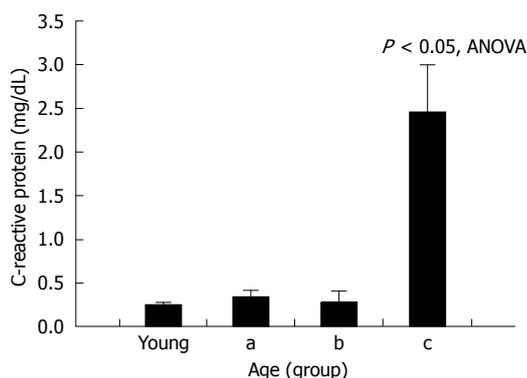

Figure 4 Effect of age on serum C-reactive protein level 24 h after induction of sodium taurocholate pancreatitis. Data for young vs old animals were not significantly different and are shown in the text and Table 1. However, when animals were sorted into young, and subgroups of aged (subgroup a), very aged (subgroup b) and most aged (subgroup c), a significant increase in C-reactive protein was seen in the most aged group (subgroup c). ANOVA: Analysis of variance.

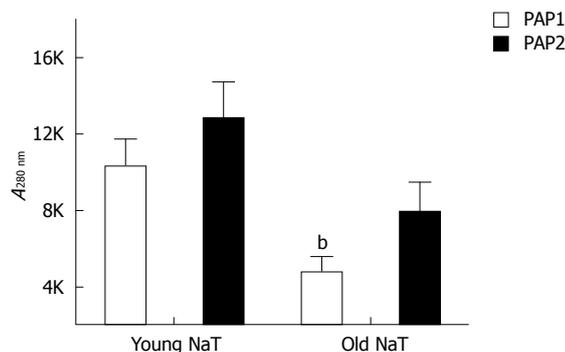

Figure 5 Western blotting analysis of pancreatitis-associated protein 1 and pancreatitis-associated protein 2 protein levels from pancreatic tissue 24 h after induction of sodium taurocholate pancreatitis. Both decreased with age, with statistical significance in the pancreatitis-associated protein (PAP)1 group (^b*P* = 0.003), and near significance in the PAP2 group (*P* = 0.06). Units are based on densitometry and expressed as intensity × area (mm²). NaT: Sodium taurocholate.

5 of 9 young animals with NaT pancreatitis grew GPC, while 8 of 9 grew GNR; only one animal had no culture positive. In the older group, 8 of 19 grew GPC, while 18 of 19 grew GNR; only one had no culture positive.

In order to accurately quantitate bacterial infiltration of the pancreas, we employed a novel molecular technique to discern the amount of bacterial genomic ribosomal RNA (rRNA) in the pancreata. As shown in Figure 9,

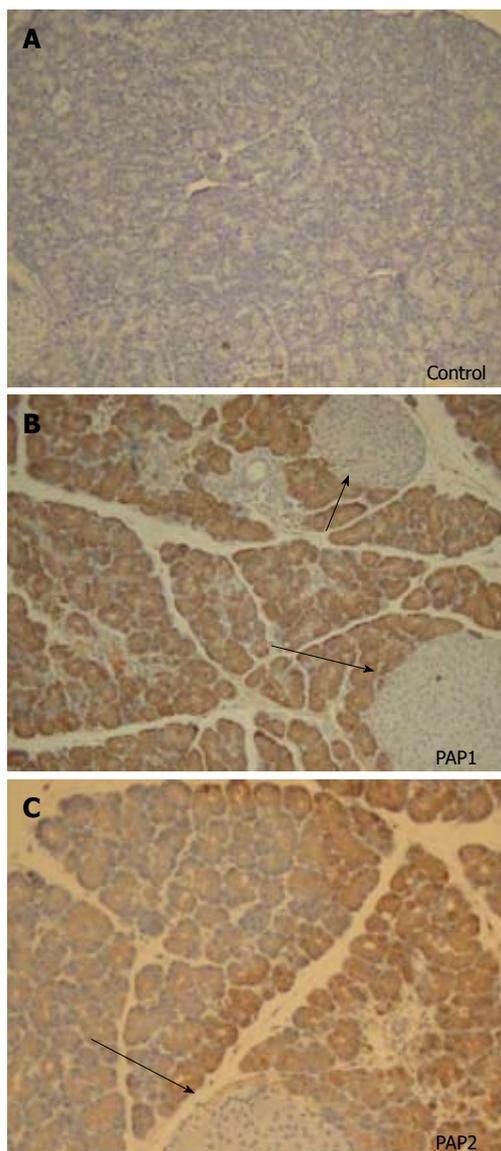

Figure 6 Immunohistochemistry for pancreatitis-associated proteins (40×) in a young control animal without pancreatitis (A) compared to pancreatitis-associated protein 1 (B) and pancreatitis-associated protein 2 (C) in young animals 24 h after sodium taurocholate pancreatitis. No staining is seen in controls, uniform brown colored staining is seen for pancreatitis-associated protein (PAP)1 (B). Preparation of the slides was done side by side. A different, heterogeneous pattern of staining is seen for PAP2 (C). Note that islets of Langerhans (arrows) do not stain at all for PAPs in normal animals or animals with acute pancreatitis.

compared to sham-operated animals, there was an increase in bacterial genomic rRNA in both the young and old NaT animals, and a more intense amount of bacterial rRNA in the older animals when compared to young.

DISCUSSION

In the present study, we found that 24 h after induction of AP, the pancreata of older animals have less edema, decreased inflammatory response and increased bacterial infiltration. This is associated with decreased expression of PAPs as measured by Western analysis and immunohistochemistry. While there were no differences between young

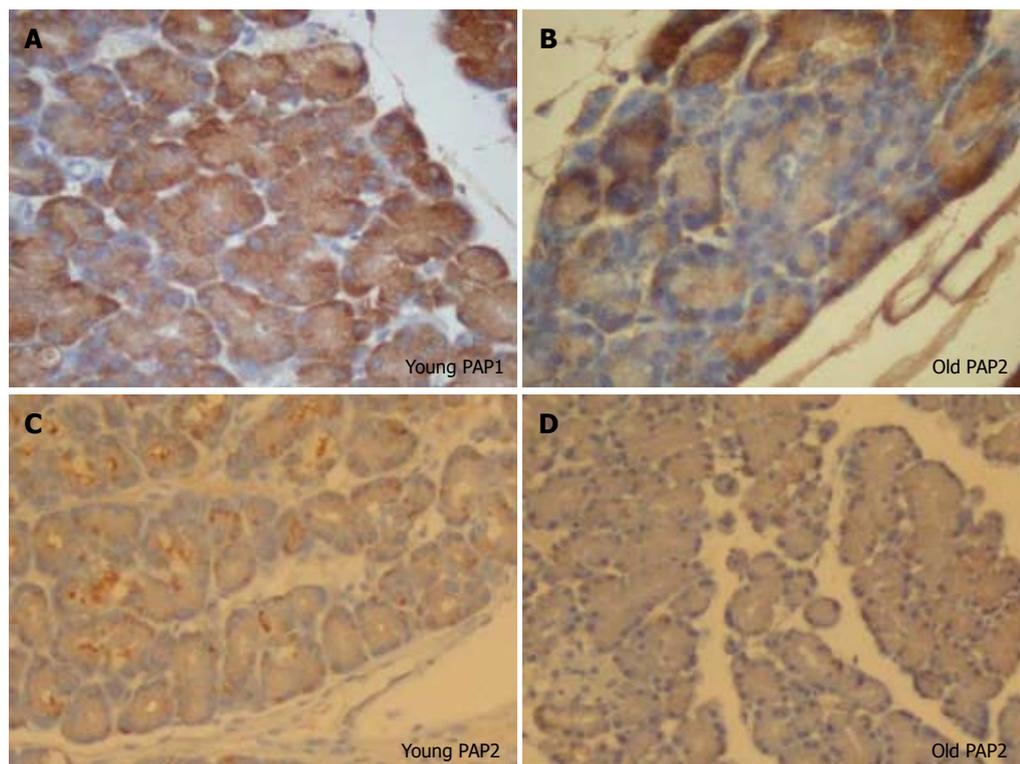

Figure 7 Immunohistochemical staining for pancreatitis-associated protein 1 and 2, high power (100×). Young animals (A, C) are compared to older (B, D). A decreased intensity of staining is observed in aging, and while pancreatitis-associated protein (PAP)1 staining in younger animals is uniform, in older animals it is heterogeneous. In contrast, while PAP2 staining patterns are heterogeneous in younger animals, they are more uniform in older ones. Note the clumping of PAP2 within the cells of the younger animals, which is absent in the older group.

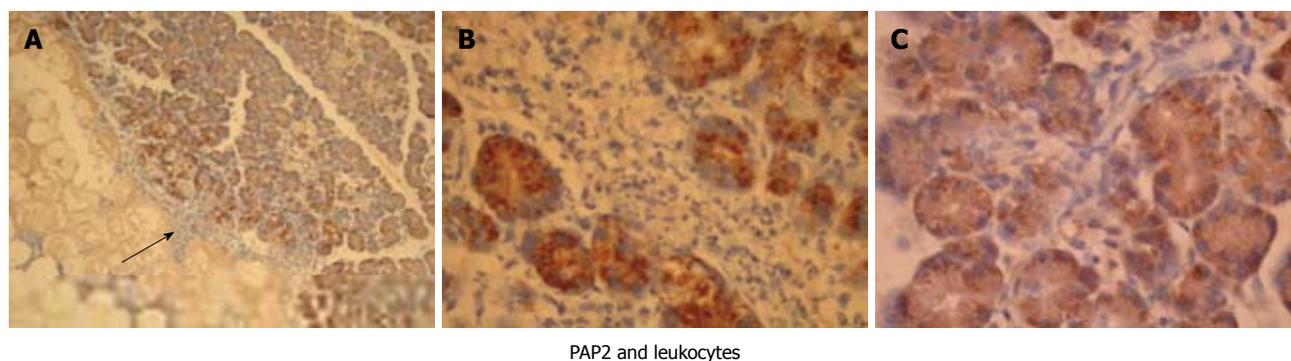

Figure 8 Association of pancreatitis-associated protein 2 staining with inflammatory infiltrates. A: Immunohistochemical staining in animals 24 h after sodium taurocholate. The arrow points to intense stromal infiltration near the periphery of intense pancreatitis-associated protein (PAP2) staining (40×); B: Association of PAP2 positive cells with stromal leukocyte infiltration depicted by arrow in A (100×); C: Association of PAP2 positive cells with parenchymal leukocyte infiltration (100×). This association was not seen for PAP1 (not shown).

and old animals in serum amylase and lipase activity, in the most-aged subgroup (c), there was an increase in CRPs.

These data suggest that the local response to AP is less severe in the older animals, and the systemic response may be worse. PAPs are endogenous protectors against pancreatic injury^[14-18], and it appears that the decrease in PAPs may not be related to the decreased inflammatory infiltrate. As will be described below, the effect may be a result of an altered balance of PAP 1 and 2. The decrease of PAPs may also result in increased bacterial infiltration into the pancreas, and ultimately a worsened outcome.

While the pancreas progressively atrophies with age,

its reserve capacity results in minimal clinical changes. Studies comparing baseline and stimulated levels of pancreatic enzymes have shown no significant differences^[24,25]. However, the regenerative capacity of the pancreas is diminished^[26,27], as evidenced by decreased recovery from pancreatitis. At the molecular level, this has been attributed to decreased phosphorylation of Akt^[27].

Very little is known about the aged pancreas in AP. As we have observed in animals, in humans there seems to be a blunted local response and an exaggerated systemic one. Fan *et al*^[4] noted decreased local complications but increased systemic complications, leading to death.

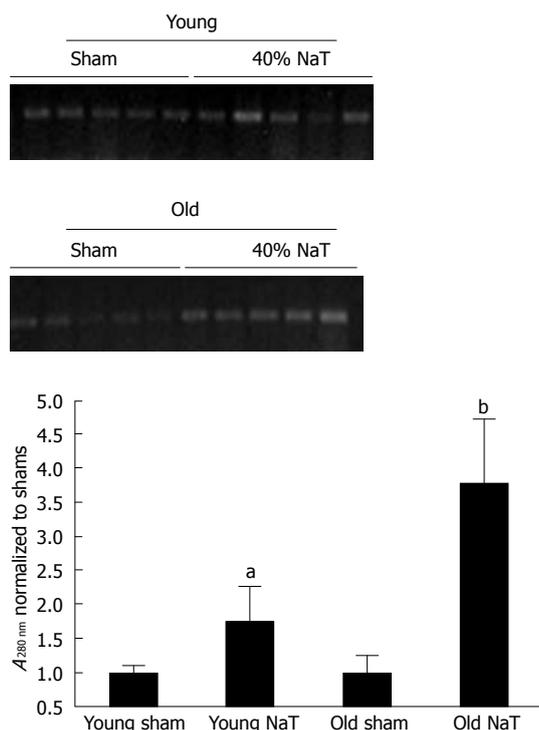

Figure 9 Molecular quantitation of bacterial levels in pancreatic tissue in unoperated controls, sham-operated animals and 24 h after sodium taurocholate pancreatitis. DNA from pancreas was subjected to semiquantitative polymerase chain reaction (PCR) using probes for the genomic sequences of bacterial ribosomal RNA. Top Panel shows representative polyacrylamide gels showing the 370 base pair PCR product; Bottom graph shows quantitated values from multiple experiments. No differences were seen between controls and sham-operated animals (not shown). There were significant differences in bacterial genomic levels between sham and sodium taurocholate (NaT) animals ($^aP < 0.05$), and between young and old ($^bP = 0.008$) NaT animals, when percent increases were compared (Mann-Whitney *U* test).

Kimura *et al.*^[28] described elderly patients with high mortality from AP, but autopsy evidence revealed only mild interstitial pancreatitis, where the inflammation was centered in the ductal and interstitial tissues regions.

We postulated that as animals age, there would be loss of protective mechanisms from the pancreas which would lead to worsened fate after pancreatitis. We focused on the PAP family since we and others have shown that they are endogenous proteins which are protective in AP^[14-16,29]. We know that expression of other genes of the PAP family decrease with aging^[20], and we formulated experiments to determine whether PAPs decreased too.

We showed that in older rats subjected to NaT, there is blunted PAP1 and 2 protein response in both Western analysis and immunohistologic staining patterns. How does this correlate with the histologic and biochemical data above?

PAP1's protective activity may be local or systemic. Locally, it has both mitogenic^[30] and anti-apoptotic^[31] effects, which affect regeneration after pancreatitis. PAP1 is a known anti-inflammatory agent^[16], and a potent modulator of lung injury in pancreatitis^[29,32]. Its loss with aging

may worsen the systemic response after acute pancreatitis.

However, our results differ from others who observed increased local inflammatory infiltrates in PAP1 knockout mice^[19]. Our model differs not only in that we employed a different rodent species, but in the fact that other proteins, such as PAP2, 3 and other inflammatory modulators, are likely also depressed.

PAP2's protective activity, on the other hand, is likely local. It can directly activate macrophages^[17], and macrophage activation has been shown to be protective in pancreatitis^[33-35]. PAP2 is a more potent immunomodulator than PAP1^[36]. In our present study we even noted that PAP2-positive pancreatic cells co-localize with leukocytes (Figure 8); this was not observed with PAP1. We also noted a positive correlation of PAP2 with pancreatic MPO activity. Activation of macrophages can induce MPO activity^[37,38], and it is possible that a decrease of PAP2 will be associated with decreased macrophages or macrophage activity, which is detrimental for the pancreas and host. The decrease in PAP2 may really be the reason for the decreased leukocyte infiltration seen in older animals.

Finally, PAP proteins directly interact with bacteria. They can bind gram-negative^[7] and gram-positive bacteria^[39], and we have discovered a bacteriocidal action of PAP1 and 2 (unpublished results). Our data suggest there is more bacterial infiltration in the older pancreata, as evidenced by increased quantity of bacterial rRNA. The blunted PAP responses may result in more acute pancreatic infection.

Increased bacterial colonization could lead to an increased systemic response to the injury, which is worsened by decreased PAP1 level. It is possible that PAPs are endogenous bacteriostatic or bacteriocidal agents that protect against infection during AP. Whether the loss of PAP with aging leads to increased clinical pancreatic infection remains to be seen. To study this, longer term experiments along with qualitative analysis of bacterial species will be necessary.

In conclusion, this is the first study to show a physiologic difference in AP between young and old animals, and the first to show that endogenous pancreatic molecules are related to the diathesis of the disease. In older animals, there is decreased edema and leukocyte infiltration, but increased bacterial infiltration and even serum CRP level. All are associated with decreased endogenous PAPs in the pancreas. Further studies are planned on the direct effect of all three PAPs in modulating the severity of pancreatitis, by focusing on their local immunomodulatory effect and effect on bacterial infiltrates, as well as the systemic response of the host.

COMMENTS

Background

Acute pancreatitis (AP) is a disease with significant impact and expense worldwide. In the United States, the cost is significant, and only recently has the impact of this disease on the elderly begun to emerge.

Research frontiers

The mechanism that puts the aged pancreas, and aged patient, at risk for severity in pancreatitis is currently being explored. Impaired immune system, host organ response to the injury or protective mechanisms from the pancreas are possibilities. A molecular mechanism is the likely source.

Innovations and breakthroughs

The authors recently showed that pancreatitis-associated proteins (PAPs) are protective in pancreatitis. The authors postulated that their expression would be depressed in elderly animals with pancreatitis, resulting in worsened disease.

Applications

By understanding how PAPs affect the outcome of pancreatitis, the authors suggest that physicians can then employ strategies to enhance their expression in elderly patients with the disease and prevent complications. The authors also employed a new way of monitoring the infiltration of bacteria into the pancreas using polymerase chain reaction (PCR), which is much more sensitive than culture techniques.

Terminology

PAPs are members of the Reg family of pancreatic regenerative proteins. They have been shown to be important in pancreatic disease, including AP and gastrointestinal malignancies. Expression was monitored by standard techniques such as Western blot and immunohistochemical staining, as well as PCR. Myeloperoxidase and monocyte chemoattractant protein-1 analysis was used to monitor inflammation. Bacterial infiltration was monitored by PCR, using their 16S ribosomal RNA as the unique target.

Peer review

The overall goal of the paper is relevant. The data presented are solid and credible. The results are interesting and clinically important.

Abstract

AIM: To investigate the role of osteopontin (OPN) and its splice variants in the proliferation of hepatocellular carcinoma (HCC).

METHODS: The expression of OPN variants in HCC cell lines as well as HCC tissue samples and non-tumour tissue was studied using polymerase chain reaction. OPN variant cDNAs were cloned into a mammalian expression vector allowing both transient expression and the production of stable OPN expressing cell lines. OPN expression was studied in these cells using Western blotting, immunofluorescence and enzyme linked immunosorbent assay. A CD44 blocking antibody and siRNA targeting of CD44 were used to examine the role of this receptor in the OPN stimulated cell growth observed in culture. Huh-7 cells stably expressing either OPN-A, -B or -C were injected subcutaneously into the flanks of nude mice to observe *in vivo* tumour

growth. Expression of OPN mRNA and protein in these tumours was examined using reverse transcription-polymerase chain reaction and immunohistochemistry.

RESULTS: OPN is expressed in HCC in 3 forms, the full length OPN-A and 2 splice variants OPN-B and -C. OPN variant expression was noted in HCC tissue as well as cognate surrounding cirrhotic liver tissue. Expression of these OPN variants in the HCC derived cell line Huh-7 resulted in secretion of OPN into the culture medium. Transfer of OPN conditioned media to naïve Huh-7 and HepG2 cells resulted in significant cell growth suggesting that all OPN variants can modulate cell proliferation in a paracrine manner. Furthermore the OPN mediated increase in cellular proliferation was dependent on CD44 as only CD44 positive cell lines responded to OPN conditioned media while siRNA knockdown of CD44 blocked the proliferative effect. OPN expression also increased the proliferation of Huh-7 cells in a subcutaneous nude mouse tumour model, with Huh-7 cells expressing OPN-A showing the greatest proliferative effect.

CONCLUSION: This study demonstrates that OPN plays a significant role in the proliferation of HCC through interaction with the cell surface receptor CD44. Modulation of this interaction could represent a novel strategy for the control of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a highly aggressive carcinoma of the liver, and is the fifth most common cancer worldwide, and the third leading cause of cancer related death^[1,2]. Risk factors for HCC include; infection with either hepatitis B virus (HBV) or hepatitis C virus (HCV), alcoholic cirrhosis and exposure to environmental toxins such as aflatoxin. HCC is a global disease most prevalent in Southeast Asia and sub-Saharan Africa^[3], however, in countries such as the United States and Japan, HCC incidence is on the increase, primarily as a result of infection with HCV^[4,5]. Despite intense investigation, therapeutic intervention for HCC is extremely limited, with a poor prognosis due to high rates of recurrence and intrahepatic metastasis following surgical resection. Furthermore, there is a significant gap in our knowledge of the molecular mechanisms responsible for HCC development and progression.

Osteopontin (OPN) is a secreted multifunctional matrix-glycoprotein that is emerging as a significant protein in the biology of HCC. It is involved in normal tissue remodelling processes and is secreted to high levels in numerous tumours including HCC^[6]. OPN is overexpressed in HBV-related metastatic HCC^[7], while OPN antibodies can suppress pulmonary metastasis of HCC cells in a nude mouse model, suggesting that it plays a significant role in the metastatic potential of HCC^[8]. However, its role in development and proliferation of HCC is relatively unexplored, although a recent study involving the silencing OPN mRNA expression in HCC cell lines, suggested it may also have proliferative effects^[9]. OPN binds to the family of $\alpha\beta$ integrins, and the cell-surface adhesion molecule CD44, to initiate cellular signals that enable tumour progression^[10-12]. However, the role, if any, of CD44 and OPN in modulating HCC cell growth, is unknown.

Osteopontin is expressed as a heterogenous protein, dependent on glycosylation patterns and the type of cell from which it is expressed. For example, OPN derived from osteosarcoma-derived cells is smaller than that from non-transformed bone cells, with expression of the smaller form correlating with anchorage independence, suggesting that different forms of OPN have different phenotypic effects^[13]. In addition, the existence of two OPN splice variants have been described, with deletions in exon 4 (termed OPN-C) and 5 (termed OPN-B)^[14]. These variants were originally described in glioma cells and more recently OPN-C has been implicated in the invasiveness of breast cancer cell lines^[15] while in HCC

derived cell lines OPN-C promotes the extracellular cleavage by matrix metalloproteinase (MMP)-9, releasing a distinct 5 kDa OPN fragment that is essential for HCC cellular invasion^[16]. However, the relative expression of the OPN variants in HCC has not been formally demonstrated, nor have their effects on HCC cell growth been studied. In this study we demonstrate that all splice variant forms of OPN are expressed in HCC at the mRNA level and that all have the ability to stimulate the growth of HCC derived cell lines *in vitro* and in an *in vivo* ectopic xenograft mouse model. Furthermore this growth promoting effect was mediated by interaction of OPN with CD44 and adds significantly to our understanding of the role of OPN in HCC.

MATERIALS AND METHODS

Cells and tissue samples

The human hepatoma-derived cell lines used in this study were Huh-7, Hep G2 and Hep3B, while Hepa 1-6 cells are of mouse hepatoma origin. All cells were maintained in Dulbecco's Modified Eagle Medium, containing 4.5 g/L D-Glucose, 25 mmol 2-[4-(2-Hydroxyethyl)-1-piperazinyl]ethanesulfonic acid and 2 mmol/L L-glutamine (Invitrogen, CA, United States). Media was supplemented with 10% fetal calf serum, 12 μ g/mL penicillin and 16 μ g/mL gentamycin. To monitor cell growth, cultured cells were seeded at a density of 7×10^4 cells per well in a 12-well plate and cell numbers monitored daily using trypan blue exclusion. All experiments were performed at least in triplicate. Human HCC tissue and cognate surrounding tissue were collected from patients undergoing HCC resection at the Royal Adelaide Hospital (collection was approved by the Hospital's ethics committee).

Construction of OPN expression plasmids and transfection

Full-length OPN cDNA and splice variants were amplified from Huh-7 cells by reverse transcription polymerase chain reaction (RT-PCR). Total RNA and cDNA synthesis were performed as described elsewhere^[17]. The coding sequence for OPN was amplified using the primers 5'-GTTGAAGCTTCTCACTACCATGAGATTGACAGTG-3' and 5-TAGTTCTAGACCTTTTAATTGACCTCAGAAGATG-3' and cloned into the mammalian expression vector pRC-CMV using *Xba* I and *Hind* III to generate pRC-CMV-OPN-A. During sequence verification, two smaller cDNAs were isolated that corresponded to OPN-B and OPN-C. These vectors were used in transient expression assays and to generate stable OPN expressing clones in Huh-7 cells using the transfection reagent Fugene (Roche, Australia) and G418 selection.

RNA extraction, cDNA synthesis and PCR analysis

Total cellular RNA was isolated from cells using Trizol (Invitrogen) and first strand cDNA was synthesized

and standard PCR performed as mentioned previously^[17]. Primers used for OPN cDNA detection were 5'-ATGAGA ATTGCAGTGATTTGCTTTTGCCT-3' and 5'-CATGGTCATCATCATCTTCATCATC-3'; primers utilised for the detection of CD44 were 5'-GACACATATTGCTTCAATGCTTCAGC-3' and 5'-GATGCCAAGATGATCAGCCATTCTGGAAT-3'; and glyceraldehyde-3-phosphate dehydrogenase primers were 5'-ACCACAGTCCATGCCATCAC-3' and 5'-TCCACCACCCTGTTGCTGTA-3'. Amplicons were electrophoresed through a 1% agarose gel before visualisation on a ultraviolet transilluminator.

Detection of OPN and CD44

Huh-7 cells, either stably selected or transiently expressing OPN, were lysed using RIPA buffer and total protein separated *via* sodium dodecyl sulfate polyacrylamide gel electrophoresis and transferred to nitrocellulose as previously described^[18]. Membranes were blocked with 5% skim milk in 0.1% phosphate buffered saline Tween-20 (PBS-T) and incubated overnight at 4 °C with either 400 ng/mL of goat anti-human OPN antibody (K-20: SCBT, SantaCruz, CA) or mouse anti-human CD44 antibody (Labvision, Fremont, CA, United States) at 200 ng/mL followed by either 33 ng/mL of anti-goat or anti-mouse horseradish peroxidase (HRP) antibody (Rockland, Gilbertsville, PA, United States). Washes between antibody binding were with 0.1% PBS-T. Protein bound to antibody was visualised *via* chemiluminescence (ECL; Amersham Biosciences, Piscataway, NJ, United States).

Cellular localisation of transiently expressed OPN was performed *via* indirect immunofluorescence as previously described^[19] with the exception that cells were incubated in 1 µg/mL of anti-OPN antibody followed by 10 mg/mL anti-goat Alexa 488-conjugated antibody (Molecular probes, Eugene, OR). CD44 expression was visualised using a mouse anti-human CD44 antibody at 4 µg/mL on cells that had been fixed in 5% formalin but not permeabilised for detection of surface CD44 only. Cells were visualised using a BioRad Radiance 2100 confocal microscope.

OPN concentration in cell culture supernatants was determined using an "in house" sandwich enzyme linked immunosorbent assay (ELISA) as described previously^[17]; where plates were coated with a monoclonal anti-OPN antibody (3 µg/mL R and D Systems, Minneapolis, MN, United States) and detection performed with a polyclonal anti-OPN antibody (200 ng/mL R and D Systems). CD44 blocking antibody (sc-7946; Santa Cruz, CA, United States) for 30 min at room temperature. The blocking antibody is a polyclonal antiserum raised against amino acids 21-320 of CD44^[20].

siRNA knockdown of CD44

StealthTM siRNA double stranded RNA oligonucleotides (Invitrogen) designed to "knock down" or minimise expression of the OPN receptor CD44 were transfected into Huh-7 and HeLa cells using the reverse transcription method of LipofectamineTM 2000 (Invitrogen) as

per the manufacturer's instructions. Cells were assayed for CD44 expression (and growth rate when required) 24-96 h post transfection *via* immunoblot assay. Three different siRNA oligonucleotides, designed to target the conserved exons present in all CD44 isoforms, were tested for their ability to minimise CD44 expression in a transient system using both RT-PCR and immunoblotting as described above. Of the three, two demonstrated consistent knockdown of CD44 at the RNA level by RT-PCR and immunoblot analysis and were pooled for further experiments.

In vivo tumour growth

Five week-old female Balb/c nude mice were implanted subcutaneously with 5×10^6 cells from Huh-7 OPN-A expressing cell lines and the Huh-7 parent cell line as a control. Cells were diluted in 100 µL of PBS and injected into both dorsal flanks ($n = 6$). Tumour growth was monitored by calculation of tumour volume [V (mL) = (width² × length²)/2] and measured daily for approximately 25 d. The mice were sacrificed and tumours removed for histological analysis. These experiments were approved by the University of Adelaide and Institute of Medical and Veterinary Science animal ethics committees.

Immunohistochemical staining of tissue sections

Paraffin embedded sections of liver and tumour tissue were processed as previously described^[17]. Five micron sections were re-hydrated and incubated in either anti-OPN (LabVision, Fremont, CA, United States), or normal rabbit IgG (Cell signalling, Boston, MA, United States) (diluted to 1 µg/mL in PBS + 3% (v/v) normal horse serum) for 30 min, before being incubated in ADVANCETM HRP-Link (Dako, Glostrup, Denmark), and then in ADVANCETM HRP Enzyme (Dako) for 30 min each. Slides were then incubated in diluted DAB + chromagen (Dako; 20 µL DAB + chromagen in 1 mL DAB + substrate buffer) for 5 min and then following a 5 min wash in H₂O, slides were counterstained with haematoxylin.

Statistical analysis

Student *t* tests were performed to analyse the distributions of 2 independent data sets and all statistical analysis were performed using SPSS 10.0.

RESULTS

Multiple OPN forms are expressed in HCC

The existence of multiple forms of OPN, termed OPN-A, OPN-B and OPN-C, has been previously described^[14], however, their expression and physiological roles in tumour biology, including HCC has not been well studied. We therefore investigated expression of these OPN variants in the HCC cell lines, Huh-7, HepG2, Hep3b and the mouse HCC line Hepa1-6, using PCR primers that spanned exons 2-6 (Figure 1A). As predicted, all HCC cell lines expressed the full-length OPN-A mRNA (Figure 1B). In addition, two smaller transcripts were identified

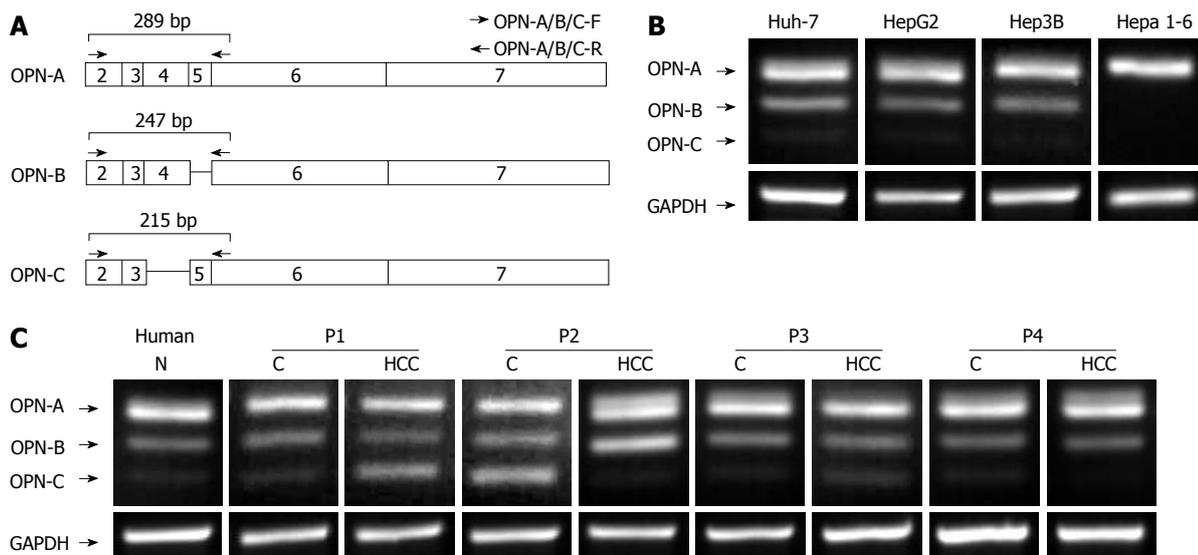

Figure 1 Osteopontin splice variants are expressed at different levels in the liver of hepatocellular carcinoma patients and in various cell lines. A: Schematic representation of the three osteopontin (OPN) splice variants; B: Polymerase chain reaction (PCR) performed on cDNA from different cell types shows varying distribution patterns of OPN mRNA; C: PCR performed on cDNA taken from patient hepatocellular carcinoma (HCC), and its surrounding tissue indicates altered OPN splice variant expression in HCC. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

in all cell lines (with the exception of Hepa 1-6 cells) with OPN-B consistently expressed to a higher level than OPN-C (OPN-C cDNA is readily visible on longer exposure). These smaller transcripts were identified by cloning and sequencing and shown to be specific for OPN-b and OPN-C that lack exons 5 and 4 respectively (Figure 1A). OPN-A is clearly the dominantly expressed OPN transcript followed by OPN-B and OPN-C respectively. Interestingly mouse tissue only expressed the full length OPN-A and this is consistent with a previous report indicating that OPN-A is exclusively expressed in mouse tissues^[15].

We next investigated OPN mRNA expression in HCC tissue samples and cognate non-tumour tissue using the primers described above. Attempts to generate a quantitative real-time assay for detection of all OPN variant simultaneously was unreliable. Nevertheless, it is clear that normal human liver tissue expressed the 3 OPN transcripts to variable degrees, while OPN variant expression was variable between HCC samples. For example, OPN-C expression was increased in HCC P1 compared to cognate liver tissue, while in P2, expression of OPN transcripts in non-tumour tissue was significantly different from that of the corresponding tumour (Figure 1C). This suggests that OPN transcript expression is variable and that individual OPN variants may have specific physiological roles. The detection of all OPN splice variants in normal liver tissue (OPN-C visible on long exposure) is in contrast to previous reports in which it was suggested that OPN-C expression is specific to tumour cells^[14,15].

Stable expression of OPN splice variants in Huh-7 cells

In order to study the physiological roles of the distinct OPN splice variants, cDNAs representing OPN-A,

OPN-B and OPN-C, were cloned into a mammalian expression vector to allow both transient expression and the production of stable OPN expressing cell lines. Following transfection of cDNA constructs representing the OPN variants, detection of OPN expression by confocal microscopy was unsuccessful, suggesting efficient secretion of OPN into the media. However, following treatment of transiently transfected cells with brefeldin A, which inhibits cellular secretion pathways and causes retention of OPN within the cell, we could detect intracellular expression of OPN variants (Figure 2A). OPN is predominantly thought to act at the extracellular level, however, OPN can be detected in tumourogenic hepatocytes by immunohistochemistry suggesting it may, at least in part, have a role at the intracellular level^[6]. Following brefeldin-A treatment, OPN variants exhibited different cytoplasmic distribution in Huh-7 cells, suggesting that each variant may have different effects on tumourogenic hepatocytes, however, this requires further investigation.

To investigate the role of the OPN variants on cell growth, stable clones were produced in a Huh-7 cell line that has low OPN mRNA expression and undetectable protein expression by ELISA (results not shown) and immunoblot. Multiple clones were isolated after G418 selection with no adverse effect on cell morphology or growth. Intracellular OPN was not detected in any clones (results not shown) consistent with efficient expression of OPN, however, OPN mRNA, specific for the OPN variant of interest, was detected by RT-PCR (Figure 2B), while OPN protein was detected by immunoblot (Figure 2C). Furthermore, OPN ELISA performed on media from stable cell lines revealed secretion of OPN in parent Huh 7 and vector transfected cells to be below the limit of detection (< 7.81 ng/mL).

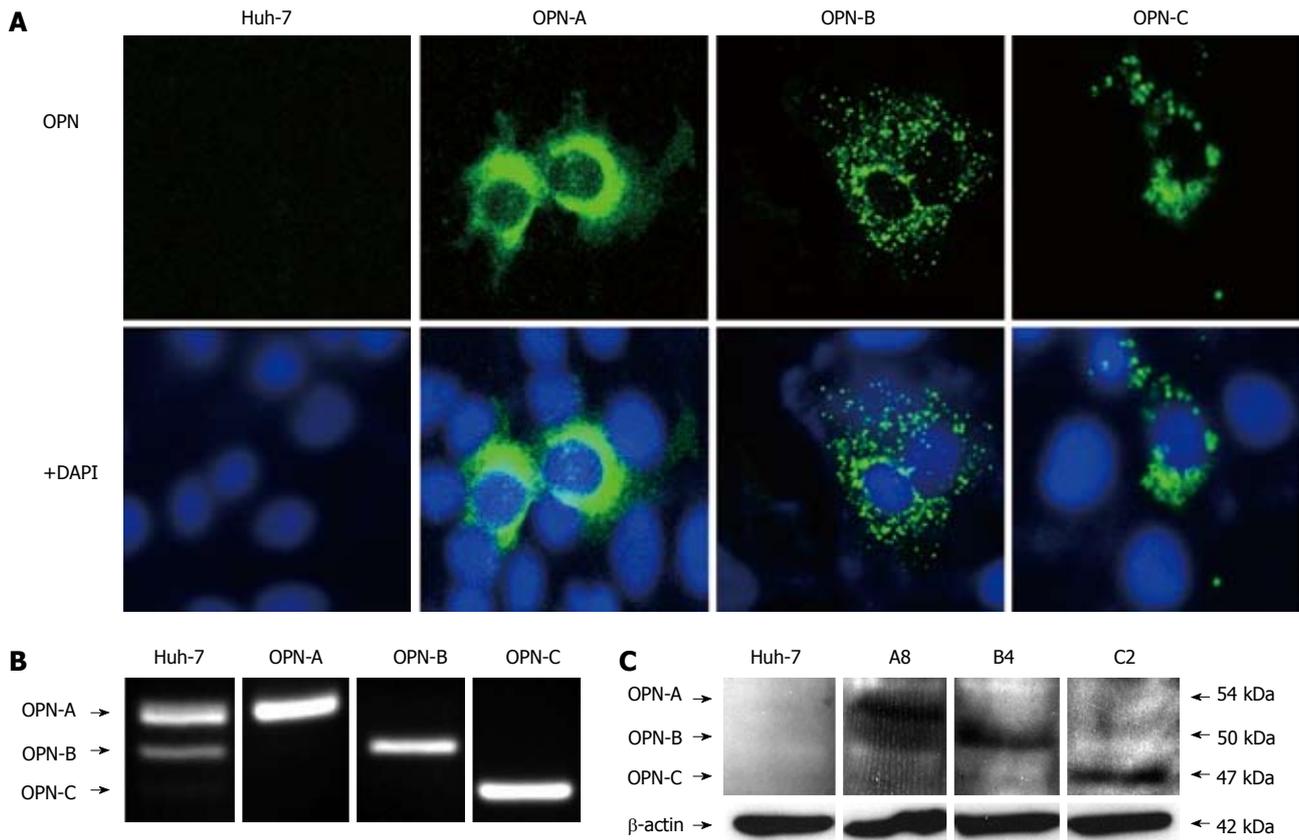

Figure 2 Stable expression of osteopontin splice variants demonstrates unique localisation patterns. Huh-7 cell stably overexpressing osteopontin (OPN)-A, -B, -C, or the control, were stained for OPN expression and visualised fluorescently to demonstrate localisation of the three splice variants (A); Stable expression was confirmed using polymerase chain reaction (B), and Western blotting (C). DAPI: 4',6-diamidino-2-phenylindole.

In contrast OPN-A was detected at 160.4 ng/mL and OPN-B at 127.1 ng/mL. We could not detect OPN-C by ELISA for reasons that are not entirely clear, however the OPN detection ELISA Ab was raised against OPN purified from human milk in which OPN-C is not present^[21]. However, OPN-C is clearly expressed in our system as detected by RT-PCR, immunofluorescence and immunoblotting (Figure 2).

OPN variants facilitate proliferation of HCC derived cell lines

Little work has been done regarding the role of OPN and associated splice variants on cell growth. However recent work from Sun *et al.*^[9] suggests that OPN can enhance cell growth of liver-derived cell lines, although the role of OPN splice variants was not investigated. Therefore, using our stably transduced OPN Huh-7 cells, we determined the impact of the individual variants on Huh-7 cell growth. Huh-7 cells expressing either OPN-A, -B or -C grew significantly faster after 4 d of culture compared to cells transfected with the vector only and the parent cell line (Figure 3A). This increase in growth rate was seen in multiple selected OPN transformants, removing the possibility of clonal selection bias. OPN is readily secreted from these Huh-7 cells and to determine if OPN was exerting its effect by either an autocrine or paracrine mechanism, we incubated Huh-7

cells with conditioned media from OPN-A, -B or -C stable transformants. As can be seen in Figure 3B, conditioned media from all stable transformants increased Huh-7 cell growth, suggesting OPN was exerting its effect in a paracrine manner. This increase in Huh-7 cell growth was directly attributable to the action of OPN because the addition of an anti-OPN antibody, but not a control immunoglobulin, to the cultures, suppressed the increase in cell growth when OPN-A conditioned media was added to Huh-7 cells (Figure 3C). Similar results were obtained for OPN-B and -C conditioned media (results not shown). These results suggest that all variants of OPN can enhance Huh-7 cell proliferation *in vitro*.

OPN exerts its growth proliferative effect through CD44

The C-terminal region of OPN binds the CD44 variant v6/7 to induce cellular signals responsible for tumour progression^[22]. To investigate if OPN was exerting its growth effect in a CD44-dependent manner, we stimulated a number of cell lines possessing different levels of CD44 with OPN conditioned media. As can be seen in Figure 4A, Huh-7, HepG2 and HeLa cells all express cell surface CD44 as determined by immunofluorescence microscopy of unpermeabilised cells, while Hep3b cells do not express CD44. Consistent with this observation, Huh-7, HepG2 and HeLa cells, when stimulated with OPN-A conditioned media, all showed a significant in-

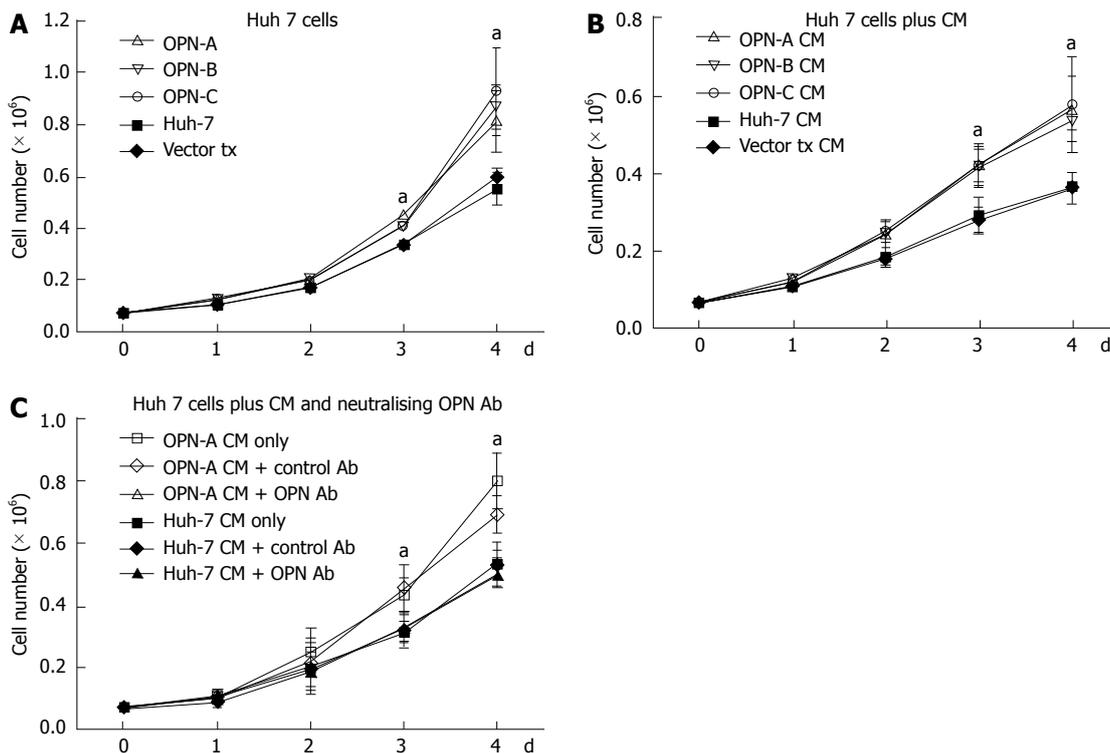

Figure 3 Osteopontin splice variants increase Huh-7 cell growth. A: Osteopontin (OPN)-A, -B, -C and control-expressing Huh-7 stable cell lines in conjunction with Huh-7 cells, were seeded at a density of 7×10^4 cells per well in a 12-well plate and cell numbers monitored daily using trypan blue exclusion; B: Conditioned media (CM) was removed from OPN-A, -B, -C and control-expressing Huh-7 stable cell lines in conjunction with Huh-7 cells and placed onto Huh-7 cells. Cells were monitored as mentioned above; C: Huh-7 cells were seeded at a density of 7×10^4 cells per well in a 12-well plate and conditioned media from OPN-A, -B, -C and control expressing-Huh-7 stable cell lines placed onto the cells in conjunction with either anti-OPN (OPN Ab) or an control immunoglobulin. ^a $P < 0.05$.

crease in cell growth (Figures 3B, 4B and C). However no cell growth was noted in Hep3Bs consistent with a lack of CD44 expression (Figure 4D). These observations were confirmed following the addition of CD44 blocking antibody to the conditioned media that completely suppressed the OPN growth effect (Figure 5A and B). Addition of control immunoglobulin to the cultures had no effect on OPN induced cell growth. To further confirm the role of CD44, we suppressed CD44 expression using an siRNA approach. Transfection of an siRNA targeting CD44 resulted in a significant decrease in CD44 mRNA and CD44 protein expression as determined by PCR and immunoblot in Huh-7 and HeLa cells (Figure 6A and B). This knockdown, in turn, correlated with a decrease in OPN-mediated dependent cell growth of both cell lines (Figure 6C and D). Collectively, these experiments indicate that the increase in OPN induced cell growth results from an interaction between OPN and CD44.

OPN-A induced tumour growth in an ectopic xenograft mouse model

Our *in vitro* data prompted us to examine whether the different OPN splice variants regulate tumour growth in an ectopic xenograft nude mouse model. Accordingly, Huh-7 cells stably expressing either OPN-A, -B or -C were injected subcutaneously into the flanks of nude mice. Mice injected with OPN-A expressing Huh-7 cells were sacrificed approximately 18 d post injection

as the tumour size was causing mice discomfort, while all other mice were sacrificed at approximately 22 d post injection. The typical gross appearance of the tumours is shown in Figure 7A, while the mean tumour volume throughout the experiment is shown in Figure 7B. Compared to parent control Huh-7 cells, mice injected with OPN expressing cell lines showed an increase in tumour growth. This increase in cell growth was most noticeable in mice injected with Huh-7 cells expressing full-length OPN-A (Figure 7B). These mice developed tumours at day 10, after which the growth rate was faster than that of the control tumours. To confirm OPN expression in isolated tumours, RNA was isolated and mRNA expression of the different OPN splice variants was confirmed by RT-PCR (Figure 7C). Detection of OPN *in situ* was performed by immunohistochemistry in which OPN-A expressing tumours expressed significantly more OPN-A than control Huh-7 cells (Figure 7D). OPN-B and -C were similarly detected by immunohistochemistry (results not shown). No differences were noted histologically between the tumours, with the exception that OPN-A tumours contained a greater number of cells undergoing various stages of the mitotic pathway. These data clearly suggest a role for OPN in promoting the growth of Huh-7 cells in an ectopic xenograft mouse model.

DISCUSSION

OPN is a secreted phosphoglycoprotein that binds to

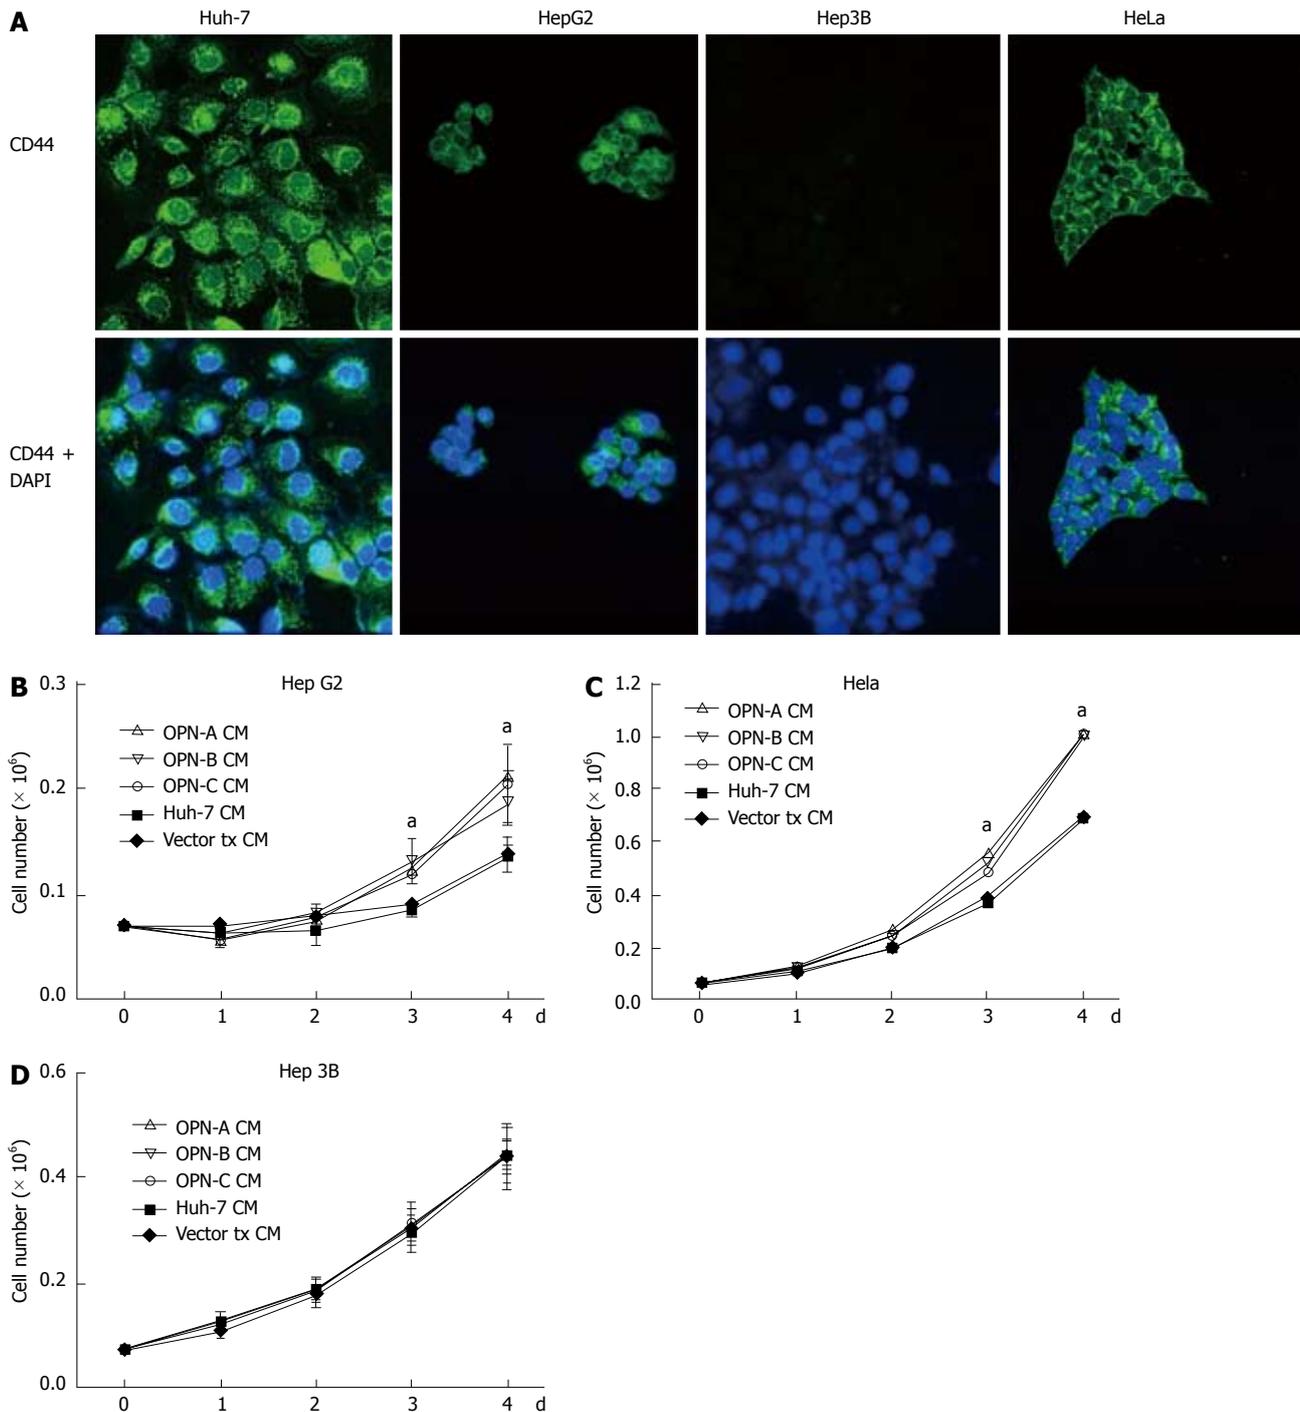

Figure 4 CD44 expression is necessary for increased cellular growth due to osteopontin expression. Huh-7, HepG2, Hep3B and HeLa cells were immunostained for 4',6-diamidino-2-phenylindole (DAPI) and CD44 expression (A); Conditioned media (CM) was removed from osteopontin (OPN)-A, -B, -C and control-expressing Huh-7 stable cell lines in conjunction with Huh-7 cells and placed onto Hep G2 cells (B); HeLa cells (C) or Hep 3B cells (D); cell numbers were monitored daily using a trypan blue exclusion. * $P < 0.05$.

the family of cellular receptors integrin $\alpha v \beta$ and CD44 to exert its biological effects, and of late has gained attention as its expression is associated with invasion and metastasis of a number of malignant tumours, including HCC^[8,23-26]. In many of these tumours, increased plasma levels of OPN have shown promise as potential prognostic biomarkers as OPN expression correlates with metastatic potential, early recurrence and decreased

patient survival. While our understanding of the role of OPN in HCC biology is expanding, there is still a paucity of information regarding the role of OPN (and its splice variants) in proliferation of HCC and the molecular mechanisms responsible.

OPN undergoes post-translational modifications *via* phosphorylation, glycosylation and cleavage by thrombin and MMPs to produce differentially active forms^[10].

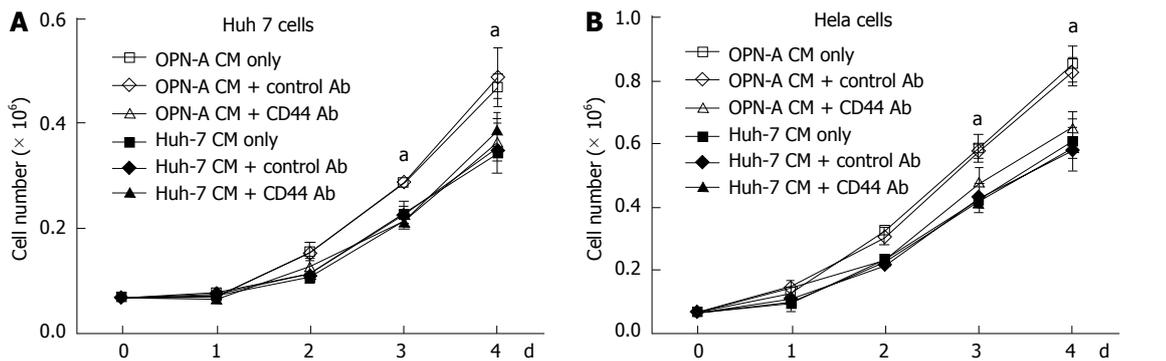

Figure 5 CD44 engagement is necessary for osteopontin-a induced cell growth in Huh-7 and HeLa cells. (A) Huh-7 or (B) HeLa cells were seeded at a density of 7×10^4 cells per well in a 12-well plate and conditioned media from osteopontin (OPN)-A Huh-7 stable cell lines or Huh-7 cells alone placed onto the cells in conjunction with either anti-CD44 or a control immunoglobulin. Cell numbers were monitored daily using trypan blue exclusion. CM: Conditioned media. ^a*P* < 0.05.

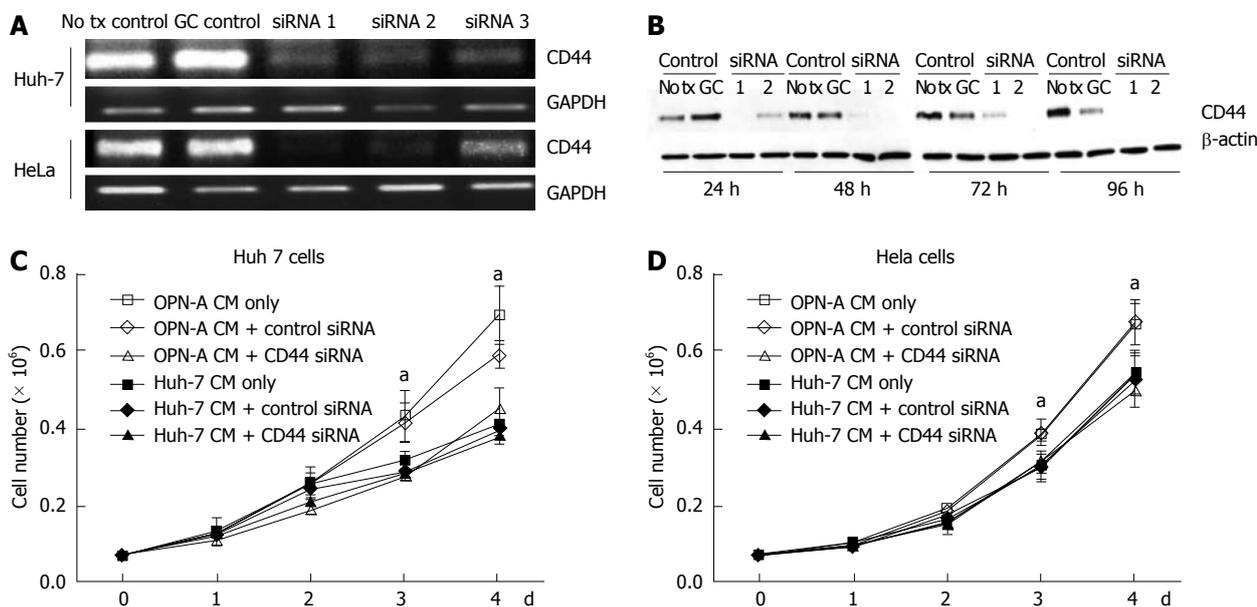

Figure 6 CD44 knockdown inhibits osteopontin-a-induced cell growth in Huh-7 and HeLa cells. A panel of 3 Stealth siRNA's were investigated for their ability to limit CD44 mRNA expression using polymerase chain reaction (A), further validation was achieved by examining protein reduction of CD44 using Western blotting (B). (C) Huh-7 or (D) HeLa cells were seeded at a density of 7×10^4 cells per well in a 12-well plate and a CD44 siRNA pool containing Stealth siRNA1 and 2 was transfected into the cultures 24 h prior to placing conditioned media from osteopontin (OPN)-A Huh-7 stable cell lines or Huh-7 cells alone onto the cells. Cell numbers were monitored daily using trypan blue exclusion. CM: Conditioned media; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase. ^a*P* < 0.05.

For example, the MMP-9 cleaves OPN into specific fragments of which a 5 kDa fragment induces HCC cellular invasion *via* the CD44 receptor^[16]. Furthermore, stromelysin (MMP-3) and matrilysin (MMP-7) have been reported to cleave OPN at residues 166 and 210, resulting in tumour cell adhesion, while thrombin cleavage of OPN mediates increased adhesion and migration of tumour cells, *via* binding of the OPN RGD motif to cell surface integrins^[27,28]. Clearly the role of OPN and its derivatives in tumour biology is complex, which is further complicated by the expression of OPN splice variants. In humans, the existence of two OPN splice variants with deletion of exon 4 (OPN-C) or exon 5 (OPN-B) were first described in glioma cells^[29] and more recently in breast cancer cell lines^[15], however, in HCC, the roles of the OPN splice variants is relatively unde-

finied, although a recent report suggests that expression of OPN-A and -B in HCC-derived cell lines confers a robust migratory phenotype through activation of the p42/44 Map kinase pathway^[30].

There has been little investigation of the expression of OPN splice variants and the mechanisms by which OPN regulates cellular proliferation. Our initial investigations focused on OPN splice variant expression in various HCC cell lines, and in HCC and its cognate surrounding normal liver. At the mRNA level, we observed expression of all three OPN splice variants in human HCC cell lines, although OPN-A was clearly the dominant species followed by OPN-B and to a lesser extent-c. This observation is consistent with the work of Takafuji *et al*^[16] who showed that greater levels OPN-C were expressed in HCC cell lines with high metastatic potential

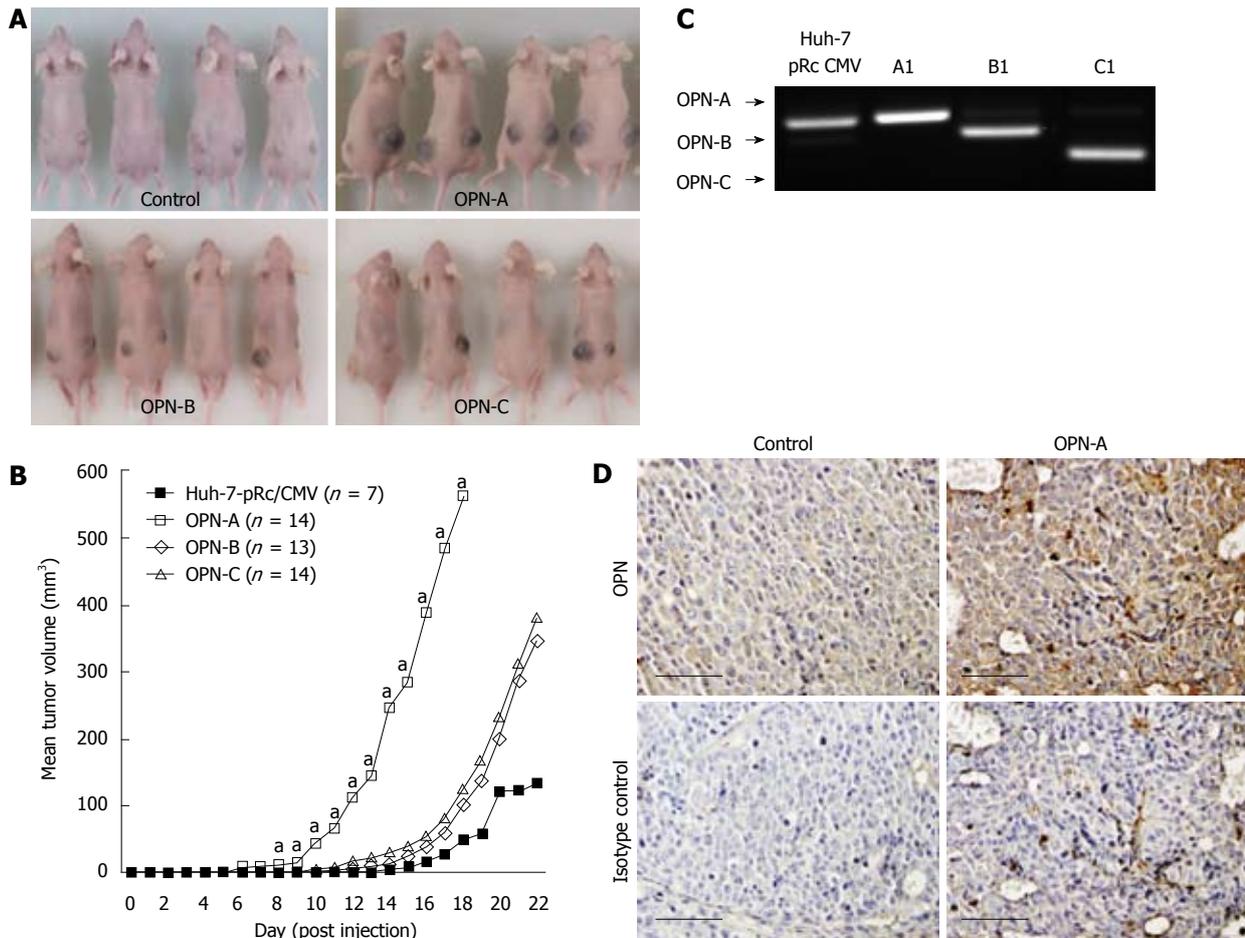

Figure 7 Over expression of the three osteopontin splice variants promotes Huh-7 tumour growth in Balb/c nude mice. A: Growth of tumours in mice injected in the hind flanks with osteopontin (OPN)-A, -B, -C or control-expressing stable cell lines, with mean tumour volumes at the time of euthanasia expressed graphically in (B) $^aP < 0.05$ OPN-A/Huh-7 vector only; C: Polymerase chain reaction analysis of a representative tumour from each of the 4 groups showing OPN mRNA expression in all tumours; D: OPN-a expressing tumours display increased levels of OPN protein. Control and OPN-A tumour sections were immunostained for OPN in conjunction with a rabbit isotype control. Bar represents 100 μm .

(the cell lines studied here are not of high metastatic potential). However, the expression of OPN-B and other splice variants was not investigated in primary HCC. Thus this study represents a comprehensive description of complete OPN variant expression *in vivo* and *in vitro*. Transcripts for all OPN variants were expressed in both primary HCC and cognate surrounding tissue, however, levels of expression varied between paired samples and between different patient HCCs. While our RT-PCR is only semi-quantitative (development of a quantitative real time assay for all OPN variants was not reliable) these results in-part confirm the work of He *et al*^[15] and show that expression of OPN splice variants can be detected in surrounding non-cancerous tissue. It has been reported that the OPN splice variants are specific to tumour cells and are rarely, if ever, expressed in normal tissue^[15]. However, we noted expression of all OPN variants in non-diseased liver tissue, suggesting that OPN splice variant expression is not restricted to tumour cells, and different forms of OPN may play different roles depending on the cell type that expresses OPN and the context in which it is expressed.

A significant finding of this study was the role of OPN and splice variants in *in vitro* proliferation and *in vivo* tumour growth of HCC. It is becoming increasingly clear that in addition to the role of OPN in the metastatic process it also has a role in cellular proliferation of a number of tumours. However, its role in HCC is not well studied, although, recently, an siRNA OPN knock-down approach suggested that OPN is important for HCC proliferation. Nevertheless, the relative roles of OPN variants or the cellular receptor responsible were not investigated^[9]. In contrast to the above OPN RNA interference study, we exogenously expressed OPN variants in the HCC Huh-7 cell line, and investigated cellular proliferation *in vitro* and in an ectopic xenograft nude mouse model. Stable ectopic expression of OPN-A, -B and -C resulted in secretion of all OPN forms into the culture media, and significant proliferation of Huh-7 cells, either directly or through the addition of conditioned media to naive Huh-7 cells. This suggests that at least *in vitro* OPN exerts its proliferative effect in either an autocrine or paracrine manner, which is consistent with the secreted nature of this protein, and was con-

firmed through the use of a neutralizing OPN antibody that abolished the proliferative effect of conditioned media. This proliferation effect was also seen in an *in vivo* HCC proliferation model in which Huh-7 cell lines, expressing either OPN-A, -B or -C, all proliferated faster than the control Huh-7 line. Interestingly compared to the *in vitro* proliferation assays, OPN-A showed the most significant proliferation advantage over OPN-B and -C. The reason for this discrepancy is unclear as all cell lines expressed similar amounts of OPN but may be related to stability or processing of OPN in an *in vitro* environment. To our knowledge, this is the first report that OPN and its splice variants play a significant role in cellular proliferation and growth of HCC, in addition to its role in invasiveness. Our collective studies strongly suggest that OPN plays a role in cellular proliferation however we cannot exclude the possibility that OPN expression also plays a role in increased cell survival given the recent observations from Zhao *et al.*^[31].

The CD44 family are cell surface adhesion molecules that mediate cell-matrix interactions, and in addition to the standard form, multiple isoforms arise from differential splicing of ten variant exons, and are designated CD44v6-15^[32]. CD44 variants, especially CD44v6, have been identified as protein markers for metastatic behaviour in a number of cancers, including HCC^[33-36]. A C-terminal region of OPN can specifically interact with CD44v6 and or v7 to mediate cellular chemotaxis^[37] and a thrombin-cleaved C-terminal OPN fragment induces macrophage migration *via* CD44^[38]. While OPN CD44v6-7 binding has been associated with metastasis and invasion, little work has been done in regard to the CD44 OPN interaction and tumour growth, although one study revealed that knockdown of CD44 expression reduces tumour growth in colon carcinoma cells^[39]. In this study, we show that the increased growth rate of Huh-7 cells in response to OPN conditioned media was as a result of CD44 expression because blocking CD44 with a neutralising antibody completely abolished this growth effect. Furthermore, HepG2 and HeLa cells, which both express CD44v6/7, also showed this growth effect while the Hep3B cell line, which is negative for CD44v6/7, was unresponsive to OPN in the conditioned media. To conclusively demonstrate a role for CD44, a siRNA approach was employed that successfully reduced CD44 expression in both Huh-7 and HeLa cells. Consistent with the above, this reduction in CD44 in both cell lines resulted in a decrease in cellular proliferation in response to OPN conditioned media. To our knowledge this is the first report that the interaction between OPN and CD44 results in signals that drive cellular proliferation in HCC. This is not surprising considering the recent work describing a role for OPN in regulating MKK3/6 and p38 dependent nuclear factor kappa B activation in cervical cancer leading to furin expression, a proprotein convertase that plays crucial roles in regulation of tumour progression metastasis and angiogenesis^[40]. Cervical cancer cells over expressing OPN

showed enhanced cell growth, while shRNA-mediated silencing of OPN suppressed cell growth in a CD44-mediated MKK3/6 dependent p38 activation mechanism^[40]. While similar mechanisms may be at play in HCC, the signalling pathways driven by OPN and CD44 activation in HCC require further investigation. Thus, understanding the molecular mechanisms that underpin increased HCC cell proliferation through the OPN/CD44 interaction and activation of downstream signalling pathways could provide potential targets for therapeutic strategies for the treatment of HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is a highly aggressive carcinoma of the liver, and is the fifth most common cancer worldwide. It is the third leading cause of cancer related death. Osteopontin (OPN) is a secreted multifunctional matrix-glycoprotein involved in normal tissue remodelling processes but is secreted at high levels in numerous tumours, including HCC. OPN is expressed as 3 isoforms and their role in HCC biology is not entirely known.

Research frontiers

Human OPN is known to be expressed in three different isoforms with potentially differing functions. Despite evidence of elevated OPN in several cancers and correlation of levels to malignant invasiveness, the expression of OPN isoforms in the context of HCC has not previously been investigated. Similarly the affect of OPN and its isoforms on HCC growth is unexplored.

Innovations and breakthroughs

This study demonstrates that all isoforms of OPN are expressed in HCC tissues and cell lines, at the mRNA level, and that each isoform can stimulate the growth of HCC derived cell lines both *in vitro* and *in vivo*, in an ectopic xenograft mouse model. Furthermore, this growth promoting effect has been shown to occur through a mechanism requiring functional CD44. These cellular proliferation signalling pathways, driven by OPN and CD44 activation, require further investigation.

Applications

Understanding the molecular mechanisms that underpin increased HCC cell proliferation could provide potential targets for therapeutic strategies for the treatment of HCC.

Peer review

Authors elegantly and convincingly demonstrated that OPN plays a relevant role in the expansion of HCC cells through interaction with the cell surface receptor CD44; this information is potentially interesting for novel anti HCC therapeutic approaches.

Abstract

AIM: To determine which patients might benefit most from retrograde viewing during colonoscopy through subset analysis of randomized, controlled trial data.

METHODS: The Third Eye® Retroscope® Randomized Clinical Evaluation (TERRACE) was a randomized, controlled, multicenter trial designed to evaluate the efficacy of a retrograde-viewing auxiliary imaging device that is used during colonoscopy to provide a second video image which allows viewing of areas on the proximal aspect of haustral folds and flexures that are difficult to see with the colonoscope's forward view. We performed a post-hoc analysis of the TERRACE data to determine whether certain subsets of the patient population would gain more benefit than others from use of the device. Subjects were patients scheduled for colonoscopy for screening, surveillance or diagnostic workup, and each underwent same-day tandem examinations with standard colonoscopy (SC) and Third Eye colonoscopy (TEC), randomized to SC followed by TEC or *vice versa*.

RESULTS: Indication for colonoscopy was screening in 176/345 subjects (51.0%), surveillance after previous polypectomy in 87 (25.2%) and diagnostic workup in 82 (23.8%). In 4 subjects no indication was specified.

Previously reported overall results had shown a net additional adenoma detection rate (ADR) with TEC of 23.2% compared to SC. Relative risk (RR) of missing adenomas with SC *vs* TEC as the initial procedure was 1.92 ($P = 0.029$). Post-hoc subset analysis shows additional ADRs for TEC compared to SC were 4.4% for screening, 35.7% for surveillance, 55.4% for diagnostic and 40.7% for surveillance and diagnostic combined. The RR of missing adenomas with SC *vs* TEC was 1.11 ($P = 0.815$) for screening, 3.15 ($P = 0.014$) for surveillance, 8.64 ($P = 0.039$) for diagnostic and 3.34 ($P = 0.003$) for surveillance and diagnostic combined. Although a multivariate Poisson regression suggested gender as a possibly significant factor, subset analysis showed that the difference between genders was not statistically significant. Age, bowel prep quality and withdrawal time did not significantly affect the RR of missing adenomas with SC *vs* TEC. Mean sizes of adenomas detected with TEC and SC were similar at 0.59 cm and 0.56 cm, respectively ($P = \text{NS}$).

CONCLUSION: TEC allows detection of significantly more adenomas compared to SC in patients undergoing surveillance or diagnostic workup, but not in screening patients (ClinicalTrials.gov Identifier: NCT01044732).

INTRODUCTION

Colonoscopy is generally regarded to be the “gold standard” for the detection of colorectal neoplasia, and is the only method that allows detection and removal during a single procedure^[1,2]. If the colon were a straight pipe, the standard colonoscope would be the perfect instrument for examining its lining, but lesions can be missed during colonoscopy, especially when located on the proximal aspect of haustral folds or on the inner curve of flexures^[3-8].

The Third Eye Retroscope (TER) (Avantis Medical Systems, Sunnyvale, California) provides an additional, retrograde view that helps to visualize areas behind folds and flexures^[9-11]. We recently showed in the Third

Eye Retroscope Randomized Clinical Evaluation (TERRACE) study that Third Eye colonoscopy (TEC) detected 23.2% additional adenomas compared to standard colonoscopy (SC)^[12].

As concerns about medical costs increase, there is growing interest in finding ways to target interventions and new technologies to specific patient sub-populations that will experience the greatest benefit^[13,14]. In this follow-up of our initial report of TERRACE results, we performed a post-hoc subset analysis of the data to determine whether specific indications for colonoscopy (screening, surveillance or diagnostic workup) or other patient characteristics were associated with higher additional adenoma detection rates (ADR) with TEC. Such information may be useful for targeting those segments of the colonoscopy population that would benefit most from use of this new technology. We also wished to evaluate the clinical significance of the additional adenomas detected through TEC and determine how finding those additional adenomas would affect recommendations for follow-up intervals.

MATERIALS AND METHODS

The TERRACE study was a prospective, randomized, controlled trial that used a “tandem” design involving two same-day, back-to-back procedures to provide a head-to-head comparison between TEC and SC.

Between March 2009 and February 2010, 15 experienced endoscopists at 4 European and 5 United States sites enrolled 448 patients who were scheduled to undergo colonoscopy for routine screening, surveillance after previous polypectomy, or diagnostic workup for symptoms possibly related to the lower gastrointestinal tract. Subjects were excluded for history of inflammatory bowel disease, colonic resection, polyposis syndrome or radiation therapy to abdomen or pelvis, or for active diverticulitis, suspicion of colonic stricture or concurrent enrollment in another study.

Upon arrival in the endoscopy suite, subjects were randomized to one of two groups by a research assistant utilizing a Web-based randomization module stratified both by center and by individual endoscopist. Each subject then underwent two complete examinations by the same endoscopist, who was informed of the order of exams immediately before beginning intubation.

Group A underwent SC first, followed by TEC, using the same colonoscope for both procedures. Group B underwent TEC first, then SC.

For TEC, following intubation of the cecum with a standard colonoscope, the TER was inserted through the biopsy channel of the colonoscope. When the TER emerges, its distal tip automatically turns 180 degrees so its miniature video camera and light are oriented backwards. As the colonoscope and TER are withdrawn together, the device provides a continuous retrograde view that complements the forward view of the colonoscope. The two video images are displayed side-by-side on a

monitor.

Tandem miss rate studies have demonstrated a “second-pass effect” - i.e., looking a second time generally yields additional lesions^[3-5]. In Group B the detection rate for SC as the second procedure served as a proxy for second-pass effect. Subtracting that from the additional detection rate with TEC in Group A yielded the net additional detection rate attributed to TEC.

Polyps were removed when detected and sent for histological evaluation. Advanced adenomas were defined as adenomas that measured at least 1 cm in diameter or those with villous or tubulovillous components, high-grade dysplasia or adenocarcinoma. An assistant recorded withdrawal time (from cecum to anal verge, subtracting pauses for polypectomy or extensive irrigation/suctioning) and total procedure time (from initial insertion of the colonoscope to withdrawal through the anal verge, not subtracting pauses). Bowel preparation was graded with the Ottawa Bowel Preparation Quality Scale Score^[15]. Telephone interviews were performed 24-72 h after procedures to assess each subject for adverse events.

Subjects were withdrawn from the study if they withdrew consent, had inadequate bowel preparation or developed complications, if the endoscopist was unable to intubate the cecum or identified a condition in which back-to-back examinations might create risk for the subject, or if there were device malfunctions, technical errors or deviations from the protocol.

The primary outcome measure was per-polyp detection rates for adenomas and for all polyps with SC and TEC. Secondary outcome measures were polyp size, polyp histology, withdrawal time and total procedure time.

Patients presenting for routine screening were regarded as having a low-to-average risk of developing colorectal cancer (CRC), while the non-screening patients - those presenting for surveillance colonoscopy as a follow-up after previous removal of adenomas or for diagnostic workup of symptoms - were considered to have an above-average risk for CRC.

The protocol was approved by the Institutional Review Board of each institution, and all patients signed an informed consent. The study was registered with ClinicalTrials.gov (Identifier Number NCT01044732) and was reported in compliance with the Consolidated Standards of Reporting Trials (CONSORT) 2010 Statement.

Statistical analysis

Statistical analyses were performed on the per-protocol population using the SAS statistical package, version 9.1 (SAS Institute, Cary, NC). Because non-adenomatous polyps are generally regarded as having limited clinical significance, subset analysis was applied only to adenomas. Sample size determination was discussed in our earlier report of TERRACE results^[12].

Because it is not possible to directly determine *P* values for the net additional ADR, we evaluated the statistical significance of the detection rates indirectly by calculating the relative risk (RR) of missing an adenoma

during first exams with SC *vs* first exams with TEC. RR for missing adenomas during the first exam was estimated by Poisson regression including only study group (TEC first *vs* SC first) as an explanatory variable. *P* values < 0.05 were considered statistically significant.

To further assess the effect of the order of procedures on adenoma miss rates during the first exam, an exploratory analysis was performed to examine the influence of the independent variables including study group, age, gender, bowel prep quality (Ottawa Score), withdrawal time and indication for procedure (screening, surveillance, or diagnostic workup). Interactions between study groups (i.e., order of exams) and each of the explanatory variables were also examined. A multivariate Poisson regression with backward selection was performed to determine whether the above variables predicted differences in the number of adenomas missed during first exams with SC *vs* TEC. Independent variables with *P* values < 0.10 were included in the model for the multivariate analysis. Independent covariates included in the final model from the multivariate Poisson regression were further evaluated through subset analysis, where *P* values < 0.05 were considered statistically significant.

For the subsets of subjects by indication for procedure, Fisher's exact test was performed to compare results for second exams in terms of additional subjects found to have at least one adenoma and additional subjects found to meet criteria for shortened surveillance intervals as a result of findings during the second exam.

RESULTS

Patient demographics and a study flow diagram describing withdrawal of subjects to yield a per-protocol population of 349 subjects are shown in Figure 1.

Indication for colonoscopy was screening in 176/345 subjects (51.0%), surveillance after previous polypectomy in 87 (25.2%) and diagnostic workup in 82 (23.8%). In 4 subjects no indication was specified.

Previously reported overall TERRACE results had shown a net additional ADR with TEC of 23.2% compared to SC (Table 1). The RR of missing adenomas with SC *vs* TEC was 1.92 (*P* = 0.029) (Table 2).

Using a multivariate Poisson regression, we determined the risk of missing adenomas during the first exam. Study group (TEC first *vs* SC first) and gender were selected as possibly significant factors, and the interaction between indication for procedures and study group was found to be predictive. Age, bowel prep quality and withdrawal time did not significantly affect the risk.

Subset analysis segmenting the population by indication showed that additional ADRs for TEC compared to SC were 4.4% in the screening group, 35.7% in the surveillance group, 55.4% in the diagnostic group and 40.7% in the non-screening patients (surveillance and diagnostic groups combined) (Table 1). The RR of missing adenomas with SC *vs* TEC was 1.11 (*P* = 0.815) for screening

Table 1 Additional adenoma detection rates for second exams by indication for procedure

Indication	Group A (SC, then TEC)			Group B (TEC, then SC)			Net additional detection with TEC (%)
	SC 1st	TEC 2nd	Additional in 2nd exam (%)	TEC 1st	SC 2nd	Additional in 2nd exam (%)	
All indications	107	49	45.8	115	26	22.6	23.2

subjects, 3.15 ($P = 0.014$) for surveillance subjects, 8.64 ($P = 0.039$) for diagnostic subjects and 3.34 ($P = 0.003$) for the surveillance and diagnostic subjects combined (Table 2).

In the diagnostic group, due to detection of lesions with TEC that had been missed with SC (after correction for second-pass effect), 75.0% additional subjects were found to have at least 1 adenoma. In the surveillance group, 42.9% additional subjects were found to have at

least 1 advanced adenoma or at least 3 small adenomas criteria for 3-year follow-up according to joint guidelines published by the United States Multi-Society Task Force on CRC, American College of Radiology and American Cancer Society^[16]. However, the numbers of subjects with these findings were small, and the differences did not reach statistical significance.

Segmenting the population by gender, additional

Table 3 Per-polyp miss rates for standard colonoscopy and Third Eye colonoscopy by size of adenoma and indication for procedure

	Adenomas missed with standard colonoscopy during 1st exams in group A (%)			Adenomas missed with Third Eye colonoscopy during 1st exams in group B (%)		
	< 10 mm	≥ 10 mm	All sizes	< 10 mm	≥ 10 mm	All sizes
All indications	33.8	11.8	31.4	20.8	0	18.4
Screening	27.7	12.5	26.0	28.1	0	23.5
Surveillance	37.7	0	35.1	16.7	0	15.5
Diagnostic	42.9	20.0	38.5	7.1	0	6.7
Surveillance + diagnostic	39.2	11.1	36.1	14.7	0	13.7

Table 4 Mean procedural times (min)

Indication	All exams with SC		All exams with TEC	
	Withdrawal time	Total procedure time	Withdrawal time	Total procedure time
All indications	7.6	17.0	9.5	20.9
Screening	7.5	16.0	9.6	19.4
Surveillance	7.9	16.4	9.5	21.8
Diagnostic	7.5	19.8	9.6	23.2
Surveillance + diagnostic	7.7	18.1	9.5	22.5

Total procedure time: Total time from initial insertion of the colonoscope to withdrawal through the anal verge; Withdrawal time: Time from cecum to anal verge, excluding pauses for polypectomy or extensive suctioning; TEC: Third Eye colonoscopy; SC: Standard colonoscopy.

ADRs for TEC compared to SC were 25.9% for males and 8.5% for females ($P = \text{NS}$). Segmenting by age, additional ADRs for TEC compared to SC were 22.0% for subjects less than 65 years of age and 25.8% for those at least 65 years ($P = \text{NS}$).

Per-polyp miss rates in the surveillance and diagnostic groups were lower for TEC than for SC, and no large adenoma (at least 10 mm) was missed with TEC in any subgroup (Table 3).

Mean sizes of adenomas detected with TEC and SC were similar at 0.59 cm and 0.56 cm, respectively ($P = \text{NS}$). Mean procedure times are shown in Table 4.

No adverse events were reported.

DISCUSSION

We report a subset analysis of results from the TER-RACE study, which was the first “head-to-head” comparison of TEC with SC and was designed to provide correc-

tion for the “second-pass effect” that invariably occurs in tandem studies^[12]. Reversing the order of procedures in the control group (TEC first, followed by SC) provided a proxy for the second-pass effect, which was then subtracted from the additional detection rate in the study group (SC first, followed by TEC) to yield the net additional ADR for TEC compared to SC.

This subset analysis provides additional insight regarding which segments of the population are likely to benefit most from TEC and the clinical significance of the adenomas that were detected with TEC after having been missed during SC.

As shown in Table 1, overall results demonstrated a 23.2% net additional ADR for TEC compared to SC. This was consistent with the outcome of a previous study by DeMarco *et al*^[11], in which investigators using a different methodology found a 25% additional ADR with the TER after each endoscopist had gained experience through performing 15 procedures.

Subset analysis segmenting the population by indication for procedure showed that in subjects undergoing colonoscopy for surveillance or diagnostic workup, TEC demonstrated additional ADRs of 35.7% and 55.4%, respectively, compared to SC. Pooling the results for those two groups of patients, who can be considered to have above-average risk for CRC, TEC showed an additional ADR of 40.7% compared to SC. In subjects undergoing screening colonoscopy, who can be regarded as having a low-to-average risk for CRC, TEC showed an additional ADR of 4.4% after correction for second-pass effect (Table 1).

In order to determine the statistical significance of these differences, we calculated the RR of missing an adenoma during first exams with SC *vs* first exams with TEC. The advantage with TEC proved to be statistically

significant for the surveillance and diagnostic groups, both separately and combined. However, the difference for the screening population was not significant (Table 2).

It is not surprising to find proportionally more lesions behind folds in surveillance patients because, by definition, they have had at least one previous colonoscopy during which polyps that were seen with the colonoscope were removed, while lesions that were hidden behind folds may have been left behind. In contrast, screening patients have not had adenomas removed, so whatever polyps they have are likely to be more evenly distributed. However, the reason for the difference in results between diagnostic patients and screening patients is not clear.

A multivariate analysis indicated that more adenomas were found during second exams with TEC than with SC, and more were found during second exams in males than in females. However, subset analysis showed that while the net additional ADR for TEC compared to SC trended lower for females than for males, the total number of adenomas detected in females during all exams was relatively small, and the difference between genders was not statistically significant.

The multivariate Poisson regression showed no significant influence of age, bowel preparation quality or withdrawal time on adenoma miss rates. These findings were confirmed by subset analysis in which patient age and bowel prep quality had no significant impact.

Mean withdrawal times for TEC were essentially identical for the groups segmented by indication for procedure, suggesting that the amount of time spent examining the mucosa could not explain the differences among those groups. However, total procedure times for TEC were somewhat longer for the surveillance and diagnostic populations, most likely because many more polypectomies were performed in those subjects compared to the screening group.

In this study, overall adenoma miss rates for SC were 31.4% for all-size and 11.8% for large adenomas (at least 10 mm). These miss rates are higher than suggested by previous studies involving two same-day colonoscopies. One such study found miss rates of 24% for all-size and 6% for large adenomas^[3]. Another found miss rates of 21% for all-size and 11% for advanced adenomas (but did not specify how many of those advanced adenomas were at least 10 mm)^[5]. These discrepancies are not surprising, since many authors have acknowledged the limitation inherent in comparing two examinations with identical technology: lesions that are hidden from the colonoscope during one exam are likely to be hidden during the second exam as well, causing them to be missed on the second exam and thus underestimating the true miss rate^[3-5,17].

Our 11.8% miss rate for large adenomas with SC is similar to the finding of a 12% miss rate for large adenomas in one study comparing colonoscopy with CT colonography (CTC)^[8]. Another comparison with CTC showed a 17% miss rate with SC for all polyps at least 10 mm, but did not indicate a miss rate specifically for large

adenomas^[17]. Due to the limited sensitivity of CTC for smaller lesions, neither study could reliably estimate the all-size adenoma miss rate for SC.

In Tables 1 and 2, we show that, except in the screening group, TEC provided a significant improvement in ADR on a per-polyp basis (i.e., number of adenomas per patient). As we currently think that each adenoma has the potential to develop into malignancy, it is desirable to detect and remove as many adenomas as possible except in the relatively uncommon circumstance in which the patient has a high risk for complications from a polypectomy of small lesions.

One might argue that it is important to determine ADR on a per-patient basis (i.e., the number of patients in whom at least one adenoma is found), because the detection of even one adenoma identifies the patient as a “polyp-former” who might be followed more carefully than a “non-polyp-former.” However, for example, if a patient had one diminutive tubular adenoma (5 mm or smaller) and two large advanced adenomas, this measure would attribute the same quality to an exam whether the endoscopist detected all 3 lesions or found only the small adenoma and missed the 2 more significant lesions.

Furthermore, the finding of a single small adenoma does not necessarily dictate close follow-up according to joint guidelines published by the United States Multi-Society Task Force on CRC, American College of Radiology and American Cancer Society^[16], which recommend follow-up at 3 years only for those patients who are at a high risk, defined as those with at least 1 advanced adenoma or at least 3 small adenomas. For patients with only 1-2 small tubular adenomas, who are at a low risk, the guidelines recommend repeat colonoscopy in 5-10 years.

Therefore, if we wished to consider a quality metric other than the per-polyp ADR, it might be more useful to calculate the number of subjects who are determined to be at high risk, i.e., those with at least 1 advanced adenoma or at least 3 small adenomas. In the surveillance group, due to detection of lesions with TEC that had been missed with SC, 42.9% additional subjects would be advised to return for 3-year follow-up per guidelines. However, the numbers were small and were not statistically significant.

Our results suggest that TEC offers an improvement in adenoma detection that can currently not be matched by other techniques or technologies. There is growing interest in improving quality in colonoscopy, and substantial evidence indicates that optimizing bowel preparation^[18-20], spending adequate time examining the mucosa^[21-24] and practicing high-quality withdrawal technique^[21,25,26] are associated with improved detection rates. However, none of these measures fully addresses the difficulty of detecting neoplasia located behind folds and flexures. According to one study comparing SC with CTC, two-thirds of adenomas missed with the colonoscope were located behind folds^[8], where they would likely be missed again during repeated exams.

CTC can reveal lesions on both sides of folds, but lacks sensitivity for small and flat lesions, and requires

referral for colonoscopy when abnormalities are identified^[27,28]. Cap-assisted colonoscopy does not require a second procedure, but studies have shown mixed results^[29-32] and even the most encouraging study demonstrated an advantage only for the detection of diminutive adenomas^[32]. Retroflexion of a colonoscope in the proximal colon has been found to be feasible by highly-experienced endoscopists, but results of studies so far have been mixed^[33-35]. Moreover, the safety, practicality and time requirement for routine retroflexion proximal to the rectum still need to be established.

Reducing the prevalence of CRC in a cost-effective manner requires use of the proper examination for each patient, so it is important to identify which segments of the population are most likely to benefit from various technologies. The findings in this subset analysis may have implications for evidence-based patient selection for TEC. In our study, TEC demonstrated a clinically and statistically significant benefit for the subsets of patients who presented for surveillance in follow-up of previous polypectomy and for diagnostic workup of symptoms. However, our results did not provide evidence for efficacy in patients who presented for routine screening.

Cost-effectiveness also requires appropriate timing of examinations. There is evidence that many endoscopists perform surveillance colonoscopy at shorter intervals than those recommended by guidelines^[16,36,37]. Their decisions regarding surveillance intervals may be influenced by the growing recognition that limitations in technology result in substantial miss rates during SC and by associated medico-legal concerns^[36,37]. Improving the quality of colonoscopy through use of a retrograde-viewing device could instill confidence in physicians and patients that the likelihood of missing significant neoplasia is very low and thus foster greater compliance with guidelines for surveillance intervals.

Limitations

The TERRACE study was not powered for analysis of subsets, and some numerical trends revealed by this post-hoc analysis, such as difference in additional detection rates between genders, did not reach statistical significance.

Only 33.5% of the subjects were female. Some of this discrepancy was due to one of the sites being a Veteran's Administration Medical Center, where 55 of the 57 subjects were male. Another, probably more significant, factor was that the TERRACE study was performed with the first-generation Retroscope, which was too large to fit through the working channel of "pediatric" size colonoscopes. With the growing trend toward using these smaller colonoscopes when examining female patients, it is likely that some investigators may have chosen not to enroll some of their female patients in the study on the basis that use of an "adult" colonoscope might have made the examination more difficult and/or uncomfortable (The second-generation device that is currently in use differs in that it has a higher-resolution camera and a smaller diameter that allows its use with all colonoscopes).

In conclusion, the results of this subset analysis demonstrated that adenoma miss rates for SC are even higher than those previously estimated through performance of back-to-back colonoscopy exams.

Use of a retrograde-viewing device significantly improves the quality of colonoscopy by increasing the detection of adenomas of all sizes. Use of the retrograde-viewing device along with a colonoscope appears to have the greatest value for patients undergoing colonoscopy for surveillance or for diagnostic workup of symptoms, and the study results do not provide evidence for efficacy of the device in routine screening colonoscopy. These findings could provide endoscopists with an evidence-driven basis for selection of patients most likely to benefit from this new technology.

COMMENTS

Background

This article expands on a previously-published report of the Third Eye Retroscope Randomized Clinical Evaluation (TERRACE), which was a large randomized, controlled trial. TERRACE evaluated the effectiveness of a device that provides an additional, retrograde (backward) view to allow examination of areas located behind folds in the colon wall that hide them from the forward-viewing camera during standard colonoscopy (SC). The previously-published overall TERRACE results showed that Third Eye colonoscopy (TEC) detected 23.2% additional pre-cancerous adenomas not found with SC.

Research frontiers

This new report focuses on post-hoc analyses of the TERRACE data to determine whether some subsets of patients might benefit more than others from TEC, to evaluate the clinical significance of the additional adenomas detected through TEC and to determine how finding those additional adenomas would affect recommendations for follow-up intervals.

Innovations and breakthroughs

These new analyses of the TERRACE data showed that, of all the variables that might influence the effectiveness of TEC, only the indication - i.e., the reason for performing the colonoscopy procedure - was significant. Patients who were having "surveillance" colonoscopy because they were found to have adenomas during previous exams, or "diagnostic" colonoscopy to look for a cause for symptoms, are considered to have above-average risk for colorectal cancer (CRC), and pooled results for those groups showed a 40.7% net additional adenoma detection rate (ADR) for TEC compared to SC. In contrast, patients who were having routine "screening" colonoscopy - who are considered to have low-to-average risk - had a 4.4% net additional ADR with TEC. In all of the groups combined, SC missed 11.8% of large adenomas, while none were missed during TEC.

Applications

These results confirm that use of a retrograde-viewing device allows detection of substantial numbers of clinically-significant adenomas that would be missed with the colonoscope alone. The finding that use of the device appears to offer more benefit for patients undergoing surveillance or diagnostic colonoscopy than for screening patients may provide physicians with a basis for selecting patients in whom they will use the device.

Terminology

Adenomas are polyps that have the potential to transform into CRC, and most cases of CRC arise from adenomas. The term "post-hoc" refers to additional analyses that were not anticipated in the original study protocol.

Peer review

The results of this post-hoc analysis will be helpful in supporting use of the Third Eye Retroscope (TER) in high-risk patients, which will allow for a more cost-effective approach as endoscopists continue to improve quality in colonoscopy. The authors are congratulated on demonstrating how TEC can detect additional adenomas during colonoscopy. Furthermore, the post-hoc analysis answers the question of who should have a TER used during colonoscopy. Based on the data from this manuscript, it would be those undergoing surveillance and diagnostic exams.

Abstract

AIM: To clarify the strategy for early diagnosis of pancreaticobiliary maljunction (PBM) without biliary dilatation and to pathologically examine gallbladder before cancer develops.

METHODS: The anatomy of the union of the pancreatic and bile ducts was assessed by using endoscopic retrograde cholangiopancreatography (ERCP). Patients with a long common channel in which communication between the pancreatic and bile ducts was maintained even during sphincter contraction were diagnosed as having PBM. Of these, patients in which the maximal diameter of the bile duct was less than 10 mm were

diagnosed with PBM without biliary dilatation. The process of diagnosing 54 patients with PBM without biliary dilatation was retrospectively investigated. Histopathological analysis of resected gallbladder specimens from 8 patients with PBM without biliary dilatation or cancer was conducted.

RESULTS: Thirty-six PBM patients without biliary dilatation were diagnosed with gallbladder cancer after showing clinical symptoms such as abdominal or back pain ($n = 16$) or jaundice ($n = 12$). Radical surgery for gallbladder cancer was only possible in 11 patients (31%) and only 4 patients (11%) survived for 5 years. Eight patients were suspected as having PBM without biliary dilatation from the finding of gallbladder wall thickening on ultrasound and the diagnosis was confirmed by ERCP and/or magnetic resonance cholangiopancreatography (MRCP). The median age of these 8 patients was younger by a decade than PBM patients with gallbladder cancer. All 8 patients underwent prophylactic cholecystectomy and bile duct cancer has not occurred. Wall thickness and mucosal height of the 8 resected gallbladders were significantly greater than controls, and hyperplastic changes, hypertrophic muscular layer, sub-serosal fibrosis, and adenomyomatosis were detected in 7 (88%), 5 (63%), 7 (88%) and 5 (63%) patients, respectively. Ki-67 labeling index was high and K-ras mutation was detected in 3 of 6 patients.

CONCLUSION: To detect PBM without biliary dilatation before onset of gallbladder cancer, we should perform MRCP for individuals showing increased gallbladder wall thickness on ultrasound.

INTRODUCTION

Pancreaticobiliary maljunction (PBM) is a congenital anomaly defined as a junction of the pancreatic and bile ducts located outside the duodenal wall, and usually forming a markedly long common channel. As the action of the sphincter of oddi does not have a functional impact on the junction of the pancreatic and bile ducts in PBM cases, PBM causes a continuous reciprocal reflux of pancreatic juice and bile^[1,2]. This results in various pathological conditions of the biliary tract and pancreas. Given that the hydropressure in the pancreatic duct is usually greater than that in the bile duct, pancreatic juice frequently flows back into the biliary duct (pancreatobiliary reflux), and this becomes a high risk factor for biliary cancer^[3-5]. In a Japanese analysis^[6], biliary cancer was associated with 131 (10.6%) of 1239 cases with PBM with biliary dilatation (congenital choledochal cyst); 44 (33.6%) of the 131 cases had cancer of the extrahepatic bile duct and 85 cases (64.9%) had gallbladder cancer. On the other hand, PBM without biliary dilatation was associated with biliary cancer in 147 (37.9%) of 388 cases, and 137 (93.2%) of these cancers were gallbladder cancer.

Most PBM cases detected in childhood are associated with bile duct dilatation, but one third of PBM detected in adults do not show dilatation of the bile duct. Many patients with PBM with biliary dilatation have clinical symptoms due to cholangitis or pancreatitis in childhood, whereas in PBM without biliary dilatation, few patients have symptoms in childhood and they are usually not diagnosed until adulthood^[7]. Furthermore, many patients with PBM without biliary dilatation are diagnosed in association with advanced-stage gallbladder cancer, which carries a poor prognosis^[2,6,7]. It is necessary to clarify a strategy to diagnose PBM without biliary dilatation early, before cancer occurs. In the present study, we investigated the process for diagnosing patients with PBM without biliary dilatation and examined histopathological findings from the gallbladder of patients with PBM without biliary dilatation before cancer developed.

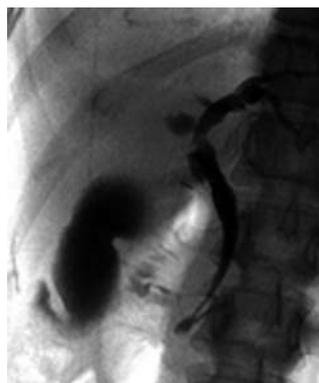

Figure 1 Endoscopic retrograde cholangiopancreatography of a patient with pancreaticobiliary maljunction without biliary dilatation showing a long common channel and deformity with fuzzy irregularity of the gallbladder.

MATERIALS AND METHODS

Study patients

We studied the anatomy of the union of the pancreatic and bile ducts using endoscopic retrograde cholangiopancreatography (ERCP). Patients with a long common channel in which communication between the pancreatic and bile ducts was maintained in both relaxation and contraction of the sphincter under serial observation during ERCP were diagnosed as having PBM^[1,2]. Of these, patients in whom the maximal diameter of the bile duct was less than 10 mm were diagnosed with PBM without biliary dilatation (Figure 1). When the common bile duct was involved with associated gallbladder cancer, diameter of the intact distal portion of the bile duct was measured.

Between January 1975 and December 2010, 104 patients were diagnosed with PBM with ERCP. Endoscopic ultrasonography (EUS) and magnetic resonance cholangiopancreatography (MRCP) were performed from 1990 and 2001, respectively. Of these, 54 patients (12 men and 42 women; median age at initial diagnosis of PBM 56.6 years, range 30-77 years) were diagnosed with PBM without biliary dilatation. The process leading to diagnosis of these patients was retrospectively investigated. This study was approved by the institutional review board.

Histopathological and immunohistochemical examinations

We conducted histopathological analysis of resected gallbladder specimens from 8 patients with PBM without biliary dilatation or cancer. Tissues were fixed in 10% buffered formalin and embedded in paraffin. Serial 3- μ m sections were stained with hematoxylin and eosin for evaluation. Thickness of the gallbladder wall and mucosal height of each specimen were measured using a semiautomatic image analyzer. Hyperplastic changes were defined as an increased number of mucosal folds that were longer than normal, irregular, and frequently branched. Immunohistochemistry was performed us-

Table 1 Clinical features of 8 pancreaticobiliary maljunction patients without biliary dilatation or cancer

Case	Age (yr)	Sex	Process leading to ultrasound	Amylase level in bile (IU/L)	Follow-up
1	30	F	Screening for hepatitis A	528 000	Follow-up after 236 mo
2	55	F	Screening for chronic hepatitis C	69 850	Follow-up after 47 mo

ing antisera for Ki-67 (clone MIB-1: Immunotech SA, Marseille, France) by the avidin-biotin horseradish peroxidase method (Vectastain Elite ABC kit; Vector, Burlingame, CA, United States). Ki-67-positive cells were defined as a cell with brown staining of the nucleus, and Ki-67 labeling index was determined by counting a minimum of 500 cells in the area representing the most homogenous region of positive cells.

Gallbladder epithelium was microdissected from 20- μ m formalin-fixed paraffin-embedded sections. Genomic DNA was extracted from the tissues by using Takara Dexpattm (Takara Shuzo, Otsu, Japan). A point mutation of K-ras codon 12 was analyzed by polymerase chain reaction enzyme-linked minisequence assay (Sumitomo Metal Industry, Tokyo, Japan). The precise methodology of this assay is described elsewhere^[8].

Ten cases of normal gallbladder that were resected at pancreatoduodenectomy for pancreatic diseases were selected as controls.

Statistical analysis

Statistical analysis was performed using chi-squared analysis or Mann-Whitney's *U* test. *P* values of less than 0.05 were considered statistically significant.

RESULTS

Process of diagnosing PBM without biliary dilatation

Clues associated with a diagnosis of PBM without biliary dilatation were the presence of gallbladder cancer (*n* =

36), other malignancies (*n* = 4), chronic pancreatitis (*n* = 1), intrahepatic stones (*n* = 1), gallstones (*n* = 1), gastritis (*n* = 1), previous cholecystectomy (*n* = 2), and gallbladder wall thickening (more than 3 mm) on ultrasound (US; *n* = 8) (Figure 2). Thirty-one patients with gallbladder cancer had clinical symptoms such as abdominal or back pain (*n* = 16), jaundice (*n* = 12), and abdominal discomfort (*n* = 3), and the other 5 gallbladder cancers were detected using screening tests such as US (*n* = 4) and fluorode-oxyglucose positron emission tomography (*n* = 1). Radical surgery was possible in only 11 (31%) of 36 cases of gallbladder cancer and only 4 patients (11%) survived for 5 years. Three PBM patients without biliary dilatation associated with benign diseases (chronic pancreatitis, gallstones and gastritis) were diagnosed before 1985, and they were lost to follow up without surgery.

PBM patients without biliary dilatation diagnosed from gallbladder wall thickening on US

PBM without biliary dilatation was suspected in 8 patients based on finding of gallbladder wall thickening on US. Abdominal US was performed for symptoms such as abdominal pain in 5 patients to screen for associated diseases. Following US, computed tomography (*n* = 8), EUS (*n* = 5), MRCP (*n* = 4), and ERCP (*n* = 8) were done. The median age of patients was 48.2 years (range 30-70 years; 3 men and 5 women), which was significantly younger than that of PBM patients with gallbladder cancer (median age, 58.5 years; *P* < 0.01). Based on the diagnosis of PBM without biliary dilatation, all patients underwent prophylactic cholecystectomy. Amylase levels in the bile were markedly elevated in all patients. Five patients have been regularly followed, and 3 patients were lost to follow up 1-75 mo after surgery. Bile duct cancer has not occurred in any patient (Table 1). On EUS, thickening of the inner hypochoic layer and outer hyperechoic layer was detected in 2 patients (Figure 3), and thickening of the inner hypochoic layer, a middle, more hypochoic layer, and the outer hyperechoic layer was observed in 3 patients.

Histopathological findings of the gallbladder of PBM patients without biliary dilatation diagnosed from gallbladder wall thickening on US

On histological findings of the resected gallbladder, the gallbladder wall was more thickened in PBM (7.7 ± 7.0 mm, mean \pm SD) than in control cases (2.0 ± 0.5 mm, *P*

< 0.01). Mucosal height was significantly higher in PBM (1.0 ± 0.7 mm) than in control cases (0.5 ± 0.2 mm, *P* < 0.01). Hyperplastic changes, hypertrophic muscular layer, subserosal fibrosis, and adenomyomatosis were detected in 7 (88%), 5 (63%), 7 (88%) and 5 (63%) of PBM patients, respectively, compared with no control cases (Figure 4). No dysplastic changes were observed. Ki-67 labeling index was higher in PBM ($6.0\% \pm 2.1\%$) than control cases ($1.2\% \pm 0.3\%$, *P* < 0.01). K-ras mutation was detected in 3 (50%) of 6 PBM patients (Table 2). Adenomatous changes were not observed in any patient.

DISCUSSION

Because PBM patients have a high incidence of biliary cancer due to pancreatobiliary reflux, once PBM is diagnosed, prophylactic biliary surgery is recommended before the onset of malignant change^[2]. In particular, PBM without biliary dilatation is frequently associated with gallbladder cancer. However, PBM cases without biliary dilatation rarely evoke symptoms, and most patients are not diagnosed until the onset of advanced-stage gallbladder cancer^[2,6,7].

In this series, 36 (67%) of 54 PBM patients without biliary dilatation were diagnosed based on associated gallbladder cancer. Most gallbladder cancers were in an advanced stage, and resection was possible in only 11 patients (31%). Since a paper^[9] published in 1991 reported that gallbladder wall thickening was sometimes observed in PBM cases without biliary dilatation, we have prospectively checked for PBM after finding gallbladder wall thickening on US. This additional investigation using MRCP and ERCP allowed us to identify 8 patients with PBM without biliary dilatation before the onset of gallbladder cancer. All 8 patients underwent prophylactic cholecystectomy, and bile duct cancer has not occurred in any patient. The median age of the 8 patients was about 10 years younger than PBM patients with associated gallbladder cancer. The age of PBM patients with gallbladder cancer at the time of diagnosis peaked in the 50s, and was younger by a decade than that of gallbladder cancer patients without PBM^[10]. Chronic injury to the epithelium of bile duct by pancreatic juice induces severe inflammation and malignant changes in PBM patients; therefore, age can be a major determinant of

risk. To eliminate the risk of gallbladder cancer, we must detect PBM without biliary dilatation early in adults.

Epithelial hyperplasia of the gallbladder induced by longstanding continuous stasis of the bile intermingled with refluxed pancreatic juice has been reported to be one of the characteristic pathological changes in PBM patients^[11-13]. The incidence of epithelial hyperplasia of the gallbladder of PBM patients without biliary dilatation was reported to be 72%^[11] to 91%^[12]. Tanno *et al*^[12] reported that the Ki-67 labeling index of epithelial hyperplasia of PBM patients was elevated to $6.1\% \pm 1.5\%$ and K-ras mutation was detected in 2 (13%) of 15 patients. Histopathological findings of our 8 cases were similar to the above findings. Considering that increased cell proliferation is linked to the development of cancer by means of tumor promotion and an increased rate of random mutations, gallbladder epithelium of PBM patients can be considered to represent a premalignant lesion.

Interestingly, hypertrophic muscular layer, subserosal fibrosis, and adenomyomatosis were detected in 63%, 88% and 63%, respectively. Sugai *et al*^[14] reported that subserosal fibrosis with chronic inflammation was detected in 33% of gallbladders of 27 PBM patients, and Tsuchida *et al*^[11] found K-ras mutations in 5 (50%) of 10 gallbladders of PBM without biliary dilatation. Long-standing continuous stimulation with bile containing pancreatic juice may induce these three changes as well as epithelial hyperplasia.

EUS shows the normal gallbladder wall to be a two-layered structure consisting of an inner hypoechoic layer composed of the mucosa and the muscular layer, and an outer hyperechoic layer composed of the subserosal layer and the serosa^[15]. On EUS, the gallbladder wall of patients with PBM appeared as two thickened layers showing epithelial hyperplasia and subserosal fibrosis or three thickened layers containing a middle, more hypoechoic, layer showing a hypertrophic muscular layer.

Although ERCP is the gold standard for diagnosis of PBM, MRCP has recently become a common non-invasive method for obtaining quality images of the pancreaticobiliary tract. MRCP can diagnose many PBM cases based on findings of an anomalous union between the common bile duct and the pancreatic duct, although some atypical PBM cases with relatively short common channel cannot be diagnosed only by MRCP, and should be confirmed by ERCP^[16]. To detect patients with PBM without biliary dilatation early requires that certain patients undergo MRCP before gallbladder cancer occurs. Gallbladder wall thickness on US during medical checkups may serve as an indication for MRCP and EUS before ERCP for suspected PBM without biliary dilatation. Once PBM is diagnosed in patients with increased gallbladder wall thickness, prophylactic biliary surgery is recommended before the onset of malignant change.

In conclusion, hyperplastic gallbladder mucosa of PBM patients represents a premalignant lesion. To detect PBM without biliary dilatation before onset of gallbladder cancer, we should perform MRCP for individuals showing gallbladder wall thickness on US.

COMMENTS

Background

Pancreaticobiliary maljunction (PBM) causes a continuous reciprocal reflux of pancreatic juice and bile. PBM cases without biliary dilatation rarely evoke symptoms, and most patients are not diagnosed until the onset of advanced-stage gallbladder cancer. It is necessary to clarify a strategy to diagnose PBM without biliary dilatation early, before cancer occurs.

Research frontiers

The authors investigated the process for diagnosing patients with PBM without biliary dilatation and examined histopathological findings from the gallbladder of patients with PBM without biliary dilatation before cancer developed.

Innovations and breakthroughs

Thirty-six (66%) out of 54 PBM patients without biliary dilatation were diagnosed with gallbladder cancer. Radical surgery for gallbladder cancer was only possible in 11 patients and only 4 patients survived for 5 years. Eight patients were suspected as having PBM without biliary dilatation from the finding of gallbladder wall thickening on ultrasound and the diagnosis was confirmed by endoscopic retrograde cholangiopancreatography and/or magnetic resonance cholangiopancreatography (MRCP). The median age of these 8 patients was younger by a decade than PBM patients with gallbladder cancer. All 8 patients underwent prophylactic cholecystectomy and bile duct cancer has not occurred. Wall thickness and mucosal height of the 8 resected gallbladders were significantly greater than controls, and hyperplastic changes were detected in 7 (88%) patients. Ki-67 labeling index was high and K-ras mutation was detected in 3 of 6 patients.

Applications

To detect PBM without biliary dilatation before onset of gallbladder cancer, people should perform MRCP for individuals showing increased gallbladder wall thickness on ultrasound.

Peer review

The study has a good-sized patient cohort and involves appropriate methods of analysis. The interpretation and presentation of the results are both appropriate. The findings of this study should contribute in the effective management of patients with PBM.

Abstract

AIM: To determine the effect of oral sumatriptan on gastric emptying using a continuous ¹³C breath test (BreathID system).

METHODS: Ten healthy male volunteers participated

in this randomized, 2-way crossover study. The subjects fasted overnight and were randomly assigned to receive a test meal (200 kcal/200 mL) 30 min after pre-medication with sumatriptan 50 mg (sumatriptan condition), or the test meal alone (control condition). Gastric emptying was monitored for 4 h after administration of the test meal by the ¹³C-acetic acid breath test performed continually using the BreathID system. Then, using Oridion Research Software (β version), the time taken for emptying of 50% of the labeled meal ($T_{1/2}$) similar to the scintigraphy lag time for 10% emptying of the labeled meal (T_{lag}), the gastric emptying coefficient (GEC), and the regression-estimated constants (β and κ) were calculated. The statistical significance of any differences in the parameters were analyzed using Wilcoxon's signed-rank test.

RESULTS: In the sumatriptan condition, significant differences compared with the control condition were found in $T_{1/2}$ [median 131.84 min (range, 103.13-168.70) vs 120.27 min (89.61-138.25); $P = 0.0016$], T_{lag} [median 80.085 min (59.23-125.89) vs 61.11 min (39.86-87.05); $P = 0.0125$], and β [median 2.3374 (1.6407-3.8209) vs 2.0847 (1.4755-2.9269); $P = 0.0284$]. There were no significant differences in the GEC or κ between the 2 conditions.

CONCLUSION: This study showed that oral sumatriptan significantly delayed gastric emptying of a liquid meal.

Effect of sumatriptan on gastric emptying: A crossover study using the BreathID system. *World J Gastroenterol* 2012; 18(26): 3415-3419 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i26/3415.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i26.3415>

INTRODUCTION

Sumatriptan, a selective 5-HT₁ receptor agonist, was launched in the market in 1991, representing the single most remarkable advance to date in the treatment of migraine^[1]. It was suspected that the drug might delay gastric emptying of liquids in healthy subjects by prolonging the lag phase of gastric emptying^[2,3]. Several studies have reported that sumatriptan restores gastric accommodation in patients with functional dyspepsia^[4-9].

A recent study showed that the accelerated gastric emptying of nutrient liquids can be a surrogate marker of impaired distension-induced accommodation^[10]. After aggressive filling of the stomach with a nutrient liquid, the resultant increase in intragastric pressure determines the rate of gastric emptying; higher luminal pressure caused by defective accommodation accelerates gastric emptying^[10,11]. Conversely, it would be logical to consider that the gastric emptying of a nutrient liquid would be delayed when distension-induced accommodation is enhanced. Compared with second-generation 5HT_{1B/1D} receptor agonist antimigraine drugs, sumatriptan shows poor oral bioavailability and a relatively short elimination half-life^[6]. According to a previous report, the T_{max} of sumatriptan is 2-3 h, the T_{1/2} is 2 h, and the oral bioavailability is 14%^[6]. The aim of this preliminary study was to test our hypothesis that oral sumatriptan intake would cause a delay in the gastric emptying of nutrient liquids. If the hypothesis were proven to be true, it would lend indirect support to the suggestion that sumatriptan enhances distension-induced gastric accommodation^[11].

In this study, we investigated the physiologic effect of sumatriptan on the rate of gastric emptying using a continuous real-time ¹³C breath test (BreathID system: Exalenz Bioscience Ltd., Israel).

MATERIALS AND METHODS

Ethics

The study was conducted in accordance with the principles laid down in the Declaration of Helsinki. The study protocol using the BreathID system was approved by the Ethics Committee of Yokohama City University School of Medicine (No. A110929010).

Subjects

The subjects were 10 asymptomatic male volunteers, all of whom were students of Yokohama City University,

non-smokers, none were habitual drinkers, and none had a history of gastrointestinal disease or abdominal surgery. None of the subjects were on any routine medications at the time of the study.

¹³C-acetic acid breath test

Ten subjects participated in this randomized, 2-way crossover study. The 2 tests were conducted as follows: (1) The subjects were assigned to receive a test meal 30 min after intake of a 50 mg tablet of sumatriptan; and (2) The subjects only received the test meal. The two test protocols were administered in crossover fashion separated by a washout period of at least 7 d. In both experiments, the protocols were started after the patients had fasted overnight (for at least 8 h), and the breath test was performed for 4 h while the subjects were seated.

In experiment A, subjects were asked to take a 50 mg tablet of sumatriptan prior to the administration of a test meal. The test meal consisted of a 200 kcal/200 mL liquid meal (Racol with milk flavor, Otsuka Pharmaceutical, Tokyo, Japan) containing 100 mg of ¹³C-acetic acid (Cambridge Isotope Laboratories, Boston, MA, United States)^[12-23], which the patients were requested to consume within 5 min. In experiment B, subjects underwent the breath test after ingestion of the test meal alone. Breath samples were continuously collected *via* a nasal tube using the BreathID system (Exalenz Bioscience Ltd., Israel) from baseline, before administration of the test meal, until 4 h after completion of the test meal ingestion (time 0)^[14-23].

Analysis of the ¹³C-acetic acid breath test data

The data from the ¹³C acetic acid breath test were analyzed using the Oridion Research Software, version β (Oridion Medical Ltd., Israel)^[14-23]. The time *vs* ¹³CO₂ excretion rate curve was fitted to the conventional formula of $z(t) = m(1 - e^{-\kappa t})^\beta$, and the regression-estimated constants κ and β were determined^[24]. After the mathematical analysis, the time required for emptying of 50% of the labeled meal (T_{1/2}) similar to the scintigraphy lag time for 10% emptying of the labeled meal (T_{lag}), the gastric emptying coefficient (GEC), and the regression-estimated constants (β and κ) were also calculated. A larger (smaller) value of β indicates slower (faster) emptying in the early phase, and a larger (smaller) value of κ indicates faster (slower) emptying in the later phase.

Statistical analysis

Statistical evaluation was carried out using the Wilcoxon's signed-rank test. The level of significance was set at $P < 0.05$. The statistical analysis were performed with the StatView software (SAS Institute, Cary, NC, United States).

RESULTS

The study was completed in 10 male subjects (mean age, 30.7 years; median age, 31 years; range, 24-38). No adverse events occurred during the study. The subjects'

Table 1 Comparison of breath test parameters

	Sumatriptan	Control	P value
T _{1/2}	131.84 (103.13-168.70)	120.27 (89.61-138.25)	0.0166
T _{lag}	80.085 (59.23-125.89)	61.11 (39.86-87.05)	0.0125
GEC	3.545 (3.20-3.97)	3.55 (3.19-4.03)	0.6460
β	2.3374 (1.6407-3.8209)	2.0847 (1.4755-2.9269)	0.0284
κ	0.5833 (0.3689-0.7836)	0.6180 (0.4661-0.8872)	0.3329

T_{1/2}: Time to emptying of 50% of the labeled meal (min); T_{lag}: Very similar to the percentage dose recovery peak time (min); GEC: Gastric emptying coefficient; β and κ: Regression-estimated constants. A larger (smaller) value of β indicates slower (faster) emptying in the early phase, and a larger (smaller) value of κ indicates faster (slower) emptying in the later phase.

mean height was 171.5 cm, their median height was 171 cm (range, 165-180 cm), their mean weight was 72.6 kg, and their median weight was 69.5 kg (range, 62-92 kg).

Table 1 summarizes the sumatriptan-induced changes in the breath test parameters. In the sumatriptan condition, significant differences compared with the control condition were found in T_{1/2}, [median, 131.84 min (range, 103.13-168.70) *vs* 120.27 min (89.61-138.25); *P* = 0.0016], T_{lag}, [median, 80.085 min (59.23-125.89) *vs* 61.11 min (39.86-87.05); *P* = 0.0125], and value of β [median 2.3374: 1.6407-3.8209) *vs* 2.0847 (1.4755-2.9269); *P* = 0.0284]. On the other hand, there were no significant differences in GEC [median, 3.545 (3.20-3.97) *vs* 3.55 (3.19-4.03); *P* = 0.6460] or κ [median, 0.5833 (0.3689-0.7836) *vs* 0.6180 (0.4661-0.8872); *P* = 0.3329] between sumatriptan and control conditions, respectively.

DISCUSSION

In this study, we examined the changes in the rate of gastric emptying during the first 4 h after oral administration of a 50 mg tablet of sumatriptan half an hour prior to a test meal in healthy subjects. The rate of gastric emptying was measured by the ¹³C-acetic acid breath test.

The ¹³C-acetic acid breath test is a non-invasive and well-established test for measuring the rate of gastric emptying of liquid meals, and the results of this test have been shown to be significantly correlated with those of scintigraphy^[12-24]. The subject ingests ¹³C-labeled acetic acid, which passes through the stomach and is absorbed in the duodenum and upper small bowel. The ¹³C-labeled acetic acid is then metabolized in the liver and excreted from the lung as ¹³CO₂. This test thus enables gastric emptying to be measured in a non-invasive manner^[12-24]. The BreathID system allows continuous evaluation of gastric emptying. In patients, it allows real-time breath analysis with a shortened examination time and minimal patient discomfort. Continuous analysis also provides quick, immediate results^[14-23].

In general, administration of sumatriptan, a 5HT₁ receptor agonist, has been reported to delay gastric emptying of calorie-containing liquids, and to restore gastric accommodation. In other words, sumatriptan allows both increased gastric relaxation after ingestion of

a meal and an increased caloric intake at maximum satiety^[9,25,26]. However, several studies have reported these effects of sumatriptan after subcutaneous sumatriptan injection^[3,9,26-28]. As previously mentioned, sumatriptan shows poor oral bioavailability and a relatively short elimination half-life profile. To the best of our knowledge, no researchers have reported the aforementioned effects following administration of sumatriptan *via* the oral route. Therefore, we studied the effect of oral sumatriptan on the rate of gastric emptying.

Sumatriptan has been reported to be effective in relieving nausea associated with a migraine attack^[7], although specific antiemetic agents are often required to control the symptoms and to restore normal gastrointestinal motor patterns^[7,9].

In the present study, the amount of sumatriptan administered was not adjusted to the body weight of each individual, with the drug being administered *via* the oral route. T_{lag} of sumatriptan has been reported to be 2 or 3 h. In a recent study, the BreathID examination was started half an hour after the subjects took sumatriptan orally, and was continued for 4 h. Therefore, the T_{lag} of sumatriptan would have been reached while the BreathID examination was still ongoing.

In the present study, an increase in T_{lag} and T_{1/2}, and also in the value of β, was observed in the subjects administered sumatriptan prior to the test meal. Thus, sumatriptan delayed gastric emptying. In addition, the increase in the value of β indicated that sumatriptan in particular delayed the early phase of gastric emptying. We think that these findings were attributable to restoration of distention-induced gastric accommodation by sumatriptan. Several studies have shown that in patients with functional dyspepsia, who showed impaired accommodation of the proximal stomach, subcutaneously administered sumatriptan restored gastric accommodation, thereby significantly improving meal-induced satiety^[9,26,27]. In healthy volunteers, accommodation of the proximal stomach may be thought to increase after administration of sumatriptan. A previous study using real-time ultrasonography and computed tomography demonstrated that subcutaneous administration of sumatriptan, after distention of the stomach with liquids, produced a reduction in the proximal and distal transverse area and an increase in the sagittal axis of the proximal stomach^[28]. Another study using duplex sonography showed that subcutaneous administration of sumatriptan 10 min postprandially caused a significant widening of both the gastric antrum and the proximal stomach. Therefore, the authors concluded that the time to commencement of peristalsis-related emptying is delayed following administration of sumatriptan^[26].

The effect of 5-HT on gastric fundus tone has not been studied. However, Tack *et al.*^[29] recently showed that sumatriptan, which is a 5-HT₁ receptor agonist, is an agonist at 5-HT_{1P} receptors on nitrergic myenteric neurons in the stomach. We consider this action was induced through 5-HT_{1P} receptors as one of the side effects of

sumatriptan.

In the present study, we found that despite its low bioavailability, oral administration of even one tablet of sumatriptan consistently affected the rate of gastric emptying. Delayed gastric emptying may represent an increase in gastric accommodation.

In conclusion, this study suggests that sumatriptan, which can restore gastric accommodation, may be of benefit to many patients suffering from the distress of early satiety.

COMMENTS

Background

The incidence of functional gastrointestinal disorders is currently increasing worldwide though the cause of this disease is largely unknown. Rome III criteria included postprandial distress syndrome, which might come from impaired gastric accommodation and gastric emptying.

Research frontiers

It is accepted that both gastric emptying and gastric accommodation are important in functional gastrointestinal disorders. However, how gastric accommodation affects gastric emptying in a breath test has not been researched. In this study, the authors demonstrated that oral sumatriptan significantly delayed gastric emptying and suggest that delayed gastric emptying may represent an increase in gastric accommodation.

Innovations and breakthroughs

This is the first study to report that oral administration of sumatriptan affected the rate of gastric emptying. Furthermore, the studies would suggest that delayed gastric emptying may represent an increase in gastric accommodation.

Applications

By understanding both gastric emptying and gastric accommodation, this study may represent a future strategy for therapeutic intervention in the treatment of patients with functional dyspepsia.

Terminology

The BreathID system allows measurement of gastric emptying by a breath test. This allows continuous and real-time evaluation of gastric emptying. Continuous analysis also provides quick, immediate results.

Peer review

This paper demonstrated a new way to identify the gastric emptying in human subjects; this is the main merit of this study.

Abstract

AIM: To study the safety and effectiveness of propofol sedation for outpatient colonoscopy.

METHODS: Propofol was given by bolus injection with an age-adjusted standard protocol consisting of 60 mg for patients < 70 years old, 40 mg for patients age 70-89 years, and 20 mg for those \geq 90 years, and additional injections of 20 mg propofol were given up to a maximum of 200 mg. The principal parameters were the occurrence of adverse events within 24 h after colonoscopy and overall satisfaction for this procedure. Secondary parameters included successful procedure, respiratory depression, and other complications.

RESULTS: Consecutive patients were entered prospectively and all 2101 entered successfully completed

outpatient colonoscopy. The mean dose of propofol used was 96.4 mg (range 40-200 mg). Younger patients required higher doses of propofol than older patients (20-40 years *vs* \geq 61 years: 115.3 ± 32 mg *vs* 89.7 ± 21 mg, $P < 0.001$). Transient supplemental oxygen supply was needed by five patients (0.2%); no other complications occurred. The questionnaires were completed by 1820 (87%) of 2101 patients and most rated their overall satisfaction as excellent (80%) or good (17%). The majority (65%) of patients drove home or to their office after their colonoscopy. Most (99%) were willing to repeat the same procedure. No incidents occurred within 24 h after colonoscopy.

CONCLUSION: Propofol sedation using a dose < 200 mg proved both safe and practical for outpatient colonoscopy.

INTRODUCTION

Colorectal cancer is one of the main causes of death

from cancer in western countries and in Japan. There is no clear strategy for reducing the incidence of colorectal cancer, therefore, reduction in mortality relies on removal of premalignant lesions and detection of cancer at an early stage by colonoscopy^[1,2]. In the face of increasing demands for gastroenterological services, the success of colonoscopic screening in the outpatient setting depends on patient acceptability^[3]. CO₂ insufflation and the water method for unsedated colonoscopy have been shown to be more acceptable than unsedated conventional colonoscopy^[4,5]. We previously demonstrated that use of a small-caliber pediatric colonoscope resulted in completed colonoscopies in patients who had an unsuccessful procedure using a standard colonoscope^[6]. The use of variable stiffness colonoscopes significantly reduced procedure-related pain and the dose of propofol required for sedation during colonoscopy^[7].

Recently, the feasibility and safety of endoscopist-directed propofol administration was confirmed in a study of 646 080 cases from 28 centers^[8]. Endoscopist-directed propofol sedation refers to administration of propofol by a non-anesthesia specialist under the direct supervision of the endoscopist performing the endoscopic procedure. Propofol sedation for colonoscopy was shown to be superior to other sedation methods in that propofol was associated with a low incidence of cardiopulmonary complications and was superior to benzodiazepines with regard to rapidity of both induction of sedation and recovery^[9-11].

These results have been confirmed by meta-analysis^[12]. We have previously reported that propofol sedation was both safe and practical for diagnostic esophago-gastroduodenoscopy and endoscopic procedures in patients aged ≥ 90 years^[13-16]. In addition, we have allowed our patients to drive home after colonoscopy, based on the experience with diagnostic esophagogastroduodenoscopy in our endoscopy unit^[13,14]. Here, we report a prospective evaluation of the safety and effectiveness of propofol sedation with follow-up for 24 h after outpatient colonoscopy.

MATERIALS AND METHODS

Patients

The study was done at the Showa Inan General Hospital and included outpatients who underwent only colonoscopy. Emergency procedures were excluded. Patients were also excluded if they were < 20 years old, pregnant, assigned to American Society of Anesthesiologists (ASA) class III and IV, overweight (> 100 kg), or allergic to the drugs used or their components (soybeans or eggs). Routine standard monitoring at this unit included continuous assessment of peripheral oxygen saturation (SpO₂) and heart rate. Clinical assessment of the patients included measurement of respiratory effort by visual assessment and by palpation of the chest wall and abdominal excursion and/or palpation of exhaled breath. When oxygen desaturation (SpO₂ < 90%) continued for

> 20 s, supplemental oxygen was given. The endoscopic team consisted of the nurse who administered the drugs and was responsible for the patient, the endoscopist, and a second nurse to assist the endoscopist and the patient-monitoring nurse.

Propofol was administered for endoscopic sedation by nurses supervised by endoscopists. Both the nurses and endoscopists had advanced cardiac life support certification, advanced airway training, didactic training on propofol, observation of cases, and supervised administration of propofol by anesthesiologists before beginning propofol administration supervised by the endoscopist. The training period typically lasted about 2 wk.

The study was conducted in accordance with the Helsinki Declaration and was approved by the ethics committee at the hospital. Verbal and written informed consent was obtained from all patients.

All colonoscopies were performed by six skilled endoscopists (Horiuchi A, Nakayama Y, Kajiyama M, Kato N, Kamijima T, Ichise Y) who each perform > 300 colonoscopies/year. All the procedures were conducted under propofol sedation (AstraZeneca, Osaka, Japan)^[13,14]. The standard bowel preparation was a polyethylene glycol solution (Ajinomoto Pharmaceutical Co, Tokyo, Japan).

Study design

Colonoscopy was performed in the lateral decubitus position. A butterfly needle for the bolus injection of propofol was placed on the patient's forearm shortly before the start of colonoscopy and was removed after completion of the procedure. Propofol was given by bolus injection with an age-adjusted standard protocol of 60 mg for patients aged < 70 years, 40 mg for patients aged 70-89 years, and 20 mg for those aged ≥ 90 years. Adequate sedation was considered achieved when the patients passed through the following sequence: eyes closing, one or two yawns, and cessation of body movements. The target level of sedation was moderate conscious sedation with the patients still being able to respond purposefully to verbal commands. When the target level was not obtained or the patients were under-sedated, additional injections of 20 mg propofol were given up to a maximum of 200 mg.

A decline in SpO₂ to < 90% that continued for > 20 s was regarded as respiratory depression associated with sedation. Vital signs were frequently assessed but not on a periodic basis. In addition to monitoring of vital signs, the patient's condition was assessed more globally by visual inspection. Monitoring and complications were recorded by a registered nurse. SpO₂ was routinely captured by visual inspection of the monitor and the value was recorded on the vital sign sheet.

After the procedure, patients were moved to a waiting room after they could stand by themselves and they were discharged after they were fully awake. Full recovery, including consciousness and psychomotor function was assessed using three criteria: (1) Level of consciousness (fully awake and responding to questions from the recov-

Values are numbers (percentages) of patients except for mean age, mean body weight, and mean procedure time.

ery room nurse); (2) Ability to stand on one-foot; and (3) Ability to walk in a straight line without instability for 5 m. These three criteria were assessed every 15 min starting 30 min after the procedure; full recovery was defined as meeting all three criteria. The nurses reconfirmed the absence of re-emerging sedative effects and finally permitted patients to leave the endoscopic unit.

In addition, we provided questionnaires. Within 2 wk after the procedure, patients were contacted by telephone and asked about overall satisfaction for this procedure, whether they drove home or to their office after colonoscopy, the occurrence of any accidents within 24 h after colonoscopy and their willingness to repeat the same procedure next time (yes/no).

Study parameters

The principal parameters were the occurrence of adverse events within 24 h after colonoscopy and overall satisfaction for the procedure. Secondary parameters included successful procedure, respiratory depression, and other complications. Respiratory depression was defined as the need of oxygen supply due to an oxygen desaturation ($SpO_2 < 90\%$) that continued more than 20 s.

Instruments

The Olympus PCF-Q260AI videoscope used has an insertion diameter of 11.3 mm, an accessory channel diameter of 2.8 mm, a total length of 1335 mm, and a working length of 1030 mm.

Table 2 Relationship between age or sex and dose of propofol used in 2101 patients who underwent colonoscopy

Age (yr)	No. (M/F)	Propofol dose (mg)			<i>P</i> value
		Total (range)	Male	Female	
20-40 ¹	150 (89/61)	115.3 ± 32 (40-200)	113.4 ± 27	118.2 ± 24	0.43
41-60	563 (316/247)	107.7 ± 27 (40-200)	106.9 ± 28	108.7 ± 25	0.19
≥ 61	1388 (744/644)	89.7 ± 21 (40-200)	87.7 ± 23	92.1 ± 19	0.32
Total	2101 (1149/952)	96.4 ± 27	95.0 ± 26	98.1 ± 25	0.18

Values are mean ± SD except for number of patients and range of dose used of propofol. *P* value shows the difference between male and female patients. ¹There were significant differences in the doses of propofol in each group between age 20-40 and ≥ 61 years ($P < 0.001$).

Statistical analysis

Data are presented as mean ± SD. The χ^2 test, with Yates' correction for continuity where appropriate, was used for comparison of categorical data. Fisher's exact test was used when the numbers were small. For parametric data, Student's *t* test was used when two means were compared. Analysis of variance was used when the three groups were compared and positive results were confirmed using Tukey's Honestly Significantly Different procedure. A value of $P < 0.05$ was regarded as significant. Statistical analysis was performed by using JMP[®] 9.0.2 version software (SAS Institute Inc., Cary, NC, United States).

RESULTS

Between January 2010 and December 2010, 2101 consecutive patients received outpatient colonoscopy based on a standard protocol of age-adjusted doses of propofol (Table 1). All procedures were completed successfully. The patients' ages ranged from 20 to 94 years. The most common indications for colonoscopy were: colorectal cancer screening in 785 (37%), hemopositive stools in 538 (26%), and abdominal symptoms in 406 (19%). Mean procedure time was 14 min (range, 8-46 min). A biopsy and/or polypectomy was performed in 775 patients (37%). Oxygen desaturation requiring supplemental oxygen (1-3 L/min) occurred in 0.2% (five patients); mask ventilation or endotracheal intubation was not required in any case. In no case did respiratory event or laryngospasm occur. No other complications occurred (Table 1). Full recovery within 60 min after the procedure was present in 100%.

The mean dose of propofol used was 96.4 mg (Table 2). There were no significant differences in the dose of propofol used between men and women (95.0 ± 26 mg *vs* 98.1 ± 25 mg, $P = 0.18$), however younger patients required higher doses of propofol than older patients (20-40 years *vs* ≥ 61 years, 115.3 ± 32 mg *vs* 89.7 ± 21 mg, $P < 0.001$). Of the 2101 patients, 495 (24%) had at least an adenoma detected. Fifty-two (3%) had invasive colorectal cancer. Colorectal adenomas with high-grade dysplasia were found in 32 (2%) patients. The detection rate of adenoma in this study was 53 adenomas/100

colonoscopies. Adenomas were distributed evenly in the colon and rectum.

The questionnaires were completed by 1820 (87%) of 2101 patients (Table 3). Their mean age and mean body weight were 65 years and 58.7 kg. The majority rated their overall satisfaction for this procedure as excellent (80%) or good (17%). The majority (65%) of subjects drove home or to their office after their colonoscopy. No associated incidents within 24 h after colonoscopy occurred. Most (99%) were willing to repeat the same procedure.

DISCUSSION

This study describes the safety and outcomes of propofol sedation given to 2101 patients for outpatient colonoscopy. Previous studies have involved propofol dosages ranging from 60 to 300 mg using an indwelling catheter for endoscopic sedation^[9-12,17-21]. In the present study, the mean dose of propofol used was 96.4 mg, which corresponded to that of a previous study in the Japanese population^[17]. On the basis of our previous experiences^[13,14], the protocol adopted here focused on safety with the initial dose of 40 or 60 mg propofol designed to minimize hypoxemia during the procedure; only 0.2% required oxygen, which is less than previous studies^[9-12]. No subject required mechanical ventilation during the procedures via either endotracheal intubation or a mask (Table 1). The routine use of supplemental oxygen during colonoscopy may mask respiratory depression^[22], therefore, we chose to administer supplemental oxygen only when needed. No subjects experienced bradycardia (heart rate < 50 beats/min). Other studies with low-dose propofol have reported rates of bradycardia up to 10%^[23]; the differences may relate to difference in the sedation method because studies with bradycardia have typically used a combination of propofol, midazolam

and meperidine. All procedures were done with pediatric variable stiffness colonoscope, thus, it is impossible to assess whether the pediatric variable stiffness colonoscope, or the lower dose of propofol required, was responsible for the low incidence of cardiopulmonary depression.

Generally, patients are not permitted to drive themselves within the first day after endoscopic sedation. Riphaut *et al.*^[24] have reported that current recommendations that patients should be refrain from driving and unescorted use of public transport for 24 h after sedation may need to be reconsidered in patients who receive propofol sedation. Based on our previous study using a driving simulator showing that driving ability recovered to the basal level within 60 min of low-dose propofol sedation^[13], patients have been permitted to drive themselves after colonoscopy as well as esophagogastroduodenoscopy at our endoscopy unit. In this study, the majority (65%) of patients drove home or to their office after their colonoscopy. No sedation-associated incidents within 24 h after colonoscopy occurred in the 1820 subjects responding.

Our recent study used a number connection test and a driving simulator test to assess psychomotor recovery before and 1 h and 2 h after colonoscopy^[25]. Psychomotor recovery was evident as early as 1 h after propofol sedation. Additional studies are needed before it can be routinely recommended that patients be permitted to drive home after endoscopy using only propofol sedation. Effective endoscopic sedation depends on the type of procedure and the procedure time. In most patients, an appropriate level of sedation can be reached through the use of a benzodiazepine combined with a narcotic. In contrast, we gave propofol by bolus titration with an initial dose of 40-60 mg followed by dose of 20 mg beginning 30-60 s later. The appropriateness of additional bolus doses was determined by the level of sedation and the respiratory effect. When moderate conscious sedation was not obtained or the patients were undersedated, additional injections of 20 mg propofol were given up to a maximum of 200 mg; 180-200 mg were required in only 25 patients (1.2%). The advantages of propofol using a butterfly needle include immediate onset of action and fast recovery, which likely contributed to the high level of acceptability and cost-effectiveness for outpatient colonoscopy. In our facility, a butterfly needle has been used instead of an indwelling cannula for about 60 000 patients. Even if a patient in conscious sedation moves his/her arm, the butterfly needle is usually placed stably in the vein. This butterfly needle method is thought to be a safe and practical way to administer propofol over 15-30 min.

The average procedure time was 14 min and the detection rate of adenoma was 24% as the proportion of patients in whom at least one adenoma was identified in this study. The adenoma detection rate that was reported to be an independent predictor of the risk of interval colorectal cancer after screening colonoscopy was compatible to our

data^[26]. Therefore, this sedation method is likely an important variable in ensuring quality in colonoscopy.

Unsedated colonoscopy is still the main type of procedure in many countries. Even if sedation is safe, it requires an extra nurse and a team educated for monitoring, resulting in higher costs. The requirement for an escort and time burden of recovery from sedation are both barriers to the acceptance of screening colonoscopy. Improved acceptance of colonoscopy is important to allow full use of colonoscopy in cancer screening and prevention. Colonoscopy can be completed without sedation in the majority of patients and undoubtedly there is a place for unsedated colonoscopy, especially in areas where cost containment is a primary concern^[27-29].

This study had some limitations. The sedation level was assessed using minimal, moderate, and deep sedation on the basis of the ASA level^[30], but this was not recorded for each patient during the study. Although the patients may have had amnesia after propofol sedation, the questionnaire in this study did not include any questions related to amnesia. Blood pressure monitoring was not routinely performed in this study. Blood pressure monitoring is generally a standard practice whenever administering propofol in the United States but not in Japan. We were therefore unable to comment on episodes of hypotension in our series. The monitoring used (e.g., continuous assessment of SpO₂ and heart rate) is the standard in Japan.

In conclusion, propofol sedation was associated with good acceptance of colonoscopy and willingness to repeat the procedure and enabled patients to drive home safely by themselves after colonoscopy. Propofol sedation using a dose < 200 mg was safe and practical. Increased use of this sedation method may improve the acceptability of colonoscopy, which may enable population wide screening and decrease colorectal cancer mortality.

COMMENTS

Background

Despite the increasing usage of short-acting sedatives, the recommendations that patients should refrain from driving and the unescorted use of public transport for 24 h after sedation remain unchanged. The authors previously reported that recovery after low-dose propofol sedation for diagnostic esophagogastroduodenoscopy was such that the patients were able to drive home. In addition, the recent study using a number connection test and a driving simulator test demonstrated that psychomotor recovery was evident as early as 1 h after propofol sedation for outpatient colonoscopy.

Research frontiers

The authors report a prospective evaluation of the safety and effectiveness of propofol sedation with follow-up for 24 h after outpatient colonoscopy.

Innovations and breakthroughs

Propofol sedation was associated with good acceptance of colonoscopy and willingness to repeat the procedure and enabled patients to drive home safely by themselves after colonoscopy. Propofol sedation using a dose < 200 mg was safe and practical. Increased use of this sedation method may improve the

acceptability of colonoscopy, which may enable population-wide screening and decrease colorectal cancer mortality.

Applications

The findings in this study indicate that patients sedated with propofol may be capable of safely driving 1 h after colonoscopy. The ability to drive home after sedation reduces the need for an accompanying individual and thus lowers the costs and burden associated with endoscopy.

Peer review

This is a well-written paper providing new data on safety of propofol sedation and new information about patients checking out and driving home after propofol sedation.

Abstract

AIM: To investigate the efficacy of hepatic arterial infusion chemotherapy (HAIC) using floxuridine (FUDR) in patients with advanced hepatocellular carcinoma (HCC) confined to the liver.

METHODS: Thirty-four patients who had advanced HCC with unresectability or unsuccessful previous therapy in the absence of extrahepatic metastasis were treated with intra-arterial FUDR chemotherapy at our

hospital between March 2005 and May 2008. Among the 34 patients, 9 patients were classified as Child class C, and 18 patients had portal vein tumor thrombus (PVTT). One course of chemotherapy consisted of continuous infusion of FUDR (0.3 mg/kg during day 1-14) and dexamethasone (10 mg on day 1, 4, 7 and 11), and this treatment was repeated every 28 d.

RESULTS: Two patients (5.9%) displayed a complete response, and 12 patients (35.3%) had a partial response. The tumor control rate was 61.8%. The median overall survival times were 15.3 mo, 12.4 mo and 4.3 mo for the patients who were classified as Child class A, Child class B and Child class C, respectively ($P = 0.0392$). The progression-free survival was 12.9 mo, 7.7 mo and 2.6 mo for the patients who were classified as Child class A, Child class B and Child class C, respectively ($P = 0.0443$). The cumulative survival differed significantly according to the Child-Pugh classification and the presence of PVTT. In addition to hepatic reserve capacity and PVTT, the extent of HCC was an independent factor in determining a poor prognosis. The most common adverse reactions to HAIC were mucositis, diarrhea and peptic ulcer disease, but most of these complications were improved by medical treatment and/or a delay of HAIC.

CONCLUSION: The present study demonstrates that intra-arterial FUDR chemotherapy is a safe and effective treatment for advanced HCC that is recalcitrant to other therapeutic modalities, even in patients with advanced cirrhosis.

Efficacy of hepatic arterial infusion chemotherapy in advanced hepatocellular carcinoma. *World J Gastroenterol* 2012; 18(26): 3426-3434 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i26/3426.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i26.3426>

INTRODUCTION

Hepatocellular carcinoma (HCC), which is one of the most common malignancies worldwide, causes over 600 000 deaths per year and is the third most common cancer in South Korea^[1,2]. Although surgical resection or liver transplantation can be curative for HCC, most patients are not candidates for surgery at the time of diagnosis because it is difficult to detect HCC at an early stage. In addition, some patients have advanced cirrhosis by the time of diagnosis^[3].

Although recent advances in therapeutic modalities, such as hepatic resection, percutaneous ethanol injection, radiofrequency ablation (RFA), transarterial chemoembolization (TACE), radiotherapy and liver transplantation, have improved the treatment of HCC, the prognosis for patients with advanced HCC remains poor. In addition, these current therapies have many limitations, and recurrence and metastasis are relatively common^[4-7]. Among the currently available therapies, TACE is the current standard of care for patients who are not candidates for curative therapy. The survival benefit conferred by TACE was reported in a randomized controlled trial^[8], which showed that the median survival of the patients in the TACE group was approximately 14 mo. However, TACE is contraindicated in advanced HCC with main portal vein tumor thrombus (PVTT), massive or diffuse infiltration, poor liver function with Child class C, and severe hepatic arterioportal shunt.

Regional hepatic arterial infusion chemotherapy (HAIC) has also been used in patients with advanced HCC because liver cancers receive most of their blood supply from the hepatic artery, whereas normal liver tissue has a dual vascular supply (i.e., 20% of the blood supply comes from the hepatic artery, and the remaining 80% comes from the portal vein). Thus, HAIC may be used, albeit with caution, in cases in which TACE is not indicated or is ineffective^[9]. HAIC may provide higher concentrations of chemotherapeutic agents directly to the HCC and produces minimal systemic concentrations of chemotherapeutic agents, which can minimize systemic toxicity^[10].

Floxuridine (FUDR) is an active metabolite of 5-fluorouracil (5-FU) that has the advantage of being rapidly metabolized, with a 94%-99% extraction rate within the liver *via* first-pass metabolism. FUDR is maintained at an intrahepatic concentration that is more than tenfold

greater than that of 5-FU, cisplatin, mitomycin or doxorubicin, which permits maximal tumor cell death while preventing systemic toxicity^[11,12].

Most previous studies have reported the efficacy of HAIC using 5-FU and cisplatin in advanced HCC or HAIC using FUDR in patients with hepatic metastasis from colorectal cancer^[10,13,14].

In the present study, we evaluated the efficacy and toxicity profile of HAIC using FUDR in patients with advanced HCC confined to the liver who failed to respond to previous therapy or who were unable to receive other therapeutic modalities.

MATERIALS AND METHODS

Patient eligibility

Thirty-four patients with advanced HCC that was unresectable or resistant to previous therapy in the absence of extrahepatic metastasis were treated with intra-arterial FUDR chemotherapy at our hospital between March 2005 and May 2008. The criteria for unresectability included bilobar disease with 4 or more lesions, large tumors occupying more than 50% of the liver, and invasion of the tumor into major vascular structures. Previous therapies included RFA, TACE and radiotherapy. All of the patients belonged to tumor node metastasis stage IIIA or IIIB. To assess the eligibility for inclusion, each patient received a computed tomography (CT) scan of the abdomen and pelvis. Each patient provided a full medical history and underwent a physical examination, chest X-ray, and laboratory tests, including a test for alpha-fetoprotein. Additional examinations, such as magnetic resonance imaging (MRI) scans, liver biopsy and angiography, were performed if the CT scan and tumor marker analyses were insufficient for diagnosis. Among the 34 patients, disease was histologically confirmed in 5 patients. When metastasis was suspected, positron emission tomography scans and bone scans and/or CT scans of suspicious areas were conducted. Patients with distant metastases were excluded. Informed consent was obtained from all of the patients.

A pump catheter was inserted at the proper hepatic artery from the superior mesenteric artery. The distal gastroduodenal artery, the right gastric artery, the small branches supplying the stomach or duodenum, and all of the accessory hepatic arteries received ligations to prevent gastrointestinal toxicity. The patients with hepatitis B received prophylactic or therapeutic antiviral agents before HAIC. Some of the patients with hepatitis C had previously been treated with pegylated-interferon/interferon and ribavirin. The remaining hepatitis C patients were carefully monitored because antiviral treatment was deferred because of underlying bone marrow and immune suppression complications.

Assessment of responses

The patient responses were classified according to the Response Evaluation Criteria In Solid Tumors guidelines.

Table 1 Baseline characteristics *n* (%)

Characteristics	IA-FUDR (<i>n</i> = 34)
Age (yr)	62.2 ± 7.4
Sex	
Male	27 (79.4)

HCC: Hepatocellular carcinoma; AFP: Alpha-fetoprotein; RFA: Radio-frequency ablation; TACE: Transarterial chemoembolization; IA-FUDR: Intra-arterial floxuridine; INR: International normalized ratio.

Complete response (CR) was defined as the disappearance of all evidence of disease and the normalization of tumor markers for at least 4 wk. Partial response (PR) was defined as a $\geq 30\%$ reduction in unidimensional tumor measurements without the appearance of any new lesions or the progression of any existing lesion. Progressive disease (PD) was defined as any of the following: a 20% increase in the sum of the diameters of five measurable lesions, the appearance of any new lesions, or the reappearance of any lesion that had previously disappeared. Stable disease (SD) was defined as a tumor response that did not fulfill the criteria for CR, PR or PD. CT scans or MRIs of the measurable lesions were carried out within 4 wk before the start of treatment and repeated every 2 cycles (2 mo). Responses were confirmed by subsequent CT or MRI scans after the documentation of the initial response.

Toxicity assessment

Toxicity was assessed according to the National Cancer Institute Common Toxicity Criteria. The FUDR dose was modified when grade 3-4 toxicity was observed.

Hepatic toxicity was defined as a significant increase over baseline values (3- to 4-fold for aspartate transaminase or alanine transaminase and greater than 1.5-fold for bilirubin), and the increases in hepatic enzyme levels

caused by the disease varied across patients. If a patient complained of epigastric pain, an evaluation that included an upper gastrointestinal endoscopy was performed. If an ulcer or gastroduodenitis was identified, then chemotherapy was stopped until recovery. If a patient had severe diarrhea or abdominal pain, chemotherapy was stopped until recovery. In addition, angiography was performed to block collateral vessels when extrahepatic perfusion was suspected.

Chemotherapy regimen

Local chemotherapy was started between 3 and 5 d after pump insertion. The patients received FUDR (0.3 mg/kg per day for 14 d) and dexamethasone (10 mg on day 1, 4, 7 and 11) *via* an intra-arterial pump. FUDR was synthesized by APP Pharmaceuticals, LLC (Schaumburg, IL, United states). After the 14 d of treatment with FUDR, the pump was emptied and refilled with 30 000 units of heparin in 0.9% saline for 14 d. This treatment was repeated every 28 d. FUDR was given indefinitely until the disease progressed or the therapy was discontinued due to toxicity or patient death.

Statistical analysis

The objective of the present study was to estimate the efficacy and toxicity of continuous HAIC with FUDR *via* an implantable pump. All of the analysis were performed using SPSS version 18.0.

Survival times were calculated from the start of the study treatment until patient death or the final follow-up. Progression-free survival (PFS) was calculated from the first day of chemotherapy until the date of progression. PFS and overall survival (OS) curves were obtained using the Kaplan-Meier method, and comparisons were made using the log rank test. Multivariate analysis to evaluate the influence of prognostic factors on survival was performed using Cox proportional hazard methods. Statistical significance was established as $P < 0.05$.

RESULTS

Patient characteristics

A total of 34 patients, 27 men and 7 women, with a median age of 62.2 years received intra-arterial FUDR chemotherapy between March 2005 and May 2008. The patient baseline characteristics are shown in Table 1. The major etiology of the patients' liver disease was hepatitis B virus (27 of 34, 79.4%). Eighteen patients had PVTT, whereas 16 patients did not have PVTT. The majority of patients had received TACE as the previous therapeutic modality (20 of 34, 58.8%).

Response to treatment

Patients received 2-10 (the median was 3.5) cycles of chemotherapy. All of the patients received at least 2 cycles of intra-arterial FUDR chemotherapy, and 17 (50%) patients received more than 4 cycles.

The patients' responses to treatment are summarized

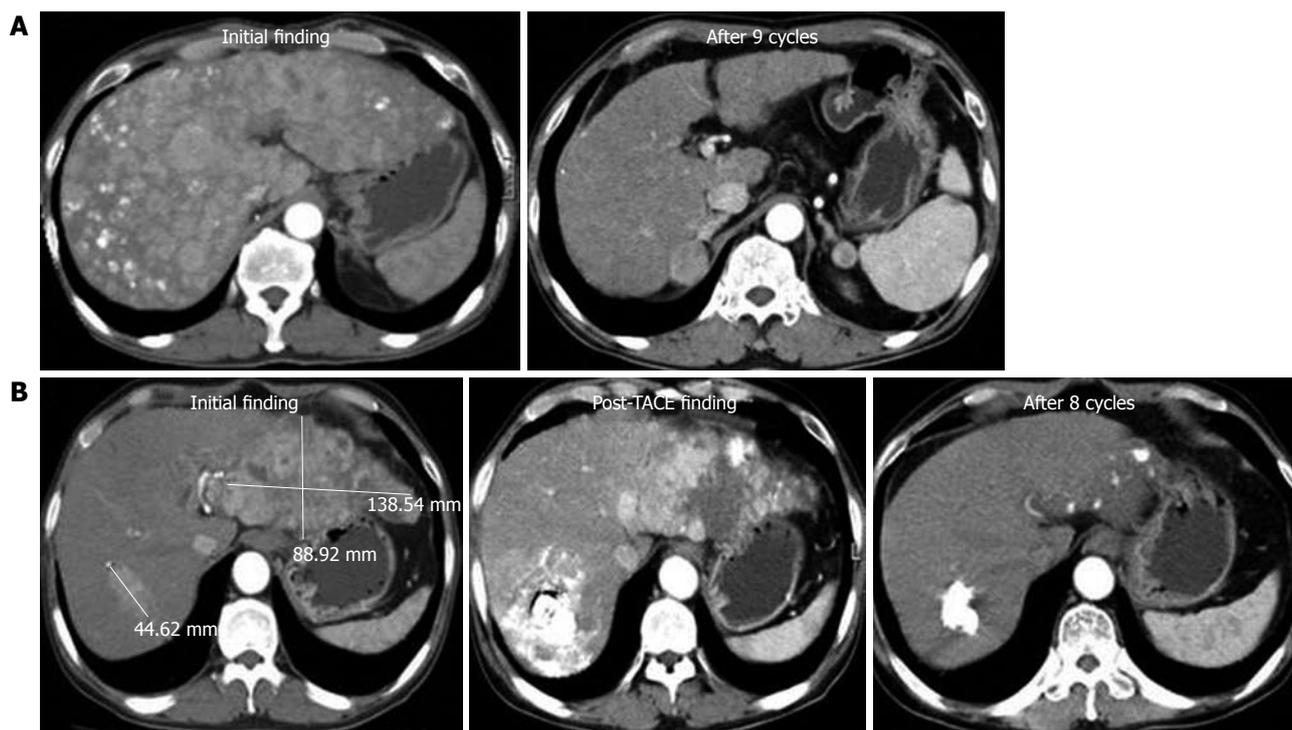

Figure 1 Two cases of nearly complete response. A: The first case was a 54-year-old patient with diffuse, multinodular hepatocellular carcinoma throughout the whole liver. After 9 cycles of hepatic arterial infusion chemotherapy (HAIC) with floxuridine, no enhancing nodular lesions were observed by dynamic contrast-enhanced computed tomography (CT); B: The second case was a 48-year-old patient with a large mass in the left lobe and intrahepatic metastasis in the right lobe. After transarterial chemoembolization treatment, viable masses were still observed in sequential CT images, and HAIC was started. After 8 cycles of chemotherapy, no viable masses were observed. TACE: Transarterial chemo-embolisation.

in Table 2. Two patients (5.9%) had CR, 12 (35.3%) had PR, seven (20.6%) had SD, and 13 (38.2%) had PD. The CT findings for the two patients with CR (Figure 1). Among the patients who were classified as Child class A or B, 2 (8%) had CR and 11 (44%) had PR. The patients who were classified as Child class A or B had a response rate of 52% and a disease control rate of 72%.

Survival

The cumulative survival of the 34 patients is presented in Figure 2A and B. The median OS was 8.9 mo, and the median PFS was 6.6 mo.

We assessed the cumulative survival according to the Child-Pugh classification and the presence of PVTT

(Figure 3). The median OS times were 15.3 mo, 12.4 mo and 4.3 mo in the patients who were classified as Child class A, Child class B and Child class C, respectively, and there were significant differences between the groups ($P = 0.0392$). Similarly, there were significant differences in the median PFS times, which were 12.9 mo, 7.7 mo and 2.6 mo in the patients who were classified as Child class A, Child class B and Child class C, respectively ($P = 0.0443$) (Figure 3A and B). These findings showed that the patients who were classified as Child class C had significantly shorter survival times compared with the patients who were classified as Child class A or Child class B.

Further differences were found in the OS and PFS according to the presence of PVTT, which indicated a negative impact of PVTT on survival time. The median OS and PFS of the patients without PVTT were 13.1 mo and 8.2 mo, respectively, compared with 8.2 mo and 3.4 mo, respectively, for the patients with PVTT (Figure 3C and D).

Prognostic factors

We conducted univariate and multivariate analyses of baseline characteristics, such as age, sex, Child-Pugh classification, PVTT, extent of HCC, bilirubin, albumin and PT international normalized ratio (INR), using a Cox proportional hazards model to evaluate the prognostic factors for survival (Table 3). The multivariate analysis showed that 4 variables (i.e., child classification, PVTT, HCC type and PT INR) were independent predictors of survival.

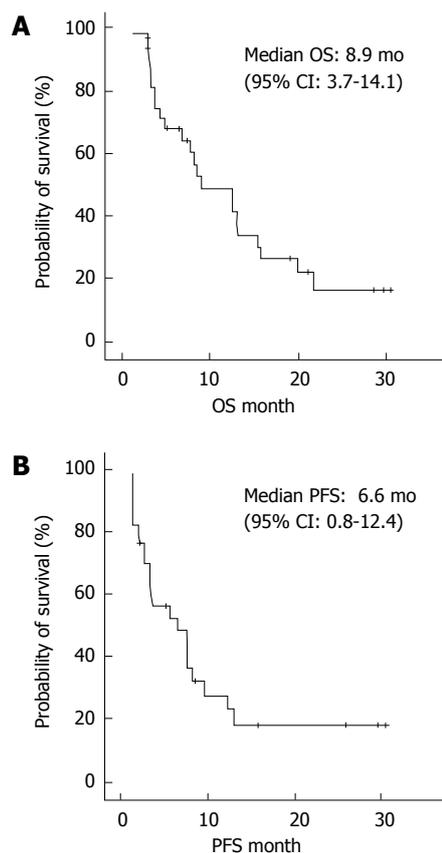

Figure 2 The overall survival and the progression-free survival determined by Kaplan-Meier analysis. A: The overall survival (OS) determined by Kaplan-Meier analysis; B: The progression-free survival (PFS) determined by Kaplan-Meier analysis.

Adverse reactions and complications

The treatment-related adverse reactions and complications that were observed in the 34 patients who were treated with HAIC (Table 4). Severe hematologic toxicity during HAIC was not noted in any of the patients. The most common grade 3-4 adverse reaction was gastric or duodenal ulcer (11.8%). Most of the adverse reactions were improved by medical treatment and/or delaying HAIC. One patient with hepatitis C experienced progressive hepatic failure during the third cycle of chemotherapy and eventually died. In addition, a major complication related to the indwelling catheter occurred in 1 patient. Indeed, an infection occurred around the catheter, but it was controlled by antibiotics and removal of the port. This patient continued HAIC after insertion of another catheter in the opposite site. Another major complication that has commonly been reported to be associated with FUDR treatment is biliary sclerosis; however, the patients in the present study received prophylactic dexamethasone on a regular schedule, and none of the present patients experienced biliary sclerosis.

Cause of death

During treatment and follow-up, 9 patients died from various causes, including tumor progression, hepatic failure, gastrointestinal bleeding and sepsis. Among the

Table 3 Prognostic significance of the clinical factors influencing survival

patients who died, 4 (44.4%) died of hepatic failure related to an advanced cirrhotic condition. Only 1 of the 4 patients had hepatic failure in relation to therapy, and the remaining patients died after loss to follow-up or the incidence of another illness. Tumor progression and sepsis were the causes of death in 2 patients each (22.2%). One patient died of upper varix bleeding.

DISCUSSION

Many therapeutic modalities are available for the treatment of HCC, such as hepatic resection, percutaneous ethanol injection, RFA, TACE, radiotherapy and liver transplantation^[15]. Among these therapies, TACE has been the main treatment modality for the management of unresectable or recurrent HCC. A randomized controlled trial revealed that the median survival for patients undergoing TACE was approximately 14 mo^[8]. However, this treatment has not been useful in patients with PVTT or large infiltrative HCC because of the potential risk of hepatic failure resulting from ischemia^[16,17].

HAIC can be safely used in patients with impaired liver function due to advanced HCC or underlying liver

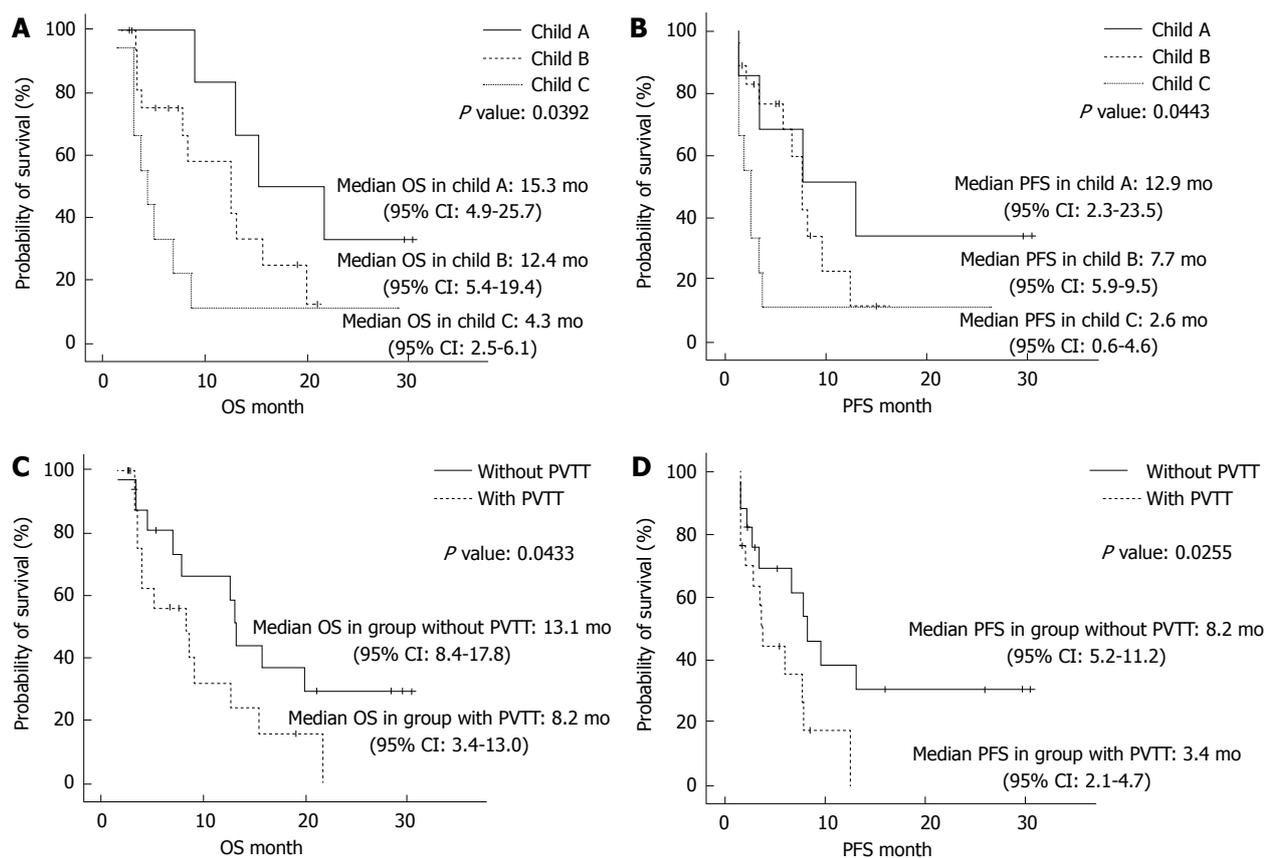

Figure 3 Kaplan Meier plot estimates of the overall survival and the progression-free survival according to the Child-Pugh classification and existence of portal vein tumor thrombus. A: Kaplan Meier plot estimates of the overall survival (OS) to the Child-Pugh classification; B: Kaplan Meier plot estimates of the progression-free survival (PFS) according to the Child-Pugh classification; C: Kaplan Meier plot estimates of the OS according to existence of portal vein tumor thrombus (PVTT); D: Kaplan Meier plot estimates of the PFS according to existence of PVTT.

cirrhosis because hepatic arterial blocking agents, such as lipiodol or gelatin sponges, are not used in HAIC^[18]. Thus, HAIC is not limited by tumor size, number, and/or proximity to major vasculature, all of which are common contraindications to resection and/or ablation. In addition, HAIC has several other advantages. For example, in most cases, there is no need for the administration of antiemetics or exogenous hydration, which can cause ascites or peripheral edema. Moreover, the higher first-pass hepatic extraction of infused drugs produces elevated local concentrations with lower systemic exposure, which results in fewer side effects than systemic chemotherapy^[10].

HAIC using 5-FU with cisplatin has been extensively studied as a treatment for advanced HCC^[19,19,20]. However, the pharmacokinetics of 5-FU are not linear over a hepatic extraction gradient of 19%-90%, and there are decreases in both systemic clearance and hepatic extraction at higher doses, which reduce the selective regional advantage^[21].

Intra-arterial FUDR, which is a metabolite of fluorouracil, is preferable because it is associated with an increased response rate due to its higher hepatic extraction (> 95%) and an intrahepatic concentration that is more than tenfold greater than that of 5-FU, cisplatin, mitomycin or doxorubicin^[11,12]. Therefore, FUDR is

associated with decreased toxicity and improved survival through maximal tumor cell death. Despite these advantages, regional chemotherapy using FUDR *via* an implantable pump has rarely been studied in HCC, although it has been studied extensively in patients with liver metastasis from colorectal cancers^[14,22-24]. Therefore, we hypothesized that the study of HAIC using FUDR in patients with advanced HCC could yield significant results.

In general, the prognosis is poor for patients with advanced HCC. Many studies have reported a median survival of 3-6 mo for unresectable and untreated HCC^[25]. Recently, a multinational phase III, randomized, double-blind, placebo controlled trial was conducted to assess the efficacy and safety of new therapeutic options in a group of Asian-Pacific patients with advanced HCC^[26]. The controlled trial reported a median OS and PFS of 4.2 mo and 1.4 mo, respectively, in the patients without treatment. Interestingly, most of the patients were classified as Child class A (Child class A: 220 and Child class B: 6). Many studies of HAIC have reported good results compared with those of untreated cases^[27,28]. In the present study, the response rate and the median survival time of the 34 patients who were treated with intra-arterial FUDR were 41.2% and 8.9 mo, respectively. Despite the inclusion of patients who were classified as Child class

C, the present outcomes are similar or better than those observed in other studies.

Studies have clearly shown that survival times are longer in patients with a good functional hepatic reserve. Many studies have shown that a patient's Child-Pugh status significantly influences survival, which is consistent with the present results^[29,30]. The OS times of the patients who were classified as Child class A, B and C were 15.3 mo, 12.4 mo and 4.3 mo, respectively. Similarly, the PFS times of the patients who were classified as Child class A, B and C were 12.9 mo, 7.7 mo and 2.6 mo, respectively. Most other studies excluded patients who were classified as Child class C because early reports demonstrated poor outcomes in these patients and no differences in survival between treated and untreated groups^[29]. The present study included patients who were classified as Child class C if they demonstrated a desire to receive therapy and had a relatively good performance status. The nine patients in the present study who were classified as Child class C had similar or slightly better outcomes compared with untreated patients. Interestingly, only 1 of the Child class C patients suffered from a serious adverse event (i.e., hepatic failure). Compared with other studies, the present study also showed relatively good results in the patients who were classified as Child class B.

Like the Child-Pugh classification, PVTT is a major independent factor in the determination of a poor prognosis in patients with advanced HCC^[30]. The median survival of untreated HCC with PVTT was reported to be 2.7 mo^[31]. One study reported a median survival time of 6 mo in patients with advanced HCC with PVTT (excluding Child class C patients) who received HAIC with 5-FU and cisplatin along with systemic chemotherapy^[32]. In the present study, the median OS in the groups with and without PVTT were 8.2 mo and 13.1 mo, respectively, and this difference was significant. In addition, the difference in the median OS times in the groups with and without PVTT also demonstrated the relatively good outcomes that were observed in the present study compared with those of other studies (despite the inclusion of Child class C patients with PVTT). The present study showed that the presence of PVTT, the extent of HCC, and hepatic function (as assessed by the Child classification) were major predictors of survival. Indeed, the present study demonstrated the significance of these factors using multivariate analysis.

Treatment tolerability and patient quality of life are also important when deciding therapies for advanced cancers. Only 1 of the 34 patients in the present study (2.9%) experienced progressive impaired hepatic function that justified the withdrawal of FUDR, and the majority of the patients demonstrated a relatively sustained quality of life during the HAIC.

Several studies have reported the outcomes of HAIC using FUDR in advanced HCC. One study investigated the efficacy of HAIC using FUDR for 5 patients with HCC and reported a response rate of 80% and a 1-year survival rate of 100%^[22]. In 2009, Jarnagin *et al.*^[33] report-

ed that HAIC with FUDR therapy could be effective and safe in patients with unresectable primary liver cancer. They reported a response rate of 25% and a tumor control rate of 62.5%. These two studies demonstrated positive results of HAIC with FUDR for HCC; however, they only included 5 and 8 patients, respectively. Compared with these two reports, the present study was significant in that it included more patients and demonstrated the efficacy and safety of HAIC with FUDR even in patients with advanced HCC.

Sorafenib was the first systemic agent to be approved for the treatment of advanced HCC. Both the Study of Heart and Renal Protection trial, which was conducted in Europe and North America, and an Asia-Pacific trial showed that sorafenib prolonged the time to progression by 1.4-2.7 mo and prolonged the OS by 2-3 mo^[26,34]. In the present study, the outcomes of HAIC with FUDR were superior to treatment with sorafenib. In addition, there are limitations to sorafenib therapy, namely its decreased efficacy over time (i.e., disease-stabilization for only a few months) and potential side effects. Moreover, the safety and efficacy of sorafenib in patients who are classified as having Child class B or C cirrhosis remain unclear. Many factors could eventually limit the potential advantages of anti-angiogenic sorafenib effects. Several mechanisms of resistance to vascular endothelial growth factor signaling-targeted therapy have been proposed, and other pre-existing or distinct oncogenic signaling pathways may begin to drive tumor growth during therapy^[35]. Recently, approaches to overcome resistance to anti-angiogenic sorafenib therapy in advanced HCC are being pursued. One of these approaches is the combination of anti-angiogenic therapy and metronomic chemotherapy to induce durable tumor shrinkage or disease stabilization in refractory cancer^[36,37]. Therefore, the combination of sorafenib and HAIC with FUDR may be a promising therapeutic approach for advanced HCC.

The present study has several limitations. For example, high doses of FUDR in HAIC can produce toxicity, which results in a fibrotic narrowing of the bile ducts that is similar to primary biliary sclerosis (up to 30% of patients)^[38]. The use of regional dexamethasone with FUDR, however, can reduce hepatic toxicity. In some studies, the biliary sclerosis rate was 3% or lower, and the patient response rate and survival also improved with the addition of dexamethasone^[39]. None of the patients in the present study had biliary sclerosis, which was likely due to the inclusion of dexamethasone in our treatment protocol.

Another limitation of the present study was that FUDR had to be administered for 14 d with continuous infusion, which might have been associated with poor patient compliance. Hepatic drug uptake and metabolic capacity can be saturated at high drug delivery rates^[40]. Therefore, continuous hepatic arterial infusion is regarded as the most effective means of delivery to maximize the regional advantage. In the present study, all but one patient continued therapy and showed relatively good compliance.

The final limitation of the present study was that we did not use a randomized design (i.e., HAIC was not compared with other therapeutic modalities). However, the present study was the first formal attempt to test HAIC using FUDR in patients with advanced HCC, including patients with advanced cirrhosis. Importantly, the present study demonstrated that survival was better in patients who received HAIC with FUDR compared with patients with unresectable tumors or in whom other therapeutic modalities had been used unsuccessfully.

In conclusion, the present study shows that intra-arterial FUDR chemotherapy is safe and effective for patients with severely advanced HCC confined to the liver for which other therapeutic modalities are ineffective, even in patients with advanced cirrhosis. Based on these results, additional large prospective randomized clinical trials should be performed to prove the efficacy and safety of HAIC using FUDR. Eventually, HAIC using FUDR could be widely applied for the treatment of advanced HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide. Despite recent advances in therapeutic modalities, the prognosis of advanced HCC remains poor. The current therapies have many limitations, and recurrence or metastasis is relatively frequent. Regional hepatic arterial infusion chemotherapy (HAIC) has been used in patients with advanced HCC. HAIC is believed to provide higher concentrations of chemotherapeutic agents directly to the HCC, which would minimize systemic concentrations of chemotherapeutic agents and potentially minimize systemic toxicity. However, previous studies of HAIC in HCC have shown various results.

Research frontiers

Floxuridine (FUDR) is an active metabolite of 5-fluorouracil (5-FU) that has the advantage of being rapidly metabolized (i.e., a 94%-99% extraction rate within the liver). Furthermore, FUDR is maintained at an exceptionally high intrahepatic concentration (i.e., more than tenfold greater than 5-FU, cisplatin, mitomycin or doxorubicin), which permits maximal tumor cell death while preventing systemic toxicity. In the present study, the authors demonstrated the efficacy and safety of HAIC using FUDR in patients with advanced HCC that was confined to the liver.

Innovations and breakthroughs

Most previous studies have reported the efficacy of HAIC using 5-FU and cisplatin in advanced HCC, whereas HAIC using FUDR in advanced HCC has rarely been reported. The present paper describes the results of HAIC using FUDR in 34 patients with advanced HCC.

Applications

HAIC with FUDR can be performed in patients with advanced HCC that is unresectable or has not responded to previous therapy.

Terminology

HAIC provides chemotherapeutic agents directly to the HCC *via* a pump catheter. The pump catheter is inserted at the proper hepatic artery from the superior mesenteric artery. The distal gastroduodenal artery, right gastric artery and small branches supplying the stomach or duodenum are ligated to prevent gastrointestinal toxicity.

Peer review

The importance of the present study is that HAIC with FUDR could be a promising therapeutic approach for patients with advanced HCC.

Abstract

AIM: To survey glutathione (GSH) S-transferase (GST) isoforms in mitochondria and to reveal the isoforms' biological significance in diabetic mice.

METHODS: The presence of GSTs in mouse liver mitochondria was systematically screened by two proteomic approaches, namely, GSH affinity chromatography/two dimensional electrophoresis (2DE/MALDI TOF/TOF MS) and SDS-PAGE/LC ESI MS/MS. The proteomic results were further confirmed by Western blotting using monoclonal antibodies against GSTs. To evaluate the liver mitochondrial GSTs quantitatively, calibration curves were generated by the loading amounts of individual recombinant GST protein vs the relative intensities elicited from the Western blotting. An extensive comparison of the liver mitochondrial GSTs was conducted between normal and db/db diabetic mice.

Student's *t* test was adopted for the estimation of regression and significant difference.

RESULTS: Using GSH affinity/2DE/MALDI TOF/TOF MS, three GSTs, namely, alpha3, mu1 and pi1, were identified; whereas five GSTs, alpha3, mu1, pi1, kappa1 and zeta1, were detected in mouse liver mitochondria using SDS-PAGE/LC ESI MS/MS, of these GSTs, GST kappa1 was reported as a specific mitochondrial GST. The R^2 values of regression ranged between values of about 0.86 and 0.98, which were acceptable for the quantification. Based on the measurement of the GST abundances in liver mitochondria of normal and diabetic mice, the four GSTs, alpha3, kappa1, mu1 and zeta1, were found to be almost comparable between the two sets of animals, whereas, lower GST pi1 was detected in the diabetic mice compared with normal ones, the signal of Western blotting in control and db/db diabetic mice liver mitochondria is 134.61 ± 53.84 vs 99.74 ± 46.2 , with $P < 0.05$.

CONCLUSION: Our results indicate that GSTs exist widely in mitochondria and its abundances of mitochondrial GSTs might be tissue-dependent and disease-related.

INTRODUCTION

The glutathione (GSH) S-transferase (GST, EC2.5.1.18) superfamily contains eight subclasses classified by their properties of sequence homology, immunology, substrate specificity and isoelectric point. GSTs catalyze the reactions between reduced GSH and unsaturated aldehydes, quinines, and many other substrates, especially under conditions of oxidative stress^[1-3]. These enzymes are involved in many physiological functions, such as the reduction of free radical damage, detoxification, metabolism, regulation of cell signaling and nitric oxide storage^[2-7]. The abundance of GSTs is closely related with the disease status of the organism^[8-12]. For instance, regarding a cancer biomarker, GST pi was found in higher abundance in several cancer cells and tissues and was believed to be involved in drug resistance^[13-15]. GST alpha has main functions in detoxification in the liver, and when hepatocytes are damaged, GST alpha enters the bloodstream. Therefore, GST alpha in blood and urine is an ideal marker indicating hepatocellular impairment^[16]. The accurate measurement of GSTs in tissues or body fluids is urgently required in biomedicine.

GSTs have been identified mainly in the cytoplasm, but they have also recently been detected in organelles, including the microsome, nucleus, mitochondria and peroxisomes^[17-20]. Mitochondria are the primary intracellular sites of oxygen consumption and reactive oxygen species (ROS) generation. GST kappa1 was identified in mitochondria and peroxisomes but is absent in the cytoplasm, and GST kappa was reported to participate in energetic and lipid metabolism in the mitochondria^[21]. In contrast to the cytoplasmic GSTs, the physiological functions of the mitochondrial GSTs have yet to be explored. Generally, it is accepted that GSTs are able to protect mitochondria from dysfunctions of catalase and superoxide dismutase by maintaining the redox balance^[22-24]. A high abundance of GST pi protected the decrease of the mitochondrial membrane potential induced by rotenone. Raza group observed that under oxidative stress, GST alpha was translocated from the cytoplasm into the mitochondria, but its functions in the mitochondria were not elucidated^[23]. To understand the functions of the mitochondrial GSTs fully, we must first define how many GST isoforms exist in the mitochondria. Although there were several reports regarding the distribution of GSTs in different tissue mitochondria, a systematic investigation in this field has not been undertaken.

Recently, proteomic approaches have provided a good opportunity to survey the members of a protein family, as they usually share similar properties, such as immunofluorescence, ligand binding sites, homology sequences and catalytic substrates. Using chromatography or electrophoresis based on these properties, protein family members could be separated from one another in a mixture. Moreover, mass spectrometry is able to identify the separated proteins. Such a proteomics strategy has been widely used in exploring protein isoforms^[25-27].

In this study, we propose a proteomic strategy to

define the GSTs in mouse tissue mitochondria. With combined separation based on size exclusion and affinity chromatography, we enriched the mitochondrial GSTs from a mitochondria preparation of mouse liver. Using MALDI TOF/TOF MS or ESI MS/MS, five GSTs were identified in the mitochondria. The presence of GSTs was further verified by Western blot using monoclonal antibodies. We constructed calibration curves of the GST quantification and employed a quantitative assay of the immunoblots to estimate the different abundances of the mitochondrial GSTs between normal and diabetic mice. For the first time, we found that GSTs are widely distributed in the mitochondria of many tissues and that mitochondrial GST pi1 is sensitive to the development of diabetes.

MATERIALS AND METHODS

Preparation of mitochondria from mouse tissue

The C57BLKS/J db/db and control mice were provided by Peking University Diabetes Center. The heart, kidney and liver tissues of the mice were minced and homogenized in buffer (25 mmol sucrose, 0.5% protease inhibitor cocktail and 10 mmol HEPES, pH 7.4). The crude mitochondria were prepared by differential centrifugation at $1000 \times g$ for 30 min and at $10\,000 \times g$ for 20 min at 4 °C. The purified mitochondria were extracted from a Nycodenz gradient at the interface of 25%-30% Nycodenz solution after centrifugation at $52\,000 \times g$ for 90 min. The purity and integrity of the mitochondria were determined by Western blotting and transmission electron microscopy (TEM). Mitochondrial proteins were extracted using lysis buffer [7 mol/L urea, 2 mol/L thiourea, 4% CHAPS, 40 mmol/L Tris-HCl (pH 7.4) and protease inhibitor cocktail].

The animal experiments described in this article were approved by the Animal Care and Welfare Committee at the Beijing Institute of Genomics, Chinese Academy of Sciences.

GSH-affinity chromatography

We purified the GSTs using GSH-affinity chromatography with GSH-Sepharose 4B (Amersham Biosciences, United States). The GSH-Sepharose 4B was equilibrated with binding buffer [150 mmol/L NaCl, 50 mmol/L Tris-HCl (pH 8.0), 1 mmol/L ethylene glycol tetraacetic acid, and 0.1% Triton \times 100]. The mitochondria were re-suspended in 500 μ L binding buffer and were sonicated. After centrifugation, the supernatant was mixed with the equilibrated resin and centrifuged for 30 min 3000 r/min at 4 °C. The affinity resin was washed 3 times with binding buffer, and the proteins were eluted from the resin using 30 mmol/L reduced GSH. A sample of the elution products was retained for two-dimensional electrophoresis (2-DE) separation.

2-DE

The first dimension separation was conducted using an

Ettan IPGphor IEF system with 7 cm (pH 6-11) IPG strips at 20 °C. The proteins isolated by GSH-affinity chromatography were loaded onto strips, and the strips were rehydrated without voltage for 4 h and with 50 V for 8 h. The isoelectric focusing was programmed for 1 h at 500, 1000 and 4000 V, respectively, and was subsequently focused at 4000 V up to a total of 30 kVh. The focused strips were equilibrated in buffer with 6 mol/L urea, 50 mmol/L Tris-HCl, 30% glycerol, 2% SDS and trace bromophenol blue and were subsequently reduced by dithiothreitol and alkylated by iodoacetamide. The treated strips were inserted into a 15% SDS-PAGE gel running in 2.5 W (each gel) for 30 min and 15 W (each gel) thereafter until the bromophenol blue dye reached the bottom of the gels. The gels were stained by silver staining.

Mass spectrometry for protein identification

The proteins were identified by two mass spectrometry methods: MALDI TOF/TOF and LC ESI MS/MS.

The proteins that were separated by GSH-affinity chromatography and 2D gel electrophoresis were excised and in-gel digested with trypsin overnight and identified by MALDI TOF/TOF MS. Briefly, the tryptic digests were co-crystallized with a matrix of α -cyn-4-hydroxycinnamic acid spotted onto the AnchorChip and desalted by 0.1% trifluoroacetic acid. The AnchorChip was analyzed using an Ultraflex TOF/TOF MS mass spectrometer (Bruker Dalton, Bremen, Germany) for protein identification. Positively charged ions were analyzed in the reflector mode. Typically, 100 shots were cumulated per spectrum in the MS mode and 400 shots in the MS/MS mode. The mass spectra and tandem mass spectra obtained were processed using the FlexAnalysis 2.2 and BioTools 2.2 software tools. The protein identification was performed using the Mascot software (<http://www.matrixscience.com>), and the NCBI database was searched using mouse as the taxonomy. The following parameters were used for the database searches: one incomplete cleavage, alkylation of cysteine by carbamidomethylation, oxidation of methionine, and pyro-Glu formation of the N-terminal Gln.

The 20-30 kDa proteins separated by SDS-PAGE were a mixture of many proteins, and the proteins were examined by LC ESI MS/MS after the in-gel trypsin digestion. Briefly, after capillary reversed-phase high-performance liquid chromatography, the separated peptides were analyzed using an ion-trap mass spectrometer LCQ DecaXP ion-trap mass spectrometer (Thermo Finnigan, Ringoes, NJ) with 3.2 kV of spray voltage and 150 °C at the heated desolvation capillary. A mass-to-charge (m/z) range from 400 to 2000 was scanned over 1.2 s, and the ions were detected with a high energy conversion dynode detector. The MS/MS data were converted into DTA-format files, which were further searched for proteins with Sequest software. All of the accepted results had a deltaCn of 0.1 or greater. Furthermore, a singly charged peptide must be tryptic, and the cross-correlation score (Xcorr) had to be more than 1.9. The tryptic peptides with a charge state of

+ 2 must have a Xcorr of more than 2.2. Triply charged tryptic peptides were accepted if the Xcorr was ≥ 3.0 .

Generation of monoclonal antibodies

To generate the specific antibodies against these five GST isoforms, we cloned these five *GST* genes and expressed the recombinant protein by inserting these genes into the prokaryotic expression vector, named pET-28a. The recombinant proteins expressed from the pET-GST plasmids were 6 \times His-tagged. After expression in *E. coli* BL21 (DE3), the proteins were purified using Ni-NTA agarose resin (Qiagen, United States) and metal chelate chromatography.

Six-weeks-old female BALB/c mice were immunized subcutaneously with the recombinant protein in Freund's complete adjuvant. After booster injections, the mice with positive serum immunogenicity against the recombinant protein were used for the monoclonal fusion experiments. The mice's spleens were excised, and single-spleen cell suspensions were fused with Sp2/0 myeloma cells. After several days of fusion, the hybridomas were picked and cultured in complete medium supplemented with 1% HT. Ascitic fluids were collected from the mice after an intraperitoneal injection of the hybridomas, and the antibodies were purified by protein A/G-Sepharose affinity chromatography. The protein concentrations of the purified antibodies were determined using the Bradford method, and the antibodies were diluted to 1 mg/mL and stored in 50% glycerin at -20 °C.

Western blotting

Proteins were separated by 15% SDS-PAGE and were electro-transferred onto polyvinylidene fluoride (PVDF) membranes. The PVDF membranes were blocked with 5% non-fat milk dissolved in Tris-buffered saline with 0.05% Tween-20 (TTBS) at 37 °C for 90 min. The membranes were incubated with the primary antibodies at a dilution of 1:5000 in blocking reagent at room temperature for 2 h. The antibodies against the GSTs were generated by our laboratory, and the anti-ATP synthase β antibody was purchased from BD Biosciences. The membranes were incubated in goat anti-mouse/rabbit IgG conjugated with horseradish peroxidase at a 1:3000 dilution at room temperature for 1 h. The membranes were developed using the Super ECL Plus Detection Reagent kit, and the images were captured using ImageQuant ECL (GE Healthcare, United Kingdom).

Statistical analysis

To quantify the GSTs, calibration curves were constructed using the protein concentrations and immunosignal obtained from the Western blotting. To analyze the quantities of GSTs in the diabetes mouse model statistically, the relative intensity of the Western blotting signals in the samples was quantified using ImageQuant TL software. The three pairs of samples from the control and db/db mice were then randomly paired, and the relative abundance ratios of the five GST proteins were

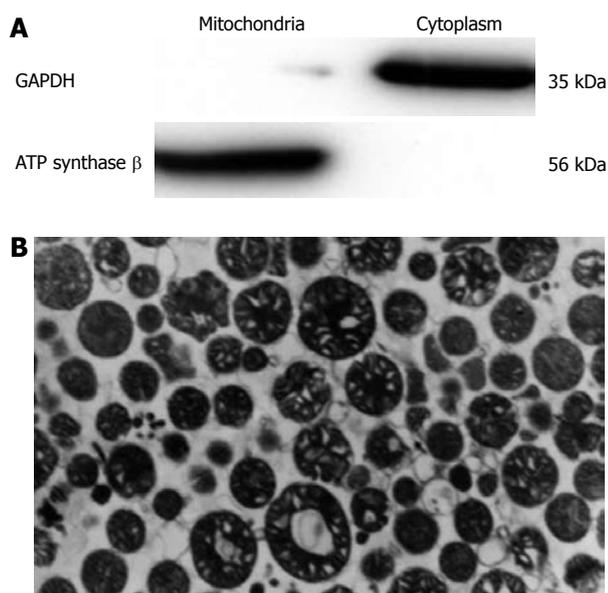

Figure 1 Measurement of mitochondrial purity by Western blotting and transmission electron microscopy. A: Glyceraldehyde-3-phosphate dehydrogenase is an indicator of cytoplasm and ATP synthase an indicator of mitochondria; B: Image of products purified by Nycodenz gradient centrifugation.

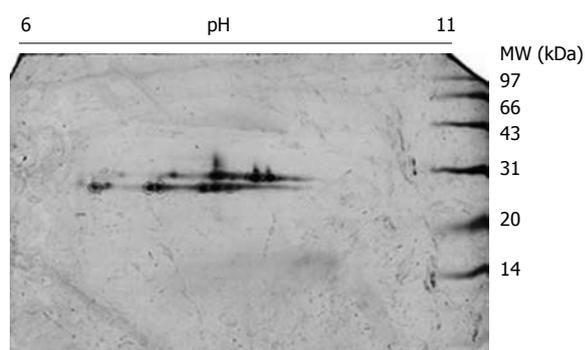

Figure 2 Two dimensional electrophoresis image of proteins purified by glutathione-affinity chromatography. The mitochondrial proteins enriched by glyceraldehyde affinity column were separated in two dimensional electrophoresis with pH 6-11 strips and 15% sodium dodecyl sulfate polyacrylamide gel electrophoresis. The string spots around molecular weight (MW) 28 kDa appeared on the gels labeled by circles were identified.

statistically analyzed and were normalized using the levels detected in normal mice based on two parallel experiments. All of the values are expressed as the mean \pm SD, and the statistical significance was set to a $P < 0.05$.

RESULTS

Screening of GST isoforms in liver mitochondria

Considering that the purity of the mitochondria is a key element in studying mitochondrial components, Nycodenz gradient centrifugation was employed for the preparation of the mouse liver mitochondria. The mitochondrial integrity and purity were examined by Western blot and TEM. Our data as shown in Figure 1 indicated that the purity and integrity of the mitochondria were satisfactory for further analysis.

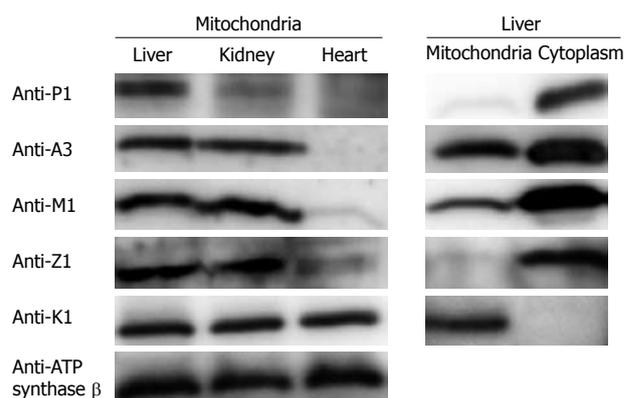

Figure 3 The distribution of glutathione S-transferases in mouse tissue mitochondria, as measured by Western blotting. A total of 20 μ g mitochondrial and cytoplasmic protein from mouse heart, kidney, and liver were loaded in each lane. Left: Glutathione S-transferases (GSTs) in mouse tissue mitochondria; Right: GSTs in liver mitochondria and cytoplasm.

The mitochondrial lysates were loaded onto GSH affinity columns, and the fractions eluted by GSH were collected and subjected to 2DE using pH 6-11 strips and 15% SDS-PAGE. After silver staining, a string spots of approximately 28 kDa and pI 7-10 appeared on the gels (Figure 2), whereas no spots were detected in other parts of the gel, indicating that the affinity enrichment was effective to remove non-GSH-binding proteins. The silver-stained spots were excised and digested with trypsin followed by protein identification using MALDI TOF/TOF MS. In total, three GSTs, GST alpha3, GST mu1 and GST pi1, were found in the liver mitochondria. Because all of the GSTs have similar MWs (about 28 kDa), we attempted to separate the mitochondrial GSTs from the other mitochondrial proteins through size-exclusion methods. The mitochondrial lysates were loaded onto a 15% SDS-PAGE gel, and the portion corresponding to 20-30 kDa was sliced into 19 fractions. These fractions were digested with trypsin, and the digested fractions were further analyzed using LC ESI MS/MS. All of the unique peptide sequences of GSTs are listed in Table 1, indicating five GSTs: GST pi1, GST alpha3, GST mu1, GST kappa1 and GST zeta1. All of the GSTs identified by GSH/2DE/MALDI TOF/TOF MS are included in the list of the identified GSTs by SDS-PAGE/LC ESI MS/MS; therefore, the SDS-PAGE/LC ESI MS/MS approach exhibits a better sensitivity for the detection of GSTs.

The existence of GSTs in the liver mitochondria was further confirmed by Western blotting using monoclonal antibodies against the individual GSTs (the specificity of detection is described below). As depicted in Figure 3, the five GST isoforms detected by the proteomic methods showed positive immunoreactivity; this evidence strongly supports the conclusion reached with the proteomic analysis. Furthermore, we prepared the tissue mitochondria from mouse kidney and heart and conducted Western blotting to evaluate the abundance of the GSTs in the mitochondria from different tissues. The left panel in Figure 3 reveals the wide distribution of GSTs in

MH+ stands for the mass of ions detected by LC ESI MS/MS. XC stands for the cross-correlation score. GST: Glutathione S-transferase.

the mitochondria from the three tissues with relatively different abundances. As a specific GST only located in mitochondria, GST kappa1 exists in all three tissues with similar abundances. GST pi1 is clearly detected in the mitochondria of all three of the tissues, whereas GST pi1 in the liver mitochondria is in the highest abundance. The three GSTs, GST alpha1, GST mu1, and GST zeta1, are clearly observed in the liver and kidney mitochondria, whereas they are almost undetected in the heart. Furthermore, we examined the cytoplasmic GSTs and the mitochondrial GSTs in the mouse liver using Western blotting. The data illustrated in the right panel in Figure 3 indicate that GST kappa1 is the only isoform undetectable in the cytoplasm, whereas the other GST isoforms are readily detected in the two subcellular fractions. When equal amounts of proteins, either cytoplasmic or mitochondrial, are loaded onto an SDS-PAGE gel, the analysis of the relative intensities demonstrate that the abundances of GSTs in the cytoplasm are commonly higher than those in the mitochondria.

Quantitative analysis of the mitochondrial GST using Western blotting

The five GSTs in liver mitochondria were first discovered by proteomic approach. As a routine assay in laboratory, mass spectrometry is not a common instrument and easy in use. Western blotting is still a widely acceptable and enough sensitive approach to detect proteins. We therefore developed a quantitative assay for the mitochondria GSTs based on immuno-blot. It is well known that specificity and sensitivity of antibody are a key factor for a successful Western blotting. To have the qualified antibodies against GSTs, we generated a set of monoclonal antibodies of GSTs, and performed a strict screening. A qualified antibody should match to criteria: (1) It can recognize 2 ng of the correspondent recombinant protein; and (2) It cannot pick up any signals to 20 ng of unrelated GSTs. The qualified GST antibodies are illustrated in the upper panel of Figure 4.

Selection of the concentration ranges for the recombinant GSTs is an important consideration for quantitative calibration. In our routine experiments, the

maximum loading of mitochondrial proteins are approximately 20 μ g; therefore, we loaded 20 μ g of proteins and different amounts of recombinant GSTs on a relatively large scale onto the same gels and performed the Western blotting analysis. After determining the band intensities, we were able to estimate the proper amounts of the recombinant GSTs for the generation of calibration curves. As shown in Figure 4, five calibration curves are generated corresponding to the multiple assays of our Western blotting. However, Western blotting has a disadvantage in quantitative measurements because the reproducibility of the band intensities is relatively poor. The data shown in Figure 4 is in agreement with the observation, although some spots indeed display a large deviation. However, the regression calculation revealed that the values of R^2 ranged from 0.85-0.98, which are generally accepted in quantitative measurements using Western blot. We further estimated the possible dynamics of the GST abundances in the liver mitochondria. With the exception of GST pi1, measuring approximately 50 ng to 300 ng, the other four GSTs were between 10 ng to 40 ng, indicating that GST pi has the highest abundance in liver mitochondria. According to the regression curves in Figure 4, the mitochondrial GST abundances were quantitatively estimated as follows: $134.61 + 53.84$, $38.83 + 2.33$, $29.25 + 0.29$, $27.28 + 0.27$, $15.84 + 0.16$ ng per μ g mitochondria protein for GST pi1, mu1, alpha3, kappa1, and zeta1, respectively.

Comparison of the GSTs' abundances in liver mitochondria between normal and diabetes mice

The db/db mouse is a well-accepted type II diabetes model, and previous studies have shown that free radicals were increased in most of the tissues in this model. After carefully examining the mice's blood glucose and body weight to ensure diabetes development, we collected the livers from three normal and three db/db mice; the prepared mitochondria were analyzed by Western blot to quantify the contents of the GSTs. Figure 5A shows such a typical Western blotting, suggesting that the immunoreactivity of GST pi1 is significantly attenuated in the mitochondria of the diabetic mice, the signal of Western

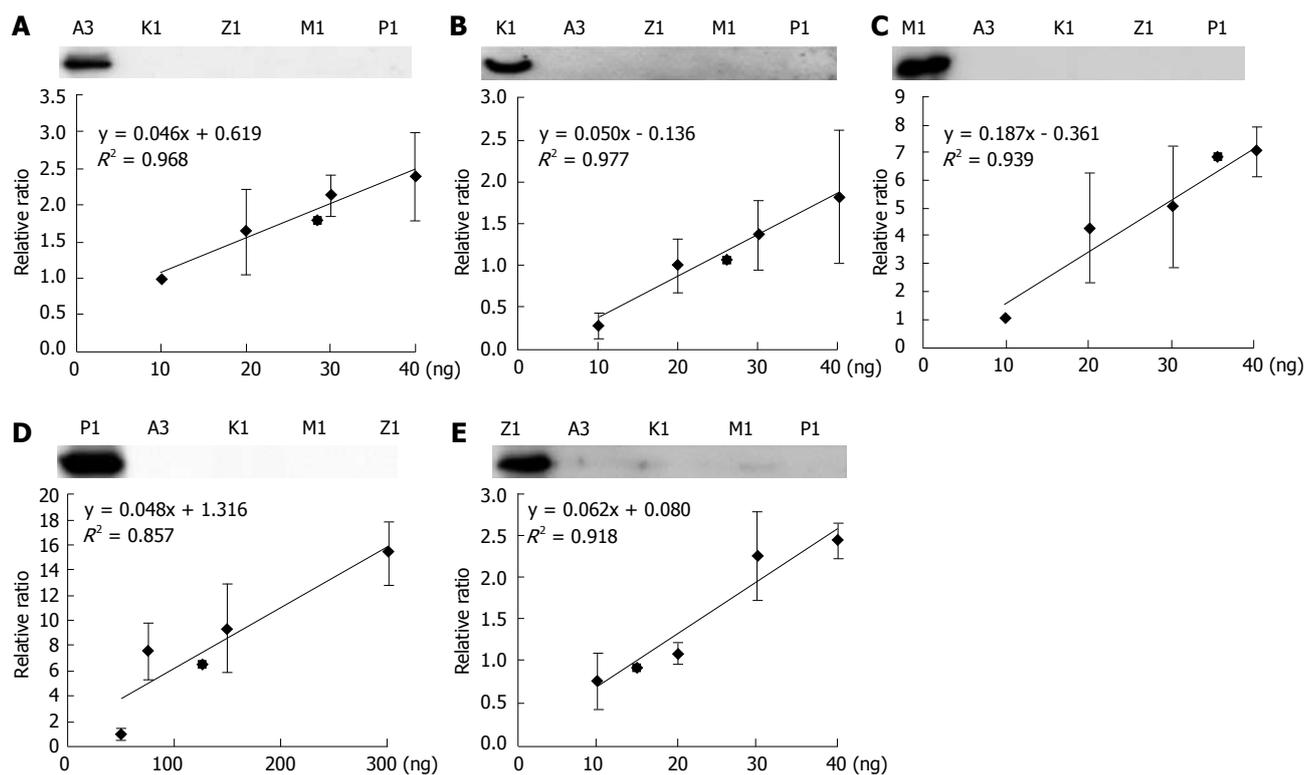

Figure 4 The calibration curves of mitochondrial glutathione S-transferase proteins. Upper panel in A, B, C, D, E: Examination of the specificity of the five glutathione S-transferase (GST) antibodies, 2 ng of the corresponding GST was loaded in all of the left lanes, and 20 ng of the other unrelated GSTs was loaded in the other four lanes; Lower panel in A, B, C, D, E: The X-axis represents the amounts of recombinant GSTs loaded (ng), and the y-axis represents the relative intensity of the Western blotting, taking the signals generated from the lowest GST amount as the reference. The calibration curves were generated by regression. Insert: The linear equations and R^2 were generated by regression.

blotting in control and db/db diabetic mice liver mitochondria is 134.61 ± 53.84 vs 99.74 ± 46.2 , with $P < 0.05$, whereas the other four GST isoforms are nearly comparable between the normal and diabetic mice. Statistically, we performed pairwise comparisons and estimations of the significant differences based on multiple Western blotting. The comparison data depicted in Figure 5B support the conclusion drawn from Figure 5A that the abundance of mitochondrial GST pi1 in diabetic mice is lower than in normal mice, whereas the other mitochondrial GSTs did not exhibit significant changes.

We screened the response of the GSTs to diabetes in the db/db liver mitochondria. As depicted in Figure 5A, which shows representative images of mitochondrial tissue from one pair of mice (control vs db/db), GST pi1 showed a decrease in the db/db mouse when we compared three pairs of mice. In contrast, similar expression levels of GST alpha3, mu1, and zeta1 were observed in the liver mitochondria of the db/db mice and control mice. The statistical analysis indicated in Figure 5B supported these observations.

DISCUSSION

GSTs have been detected as a group of oxidative stress proteins in mitochondria, and they were characterized as associated with the maintenance of mitochondria functions^[22,28]. For example, alpha-class isozymes of

GST translocated into the mitochondria under oxidative stress, and the isozymes showed glutathione peroxidase activity toward phospholipid hydroperoxide in the rat liver cytosol. Chemicals that generate reactive oxygen species, such as rotenone and antimycin A, reduced the cell viability and mitochondrial membrane potential, and the overexpression of GST pi1 diminished these changes.

In general, GSTs were determined by their enzymatic activities and immunological features; however, these methods had limitations in evaluating the presence of GST. The substrate specificity of purified rat liver GSTs has been investigated by a series of gamma-glutamyl-modified GSH analogues, and GST had a different ability to conjugate with the substrates. Furthermore, a product of the purification using GSH could not provide the status of GST *in vivo*. Therefore, the uncertainty of the type of GSTs localized in the mitochondria and the antibody specificity led to the uncertainty of an increase or decrease of GSTs under oxidative stress or in a pathological condition.

In this study, we have taken multiple approaches to identify the GSTs in mouse liver mitochondria. The mitochondrial proteins were separated by SDS-PAGE, and the 20-30 kDa proteins were analyzed by liquid chromatography and subsequently identified by ESI MS/MS. Five GST isoforms were detected in the liver mitochondria. Our strategy has two advantages: more proteins could be resolved regardless of the solubility by SDS-

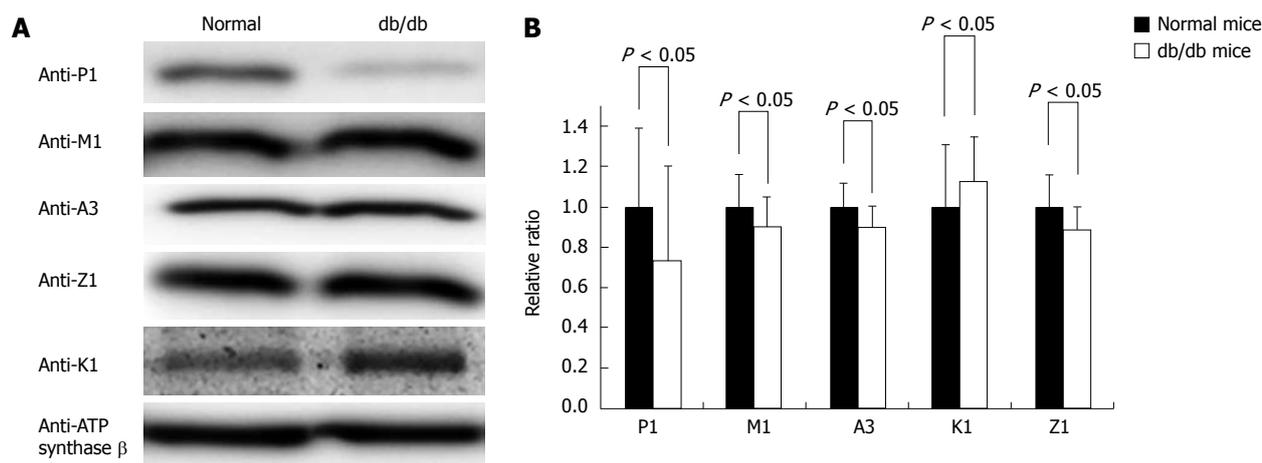

Figure 5 Comparison of mitochondrial glutathione S-transferase abundances between normal and diabetic mice by Western blotting. A: A typical image of a Western blotting comparing a pair of mouse liver mitochondria from normal and diabetic mice. Approximately 20 μ g mitochondrial proteins were loaded in each lane. Anti-ATP synthase β acted as a control to normalize the loading; B: The statistical comparison of the relative ratio of mitochondrial glutathione S-transferases (GSTs) between normal and diabetic mouse liver when normalized by the GSTs in normal mice ($n = 3$).

PAGE, and the sample complexity was reduced when the proteins distributed in the 20-30 kDa range were divided into 19 fractions for digestion and separation by liquid chromatography. Although we could not dismiss the possibility of other GSTs in the mitochondria, our multiple proteomic techniques provided new insights into analyzing GST isoforms, especially for those of low abundance.

GSH is not generated in mitochondria and is instead transferred from the cytoplasm; a GSH concentration of 5-10 mmol is maintained in mitochondria^[29]. GSH is a major defense molecule against ROS, and mitochondrial GST may play an important role in responding to chemical and oxidative stress because GST is the main phase II enzyme that catalyzes the conjugation of GSH with numerous reactive electrophiles. The identification of GSTs would influence the study of the functions of mitochondrial GST.

We discovered GST zeta1 in the mitochondria. GST zeta1 is localized in the cytoplasm and plays a significant role in the catabolism of phenylalanine and tyrosine^[5]. When GST zeta1 is lacking in mice, the inductions of the class alpha, mu, and pi GSTs could be detected by Western blotting and high-performance liquid chromatography analysis of glutathione affinity-purified proteins^[50]. The role of GST zeta1 in the mitochondria will be investigated further.

The expression of GSTs is different in distinct tissues. Our data indicate that mitochondrial GST also has tissue-specific expression. GSTs are abundant in the liver but are scarce in heart tissue. The abundance of GST kappa1 in the heart, kidney, and liver is similar, but this GST is only detected in the mitochondria, indicating that it might perform a conserved function in the mitochondria of different cell types.

We screened these mitochondrial GSTs in the diabetes mouse model and found that the GST response to

oxidative stress varies: only GST pi1 is decreased in the db/db mouse compared to normal mice, and the levels of the other four isoforms did not change. This result indicated that a decrease of GST pi1 might accelerate the pathological progress of diabetes.

COMMENTS

Background

The glutathione (GSH) S-transferase (GST) involve in many physiological functions. They are located mainly in the cytoplasm, but they have also been detected in suborganelles. Because mitochondria are the primary intracellular sites of oxygen consumption and reactive oxygen species generation, the mitochondrial GSTs abundances may relate with disease status. The goal was to survey GST isoforms in mitochondria and to reveal their biological significance in diabetic mice.

Research frontiers

It is reported that GSTs are able to protect mitochondria from oxidation by maintaining the redox balance, but their functions in the mitochondria were not elucidated. To fully understand the functions of the mitochondrial GSTs, new method to monitor the mitochondrial GSTs is urgently required.

Innovations and breakthroughs

The mitochondrial GSTs are measured by the combined quantitative proteomic strategies based on mass spectrum and antibodies. The authors discovered that GSTs are widely distributed in tissue mitochondria and their responses to the diabetes physiology. It is noted the mitochondrial GST pi1 is sensitive to diabetic development.

Applications

This research showed how the proteomics produces meaningful information and offered a relatively easy and simple workflow to detect GSTs in liver mitochondria and to reveal their biological significance of normal and diabetes mouse. At the same time, the application of this strategy provides an alternative tool to analyze how isoforms of protein family response to disease in complex biological systems.

Terminology

Proteomics is the protein map of a biological system and involves the systematic study of proteins in order to provide a comprehensive view of the function and regulation of proteins.

Peer review

This paper provides solid data on systematic analysis of GST isoforms in mouse liver mitochondria.

Abstract

AIM: To compare the incidence of early portal or splenic vein thrombosis (PSVT) in patients treated with irregular and regular anticoagulation after splenectomy with gastroesophageal devascularization.

METHODS: We retrospectively analyzed 301 patients who underwent splenectomy with gastroesophageal devascularization for portal hypertension due to cirrhosis between April 2004 and July 2010. Patients were categorized into group A with irregular anticoagulation and group B with regular anticoagulation, respectively. Group A (153 patients) received anticoagulant monotherapy for an undesignated time period or with aspirin or warfarin without low-molecular-weight heparin (LMWH) irregularly. Group B (148 patients) received subcutaneous injection of LMWH routinely within the

first 5 d after surgery, followed by oral warfarin and aspirin for one month regularly. The target prothrombin time/international normalized ratio (PT/INR) was 1.25-1.50. Platelet and PT/INR were monitored. Color Doppler imaging was performed to monitor PSVT as well as the effectiveness of thrombolytic therapy.

RESULTS: The patients' data were collected and analyzed retrospectively. Among the patients, 94 developed early postoperative mural PSVT, including 63 patients in group A (63/153, 41.17%) and 31 patients in group B (31/148, 20.94%). There were 50 (32.67%) patients in group A and 27 (18.24%) in group B with mural PSVT in the main trunk of portal vein. After the administration of thrombolytic, anticoagulant and anti-aggregation therapy, complete or partial thrombus dissolution achieved in 50 (79.37%) in group A and 26 (83.87%) in group B.

CONCLUSION: Regular anticoagulation therapy can reduce the incidence of PSVT in patients who undergo splenectomy with gastroesophageal devascularization, and regular anticoagulant therapy is safer and more effective than irregular anticoagulant therapy. Early and timely thrombolytic therapy is imperative and feasible for the prevention of PSVT.

INTRODUCTION

Although endoscopic surgery has been widely used to treat esophagogastric variceal bleeding (EGVB), splenectomy with gastroesophageal devascularization is still the primary method to treat and prevent recurrent EGVB in East Asia^[1,2]. Portal or splenic vein thrombosis (PSVT) is a common and potentially life-threatening complication of splenectomy with gastroesophageal devascularization for portal hypertension due to cirrhosis. Severe PSVT can reduce hepatopetal blood flow in the portal system and elevate the blood pressure in the visceral side of portal vein, leading to further deterioration of liver function and the recurrence of upper gastrointestinal (GI) bleeding^[3,4]. In serious cases, PSVT can significantly affect patient's life expectancy.

A prospective study with contrast-enhanced computed tomography scan showed that PSVT occurred in 12 (55%) patients of the laparoscopic splenectomy (LS) group, but in only 4 (19%) of the open splenectomy (OS) group, and the difference was significant^[5]. A recent clinical study performed by the same group of authors has emphasized that the incidence of PSVT still reached 51.52% in 33 cases after LS without any anticoagulation therapy^[6]. The different incidences of PSVT between laparoscopic and open splenectomy may be caused by the operative technique of pneumoperitoneum and ligation of splenic hilar vessels. In the OS group, splenic hilar vessels were ligated conventionally, while these vessels were divided with an endoscopic vascular stapler in the LS group^[5]. But in some other studies, the incidence of PSVT varied after splenectomy with gastroesophageal devascularization^[7-9].

The literatures mentioned above focused on splenectomy to treat hematologic and metabolic disorders. The reported incidence of PVST related to these diseases may be different from that related to liver cirrhosis because of the different disease spectrum. Kawanaka *et al*^[10] analyzed 50 consecutive cirrhotic patients who underwent splenectomy, the PVST incidence was 36.0% (9/25) up to postoperative day (POD) 7 without any prophylactic anticoagulation therapy, the PVST incidence of the other 25 patients was only 4.0% (1/25) up to POD 30 who received antithrombin III (AT-III) therapy in the first three POD. Ushitora *et al*^[11] retrospectively examined 38 consecutive cirrhotic patients who underwent splenectomy, the total incidence of PSVT detected by postoperative dynamic computed tomography was 34.2% (13/38) without any prophylactic anticoagulation therapy. Deng *et al*^[12] reported a 33.69% incidence of PVT 7 to 14 d after portal hypertension surgery (splenectomy with gastroesophageal devascularization) in 52 surgically treated patients with portal hypertension due

to hepatitis B virus (HBV)-related cirrhosis. The 10-year survival rate among adults with PSVT was 38%-60%, the mortality rate from variceal bleeding in patients with PSVT with cirrhosis was 30%-70%, significantly higher than 5% from variceal bleeding in patients with PSVT without cirrhosis^[13].

Therefore, PSVT is indeed a common complication of splenectomy with gastroesophageal devascularization with a high incidence and morbidity even though with different disease spectrum. PSVT was considered contraindicated for liver transplantation in the past because of technical difficulties^[14] and currently it still remains as a risk factor^[15]. It makes the surgical procedure more cumbersome, resulting in a higher morbidity and mortality in the PSVT patients^[16,17]. Englesbe *et al*^[18] found that mortality of patients with previous portal vein thrombosis (PVT) after liver transplantation was higher than that of patients without PVT (at 30 d 17.7% *vs* 4.4%, $P = 0.07$; at 1 year 33.0% *vs* 25.0%, $P = 0.354$; and at follow-up 36.7% *vs* 28.4%, $P = 0.371$), even these differences were not statistically significant. And patients with cirrhosis complicated with PVT have significantly increased risks of death after liver transplantation (hazard ratio 7.389, 95% CI: 2.392-22.827).

So, it is very important to prevent the occurrence of PSVT after splenectomy with gastroesophageal devascularization for the better long-term clinical outcomes and following possible liver transplantation. Prophylactic anticoagulation therapy is a prime method to prevent PSVT after splenectomy with gastroesophageal devascularization. The most frequently used drugs are low molecular weight heparin (LMWH), vitamin K antagonist such as warfarin^[5], and aspirin^[19-21]. But the coarse and dosage of these drugs were variable according to different literatures, there was no generally acceptable PSVT prophylactic regimen for all patients after splenectomy with gastroesophageal devascularization^[22,23].

We studied retrospectively the efficacy of regular anticoagulant therapy on preventing early postoperative PSVT in the cirrhotic patients who received splenectomy with gastroesophageal devascularization in Beijing You-An Hospital of Capital Medical University from December 2004 to July 2010.

MATERIALS AND METHODS

Inclusion and exclusion criteria

Inclusion criteria: Patients with liver cirrhosis due to any causes; liver function grade: Child-Pugh A-B; splenomegaly and hypersplenism; severe esophageal varicose confirmed by gastroscopy; and previous histories of recurrent upper gastrointestinal bleeding. All patients signed the informed consent and the study was approved by the Ethics Committee of the hospital. These patients' data within one month after splenectomy with gastroesophageal devascularization were collected and analyzed.

Exclusion criteria: Patients who did not fulfill the inclusion criteria and could not tolerate surgical treatment were excluded.

Clinical examinations

After fasting for 8 h, all patients lied in the supine or left lateral position, and color Doppler ultrasound examination was performed with ACUSON Sequola 512 SIE-MENS Ultrasound system with a probe frequency of 3.5 MHz. The inner diameter of the portal vein and the splenic vein were measured in the sagittal position. Platelets/international normalized ratio (PLT/INR) was also measured before surgery and at day 1, day 3, day 7 and 1 mo after surgery.

Surgical procedure and portal venous pressure measurement

Selective gastroesophageal devascularization was performed using intraoperative free portal venous pressure (FPVP) as guidance^[24]. A 20G antithrombotic catheter (BD Insyte, Becton Dickinson Medical Devices Co, Ltd. Suzhou, China) was inserted into the right gastro-omental vein to test FPVP after laparotomy and splenectomy, respectively. Gastroesophageal devascularization was performed according to the FPVP.

Treatment and grouping

The patients were classified into two groups according to whether regular anticoagulation was administered. In group A, the patients received irregular anticoagulant aspirin or warfarin monotherapy for an undesignated time period without LMWH due to poor blood clotting after surgery and perioperative abdominal or GI bleeding.

Patients in group B had nearly normal blood clotting before and after surgery; 24 h after surgery, they received subcutaneous injection of LMWH routinely, 0.3 mL per 12 h for 5 d and then maintained by oral therapy with warfarin for one month to keep the target prothrombin time/international normalized ratio (PT/INR) at a level between 1.25 and 1.5. If the postoperative platelet level was increased to $100 \times 10^9/L$ or above, aspirin 100 mg daily was added for one month. If the postoperative platelet level was increased to $300 \times 10^9/L$ or above, ticlopidine was added with the dose of 0.25 g daily for one month.

Color Doppler ultrasound examination and PLT/INR measurement were repeated. Once PSVT was confirmed after splenectomy with gastroesophageal devascularization, the patients would receive a thrombolytic therapy. Urokinase was administered *via* the peripheral venous route with a bonus dose of 200 000 units within 30 min, followed by continuous infusion of 20 000-50 000 units/h for 3-5 d *via* a micro-infusion pump. During the thrombolytic treatment, PT/INR and PLT were measured daily. Following the thrombolytic treatment, the patients were administered with oral warfarin (2.5 mg, 1-2 times daily) and aspirin (100 mg daily). The drug doses were adjusted according to PT/INR and PLT levels. If repeated color

Doppler ultrasound examinations showed complete or partial dissolution of target thrombus, the treatment was considered effective and switched to oral warfarin monotherapy (2.5 mg, 1-2 times daily) for one month. If repeated color Doppler ultrasound examinations showed little change or even enlargement of the target thrombus, the thrombolytic therapy was defined as ineffective. The patients would continue to receive oral warfarin and aspirin and followed up regularly.

Statistical analysis

SPSS version 11.5 software (SPSS Inc., Chicago, IL, United States) was used for statistical analyses. Continuous data were presented as mean \pm SD and compared with two-tailed nonpaired Student's *t* test. Categorical data were analyzed with Chi-square or Fisher exact test. Chronologic changes in the laboratory data were analyzed by the analysis of variance for repeated measures. $P < 0.05$ was considered statistically significant.

RESULTS

A total of 301 cirrhotic patients undergoing splenectomy with gastroesophageal devascularization in our department was included in the study, including 202 males and 99 females with an average age of 45.96 years (range, 14-77 years). They were divided into two groups: Group A, 153 patients, including 103 men and 50 women with a mean age of 46.14 ± 10.39 years; and Group B, 148 patients, including 99 men and 49 women with a mean age of 46.47 ± 9.58 years. There were 254 cases of HBV related cirrhosis, 19 cases of hepatitis C virus related cirrhosis, 22 cases of alcoholic cirrhosis, 3 cases of idiopathic portal hypertension and 3 cases of primary biliary cirrhosis.

As for liver function grade, Child-Pugh A was found in 246 patients and Child-Pugh B in 55 patients. Of the 301 patients, 236 patients (78.40%) had a history of upper GI bleeding before surgery. All major clinical parameters were not significantly different between the two groups (Table 1).

The FPVP before splenectomy was 37.79 ± 5.03 cm H₂O in group A and 36.66 ± 5.24 cm H₂O in group B ($P = 0.179$). The FPVP after splenectomy with gastroesophageal devascularization was 30.01 ± 4.58 cm H₂O in group A and 29.59 ± 4.37 cm H₂O in group B ($P = 0.559$).

Sixteen patients (5.31%) had preoperative spontaneous mural PSVT, with an incidence of 3.92 % (6/153) in group A and 6.76 % (10/148) in group B ($\chi^2 = 1.201$, $P = 0.273$).

The total incidence of postoperative mural PSVT was 31.22 % (94/301), 41.17% (63/153) in group A and 20.94 % (31/148) in group B ($\chi^2 = 15.009$, $P = 0.002$). There were 50 (32.67%) cases of mural thrombi in the main trunk of the portal vein in group A and 27 (18.24%) cases in group B ($P = 0.004$). As shown in Table 2, there was no difference in terms of the location of thrombi between the two groups. No single case of thrombosis involved whole portal system. The incidence of throm-

basis in the portal vein main trunk was significantly different between the two groups ($\chi^2 = 8.236$, $P = 0.004$).

During the anticoagulant therapy, mild GI bleeding occurred in 3 patients, including 1 in group A and 2 in group B. The anticoagulant therapy was terminated immediately and hemostatic agents were administered. Bleeding was successfully controlled, and the patients recovered well.

All 94 patients with postoperative PSVT were treated with thrombolytic drug, urokinase, anticoagulant and antiaggregation agents. Among the 94 patients, 76 achieved complete or partial thrombus dissolution, including 50 (79.37%, 50/63) patients in group A and 26 (83.87%, 26/31) patients in group B ($\chi^2 = 0.272$, $P = 0.602$). No thrombolytic therapy-related complications such as bleeding were noted.

As shown in Figure 1, platelet count was not significantly different between the two groups ($P = 0.981$). However, the PT/INR in group B was gradually increased from day 7 after surgery, which was statistically different from that in group A ($P = 0.020$). We also compared the patients with and without PSVT and found that the PT/INR in patients without PSVT was greater than those with PSVT at day 14 after surgery (1.30 ± 0.21 vs 1.23 ± 0.17 , $P = 0.037$). Similar results were found in patients with and without PSVT in group B (1.28 ± 0.21 without PSVT vs 1.18 ± 0.14 with PSVT, $P = 0.017$) (Figure 2).

DISCUSSION

Selection of thrombosis prevention regimens after splenectomy with gastroesophageal devascularization

Currently, a number of studies have suggested possible mechanisms of PSVT formation following splenectomy with gastroesophageal devascularization, including elevated postoperative platelet count, hemodynamic changes in splenic and portal veins, endothelial damage, spleen size, postoperative release of procoagulant factors, the reduction of anticoagulant factors, and the postoperative use of hemostatic drugs^[10,25,26]. PSVT may lead to severe clinical adverse events or poor outcomes^[3,4]. Therefore, the importance of PSVT prevention has been gradually recognized and emphasized^[19-21,27].

Various prevention protocols have been proposed^[25,28,29], but the effectiveness of these protocols varied^[4,22,30] because the duration and doses of these drugs were variable. Therefore, there was no generally acceptable PSVT prophylactic regimen for all patients^[22,23]. There are many blood coagulation factors involved in the formation of thrombosis^[31]. Xa is a major factor in the procedure of thrombosis^[32,33]. LMWH can suppress factor Xa by combining with ATIII to depress the activation of thrombin and formation of thrombosis^[34]. LMWH is safer than heparin because of its lower molecular weight, weaker inhibition of factor IIa and longer impact on co-

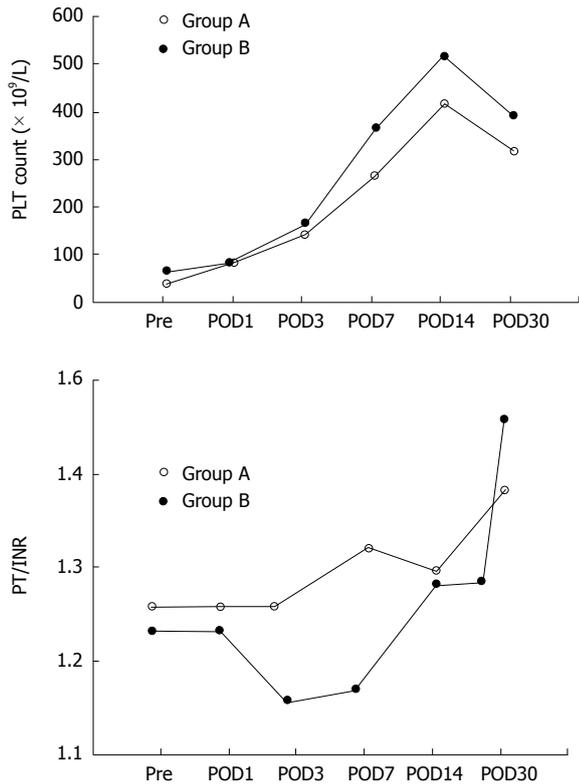

Figure 1 Changes in platelet count and prothrombin time/international normalized ratio in group A and group B. It was not different in platelet (PLT) between the two groups ($P = 0.981$), but it was statistically different in prothrombin time/international normalized ratio (PT/INR) between the two groups ($P = 0.020$). PT/INR in group A had no sequential changes pre- and post-operatively ($P = 0.479$) and PT/INR in group B was increasing gradually from postoperative day 7 with statistical difference ($P = 0.003$). POD: Postoperative day.

agulation system^[35,36].

The increased count and augmented aggregation competence of PLT after operation were important factors related to PSVT^[25]. These factors should be taken into account when selecting anticoagulation drugs. Aspirin has been applied in prevention and treatment of thrombotic diseases with satisfied safety because of its anti-PLT aggregation competence^[37,38]. Also, warfarin is an important antagonist of vitamin K (VK) with powerful anticoagulation effects by inhibiting VK-dependent coagulation factors such as II, VII, IX, X^[39,40]. We selected LMWH, warfarin and aspirin as a regular PSVT prevention regimen, which targets the major factors of mechanisms of PSVT. It was reported that the median interval between splenectomy and PSVT was 1-2 wk after surgery^[5,22,23,41].

Therefore, we used LMWH for 2-5 d followed by oral warfarin and aspirin after surgery in group B. Oral warfarin or aspirin was merely applied to those postoperative patients who were not suitable for LMWH in early postoperative phase as an irregular PSVT prevention regimen in group A.

In this study, we collected and analyzed retrospectively the data about the thrombosis prevention regimens for cirrhotic patients after splenectomy with gastroesophageal devascularization who were treated at our de-

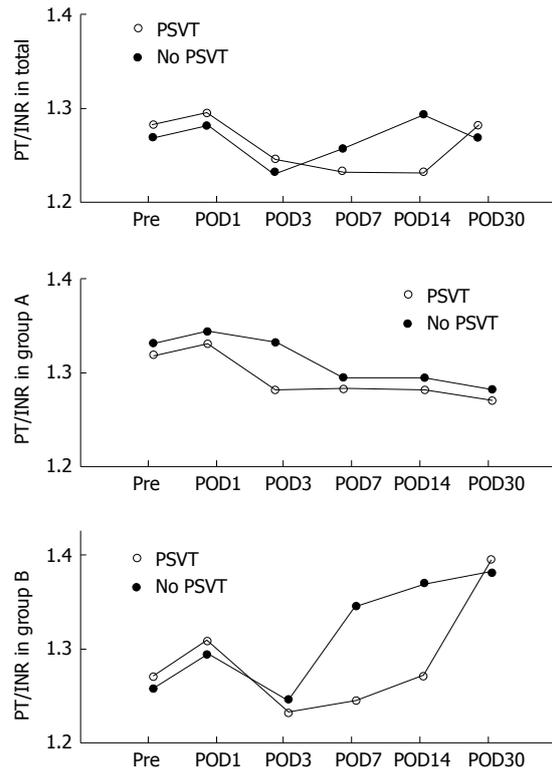

Figure 2 Changes in prothrombin time/international normalized ratio in patients without portal or splenic vein thrombosis and portal or splenic vein thrombosis. In group A, patients with or without portal or splenic vein thrombosis (PSVT) had similar prothrombin time/international normalized ratio (PT/INR), and the difference was not significant between the two subgroups. Patients with or without PSVT presented different PT/INR only at day 14 after surgery, with statistical significance (1.23 ± 0.17 vs 1.30 ± 0.21 , $P = 0.037$) by Student's *t* test. In group B, patients with or without PSVT had different PT/INR only at day 14 after surgery, with statistical significance (1.18 ± 0.14 vs 1.28 ± 0.21 , $P = 0.017$) by Student's *t* test. POD: Postoperative day.

partment over the past six years. Our results showed that the early use of LMWH followed by a long-term maintenance therapy with warfarin and aspirin could reduce the incidence of PSVT in group B (20.94%) without causing major bleeding complications, as compared with group A (41.17%) and other studies (51.5%-55%)^[5,6]. We also compared the patients with and without PSVT and found that the PT/INR in patients without PSVT was greater than those with PSVT at day 14 after surgery. Similar results were found in patients with and without PSVT in group B, suggesting that our anticoagulant regimen with the PT/INR target value set at 1.25-1.5 was reasonable and effective.

Classification and treatment of PSVT

PSVT in patients with portal hypertension due to cirrhosis following splenectomy with gastroesophageal devascularization can have various clinical manifestations, from no symptoms in mild cases to life-threatening recurrence of upper GI bleeding or small bowel necrosis in serious cases^[29]. The difference in clinical consequences stems from the location of PSVT, degree of obstruction, and its impact on portal vein (PV) hemodynamics. In fact, grade IV PSVT (Yerdel's classification^[42]), which involved

PV and superior mesenteric vein (SMV), would result in significant reduction in venous blood return to the liver and elevation in PVP, leading to esophageal and gastric variceal rupture and bleeding. SMV thrombosis can impede venous blood return from the bowels and cause small bowel necrosis, which could be vital for patients.

In this study, all 94 PSVT cases were grade I, which led to almost no clinical manifestations, such as variceal bleeding recurrence and bowel necrosis, and were easy to treat. Thrombolytic therapy has been proven to be effective for acute PSVT. Previous studies have recommended early and timely thrombolytic anticoagulant therapy^[43,44] and commonly used drugs, including urokinase, recombinant tissue plasminogen activator (rt-PA), LMWH, warfarin and dipyridamole. Intervention can be categorized by the administration route, i.e., systemic, portal system, and intravascular interventional treatment^[45,46]. Krauth *et al.*^[23] reported that immediate thrombolytic anticoagulant therapy in PSVT patients can achieve a complete dissolution rate of 63.3% and a partial dissolution rate of 13.3%. In our study, thrombolytic therapy *via* the peripheral venous route was administered in all 94 patients with PSVT, among whom 18 patients showed no sign of thrombus dissolution, but 61 patients (64.89%) achieved complete dissolution and 15 patients (15.95%) had partial dissolution. The overall thrombolytic effectiveness in our study was similar to other studies mentioned above. These phenomena were related to the benefit of regular anticoagulant therapy, which confirmed the clinical value of the anticoagulant regimen.

Our findings suggested that regular anticoagulation and early thrombolytic therapy are safe, effective and rational for PSVT patients who had portal hypertension and underwent splenectomy with gastroesophageal devascularization. At present, splenectomy with gastroesophageal devascularization may only be used as a bridge to liver transplantation in cirrhotic patients, timely prevention and thrombolytic treatment for PSVT offers a significant clinical value in terms of facilitating the portal venous reconstruction of the recipients for liver transplantation^[47].

Dilemma between anticoagulation and bleeding

Theoretically, preventive use of anticoagulants against PSVT in cirrhotic portal hypertensive patients early after surgery would counter the dilemma of bleeding. But in fact, previous studies have demonstrated that early anticoagulant treatment in these patients is a safe and effective protocol to prevent PSVT^[48,49]. Based on our study, the regular monitoring during anticoagulant treatment is necessary, which can guarantee the safety and maintain the PT/INR level between 1.25 and 1.5. Because most of our subjects had end-stage HBV cirrhosis, our suggestion differs from previous studies on non-HBV cirrhotic patients, mostly with hematologic and metabolic disorders and alcoholic cirrhosis, for which, PT/INR value of 2-3 is recommended^[50]. In this study, only three patients presented with mild GI bleeding during the anticoagulant treatment. We immediately terminated it and

shifted to symptomatic treatment such as hemostatic agents. Bleeding was successfully controlled, and the patients were discharged uneventfully. Therefore, our anticoagulant therapy has been proven safe.

On the other hand, there is a lack of large-scale controlled and long-term studies on the prevention of PSVT in cirrhosis patients receiving splenectomy with gastroesophageal devascularization for splenomegaly and hypersplenism. Since a randomized prospective controlled study is difficult to perform, we choose to conduct this retrospective controlled study. However, randomized controlled trial is necessary in the future.

Complications of splenectomy with gastroesophageal devascularization

Overwhelming postsplenectomy infection (OPSI) syndrome is associated with a high mortality, even it is a rare condition. Major risk factors include the age of the patients with splenectomy, the time after splenectomy, the reason for splenectomy, and the overall immune status of the patients. Splenectomy performed for hematological disorders, including thalassemia, hereditary spherocytosis, autoimmune hemolysis, immune thrombocytopenic purpura, or lymphoma, appears to carry a higher OPSI risk than splenectomy performed as a result of other diseases. Treatment of OPSI is generally aggressive due to the serious nature of the condition and associated mortality. The major preventive strategy is the vaccination using the 23-valent pneumococcal polysaccharide vaccine, a 7-valent proteinconjugated pneumococcal vaccine, the hemophilus influenzae type B vaccine, and the meningococcal vaccine^[51]. Fortunately, there was no OPSI occurrence in our study. The reasons may be that all the patients are adults and no splenectomy was performed for hematological disorders, the antibiotic agents were administered for 3-5 d after surgery, and the follow-up period was too short for OPSI.

In summary, the early and regular initiation of anticoagulant treatment using LMWH followed by warfarin and aspirin has been proven safe and effective in early prevention of PSVT in patients with cirrhotic portal hypertension, undergoing splenectomy with gastroesophageal devascularization. The treatment can reduce the incidence of PSVT in the early stage after splenectomy with gastroesophageal devascularization, early and timely thrombolytic therapy is imperative and feasible for the prevention and treatment of PSVT. The protocol presented in our study may benefit the patients not only for approximate and long-term clinical outcome, but also for potential liver transplant candidates in the future. But a better designed randomized prospective study with a longer follow-up period is still needed to clarify our conclusions.

COMMENTS

Background

Portal or splenic vein thrombosis (PSVT) is a common and potentially life-threatening complication of splenectomy with gastroesophageal devascularization for portal hypertension due to cirrhosis, which may lead to further deteriora-

tion of liver function and the recurrence of upper gastrointestinal (GI) bleeding and significantly affects patient's life expectancy. In some severe cases, PSVT may be contraindicated for liver transplantation. It is therefore very important to prevent the occurrence of PSVT after splenectomy with gastroesophageal devascularization to achieve better long-term outcomes and following possible liver transplantation if required.

Research frontiers

Prophylactic anticoagulation therapy using a combination protocol of low molecular weight heparin (LMWH), vitamin K antagonists, such as warfarin and aspirin, is a prime method to prevent PSVT. But the duration and doses of these drugs were variable according to the literature, there was no generally acceptable PSVT prophylactic regimen for all patients after splenectomy with gastroesophageal devascularization. So, a safe and effective prophylactic anticoagulation protocol is needed.

Innovations and breakthroughs

In order to reduce the incidence of PSVT after splenectomy with gastroesophageal devascularization, a regular prophylactic anticoagulation protocol was established with a confirmed monitoring index. This study used the combined and sequential application of LMWH, warfarin, aspirin and ticlopidine according to the regular coagulating function test and color Doppler flow imaging. The incidence and severity of PSVT caused by anticoagulation therapy were reduced, without causing major bleeding complications.

Applications

The study results suggest that prophylactic anticoagulation therapy using LMWH, warfarin and aspirin regularly is a safer and more effective method for PSVT prevention.

Terminology

PSVT is a sort of clinical disease caused by thrombus development in the portal vein system. The major causes of PSVT included the reduced blood flow, the increased platelet count, the injured vessel endothelium and enhanced coagulation function. PSVT is a common complication of abdominal surgery, especially after splenectomy with gastroesophageal devascularization with a high incidence and morbidity.

Peer review

This is a good descriptive study in which authors analyze the preventive effect of prophylactic anticoagulation therapy using low molecular weight heparin, warfarin and aspirin for PSVT. The results are interesting and imply that a regular prophylactic anticoagulation protocol is a safer and more effective method that could be used in preventing PSVT after splenectomy with gastroesophageal devascularization.

Abstract

AIM: To investigate whether uncoupling protein 2 (UCP2) affects oleic acid-induced secretion of glucagon-like peptide-1 (GLP-1) in L-cells.

METHODS: mRNA and protein expression of UCP2 were analyzed in human NCI-H716 cells, which serve as a model for enteroendocrine L-cells, by quantitative reverse transcription-polymerase chain reaction and Western blotting before and after treatment with oleic acid. Localization of UCP2 and GLP-1 in NCI-H716 cells was assessed by immunofluorescence labeling. NCI-H716 cells were transiently transfected with a small interfering RNA (siRNA) that targets UCP2 (siUCP2) or with a non-specific siRNA using Lipofectamine 2000. The concentrations of bioactive GLP-1 in the medium were measured by enzyme linked immunosorbent assay.

RESULTS: Both GLP-1 and UCP2 granules were expressed mainly in the cytoplasm of NCI-H716 cells. NCI-H716 cells that secreted GLP-1 also expressed UCP2. Time-course experiments revealed that release

of GLP-1 from NCI-H716 cells into the medium reached a maximum at 120 min and remained stable until at least 180 min after treatment with oleic acid (the level of GLP-1 increased about 2.3-fold as compared with the level of GLP-1 in the control cells, $P < 0.05$). In an experiment to determine dose dependence, stimulation of NCI-H716 cells with ≤ 8 mmol oleic acid led to a concentration-dependent release of GLP-1 into the medium; 10 mmol oleic acid diminished the release of GLP-1. Furthermore, GLP-1 secretion induced by oleic acid from NCI-H716 cells that were transfected with si-UCP2 decreased to 41.8%, as compared with NCI-H716 cells that were transfected with a non-specific siRNA ($P < 0.01$).

CONCLUSION: UCP2 affected GLP-1 secretion induced by oleic acid. UCP2 plays an important role in L-cell secretion that is induced by free fatty acids.

INTRODUCTION

Glucagon-like peptide-1 (GLP-1) which is released from L-cells in the intestine plays an important role in post-prandial glucose homeostasis^[1]. With the recent advent

of anti-diabetic drugs aimed at either mimicking GLP-1 or preventing its degradation, researchers have turned their attention toward the L-cell and have focused on determining whether it would be both possible and beneficial to stimulate the endogenous release of GLP-1. This approach requires an understanding of the mechanisms underlying GLP-1 release from L-cells.

GLP-1 is involved in the regulation of nutrient homeostasis through insulinotropic effects on the β -cell as well as inhibition of glucagon release and gastric emptying and induction of satiety^[1,2]. Most L-cells that secrete GLP-1 are located in the distal small intestine and colon^[3]. GLP-1 release from L-cells is regulated by nutrient ingestion and demonstrates a biphasic pattern of secretion in response to either mixed meals or carbohydrate or fat alone^[4,5]. The first phase of GLP-1 secretion is regulated by neural signals originating in the proximal intestine, within minutes after a meal^[6-8]. In contrast, the second phase is induced by direct nutrient stimulation of the L-cells, resulting in secretion of GLP-1^[9-11]. In addition, *in vitro* studies using primary rat L-cells in culture have shown that the GLP-1 response to fat is highly specific, requiring mono-unsaturated fatty acids (MUFAs) with a chain length of 16 or more carbons (e.g., palmitoleic acid, 16:1 or oleic acid, 18:1). Mono-unsaturated long-chain fatty acids, such as oleic acid, are strong stimulators of GLP-1 secretion from L-cells^[9].

Uncoupling protein 2 (UCP2), a member of the UCP family, is located in the inner mitochondrial membrane and induces proton leakage and regulates the production of reactive oxygen species (ROS)^[12-14]. UCP2 plays an important role in α -cell dysfunction that is induced by free fatty acids (FFAs) *in vitro*, which may be related to its effects on oxidative stress and the insulin signaling pathway^[15]. UCP2 is also involved in the effect of FFAs on β cells, as FFAs stimulate both the expression and activity of UCP2 in α cells^[15-17]. When FFA stimulates UCP2 over-expression, the negative effects of UCP2 on ATP production result in the suppression of insulin secretion in β cells^[18]. Long-term exposure to FFAs also stimulates the release of glucagon and GLPs in a time- and dose-dependent manner in α cell lines^[19]. UCP2 is also believed to be involved in this effect in α cells. A chronic high concentration of FFAs impairs the function of both β and α cells, and this impairment involves UCP2^[16]. It is not, however, known whether UCP2 has similar effects on L-cells. In this study, we investigated the effect of oleic acid on the expression of UCP2 in human NCI-H716 cells, an L-cell model, and the effect of UCP2 down-regulation on GLP-1 secretion in these cells.

MATERIALS AND METHODS

NCI-H716 cell culture and secretion studies

Human enteroendocrine NCI-H716 cells were maintained in suspension culture as described by the American Type Culture Collection. Two days before an experiment, cells were seeded into 12-well culture plates precoated

with Matrigel as described^[20]. On the day of the experiment, the medium was replaced by PBS containing 1 mmol CaCl₂ and dipeptidyl peptidase IV inhibitor, adjusted to pH 7.2 (Millipore Corporation, Bedford, MA, United States). Cells were incubated at 37 °C for 2 h with or without different oleic acid concentrations (0, 2, 4, 6, 8, 10 mmol) and RNA interference targeting UCP2 (see below). GLP-1 was measured by enzyme linked immunosorbent assay (ELISA) (see below).

Small interfering RNA preparation and NCI-H716 cell transfection

The siRNA sequences targeting UCP2 (siUCP2) and a non-specific control small interfering RNA (siRNA) were purchased from Shanghai Shinegene Molecular Biotechnology Co., Ltd. (Shanghai, China). NCI-H716 cells were 70% confluent in 250 μ L of complete RPMI 1640 medium. Transfections of siRNA (at a final concentration of 300 nmol) were performed in NCI-H716 cells using Lipofectamine 2000 according to the manufacturer's protocol (Life Technologies, Carlsbad, CA, United States). Cells were usually examined 48 h after transfection.

Localization of uncoupling protein-2 and GLP-1 in NCI-H716 cells

The antibodies used for immunofluorescence staining in NCI-H716 cells were anti-GLP-1 (C-17; Santa Cruz) and anti-UCP2 (LS-B1911; LifeSpan Bio-Sciences). Cells were grown on coverslips, fixed in 4% paraformaldehyde in PBS for 10 min, washed with PBS, and cooled in 100% methanol at -20 °C for 20 min. Cells were then washed with PBS and permeabilized with 0.1% Triton X-100 for 10 min. After blocking with Dako blocking solution, primary antibody (anti-GLP-1; 1:100) was added and incubated at 4 °C overnight. For the secondary antibody, Cy3-conjugated donkey anti-goat (1:200; red, Beyotime Institute of Biotechnology) was incubated for 30 min at room temperature in the dark. The cells were washed with phosphate buffer saline (PBS), and anti-UCP2 (1:50) was added and incubated at 4 °C overnight. For the secondary antibody, fluorescein isothiocyanate-conjugated goat anti-rabbit (1:200; green, Beyotime Institute of Biotechnology) was added for 30 min at room temperature in the dark. Cells were then incubated for 45 min with Hoechst stain to counterstain nuclei. After a final wash with PBS, the coverslips were mounted with Slow-Fade Antifade kit (Molecular Probes).

RNA isolation and quantitative reverse transcription-polymerase chain reaction

Reagents used for RNA isolation and quantitative reverse transcription-polymerase chain reaction (qRT-PCR) included TRIzol Reagent, oligo(dT)₁₈ primers, and AMV reverse transcriptase (all from Invitrogen, Carlsbad, CA, United States) and primers and TaqMan probes (Shanghai Shinegene Molecular Biotechnology). Total cellular RNA was extracted with TRIzol Reagent. The purity and concentration of RNA was determined by measuring

the absorbance at 260 and 280 nm, with $A_{260}/A_{280} > 1.7$ considered sufficient purity^[21]. RNA (1 μ g) was reverse-transcribed into cDNA using oligo(dT)₁₈ primers at 42 °C for 1 h. Quantitative RT-PCR was performed with the ABI Prism 7000 sequence detection system (Applied Biosystems, Foster City, CA, United States) using TaqMan probes; threshold cycle numbers were obtained by ABI Prism 7000 SDS software, version 1.0. The primer and probe sequences used in this study were as follows: *UCP2* gene (sense primer, 5'-CCAATGTTGCCCGWAATG-3'; antisense primer, 5'-TGAGGTTGGCTTTCAGGAG-3'; probe, 5'-FAM+CTGGTGACCTATGACCTCATCAAAG-3'); β -*actin* gene (sense primer, 5'-GGCACCACA-CYTTCTACAATG-3'; antisense primer, 5'-GGGGGTGTGAAGGTCTCAAAC-3'; probe, 5'-FAM+TGTGGCCCTGAGGAGCACCC-3').

Amplification conditions were one cycle at 95 °C for 5 min, followed by 40 cycles at 95 °C for 30 s and 60 °C for 1 min, and one final cycle at 72 °C for 4 min.

Western blot analysis

Mitochondrial proteins from NCI-H716 cells were isolated with 1 mL of extraction buffer (250 mmol sucrose; 1 mmol ethylenediaminetetraacetic acid; 10 mmol Tris, pH 7.4) supplemented with protease inhibitors (Sigma). The mixture was centrifuged at $800 \times g$ for 10 min. The supernatant was centrifuged at $10\,000 \times g$ for 10 min, and the mitochondrial pellet was resuspended in 25 μ L of N-Tris(hydroxymethyl)methyl-2-aminoethanesulfonic acid buffer. Mitochondrial protein concentration was determined colorimetrically with the BCA Protein Assay (Pierce, Rockford, IL, United States). Mitochondrial proteins (15 μ g) were mixed with $3 \times$ sample buffer [0.5 mol phosphate buffer, pH 7.0; 30% (w/v) glycerol; 7.5% (w/v) SDS; 0.75 mmol bromophenol blue], boiled for 5 min, and electrophoresed on an SDS-PAGE gel (12.5% acrylamide). Proteins were then transferred to Immobilon PVDF membranes (Millipore). UCP2 proteins were detected with polyclonal anti-UCP2 (LifeSpan Bio-Sciences) at a dilution of 1:600 followed by incubation with horseradish peroxidase-conjugated goat anti-rabbit IgG secondary antibody (Santa Cruz) at a dilution of 1:2000 and detection with enhanced chemiluminescence (ECL detection system; NEN, Boston, MA, United States). To validate equal protein loading across various lanes, PVDF membranes were stripped and re-probed with polyclonal anti-cytochrome c (Santa Cruz Biotechnology) at a dilution of 1:1000.

GLP-1 measurement

The level of active GLP-1, GLP-1 (7-36) amide, was measured with an ELISA kit (Linco). This assay relies on a monoclonal antibody fixed in a coated micro-well plate that binds to the N-terminal region of active GLP-1. The concentration of active GLP-1 is proportional to the fluorescence generated by umbelliferone, which is produced by alkaline phosphatase-catalyzed hydrolysis of methyl umbelliferyl phosphate (conjugated to GLP-1 monoclonal

antibodies). Samples of the cell culture medium were collected, and dipeptidyl peptidase IV inhibitor (10 μ L/mL) was added to prevent GLP-1 degradation. Samples (100 μ L each) were added to individual assay wells. The ELISA has a working range of 2 to 100 pmol/L (according to Linco GLP-1 ELISA kit). Each sample was replicated three times.

Statistical analysis

Data are presented as the mean \pm SE. Statistical significance was calculated by a one-way ANOVA and unpaired two-tailed *t* test. *P* values < 0.05 were regarded as significant.

RESULTS

Localization of uncoupling protein-2 and GLP-1 in NCI-H716 cells

The localization of UCP2 and GLP-1 was studied in the human cell line NCI-H716, which serves as a model for intestinal L-cells. Immunofluorescence staining for GLP-1 was observed in the cytoplasm in NCI-H716 cells (Figure 1A1 and A2). Immunofluorescence staining for UCP2 was also observed in the cytoplasm in human NCI-H716 cells (Figure 1B1 and B2). Both GLP-1 and UCP2 granules were expressed mainly in the cytoplasm. Thus L-cells that expressed GLP-1 were also able to express UCP2. Merged picture, yellow staining shows co-expression of GLP-1 and UCP2 (Figure 1C1 and C2).

Oleic acid increases GLP-1 secretion in NCI-H716 cells

The possible effect of UCP2 on the secretion of GLP-1 which is induced by oleic acid in the intestinal enteroendocrine L-cell was investigated. Time-course experiments revealed that GLP-1 release from NCI-H716 cells into the medium peaked 120 min after treatment with oleic acid (the release of GLP-1 increased approximately 2.3-fold of the baseline value by treatment with oleic acid; $P < 0.05$) and maintained a stable plateau until at least 180 min after treatment (Figure 2A). In a dose-dependent experiment, oleic acid significantly increased GLP-1 secretion to a maximum of 2.5 ± 0.3 -fold of baseline levels at 8 mmol ($P < 0.01$); 10 mmol oleic acid led to a less robust increase in GLP-1 expression (Figure 2B). These results indicated that oleic acid led to a concentration-dependent release of GLP-1 from NCI-H716 cells (final concentration of oleic acid ≤ 8 mmol).

Oleic acid increases the expression of uncoupling protein-2 in NCI-H716 cells

We then determined the effect of oleic acid on the expression of UCP2 in NCI-H716 cells. Based on our time-course and dose-dependency results for GLP-1 expression, we pretreated NCI-H716 cells with 8 mmol oleic acid for 2 h and then collected the cells. qRT-PCR for UCP2 mRNA transcripts and western blot analysis for UCP2 protein were carried out on the isolated total RNA and mitochondrial proteins from these cells, respectively. The UCP2 mRNA level in NCI-H716 cells increased 3-fold after

Blue (Hoechst) staining indicates the nuclei. Original magnification, $\times 400$.

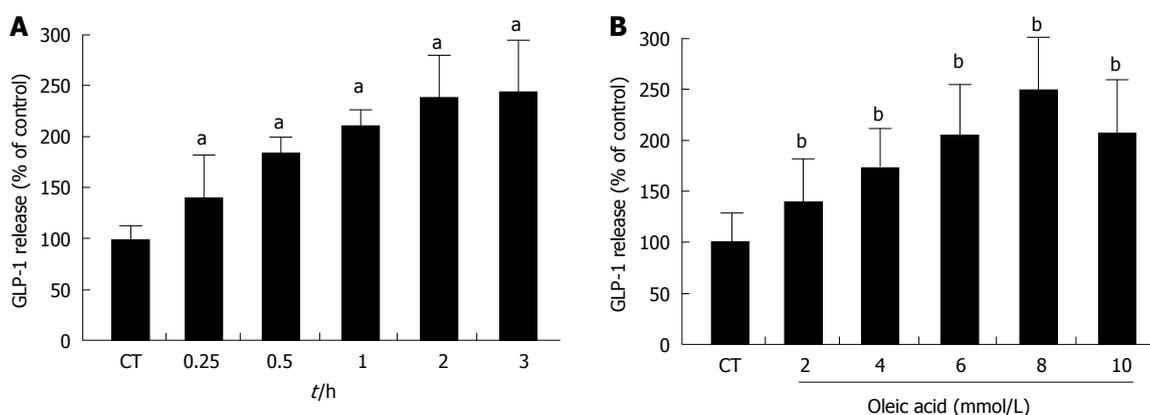

Figure 2 Glucagon-like peptide-1 secretion in NCI-H716 cells after treatment with oleic acid. A: Time course of oleic acid-induced release of glucagon-like peptide-1 (GLP-1) from NCI-H716 cells. NCI-H716 cells were incubated with 8 mmol oleic acid, and the culture medium was collected at 0.25, 0.5, 1, 2, and 3 h to detect GLP-1 levels; B: Dose-dependent oleic acid-induced release of GLP-1 from NCI-H716 cells. NCI-H716 cells were incubated with 2, 4, 6, 8, and 10 mmol oleic acid for 2 h. The culture medium was then analyzed for GLP-1 concentration. NCI-H716 cells without oleic acid exposure. ^a $P < 0.05$, ^b $P < 0.01$ vs baseline value.

treatment with 8 mmol oleic acid (Figure 3A). The UCP2 protein level also increased 1.8-fold *vs* the control amount (Figure 3B). These results indicated that oleic acid increased the expression of UCP2 in NCI-H716 cells at the transcriptional level.

Knocking down uncoupling protein-2 expression decreases oleic acid-induced secretion of GLP-1

To study the function of UCP2, a siRNA targeting UCP2 was used to specifically suppress UCP2 mRNA transla-

tion. Human NCI-H716 cells were left untransfected (blank), were mock transfected (no siRNA), or were transfected with siUCP2. After 48 h, mRNA levels of UCP2 were determined by qRT-PCR. The UCP2 mRNA level was reduced approximately 50% by siUCP2 as compared with the control level (Figure 4, up panel). There were no observable changes in the UCP2 mRNA level in mock-transfected or untransfected cells. The result from the western blot analysis also demonstrated that UCP2 protein was markedly reduced (Figure 4, up panel). Next,

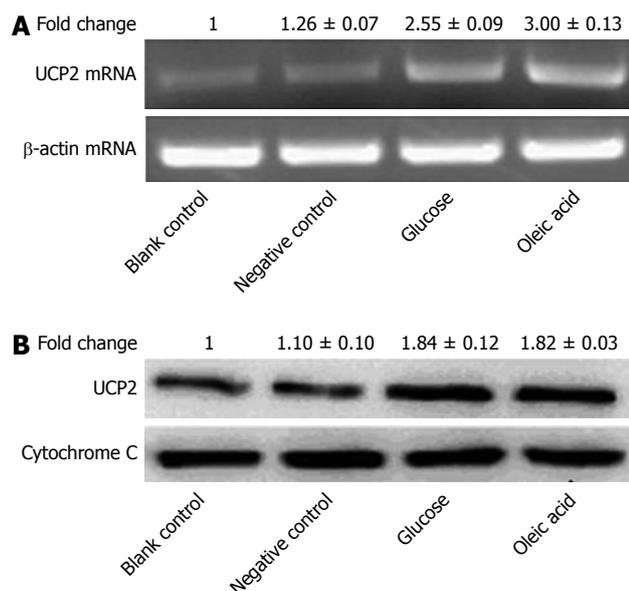

Figure 3 Expression of uncoupling protein-2 in NCI-H716 cells after treatment with oleic acid. A: Total RNA was extracted, and relative mRNA levels of uncoupling protein-2 (UCP2) were determined by quantitative reverse transcriptase polymerase chain reaction with normalization to β-actin ($P < 0.05$); B: UCP2 protein was detected by western blotting. Cytochrome C was used as the loading control ($P < 0.01$); Individual data points in this figure represent the mean ± SE of 12 determinants from four independently prepared samples each with three measurements. NCI-H716 cells were incubated with medium alone (blank control), medium containing 1% dimethyl sulfoxide (negative control), medium with 30 mmol glucose (glucose), and medium with 8 mmol oleic acid (oleic acid).

we treated NCI-H716 cells transfected with siUCP2 with 8 mmol oleic acid for 2 h. Cells that were incubated with medium alone were used as the blank control to determine baseline GLP-1 expression. Oleic acid-stimulated GLP-1 secretion decreased to 41.8% in NCI-H716 cells with siUCP2 compared to NCI-H716 cells with a non-specific siRNA ($P < 0.01$) (Figure 4, down panel).

DISCUSSION

The “incretin effect” of GLP-1 has been known for many years, and its role in the overall regulation of insulin release *in vivo* is well established. The regulation of GLP-1 secretion itself is, however, not well understood. GLP-1 is secreted from isolated perfused ileum preparations when glucose or fat is infused through the gut lumen^[22,23]. Nutrients that infuse directly into the ileal lumen can lead to the release of GLP-1^[24], indicating that direct stimulation of L-cell secretion is possible in humans. Oral glucose^[25-29], sucrose^[30], triglycerides^[27], and mixed meals also lead to an increase in plasma GLP-1^[31-34].

The mechanism of GLP-1 release is believed to involve a proximal-distal loop as well as a glucose sensor. Holst *et al.*^[35] proposed a proximal-distal loop to explain the phenomenon of GLP-1 release. This regulatory pathway involves nutrient detectors located in the upper regions of the gastrointestinal tract, which would control the release of GLP-1 from distal L-cells by neural or hormonal circuitry^[36]. Theodorakis *et al.*^[37] reported that the density

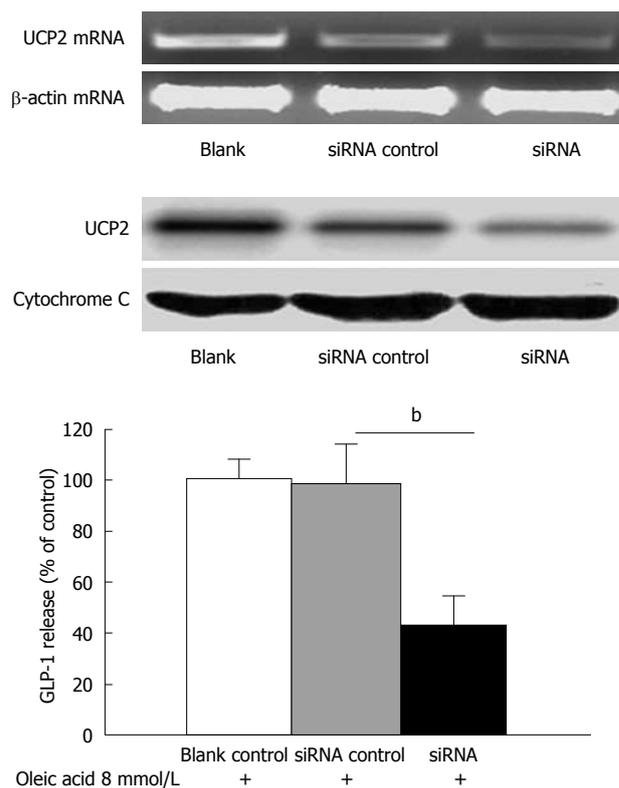

Figure 4 Knockdown of uncoupling protein-2 expression decreased oleic acid-induced secretion of glucagon-like peptide-1 in NCI-H716 cells. Up panel: The knock-down efficiency of small interfering RNA which targets UCP2 (siUCP2) in NCI-H716 cells. NCI-H716 cells were left untransfected (blank), were mock transfected (no siRNA), or were transfected with siUCP2. After 48 h, the mRNA levels of uncoupling protein-2 were determined as in Figure 4. Protein levels were determined as in Figure 4; Down panel: Effects of oleic acid on levels of secreted glucagon-like peptide-1 (GLP-1). NCI-H716 cells were transfected as described above and were then incubated with 8 mmol oleic acid for 2 h. GLP-1 concentrations were determined as in Figure 4. ^b $P < 0.01$ vs siRNA control.

of L-cells in the human duodenum may be sufficiently high to account for the early phase of GLP-1 secretion. With respect to the glucose sensor, a variety of signaling mechanisms have been proposed to explain how L-cells might sense glucose, including ATP-sensitive potassium channel closure, sodium glucose cotransporter activity, and activation of sweet taste receptors^[19,36]. Fats and protein are other well-known stimuli of GLP-1 release *in vivo*^[5,27].

G protein-coupled receptors (GPCRs) are regarded as potentially important components of signaling pathways in L-cells, as they may underlie the regulation of L-cells by certain neurotransmitters and hormones^[23,37,38], as well as by some luminal nutrients. One potential mechanism by which lipids, fatty acids, and bile acids might stimulate GLP-1 release is *via* activation of specific GPCRs on L-cells, such as GPR40, GPR120, GPR119, and TGR5. GPRs 40 and 120 are responsive to long-chain unsaturated fatty acids^[39,40]. GPR119 and TGR5 are responsive to oleoylethanolamide and bile acids, respectively^[41,42]. There is also convincing evidence that activation of protein kinase C-zeta contributes to the stimulatory action of fatty acids on GLP-1 release^[43]. These do not, however, explain the mechanism of GLP-1 release completely. Thus,

there may be other fatty acid-responsive pathways.

Chronic exposure of pancreatic islet cells to FFAs blunts glucose-stimulated insulin secretion and is accompanied by elevated levels of UCP2^[12]. UCP2 expression is regulated in tandem with the level of circulating FFAs^[44]. FFAs that increase as a result of fasting or a high-fat diet lead to UCP2 expression in adipose tissue and muscle^[45-47]. In isolated rat islets and INS-1 pancreatic β cells, long-term treatment with FFAs can increase UCP2 mRNA^[48,49].

We found that the human L-cell model, NCI-H716 cells, also expressed UCP2 in the cytoplasm. Oleic acid stimulated GLP-1 secretion in NCI-H716 cells. Time-course experiments revealed that release of GLP-1 from NCI-H716 cells into the medium peaked at 120 min after treatment with oleic acid and maintained a stable plateau at least until 180 min after treatment (Figure 2A).

Whereas the stimulation of NCI-H716 cells with \leq 8 mmol oleic acid led to a concentration-dependent increase in GLP-1 secretion into the medium, this increase was not maintained at 10 mmol (Figure 2B). It seemed that the higher concentration of oleic acid inhibited GLP-1 release from NCI-H716 cells. Lauffer *et al.*^[50] indicated that higher concentrations of oleoylethanolamide are associated with diminished GLP-1 release in all L-cell models which is suggestive of desensitization. Our results may also be related to desensitization.

Oleic acid also increased UCP2 mRNA levels in NCI-H716 cells. Furthermore, reduced UCP2 expression as a result of RNA interference decreased oleic acid-induced GLP-1 secretion (Figure 4). These results suggest that UCP2 is intimately involved in oleic acid-stimulated secretion of GLP-1 from intestinal endocrine L-cells. Understanding the mechanism responsible for this effect of UCP2 on GLP-1 secretion will require further investigation.

COMMENTS

Background

A chronic high concentration of free fatty acids (FFAs) impairs β cell function, as well as α cell function. This impairment involves uncoupling protein-2 (UCP2). Whether UCP2 has similar effects on intestinal L-cells is not clear. In this study, we investigated the effect of oleic acid, a FFA, on the expression of UCP2 in human NCI-H716 cells, which are a model for L-cells. We also analyzed the effect of UCP2 down-regulation on glucagon-like peptide-1 (GLP-1) secretion in these cells.

Research frontiers

Recent therapeutic successes of antidiabetic drugs aimed at either mimicking GLP-1 or preventing its degradation have focused attention on the L-cell and on addressing whether it would be both possible and beneficial to stimulate the endogenous release of GLP-1. However, the mechanism underlying GLP-1 secretion *in vivo* is still not fully understood.

Innovations and breakthroughs

To our knowledge, this is the first study to investigate the effect of oleic acid on the expression of UCP2 and the effect of UCP2 down-regulation on GLP-1 secretion in a model for human L-cells.

Applications

We have shown that UCP2 might be involved in a novel mechanism for regulating the secretion of GLP-1. This finding has potential benefit in finding new therapies for diabetes.

Terminology

UCP2 played an important role in α cell and β cell dysfunction. A chronic high

concentration of FFAs impairs the function of both β and α cells, and this impairment involves UCP2. The pancreatic endocrine β -cells are glucose-sensing cells and the intestinal endocrine L cells secreting GLP-1 are also glucose-sensing cells.

Peer review

The manuscript is a very interesting topic. The article is experimentally well prepared and effectively addresses the relationship between oleic acid and UCP2 and GLP-1. The research is very well described; the conclusions are applicable.

Abstract

AIM: To investigate the gene knock-down effect by the phosphoinositide-3-kinase, catalytic, alpha polypeptide (*PIK3CA*)-targeted double-stranded RNA (dsRNA) and its effect on cell proliferation and cycle distribution in SW948.

METHODS: Two *PIK3CA*-targeted dsRNAs were constructed and transfected into SW948 cells. Transfections were performed using lipofectamine™ 2000. The transfection effectiveness was calculated basing on the rate of fluorescence cell of SW948 at 6 h after transfection. Total messenger RNA was extracted from these cells using the RNeasy kit, and semiquantitative reverse transcription polymerase chain reaction was performed

to detect the down-regulation of *PIK3CA*, *AKT1*, *MYC*, and *CCND1* gene expression. Cells were harvested, proteins were resolved, and western blot was employed to detect the expression levels of *PIK3CA*, *AKT1*, *MYC*, and *CCND1* gene. Cell proliferation was assessed by 3-(4,5)-dimethylthiazoliazolo-2-yl-2,5-diphenyltetrazolium bromide assay and the inhibition rate was calculated. Soft agar colony formation assay was performed basing on colonies greater than 60 μm in diameter at $\times 100$ magnification. The effect on cell cycle distribution and apoptosis was assessed by flow cytometry. All experiments were performed in triplicate.

RESULTS: Green fluorescence was observed in SW948 cell transfected with plasmid Pgenesil-1, and the transfection effectiveness was about 65%. Forty-eight hours post-transfection, mRNA expression of *PIK3CA* in SW948 cells was 0.51 ± 0.04 vs 0.49 ± 0.03 vs 0.92 ± 0.01 vs 0.93 ± 0.03 ($P = 0.001$) in Pgenesil-CA1, Pgenesil-CA2, negative and blank group respectively. mRNA expression of *AKT1* was 0.50 ± 0.03 vs 0.48 ± 0.01 vs 0.93 ± 0.04 vs 0.92 ± 0.02 ($P = 0.000$) in Pgenesil-CA1, Pgenesil-CA2, negative and blank group respectively. mRNA expression of *MYC* was 0.49 ± 0.01 vs 0.50 ± 0.04 vs 0.90 ± 0.02 vs 0.91 ± 0.03 ($P = 0.001$) in the four groups respectively. mRNA expression of *CCND1* was 0.45 ± 0.02 vs 0.51 ± 0.01 vs 0.96 ± 0.03 vs 0.98 ± 0.01 ($P = 0.001$) in the four groups respectively. The protein level of *PIK3CA* was 0.53 ± 0.01 vs 0.54 ± 0.02 vs 0.92 ± 0.03 vs 0.91 ± 0.02 ($P = 0.001$) in Pgenesil-CA1, Pgenesil-CA2, negative and blank group respectively. The protein level of *AKT1* in the four groups was 0.49 ± 0.02 vs 0.55 ± 0.03 vs 0.94 ± 0.03 vs 0.95 ± 0.04 , ($P = 0.000$). The protein level of *MYC* in the four groups was 0.51 ± 0.03 vs 0.52 ± 0.04 vs 0.92 ± 0.02 vs 0.95 ± 0.01 ($P = 0.000$). The protein level of *CCND1* in the four groups was 0.54 ± 0.04 vs 0.56 ± 0.03 vs 0.93 ± 0.01 vs 0.93 ± 0.03 ($P = 0.000$). Both Pgenesil-CA1 and Pgenesil-CA2 plasmids significantly suppressed the growth of SW948 cells when compared with the negative or blank group at 48 h after transfection.

tion (29% vs 25% vs 17% vs 14%, $P = 0.001$), 60 h after transfection (38% vs 34% vs 19% vs 16%, $P = 0.001$), and 72 h after transfection (53% vs 48% vs 20% vs 17%, $P = 0.000$). Numbers of colonies in negative, blank, CA1, and CA2 groups were 42 ± 4 , 45 ± 5 , 8 ± 2 , and 10 ± 3 , respectively ($P = 0.000$). There were more than 4.5 times colonies in the blank and negative control groups as there were in the CA1 and CA2 groups. In addition, the colonies in blank and negative control groups were also larger than those in the CA1 and CA2 groups. The percentage of cells in the CA1 and CA2 groups was significantly higher in G₀/G₁ phase, but lower in S and G₂/M phase when compared with the negative and control groups. Moreover, cell apoptosis rates in the CA1 and CA2 groups were 5.11 ± 0.32 and 4.73 ± 0.32 , which were significantly higher than those in negative (0.95 ± 0.11 , $P = 0.000$) and blank groups (0.86 ± 0.13 , $P = 0.001$). No significant difference was found between CA1 and CA2 groups in cell cycle distribution and apoptosis.

CONCLUSION: *PIK3CA*-targeted short hairpin RNAs can block the phosphoinositide 3-kinase-Akt signaling pathway and inhibit cell growth, increase apoptosis, and induce cell cycle arrest in the *PIK3CA*-mutant colon cancer SW948 cells.

INTRODUCTION

Colon cancer is the fifth most common cancer in the United States, and the third leading cause of cancer-related death in the Western world. The phosphoinositide 3-kinase (PI3K)/Akt signaling transduction pathway is believed to play an important role in carcinogenesis. PI3K is a major signaling component downstream of growth factor receptor tyrosine kinases (RTKs), which may serve as a potential target for colon cancer therapy^[1,2]. PI3K is a heterodimer consisting of a regulatory subunit (p85) and a catalytic subunit (p110). The subtype p110a encoded by the gene phosphoinositide-3-kinase, catalytic, alpha

polypeptide (*PIK3CA*) is very important in phosphorylating phosphatidylinositol (4,5)-bisphosphate (PIP₂) to the lipid second messenger PIP₃, and PIP₃ in turn functions in the recruitment and activation of a wide range of downstream targets, including the serine-threonine protein kinase Akt. Gene reactions distal to the *PI3K*-Akt signaling pathway contribute to tumor cell proliferation, cell cycle progression, energy metabolism, and resistance to apoptosis^[3-6]. Troxell *et al*^[7] found *PIK3CA* mutations were identified in 13/24 breast columnar cell lesions (54%) and 3/8 invasive carcinomas (37%). The high prevalence of *PIK3CA* mutations in breast cancer is an emerging tumor marker which might become used in treatment-choosing process^[8]. Higgins *et al*^[9] detected the *PIK3CA* status in metastatic breast cancer using peripheral blood, and found plasma level of *PIK3CA* presented predictive biomarkers of response to targeted therapies. *PIK3CA* mutations were detected in 18% patients with breast and gynecologic malignancies, and cases with *PIK3CA* mutations treated with its inhibitors demonstrated a higher response rate than patients without mutations^[10]. Studies demonstrated *PIK3CA* mutations were not common, but its amplification was very common in gastric cancer, Akt (p-Akt) was often functionally linked to tumor progression and metastasis in gastric cancer, and double-stranded RNA (dsRNA) mediated targeting of *PIK3CA* may specifically knockdown the expression of *PIK3CA*, providing a potential implication for therapy of cancer^[11-13].

RNA interference (RNAi) is a potent gene-silencing tool, which is triggered by the introduction of dsRNA. Degradation of mRNA homologous to dsRNA can cause a post-transcriptional gene-silencing effect. Recently, the vector-based RNAi has been developed in order to achieve long-term and stable effects. Short hairpin RNA (shRNA) is formed by hairpin structures and stretches of dsRNA. After being cleaved by a ribonuclease dicer, it becomes mature microRNA (miRNA) inside the targeted cells^[14-17].

In our study, two shRNA plasmid vectors were constructed against the gene *PIK3CA*, and were transfected into the colon cancer cell line SW948. Their effects on cell proliferation and cycle distribution in this cell line were investigated.

MATERIALS AND METHODS

Cell line and culture

The human colon carcinoma cell line SW948 was routinely grown in Leibowitz's L-15 medium supplemented with 10% fetal calf serum, penicillin (100 U/mL), and streptomycin (100 µg/mL) at 37 °C in a humidified 5% CO₂/95% air atmosphere.

RNA silencing

Two small interference RNA (siRNA) for *PIK3CA* were designed according to the consensus sequence of the *PIK3CA* gene (GeneBank NM_006218) obtained from the online database of the National Center for Biotech-

nology Information, and then were cloned separately into the vector plasmid Pgenesil-1. One sequence, 5'-GCTAT-CATCTGAACAATTA-3' was designated Pgenesil-CA1, and the other 5'-GGATAGAGGCCAAATAATA-3' was designated Pgenesil-CA2. Both were verified in a basic local alignment search tool search of the database. An siRNA scrambled sequence 5'-GACTTCATAAGGCG-CATGC-3', designated Pgenesil-Neg, was used as a negative control. All siRNA sequences were synthesized by Invitrogen (Carlsbad, CA). The multicloning sites of plasmid Pgenesil-1 containing enhanced green fluorescent protein gene were as follows: *Hind*III-*ShRNA-Bam*H I -U6Promotor-*Eco*R I -*Sal*I -*Xba*I -*Dra*III. All the above RNAi sequences were transcribed with DNA polymerase III U6 promoter. Cells at 80%-90% confluency were transfected with the three shRNA vectors CA1, CA2, and Neg group, described above. Transfections were performed using lipofectamine TM2000 (Invitrogen, United State) according to the manufacturer's instructions. The Blank group was also treated with only LipofectamineTM2000, but without vector. Six hours post-transfection, 500 μ L of fetal bovine serum (FBS) was added per well. Twenty-six hours after transfection, the medium was replaced by normal medium containing 10% FBS and antibiotics up to 72 h post-transfection. The transfection effectiveness was calculated basing on the rate of fluorescence cell of SW948 at 6 h after transfection.

RNA isolation and semiquantitative reverse transcription polymerase chain reaction

Cultured cells (described above) were harvested 48 h post-transfection. Total messenger RNA was extracted from these cells using the RNeasy kit. Reverse transcription polymerase chain reaction was performed using 500 ng of total RNA samples with oligo dT primers (Fermentas, United States). β -actin mRNA was included as an internal standard for quantitative analysis. The primer pairs used in this study are listed in Table 1. Samples in each group were run in triplicate. The photodensity of the goal gene product was normalized with respect to β -actin content.

Western blotting

Cells were harvested 48 h post-transfection, and were washed twice in ice-cold 1 \times phosphate-buffered saline (PBS). Cell pellets were treated with the lysis buffer, and whole cell extracts were isolated. Proteins were resolved by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (10%), then transferred onto a polyvinylidene fluoride membrane, and subjected to immunohybridization analysis using a monoclonal antibody against the targeted proteins (Santa Cruz Biotechnology, Inc., United States). Peroxidase-conjugated secondary antibody was added later (Bolster, China). Hybridized protein bands were displayed *via* chemiluminescence reagents (Santa Cruz Biotechnology, Inc., United State) according to the manufacturer's instructions. β -actin staining was used as an internal standard. All experiments were performed in triplicate.

3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay

The transfected cells were seeded in 96-well plates (1 \times 10⁴/mL), and were allowed to attach for 24 h. Thiazolyl blue tetrazolium bromide (MTT, Sigma, United States) was dissolved in 1 \times PBS at a concentration of 5 mg/mL, and filtered as a stock solution. Ten microlitres of stock solution were added to 100 μ L of medium in each well. The plates were incubated for 4 h at 37 $^{\circ}$ C. After loading of 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT), medium was replaced with 100 μ L dimethyl sulfoxide, and was incubated for 30 min at room temperature for color development. Results were read by an enzyme-linked immunosorbent assay reader (570 nm, DG-3022A, United States) to determine absorbance values (*A*). In each group, time points for detection of absorbance values were 36, 48, 60 and 72 h after transfection. The inhibition rate was calculated as follows: Inhibition rate (IR) = [1 - *A*₁/*A*₂] \times 100%, where *A*₁ is the absorbance value of the observation group, and *A*₂ is the absorbance value of the control group.

Soft-agar colony-formation assays

Different groups of cells were mixed with culture medium containing agar at a final concentration of 0.4% 24 h after transfection. One milliliter of cell suspension was seeded onto 6-well plates coated with 0.5% agar in culture medium. Colonies greater than 60 μ m in diameter at \times 100 magnification were counted in each plate to measure the colony efficiency after 10 d incubation. The assays were performed in triplicate.

Flow cytometry

Flow cytometry was used to assess cell cycle and apoptosis. Cells were harvested 72 h after incubation, and then were washed with cold 1 \times PBS and fixed with 80% ethanol overnight at -20 $^{\circ}$ C. Next, cells were treated with RNase A (Sigma, United States), and were stained with propidium iodide (PI, Sigma, United States). All samples underwent analysis using flow cytometry (Becton Dickinson, United States). The experiments were performed three times.

Statistical analysis

Results of experimental data are reported as mean \pm SE. Significance levels were determined by one-way analysis of variance and Student's *t* test using SPSS 11.5 Statistics software. A statistically significant result is indicated by a *P* < 0.05.

RESULTS

PIK3CA-specific shRNA inhibited mRNA and protein expression of target genes

SW948 transfected with plasmid Pgenesil-1 presented green fluorescence, and the transfection effectiveness was about 65% (Figure 1). Forty-eight hours post-transfection, the expression of mRNA and protein from targeted genes was tested in SW948 cells. The results are shown in Figure 2, Tables 1 and 2. All mRNA and protein expres-

PIK3CA: Phosphoinositide-3-kinase, catalytic, alpha polypeptide. ^a*P* = 0.001, ^b*P* = 0.000 *vs* negative or blank group.

Table 3 Phosphoinositide-3-kinase, catalytic, alpha polypeptide short hairpin RNA suppressed SW948 cell proliferation (%)

	Blank	Negative	CA1	CA2
36 h	13	14	17	15
48 h	14	17	29 ^a	25 ^a
60 h	16	19	38 ^a	34 ^a
72 h	17	20	53 ^b	48 ^b

^a*P* = 0.001, ^b*P* = 0.000 *vs* negative or blank group.

Pgenesil-CA1 or Pgenesil-CA2 (*P* < 0.001, *vs* negative or blank group). No significant difference was found between the CA1 and CA2 groups. Pgenesil-Neg plasmid had no significant inhibitory effect on the expression of mRNA or protein.

PIK3CA RNA silencing inhibited SW948 cell proliferation

The effect of *PIK3CA* silencing on proliferation of SW948 cells was analyzed by the MTT assay. As demonstrated in Table 3, both Pgenesil-CA1 and Pgenesil-CA2 plasmids significantly suppressed the growth of SW948 cells when compared with the negative or blank group.

Soft-agar colony-formation assays

Soft-agar colony-formation assays were used to analyze the anchorage-independent proliferation of SW948 cells. Numbers of colonies in negative, blank, CA1, and CA2 group were 42 \pm 4, 45 \pm 5, 8 \pm 2, and 10 \pm 3, respectively. There were more than 4.5 times more than colonies in the blank and negative control groups as

Table 4 Effect of short hairpin RNA interference on cell cycle distribution and apoptosis (%)

Group	G ₀ /G ₁	S	G ₂ /M	Apoptosis
Blank	35.41 ± 2.63	47.54 ± 3.87	16.74 ± 1.59	0.86 ± 0.13
Negative	40.12 ± 2.54	41.71 ± 2.16	17.57 ± 1.26	0.95 ± 0.11
CA1	79.72 ± 4.63 ^a	15.24 ± 1.28 ^a	4.37 ± 0.43 ^b	5.11 ± 0.32 ^a
CA2	77.93 ± 4.31 ^a	16.71 ± 0.89 ^a	5.17 ± 0.29 ^a	4.73 ± 0.32 ^b

^aP = 0.001, ^bP = 0.000 vs negative or blank group.

there were in the CA1 and CA2 groups. In addition, the colonies in blank and negative control groups were also larger than those in the CA1 and CA2 groups.

Effect of PIK3CA shRNA on cell cycle distribution and apoptosis

As shown in Table 4, the percentage of cells in the CA1 and CA2 groups was significantly higher in G₀/G₁ phase, but lower in S and G₂/M phase when compared with the negative and control groups. Moreover, cell apoptosis rates in the CA1 and CA2 groups were around 5%, which was significantly higher than those in negative and blank groups. No significant difference was found between CA1 and CA2 groups in cell cycle distribution and apoptosis.

DISCUSSION

One of the areas of greatest interest in cancer research concerns the coordination of cancer cell proliferation and apoptosis. The balance between cell proliferation and apoptosis, and the distribution of cell cycles play very important roles in the process of carcinogenesis in colon cancer^[18]. Abnormal activation of the PI3K signaling pathway can cause hyper-proliferation of intestinal crypt progenitors, and promote the transformation of a normal cell to a cancer cell. This process involves a series of complicated molecular activities. The PI3K signaling cascade begins with the phosphorylation of PIP2 to PIP3, which is largely regulated by the balance of activity of PTEN and PI3Ks. Many investigators have reported that mutations of PI3Ks contribute to the process of carcinogenesis in colon cancer^[2,5]. Liao *et al.*^[19] reported that co-existence of PIK3CA exon 9 and 20 mutations, but not PIK3CA mutation in either exon 9 or 20 alone, was associated with poor prognosis of colorectal cancer patients. Thus, PI3K has become the focus of considerable attention for research into the treatment of colon cancer. Small-molecule inhibitors targeting PI3K are important to investigate, but their toxicity, drug resistance, and side-effects have prevented widespread use of these compounds^[20]. Therefore, more efficient and safer new methods have been developed to solve those problems.

RNA interference is a ubiquitous mechanism of eukaryotic gene regulation, and an excellent strategy for specific gene silencing. Recently the vector-based approach of shRNA interference has been developed in order to achieve highly specific suppression of gene ex-

pression in mammalian cells. ShRNA is formed by hairpin structures and stretches of double-stranded RNA, which determine the specificity of RNA interference. Previous reports about ShRNA interference have demonstrated their easy and stable introduction into cells, and more importantly, their consistently efficacy, which has potential as a new method for cancer therapy^[15-17,21].

PI3K is a heterodimer composed of a regulatory subunit (p85) and a catalytic subunit (p110), which has three isoforms. Among them, p110a (PIK3CA), is an important catalytic subunit that is implicated in a wide range of cancers including colon cancer. Beuers *et al.*^[22] reported strong associations were found between KRAS, PIK3CA mutations and colorectal cancers. Dukes' staging, and KRAS and PIK3CA bi-mutations were more likely to develop into liver metastasis. It naturally serves as a potent potential target for colon cancer therapy^[2-6]; however, the use of an RNA interference technique for PIK3CA gene silencing in established colon cancer cell lines has rarely been reported. In a previous study, Wee *et al.*^[23] reported successful PIK3CA gene depletion by RNA interference and consequential inhibition of proliferation in the colon cancer cell lines HCT116 and DLD1; however, the down-regulation of PIK3CA gene expression by RNAi in other colon cancer cell line has not been reported, due to the limited availability of colorectal carcinoma cell lines with PIK3CA gene mutation. Herein we describe our experience with the effects of two PIK3CA-specific shRNAs on cell proliferation and apoptosis in the colon cancer cell line SW948, which harbors mutation in the PIK3CA gene.

In this study we used plasmid Pgenesil-1 as vector into which two PIK3CA-specific interference sequences were successfully inserted. The vector Pgenesil-1 could transcribe and generate interfering RNAs continually under the control of U6 promoter. Thus, a persistent gene knock-down effect could be achieved by successfully transfecting the vectors into SW948 cells. Our results demonstrated that these two PIK3C-specific shRNAs both showed evident effects on silencing the PIK3CA gene either at the mRNA or at the protein level. At the same time, the expression of downstream genes, namely AKT1, MYC, and CCND1 was also significantly suppressed. MTT assays demonstrated that cell proliferation in the PIK3CA knockdown groups was significantly inhibited from 48 to 72 h after transfection. Similar results were achieved in detecting anchorage-independent cell proliferation by soft agar colony formation assays, in which significant reduction in either the number or the size of colonies was found in both CA1 and CA2 groups. These results suggest that PIK3CA knockdown by specific shRNAs decreased the abilities of SW948 cells to form colonies in soft agar, which was consistent with Wee's report^[23]. Our results revealed that these two PIK3CA-specific shRNAs expressed an anti-proliferation function in the PIK3CA-mutant cancer cells, and suggest that they may have therapeutic potential for colon cancer.

Our flow cytometry results showed cell cycle arrest

at G₁/S, and an increase in apoptosis in these two *PIK3CA*-specific shRNAs-transfected SW948 cells, which may have caused the inhibition of cell growth. This finding is consistent with previously published results in the HCT116 cell line^[23]. Akt, a major downstream effector of PI3K, is activated by phosphoinositide-dependent protein kinase 1, and plays an important role in cell proliferation, apoptosis, cell motility and invasion^[12]. Lots of studies have shown that Akt is activated in a variety of malignances, and is often functionally linked to cancer progression and metastasis^[13]. Another possible mechanism is that *AKT* down-regulation induced by *PIK3CA* gene silencing resulted in the degradation of cyclinD1 and down-regulation of c-myc expression *via* GSK3 β activity. CyclinD1 is a regulatory kinase that is critical in modulating the cell cycle through G₁ to S phase. C-myc is a positive regulator of G₁-specific cyclin-dependent kinases. Over-expression of these two genes may stimulate cells to overcome the cell cycle checkpoints, and thus enhance cell proliferation^[24,25]. Inhibition of these two genes may result in cell cycle arrest and increased apoptosis, and thus inhibit cell growth. Migliardi *et al*^[26] reported that PI3K/mTor inhibitor BEZ235 could produce prevalent growth-suppressive effects in patient-derived xenografts of RAS-mutant colorectal carcinomas.

In conclusion, our experiment showed that the shRNA targeted against *PIK3CA* could specifically silence the *PIK3CA* gene and consequentially suppress the expression of its downstream genes including, *AKT1*, *MYC*, and *CCND1*. This silencing effect on these genes could efficiently inhibit the growth of *PIK3CA*-mutant colon cancer SW948 cells, and might be a potential approach for treating human *PIK3CA*-mutant colon cancer.

COMMENTS

Background

The phosphoinositide-3-kinase (PI3K)/Akt signaling transduction pathway is believed to play an important role in carcinogenesis. PI3K is a major signaling component, which is a heterodimer consisting of a regulatory subunit (p85) and a catalytic subunit (p110). The subtype p110a encoded by the gene phosphoinositide-3-kinase, catalytic, alpha polypeptide (*PIK3CA*) is very important in phosphorylating, and may serve as a potential target for colon cancer therapy.

Research frontiers

The coordination of cell proliferation and apoptosis in cells is one of the hotspots in cancer research. The balance between cell proliferation and apoptosis, and the distribution of cell cycles play very important roles in the carcinogenesis process of many cancers. *PIK3CA* is the key component in this process. Thus *PIK3CA* might be a gene therapy target for lots of cancers include colon carcinoma.

Innovations and breakthroughs

In this study, two *PIK3CA* specific shRNAs showed their evident effect on silencing the *PIK3CA* gene. The results also indicated that *PIK3CA* shRNA inhibits cell growth and induces apoptosis of SW948 cell.

Applications

The shRNA interference targeted against *PIK3CA* may have potential therapeutic utility in human *PIK3CA*-mutant colon cancer.

Terminology

The official name of *PIK3CA* is "phosphoinositide-3-kinase, catalytic, alpha polypeptide". It is located on the long(q) arm of chromosome 3 at position 26.3. Phosphatidylinositol 3-kinase is composed of an 85 kDa regulatory subunit and a 110 kDa catalytic subunit. The protein encoded by *PIK3CA* gene represents the catalytic subunit. The *PIK3CA* gene has been found to be oncogenic and is

mutated in a range of human cancers. Due to the association between *PIK3CA* and cancer, it is believed to be a promising drug target.

Peer review

The *PIK3CA* knock-down effect on cells was investigated in the present study. The results showed that shRNAs transfection down-regulated *PIK3CA* and its downstream genes such as *Akt1*, *MYC* and *CCND1*, and inhibited cell growth. Further, it was demonstrated that cell cycle arrest and apoptosis were induced in *PIK3CA* shRNAs-transfected SW948 cells. The study appears to be interesting and may have therapeutic implication.

Abstract

AIM: To explore endoscopic therapy methods for gastric stromal tumors originating from the muscularis propria.

METHODS: For 69 cases diagnosed as gastric stromal tumors originating from the muscularis propria, three types of endoscopic therapy were selected, based on the size of the tumor. These methods included endoscopic ligation and resection (ELR), endoscopic submucosal excavation (ESE) and endoscopic full-thickness resection (EFR). The wound surface and the perforation of the gastric wall were closed with metal clips. Immunohistostaining for CD34, CD117, Dog-1, S-100 and smooth muscle actin (SMA) was performed on the resected tumors.

RESULTS: A total of 38 cases in which the tumor size was less than 1.2 cm were treated with ELR; three cases were complicated by perforation, and the perforations were closed with metal clips. Additionally, 18 cases in which the tumor size was more than 1.5 cm were treated with ESE, and no perforation occurred. Finally, 13 cases in which the tumor size was more

than 2.0 cm were treated with EFR; all of the cases were complicated by artificial perforation, and all of the perforations were closed with metal clips. All of the 69 cases recovered with medical treatment, and none required surgical operation. Immunohistostaining demonstrated that among all of the 69 gastric stromal tumors diagnosed by gastroscopy, 12 cases were gastric leiomyomas (SMA-positive), and the other 57 cases were gastric stromal tumors.

CONCLUSION: Gastric stromal tumors originating from the muscularis propria can be treated successfully with endoscopic techniques, which could replace certain surgical operations and should be considered for further application.

Endoscopic therapy for gastric stromal tumors originating from the muscularis propria. *World J Gastroenterol* 2012; 18(26): 3465-3471 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i26/3465.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i26.3465>

INTRODUCTION

Gastric stromal tumors are the most common mesenchymal tissue-originated tumors in the digestive tract; these tumors are often found at the gastric fundus, the front wall of the gastric corpus and the antrum and can be sorted based on tissue of origin as originating from the muscularis mucosae or the muscularis propria. As the location of the tumors originating from the muscularis

mucosae is superficial, endoscopic resection or ligation has been widely performed to treat these tumors. In contrast, the location of the tumors originating from the muscularis propria is deep, especially when the tumors grow outside the gastric wall, so perforation often occurs during endoscopic therapy and the tumor cannot be resected easily and thoroughly. Therefore, this tissue of origin has often been considered to be a contraindication for endoscopic therapy, and the traditional treatment for such tumors is a surgical or laparoscopic operation^[1-5]. In recent years, on the basis of sufficient clinical practice, we treated gastric stromal tumors originating from the muscularis propria with endoscopic techniques and obtained satisfactory therapeutic effects, which are reported as follows.

MATERIALS AND METHODS

Patients

A total of 69 patients (36 males and 33 females, age range 24-68 years, mean age 42.5 years) were diagnosed with gastric stromal tumors originating from the muscularis propria by gastroscopy and endoscopic ultrasonography from January 2008 to March 2011. Among the 69 cases, 19 tumors were located at the gastric antrum, 24 tumors were located at the gastric corpus, and 26 tumors were located at the gastric fundus. Each patient exhibited only one tumor, and no metastasis was detected *via* computed tomography (CT) examination. Routine blood tests, tests of blood coagulation function and hepatic and renal function, electrocardiograms and abdominal CTs were performed before the endoscopic therapy, and each patient's written informed consent was obtained.

Instruments

The following instruments were used: Electronic gastroscopy (Olympus GIF-Q260J, Olympus company, Japan), hyaline cap (D-201-11304, Olympus company, Japan), spiculiform cutting knife (KD-1 L-1, Olympus company, Japan), IT knife (KD-611 L, Olympus company, Japan), hook knife (KD-620 LR, Olympus company, Japan), injection needle (NM-200 L-0525, Olympus company, Japan), snare (AS-1-S, ASJ-1-S, COOK company, United States), hot biopsy forceps (FD-410 LR, Olympus company, Japan), hemostatic clip (HX-610-90, Olympus company, Japan; HX-600-135, Olympus company, Japan; Boston Resolution™, Boston company, United States), high frequency electric knife (ERBE VIO 200S, ERBE company, Germany) and Argon Plasma Coagulation instrument (ERBE APC₂, ERBE company, Germany).

Endoscopic therapeutic methods

Endoscopic ligation and resection: Endoscopic ligation and resection (ELR) was used for gastric stromal tumors of which the size was less than 1.2 cm. A COOK ligator was assembled on the tip of the gastroscopy, and the gastroscopy was inserted into the stomach. The ligator was aimed at the tumor, and sufficient aspiration

was applied to the tumor that the whole tumor entered the ligator, at which time the rubber band on the ligator was released to ligate the tumor. The purpose of the ligation was to manipulate the gastric stromal tumor into the shape of a polypoid, after which a snare was used to hitch the tumor, and it was resected. The resected tumor was removed for pathologic diagnosis, and the stump was closed with metal clips. If the procedure was complicated by perforation, the perforation was generally small and could be closed with metal clips (Figure 1).

Endoscopic submucosal excavation: Endoscopic submucosal excavation (ESE) was performed for gastric stromal tumors originating from the muscularis propria by the following steps. (1) Marking: Argon plasma coagulation (APC) was used to mark the border of the gastric stromal tumor; (2) Submucosal injection: A mixture of indicarminum, adrenalin and physiological saline (2-3 mL of indicarminum, 1 mL of adrenalin and 100 mL of physiological saline) was injected at the lateral of the mark; (3) Dissection: the mucosa was dissected with a needle knife; (4) Excavation: the submucosa was dissected with a needle knife; when the tumor was exposed, dissection was performed around the margin of the tumor, and when the dissection was finished, the tumor could be resected wholly with a snare; and (5) Wound surface handling: for small vessels bleeding on the surface, hot biopsy forceps or APC could be used for hemostasis, and if necessary, metal clips could be used (Figure 2).

Endoscopic full-thickness resection: A hyaline cap was assembled on the tip of the gastroscopy before the endoscopic full-thickness resection (EFR) procedure, and intravenous anesthesia was performed using propofol for patients. EFR was then performed using the following steps. (1) Pre-cutting the mucosa and submucosa around the gastric stromal tumor: APC was used to mark the margin of the tumor; a mixture of indicarminum, adrenalin and physiological saline (2-3 mL of indicarminum, 1 mL of adrenalin and 100 mL of physiological saline) was injected at the lateral portion of the mark, using approximately 2-3 mL of the mixture for each injected point; the mucosa and submucosa around the gastric stromal tumor were pre-cut with a hook knife, and thus the tumor was exposed; (2) Dissection of the muscularis propria around the gastric stromal tumor: a hook knife or IT knife was used to dissect the tumor from the muscularis propria to the serous membrane; (3) Dissection of the serous membrane around the tumor: typically, the tumor was in compact adhesions with the serous membrane; thus the tumor could not be directly dissected with an IT knife, so instead, the serous membrane was cut around the tumor with a needle knife or hook knife, and an "artificial" perforation was made; (4) Full resection of the tumor: the liquid in the stomach was aspirated completely, and an IT knife or hook knife was used to cut the serous membrane around the tumor, after which the tumor was completely resected; and (5)

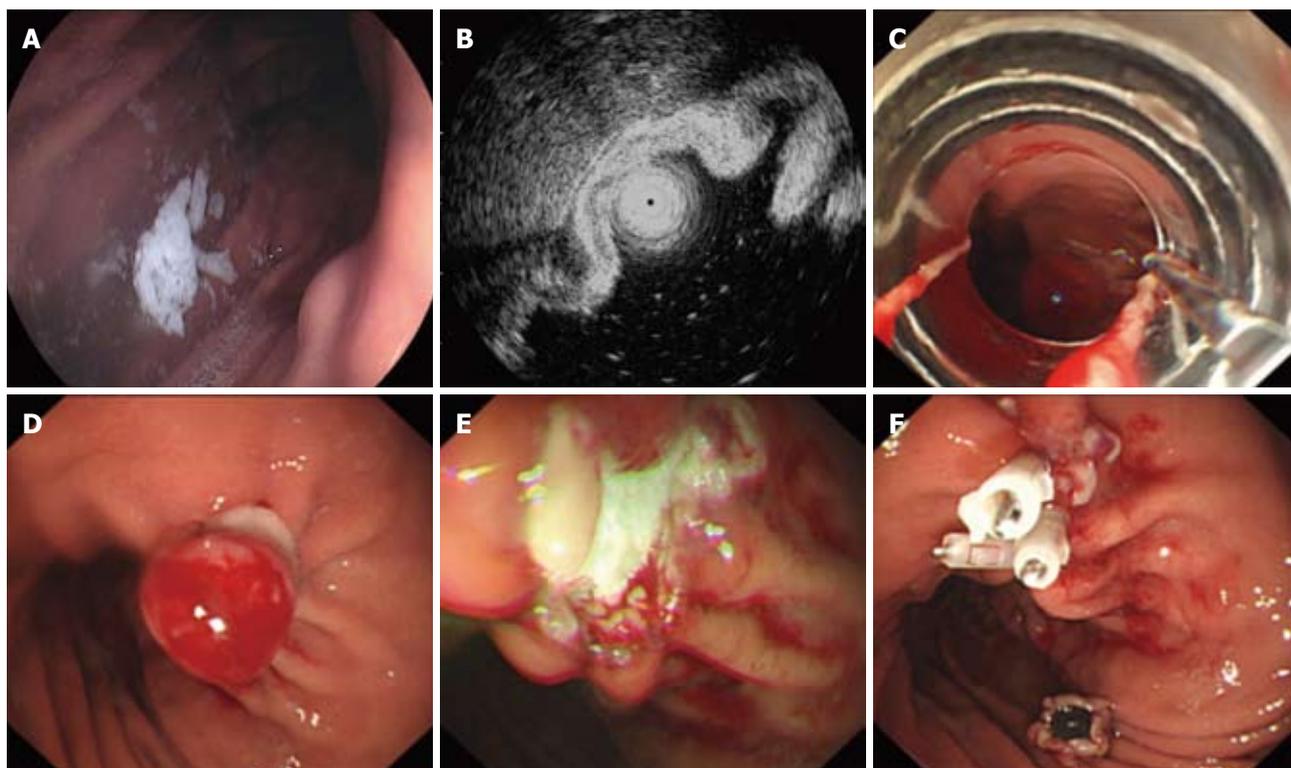

Figure 1 Endoscopic ligation and resection treatment for a gastric stromal tumor less than 1.2 cm in size originating from the muscularis propria. A: Submucosa lesion at the posterior wall of the gastric corpus; B: Endoscopic ultrasound shows that the lesion originates from the muscularis propria; C: COOK ligator aimed at the lesion, ready to ligate; D: The ligated stromal tumor was in the shape of a polypoid with deuto-stem; E: A snare was used to cut the tumor above the rubber band; F: The wound surface was closed with metal clips.

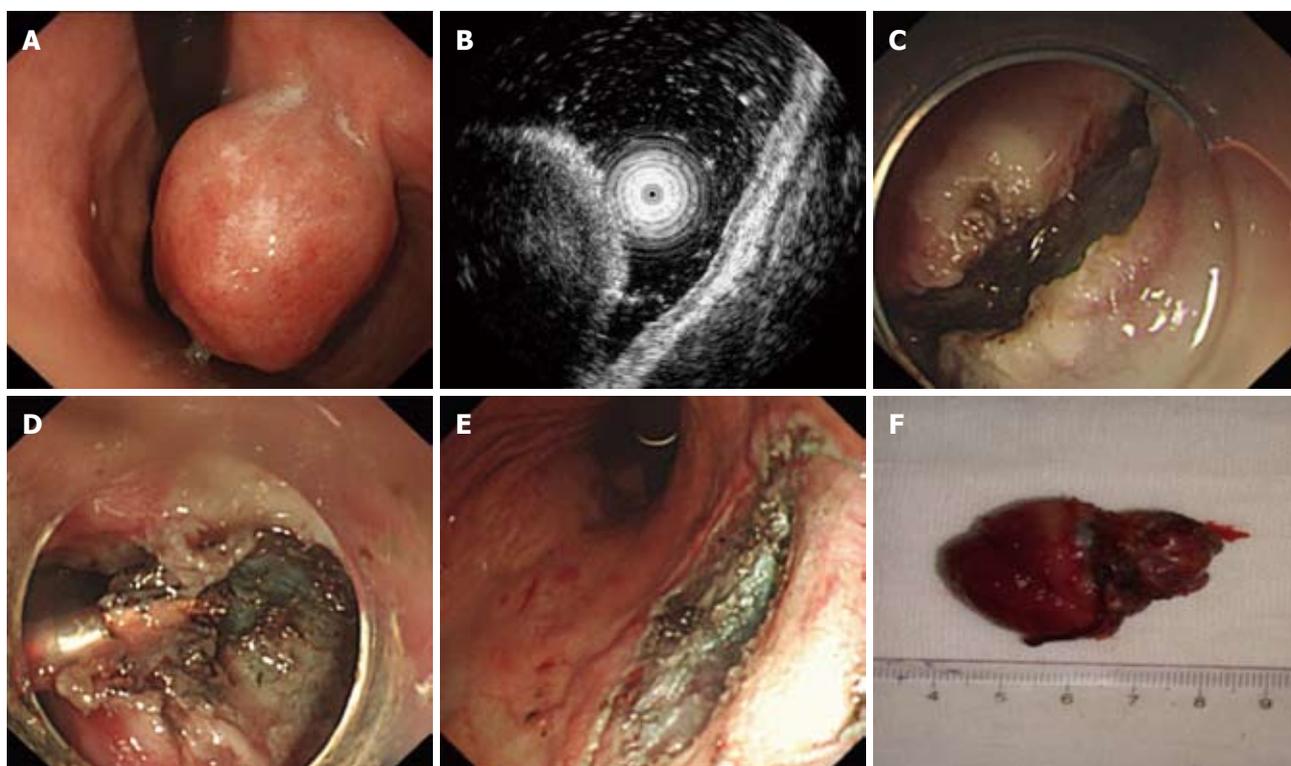

Figure 2 Endoscopic submucosal excavation treatment for a gastric stromal tumor originating from the muscularis propria that is larger than 1.2 cm. A: Submucosa lesion at the gastric corpus; B: Endoscopic ultrasound shows that the lesion originates from the muscularis propria; C: The mucosa of the stromal tumor was cut after submucosal injection; D: Dissection with an IT knife; E: The excavated wound surface, showing that no perforation occurred; F: The resected stromal tumor (4 cm in size).

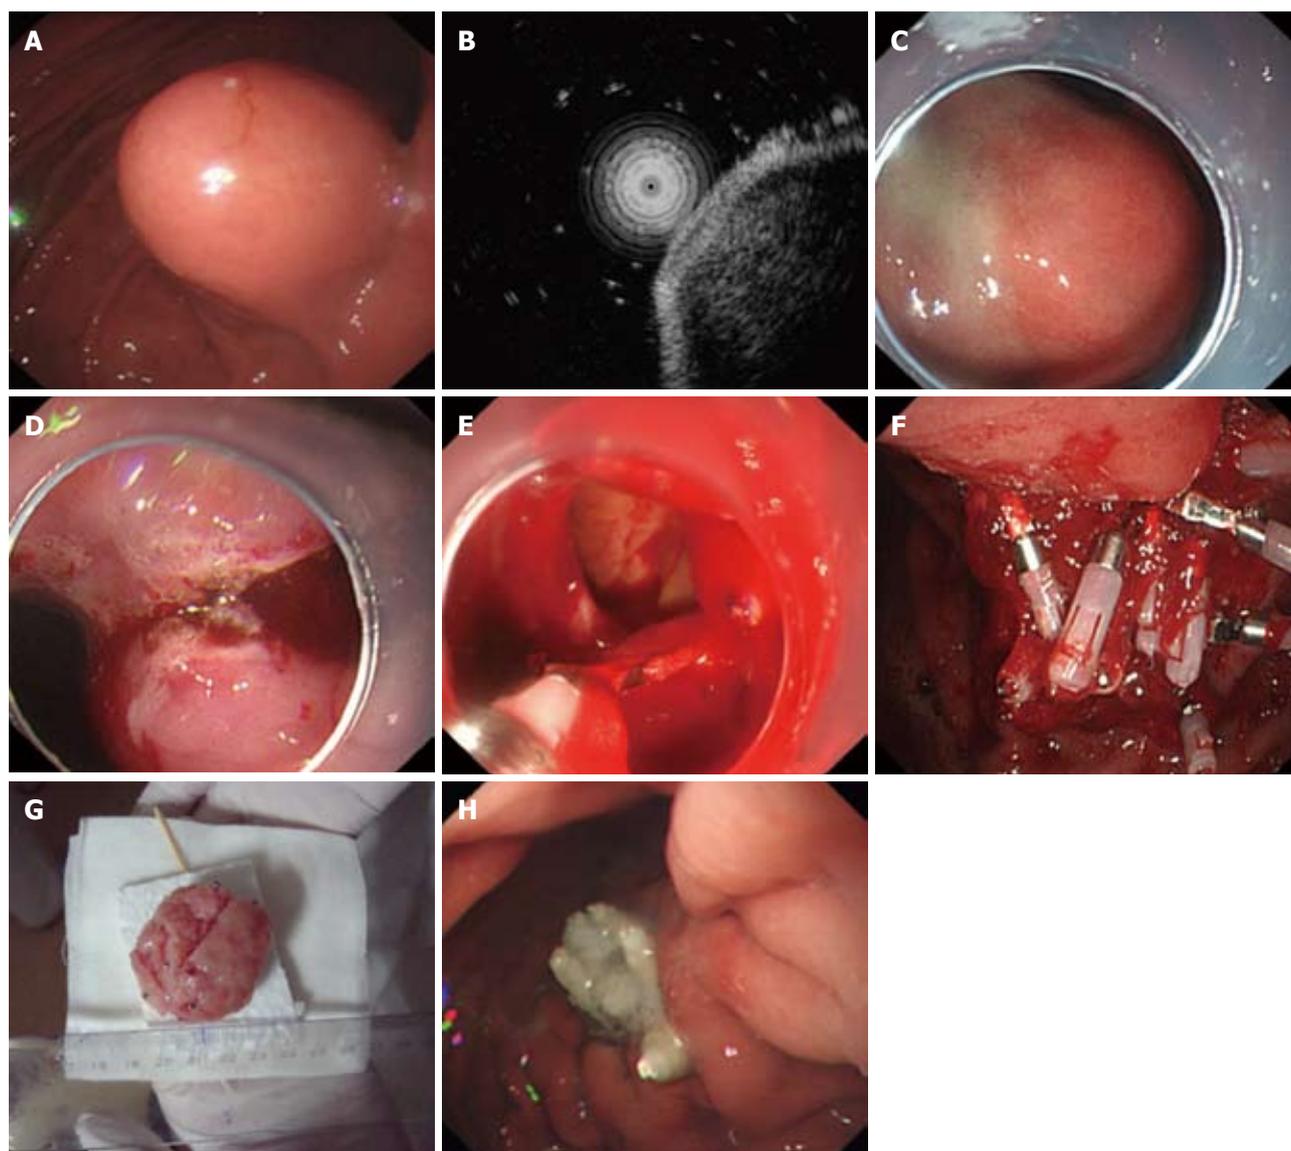

Figure 3 Endoscopic full-thickness resection treatment for a gastric stromal tumor originating from the muscularis propria larger than 1.2 cm. A: Submucosa lesion at the gastric corpus; B: Endoscopic ultrasound shows that the lesion originates from the muscularis propria; C: Submucosal injection of the mixture of indicarninum, adrenalin and physiological saline; D: Dissection with an IT knife; E: “Artificial” perforation after gastric stromal tumor resection, closed with metal clips; F: Many clips used to close the wound defect; G: The resected tumor without mucosa (5 cm in size); H: The perforation healed 9 d after endoscopic full-thickness resection.

Closure of the wound surface of the stomach: a metal clip was used to close the wound surface from the rim to the center. If the wound surface defect was too large to be closed with a metal clip directly, negative pressure aspiration was used to aspirate the omentum majus into the stomach, and then a metal clip was used to close the wound surface defect (Figure 3).

Specimen handling

The resected specimens were fixed in neutral formalin for pathologic diagnosis. Immunohistostaining of CD34, CD117, Dog-1, S-100 and smooth muscle actin (SMA) was performed for specimens suspected of being gastric stromal tumors^[6-10].

Postoperative handling

For patients without perforation, the measures of fast-

ing, infection prevention and limiting acid with proton pump inhibitors were sufficient. For patients with “artificial” perforation, if pneumoperitoneum was serious, evacuation was performed during and after the operation. The evacuating needle was inserted into the lower right quadrant to release abdominal distension. A semi-reclining position was recommended after the operation, along with the use of fasting and gastrointestinal decompression, to allow the perforation to heal. Abdominal pain, abdominal distension and signs of peritoneal irritation after the operation were carefully observed. Meglumine diatrizoate was recommended to be taken orally three days after the operation. To confirm whether there was extravasation of the contrast media and to observe stomach motivation, ultrasonic examination was conducted to observe whether there was hydrops in the abdominal cavity and pelvic cavity. Gastroscopy was

performed one month after the operation to observe the conditions of the wound surface and whether there was residual or recurrence.

RESULTS

Effects of endoscopic therapy

ELR: Thirty-eight patients with gastric stromal tumors with a size of less than 1.2 cm underwent ELR, in which the tumor was ligated wholly and then resected. The procedure was complicated by perforations in 3 patients, and all of the wound surfaces and perforations were closed with metal clips. The patients recovered with medical treatment, and no patient needed surgical operation.

ESE: Eighteen patients with gastric stromal tumors in which the size of the specimen resected was more than 1.5 cm underwent ESE. The tumors were resected successfully, and no perforations complicated the procedure.

EFR: Thirteen patients with gastric stromal tumors, for which the size of the specimen resected was more than 2.0 cm, underwent EFR. The tumors were resected successfully, but “artificial” perforation occurred in all of the patients. All of the perforations were closed with metal clips, and meglumine diatrizoate upper gastroenterography three days after the operation showed that there was no extravasation of the contrast media. Gastroscopy showed that the wound surface of the stomach was nearly healed on the 9th day after the operation (Figure 3H).

Immunohistostaining

The positive expression rates of CD34, CD117, Dog-1, S-100 and SMA in the 69 patients who were diagnosed with gastric stromal tumors by gastroscopy were 81.2% (56/69), 82.6% (57/69), 82.6% (57/69), 0% and 17.4% (12/69), respectively, which demonstrated that, among the 69 patients, there were 12 leiomyomas, which express SMA; the other 57 patients had gastric stromal tumors.

Average stay

The average stay for all of the patients was 8.4 ± 2.4 d.

Residual or recurrence of the tumor

Gastroscopy and abdominal CT scans were performed one month after the operation; these procedures showed that the wound surfaces had healed, and there was no residual or recurrence.

DISCUSSION

Stromal tumor is the most common mesenchyme-originated tumor; as it has potential cancerous tendencies, gastric stromal tumor is recommended to be resected^[11-15]. For gastric stromal tumors originating from the muscularis propria in which the size was less than 1.2 cm, ELR was the ideal method^[16]. After ligation, each

tumor was in the shape of a polypoid with a deuto-stem, which made snare resection easy; additionally, a pathologic diagnosis could be obtained with the resected tumor. Because the wound surface in the stomach was not large, perforation would not generally occur; however, if perforation did occur, it could be closed with metal clips. With the medical treatment of fasting, gastrointestinal decompression and proton pump inhibitors, the patients would recover. There were 38 patients in this study in whom the tumor size was less than 1.2 cm; these patients were treated with ELR. Moreover, 3 of these patients were complicated by perforation; the perforations were closed with metal clips, and no surgical assistance was required. Because the texture of the stromal tumor was hard, it could not be as easily aspirated as mucosa or vascular tissue, so the ligation for the stromal tumor required a long period of aspiration. According to our experience, when the stromal tumor was ligated, a red-colored sign occurred when the tumor was aspirated, and at least another one-minute maximum aspiration was necessary to ensure that the rubber band could fully hitch the tumor.

ESE is another effective measure for the treatment of tumors originating from the submucosa or muscularis propria. For tumors of 3.0 cm or less in size originating from the muscularis propria, the achievement ratio of ESE was high and the patient suffered less, whereas the complication rate was low. ESE was able to excavate the whole tumor successfully, and a pathologic diagnosis could be performed using the resected specimen, which was able to provide a systemic and safe therapeutic method for each patient. In this study, there were 18 patients with gastric stromal tumors originating from the muscularis propria who underwent ESE; all of the tumors were excavated wholly, and no perforations occurred.

For patients with gastric stromal tumors originating from the muscularis propria, the perforation rate of endoscopic therapy is high; therefore, the traditional treatment method is surgical operation or therapeutic laparoscopy, especially for stromal tumors larger than 2 cm^[17-20]. A total of 13 patients in this study underwent EFR, and perforation occurred in all of the patients. The sizes of the 13 tumors were all larger than 2 cm, all of the perforations were closed with metal clips, the abdominal cavity pressure decreased with the use of abdominal paracentesis, all of the patients recovered with medical treatment, and no patients needed surgical help. The key point in avoiding complications was the use of endoscopic metal clips for oversewing; according to our experience, for larger perforations, the perforation should be closed with metal clips from rim to center, known as oversewing, and even some normal mucosa should be sewed up to decrease the perforation. The key point for successful EFR is to mend the perforation successfully, avoiding surgical mending and postoperative peritonitis^[21,22]. The most widely used method to mend perforation is metal clip sutura^[23,24]. For small perforations, one or several metal clips could oversee the per-

foration completely. For larger perforations, as the span of the metal clip is limited, the gas in the stomach must be aspirated properly to reduce the perforation, and several metal clips should be used to close the perforation. If the perforation is too large to be oversewn with metal clips directly, the retina mending method is recommended^[25,26]. The gas in the stomach should be aspirated with continuous negative pressure until the adipose tissue outside the gastric wall covers the perforation, at which point the perforation is closed with metal clips. The other essential point for EFR is to avoid too much gastric juice entering the abdominal cavity; to prevent postoperative infection, strict hemostasis for the wound surface should be performed, but repeat rinse hemostasis should be avoided during the procedure^[27]. The gas and liquid in the stomach should be aspirated fully before cutting the serous membrane. Postoperative gastrointestinal decompression, proton pump inhibitors and antibiotics were effective measures to prevent abdominal cavity infection, and no complications of peritonitis or peritoneal abscesses occurred in this study.

Pneumoperitoneum caused by perforation after EFR can influence the field of vision in the stomach, making endoscopic operation difficult; thus, during EFR, repeated abdominal touch was necessary. If the pressure in the abdominal cavity increased, prompt evacuation was needed; the puncture site was in the right lower quadrant, and the needle was a commonly used 20 mL injection needle. After puncture, the abdomen was compressed to exhaust the air, the needle was detained until the perforation was closed and the pneumoperitoneum had clearly improved, and the needle was removed when it was confirmed that there was no further gas exhausting from the abdominal cavity.

It is difficult to distinguish gastric stromal tumors from leiomyomas and schwannomas based on cell shape. The clinical diagnosis of this tumor type mainly depends on histopathology, immunohistochemistry (CD34- and CD117-positive) and protocols in molecular biology^[28,29]. CD34 is the antigen marker of myeloid stem cells; it resides in the marrow hematopoietic stem cell tissue. CD117 is the product of the *c-kit* oncogene; it is the receptor of tyrosine kinase growth factor. The *Dog-1* gene is located at chromosome 11q¹³; it has 26 exons and is 114 Kb in length; the protein has 8 trans-membrane functional areas; it may be a chloride channel regulated by calcium ions, and it is currently recognized as the most sensitive and specific marker for gastrointestinal stromal tumors (GIST)^[30,31]. Typical leiomyomas and schwannomas do not express CD34; SMA-positive expression is the typical characteristic of leiomyoma, and S-100-positive expression is the typical characteristic of schwannomas^[32]. The positive expression rates of CD34, CD117, Dog-1, S-100 and SMA in the 69 patients were 81.2% (56/69), 82.6% (57/69), 82.6% (57/69), 0% and 17.4% (12/69), respectively, which demonstrated that, among the 69 patients, there were 12 leiomyomas, which express SMA, and the other 57 patients had gastric stro-

mal tumors confirmed with immunohistochemistry. Currently, the main treatment method for GISTs is surgical operation; the majority of benign GISTs in this study had a good prognosis after resection, and there was no recurrence in a short time. GISTs are not sensitive to radiotherapy or chemotherapy. For malignant GISTs that could not be completely resected or with recurrence, patients could take imatinib for therapy. Imatinib is an inhibitor of tyrosine kinase; it has significant therapeutic effects on malignant GISTs that express CD117^[33-37].

With the maturation of EFR, more and more gastric stromal tumors originating from the muscularis propria would avoid surgical operations, sharing the benefits provided by therapeutic endoscopy techniques.

COMMENTS

Background

The traditional method for the treatment of gastric stromal tumor originating from the muscularis propria was laparoscopic or surgical operation; in recent years, with the development of endoscopic techniques and instruments, endoscopic therapy for gastric stromal tumors originating from the muscularis propria has been made possible.

Research frontiers

Gastric stromal tumor is the most common mesenchymal tissue-originated tumor in the digestive tract; based on the tissue of origin, it can be defined as originating from the muscularis mucosae or the muscularis propria. As the location of the tumor originating from the muscularis mucosae was superficial, endoscopic resection or ligation was commonly performed. In contrast, the location of a tumor originating from the muscularis propria was deep, especially when the tumor grew outside gastric wall, perforation often occurred during endoscopic therapy, and the tumor could not be resected easily and thoroughly. Therefore, this tissue of origin was often considered to be a contraindication for endoscopic therapy, and the traditional treatment for such tumors was surgical or laparoscopic operation. In recent years, on the basis of sufficient clinical practice, endoscopic treatment for gastric stromal tumors originating from the muscularis propria has become possible.

Innovations and breakthroughs

Depending on the size of gastric stromal tumors originating from the muscularis propria, three types of endoscopic therapy could be used to treat the tumor. These techniques were endoscopic ligation and resection, endoscopic submucosal excavation and endoscopic full-thickness resection. The wound surface and the perforation of the gastric wall were closed with metal clips. These results showed that some gastric stromal tumor originated from muscularis propria can be treated successfully with endoscopic techniques, which could replace some surgical operations.

Applications

The study results suggest that some gastric stromal tumors originating from the muscularis propria could be treated successfully with endoscopic techniques, which could replace some surgical operations.

Terminology

Gastrointestinal stromal tumor (GIST): This term indicates a particular type of low-intermedius-originating tumor in the gastrointestinal tract; usually CD117 was positively expressed. Histologically, this tumor type is often composed of spindle cells and epithelioid cells. With respect to immunophenotype, it expresses the *c-kit* protein, which is driven by mutated *c-kit* or platelet-derived growth factor receptors. It is recognized that GIST originate from the intestinal cells of Cajal in gastrointestinal tract, which are in the shape of a network structure distributed in the muscular layer of gastrointestinal tract; this network is the pacemaker of slow-wave activity in the gastrointestinal tract and participates in the mechanism of exertional disease and tumor formation in the gastrointestinal tract.

Peer review

This is a good paper on endoscopic resection of gastric stromal tumors and leiomyomas. The figures are excellent.

Abstract

Celiac disease (CD) is frequently associated with neurological disorders, but very few reports concern the association with ischemic stroke. A 26-year-old woman affected by CD with secondary amenorrhea, carrier of a homozygous 5,10-methylenetetrahydrofolate reductase mutation with hyperhomocysteinemia, was affected by two occipital ischemic strokes within a period of 5 mo. At the time of the second stroke, while she was being treated with folic acid, acetylsalicylic acid and a gluten-free diet, she had left hemianopsia, left hemiparesis, and gait imbalance. Brain magnetic

resonance imaging showed a subacute right occipital ischemic lesion, which was extended to the dorsal region of the right thalamus and the ipsilateral thalamo-capsular junction. Antitransglutaminase and deamidated gliadin peptide antibodies were no longer present, while antinuclear antibodies, antineuronal antibodies and immune circulating complexes were only slightly elevated. Since the patient was taking folic acid, her homocysteine levels were almost normal and apparently not sufficient alone to explain the clinical event. A conventional cerebral angiography showed no signs of vasculitis. Finally, rare causes of occipital stroke in young patients, such as Fabry's disease and mitochondrial myopathy, encephalomyopathy, lactic acidosis and stroke-like symptoms, were also excluded by appropriate tests. Thus, the most probable cause for the recurrent strokes in this young woman remained CD, although the mechanisms involved are still unknown. The two main hypotheses concern malabsorption (with consequent deficiency of vitamins known to exert neurotrophic and neuroprotective effects) and immune-mediated mechanisms. CD should be kept in mind in the differential diagnosis of ischemic stroke in young patients.

INTRODUCTION

Celiac disease (CD) is an immune-mediated enteropathy, resulting from a permanent intolerance to the gliadin component in dietary gluten. Its clinical presentation may include signs and symptoms of malabsorption, frequently associated with extra-intestinal manifestations. Several neurological disorders like peripheral neuropathy, cerebellar ataxia and dementia were found to be associated with the disease; epilepsy, bilateral occipital calcifications and rarely stroke^[1-7] have also been reported in CD. This article illustrates the case of a young woman with asymptomatic CD, and carrier of the homozygous mutation of the gene encoding 5,10-methylenetetrahydrofolate reductase (*MTHFR*), who was affected by two occipital strokes within a period of 5 mo.

CASE REPORT

A 26-year-old woman with history of migraine without aura presented acute left hemiparesthesias (prevailing at lips and upper limb), mild weakness in her left arm, gait imbalance, unsteadiness and asthenia, while she was working hard in an archaeological site during a hot day. Since symptoms persisted, on the following day she was transported to the emergency department of our hospital and then admitted to the Stroke Unit.

The patient had a documented positivity of antitransglutaminase and antigliadin antibodies, which she had tested 7 years before because her sister was affected by CD. The patient had no gastrointestinal symptoms, but presented a secondary amenorrhea of at least two years duration. Duodenal biopsy showed a subtotal villous atrophy with an increased number of intraepithelial lymphocytes, so confirming the CD diagnosis. Her treatment consisted of a gluten-free diet, plus an estrogen-progestin therapy that she received for a period of 6 mo. The hormone therapy had been stopped 5 mo earlier when she was hospitalized elsewhere because of a left occipital ischemic stroke (transient right lateral homonymous hemianopsia). On that occasion, laboratory and genetic testing revealed the presence of a homozygous mutation of the *MTHFR* gene with hyperhomocysteinemia (31.5 mmol/L, normal value < 15 mmol/L). The patient was prescribed folic acid and acetylsalicylic acid.

On admission to our hospital, the patient appeared alert, oriented, cooperative and afebrile. Her neck was supple. She had left lateral homonymous hemianopsia, left hemiparesthesias and mild weakness in her left leg.

Investigations

A brain CT scan showed, in addition to the previous

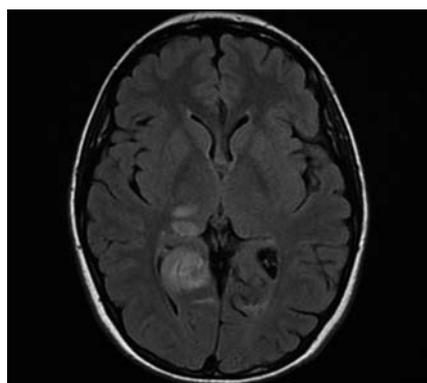

Figure 1 Magnetic resonance imaging showing a subacute right occipital lesion, extended to the dorsal region of the right thalamus and the ipsilateral thalamo-capsular junction.

left occipital infarction, a right occipital low-density area (maximum diameter 40 mm) suggesting an acute ischemic stroke involving the territory of the right posterior cerebral artery. There was no contrast enhancement of these lesions. Brain magnetic resonance imaging (MRI) confirmed the subacute right occipital lesion, which was extended to the dorsal region of the right thalamus and the ipsilateral thalamo-capsular junction (Figure 1). A conventional angiography of the aortic arch, supraortic branches and intracranial arteries showed a substantially normal picture, with poor visualization of the P3 segment and distal branches of the right posterior cerebral artery. In particular, no signs of vasculitis were found. Chest X-ray, abdominal ultrasound, electrocardiogram, electrocardiogram Holter monitoring, transthoracic echocardiogram, supraortic ultrasound and transcranial echo-Doppler with microbubbles to test the presence of patent foramen ovale, were all normal. Moreover, a bicipital muscle biopsy and an MRI spectroscopy of the gastrocnemius muscles before, during and after exercise were performed to test the hypothesis of mitochondrial disease and, in particular, of mitochondrial myopathy, encephalomyopathy, lactic acidosis and stroke-like symptoms (MELAS). Biochemical and molecular studies were performed to assess Fabry's disease. The results of all these investigations were negative.

Laboratory analyses, including complete blood count, C-reactive protein, erythrocyte sedimentation rate, renal function, cobalamin and folate levels, were normal. Serological tests for Human Immunodeficiency Virus, markers of hepatitis B and C, antigranulocyte antibodies (p-ANCA and c-ANCA), cryoglobulins, antiphospholipid antibodies and lupus anticoagulants phenomenon were also normal. The serum markers of CD, antitransglutaminase and deamidated gliadin peptide antibodies were no longer present. However, a control duodenal biopsy was not performed and antinuclear antibodies, anti-neuron antibodies and immune circulating complexes were slightly increased. Factor V Leiden and prothrombin mutation were absent. Similarly, other markers of a possible hypercoagulable status (antithrombin, protein C and

protein S) were normal. A mild hyperhomocysteinemia (16.1 mmol/L) still persisted, despite treatment with folic acid. Other laboratory tests documented secondary hypogonadism and hypothyroidism (increased FSH, LH, TSH and reduced FT4).

During hospitalization, there was a gradual improvement of neurological symptoms. The previous treatment with acetylsalicylic acid (100 mg/d) was replaced with clopidogrel (75 mg/d), and L-thyroxine (50 mcg/d) was started. Folic acid (5 mg/d), in addition to a gluten-free diet, was confirmed. At the time of discharge, the left lateral homonymous hemianopsia was still present. Five months after admission, the neurological picture was unchanged, but the patient was able to return to her job. There were no new acute cerebrovascular events.

DISCUSSION

Ischemic strokes occurring in patients younger than 30 years are a relatively rare event. The most important causes of cerebral ischemia in the young are cardioembolism, dissection of extracranial arteries, migraine, drugs and hypercoagulable states. Furthermore, premature atherosclerosis can also play an important etiological role. Uncommon causes include vasculitis, metabolic disorders and inherited diseases. However, the undetermined etiology is the most frequent reported cause of ischemic stroke in young patients^[8]. In this case report, we have considered in the differential diagnosis two rare causes of occipital stroke in young adults: MELAS syndrome and Fabry's Disease. MELAS^[9] is a progressive disease characterized by acute neurological events resembling cerebral ischemia, associated with mitochondrial myopathy and hyperlactataemia. Ten different mutations of mitochondrial DNA have been identified, but most cases (about 80%) are due to the A3243G mutation encoding the transfer RNA (tRNA) of leucine. CT and MRI often show lesions located in the occipital lobes, which are sometimes associated with brain atrophy and intracranial calcifications. Increased levels of lactate are often present in the blood, and almost constant in the cerebrospinal fluid. Muscle biopsy is abnormal in 85% of patients, showing atypical mitochondrial proliferation with presence of "ragged red fibers" at the Gomori's stain. The diagnosis is based on mitochondrial DNA analysis. Fabry's disease^[10] is a progressive multisystem inherited disease of glycosphingolipid metabolism. It is caused by mutations in the gene of α galactosidase A (chromosome Xq22). Its classic form, which mainly affects hemizygous males, is characterized by angiokeratomas, renal insufficiency with proteinuria, cardiomyopathy, and cochlear, vestibular and cerebrovascular symptoms. The final diagnosis for hemizygous males is based on the demonstration of α -galactosidase A deficiency, while in heterozygous females enzyme analysis is often inconclusive and genetic analysis is needed. In the present case, the diagnostic investigations performed for both MELAS and Fabry's disease were negative.

Our patient presented mild hyperhomocysteinemia, which is recognized as an independent risk factor for cardiovascular diseases^[11], acting through several possible prothrombotic mechanisms including the toxic action on vascular endothelium resulting in endothelial dysfunction, enhancement of both platelet adhesion and aggregation, endothelial factor V activation, protein C inhibition, and reduction of antithrombin III levels. Hyperhomocysteinemia may result from reduced elimination due to renal insufficiency, from inadequate intake or malabsorption of folic acid and B vitamins, or from a mutation of genes coding for one of the three enzymes involved in homocysteine metabolism: cystathionine β synthetase (CBS), MTHFR and methionine synthetase^[12]. The *MTHFR* gene mutation was carried by our patient. This is a fairly common condition in the Caucasian population, with a prevalence of 8%-15% for the homozygous genotype and 65% for the heterozygous genotype. It does not seem to be more prevalent among patients with CD^[13,14]. The *MTHFR* gene is located in the short arm of chromosome 1. Its mutation may be a cardiovascular risk factor only in subjects with a low intake of folic acid. At the time of the second stroke the patient was already taking folic acid. Thus, her homocysteine levels were only slightly elevated and apparently not sufficient alone to explain the clinical event.

Since no other cerebrovascular risk factors were found, we concluded that CD could be involved in the pathogenesis of recurrent strokes in this patient. CD is an immune-mediated disorder of the small bowel, resulting from a permanent gluten intolerance. Its prevalence in the general population is about 1% and its presentation may be at any age: childhood, adolescence and also adulthood. The clinical picture of CD varies greatly, ranging from asymptomatic forms, to the "classic symptomatic" form with mainly intestinal symptoms, to "atypical" forms dominated by extra-intestinal symptoms^[15]. The systemic involvement of CD may include skin, thyroid, pancreas, heart, joints, muscles, bones, reproductive system, liver, central and peripheral nervous system^[16]. Approximately 10% of CD patients show neurological symptoms, including idiopathic cerebellar ataxia, peripheral neuropathy, various forms of epilepsy, myoclonus, migraine and dementia^[17-20].

There are two main possible hypotheses concerning the pathogenesis of neurological manifestations in CD. Firstly, malabsorption with consequent deficiency of vitamins known to exert neurotrophic and neuroprotective effects (especially folic acid, vitamin B12, vitamin E) has long been thought to contribute to the neurodegenerative changes observed in patients with CD-related neurological manifestations. However, even plenty of vitamin supplementation does not improve the clinical course in these patients. Secondly, an emerging hypothesis is the possible participation of immune-mediated mechanisms. This hypothesis is strengthened by the evidence of lymphocytic infiltration of the central and peripheral nervous system^[21-22] and the presence of serum antineuronal

antibodies^[23] in CD patients with neurological complications. In this regard, neurological manifestations might result from a combination of sub-threshold neurotoxic effects caused by gluten-related immune markers (e.g., antigliadin antibodies, deamidated gliadin peptide antibodies and antibodies to one or more tissue transglutaminase isoenzymes) in combination with antibodies directed against nervous system epitopes, including anti-Purkinje cell and antiganglioside antibodies^[24]. However, the role of these antibodies in the pathogenesis of neurological dysfunction is not yet understood, even if there are elements supporting a mitochondrial-dependent neuronal apoptosis^[25].

Although the association between CD and ischemic stroke has been described by some authors, a causal link between these two conditions has never been demonstrated^[1-7]. Rush *et al*^[1] described the case of a 51-year-old white man affected by CD who had an ischemic stroke with tonic-clonic seizures, resulting from a vasculitis of the central nervous system that was documented by brain biopsy. Also, Ozge *et al*^[2] hypothesized that a vasculitis of the central nervous system could be a possible explanation for the association between CD and stroke. Moreover, Goodwin *et al*^[4] described the case of a child with CD and recurrent episodes of transient hemiplegia, suggesting an autoimmune vascular disease as the underlying mechanism. In fact, tissue transglutaminase, which is the major autoantigen of CD^[26], is also present in the central and peripheral nervous system, and it is thought to maintain vascular endothelial integrity. Pratesi *et al*^[27] found that anti-endomysium IgA antibodies, which were shown to bind to transglutaminase^[28], reacted with human brain vessel structures. This suggests an autoimmune mechanism for the association between CD and ischemic stroke. This hypothesis has also been proposed by Dogan *et al*^[7], who presented a case of stroke and dilated cardiomyopathy associated with CD.

As far as the present case is concerned, the cause of recurrent ischemic strokes remains uncertain. The negativity of indices of inflammation and autoantibodies would exclude systemic vasculitis. The hypothesis of a primary vasculitis of the central nervous system still remains. In fact, this condition cannot be ruled out even by the negativity of cerebral angiography^[29], and also cerebral biopsy is of limited value for the diagnosis due to its low sensitivity^[29]. However, in addition to the lack of small vessel involvement on neuroimaging, the benign course of the disease in our patient in the absence of immunosuppressive treatment makes this hypothesis unlikely.

In conclusion, although the involved mechanisms are still unclear, CD should be considered as a potential etiology of stroke of unknown cause, particularly in young patients, even in the absence of gastrointestinal manifestations.

Abstract

The Prague C and M Criteria have been developed for the objective endoscopic diagnosis of Barrett's esophagus (BE). BE arises between the squamocolumnar junction and the gastroesophageal junction at the proximal margin of the gastric folds. In this study, we reported that 43.0% of the subjects examined were diagnosed with BE based on the Prague C and M Criteria. Previous criticism by John Dent proposed that our data should be considered invalid because the prevalence of BE reported in our study was extraordinarily high and discordant with previous studies. Dent predicted that the position of the gastroesophageal junction in our study was judged to be lower than the actual position due to the effacement of the proximal ends of the gastric folds because of the routine use of a high degree of air distension during typical Japanese

endoscopic examinations. The endoscopic evaluation of the superior gastric folds is certainly influenced by the degree of air distension of the esophagus. However, in our study, the proximal limit of the gastric mucosal folds was prospectively imaged while the esophagus was minimally insufflated. Then, under a high level of air distension, the distal ends of the palisade-shaped longitudinal vessels were imaged because they are more easily observed when distended. In the majority of patients, the distal ends of the palisade-shaped longitudinal vessels correspond to the proximal limit of the gastric mucosal folds. Our endoscopic evaluation was appropriately performed according to the Prague C and M Criteria. We suspect that the high prevalence of BE in our study may be due to the inclusion of ultra-short-segment BE, which defines BE with an affected mucosal length under 5 mm, in our positive results.

TO THE EDITOR

In our previously published retrospective study^[1], we reported that a total of 43.0% [short-segment Barrett's esophagus (SSBE, 42.6%); long-segment Barrett's esophagus (LSBE, 0.5%)] of the patients examined were diagnosed with Barrett's esophagus (BE) based on the Prague

C and M Criteria^[2]. The study population included 869 patients, of whom 463 were men and 406 were women. The median age of the patients was 66 years and the patient age ranged from 29 to 91 years. The study population consisted of patients who underwent upper gastrointestinal endoscopic examination as part of a routine health check at the Yokohama City University Hospital. During endoscopic examination and imaging of the esophageal mucosa, the gastroesophageal junction (GEJ) was prospectively photographed prior to air distension. All of the endoscopic images were digitalised and were independently and retrospectively reviewed by two endoscopists trained to diagnose BE based on the Prague C and M Criteria^[2]. Any inconsistencies in the assessment of the endoscopic images were resolved by a joint review of the questionable endoscopic images by the two endoscopists. The Prague C and M Criteria for the endoscopic diagnosis of BE is based on the presence of columnar-appearing mucosa between the squamocolumnar junction and the GEJ, which composes the proximal margin of the gastric folds.

The findings of our study are consistent with a previous Japanese study on the occurrence of BE diagnosed based on the Prague C and M Criteria^[3]. The reported frequency of BE could be affected by differences in the interpretation of what constitutes BE, especially with regard to whether histological confirmation of specialised intestinal metaplasia of the esophagus is required. Many physicians from Western countries believe that confirmation of intestinal metaplasia by an esophageal biopsy is necessary to correctly identify BE^[4] because this condition is considered a risk factor for esophageal adenocarcinoma^[5]. However, in our study, BE was diagnosed endoscopically based on the Prague C and M Criteria without histological confirmation; therefore, positive results were referred to as endoscopic BE.

In a recent review article, Dent^[6] opined that our study appeared to be fatally flawed to the extent that our data should be considered invalid. His rationale was that the reported prevalence of BE in our study was extraordinarily high and discordant with previous studies. Dent predicted that the position of the GEJ was judged to be lower than its actual position due to the effacement of the tops of the gastric folds by the routine use of high levels of air distension during our endoscopic explorations.

The endoscopic evaluation of the proximal limit of the gastric folds is certainly influenced by the degree of air distension of the oesophagus. Furthermore, the American Gastroenterological Association workshop in Chicago has concluded that the proximal limit of the gastric mucosal folds is best visualised when the esophagus is minimally distended, although further work

may be required to define minimal insufflation^[2]. When endoscopically examining and imaging the GEJ, our protocol includes the prospective imaging of the proximal limit of the gastric mucosal folds while the esophagus is minimally insufflated. Then, we image the extreme distal ends of the palisade-shaped longitudinal vessels, which are considered topographical landmarks for the GEJ, under high levels of esophageal air distension^[7]. The distal ends of the palisade-shaped longitudinal vessels are much more easily observed under high levels of oesophageal air distension than when the oesophagus is minimally insufflated. In most study populations, the most distal ends of the palisade-shaped longitudinal vessels correspond to the proximal limit of the gastric mucosal folds.

Therefore, our endoscopic evaluation of the position of the GEJ was appropriately performed according to the Prague C and M Criteria without histopathological examination. We suspect that the relatively high prevalence of BE reported in our study may be due to the inclusion of ultrashort-segment BE, which defines BE with an affected mucosal length under 5 mm, in our positive results.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t* test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of *P* values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]”. If references are cited directly in the text, they should be put together within the text, for example, “From references^[19,22-24], we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Continent ileostomy can be defined as a surgical procedure that facilitates planned intermittent evacuation of a bowel reservoir through an ileostomy. It was devised by Nils Kock in 1969. Subsequently, continent ileostomy (or Kock pouch) became a viable alternative in the management of patients who had traditionally required an end ileostomy. Kock pouch appeared to provide substantial physical and psychosocial benefits over a conventional ileostomy. The procedure became popular until ileal pouch anal anastomosis (IPAA) was introduced in 1980. Despite its benefits, continent ileostomy had many short term complications including intubation problems, ileus, anastomotic leaks, peritonitis and valve problems. Operative mortalities have also been reported in the literature. Most of these problems have been eliminated with increasing experience; however, valve-related problems remain as an "Achilles' heel" of the technique. Many modifications have been introduced to prevent this problem. Some patients have had their pouch removed because of complications mainly related to valve dysfunction. Although revision rates can be high, most of the patients who retain their reservoirs are satisfied with regard to their health status and quality of life. Today, this procedure is still appropriate for selected patients for whom pouch surgery is not possible or for patients who have failed IPAA. Both the patient and their physician must be highly motivated to

accept the risk of failure and the subsequent need for revisional operations.

INTRODUCTION

Continent ileostomy (CI) allows planned evacuation of the small bowel through a reservoir equipped with a nipple valve. The operation was first reported by Kock in 1969^[1]. Subsequently, CI (or Kock pouch) became a viable alternative to conventional end ileostomy. This new procedure was met with initial skepticism since most patients did well with a Brooke type end ileostomy^[2]. However, some complained that an external appliance was inconvenient, some experienced complications from the conventional ileostomy, while others sought alternative procedures because of sexual and social reasons. The procedure became popular until ileal pouch anal anastomosis (IPAA) was introduced in 1980^[3]. Today, the Kock pouch is still appropriate for selected patients with ulcerative colitis (UC) and familial polyposis who are not candidates for IPAA or for those patients who have failed IPAA^[4-6].

THE EVOLVING TECHNIQUE OF CONTINENT RESERVOIR

Kock's original pouch design did not have a continence

valve mechanism (Figure 1). A segment of ileum is opened longitudinally and sutured together to create U-shaped limbs. The pouch is formed with vertical folding. A corner of the reservoir is sutured to the skin of the abdominal wall. Next, an efferent limb is added to the reservoir. His initial intent was to use the rectus abdominis muscle to serve as a constricting force around the efferent loop of bowel and thus provide continence; some of the patients achieved continence. Later, a nipple valve was provided by retrograde intussusception of the efferent limb into the pouch (Figure 2). This configuration achieved complete continence. Many surgeons have adopted this technique^[7,8]. All have expressed major concern in regard to the incidence of valve slippage. Dessusception of the valve (slippage) has been the most frequent complication in the long-term follow-up studies^[9-14]. Total valve slippage renders the pouch incontinent; partial slippage makes intubation difficult or impossible.

In the following years, many modifications of operative technique were proposed to overcome this problem. Steichen introduced the use of staples for valve stabilization^[15]. Fazio also described a stapled technique for nipple valve fixation^[16]. These modifications have led to a decrease in the incidence of valve slippage (Figure 3). Later on, synthetic materials such as polypropylene (Marlex) or polyester (Mersilene) were also used to buttress the valve mechanism. The valve slippage problem was largely controlled but the use of these materials could lead to fistula formation^[17,18].

Barnett introduced an isoperistaltic valve to avoid the slippage problem^[19]. In his technique, an afferent limb of bowel is used to construct a nipple valve with isoperistaltic intussusception. He initially reported that none of his sixteen isoperistaltic CI patients needed reoperation for valve slippage during three years of follow-up. Barnett's later works^[20] and a Cleveland Clinic study^[21] revealed that valve slippage occurs whether it is constructed in an isoperistaltic or anisoperistaltic fashion. The weakest point of the valve is on the mesenteric side where intussusception produces a large bulky mass that leads to slippage (Figure 4). Barnett was convinced that a support was absolutely necessary to avoid the problem and sought a suitable material that would not erode the valve. In 1986, he added an intestinal segment around the exit conduit to control valve slippage. This "living intestinal collar" buttressed the mesenteric side of the valve where slippage is initiated (Figure 5). The Barnett continent intestinal reservoir, including an intestinal collar and an isoperistaltic valve, has reduced the incidence of valve slippage and fistula formation^[22]. Because of the complications related to valve intussusception, Stein developed a new design pouch incorporating a serosal lined ileal antireflux mechanism for urinary diversion after cystectomy in 1998^[23]. Preliminary results of this innovative flap valve mechanism reservoir (I-pouch) indicated complete continence of the pouch but long-term results have not been reported^[24].

A novel CI has been reported by the authors^[25]. The porcine model was used to create a valveless reservoir

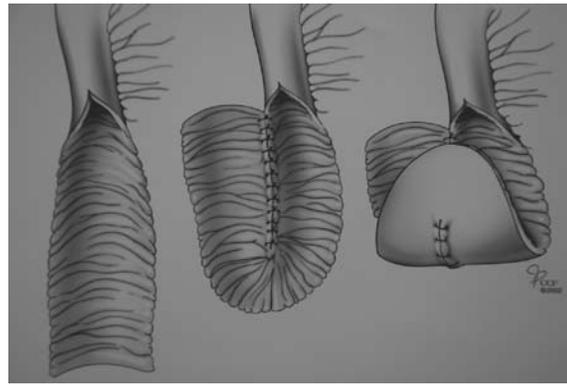

Figure 1 Original Kock pouch design without valve mechanism.

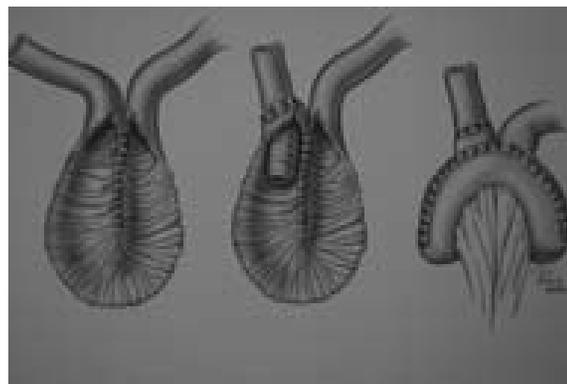

Figure 2 Continent Kock pouch.

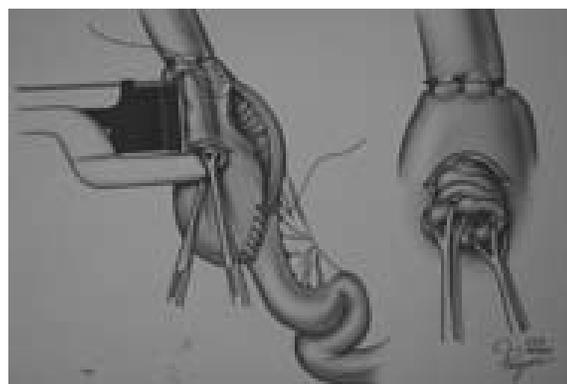

Figure 3 Stapled technique for nipple valve fixation.

and its integrity was tested. Although promising results have been achieved with this simple technique, the method has not been tested in humans.

LONG-TERM RESULTS AND QUALITY OF LIFE

Berglund *et al*^[26] and Ojerskog *et al*^[27] published their long-term experiences of CI with or without valve mechanism. A total number of 435 patients had been provided with a CI; of these 50% had their pouch constructed at the time of proctocolectomy (one-stage operation). These

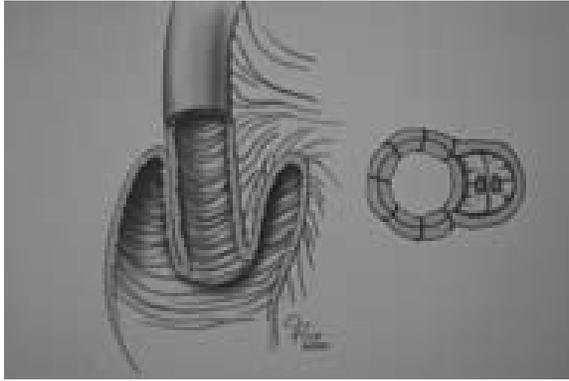

Figure 4 Valve intussusception produces a large bulky mass leading to slippage.

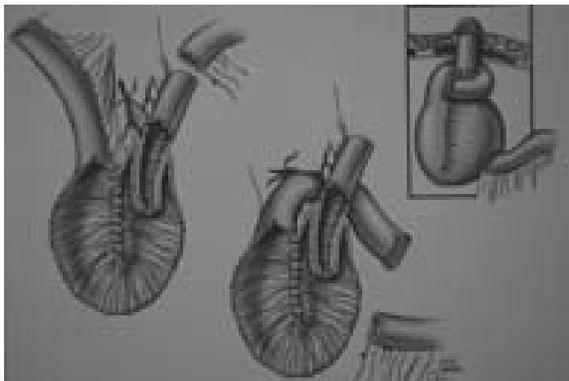

Figure 5 Barnett continent intestinal reservoir.

pioneers of CI reported a high complication rate (23%) and operative mortality (4.3%) in their early series but these figures dropped to a complication rate of 8% with no mortality in the later period. The long-term complications of CI were mainly related to the valve mechanism, including sliding of the nipple valve, fistula formation, partial or total prolapse of the valve, necrosis of the valve and/or the outlet, stricture of the stoma and inflammatory changes in the reservoir (pouchitis). Valve revisions were performed within the first postoperative year in most of the patients. They concluded that patients with CI have perfect continence unless they develop complication in the valve mechanism.

The long-term results of CI were evaluated in 129 consecutive patients who had this procedure performed by one surgeon at the University of California, San Francisco, between 1975 and 1995^[28]. The primary disease was UC in 119 (92%) patients, familial adenomatous polyposis (FAP) in 7 (5%), and multiple neoplasms in one (1%). Patient satisfaction, pouch durability and the details of the operation were evaluated using a modified 36-item short form health survey, phone calls, chart review and the personal records of the surgeon. Mean follow-up was 11.4 years (range: 1-21 years) and the late outcome was available for 85 patients (66%). Thirty-three of the patients (39%) had undergone an elective one-stage operation with total proctocolectomy and CI, whereas the

remainder had undergone emergent and elective procedures prior to CI creation. Of these patients, 54 (64%) had a functional pouch, whereas 31 patients (36%) had their pouch excised because of complications mainly related to valve dysfunction. The important feature of this study was the overall pouch failure rate which was significantly higher for those of the patients who had their CI as a secondary procedure. Despite many revisions, 97% of the survey respondents who retained their pouch were very satisfied and considered their quality of life to be good or excellent.

The Cleveland Clinic study described 330 patients who underwent Kock pouch surgery between 1977 and 2001^[21]. The mean patient age at the time of surgery was 34.9 years (range: 14-65 years) with a male to female ratio of 1:1.3. Indications for surgery included UC in 251 patients (76%); Crohn's disease in 42 (12.7%); FAP in 23 (7%); indeterminate colitis in five (1.5%); and other diagnoses including colonic inertia, Hirschsprung disease, rectal villous adenoma, and imperforate anus in nine (2.8%). Patients were followed for a median of 11 years (range: 1-27 years); during this period, 51 (16.6%) patients had their Kock pouch excised. At 10 years, 87% of all patients maintained their pouches. At 20 years, 77% of all patients still had their pouches. The 10-year and 20-year continent pouch survival for UC and FAP disease patients were 92.5% and 83.3%, respectively. Patients with Crohn's disease or indeterminate colitis had 10-year and 20-year pouch survival rates of 58.4% and 39.1%, respectively. The median complication-free pouch interval was 7 mo; the median revision-free pouch interval was 14 mo. Valve slippage was the most frequent complication leading to pouch revision (29.7%). The second most common complication was fistula formation (25.2%). The median time to valve slippage was two years. Parastomal hernia occurred in 15.5% of patients. Complete valve prolapse and stoma stricture were other complications. Patients had an average of 3.7 complications (range: 1-28 complications) and 2.9 pouch revisions (range: 1-27 pouch revisions) during their follow-up period. Patients undergoing staged procedures (such as prior restorative proctocolectomy, proctocolectomy with end ileostomy or ileorectal anastomosis) were 1.4 times more likely to undergo pouch revision compared with patients undergoing a single stage operation.

Quality of life for Kock pouch patients was evaluated in the Cleveland Clinic study. Patients with an end ileostomy were more than twice as likely to report social, work, and sexual restrictions compared with CI patients. End ileostomy patients reported higher antidiarrheal medication and fiber intake. A higher percentage of patients with CI reported having a better appetite. In addition, a higher proportion of end ileostomy patients reported having pouch-related complications. Finally, patients with CI were more likely to have the same procedure again and would recommend the procedure to someone else in comparison to the end ileostomy group of patients.

Wasmuth *et al.*^[29] evaluated 50 patients who underwent Kock CI between 1983 and 2002. The reoperation and

pouch excision rates were 44% and 8%, respectively. Re-operation rate was higher among the patients having CI as a second procedure. The Mount Sinai group evaluated 31 patients who had revisions after more than 10 years of normal Kock pouch function^[30]. Delayed pouch failure reasons were mostly related to the valve, and the pouch salvage rate was 93% with good functional outcome. Another study from Holland compared CI patients with a historical group of IPAA patients and end ileostomy patients^[31]. They found that the quality of life of CI patients was not significantly better or worse than that of the patients with either a conventional ileostomy or an IPAA.

FUTURE OF THE CONTINENT ILEOSTOMY

CI studies have revealed that this procedure has many short and long-term complications, mainly related to the valve mechanism. Despite many revisions, patients who retained their pouch were very satisfied and considered their quality of life to be good or excellent. There is a need to develop a safe and reliable continent abdominal reservoir because there are still indications for the CI. These procedures have to be performed in specialized centers.

ACKNOWLEDGMENTS

The authors wish to thank Dr. Victor W Fazio for his life-long dedication to pouch surgery and Mr. Joseph Pangrace of the Cleveland Clinic Department of Medical illustration.

Abstract

The natural history of Barrett's esophagus (BE) is difficult to quantify because, by definition, it should describe the course of the condition if left untreated. Pragmatically, we assume that patients with BE will receive symptomatic treatment with acid suppression, usually a proton pump inhibitor, to treat their heartburn. This paper describes the development of complications of stricture, ulcer, dysplasia and adenocarcinoma from this standpoint. Controversies over the definition of BE and its implications in clinical practice are presented. The presence of intestinal metaplasia and its relevance to cancer risk is discussed, and the need to measure the extent of the Barrett's epithelium (long and short segments) using the Prague guidelines is emphasized. Guidelines and international consensus over the diagnosis and management of BE are being regularly updated. The need for expert consensus is important due to the lack of randomized trials in this area. After searching the literature, we have tried to collate the important studies regarding progression of Barrett's to dysplasia and adenocarcinoma. No therapeutic studies yet reported show a clear reduction in the development of cancer in BE. The effect of pharmacological and surgical intervention on the natural history of Barrett's is a subject of ongoing research,

including the Barrett's Oesophagus Surveillance Study and the aspirin and esomeprazole cancer chemoprevention trial with interesting results. The geographical variation and the wide range of outcomes highlight the difficulty of providing an individualized risk profile to patients with BE. Future studies on the interaction of genome wide abnormalities in Barrett's and their interaction with environmental factors may allow individualization of the risk of cancer developing in BE.

INTRODUCTION

Barrett's esophagus (BE) is commonly defined as the replacement of esophageal squamous epithelium with metaplastic columnar epithelium, from the gastroesophageal junction proximally, that has been visualized endoscopically and confirmed histologically^[1-3]. The importance of the diagnosis of BE lies in the fact that it is known to increase the future risk of developing adenocarcinoma^[4]. The presence of BE is also associated with patients who have a more severe degree of acid and bile reflux compared to patients with gastro-esophageal reflux

disease without Barrett's columnar lining in their esophagus^[5,6]. This has implications in their clinical management.

There is debate about the degree to which intestinal metaplasia (IM) of the columnar-lined esophagus increases the risk of esophageal adenocarcinoma, and some observers have included the presence of IM in the definition of BE^[3,7]. Some authorities, however, do not specify IM as they believe its absence is only a reflection of sampling error and that it will invariably be present if meticulously searched for^[8-10]. It is clear that the presence of IM is common in patients who have no other diagnostic criteria of BE^[11,11], and without a consistent endoscopic abnormality the diagnosis of IM on biopsy only may have no clinical relevance. Patients with BE have a range of histological abnormalities including gastric metaplasia (fundic and/or body) and non specialized IM, often with a mosaic of different cell types spread across the epithelium.

SYMPTOMS

Patients with BE usually present with symptoms of gastroesophageal reflux disease (GERD) or its complications^[12]. Amongst a cohort of 309 BE patients described by Rudolph *et al*^[13], 98.6% reported a history of heartburn or acid regurgitation spanning at least a decade or more. Lieberman *et al*^[14] further confirmed the correlation between a long history of GERD and the presence of BE. Also, patients with uncomplicated BE seem to have less symptoms than those who have esophagitis without BE^[6]. Patients with BE have a greater frequency and severity of defective anti-reflux mechanisms^[15].

Symptom correlation with onset or progression of BE is very poor. This could be due to the observation that patients with BE have an alteration in their pain perception and thus repeated reflux events and associated tissue injury remain asymptomatic to the patient^[16]. In a prospective non randomized study of 35 patients with low grade dysplasia (LGD) in BE, only 63% had typical symptoms of GERD and 15% had no predominant symptom^[17]. Also, up to 40% of patients with BE-associated esophageal adenocarcinoma do not have reflux symptoms^[18]. Only a minority of patients with reflux symptoms develop BE. In a large prospective study of GERD patients followed up for several years, BE was found in 11% of the studied population of 6250 patients^[19], and in the recent LOTUS trial BE was diagnosed in 10.8% of a population of 554 patients with chronic reflux symptoms^[20].

Screening studies for BE in asymptomatic subjects^[21,22] use the definition of BE which relies on the endoscopic appearance of salmon pink mucosa plus the microscopic diagnosis of IM. In the absence of a defined endoscopic abnormality, they use the term specialized IM of the esophagogastric junction. The introduction of the presence of IM and the circular reasoning of assuming that any IM defines BE has created a degree of confusion in the clinical epidemiology of this condition. The abnormality of BE which has a clinical relevance has been

the endoscopic diagnosis of columnarization. When this columnarization is > 3 cm long, the likelihood that this is a hiatus hernia diminishes. When IM is found, the risk of cancer is considered greater, and, any patient with > 3 cm length of BE is likely to eventually show IM on surveillance endoscopy even if the first series of biopsies are negative. Thus an overemphasis on the presence of IM is very unhelpful. Therefore, the endoscopic finding should be the primary recorded abnormality, supported by histology.

Endoscopic features should be reported according to the Prague C and M criteria described by Sharma *et al*^[23] with precise definitions of endoscopic abnormalities, including the tongues, the circumferential extent and the position and extent of the associated hiatus hernia. The criteria include assessment of the circumferential (C) and maximum (M) extent of the endoscopically visualized BE segment, as well as endoscopic landmarks. This is very useful for long-term follow-up of individual patients and for standardizing results in clinical trials. The data in almost all of the studies reported in this review have not been recorded within the standards of the Prague classification, but future studies should uphold this current standard.

Onset of diagnosis and observation on natural history of BE over time

BE develops in the distal esophagus following tissue injury due to GERD. It is believed to be an acquired condition because of its association with more severe forms of GERD, its prevalence in older patients^[24] and the evidence from animal models^[25]. Two theories have been proposed for the evolution of BE.

Progressive theory: Amongst the proposed theories for the evolution of BE, the progressive theory is the most supported. Microscopic changes first start in the squamocolumnar junction in the form of a change from neutral to acid mucin production and formation of goblet cells. This is then subsequently visible as a columnar lined esophagus of varied length depending on the duration and severity of reflux^[26]. Thereafter, the segment length and the degree of differentiation of cells progresses according to the stimulus to which it is exposed. BE may occur after resection of the lower esophagus as observed by Hamilton *et al*^[27] and also in the upper esophagus as seen in patients who have survived cancer resections for BE-induced adenocarcinoma^[28].

Instantaneous field change theory: Most patients with BE do not demonstrate a significant increase in the length of the affected segment with time^[24,29]. This observation and the lack of good evidence for the progression of BE led to an alternative hypothesis suggested by Cameron *et al*^[24]. This instantaneous field change theory proposed that in response to a specific reflux injury, there is immediate change in the lining of the esophagus of a certain length which then remains constant. However, there is in-

creasing evidence to suggest that there is progression of BE (with regard to segment length and de-differentiation) with time^[30-32], and that long segment BE has more severe acid exposure than short segment BE^[33].

Male Caucasians (non-Hispanic whites) in the age range 60-70 years have consistently been shown to have a higher incidence of BE^[34,35]. Not surprisingly, the prevalence of BE, particularly the long segment type, is low in East Asians^[36]. Also, although BE is considered to affect the elderly, this trend seems to be changing. In a retrospective analysis of 7220 patients with BE, the mean age of diagnosis of BE had decreased between the years 1990 and 2005, with an increase in newly diagnosed BE patients below the age of 50 years^[37]. Guardino *et al.*^[38] also found that 25% of BE patients from their 837 patients registry were younger than 50 years of age. These differences in the demographics of patients with BE has not been explained by any study yet although it has implications in surveillance programs. Future studies need to address the influence of increased availability of endoscopy, lower threshold for health-seeking behavior and increasing obesity in Western countries with the increased prevalence/incidence of BE in these countries.

The influence of the extent of BE on its natural history is controversial. Patients with short segment BE were not considered to be predisposed to esophageal adenocarcinoma, and hence were often excluded from earlier studies of the natural history of BE^[39,44]. Rudolph *et al.*^[13], however, did not observe an association between segment length of BE and the risk of carcinoma in their cohort of 309 patients with BE. In their study, 32 patients with high grade dysplasia (HGD) progressed to cancer and 8 patients developed adenocarcinoma directly from benign BE, giving an overall incidence of 3.4/100 patient years (1184 years of follow-up). The length of BE, also did not influence the symptomatology of their patients significantly^[13]. More recent studies have observed a strong relationship between length of BE and development of adenocarcinoma and dysplasia^[32,45]. The demographic data for both short and long segment BE are similar, indicating that these are a continuum of the same process^[46]. The site of malignant degeneration also seems to depend on the anatomical configuration of the esophagogastric junction because cancer tends to occur in the right lateral quadrant of the esophagus in patients with BE^[47]. This is supported by Prasad *et al.*^[48] who have comprehensively studied the current evidence of various predictors that may be useful in determining the progression of BE, including clinical and demographic factors, endoscopic factors, pathologic factors and molecular biomarkers.

DEVELOPMENT OF COMPLICATIONS

Esophagitis

Erosive esophagitis occurs along with BE in a similar frequency to those symptomatic GERD patients without BE. Zaninotto *et al.*^[45] demonstrated esophagitis in 19%

of BE patients. BE can be present in nearly 27% of patients with erosive esophagitis, and its diagnosis may be missed due to the presence of inflammation. Therefore, repeat evaluation should be considered after complete healing of esophagitis^[49].

The degree and extent of inflammation is variable. Fitzgerald *et al.*^[50] showed that most patients without macroscopic evidence of esophagitis had microscopic evidence of inflammation with T cell, neutrophil and eosinophil infiltration. They also showed a higher degree of inflammation and interleukin-8 cytokine expression in proximal compared with distal BE^[51]. This proximal part of the columnar lined esophageal segment is known to be the area with the greatest risk of inflammatory complications such as stricture formation.

Stricture

In early retrospective series, strictures were present in up to 100% of cases^[52] but in prospective series, stricture rates of 15%-40% are found. They occur within the distal esophagus most frequently near the squamocolumnar junction^[53].

Ulceration

The development of ulceration within the columnar lined segment can occur in up to 60% of cases. They may be found incidentally or may present with complications such as bleeding^[16] in up to 50%, or more rarely with perforation into the mediastinum^[54], or fistula formation. Fistulation due to erosion through the esophageal wall into adjacent structures has been reported into the aorta^[55], pericardium^[56] and respiratory tree^[57].

Dysplasia

During the development of adenocarcinoma there is a gradual increase in dysplastic features of the epithelium through LGD and HGD culminating in invasive cancer^[58]. The reported incidence of dysplasia varies with different publications and is generally around 2%-5%^[43,59-63]. Studies on the natural history of patients with dysplasia in BE are summarized in Table 1.

LGD: In prospective studies, LGD is more commonly seen than HGD^[13,45]. This can progress to HGD/cancer, regress or remain static for several years^[43,58-60]. HGD is frequently found in specimens containing adenocarcinoma indicating that adenocarcinoma develops from HGD^[44].

The time it takes to progress from dysplasia to adenocarcinoma is highly variable with some rapidly developing adenocarcinoma, some having LGD for long periods^[68,69] and some progressing from LGD to HGD^[43,57-59]. Regression from HGD to LGD and HGD/LGD to absence of dysplasia is also variable. In the majority of patients, LGD is relatively stable and does not tend to progress to invasive adenocarcinoma when observed in the short term^[43,59]. However, when compared to patients with no dysplasia, those with LGD have a significantly higher risk of progressing to cancer/HGD^[61-67]. For patients with a

Weston <i>et al</i> ^[76] , 2000	15	3	6	13

HGD: High grade dysplasia.

diagnosis of LGD, the cumulative risk of progressing to HGD or carcinoma was reported as 85.0% in 109.1 mo compared with 4.6% in 107.4 mo for patients with non-dysplastic BE ($P < 0.0001$). The incidence of HGD or cancer was 13.4% per patient per year for patients with LGD^[70].

In patients with BE, dysphagia/odynophagia and nausea/vomiting were associated with a higher risk of development of dysplasia^[71]. We do not know the risk factors in patients with LGD which predispose to development of cancer, and are unable to individualize the interval for surveillance endoscopy.

HGD: HGD, similarly, has a variable course with both regression and rapid progression well documented^[58,72-76] (Table 2). Most will have HGD for several years before progressing to adenocarcinoma^[73,74]. Also, an intensive surveillance program can still miss adenocarcinoma in HGD patients^[74].

The presence of nodularity in HGD increases the likelihood that there will be submucosal invasion, and the recommendation is that all such lesions should, at a minimum, be removed by endoscopic resection, if not by esophagectomy^[75-80]. The work of Manner *et al*^[78] shows that most HGD lesions with nodularity can still be resected completely by endoscopic resection, but if the depth of submucosal invasion is beyond the upper third (into the SM3 level), lymph node involvement becomes a possibility. Hence the endoscopic appearance of nodularity alone raises the risk of an underlying cancer being present. The natural history of cancer evolution is vari-

able and patients need to be managed by individualized assessment.

Resected specimens of esophagectomy for HGD variably confirm the presence of invasive adenocarcinoma^[8,81,82], but this often quoted statistic fails to give a useful overview of the likelihood of cancer. In follow-up studies, cancer frequency in HGD patients ranged from 2%-13%. Table 2 describes the range of incidence of cancer in patients with HGD. It is important to remember while reviewing these studies that dysplastic/neoplastic changes are frequently localized within the segment, and are not a field change^[44]. Therefore areas of HGD or cancer may be missed on initial biopsy, and are only detected on follow-up biopsy, leading to apparent rapid progression.

Series in specialized centers which attract tertiary referrals are very selective. Such is the Seattle group of Levine *et al*^[83] who studied 70 patients undergoing prospective surveillance. Twelve patients were found to have invasive cancer on early follow-up (mean 2 mo). Fifteen progressed to cancer over a mean of 27 mo, while 43 remained stable or regressed during a mean of 30 mo follow-up. Such tertiary referral centers do not provide a useful guide to the management of the full range of community observed dysplastic BE and may skew practice.

Adenocarcinoma

Adenocarcinoma of the esophagus and gastroesophageal junction is amongst the fastest growing cancers in the Western world^[84,85], and is thought to be due to the increased incidence of GERD and its complications in this population. It may be important to note the recent epidemiological study of Pohl *et al*^[86] who studied the Surveillance Epidemiology and End Results database of the National Cancer Institute of USA 1973-2006. They found the incidence of esophageal adenocarcinoma to have plateaued. Whether this is true in Europe has not been reported.

The estimated risk of developing adenocarcinoma in BE varies widely (Table 3). The reasons cited for this observation are the surveillance program in place, the biopsy protocol and sampling error, publication bias and geographical variation^[87-100].

Some commentators raised the possibility that determination of cancer incidence in BE suffered particularly from reporting bias where positive studies were more likely to be published and smaller population groups tended to have a higher cancer incidence. This may be true of American series but Jankowski *et al*^[101] contended that this was not the case for European studies where there is a more normal (Gaussian) distribution of cancer incidence and population study size.

The recent very large prospective study by de Jonge *et al*^[100] however, seems to show a lower rate of progression to cancer than the previous smaller European studies (Table 3).

There may be a sex difference in cancer risk in patients with BE^[100,102]. Falk *et al*^[102] have shown that Barrett's segment length was greater in men than in women

(mean, 5.06 ± 4.2 cm *vs* 4.05 ± 3.27 cm, $P = 0.003$). Of 839 patients with BE, there were 114 cases of HGD or cancer (96 men, 18 women). Women were less likely to have HGD or cancer than men (odds ratio, 0.52; 95% confidence interval, 0.31-0.88; $P = 0.015$). There were 13 new cases of HGD or cancer (11 men, 2 women) during a mean follow-up of 4.72 years, with an incidence of 1 in 179 patient-years of follow-up for women and 1 in 91 patient-years of follow-up for men.

Accurate risk estimation is critically important to the economics of surveillance and other interventions to prevent carcinoma in BE patients, and thus to the specification of optimal clinical management policies.

Although many observers believe that the presence of IM in BE raises the cancer risk, it is now clear that cancer can occur without IM being detected^[8,103,104]. Comparison of rates of malignant degeneration are made more complex because some authors (such as Oberg *et al*^[66]) exclude all dysplastic patients at the start of the observation period while many others include all patients and document the subsequent cancer rate.

Overall health outcomes in BE patients

A very important issue for patients with BE is to understand that the natural history of BE is for the patient to suffer chronic GERD symptoms usually for a lifetime and to need a lifelong strategy of symptomatic care. This

may be by medication or by antireflux surgery. They may also be subject to regular planned endoscopic surveillance. The need for surveillance is not the subject of this article *per se*. The true value of surveillance must be assessed in each geographical and economic environment. Such a study is the BE surveillance study in the United Kingdom (BOSS trial)^[105] which will address this for the United Kingdom population and will also highlight the patients' own perceptions of the necessity for repeated endoscopic examination.

Studies of the true natural history of BE without therapy are not reported because every case series is given some form of therapy. Most patients are offered lifelong proton pump inhibitors (PPI) which are effective in symptom control. However, their ability to prevent complications, either benign or malignant has not been studied in controlled clinical trials.

Most reported studies on the outcome of reflux control by drugs or antireflux surgery are relatively short-term. Studies of open antireflux surgery have previously been compared with H2 receptor antagonist treatment and suggested better control of symptoms and prevention of complications of BE in patients who underwent antireflux surgery^[106]. However, acid suppression with PPI is more effective than H2 receptor antagonists, and the recent studies in the LOTUS trial have compared laparoscopic antireflux surgery with dose adjusted esomeprazole (often given 20 mg *bid*). Three-year results from the LOTUS trial^[20] have suggested that antireflux surgery is as efficacious in symptomatic control of BE as medical management, without significant operative or postoperative complications.

Interfering with the natural history of BE especially where treatments are directed at cancer prevention also is not the subject of this paper *per se*. It requires well controlled studies which are sparse. The aspirin and esomeprazole cancer chemoprevention trial in the United Kingdom^[107-110] is looking at the issue of dose-response of esomeprazole with or without aspirin on overall survival (both cancer and cardiovascular related).

Some authors have suggested that there might be a benefit from antireflux surgery in prevention of cancer, but there are no controlled studies on this topic. Case series and cohort studies have been reviewed by Chang *et al*^[108]. They found 25 publications with original data reports and their analysis supports this hypothesis but no conclusions can be drawn. Oberg *et al*^[66] looked specifically at 140 patients in a surveillance program, of whom 46 had undergone antireflux surgery and none developed adenocarcinoma or HGD. In patients treated with antireflux surgery, the risk of developing LGD was reduced 2.3-fold compared with patients receiving conventional acid suppression therapy^[66]. Whether a competent antireflux repair can indeed reduce the rate of malignant progression in patients with BE is still unclear, and further studies are needed to clarify this issue. Rossi *et al*^[7] reported regression from LGD to BE in 63% patients with PPI and in 94% of those who had antireflux surgery ($P = 0.03$).

Other forms of cancer prevention now proposed are ablation of dysplastic BE which again will require long-term prospectively controlled studies. Early ablation studies used Argon beam plasma coagulation which indicated potential efficacy in controlling the progression of HGD to cancer; 86% of patients studied responded to this treatment with a follow-up evaluation over 7 years^[109]. Recently, radiofrequency ablation has been introduced, which is a balloon-based technology that provides more easily standardized tissue destruction. This, when combined with endoscopic mucosal resection may dramatically alter the natural history of dysplastic BE^[110,111].

Some authors contend that survival rates of patients with BE are virtually identical to those of age- and sex-matched control populations^[87], and it is important to appreciate that, notwithstanding the increased risk of developing esophageal adenocarcinoma, the absolute risk of death from this tumor is small. In a cohort of 166 BE patients in the Netherlands with 1440 patient-years of follow-up, 79 patients died but only 2 of the deaths were due to esophageal carcinoma^[42]. Most patients with BE die from causes unrelated to their esophageal disease^[112,113], and reducing the risk of adenocarcinoma can produce no more than a small effect on overall life expectancy. Long term studies^[105,107] are eagerly awaited to guide future understanding of BE.

Understanding the natural history of BE in an individual patient requires an estimate of risk based on the geographical variations of disease progression, and an individualized assessment of patient characteristics, race, obesity, *etc.* Presenting such a risk assessment in context is important for patients so that they have a balanced perspective of risk.

Abstract

Apart from alcohol, there are other factors that may induce complications, which resemble alcohol-related liver disorders. In particular, obesity has been brought into focus as a risk factor for fatty liver disease. The term "non-alcoholic" fatty liver disease is commonly used to distinguish between obesity-related and alcohol-related hepatic steatosis. This review uses the epidemiological perspective to critically assess whether it is necessary and useful to differentiate between alcoholic and "non-alcoholic" fatty liver disease. The MEDLINE database was searched using the PubMed search engine, and a review of reference lists from original research and review articles was conducted. The concept to distinguish between alcoholic and "non-alcoholic" fatty liver disease is mainly based on specific pathomechanisms. This concept has, however, several limitations including the common overlap between alcohol misuse and obesity-related metabolic disorders and the non-consideration of additional causal factors. Both entities share similar histopathological patterns. Studies demonstrating differences in clinical presentation and outcome are often biased by selection. Risk factor reduction is the main principle of prevention and treatment of both disease forms. In conclusion, alcoholic and "non-alcoholic" fatty liver diseases are one and the same disease caused by

different risk factors. A shift from artificial categories to a more general approach to fatty liver disease as a multicausal disorder may optimize preventive strategies and help clinicians more effectively treat patients at the individual level.

INTRODUCTION

There is longstanding clinical knowledge that chronic alcohol misuse may cause severe liver damage. Hepatic steatosis is regarded as the early stage of alcohol-induced liver damage, and steatohepatitis may follow if alcohol misuse is continued. Liver cirrhosis as an end-stage of liver damage is accompanied by potentially life-threatening conditions including esophageal bleeding, hepatic encephalopathy, increased susceptibility to infections and impaired hemostasis.

It has been recognized for many decades that, apart from alcohol, other factors may induce complications,

which resemble alcohol-related liver disorders in many ways^[1]. In particular, obesity and metabolic syndrome, both with an increasing prevalence in developed communities, have been brought into scientific and clinical focus as risk factors for hepatic steatosis. Ludwig *et al*^[2] described the potential role of obesity and metabolic syndrome in hepatic steatosis in their paper on nonalcoholic steatohepatitis as a hitherto unnamed disease, which was published in 1980. From that work, the term “non-alcoholic” fatty liver disease has been established and is now commonly used to distinguish between obesity-related and alcohol-related hepatic steatosis.

Fatty liver disease is common in populations and has potential consequences for individual health. In Southern Italy, it was estimated from a population-based study^[3] that alcohol misuse accounted for 46.5% of all cases diagnosed with impaired liver function, and a further 24.0% of cases were attributed to “non-alcoholic” fatty liver disease. In Northeast Germany, where alcohol misuse, obesity and metabolic syndrome are highly prevalent^[4-6], 29.9% of adults aged between 20 and 79 years had a hypercholesterolemic pattern in their liver ultrasound. Given the expected increase in the global burden of overweight and obesity^[7], the prevalence of “non-alcoholic” fatty liver disease will continue to rise over the next years. The potential impact of fatty liver disease for societies is reflected by the fact that, over the following five years, subjects with current hepatic steatosis will cause 26% higher health care costs compared to subjects without hepatic steatosis^[8].

Currently, a large amount of research is being performed to explore risk factors, histopathological features, pathogenesis, clinical symptoms and options for the prevention and treatment of “non-alcoholic” fatty liver disease. At this moment in time, it is common in research and clinical practice to distinguish between alcoholic and “non-alcoholic” fatty liver disease. The rationale for this distinction, however, has not yet been the issue of thorough analyses.

This review uses the clinical-epidemiological perspective to critically assess whether it is necessary and useful to differentiate between alcoholic and “non-alcoholic” fatty liver disease. The general aim of this review is to summarize the evidence that alcoholic and “non-alcoholic” fatty liver diseases represent one and the same disorder with an underlying multicausal origin.

MATERIALS

Two search strategies were used to find appropriate articles for the research question. The MEDLINE database (from January 1, 1966 to December 17, 2011) was searched using the PubMed search engine to find articles on alcoholic and “non-alcoholic” fatty liver disease. The keywords used were “alcoholic” or “non-alcoholic” and “fatty liver” or “hepatic steatosis” or “steatohepatitis” or “cirrhosis”. Hereafter, a review of reference lists from original research and review articles was conducted. Articles in English and German were considered on the basis of their relevance to this review’s topic.

To illustrate some major points, data from the large-scale population-based Study of Health in Pomerania (SHIP) are used^[9]. For this study, a sample from the general population aged 20 to 79 years was drawn from population registries. Baseline examinations were performed in 4308 men and women. The longitudinal data collection included a five-year examination, morbidity and mortality follow-ups^[10]. SHIP is conducted in Northeast Germany, where both metabolic syndrome and alcohol misuse are highly prevalent and, consequently, hepatic steatosis is also commonly found on liver ultrasound^[11].

RESULTS

Definitions and risk factors

The term alcoholic fatty liver disease refers to hepatic steatosis and its liver-related sequelae, which are related to alcohol misuse, whereas the term “non-alcoholic” fatty liver disease comprises the same liver disorders attributed to obesity and metabolic syndrome^[12]. At a first glance, these definitions sound clear and intuitive, but there are at least five drawbacks for applying these definitions in clinical practice and research. These drawbacks are the main reason why the term “non-alcoholic” is put in quotation marks throughout this review.

Firstly, the term “non-alcoholic” fatty liver disease is imprecise. It implies that all risk factors for hepatic steatosis are summarized under this name. This, however, is not the case, because the term rather refers to the obesity-related causes that underlie the fatty liver disease. In addition to obesity and metabolic syndrome, other causes of fatty liver disease exist including other metabolic and hormonal disorders, acute starvation and abdominal surgery, as well as pharmacotherapeutic, toxic and genetic factors, which actually would have been also summarized under the term “non-alcoholic” fatty liver disease (Figure 1).

Secondly, with regard to hepatic steatosis, there is no consistent definition of alcohol misuse. For example, some scientists^[13,14] consider alcoholic fatty liver disease when men consume at least 80 g alcohol and define “non-alcoholic” liver disease by excluding patients who report a daily alcohol consumption of less than 20 g^[15,16]. Unfortunately, subjects with alcohol consumption of between 20 g and < 80 g are not assigned to a specific group. The resulting practical problem is illustrated by SHIP data. In fact, 26.7% of all male participants aged 20 to 79 years had reported a daily alcohol consumption in the range of 20 g to < 80 g during the past 7 d.

Thirdly, the term “non-alcoholic” implies that alcohol plays no role in the development of fatty liver disease in affected patients. Certain amounts of alcohol consumption, however, are usually tolerated in the definition of “non-alcoholic” fatty liver disease. Contrary to this, chronic daily alcohol consumption of e.g., 20 g may well increase the risk of liver damage in a considerable proportion of susceptible individuals. Thus, female sex, dietary habits, alcohol dehydrogenase deficiency and other genetic factors are major predictors of such increased susceptibility^[17,18].

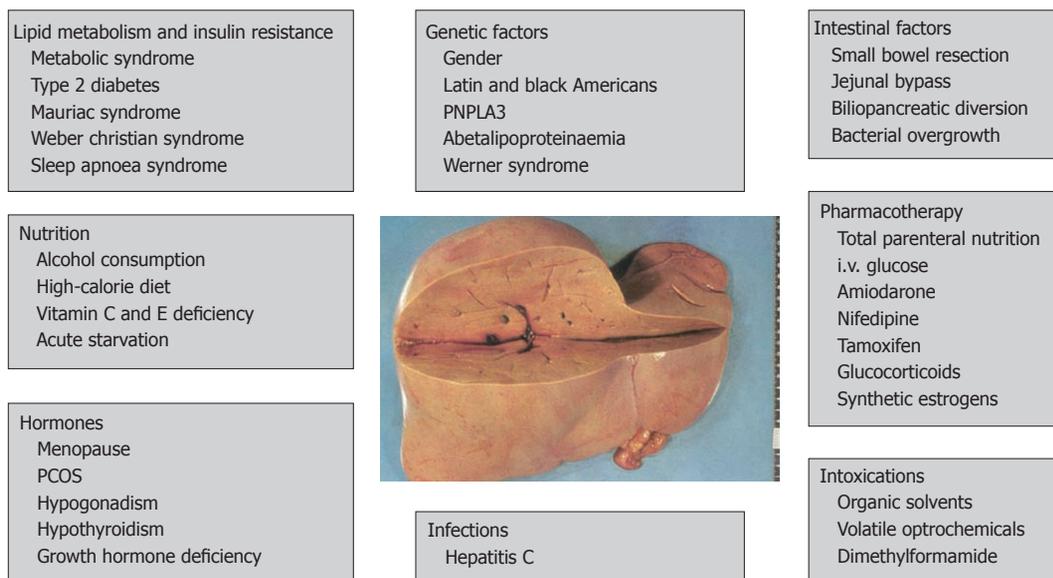

Figure 1 Risk factors for fatty liver disease^[17,32,72,82-87]. PNPLA3: Patatin-like phospholipase domain-containing protein 3; PCOS: Polycystic ovary syndrome.

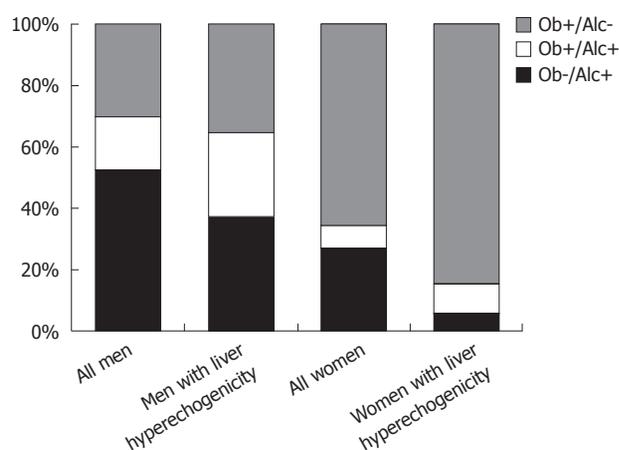

Figure 2 Obesity and alcohol consumption in the general population of Northeast Germany. Data are taken from the population-based Study of Health in Pomerania. The columns indicate the proportions of obesity (Ob; body mass index > 30 kg/m²), harmful alcohol consumption (Alc; daily alcohol consumption > 20 g in women and > 30 g in men), the combined presence of both risk factors in all subjects (1122 men, 781 women) and subjects with a hyperechogenic pattern on liver ultrasound (535 men, 276 women), in whom at least one of both risk factors was present.

Fourthly, many cases cannot be clearly assigned to either the alcoholic or the “non-alcoholic” category, because an overlap between alcohol consumption and metabolic disorders exists within many individuals. SHIP data exemplify this issue (Figure 2). In the general adult population of Northeast Germany, obesity and harmful alcohol consumption are not mutually exclusive characteristics. Rather, a broad overlap between both characteristics exists, particularly in men. Among men who are either obese or report a daily alcohol consumption of > 30 g, 17.5% fulfill both criteria. In men with hyperechogenicity on liver ultrasound, this proportion is even as high as 27.3%. In women, for whom harmful alcohol consumption of > 20 g per day is much less prevalent than in men, the overlap

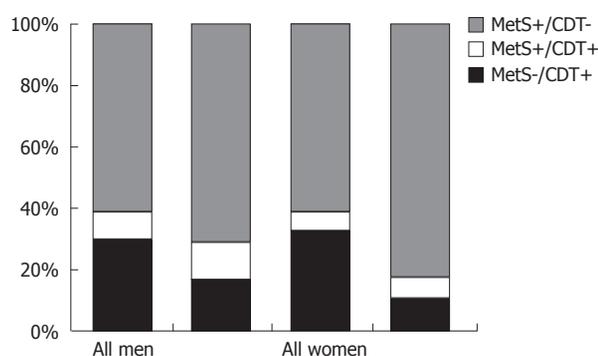

Figure 3 Metabolic syndrome and increased serum carbohydrate-deficient transferrin in the general population of Northeast Germany. Data are taken from the population-based Study of Health in Pomerania. The columns indicate the proportions of metabolic syndrome (MetS), increased serum carbohydrate-deficient transferrin (CDT > 6%), the combined presence of both risk factors in all subjects (970 men, 685 women) and subjects with a hyperechogenic pattern on liver ultrasound (486 men, 288 women), in whom at least one of both risk factors was present.

is smaller and reaches a proportion of 7.3% in the whole female population and 9.4% in women with hyperechogenic findings on liver ultrasound. After applying stricter definitions for risk factors, metabolic syndrome^[19] and increased serum carbohydrate-deficient transferrin levels are co-existent in 9.0% of men with at least one of both risk factors in the whole study population and in 11.7% in men with risk factors and liver hyperechogenicity, respectively (Figure 3). In women, these proportions are 5.8% and 7.3%. Similar findings were found in Finnish adults^[20], where subjects with alcoholic fatty liver disease were as often obese as subjects with “non-alcoholic” fatty liver disease, and the metabolic syndrome was even more common in alcoholic than in “non-alcoholic” fatty liver disease.

Current definitions of alcoholic and “non-alcoholic” fatty liver disease disregard the common presence of

risk factors for hepatic steatosis. What is the correct diagnosis for obese patients with hepatic steatosis who consume too much alcohol? Do they have alcoholic fatty liver disease, “non-alcoholic” fatty liver disease or both? And how do we name fatty liver disease if one or more additional risk factors listed in Figure 1 are present? Furthermore, it has been convincingly demonstrated that metabolic factors contribute to the risk of pure steatosis in alcoholic patients. Apolipoprotein A1 levels, body mass index, waist circumference and blood pressure are closely associated with the risk of fatty liver in these patients^[21]. On the other hand, especially in obese women, low amounts of alcohol may provoke the risk of “non-alcoholic” fatty liver disease^[22]. These data suggest that interactions among alcohol use, metabolic characteristics and other factors (Figure 1) do exist, and that the complexity of risk factor interplay is much greater than the simple distinction between alcoholic and “non-alcoholic” fatty liver disease indicates.

Finally, misclassification due to information bias represents a serious problem in correctly distinguishing between alcoholic and “non-alcoholic” forms of fatty liver disease. Given the potential stigmatization through alcohol use among patients and study participants, the under-reporting of alcohol consumption is a common problem in clinical practice and research. Thus, it can be expected that a significant alcoholic component contributes to the development of “non-alcoholic” fatty liver disease in a certain proportion of patients. Misclassification also arises from the fact that a history of alcohol consumption is usually evaluated in the present or for the very recent past. The Dionysos study^[25,24] demonstrated, however, that life-time history of alcohol consumption is more valid to define a threshold for liver cirrhosis than is the current information. Studies performed in patients with “non-alcoholic” fatty liver disease confirmed that misclassification was present in up to 10% of all cases^[22].

Misclassification of alcohol consumption may also have biased studies^[25-28], which suggested that low-to-moderate alcohol consumption is inversely associated with the risk of fatty liver diseases. The challenge in such studies is to correctly define the reference group. If this definition is only based on current self-reported denial of alcohol consumption, the reference group might not only include lifelong teetotallers, but also sick quitters with high alcohol-related morbidity^[29]. This phenomenon may also have led to oversimplified interpretation of J-shaped associations between alcohol consumption and cardiovascular mortality^[30,31] and should be considered in future studies on associations between alcohol consumption and fatty liver disease.

Taken together, the definitions of alcoholic and “non-alcoholic” fatty liver disease are not very practical for clinical applications. The current concept of “non-alcoholic” fatty liver disease does not sufficiently take into account risk factors for fatty liver disease other than obesity and metabolic syndrome.

Histopathology

Liver biopsy is the gold standard for the diagnosis of

fatty liver disease. The general stages of both alcoholic and “non-alcoholic” fatty liver disease are as follows: (1) **simple steatosis**; (2) **steatohepatitis**; and (3) **cirrhosis**. Macrovesicular, microvesicular or mixed patterns of simple steatosis are the first step of both alcoholic and “non-alcoholic” fatty liver disease^[32,33]. The diagnostic criteria for steatohepatitis are steatosis accompanied by liver cell injury, inflammatory changes and fibrosis^[32,34]. Common histopathological features of liver cell injury are ballooning of hepatocytes, vacuolated nuclei, Mallory bodies and megamitochondria. Inflammatory changes usually follow a lobular pattern. Perisinusoidal fibrosis typically occurs in acinar zone 3^[32,34]. Cirrhosis, as an end stage of multiple liver disorders, is characterized by progressive perivenular fibrosis, which may form septa between terminal hepatic venules. Regenerative nodules or diffuse pericellular fibrosis throughout the acini may develop if risk factors persist^[32].

Several studies^[34-36] have investigated the differences in the histopathological picture between alcoholic and “non-alcoholic” fatty liver disease. In one study^[35], patients with alcoholic fatty liver disease had a more diminished regional blood flow and hepatic oxygen consumption relative to patients with “non-alcoholic” fatty liver disease, suggesting that a more impaired hepatic circulation exists in the former than in the latter. Although in this small study^[35] both of the patient groups had an otherwise similar picture of hepatic steatosis, major differences existed in the extent of risk factors. Whereas the six patients with alcoholic fatty liver disease consumed a heavy amount of at least 180 g alcohol daily, the relatively moderate inclusion criterion for the “non-alcoholic” fatty liver disease group was to be “at least 30% overweight in terms of ideal standards for height”^[35]. Unfortunately, no further details on the distribution of metabolic risk factors were given in that study^[35].

Regarding steatohepatitis, a previous review^[34] has summarized current evidence by stating that the “non-alcoholic” form of steatohepatitis has greater amounts of steatosis and nuclear vacuolization, but less necroinflammatory activity, canalicular cholestasis, Mallory hyaline and periportal fibrosis than the alcoholic form. Although these differences probably exist, the limited comparability between patients with and without alcoholic steatohepatitis may limit the conclusions of many studies.

One example illustrates this notion. To investigate the histopathological disparities between patients with and without alcoholic hepatitis, Pinto *et al*^[13] compared the histopathological characteristics of patients with “non-alcoholic” and alcoholic steatohepatitis, whereby the latter group was divided into ambulatory and hospitalized patients. In relation to hospitalized alcoholic patients, those with “non-alcoholic” steatohepatitis had less severe histopathological signs of steatohepatitis, whereas ambulatory patients with alcoholic steatohepatitis displayed an intermediate histopathological picture.

Without a doubt, the study of Pinto *et al*^[13] confirmed the expectation that the clinical presentation of patients

with alcoholic steatohepatitis is associated with the histopathological severity of the disease. It still remains to be determined, however, whether it is also possible to conclude that “non-alcoholic” steatohepatitis has a less severe histopathological pattern than the alcoholic form, because additional information on the clinical status of the patients would be necessary. Unfortunately, it is unclear from that study^[13], whether the “non-alcoholic” steatohepatitis patients were ambulatory or hospitalized. It has also not been stated what the indication of liver biopsy was in the “non-alcoholic” patients. Thus, it does seem likely that, for example, asymptomatic hepatomegaly in patients with known heavy alcohol consumption may be tolerated, since this finding is well explained by alcoholism; whereas the same constellation in patients who deny alcohol abuse gives rise to greater clinical efforts to find reasons for hepatomegaly. Hence, it is unclear whether the less severe clinical status in “non-alcoholic” steatohepatitis patients and the earlier liver biopsy account for the lower severity of histopathological findings compared to patients with alcoholic steatohepatitis.

Furthermore, although Pinto *et al*^[13] provide data on medication taken by the study patients, they leave uncertainty whether liver-related side effects of these drugs were suspected by treating physicians. Hence, it is not clear whether patients were correctly assigned to “non-alcoholic” steatohepatitis as a metabolic liver disorder.

Taken together, although histopathological differences between alcoholic and “non-alcoholic” fatty liver disease exist, the general pattern of findings is very similar. Therefore, pathologists are not able to distinguish between both entities by themselves without information on risk factors provided by clinicians^[32,37,38].

Pathogenesis

The pathogenesis of alcoholic and “non-alcoholic” fatty liver disease has specific as well as common components. The relatively specific components of alcoholic fatty liver disease include the toxic effects of acetaldehyde and an increase in NADH^[18,39] leading to acidosis, hypoglycemia and, as important factors for the development of hepatic steatosis, an increased activity of lipogenic pathways and a reduced export of triglycerides from the liver^[18]. In “non-alcoholic” fatty liver disease, insulin resistance activates the breakdown of peripheral adipose tissue with the consequence of increased hepatic absorption of free fatty acids, *de novo* synthesis of fatty acids and accumulation of triglycerides in the liver^[18]. Furthermore, high serum insulin levels stimulate fatty acid synthesis and inhibit the conversion of triglycerides to very low density lipoproteins^[18].

At least five common mechanisms exist that are important for the development and progression of both alcoholic and “non-alcoholic” fatty liver disease. Firstly, inadequately high energy uptake may not only induce key mechanisms in “non-alcoholic” fatty liver disease, but may also contribute to the alcoholic form of the disease. Alcoholic beverages are calorically dense, and in

the absence of severe malnutrition in affected patients, this may result in an impaired energy balance in chronic alcoholism^[36]. Secondly, triglycerides are synthesized from fatty acids in both forms of fatty liver disease. Fatty acids are mainly derived from lipolysis of adipose tissue, but may also be generated by *de novo* lipogenesis^[36]. Thirdly, oxidative stress is highly relevant to the progression from hepatic steatosis to steatohepatitis and cirrhosis in both forms of fatty liver disease. In alcoholic fatty liver disease, ethanol generates free radicals, and the activation of CYP2E1 and mitochondrial activities release reactive oxygen species^[18,40]. Free fatty acids and mitochondrial dysfunction seem to be key mediators for the inflammatory processes induced in “non-alcoholic” fatty liver disease^[41,42]. Mitochondrial dysfunction and oxidative stress are the major contributors to the progression from pure steatosis to steatohepatitis in both alcoholic and “non-alcoholic” fatty liver disease^[43-45]. Also, in both disease forms, inflammatory cytokines reduce insulin sensitivity and thereby increase the risk of fatty liver disease^[45-47]. Fourthly, endotoxin, a toxic lipopolysaccharide located in the cell wall of Gram-negative bacteria, enhances complications of fatty liver disease by stimulating inflammatory processes. In alcoholic and “non-alcoholic” fatty liver disease, the release of endotoxin is triggered by increased gut permeability^[18,48,49]. Finally, intestinal bacteria may add an alcoholic component to the pathogenesis of “non-alcoholic” fatty liver disease. It has been demonstrated in mice studies that intestinal bacteria produce alcohol, and that the amount of alcohol production is higher in obese than in lean animals^[50]. In line with these findings from animals, hepatocytes from young human patients with “non-alcoholic” steatohepatitis and without any history alcohol consumption demonstrated expression of genes encoding all known pathways of alcohol degradation, which was much stronger than in hepatocytes from age-matched controls^[51]. These findings support the notion that alcohol may play a central role in the development of “non-alcoholic” steatohepatitis.

Taken together, there are, particularly in the early stages of fatty liver disease, some pathways that are specific for the underlying cause of the disease. In other important aspects, pathomechanisms leading to alcoholic as well as “non-alcoholic” fatty liver disease share many similarities.

Clinical presentation

Upon investigation of the clinical status of patients with “non-alcoholic” compared to alcoholic fatty liver disease, studies usually find that the former patients are less symptomatic with nausea, abdominal pain, jaundice and gastrointestinal bleeding, than are the latter^[37,52]. To interpret these findings correctly, the time of recruitment of patients for the studies during the course of the disease has to be taken into account. These studies^[37,52] are commonly histology-based. Thus, the time of recruitment is the day the biopsy was performed. As already suggested above, invasive diagnostic procedures may be performed

much later in the time course of the disease in patients with clear alcohol misuse than in those with no or less alcohol consumption. Thus, the longer exposure and, consequently, larger cumulative dose of risk factors may have significantly influenced the outcomes of studies comparing the clinical features between patients with and without alcoholic fatty liver disease.

Taken together, current research suggests that “non-alcoholic” fatty liver disease is accompanied by relatively mild symptoms compared to alcoholic fatty liver disease, but studies generally lack a well-balanced standardization with respect to the extent of underlying risk factors.

Outcome

Hepatic complications: Pure hepatic steatosis is commonly regarded as a benign disorder. However, in both alcoholic and “non-alcoholic” fatty liver disease, hepatic steatosis may progress to steatohepatitis. Fibrosis is regarded to be the result of wound healing following inflammatory changes. The final stage of alcoholic and “non-alcoholic” fatty liver disease is liver cirrhosis. Hepatic steatosis and steatohepatitis are also associated with an increased risk of hepatocellular carcinoma, and alcohol misuse and obesity are the most common risk factors for this malignant tumor in developed countries^[53,54].

One study^[37] has compared the histopathological patterns between consecutive patients with alcoholic and “non-alcoholic” hepatic steatosis, demonstrating an increased risk of steatohepatitis and fibrosis in patients with alcoholic relative to “non-alcoholic” fatty liver disease. The conclusions from that study^[37] are, however, hampered by the limited comparability between the exposure groups with respect to the extent of risk factors. The prevalence of liver fibrosis in patients who admittedly consumed at least 80 g alcohol daily was compared to that in “non-alcoholic” fatty liver disease patients, of whom 77% had a body weight of > 10% above their ideal body weight. The higher grades of lobular inflammation, fibrosis and cirrhosis might well be explained by unbalanced risk factors in that study^[37]. Another study^[55] supports this notion. Histopathological findings were investigated in 160 patients with morbid obesity who underwent gastric bypass or gastric banding surgery. The proportion of “non-alcoholic” steatohepatitis was 33.8% and thus reached higher percentages than have been previously described in heavy alcoholic drinkers^[23].

Similar to the risk of pure steatosis, there is also a possible overlap of risk factors for steatosis-related sequelae. After investigating risk factors for steatohepatitis and liver cirrhosis in patients with alcoholic fatty liver disease, it was demonstrated that the co-existence of alcohol misuse with obesity and metabolic syndrome increases the risk of complications of alcoholic fatty liver disease^[56]. Conversely, in patients with “non-alcoholic” fatty liver disease, moderate and, particularly, heavy episodic alcohol consumption increases the risk of hepatic fibrosis^[57].

A Danish register study^[58] demonstrated that, after excluding patients with liver cirrhosis, both alcoholic and

“non-alcoholic” fatty liver disease was associated with an increased risk of primary liver cancer, and that this risk was higher in the alcoholic (standardized incidence ratio 9.5; 95% CI: 5.7-14.8) than in the “non-alcoholic” group (standardized incidence ratio 4.4; 95% CI: 1.2-11.8). Unfortunately, as is commonly inherent to register studies, only a limited amount of baseline data was available. Hence, uncertainty exists as to whether “non-alcoholic” fatty liver disease was mainly due to obesity and metabolic syndrome or whether other causes were also present.

Taken together, given individual susceptibility, which cannot be fully defined by the current knowledge, hepatic steatosis may progress to steatohepatitis, liver cirrhosis and hepatocellular carcinoma. The major determinant for this progression is the persistence of risk factors, which has led to hepatic steatosis.

Extrahepatic complications: The association between hepatic steatosis and extrahepatic sequelae has become an important issue of current research. Since “non-alcoholic” hepatic steatosis is regarded to be closely related to metabolic syndrome, multiple studies have investigated its associations with atherosclerotic diseases^[59-61] and diabetes mellitus^[62-65]. Most of these studies^[59,61-63,65], however, used the relatively unspecific serum transaminase levels to define the exposure variables and commonly did not compare the risks of the outcomes between subjects with “non-alcoholic” and alcohol-related fatty liver disease.

In SHIP, we extensively studied the associations between metabolic disorders and hepatic steatosis as defined by the combined presence of ultrasound and laboratory findings. We identified strong inverse relations of hepatic steatosis with the anabolic hormones testosterone in men^[66] and insulin-like growth factor-1 in both genders^[67]. All of these relations were independent of alcohol consumption. Moreover, stratified analyses in subjects who consume more or less alcohol did not reveal any significant difference between both groups. A recent case-control study confirmed that carotid intima-media thickness was higher in all patients with fatty liver disease compared to healthy controls, but there was no difference in intima-media thickness between patients with alcoholic or “non-alcoholic” fatty liver disease^[68].

Using the longitudinal data, we demonstrated that subjects with hyperechogenicity on liver ultrasound and increased serum alanine aminotransferase levels at baseline more commonly used health care services over the following five years^[8]. Consequently, hepatic steatosis was also related to increased health care costs. Another analysis showed that increased serum γ -glutamyl transpeptidase levels were predictive of mortality if a hyperechogenic liver echo pattern was also present^[69]. All of these associations of hepatic steatosis with mortality as well as future health care utilization and costs were independent of alcohol consumption. Also, stratification of the study population according to more or less alcohol consumption did not reveal any difference in the subgroups with respect to the outcomes.

In good agreement with the hypothesis that not only the risk of fatty liver disease itself but also its outcome is determined by multiple risk factors, the NHANES III study demonstrated that the components of the metabolic syndrome are associated with overall mortality in both “non-alcoholic” and alcoholic fatty liver disease^[70]. In line with our findings, an extension of the aforementioned study by Cortez-Pinto *et al*^[13,71] demonstrated that the clinical status of patients, but not the major cause of fatty liver disease, is predictive of the outcome. Patients with “non-alcoholic” steatohepatitis as well as ambulatory and hospitalized patients with alcoholic hepatitis were followed up over a mean time of six years. Survival was similar between patients with alcoholic and “non-alcoholic” steatohepatitis. Only the subgroup of hospitalized alcoholics had a shorter survival than patients with “non-alcoholic” steatohepatitis^[71]. As mentioned earlier, this finding might be explained by the more advanced disease stage of hospitalized alcoholics, when compared to patients with “non-alcoholic” steatohepatitis at the time of recruitment.

Taken together, it is still not clear whether extrahepatic complications of “non-alcoholic” fatty liver disease are specific for the metabolic origin. Rather, it seems likely that fatty liver disease confers this risk, independent of its causes.

Prevention and therapy

The question arises as to whether specific strategies for primary and secondary prevention and treatment represent the major difference between alcoholic and “non-alcoholic” fatty liver disease. In the former, abstinence from alcohol is the major goal, while in the latter the major challenge is improvement of insulin resistance. The most efficient risk factor reduction can be achieved by lifestyle changes. In patients with alcoholic fatty liver disease the major treatment target is total abstinence from alcohol, while in patients with “non-alcoholic” fatty liver disease the central goal is weight reduction by calorie reduction and optimized food quality^[18]. Treatment can be pharmacologically supported by drugs, which improve the insulin resistance^[72].

From a more general perspective, risk factor reduction is the major principle of prevention and treatment in both forms of fatty liver disease. This more general perspective is particularly necessary, given the overlap between risk factors and their potential interactions.

Risk factor reduction is not only important to prevent the natural course of the disease from benign hepatic steatosis to steatohepatitis and cirrhosis, but it is also required to avoid recurrent fatty liver disease in allografts following liver transplantation^[72]. This general statement is appropriate for both alcoholic and “non-alcoholic” fatty liver disease and also holds true for alcoholic fatty liver disease with a “non-alcoholic” component and *vice versa*.

Beyond risk factor reduction and liver transplantation in end stage liver failure, no specific therapies for alcoholic fatty liver disease are currently accepted in clinical

medicine, and none have proven to be exclusively sufficient in patients with “non-alcoholic” or alcoholic fatty liver disease. Thus, several therapeutic strategies that aim at, for instance, supporting the antioxidative system or reducing inflammation have been tested only in specific forms of fatty liver disease^[18,72,73].

Taken together, risk factor reduction is the major goal of prevention and the basic principle of treating fatty liver disease.

CONCLUSION

This review followed the hypothesis that fatty liver disease is a multifactorial disease with alcohol consumption and metabolic factors being the most common risk factors. For many aspects, studies were found that directly confirmed the hypothesis. Other studies, which apparently did not support this notion, were critically assessed from the epidemiological perspective. Following the line of evidence presented herein, the hypothesis underlying the strict separation of alcoholic from “non-alcoholic” fatty liver disease may be less justified than taking fatty liver disease as it probably is—a multifactorial disorder.

The current concept to distinguish between alcoholic and “non-alcoholic” fatty liver disease is mainly based on the presence of alcohol misuse and obesity-related metabolic disorders as common risk factors and, at least evident for the early phase of the disease, specific pathogenetic mechanisms. This concept has, however, several limitations. These limitations include the clear distinction between both entities in the common presence of alcohol misuse and obesity-related metabolic disorders and the non-consideration of other causal factors listed in Figure 1. Both entities share similar histopathological patterns and pathways. Studies demonstrating differences in clinical presentation and outcome are sometimes biased by selection. Risk factor reduction is the main principle of prevention and treatment of both forms of the disease.

Fatty liver disease parallels other multicausal diseases in many aspects. For example, various risk factors for atherosclerosis have been established including tobacco consumption, obesity and metabolic syndrome. For all of these risk factors, specific pathways have been described^[74,75]; the outcome following acute coronary syndrome or stroke differs depending on the type and amount of risk factors accumulated^[76-78] and, beyond basic therapeutic principles, the choice of pharmaceutical drugs depends on the pattern of individual risk factor profiles. However, the presence of underlying risk factors is not mutually exclusive, the histopathological findings are not risk factor specific, and risk factor reduction is the main goal of primary and secondary prevention. In cardiovascular medicine, however, there is no concept to distinguish between tobacco and non-tobacco-related atherosclerosis.

The distinction between alcoholic and “non-alcoholic” fatty liver disease is arbitrary and artificial. It should be replaced by a concept which regards fatty liver disease as

a multicausal disorder. Such a concept opens up multiple questions, which are potentially of high clinical relevance. Examples of these questions are: Are there cumulative thresholds for the effect of risk factors for fatty liver disease and related complications, and how are those hypothetical thresholds decreased by the additional presence of other risk factors? As expected, the association between risk factors and alcoholic fatty liver disease follows a dose-response pattern^[23]. Similar findings have been documented for “non-alcoholic” fatty liver disease. In the Dionysos study^[79], the prevalence of hepatic steatosis was estimated to be 91% in obese, 67% in overweight and 24% in normal weight individuals. However, it still remains to be determined whether these risk factors interact with other factors listed in Figure 1. The multicausal approach could also be applied to investigation of the factors defining individual susceptibility for this multicausal disorder and its complications. From the clinical perspective, it would be highly valuable to explore risk scores similar to those scores established for coronary artery disease^[80] or diabetes mellitus^[81], for instance. Finally, complex therapeutic strategies, in addition to risk factor reduction, could be found.

In conclusion, alcoholic and “non-alcoholic” fatty liver diseases are one and the same disease caused by different risk factors. A shift from artificial categories to a more general approach to fatty liver disease as a multicausal disorder may optimize preventive strategies and help clinicians more effectively treat patients at the individual level.

Abstract

The regenerating islet-derived members (*Reg*), a group of small secretory proteins, which are involved in cell proliferation or differentiation in digestive organs, are upregulated in several gastrointestinal cancers, functioning as trophic or antiapoptotic factors. Regenerating islet-derived type IV (*RegIV*), a member of the *Reg* gene family, has been reported to be overexpressed in gastroenterological cancers. *RegIV* overexpression in tumor cells has been associated with carcinogenesis, cell growth, survival and resistance to apoptosis. Cancer tissue expressing *RegIV* is generally associated with more malignant characteristics than that without such expression, and *RegIV* is considered a novel prognostic factor as well as diagnostic marker in some gastroenterological cancers. We previously investigated the expression levels of *RegIV* mRNA of 202 surgical colorectal cancer specimens with quantitative real-time reverse-transcriptase polymerase chain reaction and reported that a higher level of *RegIV* gene expression was a significant independent predictor of colorectal cancer. The biologic functions of *RegIV* protein in cancer tissue, associated with carcinogenesis, anti-apoptosis and invasiveness, are being elucidated by

molecular investigations using transfection techniques or neutralizing antibodies of *RegIV*, and the feasibility of antibody therapy targeting *RegIV* is being assessed. These studies may lead to novel therapeutic strategies for gastroenterological cancers expressing *RegIV*. This review article summarizes the current information related to biological functions as well as clinical importance of *RegIV* gene to clarify the significance of *RegIV* expression in gastroenterological cancers.

INTRODUCTION

It is generally accepted that cancer develops as a result of multiple genetic alterations. A better understanding of the changes in gene expression that occur during carcinogenesis may lead to improvements in diagnosis, treatment and prevention. Identification of novel biomarkers for cancer diagnosis and novel targets for treatment is a major goal^[1]. Genes encoding transmembrane/secretory proteins strongly expressed in cancer may be ideal biomarkers for cancer diagnosis^[2]. In addition, if the function of the gene product is involved in the neoplastic process, such genes may constitute a therapeutic target.

The regenerating islet-derived members (*Reg*) are a

family of genes belonging to the calcium-dependent lectin (C-type lectin) gene superfamily^[3-6]. Reg represents a group of small secretory proteins that are essential for cell regeneration and proliferation and form an immune system^[7,8]. Reg plays a wide range of roles in human physiology as well as in disease^[9-15] (Table 1). Among the human Reg family, special attention has been paid to Regenerating islet-derived type IV (RegIV), the most recently discovered member. RegIV was originally isolated from a cDNA library of ulcerative colitis tissues by Hartupée *et al.*^[3]. It is expressed not only in various normal tissues such as stomach, colon, small intestine and pancreas^[16,17], but also in various malignant diseases, including colorectal^[18], gastric^[19], pancreatic^[20] and gallbladder cancer^[21]. The biological functions of RegIV in cancers are not fully understood; however, several possible functions have been proposed.

MOLECULAR CHARACTERISTICS OF REGIV AND OTHER REG GENES

Using sequence analysis, Hartupée *et al.*^[3] mapped the RegIV gene to chromosome 1 and determined that the RegIV gene contains 6 exons, the structure of which is preserved among members of the Reg gene family. Zhang *et al.*^[22] also showed that most members of the Reg family have similar organization with respect to exon number and chromosome location.

Previous studies have revealed that the Reg family shares strong similarities with C-type lectin^[3], which is distinguished from other lectins by sharing a calcium-dependent carbohydrate recognition domain (CRD). This domain of lectin might account for the complex events induced by RegIV and other Reg genes^[23-25]. Unlike RegIV, however, other Reg genes are present at low or undetectable levels in most tumors^[11]. Analysis of the unique structural similarities and differences between RegIV and other members of this gene family are expected to provide a basis for investigations of structure-function relations in this gene family.

As for binding of RegIV to other molecules or putative receptors, detailed interactions have not been elucidated. Ho *et al.*^[26] recently provided evidence that human RegIV binds to polysaccharides and mannan in the absence of calcium, unlike other C-type lectins. Utilizing nuclear magnetic resonance to elucidate the structural basis for carbohydrate recognition of RegIV, they found that RegIV has two calcium-independent mannan-binding sites serving as CRDs, suggesting a potential role in specific carbohydrate recognition^[26]. These findings might provide clues to understanding the sugar-binding role of RegIV proteins, as well as molecular interactions with currently unknown receptors.

REGIV OVEREXPRESSION IN GASTROENTEROLOGICAL CANCER

Although various normal tissues express RegIV, expres-

sion levels are much lower in normal tissues than in cancerous tissues^[27]. Violette *et al.*^[11] showed that the RegIV is more strongly expressed in colorectal tumors (particularly in mucinous carcinomas) and normal small intestine than in normal colorectal tissue. They also demonstrated that RegIV-positive tumor cells display different phenotypes: mucus-secreting, enterocyte-like, or undifferentiated.

Several studies have demonstrated overexpression of RegIV in gastric cancer. Oue *et al.*^[16] reported that RegIV expression was significantly higher in gastric carcinoma than in normal tissue on quantitative real-time polymerase chain reaction (PCR). Moreover, RegIV expression was associated with both intestinal mucin phenotype and neuroendocrine differentiation.

In pancreatic ductal adenocarcinoma^[20] as well as in gallbladder carcinoma^[21] amplification of RegIV in normal tissues was not apparent on quantitative real-time PCR. In contrast, high levels of RegIV were found in cancer tissues. These data suggest that overexpression of RegIV is associated with generating and maintaining cancer tissue.

IMPORTANT ROLES OF REGIV IN CANCER TISSUES

Overexpression of RegIV is an early event in carcinogenesis

Carcinogenesis is a multistep process involving somatic mutations or epigenetic changes affecting tumor suppressor genes and oncogenes. Several studies have indicated that RegIV may participate in early carcinogenesis in certain cancers.

Most colorectal carcinomas are thought to develop through the “adenoma-to carcinoma sequence” model^[28], in which adenomas are recognized as precursor lesions of the vast majority of colorectal cancers. Elucidation of the adenoma-carcinoma sequence along with its corresponding molecular genetic alterations will significantly enhance our understanding of the pathogenesis of colorectal carcinoma. However, since research on genetic mutations of adenomas is scant, the mechanism of the adenoma-adenocarcinoma sequence remains elusive.

Zhang *et al.*^[9,14] generated a large collection of candidate, differentially expressed genes in primary colorectal adenomas and found that RegIV was one of the differentially expressed genes in colorectal adenoma and adenocarcinoma. They proposed that overexpression of RegIV may be an early event in colorectal carcinogenesis.

In gastric cancer, one of the important precancerous changes is intestinal metaplasia caused by chronic inflammation^[29]. Oue *et al.*^[27] performed serial analysis of gene expression of gastric carcinoma and identified several genes potentially involved in invasion, metastasis and carcinogenesis, and reported that RegIV is a candidate gene for cancer-specific expression. They also performed immunohistochemical analysis of RegIV in gastric tissues and showed that RegIV protein was immunohistochemically expressed in the goblet cells of intestinal metaplasia of the stomach and gastric carcinoma, suggesting an association of RegIV protein with intestinal differentiation of the

Table 1 Human Reg family

Superfamily member	Length of amino acid	Chromosome localization	Main function

Reg III G	175	2p12	Lectin-mediated innate immunity by binding intestinal bacteria, forming symbiotic host-microbial relationships
RegIV	158	1p12	Cell proliferation and cell regeneration. Carcinogenesis and anti-apoptosis in gastroenterological cancers

Reg: Regenerating gene; RegIV: Regenerating islet-derived type IV.

stomach and the pathogenesis of intestinal-type gastric carcinoma^[16].

Gallbladder carcinoma is also thought to arise from epithelial dysplasia, and dysplasia appears to arise from metaplasia^[50]. Tamura *et al.*^[21] reported that RegIV participates in gallbladder carcinogenesis *via* intestinal metaplasia because RegIV expression was found not only in the cancer cells but also in the intestinal metaplastic epithelium of patients with adenomyomatosis. In contrast, RegIV expression was never apparent in the normal epithelium of the gallbladder.

Intraductal papillary mucinous neoplasms (IPMN) of the pancreas show a wide spectrum of histological differentiation from hyperplasia and adenoma, and the existence of an adenoma-carcinoma sequence has been documented^[31-33]. Adsay *et al.*^[34-36] suggested that the intestinal-type IPMN to colloid carcinoma sequence is a distinct pathway of carcinogenesis involving intestinal-related genes caudal-type homeobox transcription factor 2 (*CDX2*) and Mucin 2 intestinal (*MUC2*). They described this pathway as the “intestinal” pathway of carcinogenesis. *CDX2* is a transcriptional factor that is important for the maintenance of intestinal identity^[57], and *MUC2* is a major mucin detected in intestinal epithelium^[58]. Nakata *et al.*^[58] analyzed RegIV and *CDX2* expressions in patients with IPMNs using immunohistochemical staining and microdissection-based quantitative real-time reverse transcription PCR. The positive rates of both RegIV protein and mRNA expression were significantly higher in intestinal-type IPMN than in the other types of IPMN. A significant correlation between *RegIV* and *CDX2* mRNA levels was also demonstrated. They concluded that RegIV plays an important role in differentiation of the “intestinal” pathway of IPMN and may be regulated by *CDX2*.

Carcinogenesis is a complex, multistep process involving somatic mutations or epigenetic changes affecting tumor suppressor genes and oncogenes^[39,40]. RegIV may contribute a part of these process, however further investigation is essential for comprehensive elucidation.

RegIV as an antiapoptotic factor

Advanced malignancies are often associated with poor responses to chemotherapy or radiation. Additional generic alterations in tumorigenesis create a permissive environment for clonal expansion of cells that are resistant to apoptosis^[41]. So far, considerable attention has been given to the B-cell lymphoma 2 (*Bcl-2*) family of genes as pos-

sible regulators of intrinsic tumor resistance to therapy^[42]. Repressors of programmed cell death, such as *Bcl-2* and B-cell lymphoma-extra large (*Bcl-xL*), are known to decrease radiation- and chemotherapy-induced apoptotic cell death in cell cultures^[43] *via* the Akt signaling pathway, which is an important determinant of the response to anticancer therapy^[44]; overexpression of these genes suggests a poor prognosis in colon cancer^[45]. However, key cellular factors that regulate expression of anti-apoptotic genes in tumors are not fully clarified. Defining dominant pathways responsible for regulating apoptosis could broaden current strategies for therapeutic intervention.

Bishunpuri *et al.*^[46] investigated possible roles of RegIV in colon cancer cells, using an *in vitro* radiation-survival colony assay. Colon cancer cells were cultured with or without recombinant human RegIV (rhR4) and exposed to 4 Gy of irradiation. After irradiation, colony counts increased significantly in rhR4-treated cell lines, but decreased in untreated cells. In the absence of irradiation, rhR4 treatment did not alter the numbers of colonies in treated cells. These data indicate that RegIV promotes tumor cell survival following a potent apoptotic stimulus. Furthermore, to establish a causative association between *RegIV* and the anti-apoptotic genes *Bcl-2* and *Bcl-xL*, *rhR4* was added to cultures of colon carcinoma cell lines, and *Bcl-2* and *Bcl-xL* mRNA expression levels were analyzed. Both *Bcl-2* and *Bcl-xL* expression levels increased significantly after rhR4-treatment in colon cancer cell lines, indicating that exogenous RegIV regulates expression of the *Bcl-2* and *Bcl-xL*.

Mitani *et al.*^[19] also transfected gastric cancer cells with vector expressing RegIV to investigate the biologic significance of RegIV. To evaluate the effects of RegIV on the response to 5-fluorouracil (5-FU) treatment, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assays were performed. Overexpression of RegIV in gastric cancer cells was confirmed to significantly inhibit 5-FU-induced apoptosis compared with cells transfected with empty vector on both MTT assay and measurement of DNA fragments. They also examined the expression of dihydropyrimidine dehydrogenase (DPD), because DPD has important roles in the pharmacokinetics and toxicity of 5-FU^[47,48]. Induction of DPD expression was demonstrated in cells overexpressing RegIV compared with a negative control on Western blotting. They next examined the relevance of RegIV expression to the response of gastric cancer to low-dose 5-FU and cisplatin in patients with

Table 2 Articles reporting regenerating islet-derived type IV as anti-apoptotic factor

Author	Year	Type of cancer	Result
Bishnupuri <i>et al</i> ^[46]	2006	Colorectal	RegIV induces cell survival against radiation, and regulates Bcl-2 and Bcl-xL
Mitani <i>et al</i> ^[19]	2007	Gastric	RegIV inhibited 5-fluorouracil-induced apoptosis, and induced DPD expression
Eguchi <i>et al</i> ^[44]	2009	Pancreatic	RegIV decreased the sensitivity to radiation and gemcitabine

recurrent gastric cancer. Among 36 patients who received this regimen, the response was no change or progressive disease in all 14 patients with RegIV expression, whereas partial responses were obtained in 8 (36.4%) of the 22 patients without RegIV expression ($P = 0.013$).

To investigate the relevance of RegIV to resistance to chemotherapy or radiotherapy, Eguchi *et al*^[44] established stable RegIV-expressing cells by transfection of plasmid into RegIV-negative pancreatic cancer cells. Fluorescence-activated cell scanning analysis of radiated cells showed that the apoptotic population was 28.7% among radiated control cells, compared with only 10.7% among RegIV-expressing cells ($P < 0.001$). Similarly, the 50% inhibitory concentration (IC₅₀) of gemcitabine was 100 nmol/L against RegIV-expressing cells, but only 30 nmol/L against control cells. These *in vitro* findings suggest that RegIV has anti-apoptotic properties in pancreatic cancer cells exposed to radiation and chemotherapy.

These studies revealed that RegIV not only promotes the expression of certain factors known as anti-apoptotic proteins, but also contributes to increasing resistance to apoptotic death during treatment *in vivo* as well as *in vitro* (Table 2).

RegIV as a proinvasive factor

Rafa *et al*^[49] investigated the potential function of RegIV as a proinvasive factor in colorectal cancer cells. Colon cancer cells secreting RegIV or not were used to analyze the autocrine and paracrine effects of RegIV. They evaluated the invasive properties of cancer cells by performing collagen type I invasion assays and calculating invasion index, which is useful for judging the invasion ability^[50,51]. They demonstrated that cell lines which secreted RegIV were spontaneously invasive, whereas cells which did not secrete RegIV were non-invasive compared with positive control cells. They also added the RegIV protein to non-RegIV-secreting cell lines, and confirmed a dose-dependent increase in the invasive index. Addition of an anti-RegIV antibody to assays with the invasive cell lines significantly limited their invasive properties. These results suggest that RegIV promotes *in vitro* invasion of colon cancer cell lines in both an autocrine and a paracrine manner.

REGIV EXPRESSION AND CLINICOPATHOLOGICAL FEATURES

Several studies have contrasted clinicopathological features with expression levels of RegIV. Among 36 patients with

colorectal cancer, Oue *et al*^[16] demonstrated that lymph node metastasis was positive in 69.2% of the RegIV-positive group, but only 30.4% of RegIV-negative group, suggesting that RegIV contributes to lymph node metastasis in colorectal cancer. A relation between overexpression of RegIV and liver metastasis has also been demonstrated in patients with colorectal cancer^[18,52]. One study of 30 patients with colorectal cancer showed that metastatic recurrence in the liver during follow-up was more frequently associated with the presence than the absence of RegIV staining (63% *vs* 9%, $P = 0.010$)^[18]. Bishnupuri *et al*^[53] suggested that liver metastasis might result from RegIV inducing matrix metalloproteinase-7, which promotes liver metastasis^[54].

We studied surgical specimens of cancer tissue and adjacent normal mucosa obtained from 202 patients with colorectal cancer. We examined the relations between the expression levels of RegIV and clinicopathological features. High expression levels of RegIV were significantly related to well-differentiated histological type, deeper invasion, lymphatic invasion, liver metastasis, and advanced stage (stage IV). In contrast, RegIV expression levels were unrelated to age, gender, tumor size, tumor location, lymph node metastasis, and venous invasion^[55].

In gastric cancer, positive RegIV expression has been associated with poorly differentiated tumors, although there was no clear correlation between RegIV expression and tumor depth or lymph node metastasis^[16]. The results of an *in vitro* study by Kuniyasu *et al*^[56] suggest that RegIV might accelerate peritoneal metastasis in gastric cancer.

These studies generally discussed the unfavorable impact of RegIV expression on clinicopathological features. Cell proliferation and anti-apoptotic effect induced by RegIV may accelerate progression of cancer.

RegIV as a prognostic factor

RegIV has recently been recognized to be associated with poor prognoses in specific gastroenterological cancers. Macadam *et al*^[13] reported a significant increase in colorectal cancer-related deaths among patients with non-metastatic early stage disease whose tumors expressed Reg genes. This subgroup of patients was also at high risk for recurrent colorectal cancer after curative surgery, and such patients may benefit from adjuvant therapy^[13].

We also demonstrated that RegIV is significantly associated with outcomes in colorectal cancer. In our study, overall survival rates were significantly higher in RegIV low patients (83.5%) than in RegIV high patients (55.1%, $P = 0.002$). On multivariate Cox regression analysis, tu-

RegIV: Reporting regenerating islet-derived type IV.

mor size, liver metastasis, and a higher level of *RegIV* gene expression ($P = 0.029$) were significant independent predictors of overall survival in colorectal cancer^[55].

Miyagawa *et al*^[57] estimated RegIV mRNA levels in the peritoneal washes of 95 patients with gastric cancer by real-time reverse transcription-PCR. The RegIV mRNA level was correlated with the extent of wall penetration and peritoneal metastases. They also found that the outcomes of RegIV-positive patients were significantly worse than those of RegIV-negative patients. Multivariate analysis suggested that RegIV is an independent prognostic factor^[57].

Tao *et al*^[58] measured RegIV mRNA levels by immunohistochemical staining of tissue, and enzyme-linked immunosorbent assay of serum. Their results confirmed that the mean survival time was significantly shorter in patients with RegIV-positive gastric cancer than in those with RegIV-negative gastric cancer ($P = 0.013$)^[58].

In gallbladder cancer, Tamura *et al*^[21] reported that high expression of RegIV correlated with a well-differentiated phenotype accompanied by better outcomes, where lower expression correlated with a poorly differentiated phenotype accompanied by worse survival, suggesting that loss of RegIV expression might be associated with more malignant characteristics.

According to these data, RegIV expression is generally associated with poor outcomes in colorectal cancer and gastric cancer. Further studies will hopefully clarify differences in clinical outcomes according to the type of cancer.

RegIV as a diagnostic biomarker

Serum biomarkers for the detection of cancer are needed in order to find a larger number of candidates for suspected cancer. Several studies have assessed the feasibility of using RegIV as a serum diagnostic marker (Table 3). Oue *et al*^[18] measured serum RegIV levels in patients with colorectal cancer by enzyme-linked immunosorbent assay to investigate the diagnostic potential of RegIV. Increased preoperative levels of RegIV were found in a low numbers of serum samples from patients with stage 0-III colorectal cancer, indicating that serum RegIV is unsuitable for the detection of early colorectal cancer. In contrast, in patients with stage IV disease, the serum RegIV concentration was significantly higher in the presence than in the absence of liver metastasis, suggesting that RegIV is a good marker for metastatic recurrence in the liver after resection of colorectal cancer.

Mitani *et al*^[19] demonstrated that the serum RegIV concentration in presurgical patients with gastric cancer was significantly higher than that in healthy individuals ($1.96 \pm 0.17 \mu\text{g/L}$ vs $0.52 \pm 0.05 \mu\text{g/L}$, $P < 0.001$). The diagnostic sensitivity of serum RegIV (36.1%) was superior to that of serum carcinoembryonic antigen (CEA, 11.5%) or carbohydrate antigen 19-9 (CA19-9, 13.1%).

Kobayashi *et al*^[59] also evaluated the usefulness of serum RegIV levels as a diagnostic marker for gastric cancer. They collected pretreatment serum samples from patients with gastric cancer and healthy control subjects without cancer. RegIV levels were significantly higher in patients with early gastric cancer (median $8.42 \mu\text{g/L}$) than in the control subjects (median $5.01 \mu\text{g/L}$) ($P < 0.001$). RegIV levels were also higher in patients with advanced gastric cancer (median $13.12 \mu\text{g/L}$) than in those with early gastric cancer ($P < 0.02$). The sensitivity for gastric cancer was 73.0%, the specificity was 70.8%, and the accuracy was 71.8%, which is superior to the respective values for CEA and CA19-9. Serum RegIV levels were thus suggested to be potentially useful as a screening marker for gastric cancer, including early disease.

In pancreatic cancer, Takehara *et al*^[20] detected significantly elevated serum RegIV levels, measured with the use of an enzyme-linked immunosorbent assay system, in patients with early-stage pancreatic ductal adenocarcinomas. Their findings suggested that RegIV may become a new serological marker of pancreatic ductal adenocarcinoma.

Serum RegIV level can be a useful indicator to distinguish between patients with cancer and healthy subjects. RegIV has the potential to be used as a screening serum marker for certain cancers, including cancers in the early stages.

SIGNALING PATHWAY OF REGIV, AND REGIV-TARGETED THERAPY

Monoclonal antibody therapy has become an important option for the management of gastroenterological cancer. Bevacizumab, a humanized monoclonal antibody to vascular endothelial growth factor, is currently approved in combination with intravenous 5-FU-based regimens for first-line treatment of metastatic colorectal cancer. Besides the anti-angiogenesis factor antibody, antibodies against circulating ligands, such as hepatocyte growth factor^[60] and interleukin-6^[61], are under review as anticancer drugs.

The signaling pathway activated by *RegIV* is poorly understood; however, Bishunpuri *et al*^[53] recently demonstrat-

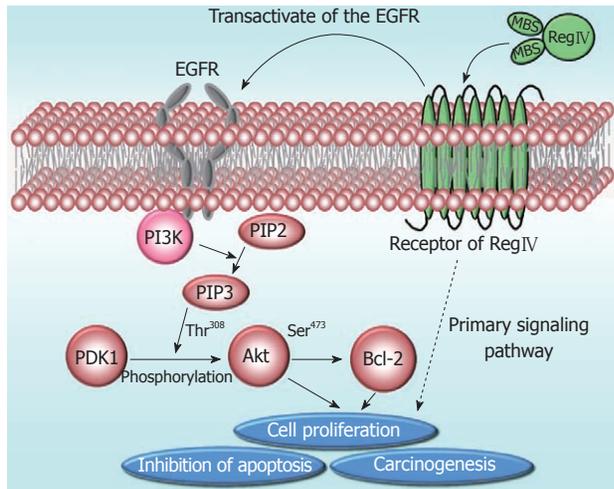

Figure 1 Schematic representation of the regenerating islet-derived type IV signaling pathway. Regenerating islet-derived type IV (RegIV) contributes to cell proliferation, inhibition of apoptosis, and carcinogenesis *via* protein kinase B (Akt) signaling pathway by transactivating the epidermal growth factor receptor (EGFR). The primary signaling pathway is now being investigated. MBS: Mannan-binding sites; PI3K: Phosphoinositide 3-kinase; PIP2: Phosphatidylinositol 4,5-bisphosphate; PIP3: Phosphatidylinositol 4,5-triphosphate; PDK1: Phosphoinositide-dependent kinase-1; Bcl-2: B-cell lymphoma 2.

ed that *RegIV* is likely to function as an anti-apoptotic factor in colon cancers through the phosphorylation of Akt and epidermal growth factor receptor (EGFR). EGFR expression and activation are common in adenocarcinomas and are associated with poor prognoses^[62-68]. The importance of EGFR in colorectal cancer has been underpinned by the clinical use of the cetuximab, a therapeutic monoclonal antibody that binds to the external domain of EGFR and blocks ligand-mediated dimerization and activation^[68].

Akt is another important downstream target of EGFR because EGFR activates Akt *via* a signaling pathway involving phosphoinositide 3-kinase (PI3K) and phosphoinositide-dependent kinase-1^[69,70]. Akt overexpression and activation by phosphorylation at Thr³⁰⁸ and Ser⁴⁷³ are well-established early events in sporadic colon carcinogenesis and are detectable in the neoplastic epithelium, but are generally absent in normal colonic epithelium^[71].

Bishunpuri *et al.*^[53] examined the effects of purified rhR4 on colon adenocarcinoma cells to determine the signaling pathways responsive to RegIV. They reported that rhR4 treatment resulted in rapid phosphorylation of EGFR at Tyr⁹⁹² and Tyr¹⁰⁶⁸ and Akt at Thr³⁰⁸ and Ser⁴⁷³. They concluded that RegIV is a potent transactivator of the EGFR/PI3K/Akt signaling pathway *via* an unknown receptor and proposed that disruption of PI3K signaling may have utility as a novel therapeutic intervention for colorectal cancer.

To examine the role of RegIV overexpression in pancreatic cancer cells, Takehara *et al.*^[20] constructed several expression vectors designed to express siRNA specific to RegIV and transfected them into a pancreatic cancer cell line that endogenously expressed RegIV at a high level. The cell line had a knockdown effect on endogenous RegIV transcription, resulting in a significant reduction in

the number of viable cells as measured by MTT assay as well as by colony formation assay compared with negative controls. RegIV was thus suggested to have a critical role in pancreatic cancer cell survival and growth. They also generated recombinant human RegIV and incubated pancreatic cancer cells in its presence to examine whether RegIV activates the Akt signaling pathway. Recombinant human RegIV treatment was confirmed to significantly increase phosphorylated Akt, suggesting that RegIV stimulates cell growth *via* the Akt signaling pathway in pancreatic cancer cells^[20]. Furthermore, by using monoclonal antibodies specific to RegIV, they succeeded in neutralizing secreted RegIV in the culture medium *in vitro* and found that treatment with these neutralizing antibodies significantly suppressed pancreatic cancer cell growth by blocking Akt phosphorylation.

Legoffic *et al.*^[72] similarly examined the effect of RegIV antibody by Western blotting analysis in mice with pancreatic cancer. They confirmed that the injection of RegIV antibody significantly reduced the intra-tumor level of proteins associated with apoptosis (Akt, Bcl-2 and Bcl-xL) after treatment compared with a control group, resulting in significant reduction of tumor.

The results of these studies suggest that RegIV may contribute to cell proliferation and anti-apoptosis by transactivating EGFR *via* an unknown receptor (Figure 1). Although a cell surface receptor for RegIV has not been identified, there are numerous examples where EGFR is transactivated by signaling molecules that do not bind directly to receptor. Bishunpuri *et al.*^[53] speculated that the RegIV receptor might be a G protein-coupled receptor, because ligands capable of transactivating EGFR usually act on such receptors. They are now focusing on identifying the RegIV binding receptor and further delineating primary intracellular signaling events^[53].

The findings outlined above suggest the feasibility of antibody therapy targeting RegIV. Neutralizing antibody therapy targeting RegIV may lead to novel therapeutic strategies for gastroenterological cancers expressing RegIV (Table 4).

CONCLUSION

This is the first systematic review of the *RegIV* gene as related to gastroenterological cancer, focusing on its role in cancer tissue and its impact on clinical outcomes. RegIV is generally upregulated in gastroenterological cancers, including those of the stomach, colorectum, and pancreas, as well as in benign diseases such as ulcerative colitis. Available evidence suggests that the basic biological effects of RegIV seem to be induction of cellular proliferation, invasion and inhibition of apoptosis, resulting in relatively worse clinicopathological features, or worse survival in patients with high-RegIV expression than those without.

Recent studies revealed that the serum RegIV level can be a novel biomarker to detect patients with colorectal, gastric, and pancreatic cancer. These studies suggested RegIV has the potential to be used as a screening serum

Table 4 Articles reporting regenerating islet-derived type IV-targetted therapy

Author	Year	Method/type of cancer	Result
Bishunpuri <i>et al</i> ^[53]	2006	Transfection of rhR4/ colorectal	Increase in pEGFR and pAkt
Takehara <i>et al</i> ^[20]	2006	Transfection of rhR4 and siRNA/pancreatic	Significant reduction in viable cells and increase in pAkt
Legoffic <i>et al</i> ^[72]	2009	RegIV antibody injection/pancreatic	Significant reductions in Akt, Bcl-2 and Bcl-xL

rhR4: Recombinant human regenerating islet-derived type IV; RegIV: Human regenerating islet-derived type IV; siRNA: Small interfering RNA; pEGFR: Phosphorylated epidermal growth factor receptor; pAkt: Phosphorylated protein kinase B; Akt: Protein kinase B; Bcl-2: B-cell lymphoma 2; Bcl-xL: B-cell lymphoma-extra large.

marker. In addition, our multivariate analysis suggested that overexpression of the *RegIV* gene is a useful prognostic biomarker in patients with colorectal cancer, which corresponds to other reports.

The signaling pathway activated by RegIV is not fully understood. However, recent studies demonstrated that RegIV is a potent activator of the EGFR/Akt signaling cascade, which is associated with cell survival and proliferation. Further investigation of RegIV, particularly its cell surface receptors and signaling pathways, will further our understanding of the basic mechanisms of this gene. Strategies designed to reduce endogenous RegIV expression or to block downstream signaling warrant additional investigations to delineate their potential roles in the prevention or treatment of established gastrointestinal adenocarcinomas.

Abstract

AIM: To evaluate the presence of progenitor cells in healthy adult rat liver displaying the equivalent advanced hepatogenic profile as that obtained in human.

METHODS: Rat fibroblastic-like liver derived cells (rFLDC) were obtained from collagenase-isolated liver cell suspensions and characterized and their phenotype profile determined using flow cytometry, immunocytochemistry, reverse transcription polymerase chain reaction and functional assays.

RESULTS: rFLDC exhibit fibroblastoid morphology, express mesenchymal (CD73, CD90, vimentin, α -smooth muscle actin), hepatocyte (UGT1A1, CK8) and biliary (CK19) markers. Moreover, these cells are able to store glycogen, and have glucose 6 phosphatase activity, but not UGT1A1 activity. Under the hepatogenic differentiation protocol, rFLDC display an up-regulation of hepa-

toocyte markers expression (albumin, tryptophan 2,3-dioxygenase, G6Pase) correlated to a down-regulation of the expression of the biliary marker CK19.

CONCLUSION: Advanced hepatic features observed in human liver progenitor cells could not be demonstrated in rFLDC. However, we demonstrated the presence of an original rodent hepato-biliary cell type.

INTRODUCTION

Liver transplantation is considered to be the standard treatment for end-stage liver diseases. Unfortunately, clinical applications are restricted by the scarcity of organs and uncertainty about the very long-term success of the procedure.

In recent years, liver cell transplantation using hepatocytes was successfully performed in patients with inborn errors of metabolism as an alternative, or at least as a bridge to orthotopic liver transplantation^[1-5]. However, the success of such a therapeutic approach remains limited by the quality of transplanted cells. In fact, cryopreservation procedures induce significant alterations at morphological

and functional levels of the thawed hepatocytes^[6,7].

To overcome these problems, several approaches to isolate and propagate liver stem or progenitor cells have been developed. In our laboratory, Najimi *et al.*^[8] isolated adult derived human liver stem/progenitor cells (ADHLSC) with hepato-mesenchymal profile. Under specific hepatogenic conditions, these cells exhibit hepato-specific functions like glycogen storage, gluconeogenesis, urea synthesis, glucuronoconjugation, and pharmacologic properties such as activity of phase I and II enzymes^[9]. These cells are also able to specifically engraft and differentiate into mature human hepatocytes in mouse liver parenchyma^[8].

Preclinical studies using homologous animal models of human liver metabolic diseases are attractive. It is therefore a prerequisite to obtain homologous cells from syngenic animals to perform such studies. The relevance of using human progenitor cells in immunosuppressed animal models is indeed questionable.

In this context, we evaluated the presence of a liver progenitor cell in adult rat liver that would express the same specifications as the previously reported human progenitor cell, referred to as ADHLSC.

In the current study we isolated and characterized rat fibroblastic-like liver derived cells (rFLDC) from healthy adult rats. Characterization included proliferation rate, phenotype, genotype and hepatic-specific functional assays.

MATERIALS AND METHODS

Rat fibroblastic-like liver derived cells

Five male Wistar rats weighing \pm 200 g were purchased from UCL *Animalerie Centrale* (Brussels, Belgium) and treated in accordance with the internal Animal Ethic and Welfare Committees (UCL/MD/2009/003).

We isolated rat liver parenchymal cells in a two-step collagenase A (1100 units/L) (Roche, Mannheim, Germany) perfusion procedure according to the Seglen method^[10]. We then obtained a hepatocyte enriched cell fraction following low-speed centrifugation (160 r/min for 3 min).

Viable hepatocytes, 1.5 million ($>$ 75%, trypan blue exclusion), were seeded onto rat tail collagen I-coated plates (Greiner, Wemmel, Belgium) in Williams' E medium (Invitrogen, Merelbeke, Belgium) supplemented with 10% fetal bovine serum (FBS) (AE Scientific, Marcq, Belgium), 25 μ g/L human epidermal growth factor (EGF) (Peprotech, London, United Kingdom), 10 mg/L human insulin (Lilly, Brussels, Belgium), 1 μ mol/L dexamethasone (Sigma, Bronem, Belgium), and 1% penicillin/streptomycin (P/S) (Invitrogen) at 37 °C in a fully humidified atmosphere containing 5% CO₂. After 24 h we changed the medium in order to eliminate the non-adherent cells and thereafter we renewed it every 3 d. On days 7-12, hepatocytes died and small colonies of spindle-shaped fibroblastic cells emerged and proliferated. At this time, we switched the culture medium to Dulbecco's modified Eagle's medium (DMEM medium) [DMEM high glucose (Invitrogen) supplemented with 10% FBS and 1% P/S]

in order to accelerate the proliferation of emerging cells. When cell cultures reached 90% confluence, we trypsinized them with 0.05% trypsin-1 mmol EDTA solution (Invitrogen) and replated them on a collagen-coated plate at a density of 10⁴ cells/cm². The medium was refreshed every 3 d.

Population doubling (PD) was evaluated after each passage using the following equation: [log (harvested cells)/log (seeded cells)]/log 2. Cumulative population doubling (CPD) was calculated with the sum of PD at all passages.

At passages 2, 4 and 8, cells were analyzed using reverse transcription polymerase chain reaction (RT-PCR), immunocytochemistry and flow cytometry.

Bone marrow mesenchymal stem cells

We obtained bone marrow from Wistar rats by flushing the femur and tibia with ice cold phosphate-buffered saline (PBS) (Lonza, Verviers, Belgium) and isolated the cell fraction using Ficoll (GE Healthcare, Uppsala, Sweden) density gradient centrifugation at 340 r/min for 30 min.

Cells were then resuspended in α -MEM (Invitrogen) supplemented with 10% FBS (Perbio, Erembodegem, Belgium) and 1% P/S (Invitrogen) and seeded in 75 cm² culture flasks. We removed non-adherent cells after 1 d and then refreshed the medium every 3-4 d. When cultures had reached 80%-90% confluence, we harvested the cells with 0.05% trypsin-1 mmol EDTA solution and replated them at a density of 7×10^3 cells/cm². These cells were used as the internal control in mesodermal differentiation studies.

Characterization of rFLDC

Flow cytometry: Cells from the initial parenchymal fraction or after passaging were suspended at a concentration of 1000 cells/ μ L in PBS and 0.5% bovine serum albumin (BSA, Sigma) and then incubated for 25 min at room temperature with the following antibodies: CD29-PE (rabbit monoclonal, 1/70), CD44-FITC (mouse monoclonal, 1/20), CD45-FITC (mouse monoclonal, 1/20) (Abcam, Belgium), CD73-FITC (mouse monoclonal, 1/20), CD90-PE (mouse monoclonal, 1/20) (BD, Erembodegem, Belgium). Unspecific binding of antibodies, was evaluated using mouse IgG1 FITC and the PE isotypes control (BD).

We then washed and fixed them in cytofix/cytoperm (BD) until analysis with a FACSCanto II flow cytometer (BD).

Immunocytochemistry: We fixed rFLDC cultured on 24 well rat collagen type-1 coated plates with 3.5 % formaldehyde (v/v, VWR, Leuven, Belgium) for 15 min at room temperature. After rinsing in PBS, we permeabilized cells with 1% Triton \times 100 (w/v Roche) in PBS for 10 min. Before incubation with specific rat antibodies, endogenous peroxidase activity was inhibited with PBS supplemented with 3% H₂O₂ (VWR) solution for 3 min. Non-specific immunostaining was prevented by incubation with 3% BSA solution (Sigma) for 1 h. Cells were

then incubated for 1 h with 0.3% BSA containing the following antibodies: fibronectin (rabbit polyclonal, 1/50) (Dako, Heverlee, Belgium), vimentin (mouse monoclonal, 1/100), and α -smooth muscle actin (ASMA) (rabbit polyclonal, 1/100) (BD). After rinsing with PBS, cells were finally incubated for 30 min with Envision[®], a secondary antibody against mouse or rabbit (Dako). Immunostaining results were evidenced by the addition of diaminobenzidine and urea reagents (Sigma) and counterstained with Mayer hematoxylin solution.

RT-PCR analysis: We extracted total RNA from expanded or differentiated rFLDC using the TriPure isolation reagent (Roche) and carried out cDNA with the Thermoscript RT-PCR system (Invitrogen) using 1 μ g total RNA, according to the manufacturer's instructions. Rat specific primers used for gene amplification are listed in Table 1. We thereafter electrophoresed amplified cDNA on a 1% agarose gel (Invitrogen) followed by 0.01% ethidium bromide (Sigma) staining.

Plasticity assessment

Hepatogenic differentiation: rFLDC from passage four were seeded at a density of $10^4/\text{cm}^2$ into 6 wells and 24 wells rat tail type I collagen-coated plates in the presence of expansion medium. When cell cultures reached 90% confluence, we switched the medium to Iscove's modified Dulbecco's medium (IMDM, Invitrogen) supplemented with 20 $\mu\text{g}/\text{L}$ human EGF (Peprotech, London, United Kingdom) and 10 $\mu\text{g}/\text{L}$ human basic fibroblast growth factor-2 (FGF2) (Peprotech) for 2 d. Thereafter, we subjected cells to differentiation induction for 10 d with IMDM containing 20 $\mu\text{g}/\text{L}$ human hepatocyte growth factor (HGF) (Peprotech), 10 $\mu\text{g}/\text{L}$ FGF2, nicotinamide 0.61 g/L (Sigma), and 1% insulin-transferrin-selenium (ITS) (Invitrogen). An intermediate step of differentiation/maturation in IMDM containing 20 $\mu\text{g}/\text{L}$ HGF, 20 $\mu\text{g}/\text{L}$ human oncostatin M (Peprotech), nicotinamide 0.61 g/L and 1% ITS was performed over 10 d. The subsequent maturation step consisted of treatment with IMDM containing 20 $\mu\text{g}/\text{L}$ oncostatin M, 1 $\mu\text{mol}/\text{L}$ dexamethasone (Sigma), and 1% ITS premix for 10 d. For each step, we changed the medium every 3-4 d.

Mesodermal differentiation: At passages 0, 2 4 and 8, rFLDC were plated at 1.5×10^4 cells/ cm^2 on six-well rat tail collagen I-coated plates. At confluency, we performed osteogenic differentiation with complete DMEM medium containing 0.1 μM dexamethasone, 0.1 mmol/L ascorbate and 10 mmol/L β -glycerophosphate (Sigma). After 4 wk, calcium deposition was evidenced using alizarin red staining. For adipogenic differentiation, we incubated cells with expansion medium complete DMEM containing 1 μM dexamethasone, 0.5 mmol/L isobutylmethylxanthine, 0.2 mmol/L indomethacin (Sigma) and 10 $\mu\text{g}/\text{mL}$ insulin (Lilly). Medium change was carried out twice a week. After 4 wk, oil red O staining revealed the presence of lipid vesicles. As a control of mesodermal differentiation capacity, the differentiation procedure was

Fn: Fibronectin; Vim: Vimentin; ASMA: α -smooth muscle actin; CK: Cytokeratin; HNF4: Hepatocyte nuclear factor 4; TAT: Tyrosine aminotransferase; TDO: Tryptophan 2,3-dioxygenase; α FP: α -fetoprotein; Alb: Albumin; UGT1A1: UDP-glucuronosyl transferase 1A1; G6Pase: Glucose-6-phosphatase; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

validated with rat bone marrow mesenchymal stem cells using α -MEM complete medium.

Functional hepatic tests

Glycogen storage: Undifferentiated and differentiated rFLDC fixed with 3.5% formaldehyde (Sigma) were incubated for 10 min in 1% periodic acid (Sigma). After washing with distilled water, the cells were incubated with Schiff's reagent (Sigma) for 15 min. The preparations were then washed and mounted.

Glucose-6-phosphatase activity: We investigated glucose-6-phosphatase (G6Pase) activity in undifferentiated and differentiated rFLDC. After washing with PBS, cells were incubated for 4 h at 37 $^{\circ}\text{C}$ in 1.5 mL 50 mmol/L Tris (Sigma) and 50 mmol/L maleate (Sigma) buffer (pH

6.7) solution containing 5 mmol/L glucose-6-phosphate (G6Pate, Sigma) and 0.03 g lead nitrate (Acros, Geel, Belgium). We obtained brownish precipitates of lead sulfate following incubation of cells in a solution containing 0.1% ammonium sulfide (Sigma)^[11]. Cells were then mounted and viewed by light microscopy (Leica DM IL, Groot-Bijgaarden, Belgium).

Bilirubin conjugation assay

Undifferentiated and differentiated rFLDC were incubated in William's medium and 1% FBS containing unconjugated bilirubin (Sigma) for 24 h and 48 h. Afterwards, we harvested the supernatant and added 2 µg/mL xantobilirubinic acid (use as internal standard: IS). We then submitted the product obtained in this reaction to an alkaline methanolysis followed by nitrogen evaporation as described by Muraca *et al.*^[12]. Precipitates were resuspended with 10 µL chloroform (Sigma) and 100 µL dimethyl sulfoxide (Sigma). We then injected ten microliters of this solution into the liquid chromatograph (Waters 515 HPLC pump) and eluted it with a C18 column (Macherey-Nagel, Düren, Germany). Elutriation flow started at 1 mL/min with methanol/water/tetrabutylammonium (solvent A) and ended after 11 min with methanol/ethanol/water/tetrabutylammonium (solvent B). Elution was continued for 6 min with solvent B, and the column was re-equilibrated with solvent A. The absorbance of the eluted pigments was monitored at 436 nm using a 996 photodiode array detector (Waters, Zellik, Belgium) and the area under peak was integrated electronically (Millennium software, Waters). We calculated the concentration, in micromoles per liter, of each bilirubin fraction in samples using the following equation: $(\text{Area}_{\text{pigment}}/\text{area}_{\text{IS}}) \times (\text{IS}/\text{IV}) \times \text{RF}$.

In which IS corresponds to micrograms of internal standard added to the sample, SV to the volume of sample (mL), and RF to the response factor.

Conjugation rate (CR) was evaluated using the equation: $(\text{Conjugated bilirubin concentration})/(\text{total bilirubin concentration}) \times 100$.

In which total bilirubin concentration was the sum of unconjugated and conjugated bilirubin.

RESULTS

Isolation and expansion of rFLDC

An enriched population of hepatocytes obtained after collagenase A digestion and low speed centrifugation was plated on type I collagen-coated 6-well plates.

During the first step of culture, mature hepatic cells present in the culture died due to their inability to proliferate (Figure 1). After 7 to 12 d, cells with a fibroblastic-like shape emerged and proliferated (Figure 1B and C). These cells demonstrated a high proliferative potential with a CPD of 294.55 ± 20.91 after 50 passages (Figure 2).

rFLDCs were reproducibly isolated from at least five different liver cell suspensions.

Characterization of rFLDC

All isolated rFLDC were analyzed and characterized after

passages 2, 4 and 8 using FACS analysis and RT-PCR. Furthermore, a stable expression profile was observed up to P50 (data not shown).

Representative flow cytometry data at passage 4 demonstrated that the most described mesenchymal markers, CD73 and CD90 constituted $44\% \pm 36\%$ and $71\% \pm 43\%$ of the cell population, respectively (Figure 3), whereas the expression of CD29 protein was only detected in $2.4\% \pm 1.1\%$. The hematopoietic marker, CD45 ($1.1\% \pm 0.6\%$) was almost undetectable.

To further characterize our cell population, we performed immunocytochemistry (ICC) for vimentin, fibronectin and ASMA proteins and compared the findings with rat bone marrow-derived mesenchymal stem cells (rBM-MSC) (Figure 4). The results indicated positive staining for ASMA, vimentin and fibronectin as observed with rBM-MSC.

To confirm the phenotypic profile of isolated rFLDC we performed RT-PCR analysis using specific mesodermal, hepatocyte and cholangiocyte markers at passage 4 (Figure 5).

The mesenchymal expression profile was confirmed by the detection of vimentin, fibronectin, ASMA, integrin β -1 (CD29), hyaluronic acid receptor (CD44), ecto 5'-nucleotidase (CD73), Thy-1 (CD90) and endoglin (CD105) mRNAs. RT-PCR also confirmed the absence of CD45 expression (Figure 5).

Because of their liver origin, rFLDC were also studied for their expression of hepatocyte and cholangiocyte markers. mRNA analysis revealed the expression of UDP-glucuronosyl transferase 1A1 (UGT1A1), cytokeratin 8 (CK8) and G6Pase (Figure 5). However, tyrosine aminotransferase (TAT), tryptophan 2,3-dioxygenase (TDO), albumin (Alb), α -fetoprotein (α FP) and hepatocyte nuclear factor 4 (HNF4) transcripts were not detected, all expressed by fully differentiated hepatocytes. mRNA analysis also revealed the expression of cytokeratin 19, a biliary marker.

In-vitro differentiation

First, we checked the ability of rFLDC to differentiate into adipocytes in the presence of specific media supplemented with dexamethasone, isobutyl-methylxanthine, indomethacin and insulin (Figure 6). We noticed that at early passages (P0-P2) two out of five rat fibroblastic-like liver derived cell cultures demonstrated a weak localized adipocytic differentiation. This ability was lost in further passages. Under osteogenic induction, no calcium deposit was noted (Figure 6).

In order to demonstrate their potential to differentiate into mature hepatocytes we seeded 10^4 cells/cm² from passage 4 in serum free-medium in the presence of several "hepatogenic" factors, as described in the Materials and Methods section. After 32 d, cells showed a slight morphology change and few cells adopted a polygonal shape (Figure 7). Using RT-PCR, we compared the expression of immature and mature hepatocytic/biliary mRNA on undifferentiated and differentiated rFLDC (Figure 5). Despite a variation in serum concentration (10% vs 2%) between the expansion medium and hepatogenic control medium, respectively, no differences in mRNA expression

were noted (data not shown). Interestingly, differentiated rFLDC lost the expression of CK19, a biliary marker. Moreover, differentiated rFLDC acquired the expression of mature hepatocyte lineage markers including TDO and albumin.

To test their liver metabolic activity, we explored their ability to store glycogen and to perform gluconeogenesis (G6Pase activity) and their potential to conjugate bilirubin.

Glycogen storage, evidenced by periodic-acid shift staining, showed that, like rat hepatocytes (Figure 8A), undifferentiated and differentiated cells can store glycogen (Figure 8B and C).

As shown at Figure 8D-F, rat hepatocytes and rFLDC cells also revealed a basal G6Pase activity. These results were corroborated by the expression of G6Pase at the mRNA level.

In addition to glycogen storage and G6Pase activity we assessed the ability of differentiated and undifferentiated

ated rFLDC to conjugate bilirubin. Therefore, we incubated 10^4 cells/cm² with William's medium-1% serum containing unconjugated bilirubin. After 24 h and 48 h, no bilirubin conjugate was observed in the culture medium in comparison with freshly isolated hepatocytes used as positive controls. For this late population the bilirubin CR reached 11% and 33% after 24 h and 48 h, respectively (Figure 9).

DISCUSSION

Because preclinical studies use animal models mimicking human diseases, we tried to isolate from rodent liver a liver progenitor cell that would display characteristics reported for ADHLSC. The use of human derived cells in animal models is considered irrelevant, as they may not engraft and function similarly in a xenogenic rodent environment.

Like human cells, rFLDC were isolated and emerged *in vitro* after culture of liver cell suspension following enzymatic-mediated disaggregation of liver. However, many differences were observed: rFLDC demonstrated a higher proliferative potential and did not reach senescence after at least 50 passages in contrast to human cells which stopped proliferating after 10-12 passages^[13]. rFLDC were able, at early passages, to differentiate into adipocytes, in contrast to ADHLSC.

Like human cells, rFLDC displayed a mesenchymal profile as evidenced by the expression of CD44, CD73, CD90 and CD105. The cell population was not contaminated by hematopoietic stem cells as evidenced by the absence of CD45 expression. These results confirmed the presence of a new enriched cell population different from the freshly isolated hepatic cells. RT-PCR also revealed expression of CK8, UGT1A1 and G6P under-

lining their hepatic-like profile. Undifferentiated rFLDCs have the capacity to store glycogen and show G6Pase activity as mature hepatocytes.

In a hepatogenic differentiation medium, low numbers of rFLDC display the polygonal morphology of mature hepatocytes. Differentiated rFLDC express both albumin and TDO. However, we did not observe the expression of more specific hepatic markers such as HNF4 or TAT.

Candidate progenitor cells reported in this study were isolated from healthy rat livers, in contrast to other progenitor liver cells described elsewhere, such as oval cells, obtained after submitting animals to carcinogenic agents or toxic injuries^[14-19]. Stellate cells^[20] and rFLDC share common features like the expression of vimentin, ASMA, CK19, and CD90, although no expression of α FP was detected in rFLDC.

Differentiated rFLDC do not express CK19 or α FP, and differ therefore from small hepatocytes and epithelial cells also recovered from normal livers^[17-19].

Recently, Sahin *et al*^[19], using a 2-step collagenase protocol, reported a cell population derived from adult rat

liver and called them LDPCs (liver-derived progenitor cells). Regarding their oval morphology and expression of HNF3 β , CD45, CD34 and CD90, these cells seem to be closely related to oval cells despite the absence of CK7, CK8 and CK19 expression.

In conclusion our results showed that rodent progenitor cells homologous to ADHLSC can not easily be obtained even when the same isolation and culture protocol was applied using a rat model. However, this protocol allowed the isolation of a novel type of liver progenitor cell population with both hepatic and biliary phenotype including G6Pase activity, glycogen storage, CK8, UGT1A1 and CK19 expression.

In the presence of a hepatogenic differentiation medium, rFLDC lose the CK19 biliary marker, but do not acquire a more mature hepatic status possibly due to the use of human cytokines and growth factors, which may not be appropriate for rodent precursors, stressing again the difficulty in generating homologous models.

Further characterization and *in vitro* hepatogenic differentiation improvement are required before their relevant use in preclinical studies.

COMMENTS

Background

Liver cell transplantation using hepatocytes was successfully performed in patients with inborn errors of metabolism. However, the success of such a therapeutic approach remains limited by the quality of transplanted cells. To overcome these problems several approaches to isolate and propagate liver stem or progenitor cells have been developed. The capacity of those cells to restore a liver metabolic function must be demonstrated.

Research frontiers

Preclinical studies using homologous animal models of human liver metabolic diseases are attractive. It is therefore a prerequisite to isolate and propagate human homologous liver stem or progenitor cells from syngenic animals to perform such studies. In this study, the authors showed that rodent progenitor cells homologous to human adult-derived liver stem/progenitor cells can not easily be obtained even when the same protocol was applied.

Innovations and breakthroughs

In this study, the authors reported the isolation of novel potential candidate liver progenitor cells isolated from healthy rat liver called rat fibroblastic-like liver derived cells (rFLDC). These cells express both hepatic and biliary phenotype and

are able to acquire some hepatic characteristics in the presence of hepatogenic differentiation medium.

Applications

Isolation and characterization of progenitor/stem cells would be very useful to assay the *in-vivo* efficacy of liver mesenchymal progenitor cells in syngeneic animal models of liver metabolic diseases, particularly in the Gunn rat, a model of hyperbilirubinemia.

Peer review

This study shows that the advanced hepatic features of human liver progenitor cells have not been demonstrated in rFLDC. Although it strengthens the unique specificity of these human liver progenitor cells, it also shows that homologous models for cell therapy can not easily be developed even when the same isolation and culture protocols are applied. The authors should make a comparison of their cells with human established liver cells.

Abstract

AIM: To investigate the effect of E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr) on hepatic ischemia-reperfusion (I/R) injury and liver regeneration in a porcine hepatectomy model.

METHODS: One hour ischemia was induced by occluding the vessels and the bile duct of the right and median lobes. A 40% left hepatectomy was performed after reperfusion. Six animals received Edr (3 mg/kg per hour) intravenously and six control animals received saline just before reperfusion. Remnant liver volume, hemodynamics, aspartate aminotransferase (AST), alanine aminotransferase, lactate dehydrogenase and lactic acid, were compared between the groups. The expression of transforming growth factor- β (TGF- β 1) and toll-like receptor (TRL) mRNA in hepatic tissues was examined using reverse transcription polymerase chain reaction. Apoptosis was demonstrated by terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining, respectively.

RESULTS: Serum AST ($P = 0.029$), and toll like receptor 4 level ($P = 0.043$) were significantly lower after 3 h

in animals receiving Edr. In addition, TUNEL staining in Edr-treated pigs showed significantly fewer hepatocytes undergoing apoptosis compared with control pigs. After 1 mo, all factors were non-significantly different between the two groups.

CONCLUSION: Edr is considered to reduce hepatic injury in the early stage of I/R injury in a porcine model.

INTRODUCTION

A potent free radical scavenger, E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr) has been shown to protect cardiomyocytes and brain against ischemia/reperfusion (I/R) injury^[1,2]. However, this beneficial protection after I/R injury in the liver, and the effect on liver regeneration is still unknown^[3].

Compression of the hepatoduodenal ligament is routinely used during partial hepatectomy for control of bleeding, but this can lead to postoperative I/R injury that may adversely affect outcome^[4]. Hepatic I/R damage is caused by multiple factors, including ischemia-induced

hypothermia, cytokines, coagulopathy and increased levels of cell adhesion molecules. Expression of transforming growth factor- β (TGF- β) has been demonstrated in a wide variety of diseases and in normal cells and tissues, and is known to be most abundant in platelets and bone^[5]. TGF- β 1 has inhibitory effects on cell growth, and acts in a stimulatory manner in fibrosis and certain mesenchymal cells^[6]. It is particularly germane in the liver, as TGF- β 1 is a potent inducer of apoptosis in hepatocytes, and inhibits liver cell proliferation *in vitro*^[6]. It also has a crucial role in terminating liver regeneration after partial hepatectomy in rats^[7].

Furthermore, Kupffer cells play a prominent role in I/R injury in the liver as this type of injury induces the release of high mobility group box 1 (HMGB1) from damaged liver cells, which then stimulate nonparenchymal cells, such as Kupffer cells through toll like receptor 4 (TLR4)^[8]. In addition, TLR4 triggers the secretion of tumor necrosis factor- α (TNF- α) and interleukin (IL)-6 by Kupffer cells, resulting in liver regeneration^[8].

To explore the effect of Edr in liver I/R injury and to extend the application of Edr clinically, experiments using large animal models are essential. We have attempted to define the effects of Edr after I/R injury in a porcine liver resection model.

In this study, we investigated the effect of Edr on hepatic I/R injury and liver regeneration, and found that Edr significantly inhibits apoptosis in liver.

MATERIALS AND METHODS

Experimental groups

The study was performed using male pigs, weighing 23-26 kg (SEASCO, Saitama, Japan), in accordance with the Guidelines for the Care and Use of Laboratory Animals, Dokkyo Medical University. Two groups of animals were prepared: Edr group ($n = 6$) in which Edr (supplied by Mitsubishi-Tanabe Pharma Co., Ltd., Osaka, Japan) was administered intravenously at a dose of 3 mg/kg per hour from the commencement of clamping for 30 min, and a control group ($n = 6$) which received physiological saline administered intravenously for the same period. The Edr dose was the same as that used in the treatment of human brain infarction^[9] (Figure 1).

Surgical procedure

A chevron incision was made under general anesthesia, and each branch of the portal vein, hepatic artery and bile duct were carefully isolated and taped. Hemi-hepatic (approximately 60%) liver ischemia was induced by clamping the right and middle hepatic vessels and bile duct using vessel tapes and maintained for 60 min; the left portal branch was kept patent to avoid bowel congestion, and the left lobe played a role in the bypass. After declamping, the left portal vein and artery were ligated, and a left hemi-hepatectomy was performed (approximately 40%). Liver transection was achieved by the crush-clamping method using Pean forceps. During the liver transection, the exposed Glisson's vessels were ligated

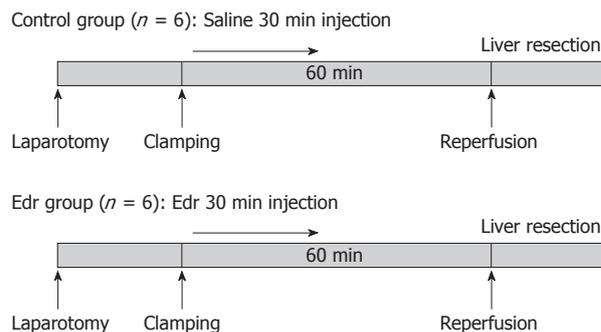

Figure 1 Two groups of animals were prepared. One group received saline and the other received E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr) which was administered intravenously at a dose of 3 mg/kg per hour from commencement of clamping to completion of the liver resection.

with 2-0 or 3-0 silk. The hepatic vein was closed by continuous sutures using 4-0 proline. The influence of I/R injury was assumed to be on the right lobe only. During this procedure, hemodynamic parameters (systolic and diastolic arterial pressure) were monitored by a femoral arterial line. All pigs received Ringer's solution during the procedure. After the operation, the pigs were transferred to the Dokkyo Medical University animal center and unlimited oral intake was allowed after the first postoperative day. No antibiotics were administered either orally or intravenously after surgery.

Measurements and sampling protocol levels

Blood samples were obtained from the arterial line immediately after laparotomy, 5 and 180 min after reperfusion, and after 1 mo. The serum levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH), and lactic acid (LA) were evaluated. Hepatic tissues were obtained from the right lobe at laparotomy, after reperfusion, and after 1 mo, and were subjected to terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining, and TLR4 and TGF- β 1 mRNA were determined. Serum AST, ALT, LDH and LA were measured using standard clinical methods for automated analysis (Model 7170, Hitachi, Inc., Tokyo, Japan).

Experimental pigs were sacrificed 1 mo after operation and remnant liver was obtained. Total liver weight was calculated based on 30 pigs. We calculated the average percentage of total liver weight to body weight (2.64%), estimated the total liver weight from pre-operative body weight, and calculated the estimated remnant liver weight 1 mo after operation by subtracting the resected liver weight at the time of operation from the estimated total liver weight. Liver weight increasing ratio (%) was calculated as follows; estimated remnant liver weight at resection/remnant liver weight after 1 wk \times 100.

Quantitative real-time polymerase chain reaction

At laparotomy, 30 mg of surgical tissue was stored in liquid nitrogen and kept at -80°C until extraction of total RNA using a Nucleospin II kit (Macherey-Nagel, Germany). Reverse transcription reactions were performed using a SuperScript III First-strand Synthesis System for t-poly-

merase chain reaction (PCR) (Invitrogen, Carlsbad, CA, United States). Briefly, 1 µg of total RNA, oligo dT primer, and dNTPs were incubated at 65 °C for 5 min, and then 10 µL of cDNA synthesis mixture was added and incubated at 50 °C for 50 min. The reaction was terminated by adding 1 µL of RNase H and incubated at 37 °C for 20 min. Real-time PCR was performed using a ABI Prism 7700 sequence detector (Applied Biosystems, Warrington, United Kingdom). The PCR reaction was carried out in a final volume of 1 µL cDNA, 2 µL 10 × SYBR Green (Applied Biosystems), using 40 cycles at 95 °C for 30 s and 60 °C for 30 s. The specific primers were designed using Primer 3 software (http://frodo.wi.edu/cgi-bin/primer3/primer3_www.cgi) and synthesized by Sigma Genosys (Hokkaido, Japan). The sequences of each primer were as follows: Glyceraldehyde-3-phosphate dehydrogenase (GAPDH): sense 5'-CCACCCAGAAGACTGTGGAT-3', anti-sense 5'-TTCAGCTCAGGGATGACCTT-3'; TLR4 and TGF-β1: sense 5'-CCCCTGTCCATCCCTTTATT-3', anti-sense 5'-AAGCCCCAGTTCCTAATCTT-3'. For each PCR run a standard curve was constructed from serial dilutions of cDNA from the PANCI cell line. The level of expression of TLR4 and TGF-β1 were calculated using the formula: relative expression (t) = [(copy number of TLR4 + TGF-β1 number/copy number of GAPDH)] × 1000. For non-template reactions and standard cDNA dilutions from PANCI cells, liver samples were assayed in triplicate. The average and standard deviation were calculated and the *t*-value was determined from the averages.

Histological examination

Tissue samples were obtained at the time of laparotomy, the remnant liver just after hepatectomy, 3 h after declamping of the right and middle hepatic arteries and portal vein, and after 1 mo, and were fixed with 10% formalin for 24 h and embedded in paraffin. Sections 3-µm thick were stained by the *in situ* terminal TUNEL method using an apoptosis *in situ* detection kit (Wako Pure Chemical, Inc., Osaka, Japan) according to the manufacturer's instructions. The mean numbers of apoptotic cells per 10 random high-power fields were calculated and compared between the two groups.

Statistical analysis

All values are expressed as mean ± SD. Parameters were evaluated using the Student *t* test and Mann Whitney *U* test. Differences between the two groups were evaluated using analysis of variance with *P* < 0.05 considered to be significant.

RESULTS

There were no significant differences in weight, amount of intraoperative hemorrhage, liver resection time, and weight of resected liver (Table 1). There was no significant difference in liver weight increasing ratio at 1 mo after operation between the two groups (*P* = 0.228, Figure 2). There were no significant differences in systolic and diastolic blood pressures between the two groups (Figure 3).

Table 1 Weight, amount of intraoperative hemorrhage, liver resection time, and weight of resected liver in the two groups (mean ± SD)

	Control	Edr	<i>P</i> value
Body weight	24.6 ± 1.1	24.7 ± 0.5	0.99
Body weight (after 1 mo)	29.4 ± 3.3	29.4 ± 3.1	0.97
Bleeding (g)	59.5 ± 44.7	57.4 ± 46.8	0.82
Resection time (min)	24.2 ± 1.6	24.7 ± 0.4	0.49
Resected liver volume (g)	295.7 ± 25.7	271 ± 41.0	0.32
Liver volume (after 1 mo)	606.3 ± 92.7	579.3 ± 60.0	0.53

Edr: E3-methyl-1-phenyl-2-pyrazolin-5-one; RxLV: Resected liver volume.

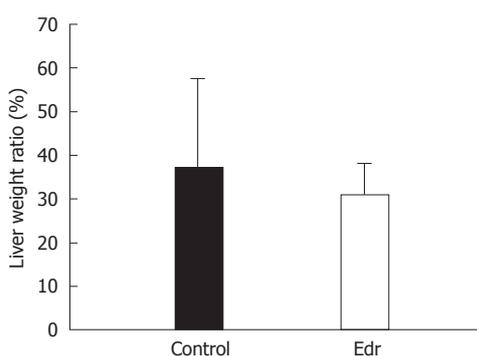

Figure 2 After 1 mo, increasing remnant liver weight ratio showed no difference between the two groups (*P* = 0.228). Liver weight increasing ratio (%) = estimated remnant liver weight at resection/remnant liver weight after 1 mo × 100. Total liver weight was calculated based on previous experimental data of 30 pigs. We calculated the average percentage of total liver weight to body weight (2.64%). Edr: E3-methyl-1-phenyl-2-pyrazolin-5-one.

Serum chemistry showed that the AST level at 3 h after reperfusion was significantly lower in the Edr-treated group than in the control group (*P* = 0.029). There were no significant differences in ALT, LDH and LA levels at any of the observation points between the two groups (Figure 4). Figure 5 shows the expression of TGF-β1-mRNA in liver tissues. Expression of TGF-β1-mRNA in the Edr-treated group tended to be lower than in the control group at 3 h (*P* = 0.285) and 1 h (*P* = 0.172) after operation. Expression of TLR4 mRNA was significantly lower in the Edr-treated group than in the control group at 3 h after operation (*P* = 0.043), however, there was no significant difference between the two groups 1 mo after operation (Figure 6). Figure 7A shows TUNEL staining. There were more TUNEL-positive cells in Control pigs than in Edr-treated pigs 5 min after hepatectomy and 3 h after declamping. Actual numbers of apoptotic cells in the Edr-treated and control groups were 22.16 ± 8.97 and 36.85 ± 1.83 at 5 min after hepatectomy (*P* = 0.015), and 24.66 ± 3.11 and 42.25 ± 3.43 at 3 h after declamping, respectively (*P* = 0.0001) (Figure 7B).

DISCUSSION

The Pringle method is usually performed to reduce the amount of hemorrhage during hepatectomy^[4]. However, this method inevitably causes I/R injury and has a risk

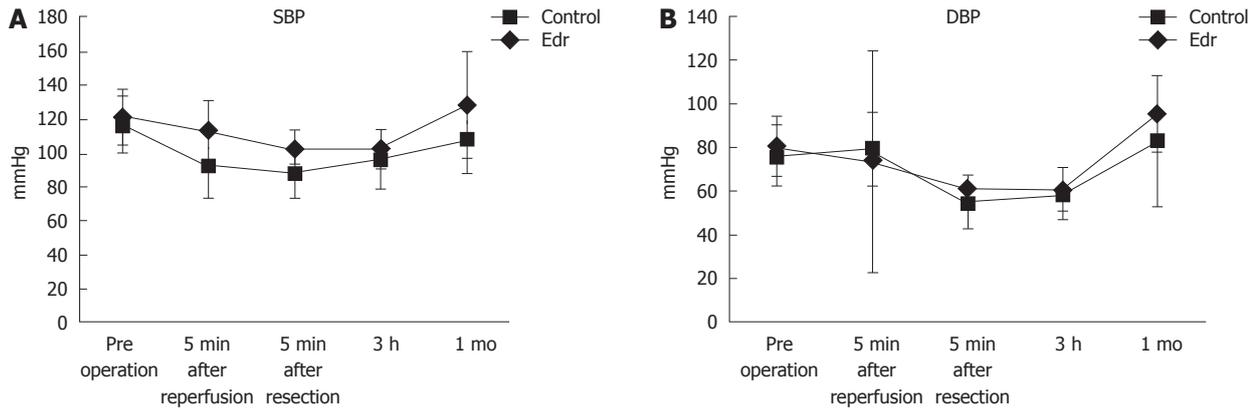

Figure 3 Systolic blood pressure and diastolic blood pressure were not different between the two groups. A: Systolic blood pressure (SBP); B: Diastolic blood pressure (DBP); Edr: E3-methyl-1-phenyl-2-pyrazolin-5-one.

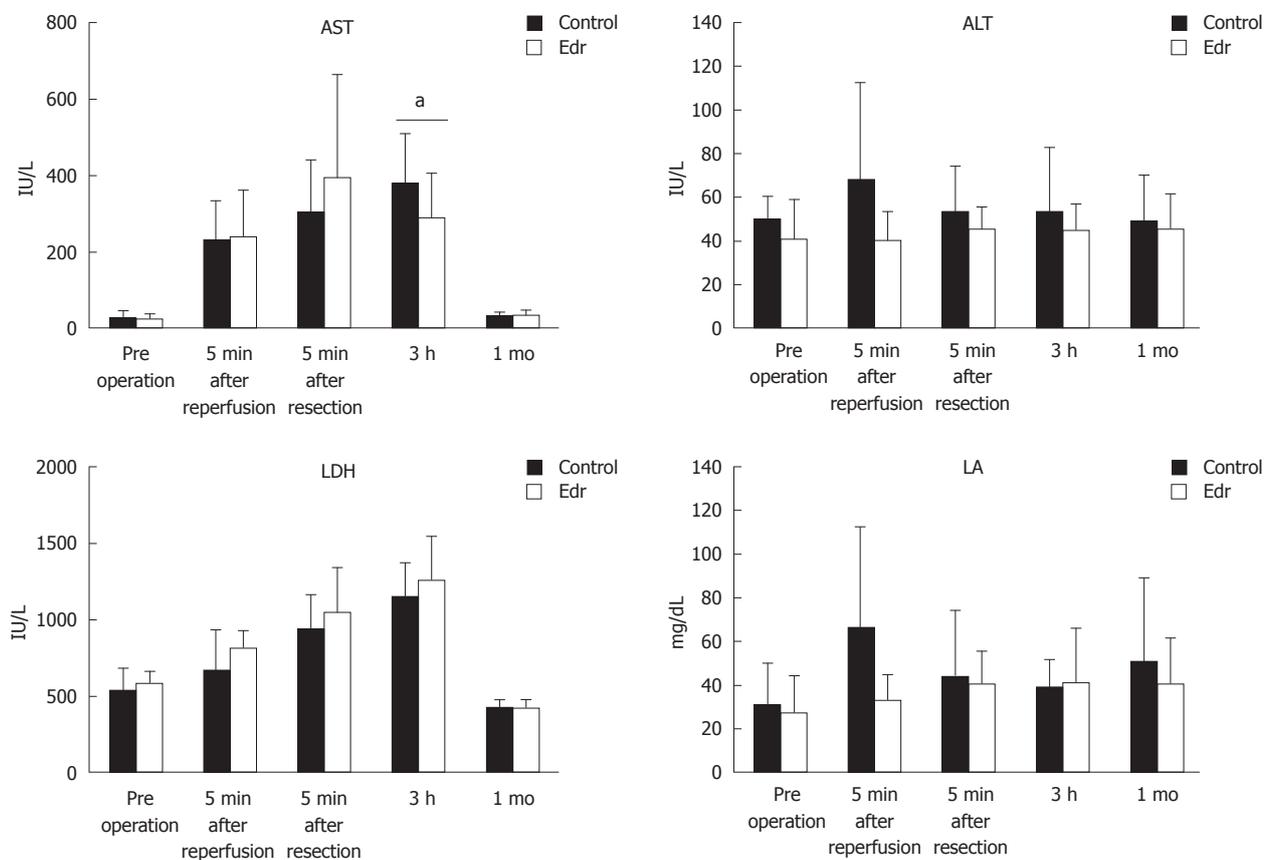

Figure 4 Aspartate aminotransferase was significantly lower 3 h after reperfusion compared to the control ($^*P = 0.029$). Alanine aminotransferase (ALT), lactate dehydrogenase (LDH), and lactic acid (LA) were not different after reperfusion in the E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr)-treated group compared to the control group. AST: Aspartate aminotransferase.

of inducing abnormally high hepatic enzyme levels, icterus, hyperammonemia, lacticidemia, and an intractable accumulation of pleural and peritoneal effusion postoperatively. I/R injury associated with the Pringle maneuver may affect outcome when the ischemic time is long, or during hepatectomy for diseased liver, such as in cases of hepatic cirrhosis and fatty liver, despite the reduction in intraoperative hemorrhage achieved using the Pringle method^[10].

I/R injury may be a causal factor in the above symp-

toms, and various countermeasures have been proposed. These include modified surgical methods, such as an intermittent Pringle method, partial hepatic pedicle clamping, and ischemic pre-conditioning, as well as drug therapy with steroids, prostaglandin E1, Sivelestat or Erythropoietin^[10-19]. However, assessment of the effectiveness of these approaches has been limited, and this may be clarified by studies in animals of similar size to humans. In general, the process of I/R injury consists of multiple steps. Hypoxia due to cessation of blood supply

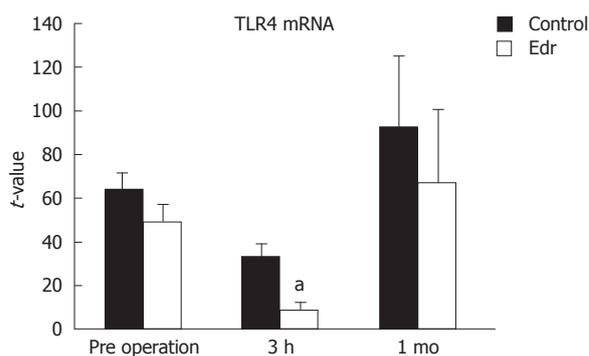

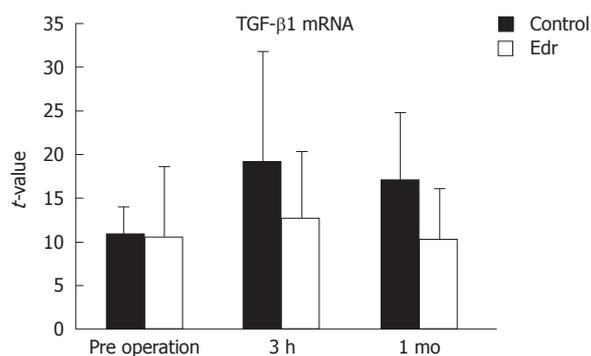

Figure 5 Transforming growth factor-β1 mRNA expression in liver tissue. Expression of transforming growth factor-β1 (TGF-β1) mRNA in the E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr)-treated group tended to decrease 3 h and 1 mo after reperfusion, however, no significant difference between the two groups was observed ($P = 0.285$, $P = 0.172$).

Figure 6 Toll like receptor 4 mRNA level. Toll like receptor 4 (TLR4) mRNA level significantly decreased in the E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr)-treated group at 3 h after surgery ($^aP = 0.004$). At 1 mo after operation, Toll like receptor 4 level showed no differences between the two groups.

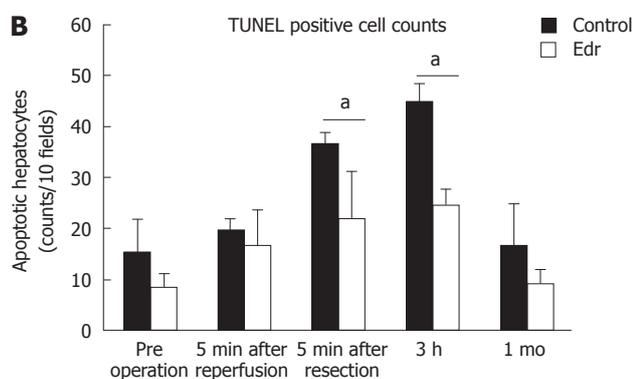

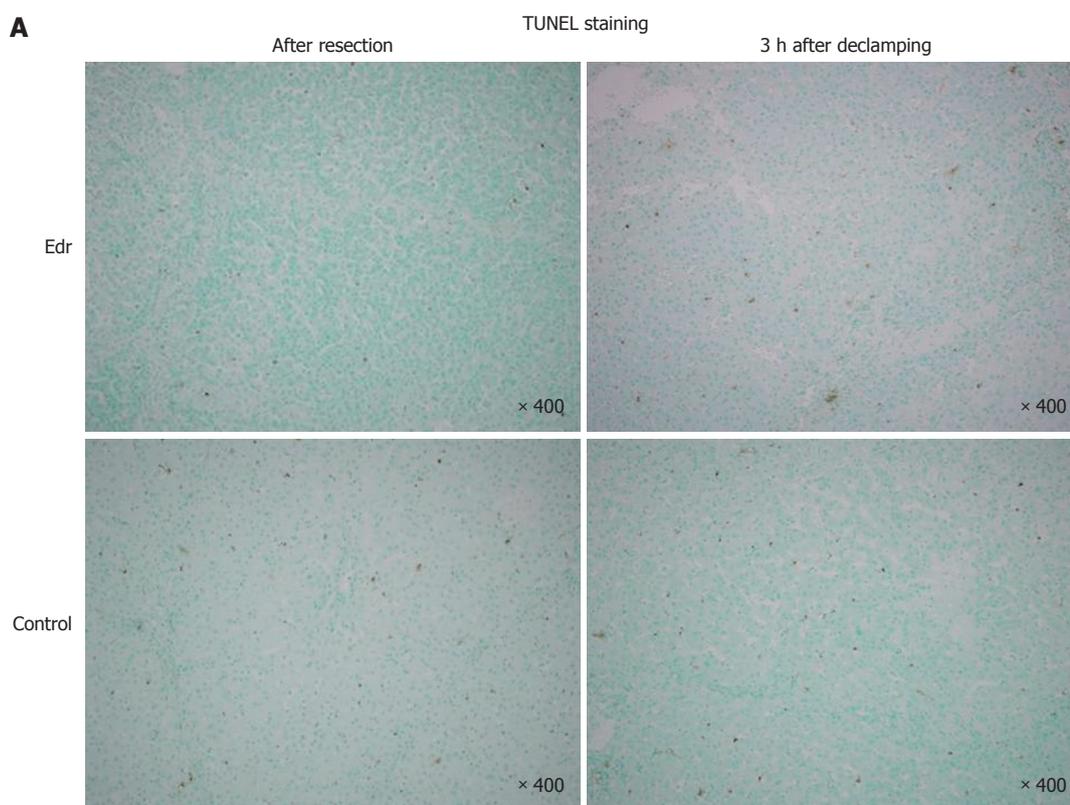

Figure 7 Morphometric evaluation of terminal deoxynucleotidyl transferase dUTP nick end labeling-positive hepatocytes in terminal deoxynucleotidyl transferase dUTP nick end labeling-stained tissue samples after resection and after 1 mo (A, B). The differences between the two groups were statistically significant 5 min after hepatectomy and 3 h after declamping (values are expressed as mean \pm SD, $n = 6$ in both groups). $^aP = 0.001$. Edr: E3-methyl-1-phenyl-2-pyrazolin-5-one; TUNEL: Terminal deoxynucleotidyl transferase dUTP nick end labeling.

impairs oxidative phosphorylation in the mitochondria, leading to profound cellular damage^[20]. Furthermore, reperfusion exacerbates cellular damage by producing reactive oxygen species, activating pro-inflammatory cytokines such as IL-10 and TNF- α ^[21], and up-regulating cell adhesion molecules such as P-, E-, and L-selectins^[22,23], resulting in tissue injury.

Edr has potent hydroxyl radical scavenging activity^[24]. In various experimental models, Edr has been reported to protect several organs such as brain^[25], heart^[26] and liver^[27-29] from free radical-mediated injuries.

Several previous studies have investigated the effect of Edr on I/R injury in the liver. Edr improves portal flow and decreases the level of hepatic enzyme^[30]. Edr also decreases oxidative damage to mitochondria in liver^[27]. However, these findings only indicate that Edr is effective in the acute phase of I/R injury. In the present study, we investigated the effect of Edr at both very early time points and at a late point (one mo after hepatectomy). No improvements in the markers of liver function including AST, ALT, LDH and LA, except AST at 3 h after hepatectomy, were noted at any of the observation periods. However, Edr successfully reduced apoptotic cells in the liver at 5 min and 3 h after hepatectomy. The anti-apoptotic effect of Edr was not observed at one mo after hepatectomy. Thus, the results suggest that Edr has a protective effect against I/R injury in liver by inhibiting apoptosis in the early phase after injury, which was reflected in the decrease in markers. However, prevention of I/R injury, particularly in the early phase, did not affect liver regeneration.

TGF- β is a key mediator involved in the progression of liver disease. TGF- β exerts cytotoxic effects, such as induction of apoptosis and aggravation of microcirculation disorders, due to induction of the expression of cell adhesion molecules^[31]. TGF- β had antiproliferative action after partial liver resection in a rat model^[7]. When administered at the time of liver resection, TGF- β clearly delayed hepatocyte proliferation^[7]. In the present study, we observed that Edr tended to suppress TGF- β 1-mRNA expression in liver tissue at 3 h and 1 mo after hepatectomy.

TLRs consist of 13 mammalian members containing a conserved TIR Toll/IL-1 receptor domain in their intracellular domain and an individual leucine-rich repeat domain in their extracellular domain. TLR1, TLR2, TLR4, TLR5, and TLR6 are expressed on the cell surface and TLR3, TLR7, TLR8 and TLR9 are expressed on the endosome-lysosome membrane. TLR4 and TLR5 are the receptors for the Gram-negative bacterial cell wall components, lipopolysaccharide, and bacterial flagellin, respectively^[32]. In the liver, TLR4 is an important key factor for liver fibrosis, I/R injury and liver regeneration. Upon I/R injury, the TLR4 ligand, HMGB1, is released from damaged hepatocytes and subsequently stimulates Kupffer cells through TLR4^[33]. Suppression of TLR4 at I/R injury, leads to the control of progress to liver regeneration by controlling liver fibrosis. Unfortunately, in this study, Edr only decreased TLR4 levels in the early phase

(less than 3 h) after liver resection. This result suggested that Edr did not have any effect on liver fibrosis and regeneration.

In conclusion, our results demonstrated that Edr has a protective effect against I/R injury in the liver by inhibiting apoptosis in early period after I/R injury. Although further studies are needed to determine the dose, timing, and duration of Edr treatment to be used in the clinical setting, we have shown, for the first time in a porcine model, that Edr may be a promising agent for ameliorating I/R injury during hepatectomy.

COMMENTS

Background

Peritoneal adhesions can cause intestinal obstruction and other severe clinical disorders, thus, it is very important to prevent peritoneal adhesions in abdominal surgical operations. However, to date, there are still no ideal methods to prevent peritoneal adhesions in clinical practice. Chitosan is a deacetylated derivative of chitin.

Research frontiers

Chitosan is a natural biological material and has been processed into many forms for medical use. Chitosan has also been used in the prevention of peritoneal adhesions and various researchers are exploring how to modify chitosan using chemical and physical methods to improve its effectiveness in preventing adhesions, and simultaneously reduce its adverse reactions.

Innovations and breakthroughs

In previous reports on the application of chitosan gels to prevent peritoneal adhesions, it was found that the gel was much too fluid and did not remain in the target area for sufficient time, moreover, the gel degraded so fast that it could only maintain effectiveness for a short period. In order to delay degradation and decrease the fluidity of the gel, the authors processed pure chitosan into films, however, the film degraded too slowly and the residual film was encapsulated by surrounding tissue and the peritoneal adhesions worsened. In order to overcome these disadvantages, we mixed chitosan with gelatin and produced blended films. The blended film degraded much faster than the previous pure chitosan film, but it also created a foreign body reaction and formed a severe foreign body granuloma around the blended film. In the present study we chemically modified chitosan during gelatinization to develop a new type of chitosan film, and showed that the film is remarkably effective in preventing peritoneal adhesions induced by wounds, ischemia and infection except foreign body-induced adhesions.

Applications

The study results suggest that the gelatinized-chitosan film is a potential therapeutic material which could be used in preventing peritoneal adhesions induced by wounds, ischemia and infection.

Terminology

Peritoneal adhesion: Peritoneal adhesion is a type of defensive reaction to peritoneal injury mainly wounds, infection, ischemia and foreign bodies, but it can also cause intestinal obstruction and severe clinical disorders; chitosan: Chitosan is a deacetylated derivative of chitin, and chitin is the second most abundant natural biopolymer derived from the exoskeletons of crustaceans and from the cell walls of fungi and insects.

Peer review

This is a good descriptive study in which authors investigate the effect of E3-methyl-1-phenyl-2-pyrazolin-5-one (Edr) on hepatic ischemia-reperfusion (I/R) injury and liver regeneration in a porcine hepatectomy model. The results are interesting and suggest that Edr is considered to reduce hepatic injury in the early stage of I/R injury in a porcine model.

Abstract

AIM: To investigate the role of polo-like kinase 1 (PLK1) as a therapeutic target for hepatocellular carcinoma (HCC).

METHODS: *PLK1* gene expression was evaluated in HCC tissue and HCC cell lines. Gene knockdown with short-interfering RNA (siRNA) was used to study *PLK1* gene and protein expression using real-time reverse transcription polymerase chain reaction (RT-PCR) and Western blotting, and cell proliferation using 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2(4-sulfophenyl)-2H-tetrazolium (MTS) and bromodeoxyuridine (BrdU) assays. Apoptosis was evaluated using the ter-

минаl deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay, and caspase-inhibition assay. Huh-7 cells were transplanted into nude mice and co-cultured with PLK1 siRNA or control siRNA, and tumor progression was compared with controls.

RESULTS: RT-PCR showed that PLK1 was overexpressed 12-fold in tumor samples compared with controls, and also was overexpressed in Huh-7 cells. siRNA against PLK1 showed a reduction in *PLK1* gene and protein expression of up to 96% in Huh-7 cells, and a reduction in cell proliferation by 68% and 92% in MTS and BrdU cell proliferation assays, respectively. There was a 3-fold increase in apoptosis events, and TUNEL staining and caspase-3 assays suggested that this was caspase-independent. The pan-caspase inhibitor Z-VAD-FMK was unable to rescue the apoptotic cells. Immunofluorescence co-localized endonuclease-G to fragmented chromosomes, implicating it in apoptosis. Huh-7 cells transplanted subcutaneously into nude mice showed tumor regression in siPLK1-treated mice, but not in controls.

CONCLUSION: Knockdown of PLK1 overexpression in HCC was shown to be a potential therapeutic target, leading to apoptosis through the endonuclease-G pathway.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common solid tumor cancer in the world, and is ranked third in terms of mortality according to GLOBALCAN 2002^[1]. Treatments for HCC other than liver transplantation, can benefit patients but are often plagued by recurrence of the tumor^[2,3]. Those with advanced HCC have a poor prognosis. Recently, vascular endothelial growth factor inhibitors showed a survival benefit^[4], albeit of only 3 mo, in the treatment of HCC. Therefore, this finding and the paucity of effective treatment options is a strong indicator for the investigation of new genomic targets that can provide better treatment outcomes for HCC patients. One genomic target that has been reported in many other tumors but only recently in HCC is polo-like kinase 1 (PLK1)^[5-8].

PLK1 is a cell cycle protein that plays multiple roles in promoting cell cycle progression^[9]. However, the most prominent role of PLK1 probably lies in regulating the spindle checkpoint at the M-phase^[10]. Mutated PLK1 alleles induce abrupt spindle formation resulting in polyploid cells^[11], and in mammalian cells depleted of PLK1, mitotic arrest with dysfunctional spindle assembly occurs^[10]. PLK1 is a highly conserved protein that has unique polo-box binding domains that can bind to phosphopeptide and render it to be regulated spatially and temporally during the cell cycle by proteins that carry the optimal phosphopeptide motif^[12].

PLK1 is overexpressed in many cancers and serves as a significant prognostic factor in cancers such as small-cell lung cancer, colon cancer and ovarian cancer^[13]. In addition, high expression levels of PLK1 in melanoma and breast cancer correlate well with the metastatic potential of these tumors^[14,15]. PLK1 overexpression may contribute to the deregulation of cell proliferation during oncogenesis by overcoming mitotic checkpoints^[16]. In this study, we sought to determine if PLK1 was a potential therapeutic target for HCC.

MATERIALS AND METHODS

Patients and samples

Tumor and surrounding non-tumor liver tissues were obtained from 56 primary HCC patients who underwent liver resection in the National University Hospital from 1998 to 2002. The study was approved by the National University of Singapore Institutional Review Board, and National Healthcare Group Domain Specific Review Board. Informed consent was obtained from every patient for the use of excised tissue. The human hepatoma cell line HepG2 was obtained from American Type Culture Collection, Huh-7 cells from the Japanese Collection

of Research Bioresources Cell Bank and HepG2.2.15 was kindly provided by Dr. Acs (Mt. Sinai Medical College, New York, NY, United States). HepG2 and Huh-7 cells were cultured in Dulbecco's modified Eagle's medium supplemented with 0.1 mmol/L sodium pyruvate, 0.1 mmol/L L-glutamine, 0.1 mmol/L non-essential amino acids, 10% fetal calf serum, and 1X antibiotic-antimycotic solution (Invitrogen, Carlsbad, CA, United States). HepG2.2.15 cells were cultured in similar media with the addition of 0.4 mg/mL G418 (Sigma-Aldrich, St Louis, MO, United States). All cell lines were maintained in an incubator with 5% CO₂ at 37 °C.

RNA extraction and cDNA synthesis

Total RNA was extracted from cell lines or patient tissues using RNeasy Mini kits (Qiagen, Hilden, Germany) or Trizol (Invitrogen), respectively according to the manufacturer's protocol. Reverse transcription was carried out in 26 µL aliquots of solution containing 5 µg of total RNA, 2.5 ng Oligo d(I)₁₈ and RNase-free water, which was then incubated for 15 min at 72 °C in a thermal cycler. After 10 min of cooling at 4 °C, 24 µL of the RT-enzyme mixture containing 5 µL 10 mmol/L dNTPs, 5 µL 0.1 mol/L dithiothreitol, 10 µL 5 × first-strand buffer, 2 µL SuperScript II reverse transcriptase (Invitrogen) and 2 µL recombinant RNasin ribonuclease inhibitor (Promega, Madison, WI, United States) was added to obtain a final volume of 50 µL. The mixture was then incubated for 90 min at 42 °C followed by 15 min incubation at 72 °C, and was subsequently cooled to 10 °C.

Real-time quantitative reverse transcription polymerase chain reaction

Primers and probes for PLK1 and FOXM1 were from TaqMan Gene Expression Assays (Applied Biosystems, Foster City, CA, United States). In brief, 20 µL reaction was set up containing 4 µL cDNA, 10 µL 2 × TaqMan Universal PCR Master Mix (Applied Biosystems), 1 µL 20 × TaqMan Gene Expression Assay Mix of corresponding target gene, 1 µL 20 × human hypoxanthine-guanine phosphoribosyltransferase endogenous control (Applied Biosystems)^[17] and 4 µL RNase-free water. The reaction was run on the ABI Prism 7000 Sequence Detection System (Applied Biosystems) with the following profile: 1 cycle at 50 °C for 2 min, 1 cycle at 95 °C for 10 min, then 40 cycles at 95 °C for 15 s and at 60 °C for 1 min. No-template control and TaqMan Control Total RNA (Human) (Applied Biosystems) as reference control were also included where applicable. Relative quantification was done using the 2^{-ΔΔC_t} method.

Short interfering RNA transfection

Short interfering RNA (siRNA) targeting human PLK1 (si-PLK1) and FOXM1 were from siGENOME On-TargetPlus Set of 4 duplex (Dharmacon, Chicago, IL, United States) and On-Target plus siCONTROL Non-targeting pool (si-NT) (Dharmacon) was used as negative control. The mixture containing 4 siRNA duplexes was transfected

into cells using Lipofectamine RNAiMAX Transfection Reagent (Invitrogen) according to the manufacturer's protocol. No-treatment and transfection-reagent-only controls were also included where suitable. The transfection period was 48 h for all assays or tests unless otherwise specified.

Cell proliferation assays

The 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2(4-sulfophenyl)-2H-tetrazolium (MTS) assay was performed using the CellTiter 96 Aqueous Non-Radioactive Cell Proliferation Assay (Promega) according to the manufacturer's protocol. The BrdU (5-bromo-2-deoxyuridine) assay was performed using Cell Proliferation enzyme-linked immunosorbent assay (ELISA), BrdU (chemiluminescent) (Roche Applied Science, Indianapolis, IN, United States) according to the manufacturer's protocol.

Western blot analysis

Cells were lysed using Complete Lysis-M (Roche Applied Science) according to the manufacturer's protocol. The protein concentration was determined using BCA Protein Assay Kit (Pierce, Rockford, IL, United States). Protein (30 μ g) was mixed 1:1 with Laemmli sample buffer (Bio-Rad Laboratories, Hercules, CA, United States) supplemented with 5% β -mercaptoethanol and heated at 95 °C for 5 min followed by 5 min incubation on ice. The sample was then loaded onto a 10% Tris-HCl Ready Gel (Bio-Rad) and subsequently electrotransferred to a Hybond-P polyvinylidene difluoride membrane (Amersham Pharmacia Biotech, Buckinghamshire, United Kingdom). The membrane was blocked for an hour at 22 °C with 5% Blotting-Grade Blocker and non-fat dry milk (Bio-Rad). After blocking, the membrane was incubated with mouse anti-human Plk1 (F-8) antibody (Santa Cruz Biotechnology, Santa Cruz, CA, United States) at 1:500 for 1 h at 22 °C followed by incubation with Cruz Marker Compatible goat anti-mouse IgG antibody (Santa Cruz) at 1:50 000 for 1 h at 22 °C. The reaction was detected using the ECL plus system (Amersham) and developed using Hyperfilm ECL (Amersham). Mouse anti-human β -actin (C4) antibody (Santa Cruz) diluted at 1:10 000 was used as loading control. The blots were analyzed with the Quantity One software (Bio-Rad).

Immunofluorescence imaging

Cells were cultured on Lab-Tek II 2-chambered glass slides (Nunc, Rochester, NY, United States). Twenty 4 h after siRNA transfection, the cells were fixed in 4% buffered paraformaldehyde for 30 min at 4 °C. The cells were then permeabilized with 0.5% Triton X-100 in phosphate-buffered solution for 10 min and subsequently blocked in 2% bovine serum albumin for 10 min. The cells were incubated with primary antibody diluted at 1:100 for 1 h at 22 °C followed by an hour's incubation at 22 °C with fluorescein isothiocyanate (FITC)-conjugated secondary antibody diluted at 1:400. The cells were subsequently mounted using Vectashield with 4',6-diamidino-

2-phenylindole (Vector Laboratories, Burlingame, CA, United States) for nuclei staining. Primary antibodies used were FITC-conjugated mouse anti- α -tubulin antibody (clone DM1A) (Sigma-Aldrich), goat polyclonal anti-human endonuclease G (Santa Cruz) and goat polyclonal anti-human apoptosis-inducing factor (Santa Cruz). The secondary antibody used was donkey anti-goat IgG-FITC (Santa Cruz). Fluorescence images were captured using Olympus Fluoview FV500 or BX60F5 (Olympus, Center Valley, PA, United States).

Chromosome fragmentation detection assay, terminal deoxynucleotidyl transferase dUTP nick end labeling assay and caspase-3 activity assay

Chromosome fragmentation was detected using Cell Death Detection ELISA^{PLUS} (Roche) according to the manufacturer's protocol. Thapsigargin (Sigma-Aldrich) treatment was used as positive control. Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay was carried out after 24 h of transfection using the DeadEnd Fluorometric TUNEL system (Promega) according to the manufacturer's protocol. Fluorescence images were captured using Olympus BX60F5 (Olympus). The caspase-3 activity assay (Roche) was performed according to the manufacturer's protocol.

Caspase inhibition assay

Cells were transfected with siRNA in the presence of cell permeable pan-caspase inhibitor Z-VAD-FMK (Sigma-Aldrich) at 100 μ mol/L for 48 h. Cell proliferation was subsequently determined with MTS assay. Camptothecin (Sigma-Aldrich) at 5 μ mol/L was used to induce apoptosis in HepG2 cells. For camptothecin treatment, HepG2 cells were incubated with the caspase inhibitor for an hour before camptothecin was added and remained till the end of incubation. An equal amount of DMSO was used in the negative control where appropriate.

In vivo nude mice experiment

Nude mice were transplanted subcutaneously with 2×10^6 Huh-7 cells in 100 μ L Matrigel (Sigma-Aldrich). The treatment was started 1 wk after the transplantation. Eighteen tumor-bearing nude mice were divided equally into a group ($n = 6$) that received si-PLK1 treatment, a group that received si-NT treatment ($n = 6$), and a control group that received no treatment ($n = 6$). Treatment groups received intratumoral injections of 1 nmol siRNA coupled with Lipofectamine RNAiMAX Transfection Reagent (Invitrogen) every alternate day. The control group was injected with saline instead. Tumor sizes recorded before treatment were calculated by the formula: volume (mm^3) = (width)² \times length/2. Animal experiments were carried out in compliance with the guidelines of the Laboratory Animals Centre, National University of Singapore and were approved by the National University of Singapore Institutional Animal Care and Use Committee.

Statistical analysis

Statistical analysis was carried out using Microsoft Excel

Table 1 Correlation between polo-like kinase-1 gene expression and clinicopathological parameters in 56 patients with hepatocellular carcinoma

Clinicopathological parameters	n	Relative <i>PLK1</i> gene expression (mean ± SE)	P value
Age (yr)			
< 65	42	18.35 ± 2.95	0.570 ¹
≥ 65	14	16.15 ± 5.11	
Sex

¹P value was determined by the Mann-Whitney *U* test; ²P value was determined by the Kruskal-Wallis test. *PLK1* gene expression in every hepatocellular carcinoma tissues was quantified relative to the non-tumor tissues counterparts using 2^{-ΔΔCt} method. PLK1: Polo-like kinase-1.

or SPSS. *P* values of less than 0.05 were deemed significant. All data was expressed as mean ± SE unless otherwise specified.

RESULTS

Baseline characteristics of the patients

The patients, 49 male, 7 female, age range 32-82 years (mean, 56 years), were hepatitis B-positive and were Asian (Table 1).

PLK1 gene expression in HCC patients and correlation with clinicopathological parameters

Gene expression of 10 candidate genes (*PLK1*, forkhead box M1, pituitary tumor-transforming gene 1, ubiquitin specific peptidase 21, reticulocalbin 2, dual specificity phosphatase 12, ubiquitin specific peptidase 1, S100 calcium binding protein P, ubiquitin specific peptidase 5, X-box binding protein 1) indentified from a literature survey of genes shown to be upregulated in tumors but not well documented in HCC, were chosen for real-time quantitative reverse transcription polymerase chain reaction (RT-PCR) analysis in 10 sets of paired HCC tumor/adjacent non-tumor tissue (data not shown). *PLK1* was found to be consistently upregulated in HCC tumor tissue. Gene expression of *PLK1* was then investigated in 46 other patient samples (a total of 56 HCC tumors) using real-time quantitative RT-PCR. The median *PLK1* gene expression was about 12 times higher in 50% of the HCC tumors when compared with non-tumor tissues (Figure 1A).

PLK1 siRNA successfully silenced *PLK1* gene expression in Huh-7 cells

PLK1 gene expression in Huh-7 cell-line was about eight times higher than other human hepatoma cell lines (HepG2 and HepG2.2.15) as determined by real-time quantitative RT-PCR (data not shown). Hence, it was selected as *in vitro* model to study the effect of silencing *PLK1* gene expression. *PLK1* knockdown with 1 nmol/L, 50 nmol/L and 100 nmol/L si-*PLK1* was able to silence of *PLK1* gene expression by 83%, 95% and 96%, respectively, compared with the Huh-7 cells transfected with an equal concentration of si-NT (Figure 1B). The reduction in *PLK1* gene expression by si-*PLK1* corresponded to the reduction observed in *PLK1* protein expression level. Using 50 nmol/L si-*PLK1*, *PLK1* protein expression was reduced by 95% when compared with the si-NT transfected Huh-7 cells (Figure 1C). Therefore, si-*PLK1* was shown to be efficient and specific in silencing *PLK1* gene and protein expression in Huh-7 cells.

Silencing of *PLK1* reduced cell proliferation in Huh-7 cells

Transfection of si-*PLK1* caused a significant reduction in Huh-7 cells proliferation as measured by the MTS cell proliferation assay (Figure 2A) and BrdU cell proliferation assay (Figure 2B), but with no apparent dose-response. On average, si-*PLK1*-treated Huh-7 cells showed 68% and 92% reductions in cell proliferation in MTS and BrdU cell proliferation assays, respectively. In addition, Huh-7 cells that were transfected with si-*PLK1* appeared to be binucleated (Figure 2C, left panel) while Huh-7 cells transfected with si-NT completed mitosis with functional spindle assembly (Figure 2C, right panel), indicative of its role in establishing functional spindle assembly.

Silencing of *PLK1*-induced apoptosis in Huh-7 cells

Nuclear fragmentation expressed as the enrichment factor (sample absorbance/absorbance of the non-transfected control) > 1, indicates enrichment of mono- and oligonucleosomes in the cytoplasm of the apoptotic cells due to DNA breakdown. The enrichment factor in Huh-7 cells that were transfected with si-*PLK1* was 3-fold higher than in the Huh-7 cells transfected with si-NT (Figure 3A). In addition, TUNEL staining of si-*PLK1*-transfected Huh-7 cells helped to identify and visualize apoptotic cells with fragmented chromosomes (Figure 3B). To examine the apoptosis pathway, caspase-3 activity was analyzed in si-*PLK1* transfected Huh-7 cells at three different time points (Figure 3C). There was activation of caspase-3 to over 500 U (compared with 2350 U in positive controls), but this was only detected at 48 h after transfection (Figure 3C). This was an unexpected finding as the TUNEL assay had already showed prominent nuclear fragmentation in apoptotic cells 24 h after transfection, and suggests that the apoptosis pathway induced by *PLK1* knockdown in Huh-7 cells may be caspase-independent.

Apoptosis induced by silencing *PLK1* gene expression is caspase-independent

A cell permeable pan-caspase inhibitor Z-VAD-FMK was

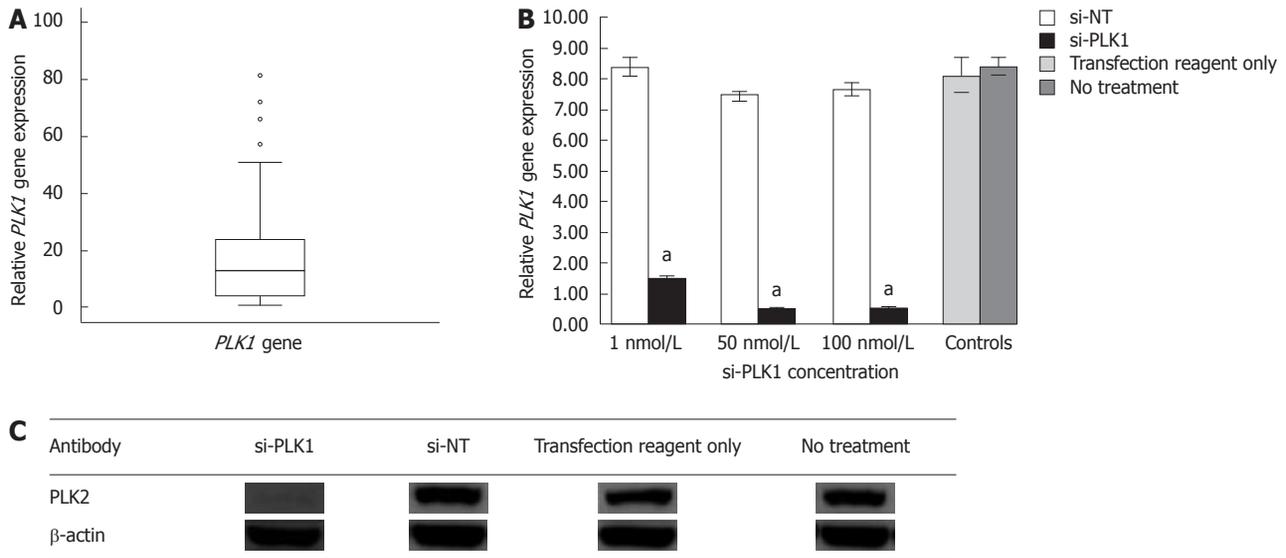

Figure 1 Upregulation of polo-like kinase 1 gene expression in 56 hepatocellular carcinoma tumors, efficiency of short-interfering RNA in silencing the polo-like kinase 1 gene, and protein expression in Huh-7 cells. A: Boxplot showing the minimum, 25th percentile, median, 75th percentile and maximum relative polo-like kinase 1 (*PLK1*) gene expression. Circles represent statistical outliers. *PLK1* gene expression in all hepatocellular carcinoma (HCC) tissue was quantified relative to the non-tumor tissue counterpart using the $2^{-\Delta\Delta Ct}$ method; B: Knockdown with short interfering *PLK1* (si-*PLK1*) at 1 nmol/L, 50 nmol/L and 100 nmol/L successfully silenced *PLK1* gene expression (using the $2^{-\Delta\Delta Ct}$ method by quantitative real-time RT-PCR) by 83%, 95% and 96% respectively, compared with short interfering non-targeting (si-NT), or controls. Data shown as mean \pm SE, using the Student *t*-test ($^aP < 0.05$); C: Western blotting showing reduction of *PLK1* protein expression in Huh-7 cells, at si-*PLK1* and si-NT (non-targeting si-RNA) concentrations of 50 nmol/L compared with si-NT or controls.

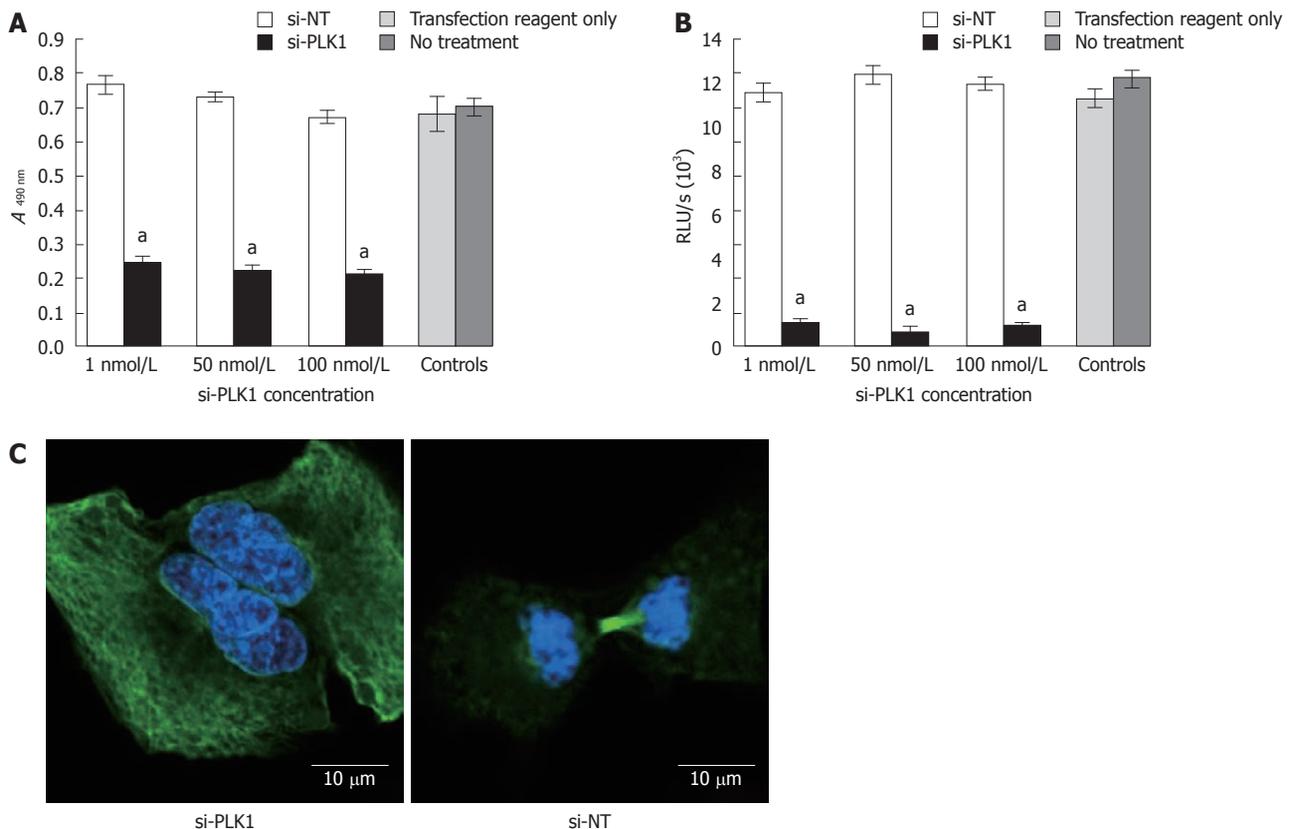

Figure 2 Reduction of cell proliferation by 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium assay and bromodeoxyuridine assay after silencing of polo-like kinase 1, and failure of mitosis after knockdown of polo-like kinase 1. A: Knockdown of polo-like kinase 1 (*PLK1*) reduced cell proliferation in Huh-7 cells in the 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTS) cell proliferation assay by a mean of 65% compared with short interfering non-targeting (si-NT) or controls; B: Knockdown of *PLK1* reduced cell proliferation in the bromodeoxyuridine cell proliferation assay in Huh7 cells by a mean of 93% with 50 nmol/L short-interfering *PLK1* (si-*PLK1*) compared with si-NT or controls; C: Confocal fluorescence images show the si-*PLK1* transfected Huh-7 cells (left panel) were binucleated, depicting failure in completing mitosis due to the lack of a functional spindle assembly. The right panel shows a functional spindle assembly in Huh-7 cells transfected with si-NT. Huh-7 cells were processed for confocal imaging after 24 h of transfection either with 50 nmol/L si-*PLK1* or si-NT; α -tubulins were stained with fluorescein isothiocyanate-conjugated antibody and nuclei were counterstained with 4',6-diamidino-2-phenylindole. Data are shown as mean \pm SE, using the Student *t*-test ($^aP < 0.05$).

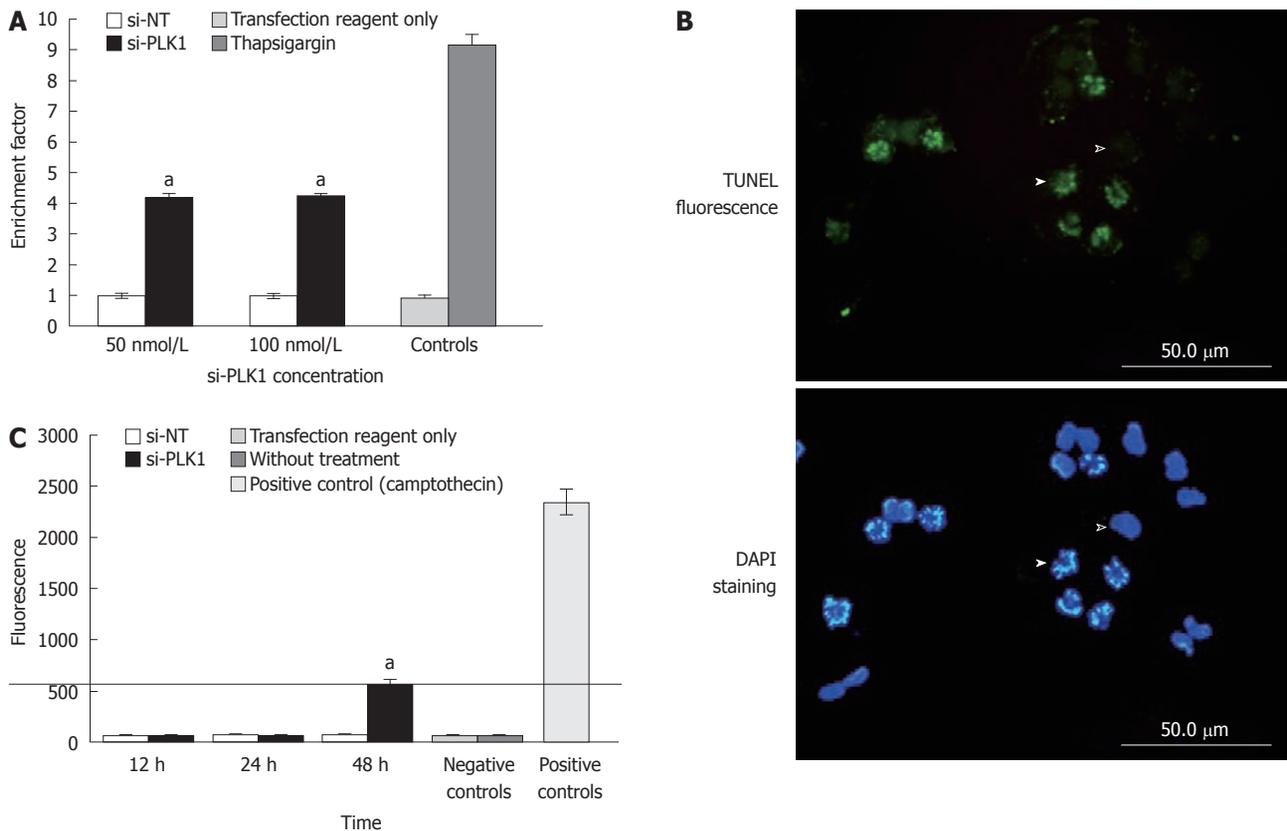

Figure 3 Increased apoptosis, apoptosis by terminal deoxynucleotidyl transferase dUTP nick end labeling staining and caspase 3 activity after knockdown of polo-like kinase 1. **A:** Increased apoptosis; apoptosis measured by enrichment factor [enrichment factor (sample absorbance/control absorbance) > 1 indicates nuclear fragmentation]. Huh-7 cells transfected with short-interfering polo-like kinase 1 (si-PLK1) showed a 4-fold increase in enrichment factor compared with short-interfering non-targeting (si-NT) or the negative control, no difference was seen between the 50 nmol/L and 100 nmol/L si-PLK1. Thapsigargin (5 μ mol/L) treated Huh-7 cells were positive controls. Data are shown as mean \pm SE, using the Student *t*-test ($^{\ast}P < 0.05$); **B:** Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) fluorescence images showing fragmented DNA labeled with fluorescein-12-dUTP using recombinant terminal deoxynucleotidyl transferase (upper image). The lower image is the corresponding 4',6-diamidino-2-phenylindole (DAPI) stain showing an apoptotic Huh-7 cell (solid arrowhead) and a non-apoptotic Huh-7 cell (hollow arrowhead). The TUNEL staining colocalized the fragmented chromosomes to apoptotic cells while is absent in non-apoptotic cells with intact chromosomes. Huh-7 cells were processed for fluorescence imaging after 24 h of transfection with 50 nmol/L si-PLK1; **C:** Caspase 3 activity was measured using a fluorometric immunosorbent enzyme assay from Huh-7 cells transfected with 50 nmol/L si-PLK1 showed no change after 12 and 24 h, with an increase to just over 500 U at 48 h compared with si-NT and negative controls. Positive controls showed values over 2350 U (cell lysates from U937 cells treated with camptothecin, supplied with the kit). Data are shown as mean \pm SE, using the Student *t*-test ($^{\ast}P < 0.05$).

applied to validate the requirement of caspase in apoptosis induced by silencing *PLK1* gene expression in Huh-7 cells. By using the MTS cell proliferation assay as the functional end-point indicator for apoptosis, the pan-caspase inhibitor was unable to rescue the reduction in cell proliferation of Huh-7 cells transfected with si-PLK1 (Figure 4A). The finding clearly demonstrates that apoptosis in si-PLK1-transfected Huh-7 cells was caspase-independent. Two exclusively mitochondrial pro-apoptotic proteins, endonuclease G (EndoG) and apoptosis-inducing factor (AIF), have been identified to be involved in the caspase-independent apoptosis pathway^[18]. In Figure 4B, EndoG was released from the mitochondria and colocalized in the fragmented chromosomes in apoptotic Huh-7 cells, indicating that EndoG was likely to be the main caspase-independent apoptotic effector. AIF was found to be absent and therefore was probably not involved in this particular apoptosis event (Figure 4B).

Targeting *PLK1* in vivo impeded tumor growth

Huh-7 cells were subcutaneously transplanted into the

flanks of nude mice and allowed to develop into HCC tumors. These tumors were later treated with repeated intratumoral injections of si-PLK1 every alternate day to evaluate the anti-tumor effect by targeting PLK1. The mean tumor volume of the si-PLK1 treatment group was significantly lower than the si-NT treatment group starting from Day 11 after five si-PLK1 treatments (Figure 5A and B). At the end of the treatment period, the mean tumor volume in the si-PLK1 treatment group was about 33% lower than in the si-NT treatment group.

DISCUSSION

PLK1 gene overexpression was seen in a majority of the HCC patients in this study, suggesting that PLK1 may have a role in the HCC tumorigenesis. Recently, PLK1 expression was significantly correlated with a higher recurrence rate in HCC patients^[19]. Moreover, PLK1 overexpression has also been recently reported to be correlated with metastatic HCC disease^[6] and poor prognosis^[5] in HCC. More recently, Pelligrino *et al.*^[8] found that PLK1

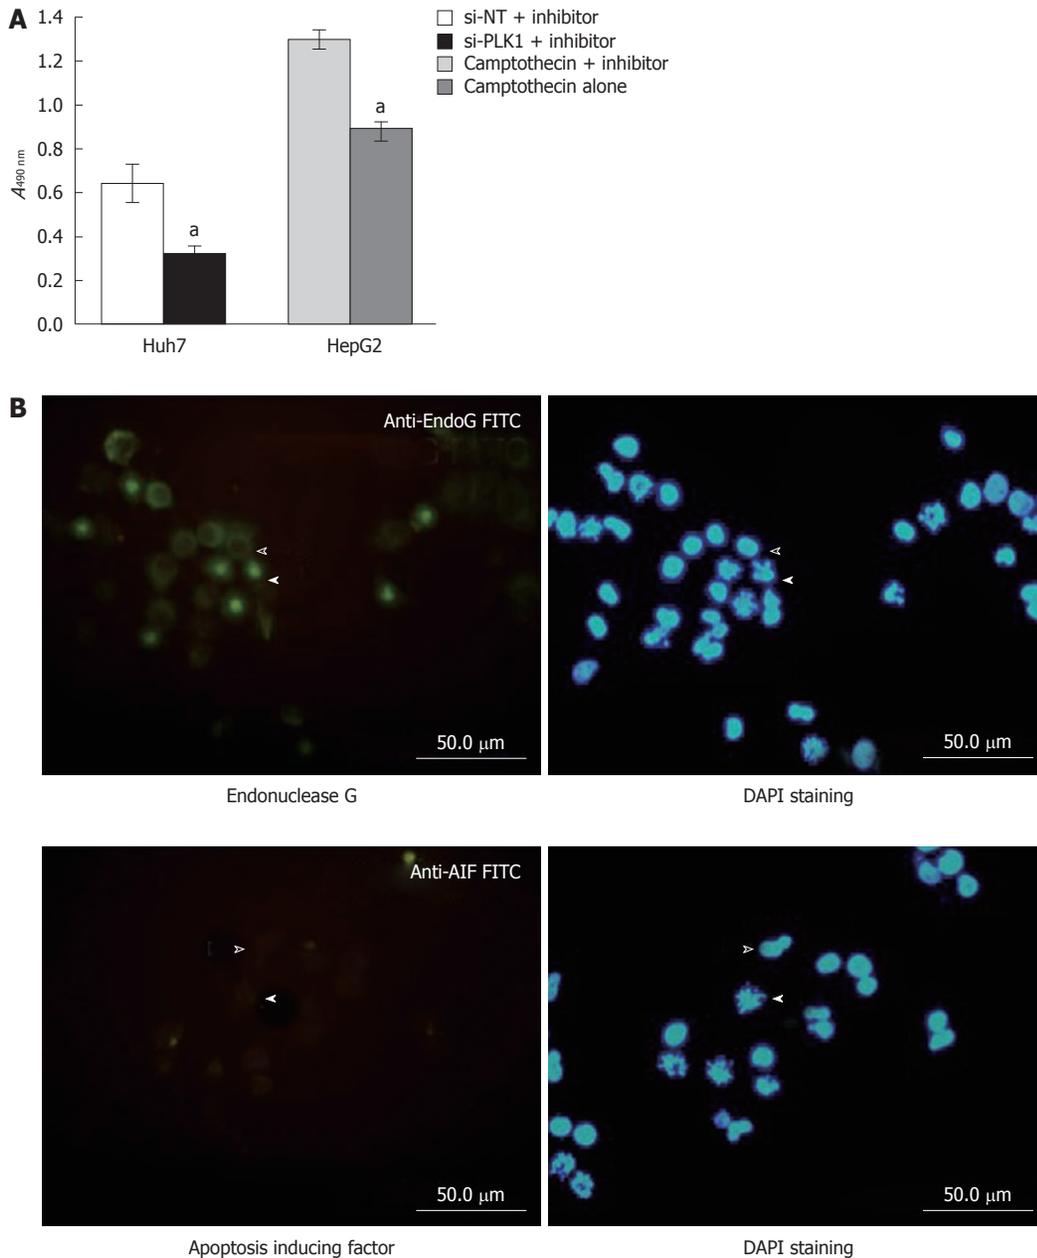

Figure 4 Lack of apoptosis protection and caspase-independent apoptosis. A: Lack of apoptosis protection by pan-caspase inhibitor Z-VAD-FML after knockdown of polo-like kinase 1 (PLK1). The MTS cell proliferation assay in Huh-7 cells transfected with either short interfering non-targeting (si-NT) or short interfering-PLK1 (si-PLK1) in the presence of the pan caspase inhibitor Z-VAD-FMK showed that the pan caspase inhibitor failed to protect si-PLK1 transfected Huh-7 cells from apoptosis. In contrast, HepG2 that were treated with camptothecin and Z-VAD-FMK were protected from apoptosis induced by camptothecin while those treated with camptothecin without Z-VAD-FMK were not protected from apoptosis. Data are shown as mean \pm SE, using the Student *t*-test ($^aP < 0.05$); B: Caspase-independent apoptosis likely due to endonuclease G. Huh-7 transfected with 50 nmol/L si-PLK1 for 24 h was probed with antibody against endonuclease G or apoptosis-inducing factor (AIF) and subsequently visualized with fluorescein isothiocyanate-conjugated secondary antibody (left panels). The corresponding 4',6-diamidino-2-phenylindole (DAPI)-stained images are shown in the right panels. Block arrowheads and hollow arrowheads mark apoptotic and non-apoptotic Huh-7 cells respectively. Endonuclease G was positively stained in apoptotic cells and colocalized to the fragmented chromosomes (upper left panel), while AIF was found to be absent (lower left panel).

silencing was associated with suppression of cell growth, while PLK2-4 silencing had the opposite effect. These studies indicate that PLK1 may have an important role in HCC.

We have shown that Huh-7 cell proliferation requires PLK1. Moreover, PLK1 knockdown in Huh-7 cells results in nuclear fragmentation, indicating apoptosis is present. Intriguingly, caspase activation is found to be unnecessary for PLK1-induced apoptosis. Consequently,

the caspase-independent pathway is likely to be active, and the apoptotic effector appears to be endoG, which is a DNase that is exclusively mitochondrial. EndoG is released from mitochondria and translocates to the nucleus to cleave DNA independently of caspase upon apoptosis induction^[20]. AIF, another potential effector candidate in the caspase-independent apoptosis pathway^[21] was found not be involved in PLK1-induced apoptosis. It is not an essential requirement for the presence of both endoG

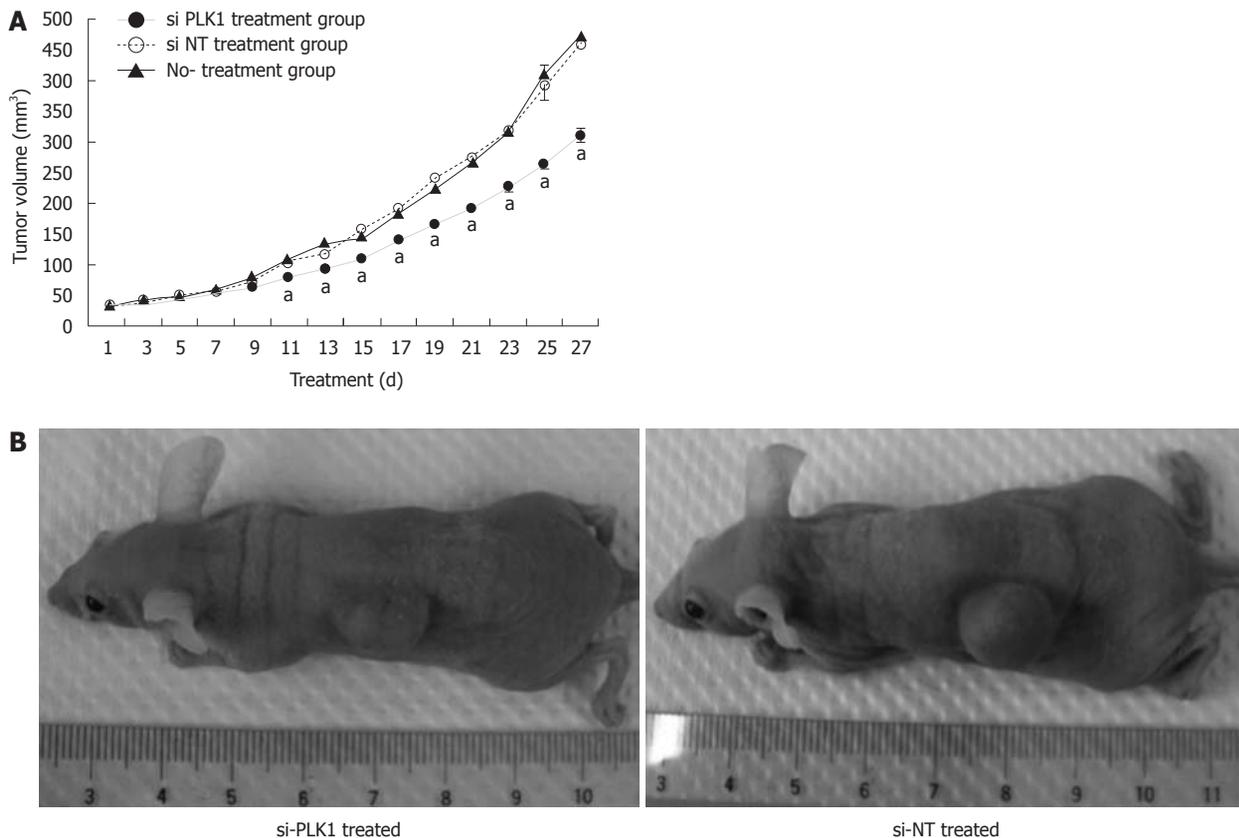

Figure 5 Reduction in hepatocellular carcinoma tumor size with knockdown of polo-like kinase 1. A: Treatment of short-interfering RNA (siRNA) against polo-like kinase 1 (PLK1) (si-PLK1, $n = 6$) in nude mice impeded the tumor growth compared with short interfering non-targeting (si-NT) ($n = 6$) or the non-treatment group ($n = 6$). Huh-7 tumor-bearing nude mice were treated with 1 nmol/L si-PLK1 intratumoral injections every alternate day for 27 d. Data are shown as mean \pm SE, using the Student *t*-test ($^*P < 0.05$); B: Images of nude mice with their tumors at day 27. The left panel shows a reduction in tumor size of subcutaneous tumors in nude mice treated with si-PLK1, while the right panel shows similar mice treated with si-NT.

and AIF to induce caspase-independent apoptosis. In galectin-1 induced T-cell apoptosis, which is independent of caspase, AIF and cytochrome *c*, only endoG was shown to be involved^[22]. The induction of apoptosis that is independent of caspase by silencing *PLK1* gene expression in Huh-7 cells has significant implications in the treatment of HCC. It is reported that caspase-1 and caspase-3 expressions are downregulated in HCC and this could contribute to the lack of efficacy of chemotherapy^[23]. Consequently, a caspase-directed strategy is unlikely to be successful, and thus targeting PLK1 may be a more effective strategy in treatment of HCC patients.

Similar to other reports of PLK1 involvement in the proliferation of cell types such as breast cancer, lung cancer, prostate cancer and esophageal cancer^[24-26], we have also shown that silencing of PLK1 significantly reduced cell proliferation and also impeded HCC growth in nude mice. *PLK1* is therefore a promising gene candidate for targeted therapy in treating not only HCC but other solid tumors as well. The requirement of PLK1 in the tumorigenesis of HCC and other cancers implies it has a critical role in the final pathway for cancer cell proliferation. Overexpression of PLK1 may help to inactivate the spindle checkpoint persistently by targeting early-mitotic inhibitor 1, which is an inhibitor of anaphase promoting complex/cyclosome, that is degraded by ubiquitin ligase

complexes^[27]. However, the exact role of PLK1 overexpression in the tumorigenesis of HCC or other cancers is still unclear since the physiological role of PLK1 is not fully defined.

The results of our study suggest that targeting PLK1 in HCC treatment is a promising therapeutic option. In addition, normal diploid cells such as hTERT-RPE1 and MCF10A cells can survive similar PLK1 depletion that otherwise causes mitotic arrest and apoptosis in cancer cell lines^[28]. Normal diploid cells still require PLK1 for survival, but at a much lower PLK1 level compared with cancer cells^[29]. Consequently, controlling the extent of PLK1 depletion could minimize the deleterious effects on HCC patients. Currently, there are a number of PLK1 inhibitors in development such as ON 01910, DAP81, TAL, BTO-1/cyclopolin, and compound 1^[30]. However, the most advanced agent is a novel small molecular inhibitor, BI2536, which inhibits the enzymatic activity of PLK1 protein with high selectivity (10 000-fold selectivity over other kinases) and high potency^[31,32]. BI2536 has now completed phase I clinical trials in patients with advanced solid tumors with reported anti-tumor activity, and neutropenia as a dose-limiting toxicity^[33]. Phase II clinical trials of BI2536 are currently ongoing for various tumor indications^[34]. Such inhibitors could probably be suitable in treating HCC or could be used in combina-

tion with other drugs, a strategy that is being explored in many cancers, for example, breast cancer^[35].

In conclusion, PLK1 is overexpressed in HCC and the silencing experiments have shown significant antiproliferative effects *in vitro* and *in vivo*, through induction of a caspase-independent apoptosis pathway that could lead to increased sensitivity of chemotherapy in HCC patients. Thus, PLK1 is a promising therapeutic target for HCC.

COMMENTS

Background

The pathogenesis of hepatocellular carcinoma (HCC) is likely to be a multi-gene process. One gene that has been described in many cancers but only recently in HCC is polo-like kinase 1 (PLK1), a kinase that is critical to spindle formation during the metaphase.

Research frontiers

PLK1 is emerging as an important therapeutic target as a number of new agents are currently undergoing clinical trials.

Innovations and breakthroughs

The authors show that PLK1 knockdown results in a reduction in PLK1 gene and protein expression with resultant reduction in cell proliferation and increase in apoptosis. The authors also show that the increase in apoptosis is caspase-independent and involves EndoG and apoptosis-inducing factor. Knockdown of PLK1 in subcutaneous tumors transplanted into nude mice showed impairment of tumor growth.

Applications

The study indicates that PLK1 inhibitors should be evaluated in clinical trials of HCC, either as monotherapy or combination therapy.

Terminology

PLK1: Polo-like kinase, an important kinase required for spindle formation in metaphase; caspase-induced apoptosis is a key pathway for apoptosis; cell proliferation is a classic method to evaluate tumor cell growth - blocking proliferation implies that tumor growth can be blocked; si-RNA knockdown: Short interfering RNAs are short complementary RNAs that bind specifically to the mRNA produced by the gene of interest, hence blocking the signal for protein expression.

Peer review

This is a good descriptive study in which authors investigate the role of PLK1 as a therapeutic target for HCC. The results are interesting and suggest knockdown of PLK1 overexpression in HCC was shown to be a potential therapeutic target, leading to apoptosis through the endonuclease-G pathway.

Abstract

AIM: To investigate the effect of zinc finger protein A20 on chronic liver allograft dysfunction in rats.

METHODS: Allogeneic liver transplantation from DA rats to Lewis rats was performed. Chronic liver allograft dysfunction was induced in the rats by administering low-dose tacrolimus at postoperative day (POD) 5. Hepatic overexpression of A20 was achieved by recombinant adenovirus (rAd.)-mediated gene transfer administered intravenously every 10 d starting from POD 10. The recipient rats were injected with physiological saline, rAdEasy-A20 (1×10^9 pfu/30 g weight) or rAdEasy (1×10^9 pfu/30 g weight) every 10 d through the tail vein for 3 mo starting from POD 10. Liver tissue samples were harvested on POD 30 and POD 60.

RESULTS: Liver-transplanted rats treated with only tacrolimus showed chronic allograft dysfunction with severe hepatic fibrosis. A20 overexpression ameliorated

the effects on liver function, attenuated liver allograft fibrosis and prolonged the survival of the recipient rats. Treatment with A20 suppressed hepatic protein production of tumor growth factor (TGF)- β 1, interleukin-1 β , caspase-8, CD40, CD40L, intercellular adhesion molecule-1, vascular cell adhesion molecule-1 and E-selectin. A20 treatment suppressed liver cell apoptosis and inhibited nuclear factor- κ B activation of Kupffer cells (KCs), liver sinusoidal endothelial cells (LSECs) and hepatic stellate cells (HSCs), and it subsequently decreased cytokine mRNA expression in KCs and LSECs and reduced the production of TGF- β 1 in HSCs.

CONCLUSION: A20 might prevent chronic liver allograft dysfunction by re-establishing functional homeostasis of KCs, LSECs and HSCs.

INTRODUCTION

Although the incidence of chronic rejection at 5 years after transplantation has decreased from 15%-20% in the 1980s to an expected incidence of 3%-5% in current recipients, probably because of the introduction of the novel drug tacrolimus^[1,2], the incidence of chronic liver

allograft dysfunction is still high in long-surviving recipients. Chronic liver allograft dysfunction, which results in the loss of approximately 2000 liver grafts every year, has a significant impact on liver graft function and long-term survival. It has been reported that a significant proportion of long-term liver allografts presented features of a hepatitis-like reaction that was not attributable to known viral agents or other agents^[3,4]. Chronic liver allograft dysfunction is now considered to be a result of various causes of hepatic injury, including immune and non-immune factors. Currently, research is focused on non-immune factors that may lead to chronic liver allograft dysfunction, including the use of donor organs of marginal quality, the use of organs from brain injury/brain-dead donors, the presence of ischemia-reperfusion injury, Kupffer cell (KC) activation, interleukin and growth factor production, damage caused by immunosuppressive drugs (chronic toxicity of damage) and cytomegalovirus infection. Because of the numerous causative factors, the prevention and treatment of chronic liver graft dysfunction represents a considerable challenge.

Pathological changes observed in cases of chronic liver allograft dysfunction include arterial proliferative occlusive disease and/or bile duct disappearance, liver cell death and eventually liver fibrosis. Bile duct disappearance is considered to be a result of arterial proliferative occlusive disease. Molecular changes include increased hepatic expression of tumor growth factor (TGF)- β , interleukin (IL)-1 β , caspase-1 and caspase-8^[5]. IL-1 has been shown to contribute to chronic rejection^[6]. IL-1 is produced by activated macrophages and many other cell types, including injured endothelial cells (ECs), and it stimulates smooth-muscle proliferation *in vitro* and increases the adhesive properties of the vascular endothelium. Overproduction of TGF- β is a chief cause of tissue fibrosis in various organs^[7]. TGF- β induces the phenotypic transition of hepatic stellate cells (HSC) into proliferating myofibroblast-like cells, thus enhancing production of extracellular components^[8]. The cellular and molecular mechanisms of chronic liver allograft dysfunction are still not completely clear, and the currently available drug treatments are ineffective.

The process of liver fibrosis is well-understood, and the basic steps can be summarised as follows: (1) various sources of liver damage induce KC activation; (2) activated KCs express and produce a variety of cytokines and co-stimulating molecules, such as TNF- α , IL-6, TGF- β , IL-1 β and CD40L^[9-11]; and (3) cytokines and co-stimulating molecules stimulate HSC activation and stimulation of myofibroblasts, which synthesize a large amount of extracellular matrix, resulting in liver fibrosis. In the process of hepatic fibrosis, nuclear factor (NF)- κ B may play an important central regulatory role by regulating functional changes of hepatocytes, KCs and HSCs^[9,11,12].

NF- κ B is a key nuclear factor involved in the regulation of KC activation. In addition to the production of pro-inflammatory cytokines, such as TNF- α , IL-1 β , TGF- β , IL-6 and IL-8, activated KC also express the co-stimulatory molecule CD40L, which is an important char-

acteristic of chronic liver allograft dysfunction^[13]. Expression of inflammatory mediators can stimulate the nuclear translocation of NF- κ B in KCs *via* autocrine or paracrine pathways and induce the production of additional inflammatory mediators, leading to an "inflammatory cascade", which results not only in liver damage, but also leads to the rapid stimulation of HSC activation and proliferation. Thus, inhibition of NF- κ B activation in KCs may down-regulate the expression of inflammatory mediators, such as TNF- α , TGF- β , IL-1 and CD40L, and thereby suppress the liver inflammatory response.

Although the role of NF- κ B in liver graft arterial lesions is not completely clear, NF- κ B plays a key regulatory role in non-organ transplant atherosclerosis. In 1996, Brand demonstrated the presence of activated NF- κ B in human atherosclerotic tissue for the first time^[14]. Activation of NF- κ B was identified in smooth muscle cells, macrophages and ECs in their study. Previous studies had shown that atherosclerosis involves activation of vascular ECs and proliferation of vascular smooth muscle cells which are subject to the regulation of NF- κ B activation^[15-19].

A20 is a zinc finger protein that was originally identified as a TNF-responsive gene in ECs^[20]. A20 is expressed in multiple cell types, including fibroblasts, B cells, T cells and β cells, in response to a variety of stimuli that activate NF- κ B, including IL-1, LPS, phorbol 12-myristate 13-acetate, H₂O₂ and CD40 ligand. In ECs and hepatocytes, A20 has a dual cytoprotective function^[21-26]. A20 is anti-inflammatory, due to inhibition of NF- κ B through a negative feedback loop, and it is antiapoptotic, due to inhibition of the caspase cascade at the level of initiator caspase-8^[21-23]. A20 can also inhibit NF- κ B activation induced by LPS, IL-1 and CD40 cross-linking through the negative feedback loop^[24-26]. A20 curtails inflammation by inhibiting NF- κ B activation, either through its association with I κ B kinase- γ /NF- κ B essential modifier within the signalosome or through its ubiquitin-editing functions^[21,22,27,28].

A previous study indicated that reduced expression of A20 might be an important pathogenic contributor to an increased susceptibility to liver allograft ischemia/reperfusion (I/R) injury^[29]. Ramsey *et al.*^[30] recently reported that A20 could protect mice from lethal liver I/R injury by increasing peroxisome proliferator-activated receptor- α expression. In addition, it has been shown that A20 expression is up-regulated in human renal allografts in response to immune injury inferred by acute rejection, and the result suggests that A20 could limit graft injury^[31]. Our previous studies indicated that A20 expression was up-regulated in immature dendritic cells derived from rat liver allografts undergoing acute rejection^[32]. Furthermore, A20 overexpression could inhibit NF- κ B activation of liver sinusoidal endothelial cells (LSECs) in rat liver allografts and suppress acute rejection^[32]. These results suggest that A20 may protect liver allografts from I/R injury and acute rejection.

Although the effects of A20 on lipopolysaccharide-

induced acute toxic lethal hepatitis, liver regeneration, hepatic I/R injury and liver allograft rejection have been investigated, little is known about the effect of A20 on chronic liver allograft dysfunction. In this work, the effect of A20 on liver allograft chronic dysfunction induced by postoperative low-dose tacrolimus administration was investigated.
