Contents

Weekly Volume 18 Number 41 November 7, 2012

- EDITORIAL** 5833 Steroid-sparing strategies in the management of ulcerative colitis: Efficacy of leukocytapheresis
Shiraki M, Yamamoto T

- TOPIC HIGHLIGHT** 5839 Omega-3 fatty acids for the treatment of non-alcoholic fatty liver disease
Di Minno MND, Russolillo A, Lupoli R, Ambrosino P, Di Minno A, Tarantino G

- GUIDELINES FOR BASIC SCIENCE** 5848 Changes of the cytokine profile in inflammatory bowel diseases
Műzes G, Molnár B, Tulassay Z, Sipos F

- GUIDELINES FOR CLINICAL PRACTICE** 5862 Crohn's and colitis in children and adolescents
Day AS, Ledder O, Leach ST, Lemberg DA

- ORIGINAL ARTICLE** 5870 Effectiveness of impedance monitoring during radiofrequency ablation for predicting popping
Iida H, Aihara T, Ikuta S, Yamanaka N
- 5879 Several factors including *ITPA* polymorphism influence ribavirin-induced anemia in chronic hepatitis C
Tsubota A, Shimada N, Abe H, Yoshizawa K, Agata R, Yumoto Y, Ika M, Namiki Y, Nagatsuma K, Matsudaira H, Fujise K, Tada N, Aizawa Y
- 5889 Characteristics of deslanoside-induced modulation on jejunal contractility
Chen DP, Xiong YJ, Tang ZY, Yao QY, Ye DM, Liu SS, Lin Y
- 5897 Expression characteristics and diagnostic value of annexin A2 in hepatocellular carcinoma
Zhang HJ, Yao DF, Yao M, Huang H, Wu W, Yan MJ, Yan XD, Chen J

- BRIEF ARTICLE** 5905 Comparative effectiveness of *i*-SCAN™ and high-definition white light characterizing small colonic polyps
Chan JL, Lin L, Feiler M, Wolf AI, Cardona DM, Gellad ZF
- 5912 Human thrombin for the treatment of gastric and ectopic varices
McAvoy NC, Plevris JN, Hayes PC
- 5918 High-fibre diet and *Lactobacillus paracasei* B21060 in symptomatic uncomplicated diverticular disease
Lahner E, Esposito G, Zullo A, Hassan C, Cannaviello C, Di Paolo MC, Pallotta L, Garbagna N, Grossi E, Annibale B

- 5925** Effects of the viability of *Lactobacillus rhamnosus* GG on rotavirus infection in neonatal rats
Ventola H, Lehtoranta L, Madetoja M, Simonen-Tikka ML, Maunula L, Roivainen M, Korpela R, Holma R
- 5932** Methane production and small intestinal bacterial overgrowth in children living in a slum
Mello CS, Tahan S, Melli LCFL, Carmo Rodrigues MS, Mello RMP, Scaletsky ICA, Morais MB
- 5940** Efficacy of endoluminal gastroplication in Japanese patients with proton pump inhibitor-resistant, non-erosive esophagitis
Tokudome K, Funaki Y, Sasaki M, Izawa S, Tamura Y, Iida A, Ogasawara N, Konagaya T, Tokura Y, Kasugai K
- 5948** Electrogastrography associated with symptomatic changes after prokinetic drug treatment for functional dyspepsia
Lim HC, Lee SI, Chen JDZ, Park H
- 5957** Comparative study of rendezvous techniques in post-liver transplant biliary stricture
Chang JH, Lee IS, Chun HJ, Choi JY, Yoon SK, Kim DG, You YK, Choi MG, Han SW
- 5965** Correlation between mitochondrial TRAP-1 expression and lymph node metastasis in colorectal cancer
Gao JY, Song BR, Peng JJ, Lu YM
- 5972** Drug-induced liver injury in hospitalized patients with notably elevated alanine aminotransferase
Xu HM, Chen Y, Xu J, Zhou Q

CASE REPORT

- 5979** Dedifferentiated liposarcoma of the rectum: A case report
Tsuruta A, Notohara K, Park T, Itoh T
- 5982** Synchronous double cancers of the common bile duct
Sumiyoshi T, Shima Y, Kozuki A
- 5986** Mucosal necrosis of the small intestine in myopathy, encephalopathy, lactic acidosis, and stroke-like episodes syndrome
Fukuyama K, Ishikawa Y, Ogino T, Inoue H, Yamaoka R, Hirose T, Nishihira T
- 5990** Newly developed autoimmune cholangitis without relapse of autoimmune pancreatitis after discontinuing prednisolone
Kim JH, Chang JH, Nam SM, Lee MJ, Maeng IH, Park JY, Im YS, Kim TH, Kim CW, Han SW

Contents

World Journal of Gastroenterology
Volume 18 Number 41 November 7, 2012

5994 Medical treatment for a fish bone-induced ileal micro-perforation: A case report
Kuo CC, Jen TK, Wen CH, Liu CP, Hsiao HS, Liu YC, Chen KH

5999 Focal peliosis hepatis in a colon cancer patient resembling metastatic liver tumor
Xiong WJ, Hu LJ, Jian YC, He Y, Zhou W, Guo XL, Zheng YX

LETTERS TO THE EDITOR **6003** Upper oesophageal images and Z-line detection with 2 different small-bowel capsule systems
Koulaouzidis A

ACKNOWLEDGMENTS **I** Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX **I** Meetings

I-VI Instructions to authors

Abstract

Active ulcerative colitis (UC) is frequently associated with infiltration of a large number of leukocytes into the bowel mucosa. Leukocytapheresis is a novel nonpharmacologic approach for active UC, in which leukocytes are mechanically removed from the circulatory system. Current data indicate that leukocytapheresis is efficacious in improving response and remission rates with excellent tolerability and safety in patients with UC. Corticosteroid therapy remains a mainstay in the treatment of active UC; however, long-term, high doses of corticosteroids usually produce predictable and potentially serious side effects. If leukocytapheresis can spare patients from exposure to corticosteroids, the risk of steroid-induced adverse events should be minimized. This may be of great benefit to patients because severe side effects of steroids seriously impair health-related quality of life. In this article, we reviewed current evidence on whether leukocytapheresis can avoid or reduce the use of corticosteroids in the management of patients with UC. Several studies have shown that leukocytapheresis was effective for steroid-naïve patients with active UC. Furthermore, both short-term and long-term studies have demonstrated the steroid-sparing effects of leukocytapheresis therapy in patients with UC. Although the evidence level is not striking, the

available data suggest that leukocytapheresis can avoid or reduce the use of corticosteroids in the management of UC. Large, well-designed clinical trials are necessary to more accurately evaluate the steroid-sparing effects of leukocytapheresis in the management of UC.

INTRODUCTION

Active ulcerative colitis (UC) is frequently associated with infiltration of a large number of leukocytes into the bowel mucosa^[1]. The infiltrated leukocytes release degradative enzymes, oxygen derivatives and proinflammatory substances that can cause bowel injury and promote further inflammation^[2,3]. Removing excess and activated circulating leukocytes by apheresis has the potential to improve the condition of patients with inflamed bowels.

LEUKOCYTAPHERESIS

Leukocytapheresis is a novel nonpharmacologic approach

for active UC, in which leukocytes are mechanically removed from the circulatory system^[4-7]. Different apheresis techniques remove different types of leukocytes, and have different adsorption capacities. The two most common techniques involve drawing blood *via* a venous catheter, pumping it through a column containing cellulose acetate beads (Adacolumn) or a filter of nonwoven polyester fibers (Cellsorba), thereafter returning it to the circulatory system. As blood passes through the system, leukocytes adhere to the beads or filter. Leukocytapheresis appears to avoid and control an excess of cytokines by removing activated leukocytes from patient peripheral blood and inflamed bowels^[5,7]. However, the detailed biochemical mechanisms underlying the effects of leukocytapheresis remain largely unknown.

CORTICOSTEROIDS

Corticosteroid therapy remains a mainstay in the treatment of active UC^[8-11]. Patients frequently experience improvement in their symptoms within days of starting corticosteroids. During an acute severe exacerbation, approximately two-thirds of patients will respond to intravenous corticosteroid therapy. For steroid-refractory patients, options are limited to surgery or second-line agents, such as cyclosporine or infliximab, used in an attempt to avoid colectomy.

In the study by Faubion *et al*^[12], 63 patients with active UC were treated with corticosteroids. Short-term outcomes (30 d) were complete remission in 54% of patients, partial remission in 30%, and no response in 16%. One-year outcomes were prolonged response in 49% of patients, corticosteroid dependence in 22%, and operation in 29%. This study underlines the fact that most patients with UC initially respond to steroids, but after one year a significant proportion loses the response; this leads to steroid-dependency or the need for surgery, even among those who initially responded to the treatment. The pathophysiology of corticosteroid resistance and dependency in UC is poorly understood^[13]. Leukocytapheresis removes from the body blood cells that contribute to UC and, therefore, unlike corticosteroids, it is not expected to induce dependency or refractoriness.

EFFICACY AND SAFETY OF LEUKOCYTAPHERESIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL TRIALS

The data obtained from uncontrolled studies^[14-18] are generally quite consistent: a high response rate has been achieved in corticosteroid-naïve patients and a remission rate of approximately 50% has been achieved in patients with steroid-dependent or steroid-refractory UC. Additionally, leukocytapheresis is safe and well tolerated^[14-18]. The largest randomized, double-blind, sham-controlled study of Adacolumn leukocytapheresis therapy failed to

demonstrate efficacy for the induction of clinical remission or response in patients with moderate-to-severe UC^[19]. A number of meta-analyses^[20-22] were conducted to assess the safety and efficacy of leukocytapheresis compared with conventional pharmacotherapy in patients with UC. In the trials that compared leukocytapheresis and corticosteroids, side effects were much less frequent in patients treated with leukocytapheresis. Few severe adverse events were observed during leukocytapheresis therapy. Unlike corticosteroids, leukocytapheresis is associated with an excellent safety and tolerability profile. Furthermore, leukocytapheresis induces a clinical remission in a higher proportion of UC patients as compared to conventional medical therapy. However, many of the studies evaluated in the meta-analyses were conducted in Japanese patients, which may limit generalizability. High-quality randomized controlled trials (RCTs) comparing leukocytapheresis with conventional medical treatment or sham procedure in Western populations are required^[20-22].

POTENTIAL ADVANTAGES OF LEUKOCYTAPHERESIS OVER CORTICOSTEROIDS

Long-term, high doses of corticosteroids usually produce predictable and potentially serious side effects. If leukocytapheresis can spare patients from exposure to corticosteroids, the risk of steroid-induced adverse events should be minimized. This may be of great benefit to patients because severe side effects of steroids seriously impair health-related quality of life. In this article, we reviewed current evidence on whether leukocytapheresis can avoid or reduce the use of corticosteroids in the management of patients with UC.

FACTORS AFFECTING EFFICACY OF LEUKOCYTAPHERESIS

In a number of studies^[23,24], factors affecting the efficacy of leukocytapheresis were identified. We conducted a prospective study to identify factors affecting clinical and endoscopic efficacies of Adacolumn leukocytapheresis in patients with active UC^[23]. In the multivariate analysis, the dose of prednisolone administered at entry and the cumulative dose of prednisolone administered before entry were significant independent factors for both clinical and endoscopic remission, and negatively impacted the efficacy of leukocytapheresis. It appears that steroid-naïve patients and patients on low dose steroid and short duration of exposure respond to leukocytapheresis. Suzuki *et al*^[24] searched for predictors of clinical response to Adacolumn leukocytapheresis. First UC episode and short disease duration appeared to be good predictors of response to leukocytapheresis. From these data, leukocytapheresis may be a promising candidate therapy for steroid-naïve patients with active UC. Furthermore, leukocytapheresis can be an effective first-line treatment in

Table 1 Leukocytapheresis for steroid-naïve patients with active ulcerative colitis

Ref.	Patients (n)	Leukocytapheresis (sessions/wk)	Remission ¹ rate (%)

¹Remission was defined as a clinical activity index (CAI) decrease to 4 or less and mucosal vascular patterns became at least partly visible in the studies by Hanai *et al*^[14], Suzuki *et al*^[24], and Nishioka *et al*^[26], a CAI decrease to 4 or less in the study by Tanaka *et al*^[25], and a CAI decrease to less than 4 in the study by Umehara *et al*^[27].

patients with active UC.

LEUKOCYTAPHERESIS FOR STEROID-NAÏVE UC

Leukocytapheresis has been mainly used for patients with steroid-dependent or steroid-refractory moderate-to-severe UC. About half of patients with steroid-dependent or steroid-refractory UC achieve clinical remission during a course of leukocytapheresis therapy^[20-22]. So far, five small-scale observational studies^[14,15,25-27] have evaluated the efficacy and safety of leukocytapheresis for steroid-naïve patients with active UC. Of these five studies, one study^[14] also included steroid-refractory patients, and one study^[25] steroid-dependent patients. Another study^[26] compared the outcomes of steroid-naïve patients treated with leukocytapheresis and corticosteroid therapy.

A brief summary of the five studies is presented in Table 1. In the short-term, the majority of patients achieved clinical improvement. The remission rate immediately after leukocytapheresis therapy ranged from 33% to 88%^[14,15,25-27]. Quantitative pooling of data was not feasible due to the diversity of interventions and outcome measures among the studies. In a prospective study by Hanai *et al*^[14], 81% of steroid-refractory and 88% of steroid-naïve patients achieved clinical remission one week after the last apheresis session. At 12 mo, 79% of patients had maintained their remission. In a prospective study by Suzuki *et al*^[15], 85% of patients achieved clinical remission during a course of leukocytapheresis therapy. At eight months, 60% of patients had maintained their remission. In the study by Tanaka *et al*^[25], the response rate was 85% in steroid-naïve patients and 58% in steroid-dependent patients. On average, remission was sustained with 5-aminosalicylic acid (5-ASA) for 7.8 mo in the responders. This is the first report showing a striking differ-

ence in clinical response to Adacolumn leukocytapheresis between steroid-naïve and steroid-dependent patients. In a controlled study by Nishioka *et al*^[26], 29 steroid-naïve patients were selected to be treated with Cellsorba leukocytapheresis ($n = 9$) or steroids ($n = 20$). In the steroid group, patients with moderately active disease received 0.5 mg/kg/d of prednisolone and those with severe disease 1.0 mg/kg/d. Eight patients (89%) in the apheresis group and 16 (80%) in the steroid group showed clinical improvement, and three (33%) in the apheresis group and seven (35%) in the steroid group achieved clinical remission. Three major adverse effects were observed in the steroid group, but none were observed in the apheresis group. The efficacy and safety of leukocytapheresis were equivalent, and in terms of severe adverse effects, superior to those of steroid therapy. In the study by Umehara *et al*^[27], 18 steroid-naïve patients with moderately active UC received weekly leukocytapheresis therapy with Cellsorba for five consecutive week. The remission rates at 8 and 48 wk after the last apheresis session were 61% and 28%, respectively. At 48 wk after achieving remission, the relapse rate was 55%, and the duration to relapse was 8.7 mo. In all studies^[14,15,25-27], leukocytapheresis was well tolerated, and no severe side effects were observed.

EFFICACY OF LEUKOCYTAPHERESIS WITHOUT CONCOMITANT STEROID THERAPY

In patients with moderately to severely active UC who failed to respond to optimal doses of 5-ASA compounds, systemic corticosteroids should be used. A few studies^[17,28] evaluated the efficacy and safety of leukocytapheresis without concomitant steroid therapy for patients who failed to respond to 5-ASA compounds. In our prospective study^[17], 30 consecutive patients with active distal UC were treated with weekly Adacolumn leukocytapheresis (a total of five sessions). During treatment, corticosteroid was not given. The median disease activity index score significantly decreased from six to two. Clinical remission was achieved in 21 patients (70%) after the last apheresis session. No serious side effects were observed. Ashida *et al*^[28] conducted a multicenter study to investigate the efficacy of leukocytapheresis without concomitant steroid therapy in patients with active UC. Twenty patients were treated with Cellsorba leukocytapheresis (twice a week for three weeks). The Litchner's clinical activity index score significantly decreased from 11.7 to 6.6 after the treatment. Of the 20 patients, 15 (75%) responded, and 7 (35%) achieved complete remission. No serious adverse reactions were observed.

In an RCT by Bresci *et al*^[29], 80 patients with active UC were randomly divided into two treatment groups: patients in the apheresis group received a five-session (one session per week) treatment with Adacolumn leukocytapheresis, and those in the steroid group were treated with methylprednisolone. Concomitant therapy with oral

5-ASA (2.4 g/d) was maintained in both groups. Patients who achieved remission were clinically and endoscopically followed for 12 mo after the end of leukocytapheresis or methylprednisolone therapy. Remission was achieved in 73% of patients in the apheresis group *vs* 50% in the steroid group. Leukocytapheresis was superior to methylprednisolone for the treatment of active UC, even though no statistically significant difference was observed. After a 12-mo follow up, a sustained remission was recorded in 40% of patients in the apheresis group *vs* 25% in the steroid group. Patients who had obtained remission after a course of leukocytapheresis showed fewer relapses during the follow up compared to those treated with methylprednisolone. During leukocytapheresis, only a transient mild headache was recorded in 10% of patients, whereas side effects were observed in 50% of those treated with methylprednisolone. The incidence of side effects in the apheresis group was significantly lower than that in the steroid group. Leukocytapheresis therapy seems able to maintain the condition of remission for a longer time after a flare.

STEROID-SPARING EFFECTS OF LEUKOCYTAPHERESIS

Leukocytapheresis could be an alternative treatment for steroid-dependent UC. A number of clinical trials^[30-34] evaluated the steroid-sparing effects of leukocytapheresis in patients with UC. Quantitative pooling of data was not feasible due to the diversity of interventions and outcome measures among the studies.

In an RCT by Hanai *et al*^[30], 69 patients with steroid-dependent UC were assigned to receive Adacolumn leukocytapheresis in addition to standard drug therapy (apheresis group, *n* = 46) or prednisolone (steroid group, *n* = 23). At week 12, 83% of patients in the apheresis group achieved remission *vs* 65% in the steroid group. During the 12 wk of treatment, the cumulative amount of prednisolone received per patient was significantly lower in the apheresis group than in the steroid group (1157 mg *vs* 1938 mg). Adacolumn leukocytapheresis therapy appeared to be an effective adjunct to standard drug therapy of moderately severe UC by promoting remission and sparing steroids.

The therapeutic benefit of leukocytapheresis in the maintenance of remission was additionally elucidated in a randomized pilot trial by Emmrich *et al*^[31]. Twenty patients with chronic active UC were treated weekly with Cellsorba leukocytapheresis for five weeks. A significant decrease in the activity index was observed. Fourteen patients achieved clinical remission, and mucosal healing was observed endoscopically in six patients. After randomization these 14 patients in remission entered a second period of either monthly leukocytapheresis (*n* = 8) or no further treatment (*n* = 6). In both groups, steroids were tapered down. After six months, five patients (63%) in the apheresis group remained in remission *vs* one patient (17%) in the control group. These results sug-

gest leukocytapheresis offers a therapeutic option in the induction and the maintenance of remission in chronic active UC.

In a prospective study by Cabriada *et al*^[32], 18 patients with steroid-dependent UC were treated with leukocytapheresis plus steroids after failure or intolerance to immunomodulators. Clinical and endoscopic examinations were conducted at one month after the last apheresis session and at 12 mo. The clinical, endoscopic remission and the relapse during the one-year follow-up were evaluated. Clinical remission was achieved in 10 patients (55%) after the treatment. At one year, sustained steroid-free clinical remission was observed in nine patients (50%). A tendency for sustained remission at one year was observed when initial endoscopic remission was achieved. These results suggest that initial remission can be maintained at one year in half of the patients without the need for additional steroids. Complete remission and endoscopic mucosal healing is proposed as an objective for achieving a lasting response.

Cabriada *et al*^[33] conducted a cohort study using a nationwide database in order to investigate short-term and long-term efficacies of leukocytapheresis for the management of steroid-dependent UC. One hundred and forty-two patients with steroid-dependent UC were treated with Adacolumn leukocytapheresis therapy. At one month after the last scheduled apheresis session, 68% of patients achieved clinical response, including 37% with steroid-free clinical remission. In the long-term, at six and 12 mo, 41% and 36% of patients were in clinical remission, respectively. Although this large-scale observational trial is uncontrolled, it clearly shows that Adacolumn leukocytapheresis allows long-term steroid-free clinical remission in up to one third of steroid-dependent UC patients.

Our recent study^[34] was conducted to determine if the introduction of Adacolumn leukocytapheresis at an early stage reduces corticosteroid administration and steroid dependency in the long-term. Twenty patients were treated with Adacolumn leukocytapheresis, with or without corticosteroids (apheresis group), and 20 patients were given corticosteroids without leukocytapheresis (steroid group). During a five-year follow-up period, five patients in the apheresis group did not require corticosteroids. The mean dose of steroid administered during the five years was significantly lower in the apheresis group than in the steroid group (2141 mg *vs* 5443 mg). Furthermore, the incidence of steroid-dependence was significantly lower in the apheresis group at the end of the study (5% *vs* 35%). In patients with first UC episode, Adacolumn leukocytapheresis therapy at an early stage significantly reduces steroid administration and steroid-dependency in the long-term.

TREATMENT COST OF LEUKOCYTAPHERESIS

When selecting a treatment option, the cost must be an

important factor. The cost of leukocytapheresis therapy (approximately \$ 1700 for one session with Adacolumn) is much higher as compared with corticosteroids. However, if leukocytapheresis can spare patients from corticosteroids, and reduce the incidence of steroid-dependency, hospitalization and surgery, it should be cost-effective.

CONCLUSION

Although the evidence level is not striking, the available data suggest that leukocytapheresis can avoid or reduce the use of corticosteroids in the management of UC. Large, well-designed clinical trials are necessary to more accurately evaluate the steroid-sparing effects of leukocytapheresis in the management of UC.

Abstract

Non-alcoholic fatty liver disease (NAFLD) has been recognized as a major health burden. It is the most important cause of chronic liver disease and a major independent cardiovascular risk factor. Lacking a definite treatment for NAFLD, a specific diet and an increase in physical activity represent the most commonly used therapeutic approaches. In this review, major literature data about the use of omega-3 polyunsaturated fatty acids (n-3 PUFAs) as a potential treatment of NAFLD have been described. n-3 PUFAs, besides having a beneficial impact on most of the cardio-metabolic risk factors (hypertension, hyperlipidemia, endothelial dysfunction and atherosclerosis) by regulating gene transcription factors

[i.e., peroxisome proliferator-activated receptor (PPAR) α , PPAR γ , sterol regulatory element-binding protein-1, carbohydrate responsive element-binding protein], impacts both lipid metabolism and on insulin sensitivity. In addition to an enhancement of hepatic beta oxidation and a decrease of the endogenous lipid production, n-3 PUFAs are able to determine a significant reduction of the expression of pro-inflammatory molecules (tumor necrosis factor- α and interleukin-6) and of oxygen reactive species. Further strengthening the results of the *in vitro* studies, both animal models and human intervention trials, showed a beneficial effect of n-3 PUFAs on the severity of NAFLD as expressed by laboratory parameters and imaging measurements. Despite available results provided encouraging data about the efficacy of n-3 PUFAs as a treatment of NAFLD in humans, well-designed randomized controlled trials of adequate size and duration, with histological endpoints, are needed to assess the long-term safety and efficacy of PUFA, as well as other therapies, for the treatment of NAFLD and non-alcoholic steatohepatitis patients. It is worthwhile to consider that n-3 PUFAs cannot be synthesized by the human body and must be derived from exogenous sources (fish oil, flaxseeds, olive oil) which are typical foods of the Mediterranean diet, known for its beneficial effects in preventing obesity, diabetes and, in turn, cardiovascular events. According to these data, it is important to consider that most of the beneficial effects of n-3 PUFAs can also be obtained by an equilibrate nutrition program.

INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) is defined as pathological fat deposition in the liver cells of patients with minimal or no alcohol intake and without any other known cause. It encompasses a wide spectrum of liver damage stages ranging from isolated hepatic steatosis or simple fatty liver (FL), to non-alcoholic steatohepatitis (NASH) or even cryptogenic cirrhosis and hepatocellular carcinoma. In more detail, about 10%-29% of individuals with NASH develop cirrhosis within 10 years^[1], and 4%-27% of NASH-induced cirrhosis can ultimately progress to hepatocellular carcinoma^[2]. NAFLD affects 10%-35% of the adult population^[3] and, because of the increasing incidence of obesity and of type 2 diabetes mellitus, it has been recognized as a major health burden and as the most important cause of chronic liver disease^[4]. Overall, NAFLD is considered as the hepatic expression of metabolic syndrome^[5,6] and it is associated with an increased risk of cardiovascular disease^[7], along with venous^[8] and arterial thrombotic events^[9]. On the other hand, the impact of NAFLD on overall cardiovascular mortality is still widely challenged^[7]. Nowadays, there is no definite treatment for NAFLD and NASH, as their physiopathology and natural history are not completely understood. Indeed, treatment is based on general approaches such as diet and physical activity^[10]. The aim of this review is to describe major literature data about clinical and pre-clinical studies evaluating the effects of omega-3 polyunsaturated fatty acid (n-3 PUFAs) supplementation on NAFLD.

MOLECULAR MECHANISMS

The pathophysiology of NAFLD is multifactorial and not completely understood. According to the "two-hit" hypothesis^[11], insulin resistance and visceral obesity promote the synthesis of fatty acids from glucose and inhibit β -oxidation of fatty acids. The excess of fatty acids leads to triglyceride synthesis and to their intrahepatic accumulation. Overall, these changes lead to FL (first hit), which is a relatively benign clinical condition^[12].

The increased levels of fatty acids and triglycerides are associated with the production of free radicals^[13,14], which, by causing lipid peroxidation and activating pro-inflammatory and fibrogenic cytokines^[15], lead to NASH establishment (second hit)^[16].

In particular, oxidative stress could be considered the

result of an imbalance between pro-oxidant and anti-oxidant processes. In fact, the excess of intra-hepatic triglyceride induces high rates of mitochondrial β -oxidation, with the consequent production of reactive oxygen species (ROS), such as superoxide radical ($O_2^{\cdot -}$) and hydrogen peroxide (H_2O_2). These reactive molecules, by inactivating the apoptotic caspase system, determine necrotic cell death^[17]. Moreover, the increase in pro-oxidant activity is associated with a decrease in the antioxidant potential (superoxide dismutase activity and glutathione content)^[13,18].

Following such an increase in pro-oxidant activity^[12], the progression from NAFLD to NASH is mediated by the activation of different transcription factors, such as sterol regulatory element binding protein 1c (SREBP-1c), peroxisome proliferator-activated receptor γ (PPAR γ) and carbohydrate responsive element-binding protein (ChREBP), which activate the expression of a series of genes essential for lipogenesis^[19-23].

Other mechanisms are involved in the pathogenesis of NASH, such as increased secretion by the adipose tissue of proinflammatory and prothrombotic adipocytokines [interleukin 6 (IL-6) and tumor necrosis factor α (TNF- α)] and the reduced production of adiponectin, a potent anti-inflammatory, insulin-sensitizing adipocytokine^[24,25]. Inflammation is a component of the wound healing process that leads to the deposition of extracellular matrix and fibrosis in the liver. There is much evidence supporting a central role for pro-inflammatory cytokines, particularly TNF- α and IL-6, in the development of NASH. In fact, increased cytokines levels are found in the liver and blood of patients with NASH^[26], and their inhibition improved NAFLD in animal^[27] and human models^[28].

Considering their beneficial impact on cardiometabolic clusters (hypertension, hyperlipidemia, endothelial dysfunction and atherosclerosis)^[29], n-3 PUFAs are emerging as a potential treatment of liver steatosis. They cannot be synthesized by the human body and, thus, must be derived from exogenous sources (fish oil, flax seeds, *etc.*).

n-3 PUFAs, especially eicosapentaenoic acid (C20:5n3, EPA) and docosahexaenoic acid (C22:6n3, DHA), by regulating gene transcription factors (i.e., PPAR α , PPAR γ , SREBP-1, ChREBP), can control key pathways involved in hepatic lipid metabolism^[30,31]. In more detail, n-3 PUFAs are potent activators of PPAR α , which up-regulates several genes involved in the stimulation of fatty acid oxidation^[32-35] and down-regulates pro-inflammatory genes, such as TNF- α and IL-6^[36]. Moreover, n-3 PUFAs activate PPAR γ , resulting in increased fat oxidation and improved insulin sensitivity^[37].

Besides enhancing hepatic beta oxidation, n-3 PUFAs can also decrease endogenous lipid production by inhibiting the expression and processing of SREBP-1, which, in response to increased glucose and insulin levels, stimulates the transcription of several lipogenic and glycolytic genes^[38-42]. Moreover n-3 PUFAs can inhibit hepatic glycolysis and lipogenesis and suppress the ac-

tivity of ChREBP, another regulator of glycolytic, and lipogenic genes, such as *L*-pyruvate kinase and fatty acid synthase^[43].

Forthcoming studies show a growing amount of other genes are involved in NAFLD pathophysiology and, in turn, in the effect of n-3 PUFAs^[44,45].

ANIMAL MODELS

A series of animal models have been used to study NAFLD. Most of them found that fat intake and obesity are strictly related to fatty liver development. In more detail, the Western lifestyle, with a high fat content diet and sedentary behavior, was found to lead to liver damage in animals^[46,47]. Further models showed that the “cafeteria diet” (a feeding regimen similar to fast food) is strictly associated with NAFLD development and subsequent hepatic necro-inflammatory changes in mice^[37]. By evaluating the mechanisms by which diet impacts NAFLD development, an increase in dietary cholesterol, sucrose or fructose was found to induce hepatic lipogenesis in mice through the up-regulation of SREBP-1 expression, which stimulates the transcription of a series of lipogenic genes^[48-51].

After proving the strict relation between diet and NAFLD, the effects of n-3 PUFAs were tested in a series of animal models.

The first interesting data were that n-3 PUFAs depletion was found to promote steatosis and insulin resistance in rodents. Thus, rats fed with a low n-3 PUFAs diet rapidly developed NAFLD^[52,53]. In a recent study^[54], a drastic drop in n-3 PUFAs was induced by feeding C57Bl/6J mice for 3 mo with a n-3 PUFAs depleted diet. The animals showed insulin resistance and hepatic steatosis, which was associated with a decrease in fatty acid oxidation. Compared to the animals following the control diet, which only differed in the n-3 PUFAs content, analysis of the liver tissue revealed higher expression of all enzymes involved in lipogenesis, as well as increased expression and activation of SREBP-1. On the contrary, supplementing the diet with n-3 PUFAs prevented or reversed hepatic steatosis in animals. Recently, it has been reported that rats fed with a high fat diet combined with n-3 PUFAs supplementation were protected against severe NAFLD development. In fact, significantly increased lipid peroxidation was seen in the group fed with the same diet without n-3 PUFAs supplementation^[55].

In a further experimental model to confirm the protective effect from NAFLD development in mice^[56], n-3 PUFA administration was also found to reverse already established hepatic steatosis in leptin deficient obese mice^[57].

Marsman *et al.*^[58] induced hepatic steatosis by a 3 wk methionine/choline deficient diet in rats, and then administered n-3 PUFAs, standard lipid solution, or NaCl for 2 wk. Compared with control animals receiving a standard diet, n-3 PUFAs treated animals showed histological evidence of mild macrovesicular steatosis. On the

contrary, severe macrovesicular steatosis was found in both standard lipid solution and saline diet groups. In the same study, liver ischemia/reperfusion injury was evaluated by clamping vessels for 40 min. At 6 and 24 h from reperfusion, n-3 PUFA treated rats showed lower alanine aminotransferase (ALT) serum levels, lower hepatic TNF- α levels and a higher anti-oxidative capacity compared with both standard lipid solution and saline diet groups. Overall, these findings suggest that n-3 PUFA treatment both reduces hepatic steatosis and attenuates hepatic ischemia/reperfusion injury in rats.

Other experimental studies analyzed further mechanisms by which n-3 PUFAs could impact on NAFLD. In particular, a diet enriched in n-3 PUFAs was shown to improve insulin sensitivity, and reduce intrahepatic triglyceride content and steatohepatitis, in both mice^[56,59] and rats^[60,61] with fatty liver. Sekiya *et al.*^[59] exposed ob/ob mice to a dietary supplementation of n-3 PUFAs, obtaining a down-regulation of the *SREBP-1* gene and a reduction of hepatic lipogenesis, with an improvement of insulin-dependent metabolism (reduction of glucose, insulin and free fatty acid serum levels).

Similarly, Levy *et al.*^[61] found that the “Quantitative Insulin Sensitivity Check Index” was higher in fish oil fed Fischer Rats than in the control animals. A possible explanation for these results comes from a murine model, in which n-3 PUFAs supplementation in obese mice induces an up-regulation of the genes involved in insulin sensitivity (PPAR γ), glucose transport (GLUT-2/GLUT-4), and insulin receptor signaling (IRS-1/IRS-2)^[37].

Apart from the effects on metabolic homeostasis, in experimental NAFLD murine models, by influencing the production of eicosanoids, prostaglandins, and of leukotrienes, n-3 PUFAs also showed anti-inflammatory properties^[62].

Overall, these results suggest that n-3 PUFAs improve insulin sensitivity and reduce markers of inflammation, all major events in NAFLD development^[37,62].

Moreover, n-3 PUFAs supplementation improves hepatic steatosis in obese animals by modifying the genetic expression of key enzymes^[63]. It has been shown that n-3 PUFAs are the natural ligands of PPAR α , which modulates lipid metabolism in hepatocytes^[64]. In fact, by inducing the expression of proteins with peroxisome proliferator response elements in their promoting region^[64], PPAR α regulates fatty acid binding and their export in very low density lipoprotein^[65,66]. In PPAR α (-/-) knockout animals, hepatic steatosis, which was minimal under normal conditions, drastically increased after a fasting period. The absence of PPAR α likely impaired mitochondrial β -oxidation in the liver during fasting, leading to hepatic steatosis development^[65]. Furthermore, there is evidence from other studies that n-3 PUFAs reduce hepatic ROS levels^[67]. n-3 PUFAs seem to improve the tolerance to oxidative stress, IRS-2 activity in the liver, brain and uterus of rats^[68]. Consequently, they may have a potential protective role against ROS-induced oxidative cellular damage in rat organs, especially in the liver. Re-

cently, using the methionine/choline deficient model of steatohepatitis, the effect of EPA, one of the most important long chain PUFAs, on hepatic fibrosis and ROS production was investigated in rat livers. For the study in question, steatosis was induced in 20 Wistar rats by a 20 wk methionine/choline deficient diet, followed by oral administration of EPA in 10/20 rats from week 12; a time at which hepatic fibrosis was already established. Control animals instead received a methionine/choline sufficient diet. At histology evaluation, EPA treatment was found to suppress hepatic fibrosis in liver sections, with repressed macronodular formation and decreased hepatic triglycerides content. EPA also suppressed the increase of hepatic fibrogenic factors, such as α -smooth muscle actin, TGF- β 1, procollagen, and connective tissue growth factor. The attenuation of hepatic fibrosis by EPA was significantly related to hepatic ROS levels. EPA also suppressed increases in hepatic ROS levels and reduced serum oxidative markers, such as 8-isoprostane and ferritin^[69].

All the aforementioned animal models show that omega-3 depletion can promote steatosis and insulin resistance. On the other hand, n-3 PUFAs supplementation, by inducing SREBP-1 up-regulation and lipogenic genes expression reduction, improving glycemic control, insulin levels and insulin sensitivity, reducing the oxidative stress, and exerting an anti-inflammatory effect, is able to prevent, or even at reverse, hepatic steatosis.

INTERVENTIONAL STUDIES

Although several clinical trials have been conducted, due to a wide variability in treatment duration, and the different n-3 PUFAs doses and preparations used, the efficacy of n-3 PUFAs in the treatment of NAFLD in humans has not yet wholly defined. The first clinical trial (Table 1) providing encouraging evidence about the efficacy of n-3 PUFAs in the treatment of NAFLD was performed by Capanni *et al*^[70]. They evaluated the efficacy of prolonged n-3 PUFAs supplementation in 56 patients with an ultrasonographic (US) diagnosis of NAFLD. 1 g/d of n-3 PUFAs was administered to 42 subjects for 12 mo. The 14 subjects refusing the same treatment served as controls. The primary outcome was the US appearance of the liver, including a quantitative measurement of fat storage on the basis of the Doppler perfusion index (DPI)^[71]. At the end of the treatment, subjects showed a significant ($P = 0.0001$) improvement of NAFLD compared with controls. A concomitant increase of DPI, proof of a hemodynamic improvement, was also reported in the treatment group, but not in the control group. In addition, n-3 PUFA supplementation was associated with a significant reduction of liver enzymes ($P = 0.003$), fasting glucose ($P = 0.02$) and triglyceride ($P = 0.02$) levels. However, it should be noted that this prospective study has some limitations, such as the absence of blindness and randomization. In a subsequent study^[72], the effectiveness of n-3 PUFAs supplementation was demon-

started on-top of a validated diet (Table 1). In this trial, 40 patients with NAFLD randomly received an American Heart Association (AHA) recommended diet^[73] plus n-3 PUFAs 2 g/d, or only the AHA diet, for 6 mo. Primary outcomes included: changes in fatty liver severity assessed by abdominal US, and liver ALT and triglyceride levels. Interestingly, inflammatory and metabolic markers such as TNF- α serum levels and insulin resistance assessed by homeostatic model assessment (HOMA) were also evaluated in this study. At the end of the treatment, patients who received diet plus n-3 PUFA supplementation had a significant reduction in ALT ($P < 0.01$), triglycerides ($P < 0.01$), TNF- α ($P < 0.05$), and HOMA ($P < 0.05$) levels. In addition, 33.4% of them showed a complete fatty liver regression. On the contrary, none of the patients receiving the diet alone showed a complete regression of the fatty liver. Indeed, this trial showed some design weaknesses, such as the lack of placebo and the lack of blindness of both participants and investigators. At variance with the latter reported studies, enrolling relatively few patients, Zhu *et al*^[74] performed a randomized clinical trial with a large sample size (Table 1). In 144 patients with NAFLD and mixed hyperlipidemia, the efficacy of n-3 PUFA from seal oils was evaluated. Patients were randomly assigned to two groups of treatment: Group A received an AHA recommended diet^[73] and 2 g of seal oils (rich in EPA, DHA, and DPA) \times 3/daily, while Group B received the recommended diet and 2 g placebo \times 3/daily. The treatment duration was 24 wk. Primary endpoints were changes in ALT and serum lipid levels, symptom scores (liver discomfort or pain, weakness, abdominal distention, and nausea) and modifications in fatty liver assessed by US. At the end of the treatment period, total symptom scores, ALT and triglycerides levels decreased more significantly ($P < 0.01$) in Group A than in Group B. At the abdominal US, a normal liver echo pattern and a significant liver steatosis improvement compared with the baseline was found in 19.7% and 53.03% of patients in Group A, respectively. On the other hand, in Group B only 7.35% of subjects achieved complete regression ($P = 0.04$) and 35.29% had some degree of liver steatosis improvement ($P = 0.04$), with no change being observed in the remaining 64.71% of patients in the group. It is noteworthy that some patients only on the diet ameliorated. Although only having a small sample size of the population, the results of a study performed by Sofi *et al*^[75] are of particular interest. It aimed to assess the efficacy of the administration of olive oil (rich in PUFAs) in patients with NAFLD. As many as 6 subjects received 5 mL/d of olive oil for 1 year, while 5 were selected as controls (Table 1). Outcome measurements were serum liver biochemistry, serum lipids, adiponectin levels, and the appearance of the liver with US and Doppler investigation. In this study, at variance with all the others, n-3 PUFAs were administered in olive oil instead of in capsules. Thus, this could be considered a “nutritional” rather than a “therapeutic” study. Since olive oil is one of the staples of the Mediterranean diet, it is interesting to note that, at the

Table 1 Summary of trials design and results

Ref.	Study design	Intervention	Population	Outcome measurements	Results	Comments
Capanni <i>et al</i> ^[70]	Open-label	Oral administration of n-3 PUFA, 1-g capsule/d for 12 mo	56 patients with NAFLD (42 subjects receiving therapy; 14 controls)	AST, ALT, GGT, TG, FG, n-6/n-3, liver echo texture by US and liver perfusion by DPI	↓AST ($P = 0.003$) and ALT ($P = 0.002$), ↓GGT ($P = 0.03$), ↓TG ($P = 0.02$) and FG ($P = 0.02$) in comparison with controls. Circulating arachidonate and n6:n3 ratio was reduced ($P = 0.0002$, and $P = 0.0001$ respectively) in treated patients. Improvement of liver echo texture ($P = 0.0001$), and increase of DPI ($P = 0.001$)	Limits of this study are the absence of blinding and randomization, and the use for comparison of a self-selected small group consisting of those patients who had been declined entry to the treatment arm
Spadaro <i>et al</i> ^[72]	Randomized; open-label	AHA diet + 2 g/d n-3 PUFA (Group DP) <i>vs</i> AHA diet (Group D) for 6 mo	40 patients with NAFLD (Group DP, $n = 20$; Group D, $n = 20$)	Liver fat assessed by abdominal US, ALT, AST, TNF- α serum levels, and HOMA	In DP group: ↓ALT ($P < 0.01$), TG ($P < 0.01$), serum TNF- α ($P < 0.05$) and HOMA (IR) ($P < 0.05$). Complete fatty liver regression in 33.4% of patients, and an overall reduction in 50%; In the D group: no significant modification of laboratory tests; no patient achieved complete regression of fatty liver, whereas some amount of reduction occurred in 27.7% of patients Group A <i>vs</i> Group B showed ↓ of total symptoms score, ALT, TG, LDL ($P < 0.05$); complete fatty liver regression in 19.7% <i>vs</i> 7.35% ($P = 0.004$); In both groups there was a tendency in improvement in AST, GGT, TCHO and HDL levels ($P < 0.05$)	Limits of the study are lack of placebo, and the non blinding of participants and investigators
Zhu <i>et al</i> ^[74]	Randomized	AHA diet + 2 g/d n-3 PUFA from seal oil (Group A) <i>vs</i> AHA diet + 2g of placebo (Group B) for 6 mo	144 patients with NAFLD and hyperlipidemia (Group A = 72; Group B = 72)	Liver fat assessed by symptom scores, ALT and serum lipid levels after 8, 12, 16, and 24 wk; fatty liver assessed by US at weeks 12 and 24 after treatment	↓ALT, AST, TG, TCHO, HOMA-IR, plasma thioredoxin; change in histological grade: steatosis: 2.4 (SD 0.5) <i>vs</i> 1.7 (SD 0.5); fibrosis: 1.7 (SD 1.1) <i>vs</i> 0.7 (SD 0.5); lobular inflammation: 2.1 (SD 0.7) <i>vs</i> 1.1 (SD 0.7); ballooning: 1.6 (SD 0.5) <i>vs</i> 0.9 (SD 0.4); NAS: 6.1 (SD 1.3) <i>vs</i> 3.7 (SD 1.4); Hepatic steatosis grade on the US changed from 2.1 ± 0.9 at baseline to 1.6 ± 1.1 after treatment ($P = 0.004$)	Limits of the study are the absence of a control group and small sample size
Tanaka <i>et al</i> ^[77]	Open label	EPA 2.7 g/d for 12 mo	23 patients with biopsy proven NAFLD	ALT, FFA, plasma soluble TNF receptor 1 and 2 levels, and serum ferritin and thioredoxin levels, body weight, blood glucose, insulin, and adiponectin concentrations; fatty liver infiltration assessed by histology	↓ALT, AST, TG, TCHO, HOMA-IR, plasma thioredoxin; change in histological grade: steatosis: 2.4 (SD 0.5) <i>vs</i> 1.7 (SD 0.5); fibrosis: 1.7 (SD 1.1) <i>vs</i> 0.7 (SD 0.5); lobular inflammation: 2.1 (SD 0.7) <i>vs</i> 1.1 (SD 0.7); ballooning: 1.6 (SD 0.5) <i>vs</i> 0.9 (SD 0.4); NAS: 6.1 (SD 1.3) <i>vs</i> 3.7 (SD 1.4); Hepatic steatosis grade on the US changed from 2.1 ± 0.9 at baseline to 1.6 ± 1.1 after treatment ($P = 0.004$)	Limits of the study are the absence of a control group and small sample size
Sofi <i>et al</i> ^[75]	Randomized	Dietary recommendation + 6.5 mL/d of olive oil enriched with n-3 PUFA (0.83 g n-3 PUFA, of which 0.47 g EPA and 0.24 g DHA) for 12 mo <i>vs</i> dietary recommendation alone	11 patients with NAFLD assessed by US (intervention group, $n = 6$; control group, $n = 5$)	Liver fat content assessed by B-mode US and DPI; liver enzymes, TG and adiponectin levels	Intervention group <i>vs</i> controls showed a ↓ of AST ($P = 0.02$), ALT ($P = 0.03$), GGT ($P = 0.03$), TG ($P = 0.04$) levels; ↑ of HDL ($P = 0.03$), adiponectin ($P = 0.04$). There was a significant ($P = 0.02$) improvement of DPI in the intervention group, while no change was observed in the control group. Improvement of liver steatosis on US in the intervention group (% of patients at T0 and T12): absent (from 0% to 16.7%); mild (from 16.7% to 50%); moderate (from 33% to 0%); severe (from 50% to 33%)	

Nobili <i>et al</i> ^[78]	Randomized	DHA (250 and 500 mg/d) <i>vs</i> placebo for 6 mo	60 children with biopsy-proven NAFLD randomly assigned to receive DHA 250 mg/d (<i>n</i> = 20), DHA 500 mg/d (<i>n</i> = 20) or placebo (<i>n</i> = 20)	Primary: change in liver fat content as detected by US; secondary: changes in ISI, ALT, TG and BMI	DHA 250 mg <i>vs</i> placebo: odds of more severe <i>vs</i> less severe steatosis (OR = 0.01, robust 95% CI: 0.002 to 0.11, <i>P</i> < 0.001); ↑ of ISI (<i>P</i> < 0.01), ↓TG (<i>P</i> < 0.05); ALT and SDS of BMI; DHA 500 mg <i>vs</i> placebo: (OR = 0.04, 0.002 to 0.46; <i>P</i> = 0.01); ↑ of ISI (<i>P</i> < 0.01), ↓TG (<i>P</i> < 0.05); ALT and SDS of BMI; DHA 250 mg <i>vs</i> DHA 200 mg: NS	
Vega <i>et al</i> ^[79]	Open label	9 g/d of fish oil for 8 wk	22 patients with previous elevated liver fat on MRS (17 patients completed the trial)	Liver fat content assessed by B-mode US and DPI; liver enzymes, TG and adiponectin levels	↓ of plasma triglyceride level by 46% (<i>P</i> < 0.03), VLDL + IDL by 21% (<i>P</i> < 0.03), ApoB by 15% (<i>P</i> < 0.03). Liver fat content 7.9% pre-treatment; 8.0% after PUFA (NS)	Causes of liver disease other than NAFLD were not excluded and alcohol intake was not reported. It is unclear whether study participants received any other interventions such as diet or lifestyle advice

NAFLD: Non-alcoholic fatty liver disease; AST: Aspartate transaminase; ALT: Alanine transaminase; GGT: γ -glutamyl transpeptidase; TG: Triglycerides; FG: Fasting glucose; US: Ultrasonographic; DPI: Doppler perfusion index; AHA: American Heart Association; PUFA: Polyunsaturated fatty acid; TNF: Tumor necrosis factor; HOMA: Homeostatic model assessment; IR: Insulin resistance index; TCHO: Total cholesterol; HDL: High-density lipoprotein; MRS: Magnetic resonance spectroscopy; VLDL: Very low density lipoprotein; ISI: Insulin sensitivity index; EPA: Eicosapentaenoic acid; DHA: Docosahexaenoic acid; DPI: Doppler perfusion index; BMI: Body mass index; SDS: Standard deviation score; NS: Not significant.

end of treatment, patients showed a significant (*P* < 0.05) improvement in liver echo-texture and DPI, a significant improvement of liver enzymes, and triglycerides (*P* = 0.04) and adiponectin levels (*P* = 0.04).

In the aforementioned studies, the lack of a liver biopsy for the diagnosis of NAFLD may hamper the relevance of their findings. However, in spite of its inherent operator-dependence, abdominal US analysis is currently thought to provide reliable, careful information about hepatic steatosis. This limits the need for liver biopsy for the diagnosis of NASH and to determine the severity of hepatic fibrosis^[76]. Moreover, despite its inherent limitations, US analysis has been validated against histopathological specimens, as well as other imaging methods, for the diagnosis of liver steatosis^[76]. In this regard, studies in which the effects of n-3 PUFAs on NAFLD are supported by histology or MRI findings have been also performed. Tanaka *et al*^[77] enrolled 23 patients with biopsy proven NASH. They received 2.7 g of EPA daily for 12 mo (Table 1). Outcome measurements were serum liver biochemistry, appearance on US, and liver histology (graded using the NAFLD activity score). All patients completed the trial and showed a significant improvement of laboratory markers of hepatic oxidative stress. The mean US steatosis degree improved significantly and, in 6 out of 7 patients who underwent repeated biopsy, steatosis, inflammation and fibrosis, resulted in significantly reduced levels. Although this was the first human study of n-3 PUFAs fatty acids to have histological data, which are the most valid outcome measurement, the absence of randomization, controls and blindness, along with the small sample size, do not allow us to draw

definitive conclusions. In another study^[78], in which the diagnosis of NAFLD was confirmed by biopsy, 60 children were randomly assigned to receive DHA 250 mg/d, DHA 500 mg/d or placebo (Table 1). The duration of treatment was 6 mo. The main outcome was the change in liver fat content as detected by US. After 6 mo, DHA supplementation was associated with lower odds of severe steatosis compared to a placebo. In addition, for the groups treated with DHA, where no effects on ALT values were found, there was an improvement of insulin sensitivity and triglycerides levels. Thus, this prospective study showed that, following this therapeutic regimen, both US and metabolic feature improvement occurred.

Therefore, Vega *et al*^[79] evaluated the efficacy of n-3 PUFAs on serum and hepatic triglycerides levels, the latter assessed by magnetic resonance spectroscopy (Table 1). Of the 22 patients enrolled, 17 completed the trial. They received a placebo for 4 wk, followed by an 8 wk treatment with 9 g/d of fish oil. Treatment with fish oil significantly reduced the levels of plasma triglycerides by 46% (*P* < 0.03), very low-density lipoprotein plus intermediate density lipoprotein cholesterol by 21% (*P* < 0.03), and total apolipoprotein B by 15% (*P* < 0.03). In contrast to the changes in plasma triglycerides, hepatic triglyceride content was not significantly reduced by fish oil treatment.

In conclusion, NAFLD may be considered the hepatic expression of metabolic syndrome^[5] which, in turn, predisposes to cardiovascular events. It is known that n-3 PUFAs have many beneficial effects on most of the metabolic syndrome features. In this regard, there is evidence suggesting that n-3 PUFAs are able to reduce

blood pressure^[80,81] and that they have favorable effects on plasma lipids levels^[82]. In addition, n-3 PUFAs also showed anti-platelet and anti-inflammatory properties which help to explain their cardio-protective effects^[29,82]. Most of the available clinical trials provide encouraging data about the efficacy of n-3 PUFAs as a treatment of NAFLD in humans^[9].

In keeping with this, in the era of poly-pills for coronary heart disease prevention, drugs with multifaceted mechanisms of action should be taken into serious consideration^[82]. On the other hand, it is worthwhile to consider that a significant amount of n-3 PUFA is contained in fish and in olive oil. All these are typical foods of the Mediterranean diet, which exhibits well known beneficial effects and is able to prevent obesity, diabetes and, in turn, cardiovascular events^[83]. For individuals eating low amounts of fish, a 500 mg/d EPA+DHA consumption is recommended in the absence of any type of cardiovascular disease, the suggested dosage being at least 800-1000 mg/d for those with coronary heart disease or congestive heart failure^[82].

According to these data, it is important to consider that most of the beneficial effects of n-3 PUFAs can also be obtained by an equilibrate nutrition program.

Well-designed randomized controlled trials of adequate size and duration, with histological endpoints, are needed to assess long-term safety and efficacy of PUFA, as well as other therapies for the treatment of NAFLD and NASH patients. Thus, while waiting for further data, current nutritional recommendations about daily intake should be strictly taken into consideration.

Abstract

Cytokines are indispensable signals of the mucosa-associated immune system for maintaining normal gut homeostasis. An imbalance of their profile in favour of inflammation initiation may lead to disease states, such as that is observed in inflammatory bowel diseases (IBD). Although Crohn's disease (CD) is often described as a prototype of T-helper 1-type diseases, and ulcerative colitis (UC) is traditionally viewed as a T-helper 2-mediated condition, the classic paradigm, which categorises cytokines into pro- and anti-inflammatory groups, has recently been changed. The inflammation regulatory pathways may not be mutually exclusive as individual cytokines can have diverse and even opposing functions in various clinical and immunological settings. None the less there are many common immunological responses in IBD that are mediated by cytokines. Although they regulate and influence the development, course and recurrence of the inflammatory process, the concrete pathogenic role of these small signaling molecules is sometimes not unambiguous in the subtypes of the disease. Our aim is to review the current information about pro- and anti-inflammatory effects of traditionally studied and recently discovered cytokines in the pathogenesis of UC and CD. The better

understanding of their production and functional activity may lead to the development of new therapeutic modalities.

INTRODUCTION

The balance of pro- and anti-inflammatory cytokines in the colonic mucosa is essential for normal gut homeostasis. A disturbance of the cytokine profile in favour of pro-inflammatory cytokine overproduction leads to disease states, such as that observed in inflammatory bowel diseases (IBD)^[1,2].

The concept that ulcerative colitis (UC) and Crohn's disease (CD) are two distinct forms of IBD has been changed recently. Instead, they are considered as a spectrum from mildly inflamed mucosa to severely active bowel inflammation with or without extraintestinal manifestations and different clinical behaviour.

CD is often described as a prototype of T-helper (Th) 1-mediated diseases because the primary inflamma-

tory mediators are the Th1 cytokines such as interleukin (IL)-12, interferon (IFN)- γ , and tumor necrosis factor (TNF)- α ^[3,4]. However, UC is usually viewed as a Th2-type condition because of the increased intestinal expression of the Th2-associated cytokine IL-5 and IL-13, although a clear association with IL-4, another definitive Th2 cytokine, has never been established^[3,4]. The role of pro-inflammatory cytokines such as IL-1 α , IL-1 β , IL-2, -6, -8, -12, -17, -23, IFN, or TNF in IBD is associated with the initiation and progression of UC and CD. Cytokines with anti-inflammatory effects, like IL-4, -10, and partly IL-13 also contribute to the pathogenesis of IBD, decreasing the inflammatory process by down-regulating pro-inflammatory cytokine production.

However, this classic paradigm has recently been changed. These pathways may not be mutually exclusive as individual cytokines can have diverse and even opposing functions in various clinical and immunological settings^[4].

Although many common immunological responses in IBD are mediated by cytokines, the concrete pathogenic role of these small peptide molecules is sometime not unambiguous in the subtypes of the disease. Therefore we aimed to review the current information about pro- and anti-inflammatory effects of traditionally studied and recently discovered cytokines in the pathogenesis of UC and CD. Controlling their expression, production and functional activity is an approach that may allow the development of more efficient and less harmful therapeutic strategies.

CYTOKINES WITH PRO-INFLAMMATORY EFFECTS IN ULCERATIVE COLITIS

The IL-1 family

The cytokines of the IL-1 family play a major role in several autoimmune inflammatory diseases, including IBD^[5]. IL-1 represents two structurally distinct forms: IL-1 α and IL-1 β . For both IL-1 α and - β , the most significant and relevant properties are the initiation of cyclooxygenase type 2, inducible nitric oxide synthase and phospholipase A2, which are produced by various cell types^[6]. Endogenous IL-1 receptor antagonist (IL-1Ra), a natural occurring antagonist of IL-1, regulates normal immune homeostasis in the gut^[1]. The increase of the IL-1/IL-1Ra ratio is parallel with the activity of colitis, while the IL-1/IL-1Ra ratio remains constant in the non-affected part of the colon and in non-IBD inflammatory controls^[7]. The main source of IL-1 in IBD is the monocyte/macrophage system as it can activate the IL-1 converting enzyme, therefore active IL-1 β is released into the colonic mucosa^[8].

IL-33, as known as IL-F11, is the newest identified member of the IL-1 family^[9,10]. It has been detected in several different cell types such as myofibroblasts, adipocytes, smooth muscle cells, endothelial cells bronchial and intestinal epithelial cells, macrophages and dendritic

cells^[10-12]. For the expression of the biological effect of IL-33 the binding to its receptor, IL-1 receptor like 1 (also known as ST2), is required^[10]. IL-33 has a pathogenic role in allergy^[13], airway inflammation^[14] and rheumatic diseases^[15]. Based on the results of Schmitz *et al.*^[10], IL-33 appears to reconstitute mucosal barrier defences against luminal pathogens, increasing epithelial protection by mucus secretion and augmenting immune response *via* type 2 helper T cell (Th2)-related cytokines, such as IL-5 and IL-13. In 2010, elevated expression of IL-33 in UC was reported by four independent groups^[16-19]. In active UC, the expression of the full-length, biologically active form of IL-33 is markedly increased in epithelial cells and in the infiltrating macrophages and B-cells of the lamina propria, while in the serum only the cleaved form of IL-33 is detectable^[18]. This latter possesses reduced biological activity^[20] therefore leading to the speculation that the presence of extracellular proteases has the ability to inactivate full-length IL-33 preventing possible harmful effects (i.e., anaphylactic shock) triggered by high levels of circulating IL-33^[21].

Similarly to IL-33, the expression of its receptor, ST2, was shown to be increased in both colonic wall and serum of IBD patients^[16]. Although the epithelial-derived ST2 expression is decreased and redistributed in IBD^[20], a marked infiltration of ST2 expressing antigen presenting cells and Th cells is present in the lamina propria and perivisceral adipose tissue^[18]. The same epithelial expression of ST2 was not detected in non-IBD colitis samples, such as diverticulitis or infectious colitis^[18]. Regarding the colon, the IL-33/ST2 axis could have a dual and perhaps dichotomous role in the pathogenesis of IBD. Pro-inflammatory cytokine stimuli, such as TNF- α and IL-1 β , and signals from pathogen-associated molecular patterns result in an increased IL-33 level in epithelial cells. After epithelial damage the released IL-33 may enhance the immune responses *via* ST2 expressing immune cells, therefore exacerbating the severity of inflammation^[20,22]. Thus, it is tempting to speculate that the blockade of IL-33 during UC may help to reduce the severity of the disease.

In line with the activation of inflammation IL-33, partly come from endothelial cells, may also act on ST2 expressing epithelial cells and myofibroblasts, promoting wound healing and angiogenesis^[20,23].

The TNF superfamily

The TNF protein superfamily consists of 18 type 2 proteins that exist in either membrane-bound or soluble forms^[24]. Receptors for these ligands are type 1 transmembrane proteins^[25]. Binding of TNF-like ligands to their receptors triggers intracellular pathways that are directly involved in cell proliferation, differentiation, and survival^[26]. Most members of the TNF/TNF-receptor protein superfamilies are expressed on immune cells and play a critical role in multiple components of the immune response, including defence against microor-

ganisms, inflammation, programmed cell death, and the development of the immune system^[24-26].

TNF- α is a master cytokine in the pathogenesis of IBD^[27]. It exerts its pleiotropic effects through the expression of adhesion molecules, fibroblast proliferation, procoagulant factors, as well as the initiation of cytotoxic, apoptotic, and acute-phase responses^[28]. It also has the ability to increase IL-1 β , IL-6, and IL-33 production as well as modulate ST2 expression in epithelial cells^[18,29]. The source of TNF- α in IBD is partly the innate immune cells, such as macrophages or monocytes, and also differentiated Th1 cells^[30]. The serum levels of TNF- α correlate with the clinical activity of UC and CD^[31]. Its orchestrating role in colonic inflammation established the basis of anti-TNF- α antibody therapy in IBD.

Tumor necrosis factor-like factor (TL1A), another newly discovered member of the TNF family, stimulates IFN- γ secretion by binding to death receptor 3 (DR3)^[32]. DR3 is expressed by a high percentage of cells from mucosal biopsies of UC and CD, and an increase of IFN- γ level has been observed with disease activity in IBD patients^[32]. Although TL1A seems to be involved in intestinal epithelial cell apoptosis in IBD^[30], its concrete role in UC pathogenesis still remains unknown.

The IL-6 family

IL-6, IL-11, IL-31, leukemia inhibitory factor, oncostatin M, cardiotrophin-1, ciliary neurotrophic factor, and cardiotrophin-like cytokine belong to the IL-6 family of cytokines.

IL-6 is an immunoregulatory cytokine that activates a cell surface signaling assembly composed of IL-6, soluble IL-6 receptor (sIL-6R), and the shared signaling receptor gp130^[33-35]. The combination of IL-6 and sIL-6R only stimulates gp130 expressing cells, a mechanism that is called trans-signalling. IL-6 signaling *via* signal transducer and activator of transcription-3 (STAT3) plays an important role in UC pathogenesis, moreover in carcinogenesis of UC-associated colorectal cancers^[36].

Mitsuyama *et al.*^[37] found that sIL-6R levels were significantly increased in patients with active UC and CD compared with inactive disease. Thereby, serum IL-6 and sIL-6R levels correlated strongly with C-reactive protein levels.

Besides mononuclear cells, intestinal epithelial cells are supposed to contribute to IL-6 production in the lamina propria^[38,39]. Recent data have shown interesting new aspects of epithelial function^[40]. It was demonstrated in Caco2 cells that IL-6 induces NF- κ B activation and then enhanced expression of the intercellular adhesion molecule 1, which is important in IBD pathogenesis and most likely in extraintestinal manifestations of the disease^[41,42].

Based on these data, the blockade of IL-6/STAT3 signaling and the use of anti-IL-6R antibodies have been suggested as promising therapeutic approaches for the future.

IL-8

IL-8, a small basic heparin-binding protein, is a member of the cysteine-amino acid-cysteine chemokine family (2 cysteines are separated by a single amino acid in the first 2 of the 4 conserved cysteine residues)^[43]. It primarily mediates the activation and migration of neutrophils into tissue from peripheral blood. In a recent study^[44], the tissue level of IL-8 was found to be higher in active UC compared to normal colonic tissue, and its serum concentration was also related to endoscopic and histological severity of UC. Based on these results, IL-8 seems to be a reliable biomarker, closely related to disease activity, but its pathogenic role in the initiation and maintain of colitis needs to be further studied.

The IL-12 family

IL-12, IL-23, IL-27 and IL-35 belong to the IL-12 family of pro-inflammatory heterodimeric cytokines and comprise IL-12p40/IL-12p35, IL-12p40/IL-23p19, Epstein-Barr virus-induced gene 3 (*EBI3*)/IL27p28(IL-30) and IL12p35/*EBI3* subunits^[45-48].

IL-12 and IL-23 are mainly produced by antigen presenting cells, dendritic cells and phagocytes^[49]. Their receptors are also heterodimeric^[49].

IL-12 receptor (IL-12R) is expressed mainly on T cells, natural killer (NK) cells and natural killer T (NKT) cells^[49]. IL-12 expression is elevated in the mucosa of UC patients and it correlates with disease activity^[50]. Recently, the basic leucine zipper protein, NFIL3, was shown to be a regulator of IL-12p40 in macrophages and mucosal immunity^[51]. Interactions of macrophages with the colonic microbiota induce NFIL3 to limit their inflammatory capacity.

IL-23 promotes the differentiation of naïve CD4+ T cells into Th17 cells^[52]. The production of IL-23 by the cells of innate immunity is a response to pattern-recognition-receptor (toll-like- and nucleotide oligomerization domain-like receptors) stimulation or endogenous signals, indicating a potential role for T cells in reinforcement of the IL-23 response^[53]. The pathogenic role of IL-23 receptor (IL-23R) polymorphisms in UC may result in part from its wide distribution among other immune cells. IL-23R is expressed by NK cells, NKT cells, CD4+ T cells and CD8+ T cells^[54]. It is possible that some of the disease-associated polymorphisms observed in the *IL-23R* gene region may influence IL-12RB2 expression, given their adjacent location on the genome^[55]. The regulation of IL-23R and IL-12RB2 expression has a key role in the regulation of T cell differentiation.

Although in most colitis mouse models IL-23 plays a pro-inflammatory role, in 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis, which is T cell mediated, IL-23 functions as an anti-inflammatory cytokine because it suppresses IL-12 production^[56,57].

There is a strong link between IL-23 and Th17 response *in vivo*. It appears that IL-23 is not necessary

for the initiation of Th17 cell differentiation but it is required at a crucial point in controlling the Th17 response^[57]. IL-23 signaling is primarily mediated through the adapter molecule, STAT3. STAT3 was also shown to be essential in the Th17 response, as it binds to the *IL-17a* gene promoter and mediates IL-23-regulated expression of IL-17A, the main effector cytokine of Th17 cells. In lack of IL-23, a decrease in the accumulation of Th17 cells appears in response to inflammatory stimuli, suggesting a regulatory role of IL-23 in Th17 cell response^[57,58]. Besides Th17 cell differentiation, IL-23 also influences the development of regulatory T cells (T_{regs}) by suppressing Foxp3 expression^[59,60]. IL-23 reduces the frequency of Foxp3+ T_{regs} in the colon and is dispensable for the pathogenesis of mucosal inflammation in the lack of T_{regs}^[61].

The main source of the newly discovered IL-35 is the T_{regs}^[48]. Recently, it has been shown^[62] that IL-35 controls the development of T-cell-dependent colitis in mice models, suggesting the potential in targeting IL-35 for patients with chronic intestinal inflammation. The role of IL-35 in the pathogenesis of human IBD needs to be further investigated.

IL-13

UC has been traditionally considered as a Th2 mediated disease, in which IL-13 was identified as an important effector cytokine^[63]. The mRNA expression of IL-13 in UC mucosa is increased^[64], and *ex vivo* cultured lamina propria mononuclear cells from UC patients secrete significantly higher amounts of IL-13 upon stimulation than those from both healthy controls and CD patients^[63]. The critical cell population for IL-13 secretion is CD161+ NKT cells, producing IL-13 in response to stimulation by CD1d+ antigen presenting cells in UC^[63].

The functional importance of NKT cell-derived IL-13 in UC has been studied in detail. It was shown that both receptors of IL-13, IL-4R α and IL-13R α 2, were expressed in colonic epithelial cells, which proves the ability for functional IL-13 signaling in UC^[65]. The UC-specific CD161+ NKT cells show cytotoxic activity against colon epithelium, which effect is, at least partially, dependent upon functional IL-13^[63]. IL-13 was also shown to exert pernicious effects on epithelial barrier function by increasing epithelial cell apoptosis, unmaking tight junction integrity, and decreasing restitution velocity^[65]. Based on these results, it was hypothesized by Fuss *et al.*^[66] that stimuli from commensal flora-derived microbial products stimulate CD161+ NKT cells to produce IL-13 in the colonic mucosa. Then, the downstream effects, such as the cytotoxic activity of NKT cells, the IL-13 induced epithelial cell apoptosis, and the disruption of tight junctions, culminate to epithelial injury. In active UC, the suppression of IL-13 production by interferon- β 1 administration or the inhibition of STAT6, a key adaptor molecule in IL-13 signaling, by small interfering RNA or a histone deacetylase inhibi-

tor result in significant epithelial healing, supporting the aforementioned hypothesis^[67-69].

Recently, it was also shown that IL-13 signaling through IL-13R α 2 led to the increase of transforming growth factor (TGF)- β 1 production, which favours to the progression of colonic wall fibrosis^[70,71].

The IL-17 family

IL-17, which is mainly produced by Th17 cells, is acting as a key mediator in delayed-type immune reactions by increasing chemokine production and recruiting monocytes and neutrophils to the inflammatory site^[72]. After sequencing the human genome 6 structurally related isoforms of the IL-17 family were described: IL-17A (also known as IL-17), IL-17B, IL-17C, IL-17D, IL-17E (also known as IL-25), and IL-17F^[73]. IL-17A and IL-17F share 55% homology, which is the highest amongst the family members, but IL-17F has significantly weaker activity than IL-17A^[57]. There are more receptors for IL-17 (i.e., IL-17RA, IL-17RC), widely expressed by epithelial cells, endothelium or fibroblasts, and it is supposed that the different receptors show different affinity for IL-17s and different signaling pathways^[74].

Although the main source of IL-17A is the Th17 cells, CD8+ T cells are also able to produce this cytokine during chronic inflammation^[57]. However, a causative relationship between UC and IL-17A remains controversial.

In most of IL-17A knock out mice dextrane sulfate sodium (DSS) treatment failed to result in a typical acute colitis^[75], and after the administration of TNBS, the TNBS-induced colitis was attenuated in the IL-17RA knock out animals^[76]. These data support the pro-inflammatory role of IL-17 in colitis models.

On the other hand, O'Connor *et al.*^[77] demonstrated IL-17A-mediated protection in the CD45RB^{hi} transfer model of colitis. An accelerated wasting disease elicited by IL-17A^{-/-} CD45RB^{hi} CD4+ T cells correlated with higher expression of genes encoding Th1 type cytokines in colon tissue. Furthermore, IL-17RA^{-/-} T cells elicited an accelerated wasting disease in Rag1^{-/-} recipients. Their findings support the observation that surprisingly IL-17A can mediate protective function rather than pathology in experimental colitis. Additionally, they have also identified T cells as not only the source but also a target of IL-17 *in vivo*.

In humans, it was recently shown that IL-17 levels were increased in UC compared to healthy colonic mucosa, but in the most reliable studies in which protein rather than messenger RNA was measured this increase was found to be far less than that found in CD^[78].

Since different results were obtained from different studies, it will be important to clarify the source and function of IL-17A in the pathogenesis of UC.

IL-25 was shown to inhibit CD14+ cell-derived cytokines, mainly IL-12 production and Th1 cell-driven experimental colitis in mice, suggesting its potential therapeutic role in both UC and CD^[79].

IL-5 and IL-21

IL-5, as known as eosinophil differentiation factor, is a selective eosinophil activating growth hormone and a member of the common β -chain-dependent cytokine family. The source of mucosal IL-5 is the mononuclear cells, which produce a high amount of this cytokine in active UC but not in CD^[3,65]. IL-5 together with IL-13 and granulocyte/monocyte colony stimulating factor have been recognized as activators of eosinophil function, including migration to the site of inflammation^[80]. Though IL-5 seems to have a regulatory role in eosinophil recruitment in UC mucosa, the role of this cytokine in priming of the blood eosinophils is not as obvious^[81,82]. There is no enhanced IL-5 production of circulating lymphocytes in UC, which indicates that in addition to IL-5 other factors may be involved in the priming of blood eosinophils in IBD.

IL-21 is a T cell derived member of the common γ -chain-dependent cytokine family, acting as a maintainer of the Th1 mediated inflammation in the colonic epithelium by inducing IFN- γ production^[83]. In IBD, IL-21 is mostly produced by CD4+ lamina propria T cells coexpressing IFN- γ and follicular T cells^[84,85]. The number of these cells is higher in CD than UC^[84]. Based on the recent results, IL-21 inhibits T_{reg} differentiation and leads to the resistance of CD4+ T cells to T_{reg}-mediated immune-suppression, therefore enhances the inflammatory process^[85].

CYTOKINES WITH ANTI-INFLAMMATORY EFFECTS IN ULCERATIVE COLITIS

The IL-10 family

IL-10 may be considered the most important anti-inflammatory cytokine in humans, secreted by CD4+ Th2 cells^[86]. During the last two decades, a range of cytokines related to IL-10 were discovered, making IL-10 the founding member of the type II cytokine family that includes IL-19, IL-20, IL-22, IL-24, IL-26, IL-28 and IL-29^[87].

IL-10 inhibits antigen presentation and the release of pro-inflammatory cytokines, hereby attenuates the inflammatory process in the mucosa. It is expressed by many cells of the innate and adaptive immune system. The former triggers IL-10 expression in a toll-like receptor (TLR)-dependent and a TLR-independent way. The major sources of IL-10 are macrophages and dendritic cells^[88]. Regarding the adaptive immune system, Th2 cells primarily promote humoral immunity express IL-10^[88].

The key role of IL-10 within the colonic mucosal immune system has been extensively studied in IL-10 knockout mice models^[89]. In UC, IL-10 mRNA expression was found to be highly increased in mucosal T cells, and the IL-10 production of T_{regs} is also important in the pathogenesis of IBD^[59,90]. A subset of IL-10 and TGF- β 1 producing B cells, namely the regulatory B cells (B_{regs}), are involved in UC pathogenesis as well^[91].

The mutations of the IL-10 pathway genes such as *IL-10* 1q32 or *Stat3* 17q21 have also been shown to be associated with UC^[92,93].

IL-19 is associated with the pathogenesis of both Th1 and Th2 mediated diseases^[94]. IL-19 produced by lipopolysaccharide activated macrophages suppresses pro-inflammatory cytokine release, especially the secretion of TNF- α , IL-6 and IL-12 by an IL-10 independent way^[95]. IL-19 deficient mice are susceptible to DSS-induced colitis^[94]. In a recent study, it was shown that IL-19 polymorphisms (rs2243188 and rs2243193) might have a protective role in the development of UC^[96]. Although these results are promising, the exact role of IL-19 in IBD needs to be further studied.

IL-22 has elevated levels in both serum and mucosa of active CD^[97], but it has been recently proven that it has a protective role in DSS-colitis murine model of UC by inducing mucin membrane bound production by goblet cells^[98]. In humans, the mucosal level of IL-22 was found to be elevated in active UC compared to inactive disease or healthy control samples^[99]. It was also recently published, that after *Trichuris trichiura* therapeutic self-infection, the active UC went into remission, and IL-22-producing Th cells accumulated in the mucosa^[100]. It seems that this kind of helminthiasis may reduce symptomatic colitis by promoting goblet cell hyperplasia and mucus production through Th2 cytokines and IL-22.

TGF- β and IL-4

TGF- β has multiple biological effects on both hematopoietic and nonhematopoietic cells^[101]. Binding of TGF- β to its receptor, TGF- β RII, phosphorylates Smad and mothers against decapentaplegic-related protein transcription factors that have primarily immunosuppressive function^[101]. Genetic mutations in TGF- β RII are linked to UC and UC-associated cancer in humans^[102], and mice lacking TGF- β responsiveness in epithelial cells or T lymphocytes develop severe intestinal inflammation^[103,104].

In human UC patients, IL-33 expression is highly up-regulated within the colonic mucosa and IL-33-deficient mice are protected from DSS-induced colitis^[10,17,19]. Recent data^[105] show that CD68TGF- β DNRII mice, lacking normal TGF- β signaling, produce high levels of IgE and IL-33 within the colon following oral DSS administration. One source of IL-33 in these mice was the intestinal macrophages, which demonstrates that TGF- β serves as an anti-inflammatory factor *via* suppressing the production of IL-33. This may be an important mechanism that could partially explain the reason how mutations in TGF- β RII in humans are associated with increased risk for UC and UC-associated neoplasias^[106].

IL-4, an anti-inflammatory cytokine, is a stimulatory factor for B and T cells, and has an immunosuppressive effect in the colon^[107,108]. IL-4 and IL-10 are able to down-regulate inflammatory mediators including TNF- α and IL-1 and favour a humoral immune response^[109]. In

proctitis, the combined effects of IL-4 and IL-10 were shown to shift the Th1/Th2 cell activation in favour of a Th2-type response^[109], which eventually ameliorated mucosal healing.

In T-cell receptor- α chain-deficient (TCR- α -/-) mice, anti-IL-4 monoclonal antibody treatment altered the cytokine profile of CD4+ $\beta\beta$ T cells (a subset of CD4+ Th2-type cells) from dominant Th2 to Th1 type, resulting in the prevention of mucosal inflammation in TCR- α -/- mice^[110]. The treatment of peripheral blood mononuclear cells from active UC and CD patients with IL-4 *in vitro* resulted in significant decrease of the vascular endothelial growth factor (VEGF) production of these cells, which suggests that the known defective immunosuppressive role of IL-4 in IBD may contribute to the pathogenesis of inflammation by VEGF mediated mechanisms^[111].

CYTOKINES WITH PRO-INFLAMMATORY EFFECTS IN CROHN'S DISEASE

The IL-1 family

Similarly to UC, the IL-1 system plays an important role in the pathogenesis of CD. The IL-1/IL-1Ra ratio is in line with the activity of CD^[7]. In a recent study using phage display technology, a short peptide (TCP-353) was identified from the blood mononuclear cells of CD patients which specifically binds to CD sera and stimulates the pro-inflammatory responses (IL-1 β , IL-6 and TNF- α) of CD mononuclear cells^[112]. This novelty may have diagnostic, pathogenic and therapeutic significance with regard to the treatment of CD.

IL-18, another member of the IL-1 family, was originally described as an important Th1 cell polarizing cytokine^[113]. The level of IL-18 is increased in the inflamed mucosa of a subgroup of CD patients^[114,115]. The balance between this pleiotropic pro-inflammatory cytokine and its natural inhibitor, IL-18-binding protein (IL-18BP), may contribute to the pathogenesis of IBD^[116]. IL-18 is localized to lamina propria cells and intestinal epithelial cells, suggesting that both groups of cells may be involved in the complex events occurring in CD^[114]. In the presence of IL-18, mucosal T cells from active CD have been shown to produce less IL-10 than control tissue^[117]. Recombinant IL-18 alone is able to induce a significant proliferative response in mucosal lymphocytes of active CD, moreover a synergy between IL-18 and IL-12 in macrophages may regulate driving of mucosal lymphocytes toward a Th1 response^[118,119].

Leach *et al.*^[116] found that IL-18, produced in the colons of children with CD, contributes to the local inflammatory changes. They showed that systemic IL-18 level is a possible and useful indicator of disease activity. Furthermore, free IL-18 was found to be greatly elevated in CD children, suggesting that compensatory increases in IL-18BP are insufficient. Further exploration of the role of IL-18 in the pathogenesis of CD is now required.

The TNF superfamily

The role of TNF- α in CD has been widely investigated^[120-122]. Binding TNF- α to serum soluble TNF receptor 1 and 2 (sTNFR1 and 2) initiates pro-inflammatory signaling. The levels of sTNFR1 and 2 are elevated in CD sera compared to both UC and normal controls, hence it can be used as a marker for disease activity and discriminatory factor between the two subtypes of IBD^[123,124]. It was recently demonstrated that TNFR1-signaling cascade in colonic myeloid lineage cells contributes to the suppression of acute damage-associated mortality presumably by controlling colonic epithelial cell homeostasis^[125].

The central pro-inflammatory role of TNF- α has substantiated the use of anti-TNF- α antibodies in the treatment of CD^[126].

The TL1A/DR3 system is also involved in the pathogenesis of CD^[32]. The macrophages of the lamina propria are a major producer of TL1A, which expression is markedly enhanced in CD compared with UC or normal colon^[127]. Kamada *et al.*^[127] found that TL1A and IL-23 synergistically promotes the production of IFN- γ and IL-17 by mucosal T cells, while TL1A alone does not induce cytokine production. Furthermore, they have also shown that TL1A promotes Th17 differentiation from naïve T cells by mucosal macrophages; however, IL-23 did not show any synergistic effects on Th17 differentiation.

TNF ligand superfamily, member 14 (TNFSF14, also known as LIGHT) is a type II membrane protein that forms a biologically active homotrimer, which can be cleaved into a soluble form or exist in an intracellular form with deleted transmembrane region and not displayed on the cell surface^[128,129]. The human intestinal mucosa may be a primary site for LIGHT-mediated pro-inflammatory activity, which shows a correlation with disease activity^[128]. In CD, it was shown that IFN-producing CD4+ lamina propria T cells express LIGHT mediating a Th1 response^[128]. As several data from transgenic mouse models^[130,131] indicated that LIGHT-dependent inflammation selectively targeted the intestine, the mucosal specificity of LIGHT-mediated inflammation could have significant pathological implications in human CD, which needs further investigation.

The IL-6 family

The IL-6/STAT3 signaling system plays a key role in the pathogenesis of CD. The circulating levels of IL-6 and sIL-6R is in correlation with the activity of the disease^[132]. The pathogenic role of IL-6-sIL-6R system in mediating the resistance of T cells to apoptosis in CD was proved by blocking IL-6 trans-signaling^[133].

Subepithelial myofibroblasts can also be a source of mucosal IL-6 in CD. It was recently demonstrated that the increased production of IL-6 synthesis related to the oxidative state, suggesting redox regulation with the involvement of extracellular signal-regulated kinase 1/2

and p38 mitogen-activated protein kinase activation^[134]. Based on these data, IL-6 may have an influence not just on the chronic inflammatory process, but on relapses occurring in the pathology of CD.

The IL-12 family

As it is in UC, the expression of IL-12 is up-regulated in active CD mucosa as well, and its level is in correlation with disease activity^[50]. Because of the elevated levels of IL-12p40 and IL-12Rβ2 in the early phase of CD, it is suggested that IL-12 is primarily involved in the early induction of Th1 polarization of naïve T cells^[135]. However, the expansion and maintenance of Th1 cell response in the colon requires additional signals. The IL-12-dependent synthesis of IFN-γ of the mucosal T cells can be enhanced by cytokines that signal through the common γ-chain receptor (i.e., IL-7, IL-15, IL-21)^[136].

IL-23 also has an elevated mucosal level in CD^[137]. Based on the results from mouse studies with targeted deletion of either the IL-12/p35 or IL-23/p19 subunit, it is suggested that IL-23 and not IL-12 is essential for manifestation of intestinal inflammation occurring in IL-10-deficient mice^[138]. The IL-23-driven intestinal inflammation seems to be mediated by IL-17 and IL-6 production. It needs to be further investigated whether the harmful effect of IL-23 on the ongoing mucosal inflammation occurs only in the absence of IL-10-related regulatory effects.

IL-27 is a newly described, heterodimeric member of the IL-12 family^[47]. It was proved by *in vitro* studies that IL-27 is mainly produced by activated monocytes and dendritic cells, it induces the proliferation of naïve CD4+ T cells and synergizes with IL-12 for IFN-γ production^[47].

The mucosal expression of IL-27p28 was shown to correlate with the activity of disease in both UC and CD^[137]. Particularly, IL-27p28 and EBI3 transcripts have shown to be significantly elevated only in active CD^[137].

The IL-17 family

In humans, the mucosal level of IL-17 levels is highly elevated in active CD^[78]. Recently, it has been shown that in CD patients increased numbers of circulating IL-17 and IFN-γ-producing CD161+ memory cells are present, and these cells constitute a high percentage of colonic mucosal cells^[139]. In addition, CD patients have increased numbers of circulating IL-23R expressing T cells, which respond to IL-23 with increased production of IL-17, IL-22 and IFN-γ, which is further increased by the presence of IL-1β. Moreover, these cells express gut homing receptors CCR6 and β7-integrin, which makes them to be programmed to recruit into the lamina propria during inflammation^[140]. Based on these results, Th17 cells producing both IL-17 and IFN-γ are identified as important elements in the inflammatory response in CD.

Dendritic cells are crucial in inducing acquired im-

munity. In CD, dendritic cells of myeloid origin were found to produce a higher amount of IL-23 and a lower amount of IL-10, when stimulated with exogenous bacterial derivative, moreover they induced a dysregulated Th1/Th17 immune response in mixed lymphocyte reaction than it is in UC and normal control^[78].

Similarly to UC, different results were obtained from different studies; therefore it will be important to clarify the source and function of IL-17 in the pathogenesis of CD.

IL-21

IL-21 is significantly overexpressed in CD mucosa^[141]. IL-21 is generated mainly by CD4+IFN-γ-producing T cells^[84]. In contrast, only a small fraction of IL-21 producing CD4+ T-cells co-express IL-17A, thus indicating that, in humans, IL-21 is produced preferentially by Th1 rather than Th17 cells. Activation of CD4+ T-lymphocytes from normal colon with anti-CD3 antibody and exogenous IL-12 increases the proportion of IL-21-secreting Th1 cells, whereas blockade of endogenous IL-12 in CD mucosal cell cultures significantly reduces IL-21 production^[142]. On the other hand, blocking IL-21 in cells from CD with antibodies or soluble receptor fusion proteins inhibits IL-17A and IFN-γ production^[142].

It was also found that intestinal epithelial cells and subepithelial fibroblasts constitutively express IL-21R and respond to IL-21 by inflammatory molecule secretion. Following IL-21 stimulation, colonic fibroblasts secrete large amounts of matrix metalloproteinase 1 and 3, enzymes involved in mucosal injury of CD^[143,144].

CYTOKINES WITH ANTI-INFLAMMATORY EFFECTS IN CROHN'S DISEASE

The IL-10 family

IL-10 plays a pivotal anti-inflammatory role in CD. An inactivation of IL-10 resulted in an increased production of the pro-inflammatory IL-12 and IFN-γ in mice^[145]. In humans, the inflamed mucosa and granulomas of CD show low IL-10 levels^[146]. It was also recently described that endogenous IL-10 constrains Th17 cell development through the control of dendritic cells' IL-1 production, which reaffirms the crucial anti-inflammatory role of IL-10 in patients with CD^[147].

On the contrary, the level of IL-22 is elevated in CD mucosa and serum^[98]. It was shown that IL-23R genotypes have an effect the serum concentrations of IL-22, which links genetic CD susceptibility to Th17 cell function^[97].

Regarding IL-22, a new regulatory pathway was recently described in CD^[148]. The aryl hydrocarbon receptor (AhR) may represent a link between the environment and the mucosal immune system. AhR is a transcription factor which is activated by a large number of environmental factors^[148]. It has been recently shown that muco-

Table 1 The disease-related immunological and pathological effects of cytokines

		Ulcerative colitis	Crohn's disease
Interleukin-1 family	IL-1	Inflammation induction	
	IL-18	NI	Mucosal T cell IL-10 secretion ↓ Th1 response ↑
	IL-33	Reconstitute mucosal barrier defence Epithelial mucus secretion ↑ Th2-response ↑ Wound healing and angiogenesis ↑	NI
Tumor necrosis factor superfamily	TNF- α	Adhesion molecules expression ↑ Fibroblast proliferation ↑ Procoagulant factors level ↑ Initiation of cytotoxic, apoptotic, and acute-phase responses IL-1 β , IL-6, IL-33 production ↑ Modulates epithelial cell ST2 expression	Initiates pro-inflammatory signaling
	TL1A	IFN- γ secretion ↑ Modulates epithelial cell apoptosis	IFN- γ , IL-17 production ↑ Th17 differentiation ↑
	LIGHT	NI	Mediates Th1 response and mucosa specific inflammation
	IL-6	Involved in colitis-associated carcinogenesis Possible role in extraintestinal manifestations	Mediates T cell resistance to apoptosis Influences of disease relapse
	IL-8	Mediates the activation and migration of neutrophils	NI
Interleukin-12 family	IL-12	Modulates macrophage activity	Early induction of Th1 polarization of naïve T cells IFN- γ of the mucosal T cells
	IL-23	Promotes Th17 cell differentiation Controlling Th17 response Influences T _{reg} cell development Number of mucosal T _{reg} cells ↓	IL-17 and IL-6 mediated intestinal inflammation
	IL-27		Proliferation of naïve CD4+ T cells ↑ IFN- γ production ↑
	IL-35	Possible controlling of T-cell dependent inflammation	NI
	IL-13	Induces cellular cytotoxicity against colonic epithelium Epithelial cell apoptosis ↑ Tight junction integrity ↓ Epithelial restitution velocity ↓ Colonic wall fibrosis ↑	NI
Interleukin 17 family	IL-17	Pro- and anti-inflammatory effects	IL-17, IL-22, IFN- γ production ↑ Enhance T cell recruitment into the lamina propria
	IL-25	Possible inhibition of IL-12 secretion Possible promotion of Th1-driven inflammation	NI
Interleukin-21	IL-21	Maintainer of Th1-mediated inflammation Inhibits T _{reg} cell differentiation CD4+ T cell resistance to T _{reg} -suppression ↑	Required for IL-17A and IFN- γ production Fibroblasts MMP secretion ↑
	IL-5	Activates eosinophil function and migration	NI
Interleukin-10 family	IL-10	Inhibits antigen presentation Pro-inflammatory cytokine release ↓	Constrains Th17 cell development
	IL-19	TNF- α , IL-6, IL-12 secretion ↓	NI
	IL-22	Goblet cell hyperplasia ↑ Mucus production ↑	Promotes mucosal healing
	IL-4	TNF- α , IL-1 production ↓ Humoral immune response ↑ Mucosal healing ↑	NI
Transforming growth factor- β	TGF- β	Monocyte/macrophage VEGF production ↓ Possible suppression of IL-33 production	Collagen synthesis ↑ Regulates the balance between matrix-degrading MMPs and their inhibitors IL-13 expression ↑ EMT ↑

IL: Interleukin; TNF: Tumor necrosis factor; IFN: Interferon; TL1A: TNF-like factor; TGF- β : Transforming growth factor- β ; LIGHT: Lymphotoxins, exhibits inducible expression, and competes with herpes simplex virus glycoprotein D for herpesvirus entry mediator, a receptor expressed by T lymphocytes; MMP: Matrix metalloproteinase; VEGF: Vascular-endothelial growth factor; EMT: Epithelial-to-mesenchymal transition; NI: (possibly) Not involved in pathogenesis.

sal T cells and NK cells isolated from active CD biopsies express low levels of AhR and respond to AhR ligands with decreasing pro-inflammatory cytokine production and up-regulating IL-22^[149]. Hereby, the changing mucosal cytokine profile promotes mucosal healing.

TGF- β

TGF- β is thought to be an inhibitory key cytokine of immunological homeostasis and inflammatory responses. On the other hand, TGF- β is also a potent profibrogenic agent inducing collagen synthesis and regulating the bal-

Figure 1 The disease-related pathogenic role of cytokines with pro-inflammatory, anti-inflammatory and pro-fibrogenic effects in ulcerative colitis and Crohn's disease. LIGHT: Lymphotoxins, exhibits inducible expression, and competes with herpes simplex virus glycoprotein D for herpesvirus entry mediator, a receptor expressed by T lymphocytes; IL: Interleukin; TNF: Tumor necrosis factor; TL1A: TNF-like factor; TGF- β : Transforming growth factor- β .

ance between matrix-degrading matrix metalloproteinases and their inhibitors^[150]. It has a role in CD-related fibrosis, as changes in TGF- β signaling and matrix metalloproteinase production were identified in the mucosa overlying strictures^[150].

It was also shown that TGF- β induces IL-13 expression and epithelial-to-mesenchymal transition of intestinal epithelial cells, while IL-13 promotes the expression of genes associated with cell invasion^[151]. Based on these data, it seems that TGF- β and IL-13 play a synergistic role in the pathogenesis of CD-associated fistulae^[151], which has therapeutic consequences.

CONCLUSION

Cytokines have important and complex role in the pathogenesis of IBD (Table 1 and Figure 1). There are several different biologic therapies directed to cytokines or their receptors which have possibilities in the treatment of IBD.

Some anti-TNF- α antibodies are currently being used to treat CD and UC. Although these molecules dramatically improved the treatment of patients, sometimes severe side effects or the development of anti-drug antibodies limits their application.

Neutralizing antibodies targeting other pathways of the immune response have been developed and tested^[152]. Antibodies targeting the IL-12 and IL-23 pathways, or pro-inflammatory cytokines (i.e., IFN- γ , IL-2, IL-6, IL-17A) initially showed a promising result, but for none of their efficacy has undoubtedly been established^[153]. Administration of the regulatory cytokines, namely IL-10 and IL-11, also failed to induce reproducible clinical effects^[152].

Accordingly to the complex effects and regulation of cytokines in IBD, the cytokine-based therapies of the future must have higher specificity and lower toxicity.

Abstract

Crohn's disease and ulcerative colitis can be grouped as the inflammatory bowel diseases (IBD). These conditions have become increasingly common in recent years, including in children and young people. Although much is known about aspects of the pathogenesis of these diseases, the precise aetiology is not yet understood, and there remains no cure. Recent data has illustrated the importance of a number of genes—several of these are important in the onset of IBD in early life, including in infancy. Pain, diarrhoea and weight loss are typical symptoms of paediatric Crohn's disease whereas bloody diarrhoea is more typical of colitis in children. However, atypical symptoms may occur in both conditions: these include isolated impairment of linear growth or presentation with extra-intestinal manifestations such as erythema nodosum. Growth and nutrition are commonly compromised at diagnosis in both Crohn's disease and colitis. Consideration of possible IBD and completion of appropriate investi-

gations are essential to ensure prompt diagnosis, thereby avoiding the consequences of diagnostic delay. Patterns of disease including location and progression of IBD in childhood differ substantially from adult-onset disease. Various treatment options are available for children and adolescents with IBD. Exclusive enteral nutrition plays a central role in the induction of remission of active Crohn's disease. Medical and surgical therapies need to be considered within the context of a growing and developing child. The overall management of these chronic conditions in children should include multi-disciplinary expertise, with focus upon maintaining control of gut inflammation, optimising nutrition, growth and quality of life, whilst preventing disease or treatment-related complications.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) comprise the inflammatory bowel diseases (IBD). These chronic conditions affecting the gastrointestinal tract are becoming increasingly common. At present there is an incomplete understanding of the causation of CD and UC. Although children and adolescents can be diagnosed with IBD at any age, the second decade of life is the most common period. From diagnosis these children face a lifetime of

illness, with many potential consequences and effects.

CROHN'S AND COLITIS

IBD is characterised by chronic inflammation of the intestinal tract with variable periods of remission and exacerbation. Traditionally IBD is thought of as the two major clinical subtypes (CD and UC). However, it can also be seen as a heterogeneous group of disorders of intestinal inflammation^[1].

Classically, UC involves disease that extends proximally for a variable distance from the rectum, with involvement of the superficial layers of the colonic mucosa. Pediatric cohort studies show that pancolitis is the most frequent presentation of UC in childhood, with few children having isolated proctitis^[2,3]. This finding contrasts greatly with the disease patterns seen in adults with UC^[2]. Furthermore, those children without pancolitis at diagnosis commonly have extension of disease to involve the whole colon over the subsequent years.

In contrast to UC, CD is characterised by transmural inflammation in a non-contiguous pattern (so-called skip lesions), anywhere from the mouth to the anus. Disease distribution of CD differs between children and adults^[2]. In paediatric CD, the ileocolonic region is the most common location of disease. Disease limited to the colon is less frequently seen, and isolated terminal ileal disease is uncommon, occurring in less than 10% of children^[2]. Involvement of the gut proximal to the terminal ileum occurs in more than half of children with CD, with common areas being the stomach and duodenum^[2,4]. Aphthoid or serpiginous ulceration are particular endoscopic features of CD: other features such as friability, oedema, granularity and loss of vascular markings, may be seen in both UC and CD.

One particular histological feature of CD is non-caseating granuloma located in the inflamed mucosa. Perianal disease, including multiple large anal tags, perianal abscesses, non-healing deep fissures or fistulas, is a feature of CD, but not of UC. The inflammatory changes in CD may be complicated by stricturing or fistulising disease, with progression in many patients towards these phenotypes over time^[5].

The term IBD-unclassified (IBDU) refers to those patients with chronic bowel inflammation whose pattern of disease is not clearly able to be classified as CD or UC. Over the course of the disease, IBDU is often reclassified as either CD or UC as the pattern and features of inflammation evolve. IBDU is more commonly reclassified as UC than CD^[6]. The term indeterminate colitis, however, should be reserved for the situation where, following colectomy and histopathological examination of the colon, the distinction between UC and CD remains unclear^[6].

EPIDEMIOLOGY

IBD can present at any age, with the peak age range of

diagnosis in the second and third decades of life^[7]. In childhood, rates of IBD increase from the first year of life, with highest rates in teenage years. Around 25% of all diagnoses of IBD are made in the first two decades of life^[8,9]. A family history of IBD is more commonly elicited in children with IBD than in adults^[7].

Generally UC is found to be more common than CD in the preschool age group, whilst CD is three times more frequent than UC in older children in many case series^[10,11]. There is also a slight male preponderance (1.5:1) in prepubescent patients with CD as opposed to a slight female preponderance in adults^[2].

Although the incidence and prevalence of IBD varies, there is overwhelming data showing increasing rates in many areas of the world^[12,13]. In more recent years, an increasing incidence has been observed in countries that traditionally did not report IBD, such as Taiwan, China and other Eastern countries^[14]. In addition, children of families migrating from the developing world to the developed world have increased rates of IBD^[15]. There is also clear evidence that the incidence of IBD in the paediatric population is increasing, especially for CD. Benchimol *et al*^[16] observed an increased incidence rate of paediatric CD in the Canadian province of Ontario from 9.5 to 11.4 per 100 000 per annum over an 11 year period to 2005; however the incidence of UC in this period remained unchanged (4.1 to 4.2 per 100 000). In Australia, recent Victorian studies clearly show increasing rates in children, with a greater than 10-fold increase in CD over the 30 year period to 2001^[17]. In addition, an eleven-fold increase in paediatric UC was seen in the same area, with particular increases over the most recent two decades^[18]. It is unclear why IBD has become more common over the last decades: suggested factors include changes in lifestyle, diet, urbanisation and other environmental changes.

PATHOGENESIS OF IBD

The most accepted hypothesis for the pathogenesis of IBD is that interactions between the gut luminal contents (especially the intestinal microflora) and the mucosa lead to dysregulated inflammation in a genetically-predisposed host. A wide range of microorganisms have been considered as potential causative agents for IBD. These include *Mycobacterium paratuberculosis*, *Listeria monocytogenes*, Novel Burkholderiales and *Escherichia coli* subtypes^[19,20]. It is also speculated that viral agents may play roles in the development of IBD^[21]. Recently, a small study conducted in Finland focused on faecal detection of viral agents in a group of 50 children being evaluated for possible IBD (33 were diagnosed with IBD whilst 17 were shown to not have IBD)^[22]. Viral agents were not detected in the IBD group but were present in 3 of the control group.

There is not yet clear data to support a role for any one of these organisms as the primary factor in the aetiology of IBD. Our recent work has focused upon several mucous-associated organisms, including members of the

Helicobacter and *Campylobacter* families^[23,24]. Although these studies show that such organisms are commonly present at the time of diagnosis of IBD, it is unclear if they have a causative role.

Some of the most exciting recent developments in our understanding of the pathogenesis of IBD have been in the field of genetics. A decade ago, *NOD2/CARD15* was identified as the first susceptibility gene for CD^[25]. *NOD2* is a member of a family of intracellular proteins that respond to bacterial proteins and contribute to host defence^[26,27]. In one large study 50% of patients with CD were found to have at least one *NOD2* gene mutation, with 17% having a double mutation^[28]. Those patients with 2 mutations were characterised as having a younger age of onset, more frequent stricturing disease, and less frequent colonic involvement, suggesting a link with earlier onset of disease. *NOD2* mutations are present at the same rates in patients with UC as in controls and are also not seen in non-European populations, such as in Japan, India and South Korea^[29-31]. Furthermore, *NOD2* mutations are not associated with early onset of disease in children of Ashkenazi background^[32]. Tumour-necrosis factor (TNF)- α promoter gene mutations were, however, associated with early onset in this group of children.

In more recent years, a number of other genes have been shown to be important for IBD—most in CD but some in UC. A recent transatlantic collaboration scanned a cohort of 3426 childhood-onset IBD patients and identified 5 new loci associated with paediatric IBD^[33]. In 2010, a multi-national collaboration identified many further loci implicated in CD, bringing the total of loci identified to 71^[34]. Mutations in the interleukin (IL)-10 receptor were recently shown in a group of infants with very early onset of severe and treatment resistant disease. Mutations in the coding for one of chains of the IL-10 receptor were identified: this change renders the patients' cells unresponsive to the anti-inflammatory effect of IL-10^[35]. A recent review article highlighted the findings of two paediatric gene wide association studies^[36]. Although emphasising key genetic pathways common to adult-onset disease, these studies also identified novel regions associated with early-onset disease, including genes encoding IL-27. The relevance of these potential links was recently outlined in a hypothesis article^[37]. In addition, a current prospective study (www.neopics.org) focusing on genetic influences on children aged less than 6 years of age should further define key aspects in this group.

PATTERNS OF PRESENTATION OF IBD IN CHILDREN

Children with IBD may present with a range of symptoms, depending on the location, severity and chronicity of inflammation. Classically, CD most commonly presents with pain, diarrhoea and weight loss, whilst UC most commonly starts with bloody diarrhoea^[38]. Children with distinct disease locations may present with other defined

gastrointestinal symptoms. For instance, oesophageal involvement may lead to odynophagia and dysphagia whilst perianal presentation may include pain, discharge or a mass. Recent studies suggest that fewer children have the so-called classical symptoms, and that children may have a range of presenting features (including atypical symptoms) including abdominal pain, diarrhoea, short stature or weight loss^[2,38]. Some children presenting with atypical or non-gastrointestinal symptoms may have delayed recognition and diagnosis. Although many of the gastrointestinal symptoms seen in paediatric IBD are similar to those reported in adults, particular features in children include linear growth failure and pubertal delay.

Despite its name, IBD is not limited to the bowel. Up to 30% of patients will develop an extra-intestinal manifestation (EIM) at some point during their lifetime^[39]. The most common EIM in children are arthritis (axial or peripheral), cutaneous changes (e.g., erythema nodosum and pyoderma gangrenosum), eye diseases (such as episcleritis and uveitis that occur in approximately 1% of patients with IBD) and liver disease^[40]. Hepatobiliary complications can take the form of primary sclerosing cholangitis, autoimmune hepatitis or overlap syndrome^[40].

IMPACT OF IBD UPON GROWTH AND NUTRITION IN CHILDREN

Weight loss, or lack of weight gain, is a presenting feature in 85% of children with CD and at least 65% of children with UC^[7]. This impairment of weight is predominantly a result of decreased oral intake due to anorexia, early satiety, nausea or pain. In addition to compromised weight, linear growth may also be impaired at diagnosis or subsequently^[41]. These consequences are primarily related to the systemic circulation of pro-inflammatory cytokines, such as TNF- α and IL-6. IL-6 influences the activity of key proteins, including insulin-like growth factor (IGF)-1, and interferes with the effects of growth hormone and other key pathways^[42].

An additional consequence of nutritional impairment and elevated levels of cytokines is delayed pubertal development. Given that many children present in the pre-pubertal or peri-pubertal period, pubertal delay can be of significant concern and importance. Failure to adequately induce disease remission at this crucial stage can have significant consequences such as missed or delayed pubertal growth spurt and reduced final height, abnormal bone mineralisation, and maintenance of prepubertal sex hormone levels^[38].

Children with IBD can also have micronutrient deficiencies. The most common of these are iron, vitamin D, vitamin B12, calcium and zinc. In a cohort of children with IBD from Sydney, Australia, only 40% had normal Vitamin D status^[43]. Lack of Vitamin D along with inadequate calcium intake (and also vitamin K deficiency) contributes adversely to bone health. Since 90% of peak bone mass is attained during childhood and adolescence, failure to attain maximal potential may increase future

fracture risk^[44]. Underlying systemic inflammation is an independent detrimental influence on bone health^[44]. Sylvester *et al*^[45] have shown low mean bone mineral density (BMD) scores in children with IBD and also demonstrated that BMD scores are associated with body mass index and IL-6 levels.

APPROACH TO POSSIBLE IBD IN CHILDREN

Diagnostic pathways begin with the consideration of possible IBD as an important first step. A suggestive history of gut symptoms may be present, but children may present with atypical symptoms. Examination findings of weight loss, chronic disease (e.g., clubbing) or extra-intestinal features of IBD (e.g., erythema nodosum) may be detected. Weight and height should be accurately measured and plotted on an appropriate growth chart. Previous growth data should be obtained from the child's health records and parental heights should be recorded to calculate mid-parental height.

Exclusion of other potential pathologies, especially enteric infections, is important. Several stool cultures should be requested to exclude an enteric infectious cause in children presenting with diarrhoea and/or abdominal pain, with inclusion of less common organisms such as *Yersinia* and *Aeromonas*. Stool can also be sent for faecal markers of inflammation-these include the presence of faecal white cells, stool α -1-antitrypsin, lactoferrin and calprotectin (where available). S100A12, another non-invasive marker of gut inflammation shows high sensitivity and specificity in differentiating between children with IBD and non-IBD conditions^[46]. Non-invasive tests such as calprotectin and S100A12 may also have roles in disease monitoring after diagnosis^[47].

Blood tests should be requested for full blood count (especially Hb, platelets, and white count), erythrocyte sedimentation rate (ESR), C-reactive protein, albumin and liver chemistry. Further baseline assessment should include iron studies, B12/folate levels and vitamin D. Serum based markers of systemic inflammation may be helpful in children with IBD, but exclusion of the diagnosis can not be made with normal tests. A recent North American study suggests that normal bloods (platelets, ESR, albumin or Haemoglobin) may be seen in 21% of mild CD, 54% of mild UC and 4% of more severe CD or UC^[48]. The addition of specific serological tests (ASCA, ANCA and pANCA) to a standard diagnostic approach is shown to improve and enhance diagnostic yield^[49].

If IBD is suspected on the basis of history, examination findings and/or the results of preliminary tests, then further investigations should be arranged. Definitive diagnosis relies on endoscopic and histologic findings, often supported by radiologic findings. Upper gastrointestinal endoscopy and ileo-colonoscopy should both be undertaken in any child or adolescent with suspected IBD, along with multiple mucosal biopsies^[50]. As an upper gut location of IBD is present in at least two

thirds of children with CD, findings in this region may be sufficient firstly to make a diagnosis of IBD or secondly assist in differentiating between CD and UC^[4].

Baseline investigations should also include an assessment of the small bowel^[50]. The vast length of the small bowel is not accessible to standard endoscopy. An increasingly preferred method to view the small bowel is a small bowel series magnetic resonance imaging, which can provide detail of the extent of inflammatory changes through the mucous without radiation exposure^[51]. This has largely supplanted the small bowel meal and follow-through as a tool to assess the small bowel. Capsule endoscopy also has an increasing role, with this modality able to identify superficial and smaller mucosal lesions^[52]. Other potential modalities include white-blood cell scans, positron emission tomography scans and ultrasound scanning^[53-55]. CT scanning, however, is rarely required in children and adolescents (and is generally discouraged due to potential cumulative radiation exposure).

MANAGEMENT OF IBD IN CHILDREN

Although the key concept in the management of IBD is inducing and maintaining remission, the pervasive effects of IBD in children mean that holistic care is essential, with consideration of multiple aspects of the condition and its complications. Provision of these management aspects in a child (and family) focused multi-disciplinary team setting is optimal to ensure superior outcomes.

In terms of control of gut inflammation, the management principles are to induce remission (control inflammation) and to then maintain remission. Although remission can be considered at clinical (relief of symptoms) and biochemical levels (normalisation of systemic markers of inflammation), histological remission (normalisation of histologic changes or mucosal healing) is seen as the ideal goal of therapy. Therapies to induce remission (e.g., corticosteroids or exclusive enteral nutrition) can be considered separately to those utilised to maintain remission [e.g., amino-salicylates (ASA) or immunomodulators such as thiopurines].

Whilst corticosteroids have traditionally been utilised to induce remission in active IBD, there is increasing support and rationale for exclusive enteral nutrition (EEN) in paediatric CD. EEN involves the sole administration of a nutritional formula, with exclusion of normal diet, for a period of up to 8 wk^[56,57]. EEN has remission rates equivalent to those of CS, but has numerous advantages such as avoiding steroid-related side-effects and in addition leads to superior rates of mucosal healing^[58]. Antibiotics (especially metronidazole and/or ciprofloxacin) may have roles in mild luminal or perianal CD. Aminosalicylates may have particular roles in inducing remission in mild to moderate active UC. Tacrolimus^[59] or cyclosporin may have a role in the management of severe colitis, whilst biologic drugs (such as infliximab) have roles in the induction of remission of severe disease.

ASA drugs have roles in the maintenance of remission

of UC, and although often also used for maintenance in CD, they are not as well supported for this by available evidence. Steroids and antibiotics do not have roles in the maintenance of remission of IBD in children. The immunosuppressive drugs have defined roles in the maintenance of remission of IBD in children. Thiopurines (azathioprine or 6-mercaptopurine) are typically used first: methotrexate tending to be used in the setting of thiopurine failure or intolerance^[60]. Early commencement of thiopurines in moderate-severe disease leads to less steroid requirement, more prolonged remission and better growth^[61]. Other drugs (such as thalidomide, tacrolimus or mycophenolate) may play a role in maintenance of remission. Supplementary nutrition can also have a role in maintaining remission in CD, but the subgroup most likely to benefit from this approach has not yet clearly been defined^[57].

Biological therapies have clear roles in the induction of remission in severe disease and in the subsequent maintenance of disease with ongoing dosing. The efficacy and safety of both infliximab^[62] and adalimumab^[63] has been considered in children and adolescents.

In addition to the current standard therapies, numerous other therapies are being developed or considered for roles in IBD. Many of these are biologic therapies that are able to be considered consequent to improved understanding of the complex inflammatory events in IBD. Other therapies that may play adjunctive roles include fish oils^[64] and probiotics^[65]. Additional novel therapies reported recently include low dose naltrexone^[66] and pig whip-worm therapy^[67]. The definitive roles for these therapies in children have not yet been proven.

One important factor in achieving optimal outcomes for children of any age with medical therapies is adherence. Recent work highlights an important relationship between adherence and disease severity^[68].

As well as medical therapies, many children with IBD require surgical intervention. Common indications in children with CD include the management of perianal disease, resection of disease unresponsive to medical therapy, or resection of a fibrotic stricture. In children with UC the indications for colectomy include fulminant UC unresponsive to medical therapy, severe colitis complicated by toxic megacolon and/or perforation, chronic colitis unresponsive to medical agents and following the development of pre-cancerous changes.

The cumulative risk of surgery in a series of 404 children with CD was 20% at 3 years and 34% at 5 years^[3]. A lower rate of resective surgery was seen in a Scottish series, with 20.2% having undergone surgery by 5 years^[2]. In this series, the authors demonstrated that the median time to first surgery was longer in their group of children with CD than a comparative adult group (13.7 years from diagnosis compared to 7.8 years; $P < 0.01$). In contrast, the reverse was seen in the individuals with UC (11.1 years from diagnosis in children contrasting to > 50 years in adults; $P = 0.38$)^[2].

The various therapeutic options need to be considered within the context of the individual patient and their disease pattern/location. Clearly the potential side-effects of an individual therapy need to be outlined in candid discussions with the patient and parents: these aspects need to be considered in the context of the potential benefits and the relative risk of the adverse effects.

In addition to the use of specific nutritional therapies to induce or maintain remission, the overall management of paediatric IBD requires close attention to growth and nutrition. Weight and height should be monitored regularly, with calculation of height velocity and assessment of pubertal development. Successful growth can be considered as an indicator of the success of therapy for IBD. Provision of a full well-balanced diet, with inclusion of adequate macronutrients (protein, fat, carbohydrates) and micronutrients (e.g., calcium and iron), should be reviewed by a paediatric dietitian regularly, with at least annual review. Monitoring of micro-nutrients is also important. Levels of iron, B12, folate and vitamin D should be reviewed on an annual basis.

The psychosocial aspects and consequences of IBD also require attention. IBD can impact greatly upon the quality of life of young patients^[69]. Disruption to schooling and social activities is common, especially in those with unstable or severe disease. Attention to coping and provision of supports, may require psychological intervention. Peer-support activities and supports also play important roles in the overall management of children with IBD.

PROGNOSIS AND OUTCOMES OF IBD IN CHILDREN

Given diagnosis in the first decades of life, infants and children have many decades of disease in front of them. Several recent cohorts have illustrated key aspects of the natural history and outcomes of IBD in children, with emphasis of key differences from adult-onset cohorts^[2,3,70].

Immune reactivity based upon a series of specific serological responses, has been shown to associate with disease outcome in children^[71]. In this group of 796 children with CD, an increased number of serological responses were linked with more aggressive disease pattern and earlier progression of disease. Subsequently, Siegel *et al*^[72] have developed a tool to outline predicted disease course in children with CD, incorporating serologic responses, along with patient and disease factors. The need for surgery has also been linked with NOD2 mutations in children with CD^[73]. Risk scores have also been considered in paediatric UC: Moore *et al*^[74] showed that white blood count and haematocrit values at diagnosis were associated with colectomy at 3 years in a cohort of 135 children with UC.

CONCLUSION

Crohn's and colitis has become an increasingly common diagnosis in children of all ages. These conditions have particular features and patterns in children, compared to adults. Early consideration of the diagnosis is important to avoid additional adverse impact upon growth, nutrition and normal functioning. Nutritional aspects are critical in the overall management of IBD. Whilst EEN is the therapy of choice to induce remission in CD, overall monitoring of growth and nutrition are key elements of ongoing management. Further work on the utility of drugs, such as antibiotics, will likely proceed in conjunction recognition of the importance of the intestinal microflora in the pathogenesis of IBD. The care of children and adolescents with IBD needs to be considered within a multi-disciplinary focus, with many different health professionals playing important roles.

Abstract

AIM: To retrospectively evaluate the effectiveness of impedance monitoring for predicting popping during radiofrequency ablation (RFA) using internally cooled electrodes.

METHODS: We reviewed 140 patients (94 males, 46 females; age range 73.0 ± 11.1 year) who underwent RFA between February 2006 and November 2008 with a modified protocol using a limited power delivery rather than a conventional one to avoid popping. All the patients provided their written informed consent, and the study was approved by the institutional review board. Intraprocedural impedances were measured for the study subjects, and the tumors were classified into three types according to the characteristics of their impedance curves: increasing, flat, or decreasing. The tumors were further sorted into seven subtypes (A-G) depending on the curvature of the impedance curve's increase or decrease. Relative popping rates were determined for the three types and seven subtypes. A chi-square test was performed to estimate statistical significance.

RESULTS: A total of 148 nodules treated by RFA were analyzed. The study samples included 132 nodules of hepatocellular carcinoma, 14 nodules of metastatic liver cancer, and two nodules of intrahepatic cholangiocarcinoma. The numbers of nodules with each impedance curve type were as follows: 37 increasing-type nodules, 43 flat-type nodules, and 68 decreasing-type nodules. Popping occurrence rates were 24.3%, 46.5% and 64.7%, respectively. Flat-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P = 0.039$). Decreasing-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P < 0.0001$). Notably, nodules that showed a sharp decrease in impedance in the latter ablation period (subtype E) exhibited a significantly higher rate of popping compared to other subtypes.

CONCLUSION: Intraprocedural impedance monitoring can be a useful tool to predict the occurrence of popping during liver tumor RFA performed with internally cooled electrodes.

INTRODUCTION

In addition to resection, radiofrequency ablation (RFA) is one of the most effective local treatments applied to liver tumors along with resection^[1-10]. The procedure is effective for relatively small tumors or tumors that recur after resection^[11-13]. In addition, it can be performed safely in elderly patients and cirrhotic patients^[14,15]. The RFA process involves inserting an electrode into the tumor and exciting it with a radio frequency current. This leads to a temperature increase in, and subsequent coagulation necrosis of, the tissue surrounding the electrode. However, complications arising from liver tumor RFA have been reported in numerous cases. Among those complications are intraperitoneal bleeding, subcapsular hematoma, biliary tract damage, portal vein thrombosis, peritoneal dissemination and gastrointestinal tract damage^[16-21].

There is a phenomenon called “popping” that refers to a form of explosive tissue disruption caused by a rapid elevation of intra-tissue pressure^[22-26]. When intra-tissue fluid vaporizes due to elevated tissue temperature, the tissue volume expands to approximately 1700 times that of the initial volume. The mechanism underlying this degree of tissue volume expansion is as follows: when 1 mol (18 mL) of water turns into gas at a standard temperature, pressure and dry, its volume increases to 22.4 L, which is 1244.4 times the volume of water. Assuming that the steam temperature is 373 K, the volume can be estimated by accounting for the increase in volume due to temperature with the following formula: $1244.4 \text{ times} \times 373 \text{ K} / 273 \text{ K} = 1700 \text{ times}$. Protein coagulation occurs at a temperature of approximately 60 °C, while vaporization occurs above 100 °C. Popping that occurs close to the subcapsular or main vessel has been thought to raise the risk of complications such as bleeding and dissemination.

In RFA procedures, two types of devices with different kinds of tips, the “internally cooled electrode” needle and the “expandable electrode” needle, are commercially available for ablation. It has been reported that the probability of popping is higher when using the internally cooled electrode due to the likelihood of intra-tissue pressure increasing more rapidly^[27]. According to the literature, there is a higher probability of scattered recurrence with the internally cool electrode^[28]. The conventional RFA protocol involves power delivery starting from 40 W followed by a power increase of 10 W every minute when using a 2-cm exposed tip; power delivery is started at 60 W, then increased by 20 W every minute when using a 3-cm exposed tip. Power output is increased with no limitations until a break occurs. A modified protocol to address the concern of complications from RFA has been introduced in recent years, and the authors reported that the likelihood of popping during RFA may be reduced by limiting power delivery^[24]. We

have applied these findings to our RFA procedure, limiting power delivery for the treatment of nodules on the surface of the liver or close to main vessels; however, a challenge still remained with respect to implementation of the modified protocol: in our hospital, popping occurred during 73 out of 148 sessions.

In our search for a safer RFA procedure, we reviewed 305 consecutive cases in which RFA was performed using the standard conventional protocol between June 2004 and January 2006. Of these 305 cases, major complications occurred in three cases (0.98%): a subcapsular hemorrhage, an intraperitoneal hemorrhage and a case of hemobilia (Figure 1). Steam popping had occurred in all three cases during RFA and it was therefore deemed as a potential contributor to the complications listed above.

In the present study, we retrospectively analyzed our RFA cases in which the modified protocol was applied between February 2006 and November 2008. The purpose of our study is to assess intraprocedural impedance monitoring to predict the likelihood of popping as hypothesized based on the aforementioned popping mechanism.

MATERIALS AND METHODS

Patients

Between February 2006 and November 2008, 280 patients in our hospital underwent RFA using internally cooled electrodes (Covidien) according to the modified protocol with limited power delivery to prevent popping. Among these individuals, 140 patients (94 males, 46 females; age range 73.0 ± 11.1 year) and 148 sessions were retrospectively analyzed in this study, excluding the 54 patients who showed unstable impedance curves and the 86 patients who did not reach the break point during RFA. In our hospital, RFA is indicated for tumors that are 3 cm or less in the largest dimension, and for patients with no more than three tumors. Patients with impaired liver function could also be candidates for RFA if they are free of ascites. Among the 140 patients analyzed, 35 had undergone transcatheter arterial chemoembolization (TACE) prior to RFA. All patients provided their written informed consent before treatment, and the study was approved by the institutional review board.

Ablation method for preventing popping

RFA was performed by three surgeons who specialize in liver surgery with 10, 20 and 25 year of experience, respectively. Midazolam (Dormicum; Astellas, Tokyo, Japan) was used for sedation at a dose of 0.03-0.06 mg/kg, and lidocaine (Xylocaine; Fujisawa, Tokyo, Japan) was used for local anesthesia. Cefazolin (Cefamezin; Astellas, Tokyo, Japan) was administered prophylactically against infection for 1-2 d following RFA. Abdominal ultrasound (Nemio; Toshiba, Tokyo, Japan) was used to

Figure 1 A case showing subcapsular (A, B) and intraperitoneal (C, D) hemorrhage after popping, which occurred during radiofrequency ablation for hepatocellular carcinoma. A, C: Before ablation; B, D: After ablation. RFA: Radiofrequency ablation; HCC: Hepatocellular carcinoma.

place the radiofrequency (RF) electrode in the tumors. A 17-gauge internally cooled electrode with either a 2-cm or 3-cm exposed tip was used, depending on the tumor

Figure 2 The ablation protocol to avoid popping involves the initiation of power delivery from 40 V with increases of 5 V every minute to a maximum of 60 V until a break is observed.

size as observed during the study period. For tumors smaller than 2 cm in diameter, a 2-cm exposed tip was used, while for tumors 2 cm or larger in diameter, a 3-cm exposed tip was used. Overlapping ablation was performed in three cases in which the tumors were greater than 3 cm in diameter. The electrodes were then connected to a generator (Series CC-1, Radionics: Covidien at present). Power was delivered using an impedance control mode to avoid popping. The RF voltage was initially 40 V and was increased by 5 V every minute to a maximum of 60 V, with no limitations on ablation time (Figure 2). This protocol was applied consistently whether using a 2-cm or 3-cm exposed tip.

The occurrence of a break was considered as one of the reasons for terminating ablation. During RFA, patients were monitored for popping before reaching the first break; the impedance curve reflects the data collected prior to popping. The time that elapsed prior to the break was recorded by the performing surgeon. When it was determined that coagulation necrosis was obtained after review of the echogram or by measuring the temperature in the ablated site after the first break, the procedure was terminated; otherwise, it continued even after reaching a break multiple times. The equipment was configured so that a break automatically occurred when the impedance increased to 25 Ω before the start of RFA. Thereafter the RF power was automatically returned to 0 W. The occurrence of popping is defined as the audible explosion sound confirmed by the rapidly expanding, highly echoic area.

RF system

During each procedure, a computer with monitoring software was connected to the main unit of the generator to record the RF power (W), RF current (mA), RF voltage (V), temperature ($^{\circ}\text{C}$), and impedance (Ω) simultaneously (Figure 3).

Statistical analysis

All statistical analyses were conducted using JMP 8.0.2

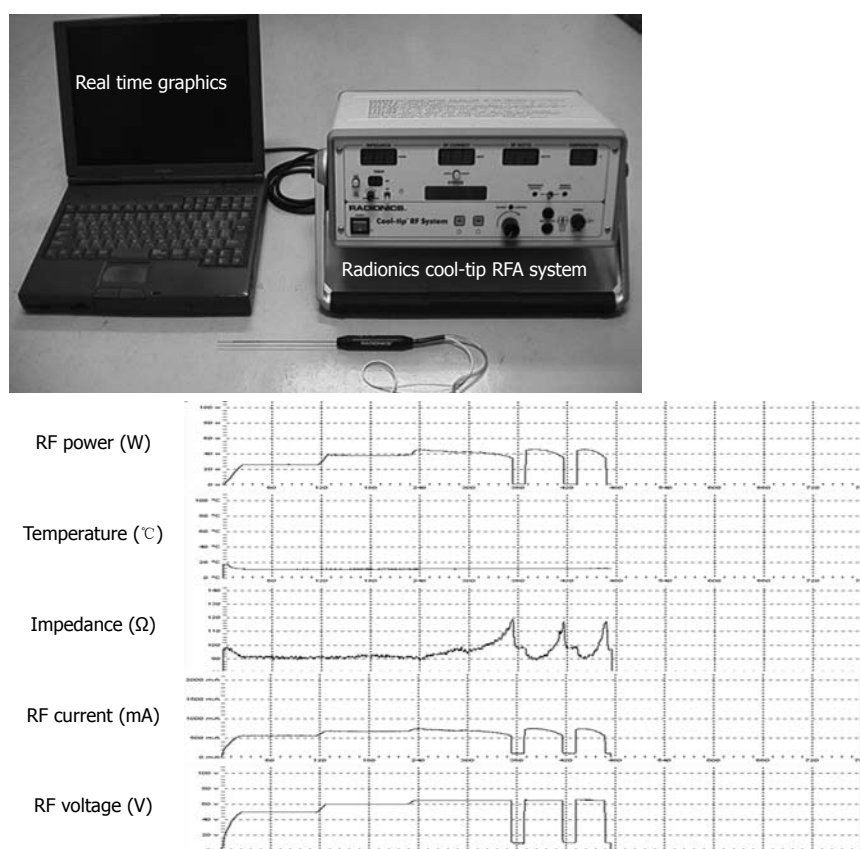

Figure 3 Radio frequency power, radio frequency current, radio frequency voltage, temperature and impedance were intraoperatively monitored using the equipment as shown in the diagram. RF: Radio frequency.

Table 1 Patient characteristics (140 patients, 148 nodules)

Characteristics	Value
Male/female (n/n)	94/46
Age (yr)	73.0 ± 11.1
ICGR 15 (%)	22.6 ± 14.4

software (Macintosh; SAS institute Japan). A χ^2 test was performed to identify any significant differences among the three types and among the seven subtypes. Differences were considered statistically significant at $P < 0.05$.

RESULTS

A total of 140 patients and 148 nodules treated by RFA were analyzed. The study samples included 132 nodules of hepatocellular carcinoma, 14 nodules of metastatic liver cancer, and two nodules of intrahepatic cholangiocarcinoma. Popping occurred in 73 out of the 148 RFA sessions (Table 1).

All 148 nodules were classified into three types according to the characteristics of their impedance curves up to the point where the first break took place (Figure 4): increasing-type nodules showed an increase in impedance; flat-type nodules showed a flat impedance curve; and decreasing-type nodules showed a decrease in impedance. Popping rates were determined for each type. The nodules were further sorted into seven subtypes, A to G, depending on the curvature of each impedance curve's increase or decrease up to the first break point. Likewise, popping rates were determined for each subtype (Figure 4).

Though there was no significant difference among subtypes in terms of maximum tumor diameters, type B exhibited significantly higher ICGR 15 levels than type C ($P = 0.028$). There was no distinct difference among subtypes in terms of tumor location (Table 2).

The nodule distribution was as follows: 37, 43 and

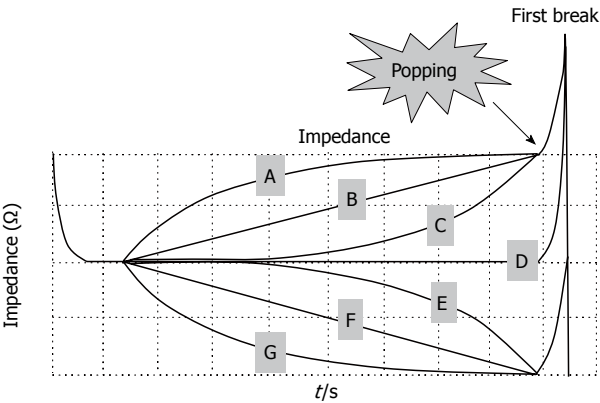

Figure 4 The graph showing the characteristic impedance curve shapes leading to the break point. The graph showing the seven characteristic impedance curves leading to the break point, which dictated the subgroups into which the previously classified nodules were further sorted. A-C: Increasing type; D: Flat type; E-G: Decreasing type; B, D, F: Three characteristic impedance curve shapes leading to the first break point, into which the 148 nodules were classified: increasing, flat and decreasing.

68 for increasing, flat and decreasing types, respectively. Popping occurred with nine increasing-type nodules (24.3%), 20 flat-type nodules (46.5%), and 44 decreasing-type nodules (64.7%) (Figure 5). Flat-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P = 0.039$). Decreasing-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P < 0.0001$). Regarding the subtype analysis, the popping occurrence rates were 1/2 (50%) for nodule subtype A, 3/9 (33.3%) for B, 5/26 (19.2%) for C, 20/43 (46.5%) for D, 19/23 (86.4%) for E, 14/21 (66.7%) for F and 11/24 (45.8%) for G (Figure 5). Notably, subtype E showed a rapid decrease in impedance during the latter half of the ablation period and exhibited a significantly higher rate of popping compared to subtypes B ($P = 0.006$), C ($P < 0.0001$), D ($P = 0.004$) and G ($P = 0.008$). The results for subtype A could not be examined statistically because of the small number of samples.

With respect to the lengths of the needles that were used, popping occurred during 36 out of the 79 (45.6%) RFA sessions using a 2-cm exposed tip, and 37 out of the 69 (53.6%) RFAs using a 3-cm exposed tip ($P = 0.328$). The distribution of nodules treated by a 2-cm exposed tip was as follows: A ($n = 2$), B ($n = 5$), C ($n = 14$), D ($n = 23$), E ($n = 11$), F ($n = 12$) and G ($n = 12$). The distribution of those treated using a 3-cm exposed tip was as follows: A ($n = 0$), B ($n = 4$), C ($n = 12$), D ($n = 20$), E ($n = 12$), F ($n = 9$) and G ($n = 12$). Popping was most common in the subtype E nodules, which showed a rapid decrease in impedance during the latter half of ablation, regardless of the exposed tip length (2 cm: 9/11 = 81.8%; 3 cm: 10/12 = 83.3%). Among 14 metastatic liver cancer samples, popping occurred in seven cases with the highest occurrence in subtypes E

Table 2 Tumor characteristics for each impedance type (148 nodules)

Impedance subtype	Maximum tumor diameter (mm) ¹	ICGR 15 (%) ¹	Tumor location (segments 1,2,3,4,5,6,7,8) ²
A	20.3±6.0	17.8±13.9	(0,1,0,0,0,0,1)
B	20.4±5.3	29.8±10.7 ^a	(1,1,1,1,1,2,1,1)
C	21.2±8.1	19.9±11.1	(0,3,3,3,5,3,3,6)
D	22.7±6.7	24.2±17.9	(0,2,8,4,8,6,4,11)
E	22.7±6.3	21.4±10.2	(1,2,1,2,1,3,8,5)

(2/3 = 66.7%) and F (2/3 = 66.7%). Popping occurred in neither of the two intrahepatic cholangiocarcinomas. TACE was performed prior to RFA in 35 nodules; in these TACE cases, popping was found in subtypes C (2/6 = 33.3%), D (4/8 = 50.0%), E (3/3 = 100%), F (3/9 = 66.6%) and G (3/9 = 66.6%). No nodule of TACE was classified as subtype A or B. We also evaluated 48 nodules located on the surface of the liver and 100 nodules close to major vessels. Among 48 nodules that were on the surface of the liver, popping was observed in subtypes A (1/1 = 100%), B (1/3 = 33.3%), C (2/10 = 20.0%), D (4/10 = 40.0%), E (9/11 = 81.8%), F (4/7 = 57.1%) and G (4/6 = 66.7%). Among 100 nodules close to major vessels, popping occurred in subtypes A (0/1 = 0%), B (2/6 = 33.3%), C (3/16 = 18.8%), D (16/33 = 48.5%), E (10/12 = 83.3%), F (10/14 = 71.4%) and G (7/18 = 38.9%). Among the samples in which TACE was performed prior to RFA, popping was observed in subtype E most frequently, regardless of tumor location.

DISCUSSION

Although the rate of complications caused by RFA varies among hospitals, it is generally between 2.2% and 9.5%^[29-33]. Peritoneal dissemination is one of the most serious complications that should be avoided and for which certain types of tumors are reportedly at a high risk, particularly subcapsular liver tumors and hepatocellular carcinomas that are poorly differentiated or that have high levels of alpha fetoprotein^[34,35]. Several studies have also shown that tumors abutting the main portal vein are at a high risk of rapid intrahepatic dissemination^[36,37]. Consequently, RFA should be performed with special caution when treating tumors that have developed close to the subcapsular or main vessel. In our hospital, because of these risks, liver tumors in these regions have been treated by RFA with limited power delivery to avoid complications.

Our results showed that decreases in impedance, particularly a rapid decrease in impedance during the latter half of the ablation period, strongly predict popping. We

Figure 5 Subtype E (nodules that showed a rapid decrease in impedance during the latter half of the ablation) exhibited a significantly higher rate of popping compared to subtypes B, C, D and G ($P < 0.05$). Decreasing-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P < 0.0001$). Flat-type nodules exhibited a significantly higher rate of popping compared to increasing-type nodules ($P = 0.039$).

investigated tumor location, diameter, and hepatic function reserve in each subtype of impedance. We used an ICGR value of 15 min for the hepatic functional reserve test. The principle is that indocyanine green (ICG) is transported to the liver in association with lipoprotein in the blood and then ingested by hepatocytes. We calculated the retention rate of ICG after 15 min of injection. If hepatic functional reserve is impaired, the retention rate is high. The result achieved with an ICGR of 15 min showed that the rate of popping was slightly higher in subtype B than in subtype C ($P = 0.028$). There were no significant differences among subgroups. We did not find any relationship between the impedance curve and the hepatic function reserve. Tumor location and diameter were also similar among the subtypes.

The reason for the drop in impedance just before the occurrence of popping is that the elevation of intra-tissue temperature activates intra-tissue molecular movement, which results in higher electrical conductivity. Electrical conductivity is the amount of electricity that a substance can conduct, and it varies for different substances, e.g., 5% NaCl has an electrical conductivity of 67 mS/cm, and 5% HCl has an electrical conductivity of 395 mS/cm. The electrical conductivity of a substance increases as the temperature rises, and it can be estimated with the formula $k_T = k_{25} [1 + 0.02 (T - 25)]$, where k_T is the electrical conductivity at temperature T ($^{\circ}\text{C}$), and k_{25} is the electrical conductivity at 25 $^{\circ}\text{C}$. Because tissue impedance is inversely related to electrical conductivity, tissue temperature increases as tissue impedance de-

creases. Thus, an abrupt decrease in impedance can be an indication of a rapid increase in intra-tissue temperature, possibly leading to steam popping following the vaporization of intra-tissue fluid.

The most favorable pattern of impedance curvature exhibited during the ablation period is the increasing type, which indicates that tissue coagulation occurs in parallel with an elevation in tissue temperature alongside a gradual increase in tissue impedance. If the temperature of intra-tissue fluid rises above 100 °C and starts to vaporize, the tissue impedance decreases, resulting in popping. As for the reason for the variation in impedance curves obtained with the same RFA protocol, we believe that fluid produced through coagulation may have played a part in some way.

Between June 2004 and January 2006, when we implemented RFA in the conventional protocol, major complications associated with RFA were observed in three out of 305 cases (0.98%). It was determined that popping had occurred during all three cases. Following this outcome, we opted for a lower power output when treating tumors on the surface of the liver or in close proximity to major vessels. Although no significant differences were found, this modified protocol may have contributed to a decrease in complications; hemobilia as a postoperative complication occurred in only one out of 473 cases (0.21%). The rates of local recurrence were equivalent in the conventional and modified protocols: 42 out of 305 cases (13.8%) between June 2004 and January 2006, and 48 out of 473 cases (10.1%) between February 2006 and November 2008. Based on the present study findings, we reduce the power delivery if we observe impedance curvatures that signal imminent popping. Between December 2008 and November 2011, we performed RFA on 731 nodules using the modified protocol; popping occurred for only 44 nodules (6.0%). No severe complication was observed in any of these cases.

There were several limitations on our analysis that have to be acknowledged. The first limitation concerns the patients excluded: for the 54 patients who showed unstable impedance curves, popping remained unpredictable; for the 86 patients who did not reach the break point during RFA (meaning that complete coagulation necrosis had not been achieved according to the present consensus on break points), there was a relatively higher risk of tumor recurrence. Second, due to a limitation resulting from the nature of our retrospective study design, a further prospective study will be necessary to confirm whether using the modified method actually improves the complication rate among patients whose tumors are close to major vessels or located subcapsularly.

In conclusion, by monitoring intraprocedural impedance during the RFA procedure, it is possible to predict popping in certain cases.

gake, Clinical Engineer at Meiwa Hospital and to Hidehiko Waki, a Clinical Technologist at Meiwa Hospital.

COMMENTS

Background

Radiofrequency ablation (RFA) is one of the most effective and safe treatments administered to patients with liver tumors. Certain complications may be induced in association with RFA, such as liver abscess, gastrointestinal tract injury, bleeding, subcapsular hematoma, biliary tract injury, portal vein thrombosis, and peritoneal seeding. A modified protocol used to address the concern of complications related to RFA has been introduced in recent years. This procedure reportedly decreased the frequency of popping by limiting power delivery.

Research frontiers

Popping is a phenomenon of vapor explosion that can occur during RFA. Popping occurs if water vaporizes prior to tumor coagulation and may pose a risk of complications. RFA using low power delivery has been advocated to avoid this phenomenon. The authors applied this procedure for the treatment of tumors near Glisson's capsule or the surface of the liver.

Innovations and breakthroughs

The authors monitored and analyzed the impedance curves to identify the characteristic warning signs that precede popping. It was found that popping was most frequent in nodules that exhibited a rapid decrease in impedance during the latter half of the ablation. This is the first such investigation.

Applications

By monitoring the intraprocedural impedance during RFA, it is possible in certain cases to predict popping. To avoid popping, power delivery should be limited when an impedance curve displays the characteristic warning signs.

Terminology

Popping is a phenomenon that refers to a form of explosive tissue disruption caused by a rapid elevation of intra-tissue pressure. The occurrence of popping should be avoided during RFA due to the risk of complications. During RFA, tumor necrosis is caused by protein coagulation, which occurs at a temperature of approximately 60 °C. However, if the temperature rises above 100 °C prior to achieving protein coagulation, intra-tissue fluid vaporizes and the tissue volume expands to approximately 1700 times that of the initial volume. This is the mechanism underlying popping, which can be anticipated through the use of intraprocedural impedance monitoring.

Peer review

The topic deals with the issue of RFA efficacy control, and the ideas presented seem to be of interest for those involved in liver tumor management. The manuscript is well structured. Materials and methods are appropriately characterized and results with tables and pictures provide evidence to draw conclusions.

received combination treatment were enrolled and assigned randomly to the derivation and confirmatory groups. Single nucleotide polymorphisms at or nearby *ITPA* were genotyped by real-time detection polymerase chain reaction. Factors influencing significant anemia (hemoglobin concentration < 10.0 g/dL at week 4 of treatment) and significant hemoglobin decline (declining concentrations > 3.0 g/dL at week 4) were analyzed using multiple regression analyses. Prediction formulae were constructed by significantly independent factors.

RESULTS: Multivariate analysis for the derivation group identified four independent factors associated with significant hemoglobin decline: hemoglobin decline at week 2 [$P = 3.29 \times 10^{-17}$, odds ratio (OR) = 7.54 (g/dL)], estimated glomerular filtration rate [$P = 2.16 \times 10^{-4}$, OR = 0.962 (mL/min/1.73 m²)], rs1127354 ($P = 5.75 \times 10^{-4}$, OR = 10.94) and baseline hemoglobin [$P = 7.86 \times 10^{-4}$, OR = 1.50 (g/dL)]. Using the model constructed by these factors, positive and negative predictive values and predictive accuracy were 79.8%, 88.8% and 86.2%, respectively. For the confirmatory group, they were 83.3%, 91.0% and 88.3%. These factors were closely correlated with significant anemia. However, the model could not be constructed, because no patients with rs1127354 minor genotype CA/AA had significant anemia.

CONCLUSION: Reliable formulae for predicting the likelihood of ribavirin-induced anemia were constructed. Such modeling may be useful in developing individual tailoring and optimization of ribavirin dosage.

Several factors including *ITPA* polymorphism influence ribavirin-induced anemia in chronic hepatitis C. *World J Gastroenterol* 2012; 18(41): 5879-5888 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i41/5879.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i41.5879>

INTRODUCTION

Development and availability of nonstructural (NS) 3 serine protease inhibitors (PIs), such as telaprevir and boceprevir, further improve treatment outcome in combination with pegylated interferon (peg-IFN) α and ribavirin (RBV) for chronic hepatitis C virus (HCV) genotype 1 infection, while the addition of novel antiviral agents increases the frequency and severity of adverse effects (including anemia), medication costs and the complexity of treatment regimens^[1-3]. Triple combination therapy with PI, RBV and peg-IFN α will be the first-line treatment for the HCV genotype 1 infection until the establishment of combination with NS3/4A PIs and NS5B polymerase or NS5A inhibitors^[4]. Meanwhile, conventional peg-IFN α plus RBV combination will be in demand for easy-to-treat patients who are infected with HCV genotype 2 or 3 or low viral loads and those who contraindicate or are intolerant of triple combination therapy. Accordingly, peg-IFN α plus RBV combination will assume a crucial role in the treatment of HCV infection for the foreseeable future.

In RBV-based treatment, hemolytic anemia is common and one of the major critical adverse effects^[1-3,5-7] and therefore makes it difficult for patients to tolerate treatment continuation, resulting in early dose reduction or premature withdrawal that may diminish the treatment efficacy. So far, many factors have been reported to be significantly associated with the significant anemia that could necessitate dose reduction or discontinuation^[8-20]. Specifically, host genetic variants at the inosine triphosphatase (*ITPA*) gene located on chromosome 20 (20p13 region) that lead to *ITPA* deficiency or low activity have an overwhelming impact on protection against RBV-induced hemolytic anemia, and decrease the need for RBV dose reduction at week 4 of treatment and throughout the treatment course^[15-18]. However, there are few reports that provide a convenient prediction model or scoring system for pretreatment screening or early identification of clinically significant anemia that has been defined previously and used generally^[15].

To modify RBV dose prior to treatment or during the early treatment phase and continue treatment as long

as possible, the present study focused on the construction of a convenient and useful model for predicting the likelihood of clinically significant anemia and quantitative decline in the hemoglobin (Hb) concentration from baseline at week 4 of treatment in peg-IFN α plus RBV treatment for chronic hepatitis C patients infected with HCV genotype 1b. Easy identification of candidates at a high risk for clinically significant anemia may facilitate intensive safety monitoring in combination treatment.

MATERIALS AND METHODS

Study population and protocol

Between 2006 and 2010, 561 chronic hepatitis C patients infected with HCV genotype 1b were consecutively enrolled in this study at Katsushika Medical Center and Kashiwa Hospital, The Jikei University School of Medicine, and Shinmatsudo Central General Hospital. Patients received peg-IFN α -2b at a dose of 1.5 μ g/kg or peg-IFN α -2a at a dose of 180 μ g once weekly and RBV at a dose of 600-1000 mg twice daily for 48 wk. The dose of RBV was adjusted according to body weight (BW); 600 mg for ≤ 60 kg, 800 mg for > 60 kg to ≤ 80 kg, and 1000 mg for > 80 kg. Leading inclusion criteria were chronic hepatitis C that were diagnosed by laboratory, virology and histology; HCV genotype 1b confirmed by the conventional polymerase chain reaction (PCR)-based method; acquisition of written informed consent to the provision of genetic material; availability of genetic DNA for genotyping single nucleotide polymorphisms (SNPs); absence of liver cancer, liver failure or other forms of liver disease; and lack of concurrent treatment with any other antiviral or immunomodulatory agent. The study protocol was conducted in accordance with the provisions of the Declaration of Helsinki and Good Clinical Practice guidelines and was approved by the Institutional Review Boards of all participating sites.

Clinical and laboratory data were assessed at baseline, once weekly during the first 4 wk, and thereafter every 4 wk. As described previously^[15], significant anemia was provisionally defined as Hb concentrations of < 10.0 g/dL at week 4 of treatment, and significant Hb decline was defined as a decline in Hb concentration of > 3.0 g/dL at week 4 of treatment. The reasons for choosing this time point (the end of 4 wk after treatment initiation) were as follows: (1) dose of RBV or peg-IFN was not reduced in most patients, and thus Hb dynamics would not be affected by treatment modification and could be evaluated in an unbiased manner; and (2) Hb decline within the first 4 wk is most prominent throughout the treatment period and reaches a nadir after approximately 4-6 wk^[6,11].

At baseline, creatinine clearance (Ccr; mL/min) was estimated by using the Cockcroft-Gault formula^[21]: Ccr (for male) = $[(140 - \text{age}) \times \text{BW (kg)}] / (72 \times \text{Scr})$ (Scr, serum creatinine; Ccr $\times 0.85$ for female). Estimated glomerular filtration rate (GFR, mL/min/1.73 m²) was

calculated according to the formula proposed by the Japanese Society of Nephrology: GFR (for male) = $194 \times \text{Scr}^{-1.094} \times \text{Age}^{-0.287}$ (GFR \times 0.739 for female). Apparent clearance of ribavirin (CL/F, L/h) was determined as follows^[9]: CL/F = $32.3 \times \text{BW} \times (1 - 0.0094 \times \text{age}) \times (1 - 0.42 \times \text{gender}) / \text{Scr}$ (gender = 0 for male and 1 for female; Scr is in $\mu\text{mol/L}$). All liver biopsy specimens were reviewed by using the established ranking system for staging of fibrosis and grading of necroinflammation activity with some modification^[22].

Virological data were assessed by monitoring serum HCV RNA levels every 4 wk during and off treatment. Viral loads were measured using a quantitative PCR assay (Amplicor HCV Monitor version 2.0 or Amplicor HCV

version 2.0; Roche Diagnostics, Basel, Switzerland). The presence or absence of serum HCV RNA was assessed using a qualitative PCR assay (Amplicor HCV version 2.0). Virological response (VR) was defined as undetectable HCV RNA by the end of treatment. Rapid virological response and slow virological response (SVR) were defined as undetectable HCV RNA at week 4 of treatment and 24 wk post-treatment. VR with relapse was defined as VR during treatment but reappearance of HCV RNA during the follow-up period. Nonvirological response (NVR) was defined as persistent presence of HCV RNA throughout the treatment.

SNP genotyping of *ITPA* and *C20orf194*

Genomic DNA was extracted from whole blood using the MagNA Pure LC and the DNA Isolation Kit (Roche Diagnostics). Genetic polymorphisms, rs1127354 at the *ITPA* exon 2^[15,17,18] and rs6051702 at the *C20orf194*^[15,18], were genotyped by real-time detection PCR using the TaqMan SNP Genotyping Assays (Applied Biosystems, Foster City, CA, United States). Another functional (splicing variant-related) SNP at the *ITPA* intron 2, rs727010, was not examined because no polymorphisms were observed in the Asian genetic population, as registered in the HapMap Project database and reported previously^[17,18,23].

Statistical analysis

Mantel-Haenszel, Pearson χ^2 test or Mann-Whitney test was used to compare frequencies in categorical data or differences in continuous data between two groups, respectively. Time-course changes in Hb decline from baseline were evaluated by using repeated measures analysis of variance. Possible variables influencing significant anemia and significant Hb decline included baseline characteristics (Table 1). Variables that reached statistical significance ($P < 0.05$) or marginal significance ($P < 0.10$) in univariate comparisons were subsequently entered into multiple logistic regression analysis using forward and backward stepwise selection method to identify significantly independent factors associated with each anemic event. Based on the final-step results, score (S) was constructed by the exposure of some set of independent factors (x_1, x_2, \dots, x_p):

$$S = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_p x_p \quad (\beta_0: \text{Intercept}, \beta_1, \beta_2, \dots, \beta_p: \text{Regression coefficients}).$$

The model could be expressed as: $P = 1/[1 + \exp(-S)]$, where $P > 0.5$ was development of anemic events and $P < 0.5$ was non-development of anemic events.

Hosmer-Lemeshow goodness of fit test and likelihood-ratio χ^2 test were used and positive/negative predictive values and predictive accuracy were calculated to evaluate the fitness of the model. Split-group validation was used to develop and validate the best fitness of the model. Patients were randomly divided into two groups in the ratio of 2:1 by using a computer-generated random number list: 66.7% of the patients (374 patients) were as-

Table 2 Time-course changes in hemoglobin concentration from baseline

	Week 2 of treatment	Week 4 of treatment
Overall cohort		
mean (SD), g/dL	-1.12 (1.13)	-2.31 (1.39)
Median (25th–75th quartile), g/dL	-1.05 (-1.8 to -0.3)	-2.3 (-3.2 to -1.3)
Derivation group		
mean (SD), g/dL	-1.09 (1.11)	-2.27 (1.40)
Median (25th–75th quartile), g/dL	-1.0 (-1.8 to -0.3)	-2.3 (-3.1 to -1.3)
Confirmatory group		
mean (SD), g/dL	-1.18 (1.17)	-2.33 (1.37)
Median (25th–75th quartile), g/dL	-1.1 (-1.95 to -0.4)	-2.3 (-3.3 to -1.35)

signed to the derivation group and 33.3% (187 patients) to the confirmatory group. The reproducibility of the resulting model based on data from the derivation group was assessed with data from the validation group. Receiver operating characteristic (ROC) curves were generated with every cut-off point of predicted probability of significant Hb decline corresponding to each Hb decline at week 2. For a balanced optimization of both sensitivity and false-positive rate [= (1 - specificity)], an optimal cut-off point value was determined by maximizing Youden's index (= sensitivity + specificity - 1). The area under the ROC curve (AUC) was calculated to assess the degree of discrimination provided by the two parameters. To formulate a predictive value of quantitative Hb decline at weeks 2 and 4, the association between Hb decline and baseline variables was also analyzed using multiple linear regression analysis. The fitness of the model was evaluated by using values of *R* and *R*² and Durbin-Watson test. The correlation between predictive and measured values in Hb decline was assessed by Spearman's ρ . All *P* values for statistical tests were two tailed and values < 0.05 denoted the presence of a statistically significant difference. All data analyses were performed using the SPSS statistical package for Windows, version 17.0 (SPSS, Chicago, IL, United States).

RESULTS

Patient profiles and treatment-induced anemia

Baseline characteristics of the study population are summarized in Table 1. There were no significant differences in the patient profiles between the groups. The mean (SD) and median (25th to 75th quartiles) of Hb decline from baseline at week 2 and 4 of treatment are shown in Table 2. The changes at each time point were not statistically different between the groups. Significant Hb decline was observed in 113 of 374 (30%) derivation group patients and 58 of 187 (31%) confirmatory group patients. Significant anemia was observed in 51 of 374 (14%) patients and 30 of 187 (16%) patients, respectively. Incidence of these anemic events was similar between

the groups. Most of the patients complained of dyspnea on effort, easy fatigability or lightheadedness. None received erythropoiesis-stimulating agents throughout the treatment period.

Of the overall patients, 255 (45%) achieved SVR, 165 (29%) had VR with relapse, and 141 (25%) showed NVR. Of the 374 derivation group patients, SVR was 45% (167 patients), VR with relapse was 30% (111 patients) and NVR was 26% (96 patients). Of the 187 confirmatory group patients, they were 47% (88 patients), 29% (54 patients) and 24% (45 patients), respectively. Treatment outcome was almost equal among the overall cohort and split groups.

Baseline factors associated with significant Hb decline

To construct the prediction model for significant Hb decline, baseline variables were statistically analyzed in the derivation group (Table 3). Patients who showed significant Hb decline were more likely to be male (*P* = 0.0163), have higher BW (*P* = 0.00518), higher body mass index (BMI; *P* = 0.00593), larger body surface area (BSA; *P* = 0.0139), higher albumin (*P* = 0.00688), higher creatinine (*P* = 4.71×10^{-4}), higher Hb (*P* = 7.75×10^{-8}), lower GFR (*P* = 5.69×10^{-4}), and SNP rs1127354 major

Figure 1 Anemic event rates in subset groups of each significantly independent baseline factor. The inosine triphosphatase single nucleotide polymorphism rs1127354 genotype, baseline hemoglobin (Hb) concentration and estimated glomerular filtration rate (GFR) were significantly associated with anemic events. Black and white vertical rectangles indicate significant anemia (< 10.0 g/dL at week 4 of treatment) and significant Hb decline (> 3.0 g/dL at week 4 of treatment), respectively.

genotype CC ($P = 8.04 \times 10^{-10}$).

Multiple logistic regression analysis identified three independent variables that were significantly associated with significant Hb decline (Table 3): baseline Hb [$P = 1.29 \times 10^{-9}$, odds ratio (OR) = 1.89 (g/dL), 95% confidence interval (CI): 1.54-2.32], SNP rs1127354 ($P = 1.60 \times 10^{-7}$, OR = 28.26, 95%CI: 8.10-98.62), and GFR [$P = 6.46 \times 10^{-4}$, OR = 0.959 (mL/min/1.73 m²), 95%CI: 0.942-0.977]. The model was expressed as: $S = -9.369 + 0.635 \times \text{baseline Hb} + 3.342 \times \text{SNP rs1127354}$ (where genotype CC was 1 and CA/AA was 0) $-0.041 \times \text{GFR}$. P values were 0.401 and 9.79×10^{-24} in the Hosmer-Lemeshow test and likelihood-ratio χ^2 test, respectively. Positive and negative predictive values and predictive accuracy were 67.5%, 79.9% and 77.0%, respectively. To validate the prediction model, it was used for the confirmatory group. Positive and negative predictive values and predictive accuracy were 76.7%, 79.7% and 79.0%, respectively. For the overall cohort, these values were 70.8%, 79.9% and 77.7%, respectively. Significant Hb decline was not associated with treatment outcome in the overall cohort [SVR, 40% (69/171); VR, 32% (55/171); and NVR 27% (47/171)] or split groups.

Baseline factors associated with significant anemia

Female ($P = 0.00896$) and older ($P = 0.0443$) patients, and those with lower albumin ($P = 0.0197$), lower white blood cell count ($P = 0.0226$), lower baseline Hb ($P = 5.34 \times 10^{-13}$), lower Ccr ($P = 1.06 \times 10^{-4}$), lower GFR ($P = 2.69 \times 10^{-4}$), lower CL/F ($P = 6.59 \times 10^{-5}$), lower BW ($P = 0.00309$), smaller BSA ($P = 0.0254$), and rs1127354 major genotype CC ($P = 2.76 \times 10^{-5}$) were more likely to have significant anemia than those who did not. In multiple logistic regression analysis, the model could not be constructed by these variables, because no patients with rs1127354 minor genotype CA/AA suffered from

significant anemia in this study population (Figure 1). All patients with significant anemia had rs1127354 major genotype CC. When SNP rs1127354 was excluded from the multivariate analysis, baseline Hb [$P = 1.67 \times 10^{-9}$, OR = 0.376 (g/dL), 95%CI: 0.274-0.517] and GFR [$P = 0.00233$, OR = 0.962 (mL/min/1.73 m²), 95%CI: 0.938-0.986] were significantly independent variables. Significant anemia was not associated with treatment outcome in the overall cohort [SVR, 31% (25/81); VR, 36% (29/81); and NVR 33% (27/81)] or split groups.

Figure 1 shows the incidence rates of significant anemia and significant Hb decline in the overall cohort according to the three significantly independent factors. Specifically, SNP rs1127354 had an overwhelming impact on the anemic events. In 431 patients with major genotype CC, significant anemia and significant Hb decline developed in 81 (19%) and 168 (39%) patients, respectively. In contrast, none (0%) and three (2%) of 130 patients with minor genotype CA/AA showed each anemic event, respectively, as described above. Positive predictive values of SNP rs1127354 alone for the likelihood of significant anemia and significant Hb decline were 14.3% and 39.1%, respectively. Negative predictive values were 100% and 97.7%, respectively. Values of predictive accuracy were 35.7% and 53.5%, respectively. Figure 2 depicts time-course changes in qualitative Hb decline from baseline according to SNP rs1127354 genotypes. The SNP genotype significantly influenced Hb decline at week 2 as well as week 4 ($P = 5.437 \times 10^{-9}$).

Contribution of Hb decline at week 2 of treatment

Hb decline from baseline at week 2 of treatment, an on-treatment factor, significantly influenced significant Hb decline ($P = 1.96 \times 10^{-33}$). An ROC curve was depicted to identify an optimal cut-off point for prediction of significant Hb decline by using Hb decline at week 2

Figure 2 Hemoglobin decline from baseline at week 2 and 4 of treatment according to the inosine triphosphatase single nucleotide polymorphism rs1127354 genotypes. Bars within boxes denote the median value of hemoglobin (Hb) decline from baseline. The boxes and the lower and upper bars represent the 25th to 75th percentiles, and the 10th and 90th percentiles, respectively. The single nucleotide polymorphism genotype significantly influenced Hb decline at week 2 and 4 ($P = 5.437 \times 10^{-9}$ in repeated measures analysis of variance).

Figure 3 Receiver operating characteristic curves generated with every cut-off point of predicted probability of significant hemoglobin decline (> 3.0 g/dL at week 4 of treatment) corresponding to each hemoglobin decline from baseline at week 2 of treatment. The area under the curve was 0.913 (95% confidence interval: 0.885-0.941, $P = 4.08 \times 10^{-43}$). When the sensitivity and false-positive rate were 0.844 and 0.131, the Youden's index value of 0.713 was maximal. The optimal cut-off point of hemoglobin decline at 2 wk was 1.45 g/dL.

(Figure 3). The AUC was 0.913 (95%CI: 0.885-0.941, $P = 4.08 \times 10^{-43}$). The maximal value of Youden's index was 0.713. The sensitivity and false-positive rate were 0.844 and 0.131, respectively. The optimal cut-off point of Hb decline at week 2 was 1.45 g/dL.

When this variable, together with baseline variables, was incorporated into multiple logistic regression analysis to generate a statistic model for predicting significant Hb decline, the re-performed analysis using the derivation group data identified four significantly independent variables: Hb decline at week 2 [$P = 3.29 \times 10^{-17}$, OR = 7.54 (g/dL), 95%CI: 4.71-12.05], GFR [$P = 2.16 \times 10^{-4}$,

Figure 4 Correlation between predicted and measured values of hemoglobin decline at week 4 of treatment. Predicted values were yielded by the multiple linear regression model that was constructed in the derivation group. Measured values were derived from the confirmatory group. There was a significant correlation between predicted and measured values (Spearman's $\rho = 0.880$, $P = 1.16 \times 10^{-56}$). The area between lower and upper parallel lines of the diagonal line includes 95% of patients analyzed.

OR = 0.962 (mL/min/1.73 m²), 95%CI: 0.942-0.982], rs1127354 ($P = 5.75 \times 10^{-4}$, OR = 10.94, 95%CI: 2.80-42.71), baseline Hb [$P = 7.86 \times 10^{-4}$, OR = 1.50 (g/dL), 95%CI: 1.18-1.90]. The model was expressed as: $\hat{S} = -8.285 - 2.020 \times \text{Hb decline at week 2} - 0.039 \times \text{GFR} + 2.393 \times \text{SNP rs1127354}$ (where genotype CC was 1 and CA/AA was 0) + $0.405 \times \text{baseline Hb}$. P values were 0.587 and 1.59×10^{-58} in the Hosmer-Lemeshow test and likelihood-ratio χ^2 test, respectively. Positive and negative predictive values and predictive accuracy were 79.8%, 88.8% and 86.2%, respectively. These values were 83.3%, 91.0% and 88.3% in the confirmatory group, and 81.3%, 89.0% and 86.7% in the overall cohort.

Prediction of Hb decline value

To predict qualitative Hb decline value at week 4 of treatment, the multiple linear regression model was constructed using data from the derivation group. The statistic model was expressed as: $\hat{y} = 0.784 - 0.748 \times \text{Hb decline at week 2} - 0.878 \times \text{SNP rs1127354}$ (where genotype CC was 1 and CA/AA was 0) - $0.178 \times \text{baseline Hb} + 0.012 \times \text{GFR}$ ($R = 0.842$, $R^2 = 0.709$, adjusted $R^2 = 0.706$, Durbin-Watson test = 1.984, $P = 2.42 \times 10^{-7}$). There was a significant correlation between predicted values in the model and measured values in the confirmatory group (Spearman's $\rho = 0.880$, $P = 1.16 \times 10^{-56}$; Figure 4).

Next, qualitative Hb decline value at week 2 was estimated by significantly independent variables in the derivation group. The model was expressed as: $\hat{y} = 2.922 - 1.067 \times \text{SNP rs1127354}$ (where genotype CC was 1 and CA/AA was 0) - $0.276 \times \text{baseline Hb} + 0.008 \times \text{GFR}$ ($R = 0.528$, $R^2 = 0.279$, adjusted $R^2 = 0.274$, Durbin-Watson test = 0.537, $P = 4.49 \times 10^{-31}$). The correlation between predicted values in the model and measured values in the confirmatory group was statistically significant but rela-

tively weak (Spearman's $\rho = 0.566$, $P = 2.41 \times 10^{-17}$).

DISCUSSION

As mentioned in the introduction section, peg-IFN α plus RBV combination will be in demand for the foreseeable future. Patients at a high risk of developing RBV-induced hemolysis will expose themselves to a more increased risk for treatment-induced anemia in triple combination treatment. Identifying such high-risk patients and predicting the severity of anemia in individuals may provide an early decision to commence treatment with normal or reduced dosage and to keep the dose reduction to a minimum to lessen the disadvantages of anemia with adequate exposure to RBV continuing. To date, many studies have proposed factors that could influence the probability of clinically significant anemia in RBV-based treatment: age, sex^[11,12], race, pre-existing cirrhosis^[14], baseline Hb concentration^[11,20], Ccr^[14,20], CL/F^[8,9], drug exposure^[12-14], plasma RBV concentration^[10], Hb decline at week 2 of treatment^[12,14,20], and SNPs at the *ITPA*^[15-18], *C20orf194*^[15] and nucleoside transporter genes^[19]. However, the definition of anemia or end point of analysis varied a little among previous studies, possibly leading to alteration of significant predictors. Despite these useful predictors, there is no convenient prediction model or formula for estimating the likelihood of clinically significant anemia that has been defined previously and used generally^[15]. This study provided relevant numerical expressions constructed by independent variables for predicting the differentially defined anemia: Hb concentration < 10.0 g/dL (significant anemia) and a decline in Hb concentration > 3.0 g/dL (significant Hb decline) at week 4 of treatment and qualitative Hb decline at week 2 and 4. This is believed to be the first report to construct the prediction models by using reliable factors: the *ITPA* SNP rs1127354, baseline Hb concentration, estimated GFR, and quantitative Hb decline at week 2 of treatment, irrespective of the different definitions of anemia. The significant baseline factors that were shown in this study appear to influence treatment-induced anemia in triple combination treatment (under investigation, data not shown).

Two functional *ITPA* variants conferring *ITPA* deficiency or reduced activity are known to contribute most to protection against RBV-induced hemolytic anemia^[15-18]. Inosine triphosphate (ITP) is hydrolyzed by *ITPA* to inosine monophosphate. Therefore, *ITPA* deficiency or low activity causes the accumulation of ITP in red blood cells (RBCs)^[24-26]. The accumulated ITP may compete with the accumulated triphosphate form of RBV that could mediate oxidative damage to the RBC membrane and extravascular destruction^[25-27], thereby protecting RBCs against RBV-induced hemolysis. As also shown in this study, one functional SNP rs1127354 is prominently associated with differentially defined anemia. Of note, however, the SNP was not always a factor

of the top significance. The combined *ITPA* activity variable with another functional SNP rs7270101 is a stronger determinant of anemia than either *ITPA* SNP alone in European-Americans^[16], whereas rs7270101 is not polymorphous in the Japanese population as registered in the HapMap database and reported by others^[17,18,23]. One SNP, rs6051702 at the *C20orf194* located near the *ITPA*, linked to the *ITPA* SNPs, also confers protection against anemia in European-Americans^[15], while the association was statistically significant but weak in one Japanese cohort^[18]. This Japanese study population showed no significant association (Table 3), supporting that rs1127354 is a single causal variant responsible for protection against anemia in the Japanese genetic cohort^[17].

Certainly, the *ITPA* SNP rs1127354 minor variant A is a strong protective allele for anemia. In this overall cohort, none (0%) and three (3%; who had genotype CA) of patients with minor variant A had significant anemia and significant Hb decline, respectively (Figure 1). Therefore, negative predictive value of minor variant A was 100% and 97.7%, respectively. The noticeable distinction was in excellent agreement with other studies^[15,18]. With respect to the likelihood of these anemic events, patients with minor variant A may be monitored less intensively and recommended to receive normal RBV doses, even in patients with relatively low baseline Hb, or more aggressive dose escalation strategies irrespective of baseline Hb. It is noteworthy that genotype AA patients with predicted *ITPA* deficiency, including seven patients with baseline Hb < 13.0 g/dL (range, 11.7-12.9 g/dL), showed no or little change in the Hb concentration (data not shown), although the number was small.

As shown in this study and another^[18], however, only 25% of the Japanese population has minor variant A. The remaining 75% have major genotype CC. Positive predictive values of major genotype CC alone for significant anemia and significant Hb decline were low (14.3% and 39.1%, respectively), and values of predictive accuracy were low (35.7% and 53.5%, respectively). The range of Hb decline varied widely among individuals with genotype CC, indicating that some of them showed little or no change in Hb decline. Even in minor genotype CA carriers, it also varied widely and was similar to that of genotype CC patients (Figure 2). These findings strongly suggest that any factors other than the strong predictor *ITPA* SNP could affect hemolysis positively or negatively. Therefore, it is highly unlikely that the *ITPA* SNP (except genotype AA) is used alone to determine clinical decision making for treatment modification. In fact, several factors independently and strongly influenced treatment-induced anemia as well as the *ITPA* SNP in this study.

The clearance rate of RBV from the body is of critical importance for influencing treatment outcome and RBV-induced anemia, because the clearance parameters, such as CL/F and Ccr, reflect plasma/serum RBV con-

centrations at week 4 of treatment, which means the steady phase of treatment^[8-10,14,20,28]. Higher or lower values of the parameters are correlated closely with lower or higher plasma/serum concentrations, respectively. Higher plasma/serum concentrations lead to an increased risk for progression of anemia as well as the higher probability of achieving SVR. Indeed, this study confirmed that the clearance rate is associated significantly and independently with RBV-induced anemia irrespective of the different definitions. This study also analyzed which of three parameters estimated by the formulae were the most stable for predicting clinically significant anemia. These formulae are composed by age, sex, BW and serum creatinine. Age and sex have been reported to affect treatment-induced anemia and dose reduction, and could reflect reactivity to treatment, tolerance and pharmacological metabolism^[11,12,29]. Japan is one of the countries with the longest living people and the world's fastest aging society, therefore, the clearance rate should especially be taken into account in RBV-based treatment of Japanese patients. The reason that estimated GFR remained an independent factor in the final model may be that the formula has been built up based on data from the Japanese population.

Higher baseline Hb concentration was significantly associated with the likelihood of significant Hb decline. Conversely, lower baseline Hb concentration was linked to significant anemia. These findings may be a matter of course. However, most of this study population received treatment without RBV dose reduction as scheduled, suggesting that kinetics of Hb decline within the first 4 wk of treatment might be delayed in patients with lower baseline Hb concentration. A certain threshold of Hb concentration might limit the progression of anemia independent of baseline Hb concentration. At least in Japanese patients, the two different definitions of anemia, significant Hb decline and significant anemia, should be separately analyzed and discussed.

In this multivariate analysis, qualitative Hb decline at week 2 of treatment was most highly predictive of significant Hb decline, compared to the strong predictor *ITPA* SNP rs1127354 and other baseline factors. Previous studies have shown that Hb decline of 2.0 g/dL at week 2 of treatment was predictive of Hb concentration < 10 g/dL or < 8.5 g/dL during the treatment^[12,20]. In another study, Hb decline of 1.5 g/dL at week 2 was predictive of Hb decline \geq 2.5 g/dL at week 4^[14]. In this ROC analysis, the best cutoff value for Hb decline at week 2 was 1.45 g/dL. Taken together, Hb decline at week 2 is an excellent early predictor of subsequent Hb decline and could identify candidates for early intervention to maintain RBV dosing and adequate exposure. Indeed, the formula including this on-treatment variable improved positive and negative predictive values and predictive accuracy for significant anemia and significant Hb decline. When considered along with other independent baseline factors predictive of qualitative Hb decline at week 4, the final model yielded high significant values

that represented goodness of fit. Using such a timely on-treatment variable and formula, more exact identification of patients prone to clinically significant anemia, early intervention with RBV dose reduction, and more careful monitoring may be indicated to reduce anemia-related adverse effects and avoid premature discontinuation of RBV.

ITPA SNP rs1127354, baseline Hb concentration and estimated GFR influenced Hb decline at week 2 significantly and independently, as well as that at week 4. However, it appears to be difficult to predict qualitative Hb decline at week 2 by using the multiple linear regression model. The point for attention is that the models and formulae did not perfectly predict the likelihood of the anemia, strongly suggesting the possibility that other unidentified factors associated with early occurring anemia might be lost, such as rare SNPs, brittleness of the RBC membrane against intracellular triphosphate form of RBV, or intracellular concentration of ITP.

In conclusion, convenient formulae for qualitatively or quantitatively predicting the likelihood of differentially defined anemia could be generated by significant independent factors in RBV-based treatment for chronic HCV infection. Such trial modeling may be useful in guiding clinical decision making on treatment modification: identifying the predisposition to develop RBV-induced anemia before treatment initiation or at the early treatment phase, and developing the individual tailoring and optimization of RBV dosage to maximize the treatment efficacy and minimize RBV-related adverse effects.

COMMENTS

Background

In ribavirin (RBV)-based treatment for chronic hepatitis C, hemolytic anemia is a major adverse effect and makes it difficult to continue treatment as scheduled. Many factors have been reported to influence clinically significant anemia that could modify or discontinue treatment. However, the definition of anemia or end point of analysis varied somewhat among studies, leading to alteration of significant predictors. Despite these useful predictors, there is no convenient prediction model for estimating the probability of clinically significant anemia.

Research frontiers

Host genetic variation at the inosine triphosphatase (*ITPA*) gene that leads to *ITPA* deficiency or low activity are known to contribute greatly to protection against RBV-induced hemolytic anemia. However, it is highly unlikely that the *ITPA* single nucleotide polymorphism (SNP) alone is used to determine clinical decision making for treatment modification. Any factors other than the strong predictor *ITPA* SNP could affect hemolytic anemia positively or negatively.

Innovations and breakthroughs

This study provided relevant numerical expressions constructed by using significantly independent factors for predicting the differentially defined anemia. The reliable factors were the *ITPA* SNP rs1127354, baseline hemoglobin (Hb) concentration, estimated glomerular filtration rate and quantitative Hb decline

at week 2 of treatment, irrespective of the different definitions of anemia. These factors independently and strongly influenced RBV-induced anemia, as well as the ITPA SNP. The ITPA SNP was not always a factor of major significance.

Applications

Such modeling may be useful in guiding clinical decision making on treatment modification: more exactly identifying candidates at a high risk for clinically significant anemia or predicting the severity of anemia in individuals before treatment initiation or at the early treatment phase, and developing the individual tailoring and optimization of RBV dosage to maximize the treatment efficacy and minimize RBV-related adverse effects with adequate exposure to RBV continuing.

Peer review

Pegylated interferon plus RBV still assumes an important role in the treatment of chronic hepatitis C. The manuscript is well written and the study has investigated a crucial point of anti-HCV treatment. Interestingly, the authors observed patients who showed significant Hb decline and significant anemia, respectively, and showed that factors associated with anemia differed according to the definitions.

Abstract

AIM: To characterize the dual effects of deslanoside on the contractility of jejunal smooth muscle.

METHODS: Eight pairs of different low and high contractile states of isolated jejunal smooth muscle fragment (JSMF) were established. Contractile amplitude of JSMF in different low and high contractile states was selected to determine the effects of deslanoside, and Western blotting analysis was performed to measure the effects of deslanoside on myosin phosphorylation of jejunal smooth muscle.

RESULTS: Stimulatory effects on the contractility of JSMF were induced ($45.3\% \pm 4.0\%$ vs $87.0\% \pm 7.8\%$, $P < 0.01$) by deslanoside in 8 low contractile states, and inhibitory effects were induced ($180.6\% \pm 17.8\%$ vs $109.9\% \pm 10.8\%$, $P < 0.01$) on the contractility of JSMF in 8 high contractile states. The effect of deslanoside on the phosphorylation of myosin light chain of JSMF in low ($78.1\% \pm 4.1\%$ vs $96.0\% \pm 8.1\%$, $P < 0.01$) and high contractile state ($139.2\% \pm 8.5\%$ vs 105.5 ± 7.34 , $P < 0.01$) was also bidirectional. Bidirectional regulation (BR) was abolished in the presence of tetrodotoxin. Deslanoside did not affect jejunal contractility pretreated with the Ca^{2+} channel blocker verapamil or in a Ca^{2+} -free assay condition. The stimulatory effect of deslanoside on JSMF in a low contractile state (low Ca^{2+} induced) was abolished by atropine. The inhibitory effect of deslanoside on jejunal contractility in a high contractile state (high Ca^{2+} induced) was blocked by phentolamine, propranolol and L-NG-nitro-arginine, respectively.

tional regulation (BR) was abolished in the presence of tetrodotoxin. Deslanoside did not affect jejunal contractility pretreated with the Ca^{2+} channel blocker verapamil or in a Ca^{2+} -free assay condition. The stimulatory effect of deslanoside on JSMF in a low contractile state (low Ca^{2+} induced) was abolished by atropine. The inhibitory effect of deslanoside on jejunal contractility in a high contractile state (high Ca^{2+} induced) was blocked by phentolamine, propranolol and L-NG-nitro-arginine, respectively.

CONCLUSION: Deslanoside-induced BR is Ca^{2+} dependent and is related to cholinergic and adrenergic systems when JSMF is in low or high contractile states.

INTRODUCTION

More than 200 naturally occurring cardiotonic glycosides (CGs, cardiac glycosides) have been identified to date^[1].

CGs have long been and will continue to be used in the treatment of congestive heart failure and have entered the clinical trial phase for treating cancer^[2-5]. CGs enhance the myocardial contraction by increasing intracellular Ca^{2+} *via* inhibiting the activities of Na^+/K^+ -ATPase^[6-8]. CGs ouabain has been found to induce excitation on colonic smooth muscle^[9]. Toxic effects of CGs are observed in clinics, e.g., atrioventricular block, bradycardia, and gastrointestinal irritation^[1]. Probably due to the fact that no therapeutic applications are yet known, the characteristics of CGs on the intestinal motility have rarely been investigated.

Intestinal motility is mainly modulated by neurotransmitters and hormones; the neuronal regulation of intestinal motility involves intrinsic, e.g., enteric nervous system (ENS), as well as extrinsic nerves, e.g., the sympathetic and parasympathetic nervous system (SPNS)^[10]. The central nervous system is able to modulate, but not entirely control, the motor activity by sending instructions *via* SPNS, and ENS modulates the motility of intestinal smooth muscle even when isolated from the body to fulfill pivotal functions^[10,11]. In this study, we proposed a hypothesis that inducible bidirectional regulation (BR) is the major autonomous control of intestinal motility in the absence of CNS control, and that both low and high contractile states of intestinal smooth muscle can be regulated back toward normal contractile state by a single CGs deslanoside-induced BR. To test the hypothesis, different low and high contractile states of intestinal smooth muscle were established. Considering both colon and small intestine are sites of “abnormal” motility in intestinal smooth muscle disorders, e.g., irritable bowel syndrome (IBS)^[12-14], and that the jejunum is a “typical” region of the small intestine, we chose to investigate the contractility of isolated jejunal smooth muscle fragment (JSMF) and its underlying mechanisms involved in deslanoside-induced BR.

MATERIALS AND METHODS

Experimental models of diarrhea and constipation

The animal protocol was approved by Dalian Medical University Animal Care and Ethics Committee, and all experimental procedures described were carried out in accordance with the Declaration of Helsinki. Sprague-Dawley rats (200-250 g) were used in the assay. Constipation-predominant (CP) rats were established by daily gavage with cool water (0 °C-4 °C) for 14 d, and the control rats were prepared by daily gavage with water at room temperature^[15,16]. Diarrhea-predominant (DP) rats were established by intracolonic instillation of acetic acid and restraint stress, and control rats received intracolonic instillation with saline^[17-19]. The granule number and the moisture content of the feces from the control group and the model group were measured daily, and the body mass was recorded once every 3 d.

Tissue preparation

Tissue fragments from the intact tubular jejunum were

prepared according to the methods described previously^[20,21]. Jejunum was isolated from normal, CP and DP rats. Jejunal fragments were cut into approximately 2 cm in length (tubes). One end of the jejunal fragment in longitudinal direction was fixed to the wall of a tissue bath chamber (20 mL volume), and the other end was connected to a force-displacement transducer. This montage measured the contractile response of JSMF.

Contractility determination

The organ bath was maintained at 37 °C, and the resting tension was set optimally at 1.0 g. Preliminary experiments showed that this load stretched tissues to their optimal length for force development during contraction. JSMF was allowed to equilibrate in aerated Krebs buffer for 50 min and the bath solution was replaced every 10 min. Contractile amplitude of JSMF was measured from the baseline to the peak and was expressed as a percentage of normal contractile amplitude. Contractile amplitude was recorded and identical time-interval of each assay with the same start and stop time was chosen to compare the amplitude before and after drug treatment in different assay conditions. The mean amplitude was calculated from six independent assays.

Ex vivo assay condition

The contractility of JSMF was measured in Krebs buffer (118 mmol/L NaCl, 4.7 mmol/L KCl, 1.2 mmol/L KH_2PO_4 , 1.2 mmol/L MgSO_4 , 4.2 mmol/L NaHCO_3 , 2.5 mmol/L CaCl_2 , 10 mmol/L glucose; pH 7.4) and selected as the normal contractile state (NCS). The jejunal contractility measured in modified low Ca^{2+} (1.25 mmol/L) and high Ca^{2+} (5.0 mmol/L) Krebs buffer was selected as the representative low contractile state (RLCS) and representative high contractile state (RHCS), respectively, since spontaneous contractions of intestinal smooth muscle were paralleled to intracellular Ca^{2+} concentration^[22,23]. One pair of low-high contractile states was established from jejunal smooth muscle isolated from CP and DP rats. The other six pairs of low-high contractile states were generated by incubating JSMF in modified low K^+ (2.5 mmol/L)-high K^+ (10.0 mmol/L) Krebs buffer, low Na^+ (100 mmol/L)-high Na^+ (150 mmol/L) Krebs buffer, high Mg^{2+} (3.0 mmol/L)-low Mg^{2+} (1.0 mmol/L) Krebs buffer, adrenaline (5.0 $\mu\text{mol/L}$)-ACh (5.0 $\mu\text{mol/L}$) Krebs buffer, quercetin (10.0 $\mu\text{mol/L}$)-capsaicin (10.0 $\mu\text{mol/L}$) and nitric oxide (NO) donor sodium nitroprusside (SNP) (5 $\mu\text{mol/L}$)-erythromycin (10 $\mu\text{mol/L}$) Krebs buffer^[24,25]. After the stable contractile state of jejunal contraction was obtained, deslanoside was added to the bath to make a final concentration of 20 $\mu\text{mol/L}$, unless otherwise indicated.

Western blotting analysis

The phosphorylation of myosin light chain (PMLC) in jejunum was examined by Western blotting as described previously^[26,27]. JSMF was immediately treated with low Ca^{2+} or high Ca^{2+} Krebs buffer for 1 min in the absence or presence of 20 $\mu\text{mol/L}$ deslanoside, and then were

Contractile amplitude of isolated jejunal smooth muscle fragment in normal contractile state is defined as 100% (control). Other data are the relative value (%) compared with control, and are expressed as the mean ± SE; ^b*P* < 0.01 *vs* the data prior to deslanoside treatment (*n* = 6). L-NNA: L-NG-nitroarginine.

frozen and stored in liquid nitrogen. Ground product was incubated for 30 min in ice-cold homogenization buffer. The blots on nitrocellulose filter membrane were probed with phosphor-myosin light chain 2 (Ser 19) antibody (1:1000) [No. 3671, Cell Signaling Technology, Inc (CST), United States] and myosin light chain 2 (total myosin light chain) antibody (1:1000) (No. 3672, CST, United States) at 4 °C with gentle shaking overnight. Anti-rabbit IgG secondary antibodies were used at 1:2500 for 60 min at room temperature and bands were detected and quantified using Multispectral imaging system (UVP, United States).

Drugs

Injectable deslanoside was obtained from Sine Pharmaceutical (Shanghai, China). Capsaicin and quercetin was purchased from Chengdu Biopurify Phytochemicals Co. Ltd, China. Tetrodotoxin (TTX) was a product of Aladdin Chemistry Co. Ltd (Shanghai, China). Unless otherwise indicated, chemicals were obtained from Sigma (United States).

Statistical analysis

Student's *t* test was used to compare statistical differences between two groups, and *P* < 0.05 was considered statistically significant.

RESULTS

Deslanoside-induced BR on the contractility of JSMF

Deslanoside exerted stimulatory effects on JSMF in NCS in a dose range of 5-160 μmol/L (Figure 1A).

Eight low and 8 high contractile states of jejunal smooth muscle were established as described in Materials and Methods. The contractility of JSMF in both low and high contractile states was statistically different from that of normal control (Figure 1). Deslanoside (20 μmol/L) was used in all the assays based on the fact that deslanoside-induced BR on jejunal contractility was observed in a dose range of 10-40 μmol/L. Deslanoside produced significant stimulatory effects (45.3% ± 4.0% *vs* 87.0% ± 7.8%, *P* < 0.01) on the contractility of JSMF in all 8 low contractile states (Figure 1B), and produced significant inhibitory effects (180.6% ± 17.8% *vs* 109.9% ± 10.8%, *P* < 0.01) on the contractility of JSMF in all 8

high contractile states (Figure 1C).

Western blotting analysis

The PMLC in jejunum was significantly decreased in RLCS in comparison with that in NCS (100.0% ± 9.4% *vs* 78.1% ± 4.1%, *P* < 0.01), and was significantly increased at RHCS in comparison with that in NCS (100.0% ± 6.7% *vs* 139.2% ± 8.5%, *P* < 0.01) (Figure 2). Deslanoside significantly increased the PMLC in RLCS (78.1% ± 4.1% *vs* 96.0% ± 8.1%, *P* < 0.01), and significantly decreased the PMLC in RHCS (139.2% ± 8.5% *vs* 105.5 ± 7.34, *P* < 0.01).

Effects of deslanoside on the contractility of JSMF in the presence of TTX

In the presence of TTX, BR was not observed when deslanoside was tested on the contractility of JSMF in RLCS and RHCS (Figure 3).

Underlying mechanisms involved in deslanoside-induced BR

Deslanoside, at bath concentrations of 5 μmol/L, 20 μmol/L and 80 μmol/L, did not affect jejunal contractility in a Ca²⁺-free assay condition, and 20 μmol/L deslanoside did not stimulate the contractility of JSMF pre-incubated with the Ca²⁺ channel blocker verapamil at normal, low and high contractile states (Figure 4).

The underlying mechanisms involved in deslanoside-induced BR were investigated. Muscarinic receptor antagonist atropine abolished the stimulatory effect of deslanoside on the contractility of JSMF in RLCS (Table 1; Figure 5A). Neither histamine H1-receptor antagonist diphenhydramine nor histamine H2-receptor antagonist cimetidine blocked deslanoside-induced stimulatory effects on the contractility of JSMF in RLCS (Table 1; Figure 5A). α-adrenergic receptor antagonist phentolamine, β-adrenergic receptor antagonist propranolol and NO synthase inhibitor L-NNA abolished deslanoside-induced inhibitory effect on the contractility of JSMF in RHCS (Table 1; Figure 5B).

DISCUSSION

Eight pairs of low-high contractile states were established to imitate intestinal hyper- and hypomotility and

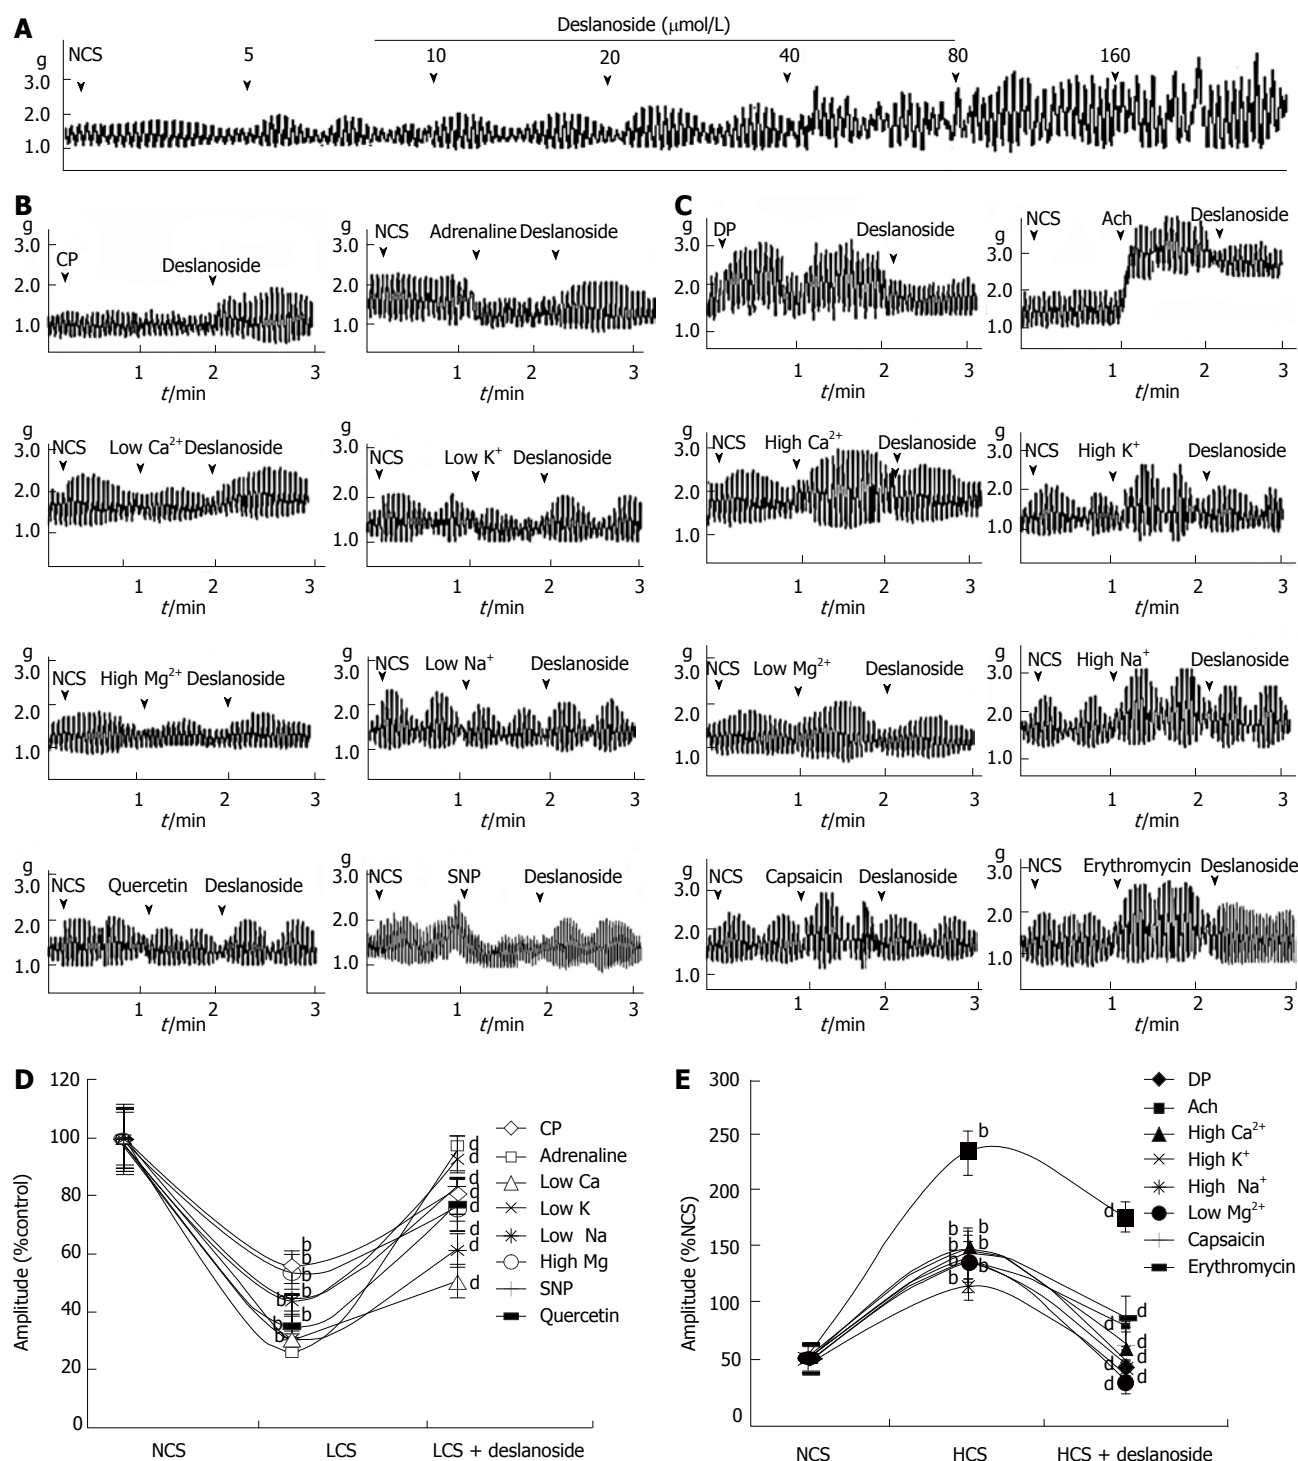

Figure 1 Deslanoside-induced bidirectional regulation on the contractility of jejunal smooth muscle fragment. **A**: Dose response relationship of Deslanoside; **B**, **D**: Representative traces and statistical analysis of total traces from six independent experiments of Deslanoside-induced bidirectional regulation on the contractility of jejunal smooth muscle fragment (JSMF) in eight low contractile states (LCS); **C**, **E**: Representative traces and statistical analysis of total traces from six independent experiments of Deslanoside-induced bidirectional regulation on the contractility of JSMF in eight high contractile states (HCS). The median value of contractile amplitude of JSMF in normal contractile state is set to 100%, normal contractile state (NCS, control). Low and high contractile states of JSMF are the relative values compared with NCS. Data are expressed as the mean \pm SE (%NCS, $n = 6$); ^a $P < 0.01$ vs the control; ^b $P < 0.01$ vs contractile amplitude of JSMF in LCS or HCS before Deslanoside administration. for patients with IBS has been difficult because of the lack of pharmacological targets and the wide range of symptomatology^[31]. Considering that the precise cause of IBS is unknown and it is unlikely that one single factor could explain all instances of IBS^[32], we established various assay conditions to mimic the possible intestinal hyper- and hypo-motility. These low and high contractile states of isolated intestinal smooth muscle were established (1) by changing ionic concentration in assay buffers; (2) using inhibitory and stimulatory neurotransmitters, or using exog-

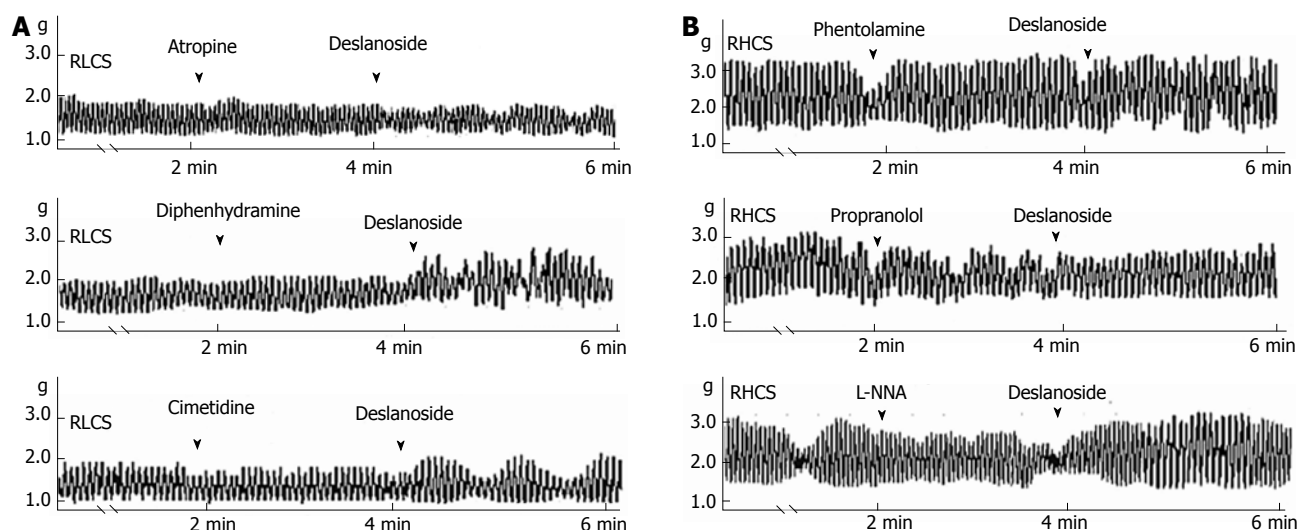

Figure 5 Effects of deslanoside on the contractility of jejunal smooth muscle fragment pretreated with receptor antagonist. A: Effects of deslanoside on the contractility of jejunal smooth muscle fragment (JSMF) pretreated with 10 $\mu\text{mol/L}$ atropine, 10 $\mu\text{mol/L}$ diphenhydramine and 10 $\mu\text{mol/L}$ cimetidine in the representative low contractile state (RLCS), respectively; B: Effects of deslanoside on the contractility of JSMF pretreated with 10 $\mu\text{mol/L}$ phentolamine, 5 $\mu\text{mol/L}$ propranolol and 10 $\mu\text{mol/L}$ L-NG-nitroarginine (L-NNA) in the representative high contractile state (RHCS), respectively.

enous inhibitors and stimulators in the assay buffers; and (3) using isolated intestinal smooth muscle obtained from constipation-prominent rat model and diarrhea-prominent rat model.

In this study, we tried to evaluate the possibility that whether deslanoside-induced adverse gastrointestinal irritation could be beneficialized as a potential therapeutic effect on the intestinal smooth muscle dysfunction, and characterized deslanoside-induced BR on the contractility of JSMF. Deslanoside was found to induce stimulatory effects on JSMF in all eight low contractile states and induced inhibitory effects on JSMF in all eight high contractile states. In accordance with deslanoside-induced BR on the contractility of JSMF, the effects deslanoside on myosin phosphorylation of JMSF were also bidirectional.

Activation of muscarinic receptor increases the intestinal motility and stimulation of α and β -adrenoceptors inhibits intestinal motility. Inhibition of intestinal motility is also mediated by NO, a nonadrenergic, noncholinergic neurotransmitter, producing its effect by directly acting on smooth muscle and by indirectly inhibiting acetylcholine and substance P releasing^[33,34]. Based on the aforementioned mechanisms involved in the modulation of intestinal contractility, our results have the following implications. The evidence that atropine blocked the stimulatory effects of deslanoside on JSMF in RLCS implies that stimulatory effects of deslanoside on JSMF in low contractile state are correlated with M receptor linked stimulation; and the evidence that phentolamine, propranolol and L-NNA abolished the inhibitory effects of deslanoside on JSMF in RHCS suggests that the inhibitory effects of deslanoside are correlated with adrenergic α , β receptor, as well as NO synthase linked relaxing mechanisms. Deslanoside-induced BR is Ca^{2+} -dependent, since it neither affected jejunal contractility in a Ca^{2+} -free assay condition, nor stimulated jejunal contractility pre-incubated with the Ca^{2+} channel blocker

verapamil in normal, low and high contractile states (Figure 4). The evidence that deslanoside-induced BR is not observed in the presence of TTX implies that deslanoside-induced BR is based on the presence of ENS.

Compared with controls (85.3 ± 37.3 min), the transit times (a measurement of bowel movement) obtained in constipation-predominant (67.4 ± 19.6 min) and diarrhea-predominant patients with IBS (108.4 ± 34.3 min) were decreased and increased, respectively ($P < 0.05$)^[35]. The results implicate that deslanoside-induced BR on jejunum is informative for preclinical investigation of a drug with potential value for the modulation of both abnormally low and high contractility of intestinal smooth muscle. To relieve the symptoms of functional bowel disorders, such as alternating-type IBS, BR-inducer deslanoside could be considered for the potential future clinical application.

It is known that ENS is highly interconnected and responsible for secreting at least 50 different modulators, regulating intestinal motility and other functions^[36]. We are still not clear about the diverse mechanisms for BR induction, including how dozens of neurotransmitters in intestinal smooth muscle are interrelated in normal contractile state, and how they correlate with BR in both the low and high contractile states. Although we have partially revealed the characteristics of deslanoside-induced BR, further study is still required to identify the detailed mechanisms.

COMMENTS

Background

Irritable bowel syndrome (IBS) is known as one of major functional gastro-

intestinal disorders, contracting approximately 10% of all adults world wide. Cardiotonic glycosides (CGs) have long been and continue to be used in the treatment of congestive heart failure and have entered clinical trials for treating cancer. Gastrointestinal irritation of CGs has been reported, however, the characteristics of CGs on intestinal motility remain unknown.

Research frontiers

Developing treatment strategies for patients with IBS has been difficult because of the lack of pharmacological targets and the wide range of symptomatology, especially in the alternating-type IBS (IBS-A) which is a functional gastrointestinal disorder with alternating symptoms of both constipation and diarrhea.

Innovations and breakthroughs

The present study established 8 pairs of low-high contractile states to mimic the possible intestinal smooth muscle disorders. These different low and high contractile states of isolated intestinal smooth muscle were established by changing ionic concentration in assay buffers; using inhibitory and stimulatory neurotransmitters; exogenous inhibitors and stimulators, respectively in the assays; and isolated intestinal smooth muscle obtained from both constipation-prominent rat model and diarrhea-prominent rat model. The results indicate that the contractile state determines deslanoside-induced effects to be stimulatory or inhibitory, namely, stimulatory effects on the contractility of intestinal fragment were induced by deslanoside in all low contractile states, and inhibitory effects were induced on the contractility of jejunal smooth muscle fragment (JSMF) in all high contractile states. The present study indicates that deslanoside-induced Bidirectional regulation (BR) requires the presence of enteric nervous system and is Ca^{2+} dependent. The possible mechanism of deslanoside-induced BR is related to cholinergic system when jejunal smooth muscle is in a low contractile state, and related to adrenergic system and nitric oxide relaxing mechanism when in a high contractile state.

Applications

The results implicate that deslanoside-induced BR on jejunum is informative for preclinical investigation of a drug with potential value for the modulation of both abnormally low and high contractility of intestinal smooth muscles. To relieve the symptoms of functional bowel disorders, such as IBS-A, BR-inducer deslanoside could be considered for the potential future clinical application.

Terminology

IBS is usually classified into three subclasses: IBS with constipation (hypomotility), IBS with diarrhea (hyper-motility), and IBS with alternating symptoms of both constipation and diarrhea.

Peer review

This is a well done study that provides interesting insight into the action of deslanoside. The study is complete, well-written and suitable for publication.

Abstract

AIM: To investigate the characteristics and diagnostic value of annexin A2 (ANXA2) expression in cancerous tissues and sera of patients with hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC).

METHODS: Levels of liver *ANXA2* gene transcription or protein expression were analyzed in HCC-, their self-controlled precancerous-, and distant cancerous- tissues from 30 HCC. Serum levels of ANXA2 expression in 115 patients with HCC, 25 with metastatic liver can-

cer, 35 with chronic hepatitis, 28 with acute hepatitis, 38 with cirrhosis, and 30 healthy controls were determined. Clinicopathological characteristics of circulating ANXA2 expression were analyzed, and its diagnostic efficiency and clinical values in HCC were evaluated.

RESULTS: ANXA2 expression was localized in both cell membrane and cytoplasm in HCC tissue, mainly in the cytoplasm of matched adjacent cancerous tissue, and there was almost no positive staining in matched distant cancerous tissue. Abnormal expression of liver ANXA2 was present in HCC tissues compared with self-controlled adjacent- and distant-cancerous tissues at protein or mRNA level. Circulating ANXA2 in HCC patients was significantly higher than that of other liver diseases ($P < 0.01$) except metastatic liver cancer. If the diagnostic cutoff value of ANXA2 level was more than 18 ng/mL, the incidence of serum ANXA2 was 86.96% in the HCC group, 80% in the metastatic liver cancer group, 31.58% in the liver cirrhosis group, none in the chronic hepatitis or acute hepatitis or normal control group, respectively. Serum ANXA2 expression in HCC patients was correlated with HBV infection (27.38 ± 5.67 ng/mL vs 18.58 ± 7.83 ng/mL, $P < 0.01$), extrahepatic metastasis (26.11 ± 5.43 ng/mL vs 22.79 ± 5.64 ng/mL, $P < 0.01$), and portal vein thrombus (26.03 ± 5.99 ng/mL vs 23.06 ± 5.03 ng/mL, $P < 0.01$), and was significantly higher ($P < 0.01$) in the moderately- (26.19 ± 5.34 ng/mL) or the poorly- differentiated group (27.05 ± 5.13 ng/mL) than in the well differentiated group (20.43 ± 4.97 ng/mL), and in the tumor node metastasis stages III-IV ($P < 0.01$) than in stages I-II. ANXA2 was not correlated with patient sex, age, size or α -fetoprotein (AFP) level. Area under the receiver operating characteristic curve for the whole range of sensitivities and specificities was 0.796 for ANXA2 and 0.782 for AFP. Combining detection of serum ANXA2 and AFP substantially improved the diagnostic efficiency (96.52%) and the negative predictive value (96.61%) for HCC.

CONCLUSION: The characteristics and distribution

of ANXA2 expression has good diagnostic potential for HCC diagnosis.

Expression characteristics and diagnostic value of annexin A2 in hepatocellular carcinoma. *World J Gastroenterol* 2012; 18(41): 5897-5904 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v18/i41/5897.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i41.5897>

INTRODUCTION

Hepatocellular carcinoma (HCC), as one of the most malignant tumors, is the third leading cause of cancer-related death, especially in the inshore area of the Yangtze River^[1,2]. Surgical resection is not suitable for a considerable number of HCC cases because of metastasis, and the long-term survival of postoperative HCC patients is not satisfactory^[3,4]. Its early detection and treatment is an effective way to improve patient survival. Detection of circulating markers is the most effective method because it is simple, accurate and low cost, but no ideal biomarker has been found so far^[5,6]. Recent studies showed that annexin A2 (ANXA2) plays an important role in hepatocyte malignant transformation and HCC development^[7-9]. ANXA2, as the best characterized of the Annexin family, is a calcium-dependent phospholipid-binding protein that plays a key role in the regulation of cellular growth and signal transduction pathways^[10]. It is reported that ANXA2 expression is upregulated in HCC compared with benign liver disease. Furthermore, its phosphorylation at residues of Tyr23 by c-Src is also increased^[11,12], and overexpression and tyrosine phosphorylation of ANXA2 may be of functional relevance.

Evaluation of the diagnostic value of ANXA2 in highly differentiated liver tumors suggests that adding sinusoidal ANXA2 expression to the marker panel [glypican 3, hepatoma-specific gamma-glutamyl transferase (HS-GGT), and heat shock protein 70] increases the reliability and objectivity of HCC diagnosis^[13]. In addition, serum ANXA2 levels in HCC patients are elevated by a quantitative sandwich enzyme linked immunosorbent assay (ELISA) method^[14]. It may be a serological marker for HCC to enable early diagnosis, as well as monitoring of aggressiveness, treatment responsiveness, recurrence and survival. However, the clinicopathologic characteristics of hepatic ANXA2 expression and the evaluation of its

diagnostic value for hepatitis B virus (HBV)-related HCC have not been reported up to now. In this study, the expression of hepatic and circulating ANXA2 was investigated in HCC patients and compared with expression in benign liver diseases to evaluate the pathologic characteristics and efficiency in HCC diagnosis.

MATERIALS AND METHODS

Collection of serum samples

We evaluated 115 HCC patients (88 men and 27 women) who were treated at the Affiliated Hospital of Nantong University, Nantong, China. Patient age ranged from 25 to 81 years (median, 48.3 years). Other cases studied included 35 with chronic hepatitis, 28 with acute hepatitis, 38 with cirrhosis, and 25 with metastatic liver cancer (liver metastasis of lung cancer, 6; gastric cancer, 6; acute myeloid leukemia, 3; breast cancer, 3; colorectal cancer, 3; cervical cancer, 2; and pancreatic cancer, 2) and samples from 30 healthy people with hepatitis viral markers [HBV-DNA, HBV surface antigen, and anti-hepatitis C virus (HCV)] and a normal alanine aminotransferase level obtained from the Nantong Central Blood Bank as controls. All cases were diagnosed by biochemical tests, viral histology, and B-ultrasonic examination. Blood samples (5 mL) were collected with heparin in the morning and sera separated immediately. α -fetoprotein (AFP) level was detected by a radiological method^[15].

Collection of liver specimens

The cancerous-, the self-matched adjacent cancerous- (more than 3 cm to cancer focus), and the distant cancerous- (more than 5 cm) specimens after surgical operation were respectively taken from 30 HCC patients who were treated at the Affiliated Hospital of Nantong University, Nantong, China. One portion of each specimen was immediately frozen in liquid nitrogen for total RNA extraction [ANXA2 mRNA by real time quantitative polymerase chain reaction (qPCR)], an extract was used to determine liver ANXA2 by Western blotting, and the remaining sample was fixed with 10% (vol/vol) formalin for ANXA2 immunohistochemistry. The diagnosis of HCC and viral hepatitis was based on the criteria proposed by the Chinese National Collaborative Cancer Research Group^[16] and at the Chinese National Viral Hepatitis Meeting^[17], respectively. Prior written informed consent was obtained from all patients according to the World Medical Association Declaration of Helsinki, and the study received ethics board approval from the Affiliated Hospital of Nantong University, Jiangsu Province, China.

ELISA

The level of serum ANXA2 was detected by using a human ANXA2 ELISA kit (Usn Life Science Inc., Wuhan, China) according to the manufacturer's instructions. To each well was added 100 μ L of serum sample or standard separately, and then 100 μ L of detection reagent A was

added and incubated for 1 h at 37 °C. Subsequently, 100 μ L of detection reagent B was added and incubated for 0.5 h at 37 °C. Then, 90 μ L of substrate solution was added and incubated for 25 min at 37 °C. Finally, 50 μ L of stop solution was added to each well, and absorbance was read at 450 nm. During the procedure, washing the plate was according to the ELISA routine method.

Total RNA isolation and synthesis of cDNA

Total RNA was isolated from 50 mg of liver tissue, using Trizol reagent (Invitrogen, United States) according to the manufacturer's instructions. The integrity of the total RNA was examined by 1% agarose gel electrophoresis, the quantity was determined based on absorbance at 260 nm (A_{260}), and the purity was analyzed based on the absorbance ratio at 260 nm and 280 nm ($A_{260/280}$) (Bio-RAD smartspecTM plus, United States). The ANXA2 cDNA was synthesized from 1 μ g of total RNA using First Strand cDNA Synthesis Kit (Fermentas, Canada) according to the manufacturer's instructions.

qPCR

The qPCR was run on an Applied Biosystems StepOneTM real-time PCR system according to the manufacturer's recommendations. The reaction solution contained 25 μ L 2 \times SYBR Premix Ex Taq (TaKaRa, Japan), 2 μ L primer mix, 1 μ L 50 \times ROX Reference Dye I, 4 μ L cDNA, and 18 μ L deionized water to make a total volume of 50 μ L. ANXA2 primers were as follows: forward, 5'-TGAGC-GGGATGCTTTGAAC-3', and; reverse, 5'-ATCCT-GTCTC TGTGCATTGCTG-3'; β -actin primers were as follows: forward, 5'-ATTGCC GACAGGATGCAGA-3', and reverse, 5'-GAGTACTTGCGCTCAGGAGGA-3' used as an internal control^[18], while no template control (H₂O) was included in each reaction run. The optimized PCR conditions were as follows: 1 cycle at 95 °C for 2 min; 40 cycles at 95 °C for 10 s, 62 °C for 1 min and final extension at 60 °C for 15 s. The relative quantitative analysis was performed by comparison of the $2^{-\Delta\Delta C_t}$ values.

Western blotting

Liver tissues were homogenized in an ice-cold homogenization buffer containing 50 mmol/L 3-(N-Morpholino) propanesulfonic acid buffer (pH 7.4), 100 mmol/L KCl, 320 mmol/L sucrose, 50 mmol/L NaF, 0.5 mmol/L MgCl₂, 0.2 mmol/L dithiothreitol, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L Na₃VO₄, 20 mmol/L sodium pyrophosphate, 20 mmol/L β -phosphoglycerol, 1 mmol/L p-nitrophenyl phosphate, 1 mmol/L benzamide, 1 mmol/L phenylmethylsulfonyl fluoride, and 5 μ g/mL each of leupeptin, aprotinin, and pepstatin A. The homogenates were centrifuged at 800 *g* for 10 min at 4 °C. The supernatants were collected, and total protein concentrations were determined by an enhanced bicinchoninic acid protein assay kit (Beyotime Institute of Biotechnology, China). A total of 20 mg of protein of each sample was run on a 15% sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The proteins were

then transferred onto polyvinylidene fluoride membranes and blocked with 5% bovine serum albumin in tris-buffered saline, pH 7.5 (100 mmol/L NaCl, 50 mmol/L Tris, and 0.1% Tween-20). Membranes were immunoblotted overnight at 4 °C with the anti-ANXA2 and anti- β -actin antibodies (Santa Cruz Biotechnology, United States), followed by respective horseradish peroxidase-conjugated secondary antibodies. The bands were subsequently visualized by a chemiluminescence detection system (Millipore, United States), and density analysis was performed by an image analyzer. The ANXA2 level was expressed with the relative ratio (RR), which was calculated by the following formula using signal intensity (SI) of ANXA2 and β -actin. $RR = SI_{ANXA2}/SI_{\beta-actin}$.

Immunohistochemistry for ANXA2

The 3 μ m thick sections were prepared from formalin-fixed, paraffin-embedded tissue blocks. Sections were deparaffinized in xylene twice for 10 min, then dehydrated through graded ethanol to distilled water for 5 min. Deparaffinized 5 μ m thick liver sections were washed three times with phosphate buffered solution (PBS) (pH 7.4), incubated in endogenous peroxidase blocking solution (Immunostain EliVision Kit, Maxim Biotech, United States), and then treated with 0.01 mol/L citrate buffer pH 6.0 for 10 min in a microwave oven at 650 W. Non-specific-antibody binding was blocked by pretreatment with PBS containing 0.5% bovine serum albumin (fraction V powder, Sigma, United States). Sections were then rinsed in PBS and incubated overnight at 4 °C with diluted anti-human ANXA2 antibody (1:500, Santa Cruz Biotechnology, United States) followed by three washes in PBS containing 0.05% Tween-20. The steps were performed using Immunostain EliVision kit according to the manufacturer's instructions. Sections were stained with 3,3'-diamino-benzidine tetrahydrochloride as a chromogen. The slide was rinsed with distilled water, counterstained with hematoxylin, dehydrated, air dried, and mounted. The negative control slides were treated with nonspecific mouse IgG. The sections were examined under light microscopy. ANXA2 staining was assessed using the immunoreactive score. In detail, the percentage of positive cells was assessed semiquantitatively and classified as follows: diffuse positive staining (+++) of more than 50% of total cells; moderate staining (++), 16%-50%; weak staining (+), 5%-15%; and negative staining (-), < 5%^[19]. The results of staining were evaluated by two independent pathologists without knowledge of the clinicopathologic features, and any difference in interpretation was resolved by consensus. Duplicate tissue cores for each tumor showed high levels of homogeneity for staining intensity and percentage of positive cells. The higher score was taken as the final score in cases of a difference between duplicate tissue cores.

Statistical analysis

The data are expressed as mean \pm SD. Differences between different groups were evaluated by using a Student

Figure 1 Annexin A2 protein level in liver tissue of hepatocellular carcinoma. A: Representative images of Western blotting. The protein levels of annexin A2 (ANXA2) and β -actin were detected and the latter served as the control; B: The statistical results indicated that the level of ANXA2 expression was obviously increased in hepatocellular carcinoma (HCC) tissues compared with the matched adjacent- or the distant-cancerous tissues ($P < 0.001$). Three independent experiments were repeated, and the results are given as mean \pm SD. HCC-T: HCC tissues; AC-T: Adjacent cancerous tissues; DC-T: Distant cancerous tissues.

t test, a χ^2 test or a rank-sum test. $P < 0.05$ was considered significant. Receiver operating characteristic (ROC) curves were constructed by calculating the sensitivities and specificities at several cutoff points^[15]. Efficiency evaluation was calculated according to sensitivity, specificity, accuracy, positive predictive value, and negative predictive value.

RESULTS

ANXA2 expression level in HCC tissues

ANXA2 protein and mRNA levels were detected in 30 self-controlled HCC tissues, and their matched adjacent- and distant-cancerous specimens by Western blotting and real-time PCR, respectively. As shown in Figure 1, the ANXA2 protein level was obviously higher in HCC tissues than in the self-controlled adjacent- and distant-cancerous specimens ($F = 498.221$, $P < 0.001$). The relative qPCR analysis (Table 1) indicated that the level of ANXA2 mRNA expression in the HCC tissues ($2^{-\Delta\Delta Ct} = 1.00$) was significantly higher ($F = 7908.11$, $P < 0.001$) than in the matched adjacent cancerous tissues ($2^{-\Delta\Delta Ct} = 0.43 \pm 0.10$) or the distant cancerous tissues ($2^{-\Delta\Delta Ct} = 0.23 \pm 0.07$). In short, ANXA2 was overexpressed in HCC tissues compared with the self-controlled adjacent- and distant-cancerous tissues, whether protein level or mRNA level.

Immunohistochemistry for ANXA2 expression and cell distribution

The expression and distribution of hepatic ANXA2 in 30 self-controlled HCC tissues, their matched adjacent- and distant-cancerous specimens are shown in Figure 2. The positive ANXA2 protein was localized in both cell membrane and cytoplasm (Figure 2A) in HCC tissue (30 of 30, 100%), mainly in the cytoplasm (Figure 2B) in matched adjacent cancerous tissue (27 of 30, 90%), and there was almost no positive staining (Figure 2C) in their matched distant cancerous tissue (0 of 30, 0%). The intensity and comparative analysis of ANXA2 expression in different liver tissues are shown in Table 1. Although no significant difference in the positive rate of ANXA2 expression ($\chi^2 = 3.518$, $P = 0.070$) was found between the HCC group and the adjacent cancerous group, the intensity of ANXA2 expression in the HCC group was significantly higher than that in the adjacent cancerous group ($Z = 6.113$, $P < 0.001$) or the distant cancerous group ($Z = 7.328$, $P < 0.001$).

Circulating ANXA2 and AFP level in patients with liver diseases

The levels of circulating ANXA2 and AFP expression in 241 patients with liver diseases are shown in Table 2. The mean level of serum ANXA2 expression in HCC patients was significantly higher than in the cases with

Figure 2 Immunohistochemistry of hepatic annexin A2 expression and distribution. Representative images of immunohistochemistry in the hepatocellular carcinoma (HCC), self-controlled adjacent- and distant- cancerous tissues (400 × magnification). A: Hepatocyte annexin A2 (ANXA2) expression in HCC tissue; B: Hepatocyte ANXA2 expression in matched adjacent cancerous tissue; C: Hepatocyte ANXA2 expression in matched distant cancerous tissue. The level of ANXA2 expression was obviously increased in HCC tissues compared with that in the matched adjacent- or the distant-cancerous tissues.

¹Serum annexin A2 (ANXA2) level > 18 ng/mL or ²Serum α -fetoprotein (AFP) level > 50 ng/mL was abnormal; ³Compared with the hepatocellular carcinoma (HCC) group. MLC: Metastatic liver cancer; LC: Liver cirrhosis; CH: Chronic hepatitis; AH: Acute hepatitis; NC: Normal controls; Pos. (%): Positive case number (%).

liver cirrhosis, chronic hepatitis, or acute hepatitis, or in control subjects ($P < 0.001$), but not compared with the metastatic liver cancer group. If the diagnostic cutoff value was more than 18 ng/mL, the incidence of circulating ANXA2 was 86.96% in the HCC group, 80% in the metastatic liver cancer group, 31.58% in the liver cirrhosis, and zero in the chronic hepatitis group, the acute hepatitis group or the normal control group. The incidence of serum AFP in the HCC patients (81 of 115, 70.44%) was significantly higher than in the metastatic liver cancer group (12 of 25, 48%, $P < 0.05$), the liver cirrhosis group (6 of 38, 15.79%), the chronic hepatitis group (5 of 35, 14.29%), the acute hepatitis group (4 of 28, 14.29%), and was zero in the normal control group.

Clinicopathologic features of circulating ANXA2 expression

The clinicopathologic features of circulating ANXA2 expression in 115 HCC patients are shown in Table 3. The

higher level of serum ANXA2 expression was correlated with HCC patients with HBV infection (Figure 3A, $t = 6.820$, $P < 0.001$), extrahepatic metastasis ($t = 3.191$, $P = 0.002$), or portal vein thrombus ($t = 2.859$, $P = 0.005$). Serum ANXA2 expression was graded, with 20.43 ± 4.97 ng/mL in the well differentiated group and significantly lower ($P < 0.001$) in the moderately- (26.19 ± 5.34 ng/mL) or the poorly- differentiated (27.05 ± 5.13 ng/mL) group, and levels of ANXA2 expression were obviously higher ($P < 0.001$) in tumor node metastasis (TNM) stage III or IV than in TNM stage I or II. ANXA2 expression was not correlated with patient sex, age, tumor size or serum AFP level (Figure 3B). Both circulating ANXA2 and AFP are useful biomarkers for HCC diagnosis.

Evaluation of serum ANXA2 level for HCC diagnosis

The evaluation of serum ANXA2 and AFP levels for HCC diagnosis is shown in Figure 4. The comparative analysis of two markers for the whole range of sensitivities and specificities was 0.796 in ANXA2 and 0.782 in AFP according to under the area under the ROC curve. The clinical evaluation of serum ANXA2 or/and AFP levels for HCC diagnosis is shown in Table 4. The sensitivity of serum ANXA2 only was 86.96%, while a combination of ANXA2 with AFP could increase the rate of HCC diagnosis (96.52%), and the negative predictive value was improved to 96.61%.

DISCUSSION

HCC prognosis is poor, and early detection is of the utmost importance. Although serum AFP is a useful biomarker for the detection and monitoring of HCC, the false-negative rate using the AFP level alone may be as high as 40% for HCC patients with small size tumors. A previous report implied that ANXA2 expression was upregulated in HCC and it could be a useful molecular marker for HCC^[10-12]. In this study, the expression of hepatic and circulating ANXA2 was investigated in HCC patients and compared with that in cases of benign liver diseases to explore the clinicopathological characteristics

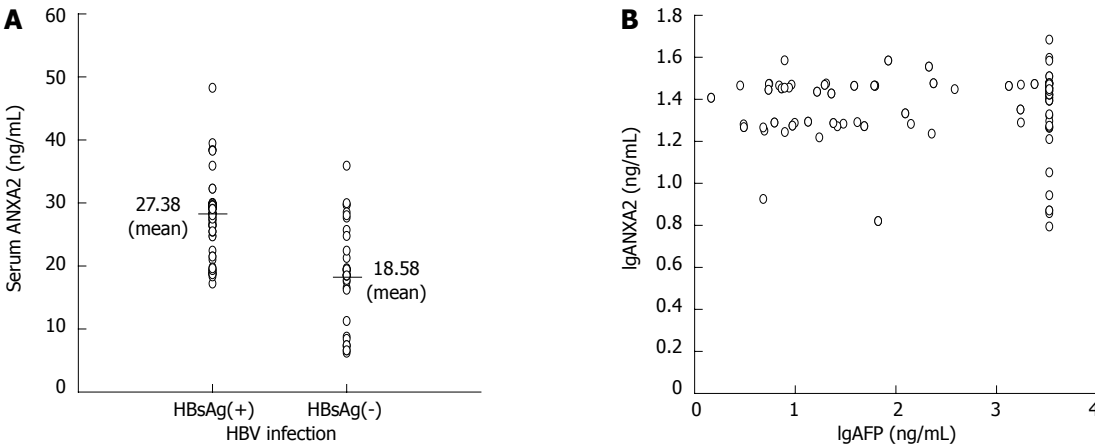

Figure 3 Relationship between serum annexin A2 level and hepatitis B virus infection or serum α -fetoprotein level in hepatocellular carcinoma patients. A: The scatter figure indicated that serum annexin A2 (ANXA2) level was obviously correlated with hepatitis B virus (HBV) infection. The serum ANXA2 level in hepatocellular carcinoma (HCC) patients was higher ($t = 6.820$, $P < 0.001$) in the positive-surface antigen of the HBV (HBsAg) group than that in the negative-HBsAg group; B: The scatter figure of denary logarithm indicated no significant correlation between serum ANXA2 and α -fetoprotein (AFP) level in HCC patients.

and diagnostic value in HCC.

The expression of hepatic ANXA2 was associated with hepatocyte malignant transformation. Hepatic ANXA2 was overexpressed in HCC tissues compared with their matched adjacent- and distant tissue, not only at protein level (Figure 1) but also at mRNA level (Table 1). Although no significant difference in the positive rate of ANXA2 expression was found between the HCC group and the adjacent cancerous group, the intensity of ANXA2 expression in the HCC group was significantly higher than in the adjacent cancerous group or the distant cancerous group (Table 1). There was a consistent overexpression of ANXA2 protein level and ANXA2 mRNA level. It is reported that adding ANXA2 to the established marker panel for the detection of early and well-differentiated

HCC should increase the diagnostic reliability and objectivity, which may particularly improve the accuracy of HCC diagnosis in minute tissue samples^[13]. It is worth mentioning that ANXA2 levels in HCC adjacent tissue present a very good intermediate state at protein or mRNA level, which might result from the change in the tumor microenvironment and the transfer of tumor cells, because a previous report suggested that ANXA2 binds with plasminogen and tissue plasminogen activator on the cell surface and promotes tumor metastasis by inducing the conversion of plasminogen to plasmin, which leads to activation of matrix metalloproteinases and degradation of extra-cellular matrix components^[7-9].

Although the mechanisms of hepatocarcinogenesis have not been elucidated, a long-lasting inflammation

Figure 4 Receiver operating characteristic curves for circulating annexin A2 level in hepatocellular carcinoma diagnosis. The area under the receiver operating characteristic curves was 0.782 for α -fetoprotein (AFP) and 0.796 for annexin A2 (ANXA2).

induced by hepatitis virus infection is a definite risk for neoplastic degeneration and the accumulation of genetic alterations. The diagnosis and monitoring of small size tumors have been always difficult due to the lack of effective biomarkers that can characterize the formation and progression of HCC development^[20,21]. The ability of several biomarkers, such as lens culinaris agglutinin-reactive AFP-L3^[22], HS-GGT, and glypican-3^[23], to detect early HCC has been examined, but the sensitivity and specificity are still not satisfactory. In this study, the circulating ANXA2 level was investigated in HCC patients and cases with benign liver diseases (Table 1). If the cutoff value of ANXA2 abnormality is more than 18 ng/mL, its incidence in patients with HCC (86.96%) or metastatic liver cancer (80%) was significantly higher than in cases with liver cirrhosis (31.58%), chronic hepatitis (0%), acute hepatitis (0%), or controls (0%). The value of ANXA2 in patients with cirrhosis is intermediate, and it may be considered as an early marker during malignant transformation of liver cells. Serum AFP is a useful serological marker for HCC diagnosis; however, a high false negative rate has been found in patients with benign liver diseases, and our study suggests that serum ANXA2 is superior to AFP and a relatively distinct marker for HCC diagnosis.

The ANXA2 gene is upregulated in HBV- and/or HCV-associated HCC^[24]. ANXA2 induces cell migration and neoangiogenesis *via* tissue plasminogen activator-dependent plasmin generation^[25], represents metastatic potential^[18], and promotes invasion and migration of HCC *in vitro* *via* its interaction with HAb18G/CD147^[7]. Moreover, Tyr23 phosphorylation-dependent cell-surface localization of ANXA2 is required for invasion and metastases^[12]. The clinicopathologic features of circulating ANXA2 expression in HCC patients (Table 3) demonstrated that there is a very close relationship between ANXA2 level and invasion and metastasis, as well as HBV infection. The higher level of ANXA2 expression

Table 4 Efficiency evaluation of serum annexin A2 or/and α -fetoprotein levels for hepatocellular carcinoma diagnosis¹

Project of evaluation	ANXA2 (%)	AFP (%)	Both (%)
Sensitivity	86.96	70.43	96.52
Specificity	66.67	73.08	68.67
Accuracy	75.28	71.96	80.07
Positive predictive value	65.79	65.85	68.10
Negative predictive value	87.39	77.03	96.61

¹Serum annexin A2 (ANXA2) level >18 ng/mL or α -fetoprotein (AFP) level > 50 ng/mL was abnormal.

in HCC patients was correlated with HBV infection (Figure 3A), extra-hepatic metastasis, portal vein thrombus, differentiated grading, and TNM staging. However, no significant correlation was found between serum ANXA2 level and tumor size, or AFP level (Figure 3B). It deserves to be mentioned that there was no significant difference between the moderately differentiated group and the poorly differentiated group, or TNM staging III-IV. The efficiency evaluation of serum ANXA2 or/and AFP level for HCC diagnosis (Table 4, Figure 4) indicated that serum ANXA2 detection has higher sensitivity, accuracy, negative predictive value and complementary diagnostic value in combination with AFP for HCC diagnosis.

In conclusion, hepatic ANXA2 expression is associated with hepatocyte malignant transformation and plays an important role in hepatic active metabolism, development, microenvironment, and prognosis of HCC. The higher intensity of ANXA2 expression in HCC tissues and circulating ANXA2 was correlated with HBV infection, extrahepatic metastasis and portal vein thrombus. Therefore, it could be developed as an effective diagnostic marker for HCC by a series of further independent and prospective studies, and become a research hotspot to reveal the mechanism of metastasis resulting from ANXA2 in the near future.

COMMENTS

Background

Hepatocellular carcinoma (HCC), as one of the most malignant tumors, is the third leading cause of cancer-related death. The development of biomarkers for early diagnosis and accurate prognosis of HCC is important for improving patients' survival. Annexin A2 (ANXA2) could be used as a new marker for HCC in the future.

Research frontiers

It is reported that ANXA2 expression and its phosphorylation is upregulated in HCC compared with benign liver disease. Moreover, the dose-response relationship between ANXA2 and optical density was linear in the range of 0-10 μ g/mL. However, little research on the about expression characteristics and diagnostic value of ANXA2 in HCC have been reported to date. In this study, the authors analyzed the expression characteristics and specific distribution of ANXA2 as well as its diagnostic value in HCC.

Innovations and breakthroughs

This is the first report on the expression characteristics and specific distribution of ANXA2 as well as its diagnostic value in HCC. ANXA2 overexpression in HCC patients was correlated with hepatitis B virus infection, extrahepatic metastasis, portal vein thrombus, differentiated grading and tumor node metastasis staging, but not with patient sex, age, size or α -fetoprotein (AFP) level. Joint diagnosis using serum ANXA2 and AFP substantially improved the diagnostic efficiency.

Applications

The expression characteristics and specific distribution of ANXA2 have good diagnostic potential for HCC, and could be developed into an effective diagnostic marker for HCC by a series of further independent and prospective studies.

Terminology

ANXA2 as a member of the Annexin family is a calcium-dependent phospholipid-binding protein and is involved in the regulation of cellular growth and signal transduction pathways. Its expression is upregulated in HCC with increased molecular phosphorylation at residues of Tyr23 by c-Src.

Peer review

The evaluated manuscript reports ANXA2 as biomarker of HCC. The study has been well conducted and provide further validation.

Abstract

AIM: To evaluate accuracy of *in vivo* diagnosis of adenomatous *vs* non-adenomatous polyps using *i*-SCAN digital chromoendoscopy compared with high-definition white light.

METHODS: This is a single-center comparative effectiveness pilot study. Polyps ($n = 103$) from 75 average-risk adult outpatients undergoing screening or surveillance colonoscopy between December 1, 2010 and April 1, 2011 were evaluated by two participating endoscopists in an academic outpatient endoscopy center. Polyps were evaluated both with high-definition white light and with *i*-SCAN to make an *in vivo* prediction of

adenomatous *vs* non-adenomatous pathology. We determined diagnostic characteristics of *i*-SCAN and high-definition white light, including sensitivity, specificity, and accuracy, with regards to identifying adenomatous *vs* non-adenomatous polyps. Histopathologic diagnosis was the gold standard comparison.

RESULTS: One hundred and three small polyps, detected from forty-three patients, were included in the analysis. The average size of the polyps evaluated in the analysis was 3.7 mm (SD 1.3 mm, range 2 mm to 8 mm). Formal histopathology revealed that 54/103 (52.4%) were adenomas, 26/103 (25.2%) were hyperplastic, and 23/103 (22.3%) were other diagnoses include "lymphoid aggregates", "non-specific colitis," and "no pathologic diagnosis." Overall, the combined accuracy of endoscopists for predicting adenomas was identical between *i*-SCAN (71.8%, 95%CI: 62.1%-80.3%) and high-definition white light (71.8%, 95%CI: 62.1%-80.3%). However, the accuracy of each endoscopist differed substantially, where endoscopist A demonstrated 63.0% overall accuracy (95%CI: 50.9%-74.0%) as compared with endoscopist B demonstrating 93.3% overall accuracy (95%CI: 77.9%-99.2%), irrespective of imaging modality. Neither endoscopist demonstrated a significant learning effect with *i*-SCAN during the study. Though endoscopist A increased accuracy using *i*-SCAN from 59% (95%CI: 42.1%-74.4%) in the first half to 67.6% (95%CI: 49.5%-82.6%) in the second half, and endoscopist B decreased accuracy using *i*-SCAN from 100% (95%CI: 80.5%-100.0%) in the first half to 84.6% (95%CI: 54.6%-98.1%) in the second half, neither of these differences were statistically significant.

CONCLUSION: *i*-SCAN and high-definition white light had similar efficacy predicting polyp histology. Endoscopist training likely plays a critical role in diagnostic test characteristics and deserves further study.

INTRODUCTION

Fourteen million colonoscopies are performed annually in the United States, with the majority performed for screening with the goal of detecting and resecting pre-cancerous polyps^[1]. Small polyps (≤ 10 mm in size) make up the majority of polyps removed during screening colonoscopy, yet the rate of advanced neoplasia and invasive carcinoma in these polyps is low. The current standard of practice is removal of all detected polyps, regardless of size, for the purpose of histopathologic diagnosis and prevention of colorectal cancer^[2]. However, this practice may not be the most cost-effective way to utilize limited endoscopic resources^[3]. Accurate methods to predict histology of small polyps *in vivo* could prevent unnecessary polypectomies and/or promote a “resect and discard” practice^[4], thus minimizing risk to patients as well as improving efficiency and cost of endoscopy as a screening tool. However, clinical impression of lesion histology using standard white light colonoscopy has been shown to correlate poorly with neoplasia regardless of endoscopist experience^[5]. This climate creates an opportunity to expand the role for advanced colonoscopic techniques to predict histology *in vivo* and perform polypectomy in a targeted fashion. In fact, chromoendoscopy with optical magnification and pit pattern analysis can be highly accurate in optical diagnosis^[6]. Ideally, the benefit of chromoendoscopy in “optical diagnosis” could be harnessed with more time-efficient digital chromoendoscopic techniques that visually enhance mucosal surface aspects or vessel patterns without significantly prolonging endoscopic procedure time^[7].

PENTAX *i*-SCAN™, a PENTAX Medical Company digital chromoendoscopy technology, uses post-processing computer algorithms integrated into the standard high-definition processor to modulate light reflected from mucosa and highlight surface contrast. Several small studies have evaluated the accuracy of *i*-SCAN to assist physicians in predicting polyp histology *in vivo* and have shown promising results^[8-10]. However, the generalizability of these studies is limited by their reliance on experts with non-validated diagnostic criteria.

The goal of this pilot study is to build on this early

work by evaluating the accuracy of *i*-SCAN in predicting histology of small polyps (less than 10 mm) throughout the colon.

MATERIALS AND METHODS

Study design

This was a single center, prospective, comparative effectiveness pilot study conducted at a single academic medical center. The study protocol and equipment were approved by the local Institutional Review Board. The sponsor had no role in the conduct, analysis or reporting of study results.

Study population

Consecutive outpatient adults at least 45 years of age referred for screening or surveillance endoscopy at Duke University Medical Center between December 1, 2010 and April 1, 2011 were eligible for study enrollment. Based on readily available data from chart review at the time of the referral, we excluded patients with any of the following conditions: history of colorectal cancer or polyposis syndrome, acute gastrointestinal bleed, history of inflammatory bowel disease, use of anti-platelet or anticoagulant agents that prevent biopsy or polypectomy during colonoscopy, ASA Class III or greater, or inability to provide informed consent. All enrolled subjects provided written informed consent. Patient demographics including age, sex, race, and personal history of prior adenomatous polyps were recorded.

Endoscopy equipment

Endoscopies were performed using PENTAX high-definition adult and pediatric colonoscopies equipped with *i*-SCAN. A button-operated control head on the endoscope permits instant switch between high-definition white light (HDWL) and *i*-SCAN modes.

Endoscopic procedures

All colonoscopies were performed by two experienced endoscopists who have completed at least 2000 colonoscopies. Previous work with *i*-SCAN capitalized on its ability to enhance surface patterns for polyp histology prediction^[8,10], and thus Kudo pit pattern analysis was chosen for systematic histology prediction. The endoscopists had not previously used *i*-SCAN for the purpose of polyp prediction and thus underwent review of Kudo pit pattern characterization prior to enrolling patients. Posters showing pit pattern characteristics were also available for reference during all procedures.

After colonic preparation, patients underwent moderate sedation per endoscopy unit protocol. The endoscope was inserted to the cecum in standard fashion without attempt to detect polyps on insertion. Procedure time and quality of bowel preparation were graded by the endoscopist and recorded.

Upon reaching the cecum, the colonoscope was withdrawn in standard fashion using HDWL to visualize the

Figure 1 Correct prediction of small colonic polyps. A: Correctly predicted as hyperplastic, visualized under high-definition white light; B: Correctly predicted as hyperplastic, visualized under *i*-SCAN; C: Pathology demonstrating colonic mucosa with serrated architecture extending midway down the glands and non-dysplastic cytology, consistent with a hyperplastic polyp [hematoxylin and eosin (HE); 4 ×]; D: Correctly predicted as adenoma, visualized under high-definition white light; E: Correctly predicted as adenoma, visualized under *i*-SCAN; F: Pathology demonstrating colonic mucosa with hyperchromatic, elongated, and pseudostratified nuclei, consistent with a tubular adenoma (HE; 4 ×).

colonic mucosa. All polyps detected during the procedure were documented for size, location, and morphology. Size was estimated using open biopsy forceps for reference. Small polyps, those defined as less than 10 mm in size, were further evaluated as below.

When polyps less than 10 mm in size were identified by white light endoscopy, surface characteristics were first assessed using HDWL followed by *i*-SCAN. Endoscopists were not limited to any one *i*-SCAN mode. Endoscopists were asked to predict histology of the polyp in real time using Kudo pit pattern classification for each diagnostic modality. Images of the polyp in HDWL and *i*-SCAN were captured by the endoscopist (Figure 1). Polyp morphology was described using Paris classification system^[11]. Subsequently, the polyp was resected, collected in an individual specimen jar with fresh neutral buffered formalin, and sent to pathology. The samples were processed, and two hematoxylin and eosin sections were created and reviewed by a single surgical pathologist blinded to the colonoscopy findings. A maximum of five consecutive polyps per patient were examined using the *i*-SCAN modality. This restriction was implemented so as to avoid skewing results by the rare patient who might have multiple hyperplastic polyps in the rectum.

At the midpoint of the study as part of a pre-determined intervention, the study team reviewed incorrect predictions with each endoscopist. This intervention included a review of incorrectly predicted polyp images in both HDWL and *i*-SCAN.

Role of funding source

The protocol was an investigator-initiated study funded

by PENTAX Medical Company. PENTAX provided funding for the study coordinator and pathology costs. The funding source had no role in the study conduct, data collection, statistical analysis, interpretation, manuscript preparation, or decision to submit the manuscript for publication.

Statistical analysis

The primary outcome for the analysis is sensitivity, specificity, accuracy, and test characteristics of *i*-SCAN and HDWL in predicting the histology of small polyps in real time. Diagnostic test characteristics were evaluated by comparing with histopathologic diagnosis as the gold standard.

The test characteristics were calculated as binomial proportions from one-way frequency tables, and 95% confidence intervals were constructed using the exact confidence limits. Patient and polyp characteristics were compared between providers using Wilcoxon rank-sum test for continuous variables and χ^2 or Fisher's exact test for categorical variables. To assess the impact of patient and provider characteristics on the likelihood of accurate prediction, a generalized linear mixed model was used, with random effect of intercept and slope of polyp size to take within-patient dependency into account, and to allow intercept and slope differ across patients. We explored the learning curve with *i*-SCAN by comparing the endoscopists' prediction accuracy on polyps from patients from the first half of the study *vs* those from the second half. All data were analyzed by using the SAS version 9.2 (SAS Institute Inc., Cary, NC).

RESULTS

Study population characteristics

Eighty-two patients met enrollment criteria; seven patients declined to participate. Thus, 75 patients were enrolled during the study period between December 1, 2010 and April 1, 2011. The cecum was successfully intubated in 100% of cases. Baseline patient demographic data (Table 1) are shown. There were no significant differences between the two endoscopists in terms of patient age, sex, race, family history of colorectal cancer, or personal history of adenomatous polyps.

Quality metrics for the two endoscopists involved in the study are shown in Table 2. Due to scheduling variability, the majority of procedures in the study were performed by Endoscopist A. Endoscopist B took longer, on average, to complete procedures. There was no difference in polyp detection (*P* = 0.47) or polyp size (*P* = 0.34) between endoscopists.

Polyp characteristics

One hundred and three small polyps were included in the analysis among the 43 patients with polyps. The average

First Half	71.4 (57.8-82.7)	59.0 (42.1-74.4)	100 (80.5-100)
Second half	72.3 (57.4-84.4)	67.6 (49.5-82.6)	84.6 (54.6-98.1)
Sensitivity	72.2 (58.4-83.5)	63.9 (46.2-79.2)	88.9 (65.3-98.6)
Specificity	71.4 (56.7-83.4)	62.2 (44.7-77.5)	100 (73.5-100)
Positive predictive value	73.6 (61.7-85.5)	62.2 (44.6-76.6)	100 (79.4-100)
Negative predictive value	70.0 (57.3-82.7)	63.9 (46.2-79.2)	85.7 (57.2-98.2)

size of the polyps was 3.7 mm (SD 1.3 mm, range: 2-8 mm). Six of the 103 polyps (5.8%) were located in the rectum, 30 (29.1%) in the sigmoid, 7 (6.8%) were located in the descending colon, 35 (34.0%) in the transverse colon, and 25 (24.3%) in the ascending colon/cecum. By morphology, 101 of the 103 (98.1%) were described as by Paris Is, with only 1 polyp described as Paris Ip, and 1 described as Paris IIa.

Pathology revealed 54/103 (52.4%) adenomas, 26/103 (25.2%) hyperplastic, and 23/103 (22.3%) other diagnoses including “lymphoid aggregates”, “non-specific colitis”, and “no pathologic diagnosis”.

Test characteristics

The sensitivity, specificity, and accuracy of HDWL for the *in vivo* prediction of polyp histology are shown in Table 3. Overall sensitivity with all patients combined was 74.1%, specificity was 69.4%, and accuracy was 71.8%. Table 3 shows the sensitivity, specificity, and accuracy of *i*-SCAN for the *in vivo* prediction of polyp histology. Test characteristics with all patients combined showed sensitivity of 72.2%, specificity of 71.4%, and accuracy of 71.8%.

In addition to evaluating differences in the accuracy of prediction with *i*-SCAN between endoscopists, we also assessed for the presence of a learning effect. Namely, we compared the accuracy of *i*-SCAN in the first and second half of polyps examined by each endoscopist. Endoscopist A increased his accuracy from 59.0% to 67.6% whereas Endoscopist B decreased his accuracy from 100% to 84.6%. These differences were not statistically significant.

DISCUSSION

In the current study, we did not detect a difference in the

diagnostic efficacy of *i*-SCAN and HDWL in determining small colorectal polyp histology during screening and surveillance colonoscopy. The observed accuracy of HDWL in this study (74.1%) was similar to other studies in the literature^[12-14]. This suggests that poor physician performance or effort was less likely to explain suboptimal results. Furthermore, both endoscopists showed a baseline high sensitivity rate using HDWL, thus decreasing room for additional improvement when *i*-SCAN was then applied. Endoscopist B in particular showed such high baseline sensitivity and specificity for adenoma prediction (88.9% and 100% respectively) using HDWL alone that any additional improvement of *i*-SCAN as a diagnostic modality was virtually impossible.

In general, digital chromoendoscopic techniques including Fujinon intelligent chromoendoscopy (FICE), narrow band imaging, and *i*-SCAN have been shown to be practical for *in vivo* differentiation between adenomatous and hyperplastic polyps, but the accuracy has ranged across the literature from 70 to over 90 percent^[8-10,15-21]. The accuracy of *i*-SCAN in our study (71.8%) was lower than we would have expected based on published results and below the accuracy needed for clinical application^[22]. Promising studies using *i*-SCAN thus far have reported up to 90% accuracy^[10]. In addition, Hoffman *et al*^[8] showed sensitivity of 82% (9/11 adenomas) and specificity of 96% (52/54 hyperplastic polyps) in the distal 30 cm of the colon.

Our finding may be explained by a number of factors. First, in both of the above studies, endoscopies were performed by a single operator experienced in real-time polyp diagnosis. Our endoscopists, both of whom are experienced faculty members at an academic institution, did not have prior experience with digital chromoendoscopic techniques nor with pit pattern analysis prior to this study and thus underwent training with *i*-SCAN and pit pattern recognition. A specific, validated method for training practitioners in *i*-SCAN use and pit pattern recognition has yet to be described. It is promising that training methods have been validated in other chromoendoscopic techniques and have shown to improve diagnostic accuracy and interobserver agreement^[23,24]. Our findings highlight the importance of training *i*-SCAN in a standardized fashion, not only for replication of published results but also for potential future application in a general practice setting.

Another possible explanation for our results rests in the fact that magnification was not used in the study. We felt that the undue increase in procedure time and sedation for our patients, as well as poor quality of stored high magnification images, did not merit using high magnification. However, there may be an important role for high magnification in terms of improving diagnostic efficacy in combination with digital chromoendoscopic technique. For example, Kim *et al*^[17] reported in 2011 that the most significant improvements in diagnostic efficacy were found with FICE in conjunction with high magnifi-

cation, with a difference in 80.4% accuracy without high magnification to 87.0% with high magnification. In fact, high magnification was particularly helpful when evaluating polyps less than 5 mm, which was the size of the majority of polyps in our analysis.

Finally, it should also be noted that studies have employed a number of endoscopic classification schemes in studying the usefulness of digital chromoendoscopy. These include the Kudo pit pattern classification, the Japanese Society for Cancer of Colon and Rectum criteria, and specific classification schemes developed by the investigators^[10,15,25]. It remains unclear how generalizable these classification schemes are, especially when using different virtual chromoendoscopic techniques. Even with other well-studied chromoendoscopic techniques, the importance of standardizing nomenclature for surface pattern characteristics and defining interobserver variability within individual techniques has been recognized^[26].

This study does have a number of limitations. First, the training offered to the endoscopists involved in the study was not standardized, and it is unclear to what extent results may have changed with more formal training. We did not detect a significant learning effect during the course of the study though our sample size was small. Secondly, the Kudo polyp classification system used in this study has not been specifically validated for histology prediction using *i*-SCAN, though several groups have utilized surface characterization patterns to aid polyp histology prediction^[8,10]. Further studies validating a specific polyp classification system using *i*-SCAN may be helpful in this regard. Thirdly, patients were not randomized to the two imaging modalities nor was there a cross-over design. As such, it is unlikely that the accuracy of *i*-SCAN would be worse than HDWL because the polyp was first evaluated in HDWL.

There has been continued interest in real-time prediction of polyp histology for a number of practical reasons including the avoidance of unnecessary polypectomy, reducing complication risks, and improving cost efficiency from a histopathologic standpoint. While there have been many promising studies using multiple digital chromoendoscopic techniques, including *i*-SCAN, our study did not identify a benefit to using *i*-SCAN to predict polyp histology. The markedly different accuracy rate between endoscopists strongly suggests that there are endoscopist factors that predict success with *in vivo* diagnosis, similar to how endoscopist factors may predict adenoma detection rates^[27]. Further understanding these factors will be important to help guide training before the widespread application of virtual chromoendoscopic techniques in clinical practice.

COMMENTS

Background

The majority of polyps detected and removed during screening colonoscopy are small polyps (less than 10 mm in size) that are unlikely to represent advanced

neoplasm or invasive carcinoma. Accurate methods to predict histopathology of small polyps *in vivo* could potentially prevent unnecessary polypectomies or encourage a cost-effective "resect and discard" strategy during screening colonoscopy. PENTAX *i*-SCAN, a digital chromoendoscopy technology, might aid *in vivo* prediction of polyp histology. In this study, they assessed the accuracy of *in vivo* histology prediction of small colonic polyps using *i*-SCAN as compared to high-definition white light, using formal histopathology as the gold standard comparison.

Research frontiers

Several small studies using *i*-SCAN have shown promising results in improving accuracy of *in vivo* polyp histology prediction. However, the reliance on experienced experts with non-validated diagnostic criteria limits generalizability of published results.

Innovations and breakthroughs

The authors found no significant difference between the accuracy of *i*-SCAN and high-definition white light, with high baseline accuracy using high-definition white light. Interestingly, they did find a significant difference in accuracy between endoscopists, regardless of imaging modality. This suggests an important role for individual endoscopist factors and experience.

Applications

Understanding endoscopist factors and standardizing training using *i*-SCAN may improve not only the ability to reproduce published results, but also the future possibility to apply these technologies in a general practice setting.

Terminology

PENTAX *i*-SCAN is a digital chromoendoscopy technology that uses post-processing computer algorithms integrated into the standard high-definition processor to modulate light reflected from mucosa. This highlights surface contrast by "virtual chromoendoscopy" technique, analogous to the way conventional chromoendoscopy highlights surface contrast using indigo carmine dye.

Peer review

This study provides potentially useful information for improving the clinical applications of *i*-SCAN. It explains that histologic assessment of polyps is high using white light, that interobserver variability is high, and that the new refinements probably facilitate the general use of tissue recognition but may not be essential for experienced endoscopists. Endoscopist training likely plays a critical role and deserves further study and standardization.

Abstract

AIM: To evaluate the efficacy of human thrombin in the treatment of bleeding gastric and ectopic varices.

METHODS: Retrospective observational study in a Tertiary Referral Centre. Between January 1999-October 2005, we identified 37 patients who were endoscopically treated with human thrombin injection therapy for bleeding gastric and ectopic varices. Patient details including age, gender and aetiology of liver disease/segmental portal hypertension were documented. The thrombin was obtained from the Scottish National Blood Transfusion Service and prepared to give a solution of 250 IU/mL which was injected *via* a standard injection needle. All patient case notes were reviewed and the total dose of thrombin given along with the number of endoscopy sessions was recorded. Initial haemostasis rates, rebleeding rates and mortality were catalogued along with the incidence of any immediate complications which could be attributable to the thrombin therapy. The duration of follow up was also listed. The study was conducted according to the United Kingdom research ethics guidelines.

RESULTS: Thirty-seven patients were included. 33

patients (89%) had thrombin (250 U/mL) for gastric varices, 2 (5.4%) for duodenal varices, 1 for rectal varices and 1 for gastric and rectal varices. (1) Gastric varices, an average of 15.2 mL of thrombin was used per patient. Re-bleeding occurred in 4 patients (10.8%), managed in 2 by a transjugular intrahepatic portosystemic shunt (TIPSS) (one unsuccessfully who died) and in other 2 by a distal splenorenal shunt; (2) Duodenal varices (or type 2 isolated gastric varices), an average of 12.5 mL was used per patient over 2-3 endoscopy sessions. Re-bleeding occurred in one patient, which was treated by TIPSS; and (3) Rectal varices, an average of 18.3 mL was used per patient over 3 endoscopy sessions. No re-bleeding occurred in this group.

CONCLUSION: Human thrombin is a safe, easy to use and effective therapeutic option to control haemorrhage from gastric and ectopic varices.

INTRODUCTION

Haemorrhage from gastric or ectopic varices is associated with high morbidity and mortality and can account for up to one third of all cases of variceal haemorrhage^[1]. In

the presence of oesophageal varices, the prevalence of gastric varices ranges from 15% to 100%^[2,3] with the risk of bleeding generally regarded to range from 4%-65% over the first 2 years after diagnosis^[2,4]. More importantly it has been reported that although gastric varices are less likely to bleed than oesophageal varices, once they bleed, they tend to do so more severely and haemostasis can be difficult to achieve^[2].

Unlike oesophageal variceal haemorrhage, bleeding from gastric varices has not been extensively studied. The natural history of bleeding gastric varices differs from that of oesophageal varices and thus the precipitating event for gastric variceal haemorrhage remains uncertain. Predictive factors for oesophageal variceal haemorrhage such as a hepatic venous pressure gradient (HVPG) of > 20 mmHg^[5] is not felt to be as relevant to gastric variceal bleeding and this is partly attributed to the development of gastroduodenal shunts. Indeed we have previously demonstrated that a portal pressure gradient (PPG) of < 12 mmHg does not necessarily protect against gastric variceal bleeding and that a PPG < 7 mmHg is a better safeguard against rebleeding^[6]. The variceal size, tortuosity and stigmata of recent bleeding such as red signs however remain alarming features^[4].

Thrombin was first used for the management of gastric varices in 1947^[7] and affects haemostasis by converting fibrinogen to a fibrin clot. It also has other influences on the coagulation system with one effect being the enhancement of local platelet aggregation. Endoscopic treatment with thrombin has been reported in the treatment of bleeding oesophageal, gastric and duodenal varices^[8-10] with a low rate of rebleeding. The most recent study from Ramesh *et al*^[11] reported that haemostasis was achieved in the acute setting in 92% patients presenting with bleeding gastric varices, with only one patients requiring a transjugular intrahepatic portosystemic shunt (TIPS) to control bleeding. The majority of these studies are however retrospective and include small patient numbers.

The aim of this study is therefore to evaluate the use of human thrombin in the treatment of gastric and ectopic varices.

MATERIALS AND METHODS

We identified 37 consecutive patients who were treated with human thrombin (Scottish National Blood Transfusion Service) from January 1999-October 2005 for isolated bleeding from gastric and ectopic varices. Thrombin was injected rather than cyanoacrylate as this was our Units protocol. The case notes were reviewed and total volume of thrombin used and the incidence of complications recorded, as was the incidence of re-bleeding or death. Those patients with bleeding oesophageal varices who underwent banding of varices or any patient in which there was diagnostic doubt as to the aetiology of bleeding were excluded. The study was conducted ac-

cording to the United Kingdom research ethics guidelines. Following consideration by the local ethics committee, further specific ethical review and approval was not required, as the study was considered a retrospective audit using anonymised data obtained as part of usual patient care.

Patient characteristics

Twenty-eight of the patients were male (male:female ratio = 28:9) with a mean age at presentation of 53.2 years (range: 18-83 years). The underlying aetiology was alcoholic liver disease in 15 patients, splenic vein thrombosis in 6, cryptogenic cirrhosis in 6, primary biliary cirrhosis in 2, chronic active hepatitis in 2, portal vein thrombosis in 2, primary sclerosing cholangitis in 2, α 1-antitrypsin deficiency in 1, congenital hepatic fibrosis in 1 and hepatitis C in 1 patient. The Childs-Pugh grade: grade A = 5 patients, grade B = 16 patients and grade C = 10 patients. Segmental portal hypertension was defined as extrahepatic portal hypertension in the absence of liver cirrhosis and was seen in 6 patients whose underlying aetiology was splenic vein thrombosis.

Endoscopic therapy

All patients had an upper gastrointestinal endoscopy/flexible sigmoidoscopy performed by an experienced operator within 12 h of presentation. Gastric variceal haemorrhage was defined as visible spurting or oozing of blood from the lesser curve or fundal vessels at the time of endoscopy with varices subdivided into fundal and non fundal. Sarin's classification for gastric varices was used but it was noted that it is often difficult to differentiate the types of fundal varices in patients who are actively bleeding. The gastric and duodenal varices were also considered to have bled if there were stigmata of recent bleeding such as red spots or adherent clot. Rectal variceal haemorrhage was defined by the presence of rectal varices with either adherent clot or visible active bleeding combined with a history of profuse fresh blood loss per rectum.

In those patients with splenic vein thrombosis, an alternative therapy such as splenectomy may be considered by some but it is important that bleeding is controlled and therefore all these patients underwent endoscopy and stabilization of bleeding prior to consideration for splenectomy.

Protocol for thrombin therapy

All patients were adequately resuscitated at the time of endoscopy. Human thrombin concentrate obtained from the Scottish National Blood Transfusion Service and each vial was reconstituted with 5 mL of water to give a concentration of 250 U/mL. As thrombin was being used outwith its licensed use, informed written consent was obtained from each patient prior to endoscopy. The thrombin was injected directly into the varices using a standard injection sclerotherapy needle to a maximum

Figure 1 Injection of gastric varices with thrombin. A: During thrombin injection the gastric varix swells; B: Post thrombin injection.

volume of 10 mL at any one session by multiple injections. Repeat endoscopy was arranged initially for one week then at two weekly intervals until further injection was deemed unnecessary by the endoscopist as the overlying mucosa had returned to normal in which the varix appeared well covered with no stigmata of recent haemorrhage. The number of endoscopy sessions, the total volume of thrombin used and the incidence of complications were documented.

RESULTS

Thirty-three patients (89%) had thrombin for gastric varices, two (5.4%) for duodenal varices, one for rectal varices and one for gastric and rectal varices. A small number of patients in this cohort were in our original pilot study^[12]. Twenty seven patients (82%) also had oesophageal varices with 19 patients (58%) already in a banding programme. Only 3 patients were on beta-blocker therapy prior to admission. The average total volume of thrombin used per patient was 15.2 mL (range: 5-47.5 mL, combined rectal and gastric varices) over 1-7 endoscopy sessions (median 3.6 sessions).

For those patients with gastric varices, 82% were classified as gastro-oesophageal varices (GOV) type 2 with the remainder being classified as isolated gastric varices (IGV) type 1 (12 %) and type 2 (6%). In two cases where it was not absolutely clear whether they were GOV type 1 or type 2 they were included as type 2. An average of 15.2 mL of thrombin was used per patient (Figure 1). Re-bleeding occurred in four patients (10.8%), three of which bled before the 2nd endoscopy session (i.e., within 7 d of index bleed) and two of whom were managed by TIPSS. One of the TIPSS procedures was unsuccessful and the patient subsequently died after a rebleed. The two other patients were successfully treated by distal splenorenal shunt.

For those two patients with duodenal varices, an average of 12.5 mL was used per patient over 2-3 endoscopy sessions. Re-bleeding occurred at day 3 in one patient which was treated successfully by TIPSS insertion.

For the patient with rectal varices, an absolute volume

of 18.3 mL was used over three endoscopy sessions. No re-bleeding occurred in this group.

Only a small proportion of patients (15%) had additional therapy with vasopressor agents, the use of which did not change outcome. All patients with liver disease received five days of intravenous antibiotics as per our units protocol. In addition, true eradication of varices was rare with varices deemed visually eradicated in only two patients. No HVP measurements were obtained in any patient as this is not our Units protocol. Overall mortality was 2.7% after median follow up of 22 mo.

Complications

No clinically significant adverse events occurred following thrombin therapy with median follow up of 22 mo.

DISCUSSION

Gastric varices are generally classified by their location in the stomach and their relationship with oesophageal varices, as proposed by Sarin *et al*^[2]. GOV is the term used to describe gastric varices that are associated with oesophageal varices and are classified as either type 1 or type 2. IGV is used to refer to gastric varices that occur independently of oesophageal varices. It is observed that type 1 GOV (which are primarily supplied by the left gastric vein) represent 75% of all gastric varices observed. However it is generally regarded that the most serious haemorrhage occurs when type 1 IGV gastric varices (primarily supplied by the short gastric vein) bleed.

Various treatment options exist for the management of bleeding gastric varices and include endoscopic methods, TIPSS and other radiological procedures. Surgical procedures such as under running of gastric varices or devascularization procedures has previously been used but in the small studies performed have shown no great benefit and thus are rarely performed today.

Although there is debate regarding optimum treatment of gastric variceal haemorrhage, endoscopic therapy is an established treatment and it is currently recommended in the United Kingdom to be the first line treatment in the management of acute gastric variceal

haemorrhage^[13]. Endoscopic treatment options include standard sclerotherapy, band and snare ligation or endoscopic injection with cyanoacrylate or thrombin.

Standard sclerotherapy using ethanolamine as the sclerosing agent has been used with moderate success in the treatment of bleeding oesophageal varices but has limited success in the treatment of bleeding gastric varices. It is widely accepted that sclerotherapy for gastric varices requires significantly greater volumes of sclerosant^[2] which is thought to account for the increased number of side effects that are observed^[14]. The initial haemostasis rates obtained when using sclerotherapy have been reported to vary widely from 26%-100%^[11-16] which may reflect different operator ability and injection techniques. However a rebleeding rate of 60%-90% has been reported in most studies which is generally observed in patients with bleeding fundal varices^[1,17]. The majority of the rebleeding episodes have been reported to be related to ulceration at the injection site.

Endoscopic injection therapy with tissue adhesives such as cyanoacrylate has also been shown to be of benefit in the management of bleeding gastric varices and is becoming more popular due to the high rebleeding rates observed with sclerotherapy. A 90% success rate in achieving initial haemostasis has been reported in a number of non randomised studies^[18-20] but Ramond *et al*^[21] also reported a rebleeding rate of 50%. Several studies have also demonstrated that the use of tissue adhesives is superior to standard sclerotherapy. Oho *et al*^[3] have published results of a controlled but non-randomised study which demonstrated that initial control of gastric variceal bleeding and survival was significantly greater in patients treated with cyanoacrylate than standard sclerotherapy. Sarin *et al*^[22] have published results for a small randomised control trial which again suggested that the use of cyanoacrylate was superior to standard sclerotherapy. Complications rates between the two procedures have been reported to be similar but of course this depends primarily on the expertise available. In the hands of inexperienced operators, tissue adhesives can cause irreparable damage to the endoscope. In addition, a few centres have reported the occurrence of systemic emboli after the use of tissue adhesives to control variceal haemorrhage^[23,24].

Gastric variceal band ligation using 'O' rings and detachable snares have also been used in the management of gastric variceal haemorrhage but with high rebleeding rates being observed^[25]. Yoshida *et al*^[26,27] have however published data on the combined use of the detachable snare and simultaneous injection sclerotherapy and O-ring ligator. In a study of 43 patients^[26], 97% had eradication of gastric varices with an 8% rebleeding rate observed within a 2 year follow up period.

The optimal treatment for the management of gastric varices therefore remains uncertain but as our results suggest, a promising therapeutic option is the use of intravariceal injection of thrombin. The use of thrombin

in bleeding gastric or ectopic varices has only previously been reported in a handful of studies in which a variety of thrombin preparations have been used. To our knowledge, this study is currently the largest published study using human thrombin.

For the management of bleeding gastric varices, our rates of achieving initial haemostasis were in keeping with 93% published by Datta *et al*^[10] and 100% by Williams *et al*^[9]. Our rebleed rate of 14% was again in keeping with data published by Williams *et al*^[9] but it should however be recorded that the median follow up time in these studies varied greatly from six weeks to nine mo. It should also be documented that this rebleed rate was observed without us actively attempting to visually eradicate the varices and may suggest that continued thrombin injection to achieve visual eradication appears unnecessary. This point was emphasised when we examined the number of endoscopic sessions in which thrombin was given as initially the procedure was performed out to 7 sessions. It was only after analysis of these pilot data that rebleeding was deemed extremely rare after 3 endoscopic sessions and that eradication of gastric varices was unnecessary. It is therefore now our Units adopted policy that patients should be treated with thrombin for 3 endoscopic sessions. Overall, our mortality rate of 2.7% highlights how effective thrombin therapy can be, but it should be recorded that these results were obtained after 5 patients who rebleed underwent further interventions: namely TIPSS or splenorenal shunt surgery.

The thrombin used in this study was obtained free of charge from Blood Transfusion Service but we have now changed to using a recombinant thrombin preparation at cost of £250 for concentration of 250 IU/mL. This is comparable to the cost of cyanoacrylate and the cost of TIPSS (at £5000).

Currently, no randomised controlled trials comparing thrombin with tissue adhesives or sclerotherapy have been performed. Interestingly however, Kojima *et al*^[28] have published results for 30 patients with bleeding fundal varices that underwent sclerotherapy with ethanolamine under fluoroscopic guidance with the injection site being sealed with topical thrombin glue. All participants also received intravenous vasopressin and transdermal nitroglycerin. They reported an initial haemostasis rate of 93% with a rebleed rate of 19% after 5 years of follow up. The efficacy of the topical thrombin is however difficult to determine and the specialized technique and equipment required for this procedure may limit its future application.

With regards to the safety of human thrombin, we did not record any complications of thrombin use and this is again in keeping with all of the previously published studies that have used human thrombin. Complications such as anaphylaxis or altered thrombogenesis that have previously been reported with the use of bovine thrombin did not occur^[29].

Although in this study we have not monitored the

effect of thrombin by any means, we have evidence that results can be further improved by assessing clot formation with other means such as endoscopic ultrasound^[30].

In conclusion, We have shown that human thrombin is a safe, easy to use and effective therapeutic option in the management of bleeding gastric and ectopic varices. Our study also suggests that continued thrombin injection to achieve visual eradication appears unnecessary. Larger randomised control trials are necessary to compare the use of human thrombin with the current available therapeutic modalities.

COMMENTS

Background

Haemorrhage from gastric or ectopic varices is associated with high morbidity and mortality and can account for up to one third of all cases of variceal haemorrhage.

Research frontiers

Unlike oesophageal variceal haemorrhage, bleeding from gastric varices has not been extensively studied. The natural history of bleeding gastric varices differs from that of oesophageal varices and thus the precipitating event for gastric variceal haemorrhage remains uncertain.

Innovations and breakthroughs

Initial haemostasis rates, rebleeding rates and mortality were catalogued along with the incidence of any immediate complications which could be attributable to the thrombin therapy. The duration of follow up was also listed. The study was conducted according to the United Kingdom research ethics guidelines.

Applications

Human thrombin is a safe, easy to use and effective therapeutic option in the management of bleeding gastric and ectopic varices.

Peer review

The results of a retrospective study concerning 37 patients, who were treated with thrombin injection for bleeding gastric or ectopic varices. Their major finding is that in patients with gastric varices this treatment is effective. The authors conclude that thrombin injection may be used to treat patients with gastric or ectopic variceal bleeding.

Abstract

AIM: To investigate in symptomatic uncomplicated diverticular disease the efficacy of symbiotics associated with a high-fibre diet on abdominal symptoms.

METHODS: This study was a multicentre, 6-mo randomized, controlled, parallel-group intervention with a preceding 4-wk washout period. Consecutive outpatients with symptomatic uncomplicated diverticular disease, aged 40-80 years, evaluated in 4 Gastroenter-

ology Units, were enrolled. Symptomatic uncomplicated diverticular disease patients were randomized to two treatment arms A or B. Treatment A ($n = 24$ patients) received 1 symbiotic sachet Flortec® (*Lactobacillus paracasei* B21060) once daily plus high-fibre diet for 6 mo. Treatment B ($n = 21$ patients) received high-fibre diet alone for 6 mo. The primary endpoint was regression of abdominal symptoms and change of symptom severity after 3 and 6 mo of treatment.

RESULTS: In group A, the proportion of patients with abdominal pain < 24 h decreased from 100% at baseline to 35% and 25% after 3 and 6 mo, respectively ($P < 0.001$). In group B the proportion of patients with this symptom decreased from 90.5% at baseline to 61.9% and 38.1% after 3 and 6 mo, respectively ($P = 0.001$). Symptom improvement became statistically significant at 3 and 6 mo in group A and B, respectively.

The proportion of patients with abdominal pain > 24 h decreased from 60% to 20% then 5% after 3 and 6 mo, respectively in group A ($P < 0.001$) and from 33.3% to 9.5% at both 3 and 6 mo in group B ($P = 0.03$). In group A the proportion of patients with abdominal bloating significantly decreased from 95% to 60% after 3 mo, and remained stable (65%) at 6-mo follow-up ($P = 0.005$) while in group B, no significant changes in abdominal bloating was observed ($P = 0.11$). After 6 mo of treatment, the mean visual analogic scale (VAS) values of both short-lasting abdominal pain (VAS, mean \pm SD, group A: 4.6 ± 2.1 vs 2.2 ± 0.8 , $P = 0.02$; group B: 4.6 ± 2.9 vs 2.0 ± 1.9 , $P = 0.03$) and abdominal bloating (VAS, mean \pm SD, group A: 5.3 ± 2.2 vs 3.0 ± 1.7 , $P = 0.005$; group B: 5.3 ± 3.2 vs 2.3 ± 1.9 , $P = 0.006$) decreased in both groups, whilst the VAS values of prolonged abdominal pain decreased in the Flortec® group, but remained unchanged in the high-fibre diet group (VAS, mean \pm SD, group A: 6.5 ± 1.5 vs 4.5 ± 2.1 , $P = 0.052$; group B: 4.5 ± 3.8 vs 5.5 ± 3.5).

CONCLUSION: A high-fibre diet is effective in relieving

abdominal symptoms in symptomatic uncomplicated diverticular disease. This treatment may be implemented by combining the high-fibre diet with Flortec[®].

INTRODUCTION

Diverticular disease (DD) of the colon is a very common disorder which remains asymptomatic in nearly 80% of patients. The remaining patients develop recurrent abdominal symptoms and some complications, such as diverticulitis and bleeding, requiring hospital admission and surgery^[1-3]. The main goals of symptomatic DD management are both relief of abdominal symptoms and prevention of acute diverticulitis^[4].

The standard therapeutic approach for symptomatic uncomplicated DD still remains to be defined. Guidelines of the American College of Gastroenterology, the European Association for Endoscopy Surgery, and the World Gastroenterology Organization recommend a high-fibre diet in patients with symptomatic uncomplicated DD^[5,6]. Some data would suggest that cyclic treatment with nonabsorbable antibiotics plus high-fibre diet is more effective in obtaining symptom relief as compared to diet alone^[7,8], and it reduces the incidence of first episode of acute diverticulitis at 1 year^[9]. However, the level of evidence of superiority of nonabsorbable antibiotics over dietary fibre or fibre supplementation is poor^[10], and both the cost and efficacy of a long-life cyclic treatment with nonabsorbable antibiotics to prevent diverticulitis in all symptomatic DD patients has been questioned^[11,12].

A recent systematic review suggest the potential usefulness of fibre, rifaximin, mesalazine, and probiotics, and their possible combination in symptomatic uncomplicated DD treatment, but reliable controlled therapeutic trials are still lacking^[12].

Probiotics, prebiotics, and symbiotics may modify

the gut microbial balance leading to health benefits^[13-16]. Changes in peri-diverticular bacterial flora have been suggested as a potential key step in the pathogenesis of diverticular microscopic inflammation. This, in turn, may play a role in generating abdominal symptoms in uncomplicated DD, thus making probiotics an appealing therapy for DD. Some data suggest that probiotic therapy is safe and potentially useful in the management of DD patients^[17]. Flortec[®] is a totally natural symbiotic agent, consisting of the synergistic combination of *Lactobacillus paracasei* (*L. paracasei*) B21060 (probiotic component) and arabinogalactan/xylooligosaccharides (prebiotic component). Flortec[®] treatment has been shown to be effective in relieving symptoms associated with irritable bowel syndrome^[18], and in the treatment of acute diarrhea in adults treated at a primary care setting^[19]. The therapeutic benefit of this symbiotic formulation in addition to a high dietary fibre intake in symptomatic uncomplicated DD remains to be defined. The primary aim of this cluster randomized study was to investigate the efficacy of a patented symbiotic preparation containing *L. paracasei* B21060 in association with high-fibre diet compared to high-fibre diet alone on relief of abdominal symptoms in patients with symptomatic uncomplicated DD.

MATERIALS AND METHODS

Study population

Consecutive outpatients were evaluated in 4 Gastroenterology Units (1 academic and 3 nonacademic) for enrolment in the study. Inclusion criteria were a well-established diagnosis of symptomatic uncomplicated DD and age ranging from 40 to 80 years. The study was performed over a 10 mo period from March, 2010 to January, 2011.

Symptomatic uncomplicated DD was defined as the presence of colonic diverticula associated with abdominal pain and/or bloating for at least 6 mo before recruitment, without signs of acute diverticulitis^[20]. Signs of acute inflammation were excluded by physical examination (to ascertain the absence of abdominal rigidity, rebound tenderness, and/or guarding in one or more abdominal quadrants), as well as routine biochemistry (complete blood count, erythrocyte sedimentation rate, C-reactive protein, protein electrophoresis). To quantify and localize the colonic diverticula, double contrast enema and/or colonoscopy was performed. Exclusion criteria were: presence of less than 5 diverticula, recent history (< 3 mo) or actual clinical evidence of acute diverticulitis, previous colonic surgery, antibiotics, mesalazine, nonsteroidal anti-inflammatory drugs or laxative use during the four weeks before enrolment, coexisting inflammatory bowel disease, diseases with possible small intestine bacterial overgrowth. Patients were also excluded if dyspeptic symptoms were predominant over abdominal symptoms and when low compliance or motivation could be expected for any reason. All patients provided written informed consent.

Figure 1 Flowchart of the patients throughout the study. ¹3 patients dropped out after 3 mo of treatment, 1 patient for new onset of constipation and 2 patients for worsening of abdominal symptoms.

Study design

This study was a multicentre, 6-mo randomized, controlled, parallel-group intervention with a preceding 4-wk washout period. All patients were instructed to follow a high-fibre diet containing at least 30 g daily intake of dietary fibre as well as a daily water intake of at least 1.5 L. For this purpose, all patients were given an information sheet regarding the content of dietary fibre in commonly consumed fruits, vegetables and cereals, and dietary counselling was performed. According to cluster randomization^[21], each participating centre was randomly assigned to recruit patients for either treatment A or B. For 6 mo, treatment arm A received a once daily dose of the symbiotic preparation Flortec[®] administered orally, plus high-fibre diet, while treatment arm B was treated with high-fibre diet only (Figure 1). Rescue medication was not allowed during the study period.

All patients underwent 3 clinical interviews: at study entry and after 3 and 6 mo of intervention. Patients were evaluated for abdominal symptoms, compliance to therapy assessed by a structured questionnaire, and routine biochemistry (complete blood count, erythrocyte sedimentation rate, C-reactive protein, protein electrophoresis) was done to exclude signs of acute inflammation. In order to assess compliance to the high-fibre diet and to verify eventual changes in dietary fibre intake, at study entry and 3- and 6-mo follow-up clinical interviews, the daily fibre intake during the 7 d before the interview was recorded (a semiquantitative score ranging from 0–28 was used: for each day of the week max 4 points were assigned: 1 point for intake of fruit and another point for intake of vegetables or whole grain cereals at lunch and/or dinner). The primary endpoint considered was the regression of abdominal symptoms and change in symptom severity after 3 and 6 mo of treatment. As a secondary endpoint the tolerability of treatment - i.e., oc-

currence of adverse effects was considered.

Symptom assessment

Symptoms of patients were evaluated at study entry and after 3 and 6 mo of treatment by assessing the presence/absence and intensity of abdominal pain lasting more or less than 24 h and the presence/absence and intensity of abdominal bloating^[19,21]. Patients were asked to grade the intensity of abdominal symptoms on a visual analogic scale (VAS) consisting of a 10 cm long line with 0 cm indicating “no sensation” and 10 cm indicating “the strongest sensation ever felt”.

Symbiotic preparation, Flortec[®]

Flortec[®] (Bracco Co, Milan, Italy) is a composite symbiotic formulation and each 7 g sachet contains 5×10^9 colony-forming units viable lyophilized *L. paracasei* B12060. The dry powder bacteria were mixed with the following excipients: xylo-oligosaccharides (700 mg), glutamine (500 mg), and arabinogalactone (1243 mg). As glutamine and oligosaccharides have some prebiotic activities on human fecal flora, the Flortec formulation combines the synergistic effect of a prebiotic with a probiotic (a symbiotic formulation). The study preparation was in powder form. Patients were instructed to store the preparation at room temperature (< 20 °C) in a dry place and to dissolve the powder preparation in 100 mL of water once daily and to ingest it immediately 2 h after lunch.

Statistical analysis

The sample size was calculated considering data reported in literature: we expected that dietary fibre supplementation would be effective in 30% of cases, accepting a range from 15% to 45% (5, 12) s Because the combined efficacy of high-fibre diet and symbiotic supplementation is not known in literature, for this pilot study a superiority

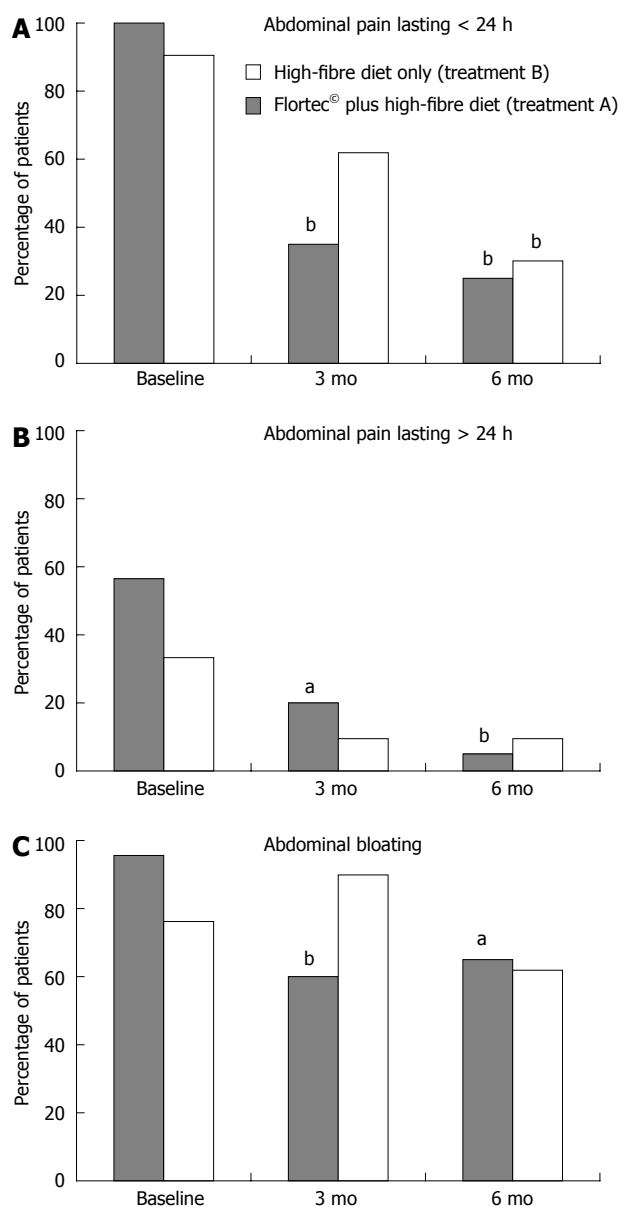

Figure 2 Change of abdominal symptoms after treatment according to intention-to-treat analysis. A: Abdominal pain lasting < 24 h; B: Abdominal pain lasting > 24 h; C: Abdominal bloating. ^a $P < 0.05$, ^b $P < 0.01$ vs baseline.

of about 30% for the second treatment arm over the first one was supposed, and a total of 50 cases (25 for each arm) were needed, with an α error of 10% and a study power of 80%.

The analysis was carried out on the intention-to-treat (ITT) population, defined as all randomized patients who performed at least one follow-up assessment after baseline, and on the per-protocol population, defined as all patients who completed the prescribed treatment in the 6-mo-treatment period. The presence of abdominal symptoms was expressed as number (%) of total patients and in terms of severity as mean \pm SD of VAS. Data were analysed by Fisher's exact and/or Student's *t*-test. To test for differences between the baseline, 3- and 6-mo sets of proportion of patients presenting abdominal pain or bloating, Cochran's *Q* test was performed. The results

Table 1 Demographic characteristics and baseline symptoms

VAS: Visual analogic scale. Data are presented by mean \pm SD or n (%).

were coded 0 for absence and 1 for presence of abdominal symptoms. The compliance to high-dietary fibre intake was assessed by analysis of variance. The *P* values were considered significant if they were less than 0.05. The statistical analyses were carried out using a dedicated software package (MedCalc Software, Mariakerke, Belgium, version 10.1.2).

RESULTS

Baseline characteristics

Of the 52 randomized patients with symptomatic uncomplicated DD (35 females, mean age 66.3 ± 9.5 years), at baseline 48 (92.3%) had abdominal pain lasting less than 24 h, 22 (42.3%) had abdominal pain lasting more than 24 h, and 42 (80.8%) had abdominal bloating, whereas dyspeptic symptoms were present in only 6 (11.5%) patients. Demographic and clinical characteristics of patients are given in Table 1. No differences between the treatment groups were observed with respect to baseline characteristics and gastrointestinal symptoms. The dietary fibre intake score was not statistically different between groups (13.3 ± 7.3 vs 16.0 ± 9.1 , $P = 0.30$).

The flowchart in Figure 1 shows the progress of patients from recruitment until the end of the study. Of the 52 randomized patients, 30 (57.7%) were allocated to the Flortec® plus high-fibre diet group (group A) and 22 (42.3%) to the high-fibre diet group (group B). Eight patients were lost at 3-mo follow-up, and, therefore, 44 patients were included in the ITT population. In group A, 3 patients dropped out after 3 mo of treatment, 1 patient for new onset of constipation and 2 patients for worsening of abdominal symptoms, while in group B all 21

patients completed the 6-mo treatment period. Thus, the PP population consisted of 41 patients.

Compliance to high-fibre diet

At baseline, 3- and 6-mo evaluation, the dietary fibre intake scores were not different between the Flortec[®] group and the high-fibre diet group. In particular, in group A patients, the dietary fibre intake score was 16 ± 9.1 at baseline (17.9 ± 7.3 *vs* 16 ± 9.1 , $P < 0.01$ at 3 mo; 18.3 ± 7 *vs* 16 ± 9.1 , $P < 0.01$ at 6 mo). In group B patients, this score increased from 13.3 ± 7.3 at baseline to 18.4 ± 6.1 at 3 mo ($P < 0.0001$) and to 21.4 ± 4.5 at 6 mo ($P < 0.0001$). Dietary fibre intake similarly increased in both groups over the study period ($P = 0.702$).

Efficacy of treatment

As shown in Figure 2, in group A the proportion of patients with abdominal pain lasting less than 24 h significantly decreased from 100% at baseline to 35% after 3 mo and to 25% after 6 mo of treatment ($P < 0.001$ by Cochran's Q test). In group B the proportion of patients with this symptom decreased from 90.5% at baseline to 61.9% after 3 mo and to 38.1% after 6 mo of treatment ($P = 0.001$ by Cochran's Q test). The symptom improvement became statistically significant at 3 and 6 mo in groups A and B, respectively.

In group A, the proportion of patients with abdominal pain lasting more than 24 h (Figure 2) significantly decreased from 60% at baseline to 20% after 3 mo and further decreased to 5% after 6 mo of treatment ($P < 0.001$ by Cochran's Q test). In group B, the proportion of patients with prolonged abdominal pain significantly decreased from 33.3% at baseline to 9.5% after 3 mo, and remained stable (9.5%) at 6-mo follow-up ($P = 0.03$ by Cochran's Q test).

As shown in Figure 2, in group A the proportion of patients with abdominal bloating significantly decreased from 95% to 60% after 3 mo, and remained stable (65%) at 6-mo follow-up ($P = 0.005$ by Cochran's Q test). In group B, no significant changes in abdominal bloating was observed, the proportion of patients complaining such a symptom being 76.2%, 80.9%, and 61.9% at entry, 3-, and 6-mo follow-up, respectively ($P = 0.11$ by Cochran's Q test).

In the high-fibre diet group, 3 patients described the new onset of abdominal symptoms during the study period; 1 patient experienced prolonged abdominal pain and 2 patients abdominal bloating, whilst no onset of new symptoms occurred in the Flortec[®] group.

After 6 mo of treatment, the mean *VAS* values of both short-lasting abdominal pain (*VAS*, mean \pm SD, group A: 4.6 ± 2.1 *vs* 2.2 ± 0.8 , $P = 0.02$; group B: 4.6 ± 2.9 *vs* 2.0 ± 1.9 , $P = 0.03$) and abdominal bloating (*VAS*, mean \pm SD, group A: 5.3 ± 2.2 *vs* 3.0 ± 1.7 , $P = 0.005$; group B: 5.3 ± 3.2 *vs* 2.3 ± 1.9 , $P = 0.006$) decreased in both groups, whilst the *VAS* values of prolonged abdominal pain decreased in the Flortec[®] group, but remained unchanged in the high-fibre diet group (*VAS*,

mean \pm SD, group A: 6.5 ± 1.5 *vs* 4.5 ± 2.1 , $P = 0.052$; group B: 4.5 ± 3.8 *vs* 5.5 ± 3.5).

None of the patients developed altered biochemical inflammatory parameters, acute diverticulitis or other diverticular disease complications throughout the 6-mo study period. In both groups no adverse event was registered over the 6-mo treatment period.

DISCUSSION

High-fibre diet is largely suggested for symptomatic uncomplicated DD patients^[5,6]. Probiotic therapy may be of benefit in DD patients, but its efficacy when combined with high-fibre diet remains to be established. This pilot study investigated the efficacy of a continuous 6-mo treatment with a symbiotic preparation containing *L. paracasei* B21060 associated with a high-fibre diet compared to a high-fibre diet alone in patients with symptomatic uncomplicated DD. The main findings of this study were that (1) a high-fibre diet alone is effective on some abdominal symptoms of symptomatic uncomplicated DD patients, but the combination of this approach with a symbiotic preparation containing *L. paracasei* B21060 allows an increase in the therapeutic response; and (2) the prescription of a high-fibre diet increases the intake of dietary fibre over time, regardless of whether a single diet or combined approach with symbiotic supplementation is used.

In detail, the high-fibre diet alone was effective in reducing short-lasting abdominal pain following 6 mo of treatment, but using the combined approach with Flortec[®] a regression of this symptom was already observed after 3 mo. With the dietary approach alone regression of prolonged abdominal pain was observed ($P = 0.03$), but this therapeutic response was more accentuated with the combined treatment strategy. Finally, abdominal bloating significantly regressed only with the symbiotic treatment, while high-fibre diet alone had no beneficial effect on this symptom. Taken together, these findings show that the combined approach offers an advantage over the dietary approach alone in improving the therapeutic response of patients with symptomatic uncomplicated DD with regard to abdominal symptoms.

Our study also showed that both groups significantly increased dietary fibre intake over the study period. This result may be explained by the fact that according to our study design the prescription of a high-fibre diet was supported by a dietary information sheet and followed over time by registering an intake score. It is likely that this systematic approach may have increased the intake of dietary fibre over time, perhaps due to an increased awareness that the prescription of diet needs to be taken seriously, like a real treatment option and not as a simple suggestion.

To date, the underlying mechanisms of the therapeutic benefit of dietary fibre in diverticular disease are not fully understood, albeit a relationship with stool volume and transit time has been hypothesized^[15,22]. More recently,

it has been shown that vegetarians are less likely than non-vegetarians to have radiologically confirmed diverticulosis (12% *vs* 33%), and that the insoluble component of fibre is associated with a decreased risk (relative risk 0.63, 95%CI: 0.36 to 0.75) of DD^[23], thus giving an indirect rationale for the high-fibre diet in symptomatic uncomplicated DD.

However, abdominal bloating was not effectively treated with a high-fibre diet, but a good therapeutic response was obtained in the Flortec[®] group only. This result is not surprising because it is well known that a high-fibre diet may increase the presence of intestinal gas due to an increase in the gas-producing intestinal microflora^[24]. Indeed, among our study population, it was only in the high-fibre diet group that patients with a new onset of abdominal bloating during the study period were registered.

The rationale for the use of probiotics in symptomatic uncomplicated DD is given by their anti-inflammatory effects and capability to enhance anti-infective defences by (1) maintaining an adequate bacterial colonization in the gastrointestinal tract; (2) inhibiting colonic bacterial overgrowth and metabolism of pathogens; and (3) reducing proinflammatory cytokines^[13,14]. In DD, local alterations of the peridiverticular colonic flora have been included as one of the causes leading to periods of symptomatic disease^[1-3]. Thus, the therapeutic benefit of the supplementation of *L. paracasei* B21060 observed in our study may be explained by the ability of probiotics to ensure an optimal colonic microenvironment, which is probably able to prevent local diverticular inflammation and to reduce abdominal symptoms. This idea is supported by experimental data showing that *L. paracasei* is able to survive the passage through the gastrointestinal tract, to persist in stools after administration is discontinued, and to temporarily associate throughout different sites of the entire human colon, suggesting a positive ecological role played by this probiotic strain^[25,26].

Literature data on the role of probiotics in the management of DD are still scant. The benefit of a cyclic 6-mo supplementation with a *L. paracasei sub. paracasei* F19 in association with a high-fibre diet on prolonged abdominal pain and bloating in symptomatic uncomplicated DD has been described, while the high-fibre diet alone appeared to be ineffective^[19]. Compared to the current study, in this study the prescription of a high-fibre diet was not accompanied by detailed dietary information and compliance to the high-fibre diet was not assessed, thus making it difficult to evaluate the therapeutic response in this treatment arm. Other previous studies investigated the efficacy of probiotics, as a non-pathogenic *Escherichia coli* strain or *Lactobacillus casei* and VSL#3 together with other therapeutic agents such as antibiotics or mesalazine in patients with DD^[27-31], making the results of these studies not comparable with our findings.

We are aware that the relative low sample size of this pilot study may have limited the statistical power of results. However, we preferred to analyse data with

respect to single abdominal symptoms rather than to a global symptom score, thus further reducing the sample number. But in this way, the efficacy of treatment on each single symptom could be evaluated more accurately. Furthermore, in this study two treatment arms were compared without a true control and cluster randomization was performed, thus limiting the interpretation of the results with particular regard to placebo effect. Considering that symptoms in symptomatic uncomplicated DD are likely to be influenced by the placebo effect, a placebo-controlled study is necessary to confirm our results.

To conclude, this study provides evidence that a high-fibre diet alone is effective in relieving abdominal pain in patients with symptomatic uncomplicated DD. This therapeutic response may be implemented by combining the dietary approach with Flortec[®] treatment which is effective in abdominal bloating, too. Data from this pilot study need to be confirmed in other larger trials.

COMMENTS

Background

The standard therapeutic approach for symptomatic uncomplicated diverticular disease (DD) still remains to be defined. Guidelines of American and European Gastroenterology Associations recommend a high-fibre diet in patients with symptomatic uncomplicated DD. A recent systematic review suggests the potential usefulness of fibre, rifaximin, mesalazine, and probiotics, and their possible combination in symptomatic uncomplicated DD treatment, but reliable controlled therapeutic trials are still lacking.

Research frontiers

Probiotics, prebiotics, and symbiotics may modify the gut microbial balance and changes in peri-diverticular bacterial flora likely play a role in the pathogenesis of diverticular microscopic inflammation and in generating abdominal symptoms in uncomplicated DD. Probiotic therapy is safe and potentially useful in the management of DD patients. Flortec[®] is a totally natural symbiotic agent, consisting of the synergistic combination of *Lactobacillus paracasei* (*L. paracasei*) B21060 (probiotic component) and arabinogalactan/xylooligosaccharides (prebiotic component), shown to be effective in relieving symptoms associated with irritable bowel syndrome and acute diarrhea. The therapeutic benefit of a symbiotic formulation in addition to a high dietary fibre intake in symptomatic uncomplicated DD remains to be defined.

Innovations and breakthroughs

In this study, for the first time the efficacy of a symbiotic formulation in addition to a high dietary fibre intake in symptomatic uncomplicated DD is investigated. All patients were instructed to follow a high-fibre diet containing at least 30 g daily intake of dietary fibre as well as a daily water intake of at least 1.5 L. For this purpose, all patients were given an information sheet regarding the content of dietary fibre in commonly consumed fruits, vegetables and cereals, and dietary counselling was performed.

Applications

The high-fibre diet alone is effective in relieving abdominal pain in patients with symptomatic uncomplicated DD. Adherence to diet should be monitored by dietary counselling. The combination of the high-fibre diet with a symbiotic preparation may improve the therapeutic response. Data of this pilot study need to be confirmed in other larger, placebo-controlled trials.

Terminology

Colonic diverticula is a wide-ranging condition running the spectrum from a symptomless to a severe, chronic, recurrent disorder, and has been classified in four clinical stages: (1) the development of diverticula (stage 1); (2) the symptom-free stage (stage 2); (3) the symptomatic uncomplicated diverticular disease (stage 3); and (4) the complicated diverticular disease (stage 4). Symbiotics are the synergistic combination of a probiotic component, as for example *L. paracasei* B21060, and a prebiotic component, as for example arabinogalactan and/or xylooligosaccharides.

Peer review

The article demonstrates that the combination of high-fibre diet and *L. paracasei* B21060 can relieve abdominal bloating as well as abdominal pain. The result is interesting and suggests that a high-fibre diet is effective in relieving abdominal symptoms in symptomatic uncomplicated diverticular disease. This treatment may be implemented by combining a high-fibre diet with Flortec®.

Abstract

AIM: To study the effects of live and dead *Lactobacillus rhamnosus* GG (GG) on rotavirus infection in a neonatal rat model.

METHODS: At the age of 2 d, suckling Lewis rat pups were supplemented with either live or dead GG and the treatment was continued daily throughout the experi-

ment. At the age of 5 and 6 d the pups received oral rotavirus (RV) SA-11 strain. The pups were sacrificed at the age of 7 or 8 d by decapitation. The gastrointestinal tract was removed and macroscopic observations were done. The consistency of feces in the colon was classified using a four-tier system. RV was detected from the plasma, small intestine, colon and feces by real-time quantitative polymerase chain reaction (PCR).

RESULTS: In this neonatal rat model, RV induced a mild-to-moderate diarrhea in all except one pup of the RV-inoculated rats. RV moderately reduced body weight development from day 6 onwards. On day 7, after 2 d of RV infection, live and dead GG groups gained significantly more weight than the RV group without probiotics [36% ($P = 0.001$) and 28% ($P = 0.031$), respectively]. In addition, when compared with the RV control group, both live and dead GG reduced the weight ratio of colon/animal body weight to the same level as in the healthy control group, with reductions of 22% ($P = 0.002$) and 28% ($P < 0.001$), respectively. Diarrhea increased moderately in both GG groups. However, the diarrhea incidence and severity in the GG groups were not statistically significantly different as compared with the RV control group. Moreover, observed diarrhea did not provoke weight loss or death. The RV control group had the largest amount of RV PCR-positive samples among the RV-infected groups, and the live GG group had the smallest amount. Rats receiving live GG had significantly less RV in the colon ($P = 0.027$) when compared with the RV control group. Live GG was also more effective over dead GG in reducing the quantity of RV from plasma ($P = 0.047$).

CONCLUSION: Both live and dead GG have beneficial effects in RV infection. GG may increase RV clearance from the body and reduce colon swelling.

INTRODUCTION

Group A rotaviruses are the leading cause of acute gastroenteritis in children < 2 years of age and account annually for nearly 600 000 child deaths worldwide^[1]. Rotavirus-induced diarrhea causes severe dehydration and vomiting which can be fatal for malnourished babies. In developed countries rotavirus gastroenteritis causes a large economic burden with a substantial number of hospitalizations, doctor visits, and medical costs. Two vaccines are available to prevent RV infection, but their use may be limited by financial constraints especially in low-income countries.

The use of probiotic bacteria has gained considerable attention as a safe and accessible form of treatment for gastrointestinal diseases^[2,3]. *Lactobacillus rhamnosus* GG (GG), in particular, has been effective in reducing both duration^[3-6], and severity^[6,7] of rotavirus-induced diarrhea. The therapeutic capacity of GG against rotavirus gastroenteritis might be due to its ability to adhere to intestinal epithelial cells and compete for binding with the pathogens^[8,9], or displace bound pathogens^[10], stabilize and reinforce the mucosal barrier^[11-13], and stimulate the local antigen specific and nonspecific immune responses^[5,12,14]. However, the effect mechanisms of GG in rotavirus diarrhea are not completely understood.

Only a few studies have addressed the effects of inactivated probiotics in rotavirus diarrhea^[5,15]. When studying the effects of inactivated and live GG on acute RV diarrhea in children, both product forms equally promoted clinical recovery from diarrhea, but only live GG enhanced an IgA antibody response to RV^[5]. In mice, in contrast to live GG, heat-killed GG failed to protect animals from duration or severity of RV diarrhea^[15]. However, these studies did not include an untreated control group to allow comparison between the effects of product forms and RV.

In order to gain more understanding of the effect mechanisms of live and dead GG in RV-induced diarrhea, we compared their effects in the suckling rat RV SA-11 infection model with regard to parameters of infection severity such as weight gain, colon weight, con-

sistency of the feces, and also measured the amount of rotavirus in plasma, intestine, and feces.

MATERIALS AND METHODS

Animals

This study was approved by the Animal Care and Use Committee of the State Provincial Office of Southern Finland (license number ESAVI-2010-06221_Ym-23). Pregnant-specific pathogen-free Lewis rats were obtained from Harlan (Horst, The Netherlands) and they were allowed to give birth naturally in the test facility. The birth time of the pups was monitored twice a day. All pups were born on the same day within 12 h. Prior to all experiments, each litter was adjusted to 6 pups per dam to avoid biological variation due to litter size. The litters were randomly assigned to 4 experimental groups (4 dams with 6 pups each, $n = 24$): rats infected with RV SA-11 alone (RV control group); dead GG treated + RV SA-11 infected rats (dead GG group); live GG treated + RV SA-11 infected rats (live GG group); and minimum essential medium (MEM) control animals (healthy control group). The rat pups remained with their dams throughout the study. Control and inoculated groups were housed in the same individually ventilated Scantainer (Scanburg, Denmark), and each RV-infected group in its own Scantainer, in a normal rat cage (Makrolon III) with Aspen chips bedding (Tapvei Oy, Kaavi, Finland) and nest material (Aspen chips PM90L/R). The temperature was 22 ± 2 °C with relative humidity 50%-95%. Lighting was artificial, 12 h light and 12 h dark (18:00-06:00). Food (TEKLAD T.2916 IRR*; Irradiated Global 16%, Rodent Diet for mice and rats, Harlan) and deionized water were autoclaved and provided *ad libitum* from the day of the rats arrival until the completion of the experiments. The animals were identified individually by dorsal numbering.

Lactobacillus rhamnosus GG products

Viability was determined by plating the GG preparation after inactivation and no colony forming units (cfu) were detected. Both live and dead GG (ATCC 53103) were obtained from Valio (Valio Ltd, Helsinki, Finland). Prior use live GG stock (10^{11} cfu/mL) was aliquoted in de Man, Rogosa and Sharpe culture medium broth and stored at -20 °C. Powdered dead GG (killed at Valio Ltd, trade secret) at an equivalent cfu number of 10^{11} cfu/g of viable GG was maintained at room temperature. For the experiments live GG was thawed and dead GG weighed, and both were prepared daily in PBS at a concentration of 3×10^9 cfu/mL.

Virus propagation

Simian RV SA-11 strain was grown in a continuous cell line of rhesus monkey kidney cells, MA-104. The cells were cultivated in MEM containing 10% heat-inactivated fetal bovine serum supplemented with 2 mmol L-glutamine, penicillin and streptomycin in roller flasks in roller apparatus at 37 °C. When the cells had a

confluency of 70%-80%, they were inoculated from a stock containing 10^8 pfu/mL of plaque-purified rotaviruses. Before inoculation, RV stock was treated with 10-20 µg/mL (final concentration) of trypsin (Sigma, St Louis, United States) for 30 min at 37 °C. RV stock in dilution 10^{-4} was added to each roller bottle. After incubation for 1 h, 30 mL of serum-free MEM with 1 µg/mL of trypsin was added, and the cultivation was continued for 48 h at 37 °C. RV were harvested by freeze-thawing of cells for 3 times, cell debris was removed by low-speed centrifugation, supernatant was collected, divided into aliquots, and stored at -70 °C until use. RV titre was determined as 1.4×10^8 pfu/mL.

Animal experiments

The pups were weighed at fixed times daily before, and twice a day after, RV infection. At the age of 2 d, pups received a single daily 0.05 mL dose of either dead or live GG supplementation (1.5×10^8 cfu/pup). RV SA-11 was inoculated by plastic feeding tube in 3 separate doses to achieve the total amount of 10^8 pfu/pup as follows: at the age of 5 d pups received 2 RV doses (0.3 mL each), and the third dose at the age of 6 d (0.12 mL) in order to boost the RV infection. MEM containing 100 × glutamine, penicillin 100 IU/mL, streptomycin 100 µg/mL was used as a healthy control. After inoculations pups were returned to their dams and allowed to suckle.

Clinical indices and specimen collection

The pups were randomized to be exsanguinated from either 2 d or 3 d post-infection at the age of 7 d and 8 d. The blood samples were collected from all animals by decapitation into EDTA tubes (Venosafe™), and the plasma was obtained by centrifugation (10 min, 4000 rpm), and frozen at -20 °C within 1 h from sampling. The gastrointestinal tract was removed for macroscopic observations and specimen collection immediately after blood sampling. Small intestine was collected and weighed; colon tissue was collected and removed from its content by gently pushing along the tissue length by a spatula after which it was weighed. The feces were collected by carefully emptying the colon and rectum. Specimens were stored in dried ice until storing them at -80 °C. Consistency of feces was classified from 0-3 using a four-tier system: [0 = normal feces, 1 = slight diarrhea (feces is pale but solid); 2 = moderate diarrhea (feces is pale and semi-solid); 3 = strong diarrhea (feces is clearly wet)].

Sample processing

Plasma samples were thawed and viral RNA was extracted from 0.1 mL of sample with BioSprint® 96 One-For-All Vet-kit (Qiagen GmbH, Hilden, Germany), using the automated KingFisher mL purification system (Thermo Fisher Scientific, Vantaa, Finland) according to the manufacturer's instructions.

Frozen small intestine, colon, and feces were homogenized for nucleic acid extraction. Feces were processed on ice in 0.2 mL of 10% protease-inhibitor solution containing 1% bovine serum albumin, 10 mmol pefabloc

(Roche Applied Science, Mannheim, Germany), 100 µg/mL aprotinin (Sigma-Aldrich, St. Louis, MO, United States) 100 µg/mL leupeptin (Sigma-Aldrich) in Eagle minimum essential medium I (Gibco, Carlsbad, CA) supplemented with 5% fetal calf serum, and 20 mmol Hepes (pH 7.4). Suspensions were vortexed with sterile glass beads, centrifuged (10 min, 5000 rpm), and viral RNA was extracted from supernatants with E.Z.N.A.® Total RNA Kit (Omega Bio-Tek, Doraville, GA, United States) according to manufacturer's instructions.

Colon and the entire small intestine with its contents were homogenized with sterile glass rods, and 30 mg of homogenized tissue was added into 0.6 mL of RLT buffer (Qiagen) and incubated at 37 °C for 10 min in a water bath. The lysate was centrifuged with QIAshredder (Qiagen) (2 min, $12\,000 \times g$), and RNA was extracted with RNeasy Mini Kit (Qiagen) or BioSprint® 96 One-For-All Vet-kit (Qiagen) using the automated KingFisher mL purification system as above.

Detection of rotavirus

A total of 10 µL of the viral RNA was reverse transcribed into cDNA with the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA, United States) in a 20 µL reaction volume according to the manufacturer's instructions. real-time (RT) reaction was performed as described with few modifications^[16]. Depending on the sample material, RNA was first denatured for 5 min at 95 °C, and RT was performed by incubating the reaction mixture for 10 min at 25 °C, 120 min at 37 °C, and 5 min at 85 °C. The quantitative polymerase chain reaction (qPCR) protocol and the primers which target the VP7 gene of RV were designed according to the primers described by Li *et al*^[17]. Briefly, the qPCR reaction was carried out in 25 µL reaction mixtures consisting of 12.5 µL of 2 × SYBR Premix Ex Taq™ (Takara, Dalian, China), 0.5 µL of each primer (20 µmol/L final concentrations), 0.5 µL ROX Ref Dye II (50 ×), 4 µL of RV cDNA template, and 7 µL of sterile water (Sigma-Aldrich). The thermocycling profile included initial denaturation at 95 °C for 30 s, followed by 45 cycles of 95 °C for 5 s, 58 °C for 20 s, and 72 °C for 30 s. Finally, the melting curve analysis was performed at 95 °C for 1 min, 55 °C for 30 s, and 95 °C for 30 s. RNA isolated from cultured RV SA-11 samples was used as a positive control to establish the standard curve, and sterile water (Sigma-Aldrich) as a negative control. The samples were regarded RV SA-11 positive if the melting peak temperature was 83 ± 1.5 °C. The results were analyzed by comparing the cycle threshold (CT) values, which were inversely correlated with the amount of RV VP7 gene in the sample, i.e., the lower the CT value, the greater the amount of gene in sample.

Statistical analysis

Analysis of variance was applied to compare the groups with respect to weight gain and colon weight, and the results are given as means with standard error of the mean ± SE. In cases of significant global *P*-values,

Figure 1 Percentage weight gain of the rats. The rat pups were weighed 1-2 times daily after day 2 during the experiment. On days 5 and 6, rotavirus (RV) was inoculated orally to the rats. Weight gain is expressed as percentual weight gain from the beginning of the experiment. ^a $P < 0.05$ vs RV control group; ^c $P < 0.05$ vs dead GG group.

Figure 2 Weight of colon without feces. Results between groups are presented as the weight ratio of colon/animal. $P = 0.002$, $P = 0.001$, $P < 0.001$ vs rotavirus (RV) control.

multiple comparisons were performed and the P -values were Bonferroni corrected. RV diarrhea occurrence and severity between the study groups were analyzed using logistic regression analysis. Statistical differences in the CT -values between RV-infected groups were analyzed using Kruskal-Wallis test (global test) and Mann-Whitney U -test (pair-wise comparisons). P -values < 0.05 were considered statistically significant. The data were analyzed using PASW version 18.0 (SPSS Inc. Chicago, IL, United States).

RESULTS

Clinical investigations

Weight gain: The pups were weighed 1-2 times daily

Table 1 Classification of diarrhea

Healthy control group ($n = 5$)	RV control group ($n = 6$)	Dead GG group ($n = 6$)	Live GG group ($n = 6$)
0	0	2	3
0	1	2	2
0	2	2	2
0	1	3	3
0	2	2	3
NA ¹	1	1	1

There was no statistically significant difference between groups. ¹Animal deceased during the experiment due to technical error in dosing. RV: Rotavirus; NA: Not analyzed.

Table 2 Number of rotavirus polymerase chain reaction-positive samples in the indicated test groups

Group	RV PCR-positive samples			
	Plasma	Small intestine	Colon	Feces
Healthy control group	0/5	0/5	0/5	0/5
RV control group	6/6	5/6	6/6	5/6
Dead GG group	6/6	4/6	6/6	4/6
Live GG group	6/6	2/6	6/6	3/6

Samples with cycle threshold (CT)-values < 45 were regarded as positive. RV: Rotavirus; PCR: Polymerase chain reaction.

during the experiment. There were no significant differences in body weight development before the virus inoculation between the study groups. RV moderately reduced body weight development from day 6 onwards (1 d after the infection) when compared with the pups receiving only MEM (Figure 1). RV did not severely compromise the condition of the pups. One pup died from the healthy group due to technical difficulties in dosing. The groups pre-colonized with live or dead GG had gained significantly more weight on day 7 than the RV group without probiotics [36% ($P = 0.001$) and 28% ($P = 0.031$), respectively].

Colon weight: Tissue samples were blindly collected and weighed at necropsy. In the large intestine, RV increased the weight of colon. Results between groups were compared by measuring the ratio of colon weight/body weight (Figure 2). When compared with the RV control group, both live and dead GG reduced the weight ratio of the colon to the same level as seen in the healthy control group, with reductions of 22% ($P = 0.002$) and 28% ($P < 0.001$), respectively.

Diarrhea: At the necropsy, diarrhea was determined in a blinded fashion by scoring the consistency of feces using the four-tier system from 0-3. RV induced a mild-to-moderate diarrhea in all except one of the RV-inoculated rats when compared with the healthy control group. In live and dead GG groups, diarrhea seemed to be moderately increased. However, the diarrhea incidence or severity in the groups was not statistically significant ($P > 0.05$) as compared with the RV control group (Table 1).

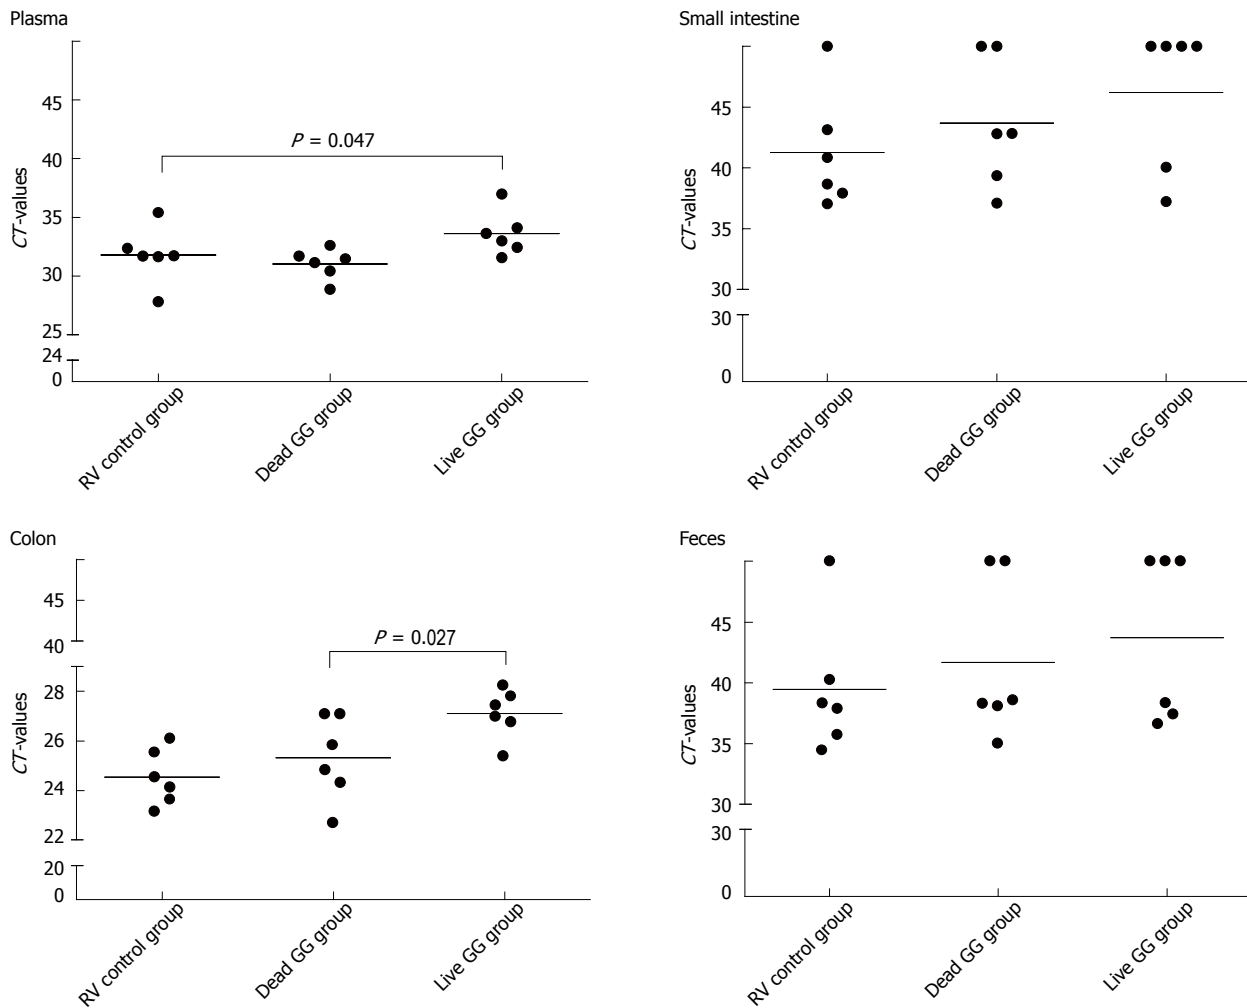

Figure 3 Rotavirus detection in plasma, small intestine, colon, and feces by real-time quantitative polymerase chain reaction. Limit of detection of the reaction was cycle threshold (CT) 45. The lines represent the mean of the CT-values. $P = 0.047$ vs RV control group, $P = 0.027$ vs dead GG group.

Rotavirus detection

The number of RV PCR-positive samples in the study groups is shown in Table 2. In the healthy control group, RV was detected from none of the samples. Overall, the RV control group had the largest amount of RV PCR-positive samples among the 3 groups, and live GG group the smallest amount. By comparing the CT values between the groups, we found that rats receiving live GG had significantly less RV VP7 gene in the colon ($P = 0.027$) when compared with the RV control group (Figure 3). Live GG was also more effective than dead GG in reducing the quantity of RV from plasma ($P = 0.047$).

DISCUSSION

In the present study conducted in a neonatal rat model, we characterized the effects of live and dead probiotic strain *Lactobacillus rhamnosus* GG on RV-induced diarrhea. We found that both groups receiving GG had smaller amounts of RV in the intestinal tissues and feces over the RV control group. In particular, live GG was effective in reducing the number of RV in the colon. Similar studies exist in mice, where live GG supplementation in

combination with antibodies reduced rhesus RV load in the small intestine^[15]. This increased RV clearance could be one of the effect mechanisms of GG in RV diarrhea, as it could shorten the duration of disease, as seen in clinical studies^[5,18,19]. Since RV is also capable of spreading systemically, and infecting extraintestinal tissues such as liver, kidney, and central nervous system^[20-23], the other potentially beneficial effect mechanism of GG against RV diarrhea might be its ability to inhibit the virus entering the blood circulation. Here, live GG appeared to reduce the quantity of RV in plasma.

Similar to other studies, RV SA-11 was effective in inducing diarrhea in the rat pups^[24,25]. Interestingly, we found that both live and dead GG seemed to slightly, though not significantly, increase diarrhea. *Lactobacillus* species in general seem to have an anti-diarrheal effect in clinical and *in vivo* studies^[5,6,26,27]. Especially in neonatal rats, *Lactobacillus casei* (L. casei) DN-114 001 strain in fermented milk decreased clinical signs of RV SA-11-induced diarrhea, reduced the number of RV antigens from the small intestine 48 h after infection, and reduced RV antigen load in the feces^[24]. Our results may be explained by the fact that nitric oxide (NO), which may

stimulate the enteric nervous system and induce water secretion into a luminal space further causing diarrhea^[28], is released by RV-infected enterocytes^[29], and GG also induces NO in macrophages^[30]. Enhanced diarrhea in the GG groups may further lead to the increased clearance of RV from the intestinal tissues by inhibiting adherence of RV, and “flushing” the virus from the body. However, we did not include a group receiving only GG, and cannot confirm whether the amount of GG could have an effect on the consistency of feces. On the other hand, another study did not report any changes in the feces in groups receiving probiotic supplements alone^[24].

Although the pups suffered from diarrhea, both groups receiving either live or dead GG gained more weight than the RV control group after RV inoculation. However, another probiotic strain, *L. casei* DN-114 001, failed to induce weight gain in a similar RV SA-11 rat model^[24], suggesting that the effect is strain specific. Interestingly, after day 6, the percentage weight gain was also reduced in the uninfected healthy control group. It is possible that a relatively large number of dosings during a short period of time partly inhibited rat pups to suckle milk from their dams.

RV induces inflammation and promotes tissue swelling by activating cytokine response of intestinal epithelial cells^[31]. RV-induced tissue swelling could this way increase weight of the colon. Interestingly, we found that both live and dead GG reduced colon weight. In the GG group this reduction may result from the GG's ability to stimulate the production of anti-inflammatory cytokines^[32]. These results further support the idea that GG might shorten the duration, and enhance the recovery from RV diarrhea.

The question of whether unviable and killed bacteria could have similar beneficial effects as live probiotic strains is contradicted. In clinical studies, heat-inactivated GG in children was unable to elicit local or systemic effects in rotavirus diarrhea^[5]. In addition, a heat-inactivated probiotic mixture including GG was ineffective against antibiotic-associated diarrhea when compared to equivalent live strains^[33]. In children with milk allergy, heat-inactivated GG treatment was associated with diarrhea^[34]. However, animal experiments conducted with unviable GG showed that the unviable form has beneficial effects against several inflammatory conditions such as arthritis and *Escherichia coli* lipopolysaccharide-induced inflammation in the lungs and liver of rats^[32,35]. This finding was possibly seen in our study as reduced colon weight. Nevertheless, live GG seemed to be more effective over dead GG in increasing the weight gain of rat pups after RV infection, and was more efficient in reducing the number of RV from plasma. The effects of dead bacteria, however, might depend on the method of inactivation. For instance, inactivation by heat or irradiation might disrupt the surface protein conformation of the bacteria, inhibiting the probiotic's ability to adhere to epithelial cell^[36]. In case the anti-diarrheal effects are due to secreted bioactive or antimicrobial peptides^[13,36,37], GG

needs to be viable.

In conclusion, only live GG decreased the number of RV in the colon of infected rat pups. However, dead GG had also some potential to alleviate RV infection possibly by reducing tissue swelling. The results provide new insights into aspects of the bacterial strain's viability, offering new possibilities to develop novel functional food matrices.

COMMENTS

Background

Group A rotaviruses are responsible for most cases of gastroenteritis in children under 2 years of age worldwide. Probiotics have gained an important role as adjuvant therapy in the treatment of acute diarrhea. Probiotic strain *Lactobacillus rhamnosus* GG (GG) in particular is known to reduce the duration of rotavirus-induced diarrhea in young children. However, it is unknown whether the viability of the strain plays a critical role in the probiotic's beneficial effects on diarrhea.

Research frontiers

The potential of unviable/inactivated/killed bacteria to relieve rotavirus (RV) gastroenteritis is not known. In this preliminary study, the authors explored the effects of both live and dead GG in RV infection in a neonatal rat model.

Innovations and breakthroughs

Recent clinical and animal studies have shown that GG relieves RV infection by shortening the duration of diarrhea, and reduces the amount of RV in intestinal tissues. In the present study the authors found only live GG reduced the amount of RV in intestinal tissues. However, the dead product form was found to have a potential to decrease RV diarrhea-induced weight reduction, and inhibit RV-induced colon swelling.

Applications

The results of this study indicate that the viable and dead forms of the bacterium have different favorable effects on RV infection. Dead product forms would have a great potential in the food industry by providing new product applications, increasing product shelf life, and reducing storage costs.

Terminology

Probiotic bacteria are defined as live microorganisms that have beneficial effects on human health. However, data regarding whether dead bacteria could have similar favorable health effects to live probiotic strains is limited.

Peer review

This study has investigated in experimental animals the effects of probiotics on rotavirus-induced diarrhea using *Lactobacillus* strain. They have used killed and live *Lactobacillus* strain in animals in which diarrhea was induced by rotaviruses. The findings are supportive of early observations of similar nature and are of clinical significance.

to assess small intestinal bacterial overgrowth (SIBO). SIBO was diagnosed when there was an increase in $H_2 \geq 20$ ppm or $CH_4 \geq 10$ ppm with regard to the fasting value until 60 min after lactulose ingestion.

RESULTS: Children from the slum group had worse living conditions and lower nutritional indices than children from the private school. SIBO was found in 30.9% (26/84) of the children from the slum group and in 2.4% (1/41) from the private school group ($P = 0.0007$). Greater hydrogen production in the small intestine was observed in children from the slum group when compared to children from the private school ($P = 0.007$). A higher concentration of hydrogen in the small intestine ($P < 0.001$) and in the colon ($P < 0.001$) was observed among the children from the slum group with SIBO when compared to children from the slum group without SIBO. Methane production was observed in 63.1% (53/84) of the children from the slum group and in 19.5% (8/41) of the children from the private school group ($P < 0.0001$). Methane production was observed in 38/58 (65.5%) of the children without SIBO and in 15/26 (57.7%) of the children with SIBO from the slum. Colonic production of hydrogen was lower in methane-producing children ($P = 0.017$).

CONCLUSION: Children who live in inadequate environmental conditions are at risk of bacterial overgrowth and methane production. Hydrogen is a substrate for methane production in the colon.

Abstract

AIM: To analyze small intestinal bacterial overgrowth in school-aged children and the relationship between hydrogen and methane production in breath tests.

METHODS: This transversal study included 85 children residing in a slum and 43 children from a private school, all aged between 6 and 10 years, in Osasco, Brazil. For characterization of the groups, data regarding the socioeconomic status and basic housing sanitary conditions were collected. Anthropometric data was obtained in children from both groups. All children completed the hydrogen (H_2) and methane (CH_4) breath test in order

INTRODUCTION

Recent studies have identified small intestinal bacterial overgrowth (SIBO) as being involved in several clinical conditions, such as chronic constipation^[1], irritable bowel syndrome^[2,3] and short bowel syndrome^[4]. SIBO is also present in tropical/environmental enteropathy^[5,6].

SIBO is favored by environmental contamination and inadequate basic sanitation conditions^[7], and is often the result of ingesting food and/or water that is not appropriate for consumption^[8]. Thus, an excessive quantity of bacteria colonizes the upper intestinal tract, causing diarrhea^[9,10] and malnutrition^[5,10] due to nutrient malabsorption^[9,10]. A reduction in the absorption of carbohydrates, proteins, lipids and some vitamins can be observed, even in asymptomatic patients^[11]. Therefore, environmental enteropathy is a condition that may compromise child growth^[12].

The breath test is a noninvasive method that has been widely used in the diagnosis of SIBO^[10]. The breath test measures the production of hydrogen derived from the fermentation of lactulose by intestinal bacteria^[5,7,9,13,14]. In addition to hydrogen, methane may also be detected in the exhaled breath during the test. However, the significance of methane in the diagnosis of bacterial overgrowth in the small intestine is still controversial, and in general, it is not considered in the interpretation of the breath test^[5,7,13]. However, some studies^[1,2,9,14,15] have suggested that methane is also an indicator of bacterial overgrowth in the small intestine. A universal criterion for breath test interpretation has not been proposed.

The design of the present study was based on the fact that no other community study had used both hydrogen and methane as SIBO diagnostic criteria. In addition, the relationship between methane production, environmental conditions and the presence of SIBO was considered.

Considering the above rationale, the aim of the present study was to analyze SIBO using the lactulose hydrogen and methane breath test in school-aged children from two distinct socioeconomic strata, and to assess the relationship between intestinal production of hydrogen and methane, environmental conditions and SIBO.

MATERIALS AND METHODS

Design, study population and sample size

A transversal study was performed in the municipality of Osasco, in the state of Sao Paulo, Brazil. The study par-

ticipants consisted of two groups of children belonging to distinct socioeconomic strata.

The sample size was calculated taking into account a power of 80% and an alpha of 5%. Two aspects of the study were considered: (1) The prevalence of SIBO in the slum community was the first parameter determined. The population in this community included 1220 children aged between 6 and 10 years. The expected prevalence of SIBO was 35%^[5], with a maximum variation of 10%. Epi Info 3.4.3 software was used which indicated that 82 children in the slum group were needed to define the prevalence of SIBO; and (2) For comparison with the slum group, the necessary sample size of the private school group was estimated taking into account an expected prevalence of 35% for SIBO in the slum group and of 6% in the private school group^[5]. According to Epi Info 3.4.3, each group should have at least 36 children.

The first group was composed of children whose families lived in poor socioeconomic conditions and who resided in a slum in the vicinity of a landfill without adequate housing or basic sanitation conditions. To obtain a representative sample of the population, the children were selected at random by performing a survey of households in the slum area. Of the 100 children randomly selected, 85 agreed to participate in the study.

The second group was composed of children from a private school who belonged to socioeconomically advantaged families and had satisfactory housing and basic sanitation conditions. Of the 60 children whose parents or guardians showed an interest in participating in the study, 43 (71.6%) completed the study.

To be included in the study, the children had to be between 6 and 10 years of age and not have suffered from diarrhea for at least 30 d. The presence of clinical evidence that could mark a serious illness, such as heart disease, nephropathy, or neuropathy, was a criterion for exclusion from participation in the study. In addition, the use of antibiotics up to 15 d before the breath test was considered a criterion for exclusion from the study.

This project was evaluated and approved by the Research Ethics Committee of the Federal University of Sao Paulo. A signed informed consent form was obtained from the parents or guardians of each participant at the time of admission into the study.

Characterization of socioeconomic and basic sanitation conditions

A questionnaire was given to the parents and/or guardians of the children who participated in the study. Information regarding the presence of a water supply, a sewage system (destination of waste) and garbage collection was obtained.

Analysis of water contamination

An analysis of the water used for household consumption by the children in the slum group was performed. To determine the levels of total and fecal coliforms, the water was stored in 100 mL sterile plastic bags containing

a sodium thiosulfate tablet, which neutralizes the action of chlorine used in water treatment. The samples were transported and then incubated at 37 °C for 18 and 24 h, respectively, on the same day as the material was collected. Subsequently, the samples were analyzed using the Colilert Substrate method (IDEXX Laboratories, Maine, United States), which enumerates the levels of total and fecal coliforms (*Escherichia coli*) simultaneously in the same water sample, according to the manufacturer's instructions.

Anthropometric indicators

The weight and height of the children participating in the study were measured according to the recommendations of Jelliffe^[16]. To measure weight, a mechanical balance with a capacity of 150 kg and a sensitivity of 100 g was used. For height measurements, a portable vertical anthropometer with the capacity to measure up to 190 cm and a sensitivity of 0.1 cm was used.

Z-scores were calculated for weight-for-age, height-for-age, and body mass index (BMI), with adjustments for age and sex^[17]. The anthropometric indicators were calculated using the Epi Info version 3.4.3 program and the reference values from the National Center for Health Statistics^[18].

Hydrogen and methane breath test

The lactulose breath test was performed in the morning following oral hygiene using 0.05% chlorhexidine. The children fasted for a period of 12 h prior to the test.

Breath samples were collected using a non-rebreathing valve setup (QuinTron Instrument Co. Inc., Menomonee Falls, Wisconsin, United States). After collection of the fasting breath, 10 g of lactulose (Daiichi Sankyo, Sao Paulo, Brazil) was administered orally as a 10% aqueous solution. Subsequently, new breath samples were collected 15, 30, 45, 60, 90, 120, and 180 min after ingestion of lactulose.

The levels of hydrogen (H₂) and methane (CH₄) in the samples were simultaneously measured by gas chromatography using a 12i model QuinTron MicroLyzer unit (QuinTron Instrument Company, Milwaukee, Wisconsin, United States). Study participants were considered to exhibit SIBO when an increase in H₂ ≥ 20 ppm or CH₄ ≥ 10 ppm with respect to the fasting value was observed up to 60 min after the ingestion of lactulose^[1]. The study participants were treated as methane producers when the concentration of methane in the breath was higher than (or equal to) 3 ppm with respect to the concentration of methane in the environment^[19].

Information was also collected on the intestinal habits of the children from both groups, taking into account the existence of an association between the production of methane and evacuation disorders.

Statistical analysis

For data analysis, Sigma Stat 3.5 and Epi Info 3.4.3 software were used, setting 5% as the level to reject the null

hypothesis.

RESULTS

Of the children studied, 85 were living in a slum and 43 were enrolled in a private school. Table 1 describes the demographic data, nutritional status indicators, and basic sanitation conditions of the studied population. There were no statistical differences in age or gender between the children in the two groups. The children in the slum group exhibited lower Z-score values for weight-for-age, height-for-age, and BMI when compared with children in the private school group. It was found that the majority of families in the slum did not have access to public service sewage or household garbage collection. Clandestine water supplies existed in 41.2% (35/85) of the households, and water analysis revealed the presence of total coliforms in 65 (77.4%) and fecal coliforms in 43 (51.2%) of the 84 samples analyzed.

During the study, three children did not perform the breath test; one child was from the slum group, and two children were from the private school group. SIBO was found in 30.9% (26/84) of the children in the slum group and in 2.4% (1/41) of the children in the private school group (χ² test, *P* = 0.0007). In the slum group, 65.4% (17/26) of the children with SIBO had increased hydrogen production with respect to the fasting value (H₂ ≥ 20 ppm), 23.1% (6/26) had increased methane concentrations with respect to the fasting value (CH₄ ≥ 10 ppm) and 11.5% (3/26) fulfilled both criteria for SIBO. In the private school group, the one child with SIBO fulfilled only the hydrogen criterion.

The demographic data, nutritional status indicators, and basic sanitation conditions of the children from the slum group with or without SIBO are shown in Table 2. No statistically significant differences for any of the variables analyzed (*P* > 0.05) were observed. It is important to emphasize that all the cases of SIBO were

asymptomatic.

The hydrogen concentrations (ppm) obtained by the lactulose breath test were analyzed for the areas under the individual curves. It was found that the children in the slum group exhibited greater (Student's *t*-test, *P* = 0.007) hydrogen production during the first hour of the test, which presumably originated from the small intestine, when compared with the children in the private school group (491.16 ± 369.05 ppm *vs* 314.45 ± 251.49 ppm per min, respectively). Between 60 min and 180 min of the test, the period during which hydrogen production occurs predominantly in the large intestine, the concentration of hydrogen in the breath of the children in the slum and private school groups were similar (4363.93 ± 1045.63 ppm *vs* 4275.0 ± 1390.55 ppm per min, respectively, *P* = 0.690) (Figure 1A).

Figure 1B shows the mean hydrogen concentrations (ppm) obtained from the breath tests of children with and without bacterial overgrowth in the slum group. A greater area under the curve for the small intestine was observed among the 26 children with SIBO compared with the 58 children without SIBO up to 60 min after the ingestion of lactulose (344.22 ± 185.23 ppm *vs* 818.94 ± 460.55 ppm per min; Student's *t*-test, *P* < 0.001). A similar response was observed for the colon during the 60 to 180 min of the test (4021.03 ± 711.73 ppm *vs* 5128.85 ± 1262.40 ppm per min; Student's *t*-test, *P* < 0.001).

Methane production was observed in 63.1% (53/84) of the children in the slum group and in 19.5% (8/41) of the children in the private school group (χ^2 test, *P* < 0.0001). The mean methane concentration remained relatively constant in both groups during the breath test and did not vary after lactulose ingestion. Among the 8 children in the private school group who were methane producers, 3 (37.5%) had intestinal constipation without fecal incontinence. There were no cases of constipation among the 53 children in the slum group who were methane producers (χ^2 test, *P* < 0.0001).

Figure 1C shows the mean methane concentrations (ppm) obtained from the breath tests of children with and without bacterial overgrowth in the slum group. In the small intestine, differences in the area under the curve were not observed among the 26 children with SIBO in relation to the 58 children without SIBO up to 60 min after the ingestion of lactulose (730.96 ± 829.56 ppm *vs* 576.72 ± 573.72 ppm per min; Student's *t*-test, *P* = 0.327). In addition, no significant difference was observed in the area under the curve for the colon during the 60 min to 180 min of the test (3835.34 ± 1159.71 *vs* 4324.04 ± 2053.62 ppm per min; Student's *t*-test, *P* = 0.168).

Methane production was observed in 38 (65.5%) of the 58 children who did not exhibit bacterial overgrowth and in 15 (57.7%) of the 26 children with bacterial overgrowth (χ^2 test, *P* = 0.658).

Figure 1D shows the concentration of hydrogen (ppm) in the breath for individual methane producers (*n* = 53) and non-producers (*n* = 31) in the slum group. An analysis of the area under the curve revealed that between 0 min and 60 min after lactulose ingestion, no difference existed in the levels of hydrogen production between the methane-producing and nonproducing children (448.16 ± 316.03 ppm *vs* 564.68 ± 441.40 ppm per min; Student's *t*-test, *P* = 0.164). In the period between 60 and 180 min of the test, less hydrogen production was observed among the methane-producing children (4157.55 ± 952.64 ppm per min) than among the methane non-producers (4716.77 ± 1117.13 ppm per min; Student's *t*-test, *P* = 0.017).

DISCUSSION

SIBO was found in 30.9% of the children in the slum group and in 2.4% of the children in the private school group. These values are similar to those previously reported in Brazil^[5] for children living in a slum and those attending a private health clinic (37.5% and 2.1% SIBO in each group, respectively). In Australia, SIBO was found in 27.2% of aboriginal children under 5 years old^[13]. These studies^[5,13] did not evaluate the methane concentration in the breath test. In the present study, 6 (23.1%) of the 26 children were diagnosed as having SIBO only by an increase in the breath methane level compared with the fasting values. Therefore, using the criteria that takes into account not only breath hydrogen but also breath methane, the diagnosis of SIBO may be more comprehensive. The higher frequency of bacterial overgrowth in the groups living in slums may be hypothetically explained by the different environmental and socioeconomic conditions to which they are exposed (Table 1).

Table 1 shows that the weight and height of children in the slum group were lower than those of the children in the private school group. This situation may be caused, at least in part, by the existence of digestive-absorptive abnormalities linked to bacterial overgrowth and tropical enteropathy^[5]. In addition, two factors may support the occurrence of the anthropometric deficit in the children in the slum group. The first factor corresponds to a diet

A

Figure 1 Small intestinal bacterial overgrowth in school-aged children and the relationship between hydrogen and methane production in breath test. A: Mean concentrations of hydrogen (ppm) in breath samples collected after fasting and at 15, 30, 45, 60, 90, 150 and 180 min after lactulose ingestion from children in the slum ($n = 84$) and private school ($n = 41$) groups; B: Mean concentrations of hydrogen (ppm) in breath samples collected after fasting and at 15, 30, 60, 90, 120, 150 and 180 min after lactulose ingestion from children in the slum group with ($n = 26$) and without ($n = 58$) small intestinal bacterial overgrowth (SIBO); C: Mean concentrations of methane (ppm) in breath samples collected after fasting and at 15, 30, 60, 90, 120, 150 and 180 min after lactulose ingestion from children in the slum group with ($n = 26$) and without ($n = 58$) SIBO; D: Mean concentrations of hydrogen (ppm) in breath samples collected after fasting and at 15, 30, 60, 90, 120, 150 and 180 min after lactulose ingestion from methane-producing ($n = 53$) and non-producing ($n = 31$) children in the slum group. Student's t -test; comparison between groups for collection time during the breath test (complementation of the analysis of area under the curve). ^a $P < 0.05$ vs the private school group; ^c $P < 0.05$ vs the slum group without SIBO in relation of the hydrogen production in breath test; ^b $P < 0.05$ vs the slum group without SIBO in relation of the methane production in breath test; ^g $P < 0.05$ vs the slum group non-methane producing in relation of the hydrogen production in breath test.

probably deficient in quality and quantity. Data from the food surveys showed that children in the slum group had less caloric intake, less protein consumption, less lipid consumption and less iron, calcium and vitamin A ingestion compared with children in the private school group (data not shown). The second factor corresponds to the inadequate basic sanitation conditions to which the children are exposed, exemplified by the high rates of water contamination, which may be directly related to recurrent infectious outbreaks and, consequently, to recurrent harm during physical development^[20].

In the lactulose breath test, the elevated concentrations of hydrogen observed in the breath of children in the slum group after 60 min of the test (Figure 1A) are consistent with the greater prevalence of bacterial overgrowth in these children.

One result of the present study that has yet to be explored in the literature involves the greater colonic production of hydrogen after the first hour of the breath test in the children in the slum group with SIBO (Figure 1B). It was found that these children, in addition to exhibiting greater hydrogen production in the small intestine up to 60 min after the start of the breath test, also showed elevated production of hydrogen from 60 to 180 min after the start of the test when compared with those without SIBO. This difference was found to be statistically significant with respect to the values corresponding to the area under the curve. It is likely that children with bacterial overgrowth possess greater quantities of fermenting bacteria, both in the small intestine and in the colon, when compared with children without SIBO who live in the same environmental conditions. Hydrogen excretion in the colon depends on fermentable substrates supplied by

the colonic bacteria^[21].

The presence of *Lactobacilli* and *Bifidobacteria* in the feces was also evaluated in this same group of children; however, no difference in the counts in the children with or without SIBO from the slum group was found (data not shown). Nevertheless, the number of *Lactobacilli* and *Bifidobacteria* colonies in the feces of children in the slum group was lower than that observed in the children in the private school group^[22,23]. There is currently no published information which relates SIBO with differences in the colonic microbiota.

Another interesting result of our study was the elevated prevalence of methane producers (63.1%) in the slum group. Considering the proximity of the slum to the municipal landfill, methane is produced by the intense anaerobic degradation of organic waste^[24], and methanogenic bacteria which may be present in the soil could potentially colonize the human intestine. These effects constitute an indication of the effects of the environment on the biological condition of individuals exposed to methane gas. Early age, close contact and poor personal hygiene may be factors explaining the high percentage of methane producers^[21] in the slum group.

Furthermore, there is concern about the association between the production of methane and the occurrence of diseases related to intestinal motility^[25,26]. It should be stressed that, in children, methane production has been related to intestinal constipation with fecaloma and fecal escape^[1,27,28], which are associated with a greater slow small intestine^[29] and colonic transit time^[28]. In our study, an association was not found between methane production and constipation in the children from the slum. However, 3 (37.5%) of the 8 children in the private

school group who were methane producers had intestinal constipation without fecal incontinence.

No differences were observed in the methane production between the children from the slum group with or without SIBO (Figure 1C), both in the colon and in the small intestine. Ingestion of non-absorbable disaccharide did not influence breath CH₄ excretion, different to that which occurred in H₂ excretion^[21].

The children in the slum group who were characterized as methane producers exhibited lower hydrogen concentrations in the colon when compared with the methane non-producers (Figure 1D); this result is similar to previously reported results in adults^[6]. Assuming that methane production is a good indicator of intracolonic metabolism^[19,21,30], this profile may be a consequence of the transformation of hydrogen into methane by methanogenic bacteria present in the colon^[14,30]. Methane is synthesized by bacteria in the intestine, where four mmols of hydrogen and one mmol of carbon dioxide create one mmol of methane and water^[10]. *Methanobrevibacter smithii* is the main methanogenic bacterium found in humans, and preferentially colonizes the left colon^[31]. Approximately 15% of individuals in the general population are producers of methane instead of hydrogen^[15], which is lower than the frequency observed in the slum group.

A previous study performed with adults^[14] raised the hypothesis that methane production may be responsible for the false-negative results obtained from studies on SIBO. In previous studies of SIBO in children, the concentration of methane in the breath was not determined. Despite the consistent absence in the literature of methane, in addition to hydrogen, as an indicator of SIBO, the data from our current study indicate that this possibility should be analyzed in future research.

In conclusion, in the present study, we observed a high prevalence of methane producers in children with or without SIBO who were exposed to poor living conditions. However, there was no direct relationship between the presence of SIBO and increased methane production in these children. Thus, the presence of breath methane seems to be a common condition in individuals exposed to inadequate environmental factors, as previously reported^[21]. Methane production appeared to be relatively constant during the course of the 3 h breath test. The value of the inclusion of a methane increment as an additional criterion for the diagnosis of SIBO should be evaluated in further studies. With respect to the use of hydrogen as a substrate for methane production in the colon, our hypothesis was confirmed, based on our observation regarding increased hydrogen production in the colon of methane non-producers in the slum.

COMMENTS

Background

Small intestine bacterial overgrowth (SIBO) is a clinical disorder characterized by an excessive quantity of bacteria in the upper intestinal tract. SIBO occurrence is common when associated with environmental enteropathy. Poverty

associated with ingestion of contaminated water and foods are involved in the etiology of this disease. Some of the consequences of SIBO are diarrhea and malnutrition, however, asymptomatic cases are observed. Breath tests are non-invasive tests used in the diagnosis of SIBO.

Research frontiers

In breath tests, hydrogen and methane can be detected. Both gases originate from bacterial fermentation. However, the relationship between methane production and SIBO diagnosis is still unclear.

Innovations and breakthroughs

This is the first study in which methane production was observed in individuals residing in a slum area. In the present study, high methane production was observed in children from a slum area with or without a diagnosis of SIBO. Thus, in addition to literature data relating methane production with severe constipation, methane can also be characterized as an indicator of environmental contamination. These results confirm the hypothesis that hydrogen is used as a substrate for methane production in the colon.

Applications

The results of this study suggest that the respiratory tests, characterized by the production of hydrogen and methane, can be performed in the research of SIBO in individuals exposed to unsanitary/unhealthy environments.

Terminology

SIBO: Clinical disorder characterized by the presence of contaminating bacteria in the small intestine; Environmental enteropathy: Syndrome characterized by a set of nonspecific changes, functional and/or morphological, in the small intestine associated with or without gastrointestinal symptoms. This is a clinical condition associated with environmental contamination; Breath test: The test consists of administering a carbohydrate which is degraded and metabolized by bacteria in the intestine, producing an increase in hydrogen levels in expired air. Others gases can be detected in the expired air, for example, methane.

Peer review

This is an original study looking for methane and hydrogen expiration in two children communities, as a token of SIBO.

Abstract

AIM: To evaluate the efficacy, safety, and long-term outcomes of endoluminal gastroplication (ELGP) in patients with proton pump inhibitor (PPI)-resistant, non-erosive reflux disease (NERD).

METHODS: The subjects were NERD patients, diagnosed by upper endoscopy before PPI use, who had symptoms such as heartburn or reflux sensations two or more times a week even after 8 wk of full-dose PPI treatment. Prior to ELGP, while continuing full-dose PPI

medication, patients' symptoms and quality of life (QOL) were assessed using the questionnaire for the diagnosis of reflux disease, the frequency scale for symptoms of gastro-esophageal reflux disease (FSSG), gastrointestinal symptoms rating scale, a 36-item short-form. In addition, 24-h esophageal pH monitoring or 24-h intraesophageal pH/impedance (MII-pH) monitoring was performed. The Bard EndoCinch™ was used for ELGP, and 2 or 3 plications were made. After ELGP, all acid reducers were temporarily discontinued, and medication was resumed depending on the development and severity of symptoms. Three mo after ELGP, symptoms, QOL, pH or MII-pH monitoring, number of plications, and PPI medication were evaluated. Further, symptoms, number of plications, and PPI medication were evaluated 12 mo after ELGP to investigate long-term effects.

RESULTS: The mean FSSG score decreased significantly from before ELGP to 3 and 12 mo after ELGP (19.1 ± 10.5 to 10.3 ± 7.4 and 9.3 ± 9.9 , $P < 0.05$, respectively). The total number of plications decreased gradually at 3 and 12 mo after ELGP (2.4 ± 0.8 to 1.2 ± 0.8 and 0.8 ± 1.0 , $P < 0.05$, respectively). The FSSG scores in cases with no remaining plications and in cases with one or more remaining plications were 4.4 and 2.7, respectively, after 3 mo, and 2.0 and 2.8, respectively, after 12 mo, showing no correlation to plication loss. On pH monitoring, there was no difference in the percent time pH < 4 from before ELGP to 3 mo after. Impedance monitoring revealed no changes in the number of reflux episodes or the symptom index for reflux events from before ELGP to 3 mo after, but the symptom sensitivity index decreased significantly 3 mo after ELGP (16.1 ± 12.9 to 3.9 ± 8.3 , $P < 0.01$). At 3 mo after ELGP, 6 patients (31.6%) had reduced their PPI medication by 50% or more, and 11 patients (57.9%) were able to discontinue PPI medication altogether. After 12 mo, 3 patients (16.7%) were able to

reduce the amount of PPI medication by 50% or more, and 12 patients (66.7%) were able to discontinue PPI medication altogether. A high percentage of cases with remaining plications had discontinued PPIs medication after 3 mo, but there was no difference after 12 mo. No serious complications were observed in this study.

CONCLUSION: ELGP was safe, resulted in significant improvement in subjective symptoms, and allowed less medication to be used over the long term in patients with PPI-refractory NERD.

INTRODUCTION

Non-erosive reflux disease (NERD) refers to a syndrome that is characterized by complaints of reflux symptoms such as heartburn without endoscopic evidence of mucosal injury^[1]. It accounts for more than half of gastroesophageal reflux disease (GERD) cases in Japan, as it does in Europe and the United States^[2]. NERD and erosive GERD cannot be distinguished by the severity of symptoms or their frequency, and they are equally characterized by compromised quality of life (QOL)^[3,4]. Proton pump inhibitors (PPIs), which are first-line drugs for GERD, are less effective for NERD than they are for erosive GERD^[5]. NERD symptoms are often not amenable to treatment with oral medication. It was recently proposed that NERD is not just a milder form of reflux disease but a group of symptoms with pathophysiologic mechanisms that differ from those of erosive GERD^[6]. It has been reported that a number of etiologies may contribute to the symptoms of heartburn, including motor events, reflux of nonacidic gastric contents, minute changes in intraesophageal pH, visceral hypersensitivity, and emotional or psychological abnormalities^[7-9]. However, many of the details involved in its mechanism remain unknown. The recent use of ambulatory multichannel intraluminal impedance-pH (MII-pH) monitoring has made it possible to learn about various symptom-inducing factors that could not be determined by conventional pH monitoring alone^[10], and it has elucidated the patho-

physiology involved in PPI-refractory NERD. It is now believed that factors other than gastroesophageal reflux or non-acid reflux are involved in its pathophysiology^[11].

The surgical treatment of erosive GERD originated with Allison *et al*^[12] in 1951. Laparoscopic fundoplication (Nissen fundoplication or Toupet fundoplication) is now widely used and is reportedly useful over the long-term^[13,14]. However, its inherent invasive nature as a surgical procedure remains problematic. In response to the inconvenience and non-compliance associated with drug use, as well as the complications associated with laparoscopic surgery, a number of endoscopic techniques have been developed since 2000, primarily in Europe and the United States, as less invasive but effective methods. In Japan, only endoluminal gastroplication (ELGP) using the Bard EndoCinchTM (C. R. Bard, Murray Hill, NJ, United States) has been covered by national health insurance (K667-3: 12 000 points). This procedure permits less invasive fundoplication to be accomplished using an endoscope, and it has been reported to be useful over the long term^[15]. However, it is used in cases in which PPI treatment is effective. The efficacy of endoscopic treatment in PPI-resistant GERD not amenable to treatment with oral medication has not yet been sufficiently studied.

Until recently, NERD has been assumed to be milder than erosive GERD, and NERD has not been considered suitable for surgical treatment. However, surgical fundoplication is now performed in cases of NERD not amenable to drug treatment, and its efficacy is becoming increasingly clear^[16,17]. However, the efficacy of endoscopic treatment in NERD patients has not been studied. Therefore, the efficacy, safety, and long-term course of ELGP as endoscopic treatment in patients with PPI-resistant NERD, who are the most intractable of NERD patients, were studied.

MATERIALS AND METHODS

This was a prospective study conducted at Aichi Medical University Hospital. Nineteen subjects were enrolled between March 2005 and June 2009 (14 males and 5 females; average age 53.0 ± 4.3 years). The study was approved by the Aichi Medical University School of Medicine Ethics Review Board and was conducted with the written informed consent of patients who had been given a full explanation of the study. The subjects were NERD patients, diagnosed by upper endoscopy before PPI use, who had symptoms such as heartburn or reflux sensations two or more times a week even after 8 wk of full-dose PPI-treatment (i.e., 30 mg of lansoprazole, 20 mg of rabeprazole, or 20 mg of omeprazole per day). The following exclusion criteria were used: < 18 years of age; hiatal hernia (≥ 2 cm); erosive GERD (Los Angeles Grade A or higher) before PPI use; Barrett's esophagus; gastroesophageal varices; past history of gastroesophageal surgery; gross obesity (body mass index > 40 kg/m²); esophageal stenosis; dysphagia; and primary esophageal motility disorders diagnosed by intraesophageal manom-

etry (Polygraf ID, Sierra Scientific, Los Angeles, CA, United States).

Interview and tests

Prior to ELGP, while continuing full-dose PPI medication, patients were assessed for reflux symptoms based on the questionnaire for the diagnosis of reflux disease (QUEST)^[18] and the frequency scale for symptoms of GERD (FSSG)^[19]. The gastrointestinal symptoms rating scale (GSRS) was used as an indicator of gastrointestinal symptoms, and 36-item short-form (SF-36)^[20] interview was conducted as an assessment of the activity index. In addition, 24-h esophageal pH monitoring (Digitrapper MK III, Synectics Medical, Los Angeles, CA, United States) or 24-h transesophageal pH/impedance monitoring (Sleuth® multi-impedance pH monitoring system, Sandhill Scientific, Highlands Ranch, CO, United States)^[10] was performed. After ELGP, all acid reducers were temporarily discontinued, and medication was resumed depending on the development and severity of symptoms.

Reflux symptoms were assessed by the QUEST and FSSG interviews at 3 and 12 mo after ELGP. The GSRS and SF-36 interviews, as well as 24-h esophageal pH monitoring or 24-h intraesophageal pH/impedance monitoring, were performed after 3 mo. Analysis was performed using the automatic analysis program BioVIEW Analysis® (version 5.3.4; Sandhill Scientific, Inc.)^[21] to compare the symptom index (SI), the symptom sensitivity index (SSI), number of reflux episodes, and number of symptom events. SI is defined as the number of symptoms associated with reflux divided by the total number of symptoms during 24 h, and it primarily assesses the specificity of a patient's reflux symptoms; it is considered positive if more than 50% of the symptoms are associated with reflux^[22]. SSI is defined as the number of reflux events associated with symptoms divided by the total number of reflux events in 24 h, and it quantifies the subject's sensitivity for reflux; it is considered positive if more than 10% of the reflux events are associated with symptoms^[23]. Upper endoscopy was also performed 3 and 12 mo after ELGP to compare the number of remaining plications.

ELGP method

The Bard EndoCinch™ (C. R. Bard) was used for endoluminal gastroplication. After the esophagus had been examined by routine endoscopy, an endoscope with a capsule-shaped plication device (with a side hole) mounted at the tip was brought to the level of the squamocolumnar junction through the over-tube, where the side hole was brought into close contact to draw the mucosa into the capsule with at least 400 mmHg of air suction. After it had been confirmed that all tissue had been drawn in, a puncture needle with 3-0 nonabsorbable suture attached (suture tag), which had been inserted into the biopsy channel, was passed through. The suction pressure was released, and the capsule was carefully rotated away from the stitches side. A suture tag was again set up in the endoscope, and a second set of stitches was placed follow-

ing the same procedure at a position rotated 30 to 60 degrees away from the first set of stitches. The two sutures made a plication using a suturing device (knotting device) that had been inserted into the biopsy channel of a separate endoscope, and plication was completed by plicating the tissue in the form of a pouch. The second and third plications were performed in either a linear or circumferential manner, or a combination of the two, depending on the available area within the gastro-esophageal junction and position preference^[23-27].

Statistical analysis

Data are shown as the means ± SD. Analysis was based on Wilcoxon's signed-rank test, the Kruskal Wallis test, and the Steel-Dwass or χ^2 test. A significant difference was defined as $P < 0.05$.

RESULTS

Table 1 shows the characteristics of the 19 subjects enrolled in this study. One patient died of an accident during long-term follow-up. Therefore, only 18 subjects completed long-term follow-up for 12 mo. The QUEST questionnaire and FSSG questionnaire were each collected from 19 (100%) and 12 (66.7%) subjects 3 and 12 mo after ELGP, respectively. Ten subjects consented to GSRS, SF-36, and 24-h intra-esophageal pH/impedance monitoring. Six patients failed to attend for endoscopy at 12 mo. No serious complications were observed in this study. Minor hemorrhage due to mucosal injury during the ELGP procedure was observed in only 2 cases.

The mean QUEST score did not change, but the mean FSSG score decreased significantly, from before ELGP to 3 and 12 mo after. The total number of plications decreased significantly at 3 and 12 mo after ELGP (Table 2).

On 24-h esophageal pH monitoring, there was no difference in the percent time pH < 4 from before ELGP to 3 mo after. Impedance monitoring revealed no changes in the number of reflux episodes or the symptom index (SI) for reflux events from before ELGP to 3 mo after, but the number of symptom events and SSI decreased significantly 3 mo after ELGP (Table 3, Figure 3).

At 3 mo after ELGP, 2 patients were still on full-dose PPI (10.5%), 6 patients had reduced their PPI medication by 50% or more (31.6%), and 11 patients were able to discontinue PPI medication altogether (57.9%). After 12 mo, 2 patients were still on full-dose PPI (11.1%), 3 pa-

tients had reduced their PPI medication by 50% or more (16.7%), and 12 patients were able to discontinue PPI medication altogether (66.7%) (Figure 1).

The GSRS total score, reflux score, abdominal pain score, and indigestion score had improved significantly from before ELGP to 3 mo after. Prior to ELGP, the SF-36 scores were all below the national standard scores. After 3 mo, physical functioning and overall health had improved significantly (Table 4).

Three months after ELGP, one or more plications remained in 80%, and two or more remained in 40%. After 12 mo, one or more plications remained in 43%, and it was confirmed that the sloughing off of plications was followed by scar formation in 75%. Therefore, the correlation of medication dose to loss of antireflux function and symptoms induced by the sloughing off of plications was studied. The FSSG score in cases with no remaining plications and in cases with one or more remaining plications was 4.4 and 2.7, respectively, after 3 mo, and 2.0 and 2.8, respectively, after 12 mo, revealing no correlation to plication loss (Figure 2A). After 3 mo, 33.3% and 66.7%, respectively, had discontinued PPI medication, whereas 83.3% had done so in both groups after 12 mo. A high percentage of cases with remaining plications had discontinued PPIs medication after 3 mo, but there was no difference after 12 mo (Figure 2B).

DISCUSSION

This is the first report showing that ELGP is useful in improving symptoms in Japanese PPI-resistant NERD

patients, reducing their PPI dose and improving their QOL. Surgical fundoplication has been shown to be effective in reducing esophageal reflux in erosive GERD, as well as in NERD. Omura *et al*^[16] have reported that, after laparoscopic fundoplication in 21 NERD patients with acid or bilirubin reflux, all subjects experienced improvement in symptoms of heartburn and were able to discontinue or reduce PPI medication. Broeders *et al*^[17] performed Nissen fundoplication in 96 NERD patients and 117 erosive GERD patients, with improvement in symptoms in 89% and 96%, respectively, after 5 years. In addition, there were no differences between the two groups in terms of the effect in reducing PPI medication, improving QOL score, and reducing acid exposure times, suggesting the long-term efficacy of fundoplication. The efficacy of surgical fundoplication thus continues to be established in GERD, as well as in NERD. However,

Figure 2 Relationship with the plication number and symptom or proton pump inhibitor use. A: Relationship between the number of plications and the score of the frequency scale for symptoms of gastro-esophageal reflux disease. There is no significant difference between the two groups (remaining plications 0 vs one or more) after 3 or 12 mo after endoluminal gastroplication (ELGP); B: Relationship between the number of plications and the rate of proton pump inhibitor (PPI) use. The group with one or more remaining plications shows a tendency to reduced PPI use 3 mo after ELGP ($P = 0.07$). However, there is no significant difference between the groups after 12 mo of ELGP.

Figure 3 Symptom sensitivity index transition at baseline and 3 mo after endoluminal gastroplication.

it has been reported that surgical fundoplication is associated with complications approximately 10% of the time, and that dysphagia lasting 3 mo or longer has been observed^[28]. The procedure is also associated with an operative mortality of about 0.5% to 0.7%^[29], which may be considered a problem for the treatment of a benign disease. There are also no differences in the long-term (140 mo) effect compared to drug treatment^[30], and the cost is higher compared to 10 years of treatment with omeprazole^[31]. It was in light of this background that endoscopic treatments were proposed as less invasive but effective treatment methods^[32,33]. Endoscopic fundoplication is an extremely safe method among such treatments, and its efficacy in erosive GERD is also being studied^[34,35].

The results of 6, 12, and 24 mo of observation have been reported by Filipi *et al.*^[36], Mahmood *et al.*^[25], and Chen *et al.*^[26] in typical clinical studies of ELGP. All reported significant improvements in heartburn and reflux scores, as well as a significant reduction in PPI medication, and these effects lasted as long as 24 mo. In the only randomized, double-blind, comparative study, which was

conducted by Schwartz *et al.*^[37] in 2007, 60 patients with GERD were assigned to an EndoCinch group, a sham treatment group, and an observation group, each composed of 20 subjects, and the subjects were assessed at 3, 6, and 12 mo. After 3 mo, the active treatment group showed a significant reduction in medication and improvement in GERD symptoms and QOL compared to the sham treatment group, and these effects lasted as long as 12 mo. However, there was no difference in esophageal acid exposure between the treated and sham groups, and 29% of the cases required re-treatment. In the only report of a clinical study in Japan, 48 patients with erosive GERD underwent ELGP and were followed-up for 2 years. On 24-h pH monitoring, there was improvement in the percent time pH < 4 from 23.3% ± 26.3% to 10.4% ± 9.6%, as well as 80% improvement from a Los Angeles endoscopic classification of Grade A, B, or C to Grade O. Overall, 66% discontinued PPIs or H₂RA medication, 76% discontinued at least 50% of their medications, and 54% to 66% experienced complete resolution of GERD symptoms^[15]. Meanwhile, Arts *et al.*^[27] performed ELGP in 20 PPI-resistant GERD patients, and reported that 13 and 6 patients were able to discontinue PPI medication 3 and 12 mo later, respectively, and pH monitoring also revealed normalization. These results showed that this treatment method could be indicated for PPI-resistant patients, but there have thus far not been any reports involving PPI-resistant NERD patients.

As previously reported, the mechanism of ELGP is believed to involve a decrease in esophageal acid exposure^[15]. However, in the present study, 24-h intraesophageal pH monitoring revealed mild worsening rather than improvement in the percent time pH < 4 after ELGP. Although it can be said that this was caused by the fact that pH was monitored prior to ELGP while the patients were on full-dose PPI, the fact that symptoms improved and that the rate of PPI medication decreased in patients with GERD symptoms despite being on PPI medication

suggests that factors other than esophageal acid exposure are involved in the development of symptoms in PPI-resistant NERD patients. ELGP involves the endoscopic formation of folds, which are believed to physically prevent reflux through bosselation at the gastroesophageal junction. However, 24-h intraesophageal pH impedance monitoring in the present study did not reveal significant decreases in the percent time pH < 4 or number of episodes of reflux before and after ELGP. Although the possibility cannot be ruled out that esophageal reflux was not adequately controlled because of the spontaneous sloughing off of plications 3 mo after ELGP, it has also been reported elsewhere that pH monitoring revealed no changes before and after surgery^[36,37], and many questions remain regarding the relationship between esophageal acid exposure and the development of symptoms.

In the present study, the number of symptom events and SSI decreased significantly, regardless of the lack of change in the number of episodes of reflux and SI (Figure 3). These results mean that the specificity of a NERD patient's reflux symptoms did not change, but the subject's sensitivity for reflux decreased after surgery. This suggests that factors other than esophageal reflux are involved in the development of the symptoms of NERD, and the presence of esophageal hyperesthesia may be one such factor. Patients with GERD experience proximal esophageal reflux more than normal individuals, but the incidence of proximal esophageal symptoms is significantly higher in NERD patients than in GERD patients^[38]. In addition, the time for symptoms to develop during 10 min of intraesophageal hydrochloric acid infusion, the intensity of symptoms, and the sensitivity index are significantly higher in NERD patients than in normal individuals, patients with reflux esophagitis, and patients with Barrett's esophagus^[39].

Animal studies have confirmed fibrosis near plications and local thickening of smooth muscle of the gastroesophageal junction^[40,41]. It has thus been postulated that sensory nerves densely distributed in the gastroesophageal junction might be damaged by plication, resulting in a loss of sensitivity^[42]. The lack of apparent differences in symptom scores between cases in which plications completely disappeared and cases in which they remained suggests the involvement of esophageal hyperesthesia in the pathology of PPI-resistant NERD. Mechanisms in which tissue degeneration and scar formation in the gastroesophageal junction result in changes in compliance and internal pressure, as well as transient lower esophageal sphincter relaxation, have also been considered^[43].

GSRS has found overlap in various gastrointestinal symptoms and decreases in the scores of all items in the SF-36, and decreases in health-related quality of life (HR-QOL) have been confirmed in PPI-refractory NERD patients. In the present study, ELGP was found to improve HR-QOL in PPI-resistant NERD patients, and the long-term effects were confirmed not only at 3 mo after surgery, but also at 12 mo, showing no recurrence of GERD symptoms and a decrease in PPI use. These find-

ings suggest that HR-QOL was maintained.

Montgomery *et al.*^[44] conducted a randomized, comparative study of ELGP and placebo treatment in 46 patients with erosive GERD. After 3 mo, there was significant improvement in heartburn symptoms and PPI use in the ELGP group, but it was reported that the differences from the sham treatment group disappeared after 12 mo. Overall, 71% and 67% of the plications remained after 3 and 12 mo, respectively, and the attenuation of the effects was attributed to the decrease over time in the percentage of remaining plications^[45,46]. On the other hand, while an apparent loss of plications over time was observed in the present study of PPI-resistant NERD patients, there was virtually no recurrence of symptoms, and patients were able to wean themselves off of medication over the long term. It is therefore possible that ELGP is more useful in NERD, particularly PPI-resistant NERD that is not amenable to oral treatment, than in erosive GERD. The results also suggest differences in the pathology of erosive GERD and NERD.

Most endoscopic treatment in GERD to date has been in patients for whom oral treatment was effective, but the present study was unique in that it looked at cases not amenable to oral treatment and demonstrated the efficacy and safety of the treatment. However, the study suffered from several shortcomings. The first is the lack of any placebo treatment as a control, and the limited number of cases. In actuality, no sham groups were established in many preceding studies of endoscopic treatment^[15,25-27,36,47]. It is often difficult to establish a rigorous model, because the frequent development of complications in active treatment groups hinders blinding, and because increased efficacy is also sometimes observed in sham groups. In the future, it will be necessary to conduct a blinded, randomized, comparative study with a sufficient sample size in order to confirm the efficacy of ELGP treatment in PPI-resistant NERD patients suggested in this study. Second, the 12-mo observation period was inadequate, and it will be necessary to study efficacy for a longer period of time from medical and economic perspectives. It is also possible that the improvement in symptoms by ELGP in PPI-resistant NERD patients results from a variety of mechanisms, including esophageal hyperesthesia, in addition to the physical action of preventing reflux, and further study from that perspective is also necessary.

Despite the many limitations of this study, this is the first report to show endoscopic treatment to be highly effective and safe in PPI-resistant NERD patients who are not amenable to oral treatment and who suffer from significantly compromised QOL. With the accumulation of evidence in the future, it is possible that there will be new indications for endoscopic therapy, including post-gastrectomy GERD and complementary therapy until surgery or postoperative salvage for GERD.

In conclusion, in this study, ELGP significantly improved subjective symptoms and reduced long-term oral medication in Japanese PPI-resistant NERD patients, and it appears to be a safe and useful method of treatment.

COMMENTS

Background

Non-erosive reflux disease (NERD) refers to a syndrome that is characterized by complaints of reflux symptoms such as heartburn without endoscopic evidence of mucosal injury. The severity and frequency of NERD symptoms is similar to erosive gastroesophageal reflux disease (GERD) and is often not amenable to treatment with oral medication. Especially, PPI-resistant NERD is the most intractable NERD patients. Instead of medication therapy, the surgical treatment of erosive GERD, laparoscopic fundoplication, has been developed. On the other hand endoscopic techniques have been developed recently as less invasive but effective methods for erosive GERD.

Research frontiers

Endoscopic treatments were proposed as less invasive but effective treatment methods for GERD. Especially, endoluminal gastroplication (ELGP) is an extremely safe method among such treatments and its efficacy in erosive GERD is also being studied. Most endoscopic treatment in GERD to date has been in patients for whom oral treatment was effective, but the present study was unique in that it looked at cases not amenable to oral treatment and demonstrated the efficacy and safety of the treatment.

Innovations and breakthroughs

Before and after ELGP, patients' symptoms, quality of life (QOL) and 24-h intra-esophageal pH/impedance (MII-pH) monitoring were assessed. After ELGP, the symptoms, QOL and esophageal sensitivity improved significantly. Furthermore, 66.7% patients were able to discontinue proton pump inhibitor (PPI) medication. This is the first report to show endoscopic treatment to be highly effective and safe in PPI-resistant NERD patients who are not amenable to oral treatment and who suffer from significantly compromised QOL.

Applications

With the accumulation of evidence in the future, it is possible that there will be new indications for endoscopic therapy, including postgastrectomy GERD and complementary therapy until surgery or postoperative salvage for GERD.

Terminology

NERD: It is a syndrome that is characterized by complaints of reflux symptoms such as heartburn without endoscopic evidence of mucosal injury; ELGP is a recently introduced endoscopic therapy for GERD refractory to medical therapy. This novel approach involves the insertion of an endoscopic suturing device into the esophagus to create partial-thickness, internal gastric plications that serve as an anti-reflux barrier.

Peer review

This is a good clinical study in which authors analyze the endoscopic therapy effects for PPI-resistant NERD patients who are not amenable to oral treatment. The results are interesting and suggest that this endoscopic technique create a new indication for NERD therapy, especially PPI-resistant NERD who are the most intractable of NERD patients.

Abstract

AIM: To evaluate the effect of prokinetic drugs on electrogastrography (EGG) parameters according to symptomatic changes in patients with functional dyspepsia (FD).

METHODS: Seventy-four patients with FD were prospectively enrolled in this study between December 2006 and December 2010. We surveyed the patients using a questionnaire on dyspeptic symptoms before and after an 8-wk course of prokinetic drug treatment. We also measured cutaneous pre-prandial and post-prandial EGG recordings including percentage of gastric waves (normogastria, bradygastria, tachygastria), dominant frequency (DF), dominant power (DP), dominant frequency instability coefficient (DFIC), dominant power instability coefficient (DPIC), and the ratio of post-prandial to fasting in DP before and after the 8-wk course of prokinetic drug treatment.

RESULTS: Fifty-two patients (70%) achieved symptomatic improvement after prokinetic drug treatment.

Patients who had normal gastric slow waves showed symptom improvement group after treatment. Post-prandial DF showed a downward trend in the symptom improvement group, especially in the itopride group. Post-prandial DP was increased regardless of symptom improvement, especially in the itopride group and mosapride group. Post-prandial DFIC and DPIC in the symptom improvement group were significantly increased after the treatment. The EGG power ratio was increased after treatment in the symptom improvement group (0.50 ± 0.70 vs 0.93 ± 1.77 , $P = 0.002$), especially in the itopride and levosulpiride groups.

CONCLUSION: Prokinetics could improve the symptoms of FD by regulating gastric myoelectrical activity, and EGG could be a useful tool in evaluating the effects of various prokinetics.

INTRODUCTION

Electrogastrography (EGG) is a noninvasive technique for recording gastric myoelectrical activity using electrodes on the abdominal wall overlying the stomach. EGG has been used as a diagnostic tool to determine the mechanism of symptom generation in patients who have dyspeptic symptoms, including nausea, vomiting, post-prandial fullness, bloating, and early satiety, due to gastric motility disorders and abnormal gastric myoelectrical activity^[1]. The EGG records the rhythms of gastric slow waves, which provide information on the velocity and propagations of gastric contractions. The previous studies showed the associations of tachyarrhythmia with absent antral contractions, and bradyarrhythmia with strong or absent antral contractions^[2]. Gastric dysrhythmia including bradygastria and tachygastria is observed in 31%-69% of patients with functional dyspepsia (FD), and several gastric rhythm abnormalities were described in patients with diabetic gastroparesis and motion sickness^[3-6]. EGG also records the gastric myoelectrical activities which show the amplitude of gastric contraction. The amplitude increases in the post-prandial state in healthy populations (90%-95%) and a lack of an increase is believed to reflect decreased gastric motor activity^[7].

Prokinetic drugs are used to treat FD by potentially enhancing gastrointestinal motility and accelerating gastric emptying. Several prokinetic drugs, such as cisapride and domperidone, are known to correct dysrhythmias and symptoms in patients with gastroparesis and dyspepsia^[8,9]. Recently, prokinetics drugs, such as itopride hydrochloride, mosapride citrate, and levosulpiride, were used widely for treatment of upper gastrointestinal motility disease, but the clinical utility of changes in EGG parameters after treatment with these prokinetics in patients with FD symptoms has not been well established^[10].

This prospective study was conducted to evaluate the effect of itopride hydrochloride, mosapride citrate, and levosulpiride on EGG parameters according to symptomatic changes in patients with FD.

MATERIALS AND METHODS

Patients

This study was a prospective study approved by the Institutional Review Committee of Yonsei University Health System and was conducted in compliance with the Declaration of Helsinki. All patients were fully informed of the purposes of the study and written informed consent was obtained from all patients prior to participation.

We reviewed patients who visited the Gangnam Severance Hospital, Yonsei University, South Korea for dyspeptic symptoms between December 2006 and December 2010. Patients with symptoms meeting the Rome III criteria for FD underwent the following procedures^[11]: an interview on medical history, physical examination,

hematologic and chemical evaluations, upper esophagogastro-duodenoscopy or an upper gastrointestinal series, before taking prokinetic drugs. Exclusion criteria included patients (1) who had organic or metabolic diseases (i.e., diabetes mellitus, liver cirrhosis); (2) who had gastrointestinal diseases which had associated dyspeptic symptoms such as inflammatory bowel disease, cancer and ulcers; (3) who had a history of abdominal surgery; and (4) who were taking drugs which could affect gastrointestinal motility, including other prokinetics, cholinergic/anticholinergic agents, and antidepressive agents, for at least 4 wk prior to study start.

Method

Protocol for drug administration: A prokinetic drug was administered after patients completed the questionnaires on FD and baseline EGG recordings were completed. The patients were assigned to one of 3 groups based on the type of treatment drug: itopride hydrochloride (Ganaton[®], Choogwae Pharma, South Korea) ($n = 24$), mosapride citrate (Gasmotin[®], Daewoong Pharma, South Korea) ($n = 28$), and levosulpiride (Levopride[®], SK Chemical Life Science, South Korea) ($n = 22$). Itopride hydrochloride (50 mg tablet), mosapride citrate (5 mg tablet), and levosulpiride (25 mg tablet) were administered to patients in each group 3 times a day in the post-prandial state for 8 wk, and drugs which could affect gastrointestinal function were not allowed to be used throughout the study.

Questionnaires for functional dyspepsia: Symptoms of epigastric pain, epigastric burning, post-prandial fullness, early satiety, post-prandial bloating, and post-prandial nausea or excessive belching were scored in accordance with the following scheme: 0 = none, 1 = mild (symptoms could be ignored if the patient did not think about it), 2 = moderate (symptoms could not be ignored but did not influence daily activities), 3 = severe (symptoms influenced daily activities)^[12]. For each patient, the total symptom severity score was the sum of the 6 symptom scores (minimum 0 to maximum 18). The frequency of dyspeptic symptoms also described above was scored in accordance with the following scheme: 0 = none, 1 = once or twice a month, 2 = once or twice a week, 3 = more than 3 times a week. These scores were added to yield the total symptom frequency score (minimum 0 to maximum 18). The questionnaires were completed again after 8-wk treatment.

Electrogastrography: EGG (Digitrapper EGG; Synetics Medical Inc, Stockholm, Sweden) was used to record gastric myoelectrical activity with low and high cutoff frequencies of 1 and 10 cpm, respectively. After an overnight fast, EGG recordings were obtained in the morning for 30 min in the fasting state and for another 30 min after a test meal at baseline before treatment. This procedure was repeated after 8-wk treatment. To

Table 1 Patient demographics and pattern of dysrhythmia according to symptom improvement

reduce the resistance between electrode and skin, hair was shaved and skin abraded with prepping paste (OMNI PREP[®], D.O. Weaver & Co. United States) on the abdomen, and conductive cream (Signa Creme[®], Parker Laboratories, United States) was applied to the skin. Two electrodes were placed on the abdomen, one midway between the xyphoid process and umbilicus, and the other 5 cm to the left, just below the costal margin. A reference electrode was placed on the right side of the abdomen. These electrodes were connected to a Digitrapper EGG recording devices. The patients were in a sitting position leaning 45° in a comfortable chair. The test meal was composed of solid food (rice rolled up in dried seaweed with orange juice, 500 kcal). The EGG data were uploaded into a personal computer and analyzed by a software program (Polygram for Windows, version 6.40, Synetics Medical Inc, Stockholm, Sweden).

EGG recordings were analyzed to derive the following parameters: (1) percentage of normal gastric waves (2.0-4.0 cpm), bradygastric waves (1.0-2.0 cpm), and tachygastric waves (4.0-10.0 cpm); (2) dominant frequency (DF); (3) dominant power (DP); (4) dominant frequency instability coefficient (DFIC, %); (5) dominant power instability coefficient (DPIC, %); and (6) the ratio of post-prandial to fasting in DP. A percentage of normal slow wave frequency of more than 70% was defined as normal.

Statistical analysis

The patients were classified into 2 groups: a symptom improvement group if symptom severity and frequency scores decreased after treatment with prokinetic drugs; and a symptom resistance group if symptom severity and frequency scores increased or were unchanged after treatment. EGG parameters at baseline were compared with post-treatment EGG parameters, according to symptomatic improvement and types of prokinetic

drugs used in this study.

Demographic data, questionnaire scores and parameters recorded in EGG were statistically analyzed by the paired Student *t* test and Fisher's exact test using SPSS 17.0. Data are expressed as the mean ± SE and a *P*-value < 0.05 was considered significant.

RESULTS

This study included 74 patients (26 men, 48 women: median age 51.7 years, range: 19-70 years). After 8 wk of prokinetic drug treatment, 52 patients (70%) showed symptomatic improvement, while 22 patients (30%) had no improvement or aggravated symptoms. There were no significant demographic differences between patients with improved symptoms and those without improvement (Table 1). There were no significant differences in demographics, and symptom improvement rate among the itopride hydrochloride group, the mosapride citrate group, and the levosulpiride group (Table 2).

Symptom scores for functional dyspepsia

The mean symptom severity score for all patients was 8.09 ± 0.43 at baseline vs 5.51 ± 0.46 post-treatment (*P* < 0.05). Symptom severity scores were significantly decreased in the symptom improvement group, while there were no significant changes in the symptom resistance group. Symptom severity scores were significantly decreased after all prokinetic drugs (Table 2).

The mean symptom frequency score of all patients was 9.27 ± 0.49 at baseline and 6.81 ± 0.54 after treatment (*P* < 0.05). Symptom frequency scores were significantly decreased in the symptom improvement group, while there were no significant changes in the symptom resistance group. Symptom severity scores were decreased after all prokinetic drugs, but significant differences were shown only in the itopride hydrochloride

group (Table 2).

Parameters of EGG recording

Patients who had gastric dysrhythmia: After prokinetic treatment, the number of patients who had normal gastric slow waves was increased in the symptom improvement group and in the itopride treatment group. In particular, the number of patients who had tachygastria were decreased in the symptom improvement group and in the itopride treatment group (Tables 1 and 2).

Percentage of gastric slow waves: The pre-prandial percentage of gastric slow waves was 64.99% ± 2.93% for normal, 14.01% ± 1.93% for bradygastria, and 18.73% ± 2.24% for tachygastria at pre-treatment (Figure 1A). At the end of the 8-wk treatment, the percentage of pre-prandial gastric slow waves was 68.47% ± 2.54% for normal, 16.12% ± 2.94% for bradygastria, and 15.09% ± 1.71% for tachygastria. Dysrhythmia did not show significant changes regardless of symptom improvement. The itopride treatment group showed significant decreases in pre-prandial tachygastria, but there were no significant changes in the mosapride and levosulpiride treatment groups. The percentage of post-prandial gastric slow waves was 63.08% ± 2.25% for normal, 16.52% ± 2.22% for bradygastria and 20.09% ± 2.05% for tachygastria at pre-treatment. At the end of prokinetic treatment, the percentage of post-prandial gastric slow waves was 63.87% ± 2.25% for normal, 16.52% ± 1.92% for bradygastria, and 20.09% ± 19.48% for tachygastria (Figure 1B). There were no significant changes regardless of symptom improvement, nor were there any significant changes among the itopride, mosapride, and levosulpiride treatment groups.

Dominant frequency and dominant power: Pre-pran-

dial DF showed no significant changes regardless of symptom improvement or type of prokinetic drug (Figure 2). Post-prandial DF was decreased after treatment in the symptom improvement group and especially in the itopride treatment group. Pre-prandial DP showed no significant changes regardless of symptom improvement or prokinetic drug after treatment. Post-prandial DP was increased regardless of symptom improvement especially in the itopride group (19.34 ± 6.08 at baseline vs 42.49 ± 6.13 after treatment, *P* = 0.010) and mosapride group (24.04 ± 6.47 at baseline vs 56.24 ± 11.83 after treatment, *P* = 0.020).

Dominant frequency instability coefficient and dominant power instability coefficient: Pre-prandial DFIC and DPIC after treatment were not changed regardless of symptom improvement and type of prokinetic drug (Figure 2). Post-prandial DFIC and DPIC were significantly increased after treatment (74.29% ± 24.45% vs 82.69% ± 27.05%, *P* = 0.035) in the symptom improvement group, but there was no significant differences between the prokinetics.

Power ratio: After treatment, the EGG power ratio was increased in the symptom improvement group (0.64 ± 0.07 vs 1.23 ± 0.16, *P* = 0.002), especially in the levosulpiride treatment group (Figure 3).

DISCUSSION

FD is a common clinical syndrome characterized by pain or discomfort in the upper abdomen without any identifiable structural or biochemical abnormality. The pathophysiology of FD involves various mechanisms, including delayed gastric emptying, impaired accommodation in the proximal stomach, and increase duodenal

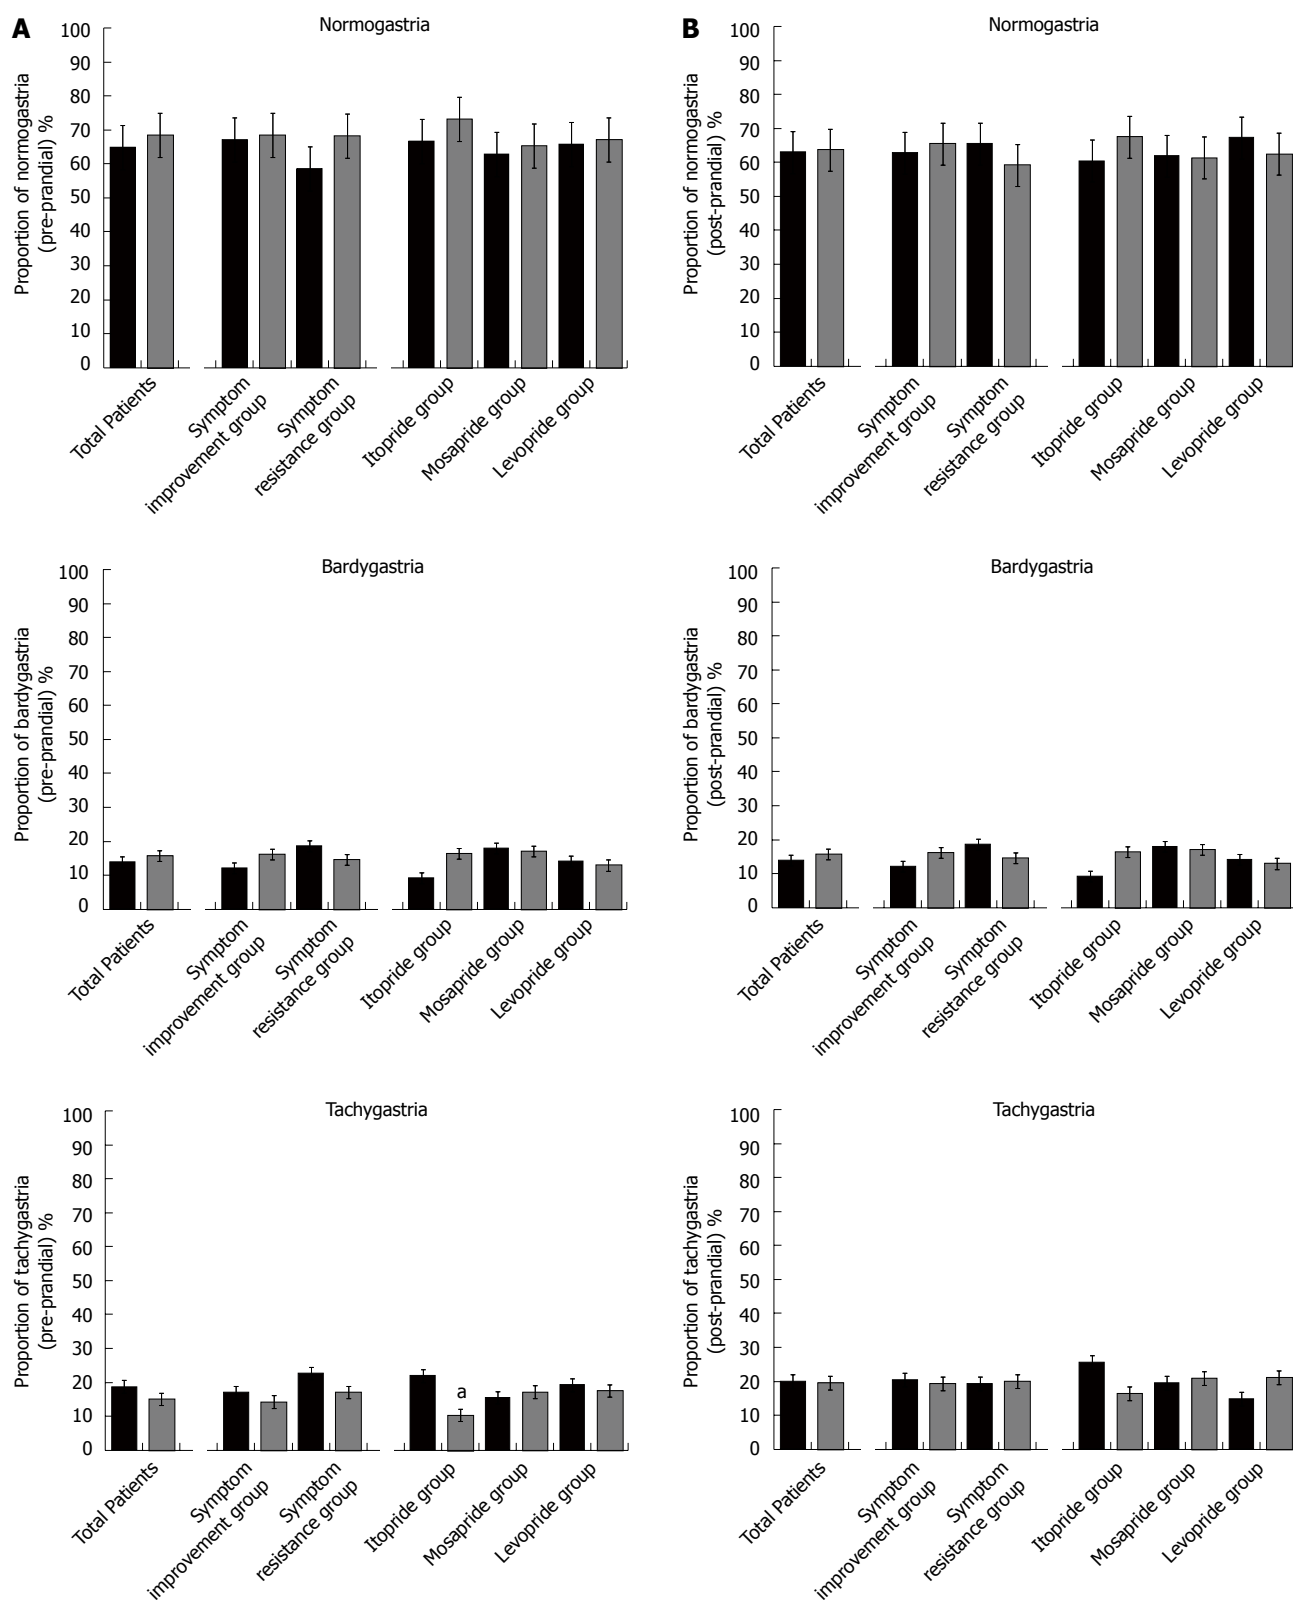

Figure 1 Proportion of gastric slow waves on electrogastrography. A: Pre-prandial; B: Post-prandial. ^a $P < 0.05$ vs pre-treatment.

sensitivity to lipid or acid, and pathologic factors include genetic susceptibility, *Helicobacter pylori* (*H. pylori*) infection, and psychological factors^[13]. There has been no single available therapy for FD due to the heterogeneity of the symptoms and various mechanisms and pathologic

factors. Accordingly, a wide variety of treatment methods have been used for FD such as dietary and lifestyle modification, *H. pylori* eradication, antacids, mucosal protectants, prokinetics, and psychological and complementary therapy^[13].

Figure 2 Changes in dominant frequency and dominant power, dominant frequency instability coefficient and dominant power instability coefficient after prokinetic treatment. A: Dominant frequency (DF) in pre-prandial electrogastrography (EGG); B: DF in post-prandial EGG; C: Dominant power (DP) in pre-prandial EGG; D: DP in post-prandial EGG; E: Dominant frequency instability coefficient (DFIC) in pre-prandial EGG; F: DFIC in post-prandial EGG; G: Dominant power instability coefficient (DPIC) in pre-prandial EGG; H: DPIC in post-prandial EGG. ^a $P < 0.05$ vs pre-treatment.

Figure 3 Power ratio before and after the 8-wk course of treatment. ^a $P < 0.05$ vs pre-treatment.

Abnormal gastric motility such as delayed gastric emptying or uncoordinated antral contraction is common in functional dyspepsia^[14,15]. Gastrointestinal motor dysfunctions can be assessed by gastric emptying scan and/or manometry, and gastric myoelectrical abnormalities can be detected by noninvasive cutaneous EGG. EGG as a diagnostic technique has been frequently used for the detection of gastric dysrhythmia in patients with nausea, vomiting and other dyspeptic symptoms. Several previous studies have shown a positive correlation between abnormal EGG and delayed gastric emptying^[16-18].

The most common abnormal EGG finding is dysrhythmia, low EGG power ratio and high instability coefficient^[19-22]. The percentage of patients who had gastric dysrhythmia (percent of normal slow waves $< 70\%$) were 55.4% at pre-prandial and post-prandial periods in our study. This data was similar to previous studies which reported dysrhythmias in 31%-69% of functional dyspepsia cases^[4]. However, we did not find any significant difference in the percentage of gastric slow waves between the symptom improvement group and the symptom resistance group after treatment and there were no correlations between gastric dysrhythmia and symptom severity or symptom frequency either. This could be because FD symptoms are caused by different abnormalities, for example, impaired gastric accommodation (vagally and nitrergically mediated mechanisms) may cause symptoms but this has little to do with gastric slow waves^[23].

Prokinetics such as cisapride (5-HT₄ agonist/weak 5-HT₃ antagonist) and domperidone (D₂ antagonist) have been shown to improve gastric dysrhythmia in patients with diabetic gastroparesis, whereas low dose erythromycin was reported to have no effects on dysrhythmia^[24-27]. Few studies showed that mosapride improved the gastric dysrhythmia and power ratio. In our study, itopride, mosapride and levopride showed

improvements in gastric dysrhythmia in the pre-prandial state, but significant differences were shown only with itopride^[28,29].

The DF reflects the regularity of gastric slow waves and the DP reflects the amplitude of gastric slow waves. However, the relationship of DF and DP with functional dyspepsia was not clear^[30]. Our data showed a decrease in post-prandial DF in the symptom improvement group, and post-prandial DP was high regardless of symptom improvement. Itopride significantly decreased post-prandial DF, and both itopride and mosapride increased post-prandial DP. According to this study, prokinetics might improve the symptoms of FD by improvement in dysrhythmic gastric movement which is represented by decreased DF, and by activating gastric movement which is represented by increased DP.

DPIC increases during antral contractions, and DFIC increases during pregnancy and in patients with gastroesophageal reflux disease. Previous studies showed that pediatric patients who have dyspeptic symptoms reported a high instability coefficient, however, there was not enough data showing the relationship between the DPIC/DFIC and clinical symptoms in FD patients clearly^[31-33]. Our data showed increased DPIC/DFIC in the symptom improvement group after prokinetic drug treatment^[34]. Increased DPIC/DFIC might be due to the increased variability of changes in gastric movement activated by prokinetics.

The EGG power ratio increases after an appropriate test meal in normal subjects, and decreases in gastroparesis and FD patients^[1]. The EGG power ratio increased in responders after prokinetic treatment with itopride and levosulpride, but not with mosapride in our study. The EGG power ratio is believed to be associated with gastric contractility; the increase in the EGG power ratio observed in this study reflected an increase in gastric contractions. This data is in agreement with previous studies in that prokinetics, especially levosulpride, increased gastric contractions or gastric emptying^[35].

In summary, dysrhythmia was recorded about half of the time in FD patients, and prokinetic treatment successfully improved symptoms. The symptom improvement group showed decreased post-prandial DF and increased post-prandial DP, DFIC/DPIC and power ratio after treatment with prokinetics. Itopride improved gastric dysrhythmia, decreased post-prandial DF, and increased post-prandial DP; mosapride increased post-prandial DP and levosulpride increased the EGG power ratio.

The mechanism of prokinetics on gastric electrical activity could be (1) to stabilize the gastric slow waves which is represented by an improvement in gastric dysrhythmia and a decrease in post-prandial DF; and (2) to increase gastric motility which is represented by an increase in post-prandial DP and in the EGG power ratio by activating gastric movements which is represented by increased DPIC/DFIC.

In conclusion, the findings of this study suggest that prokinetics could improve the symptoms of FD by regulating gastric myoelectrical activity, and the EGG could be a useful tool to evaluate the effects of various prokinetics.

COMMENTS

Background

Electrogastrography (EGG) abnormalities are frequently observed in patients with functional dyspepsia (FD). However, changes in EGG parameters after treatment with prokinetics according to symptom improvement have not been well investigated.

Research frontiers

Prokinetic drugs are used in functional dyspepsia to enhance gastrointestinal motility and correct dysrhythmias in FD patients. In this study, the authors observed that prokinetics could improve the symptoms of FD by regulating gastric myoelectrical activity.

Innovations and breakthroughs

Prokinetics successfully improved symptoms of FD, but the improvement did not seem to be correlated with any of the EGG parameters. Instead, there were some unique changes in EGG parameters according to the prokinetic drug. This study suggests that different prokinetics may have different mechanisms of action in regulating gastric myoelectrical activity, and the EGG could be a useful tool in evaluating the effects of various prokinetics.

Applications

There was controversy in the significance of EGG as diagnostic tool in FD due to the lack of data and standardized methodology. By understanding the changes in EGG parameters, this study might indicate a future strategy for EGG in evaluating the improvement in FD after prokinetic drug treatment. This study is an important basis for future experiments using EGG in pharmacology.

Terminology

EGG represents gastric myoelectrical activity. Dysrhythmia (bradygastria, tachygastria) reflect uncoordinated antral contraction, and the power ratio reflects gastric contractions. Dominant frequency reflects the regularity of gastric slow waves and dominant power reflects the amplitude of gastric slow waves. Dominant power instability coefficient increases during antral contractions and, dominant frequency instability coefficient increases during pregnancy.

Peer review

The authors tried to clarify the relation of EGG and FD symptoms and found the symptom improvement group after prokinetics therapy showed decreased post-prandial dominant frequency and increased dominant frequency instability coefficient/dominant power instability coefficient and increased power ratio.

Published online: November 7, 2012

stents was 100% in both groups. A KMP catheter was easier to manipulate than a guidewire. The mean procedure time in the KMP catheter group (1012 s, range: 301-2006 s) was shorter than that in the guidewire group (2037 s, range: 251-6758 s, $P = 0.022$). The cumulative probabilities corresponding to the procedure time of the two groups were significantly different ($P = 0.008$). The factors related to procedure time were the rendezvous technique method, the number of inside stents, the operator, and balloon dilation of the stricture ($P < 0.05$). In a multivariate analysis, the rendezvous technique method was the only significant factor related to procedure time ($P = 0.010$). The procedural complications observed included one case of mild acute pancreatitis and one case of acute cholangitis in the guidewire group, and two cases of mild acute pancreatitis in the KMP catheter group.

CONCLUSION: The rendezvous technique involving use of the KMP catheter was a fast and safe method for placing inside stents in patients with LDLT biliary stricture that represents a viable alternative to the guidewire rendezvous technique.

Abstract

AIM: To investigate the usefulness of a new rendezvous technique for placing stents using the Kumpe (KMP) catheter in angulated or twisted biliary strictures.

METHODS: The rendezvous technique was performed in patients with a biliary stricture after living donor liver transplantation (LDLT) who required the exchange of percutaneous transhepatic biliary drainage catheters for inside stents. The rendezvous technique was performed using a guidewire in 19 patients (guidewire group) and using a KMP catheter in another 19 (KMP catheter group). We compared the two groups retrospectively.

RESULTS: The baseline characteristics did not differ between the groups. The success rate for placing inside

Key words: Rendezvous; Biliary stricture; Liver transplantation; Endoscopic retrograde cholangiography; Percutaneous transhepatic biliary drainage

INTRODUCTION

Biliary strictures develop in approximately 30% of patients after living donor liver transplantation (LDLT) and 50%-70% of biliary strictures can be treated by endoscopic retrograde cholangiopancreatography (ERCP)^[1,2]. However, percutaneous transhepatic biliary drainage (PTBD) is recommended for patients in whom ERCP has failed^[3]. Because of complications associated with the use of PTBD catheters such as pain, leakage, or infection, replacing PTBD catheters with inside stents by ERCP is required in many patients with PTBD catheters. When an angulated or twisted biliary stricture interrupts passage of a guidewire over the stricture, it is difficult to replace the PTBD catheter with inside stents by ERCP^[1,4,5]. The rendezvous technique can be used to overcome this difficulty.

The rendezvous procedure combines the endoscopic technique with percutaneous transhepatic cholangiography (PTC) to facilitate cannulation of the bile duct in cases where previous endoscopic attempts have failed^[6-9]. This combined technique increases the success rate of biliary tract cannulation and facilitates the diagnosis and treatment of biliary tract disorders^[10-12]. We previously reported that the rendezvous technique allows for successful placement of inside stents in angulated or twisted biliary strictures after LDLT^[13]. In the classic rendezvous technique, a guidewire is used for an endoscopic approach to the bile duct. However, manipulation of the guidewire is difficult and somewhat cumbersome, and kinking or breakage of the guidewire can occur^[14]. The modified rendezvous technique involves pushing the guidewire from the common bile duct into inside the lumen of an ERCP cannula outside the ampulla in the duodenum^[14]. It is also often difficult to push the guidewire inside the lumen of the ERCP cannula.

We attempted to resolve these problems by using a Kumpe (KMP) catheter (5F, 40 cm, Cook, Bloomington, IN, United States; Figure 1) instead of a guidewire. A KMP catheter is short enough for easy manipulation and also reduces the risk of contamination during the procedure. The end of a KMP catheter is slightly angulated and turning the end is simple, which allows the KMP catheter to approximate the ERCP cannula, end-to-end. Herein, we evaluated the usefulness and safety of the new modified rendezvous technique using a KMP catheter to place inside stents into biliary strictures after LDLT and compared it with the rendezvous technique performed using a guidewire.

MATERIALS AND METHODS

Patients

Between November 2006 and June 2011, patients undergoing the rendezvous technique performed using a KMP catheter ($n = 19$) were compared retrospectively with those undergoing the rendezvous technique performed using a guidewire ($n = 19$) at a single institution. Abdominal computed tomography and magnetic resonance chol-

Figure 1 Kumpe catheter (5F, 40 cm).

angiography revealed that patients had biliary strictures at the anastomotic site after LDLT. They had PTBD catheters that were intended to be exchanged with inside stents. The rendezvous procedure was performed, because their anastomotic strictures were too angulated or twisted to place inside stents by ERCP. The rendezvous technique was performed using a guidewire before 2010. We invented the rendezvous technique using a KMP catheter in 2010, and have subsequently performed it ever since. No patient was treated using both techniques. All patients undergoing the rendezvous technique were consecutively enrolled. Patient anonymity was preserved and the Institutional Review Board of Seoul St. Mary's Hospital approved the study (KC11RISI0845). This study protocol was in complete compliance with the Declaration of Helsinki for medical research involving human subjects, as revised in Seoul in 2008.

Guidewire technique

One or two PTBD catheters were passed over the stricture in all patients. After an overnight fast, patients were sedated using midazolam and pethidine in the supine position. PTC was performed by injecting contrast medium through the PTBD catheter (Figure 2A). A guidewire (0.035 inch Jagwire; Boston Scientific, Natick, MA, United States) was introduced along the PTBD catheter until it advanced over the major ampulla into the duodenum, which was followed by removing the PTBD catheter (Figure 2B). After the patients were moved into a prone position, ERCP was performed using a video duodenoscope (ED-450XT5; Fujinon, Saitama City, Saitama, Japan). The guidewire exited the papilla and was identified inside the duodenal lumen using a duodenoscope. A minor sphincterotomy was performed alongside the guidewire in cases where an endoscopic sphincterotomy had not been performed. A bottle-top metal-tip ERCP cannula (MTW Endoscopie, Wesel, Germany) was introduced through the accessory channel of the duodenoscope and placed in front of the end of the guidewire (Figure 2C). The bottle-top metal-tip ERCP cannula and the guidewire were manipulated cautiously to insert the end of the guidewire into the ERCP cannula, which

Figure 2 Guidewire technique. A: The percutaneous transhepatic biliary drainage (PTBD) catheter was located over the anastomotic stricture into the duodenum. The angle between the right hepatic duct and the common bile duct was steep (100°); B: The 0.035 inch guidewire was inserted through the PTBD catheter, and then the PTBD catheter was removed; C: The end of the guidewire was placed outside the papilla; D: The guidewire was inserted through a bottle-top metal-tip endoscopic retrograde cholangiopancreatography (ERCP) cannula, and then the ERCP cannula was advanced into the intrahepatic bile duct; E: Two inside stents were placed over the stricture in the anterior and posterior branches of the right hepatic duct in the recipient liver.

minimized damage to the guidewire (Figure 2D). The guidewire was pushed through the ERCP cannula and the ERCP cannula was advanced along the percutaneously inserted guidewire over the biliary stricture. Then, the percutaneously inserted guidewire was progressively withdrawn while another endoscopically inserted guidewire was pushed through the ERCP cannula. If the guidewire was not pushed easily through the ERCP cannula, the guidewire passing through the ampulla was captured by a basket and then withdrawn through the endoscopic working channel^[13]. After pulling the guidewire was completely out of the scope, the soft or floppy end of the guidewire was placed back into the ERCP cannula and advanced into the biliary tree. When a remaining stricture was suspected at the anastomotic site, balloon dilation of the anastomotic strictures was performed using a balloon catheter (6 or 8 mm in diameter; Hurricane RX; Boston Scientific, Natick, MA, United States). The inside stents were placed over the guidewire (Amsterdam-type biliary stents; 7F-11.5 F in diameter, 10-16 cm in length; Wilson-Cook Medical Winston-Salem, NC, United States, or Medi-Globe, Achenmuhle, Germany). The proximal side of the stent was located to cover the stricture, and the distal side of the stent passed 1-2 cm outside of the major papilla (Figure 2E). We intended to place the proximal end of the inside stent in the bile duct, not in the liver parenchyma, with assistance from fluoroscopic imaging. If we needed to insert another inside stent over the stricture, another guidewire was inserted retrogradely over the stricture site, and a second inside stent was placed along the second guidewire (Figure 2E). In cases where two guidewires had been inserted at different branches of the bile ducts along two PTBD tracts during PTC, two inside stents were placed along these guidewires.

The anastomotic angle between the common hepatic duct of the recipient and the right hepatic duct of the donor (confluence of the anterior and posterior branches) were measured. If a confluent duct was not obvious, we chose the intrahepatic duct (IHD) in which the PTBD catheter had been placed. After successful insertion of

the stents, a follow-up ERCP was performed within 3-6 mo. During the follow-up ERCP, the stents placed previously were removed, and the degree of improvement in biliary stricture and IHD or common bile duct (CBD) stones was evaluated. Restenting was performed if the stricture remained.

Kumpe catheter technique

The basic PTC and ERCP techniques were the same as the guidewire technique. During PTC, a guidewire was introduced along the PTBD catheter until it advanced over the major ampulla into the duodenum, which was followed by removal of the PTBD catheter. The KMP catheter (5F, 40 cm) was placed along the guidewire, and then the guidewire was removed (Figure 3A). In cases where two PTBD catheters had been inserted at different branches of the bile ducts, two KMP catheters were placed along two PTBD tracts. ERCP was performed after the patients were moved into the prone position. The KMP catheter was pulled back until the end of the catheter was located near the major ampulla in the duodenum (Figure 3B, C). The KMP catheter was rotated to approximate the short angulated tip of the KMP catheter and the end of the ERCP cannula, and then the preloaded guidewire in the ERCP cannula was advanced through the KMP catheter (Figure 3D, E). The KMP catheter was pulled back proximal to the stricture for placement of inside stents. Inside stents were placed over the stricture by endoscopy as described in the guidewire technique (Figure 3F). When additional information about the recipient's bile duct was required, a cholangiogram was performed by injecting contrast via the KMP catheter. The KMP catheter was removed after insertion of the inside stents.

Statistical analysis

Procedure time was defined as the time after positioning the end of the duodenoscope in front of the major ampulla until placement of the inside stents. A Pearson's χ^2 test or Fisher's exact test was used to compare categorical data and Student's *t*-test or the Mann-Whitney *U*-test was

Figure 3 Kumpke catheter technique. A: Two Kumpke (KMP) catheters were placed along the previous percutaneous transhepatic biliary drainage tracts; B, C: The KMP catheters were located out of the major ampulla in the duodenum; D, E: The KMP catheter was pulled back and rotated to approximate the slightly angulated end of the KMP catheter and the end of the endoscopic retrograde cholangiopancreatography (ERCP) cannula. Then, a preloaded guidewire in the ERCP cannula was advanced through the KMP catheter; F: Two inside stents were placed over the stricture in the anterior and posterior branches of the right hepatic duct of the recipient liver.

used for comparisons of continuous data to analyze differences between the groups. The cumulative probability curves corresponding to the procedure time for each rendezvous technique were determined using the Kaplan-Meier method, and these were compared using the log rank test. A multivariate analysis was performed with the significant factors identified from the univariate analysis using the Cox proportional hazard regression model (forward: conditional method). Odds ratios and 95% confidence intervals were calculated. Statistical analyses were performed with SPSS software, version 14 (SPSS, Inc., Chicago, IL, United States). *P*-values < 0.05 were considered significant.

RESULTS

Patients

The baseline characteristics of the patients are described in Table 1. No significant differences were observed between the guidewire and KMP catheter groups. The mean duration between LDLT and the rendezvous procedure was 388 d (range: 31–2116 d), and the mean duration between PTBD and the rendezvous procedure was 154 d (range: 4–1526 d). Twenty-seven patients received one PTBD catheter, and 11 patients received two PTBD catheters. Laboratory findings showed normal or mildly elevated serum liver function tests, but no evidence of cholangitis.

Rendezvous procedure outcomes

Inside stents were successfully placed in all patients. Thus, the technical success rate in both groups was 100% (Table 1). No patient was treated with the KMP catheter technique after failure of the guidewire technique. In the guidewire group, the guidewire was pushed through the ERCP cannula and the ERCP cannula was advanced along the percutaneously inserted guidewire over the biliary stricture in 12 patients. In the remaining seven patients, the guidewire passing through the ampulla was captured by a basket and then withdrawn through the endoscopic working channel. IHD or CBD stones were identified in two patients in the KMP catheter group, and the stones were removed during the procedure. Dilation of the anastomotic stricture was performed in four patients in the guidewire group because of a tight stricture. We used the ERCP cannula preloaded with a guidewire in the KMP catheter group, and thus, it was not necessary to pull the guidewire back and reinsert it. It was easier to manipulate the KMP catheter than a guidewire. The procedure time was significantly shorter in the KMP group than in the guidewire group; the mean procedure time was 1012 s vs 2037 s, respectively (*P* = 0.022). In the cumulative probability curve corresponding to procedure time, the probability curves of the two rendezvous groups differed significantly according to the log rank test (*P* = 0.008, Figure 4), suggesting that the use of a KMP catheter was associated with a significantly shorter procedure time. Serum levels

balloon dilation of the stricture were significant factors related to procedure time. The procedure times did not differ between the first and second half in each rendezvous group.

Four significant factors in univariate analysis were evaluated for multivariate analysis. The number of inserted stents, operator, and balloon dilatation of the biliary stricture were not significant in the Cox proportional hazard regression model ($P > 0.05$). The rendezvous technique method was the only significant factor related to procedure time ($P = 0.010$, odds ratio 2.663, 95%CI 1.258-5.637, Table 3). Therefore, the rendezvous technique was an independent factor related to procedure time.

Complications and follow-up after the rendezvous procedure

Acute complications occurred in two patients after rendezvous procedures (10.5%) in each group. In the guide-

wire group, one case of acute cholangitis and one mild case of acute pancreatitis developed after the procedures. Acute cholangitis with fever and epigastric pain occurred due to the migration of an inside stent proximally, resulting in obstruction of the distal end of the stent. We removed the original inside stent and put a new one in its place. The patient ultimately recovered. The patient with acute pancreatitis had the longest procedure time in the guidewire group (112 min) and a sustained elevation into total serum bilirubin for 4 d after the procedure. During the procedure, guidewire manipulation was difficult because the two guidewires were tangled. Two mild cases of acute pancreatitis developed after the procedure in the KMP catheter group. Peak serum amylase levels were 873 U/L and 847 U/L, respectively. Their abdominal pain lasted for 2 d.

We followed the patients in the guidewire and KMP catheter groups for average of 40 mo (range: 12-57 mo) and 8 mo (range: 2-14 mo), respectively. Inside stents were exchanged a mean of 0.8 times (range: 0-4 times) until they were free of biliary stricture. Finally, 19 patients reached stent-free status (seven in the KMP catheter group and 12 in the guidewire group), and 14 patients (nine in the KMP catheter group and five in the guidewire group) still had inside stents. Four patients had plastic inside stents that had been replaced with covered metal stents to treat a biliary stricture. The attempt to change an inside stent by ERCP failed in one patient, and the patient required to undergo PTBD again. IHD or CBD stones developed in seven patients and a biliary cast developed in one patient; these were removed by ERCP. Two patients died during follow-up. One patient in the guidewire group died from recurrent hepatocellular carcinoma 14 mo after the rendezvous procedure, and another patient in the KMP catheter group died from a hepatic artery occlusion and hepatic failure 12 mo later.

DISCUSSION

The present study demonstrated that the rendezvous technique using a KMP catheter is easy, fast, and safe when used to place inside stents for a biliary stricture after LDLT and represents a viable alternative to the rendezvous technique performed using a guidewire. No significant complications were observed.

Patients in whom ERCP stent placement failed needed to undergo PTBD or surgical treatment^[3,16,17]. Al-

though maintaining a PTBD catheter for a long period is beneficial for treating biliary strictures^[18-20], it may be difficult for patients due to the development of PTBD catheter-related complications, such as leakage, pain, infection, and accidental removal of the PTBD catheter^[21,22]. The discomfort caused by carrying a PTBD catheter also reduces the patient's quality of life and disturbs his or her daily routine. Hence, replacing PTBD catheters with inside stents is recommended. However, stenting using ERCP in patients with angulated or twisted biliary strictures is difficult and sometimes fails. Our previous study showed that the rendezvous technique is a useful alternative method for successful placement of inside stents in these patients^[13]. A few cases of biliary complication after liver transplantation have supported the usefulness of the rendezvous technique for biliary strictures and stones or biliary leakage from bile duct anastomosis^[23-25].

Although the rendezvous technique is useful and facilitates cannulation of the bile duct in cases where previous endoscopic attempts have failed^[6-9], there were some drawbacks to the conventional version of the rendezvous technique. In the classic rendezvous technique, grasping the guidewire outside of the ampulla with a forcep or snare is occasionally difficult due to its slippery surface. Kinking or breakage of the guidewire can also occur while grabbing and pulling guidewires through the accessory channel of the duodenoscope. A long guidewire outside the skin of the PTBD tract is difficult to manipulate and increases the risk of contamination. Additionally, it is inconvenient to pull the guidewire back and place the soft or floppy end of the wire back into the ERCP cannula, and then advance it into the biliary tree to reduce liver damage from the stiff end of the guidewire. To reduce these shortcomings, a modified rendezvous technique was introduced so that the end of the guidewire is pushed inside the lumen of an ERCP cannula and the ERCP cannula is advanced along the wire into the CBD^[14]. However, this technique also has its disadvantage. The guidewire is not easily pushed inside the ERCP cannula lumen, and this procedure is frequently time-consuming. A parallel cannulation technique using a sphincterotome in a retrograde fashion, alongside a biliary drainage catheter, can be useful for selective CBD cannulation^[26]. However, parallel cannulation is not suitable for selective IHD cannulation.

A KMP catheter is useful for overcoming these drawbacks. The KMP catheter was introduced as a vascular catheter and has been widely used in the interventional radiology. A KMP catheter is as short as 40 cm, so the portion outside the skin from the PTBD tract is short enough for easy manipulation including to-and-fro motion and turning, which are used to move the curved distal end of the KMP catheter up-and-down and right-to-left and reduces the risk of contamination. Because the end of a KMP catheter is slightly angulated and turning the end is simple, end-to-end contact between the ends of an ERCP cannula and a KMP catheter is easy to achieve without the use of a sphincterotome. It is pos-

sible to insert a preloaded guidewire within the ERCP cannula into the KMP catheter retrogradely. Therefore, it is unnecessary to pull the guidewire back out of the duodenoscope and to reinsert the soft or floppy end of the wire first. When ERCP is delayed after placing a KMP catheter, the KMP catheter can be kept in place for a few hours until ERCP is performed, and it is impossible when using the guidewire technique. Even if two KMP catheters are placed along two previous PTBD tracts, the degree of discomfort is reduced due to the thin caliber of the KMP catheter, and two KMP catheters are not likely to tangle, in contrast to guidewires. Additionally, a cholangiogram can be performed by injecting contrast via the KMP catheter during ERCP, which provides additional information about the recipient's bile duct. If the rendezvous procedure fails, reinserting a PTBD catheter is easy when a KMP catheter is in place. Recently a case report on the rendezvous technique with a C2 catheter which is similar to a KMP catheter, was introduced in a patient with gallbladder carcinoma and a metastatic right intrahepatic bile duct obstruction^[27].

Because this study was retrospective and not randomized, there were some limitations. First, the time to perform the procedures differed between the two groups. The guidewire group procedures preceded those of the KMP catheter group. It is possible that our familiarity with each of the rendezvous procedures differed somewhat. However, the procedure times in chronological order in each rendezvous group did not differ significantly; moreover, those of the first and second half in each group were not different in the factor analysis. Second, we performed an analysis of the factors related to procedure time, but other factors affecting procedure time that were not analyzed in our study may have played a role. For example, the severity and condition of stricture differed somewhat among the patients. However, we supposed that these factors were minor and not significantly related to procedure time. The rendezvous technique itself can overcome the state of the stricture in difficult situation. Third, although we connected the 5F KMP catheter with the tip of the ERCP cannula by a guidewire without great difficulty, the wider diameter of the catheter might make it easier to connect the catheter and ERCP cannula. If a straight catheter is used, a sphincterotome will facilitate the insertion of a guidewire through the catheter.

In conclusion, the rendezvous technique performed with a KMP catheter is a fast and safe method for placing inside stents in biliary strictures in LDLT patients who need to exchange the PTBD catheter for inside stents and represents a viable alternative to the guidewire technique. The KMP catheter rendezvous technique is recommended for LDLT patients who have angulated or twisted anastomotic biliary strictures. We expect further comparative prospective studies with a larger cohort of patients to demonstrate the benefits of the KMP catheter technique in the future.

COMMENTS

Background

The rendezvous technique allows for the successful placement of inside stents in angulated or twisted biliary strictures after liver transplantation. In the classic rendezvous technique, a guidewire is used for the endoscopic approach to the bile duct. However, manipulation of the guidewire is difficult and somewhat cumbersome, and kinking or breakage of the guidewire can occur.

Research frontiers

A Kumpe (KMP) catheter (5F, 40 cm) is useful for overcoming the drawbacks associated with the classic rendezvous technique. The KMP catheter is short enough for easy manipulation and it also reduces the risk of contamination during the procedure.

Innovations and breakthroughs

Because the end of a KMP catheter is shortly angulated and turning the end is simple, end-to-end contact between the ends of an endoscopic retrograde cholangiopancreatography (ERCP) cannula and a KMP catheter is easily achieved even without the use of a sphincterotome. It is possible to insert a preloaded guidewire within the ERCP cannula into the KMP catheter in retrograde fashion. The rendezvous technique involving use of the KMP catheter was a fast and safe method for placing inside stents in living donor liver transplantation (LDLT) biliary strictures and represents a viable alternative to use of the guidewire rendezvous technique.

Applications

The KMP catheter rendezvous technique is recommended for LDLT patients who have angulated or twisted anastomotic biliary strictures.

Peer review

The authors demonstrated the usefulness of a new rendezvous technique for placing stents using a KMP catheter in angulated or twisted biliary strictures. The results are interesting and suggest that rendezvous technique involving use of the KMP catheter was a fast and safe method for placing inside stents in patients with LDLT biliary stricture that represents a viable alternative to the guidewire rendezvous technique.

Abstract

AIM: To evaluate the effect of mitochondrial tumor necrosis factor receptor-associated protein-1 (TRAP-1) on the lymph node metastasis (LNM) in Chinese colorectal cancer (CRC) patients, and develop potential LNM-associated biomarkers for CRC using quantitative real-time polymerase chain reaction (RT-PCR) analysis.

METHODS: Differences in mitochondrial TRAP-1 gene expression between primary CRC with LNM (LNM CRC) and without LNM (non-LNM CRC) were assessed in 96 Chinese colorectal carcinoma samples using quantitative RT-PCR analysis, Western blotting, and confirmed with immunohistochemical assay. The relationship between clinicopathological parameters and potential diagnostic biomarkers was also examined.

RESULTS: TRAP-1 was significantly upregulated in LNM CRC compared with non-LNM CRC, which was confirmed by RT-PCR, Western blotting and immunohistochemical assay. The expression of TRAP-1 in two different metastatic potential human colorectal cancer cell lines, LoVo and HT29, was analyzed with Western blotting. The expression level of TRAP-1 was dramatically higher in LoVo than in HT29. Overexpression of TRAP-1 was significantly associated with LNM (90.2% in LNM group vs 22% in non-LNM group, $P < 0.001$), the advanced tumor node metastasis stage (89.1% in LNM group vs 26.9% in non-LNM group, $P < 0.001$), the increased 5-year recurrence rate (82.7% in LNM group vs 22.6% in non-LNM group, $P < 0.001$) and the decreased 5-year overall survival rate (48.4% in LNM vs 83.2% in non-LNM group, $P < 0.001$). Univariate and multivariate analyses indicated that TRAP-1 expression was an independent prognostic factor for recurrence and survival of CRC patients (Hazard ratio of 2.445 in recurrence, $P = 0.017$; 2.867 in survival, $P = 0.028$).

CONCLUSION: Mitochondria TRAP-1 affects the lymph node metastasis in CRC, and may be a potential biomarker for LNM and a prognostic factor in CRC. Overexpression of TRAP-1 is a predictive factor for the poor outcome of colorectal cancer patients.

INTRODUCTION

Invasion into adjacent tissues and metastasis to distant sites are major features of malignant cancer cells, which are complex processes that require a coordinated action of a large assortment of growth factors and their receptors, as well as downstream signaling intermediates^[1]. Colorectal cancer (CRC) is the third most common cancer in both men and women and the second most common cause of cancer-related death^[2]. CRC frequently migrates through the lymphatic route, depositing tumor cells into local lymph nodes, namely lymph node metastasis (LNM). The status of the local lymph nodes delivers crucial information concerning cancer staging, prognosis, and clinical decision making. The existence of LNM notably reduces the chance of CRC survivals^[3].

Unfortunately, the mechanisms related to LNM remain poorly understood at present because LNM is a complicated process that involves cancer cell detachment from the primary tumor, migration, invasion, adhesion and implantation in the new environment. A variety of dysregulated molecules play a significant role in this highly sophisticated process^[4,5]. Therefore, LNM has become a focus of cancer studies.

Clinicopathological features such as poor differentiation, depth of wall penetration, lymphovascular invasion, and tumor size are considered to be associated with CRC with LNM (LNM CRC)^[6,7].

Proper staging is important for choosing the right treatment for a patient: the most useful staging system is the tumor node metastasis (TNM) system established collaboratively by the American Joint Committee on Cancer and the International Union for Cancer Control^[8].

However, these characteristics are still insufficient to predict the existence of LNM. In order to improve the diagnosis and prognosis of CRC, there is an urgent need to identify specific tumor molecular markers to recognize patients with LNM, which can define a subset of CRC patients who could benefit from rational management.

Heat shock protein 90 (Hsp90) is an abundant molecular chaperone that is further overexpressed or activated in cancer cells, suggesting that it could be a crucial regulator of growth and/or survival of tumor cells^[9,10]. Recent data have shown that Hsp90 family may function as novel regulators of mitochondrial permeability transition, especially in tumor cells^[11-13]. Inhibitors of Hsp90 have been studied for the treatment of cancer, and a small molecule Hsp90 antagonist derived from geldanamycin (GA), i.e., 17-allylamino-demethoxygeldanamycin (17-AAG), has entered clinical testing in cancer patients, but progress has been questionable, and the response to this agent proved difficult to interpret^[14,15]. This reflected

a modest anticancer activity that was inconsistent with a predicted essential role of Hsp90 in tumor maintenance, paradoxical activation of oncogenic kinases, induction of anti-apoptotic mechanisms, and increased metastatic dissemination^[16].

Accordingly, Hsp90 and its ortholog, and tumor necrosis factor receptor-associated protein-1 (TRAP-1) are abundantly localized to the mitochondria of tumor, but not present in most of the normal cells. Mitochondria play a critical role in cell survival and cell death^[17]. Consistent with a general role of Hsp90 as a drug target in colorectal cancer, the mitochondria-compartmentalized cytoprotective pathway could provide a novel therapeutic target to enhance tumor cell apoptosis^[13].

TRAP-1 associated with cancer has been reported recently in several studies, especially in metastasis of cancer cells^[18-20], but there were a limited number of studies on the association of TRAP-1 with metastasis in Chinese CRC patients. In this study, we employed quantitative real-time polymerase chain reaction (RT-PCR) to analyze the expression of mitochondrial TRAP-1 in the groups of LNM CRC and non-LNM CRC. We studied the correlation between expression of TRAP-1 in LNM CRC and non-LNM CRC with quantitative RT-PCR and Western blotting. Confirmed with immunohistochemical (IHC) study, we also investigated the relationship between TRAP-1 expression and lymph node metastatic phenotype of CRC, and determined the prognostic value on the metastasis in Chinese CRC cases.

MATERIALS AND METHODS

Patient population and characteristics of tissue samples

A total of 96 Chinese colorectal carcinoma samples were collected in our hospital (Fudan University Shanghai Cancer Center, Shanghai, China) after informed consent was obtained from the patients. None of the patients received chemotherapy or radiotherapy before surgery. Resected specimens were reviewed by two senior pathologists according to the criteria described in the American Joint Committee on Cancer: Cancer Staging Manual (7th edition, 2009)^[8]. The number of lymph nodes retrieved was not less than 12 in the non-LNM CRC. None of them had distant metastasis. The fresh colorectal tumor tissues were obtained immediately after surgery, washed twice with chilled phosphate buffered saline, immediately stored in liquid nitrogen at -80 °C in our tissue bank until further use. This study was approved by the Cancer Center Research Ethics Committee of Fudan University.

Cell lines and culture

For detection of the expression of TRAP-1 in different metastatic potential human colorectal cancer cells, we chose two human colorectal cancer cell lines, LoVo and HT29 in the experiment, to make sure if the TRAP-1 expressed differently in different metastatic potential human colorectal cancer cell lines. The cell line HT29 was cultured in McCoy 5a medium containing 5% fetal bovine

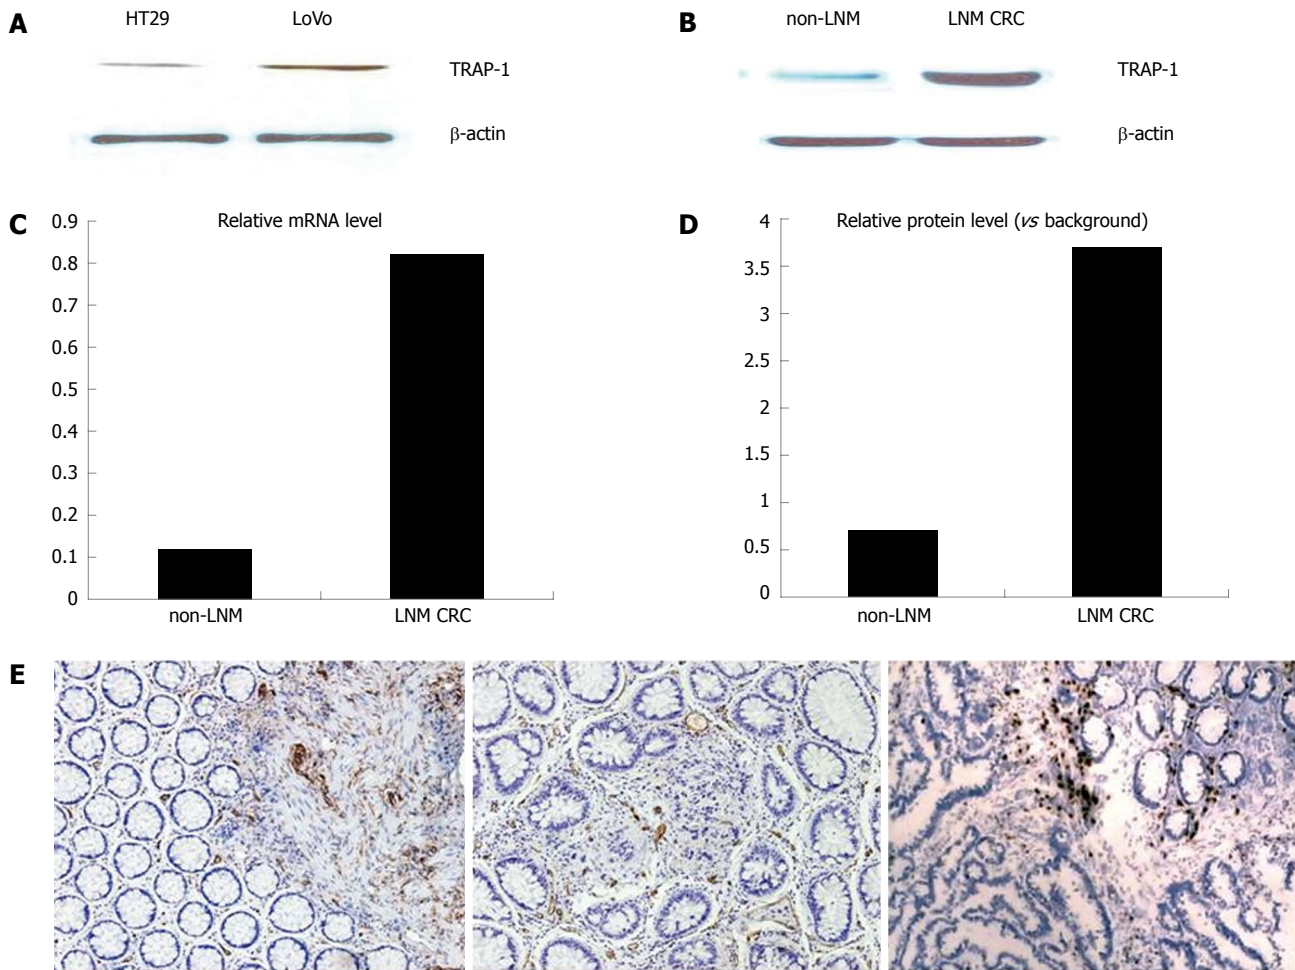

Figure 1 Confirmation of the overexpression of tumor necrosis factor receptor-associated protein-1 in colorectal cancer. A: Western blotting analysis for tumor necrosis factor receptor-associated protein-1 (TRAP-1) expression in different metastatic potential LoVo cell and HT29 cell. β -actin was used as the internal loading control. The histogram shows the relative expression levels of TRAP-1 in LoVo and HT29 cell; B: Western blotting analysis for TRAP-1 expression in non-lymph node metastasis (LNM) and LNM groups. Data represent the mean \pm SE ($P < 0.001$, Student *t* test); C, D: mRNA level of TRAP-1 via quantitative real-time polymerase chain reaction. TRAP-1 was consistently increased in the LNM group compared with non-LNM group. The mRNA level was normalized to that of β -actin. Data represent the mean \pm SE ($P < 0.001$, Student *t* test); E: Immunohistochemical labeling for the TRAP-1 in the CRC sample. TRAP-1 was identified in non-LNM cancer tissues (weak in middle) and strong staining in LNM cancer group (right), but was rare in normal mucosa (left).

serum (FBS). LoVo cells were cultured in F-12K medium containing 10% FBS. All the cell lines were maintained at 37°C in 95% air and 5% CO₂.

RNA isolation and reverse transcription

Total RNA was isolated from the human tissue or cultured colon cancer cell lines using the TRIzol according to manufacturer's instructions (Invitrogen). After the RNA concentration measurement and the integrity of the isolated RNA analysis, 1 μ g of RNA was reverse-transcribed into cDNA according to the manufacturer's protocol (Promega).

Quantitative RT-PCR

Quantitative RT-PCR was analyzed using SYBR Green Supermix (Promega). For PCR, 10 ng of the RT reaction was used for a 25- μ L reaction using the ABI Prism 7700 sequence detector system (Applied Biosystems, Branchburg, NJ, United States). Target genes were normalized to β -actin and quantified using the comparative

Ct method^[21]. TRAP-1 expression levels were measured in triplicate, with a good reproducibility, and the average was calculated.

β -actin was applied as an internal control. The primers for β -actin (205 bp) were 5'-TGACGTGGACATCC-GCAAAG-3' (sense) and 5'-CTGGAAGGTGGACAGCGAGG-3' (antisense). The primers for TRAP-1 (185 bp) were 5'-ATGGTGG CTGACAGAGTGGAGG-3' (sense) and 5'-GCAGTCGGATTTCAGGTGGA TG-3' (antisense).

Western blotting

Briefly, 30- μ g protein samples from each case were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and subsequently transferred to polyvinylidene fluoride membranes. The membranes were incubated with rabbit polyclonal antibody against TRAP-1 (1:1000 dilution; Abcam, Cambridge, United Kingdom) and then incubated with a horseradish-peroxidase-conjugated secondary antibody (1:100 dilution; Proteintech,

¹Statistical analysis was performed with χ^2 test; ²Grading of differentiation status and tumor node metastasis (TNM) classification for colorectal cancer were based on the American Joint Committee on Cancer: Cancer Staging Manual (7th edition, 2009). The tumors were classified into two groups: Well differentiated (grades I and II) and poorly differentiated (grades III and IV).

Chicago, IL, United States). β -actin was detected simultaneously as a loading control (anti- β -actin, 1:1000 dilution; Kangchen, Beijing, China). All blots were visualized using an ECL detection system (Amersham, Arlington Heights, IL, United States) and quantitated by densitometry using an LAS-3000 imager.

Immunohistochemistry

TRAP-1 expression was examined immunohistochemically using paraffin-embedded tissues. In brief, 4- μ m-thick tissue sections were heated in 6.5 mmol/L citrate buffer (pH 6.0) at 100 °C for 28 min, and incubated with antibody against TRAP-1 (1:200 dilution). Immunostaining was performed using the DAKO EnVision System (Dako Diagnostics, Zug, Switzerland). In the negative control group, PBS was used instead of primary antibody. TRAP-1 expression was scored by two independent experienced pathologists. Each sample was graded according to the intensity and extent of staining. The intensity of staining was scored as 0 (no staining), 1 (weak staining), and 2 (strong staining). The extent of staining was based on the percentage of positive tumor cells: 0 (no staining), 1 (1%-25%), 2 (26%-50%), 3 (51%-75%), and 4 (76%-100%). The final score was assessed by summarizing the results of intensity and extent of staining. The

**Figure 2** Overexpression of tumor necrosis factor receptor-associated protein-1 correlated with poor prognosis in 96 colorectal cancer patients.

A: Cumulative recurrence; B: Cumulative survival. The tumor necrosis factor receptor-associated protein-1 (TRAP-1)-positive vs TRAP-1-negative groups ($P < 0.001$, log-rank test).

case was considered negative if the final score was 0 or 1 (-) or 2 or 3 (\pm), and positive if the score was 4 or 5 (+) or 6 or 7 (++). In most cases, the two reviewers provided consistent results. Any inconsistencies were resolved through discussion to achieve a consensus score.

Statistical analysis

The Student *t* test was used to evaluate the differences in TRAP-1 expression between LNM CRC and non-LNM CRC. The χ^2 test was used to assess the relationship between TRAP-1 expression and clinicopathological factors. The cumulative recurrence and survival probability were estimated using the Kaplan-Meier method, and differences were calculated by log-rank test. Prognostic factors were determined using Cox regression analysis. The recurrence-free and overall survival duration were calculated from the first resection of the primary tumor to first evidence of recurrence or to death from any cause, respectively. The diagnosis of recurrence was based on the typical features presented on computed tomography/magnetic resonance imaging and elevated serum carcinoembryonic antigen. All *P* values were two-sided, and $P < 0.05$ was considered to be significant. Statistical analyses

were performed using SPSS 13.0 software.

RESULTS

TRAP-1 expression in CRC specimens and different metastatic potentials of two human colorectal cancer cell lines, LoVo and HT29, were determined by Western blotting and quantitative RT-PCR. The expression of TRAP-1 in LoVo cells and HT29 cells was analyzed with Western blotting. The expression level of TRAP-1 was dramatically higher in LoVo than in HT29 cells. Representative Western blotting results are presented in Figure 1A.

Quantitative RT-PCR and Western blotting were used to analyze the TRAP-1 expression in different groups of CRC. Relative gene and protein expression quantifications were calculated by the comparative Ct method using β -actin as an endogenous control. The results revealed that TRAP-1 mRNA and protein levels were higher in LNM CRC than in non-LNM CRC ($P < 0.001$, Figure 1B and C, D), which is consistent with the results by the Western blotting.

Immunohistochemistry was applied to confirm the upregulation of TRAP-1 in different groups (Figure 1E). In non-LNM CRC, there was weak staining in cancer cells compared to the strong staining in both primary and matched metastatic lymph node cancer cells in LNM CRC samples.

Association between TRAP-1 expression and clinicopathological features and postoperative prognosis of CRC patients

To detect the relationship between TRAP-1 expression and clinicopathological features and whether TRAP-1 could be a prognostic factor in predicting clinical outcomes of CRC patients, we evaluated TRAP-1 expression with the same samples. In the LNM CRC samples, 87% were positive for TRAP-1 expression, whereas 10.2% of the non-LNM CRC samples had positive expression.

Statistical analysis revealed that positive expression of TRAP-1 was significantly associated with LNM, and advanced TNM stage ($P < 0.001$). However, no significant correlations were observed between TRAP-1 expression and other clinicopathological parameters of sex, age, tumor size, tumor differentiation and tumor location (Table 1).

Furthermore, we found that patients with TRAP-1-positive CRC had significantly poorer prognosis than those with TRAP-1-negative CRC. The 5-year cumulative recurrence rate was significantly higher in patients with TRAP-1-positive CRC than in the TRAP-1-negative group ($P < 0.001$, Figure 2A). The 5-year cumulative survival rate in patients with TRAP-1-positive CRC was much lower than in those with TRAP-1-negative CRC ($P < 0.001$, Figure 2B). Univariate analyses revealed that LNM, TNM stage and TRAP-1 expression were associ-

ated with recurrence and overall survival. In multivariate analysis, LNM, TNM stage and TRAP-1 expression were also independent prognostic factors for recurrence and overall survival ($P < 0.05$, Table 2).

DISCUSSION

Metastasis remains one of the major challenges in management of CRC patients. LNM is the most common form of metastasis in CRC. To study the correlation between expression of TRAP-1 and LNM metastasis in East Asian CRC patients, develop potential LNM-associated biomarkers for CRC, we used the quantitative RT-PCR to determine the expression of TRAP-1 in clinical LNM CRC and non-LNM CRC patients, and employed immunohistochemical assay in the same samples to confirm the outcome of PCR and Western blotting.

Recently, several studies have shown that TRAP-1 is an important factor relevant to progression and prognosis in various human cancers, such as glioblastoma^[22], ovarian^[23], prostate^[24], colorectal^[25], and bladder^[26] cancer. In particular, some studies have revealed that overexpression of TRAP-1 strongly indicates the presence of LNM^[22-24], which accords with the objectives of our study. However, similar investigations have been limited to the relationship between TRAP-1 expression and LNM in CRC. Therefore, it is of interest to notice that TRAP-1, one of the significantly upregulated proteins identified in LNM CRC compared with non-LNM CRC, has been confirmed at the protein and mRNA levels.

TRAP-1 is abundantly and differentially expressed in metastatic CRC in humans, but in normal colon cells, TRAP-1 was undetectable or minimally expressed. The different distribution of TRAP-1 in colorectal cancer cells *vs* normal cells is in agreement with another survey of different tumor types, where TRAP-1 was also differentially expressed in tumors of breast, lung, prostate and pancreas as compared with normal matched tissues^[13]. The up-regulation of TRAP-1 in LNM CRC played a major role in crucial biological functions that influence various aspects of cell physiology, including proliferation and apoptosis, and differentiation and morphogenesis. It is also significantly involved in cell adhesion and motility, and cancer invasion and metastasis^[27,28].

The relationship between TRAP-1 expression and the LNM phenotype of CRC was also studied in the experiment with the same CRC samples. We found that the increase in TRAP-1 expression level was significantly correlated with LNM and advanced TNM stage, which suggests that TRAP-1 plays an important part in the progression of CRC from a localized to lymph node metastatic disease. In addition, patients with TRAP-1-positive CRC had an increasing risk of recurrence and significantly reduced overall survival. Univariate and multivariate analyses indicated that TRAP-1 expression is an independent prognostic factor for recurrence and overall survival in CRC, which indicates the considerable prognostic value

of TRAP-1 expression.

In conclusion, the present study provided evidences in the association between differently expressed TRAP-1 and LNM in CRC based on a quantitative mRNA expression analysis. TRAP-1 was identified and confirmed to be significantly overexpressed in LNM CRC. Further evaluation by Western blotting and IHC assay using the same sample sets suggested that TRAP-1 acts as a potential biomarker for LNM and prognosis in CRC.

Most epithelial malignancies, including colorectal cancer exhibit a higher anti-apoptotic threshold, which contributes to disease progression^[29-31]. However, many questions remain to be answered^[32-34] with respect to the cellular function of TRAP-1 and how it exerts its influence on metastatic progression, and the molecular basis for the different localization of Hsp90 and TRAP-1 to the tumor *vs* normal mitochondria awaits further studies.

COMMENTS

Background

Colorectal cancer (CRC) is the third most common cancer in both men and women and the second most common cause of cancer-related death. CRC frequently migrates through lymph node metastasis (LNM), but the variables used to predict the existence of LNM are not available. In order to improve the diagnosis and prognosis of CRC, there is an urgent need to identify specific tumor molecular markers to recognize patients with LNM, which can define a subset of CRC patients who could benefit from rational management.

Research frontiers

Accordingly, Hsp90, and its ortholog, tumor necrosis factor receptor-associated protein-1 (TRAP-1) are abundantly localized to mitochondria of tumor, but not to the normal cells. Mitochondria play a critical role in cell survival and cell death. Consistent with a general role of Hsp90 as a drug target in colorectal cancer, the mitochondria-compartmentalized cytoprotective pathway could provide a novel therapeutic target to enhance tumor cell apoptosis.

Innovations and breakthroughs

The association between TRAP-1 and cancer has been reported in several studies recently, especially the relationship of TRAP-1 with metastasis of cancer cells. There was a limited number of studies on the association of TRAP-1 with metastasis in Chinese CRC patients. In this study, the authors analyzed the expression of mitochondrial in different groups of LNM CRC and non-LNM CRC using quantitative real-time polymerase chain reaction (RT-PCR), and investigated the correlation between expression of TRAP-1 in LNM CRC and non-LNM CRC with quantitative RT-PCR and Western blotting. Confirmed with immunohistochemical assay in the same samples, the authors also investigated the relationship between TRAP-1 expression and lymph node metastatic phenotype of CRC, and determined the prognostic value on the metastasis in Chinese CRC cases.

Applications

This study suggests that the mitochondria TRAP-1 affect the lymph node metastasis in CRC, and it may be a potential biomarker for LNM and a prognostic factor in CRC. Over-expression of TRAP-1 is a predictive factor for the poor outcome of CRC patients.

Terminology

Hsp90 ortholog, TRAP-1 are abundantly localized to mitochondria of tumor, but not to normal cells. TRAP-1 is a 75 kDa heat shock protein that is encoded in humans by the TRAP-1 gene.

Peer review

The study is well-designed, although there are some technical points that need rethinking during the interpretation of the results. The topic is of great clinical importance as colorectal carcinoma represents a worldwide health problem, and finding possible biomarkers that can be prognostic factors may help the clinicians in their daily routine.

Abstract

AIM: To identify the proportion, causes and the nature of drug-induced liver injury (DILI) in patients with notably elevated alanine aminotransferase (ALT).

METHODS: All the inpatients with ALT levels above 10 times upper limit of normal range (ULN) were retrospectively identified from a computerized clinical laboratory database at our hospital covering a 12-mo period. Relevant clinical information was obtained from medical records. Alternative causes of ALT elevations were examined for each patient, including biliary abnormality, viral hepatitis, hemodynamic injury, malignancy, DILI or undetermined and other causes. All suspected DILI cases were causality assessed using

the Council for International Organizations of Medical Sciences scale, and only the cases classified as highly probable, probable, or possible were diagnosed as DILI. Comments related to the diagnosis of DILI in the medical record and in the discharge letter for each case were also examined to evaluate DILI detection by the treating doctors.

RESULTS: A total of 129 cases with ALT > 10 ULN were identified. Hemodynamic injury ($n = 46$, 35.7%), DILI ($n = 25$, 19.4%) and malignancy ($n = 21$, 16.3%) were the top three causes of liver injury. Peak ALT values were lower in DILI patients than in patients with hemodynamic injury (14.5 ± 5.6 ULN *vs* 32.5 ± 30.7 ULN, $P = 0.001$). Among DILI patients, one (4%) case was classified as definite, 19 (76%) cases were classified as probable and 5 (20%) as possible according to the CIOMS scale. A hepatocellular pattern was observed in 23 (92%) cases and mixed in 2 (8%). The extent of severity of liver injury was mild in 21 (84%) patients and moderate in 4 (16%). Before discharge, 10 (40%) patients were recovered and the other 15 (60%) were improved. The improved patients tended to have a higher peak ALT (808 ± 348 U/L *vs* 623 ± 118 U/L, $P = 0.016$) and shorter treatment duration before discharge (8 ± 6 d *vs* 28 ± 12 d, $P = 0.008$) compared with the recovered patients. Twenty-two drugs and 6 herbs were found associated with DILI. Antibacterials were the most common agents causing DILI in 8 (32%) cases, followed by glucocorticoids in 6 (24%) cases. Twenty-four (96%) cases received treatment of DILI with at least one adjunctive drug. Agents for treatment of DILI included anti-inflammatory drugs (e.g., glycyrrhizinate), antioxidants (e.g., glutathione, ademetionine 1,4-butanedisulfonate and tiopronin), polyene phosphatidyl choline and herbal extracts (e.g., protoporphyrin disodium and silymarin). Diagnosis of DILI was not mentioned in the discharge letter in 60% of the cases. Relative to prevalent cases and cases from wards of internal medicine, incident cases and cases from surgical wards had a higher risk of missed diagnosis in discharge letter [odds ratio (OR) 32.7, 95%CI (2.8-374.1),

and OR 58.5, 95%CI (4.6-746.6), respectively].

CONCLUSION: DILI is mostly caused by use of antibacterials and glucocorticoids, and constitutes about one fifth of hospitalized patients with ALT > 10 ULN. DILI is underdiagnosed frequently.

INTRODUCTION

Hepatic injury is encountered frequently in clinical practice. Acute hepatic injury can be recognized by the increased activities of aspartate aminotransferase (AST) and/or alanine aminotransferase (ALT) and can be diagnosed by the presence of ALT levels above 10 times upper limit of normal range (ULN). Viral hepatitis and toxic and ischemic hepatic injury are the most common causes of acute hepatic injury. Rarely, Wilson disease and autoimmune hepatitis can also present as acute hepatic injury^[1]. The frequency of different causes of acute hepatic injury remains unknown and varies worldwide.

Among these causes of acute hepatic injury, drug-induced liver injury (DILI) represents an important challenge for physicians^[2]. DILI is the leading cause of death from acute liver failure and accounts for approximately 13% of cases of acute liver failure in the United States^[3,4]. Furthermore, drug-induced hepatotoxicity is one of the main reasons for postmarketing regulatory decisions, including drug withdrawal^[5]. However, because there are no specific markers coupled with the highly variable clinical presentations of DILI, the recognition and diagnosis of DILI are often difficult and delayed due to the need to exclude more common competing causes of liver injury^[6,7]. The real proportion and seriousness of DILI in patients with acute hepatic injury remain unknown. A previous study showed that DILI was observed in 18%-22% of medical inpatients fulfilling Council for International Organizations of Medical Sciences (CIOMS) laboratory criteria^[8]. Since hepatocellular DILI is the most common type of DILI, the proportion of DILI in patients with ALT > 10 ULN might be higher than in medical inpatients.

The aim of this study was to determine the propor-

tion of DILI in patients with ALT > 10 ULN and identify the causes and the nature of DILI. And we also wanted to know the applicability of ALT > 10 ULN as a criterion for screening DILI patients.

MATERIALS AND METHODS

Case identification

This study was carried out in a 2300-bed teaching hospital of Zhejiang University School of Medicine, China. All hospitalized patients with ALT > 10 ULN (reference value 0-50 U/L) were retrospectively identified from a computerized clinical laboratory database at our hospital covering a 12-mo period (January 2010-December 2010). The medical records for all these patients were independently reviewed by two clinical pharmacists. Alternative causes of ALT elevations were examined for each patient, including biliary abnormality, viral hepatitis, hemodynamic injury, malignancy, DILI or undetermined and other causes (such as liver surgery or trauma, and autoimmune disease). Causes of liver injury were determined based on clinical data and results of investigations such as virology detection, ultrasonography, computed tomographic scanning or magnetic resonance imaging of the liver and biliary tree, antinuclear antibody, smooth-muscle antibody, and gamma globulins detection. A history of alcohol consumption or hypotension which might cause ischemic hepatitis was also needed for diagnosis. As chronic hepatitis B is prevalent in China, presence of hepatitis B surface antigen could not exclude diagnosis of DILI, unless it was accompanied by elevated HBV DNA titer > 1 × 10³^[9].

DILI was suspected based on the following criteria: (1) an appropriate temporal relationship between the intake of the drug and the onset of liver injury, and between the withdrawal of the drug and the course of the reaction; and (2) exclusion of other causes of liver disease^[10]. The CIOMS scale was used to assess the suspected DILI cases^[11], and only the cases classified as highly probable, probable, or possible were diagnosed as DILI. Immune-mediated DILI is an important component of idiosyncratic DILI, which is characterized by presence of fever, rash, eosinophilia and autoantibodies. Extrahepatic manifestations of immune-mediated DILI such as rash, fever, arthralgia, eosinophilia and cytopenia were also reviewed. Prevalent cases referred to the DILI cases with no documented normal baseline values of aminotransferase during hospitalization. In contrast, incident cases were defined as the patients having at least one normal liver parameter prior to DILI development during the hospitalization.

Type of DILI

According to the CIOMS criteria, cases with ALT > 2 ULN alone or an ALT/alkaline phosphatase (AP) ratio ≥ 5 (ALT and AP expressed as multiples of their upper normal limit) were classified as hepatocellular, cases with ALT/AP ratio ≤ 2 as cholestatic and cases with an

ALT/AP ratio between 2 and 5 as mixed liver injuries.

Severity of DILI

The severity of DILI was categorized according to the previous report with minor modifications^[12]: mild [ALT was elevated, but total serum bilirubin was < 2.5 mg/dL and International Normalized Ratio (INR) was < 1.5]; moderate (ALT was elevated and serum bilirubin was ≥ 2.5 mg/dL or INR was ≥ 1.5); and severe [ALT was elevated, and total serum bilirubin ≥ 2.5 mg/dL and with at least one of the following: (1) hepatic failure (INR ≥ 1.5, ascites or encephalopathy); (2) other organ failure believed to be caused by DILI event; and (3) death or liver transplantation because of DILI event].

Drug causality assessment

Drug causality for each case of DILI was assessed according to the WHO definitions for adverse drug reactions: The drug causality was classified as probable if only one drug could be identified as causative for the DILI; it was labeled as certain if a rechallenge was positive; and labeled as possible if more than one drug could have caused the DILI. Drugs were sorted and grouped according to the Anatomical Therapeutic Chemical classification.

Outcome

Cases with a documented decline of all liver parameters < 3 ULN before discharge were labeled as recovery, whereas cases with a documented decline but with liver parameters remaining > 3 ULN were labeled as improvement. Cases without a documented decline of liver parameters before discharge were labeled aggravation.

Detection and evaluation of DILI by treating doctors

In order to evaluate DILI detection by the treating doctors, any comments related to the diagnosis of DILI in the medical record and in the discharge letter for each case were examined. With respect to cases in which DILI was mentioned, we checked whether the causative drugs were specified in these documents.

Statistical analysis

Data were expressed in mean ± SD or mean (range) unless otherwise stated, and were analyzed using the SPSS version 13.0 (Chicago, IL, United States). Continuous variables were compared using independent-sample *t* test between two groups and one-way analysis of variance and *Post hoc* tests among more than two groups. Categorical variables were compared by χ^2 (Fisher's exact) test and the likelihood ratio test. Differences were reported as statistically significant if *P* < 0.05.

RESULTS

Causes of increased ALT > 10 ULN

A total of 129 patients with ALT > 10 ULN were identified in this study. Their mean age was 51 years (range, 6-83

Table 1 Characteristics of patients with alanine aminotransferase > 10 upper limit of normal range (mean ± SD)

Causes	<i>n</i> (%)	Age (yr)	Female <i>n</i> (%)	Peak ALT values (× ULN)
Hemodynamic injury	46 (25.7)	54.2 ± 17.2 ^a	14 (30.4)	32.5 ± 30.7 ^b
Drug-induced liver injury	25 (19.4)	45.4 ± 16.8	9 (36.0)	14.5 ± 5.6
Malignancy	21 (16.3)	55.8 ± 14.6 ^a	2 (9.5)	17.5 ± 10.3
Biliary abnormality	15 (11.6)	52.3 ± 14.4	7 (46.7)	14.3 ± 7.7
Viral hepatitis	12 (9.3)	47.8 ± 16.8	4 (33.3)	18.6 ± 10.0

Total	129 (100)	51.1 ± 16.4	41 (31.8)	23.0 ± 22.7
<i>P</i> (between different causes)	-	0.085	0.15	0.004

Post hoc tests ^a*P* < 0.05, ^b*P* < 0.01 *vs* drug-induced liver injury group. ALT: Alanine aminotransferase; ULN: Upper limit of normal range.

years). Table 1 shows the number of patients with ALT > 10 ULN, age, female percentage as well as peak ALT values derived from all causes. Hemodynamic injury (*n* = 46, 35.7%), DILI (*n* = 25, 19.4%) and malignancy (*n* = 21, 16.3%) were the top three causes of acute liver injury. The other causes included biliary abnormality (11.6%), viral hepatitis (9.3%) and undetermined and other causes (7.8%). There was no difference in gender distribution among different cause groups, but patients were older (54.2 ± 17.2 years *vs* 45.4 ± 16.8 years, *P* = 0.029) and the magnitude of ALT alteration was higher (32.5 ± 30.7 ULN *vs* 14.5 ± 5.6 ULN, *P* = 0.001) in the group caused by hemodynamic injury than in the group caused by DILI.

Features of DILI

Among the DILI patients, the median age was 47 years (range, 20-83 years) and 9 (36%) were female. A total of 10 (40%) patients were 50 years or older and 3 (12%) had a history of alcohol consumption. Sixty-eight percent of patients developed DILI during hospitalization. The median duration between first exposure to the implicated agent and DILI recognition was 6 d (range, 1-40 d). The peak values for serum biochemistries (mean ± SD) were as follows: ALT, 733.7 ± 290.3 U/L; AP, 167.8 ± 120.0 U/L; and total bilirubin, 1.2 ± 1.3 mg/dL. A hepatocellular pattern was observed in 23 (92%) cases and mixed in 2 (8%) cases, and 4 (16%) cases had jaundice. Two (8%) cases had rash, 12 (48%) had fever and 6 (24%) had cytopenia. Neither arthralgia nor eosinophilia was observed. The degree of severity of the liver injury was judged to be mild in 84% and moderate in 16%. The median time to biochemical resolution ≥ 50% from the peak values following discontinuation of the offending drug was 6 d (range, 2-12 d). A definite causal relationship was found in one (4%) case, probable in 19 (76%) and possible in 5 (20%) cases. Ten (40%) cases were recovered and the other 15 (60%) were improved before discharge. Clinical features of 25 DILI patients are listed in Table 2. The improved patients tended to have a

higher peak ALT and shorter treatment duration before discharge compared with the recovered patients (mean peak ALT, 808 ± 348 U/L *vs* 623 ± 118 U/L, *P* = 0.016; and mean treatment duration before discharge, 8 ± 6 d *vs* 28 ± 12 d, *P* = 0.008).

Causative agents

DILI was caused by a single prescription medication in 16% of the cases, by multiple agents in 40% and by herbs in 16%. Twenty-two chemical agents and 6 herbs were associated with DILI. Antibacterials were the most common class of agents associated with DILI in 8 (32%) cases. The antibacterials most often encountered were furbenicillin (*n* = 2), cefminox (*n* = 2), ornidazole (*n* = 2), panipenem and betamipron (*n* = 2), meropenem (*n* = 1), piperacillin and sulbactam (*n* = 1) and cefoxitin (*n* = 1). DILI was caused by glucocorticoids in 6 cases (24%), including 5 cases treated with methylprednisolone, which was the leading individual drug and one case treated with dexamethasone. Implicated causative chemical drugs in 25 subjects with DILI are shown in Table 3. Characteristics of the 6 DILI patients caused by glucocorticoids are presented in Table 4.

Table 3 Implicated causative chemical drugs in 25 subjects with drug-induced liver injury

Classification (<i>n</i>)	Specific drugs (<i>n</i>)
Proton pump inhibitors (2)	Omeprazole (2)
Cardiovascular system (3)	Amiodarone (1), atorvastatin (1), cinepazide (1), telmisartan (1)
Glucocorticoids (6)	Methylprednisolone (5), dexamethasone (1)
Antibacterials for systemic use (8)	Furbenicillin (2), cefminox (2), ornidazole (2), panipenem and betamipron (2), meropenem (1), piperacillin and sulbactam (1), cefoxitin (1)
Monoclonal antibodies (1)	Bevacizumab (1)
Musculo-skeletal system (4)	Diclofenac (1), celecoxib (1), parecoxib (1), baclofen (1)
Nervous system (2)	Olanzapine (2), fluoxetine (1)

Underdiagnosis rate of DILI

DILI was mentioned in medical records of 19 (76%) cases and in the discharge letter of 10 (40%) cases. Those who had missed diagnosis of DILI in medical records also had a higher risk of missed diagnosis of DILI in discharge letters [odds ratio (OR) 1.7, 95%CI (1.1-2.5), *P* = 0.022]. Among the 19 cases of DILI, there were 9 (47.4%) cases without information of specified causative drugs. As shown in the discharge letter, patients from surgical wards had a higher risk of missed diagnosis of DILI compared with those from internal medicine wards [OR 58.5, 95%CI (4.6-746.6), *P* < 0.001]. Similarly, incident cases had a higher risk of underdiagnosis of DILI in their discharge letter compared with the prevalent cases [OR 32.7, 95%CI (2.8-374.1), *P* = 0.001].

Adjunctive drugs for treatment of DILI

Only one case was not treated by any hepatic disease adjunctive drugs. DILI was treated by a single medication in 12% of the cases, and by at least two agents in 84% cases (Table 5). Ten agents were used for treatment of DILI. Anti-inflammatory drugs such as glycyrrhizinate were the most common agents used for treatment of DILI, with a total of 21 (84%) cases. The antioxidants were prescribed for 18 (72%) cases, including glutathione (*n* = 17), ademetionine 1, 4-butanedisulfonate (*n* = 6) and tiopronin (*n* = 1). Polyene phosphatidyl choline was used in 13 (52%) cases.

DISCUSSION

Among the hospitalized patients with ALT > 10 ULN, DILI was the second common cause of liver injury, accounting for 19.4% of cases. Antibacterials and glucocorticoids were the most frequently causative agents for DILI. The degree of severity of DILI was mild or moderate. Ninety-six percent of DILI cases received at least one adjunctive drug for treatment of DILI. All DILI patients were either recovered or improved when they discharged from the hospital. The underdiagnosis rate of DILI in discharge letters was 60%.

ALT and AST are enzymes highly concentrated in the

Table 4 Characteristics of 6 cases of drug-induced liver injury caused by glucocorticoids

Age/sex	Principal disease	Drug	Dose (mg/d)	Treatment duration (d)	Peak values					Follow-up
					ALT (U/L)	AST (U/L)	AP (U/L)	TB (mg/dL)	GGT (U/L)	
20/F	SLE	MP	20-160	84	600	138	83	2.31	183	Recovered

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; AP: Alkaline phosphatase; TB: Total bilirubin; GGT: γ -glutamyl transpeptidase; F: Female; SLE: Systemic lupus erythematosus; MP: Methylprednisolone; DXM: Dexamethasone.

Table 5 Adjunctive drugs used for treatment of drug-induced liver injury

Classification (n)	Specific drugs (n)
Anti-inflammation (21)	Diammonium glycyrrhizinate (9), magnesium isoglycyrrhizinate (8), compound monoammonium glycyrrhetate S (4), compound glycyrrhizin (3)
Antioxidants (18)	Glutathione (17), ademetonine 1,4-butanedisulfonate (6), tiopronin (1)
Phospholipids (13)	Polyene phosphatidyl choline (13)
Herbal extrats (3)	Protoporphyrin disodium (2), silymarin (1)

liver and are sensitive indicators of hepatocyte damage. Patients with a marked increase in aminotransferase levels (> 10 ULN) typically have acute hepatic injury. The study of the causes of notably elevated AST of liver origin in the United Kingdom^[13] showed that hepatic hypoxia was the most common cause (50%), followed by pancreato-biliary disease. Since viral hepatitis is prevalent in many Asian countries and it is the primary cause in 95%-100% of patients with acute hepatic failure in India^[14], viral hepatitis was supposed to be the most common cause of elevated ALT > 10 ULN in China. However, our results showed that hemodynamic injury is the most common cause of notably elevated ALT (36%) similar to the results from the AST study. Viral hepatitis accounts for 9.3% patients with ALT > 10 ULN, which is more than two times higher than the proportion (3.6%) in the AST study. From the results of present study, we should take a new look at causes of acute liver injury in China. Unlike the results from the study of AST, DILI accounts for 19.4% of inpatients with ALT > 10 ULN, which is more than two times higher than the proportion of 8.8% in patients with AST > 10 ULN, indicating that ALT is a more suitable indicator for diagnosis of drug-induced hepatocellular injury than AST.

Although there can be grey areas in which a range of causes overlap, the magnitude and rate of ALT change may provide initial insight into a different diagnosis. A very high ALT (> 75 ULN) are more likely caused by ischemic or toxic liver injury^[6]. In our study, we found that the average peak ALT value in patients with hemodynamic liver injury was more than two times higher than the value in patients with DILI and ALT > 50 ULN was

less likely caused by DILI. However, the average peak ALT values were similar among patients with DILI, liver malignancy, biliary abnormality and viral hepatitis. Therefore, it was hard to identify these etiologies of liver injury merely according to the ALT levels.

DILI is usually recorded by spontaneous reporting in postmarketing surveillance. However, spontaneous reporting frequencies of DILI to the pharmacovigilance authorities are always low in most countries^[15]. The CIOMS laboratory criteria are widely used in studies of DILI. The CIOMS laboratory criteria require at least two determinations of ALT > 2 ULN, conjugated bilirubin > 2 ULN, or combined increases of AST, AP and total bilirubin with one value > 2 ULN, which are too complicated as criteria for screening DILI in real practice. Proportion of DILI in different populations varies depending on different screening laboratory criteria. In our study, among 129 inpatients with ALT > 10 ULN, 25 patients had DILI resulting in a positive predictive value of 19.4% for a case detection based on ALT > 10 ULN. This is similar to the values of 18%-22% in medical inpatients fulfilling CIOMS laboratory criteria^[8]. Because of the hepatocellular predominance of ALT, 92% of DILI cases in this study were of hepatocellular injury. Thus, positive predictive rate of drug-induced hepatocellular injury was 18% in cases with ALT > 10 ULN, which was more than two times higher than the values of 8% in patients fulfilling CIOMS laboratory criteria^[16]. However, it must be noted that the criteria used in our study increased the positive predictive value for diagnosis of drug-induced hepatocellular injury at a cost of missing drug-induced cholestatic injury.

The underdiagnosis of DILI is well known^[8]. In the present study, among 25 cases of DILI, comments about the diagnoses of DILI were given in only 10 (40%) cases in their discharge letters. Nineteen (76%) cases had a diagnosis of DILI during hospitalization, but causative drugs were specified in only less than half of the cases. Underdiagnosis of DILI occurred more often in incident cases and cases from surgery wards. Although the diagnosis rate in our study was not optimistic according to the patients discharge letters, the rate of 40% was more than five times higher than the rate of 7% in a previous study by Meier *et al.*^[8]. This may be due to different detection criteria used, e.g., CIOMS laboratory criteria were

used in that study, but ALT > 10 ULN was used in our study. Doctors might pay more attention to ALT > 10 ULN than to ALT > 2 ULN, which is one of the CIOMS laboratory criteria. Underdiagnosis of DILI may lead to a severe underestimation of the prevalence and incidence of DILI, especially for the studies based on a computerized diagnosis database. It is still a worldwide problem with respect to the methods for improving the reporting rate of DILI. One of the aims of our study is to identify whether ALT > 10 ULN is a good cut-off point for screening DILI patients. From the results of our study, we can conclude that a cut-off in all patients with ALT > 10 ULN for screening DILI has yielded at least the same positive predictive value as the CIOMS laboratory criteria which might be more easily accepted by doctors.

Because inpatients rarely received only a single drug for treatment, which makes it difficult to determine which drug is the most responsible agent inducing liver injury even using the CIOMS criteria, we labeled possible for all suspected drugs. The drugs causing DILI vary among countries. In European countries and the United States, antibiotics, cardiovascular and central nervous system drugs are the most frequent causes of DILI^[3,5,10,17]. In Asian countries, herbal and dietary supplements are often the most common causes of DILI^[9,18]. The current study revealed that the most common type of drugs was antibacterials, accounting for 32% of all DILI cases. The ratio of DILI caused by antibacterials in our study is very similar to the data in outpatients of a Swedish university hospital and inpatients in Switzerland hospitals^[8,15]. Discrepancies in the published data on the category of antibacterials related with DILI may attribute to the different local therapeutic strategies and prescribing behaviors in different countries^[15,19]. Similar to previous studies, hepatotoxicity induced by NSAIDs, omeprazole, amiodarone, statins and olanzapine was recognized. Unexpectedly, we found that 6 cases of DILI might be caused by glucocorticoids. Glucocorticoid is a relatively uncommon cause of liver injury; moreover, it is the choice of treatment for severe hepatitis. However, some cases of corticosteroid-induced hepatotoxicity, mostly induced by the high-dose methylprednisolone have been reported^[20]. In our study, liver injuries were all induced by low-doses of glucocorticoids. The mechanisms of corticosteroid-induced liver injury still remains unclear. Reactivation of HBV infections, excipient of the methylprednisolone preparation and/or idiosyncrasy reactions might all be associated with the liver injury. The significance and mechanism of liver injury caused by glucocorticoids deserve more attention and need more researches. Herbal medicines seem to be the major causes of DILI in Asian countries^[9]. In our study, we found that herbal medicines were responsible for 16% of DILI cases which is higher than the proportion rate in Japan^[18], but much lower than the rate in Singapore^[9]. This may be explained by different herbs consumptions among countries.

Up till now, therapeutic interventions for DILI remain principally limited to the cessation of the causative drugs, supportive therapy and monitoring for acute he-

patic failure^[21]. However, in our study, adjunctive drugs were used in 96% of DILI patients after cessation of the inducing drugs. Glycyrrhizinate, antioxidants and polyene phosphatidyl choline were the most common agents used for treatment of DILI. Data from some clinical studies showed that these drugs are beneficial to patients with DILI^[22-25]. In the current study, none of the patients died from DILI and all patients were either recovered or improved when they were discharged, in spite of the fact that 4 (16%) patients had jaundice. If both drug-induced hepatocellular injury and jaundice occur at the same time, a mortality of at least 10% can be expected according to the Hy's rule^[26]. The reason why we did not detect any fatal cases may somewhat attribute to the use of adjunctive drugs. We did not find any significant difference between recovered patients and improved patients in how many adjunctive drugs were used and which drug was chosen for treating DILI. Although our sample size was small and the follow-up of the patients was done only till discharge, but not till the time of complete recovery, our findings suggest that adjunctive drugs may be effective for treatment of DILI, however, further studies are needed to determine their efficacy and safety in subjects with DILI.

Our study is limited by its retrospective nature. A detailed medical history of the DILI patients before hospitalization could not be obtained if the doctors had not described it in the medical records. For prevalent cases, our data were mainly based on the doctors' judgments. Some patients had not undergone a complete investigation to exclude other possible causes of liver disease. We found that even among cases of DILI diagnosed by treating doctors, many critical elements needed for a diagnosis of DILI were not available. A checklist of minimum elements required for diagnosis of DILI^[19] would be helpful for improving the DILI diagnosis rates and future DILI research.

In conclusion, our study demonstrates that DILI was most frequently caused by use of antibacterials and glucocorticoids and constituted about one fifth of hospitalized patients with ALT > 10 ULN. Underdiagnosis of DILI is common, especially in patients from surgical wards and incident cases. An online warning for diagnosis of DILI when a patient's ALT was > 10 ULN and a checklist of minimum elements required for diagnosis of DILI may both be helpful for improving DILI diagnosis rates and future DILI research.

COMMENTS

Background

Drug-induced liver injury (DILI) is being increasingly recognized as an important cause of acute hepatic injury. It is the leading cause of acute liver failure in several Western countries and the most common reason for postmarketing regulatory decisions. The recognition and diagnosis of DILI are often difficult and delayed because of the lack of specific diagnostic markers coupled with the highly variable clinical presentations of DILI.

Research frontiers

The real incidence of DILI remains unknown because of the difficulty in diagnosis and the low spontaneous reporting frequency to the pharmacovigilance

authorities. The focus of DILI research is how to improve the detection of DILI to better understand the causes, risk factors and nature of DILI. Screening laboratory results of patients and using diagnostic scales, such as the Council for International Organizations of Medical Sciences scale for patients with suspected DILI, may help improve the detection of DILI.

Innovations and breakthroughs

In this study, the authors identified that DILI was the second common cause of alanine aminotransferase (ALT) > 10 times upper limit of normal range (ULN) and a positive predictive value of 19.4% for DILI detection based on ALT > 10 ULN. Antibacterials were the most common causative agents for DILI. Unexpectedly, glucocorticoids, which are commonly used for severe hepatitis treatment, were found to be the second common causative agents. A high rate (60%) of underdiagnosis of DILI was found in patients with ALT > 10 ULN, especially in incident cases and cases from surgical wards.

Applications

The results suggest that underdiagnosis of DILI is frequent and ALT > 10 ULN can be used as a laboratory screening criterion to improve the detection of DILI. The significance and mechanism of causative drugs of DILI, such as glucocorticoids, await further researches.

Terminology

CIOMS scale: This scale is determined by a score based on 7 criteria, including temporal relationship, clinical course (response after withdrawal of drug), risk factors, concomitant drugs, exclusion of other non-drug etiologies, likelihood of a reaction based on package labeling, and rechallenge. The categories of suspicion are definite or highly probable (score > 8), probable (score 6-8), possible (score 3-5), unlikely (score 1-2) and excluded (score ≤ 0).

Peer review

The authors retrospectively investigated the proportion and causality assessment of possible DILI cases in hospitalized patients in a university hospital in China. The research has novelty in identifying and classifying DILI cases. The causality assessment of the DILI cases in this research also provides meaningful information about unique drugs implicated in non-fulminant DILI in the studied patients.

Abstract

Liposarcoma is one of the most common soft tissue sarcomas found in adults, and it usually occurs in the retroperitoneum and the extremities. Here, we describe a case of dedifferentiated liposarcoma originating from a well-differentiated liposarcoma of the mesorectum that presented as a protruding mass in the rectal lumen. Hartmann's operation with total mesorectal excision was performed and the tumor was removed radically. No management guidelines are currently available for liposarcoma of the rectum. We propose that complete surgical resection be required for the treatment of rectal liposarcoma and that a long-term detailed follow up is necessary.

INTRODUCTION

Liposarcoma is one of the most common malignant soft tissue tumors found in adults. Most liposarcoma patients are between 40 and 60 years of age, and the incidence in men and women with this disease is approximately equal. Currently, classification of liposarcoma is divided into five subtypes: myxoid, pleomorphic, dedifferentiated, round cell, and well-differentiated liposarcoma (WDLPS)^[1]. WDLPS is the most common histological subgroup, whereas dedifferentiated liposarcoma (DDLPS) has a comparatively worse prognosis. In this report we describe a WDLPS arising from the mesorectum and presenting as an endoluminal mass. Additionally, this tumor had histological characteristics consistent with DDLPS and had transmurally invaded into the rectum.

CASE REPORT

A 77-year-old Japanese male patient complaining of constipation and urinary retention, was admitted to Kurashiki Central Hospital and examined by a gastroenterologist. The patient had diabetes mellitus that was under control with anti-diabetic drugs. Physical examination revealed a large mass in the lower abdomen, and an abdominal computed tomography (CT) scan showed a large tumor mass in the rectum accompanied by prostatomegaly. Pelvic magnetic resonance imaging revealed a 9 cm × 7 cm × 5 cm sized polypoid tumor in the rectal cavity, with the dorsal side of the mesorectum appearing to protrude into the tumor (Figure 1). A colonoscopy revealed a smooth-

Figure 1 T2-weighted magnetic resonance image demonstrating a high-intensity mass in rectum with prostatomegaly.

surfaced, oval-shaped, large tumor in the rectum, with the lower end located about 10 cm from the anal verge. The first preoperative colonoscopic biopsy retrieved some necrotic but no malignant tissue. The immunohistochemical analysis of the second biopsied specimen demonstrated positive staining for CD34, CD31 and Ki67, and negative staining for c-kit, AE1/AE3 and epithelial membrane antigen, with the MIB-1 index at 30%. Preoperative diagnosis was not definitive but indicated a possible high-grade sarcoma. The tumor marker carbohydrate antigen 19-9 was detected at an abnormally high level, while other tumor markers were within normal ranges. The gastroenterologist suspected that the preoperative diagnosis was angiosarcoma, malignant solitary fibrous tumor, or c-kit negative gastrointestinal stromal tumor and introduced the patient to the surgical department for surgical resection. A preoperative digital examination confirmed that the distance between the lower end of the tumor and the anal verge was 10 cm and that the tumor was mobile.

The patient underwent a laparotomy, which revealed a large palpable tumor in the rectum. Since the preoperative diagnosis indicated a possible high-grade sarcoma, the local recurrence rate after the operation was not expected to be low, even if the tumor was resected radically. Therefore, total mesorectal excision was performed in addition to Hartmann's operation to help decrease the risk of pelvic recurrence. A part of the mesorectum was slightly hard and the tumor was resected radically. Gross examination revealed a large submucosal tumor with invagination of the surrounding large intestine. Following surgery, the patient was discharged without any postoperative complications.

The resected solid tumor was 85 mm × 67 mm × 32 mm in size and pedunculated (Figure 2A). Histological examination revealed a high-grade sarcoma consisting of spindle-shaped tumor cells with hyperchromatic oval nuclei and eosinophilic cytoplasm (Figure 2B, C). The differentiation status of the tumor was determined morphologically as well as immunohistochemically. The tumor was positive for Bcl-2, vimentin, desmin, CD34, CD56, CD10, and CD99. However, the mass was found to be present transmurally in the rectum, and was con-

Figure 2 Dedifferentiated liposarcoma in rectum. A: Gross picture showing a huge dedifferentiated liposarcoma in rectum; B: Dedifferentiated component identified in polypoid lesion at rectum [hematoxylin and eosin (HE), × 400]; C: Well-differentiated liposarcoma at mesorectum (HE, × 400).

tinuous to WDLPS, consisting of mature adipose tissue, intervening fibrous tissue, and scattered atypical cells with large, unusual nuclei in the mesorectum. Thus, a diagnosis ofDDLPS arising from WDLPS was rendered.

Three months postoperatively, no recurrence or metastasis was identified *via* CT scan.

DISCUSSION

Retroperitoneal malignant tumors are rare; however, liposarcoma is the most common type^[2-6]. Liposarcoma tends to occur in the fourth to sixth decades of life, with no difference in frequency among the sexes. Liposarcomas have been divided into five subtypes by the World Health Organization (well differentiated, dedifferentiated, myxoid, pleomorphic, and mixed type)^[1]. In 1979, Evans^[7] was the first to characterize a liposarcoma. He

described a combination of WDLPS and a non-lipogenic dedifferentiated sarcoma-like component. In 1971 Dahlin *et al*^[8] described the dedifferentiated chondrosarcoma as a morphologically biomorphic neoplasm showing areas of well-differentiated, low-grade tumors juxtaposed with high-grade non-chondroblastic tumors without obvious areas of gradual transition. Dedifferentiation can take place through a *de novo* mechanism or through the recurrence of WDLPS in which additional changes have occurred^[9]. The original definition of DDLPS has been modified over time. Dedifferentiation into exclusively low-grade areas or into a combination of low and high-grade areas has been included in this subtype. DDLPS has a less aggressive clinical course than other types of high grade sarcoma, although the underlying mechanism remains unclear. Approximately 40% of DDLPSs will recur locally and 17% will metastasize and 28% of patients will ultimately die as a result of the tumor^[1].

In our case, the mesorectum spindle cells in the pleomorphic lipoma were positive for CD34, indicating a well-differentiated liposarcoma. Preoperative immunohistochemical staining with CD117 was negative, suggesting that the tumor was not a typical GIST. Postoperative histological findings revealed a transition from WDLPS to a non-lipogenic sarcoma with a variable grade at the polypoid lesion indicating a DDLPS.

The most common sites of DDLPS are the retroperitoneum and extremities, with other anatomic locations occasionally reported. Excluding case of DDLPS in the retroperitoneum, we found nine cases of localized DDLPS. Six of the DDLPS cases occurred in the small bowel mesentery^[10,11] and two cases of primary advanced DDLPS occurred in the colon^[12,13]. The final case of DDLPS occurred in the sigmoid mesocolon^[14]. The case we present here is an example of primary retroperitoneal WDLPS with secondary involvement of the rectum. An unusual feature of this case was that the DDLPS was detected in a polypoid lesion in the rectum.

The appropriate diagnostic and therapeutic approach to treat DDLPS has not yet been determined; although, it is generally accepted that complete surgical resection of the tumor should be performed to increase the cure rate of this disease. In our case, total mesorectal excision of the rectum was performed and was expected to have removed the tumor radically. The patient has been followed-up and no signs have been detected to suggest further need for therapy. However, prognosis of DDLPS mainly depends on local recurrence and almost all retroperitoneal cases recur locally in 10-20 years following

treatment^[15]. Therefore, we recommend that complete surgical resection and long-term follow up after surgery be required for the treatment of DDLPS due to the risk of recurrence.

Abstract

We report an extremely rare case of synchronous double cancers of the common bile duct without pancreaticobiliary maljunction. Only two similar cases have been reported in the English literature. Endoscopic retrograde cholangiopancreatography showed a tuberosus filling defect in the middle and superior parts of the common bile duct, and mild stenosis in the inferior duct. Computed tomography (CT) showed a well enhanced mass in the middle and superior parts of the common bile duct. A single cancer of the middle and superior bile duct was suspected and extra-hepatic bile duct resection was performed. CT eleven months after surgery revealed enhanced inferior bile duct wall and a slightly enhanced tumor within it. Retrospective review of the CT images taken before first surgery showed enhanced inferior bile duct wall without intrabiliary tumor only on the delayed phase. The inferior bile duct tumor was suspected to have originally co-existed with the middle and superior bile duct tumor. Pancreaticoduodenectomy was performed subsequently. Histopathological examination revealed that the middle and superior bile duct tumor was a moderately differentiated tubular adenocarcinoma while the inferior bile duct tumor was a papillary adenocarcinoma. The two tumors were separated and had different histological findings and growth patterns, further suggesting that they were two primary cancers.

INTRODUCTION

Synchronous double cancers in the biliary system are rare^[1]. Most such tumors are double cancers in the common bile duct (CBD) and the gallbladder associated with pancreaticobiliary maljunction (PBM)^[1-3]. We report here an extremely rare surgical case of synchronous double cancers of the CBD without PBM. To our knowledge, only two similar cases have been reported in the English literature^[4,5].

CASE REPORT

A 78-year-old male presented with abdominal pain and jaundice. Computed tomography (CT) showed dilatation of the intrahepatic bile duct and a well-enhanced mass in the middle and upper parts of the CBD (Figure 1A). No mass was detected in the inferior part of the CBD (Figure 1B). The results of laboratory tests showed elevated serum levels of several liver enzymes (total bilirubin 19.6 mg/dL, glutamic oxaloacetic transaminase 54 mg/dL, glutamic pyruvic transaminase 103 mg/dL), and high levels of carcinoembryonic antigen (5.4 ng/dL) and carbohydrate antigen 19-9 (375 U/mL). Endoscopic ret-

Figure 1 Imaging findings before the first surgery. A: Computed tomography showed a well enhanced mass in the middle and superior parts of the bile duct (black arrow); B: No mass was detected in the inferior part of the bile duct (white arrow); C: Endoscopic retrograde cholangiopancreatography revealed a tuberos filling defect in the middle and superior parts of the bile duct (black arrows) and mild stenosis in the inferior part (white arrows).

Figure 2 Macroscopic and microscopic findings of resected specimen at the first surgery. A: Resected specimen of the extra-hepatic bile duct showed whitish tuberos tumor in the middle and inferior parts of the bile duct (cancer marked by the white arrows); B: Microscopically, the tumor was moderately differentiated tubular adenocarcinoma with invasive growth (hematoxylin-eosin; magnification; $\times 100$). GB: Gallbladder; HDM: Hepatic duct margin; LBDM: Lower bile duct margin.

rograde cholangiopancreatography (ERCP) showed the absence of PBM and the presence of a tuberos filling defect in the middle and superior parts of the CBD and mild stenosis in the inferior bile duct (Figure 1C). Endoscopy showed no abnormal finding in the papilla of Vater. Although a mild stenosis of the inferior part of the CBD was detected on ERCP, no tumor could be detected in that part of the duct on CT, suggesting that the stenosis was not caused by a malignant tumor. The provisional diagnosis was a solitary tumor in the middle and superior parts of the bile duct. Extra-hepatic bile duct resection with regional lymph node dissection was performed. Histopathological examination showed a moderately differentiated tubular adenocarcinoma with invasive growth (Figure 2). Both the proximal and distal ductal margins

were negative. The postoperative course was uneventful. A repeat CT taken 11 mo after surgery showed enhanced inferior bile duct wall and a slightly enhanced tumor measuring 1.6 cm in diameter within the duct (Figure 3A). Cholangioscopy revealed a papillary tumor in the remaining inferior bile duct (Figure 3B). Retrospective review of the CT images before the first surgery confirmed the lack of abnormal findings in the inferior bile duct on the arterial and portal venous phases. However, the enhanced inferior bile duct wall was detected only on the delayed phase (Figure 3C). Based on the clinical course and CT findings, the inferior bile duct tumor was suspected to have originally co-existed with the middle and superior bile duct tumor although it was not detected before the first surgery. Pancreaticoduodenectomy was performed

Figure 3 Imaging findings before the second surgery and retrospectively reviewed computed tomography finding before the first surgery. A: Computed tomography (CT) taken 11 mo after the first surgery showed enhanced inferior bile duct wall (white arrow) and slightly enhanced tumor within the duct; B: Cholangioscopy revealed a papillary tumor in the remaining inferior bile duct; C: Retrospective review of the CT images before the first surgery revealed enhanced inferior bile duct wall (white arrow) only on the delayed phase.

Figure 4 Macroscopic and microscopic findings of resected specimen at the second surgery. A: Specimen resected during pancreaticoduodenectomy. Note the papillary tumor in the inferior bile duct (white arrow); B: Microscopic examination showed papillary adenocarcinoma with expansive growth (hematoxylin-eosin, magnification; × 100). Tumor cells were confined within the fibromuscular coat. BDM: Bile duct margin.

as the second surgery. Histopathological examination showed a papillary adenocarcinoma with expansive growth (Figure 4), and a negative distal ductal margin. Postoperatively, the patient received adjuvant chemotherapy with S-1. However, multiple liver metastases were detected 10 mo after the second surgery. The patient received additional chemotherapy with gemcitabine for the recurrent metastases, but the metastatic foci showed aggressive growth, resulting in death at 31 mo after the first surgery (18 mo after the second surgery).

DISCUSSION

Synchronous double cancers in the biliary system are rare. Most of the reported cases are double cancers of the CBD and the gallbladder associated with PBM^[1-3]. Fujii *et al.*^[6] reported that 62.5% of synchronous double cancers and 100% of metachronous double cancers of the biliary tract were associated with PBM. Biliary cancers with PBM are thought to develop multicentrally, due to the effect of pancreatic juice reflux on the mucosa of the biliary tract^[7]. Our patient had synchronous double cancers of the middle and superior bile ducts and the inferior bile duct. Although ERCP before the first surgery revealed a

mild stenosis in the inferior part of the bile duct, no mass was detected on CT, and the diagnosis was a single bile duct cancer. However, retrospective review of the first CT images identified enhanced inferior bile duct wall only on the delayed phase, and the site of the enhanced wall was identical to the site of the inferior bile duct tumor detected on the CT eleven months after the first surgery. These imaging findings and the clinical course indicate that the inferior bile duct tumor originally co-existed with the tumor identified in the middle and superior bile duct. We believe that other tests such as endoscopic ultrasonography or cholangioscopy should have been conducted before the first surgery, considering the finding of ERCP. As an extremely rare entity, synchronous double cancers of the CBD without PBM can exist. When a tumor is suspected in the biliary tract, careful and meticulous pre-operative assessment is necessary.

A search of the PubMed database identified only two reports of synchronous double cancers of the CBD without PBM in the English-language literature^[4,5]. With regard to cases of biliary cancer without PBM, the presence of synchronous double tumors poses the question of whether they are independent primary tumors or one tumor that have metastasized from a single tumor. Dif-

ferentiation between these events is important since these two origins imply different stage of the disease, as well as different subsequent treatment and prognosis. In their case report, Ogawa *et al*^[6] described synchronous double cancers of the superior and middle bile duct and inferior bile duct. The upper cancer was pathologically diagnosed as poorly differentiated adenocarcinoma, while the lower one was moderately differentiated adenocarcinoma. In their case, the upper cancer was considered a metastasis from the lower one, based on genetic analysis of loss of heterozygosity^[8,9]. Bedoui *et al*^[5] reported another case of synchronous double cancers of the middle bile duct and inferior bile duct, and both cancers were pathologically diagnosed as adenocarcinomas. That case was preoperatively diagnosed as a single bile duct cancer, similar to the present case. The diagnosis of another inferior bile duct tumor was made during surgery. In their case, there was no communication in either the mucosal layer or the subepithelial layer between the two cancers, and the two tumors were thought to be primary. In our case, the two cancers were separate entities with different histopathological diagnosis, suggesting that they were two primary tumors.

Abstract

This report presents a case of massive mucosal necrosis of the small intestine in a patient with mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS), which particularly affects the brain, nervous system and muscles. A 45-year-old Japanese female, with an established diagnosis of MELAS, presented with vomiting. Computed tomography showed portomesenteric venous gas and pneumatosis intestinalis. She underwent a resection of the small intestine. A microscopic study showed necrosis of the mucosa and vacuolar degeneration of smooth muscle cells in the arterial wall. Immunohistochemistry showed anti-mitochondrial antibody to be highly expressed in the crypts adjacent the necrotic mucosa. The microscopic and immunohistochemical findings suggested the presence of a large number of abnormal mitochondria in MELAS to be closely linked to mucosal necrosis

INTRODUCTION

Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS) is one of a family of mitochondrial cytopathies^[1]. MELAS particularly affects the brain and nervous system and muscles. Gastrointestinal symptoms, such as nausea, vomiting and anorexia, are also common^[2]. Although scattered focal necrosis is sporadically seen^[3], massive intestinal necrosis in MELAS is rare. Only two cases of massive large intestinal necrosis in MELAS have been reported to date^[4,5]. This report presents the case of a MELAS patient with massive mucosal necrosis of the small intestine. This is the first case report of MELAS with massive mucosal necrosis of the

small intestine.

CASE REPORT

A 45-year-old Japanese female presented with vomiting. Abdominal computed tomography (CT) showed portomesenteric venous gas; therefore she was referred to this hospital for further investigation and treatment.

Her medical history revealed that she presented with progressive sensorineural hearing loss at 24 years of age. In addition, she experienced headaches, seizures, homonymous hemianopsia, right hemi paresis, limb weakness and a stroke-like episode at 43 years of age. Her lactic acid and pyruvate level were 112.4 mg/dL (normal < 17 mg/dL) and 2.16 mg/dL (normal < 0.94 mg/dL), respectively. She did not undergo a muscle biopsy. However, the mitochondrial mutation A3243G was detected in her son. A diagnosis of MELAS was therefore established because MELAS is transmitted by maternal inheritance^[2,6].

Her height and body weight were 143 cm, and 26.6 kg, respectively, at the time of admission. Physical examinations revealed abdominal distension. Guarding, rebound tenderness or rigidity could not be estimated properly due to the presence of generalized muscle atrophy and difficulties in communicating with the patient. She was in a state of septic shock. Her heart rate and blood pressure were 88 beats/min and 73 mmHg/31 mmHg, respectively. A semi-quantitative measurement showed her procalcitonin level to be ≥ 10 ng/mL.

CT showed a massive amount of portomesenteric venous gas and pneumatosis intestinalis involving the duodenum, jejunum and ileum (Figure 1). An emergency operation was indicated. Mucosal necrosis from the duodenum to the ileum was recognized transluminal from the serosal. The pulse of the superior mesenteric artery and the vasa recta was palpable. She underwent a massive resection of the small intestine from 10 cm distal to the Treitz ligament to 30 cm proximal to the ileocecal valve, followed by jejunostomy and ileostomy, as damage control surgery because her vital signs indicated the patient to be in a state of shock.

The specimen was 150 cm in length (Figure 2A). Macroscopic observation revealed diffuse mucosal necrosis in two thirds of oral-sided area, and mottled necrosis in the remaining area. The microscopic analysis revealed coagulation necrosis of the mucosa and the lamina propria (Figure 2B). The external longitudinal layer of muscularis propria was also degenerated and partially diminished (Figure 2B). Vacuolar degeneration of smooth muscle cells was observed in the arterial wall and the muscular layer of the intestinal wall (Figure 3).

Anti-mitochondrial antibody (AMA), ab92824, was highly expressed in the crypt and slightly in the remaining mucosa that was observed in the necrotic area (Figure 4). On the contrary, AMA expression in the crypts was moderate in the non-necrotic area. The resected strangulated ileum of a non-MELAS patient stored in the pathological department was used as a control. This sample showed

Figure 1 Preoperative computed tomography. There was a massive amount of portomesenteric venous gas (arrow head) and pneumatosis intestinalis in the small intestine (arrow).

Figure 2 Macroscopic findings of resected tissue and specimen. A: Macroscopic findings of resected tissue. The specimen measured 150 cm in length. There was diffuse mucosal necrosis in two thirds of oral-sided area, and mottled necrosis in the remaining area. Arrow: Oral stump; B: Microscopic findings of the resected specimen. Coagulation necrosis of the mucosa and lamina propria was observed (arrows). The external longitudinal layer of the muscularis propria was partially diminished (arrow heads). Hematoxylin and eosin, Bar = 500 μ m.

moderate AMA expression in the crypt in comparison to that of the current patient (Figure 5; Table 1). Expression patterns of AMA in both specimens are shown in Table 1.

A series of antibiotics were administered based on culture evaluations in order to control infection. She required support for renal insufficiency with continuous hemodiafiltration for a 3-d period after surgery; blood pressure support with catecholamine administration, mechanical ventilation support for a 3-wk period after

Figure 3 Vacuolar degeneration. A: Artery wall (arrow); B: Muscular layer (arrow head). Hematoxylin and eosin, Bar = 100 μ m.

Figure 4 Immunohistochemical study. Anti-mitochondrial antibody is markedly expressed in the crypts (arrow) and preserved mucosa (arrow head). Bar = 500 μ m.

Figure 5 Expression of anti-mitochondrial antibody. A: Necrotic area of the present patient; B: Non-necrotic area of the present patient; C: Necrotic area of strangulated small intestine of a non-myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS) patient; D: Non-necrotic c area in the strangulated small intestine of a non-MELAS patient. surgery. The patient's condition eventually recovered along with the restoration of the necrotic mucosa, based on observations of the oral stoma and thereafter she was discharged. Home parenteral nutrition was indicated because intestinal continuity had not been reestablished

Table 1 Summary of anti-mitochondrial antibody expression

in consideration of her general condition. She died of severe metabolic disorder due to MELAS 3 mo after discharge.

DISCUSSION

MELAS is a rare type of metabolic disorder causing multi-organ disorders, such as brain ischemia and the degeneration of skeletal muscle. MELAS is caused by mutations in mitochondrial DNA encoding transfer RNA^{LEU(UUA/UUG)} and it is transmitted by maternal inheritance^[2,6]. Though MELAS particularly affects the brain, nervous system and muscles, the occurrence of massive intestinal necrosis due to MELAS is rare.

Many MELAS symptoms caused by mitochondrial A4243G mutation are thought to depend on the mutation load and the tissue distribution of abnormal mitochondria^[7]. Therefore, an immunohistochemical study was conducted using AMA, which is a highly sensitive and specific method for identifying the mitochondria^[8], to investigate the relationship between mucosal necrosis and the distribution of mitochondria. This method is applied when the distribution of mitochondria cannot be determined by electron microscopy because the tissue was fixed for light microscopy, as in the present case^[9]. Though an increase in the number of mitochondria does not always indicate the presence of abnormal mitochondria, an increase in the number of mitochondria is more likely to be a sign of mitochondrial disease and aggregation of large mitochondria a characteristic ultra-structural finding in mitochondrial disease^[10,11]. The current patient showed a marked expression of AMA in the crypts, where adjacent villi had almost completely disappeared (Figure 4; Table 1). A marked expression was also observed in the remaining mucosa in the necrotic area. No such marked expression was observed in the crypts of non-necrotic areas in the present case or a necrotic area in the non-MELAS specimen (Figure 5; Table 1). These findings suggest that an increase in the number of

mitochondria, which is likely abnormal, therefore, may contribute to mucosal necrosis. The mucosa containing a higher number of abnormal mitochondria may be vulnerable to ischemia.

Microscopic examination revealed vacuolation of the smooth muscle cells in the small arteries in the current case (Figure 3). However, there was no narrowing of the small arteries. An electron microscopic study of cerebral vessels of patients with MELAS showed a striking increase in the number of mitochondria in the smooth muscle and endothelial cells causing the vascular changes^[12]. The increase is most prominent in arterioles and small arteries. These MELAS-related vascular changes are likely to attribute to a decrease in blood flow^[5]. Therefore, the current patient probably experienced transient non-occlusive ischemia, such as a vasospasm that eventually triggered mucosal necrosis.

In addition to the mucosa, the muscularis mucosa, and inner circular and external longitudinal layer of the muscularis propria were also affected in the present case. Therefore, MELAS may affect any layer of the small intestine.

In conclusion, the presence of abundant abnormal mitochondria may be closely linked to necrosis in the intestinal mucosa, and MELAS-related vascular changes may therefore be a prerequisite for necrosis.

ACKNOWLEDGMENTS

We thank KYODO BYORI. Inc. for the immunohistochemical study using AMA.

Abstract

A 57-year-old man presented with a 2-wk history of painless jaundice and weight loss. He had a large ill-defined enhancing mass-like lesion in the uncinate process of the pancreas with stricture of the distal common bile duct. Aspiration cytology of the pancreatic mass demonstrated inflammatory cells without evidence of malignancy. Total serum immunoglobulin G level was slightly elevated, but IgG4 level was normal. After the 2-wk 40 mg prednisolone trial, the patient's symptoms and bilirubin level improved significantly. A follow-up computed tomography (CT) scan showed a dramatic resolution of the pancreatic lesion. A low dose steroid was continued. After six months he self-discontinued prednisolone for 3 wk, and was presented with jaundice again. A CT scan showed newly developed intrahepatic biliary dilatation and marked concentric wall thickening of the common hepatic duct and the proximal common

bile duct without pancreatic aggravation. The patient's IgG4 level was elevated to 2.51 g/L. Prednisolone was started again, after which his serum bilirubin level became normal and the thickening of the bile duct was resolved. This case suggests that autoimmune pancreatitis can progress to other organs that are not involved at the initial diagnosis, even with sustained pancreatic remission.

INTRODUCTION

Autoimmune pancreatitis (AIP) is a type of chronic pancreatitis characterized by an autoimmune inflammatory process in which prominent lymphocyte infiltration with associated fibrosis of the pancreas leads to organ dysfunction. Steroids are the first choice of therapy in

patients with AIP and the response to steroid therapy is usually dramatic^[1]. However, 20% to 60% of patients with AIP are found to relapse after the initial course of corticosteroid therapy^[2]. The relapse can occur with or without the involvement of other organs such as the bile duct, retroperitoneum, kidneys, salivary or lacrimal gland^[3]. However, cholangitis in the proximal extrahepatic bile duct without pancreatic relapse has rarely been reported. Herein we report a case of newly developed autoimmune cholangitis in a patient with AIP with sustained pancreatic remission.

CASE REPORT

A 57-year-old man presenting with painless jaundice and 2 kg weight loss in 2 wk, was admitted to our hospital. He was an inactive carrier of hepatitis B and his liver function test was within the normal limits at a regular follow up 6 mo ago. He drank socially and had a 30-pack-year history of smoking. On physical examination, he was deeply jaundiced, but other clinical examinations were unremarkable. Laboratory tests revealed white blood cell count of 5850/mm³, aspartate aminotransferase 112 U/L, alanine aminotransferase 230 U/L, alkaline phosphatase (ALP) 326 IU/L, gamma-glutamyl transpeptidase (GGT) 584 U/L, total bilirubin 24.7 mg/dL, amylase 91 U/L and lipase level of 56 IU/L. Abdominal computerized tomography (CT) revealed an ill-defined enhancing mass-like lesion in the uncinate process of the pancreas measuring 5.7 cm × 3.2 cm with regional infiltrations and small amounts of fluid collections around the pancreas head (Figure 1). Magnetic resonance cholangiopancreatography showed moderate dilation of the intrahepatic duct and common bile duct (CBD) but the pancreatic duct was unremarkable (Figure 2A). Endoscopic retrograde cholangiopancreatography revealed a distal biliary stricture (Figure 2B), and brush cytology demonstrated no malignant cells. 7-Fr Amsterdam type inside stent was placed to decompress the biliary system. A subsequent endoscopic ultrasound (EUS) demonstrated a hypoechoic lesion located in the head of the pancreas with blurred delineated margins, which suggested inflammation rather than malignancy. EUS guided fine needle aspiration cytology revealed lymphocytes, neutrophils, and irregular sheets of bland ductal epithelial cells lacking atypia (Figure 3). Serum tumor markers were unremarkable; carbohydrate antigen 19.9 was 20.36 U/mL (normal < 37 U/mL), and carcino-embryonic antigen was 0.8 ng/mL (normal < 7.5 ng/mL). Serum immunoglobulin G level was slightly elevated to 1703 mg/dL (normal < 1600 mg/dL), but serum IgG4 level was 0.41 g/L (normal < 1.21 g/L). In consideration of autoimmune pancreatitis, we started with 40 mg/d prednisolone orally for 2 wk. After that, the patient's symptoms and bilirubin level improved significantly. A follow-up CT scan showed a dramatic resolution of the pancreatic lesion. The daily dose of prednisolone was gradually tapered and 2.5 mg of prednisolone per day was maintained. The stent in the CBD was removed two months later. He remained well

Figure 1 Initial abdominal computed tomography scan revealed an ill-defined enhancing mass-like lesion in the uncinate process of the pancreas with a dilatation of common bile duct. A: The uncinate process of the pancreas (white arrow) measuring 5.7 cm × 3.2 cm with regional infiltrations; B: In addition to this, there is small amounts of fluid collections around the pancreas head (white arrows).

Figure 2 Magnetic resonance cholangiopancreatography and endoscopic retrograde cholangiography. A: Magnetic resonance cholangiopancreatography showed moderate dilatation of the intrahepatic and common bile duct. The distal common bile duct had an abrupt narrowing. The pancreatic duct was unremarkable; B: Endoscopic retrograde cholangiography revealed a beak shaped stricture of the distal common bile duct with biliary dilatation above it.

until six months later, when he was readmitted with acute jaundice after self-discontinuation of prednisolone for 3 wk. The total bilirubin level was elevated to 19.2 mg/dL. ALP and GGT were 222 IU/L and 447 IU/L, respectively. IgG4 level was also elevated to 2.51 g/L, which was two times above the upper limit of the normal range. The following CT scan showed a stricture at the proximal extrahepatic bile duct and dilation of the intrahepatic bile duct (Figure 4A). The common hepatic duct and proxi-

Figure 5 Abdominal computed tomography scan after retreatment with prednisolone showed resolution of the thickening of the bile duct (white arrow).

Figure 4 Follow up abdominal computed tomography scan. A: Coronal image revealed a stenosis of the common hepatic and the proximal common bile duct (white arrow) with significant thickening and inner wall enhancement of the bile duct; B: There was no pancreatic relapse (white arrow).

mal CBD showed marked concentric wall thickening and enhancement. However, there was no pancreatic aggravation (Figure 4B). Newly developed autoimmune cholangitis was strongly suspected. He was treated with 40 mg prednisolone/d for 2 wk, after which serum bilirubin, ALP, and GGT became normal and the following CT scan showed resolution of the thickening of the bile duct (Figure 5). After tapering of the prednisolone, he took 5 mg of prednisolone daily without aggravation of clinical findings.

DISCUSSION

AIP is a form of chronic pancreatitis of presumed autoimmune etiology^[1]. It is frequently presented with obstructive jaundice and pancreatic swelling. AIP presents with lympho-plasmacytic infiltration and fibrosis in the pancreas and shows a dramatic response to steroids^[4]. Lympho-plasmacytic infiltrate in AIP shows abundant IgG4-positive plasma cells on immunostaining^[5]. Elevation of serum IgG4 is the most remarkable characteristic of this disease. Since AIP can mimic pancreatic cancer, its diagnosis is important to avoid unnecessary surgery. The classic appearance of AIP on abdominal CT is sausage-shaped enlargement of the pancreas with a capsule-like rim. However, AIP can be presented as a pancreatic mass-like lesion, similar to the present case. In such case, pancreatic cancer should be discriminated from AIP. Serum autoimmune markers are helpful for the diagnosis of mass forming AIP, but histological diagnosis is necessary to confirm AIP in many cases^[1]. Because histological confirmation of AIP is difficult, “a 2-wk steroid trial and subsequent assessment of its response” is introduced as a diagnostic tool in patients whose clinical and laboratory findings are equivocal for AIP^[6]. Our patient showed rapid resolution of the pancreatic mass after treatment with steroid despite the normal IgG4 level. Since serum IgG4 level was elevated afterward, our case was diagnosed as type I AIP by International Consensus Diagnostic Criteria for AIP^[4].

AIP can be associated with sclerosing extrapancreatic lesions^[7]. Because all tissues involved have characteristic infiltration of IgG4-positive cells, the term “IgG4-associated systemic disease” has been proposed. The most common sites of extrapancreatic involvement in AIP are the bile duct, followed by salivary glands, retroperitoneal fibrosis, orbital pseudotumors, lymphadenopathy, and renal parenchyma^[5,7]. Although the stenosis of the CBD in the intrapancreatic area usually occurs with AIP, there are some debates about whether the involvement of only distal CBD should be included in the category of IgG4-associated cholangitis (IAC). Because the narrowing of the intrapancreatic CBD may merely be a secondary

phenomenon from an extrinsic compression owing to the pancreatic enlargement of AIP, intrapancreatic CBD involvement is considered as a part of AIP rather than as a IAC^[8]. Our patient had a beak shaped intrapancreatic CBD stenosis without proximal extrahepatic or intrahepatic biliary involvement at initial presentation. Therefore, IAC was not combined at first.

AIP responds well to steroids. The general initial recommended dose of oral prednisolone for the induction of remission is 0.6 mg/kg per day for 2-4 wk^[9]. Pancreatic size usually normalizes within a few weeks, and biliary drainage becomes unnecessary within about 1 mo. Rapid response to the steroid confirms the diagnosis of AIP^[10]. Remission of AIP is defined as the disappearance of clinical symptoms and the resolution of the pancreatic and/or extrapancreatic manifestations in the imaging studies. Our patient had a rapid response to the steroid treatment showing improvements in symptoms, hepatic biochemistry, biliary stricture, and pancreatic lesion.

Relapse of AIP is defined as reappearance of symptoms such as weight loss, jaundice, or abdominal discomfort and elevation of serum IgG4 concentrations with reappearance of pancreatic and/or extrapancreatic abnormalities in the bile duct, salivary gland, or retroperitoneum on imaging studies^[3]. The relapse rate after remission of AIP is variable between 20% and 60%^[2,10]. Relapse patterns regarding the pancreas or extrapancreatic lesions have not been established and it is not certain that the extrapancreatic involvements at the diagnosis is related to the relapse of AIP. Although initial extrapancreatic involvement was not defined, Kamisawa *et al.*^[9] reported that the relapse of AIP occurred in the pancreas (52%), bile duct (34%) and other lesions ($n = 19$). Moreover, Sandanayake *et al.*^[11] reported that all relapsed AIP patients have had extrapancreatic or proximal biliary strictures at the time of diagnosis. When defining relapse, authors generally do not distinguish between relapse of the pancreatic manifestation of IgG4-associated systemic disease, namely AIP, versus occurrence of the disease in another organ, either de novo or true relapse of a previously treated disease in that organ^[3]. Newly developed proximal extrahepatic biliary involvement without pancreatic relapse is very rare. One case of hilar and proximal extrahepatic bile duct involvements with sustained pancreatic remission in a diffuse type AIP patient was reported briefly^[12,13]. In our case, the focal enlargement type AIP relapsed as the proximal extrahepatic biliary stricture with marked wall thickening and no pancreatic aggravation. The feature of our case is that the serum IgG4 level was normal at initial diagnosis of AIP, but it was markedly elevated with the relapsed autoimmune cholangitis. Although it has been reported that the predictors for relapse of AIP is elevated serum IgG4 levels during remission^[10], this case showed that seronegative AIP could relapse as seropositive autoimmune cholangitis, which

means progression of the autoimmune disease.

In summary, autoimmune pancreatitis may relapse to other organs as IgG4-associated systemic disease without pancreatic aggravation, even if the organs were not involved and IgG4 level was normal at initial diagnosis. Therefore, clinicians should pay close attention to involvement of other organs during follow up of patients with AIP even with sustained pancreatic remission.

Abstract

Ingested fish bone induced intestinal perforations are seldom diagnosed preoperatively due to incomplete patient history taking and difficulties in image evidence identification. Most literature suggests early surgical intervention to prevent sepsis and complications resulting from fish bone migrations. We report the case of a 44-year-old man suffered from acute abdomen induced by a fish bone micro-perforation. The diagnosis was supported by computed tomography (CT) imaging of fish bone lodged in distal ileum and a history of fish ingestion recalled by the patient. Medical treatment was elected to manage the patient's condition instead of surgical intervention. The treatment resulted in a complete resolution of abdominal pain on hospital day number 4 without complication. Factors affecting clinical treatment decisions include the nature of micro-perforation, the patient's good overall health condition,

and the early diagnosis before sepsis signs develop. Micro-perforation means the puncture of intestine wall without CT evidence of free air, purulent peritoneum or abscess. We subsequently reviewed the literature to support our decision to pursue medical instead of surgical intervention.

INTRODUCTION

The ingestions of foreign bodies result in gastrointestinal (GI) perforations in less than 1% of patients. Fish bones are the most common objects leading to gastrointestinal perforations^[1]. Correct preoperative diagnoses are seldom made. Few patients can recall the instance of foreign body ingestions. The most common site of perforation by fish bones is the distal ileum^[2]. Abdominal computed tomography (CT) examination may provide preoperative diagnosis of foreign bodies^[1,3], but more often, they are confirmed after diagnostic laparoscopy^[4-6]. Most literature emphasizes early surgical intervention with resection of the partial bowel, because of high risk of intra-abdominal

abscess formation and the potential of delayed complications due to fish bone migration^[7,8]. We report a case in which medical treatment was selected, instead of surgical intervention, for a fish bone-induced micro-perforation of distal ileum.

CASE REPORT

A 44-year-old man with abdominal pain came to emergency room (ER) at 8 PM. He started to feel abdominal discomfort 6 h before. He began experiencing severe sharp abdominal pain with a sudden onset 3 h before. The pain persisted even after the patient took some anti-acid drug at home. He recalled that he had dinner with fish the previous night. He appeared acutely ill without any vomiting, shortness of breath, diarrhea or fever. At the time of his arrival in the ER, he was alert and oriented. His blood pressure was 144/86 mmHg, heart rate 72 beats/min, respiratory rate 18 breaths/min, and body temperature 37.1 °C. He reported no past history of hypertension, diabetes or abdominal surgery. The initial physical examination revealed normal breathing sounds and regular heart beat without murmur. He had normal active bowel sounds and diffuse abdominal tenderness particularly over the right lower quadrant abdomen, coupled with muscle guarding and rebounding pain. Focus echogram showed no ascites, distended gall bladder with Murphy's sign on sonography, or hydronephrosis. Radiography of the kidney-ureter-bladder revealed normal bowel gas without signs of intestinal obstruction or free air. Serum laboratory examinations showed white blood cell count of 10 100/ μ L, neutrophils of 82.2%, lymphocytes of 12.1%, hemoglobin of 14.8 g/dL, and platelet count of 210 000/ μ L. Serum biochemistry tests revealed a glucose level of 121 mg/dL, and aspartate aminotransferase of 27 U/L, cereal third transaminase of 43 U/L, total bilirubin of 0.5 mg/dL, direct bilirubin of 0.2 mg/dL, creatinine of 1.3 mg/dL, and Na^+/K^+ of 145/3.8 mEq/L. After primary ER medical treatment with intravenous tenoxicam 20 mg and buscopan 20 mg, his pain was localized to the right lower quadrant abdomen, but rebounding pain was still noted. Abdominal CT revealed a 26 mm radiopaque linear shadow transversely lodged in the distal ileum with thickened wall, which is consistent with signs of fish bone retention. Minimal peritoneal contamination without pneumoperitoneum or abscess formation was noted. A normal appendix was identified. A fish bone-induced micro-perforation in the distal ileum was highly suspected (Figure 1).

A general surgeon was consulted. The patient and his families were informed of the indication for surgical intervention and the option of a more conservative medical treatment. Given the nature of micro-perforation, the patient's good overall health condition, and the early diagnosis (6 h after symptom onset) before sepsis signs developed, initial medical treatment was elected to manage the patient's condition, instead of surgical intervention with the consent of the patient and his families.

Figure 1 An unenhanced abdominal computerized tomography image reveals a 26 mm in length radiopaque linear shadow in the distal ileum lodged into the thickened intestinal wall at both ends (black arrow). Minimal peritoneal contamination without pneumoperitoneum, or abscess formation is noted, which is consistent with signs of fish bone induced micro-perforation.

Intravenous saline hydration without oral intake, sub-acillin (ampicillin 2 g + sulbactam 1 g) and SABS (metronidazole) 500 mg were provided at ER. After admission to the ward, fever was noted up to 38 °C in the first 2 d. Subacillin 1.5 g *iv* every 8 h was prescribed for 5 d, followed by Soonmelt (amoxicillin 250 mg/clavulanic acid 125 mg) one tablet orally every 8 h for 7 d. During the first day of admission, the pain score went down from 10 to 3. Rebounding pain and muscle guarding also subsided. However, tenderness over the right lower quadrant abdomen and the periumbilical area was still noted.

On the fourth day, the patient felt hungry and experienced no more abdominal pain or tenderness. Laboratory examinations revealed white blood cell (WBC) count of 3700/ μ L, neutrophils of 49.7%, lymphocytes of 37.3%, hemoglobin of 14.1 g/dL, platelet count of 227 000/ μ L and a C-reactive protein level of 2.97 mg/dL (normal < 0.5 mg/dL). As a result of the improved clinical condition, an oral soft diet was initiated. The patient was tolerant of the soft diet without any deterioration of symptoms. A follow up abdominal CT without contrast, which revealed the radiopaque linear shadow still lodged in the same intestinal segment, was performed on the fourth day. The fish bone rotated and became parallel to the distal ileum lumen with one end penetrating out the intestinal wall into the mesenteric fat. Minimal local inflammatory infiltration was seen around the protruding part. No free air or abscess was noted (Figure 2). There was no surgical intervention because clinical symptoms had been completely resolved. The patient was discharged on the sixth day with normal oral intake and stool passage. At 3- and 6-mo follow-ups with the patient, no recurrent abdominal pain or complication was noted.

DISCUSSION

Unintentional, unconscious foreign body ingestions in adults are usually dietary. Nearly two-thirds of foreign

Figure 2 Two follow-up unenhanced abdominal computer tomography images, which reveal the radiopaque shadow still lodged in the intestinal segment. The fish bone rotates and becomes parallel to the distal ileum lumen. A: Most of the fish bone is still inside the intestinal lumen (white arrow). One end of the fish bone penetrates out the intestinal wall into the mesenteric fat; B: Minimal local inflammatory infiltration contains the protruding part. No free air or abscess is noted (black arrow). The distance between these two images is 18 mm.

bodies are fish bones^[2]. However, most digested foreign bodies pass through the GI tract within a week, and seldom cause major complications^[1,9-12]. The ingestion of foreign bodies results in gastrointestinal perforations in less than 1% of patients. Fish bones are the most common objects leading to gastrointestinal perforation^[1]. The most common perforation site is the distal ileum^[2]. Clinical presentations of GI tract perforation caused by digested foreign bodies vary from case to case, and can be acute, subtle, chronic or even asymptomatic^[2,13,14]. The clinical presentations include acute peritonitis, abdominal wall tumor or abscess^[2,15], intra-abdominal mass and abscess formation^[2,16]. Patients who experience gastric and duodenal perforation tend to present with highly acute pain due to a rapid chemical peritonitis, often followed by the systemic inflammatory response syndrome, which can lead to rapid clinical deterioration^[8,17,18]. Patients often recall the exact time of symptom onset. The perforation may progress to an infected peritonitis and sepsis in untreated patients or in patients who have late-stage presentations^[8]. Colon perforations may present without immediate perforation-associated pain and tend to have a slower clinical progression, with the development of a secondary bacterial peritonitis or localized abscess formation partly due to the relatively neutral and non-erosive nature of the chemical environment within the colon^[19-21]. Because of the variety of clinical manifestations, the correct preoperative diagnosis is seldom made. Goh *et al.*^[2] reported that a correct preoperative diagnosis was made in only 10 (23%) of 44 patients. Furthermore, only a few patients can recall foreign body ingestion. In the report of Goh *et al.*^[2], only one (2%) patient provided a definitive history of foreign body ingestion.

Plain radiographs are usually unhelpful with a sensitivity of 32% for fish bones, which varies according to species^[22,23]. CT scan is preferred and will usually demonstrate a linear calcified lesion, which if initially

missed, can be seen in retrospect. Goh *et al.*^[1] reported that the sensitivity of a CT scan in the detection of intra-abdominal fish bones was 71.4% (5/7) in initial reports. Gastrointestinal perforation causes considerable mortality and usually requires emergency surgery. Mortality of secondary peritonitis is still 30% to 50% despite advances in antibiotics, surgical technique, radiographic imaging, and resuscitation therapy^[7,8]. The reported indications for surgical intervention are as follows: (1) bowel perforation; (2) peritonitis due to bowel perforation; (3) migration to other organs adjacent to the perforation site; (4) bleeding or severe inflammation in the abdominal cavity; (5) penetration of vessels; and (6) abscess formation^[24]. Nonsurgical management highly depends on the time of diagnosis, location and size of the perforation, degree of contamination, and condition of the patient. Nonsurgical management can be successful in stable patients who have minimal signs and symptoms of peritonitis and who have small injuries to the stomach, duodenum, and retroperitoneal portions of the colon^[25]. These locations offer possible anatomic containment of the perforation by the retroperitoneal space or omentum. Perforations of the intra-peritoneal small bowel and colon usually require surgery, except for micro-perforations. Micro-perforations often cause minimal peritoneal contamination and can seal spontaneously^[25,26]. Micro-perforation means puncture of intestine wall but no CT evidence of free air, purulent peritoneum or abscess. Selected colon perforations, such as certain iatrogenic injuries or perforation secondary to diverticulitis may also be managed non-operatively. Spontaneously sealed perforations and perforations that are contained with the development of an associated abscess cavity can often be successfully managed without surgery^[27]. An excellent and clinically useful classification system for diverticular perforations was developed by Hinchey and colleagues and modified by others^[19,27]. The treatment of gastrointestinal perforation includes fluid resuscitation, antibiotics, source control, organ system support, and nutrition. Antibiotics are standard treatment for gastrointestinal perforation^[7,8,18,28-30]. Many efficacious regimens have been described, and no single agent or combination of agents has been found to be superior to the others^[28-32]. We started Subacillin plus SABS initially at ER. Owing to a good response, we then shifted to Subacillin only in the ward.

The duration of antibiotic coverage is controversial^[28,33]. Some authors advocate a standard treatment of 7 to 14 d, whereas others recommend continuing antibiotics until the WBC count has normalized and the patient is afebrile^[28,30]. Current general consensus advocates antimicrobial therapy for 5 to 7 d if clinical signs of infection have resolved^[28,33]. If the patient fails to improve or worsens during this period, the adequacy of source control or the appropriateness of antibiotic coverage must be questioned^[28]. Our patient responded well to medical treatment. He was afebrile on the third day. WBC count had normalized on the fourth day. Clinical signs of infection were resolved after oral intake on the fourth day.

After 5 d of intravenous Subacillin, the patient received 7 additional days of the oral antibiotic Soonmelt.

We found one recent case report of fish bone induced distal ileum micro-perforation which was spontaneously relieved one day after admission while awaiting surgical intervention^[34]. There were two previous documented cases of hepatic abscess secondary to fish bone perforation that were successfully treated with medical therapy, because of contraindication for operation^[35,36]. The impacted fish bone remains unchanged in the pylorus. The patient remained asymptomatic during the 18 mo of follow-up.

The clinical improvement is not necessarily a result of fish bone pass out. Because the fish bone is sharp and linear, it could penetrate the small intestinal wall and migrate into the surrounding soft tissue. It may cause delayed complications. Reported complications of migrated fish bones include retropharyngeal abscesses^[37], gastric submucosal mass^[38], inflammatory omentum mass^[39], pancreatitis with intraluminal thrombosis of superior mesenteric vein due to penetrating into the superior mesenteric vein^[40], migration into the right renal vein^[41], and liver abscess^[35,36,42-45]. Most complications following foreign body impaction will require surgery at some stage, even many years after ingestion has occurred^[46]. Because there are vital organs nearby (such as the mediastinum, great vessel, liver and pancreas), fish bones migrated from the esophagus, stomach or duodenum may induce catastrophic complications. It is important to be mindful of the delayed complications of fish bones migration.

In conclusion, ingestion of foreign bodies is a common event. However, perforation of the GI tract by fish bones is not common. Key hints for the diagnosis of a fish bone induced GI tract perforation are the following: acute onset of peritonitis signs, patient's dietary history with an emphasis on fish, and image evidence of abdominal CT. Key factors affecting clinical treatment decisions include the nature of perforation, the patient's overall health condition, and the timing of diagnosis. Medical treatment may be one of the choices in micro-perforation of the distal ileum induced by fish bone in select patient.

Abstract

Peliosis hepatis (PH) is a rare benign condition characterized by the presence of multiple, randomly distributed, blood filled cystic areas of variable size within the liver parenchyma. PH is difficult to recognize and may be mistaken for neoplasm, metastases or multiple abscesses. A 75-year-old female with a previous history of colon cancer was admitted when a liver mass in the right liver lobe was found 11 mo after surgery during the follow-up period. Computed tomography and magnetic resonance imaging scan of the abdomen were performed. The initial possible diagnosis was metastatic hepatocellular carcinoma. The patient underwent excision of the hepatic segment where the nodule was located. The pathological diagnosis of the surgical specimen was PH. PH should be considered in the differential diagnosis of new liver lesions in patients whose clinical settings do not clearly favor metastasization. Clinicians and radiologists must recognize these lesions to minimize the probability of misdiagnosis and inappropriate treatment.

INTRODUCTION

Peliosis hepatis (PH) is a rare benign condition characterized by the presence of multiple, randomly distributed, blood filled cystic areas of variable size within the liver parenchyma^[1]. PH has been associated with malignancies, immunosuppression, infections and medications. PH is difficult to recognize, and the diagnosis is often missed or delayed because its imaging findings are often non-specific and the condition may be mistaken for neoplasm, metastases or multiple abscesses. Here, we present a case of focal PH in a colon cancer patient mistaken for liver metastases in the initial diagnosis. A review of the literature on PH in relation to etiology and imaging diagnosis was performed, and the presentation and management of this rare condition are discussed.

CASE REPORT

A 75-year-old female with a previous history of colon

Figure 1 Positron emission tomography plus computed tomography and computed tomography scan findings in our patient. A: Positron emission tomography plus computed tomography (PET/CT) scan showed thickening of the ileocecal region (white arrow), and no liver lesions; B: PET/CT scan showed increased metabolic areas in the ileocecal region (white arrow), no increased metabolic areas in the liver; C: Six months later a follow-up CT scan showed no liver lesions; D: Eleven months later a follow-up CT scan showed one low-density lesion in the right liver lobe (white arrow).

cancer treated with radical resection, was admitted to Shanghai East Hospital when a liver mass in the right liver lobe was found 11 mo after surgery during the follow-up period. The pathological diagnosis of colon cancer was moderately differentiated adenocarcinoma. After colon cancer surgery, the patient received a number of chemotherapeutic protocols including capecitabine (Xeloda) and oxaliplatin. She had a history of type 2 diabetes for over 20 years. She took gliclazide for the treatment of diabetes, and glucose was well-controlled. She had no history of viral hepatitis or alcohol abuse.

Laboratory evaluations revealed hemoglobin of 120 g/L, and a normal white cell and platelet count. Prothrombin time, electrolytes, BUN and creatinine were normal. Liver chemistry revealed aspartate aminotransferase 24 IU/L, alanine aminotransferase 16 IU/L, total bilirubin (TB) 10.6 μ mol/L, direct bilirubin (DB) 4.5 μ mol/L, alkaline phosphatase 97 IU/L, lactate dehydrogenase 184 IU/L and albumin 44 g/L. Hepatitis B virus examination showed: hepatitis B surface antigen, hepatitis B e antigen, hepatitis B e antibody negative, hepatitis B surface antibody, hepatitis B core antibody positive and HBV DNA < 500 copies/mL. α -fetoprotein was 2.78 ng/mL, carcinoembryonic antigen (CEA) 3.32 ng/mL, CA125 24.50 U/mL, CA153 12.29 U/mL, CA199 52.49 U/mL, and CA724 1.24 U/mL. Thyroid function tests were normal. Human immunodeficiency virus was negative.

CT and magnetic resonance imaging (MRI) scan of the abdomen were performed. Plain CT scan at the level of the upper abdomen (Figure 1D) showed the presence of one hypodense lesion in the right liver lobe, which was not present on a previous positron emission tomography and computed tomography (PET/CT) or CT scan per-

formed 11 mo previously (Figure 1A-C).

MRI T1-weighted images (Figure 2A) of the upper abdomen showed that the hepatic lesion demonstrated low signal intensity compared with adjacent liver tissue, while on T2-weighted images (Figure 2B) hyperintense signal intensity was observed. Following administration of gadolinium contrast medium (Figure 2C) the mass remained unenhanced. During the portal (Figure 2D), and delayed (Figure 2E) phases, the lesion displayed peripheral enhancement with a centripetal progression.

Because the patient had a history of colon cancer, the initial diagnosis was possible metastatic hepatocellular carcinoma. After informed consent was obtained, the patient underwent excision of hepatic segment VII, where the nodule was located. The pathological diagnosis of the surgical specimen was PH (Figure 3). The patient had an uneventful postoperative recovery without complications, and was discharged one week after surgery.

DISCUSSION

PH was first reported in the German literature in 1861 by Wagner, and named by Schoenlank in 1916. The first description in the English literature was in 1950 by Zak^[2]. Although the exact origins of this disorder are unknown, PH has been associated with the prolonged use of a number of drugs and infectious causes such as *Bartonella henselae*^[3], tuberculosis, acquired immunodeficiency syndrome^[4], gummatous syphilis^[5] and several debilitating illnesses such as hematological malignancies^[6]. In this case, PH was found during the follow-up period after capecitabine and oxaliplatin treatment which suggests that chemotherapy could be responsible for the development of PH. Drugs reported to be associated with PH

Figure 2 Magnetic resonance imaging scan findings in our patient. A: On T1-weighted images, the hepatic lesion shows low signal intensity; B: On T2-weighted images, the lesion shows hyperintense signal intensity; C: In the arterial phase, the lesion remains unenhanced; D, E: During the portal and delayed phases, the lesion displays peripheral enhancement with a centripetal progression. L: Left; A: Ahead.

include thiopurine^[7,8], azathioprine^[9], 6-thioguanine^[10], tamoxifen^[11], androgen^[12], oral contraceptives, diethylstilbestrol and toxin (e.g., polyvinyl chloride, arsenic, thorium oxide) exposure^[13]. To our knowledge, PH associated with capecitabine and oxaliplatin treatment has not been reported.

The clinical presentation and laboratory data in patients with PH are non-specific. Its clinical presentation is variable, ranging from asymptomatic cases discovered at autopsy to progressive cases with cholestasis, liver failure, portal hypertension or even spontaneous rupture^[14]. Death may result from hepatic failure or intraperitoneal hemorrhage. PH regresses after drug withdrawal, cessation of steroid therapy, or resolution of an associated infectious disease. Its variable clinical presentation makes the correct diagnosis of PH important, because misdiagnosis could lead to inappropriate treatment in asymptomatic cases, and in advanced cases could lead to progres-

sion and a fatal outcome if appropriate treatment is not given. Cohen *et al*^[15] reported a case of PH simulating a hepatic abscess both clinically and radiographically in a patient with sepsis. CT-guided drainage of the presumed liver abscess led to a fatal outcome.

The definitive diagnosis of PH is by histology. A percutaneous needle biopsy can also be used to confirm the diagnosis. However, even when ultrasound-guided, the procedure has a high risk of life-threatening hemorrhage^[16]. The imaging appearance of PH is difficult to differentiate from multiple abscesses, adenoma, focal nodular hyperplasia, hemangiomatosis, and metastases. CT findings of PH have been reported to display early globular enhancement centrally with centrifugal progression and eventual homogenous enhancement on the delayed phase^[17]. Wannesson *et al*^[18] reported CT findings in a case of PH which displayed peripheral enhancement with a centripetal progression between the arte-

Figure 3 Photomicrograph of a liver section from our case showing variable-sized, blood-filled cystic spaces (hematoxylin and eosin, 200 \times).

rial and portal phases. Iannaccone *et al.*^[13] reported PH lesions with typical centrifugal progression of contrast enhancement, however, centripetal enhancement can also be observed. The enhancement pattern of PH varies depending on the freshness of the blood filling the peliotic cavities. Fresh circulating blood within the peliotic cavities is associated with marked enhancement, whereas retention of old blood is associated with mild or no enhancement^[19]. Characteristic MRI findings of PH include T1 hypointense and T2 hyperintense lesions, which show early peripheral and late diffuse contrast enhancement on dynamic imaging. Additionally, several T1 and T2 hyperintense hemorrhagic lesions may be detected due to hemorrhage^[20].

There is no specific treatment for PH. Treatment is primarily symptomatic and includes discontinuation of offending medications, partial hepatectomy or transarterial embolization^[21] due to liver rupture causing intraabdominal bleeding, or occasionally liver transplantation^[22] in patients with irreversible liver insufficiency.

In our case, points supporting metastatic liver cancer were: (1) a new liver lesion on follow-up; (2) a history of colon cancer; and (3) MRI imaging compatible with a metastasis. Points not supporting metastatic liver cancer were: (1) the presence of just one lesion; and (2) normal CEA level. An uncertain diagnosis in this situation led to antitumor therapies.

In conclusion, it is likely that PH is underdiagnosed in radiologic studies. PH should be considered in the differential diagnosis of new liver lesions in patients whose clinical settings do not clearly favor metastasization. Clinicians and radiologists must recognize these lesions to minimize the probability of misdiagnosis and inappropriate treatment.

Abstract

Transmission of oesophageal images may vary between different small-bowel capsule endoscopy models. A retrospective review of 100 examinations performed with 2 different Small-bowel capsule endoscopy (SBCE) systems (PillCam[®] and MiroCam[®]) was performed. The oral cavity/aero-digestive tract (i.e., tongue, uvula and/or epiglottis) was captured/identified in almost all (99%) of PillCam[®] videos but in none of MiroCam[®] cases, $P < 0.0001$. Furthermore, oesophageal images (i.e., from the upper oesophageal sphincter to the Z-line) were captured in 99% of PillCam[®] videos (mean \pm SD, 60.5 \pm 334.1 frames, range: 0-3329 frames) and in 66% of MiroCam[®] cases (mean \pm SD, 11.1 \pm 46.5 frames, range: 0-382 frames), $P < 0.0001$. The Z-line was identified in 42% of PillCam[®] videos and 17% of MiroCam[®], $P = 0.0002$. This information might be useful when performing SBCE in patients with high risks for aspiration.

TO THE EDITOR

Small-bowel capsule endoscopy (SBCE) is likely one of the safest procedures in every day gastroenterology practice. Aside acute small-bowel obstruction from retained capsules^[1,2], aspiration of capsule endoscopes has also been reported^[3-5]. Albeit rare -and likely associated with spontaneous resolution-, capsule aspiration is a potentially life-threatening complication and a single fatality has been reported to date^[6].

We have previously noted that the MiroCam[®] SBCE system (IntroMedic[®] Co, Seoul, Korea) has a theoretical advantage, over other SBCE systems, of being smaller in size (11 mm \times 24 mm), as well as lighter (3.25 g)^[5,7]. The fact that to date there are no reported cases of tracheal aspiration involving MiroCam[®] capsules concurs to this. Conversely, PillCam[®] is 10.8 mm \times 26 mm and weighs 3.45 g. Furthermore, the 2 capsule systems have different centre of gravity and that may have some role in determining the direction of propagation in the small-bowel^[7]. The transmission of oesophageal images though may vary between different SBCE models and it is our experience that it fails more frequently with MiroCam[®]. In our hospital, a tertiary-care referral centre for capsule endoscopy for the East of Scotland, we have simultaneously operated two SBCE systems (MiroCam[®] and PillCam[®] SB, Given[®] Imaging Ltd, Yokneam, Israel) since May 2009^[8].

We retrospectively reviewed the last 100 examinations performed with each SBCE system in order to check the performance of the 2 systems in capturing images of

the upper most part of the gastrointestinal (GI) tract. Procedures involving endoscopic capsule placement ($n = 2$) and those where a capsule stayed for > 30 min in the oesophagus were excluded (one for each SBCE system). MiroCam[®] was used in 51 males/49 females (age: 55.3 ± 16.9 years) with the following indications: suspected/established Crohn's disease: 25; overt/occult GI bleeding: 64; other indication/s: 11. PillCam[®] was used in 34 M/66 F (age: 56.3 ± 14.9 years) of which, 32 had suspected/established Crohn's disease, 62 overt/occult GI bleeding and 6 other indication/s.

A single, experienced capsule endoscopist (> 1000 SBCE reviews) re-evaluated the SBCE videos for confirmation of capture of oropharyngeal images, number of oesophageal frames and detection of Z-line. Any frame that included a part of Z-line, was calculated as positive for the latter. The Fisher's exact test, mean \pm SD were used; P values of < 0.05 are considered statistically significant. All analyses were performed with GraphPad InStat (GraphPad Software, Inc, La Jolla, United States).

Interestingly, the oral cavity/aero-digestive tract (i.e., tongue, uvula and/or epiglottis) was captured/identified in almost all (99%) of PillCam[®] videos but in none of MiroCam[®] cases, $P < 0.0001$.

Furthermore, oesophageal images (i.e., from the upper oesophageal sphincter to the Z-line) were captured in 99% of PillCam[®] videos (mean \pm SD, 60.5 ± 334.1 frames, range: 0-3329 frames) and in 66% of MiroCam[®] cases (mean \pm SD, 11.1 ± 46.5 frames, range: 0-382 frames), $P < 0.0001$. The Z-line was identified in 42% of PillCam[®] videos and 17% of MiroCam[®], $P = 0.0002$. MiroCam[®] uses electric field propagation rather than radiofrequency, with a single skin electrode, two external contact plates on the capsule and the body as a conductor for signal transmission^[9]. This effectively means that a water interface would offer a better conductive surface area and it might explain the scarcity of images from the higher part of the GI tract and -potentially- the lack of documentation of a capsule aspiration.

In a recent retrospective study, Hong *et al*^[10] compared the diagnostic yield of MiroCam[®] and PillCam[®] SB capsules using the detection rates of the Z-line and the duodenal ampulla in a cohort of 141 individuals who under-

went SBCE for various clinical indications. In this cohort, the Z-line was detected in 36.9% of PillCam[®] videos and 47.7% of MiroCam[®] examinations ($P = 0.227$).

It is useful to remember that the advent of real-time viewers allows us to follow the procedure from the very first steps of capsule ingestion, providing of course that images are captured during this phase. This may have clinical implications, especially when the procedure is performed in unfit, elderly patients or individuals with known swallowing difficulties, since a number of capsule aspiration cases are relatively asymptomatic^[4,5].

ACKNOWLEDGMENTS

Acknowledgments to reviewers of World Journal of Gastroenterology

We acknowledge our sincere thanks to our reviewers. Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of our World Series Journals. Both the editors of the journals and authors of the manuscripts submitted to the journals are grateful to the following reviewers for reviewing the articles (either published or rejected) over the past period of time.

Clifford S Cho, MD, Assistant Professor, Department of Surgery, Section of Surgical Oncology, University of Wisconsin School of Medicine and Public Health, H4/724 Clinical Sciences Center, 600 Highland Avenue, Madison, WI 53792-7375, United States

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Advances in molecular cell biology over the last decade have clarified the mechanisms involved in cancer growth, invasion, and metastasis, and enabled the development of molecular-targeted agents. To date, sorafenib is the only molecular-targeted agent whose survival benefit has been demonstrated in two global phase III randomized controlled trials, and has been approved worldwide. Phase III clinical trials of other molecular targeted agents comparing them with sorafenib as first-line treatment agents are ongoing. Those agents target the vascular endothelial growth factor, platelet-derived growth factor receptors, as well as target the epidermal growth factor receptor, insulin-like growth factor receptor and mammalian target of rapamycin, in addition to other molecules targeting other components of the signal transduction pathways. In addition, the combination of sorafenib with standard treatment, such as resection, ablation, transarterial embolization, and hepatic arterial infusion chemotherapy are ongoing. This review outlines the main pathways involved in the development and progression of hepatocellular carcinoma and the new agents that target these pathways. Finally, the current statuses of clinical trials of new agents or combination therapy with sorafenib and standard treatment will also be discussed.

INTRODUCTION

Advances in molecular cell biology over the last decade have clarified the mechanisms involved in cancer growth, invasion and metastasis, and enabled the development of molecular-targeted agents, best represented by trastuzumab for breast cancer, imatinib and rituximab for hematopoietic tumors, and gefitinib and erlotinib for lung cancer. These molecular-targeted agents are broadly classified into two categories: drugs targeting cancer cell-specific molecules, and nonspecific molecular-targeted drugs for molecular biological abnormalities induced in the host stroma or blood vessels by the presence of cancer. Examples of the former approach include trastuzumab, which targets human epidermal growth factor receptor 2 (HER2), the expression of which is a poor prognostic factor for breast cancer; rituximab, which is used to treat B-cell lymphoma, targets CD20 expressed on normal and neoplastic mature B cells; while imatinib binds to the ATP-binding site of Bcr-abl, a protein that causes chronic myelogenous leukemia. However, no critical target molecules responsible for treatment response have been identified in hepatocellular carcinoma (HCC).

In recent years, clinical trials have been conducted for many agents that act on growth factor receptors, such as epidermal growth factor receptor (EGFR) and vascular endothelial growth factor receptor (VEGFR), and intracellular signaling pathways. In addition, multi-kinase inhibitors, including sorafenib, have emerged and been evaluated. Clinical trials are ongoing to compare drugs with the same mechanism of action and to test the combined efficacy and relative merits of these drugs with existing drugs for many cancers. Since the main treatment option for metastatic, advanced stage cancers, such as breast and colorectal cancer, is systemic chemotherapy, clinical trials are ongoing to investigate how to combine molecular-targeted agents with standard therapies based on the results of long-term, large-scale clinical trials, and to identify which molecular-targeted agents should be used as initial or second-line therapy.

However, for HCC, background liver damage limits the indication for systemic chemotherapy and no anti-cancer drugs were found to be effective in large-scale randomized controlled trials except sorafenib. Now that the usefulness of sorafenib has been demonstrated in two large scale randomized clinical trials, the development of new drugs that are effective for poor-prognosis advanced HCC, who are resistant to a standard of care agent, sorafenib.

In this review, the clinical impact of sorafenib and ongoing trials of new agents or combination trials with sorafenib will be described.

SIGNALING PATHWAYS AND MOLECULAR-TARGETED AGENTS IN HCC

As in other cancers, the molecular mechanisms involved in the development and progression of HCC are complex. After hepatitis B virus and hepatitis C virus infection and alcohol or aflatoxin B1 exposure, genetic and epigenetic changes occur, including oncogene activation and tumor-suppressor gene inactivation due to inflammation-induced increase in hepatocyte turnover and oxidative stress-induced DNA damage. Through apoptosis and cell proliferation, these changes lead to the multistep development and progression of a hyperplastic to dysplastic nodule, early HCC, and advanced HCC. A number of studies have reported changes in gene expression, chromosomal amplification, mutations, deletions and copy number alterations (gain/loss), somatic mutations, CpG hypermethylation, and DNA hypomethylation, as well as molecular abnormalities, which can constitute therapeutic targets^[1-5].

The binding of growth factors to their receptor proteins activates protein-phosphorylating enzymes, thus activating a cascade of proliferative signaling pathways to transmit proliferative signals into the nucleus. Growth factors, such as EGF, transforming growth factor (TGF)- α / β , insulin-like growth factor (IGF), and VEGF, also function in liver regeneration after injury, while fibroblast

growth factor (FGF) and the platelet-derived growth factor (PDGF) family are involved in liver fibrosis and HCC growth^[6-8]. The receptors for these growth factors are broadly classified into G protein-coupled receptors and protein kinases. On ligand binding, these receptors activate their downstream intracellular molecules in a cascade fashion. Many of the growth factor receptors and oncogenes have tyrosine kinase activity, and the tyrosine kinases are classified into transmembrane receptor tyrosine kinases, such as the EGFR and VEGFR, and cytoplasmic non-receptor tyrosine kinases, such as Abl and Src. On the other hand, Raf, mitogen-activated protein kinase (MAPK)/extracellular signaling-regulated kinase (ERK) kinase (MEK), and mammalian target of rapamycin (mTOR) are serine/threonine kinases.

In general, the MAPK, phosphoinositide 3-kinase (PI3K)/Akt/mTOR, c-MET, IGF, Wnt- β -catenin and Hedgehog signaling pathways, and the VEGFR and PDGF receptor (PDGFR) signaling cascades show altered activity in HCC, and agents targeting these pathways are under development (Figures 1-3; Table 1)^[9-12]. Many molecular-targeted agents are now under development and the target signaling pathways and growth factors are outlined below.

MAPK pathway (Ras/Raf/MEK/ERK)

The MAPK intracellular signaling pathway, which is mainly involved in cell growth and survival, and regulates cell differentiation, is upregulated in cancer cells. Therefore, this pathway has been extensively studied as a therapeutic target. The MAPK pathway is a common downstream pathway for the EGFR, PDGFR and VEGFR, and is universally used for signal transduction downstream of cytokine receptors, integrin complexes, and G-protein receptors to Ras. The MAPK pathway also plays an important role in HCC, in that its activation is reportedly involved in HCC growth and survival. The downstream ERK is activated by two upstream protein kinases, which are coupled to growth factor receptors by Ras proteins. Ras, which is activated by ligand binding, activates Raf serine/threonine kinases and MEK (MAP kinase/ERK kinase), while MEK phosphorylates and activates ERK, which phosphorylates proteins involved in cell growth, apoptosis resistance, extracellular matrix production and angiogenesis^[13-15].

Raf and Ras inhibitors: Raf and Ras are proto-oncogenes. In particular, K-Ras mutations are commonly observed in many cancers, including pancreatic and colorectal cancers. One study reported that 30% of HCCs have Ras mutations^[16]. To our knowledge, no agents targeting Ras are planned to enter clinical trials at the present. However, because the binding of Ras protein to the cell membrane and its functional activation require farnesylation, several farnesyltransferase inhibitors are being tested for Ras-related tumors. In addition, vaccine therapy for mutant Ras proteins is currently being tested for solid cancers, including HCC.

Figure 1 Signal transduction in solid cancer cells including hepatocellular carcinoma. Some of the genes known to be functionally altered are highlighted in red. These signaling pathways, including growth factor pathway, Wnt pathway, Hedgehog pathway, Akt/mammalian target of rapamycin (mTOR) pathway, and Jak/Stat pathway, can be a molecular targets for treatment of hepatocellular carcinoma. (Cited and modified from Hanahan *et al*^[10] with permission.) EGFR: Epidermal growth factor receptor; TGF: Transforming growth factor; IGF: Insulin-like growth factor; MAPK: Mitogen-activated protein kinase; PI3K: Phosphoinositide 3-kinase; ERK: Extracellular signaling-regulated kinase; NF-κB: Nuclear factor-kappa B; IL: Interleukin.

Table 1 Molecular targeted agents for hepatocellular carcinoma: Targets and development status

Agents	Targets (angiogenesis)			Targets (proliferation)				Positioning	Development status
	VEGFR	PDGFR	FGF	EGFR	Raf	mTOR	TRAIL-R2	DR5	
Sorafenib	●	●			●			1st line	Approved
Sunitinib	●	●						1st line	P III terminated
E7080	●	●	●					1st/2nd line	P II ongoing
Tigatuzumab (CS1008)							●	1st line (sorafenib combination)	P I / II ongoing
Linifanib (ABT-869)	●	●						1st line	P III ongoing
Brivanib		●			●			1st line, 2nd line, TACE adjuvant	P III ongoing
TSU-68		●	●					TACE combination	P III ongoing
Ramucirumab		●						2nd line	P III ongoing
Everolimus (RAD001)						●		2nd line	P III ongoing
Axitinib		●	●					2nd line	P III ongoing

VEGFR: Vascular endothelial growth factor receptor; PDGFR: Platelet-derived growth factor receptor; FGF: Fibroblast growth factor; EGFR: Epidermal growth factor receptor; mTOR: Mammalian target of rapamycin; TACE: Transarterial chemoembolization.

The Raf family consists of three isoforms, A-Raf, B-Raf and C-Raf/Raf-1. Genetic abnormalities, such as point mutations and gene rearrangements, have been reported in various cancers^[17]; however, in HCC, *ras/raf* mutations are rare, and no *k-ras* or *b-raf* mutations have been detected^[18]. On the other hand, wild-type Raf-1 was reported to be hyperactivated in many cancers, including HCC^[19-21]. Sorafenib inhibits Raf, and has multiple characteristics in that it exhibits strong inhibitory activity against Raf-1 (C-Raf) kinase, B-Raf (wild-type B-Raf and mutant V600E B-Raf) serine/threonine kinase, the pro-angiogenic receptor tyrosine kinases VEGFR,

PDGFR and FGFR1, and tyrosine kinases, such as c-kit, Flt-3 and RET, which are involved in tumor progression and overall prognosis^[22].

MEK: The MEK family consists of MEK1 and MEK2 proteins, which specifically phosphorylate tyrosine and threonine residues, and phosphorylates downstream Erk1 and Erk2^[23].

In an immunohistochemical study, MEK1/2 overexpression, ERK1/2 overexpression, and ERK1/2 phosphorylation were observed in 100% (46/46), 91% (42/46), and 69% (32/46) of HCCs, respectively. In ad-

Figure 2 Signaling pathways and potential drug targets to inhibit hepatocarcinogenesis. Activation of receptor tyrosine kinases by their ligands activates downstream signaling pathways with effects on angiogenesis, proliferation, migration and invasion, and apoptosis or survival of cells. Monoclonal antibodies inhibit ligand binding to the receptor and small-molecule tyrosine kinase inhibitors inhibit propagation of the downstream signal. (Cited from Spangenberg *et al*^[11] with permission.) IGF: Insulin-like growth factor; MAPK: Mitogen-activated protein kinase; PI3K: Phosphoinositide 3-kinase; EGF: Epidermal growth factor; VEGF: Vascular endothelial growth factor; PDGF: Platelet-derived growth factor; mTOR: Mammalian target of rapamycin; HIF: Hypoxia-inducible factor; SCF: Stem cell factor.

dition, the *in vitro* treatment of HepG2 and Hep3B cells with MEK1/2 inhibitors inhibited cell growth and up-regulated apoptosis^[24].

The MEK inhibitors CI-1040, PD0325901, AZD6244, and RDEA119/BAY869766 have been tested in several cancers, including solid tumors such as HCC. Recently, the results of Phase I of AS703026 and E6201 studies against solid tumors were reported in ASCO2010. A phase II study of AZD6244 (selumetinib, ARRY-142866) and a phase I / II study of RDEA119/BAY869766 in combination with sorafenib are being conducted.

PI3K/Akt/mTOR pathway

The PI3K/Akt/mTOR pathway also plays an important role in cell growth, survival regulation, metabolism, and anti-apoptosis. The membrane lipid phosphatidylinositol 4,5-bisphosphate (PIP₂) is phosphorylated by PI3K into phosphatidylinositol 3,4,5-triphosphate (PIP₃), which binds to and activates the serine/threonine kinase Akt. The tumor suppressor gene product phosphatase and tensin homolog (PTEN) deleted on chromosome is antagonistic to PI3K activity. PTEN is a lipid phosphatase that

dephosphorylates inositol phosphates, such as PIP₃. The inactivation of PTEN through gene deletion increases PIP₃ levels, and activates Akt, which inhibits apoptosis, leading to the development of tumors. The serine/threonine kinase mTOR is an important mediator in the PI3K/Akt pathway, which binds intracellularly to a protein called raptor or rictor, and exists as two different complexes, complex 1 and 2 (mTORC1 and mTORC2). mTORC2 (mTOR-rictor) activates Akt, while mTORC1 (mTOR-raptor) is activated downstream of Akt; thus, both molecules regulate protein synthesis (Figures 4 and 5)^[25].

Inhibiting mTOR with molecules, such as RAD001, generates additive effects that accompany upstream and downstream target inhibition. Alternatively, upstream receptor inhibition is compensated for by inhibiting the downstream pathway, even if some resistance develops against receptor inhibition regardless of initial or acquired resistance. Therefore, RAD001 is a potential targeted agent for HCC.

Besides the finding that mTOR plays a key role in cell biology, it was also demonstrated that mTOR and S6K are overexpressed in 15%-41% of HCCs. mTOR inhibitors also have antitumor effects in various HCC cell lines and animal models^[26-29]. Activation of mTOR is correlated with the development of HCC and recurrence after the excision of early HCC. Regulating this specific intracellular pathway (Ras-Raf pathway) with RAD001 is potentially more effective in suppressing sorafenib-resistant tumors.

A study of 528 HCC samples showed that the expression of pAkt, PTEN, p27 and S6 ribosomal protein (pS6) was a poor prognostic factor for survival^[30]. A tissue microarray analysis of HCC samples revealed that the loss of PTEN and overexpression of pAkt and p-mTOR were correlated with tumor grade, intrahepatic metastasis, vascular invasion, TNM stage, Ki-67 labeling index, and matrix metalloproteinase (MMP)-2 and -9 upregulation. Meanwhile, PTEN mRNA expression in the cancerous tissue was downregulated compared with that in the non-cancerous tissue. The levels of PTEN, MMP-2, and MMP-9 mRNA expression were correlated with tumor stage and metastasis, and the levels of PTEN and MMP-9 mRNA expression were inversely correlated^[31]. In an extensive analysis of 314 HCC samples in terms of mutation analysis, DNA copy number changes, mRNA levels and immunostaining, Villanueva *et al*^[32] found that activation of the IGF pathway, upregulation of EGF, dysregulation of PTEN, and aberrant mTOR signaling were present in half of the samples, and that inhibiting mTOR activity with everolimus was effective in improved survival and suppression of recurrence.

The PI3K inhibitor RG7321 and the Akt inhibitor perifosine target the PI3K/Akt/mTOR pathway and are in early stages of clinical development, while the mTOR inhibitors everolimus (RAD001), sirolimus (Rapamune), and temsirolimus (CCI-779) are at more advanced stages of development. Everolimus is used to treat sorafenib-

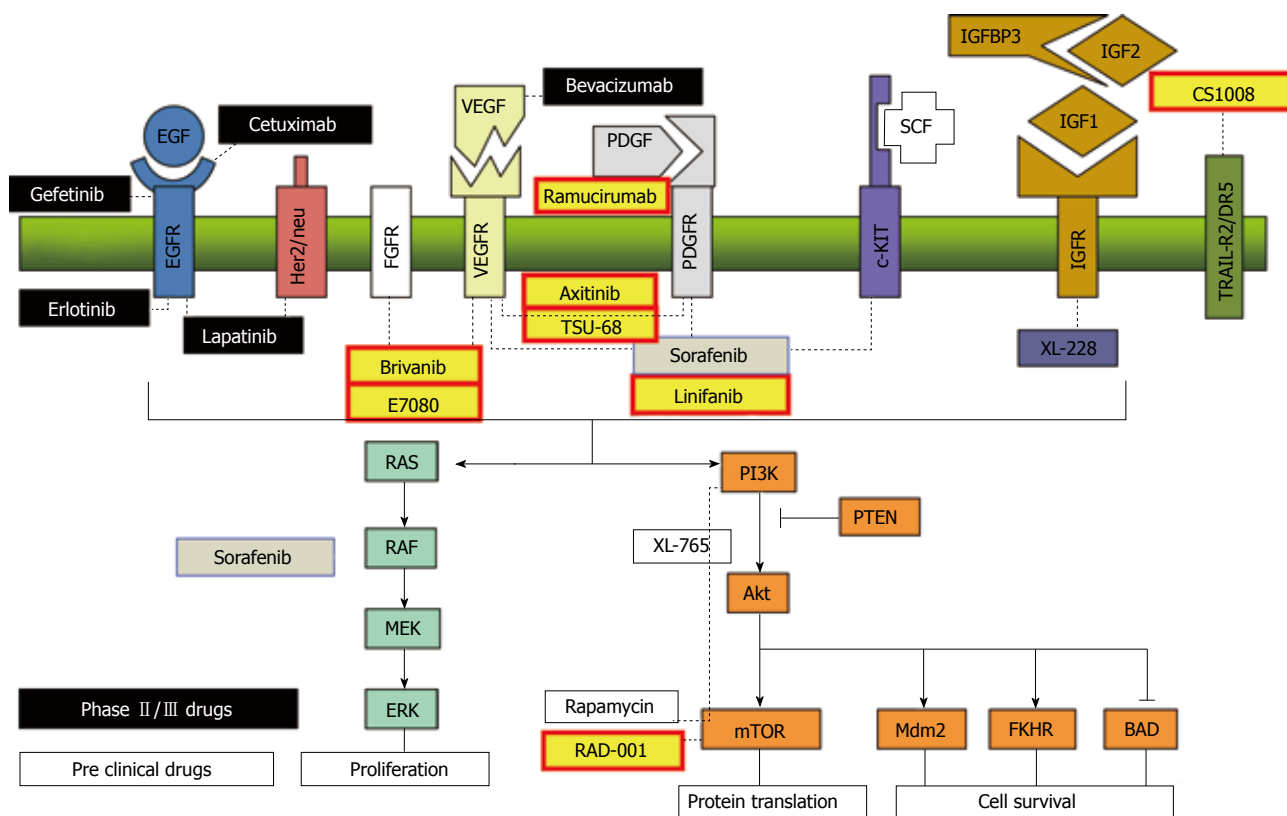

Figure 3 Target molecular and targeted agents under development. Monoclonal antibodies (VEGF: bevacizumab, EGFR: cetuximab), tyrosine kinase inhibitors (VEGFR: sorafenib, brivanib, linifanib, axitinib, TSU-68; FGFR: E7080, brivanib), EGFR: erlotinib, lapatinib), serine/threonine kinase inhibitors (Raf: sorafenib, mTOR: rapamycin and everolimus) and agonistic ligand of TRAIL-R2/DR5 (CS1008). (Cited and modified from Villanueva *et al*^[12] with permission.) IGF: Insulin-like growth factor; PI3K: Phosphoinositide 3-kinase; EGF: Epidermal growth factor; VEGF: Vascular endothelial growth factor; PDGF: Platelet-derived growth factor; mTOR: Mammalian target of rapamycin; PTEN: Phosphatase and tensin homolog; SCF: Stem cell factor; FGFR: Fibroblast growth factor receptor.

intolerant patients, or for patients showing disease progression after sorafenib administration. A phase III study to compare everolimus and a placebo (EVOLVE-1: Advanced Hepatocellular Carcinoma after Disease Progression or Intolerance to Sorafenib Everolimus for Liver

cancer Evaluation) and a phase I /randomized phase II study (sorafenib + everolimus *vs* sorafenib alone) to test the efficacy and tolerance of sorafenib in combination with everolimus are underway. Since mTOR inhibitors exhibit cytostatic and antiangiogenic effects, they are

expected to be effective in combination with other angiogenesis inhibitors, such as bevacizumab, and may be appropriate for administration after transarterial chemoembolization (TACE). Furthermore, since the mTOR pathway is stimulated by factors such as EGFR, PDGFR, and TGF α , and is closely related to other signaling pathways, including the Ras/Raf/MEK/ERK pathway, they are likely to show promising efficacy when used in combination with other growth factor inhibitors^[33].

VEGF/VEGFR, PDGFR, FGFR

Angiogenesis is an important event not only for HCC, but also for cancer growth and metastasis, and occurs because of complex alterations involving promoting factors such as VEGF, angiopoietin, and FGF, and inhibitory factors including thrombospondin and angiostatin, as well as the surrounding tissue. The VEGF family consists of VEGF-A, -B, -C, -D and -E, and placental growth factor (PlGF). The VEGFR family comprises VEGFR-1 (flt-1), VEGFR-2 (flk-1/KDR), and VEGFR-3 (flt-4). VEGF-A binds to VEGFR-1 and -2 and is involved in angiogenesis and the maintenance of mature blood vessels, while VEGF-C and -D mainly bind to VEGFR-3, are involved in lymphangiogenesis^[34,35]. VEGF isoforms, such as VEGF₁₂₁ and VEGF₁₆₅, have been identified, and isoform subtypes also exist, such as EGF_{166b}. Thus, it is clear that these growth factors do not exhibit angiogenesis-promoting effects alone, and they have attracted attention as new therapeutic targets^[36].

HCC typically exhibits active angiogenesis. During the progression from early to well- and moderately-differentiated HCC, angiogenesis increases and cancer cells acquire the ability to invade vessels and metastasize. Scientific and clinical studies have revealed that, during the progression from hepatitis to cirrhosis, angiogenesis and disruption of the vascular architecture are linked to the progression of HCC, and contribute to increased hepatic vascular resistance and portal hypertension, and decreased hepatocyte perfusion^[37]. In addition, a meta-analysis has demonstrated that VEGF expression is a prognostic factor in HCC^[38].

Phase II studies have been started to test the usefulness of bevacizumab (Avastin[®]), which directly targets VEGF, in TACE-treated HCC, and the use of bevacizumab in combination with erlotinib (Tarceva[®]), an EGFR tyrosine kinase inhibitor.

Sunitinib (Sutent[®]) is a multi-kinase inhibitor that inhibits tyrosine kinases, such as VEGFR-1, -2, -3, PDGFR- α , - β and c-Kit. A phase II study of sunitinib in 37 advanced HCC patients showed that the median progression-free survival (PFS) and median overall survival (OS) were 3.7 and 8 mo, respectively. In that study, adverse events included grade 3/4 thrombocytopenia in 37.8% of patients, neutropenia in 24.3%, asthenia in 13.5%, and hand-foot syndrome in 10.8%^[39]. Since sunitinib has a lower IC₅₀ for each target than sorafenib, it is expected to exhibit greater antitumor activity. However, this factor may be responsible

for the higher incidence of adverse events with sunitinib. The main evaluation item in the above phase II trial was the response rate, which did not reach the expected value, leading to the conclusion that it was a negative study^[40]. In that study, sunitinib was administered at 50 mg/d for four weeks followed by two weeks of rest per cycle^[39], whereas Zhu *et al*^[40] used a dosing schedule of 37.5 mg/d for four weeks followed by two weeks of rest per cycle, and reported that the median PFS and OS were 3.9 and 9.8 mo, respectively. An ongoing global cooperative phase III controlled clinical trial to compare sorafenib and sunitinib head-to-head, and to seek approval for first-line indications for advanced HCC, adopted a sunitinib dosing schedule of 37.5 mg/d. However, in a "Reflection and Reaction" regarding the above trial results, Forner *et al*^[41] cast doubt on whether the drugs at this dose could maintain tolerance and ensure efficacy. Consequently, the trial was terminated on March, 2010 because of the recommendation by data monitoring committee based on interim analysis, showing relatively high toxicity and no superior efficacy to sorafenib.

Brivanib is a kinase inhibitor that selectively inhibits VEGFR-1, -2 and -3, and FGFR-1, -2 and -3. Recent studies suggest that tumor progression following treatment with antiangiogenic agents that target the VEGF signaling pathway alone may result from either evasive or intrinsic resistance^[42]. Furthermore, there is strong evidence to support the hypothesis that evasive resistance to anti-VEGF blockade is associated with reactivation of tumor angiogenesis by alternative signaling pathways. One such mechanism of resistance is the activation of the FGF signaling pathway^[43,44]. Basic FGF (FGF2) is a potent angiogenic factor. Indeed, expression of FGF2 enhances growth, invasion, and angiogenesis of many tumor types^[45,46]. Moreover, recent evidence has shown that FGF is overexpressed and activated in HCC, and that high FGF2 levels may predict a poor clinical outcome among patients with HCC^[46].

Considering the proposed importance of FGF signaling in HCC angiogenesis, it is clear that novel antiangiogenic agents that combine inhibition of FGF receptor signaling with inhibition of VEGFR signaling might provide a potential mechanism to overcome anti-VEGF resistance in HCC (Figure 6). With this in mind, it is worthwhile considering the potential future impact of brivanib on the treatment of advanced HCC. Brivanib, a small-molecule tyrosine kinase inhibitor, is the first oral selective dual inhibitor of FGF and VEGF signaling. In multiple preclinical models of human xenograft tumors, including patient-derived HCC xenografts, brivanib has shown potent antitumor activity and no overt toxicity when dosed orally^[47,48]. Furthermore, brivanib has demonstrated promising antitumor activity and acceptable tolerability in a phase II, open-label study in patients with unresectable locally advanced or metastatic HCC^[49,50]. Crucially, within this trial, brivanib showed activity both as first-line therapy (overall survival: 10 mo) or as second-

Figure 6 Brivanib may be effective for the failure or resistance of first line anti-angiogenic therapy for vascular endothelial growth factor. In addition, there is a possibility that anti-FGF agents can be first line anti-angiogenic agents. FGF: Fibroblast growth factor; VEGF: Vascular endothelial growth factor; PDGF: Platelet-derived growth factor.

line therapy in patients who had failed prior antiangiogenic treatment, primarily with sorafenib (overall survival: 9.5 mo)^[50]. Of note, the incidence of all-grade hand-foot syndrome was only 8% in this study.

As for brivanib, an international global phase III clinical trial to compare brivanib and sorafenib head-to-head and to seek approval for first-line therapy for advanced HCC has already been started, and the results are eagerly awaited. Since brivanib targets FGF and VEGF, and is associated with relatively mild adverse effects, a second-line study of brivanib in sorafenib-ineffective and -intolerant patients, and a trial to evaluate the use of brivanib in combination with TACE, are underway. Depending on the results of these trials, indications for use in HCC may be obtained; therefore, positive results are eagerly anticipated.

The results have been reported for a phase II study of brivanib in 55 patients (cohort A) who had not received systemic therapy for curatively unresectable HCC and 46 patients (cohort B) previously treated with angiogenesis inhibitors, such as sorafenib or thalidomide^[49]. The median TTP and OS were 2.8 mo and 10 mo, respectively, in cohort A versus 1.4 mo and 9.8 mo, respectively, in cohort B. Adverse events included fatigue (51.5%), diarrhea (41.6%), hypertension (42.6%), anorexia (41.6%), and nausea/vomiting (40.6%/30.7%) in total. Thus, these results demonstrated the efficacy of brivanib as a second-line treatment. The results of three phase III clinical trials,

BRISK-PS (sorafenib failure or sorafenib-intolerant patients; brivanib + best supportive care (BSC) *vs* placebo + BSC), BRISK-FL (advanced HCC; brivanib *vs* sorafenib), and BRISK-TA (patients with unresectable HCC, brivanib *vs* placebo as post-TACE adjuvant therapy) are awaited (Table 2).

Linifanib (ABT-869), which strongly inhibits VEGFR and PDGFR, is also under global phase III trial.

In a Japanese phase I / II trial of TSU-68, an oral molecular inhibitor of VEGFR, PDGFR, and FGFR, to test its safety and efficacy in 35 HCC patients, the response rate was 5.6% (CR, PR, SD, PD and NE in 1, 2, 15, 16 and 1 patients, respectively), and the disease control rate was 51.4%^[51]. The global phase III trial of TACE in combination with TSU-68 has just started on January 2011.

In addition, several phase I / II trials are being conducted to assess kinase inhibitors such as cediranib (AZD2171), which inhibit VEGFR, PDGFR, CSF-1R (cFms), Kit, and Flt3. Furthermore, a phase III global study of axitinib, which is currently being tested in renal cell carcinoma, has also been started as a second line agents on 2011.

EGF/EGFR

EGFR is a member of the HER family, which includes EGFR (erbB1), HER2/neu (erbB3), and HER4 (erbB4). All members of this family, except HER3, have an intracellular tyrosine kinase domain, and the binding of a ligand to its extracellular domain triggers signal transduc-

tion through the above-described MAPK and PI3K/Akt/mTOR pathways. Thus, these receptors are involved in cell growth, differentiation, survival, and adhesion^[52]. EGFR over expression has been reported in many cancers, and in HCC. For example, Buckley *et al*^[53] reported that EGFR, detected by immunohistochemical analysis, was overexpressed in 50 (66%) of 76 HCCs, and that fluorescence *in situ* hybridization showed extra EGFR gene copies in 17 (45%) of 38 HCCs.

EGFR-targeting drugs include anti-EGFR antibodies, such as cetuximab and panitumumab, and small-molecule inhibitors of EGFR tyrosine kinases, such as gefitinib *etc.*, and have been used widely for the treatment of several cancers other than HCC. Unfortunately, except for phase II trial data, there are little clinical data on the efficacy of these drugs for the treatment of HCC.

Similar to gefitinib (Iressa®), erlotinib (Tarceva®) is an oral EGFR tyrosine kinase inhibitor. Philip *et al*^[54] and Yau *et al*^[55] have reported the results of phase II studies of erlotinib in HCC; the median OSs in their studies were 13 and 10.7 mo, respectively. A phase III clinical study (SEARCH study: Sorafenib and Erlotinib, a Randomized Trial Protocol for the Treatment of Patients with Hepatocellular Carcinoma) for sorafenib in combination with erlotinib *vs* sorafenib plus placebo is ongoing. Since erlotinib is associated with a high incidence of skin rash, dry skin and gastrointestinal toxicity, such as diarrhea, the results of the SEARCH study should be evaluated to assess whether this combination therapy can be used in clinical settings. Thomas *et al*^[56] conducted a phase II clinical study of erlotinib in combination with bevacizumab in 40 advanced HCC patients, and reported promising results; the median PFS and OS were 9 mo and 15.7 mo, respectively. However, they noted frequent treatment-related grade 3/4 toxicities, including fatigue

(20%), hypertension (15%), gastrointestinal bleeding (12.5%), wound infection (5%), diarrhea (10%), elevated transaminase levels (10%), and thrombocytopenia (10%), which necessitates further evaluation for drug tolerance. Although a clinical study of erlotinib in combination with bevacizumab (OPTIMOX-3 study) was also conducted in colorectal cancer patients, no tolerance was observed, which led to a change in the protocol^[57,58].

After the introduction of a number of molecular-targeted drugs, strategies for the inhibition of similar or different signaling pathways (vertical or horizontal inhibition) with several drugs have been proposed. However, the combined use of molecular-targeted agents has remained largely unsuccessful, including panitumumab in combination with bevacizumab for the treatment of colorectal cancer^[59]. Similarly, the results of sorafenib in combination with bevacizumab (vertical inhibition) have been reported^[60]. Although some therapeutic responses were obtained, the combination therapy resulted in greater toxicity^[60], suggesting the need for detailed evaluation of the dosing regimen.

Lapatinib (Tykerb®) is a dual inhibitor of EGFR and HER-2/neu, and inhibits tumor growth by downregulating MAPK, AKT, and p70S6 kinase^[61]. In Japan, lapatinib is indicated for the treatment of breast cancer. In a phase II clinical trial of lapatinib in 26 patients with unresectable advanced HCC, the median PFS and OS were 1.9 mo and 12.6 mo, respectively, and adverse events included diarrhea (73%), nausea (54%), and skin rash (42%)^[62].

Cetuximab (Erbix®) is a human/mouse chimeric monoclonal antibody consisting of the variable region of a mouse anti-human EGFR monoclonal antibody and the human immunoglobulin G1 constant region. Cetuximab inhibits the binding of endogenous EGFR ligands, such as EGF and TGFα, to EGFR. In a phase II clinical trial of cetuximab in 30 patients with unresectable or metastatic HCC, the median PFS and OS were 1.4 mo and 9.6 mo, respectively, and treatment-related toxicities included grade 3 hypomagnesemia (3.3%) and grade 1/2 acne-like rash (83.3%), which was observed for the duration of anti-EGFR therapy in that study^[63].

The EGFR offers a very interesting therapeutic target. As described above, the use of erlotinib in combination with sorafenib is still in the research stage. However, based on the results of phase II studies, the efficacy of cetuximab or lapatinib as a monotherapy seems to be limited, and the results of further studies evaluating their efficacy in sorafenib-refractory or -intolerant patients are awaited with interest.

Hepatocyte growth factor/c-Met pathway

Since the hepatocyte growth factor (HGF)/Met pathway is involved in tumor growth, invasion, and angiogenesis in a wide range of neoplasms, HGF and Met have recently attracted attention as therapeutic targets. HGF is a heterodimer consisting of α and β chains bound together by a disulfate bond. The α-chain contains four

Figure 7 Consensus-based treatment algorithm for hepatocellular carcinoma proposed by Japan Society of Hepatology, revised in 2010. (Cited and modified from Kudo et al.^[67] with permission.) *1: Treatment should be performed as if extrahepatic spread is negative, when extrahepatic spread is not considered as a prognostic factor in Child-Pugh class A/B patients; *2: Sorafenib is the first choice of treatment in this setting as a standard of care; *3: Intensive follow-up observation is recommended for hypovascular nodules by the Japanese Evidence-Based Clinical Practice Guidelines. However, local ablation therapy is frequently performed in the following cases: (1) when the nodule is diagnosed pathologically as early hepatocellular carcinoma (HCC); (2) when the nodules show decreased uptake on Gd-EOB-MRI, or (3) when the nodules show decreased portal flow by CTAP, since these nodules frequently progress to advanced HCC; *4: Even for HCC nodules exceeding 3 cm in diameter, transcatheter arterial chemoembolization (TACE) in combination with ablation is frequently performed when resection is not indicated; *5: TACE is the first choice of treatment in this setting. Hepatic arterial infusion chemotherapy (HAIC) using an implanted port is also recommended for TACE-refractory patients. The regimen for this treatment is usually low-dose FP [5-fluorouracil (5-FU) + CDDP] or intra-arterial 5-FU infusion combined with systemic interferon therapy. Sorafenib is also recommended for TACE or HAIC-refractory patients with Child-Pugh class A liver function; *6: Resection is sometimes performed when more than 4 nodules are detected. Ablation is sometimes performed in combination with TACE; *7: Milan criteria: Tumor size ≤ 3 cm and tumor number ≤ 3, or solitary tumor ≤ 5 cm. Even when liver function is good (Child-Pugh A/B), transplantation is sometimes considered for frequently recurring HCC patients; *8: Sorafenib and HAIC are recommended for HCC patients with major portal invasion such as Vp3 (portal invasion in the 1st portal branch) or Vp4 (portal invasion in the main portal branch); *9: Resection and TACE are frequently performed when portal invasion is minor, such as Vp1 (portal invasion in the 3rd or more peripheral portal branch) or Vp2 (portal invasion in the 2nd portal branch); *10: Local ablation therapy or subsegmental TACE is performed even for Child-Pugh C patients when transplantation is not indicated when there is no hepatic encephalopathy, no uncontrollable ascites, and a low bilirubin level (< 3.0 mg/dL). However, it is regarded as an experimental treatment because there is no evidence of a survival benefit in Child-Pugh C patients. A prospective study is necessary to clarify this issue.

kringle domains, and the β -chain contains a serine protease-like domain. Met is a receptor tyrosine kinase for the HGF ligand, and contains a semaphorin-like domain. HGF or Met overexpression, and *Met* gene mutations and duplications, have been reported in various cancers, and abnormalities due to HGF/Met pathway activation have also been noted^[64]. These abnormalities activate the downstream signaling cascade, leading to epithelial-mesenchymal transition and increased proliferative, migratory, invasive, and metastatic potentials of cancer cells^[64].

HGF/c-MET-targeted drugs, including kinase inhibitors, HGF inhibitors and decoy c-Met receptor molecules are being developed. Of particular interest is ARQ-197, a

c-Met receptor tyrosine kinase inhibitor, which is a non-ATP-competitive molecule that binds near the ATP-binding site. A randomized phase II study of ARQ-197 vs placebo is ongoing in patients with unresectable HCC after systemic therapy failure. In addition, the results of a phase I study of ARQ-197 in combination with sorafenib was reported in ASCO 2010 (Abstract 3024).

IGF/IGFR

The IGF/IGFR system is involved in cell growth and the chemotherapeutic response. The ligands IGF- I and - II bind to their receptors IGF-1R and IGF-2R, and are involved in DNA synthesis and cell growth. Abnormali-

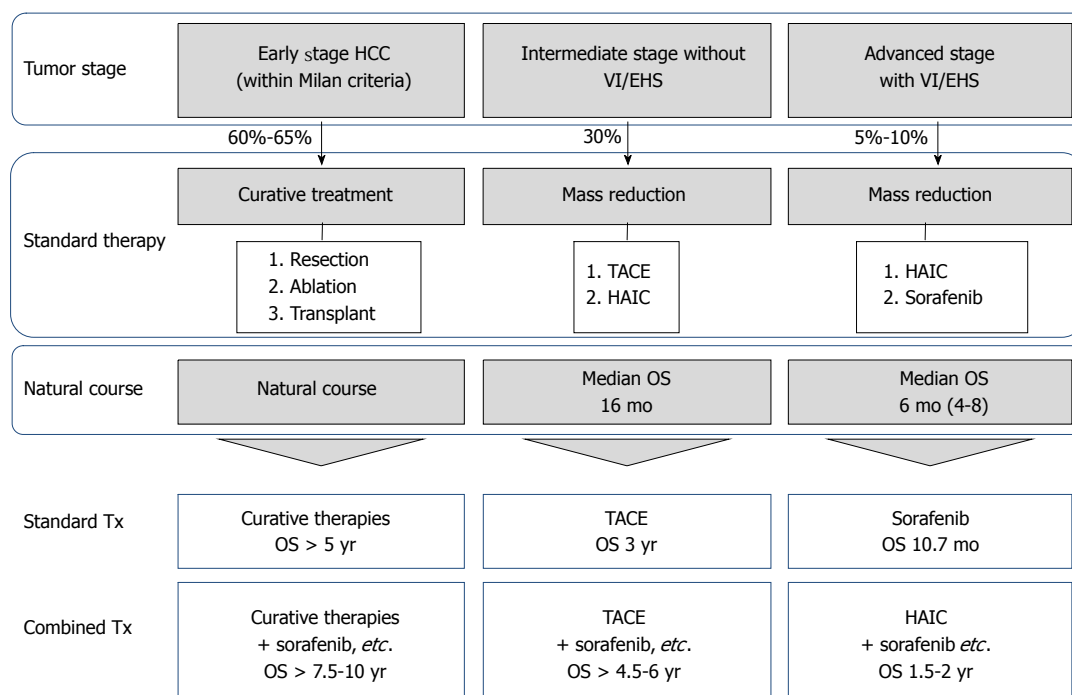

Figure 8 Outcomes of standard treatment modalities and expected future outcomes of combination therapy with molecular-targeted agents. By combining molecular targeted agents with resection or ablation, life expectancy [overall survival (OS)] is expected to be prolonged to 7.5-10 years. In addition, for intermediate stage hepatocellular carcinoma (HCC), the prognosis is expected to be improved to 4.5-6 years by combination with transarterial chemoembolization (TACE). For advanced stage HCC, the prognosis is expected to be improved to 1.5-2 years by combination with hepatic arterial infusion chemotherapy (HAIC).

Table 3 Subanalysis data of the SHARP study

	Advanced HCC with vascular invasion and/or extrahepatic spread	Advanced HCC without vascular invasion and/or extrahepatic spread
Hazard ratio	0.77 (95% CI: 0.60-0.99)	0.52 (95% CI: 0.32-0.85)
Median OS (MST) (mo)		
Sorafenib	8.9 (n = 209) (95% CI: 7.6-10.3)	14.5 (n = 90) (95% CI: 14.0-N/E)
Placebo	6.7 (n = 212) (95% CI: 5.2-8.0)	10.2 (n = 91) (95% CI: 8.6-15.5)

HCC: Hepatocellular carcinoma; OS: Overall survival; MST: Median survival time.

ties in IGF and IGF-1R, or their overexpression, have been reported in various cancers, including HCC. Their associations with disease stage, metastasis, survival^[65], and the functions of IGF and IGFR in HCC^[66] have been reported.

IGF-targeting drugs are currently being developed, and are mainly anti-IGF-1R antibodies, such as BII B022, AVE1642, and cixutumumab (IMC-A12). A phase II study of cixutumumab, a phase I b/II study of sorafenib *vs* sorafenib plus BII B022, and phase I /II studies of AVE1642 as monotherapy or in combination with sorafenib or erlotinib are ongoing.

COMBINATION THERAPY OF STANDARD TREATMENT WITH SORAFENIB

In addition to the pharmaceutical-sponsored clinical trials of linafianib and brivanib as first- and second-line therapy in sorafenib-refractory patients, investigator initiated trials (IIT) of sorafenib in combination with hepatic arte-

rial infusion chemotherapy (SILIUS trial: trial number NCT01214343), pharmaceutical and IIT trials of sorafenib in combination with TACE [SPACE, TACICS (trial number: NCT 01217034) and BRISK-TA trials], and a trial to test the inhibitory effect of sorafenib on tumor recurrence after curative treatment (STORM trial) are ongoing. The results of these trials are eagerly awaited (Figure 7)^[67,68].

The working hypotheses in these studies can be deduced by extrapolating the median survival time (MST) and hazard ratios in overall survival (OS) calculated in a subanalysis of the SHARP study (Table 3). The results obtained suggest that starting treatment with molecular-targeted drugs at an earlier tumor stage in combination with standard treatment options such as resection, ablation, TACE, or hepatic arterial infusion chemotherapy can improve the prognosis of HCC. Thus, sorafenib has the potential to induce a paradigm shift in the treatment of HCC. For example, in a subanalysis of the SHARP trial, the hazard ratios for OS and MST ratio in intermediate stage HCC without vascular invasion or extrahepatic spread were 0.52 and 1.50, respectively (Table 3). This

suggests that survival of early stage HCC and intermediate stage HCC may be prolonged from 5 years to 7.5-10 years by using sorafenib in an adjuvant setting after curative treatment, and from 3 years to 4.5-6 years by using sorafenib in combination with TACE (Figure 8)^[68].

CONCLUSION

Several clinical trials^[39,40,49,54,63,69-74] of the molecular-targeted agents are ongoing. Angiogenesis-inhibiting drugs, particularly sorafenib, have been established for HCC, and drugs targeting several molecules are being developed.

Although sorafenib was recently approved, many issues remain to be addressed, including: (1) how to determine and define refractoriness; and (2) whether to continue TACE or hepatic arterial infusion chemotherapy (a de facto standard in Japan) in patients with TACE-refractory HCCs or portal tumor thrombi before starting sorafenib therapy. We strongly recommend that, based on the molecular-targeted agents currently under development, clinical studies (including IITs) should be conducted aggressively, and therapeutic strategies should be devised to resolve the limitations of currently used therapeutic approaches and to improve the therapeutic outcomes.

The introduction of sorafenib to treat HCC in 2007 in Western countries and in 2009 in Japan was undoubtedly the real beginning of a paradigm shift of HCC treatment, representing a significant breakthrough for HCC treatment not previously experienced for this unique tumor. Further development of survival benefit in HCC patients with new targeted agents are greatly expected.

Abstract

Genome-wide and candidate gene association studies have identified several variants that predispose individuals to developing nonalcoholic fatty liver disease (NAFLD). However, the gene that has been consistently involved in the genetic susceptibility of NAFLD in humans is patatin-like phospholipase domain containing 3 (*PNPLA3*, also known as adiponutrin). A nonsynonymous single nucleotide polymorphism in *PNPLA3* (rs738409 C/G, a coding variant that encodes an amino acid substitution I148M) is significantly associated with fatty liver and histological disease severity, not only in

adults but also in children. Nevertheless, how *PNPLA3* influences the biology of fatty liver disease is still an open question. A recent article describes new aspects about *PNPLA3* gene/protein function and suggests that the I148M variant promotes hepatic lipid synthesis due to a gain of function. We revise here the published data about the role of the I148M variant in lipogenesis/lipolysis, and suggest putative areas of future research. For instance we explored in silico whether the rs738409 C or G alleles have the ability to modify miRNA binding sites and miRNA gene regulation, and we found that prediction of *PNPLA3* target miRNAs shows two miRNAs potentially interacting in the 3' UTR region (hsa-miR-769-3p and hsa-miR-516a-3p). In addition, interesting unanswered questions remain to be explored. For example, *PNPLA3* lies between two CCCTC-binding factor-bound sites that could be tested for insulator activity, and an intronic histone 3 lysine 4 trimethylation peak predicts an enhancer element, corroborated by the DNase I hypersensitivity site peak. Finally, an interaction between *PNPLA3* and glycerol-3-phosphate acyltransferase 2 is suggested by data miming.

INVITED COMMENTARY ON HOT ARTICLES

We have read with great interest the recent article by Kumari *et al.*^[1] describing new aspects about patatin-like phospholipase domain containing 3 (*PNPLA3*, also known as adiponutrin) gene function. Notably, the authors reported that human and murine *PNPLA3* exhibit increased lysophosphatidic acid acyltransferase (LPAAT) activity leading to increased cellular lipid accumulation. Kumari *et al.*^[1] concluded that the I148M substitution promotes hepatic lipid synthesis due to a gain of function, and that this property provides a plausible biochemical mechanism for the development of liver steatosis in subjects carrying the 148M variant (rs738409, allele G) as discussed below.

These results give new answers to the previous conflicting data around the question of whether the rs738409 is associated with a gain or loss of gene/protein function (Figure 1). For instance, several functional studies were elegantly performed to decipher whether the I148M substitution interferes with hepatic triglyceride (TG) hydrolysis and thus promoting hepatic steatosis^[2]. Based on an *in vitro* structural model of the patatin-like domain of PNPLA3 protein, He *et al.*^[2] showed that the 148M variant interferes with TG hydrolysis, affecting the association of PNPLA3 with the lipid droplets. Thus, the resulting mutant enzyme is inactive against its substrates. In addition, Huang *et al.*^[3] recently demonstrated that PNPLA3 plays a role in the hydrolysis of glycerolipids, and the I148M substitution causes a loss of function.

Several animal studies were conducted to evaluate the effect of the PNPLA3 loss of function by using knockout models, for instance *PNPLA3*^{-/-} mice by gene targeting^[4]. Surprisingly, loss of PNPLA3 does not cause fatty liver, liver enzyme elevation, or insulin resistance in mice under a standard or a high-sucrose/high-fat diet^[4]; a finding replicated by global targeted deletion of the *PNPLA3* gene^[5].

Interestingly, a human study demonstrated that the rs738409 PNPLA3 G allele is associated with morphological changes in adipocyte cell size^[6], and this concept strongly supports a role of the variants in the liver fat remodeling; unfortunately, these findings were not replicated.

Finally, Kumari *et al.*^[1] confirmed that PNPLA3 functions as a TG hydrolase in mice and humans but found that the specific TG hydrolase activity is much lower than that of adipose triglyceride lipase (ATGL).

Can a loss or gain of function in a single protein explain such a strong effect in the biology of nonalcoholic fatty liver disease?

The question as to whether the role of the rs738409 in the pathobiology of nonalcoholic fatty liver disease (NAFLD) is associated with a gain or loss of function is hard to answer because the biological function attributed to the PNPLA3 in lipid-related pathways is shared with other related proteins. For example, almost all members of the PNPLA family have established TG hydrolases and phospholipases activities, and PNPLA3 shares, as expected, protein domains with the PNPLA family (PNPLA1, PNPLA2, and PNPLA4-8), and also with

PLA2G6 (phospholipase A2, group VI cytosolic, calcium-independent, also known as PNPLA9). *In silico* prediction of PNPLA3 protein function by imputation of functional association data^[7] shows that only PNPLA2, PNPLA3, PNPLA8, and PLA2G6 have carboxylesterase and lipase activities ($P < 4.8$ and 9.4×10^{-5}) and PNPLA3, PNPLA8, and PLA2G6 have phospholipase A2 activity ($P < 1.6 \times 10^{-4}$). As we mentioned recently, these similarities with enzymes with the potential of releasing arachidonic acid as the precursor of potent inflammatory substances such as prostaglandins may have therapeutic implications^[8].

In addition, neutral lipid, triglyceride, or glycerolipid catabolic processes are shared by only PNPLA2 and PNPLA3 ($P < 0.05$). This finding is also consistent with the notion that PNPLA3 plays a role in the hydrolysis of glycerolipids as shown by Huang *et al.*^[3].

Furthermore, *in silico* prediction of the protein network related to PNPLA3 is beyond the PNPLA family (Figure 2), suggesting that some other interesting and still unexplored issue about the putative role of the rs738409 in liver steatosis are waiting for answers. For instance, the putative interaction between PNPLA3 and genes in the related networks, particularly glycerol-3-phosphate acyltransferase 2 (GPAT2, mitochondrial), whose protein esterifies acyl-group from acyl-ACP to the sn-1 position of glycerol-3-phosphate, an essential step in glycerolipid biosynthesis^[9]. We wonder to what extent the PNPLA3 and GPAT2 interaction modulates hepatic fat content. We used a data integration and data mining platform to explore the putative interaction between PNPLA3 and GPAT2, and as shown in Figure 3, PNPLA3 and GPAT2 are involved in shared metabolic pathways, including triglyceride biosynthetic process, glycerolipid metabolism pathways, and acyltransferase activity, which may explain an interaction in the pathogenesis of NAFLD. This prediction is biologically plausible as GPAT2 catalyzes the initial and rate-limiting step in glycerolipid synthesis, and overexpression and knock-out studies suggest that GPAT isoforms can play important roles in the development of hepatic steatosis, insulin resistance, and obesity^[10].

Impact of rs738409 on genetic risk of NAFLD

The first description about the association between a nonsynonymous single nucleotide polymorphism (SNP) of PNPLA3, the rs738409 C/G, (a coding variant that encodes an amino acid substitution I 148M as described) and fatty liver was reported by Romeo *et al.*^[11] by performing a genome-wide association study (GWAS) of nonsynonymous sequence variations ($n = 9229$) in a large multiethnic population-based epidemiological study of fatty liver. This initial finding was further replicated in several populations confirming that the G allele in the forward strand is significantly associated with increased risk of hepatic triglyceride accumulation and fatty liver disease, as reviewed recently in a meta-analysis^[12]. Likewise, the rs738409 variant was associated with fatty liver in pediatric patients with NAFLD^[13-16], and patients with NAFLD related comorbidity, such as type 2 diabetes^[17-19] or morbid

The interactions include direct (physical) and indirect (functional) associations; they are derived from four sources: Genomic Context, High-throughput Experiments, Conserved-Coexpression and Previous Knowledge. PNPLA3: Patatin-like phospholipase domain containing 3; LIPF: Lipase, gastric; SNX4: Sorting nexin 4; AGPAT9: 1-acylglycerol-3-phosphate O-acyltransferase 9; MGLL: Monoglyceride lipase; GPAM: Glycerol-3-phosphate acyltransferase, mitochondrial; AGPAT3: 1-acylglycerol-3-phosphate O-acyltransferase 3; LIPC: Lipase, hepatic; MBOAT2: Membrane-bound O-acyltransferase domain containing 2; LCLAT1: Lysocardiolipin acyltransferase 1; AGPAT4: 1-acylglycerol-3-phosphate O-acyltransferase 4; LPCAT3: Lysophosphatidylcholine acyltransferase 3; AGK: Acylglycerol kinase; PNLIIPRP1: Pancreatic lipase-related protein 1; GPAT2: Glycerol-3-phosphate acyltransferase 2, mitochondrial; PNLIIP: Pancreatic lipase; PDLIM1: PDZ and LIM domain 1; AGPAT2: 1-acylglycerol-3-phosphate O-acyltransferase 2; CEL: Carboxyl ester lipase; EIF2C4: Eukaryotic translation initiation factor 2C, 4; HCK: Hemopoietic cell kinase; AGPAT6: 1-acylglycerol-3-phosphate O-acyltransferase 6; ENSG00000228892: 1-acyl-sn-glycerol-3-phosphate acyltransferase.

obesity^[15], although it remained to be explored whether these associations are truly independent of NAFLD^[12].

Interestingly, we demonstrated for the first time^[20] that the rs738409 was also significantly associated with histological disease severity; a finding that was replicated by others^[21-23]. In fact, the G allele significantly increases the risk of progressive liver disease (odds ratio 1.88 per G allele; 95% CI: 1.03-3.43; $P < 0.04$)^[20,12].

Overall, the most remarkable conclusion about the impact of the genetic variation in PNPLA3 on NAFLD-related outcomes is the strong effect that the rs738409 has on the susceptibility of fatty liver, because the pro-

portion of the total variation attributed to the SNP genotypes is about 5.3%^[20]. This effect is perhaps one of the strongest ever reported for a common variant modifying the genetic susceptibility for a complex disease.

Furthermore, the rs738409 variant not only modifies the biology of NAFLD but also has a considerable impact on the genetic susceptibility to alcoholic liver disease^[24-26], and hepatitis-C-virus-induced fatty liver^[23], and is a strong predictor of hepatocellular carcinoma occurrence among patients with cirrhosis^[27,28], indicating that these diverse liver diseases may share common pathological pathways.

PNPLA3: Short summary about gene structure and variation

PNPLA3 gene is located in chromosome 22 (22q13.31) and has nine exons; its transcript length is 2805 bp and it is translated to a protein of 481 amino acids. There are 34 SNPs with reported frequency and heterozygosity information in the HapMap (www.hapmap.org). Nevertheless, among all known *PNPLA3* variants in coding or noncoding regions, there are three SNPs that have shown association with NAFLD-related phenotypes, including the rs738409. One is the rs6006460 (S453I) that after gene resequencing is associated with lower hepatic fat content in African Americans^[11]. The other SNP is the nonsynonymous rs2294918 (Lys434Glu) that is significantly associated with serum alanine aminotransferase levels^[29]. Haplotype analysis of *PNPLA3* shows that the rs738409 is in moderate linkage disequilibrium (LD) (r^2 : 0.65) with the other variants, including rs2294918 (Figure 4). Thus, this scenario precludes any imputation across the *PNPLA3* locus centered on rs738409, and suggests that the T148M variant might be the casual variant in the susceptibility of fatty liver. However, Figure 5 shows annotation of nearby SNPs in LD (proxies) with rs738409 based on HapMap data and a nearby locus, such as SAMM50 that is a component of the sorting and assembly machinery (SAM) complex of the outer mitochondrial membrane. The SAM complex has a role in integrating β -barrel proteins into

the outer mitochondrial membrane, and makes SAMM50 a good candidate because mitochondrial dysfunction may play a major role in NAFLD pathogenesis, as suggested by experimental models^[30] and human studies^[31]; nevertheless, this issue deserves further investigation.

Another interesting feature to highlight is the population diversity of rs738409. Genome diversity data extracted from <http://www.ncbi.nlm.nih.gov/SNP/> shows that the risk allele G is highly prevalent around the world, with an average prevalence close to 0.70 from Caucasian to Yoruban populations. Negative selection of the ancestral allele that seems to be the C allele (<http://www.ensembl.org>), which is shared by chimpanzees, orangutans, macaques, and other species, suggests that environmental pressures have exerted a strong influence. However, this picture probably reflects a sort of confusion about the reference strand and probably these annotation data refer to the minus strand when the gene is located in the plus strand, and the real frequency of the risk allele G is < 50% in all populations. In fact, published data^[12] from rs738409 association studies show that the most prevalent allele is certainly the reference allele C.

PNPLA3: Mechanisms of control of gene and protein expression and unexplored areas of research

PNPLA3 is a multifunctional enzyme that has both triac-

Figure 4 Linkage disequilibrium plot across the patatin-like phospholipase domain containing 3 gene. The horizontal white line depicts the DNA segment of chromosome 22q13.31. The rs738409 location is highlighted in a black ellipse. An LD plot is depicted in the bottom part of the figure: each diamond represents the magnitude of LD for a single pair of markers, with colors indicating strong LD (red $r^2 = 1.0$) and no LD (white, $r^2 = 0$) as the extremes (different red tones indicate intermediate LD). Numbers inside the diamonds stand for r^2 values. Haplotype analysis of PNPLA3 shows that the rs738409 is in moderate LD (no more than $r^2: 0.65$) with other variants. Plot was obtained by the software Haploview 2.0 freely available at www.broad.mit.edu/mpg/haploview/. LD: Linkage disequilibrium; PNPLA3: Patatin-like phospholipase domain containing 3.

ylglycerol lipase and acylglycerol O-acyltransferase activity^[32]; subfamily hierarchy of PNPLA3 protein is shown in Figure 6. A summary of PNPLA3 protein characteristics and mechanisms of gene regulation is shown in Table 1. A very interesting feature of PNPLA3 protein is that is induced by several nutritional factors, such as oleic acid, C18:2 fatty acid, palmitic acid, glucose, insulin and lactone. Moreover, it was shown that the promoter activity of PNPLA3 is upregulated by glucose concentrations in a dose-dependent manner^[33]. Adiponutrin was initially regarded as a dietary and obesity-linked protein^[34]. Furthermore, Hockstra *et al.*^[35] suggested that PNPLA3 plays an important role in hepatic lipid metabolism under conditions of lipid excess. In the light of these findings, subsequent studies were conducted to evaluate how *PNPLA3* is transcriptionally regulated, and most of the experiments were focused to answer the question whether the lipogenic transcription factor sterol regulatory element binding protein 1 (SREBP-1) was orchestrating these events. Interestingly, Huang *et al.*^[36] demonstrated in mice that *PNPLA3* mRNA levels are regulated by SREBP-1c as they found a SREBP1c binding site mapped to intron 1 of *PNPLA3*. In particular, Huang *et al.*^[36] observed robust transcriptional upregulation of *PNPLA3* expression with carbohydrate feeding mediated by activation of liver X receptor/retinoic acid receptor (RXR) and increased levels of SREBP1c. In agreement with this finding, we observed in a high-fat-induced rat NAFLD model that liver transcript levels of RXR- α were significantly upregulated in fatty liver in comparison with normal liver (RXR- α mRNA/TATA box binding protein mRNA ratio: 11.71 ± 1.11 vs 6.48 ± 1.15 , respectively, $P = 0.008$), data adjusted by HOMA-IR (homeostatic model assessment-insulin resistance) using analysis of covariance, (unpublished data).

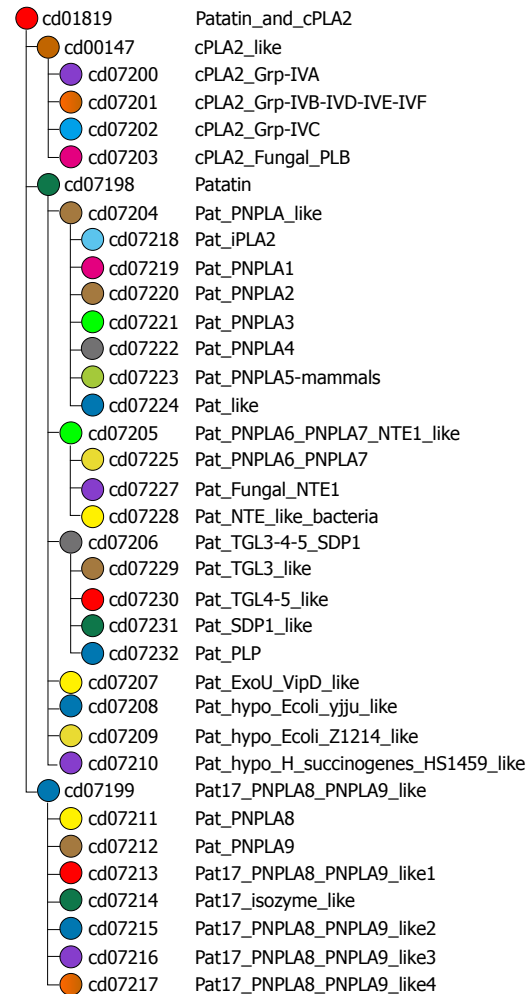

Figure 6 Domain family hierarchy of patatin-like phospholipase domain containing 3 protein. Data extracted from NCBI-curated domains at <http://www.ncbi.nlm.nih.gov/Structure/cdd/cdd.shtml>. This picture provides data about how patterns of residue conservation and divergence in a family relate to functional properties. In this particular case, picture shows the patatin-like phospholipase family. Patatin is a storage protein, but it also has the enzymatic activity of a lipid acyl hydrolase, catalyzing the cleavage of fatty acids from membrane lipids. Members of this family have also been found in vertebrates. This family also includes the catalytic domain of cytosolic phospholipase A2 (PLA2; EC 3.1.1.4) hydrolyzes the sn-2-acyl ester bond of phospholipids to release arachidonic acid. At the active site, cPLA2 contains a serine nucleophile through which the catalytic mechanism is initiated. PNPLA3: Patatin-like phospholipase domain containing 3; TGL: Triglyceride lipase; PLP: Pyridoxal phosphate.

In addition, *in vitro* data show that mouse but not human *PNPLA3* gene expression is under the transcriptional control of carbohydrate-responsive element-binding protein (ChREBP)^[37].

Unexplored mechanism of gene expression regulation

As shown in Figure 7, the promoter of *PNPLA3* gene has a typical chromatin structure [a peak of histone 3 lysine 4 trimethylation (H3K4me3) between the bimodal peaks of H3K4me1] and is DNase hypersensitive. The gene lies between two CCCTC-binding factor (CTCF)-bound sites that could be tested for insulator activity. An intronic H3K4me1 peak predicts an enhancer element, corroborated by the DNase I hypersensitivity site peak. The presence of a CpG island is typical of an active

Concluding remarks and future research directions: Possible role for rs738409 alleles in modifying miRNA target sites

SNPs associated with polygenetic disorders, such as NAFLD, can destroy or create miRNA binding sites. We hypothesize that disruption of miRNA target binding by rs738409 alleles may play a role in the effect of the gene variant on fatty liver disease susceptibility. To test this, we analyzed *in silico* whether the rs738409 C or G alleles have the ability to modify miRNA binding sites and miRNA gene regulation by using the PITA microRNA prediction tool (http://genie.weizmann.ac.il/pubs/mir07/mir07_prediction.html). We observed that rs738409 alleles show potentially different miRNA binding sites (Table 2), suggesting a putative different role in regulation of gene regulation; a hypothesis that has to be proven experimentally. Finally, although these data do not explain the association of the rs738409 variant with NAFLD, it is worth noting that prediction of PNPLA3 target miRNA by DIANA-microT v3.0 (<http://diana.cs-lab.ece.ntua.gr/microT/>) shows two miRNAs potentially interacting in the 3'UTR region (hsa-miR-769-3p and hsa-miR-516a-3p) (Table 3).

Abstract

A substantial part of the human genome is derived from transposable elements; remnants of ancient retroviral infections. Conservative estimates set the percentage of human endogenous retroviruses (HERVs) in the genome at 8%. For the most part, the interplay between mutations, epigenetic mechanisms and post-transcriptional regulations silence HERVs in somatic cells. We first highlight mechanisms by which activation of members of several HERV families may be associated with tumor development before discussing the arising chances for both diagnosis and therapy. It has been shown that at least in some cases, tumor cells expressing HERV open reading frames (ORFs) thus gain tumor-promoting functions. However, since these proteins are not expressed in healthy tissues, they become prime target structures. Of potential pharmacological interest are the prevention of HERV transposition, the inhibition of HERV-encoded protein expression and the interference with these proteins' activities. Evidence from recent studies unequivocally proves that HERV ORFs represent a very interesting source of

novel tumor-specific antigens with even the potential to surpass entity boundaries. The development of new tumor (immune-) therapies is a very active field and true tumor-specific targets are of outstanding interest since they minimize the risk of autoimmunity and could reduce side effects. Finally, we postulate on main future research streams in order to stimulate discussion on this hot topic.

HUMAN ENDOGENOUS RETROVIRUSES: AN INTRODUCTION

Human endogenous retroviruses (HERVs) are remnants of ancient retroviral infections. Many insertions into the genome have taken place tens of millions of years ago^[1,2]. Since the first set of data on the human genome project has been published in 2001, it is well established that about 8% of the genome consists of HERVs and their total number is approximately 3×10^5 copies^[3]. Generally, HERVs are classified into three groups:

class I [gamma (like) retroviruses], class II [beta (like) retroviruses] and class III [spuma (like) retroviruses]^[1]. The most common nomenclature utilizes the single-letter amino acid code corresponding to the tRNA primer that is used for reverse transcription of the HERV genome^[4]. For the most part, their canonical structure of a single open reading frame (ORF) consists of the *gag*, *pol* and *env* genes flanked by 5' and 3' long terminal repeats (LTR)^[2,5]. The latter features are what endogenous and exogenous retroviruses have in common.

ENDOGENIZATION

Following a retroviral infection, the fate of the host depends on the pathogenicity of the infectious virus. Highly pathogenic ones will kill the host whereas ones with only weak pathogenicity may manage to infect many different cell types, including reproductive tissue cells. Subsequently, an endogenous retrovirus will establish if virus and host proceed to fixation of the virus' sequences in the host genome. This process has been termed endogenization or molecular domestication^[6]. In most cases, HERV activities have been silenced by a variety of mechanisms. Mutational inactivation includes deletions as well as point mutations and probably has been triggered by specific regulatory proteins such as APOBEC^[7,8]. Furthermore, epigenetic mechanisms including methylation and histone modification contributed to HERV inactivation^[9]. Besides directly silencing the expression, posttranscriptional regulation further protects the host's genome^[10]. It has been argued that the presence of such a high number of HERV copies must be advantageous for the host, too^[11]. An amazing idea suggests that over time of evolution, retroelements like HERVs actively contribute to the development of novel physiological capacities^[12,13]. It is for example easily imaginable that a *de novo* ORF which basically encodes a membrane protein may give rise to a protein with novel functions when mutated. If such a protein is beneficial to the host, it will be fixed. Thus, HERVs are together with other mobile genetic elements drivers of the (human) evolution by providing material for genomic evolution, variation and natural selection^[6,12,14]. This argumentation adds another level of complexity to the relationship of humans (and all other vertebrates) and retroviruses^[15]. Consequently, HERVs must not be considered as parasites but as true symbionts - on the population level. However, the individual risk for *de novo* insertions is rather low with estimated rates of only 1 in 100 births^[16].

PRESERVED FUNCTIONS

Although the vast majority of HERV sequences have been inactivated over time as outlined above, there are some examples of HERVs with potentially useful functional modules; comparable to the proviruses of their exogenous counterparts. Among the cellular functions

influenced by HERVs are enhancement and promotion of gene expression. In a study on primate evolution ERV-9 LTR sequences were found in higher primates and humans. In the latter, tissue specific enhancer activity could be detected in hematopoietic cells and even stronger in embryonic cells^[17]. HERV-E LTR functions as enhancer for endothelin B receptor and apolipoprotein C- I genes in humans^[18]. Furthermore, HERV sequences also give rise to novel or alternative splicing and polyadenylation sites^[19]. They also can be involved in membrane fusion, with Syncytin in the placenta being the most prominent representative here of^[20].

HERV AND CANCER

A variety of oncogenic mechanisms have been attributed to animal oncogenic retroviruses^[21,22]. Moreover, it has been suggested, that failures and errors in single somatic cells' efficiency to control HERV activity potentially results in genome damage and may thus contribute to the formation of cancer^[14]. The possible oncogenic mechanisms of HERVs include (Figure 1): (1) the general or more specific (re)activation of HERV sequences by hypomethylation^[23-25]; (2) the expression of HERV encoded oncogenes such as Rec and NP9^[26]; (3) the inactivation of tumor suppressor genes by *de novo* insertion or translocation of retroelements within the genome^[26]; (4) the regulation of nearby (proto-) oncogenes or growth factors by the regulatory sequences of LTRs^[27,28]; and (5) the potential of Env proteins to induce cell fusions, which may contribute to tumor progression or even aid in metastasizing processes^[29]. Far from being complete, this is already a quite impressive list. An additional aspect comes from the observation that Env proteins of the mouse leukemia virus, the Mason-Pfizer monkey virus and also of HERV-K have strong immunosuppressive properties and may thus help tumor cells evade an antitumoral immune response^[26,30,31].

Methylation

As a general rule, all human regulatory genomic sequences become methylated unless specific factors prevent methylation^[23]. In addition, methylated sites are more prone to mutations^[23] and by this means, virus inactivation is further strengthened. Demethylation of regulatory regions is possible in the context of normal physiological processes by strong transcriptional activators. Re-expression of methylated sites is also possible during cell stress dependent on chromatin remodeling as a reaction to this stress^[32]. Obviously, the maintenance of methylation patterns and status must play a central role in HERV transcriptional control. In healthy somatic and mature germ cells HERV sequences are generally (hyper-) methylated. Thus, HERV transcriptional activity is mainly restricted to germ cell development or the desensitization of check-point activation in meiotic cells. This mechanism may also be responsible for a high(er) retroelement expression in germ cell tumors^[23]. In somatic cells, severe global hypomethylation

Figure 1 Possible mechanisms by which human endogenous retroviruses contribute to oncogenesis. Human endogenous retroviruses (HERVs) transcripts or proteins may directly have tumor promoting properties. The long terminal repeat (LTR) elements can function as promoters or enhancers for nearby (proto-) oncogenes or growth factors. Especially Env proteins might attract regulatory immune cells and thus provide an immunosuppressive microenvironment. And finally, the Env proteins may be directly involved in the metastasizing process.

leads to apoptosis induction mediated by TP53 and other tumor suppressive factors^[33]. Premalignant and malignant cells are typically insensitive to apoptosis induction^[34] and aberrant expression from normally methylated promoters is a main oncogenic force. In line with this, a general hypomethylation of HERV sequences can be found in the cancer cells of different entities, including testicular germ cell cancer, teratocarcinomas, colorectal, breast and ovarian cancer^[35-39]. However, methylation analyses are biased by a lack of accuracy of the bisulfide sequencing technique^[40]. When not highly standardized, this may account for a number of false positive or negative results in methylation analyses. Thus, it is always recommended to combine methylation analyses together with an investiga-

tion of mRNA or superior protein expression.

HERV ORF expression

Of interest, Syncytin-1 is the only expressed HERV sequence with a presumable physiological function. Syncytin-1 expression takes place in the placenta in the context of syncytiotrophoblast generation by cellular fusion of precursor cells, the cytotrophoblasts^[41,42]. This expression follows after a general hypomethylation of a HERV-W *env* sequence and the Env protein is considered to contribute to this cellular fusion process. It may be a coincidence, but for many tumor entities, naturally occurring cellular fusions have been described^[43-45] and this may hint towards the expression of similar HERV Env proteins.

Expression of HERV sequences has been described for several tumor entities including melanoma, breast, ovarian, prostate and colon cancer^[37-39,46,47]. Active retrotranspositions cause DNA strand-breaks and will thus lead to an activation of check-point signaling, e.g., TP53. Thus, transpositions as another mechanism for HERV re-expression may consequently occur especially in tumors with defect check-points and TP53 mutations^[23].

Tumor induction/promotion

Beside sheer tumor specific expression, HERVs have repeatedly been discussed to induce or promote tumorigenesis. Potential mechanisms have been outlined in the preceding paragraphs. Here we want to gather the bits of evidence that have been obtained so far.

Several groups could show the production of HERV-derived proteins or even of viral particles in tumor cells^[48-54]. In a mouse study, Howard and coworkers could directly link genome hypomethylation to ERV up-regulation^[55]. Further research could make the connection between hypomethylation of (H)ERVs and chromosomal instability; it is by mediating ectopic recombination^[56]. These HERV-induced recombination events have been found to produce large scale chromosomal anomalies^[57], a hallmark of most tumors^[34]. Finally, Lamprecht and colleagues could link the deregulated expression of the colony-stimulating factor 1 receptor (CSF1R) in B cell-derived Hodgkin's lymphoma cells to hypomethylation of an up-stream HERV-derived LTR, which promotes ectopic expression of the CSF1R proto-oncogene^[58]. However, the question if the reactivation of a (pro-) virus could actively promote cellular transformation or at least contribute to tumor progression is formally unsolved for human cancer. Similarly, it is unknown, if HERV activation is an early or a late step in tumor formation. Still, when considering the above listed bits of evidence, it seems reasonable to conclude that HERVs' contribution to the multi-step process of tumor development in humans is very likely^[14].

Immune responses towards HERV sequences

The human immune system's capability to recognize HERV sequences has so far only scarcely been analyzed. However, some examples can be found in the literature. In patients with kidney cancer, cytotoxic T lymphocytes (CTLs) reactive to a HERV-E sequence encoded on chromosome 6q were found^[59]. Serological responses and CTLs reactive to HERV-K sequences were detected in melanoma patients^[60,61]. Anti-Env antibodies for HERV-K, -E and ERV3 were present in sera of patients with ovarian cancer^[38] and in male patients with germ cell tumors^[62]. Similarly, in breast cancer patients, anti-HERV-K serum antibodies were detected together with HERV-K-specific CTLs^[63]. The orchestrated activation of both arms of the adaptive immune system in the latter cases is a strong indicator of HERV sequences' high immunogenicity. Consequently, one may conclude that at least no strong tolerance towards HERV encoded sequences is induced during lymphocyte development.

Future studies will have to analyze whether the immunological recognition of HERV sequences is executed by highly avid or only by intermediate avid T cells and antibodies. Also, it must be carefully analyzed, which HERV sequences give rise to strong immune responses when aberrantly expressed in tumor cells. We would like to state that immune recognition is a strong indicator for endogenous expression of a given HERV protein, as has been shown for other tumor antigens^[64]. Of note, T cell reactions against HERVs, such as HERV-K, HERV-L and HERV-H, were associated with successful control of human immunodeficiency virus (HIV) in a subset of HIV patients^[65]. It can be anticipated that this association of successful HIV control by HERV specific immune reactions will be translated into the tumor field. One of the major questions with clinical relevance is whether HERV-specific immune signatures can be associated with better prognosis or not.

THERAPEUTIC STRATEGIES

Assuming that in the normal physiology of adult tissues, HERVs do not play a vital role and following the line of evidence that HERV sequences are of significance in tumor formation, development and metastasis, HERVs recommend themselves as prime targets for tumor therapy. Several targeting strategies have been suggested (Figure 2 for an overview) and first experimental results can be found in the literature.

Inhibition

In the light of the tremendous success in HIV control with infected people treated by antiretroviral combination therapies, it would make sense to simply reverse the expression of HERV sequences in human tumor cells. The group of Carlini analyzed the effect of a reverse transcription inhibitor (Abcavir) on prostate cancer cell lines^[66]. It showed a strong anti-proliferative capacity and even triggered senescence in the cancer cells. Interestingly, the authors found an up-regulation of transcripts from LINE elements in the treated cells but unfortunately, they did not analyze HERV expression^[66].

A direct targeting of HERV proteins by small molecular inhibitors or via RNA interference would also be worth trying. However, this has not yet been done. Therapeutical use of natural inhibitors of retroviruses such as APOBEC^[67,68] or TRIM5^[69] would be another possible future option. First, detail knowledge on how and when such retroviral restriction elements act on HERVs must be build up.

Passive immune therapy

Only very recently, Wang-Johanning and coworkers designed a monoclonal antibody (mAb) recognizing a HERV-K Env protein. They described that HERV-K Env protein expression was substantially higher in malignant breast cancer cell lines than in non-malignant breast cells. Furthermore, HERV-K expression was detected in 148

Figure 2 Therapeutic possibilities to target tumor cells with active human endogenous retroviruses. Expressed Env proteins may be targeted by therapeutic monoclonal antibodies. (Re-) activation of retroelement-controlling proteins may help to reduce human endogenous retrovirus (HERV) activities. Small molecule inhibitors of HERV proteins or inhibitory targeting of expressed HERV sequences potentially will prevent oncogenic properties of HERV and harm or kill tumor cells with activated HERV oncogenesis. HERV proteins with tumor-specific antigen properties can be targeted by specific T cells. LTR: Long terminal repeat; MHC: Major histocompatibility complex.

(66%) of 223 primary breast tumors. And a higher rate of lymph node metastasis was associated with HERV-K-positive tumors. Anti-HERV-K-specific mAbs inhibited tumor growth and induced apoptosis of breast cancer cells *in vitro*. Mice treated with these mAbs showed significantly reduced growth of xenograft tumors. *In vitro*, this treatment resulted in an over-expression of several proteins involved in the apoptotic signaling pathways in malignant breast cells^[70]. In principle, targeting HERV Env proteins by therapeutical antibodies should be exploitable to all individual tumors expressing HERV Env. Moreover, passive immune therapies may well be applied in combination with active immune therapies.

Active immune therapy

The ideal cancer therapeutic agent should be able to discriminate between cancer and normal cells (i.e., specificity) and be potent enough to kill small or large numbers of tumor cells (i.e., sensitivity). A feature that makes immunotherapies unique is that an ideal cancer immunotherapy should be able to prevent recurrence of the tumor (i.e., durability). In the last decades it became increasingly apparent that this durability in prevention of tumor recurrences is due to persistent recognition of

tumor antigens by lymphocytes.

Researchers distinguish between tumor-associated antigens (TAAs) and tumor-specific antigens (TSAs). TAAs are antigens that are expressed in normal tissue but to a much higher extent in malignant cells. Contrary to this, TSA are truly specifically expressed in tumor cells alone. Beside specific point^[71] or frameshift mutations^[72], proteins from tumor-inducing viruses^[73] for the most part form this class of tumor antigens. Most of the features an ideal TSA should possess have been assigned to HERV encoded proteins. This being beside exclusivity also the necessity of expression for maintenance of the cancer cells' transformed state. Thus, immune-escape by simple down-regulation of expression is prevented^[74]. Moreover, to ease therapy development, ideal TSA expression should be not only present in single tumors but shared between individual tumors of a given entity or even superior between tumors of different entities^[75,76]. Finally, the immune system should be able to mount both a cellular and a humoral response^[63]. When summing up these desired properties of TSAs attributable to (at least some) HERV-encoded proteins, one may conclude that they might indeed be ideal targets for tumor immunotherapy. Because of the multitude of HERV-

encoded sequences one can even expect that the development of a polyvalent (i.e., containing many epitopes) vaccine basing only on HERV epitopes may be possible. Even more visionary, actual bioinformatics approaches will allow the identification of immunogenic core epitopes shared between different HERV copy ORFs active in different tumor entities in order to design a universal HERV-based vaccine. As a first step in that direction, we recently described two CD8⁺ T cell epitopes encoded by a HERV-H copy located on Xp22.3^[77].

FUTURE PERSPECTIVES

At the moment, in the field of HERVs more questions are open than answered. Are there human (tumor-) cells producing virus particles? If so, are those particles infectious? Further analyses on expression of HERV sequences and proteins - and in especially of Env proteins - would add to the full picture and understanding of the relationship of tumors and endogenous retroviruses. In a first step the mutual interaction between HERV Env and the immune system, also in a suppressive manner, has been addressed^[26,30,31]. These analyses should be expanded. Especially a broader knowledge on tumor infiltrating cells specific for HERV epitopes and their prognostic value would be interesting. Furthermore, it would be very beneficial to know if there is a correlation between tumor grade, stage, progression or outcome and the expression of HERV sequences.

CONCLUSION

Our understanding of HERVs has come a long way. They must be considered as domesticated retroviruses with even main functions in evolution. On the level of an individual human being, however, their activities most likely are tightly controlled. Heavy genetic disorders, as present in tumor cells, generally seem to be linked with HERV activities. The tumor-specific expression of HERV-encoded proteins opens the way to diagnostically and therapeutically interesting opportunities: (1) The targeting of HERV proteins either biochemically or immunologically as TSAs; (2) Immune recognition of tumor cells takes place already early in tumor development. HERV-encoded ORF-derived proteins are likely candidates of this early recognition. Consequently, they may be ideal for screening people at risk to develop cancer as we suggested for frameshift mutations in lynch syndrome^[72,78]; (3) the recognition of expressed HERV sequences by the adaptive immune system is likely to result in a better prognosis for patients raising to-be-defined minimum levels of immune responses. Such HERV-specific responses may well be suited for prognostic purposes.

POSTULATES

We would like to take the chance and hypothesize on

some of the open questions and obvious tasks in the HERV/tumor field: APOBEC and other retroelement controlling factors are likely to be inactivated in cancer cells with active HERV-driven oncogenesis. If this is frequently the case, they must be considered tumor suppressor genes and screening for their inactivation would possibly hint towards specific HERV activation.

HERV-encoded TSAs are released into the circulation^[79] and thus screening of HERV-TSA blood levels will become an interesting field of investigation. Similarly, HERV-specific (immune-) therapies will be developed in the near future for several tumor entities. For these immunotherapies, beside knowledge about expression in different tumors, the level of tolerance towards HERV-TSAs will guide the decision on which candidates to investigate in clinical trials.

Abstract

Celiac disease (CD) is one of the most common diseases, resulting from both environmental (gluten) and genetic factors [human leukocyte antigen (HLA) and non-HLA genes]. The prevalence of CD has been estimated to approximate 0.5%-1% in different parts of the world. However, the population with diabetes, autoimmune disorder or relatives of CD individuals have even higher risk for the development of CD, at least in part, because of shared HLA typing. Gliadin gains access to the basal surface of the epithelium, and interact directly with the immune system, *via* both trans- and para-cellular routes. From a diagnostic perspective, symptoms may be viewed as either "typical" or "atypical". In both positive serological screening results suggestive of CD, should lead to small bowel biopsy followed by a favourable clinical and serological response to the gluten-free diet (GFD) to confirm the diagnosis. Positive anti-tissue transglutaminase antibody or anti-endomysial antibody during the clinical course helps to confirm the diagnosis of CD because of their over 99%

specificities when small bowel villous atrophy is present on biopsy. Currently, the only treatment available for CD individuals is a strict life-long GFD. A greater understanding of the pathogenesis of CD allows alternative future CD treatments to hydrolyse toxic gliadin peptide, prevent toxic gliadin peptide absorption, blockage of selective deamidation of specific glutamine residues by tissue, restore immune tolerance towards gluten, modulation of immune response to dietary gliadin, and restoration of intestinal architecture.

INTRODUCTION

Celiac disease (CD) is a life-long gluten-sensitive autoimmune disease of the small intestine affecting genetically susceptible individuals worldwide. CD individuals may present gastrointestinal symptoms, extraintestinal symptoms or no signs of symptoms. The classical symptoms include gastrointestinal-related symptoms such as diarrhea, steatorrhea and weight loss due to malabsorption. About 50% of CD patients present extraintestinal or

atypical symptoms, such as anemia, osteoporosis, dermatitis herpetiformis, neurological problems and dental enamel hypoplasia^[1-3]. The variable clinical picture of CD is due to having both genetic and immunological bases, with age of onset, extent of mucosal injury, dietary habits, and gender^[4], affecting the clinical manifestation of the disease.

CD diagnosis is based on presence of predisposing genetic factor human leukocyte antigen (HLA) DQ2/8, with positive biopsy and serological antibodies upon gluten contained diet. The spectrum of CD may present in different forms^[5]. The classical form may be diagnosed at any age of life and is often characterized by crypt hyperplasia and villous atrophy along with features of malabsorption. The atypical form is characterized by positive celiac serology, limited abnormalities of the small intestinal mucosa or no intestinal symptoms, but associated extraintestinal conditions such as osteoporosis, peripheral neuropathy, anemia and infertility. The latent form is defined by presence of predisposing gene HLA-DQ2 and/or HLA-DQ8, normal intestinal mucosa and, possible positive serology. Extraintestinal features and biopsies of the small bowel show alterations with gluten intake (i.e., gluten-sensitive). Rarely, usually after age 50 years^[6], some that have initially responded to a gluten-free diet (GFD), develop recurrent symptoms and biopsy changes despite a GFD. This is the refractory form^[7]. If no response to GFD was initially documented, however, the use of sprue-like intestinal disease or unclassified sprue has been used.

PREVALENCE

CD originally thought to almost exclusively affect white Europeans, is now known to be widely distributed worldwide^[8]. Epidemiological studies conducted in areas supposedly free of CD, including Africa, the Middle East, Asia, and South America, show that the disease was previously underdiagnosed^[9]. This provides evidence that CD is one of the most common genetic diseases, resulting from both environmental (gluten) and genetic (HLA and non-HLA genes) factors.

The world distribution of CD seems to have followed the mankind wheat consumption and the migratory flows. Man originally fed on meat, fruit and vegetables, with no exposure to gluten-containing cereals. It was only about 10 000 years ago in a small region called the "Fertile Crescent" of the Middle-East (including Anatolia (Southern Turkey), Lebanon, Syria, Palestine and Iraq) where wild wheat and barley grains successfully cultivated due to favorable environmental conditions. In the Fertile Crescent some tribes changed from nomadic to stable settlement style of living because land cultivation permitted food storage, and later migrated westwards to obtain new lands for cultivation. These persons spread through the Mediterranean area (Northern Africa, Southern Europe) and Central Europe. The expansion continued from 9000 to 4000 BC by which

time the cultivation of wheat and barley had spread all over the Old Continent, also reaching Northern Europe (Ireland, Denmark and the Scandinavian countries). This expansion in farming was due to the diffusion of agricultural practices and replacement of local inhabitants by descendants from the Middle-East^[10]. Hence, the European and North-African populations share genetic background with the peoples of Middle-East origin.

In the last few years a number of studies in different populations have been carried out using molecular genetics methods to identify genes causing CD. CD-predisposing genetic loci are *CELLAC1* on chromosome 6, *CELLAC2* on chromosome 5q31-33^[11], *CELLAC3* on chromosome 2q33^[12], and *CELLAC4* on chromosome 19p13.1^[13]. *PARD3* and *MAGI2* tight junction genes associations have also been reported in Dutch CD or ulcerative colitis patients, suggesting a common intestinal defect in these two conditions^[14]. Another gene expressed in major histocompatibility complex (MHC) I antigen presenting cell is *HLA B8*, was found to be associated with CD in Algeria^[15], Iraq^[16,17] and Turkey^[18]. Moreover, atypical CD Saharawi patients were found to over-express the MHC class I chain-related gene A (MICA) allele 5.1^[15], which have also been reported in Western countries^[19]. Increased prevalence of HLA-A25 in Turkish children with CD was also reported, suggesting that this genotype is particularly encountered among this population^[18], with no association described in Western countries.

Useful Background: Genes causing CD *CELLAC1* on chromosome 6 (*HLA-DQ2* and *HLA-DQ8*); *CELLAC2* on chromosome 5q31-33^[11]; *CELLAC3* on chromosome 2q33 (containing T lymphocyte regulatory genes *CD28*, *CTLA4* and *ICOS*)^[12]; and *CELLAC4* (myosin IXB gene, *MYO9XB*) on chromosome 19p13.1^[13].

HLA genotype contributes to the genetic risk for CD at 30%-50%^[20,21]. Non-HLA genes contribute more evidence to the CD genetic background than the HLA genes, but each by itself contributes only a modest to the disease development. Hence, it is reasonable to assume that the susceptibility to CD involves with polymorphic genes that influence the immune response to gluten, as shown for the HLA-linked genes^[22].

Ninety percent of European patients with CD carry the HLA-DQ2 molecule, encoded either in cis on the HLA-DQA1*0501-DQB1*0201 haplotype (HLA-DQ2.5cis) or in trans on the HLA-DQA1*0505 DQB1*0301/DQA1*0201-DQB1*0202 haplotypes (HLA-DQ2.5trans). Approximately 5% express HLA-DQ8, encoded by HLA-DQA1*0301-DQB1*0302. The majority of the remainder carry the HLA-DQA1*0201-DQB1*0202 haplotype^[20]. With genetic testing, DQ2 is almost synonymous with DQB1*02, a gene with two common alleles designated DQB1*0201 and DQB1*0202. The DQ2 frequency in Caucasian in Western Europe populations has been estimated at 20%-30%, and relatively high frequencies also occur in Northern and Western Africa, the Middle East and central Asia^[23]. Thereafter, the overall frequency of DQ2 declines from West to East with low frequencies in

populations in South-East Asia and the virtual absence of DQ2 in Japan (Table 1). DQ8 frequency has a worldwide distribution, whereas DQ2.5, is common in South and Central America; approximately 90% of Amerindian populations carry DQ8 and may display the celiac phenotype^[24,25]. The frequency of DQ8 population is shown in Table 1.

In the past, the prevalence of CD had been underestimated, but it is now regarded one of the most common genetic disorders in the West with 1% prevalence^[26-28]. In-

**Figure 1** Prevalence of celiac disease worldwide. N/A: Not available.

terestingly, there is increased prevalence of CD amongst women compared to men with male:female ratio of 1:2.8^[29]. This could be due to the finding that men with CD were diagnosed at an older age^[30]. Indeed, there have been reported CD cases among immigrant children native of Eastern Europe, Northern, West and East Africa, the Middle East and Southern Asia, according to their acquisition of Western dietary practices (i.e., short period or lack of breast feeding and early weaning with a great amount of gluten intake)^[31]. This suggests that many persons may have the genetic predisposition to CD but the clinical presentation only occurs when there is sufficient gluten in the diet.

Normal at-risk persons

In several parts of the world, the presence of the combination of antibody (serum tissue transglutaminase and endomysial autoantibodies) positivity and an HLA haplotype associated with CD is predictive of small-bowel abnormalities indicative of CD. For the majority of countries, the CD prevalence is unknown. Figure 1 shows a range of estimated normal at-risk CD prevalence in continents and nations around the globe. It must be noted that some studies report prevalence of CD based on serology, others on celiac compatible small bowel biopsies and a few on serology, biopsy and response to gluten challenge.

North America

CD prevalence in North American and Europe were found to be similar in symptomatic patients and not-at-risk subjects. In the United States, CD is believed to affect 0.5%-1.0% of the general population^[32]. The study by Fasano *et al*^[28] on serum antibody and biopsy screening were performed for a total of 13 145 United States subjects: first-degree ($n = 4508$) and second-degree relatives of patients ($n = 1275$) with biopsy-proven CD, symptomatic patients ($n = 3236$) (with either gastrointestinal symptoms or a disorder associated with CD), and not-at-risk individuals ($n = 4126$). The overall CD prevalence is 1:133 in the not-at-risk groups, whereas in the at-

risk group, the prevalence is 1:22 in first-degree relatives, 1:39 in second-degree relatives, and 1:56 in symptomatic patients^[28].

South America

In South America, CD had been historically considered a rare disorder and the prevalence investigations have not been extensively studied. However, during the last few years studies in Brazil disclosed a prevalence of 1:681 in healthy blood donors^[33] and 1:473 among adult out-patients attending a clinical laboratory for routine blood testing^[34]. In an urban area of Argentina, the overall prevalence of CD, among 2000 adults from the general population (996 women; median age 29 year, range 16-79 year) was 1:167, with prevalence in women double that for men^[35]. The high CD prevalence in Argentina could be correlated with HLA DQ8 (> 20%) in the Argentina population.

Europe

The overall prevalence of CD in Western populations is close to 1% (1:100) and may be higher in Northern European countries (Table 2)^[36-38]. The Scandinavian countries, Ireland, and the United Kingdom population tended to show a higher prevalence of CD of approximately 1.0%-1.5%, although there also were studies that showed a lower prevalence in these countries. A study of small-intestinal biopsy obtained from healthy Dutch blood donors at Arnhem and Nijmegen Blood Donation Centers shows that the prevalence of CD-compatible biopsies of 1:330^[39]. The prevalence of CD among 3654 children (age range, 7-16 years) in Finland was at least 1:99 based on serum autoantibodies and small-bowel abnormalities^[40]. The prevalence of CD in Northern Spain in the general population was 1:389^[41], 1:132 (0.75%) in Eastern Switzerland adolescents^[42].

Africa

In Northern African populations (including Morocco, Algeria, Tunisia, Libya and Egypt) higher incidences of 0.28%-5.6% of CD have recently been reported in the

general population^[43-46]. The prevalence of CD in asymptomatic Tunisian school children was estimated to be about 1:157, which is close to the European prevalence. In this respect, the highest world frequency of 16.4% is reported in the CD associated with Insulin Dependent Diabetes Mellitus^[47], in Oran (Algeria). A recent serological screening in 2500 Tunisian healthy blood donors^[45], showed similar that the prevalence of anti-endomysium antibodies in the general population of 1:355, to that of Europeans. Due to high wheat and barley consumption in the North American countries^[45], as well as high frequency of CD predisposing DR3-DQ2 haplotypes in these populations^[48-50], these high CD frequencies are not surprising.

Saharawi population in North Africa, who are of Arabian and Berberian origin, having a high degree of cognation and live as refugees in the Sahara desert (Algeria), has the highest prevalence of CD (5.6%) known in the world today^[43,49]. This elevated prevalence in this population may be explained both by genetic factors: very high frequency of the DR3-DQ2 haplotype, and by environmental factors: changed of dietary habits in the last few decades. The reduced rates and duration of breast-feeding and increased consumption of gluten in early life as part of the staple diet, supplied by Western countries as humanitarian aids^[51], may have played a role in this elevated CD prevalence. However, there are other unknown genetic and environmental factors that explain such a high frequency of CD in the Saharawi people, because there is a much lower prevalence of CD in Sardinia population with similar staple diet consumption and frequencies of DR3-DQ2^[52].

Australia and New Zealand

Australia and New Zealand are the two countries having the highest proportion of individuals from Caucasian background, with high prevalence of HLA DQ2 and per capita wheat consumption of > 150 and 75-150 kg per person per year, respectively^[23]. Only two prevalence studies have been carried out in these two countries. From a random population of 1064 adults in Christchurch, New Zealand (96% Caucasian), CD was confirmed histologically in all patients with positive serology giving an overall prevalence of 1:82 (1.2%)^[53]. A larger study in 3011 adults from a large Caucasian community in Western Australia, revealed an overall prevalence of CD of 1:251 (0.4%) of the population^[54].

Asia

CD is likely to be rare in Indonesia, South Korea, Philippines and many smaller Pacific islands because of their low wheat consumption and a low frequency of HLA-DQB1*02. In South-East Asia, HLA-DQB1*02 is often present in more than 5% of the population but CD is predicted to be rare, as staple diets are based on rice. In contrast, prevalence rates that are similar to those in Europe are likely to apply from Pakistan in the South to Kazakhstan in the North. Ancient migration patterns

Table 3 High risk populations for celiac disease^[73] (adapted)

Relatives, especially first-degree

Skin disorders, particularly dermatitis herpetiformis
Neurological disorders, including ataxia, seizures, myasthenia gravis
Others, including immunoglobulin A nephropathy

that determine the frequency of DQB1*02 would also predict more patients with CD in Western China than in Eastern China^[23]. Interestingly, there is one report of CD in three adult descendants of Chinese and Japanese families who migrated to Canada^[55].

In genetic studies of CD in India, the appearance of HLA associations is similar to those in Western countries with a frequency of HLA-DQB1*02 of close to 100%^[56]. This association is more frequent in the population of Northern and North-Eastern India (16%-27%)^[57], than in groups of adults in the Southern state of Tamil Nadu (9%-14%)^[58]. The prevalence of CD in India is nearly the same as that in Western Caucasian populations^[59]. In Punjab (North-west India) school children, CD frequency was estimated to be 0.3%^[60]. This prevalence is probably an underestimation. A retrospective analysis of confirmed cases of CD between 1995 and 2000 in Dayanand Medical College and Hospital (Ludhiana, Punjab) from a total of 202 cases showed an initial of 10 positive cases with a significant growth rate of 79.43% annually with a trend equation increase of 15.49 cases/year^[61]. These studies showed that CD is relatively common in Northern India where there has been a history of wheat cultivation from before 1000 BC^[62]. Hence, the relative rarity of CD in Southern India reflects the effect of both genetic and environmental factors.

The prevalence in first-degree relatives of North Indian children with CD diagnosed as per the European Society for Pediatric Gastroenterology and Nutrition criteria is 4.4% of the first-degree relatives (85% positive for HLA DQ2/DQ8), which is 14 times higher than that of the general population^[63]. There have been reports on clinical experience of biopsy-defined CD in 10 North Indian Immigrants or descendants born in Canada out of 14 Asians diagnosed since 1988 in a single Canadian teaching hospital^[55]. Several studies, particularly from Northern and North-West India, have also documented the presence of CD in children presenting with chronic diarrhea^[64].

Middle East

It seems likely that the prevalence of CD in the Middle East is similar to that of Europe^[65]. CD is a relatively common cause of chronic diarrhea in Iran, Iraq and Kuwait and has been diagnosed in 2%-8% of patients with type 1 diabetes in Iran, Israel and Saudi Arabia^[39]. Many

of these countries have a per capita wheat consumption that ranks among the highest in the world (> 150 kg per person per year)^[23]. Although only a limited number of genetic studies have been carried out, the population of countries such as Iran, Israel, Saudi Arabia and Turkey have a high frequency of HLA-DQB1*02. The prevalence of CD in adult blood donors in Iran, Israel, Syria, Turkey and Anatolia are 1:166^[66], 1:157^[67], 1:62^[68], 1:87^[69], 1:100^[70], respectively. Similar prevalence rates were determined in surveys of Iranian children (1:165, 0.6%)^[71], and Turkish children (1:115, 0.9%)^[72].

The prevalence of CD is approximately 0.5%-1% in all parts of the world, except for populations with very low and very high intake of gluten in their diet.

High at-risk persons

In the general celiac population (without classical CD symptoms, e.g., diarrhea or weight loss), there are high risk groups that may have higher CD prevalence rates (Table 3). Among factors that denote a higher risk for CD, the most important factor is familial history of biopsy proven CD with an estimate of 20% or more of first-degree relatives having CD^[73]. Some authors observed a higher prevalence in CD siblings as compared to parents^[74-76]. A study in Swedish youth (< 20 years old) diagnosed with type 1 diabetes (T1D) confirmed the low prevalence (0.7%) of diagnosed symptomatic CD at initial onset of clinical diagnosis, but document by screening an increasing prevalence of silent CD during a 5-year follow-up to reached an overall prevalence of 10%^[77]. Thus, the prevalence of an association with CD in high risk groups may increase over time.

The overall prevalence of CD is highly dependent on the HLA DQ2/DQ8 typing and gluten consumption. The population with positive HLA typing for celiac have high chances of developing celiac symptoms when on high gluten consumption. However, the population with diabetes, autoimmune disorder or relatives of CD individuals) have even higher risk for the development of CD, since they share the same HLA typing.

PATHOGENESIS

CD is an intestinal enteropathy triggered by the ingestion of gliadin and of other related prolamins in genetically predisposed individuals^[22,78]. Wheat and related species such as barley and rye also induce CD^[79]. A small minority of CD patients also react to oat^[80]. Gliadin peptides exert damaging effects since they are resistant to gastrointestinal enzymes^[81], they have amino acid sequences that are specific for HLA-DQ2, which is a class II major histocompatibility complex, they also have preferred glutamine residues for tissue transglutaminase (tTG)-mediated deamidation^[82], and lastly, they affect intestinal permeability^[83]. Hence the pathogenesis of CD is dependent on genetic and environmental factors. The environmental factor is mainly ingestion of gluten, while several genes contribute to the genetic predisposition^[13]. CD commonly

Table 4 Possible clinical manifestations of celiac disease^[8] (printed with permission)

Typical symptoms	Atypical symptoms	Associated conditions
Chronic diarrhea	Secondary to malabsorption	Possible gluten dependent
Failure to thrive	Sideropenic anemia	IDDM
Abdominal distention	Short stature	Autoimmune thyroiditis
	Osteopenia	Autoimmune hepatitis
	Recurrent abortions	Sjogren syndrome
	Hepatic steatosis	Addison disease

appears in early childhood, with severe symptoms including chronic diarrhea, abdominal distension, and failure to thrive. In many patients, symptoms may not develop until later in life, when the disease symptoms include fatigue, diarrhea, and weight loss due to malabsorption, anemia, and neurological symptoms (Table 4). Celiac disease is a life-long disorder, and if untreated, it is associated with increased morbidity and mortality^[84, 85].

Possible triggers

Genetic predisposition association (HLA, MYO9B), exogenous trigger (gluten), pro-autoimmune genetic background, viral infections, tissue damage, early termination of breastfeeding and gender contribute to the development of CD (Table 5)^[86].

Apart from introduction of gluten during the first year of life, infectious agents may play a role in development of CD. Several studies have implicated infections with Adenovirus type 12^[87-89], hepatitis C virus^[90,91], *Campylobacter jejuni*^[92], *Giardia lamblia*^[93], Rotavirus^[94] and Enterovirus infection^[95] as triggers for the development of CD. The immunologic response in persons genetically susceptible

Table 5 The most important factors contributing to the development of celiac disease^[86] (printed with permission)

Factors contributing to the onset of celiac disease	Mechanism
Gluten	Elicit T cell responses Induces cytokine production and intestinal lesion
Age of introduction of gluten	Weak gut immune during early childhood
HLA-DQ2 or HLA-DQ8	Gluten presentation
MYO9Bo	Increased permeability of the intestine
Pro-autoimmune genetic background	Shift in Th1/Th2 balance towards Th1
Viral infections	Defect in generation of active tolerance (e.g., regulatory T cells) IFN production
Tissue damage	Tissue damage Increased level of tTG Danger signals
Early termination of breastfeeding	Decreased protection against infections
Gender	Hormone-related pro-autoimmune status

Th1: T helper 1; Th2: T helper 2; tTG: Tissue transglutaminase; HLA: Human leukocyte antigen; IFN: Interferon.

CD may be triggered due shared viral sequence of 8 to 12 amino acids with the toxic gliadin fraction^[89]. Other factors such as timing of gluten ingestion and breast feeding cessation may involve in the pathogenesis and disease development of CD^[96]. Some initiating factors, such as gluten overload, gastric surgery “unmasking”, giving up smoking, and infections can also trigger the disease, which can become apparent in an abrupt manner^[97,98].

Prolamin trigger

Gluten is a protein that appears in wheat, barley, rye and oat, compositing of prolamin and glutelin. The majority of the proteins in food responsible for the immune reaction in CD are the prolamins. Prolamins is found in several grains, such as wheat (gliadin), barley (hordein) and rye (secalin), corn (zein) and as a minor protein, avenin in oats. Because of their high glutamine content and specific sequence patterns, prolamins are resistant to gastrointestinal proteolytic enzymes and are excellent substrates for deamidation by tissue transglutaminase.

The incomplete gastrointestinal digestion of gluten leads to the appearance of gluten-derived gliadin peptides such as 33mer (LQLQFPQPQLPYPQPLPYPQPQLPYPQPQPF) with a variety of characteristics^[81]. It contains overlapping T-cell epitopes, and its deamidated form is a potent T-cell stimulator, generating the glutamic acid residues essential for binding to HLA-DQ2 in celiac patients^[99]. The ingestion of prolamins from wheat, barley, rye and possibly oats causes histological changes in the small intestine mucosa of celiac patients, leading to a malabsorption syndrome^[100]. Clinical symptoms of an autoimmune attack after ingestion of the gluten containing food include digestive symptoms and skin reactions.

Gliadin peptides cause stimulation of the innate and adaptive immune system^[83,101,102]. The prototype of pep-

tides effective on innate response is peptide 31-43/49, which has been proved both *in vitro* and *in vivo* to be toxic for CD patients^[103,104]. Peptide 31-43 (p31-43) stimulates the synthesis and release of interleukin (IL)-15, a proinflammatory cytokine, that promotes the adaptive immune response^[101], involving CD4+ T cells that recognize several deamidated gliadin peptides^[82]. Unlike p31-43 which is not immunogenic for T cells, peptide 57-68 (p57-68), which binds to HLA-DQ2/8 molecules, is one of the dominant epitopes recognized by T cells isolated from the intestine of CD patients^[82]. The so-called toxic peptides, of which p31-43 is probably the most fully studied, modulate the small-intestinal mucosal biology *via* an innate immune mechanism.

Time of trigger

Several studies related the rise in childhood CD to infant feeding practices^[96,105]. Consumption of wheat, barley, and rye in the first 3 mo children have significantly increased the risk of developing CD-associated autoantibodies, as compared with exposure during first 4 to 6 mo^[105,106].

Although CD can be diagnosed at any time of life, it is present mostly in either early childhood (between 9 and 24 mo) or in the third or fourth decade of life^[8,85,107,108]. In contrast to the 1/1 sex ratio in children, in adulthood it is diagnosed twice in females. Interestingly, celiac disease is also becoming more frequently recognized in the elderly, and in this population, a 1/1 sex ratio has also been noted^[109]. Although the “classical” gastrointestinal malabsorption syndrome characterized by diarrhea, steatorrhea, weight loss, fatigue, and anemia may occur in severe cases, most patients have a milder symptoms such as abdominal discomfort, bloating, indigestion, or non-gastrointestinal symptoms (or no symptoms at all)^[8,85,107,108]. Mäki *et al.*^[2] reported a shift of 5-6 years of age at diagnosis in Finland, with less than 50% of new cases presenting typical gastrointestinal symptoms. In England^[110], Scotland^[111], Canada^[112], and the United States^[28], reports have also shown that almost 50% of newly diagnosed CD patients do not present with gastrointestinal symptoms.

GENETICS

Genetics play a strong role in CD, indicated by the high disease concordance in monozygotic twin^[113]. The CD prevalence rose to 17.6% in sisters, 10.8% in brothers, and 3.4% in parents^[21]. CD is associated with HLA alleles as well as more than 250 other MHC and non-MHC genes. The main genetic factor is the given HLA-DQ genes, i.e., the genes encoding DQ2 or DQ8 in the HLA complex on 6p21. Approximately 95% of celiac have a DQ2 comprised of DQB1*302 and DQA1*03. A small number of individuals lacking either of those heterodimers have DQB1*02 and DQA1*05 alone^[20,114]. Gene dosage also affect CD susceptibility; individuals with the heterodimer comprised of DQB1*02 and DQA1*05 and most of the remaining 5% have a DQ8 heterodi-

Figure 2 Factors necessary for celiac disease development^[96] (adapted). HLA: Human leukocyte antigen.

mer. Homozygous individuals who carry DQB1*02 and DQA1*05 in cis on both chromosomes have a great risk developing complicated forms of CD^[115]. A significant higher risk for CD of 1:7 for DQ2 and DQ8 individuals and 1:2518 for subjects lacking all predisposing factors have been determined^[21].

It is found that 30% of the Caucasian populations carry HLA-DQ2 and most will eat wheat, while only 1 in 100 will develop disease^[116]. The remaining susceptibility is thought to be due to a combination of genetic and environmental factors (Figure 2).

HLA-DQ2.5 carriage is necessary for disease development, but it is not sufficient by itself. A combination of other genetic factors influencing the mucosal barrier, the adaptive and the innate immune system also impact the likelihood of disease development. Wheat ingestion is a known environment factor that is necessary for disease development but on top of this, a number of factors such as timing of gluten ingestion and breast feeding cessation may influence disease development^[96].

Studies using twins, which are assumed to share environmental factors, have estimated the percentage of non-HLA genetic variants which predispose to disease as approximately 60%^[117]. To date a large list of variants have been suggested to predispose to CD through a combination of linkage and association studies, a large number of variants, however, do not stand up to further scrutiny. Only those that have been validated with convincing evidence in multiple populations are mentioned here.

In CD, like many common diseases, this genome wide linkage approach has been fairly unsuccessful at locating variants. Linkage was found to various regions including 5q and 19p, however, the only genomic region that was replicated with some reliability in other populations was 2q33, a region that contains the *CTLA4*^[118], *ICOS* and *CD28* genes^[117]. *CTLA4* is an excellent candidate gene for involvement in CD not only due to its integral involvement in the suppression of immune responses but also because it has been implicated as a genetic variant that increases susceptibility to T1D.

The prevalence of CD in patients diagnosed with T1D has been estimated at up to 15% in children and 6% in adults^[119]. The reason for this association has never been fully elucidated, but common mechanisms within the pathogenesis and genetics of the two conditions may provide some insights. IL-21 region displays CD associations to T1D^[120], rheumatoid arthritis^[121], Grave's

disease^[122] and psoriatic arthritis^[123]; but genetic involvement in all these conditions is not currently understood. There is possibility of shared genetic susceptibility to autoimmunity through *IL-2*, *IL-21* locus, both inside and outside of the HLA region, with almost no function identified thus far^[116]. Like the studies associated with the HLA-DQ2.5 variant, further identification of the causal variant and its function will provide a unique insight into CD and other autoimmune disease biology.

Immune function

CD is an autoimmune disease associated with the genetic predisposition HLA and tTG autoantigen. tTG is a calcium dependent enzyme that plays a crucial role in CD pathogenesis^[124]. tTG mediates ordered and specific deamidation of gliadins, creating an epitope that binds efficiently to DQ2 and is recognized by gut-derived T cells^[125]. During gluten consumption, these tTG autoantibodies are produced by the mucosa of the small intestine, and detected in patients' serum but disappear slowly from the patient's circulation on a GFD^[126]. Extraintestinal CD symptoms may be associated with immunoglobulin A (IgA) deposits on extracellular tTG in the liver, kidney, lymph nodes and muscles of CD patients^[126].

The toxic peptides, such as the 19-mer, trigger an innate immune response^[101], characterized by the production of IL-15 by epithelial cells and lamina propria dendritic cells^[127]. There is some evidence that this response is a generalized response in all individuals, but is amplified in CD patients (possibly due to a lower threshold to IL-15) who only get disease as a result of adaptive immune system involvement^[128]. IL-15 affects the epithelial barrier, both by increasing the permeability through disruption of the tight junctions^[129,130] and acting on intraepithelial lymphocytes (IELs) promoting interferon γ (IFN- γ) production as well as a potent cytotoxic activity particularly by NKG2D⁺ cells^[131,132]. Therefore, immunoadaptive peptides, like the 33-mer, can now reach the lamina propria, where they are presented by dendritic cells to gluten-specific T cells^[133,134].

Other autoantigens that are normally "cryptic" can be unmasked and cause a self-aggressive immunologic response following the gliadin-initiated inflammatory process^[8]. In fact, persistent stimulation by some proinflammatory cytokines (IFN- γ and tumor necrosis factor α) can cause further processing of autoantigens and their presentation to T lymphocytes by antigen-presenting cells. The mucosa is expanded by increased numbers of lymphoid cells both in the intraepithelial compartment, in which there is an increase in $\gamma\delta$ T cells, and in the lamina propria, which is expanded by lymphocytes and plasma cells. The intestinal crypts are elongated because of an increase in dividing epithelial cells, and villi are shortened or even completely absent because of rapid loss of mature epithelial cells from the villus tip.

Intestinal epithelium function

Intestinal epithelium plays a central role in CD disease

pathogenesis. It modulates the intestinal immune system that is acutely altered by gliadin. This indicates that gliadin can gain access to the basal surface of the epithelium, and therefore interact directly with the immune system, *via* both trans- and paracellular routes of absorption (Figure 3).

Retrotranscytosis

The protected retrotransport of secretory IgA into the intestinal lumen *via* the transferrin receptor CD71, allows the entry of intact and thus harmful gliadin peptides into the intestinal mucosa by a transcellular route. The overexpression of the transferring receptor CD71 in patients with active CD by transportation of gliadin across the intestinal mucosa through retrotranscytosis of secretory immunoglobulin-gliadin complexes is shown in Figure 4^[135,136].

Transcytosis of α 2-gliadin-33mer (an important trigger of CD) by apical-to-basal is stimulated by IFN- γ , which is a key cytokine involved in CD immunopathogenesis^[137].

Paracellular route

There have been recent hypothesis associated with non-digested gliadin absorption in the intestinal lumen during the early event in CD pathogenesis by stimulation of the innate and adaptive immune system^[83,101,102]. Zonulins provide information on the regulation of intercellular tight junctions (TJs) and increased intestinal permeability^[138-142]. It is released by the enterocyte upon apical exposure to α -gliadin digests^[129,143]. Lammers *et al.*^[143] have identified that MyD88 induces release of zonulin upon gliadin binding to CXCR3 on enterocytes, as a result inducing greater epithelial permeability and subsequent paracellular gliadin passage to the gut mucosa.

After binding to its surface receptor, gluten is internalized^[144] and subsequently triggers a series of intracellular events including phospholipase C and Protein kinase Ca activation and actin polymerization, which lead to the opening of TJs^[139,145] through Zot/Zonulin receptor (Figure 5).

Other pathways

There are several pathways including cellular signals that may be involved in the mucosal damage in CD. Deamidation of gluten peptides by tissue tTG reinforces presentation of gluten peptides by HLA-DQ2 or HLA-DQ8 molecules of plasmacytoid dendritic cells (pDCs) to T cells, which activate gluten-reactive Th1 cells and produce high levels of proinflammatory cytokines. IL-21 is overproduced in the mucosa of CD patients, where it helps sustain T-bet expression and IFN- γ production^[146]. Th1 cytokines promote increased cytotoxicity of IELs and natural killer (NK) T cells which cause apoptotic death of enterocytes by the Fas/Fas ligand system, or IL-15-induced perforin/granzyme and NKG2D-MICA signaling pathways. IFN- α released by activated pDCs perpetuates the inflammatory reaction by inducing Th1

Figure 3 Mechanisms of mucosal damage in celiac disease^[80] (adapted). Gliadin peptides cross the enterocyte by paracellular tight junctions (TJ) as a consequence of increased release of zonulin leading to impaired mucosal integrity upon 19 mer gliadin binding to chemokine (C-X-C motif) receptor 3 (CXCR3) receptor, or via transcytosis, or retrotranscytosis of secretory immunoglobulin A (IgA) through transferrin receptor CD71. Tissue transglutaminase (tTG) deamidates or crosslinks 33 mer gliadin which is then recognized by human leukocyte antigen (HLA)-DQ2 or -DQ8 molecules of antigen presenting cell (APC). APC presents the toxic peptide to CD4+ T cells. Activated gluten-reactive CD4+ T-cells produce high levels of pro-inflammatory cytokines. T helper 1 (Th1) cytokines promote increased cytotoxicity of intraepithelial lymphocytes (IELs) and natural killer (NK) T cells which cause apoptotic death of enterocytes by the Fas/Fas ligand (FasL) system, or interleukin 15 (IL-15)-induced perforin/granzyme and homodimeric natural killer-activating receptor-major histocompatibility-class I chain-related gene A complex (NKG2D-MICA) signaling pathways. The production of T-helper2 (Th2) cytokines activate and induce clonal expansion of B cells, which differentiate into (anti-gliadin and anti-tTG) antibody secreting plasma cells. Interaction between with the extracellular tTG and anti-tTG-autoantibody may induce epithelial damage. TCR: T cell receptor.

cells to produce IFN- γ . IL-21 and IL-15 produced by DCs and intraepithelial cells also inhibit transforming growth factor beta signaling and regulatory T cells (Tregs) function. Additionally, the production of Th2 cytokines, Th2 cells drives the activation and clonal expansion and differentiate of B cells into plasma cells secreting anti-gliadin and anti-tissue transglutaminase antibodies^[147], which interact with extracellular tTG, and may induce epithelial damage.

Hence in CD, there is impaired suppressor activity of Tregs. This defect in Tregs function could play a role in the pathogenesis of CD and in CD autoimmunity^[148].

DIAGNOSIS

Approach to initial CD diagnosis

In 1970, the European Society of Paediatric Gastroenterology laid down criteria for the diagnosis of CD in children, entailing three biopsies of an initial flat mucosa in the upper small intestine, restoration of the mucosa to

normal on a GFD, and a deterioration of the mucosa after gluten challenge^[149]. Given the current availability of serological tests being highly sensitive and specific, the European Society of Paediatric Gastroenterology, Hepatology, and Nutrition has proposed a revised CD diagnostic protocol^[150]. Based on this protocol, if the symptoms (either “classical” or “atypical”) and serological tests are suggestive of CD, small bowel biopsy followed by a favourable clinical and serological response to the GFD is now considered sufficient to definitely confirm the diagnosis. In asymptomatic patients improvement in mucosal appearance may be required to confirm the diagnosis, but in majority symptomatic patients, continual abnormality of mucosa at the second biopsy is more likely to indicate slow /partial mucosal recovery^[151]. This may also reflect that the site of re-biopsy (proximal small intestine) is often the last site to improve.

The current approach to evaluating CD has been modified by the advent of highly sensitive and specific serological tests. An algorithm for diagnosing CD is

Figure 4 CD71 receptor-mediated transport of immunoglobulin A-gliadin complexes in celiac disease^[136] (adapted). Gliadin bound to apically expressed CD71 receptor in active celiac disease individual allows protected transport of gliadin into the lamina propria. SIgA: Secretory immunoglobulin A.

given in Figure 6. Assays for IgA anti-tissue transglutaminase (TGA) and IgA anti-endomysial (EMA) have both the highest specificities and sensitivities, and are therefore regarded as being superior serological screening tools for diagnosis of CD^[152].

Initial CD evaluation is based on a combination of positive CD-specific serological tests, histological findings in the intestinal biopsy, CD-predisposing gene encoding HLA DQ2 or DQ8, family and medical history of CD, and clinical or histological response to GFD^[26,80]. However, CD diagnosis can be challenging in some non-responsive patients to GFD^[7]. Practically all patients with CD carry HLA-DQ2 or HLA-DQ8. Thus the absence of these gene pairs reflects a very high negative predictive value for CD and should prompt consideration of other causes of small bowel-related symptoms and pathological changes^[153,154]. Positive TGA or EMA at initial diagnosis of CD or at any time in the clinical course of the disease helps to confirm the diagnosis of CD because of their excellent specificities of over 99% when small bowel villous atrophy is present on biopsy^[155].

However, false positive serological assays may also occur^[156], in liver disease and small-bowel inflammation^[157], so documentation of gluten sensitivity is important. A combination of biopsy and serological antibody can also be used to support diagnosis to reduce false positive results. A validated subjective Celiac Dietary Adherence Test, a patient-completed tool, can also be used in conjunction with biological markers to assess dietary adherence and disease activity in individuals with CD^[158].

Diagnosis of refractory CD

The influence of noncompliance to a GFD and the substantial number of patients being undiagnosed are of greatest concern, as these factors could possibly contribute to the refractory form of CD and to the devel-

opment of malignancies. These patients' CD symptoms do not revert on GFD. The first evaluation step of a potential RCD case is to confirm correct initial diagnosis of CD^[7]. Sometimes neglected in this determination is the documentation of an initial and convincing response to a GFD, i.e., demonstration that the disease was truly a "gluten-sensitive" small bowel disorder. Otherwise, it may be difficult to ascertain if CD was initially present. More precise terms in this clinical setting include "sprue-like intestinal disease" or "unclassified sprue".

Some patients with developed RCD are likely to have negative TGA and EMA^[6,159], demonstrating that negative CD specific serology does not exclude the diagnosis of CD. A family history of CD in first-degree relatives (especially siblings) further supports the diagnosis of CD in patients, having 14% positive tTG test and 10% positive EMA with an estimated prevalence of 11% where 54% had "silent" disease, most with severe intestinal villous atrophy^[76]. The diagnosis of CD by histological findings or clinical improvement after GFD without confirmation with other diagnostic criteria may not be entirely reliable because CD is just one of many causes of villous atrophy. Clinical response to GFD or exacerbation after gluten re-introduction have low sensitivity of 59% and specificity of 92% for CD^[160], which account to a positive likelihood ratio of 7.37 (means that individuals with positive histology upon gluten re-introduction are 7.37 times more likely to have CD than those with negative histology upon gluten re-introduction) and a negative likelihood ratio of 0.44 (means that individuals with positive histology upon gluten re-introduction are 0.44 times less likely to lack CD than those with negative histology upon gluten re-introduction). Thus, a critical review of prior tests and villous histology is crucial to determine the accuracy of a prior diagnosis of CD. Ideally, documented normalization of biopsies after a GFD and then demonstration of recurrent symptoms with histological relapse best defines refractory CD (RCD). Obviously, this is not always possible.

RCD is believed to affect approximately 5% of patients with CD. It is subdivided into types I and II, with normal and aberrant (expressing cytoplasmic) CD3, but lacking surface expression of the T-cell markers CD3, CD4, CD8^[161], and the T-cell receptor, intraepithelial T lymphocytes in the small intestinal mucosa, respectively^[162]. Enteropathy-associated T-cell lymphoma (EATL) occurs in more than half of patients with RCD II within 4-6 years after RCD II diagnosis, and is the main cause of death in this group of patients^[76,163]. RCD type 1 only rarely evolves into EATL. Recent data indicate a relative risk for patients with (untreated) CD to develop EATL^[164,165].

DIAGNOSTIC TESTS

Serological tests

HLA typing: The contribution of HLA type to the genetic risk for CD has been variously estimated at

Figure 5 Proposed Zot intracellular signal mediated opening of intestinal tight junctions^[146] (printed with permission).

1: Zot interacts with a specific Zonulin receptor; 2: Leading to protein internalization; 3: Activation of phospholipase C; 4: Hydrolyzes phosphatidyl inositol to release inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG), either via DAG or (4a) through the release of intracellular Ca^{2+} via IP3; 5: Protein kinase C alpha (PKC α) is then activated; 6: Membrane-associated, activated PKC α catalyzes the phosphorylation of target protein(s); 7: With subsequent polymerization of soluble G-actin in F-actin; 8: This polymerization causes the rearrangement of the tight junctions (TJ) filaments and displacement of proteins [including zonula occludens-1 (ZO-1)]. As a result, intestinal TJ becomes loosened. IP3: Inositol trisphosphate.

30%-50%^[20,21]. Many of the polymorphic genes are involved in susceptibility to CD encode products that influence the immune response upon gluten ingestion, as shown for the HLA-linked genes^[22]. Although Non-HLA genes contribute more than HLA genes to the genetic background of CD, each of them adds only a minor contribution to the disease development.

There is strong association between CD and the presence of HLA DQA1*0501-DQB1*02 (DQ2) and DQA1*0301-DQB1 [0302 (DQ8) haplotypes. Approximately 90% to 95% of patients with CD carry DQ2 and those patients that are negative for HLA-DQ2 are usually positive for HLA-DQ8^[166,167], indicating a strong genetic risk for the disease^[100]. Several studies also have confirmed that the absence of HLA-DQ2, HLA-DQ8, or both vir-

tually excludes the diagnosis of CD^[168-170]. However, the modest sensitivity (HLA-DQ2, 70%-99.8%; HLA-DQ8, 1.6%-38%) and specificity (HLA-DQ2, 69%-77%; HLA-DQ8, 77%-85%) of the test means that a positive result is not sufficient to diagnose the disease [having a low positive predictive values (HLA-DQ2, 6.3-18; HLA-DQ8, 0.28-8.1) and likelihood ratios (HLA-DQ2, 2.25-4.33; HLA-DQ8, 0.07-2.53)]^[171]. Even the presence of HLA-DQ2 or HLA-DQ8 in patients with positive serologic test results is strongly suggestive but not pathognomonic for CD. Antibody screening to identify participants with preclinical CD may be reduced by preselecting HLA risk group from the large populations with long-term follow-up for CD^[172]. Hence HLA-DQ genotyping could be included in the algorithm of selecting large populations prospec-

Table 6 Operating characteristics of serological markers to detect the celiac disease in adults^[178] (adapted)

tively screened for CD.

Antibody level: Several serum antibodies have been used to initially evaluate patients with suspected CD, monitor adherence and response to GFD, and screen asymptomatic individuals. Anti-gliadin antibodies (AGA) detection has low sensitivity and specificity, leading to high false-positive rate in patients^[173]. Recent reports of deamidated gliadin peptide AGA (DGP-AGA) have suggested a much improved accuracy^[174]. The sensitivity and specificity for IgA DGP-AGA is 84.3% and 79.8%, whereas for IgG DGP-AGA the sensitivity and specificity are 82.3% and 98.9%, respectively^[175]. As shown in Table 6, EMA and TGA have been found to be superior to AGA and gives highest sensitivity and specificity of greater than 95% when used in combination^[173,176,177]. EMA testing, however, produces a subjective and highly observer-dependent result, whereas TGA testing is quantitative.

Small intestinal mucosal biopsy

Histopathological analysis: Although the diagnosis of CD can be suspected on clinical or laboratory grounds, or as a result of serological tests, histology of the proximal small intestinal mucosa is still the diagnostic gold standard and must always be performed. Small intestinal histopathology of CD biopsy samples are characterized by typical architectural abnormalities. Marsh^[178] has pioneered the theory of a sequence of progression of the CD lesion in the small intestinal mucosa.

According to the modified Marsh classification: normal mucosa is classified Marsh 0, intraepithelial lymphocytosis as Marsh I, intraepithelial lymphocytosis and crypt hyperplasia as Marsh II, and intraepithelial lymphocytosis, crypt hyperplasia and villous atrophy as Marsh III^[179]. Later the Marsh-Oberhuber system was developed, where stage 3 was split into three sub stages (a, b and c)^[178,180]. The Marsh-Oberhuber classification was based on a 6-stage grading, namely (1) type 1 infiltrative lesions, characterized by normal mucosal architecture with an increased number of IELs; (2) type 2 hyperplastic lesions, characterized by an increase in crypt depth without villous flattening; (3) type 3a, 3b, and 3c destructive lesion, characterized by mild, marked, and complete villous flattening, respectively; and (4) type 4 hypoplastic lesions, characterized by villous atrophy with normal crypt height and IEL count.

Considering the broad spectrum of lesions possibly present in CD, the Marsh-Oberhuber system is undoubtedly valid under optimal clinical conditions, but the considerable number of diagnostic categories involved makes it prone to a low inter-observer and intra-observer agreement.

False-positive and false negative test results may occur due to patchy mucosal damage, inter-observer variability, low-grade histopathological abnormalities and technical limitations. Hence, reliance on standard histological findings alone may result in failure to diagnose CD^[181]. Several other limitations may be evident in high-volume, service-oriented laboratories with limited attention to quality control. Poorly oriented biopsies fixed in the endoscopy suite may be prone to difficult interpretation. Inter-observer variation in pathological interpretation may occur, especially if there is limited access to a pathologist with expertise focused on interpretation of small intestinal biopsies. Some patients with low-grade histopathological abnormalities (Marsh I /Marsh II) can present with gluten-dependent symptoms or disorders before overt villous atrophy occurs. Furthermore, some patients with isolated intraepithelial lymphocytosis (Marsh I), who are not clinically suspected of having CD, may develop CD during follow-up^[182]. Although the mucosal changes in CD are thought to develop gradually, whether minor mucosal lesions in asymptomatic patients indicate CD in an early stage is not yet clear^[183].

In case of strong clinical suspicion of CD, duodenal biopsy must be performed regardless of serological analysis^[184]; in cases of low suspicion of disease or screening, duodenal biopsy probably only needs to be performed in seropositive patients. Hence, the new system for routine use of simplified grading system with uniform diagnosis and increase validity of the pathologic diagnosis of CD was developed by using only three categories (A, B1 or B2) with A representing normal villous with lymphocytic infiltration and B1 and B2 representing partial and complete villous atrophy, respectively^[185]. The new proposed grading system classified the CD lesions into non-atrophic (grade A) and atrophic (grade B)^[186]. Grade A was characterized by the isolated increase of IELs (> 25/100 enterocytes)^[187], whereas grade B was split into B1, in which the villous/crypt ratio is less than 3/1, with still detectable villi, and B2, in which the villi are no longer detectable. Figure 7 A comparison between the Marsh classification for celiac disease. 1: Marsh-Oberhuber; 2: Grading system for celiac disease, and the new grading system; 3: Representative pictures of the grades A (original magnification, 20×; insert, 60×), B1 (20×), and B2 (20×), proposed in the new grading system. An alternative classification may simply describe “mild”, “moderate” or “severe (flat)” architectural changes^[186] (printed with permission).

Table 7 Factors that support the diagnosis of celiac disease in patients with an increased density of intraepithelial lymphocytes but no villous shortening^[194] (printed with permission)

Family history of celiac disease	15% of first-degree relatives are affected
Concomitant autoimmune conditions	Risk of coeliac disease approximately 5-fold
Increased density of $\gamma\delta$ + IELs	Sensitivity 0.84, specificity 0.91
Increased density of villous tip IELs	Sensitivity 0.84, specificity 0.95
HLA DQ2 or DQ8	High sensitivity, low specificity
Gluten dependence	Negative predictive value high Should be ascertained by gluten challenge or gluten-free diet

IELs: Intraepithelial lymphocytes; HLA: Human leukocyte antigen.

grading criteria is shown in Figure 7. Figure 7C represents pictures of the grades proposed in the new histologic grading criteria.

Recently, quantitative measurements of villous height, apical and basal villous widths, and crypt length (morphometry) have been used to determine changes in duodenal morphology, particularly after the introduction of a GFD, in correlation with Marsh grade, self-reported adherence to GFD, and changes in serology. GFD resulted in increase in villous area and a progressive decrease in crypt length, with a plateau after 6-12 mo and mean villous area half that of control subjects^[188].

Intraepithelial lymphocyte: The presence of aberrant IELs appears to be a reliable prognostic marker to differentiate between RCD type I and type II patients, with characteristic normal and aberrant IELs, respectively. IELs are considered aberrant when there is cytoplasmic CD3 expression, but no expression of surface CD3, CD4

and CD8 T-cell markers^[189,190]. The current methods for double CD3/CD8 T cell receptor clonal from intestinal tissue can be done by immunohistochemistry, polymerase chain reaction or flow cytometry^[161,162,189]. The presence of these IELs is associated with a significant increase in EATL development^[161,163,191,192]. Increased IELs may be used to support or exclude diagnosis of CD, and may be useful for follow up as mentioned in Table 7^[193].

In 95% of non-refractory CD and control patients, the highest percentage of aberrant T-cells in duodenal biopsy specimens is in agreement with the cut-off of the % T cells which are aberrant. Such a cut-off has been previously suggested in the RCD group based on the clinical observation that none of the RCD patients with less than 20% aberrant T-cells eventually developed EATL^[163]. Clonal T-cell population can be found in the intestinal mucosa of RCD patients, which relates to the development of EATL^[161,194]. Immunophenotyping using flow cytometry^[162], gives significant higher negative predictive value and sensitivity (both 100%) for aberrant T-cells were found with regard to EATL development in RCD, when compared to clonality in a duodenal biopsy specimen (75% and 78%, respectively). The positive predictive values (59%) and likelihood ratios (1.85) of these tests for EATL development in RCD are almost comparable.

Aberrant T-cells is quantified by flow cytometry is well suited to identify RCD patients at risk for EATL as it has a higher predictive value and sensitivity than T-cell clonality analysis of duodenal biopsy specimens. A cut-off value of 20% appears reliable for early risk stratification^[159], and targeted therapeutic options in RCD patients^[6,27,195]. This is particularly important since once overt T-cell lymphoma has developed, treatment outcome and survival are very poor^[159,196]. Additionally, quantification of aberrant T-cells is useful for the subsequent follow-up of treated RCD II patients^[27].

Restore intestinal architecture		R-spondin-1	Discovery

tTG2: Tissue transglutaminase 2; PEP: Prolyl endopeptidases; NKG2D: Homodimeric natural killer-activating receptor; HLA: Human leukocyte antigen; IgY: Immunoglobulin Y.

Useful background for the diagnosis of CD: The HLA class II molecules DQ2 and DQ8 are required for but are not sufficient for the development of CD: 50% of Americans are positive of one of those molecules, but only 1% develop CD. Negative HLA DQ2 or DQ8 may rule out CD as a cause of the enteropathy; IgA TGA serology is > 95% sensitive for CD, especially when there is a high titre, but false positive tests can occur; Anti-gliadin antibodies have a relationship high false negative rate, and have been replaced by IgG DGP assays that appear to have a sensitivity compared to TGA; The endoscopic features of CD (scalloping of mucosal folds, less prominent folds, fissures, and a nodular/mosaic pattern) are 59% sensitive but 92% specific for CD. For example, other small bowel disorders, including Crohn disease in the duodenum, may cause mucosal scalloping and other endoscopic features of CD.

acteristic small bowel biopsy.

Gluten modification: Approaches to modify dietary gluten have been made to render gliadin non-toxic, since it is a non-invasive approach to CD patients. This approach has been less appealing due to loss of baking characteristic, public refusal for genetically modified crops, contamination of genetically modified crops with gluten contained crops grown nearby and heterogeneous uncharacterised immunostimulatory epitopes in gluten, and difference among patients response to epitopes and gluten levels^[201].

A greater understanding of the pathogenesis of CD allows alternative future treatments to be designed. A number of preliminary studies have been published that illustrate from a conceptual perspective future possible approaches that may be pursued in more detail (Table 8).

TREATMENT

Existing treatment

GFD: Currently, the only effective treatment available for CD individuals is a strict life-long GFD^[197]. In reality, total avoidance of gluten intake is extremely difficult, due to hidden gluten from food contamination^[198]. For safety purposes, United States Food and Drug Administration has set the limit (August 2011) of < 20 ppm gluten (equivalent to 10 ppm gliadin) for gluten-free foods. The total daily consumption of gluten-free foods must be taken into account as it may exceed the tolerable limit of each celiac individual. It has been estimated that the threshold of prolonged gluten ingestion in some CD individuals may be lower than 50 mg/d^[199]. However, some CD individuals can conceivably be more sensitive. The presence of hidden gliadin in contaminated food products represents an imminent risk for celiac consumers, because of long-term effect of regular ingestion of small amounts of gliadin^[200], on causing positive tTG and char-

FUTURE TREATMENT APPROACHES

Hydrolysis of toxic gliadin peptide

Prolyl endopeptidases: Prolyl endopeptidases (PEPs) are endoproteolytic enzymes expressed in micro-organisms and plants. These enzymes cleave proline-rich gluten to smaller peptides that are ready for digestion by intestinal brush-border enzymes (aminopeptidases and carboxypeptidases). Limited efficiency was found, since PEP required 3 h preincubation with gluten containing foods to achieve full detoxification of peptides and to prevent intestinal transport of active gluten fragments^[202]. This is unlikely to be achieved by co-administration of PEP and gluten-containing diet.

A two-stages cross-over phase II clinical trial was performed using asymptomatic CD patients eating, a slice of bread daily and a slice of bread pre-treated with PEP daily^[203]. After 2 wk of PEP treated gluten challenge, majority of patients did not develop malabsorption, measured by faecal fat excretion and D-xylose

malabsorption tests. The tests likely lacked the necessary sensitivity to assess minor malabsorption resulting from active CD, since no histological confirmation was performed to determine deterioration in the Marsh grading^[201]. When PEPs were consumed as jam spread on a slice of gluten-containing bread by CD patients, villous blunting was seen in small bowel biopsy histological evaluation in most patients^[204]. Further studies are needed to determine the appropriate dose of enzyme and time of administration relative to the quantity of ingested gluten.

ALV003: ALV003, a mixture of two glutenases, an endoprotease from germinating barley and PEP, was pre-treated with wheat flour and tested in CD patients^[205]. Symptoms typically associated with gluten ingestion were not significantly reduced by ALV003 pre-treatment, but ALV003 abolished immune responses induced by gluten in CD patients. A randomized controlled phase IIa clinical trial has been performed where CD patients received either ALV003 or placebo daily for 6 wk at the time of 2 g gluten contained bread. This proof-of-concept study demonstrated that ALV003 can attenuate gluten-induced small intestinal mucosal injury in CD patients^[206]. After six weeks period, biopsies proved lower small intestinal mucosal injury in patients treated with ALV003 than placebo-treated patients despite of persistent intestinal inflammation in many patients on a strict GFD. Placebo-treated patients were found to have suffered more adverse events, most commonly including abdominal distention, flatulence, eructation, abdominal pain and diarrhea^[206].

Lactobacilli: Lactobacilli added to sourdough for fermentation are able to lyse the proline-/glutamine-rich gluten peptides and thus decrease immunotoxicity^[207-210]. A mixture of fermented wheat flour with oat, millet and buckwheat allows sourdough bread to retain its baking characteristics. A pilot study in patients with CD suggested that this bread was well tolerated^[209]. However, these patients were challenged for only 2 d, which is clearly not sufficient to draw any firm conclusions. Hence, another 60-d diet of fully hydrolyzed wheat flour with sourdough lactobacilli and fungal proteases (8 ppm residual gluten; $n = 5$) was further studied. The pretreated flour was rendered non-toxic by serological, morphometrical, and immunohistochemical analysis^[211]. A larger group of subjects in the trial and palatability of digested flour baked products needs to be taken into consideration.

VSL#3: VSL#3 is a probiotic containing lyophilised bacteria, including bifidobacteria (*Bifidobacterium longum*, *Bifidobacterium infantis* and *Bifidobacterium breve*), lactobacilli (*Lactobacillus acidophilus*, *Lactobacillus casei*, *Lactobacillus delbrueckii subsp.*, *Lactobacillus bulgaricus* and *Lactobacillus plantarum*) and *Streptococcus salivarius subsp.*, *Thermophiles*. It is used to hydrolyse gliadin peptides in pre-treated flour and tested for efficacy in rat intestinal cell line and celiac jejunal biopsies^[207]. VSL#3 pre-digested gliadins did not show an increase of the infiltration of CD3+ intraepi-

thelial lymphocytes and caused a less pronounced effect on intestinal mucosa permeability (determined by lower F-actin rearrangement and zonulin release). Hence, VSL#3 may have importance during food processing to produce pre-digested gluten-free products.

Prevention of toxic gliadin peptide absorption

Larazotide: Larazotide (AT-1001, Alba Therapeutics, Baltimore, MA), is a synthetic hexapeptide derived from Zonula Occludens toxin of *Vibrio cholera*^[212]. It is used to inhibit the opening of tight junctions of the small intestine epithelial cells. Clinical trial phase I in CD patients suggested that Larazotide therapy is well tolerated by patients and reduces intestinal barrier dysfunction, pro-inflammatory cytokine production, and gastrointestinal symptoms in CD individuals after gluten exposure^[213]. Encouraging results were obtained from a 6-wk phase IIb trial in terms of symptoms and antibody titers^[214], showing larazotide acetate a promising drug candidate. This drug inhibits the paracellular route of gliadin absorption through tight junctions, which is not the only mechanism of gliadin absorption. Indeed, gliadin may gain access to the mucosa through transcellular pathways in addition to paracellular route^[135,137]. Hence, this strategy might be best exploited in combination with other treatments.

Synthetic polymer poly (hydroxyethylmethacrylate-co-styrene sulfonate): Poly (hydroxyethylmethacrylate-co-styrene sulfonate) [P (HEMA-co-SS)] forms supra-molecular particles upon gliadin complexation in gastric and intestinal conditions^[215,216], and deteriorates gliadin's effect on epithelial cells^[217]. This complexation decreases the effect of gastrointestinal (GI) digestive enzymes on gliadin absorption, and thus the formation of immunogenic peptides is reduced. Gluten-sensitive HLA-HCD4/DQ8 mice co-administered with P (HEMA-co-SS) showed attenuated gliadin-induced changes in permeability and inflammation^[217]. Low side effect, cost and possibility to be taken, occasionally with gluten-containing food, makes it an attractive option. Further investigation of the mechanisms of action and its interaction with human tissues is required before its efficacy is investigated in human trials^[218].

Anti-gliadin egg yolk antibody: Oral antibody passive immunotherapy may be of value due to the advantages of reduced cost, ease of administration, and potential to treat localized conditions in the gastrointestinal tract^[219]. Among antibodies, chicken egg yolk immunoglobulin (IgY), is ideal for passive immunotherapy, as it may be readily obtained in large quantities from egg yolk, presenting a more cost-effective, convenient, and hygienic alternative to mammalian antibodies. Oral immunotherapeutic IgY is a promising alternative to neutralize gliadin in the GI tract and prevention it from absorption^[220]. Mannitol contained antibody preparation is highly resistant against GI enzymes and proved to effectively

neutralized gliadin under simulated GI conditions in the presence of food. *In vivo* study; BALB/c mice fed with IgY formulation and gliadin ratio of 1:5 (w/w), demonstrated that gliadin absorption in the gastrointestinal tract was minimal at < 1%^[221]. Further investigations in CD patients is requires to prove its efficacy and determine dosing regimen of antibody relative to the amount of gliadin ingestion.

Blockage of selective deamidation of specific glutamine residues by tissue transglutaminase 2 inhibitor

Transglutaminases (a family of eight enzymes) have diverse functions in human and are involved in several biological and pathological processes^[222]. tTG2 is an enzyme that has a pro-inflammatory effect and increases the immunostimulatory epitopes present in the lamina propria of the small intestine. Blockage of tTG2 may be a promising approach to inhibit the inflammatory process upon gluten ingestion. There are two essential classes of tTG2 inhibitors; irreversible and reversible inhibitors^[223]. Irreversible inhibitors form a stable covalent bond with this enzyme, and thus prevent deamidation of gliadin peptides^[223,224]. Reversible inhibitors are more desirable to minimize possible side effects. These include aldehyde-bearing tTG modulators^[225], cinnamoyl triazole derivatives^[226], and the highly specific modified peptide targeting the active cysteine site of tTG2^[227]. Since a few gluten T-cell epitopes can be recognized without being deamidated by tTG2^[228,229], this approach will not inhibit the innate response^[101], or the immune response induced by non-deamidated peptides^[82]. To be able to use tTG2 inhibitors clinically, it is critical to design highly specific inhibitors, since all human tTG share high sequence homology.

Vaccine application to restore immune tolerance towards gluten

Autoimmune enteropathy in CD has been proposed to be due to impairment of immunoregulatory mechanisms that controls oral tolerance. Systematic peptide mapping of T-cell was performed to determine gliadin reactive epitopes recognized by approximately 90% of CD patients. A clinical trial phase I study has been initiated as Nexvax2® (Nexpep Pty, Ltd., Australia) peptide vaccine-containing mixture of immunotoxic α - and ω -gliadins and B-hordein^[230].

Engineered *Lactococcus lactis* secreting a DQ8-restricted gliadin peptide administered orally^[231], or recombinant α -gliadin in HLA-DQ8 administered intranasally in transgenic mouse model^[232], have been studied to modulate immune response to gluten. However, it is difficult to appreciate how the vaccine or the intranasal peptide administration can modulate the Tr1 response. More work is needed to assess the effect of these therapies on the spectrum of gluten peptides presented to the gut.

Dermal inoculation of human hookworm (*Necator americanus*) has also been used to modulate the immune response to gluten^[233]. A phase II trial with CD patients suggested that hookworm infection on its own may not

obviate the necessity for a restricted diet in CD, but appears to be safe and might impact on immune pathology^[234]. Here in, hookworm infection is expected to reduce gluten sensitivity and immune reactivity.

Modulation of immune response to dietary gliadin

HLA-DQ blocker: HLA-DQ blocker is used to block the binding sites of HLA-DQ2 or DQ8 for it to be unrecognized by T cells as well to block the presentation of the antigen. This is not a new concept that was developed without much success to treat type 1 diabetes mellitus and rheumatoid arthritis, due to difficulties in effective drug delivery^[235,236]. By amino-acid substitution of gliadin T-cell stimulatory sequence, the epitope can be converted to an agonist or antagonist, abolishing the inflammatory cascade^[237]. IFN- γ production by peripheral blood lymphocytes was prevented when either an alanine or lysine amino acid was substituted through the immunodominant α -gliadin peptide, corresponding to the peptide's anchor to the HLA-DQ cleft^[238]. To develop this as a new therapeutic agent, more studies need to be performed, looking at the mass T-cell action of the gut towards these modified peptides.

Interleukin blocker: Modulation of cytokine production has been evaluated for the treatment of several autoimmune diseases, although their side effects may be severe. Modulation of proinflammatory IL-15 and anti-inflammatory IL-10 cytokines has been suggested to influence the immune balance between tolerance and autoimmunity^[127,239-241]. Blocking IL-15 may promote maintenance of epithelial integrity, limit epithelial destruction, leading to decreased passage of dietary gliadin.

NKG2D antagonists: MICA molecules, strongly expressed on active CD epithelial cell surface upon gliadin challenge^[132], interact with the NKG2D-activating receptor on human natural killer cells and CD8 T cells, leading to villous atrophy due to an IEL-mediated damage to enterocytes^[131,132]. Thus, NKG2D antagonists^[131] and anti-NKG2D antibodies^[242], have been proposed as therapeutics in CD.

Restoration of intestinal architecture by R-spondin-1

R-spondin-1 is an intestinal mitogen, shown to stimulate crypt cell growth, accelerate mucosal regeneration and restore intestinal architecture in mouse models of colitis^[243]. This agent has yet to be tested in human to be considered as a therapeutic agent in CD.

CONCLUSION

CD has been kept in the dark for decades with very little known about what is a relatively common medical condition. It is only recently that we have greater understanding of its prevalence, diagnosis and pathogenesis, which has supported the development of new therapeutic approaches to treat CD. There are several future

Table 9 Key points from recent findings

Cause
Environmental (gluten) and genetic factors (HLA and non-HLA genes)
Prevalence
0.5%-1% worldwide in normal at-risk population
Higher risk in the population with diabetes, autoimmune disorder or relatives of CD individuals
Pathogenesis
Gliadin gains access <i>via</i> trans- and para-cellular routes to the basal surface of the epithelium, and interact directly with the immune system
Types of CD symptoms: "typical" or "atypical"
Diagnosis
Positive serological (TGA or EMA) screening results suggestive of CD, should lead to small bowel biopsy followed by a favourable clinical and serological response to the GFD to confirm the diagnosis
Current treatment
Strict life-long GFD
Alternative future CD treatments strategies
Hydrolysis of toxic gliadin peptide
Prevention of toxic gliadin peptide absorption
Blockage of deamidation of specific glutamine residues by tissue
Restoration of immune tolerance towards gluten
Modulation of immune response to dietary gliadin
Restoration of intestinal architecture

HLA: Human leukocyte antigen; CD: Celiac disease; EMA: Endomysial; TGA: Transglutaminase; GFD: Gluten-free diet.

directions to follow to treat CD, which if successful will supplement or even replace the current only effective treatment, the use of a GFD. A greater understanding of the pathogenesis of CD allows alternative future CD treatments to hydrolyse toxic gliadin peptide, prevent toxic gliadin peptide absorption, blockage of selective deamidation of specific glutamine residues by tissue, restore immune tolerance towards gluten, modulation of immune response to dietary gliadin, and restoration of intestinal architecture (Table 9).

Abstract

Over the last decade, the standard of care for the treatment of chronic hepatitis C has been the combination of pegylated-interferon-alfa (PEG-IFN) and ribavirin (RBV) which results in sustained virological response (SVR) rates of 75%-85% in patients with genotypes 2 or 3 but only of 40%-50% in patients with genotype 1. Currently, there are rapid and continuous developments of numerous new agents against hepatitis C virus (HCV), which are the focus of this review. Boceprevir and telaprevir, two first-generation NS3/4A HCV protease inhibitors, have been recently licensed in several countries around the world to be used in combination with PEG-IFN and RBV for the treatment of genotype 1 patients. Boceprevir or telaprevir based triple regimens, compared with the PEG-IFN/RBV combination, improve the SVR rates by 25%-31% in treatment-naïve genotype 1 patients, by 40%-64% in prior relapsers, by 33%-45% in prior partial responders and by 24%-28% in prior null responders. At the same time, the application of response-guided treatment algorithms according to the on-treatment virological response results in shortening of the total therapy duration to only 24 wk in 45%-55% of treatment-naïve patients. There are, however, several

challenges with the use of the new triple combinations in genotype 1 patients, such as the need for immediate results of HCV RNA testing using sensitive quantitative assays, new and more frequent adverse events (anemia and dysgeusia for boceprevir; pruritus, rash and anemia for telaprevir), new drug interactions and increasing difficulties in compliance. Moreover, the SVR rates are still poor in very difficult to treat subgroups of genotype 1 patients, such as null responders with cirrhosis, while there is no benefit for patients who cannot tolerate PEG-IFN/RBV or who are infected with non-1 HCV genotype. Many newer anti-HCV agents of different classes and numerous combinations are currently under evaluation with encouraging results. Preliminary data suggest that the treatment of chronic HCV patients with well tolerated combinations of oral agents without PEG-IFN is feasible and may lead to a universal HCV cure over the next 5-10 years.

INTRODUCTION

Chronic hepatitis C virus (HCV) infection affects approximately 170 million people worldwide^[1]. Chronic hepatitis C may lead to the development of cirrhosis, liver decompensation and hepatocellular carcinoma and is a major indication for liver transplantation, particularly in Western countries^[2]. HCV is classified into 6 major genotypes. Some genotypes have a restricted geographical distribution (genotypes 4-6), while others (genotypes 1-3) are more broadly disseminated. Genotype 1 (subtypes 1a and 1b) is the most prevalent genotype in the world. Genotype 2 is found in clusters in the Mediterranean region, genotype 3 is most prevalent among intravenous drug users and genotype 4 is found mostly in Egypt, while genotypes 5 and 6 are less frequent^[3,4]. The HCV genotypes strongly affect the likelihood of the response to treatment.

During the last decade, the standard of care (SOC) for chronic HCV patients consisted of pegylated interferon-alfa (PEG-IFN)-2a or -2b combined with ribavirin (RBV). The treatment duration has been based on the on-treatment virological responses, mainly estimated at 4 wk [rapid virological response (RVR)] and 12 wk of therapy (early virological response)^[3,5]. Recently, polymorphisms of the interleukin 28b (*IL28B*, interferon lambda 3) gene were strongly associated with the rates of sustained virological response (SVR) to PEG-IFN/RBV therapy and therefore their determination may be useful to identify a patient's likelihood of response to treatment, but the predictive value is low^[5]. In patients with HCV genotypes 2 or 3, the combination of PEG-IFN/RBV is usually given for 24 wk, achieving rates of SVR, i.e., absence of HCV RNA at 6 mo or more after cessation of therapy, of about 75%-85%. In patients with HCV genotypes 1 and 4, the combination of PEG-IFN and RBV is usually given for 48 wk, resulting in SVR rates of 40%-50% for genotype 1 and 55%-65% for genotype 4 patients^[5,6]. The SVR rates are substantially lower in previous non-responders to PEG-IFN and RBV, in whom the proportion of genotype 1 patients is higher due to the lower initial SVR rates. It has been reasonable, therefore, that new treatments with improved efficacy were mostly needed for patients with genotype 1. In addition and regardless of HCV genotype, there are chronic HCV patients who cannot be treated with PEG-IFN and RBV for several reasons. First and of most clinical relevance, PEG-IFN therapy is contraindicated in patients with decompensated liver disease. Second, patients may not tolerate and/or may have other contraindication(s) to PEG-IFN or RBV. Thus, there has definitely been a need for new antiviral drugs with better efficacy, improved tolerance and good safety profiles for chronic HCV patients.

The current review focuses on the recent rapid and continuous developments in the management of chronic HCV infection, which have been based on a better understanding of the structure of the HCV genome and the key viral enzymes.

HCV GENOME ORGANIZATION AND NEW ANTIVIRALS

HCV has a positive-sense, single-stranded RNA genome of some 9.6 kilobases that encodes a polyprotein of about 3000 amino acids^[7,8]. The open reading frame for the polyprotein is flanked by 5' and 3' untranslated regions, which contain elements that regulate translation and replication. The polyprotein is generated by the host cell translation machinery and cleaved co- and post-translationally by viral and host proteases to yield the mature viral proteins. The N-terminal segment of the polyprotein encodes the structural components of the virus (Core, E1, E2 and p7). Core protein forms the capsid shell into which the virus genome is packaged, while the glycoproteins are considered to locate to the lipid envelope surrounding the capsid. P7 is required for the virus assembly^[9,10].

The C-terminal component of the polyprotein contains non-structural proteins (NS2, NS3, NS4A, NS4B, NS5A and NS5B). NS2 and NS3 are viral proteases required for the processing of the HCV polyprotein^[11]. NS3 is a multifunctional enzyme, which provides a serine protease and helicase/nucleotide triphosphatase activity and forms a stable heterodimeric complex with its cofactor NS4A, which is essential for protein folding. The NS3/NS4A complex cleaves the junction between NS3/4A, NS4A/NS4B, NS4B/NS5A and NS5A/NS5B. NS3 has also a helicase activity and is necessary for HCV replication supporting the unwinding of HCV^[12]. NS4B is the presumed central organizer of the HCV replicase complex and a main inducer of intracellular membrane rearrangements^[13]. NS5A is a RNA-binding phosphoprotein required for RNA replication and assembly of infectious virus particles^[14]. NS5B RNA-dependent RNA-polymerase is required for viral replication.

The nonstructural proteins mentioned above have been the major targets for the evolving directly acting antivirals (DAAs) or specifically targeted antiviral therapy for hepatitis C. In particular, DAAs under development mainly include NS3/4A protease inhibitors, NS5B polymerase inhibitors and NS5A inhibitors. In addition, inhibitors of cyclophilin, which is a host protein with an important role in the HCV lifecycle, are also under development (Table 1).

NS3/4A PROTEASE INHIBITORS

Two first-generation, linear NS3/4A protease inhibitors, boceprevir and telaprevir, have recently been approved in several countries around the world for clinical use in patients with genotype 1, while many new NS3/4 protease inhibitors are currently under evaluation in clinical trials (Table 1). Boceprevir and telaprevir have high antiviral potency only against genotypes 1 and 2^[15], but a low barrier to resistance. In particular, resistant HCV strains develop within a few days of monotherapy with one of these two agents^[16,17], while most mutations confer

cross-resistance to both drugs (V36A/M, T54S/A, V55A, R155K/T/Q, A156S, A156T/V)^[18]. HCV subtype 1a develops resistance more frequently and more rapidly than subtype 1b^[19], as just one (instead of two in subtype 1b) nucleotide change (R155K) is enough for an amino acid replacement and emergence of a resistant strain. Because of the low barrier to resistance, boceprevir and telaprevir should always be used in triple combinations together with PEG-IFN/RBV. Since viral resistance may develop even in triple combinations with PEG-IFN/RBV, strict stopping rules are recommended to be applied with the use of boceprevir- or telaprevir-based regimens. Newer, first-generation NS3/4A inhibitors under development are mainly macrocyclic (danoprevir, vaniprevir, asunaprevir, *etc.*), and are expected to have better pharmacokinetics and tolerability compared with boceprevir and telaprevir. Second-generation NS3/4A inhibitors (MK-5172) are expected to have pan-genotype antiviral activity and improved resistance profiles.

Efficacy data from phase III clinical trials with boceprevir- or telaprevir-based regimens in treatment-naïve patients with genotype 1

SPRINT-2 was a randomized, double-blind, placebo-controlled trial designed to evaluate the efficacy and safety of boceprevir-based regimens compared with the previous SOC, as well as the efficacy of boceprevir-based response-guided therapy (RGT) compared with a fixed 48-wk boceprevir regimen^[20]. In total, 1097 (938 nonblack and 159 black) treatment-naïve genotype 1 patients were randomly assigned to one of three treatment arms (1:1:1). They all received PEG-IFN-2b and RBV for the first 4 wk (lead-in period) followed by (1) placebo plus PEG-IFN-2b/RBV for 44 wk (control arm); (2) boceprevir plus PEG-IFN-2b/RBV for 24 wk with or without an additional 20-wk course of placebo plus PEG-IFN-2b/RBV (boceprevir RGT arm); or (3) boceprevir plus PEG-IFN-2b/RBV for a standard period of 44 wk (boceprevir fixed arm). PEG-IFN-2b was administered subcutaneously at a dose of 1.5 µg/kg per week, RBV orally at a total daily dose of 600-1400 mg according to body weight and boceprevir orally with food at a dose of 800 mg every 7-9 h. In the boceprevir RGT arm, treatment was stopped at 28 wk in patients who achieved an extended RVR (eRVR) defined as undetectable HCV RNA between 8 and 24 wk, or continued until week 48 in patients who did not achieved such an eRVR.

The SVR rate was significantly lower in the control arm (38%) compared with both boceprevir arms (RGT: 63%, fixed: 66%; $P < 0.001$) (Table 2). In all arms, black patients achieved lower SVR rates compared with non-black patients (control arm: 23% *vs* 40%, boceprevir RGT arm: 42% *vs* 67%, boceprevir fixed arm: 53% *vs* 69%). In the RGT arm, a total of 44% of patients were eligible to receive only 28 wk of treatment having an excellent SVR rate of 96% (97% for nonblacks and 87% for blacks). The relapse rates were 22% in the control arm and 9% in the two boceprevir arms. In conclusion, boceprevir-based regimens, compared with the PEG-IFN/RBV combination, offer a 25%-28% benefit in the likelihood of SVR in treatment-naïve genotype 1 patients, while a RGT-based duration of boceprevir-based therapy has excellent results in patients with an eRVR and is not overall inferior than a fixed 48-wk boceprevir-based regimen.

ADVANCE was a randomized, double-blind, placebo-controlled trial designed to evaluate the efficacy and safety of telaprevir-based regimens compared with previous SOC as well as the optimal duration of telaprevir triple combination^[21]. In total, 1088 treatment-naïve genotype 1 patients were randomized to one of three treatment arms (1:1:1): (1) telaprevir plus PEG-IFN-2a/RBV for the first 12 wk followed by 12 or 36 wk of PEG-IFN-2a/RBV (T12PR arm); (2) telaprevir plus PEG-IFN-2a/RBV for the first 8 wk and placebo plus PEG-IFN-2a/RBV for another 4 wk followed by 12 or 36 wk of PEG-IFN-2a/RBV (T8PR arm); or (3) PEG-IFN-2a/RBV for 48 wk together with placebo

Table 2 Sustained virological response rates in phase III clinical trials with hepatitis C virus protease inhibitor-based regimens in treatment-naïve and treatment-experienced patients

Name of trial		SVR

BOC: Boceprevir; RGT: Response-guided therapy; P: Pegylated interferon- α ; R: Ribavirin; T: Telaprevir; eRVR: Extended rapid virological response; LI: Lead-in; SVR: Sustained virological response.

for the first 12 wk (PR arm). PEG-IFN-2a was administered subcutaneously at a standard weekly dose of 180 μ g, RBV orally at a total daily dose of 1000-1200 mg according to body weight and telaprevir orally with food at a dose of 750 mg every 8 h. In both telaprevir arms, treatment was stopped at 24 wk in patients who achieved an eRVR defined as undetectable HCV RNA at weeks 4 and 12, and continued up to 48 wk in patients who did not achieve such an eRVR.

Significantly more patients in the telaprevir arms achieved an SVR compared with controls (75% and 69% *vs* 44%, $P < 0.001$), while patients of the T12PR arm showed a trend for a higher SVR rate compared with patients of the T8PR arm, but this did not reach statistical significance (T12PR: 75% *vs* T8PR: 69%, $P = 0.088$). The rates of eRVR were 57% and 58% in the T12PR and T8PR arms, respectively, compared with 8% in the control arm. Among those patients with an eRVR who received only 24 wk of therapy, an SVR was achieved in 89% and 83% of cases in the T12PR and T8PR arms, respectively. Among patients who did not achieve an eRVR and continued therapy up to 48 wk,

the SVR rates were 54% and 50% in the T12PR and T8PR arms, respectively (Table 2). The relapse rate was 9% in both telaprevir arms compared with 28% in the control arm.

Based on these data, we can conclude that telaprevir-based regimens, compared with the PEG-IFN/RBV combination, offer a 25%-31% benefit in the likelihood of SVR in treatment-naïve genotype 1 patients despite more than 50% of patients in the telaprevir arms receiving only 24 wk instead of 48 wk of therapy. Because of the numerically higher response rates in the T12PR than in the T8PR arm, the 12-wk telaprevir triple combination regimens were considered to be optimal for the treatment of genotype 1 patients.

ILLUMINATE was another phase III trial which included 440 treatment-naïve genotype 1 patients to assess whether 24 wk of a telaprevir-based regimen was sufficient for patients with an eRVR^[22]. All patients received telaprevir plus PEG-IFN-2a/RBV in the same doses used in the ADVANCE trial for the first 12 wk followed by PEG-IFN-2a/RBV for 12 or 36 wk^[3]. In particular, patients with an eRVR (undetectable HCV RNA at weeks 4 and 12) were randomized at week 20 to continue PEG-IFN-2a and RBV until 24 or 48 wk, while all patients without an eRVR were maintained on PEG-IFN-2a/RBV until 48 wk. Among the 60% of patients who achieved an eRVR and continued treatment after 20 wk, SVR rates were comparable between those treated for a total duration of 24 or 48 wk (92% *vs* 88%, respectively) (Table 2). In the 22% of patients who did not achieve an eRVR but continued treatment after 20 wk, the SVR rate was 64%, while treatment was discontinued prematurely before the randomization at week 20 in 18% of cases. The conclusion of the ILLUMINATE trial was that 24 wk of a telaprevir-based regimen is enough for the treatment-naïve genotype 1 patients who achieve an eRVR.

Efficacy data from phase III clinical trials with boceprevir- or telaprevir-based regimens in treatment-experienced patients with genotype 1

RESPOND-2 was a randomized, placebo-controlled trial designed to evaluate the efficacy and safety of boceprevir-based regimens compared with previous SOC for the retreatment of treatment-experienced genotype 1 patients. In total, 403 patients (259 relapsers: HCV RNA undetectable at the end but detectable at 6 mo after the end of previous therapy; 144 partial responders: HCV RNA decline $> 2 \log_{10}$ IU/mL at 12 wk but detectable during previous therapy) were randomly assigned to one of three treatment arms (1:2:2) similar to those used in the SPRINT-2 trial (control, boceprevir RGT and boceprevir fixed 48-wk arm)^[23]. The only difference was in the RGT arm, which included the initial 4-wk lead-in phase with only PEG-IFN-2b and RBV followed by boceprevir plus PEG-IFN-2b/RBV for 32 wk (week 4 to 36) with or without the addition of 12 wk of PEG-IFN-

2b/RBV in patients with or without detectable HCV RNA at 8 wk of therapy.

SVR rates were higher in the two boceprevir arms (RGT: 59%; fixed: 66%) than in the control arm (21%, $P < 0.001$) (Table 2). SVR rates were also higher in the boceprevir arms in both relapsers (RGT: 69%, fixed: 75%, control: 29%) and partial responders (RGT: 40%, fixed: 52%, control: 7%). Among patients with undetectable HCV RNA at week 8, SVR was 86% after 36 wk of therapy in the boceprevir RGT arm and 88% after 48 wk of therapy in the boceprevir fixed arm. The overall SVR rates were found to be lower in the boceprevir RGT than the fixed arm in patients with advanced fibrosis (metavir F3-F4) (44% *vs* 68%) or mostly in patients with cirrhosis (35% *vs* 77%), but similar between these two arms in patients with milder fibrosis. The negative effect of cirrhosis on SVR was observed in both prior relapsers and prior partial responders. The probability of an SVR was also significantly higher in patients with than without a $> 1 \log_{10}$ IU/mL HCV RNA drop at the end of the 4-wk lead-in phase (76% *vs* 33%). These data showed that boceprevir-based regimens compared with the PEG-IFN/RBV combination can improve the SVR rates by 40%-46% in previous relapsers and by 33%-45% in previous partial responders with genotype 1. Moreover, it was shown that a boceprevir-based RGT might be applied in treatment-experienced non-cirrhotic patients who achieve early (at 8 wk) HCV RNA undetectability. It should be noted, however, that the probability of an SVR is not very high in patients without a $> 1 \log_{10}$ IU/mL HCV RNA drop at the end of the 4-wk lead-in phase of a boceprevir-based regimen.

Since null responders ($< 2 \log_{10}$ IU/mL decline in HCV RNA at 12 wk) were not included in the RESPOND-2 trial, a fixed 48-wk boceprevir-based regimen (4-wk lead-in with PEG-IFN-2b/RBV followed by 44 wk of triple combination with boceprevir plus PEG-IFN-2b/RBV) was subsequently evaluated in a rollover, single arm, prospective study^[24]. Preliminary results reported an SVR rate of 38% in 42 previous null responders.

REALIZE was a randomized, placebo-controlled trial designed to evaluate the efficacy and safety of telaprevir-based regimens compared with the previous SOC in treatment-experienced genotype 1 patients as well as to determine whether a 4-wk lead-in therapy with only PEG-IFN/RBV can affect the probability of SVR in telaprevir-based regimens^[1]. In total, 663 patients (354 relapsers, 124 partial responders, 184 null responders) were randomly assigned to one of three arms (1:2:2): (1) telaprevir plus PEG-IFN-2a/RBV for the first 12 wk followed by PEG-IFN-2a/RBV for another 36 wk (T12PR48 arm); (2) 4-wk lead-in phase with PEG-IFN-2a/RBV and then telaprevir plus PEG-IFN-2a/RBV for 12 wk followed by PEG-IFN-2a/RBV for another 32 wk (lead-in T12PR48 arm); or (3) PEG-IFN-2a/RBV for 48 wk (control PR48 arm).

SVR rates were similar in the two telaprevir arms

(64% and 66%) and significantly higher compared with the control arm (17%, $P < 0.001$). In particular, SVR rates were higher in the telaprevir arms in prior relapsers (83% and 88% *vs* 24%, $P < 0.001$), prior partial responders (59% and 54% *vs* 15%, $P < 0.001$) and prior null responders (29% and 33% *vs* 5%, $P < 0.001$) (Table 2). The presence of cirrhosis was found to negatively affect the SVR rates in the telaprevir arms in prior partial responders (mild-moderate fibrosis: 72%, bridging fibrosis: 56%, cirrhosis: 34%) and mostly in prior null responders (mild-moderate fibrosis: 41%, bridging fibrosis: 39% cirrhosis: 14%), but not in prior relapsers (mild-moderate fibrosis: 86%, bridging fibrosis: 85% cirrhosis: 84%). Among the patients of the lead-in telaprevir arm, the probability of an SVR was significantly higher in patients with than without a $> 1 \log_{10}$ IU/mL HCV RNA drop at the end of the 4-wk lead-in phase (82% *vs* 33%), but this effect was more clinically relevant in prior null responders (54% *vs* 15%) than in prior partial responders (59% *vs* 56%) or in prior relapsers (94% *vs* 62%). Thus, according to these data, telaprevir-based regimens compared with PEG-IFN/RBV improve the SVR rates by 59%-64% in prior relapsers, by 39%-45% in prior partial responders and by 24%-28% in prior null responders, while a 4-wk lead-in phase with only PEG-IFN/RBV does not offer any advantage to telaprevir-based regimens.

Safety issues with boceprevir- or telaprevir-based regimens

The most common and clinically important adverse event in the boceprevir trials was anemia, which developed in approximately 50% of patients treated with boceprevir-based regimens, compared with 30% of patients treated with only PEG-IFN/RBV^[20,23]. Erythropoietin was administered by the investigators in 41%-46% of boceprevir-treated patients and in 21%-24% of the controls, while discontinuation due to anemia was necessary in 2% of patients in the boceprevir arms and in 1% of patients in the control arms. It should be noted that the SVR rates in the boceprevir arms were similar in patients with or without anemia, with or without erythropoietin use and with or without RBV dose reduction. Dysgeusia was another clinically important adverse event that was reported more frequently in the boceprevir than in the control arms (37%-43% *vs* 18%)^[20,23].

The most clinically important adverse events in the telaprevir trials were pruritus, rash and anemia. In particular, pruritus was reported by 45%-50% of telaprevir-treated patients compared with 36% of controls, and rash developed in 35%-56% and 19%-37% of cases, respectively^[21,22,25]. The rash during telaprevir therapy was typically eczematous and mild-to-moderate in $> 90\%$ of patients, while it was severe (involving $> 50\%$ of the body surface area) in 6%, leading to discontinuation of telaprevir in 5%-7% of patients (1% of controls) and of all drugs in 0.5%-1.4% of patients treated with telaprevir-based regimens (0% in controls)^[21,22,25].

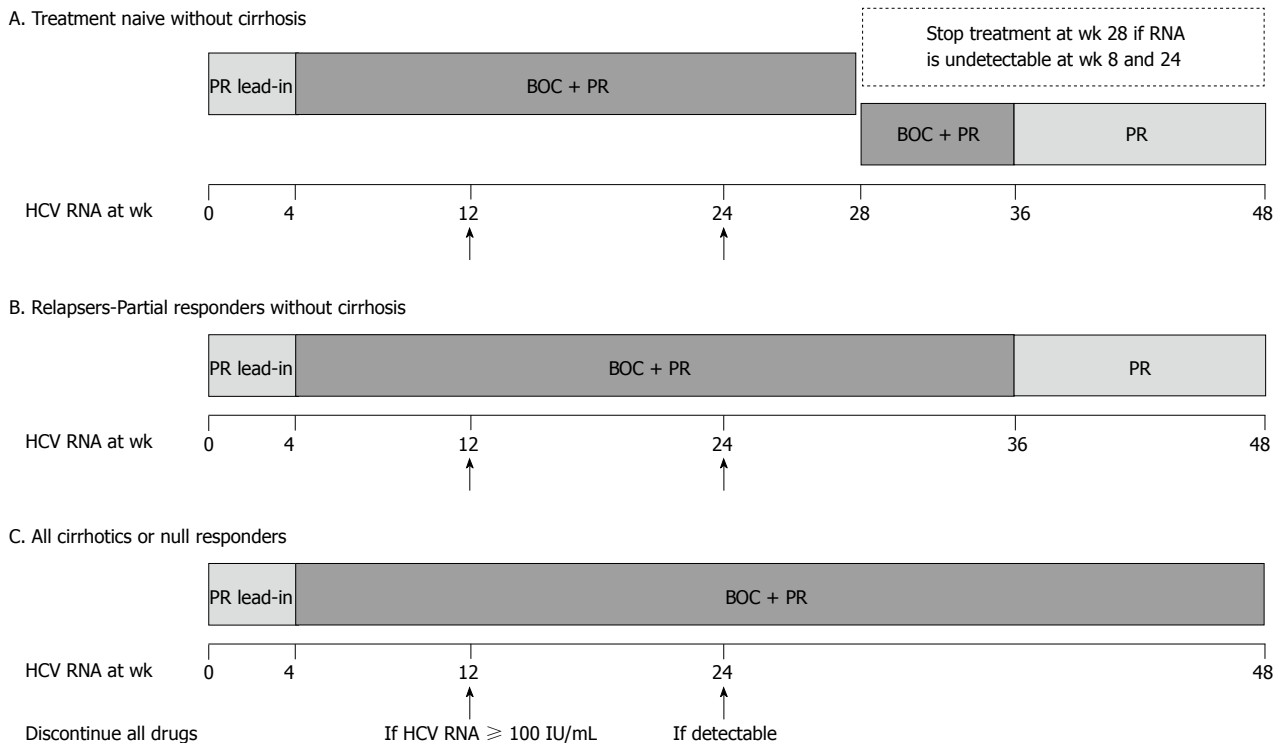

Figure 1 Treatment algorithms of boceprevir-based regimens for genotype 1 chronic hepatitis C virus patients recommended by the European Medicines Agency. All patients should start with a 4-wk lead-in phase with only pegylated interferon-alfa and ribavirin (PR). After 4 wk, boceprevir (BOC) is added. In treatment-naïve patients without cirrhosis who achieve an extended rapid virological response [eRVR: undetectable hepatitis C virus (HCV) RNA (< 10 IU/mL) at 8 and 24 wk], the triple therapy should last 24 wk and treatment end at 28 wk. In non-cirrhotic treatment-naïve patients who do not achieve such an eRVR and in all previous relapsers or partial responders without cirrhosis, the triple therapy should last 32 wk (until 36 wk of therapy) and should be followed by an additional 12 wk of PR. The United States Food and Drug Administration (FDA) recommendations suggest that prior relapsers or partial responders without cirrhosis who achieve an eRVR under BOC triple therapy can stop therapy at 36 wk without an additional 12-wk course of PR that is suggested by the European Medicines Agency. Finally, in all cirrhotics (treatment-naïve and experienced) and null responders, the triple therapy should last 44 wk (up to 48 wk of treatment). All patients should be tested for HCV RNA levels at 12 and 24 wk of total therapy and treatment should be discontinued for inefficacy if HCV RNA levels are > 100 IU/mL at 12 wk or HCV RNA is still detectable at 24 wk of therapy.

The mean time for the occurrence of rash was 22 d and the majority of rashes occurred during the first 4 wk of therapy. Anemia also developed more commonly in telaprevir-treated patients than in controls (37%–39% *vs* 19%)^[21,22,25]. Anemia was managed with RBV dose reduction, which did not affect the SVR rate^[21,22,25].

Another problem that may arise with the use of the protease inhibitors is the interactions with concomitant medications. Both boceprevir and telaprevir use hepatic drug metabolizing enzymes such as cytochrome P450 2C (CYP2C), CYP3A4, or CYP1A^[15]. Therefore, caution is definitely required for the use of these agents in patients taking other drugs metabolized by the same pathways, such as statins, calcineurin inhibitors, antiretroviral agents, methadone, *etc.*^[15]. Updated information on the possible drug-drug interactions with boceprevir and telaprevir can be found at the Food and Drug Administration (FDA) website (www.accessdata.fda.gov/scripts/cder/drugsatfda/index.cfm) or other relevant sites (e.g., www.hep-druginteractions.org).

Use of boceprevir or telaprevir in current clinical practice

Both boceprevir and telaprevir have now been approved

for the treatment of genotype 1 patients in several countries around the world. However, the approved treatment algorithms differ between the two drugs and according to the type of patients (Figures 1 and 2). In addition, there are some differences between the treatment algorithms of boceprevir-based regimens recommended by the United States and European regulatory authorities (Figure 1).

All patients who receive boceprevir should start with a 4-wk lead-in phase with only PEG-IFN/RBV. PEG-IFN-2b or PEG-IFN-2a may be used, while RBV should be administered at a weight-based dosage. After 4 wk, boceprevir is added, given with food at a dose of 800 mg (4 capsules of 200 mg each) every 8 h. In treatment-naïve patients without cirrhosis who achieve an eRVR [undetectable HCV RNA by a sensitive polymerase chain reaction (PCR) assay (HCV RNA < 10 IU/mL) at 8 and 24 wk], the triple therapy should last 24 wk and treatment finish at 28 wk. In non-cirrhotic treatment-naïve patients who do not achieve an eRVR and in all previous relapsers or partial responders without cirrhosis, triple therapy should last 32 wk (until 36 wk of therapy) and should be followed by an additional 12 wk of PEG-IFN/RBV. Finally, in all cirrhotics (treatment-naïve and experienced)

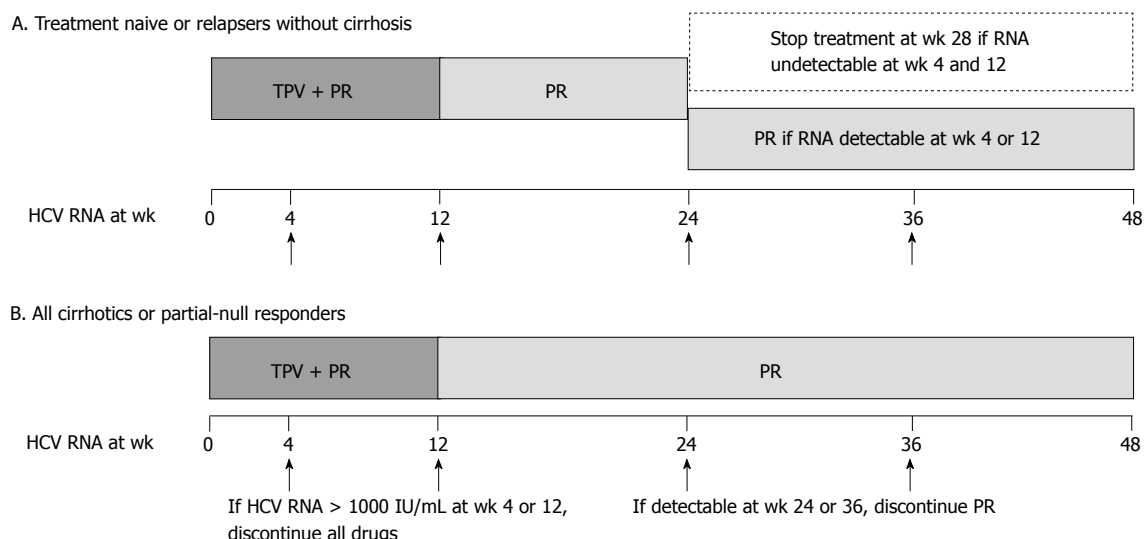

Figure 2 Treatment algorithms of telaprevir-based regimens for genotype 1 chronic hepatitis C virus patients recommended by both the European Medicines Agency and the Food and Drug Administration. All patients should start directly with the triple combination of telaprevir (TPV) plus pegylated interferon- α and ribavirin (PR). The triple combination should always last 12 wk. In treatment-naïve or previous relapser patients without cirrhosis who achieve an extended rapid virological response (eRVR) [undetectable hepatitis C virus (HCV) RNA (< 10 IU/mL) at 4 and 12 wk], triple therapy is followed by 12 wk of PR. In contrast, in non-cirrhotic treatment-naïve or relapser patients without an eRVR as well as in all cirrhotics or previous partial and null responders, triple therapy is followed by 36 wk of PR. Treatment should be discontinued for inefficacy if HCV RNA levels are > 1000 IU/mL at 4 or 12 wk or if HCV RNA is detectable at 24 or 36 wk of therapy.

and null responders, triple therapy should last 44 wk (up to 48 wk of treatment). All patients should be tested for HCV RNA levels at 12 and 24 wk of total therapy and treatment should be discontinued for inefficacy if HCV RNA levels are > 100 IU/mL at 12 wk or HCV RNA is still detectable at 24 wk of therapy.

All patients who receive telaprevir should start directly with the triple combination of telaprevir plus PEG-IFN/RBV. Theoretically, PEG-IFN-2a or PEG-IFN-2b may be used, although PEG-IFN-2a has been used in all telaprevir trials. RBV is administered at a weight-based dosage, while telaprevir should be administered orally with a fatty meal at a dose of 750 mg (2 capsules of 375 mg each) every 8 h. The triple combination should always last 12 wk. In treatment-naïve or previous relapser patients without cirrhosis who achieve an eRVR [undetectable HCV RNA by a sensitive PCR assay (HCV RNA < 10 IU/mL) at 4 and 12 wk], triple therapy is followed by 12 wk of PEG-IFN and RBV. In contrast, in non-cirrhotic treatment-naïve or relapser patients without an eRVR as well as in all cirrhotics or previous partial and null responders, triple therapy is followed by 36 wk of PEG-IFN/RBV. Treatment should be discontinued for inefficacy if HCV RNA levels are > 1000 IU/mL at 4 or 12 wk or if HCV RNA is detectable at 24 or 36 wk of therapy.

RNA chain causing chain termination^[26]. NIs are considered to have a high genetic barrier to resistance, although single amino acid substitutions are able to confer drug resistance *in vitro*. Nevertheless, because the active site of NS5 is highly conserved and amino acid substitutions in any position of the active site can result in loss of function, such resistant variants fit poorly, requiring weeks or months to grow to detectable levels in the presence of the drug. NIs have antiviral activity against all HCV genotypes (pan-genotype activity) as the active site of NS5B is well conserved across genotypes^[27]. GS-7977 seems to be a promising representative of the NIs, as it appears to be rather safe and effective, achieving very high SVR rates (100%) in genotype 2 and 3 patients even when the drug is given for 12 wk only in combination with RBV^[28].

NNIs bind to a distant site of the HCV polymerase and cause a conformational change rendering the enzyme ineffective. In particular, NNIs bind to one of 4 allosteric sites at the surface of HCV polymerase ("thumb" domain I, "thumb" domain II, "palm" domain I, "palm" domain II). NNIs have a more limited spectrum of activity being specifically against genotype 1. Because NNIs bind more distantly from the active site, resistant variants can fit in the presence of the drug, and therefore NNIs have a low barrier to resistance.

OTHER DIRECT-ACTING ANTIVIRALS

NS5B polymerase inhibitors

There are 2 categories of NS5B polymerase inhibitors: nucleos(t)ide inhibitors (NIs) and non-nucleoside inhibitors (NNIs) (Table 1). NIs mimic the naturally occurring nucleotides and thus are incorporated into the nascent

NS5A inhibitors

NS5A protein is a regulator of replication. NS5A inhibitors have high antiviral activity against different genotypes, but they have a low genetic barrier to resistance. Daclatasvir, a representative of this group (Table 1), is under evaluation in several combinations with promising results^[29].

Cyclophilin A inhibitors

Cyclophilins are host proteins involved in protein folding. They play an important role in the HCV life cycle as a regulator of replication. The cyclophilin inhibitor, alisporivir (DEB-025) (Table 1), is a cyclosporine analogue without immunosuppressive properties that has shown pan-genotype antiviral activity and has been used either alone or in combination with PEG-IFN/RBV with promising results^[30-32]. Phase III trials with alisporivir were ongoing, but very recently the development of this drug was put on hold by the FDA due to safety concerns (a few cases of pancreatitis, one of which was fatal). SCY-635 (Scynexis) is another cyclophilin inhibitor under development.

NEW COMBINATIONS

Numerous trials of many combinations of the above drugs from different classes are currently ongoing. Much effort and interest has been given to the development of PEG-IFN-free regimens. Protease inhibitors have been combined with NNIs (telaprevir plus VX-222^[33], BI201335 plus BI207127^[34,35], GS-9256 plus tegobuvir^[36]), NIs (danoprevir plus mericitabine)^[37] or NS5A inhibitors as double or triple combinations including RBV^[28]. Double combinations of a NI with RBV (GS-7977 and RBV) or with NS5 inhibitors are also being evaluated. Promising examples of PEG-IFN-free trials include the combination of the NI GS-7977 with RBV which has been shown to achieve an SVR in 10 out of 10 genotype 2 or 3 treatment-naïve chronic HCV patients treated for 12 wk^[28,38] or the combination of the NS5A inhibitor daclatasvir and the NS3 protease inhibitor asunaprevir, which has shown interesting results in difficult to treat, genotype 1, prior null responders treated for 24 wk. The latter combination showed that an SVR can be achieved in 36% of 11 genotype 1 (mostly 1a) prior null responders from the United States^[29] and in $\geq 90\%$ of 21 genotype 1b prior null responders coming from Japan^[39]. Similarly, encouraging preliminary results have been reported by a 12-wk course of the NS3 protease inhibitor ABT-450 given with ritonavir boosting the combination of NNI ABT-072 and RBV, which achieved an SVR in $> 90\%$ of treatment-naïve genotype 1, IL28B rs12979860 genotype CC, non-cirrhotic chronic HCV patients^[40]. Thus, it is clear that an SVR can be achieved with interferon-free regimens even in difficult to treat chronic HCV patients.

CONCLUSION

The recently approved boceprevir and telaprevir used in combination with PEG-IFN/RBV substantially improves the SVR rates in both treatment-naïve and treatment-experienced genotype 1 patients, while the treatment duration can be reduced to only 24 wk in a large proportion of mainly treatment-naïve patients. There are, however,

several challenges with the use of the new triple combinations. There is a need for immediate results of HCV RNA testing using sensitive quantitative assays, there are new and more frequent adverse events and drug-drug interactions, and there will be increasing difficulties in compliance. In addition, the SVR rates are still poor in very difficult to treat subgroups of genotype 1 patients, such as null responders with cirrhosis, while there is no benefit in patients who cannot tolerate PEG-IFN/RBV and in patients infected with a non-1 HCV genotype. Many new drugs and combinations are currently under evaluation with encouraging results. Although it is yet early, preliminary data suggest that the treatment of chronic HCV patients with well tolerated combinations of oral agents without PEG-IFN is feasible and may lead to a universal HCV cure over the next 5-10 years.

Abstract

AIM: To investigate colonic endocrine cells in lymphocytic colitis (LC) patients.

METHODS: Fifty-seven patients with LC were included. These patients were 41 females and 16 males, with an average age of 49 years (range 19-84 years). Twenty-seven subjects that underwent colonoscopy with biopsies were used as controls. These subjects underwent colonoscopy because of gastrointestinal bleeding or health worries, where the source of bleeding was identified as haemorrhoids or angiodysplasia. They were 19 females and 8 males with an average age of 49 years (range 18-67 years). Biopsies from the right and left colon were obtained from both patients and controls during colonoscopy. Biopsies were fixed in 4% buffered paraformaldehyde, embedded in paraffin and cut into 5 μ m-thick sections. The sections immu-

nostained by the avidin-biotin-complex method for serotonin, peptide YY (PYY), pancreatic polypeptide (PP) enteroglucagon and somatostatin cells. The cell densities were quantified by computerised image analysis using Olympus software.

RESULTS: The colon of both the patient and the control subjects were macroscopically normal. Histopathological examination of colon biopsies from controls revealed normal histology. All patients fulfilled the diagnosis criteria required for of LC: an increase in intraepithelial lymphocytes (> 20 lymphocytes/100 epithelial cells) and surface epithelial damage with increased lamina propria plasma cells and absent or minimal crypt architectural distribution. In the colon of both patients and control subjects, serotonin-, PYY-, PP-, enteroglucagon- and somatostatin-immunoreactive cells were primarily located in the upper part of the crypts of Lieberkühn. These cells were basket- or flask-shaped. There was no statistically significant difference between the right and left colon in controls with regards to the densities of serotonin- and PYY-immunoreactive cells ($P = 0.9$ and 0.1 , respectively). Serotonin cell density in the right colon in controls was 28.9 ± 1.8 and in LC patients 41.6 ± 2.6 ($P = 0.008$). In the left colon, the corresponding figures were 28.5 ± 1.9 and 42.4 ± 2.9 , respectively ($P = 0.009$). PYY cell density in the right colon of the controls was 10.1 ± 1 and of LC patients 41 ± 4 ($P = 0.00006$). In the left colon, PYY cell density in controls was 6.6 ± 1.2 and in LC patients 53.3 ± 4.6 ($P = 0.00007$).

CONCLUSION: The change in serotonin cells could be caused by an interaction between immune cells and serotonin cells, and that of PYY density might be secondary.

INTRODUCTION

Lymphocytic colitis (LC), which was first described in 1989^[1], belongs to a group of conditions known as microscopic colitides (MC). This disorder is characterised mainly by chronic or intermittent watery diarrhoea^[2], which can be severe. Up to 25% of patients present with more than 10 bowel movements per day in addition to nocturnal diarrhoea^[3]. Other symptoms such as cramping, abdominal pain and weight loss may occur^[4]. The aetiology of LC is not yet clear, although several hypotheses have been suggested, such as association to various autoimmune conditions and drug induction^[2]. LC has an incidence of 3.1 to 9.8 and prevalence of 14.2 per 100 000 people^[5-12].

Sequential treatment for LC is recommended, in which a “therapeutic ladder” is followed. The suggested drugs in this ladder are: loperamide, bismuth salicylate, budesonide, cholestyramine 5-aminosalicylic acid preparations, prednisolone, azathioprine, 6-mercaptopurine methotrexate or octreotide^[2].

In a previous study, a high density of colonic chromogranin A immunoreactive cells were reported in patients with LC^[13]. Chromogranin A is a general marker for all endocrine cells^[14-16], but it is not clear which types of colonic endocrine cells are responsible for the increase in the density of chromogranin A cells in patients with LC. Therefore, the current study was performed to identify the endocrine cell types involved.

MATERIALS AND METHODS

Patients and controls

Fifty-seven patients with a diagnosis of lymphocytic colitis during the period 2007-2010 were included in this study. The patients were diagnosed in all 3 hospitals of Helse-Fonna region in Western Norway, namely Stord, Haugesund and Odda. They were 41 females and 16 males, with an average age of 49 years (range 19-84 years). These patients did not show any clinical signs of other autoimmune disorders. They did not have coeliac disease tested either by serology or duodenal biopsies.

Twenty-seven subjects that underwent colonoscopy with biopsies were used as controls. Twenty of these subjects underwent colonoscopy because of gastrointestinal bleeding, where the source of bleeding was identified as haemorrhoids (18), or angiodysplasia (2), and seven were examined because of health worries caused by a relative being diagnosed with colon carcinoma. They were 19 females and 8 males with an average age of 49 years (range 18-67 years). All these subjects had no other gastrointestinal complaints than those mentioned above.

The study was performed in accordance with the Declaration of Helsinki and was approved by the local Committee for Medical Research Ethics. All subjects gave oral and written consent.

Colonoscopy

Colonoscopies were performed for all patients and controls, and two biopsies were taken from the caecum, from the ascending colon and from the right half of the transverse colon. These biopsies were pooled together and were labelled as right colon. In addition, two biopsies were taken from the left half of the transverse colon, from the descending colon and from the sigmoid colon. These 6 biopsies were pooled together and labelled as left colon.

Histopathology and immunohistochemistry

Biopsies were fixed in 4% buffered paraformaldehyde overnight, embedded in paraffin and cut into 5 µm-thick sections. The sections were stained with haematoxylin-eosin and immunostained by the avidin-biotin-complex (ABC) method using the Vectastain ABC-kit (Vector laboratories) as described earlier in detail^[17]. The primary antibodies used were: monoclonal anti-human leucocytes common antigen (Dako, CD 45, clone 2B11), monoclonal anti-human CD8 lymphocytes (Dako, CD 57, clone 2B01), monoclonal mouse anti-serotonin (Dako, code no. M869), polyclonal anti-porcine peptide YY (PYY) (Eurodiagnostica, code B52-1), polyclonal rabbit anti-synthetic human pancreatic polypeptide (PP) (Dako, code no. A619), polyclonal rabbit anti-synthetic human somatostatin, and polyclonal rabbit anti-porcine glucagon (Eurodiagnostica, code B31). The antibodies were used at dilutions of 1:100, 1:200, 1:1500, 1:1500, 1:1000, 1:1600 and 1:200, respectively. The anti-PYY cross reacts with PYY in all vertebrates including humans. It does not cross react with PP or neuropeptide Y in immunohistochemical system. Anti-glucagon is directed to N-Terminus of glicentin (enteroglucagon) and does not cross react with glucagon, vasoactive intestinal polypeptide or gastric inhibitory polypeptide. The second layer biotinylated mouse anti-immunoglobulin G (IgG) and rabbit anti-IgG were obtained from Dako. Negative and positive controls were the same as those described previously^[17].

Computerised image analysis

The number of immunoreactive cells and the area of the epithelial cells were measured using Olympus software:

Figure 1 Serotonin-immunoreactive cells in the colon of a control (A) and of a patient with lymphocytic colitis (B).

Figure 2 Colonic peptide YY -immunoreactive cells in a control (A) and in a patient with lymphocytic colitis (B).

Cell ^D. When using $\times 40$ objectives, the frame (field) on the monitor represents an area of 0.14 mm^2 of the tissue. Measurements were performed in 10 randomly chosen fields for each individual and hormone. The X40 objective was used. The data from fields were tabulated, and the number of cells/ mm^2 of the epithelium was computed and statistically analysed. The immunostained sections of IBS patients and controls were coded and mixed, and measurements were made without the knowledge of sections identity.

Statistical analysis

The non-parametric Mann-Whitney test was performed. $P < 0.05$ was considered to be statistically significant.

RESULTS

Endoscopy, histopathology and immunohistochemistry

The colon of both the patient and the control subjects were macroscopically normal. Histopathological examination of colon biopsies from controls revealed normal histology. All patients fulfilled the diagnosis criteria required for of LC: an increase in intraepithelial lymphocytes (> 20 lymphocytes/100 epithelial cells) and surface epithelial damage with increased lamina propria plasma cells and absent or minimal crypt architectural distribution. In the colon of both patients and control subjects, serotonin-, PYY-, PP-, enteroglucagon- and somatostatin-immunoreactive cells were primarily located in the upper part of the crypts of Lieberkühn. These

cells were basket- or flask-shaped (Figures 1 and 2).

Computerised image analysis

PP-, enteroglucagon- and somatostatin-immunoreactive cells were sparse in the biopsy material examined. This made it difficult to perform a reliable quantification of these cell types.

There was no statistically significant difference between the right and left colon in controls with regards to the densities of serotonin- and PYY-immunoreactive cells ($P = 0.9$ and 0.1 , respectively).

Serotonin cell density in the right colon in controls was 28.9 ± 1.8 (mean \pm SE) and in LC patients 41.6 ± 2.6 ($P = 0.008$). In the left colon, the corresponding figures were 28.5 ± 1.9 and 42.4 ± 2.9 , respectively ($P = 0.009$) (Figures 1 and 3). PYY cell density in the right colon of the controls was 10.1 ± 1 and of LC patients 41 ± 4 ($P = 0.00006$). In the left colon, PYY cell density in controls was 6.6 ± 1.2 and in LC patients 53.3 ± 4.6 ($P = 0.00007$) (Figures 2 and 4).

DISCUSSION

MC is a common cause of diarrhoea and 10% to 30% of older adults investigated for chronic diarrhoea have MC^[18]. LC seems to be associated with several autoimmune diseases^[19,20]. Furthermore, the prevalence of coeliac disease is high in patients with LC^[21]. The information available on the gut endocrine cells in coeliac disease is restricted to the duodenum^[22]. It is therefore difficult

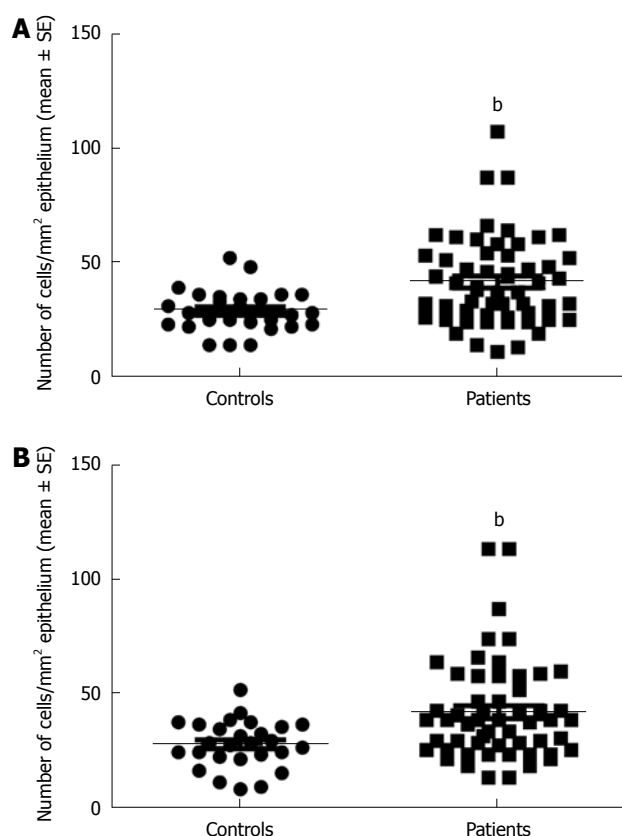

Figure 3 Serotonin cell density in the controls and patients with lymphocytic colitis in the right (A) and left colon (B). ^b $P < 0.01$ vs controls.

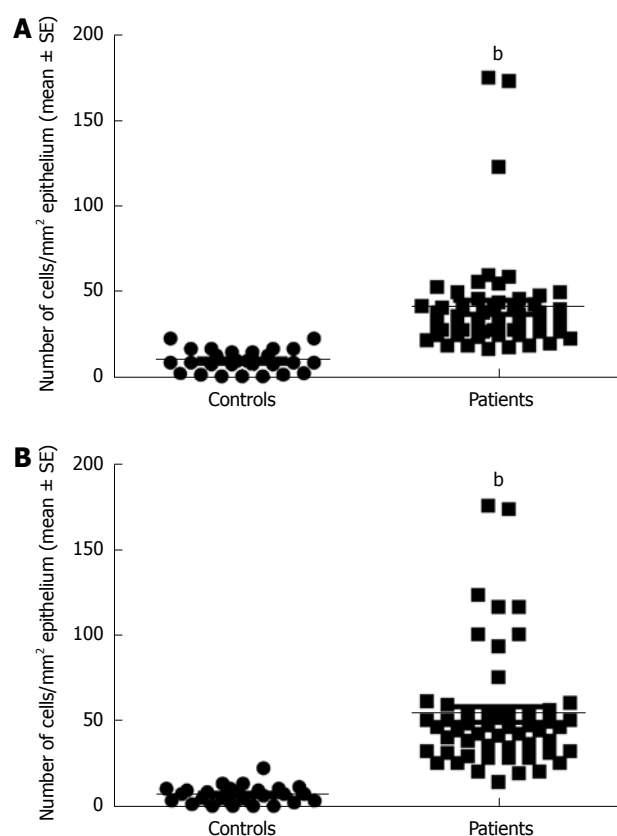

Figure 4 Peptide YY cell density in controls and patients with lymphocytic colitis in the right (A) and left colon (B). ^b $P < 0.001$ vs controls.

to compare the outcome of the present study with findings in coeliac disease.

The current study showed that serotonin and PYY cell densities were increased in both the right and left colon of patients with LC. Serotonin activates the submucosal sensory branch of the enteric nervous system, and controls gastrointestinal motility and chloride secretion *via* inter-neurons and motor neurons^[23,24]. PYY stimulates the absorption of water and electrolytes and is a major regulator of the “ileal brake”^[24]. There are several studies showing that inflammation and immune cells affect the neuroendocrine system of the gut^[25]. Thus, serotonin secreted by enterochromaffin (EC) cells can be enhanced or attenuated by secretory products of immune cells, such as CD4+T^[26]. Furthermore, serotonin modulates the immune response^[26]. The EC are in contact with or very close to CD3+ and CD20+ lymphocytes, and several serotonergic receptors have been characterised in lymphocytes, monocytes, macrophages and dendritic cells^[27].

One may speculate that the high density of serotonin cells in LC patients is caused by the interaction between the immune cells and serotonin cells in the epithelium and submucosa of LC patients. The increase in serotonin would cause accelerated colonic motility and visceral hypersensitivity. Accelerated colonic motility and visceral hypersensitivity can cause diarrhoea and abdominal pain, symptoms that occur in LC. It is probable

that the increase in PYY cell density is secondary to the increase in serotonin cell density in order to compensate for accelerated motility by activating the ileal brake and by increasing the absorption of water. In support for this assumption are the findings that large intestinal serotonin and PYY cells as well plasma levels are affected in patients with ulcerative colitis and Crohn’s disease^[28-32]. Similarly, these endocrine cells have been found to be affected in experimental animal model of colitis^[33,34].

LC and post-infectious IBS (PI-IBS) show a striking similarity. They have the same clinical presentation and both can regress spontaneously^[35,36]. Both LC and PI-IBS show intra-epithelial and submucosal infiltration of lymphocytes and mast cells, and exhibit a high density of colonic serotonin and PYY cells^[36-41]. This raises the question as to whether LC and PI-IBS are actually the same disorder. If this is proven to be true, it would have an important clinical implication. Thus, PI-IBS can be treated by the same “therapeutic ladder” which is proven to be effective in LC.

COMMENTS

Background

Microscopic colitis is a chronic condition with watery diarrhoea as the cardinal symptom, but other symptoms such as cramping, abdominal pain and weight loss may occur. Radiologic and endoscopic findings in these patients are normal. However, histopathological examinations of the colon reveal abnormal histology, which is of two distinctive types: lymphocytic colitis (LC) and collagenous

colitis. LC exhibits an increased number of colonic intra-epithelial lymphocytes (> 20/100 epithelial cells), increased inflammatory cells within the lamina propria and preserved crypt architecture. LC and irritable bowel syndrome (IBS) have similar symptoms and both are without radiologic or endoscopic abnormalities. Thus, LC can be mistakenly diagnosed as IBS. In a study on the colonic chromogranin A cell density in IBS patients, nine patients out of 50 showed extremely high colonic chromogranin A cell density. This high density was in contrast to the low density of chromogranin cells in the rest of the IBS patients studied. Re-examination of these nine patients revealed that they suffered from LC. This unexpected finding was confirmed on a larger patient's material. As chromogranin A is a common marker for endocrine cells, the present investigation was performed to identify the colonic endocrine cell-types that are affected.

Research frontiers

The current study is a further investigation of the unexpected observation that LC patients have high colonic chromogranin A cell density, which has been shown to be an excellent biomarker for the diagnosis of LC. This unexpected observation led to a novel approach toward LC, where the colonic hormones role in the symptom development in patients and their role in the pathogenesis of the disease come under focus. The current study showed that the endocrine cell-types that are affected in the colon of LC patients were peptide YY (PYY) and serotonin cells. This underlines the importance of these two hormones in LC.

Innovations and breakthroughs

The present findings underline the importance of the interaction between the gut hormones and the local immune system in the gut (the endocrine/immune axis) and its role in the pathogenesis and symptom development in disease. Such interactions should be put under the spotlight in several gastrointestinal diseases, especially those with known inflammation such as inflammatory bowel disease and coeliac disease. The similarity in the endocrine changes between LC and post-infectious irritable bowel syndrome (PI-IBS) has drawn attention to other histopathological and clinical similarities such as: both LC and PI-IBS show intra-epithelial and submucosal infiltration of lymphocytes and mast cells; both have the same clinical presentation; and both can regress spontaneously. This lead to the notion that LC and PI-IBS may be the same disorder.

Applications

Understanding the interaction between gut hormones and the local immune system of the gut would result in better understanding of the pathogenesis of gut inflammatory diseases and possibly open a new avenue for treatment. If LC and PI-IBS are proven to be the same disorder, PI-IBS can be treated by the same "therapeutic ladder" that has been proven to be effective in LC. PI-IBS constitutes a large subset of IBS without any effective treatment.

Terminology

Chromogranin A: Chromogranin A is a 68-kDa protein comprising 439 amino-acid residues. Chromogranin is co-stored and co-released with monoamines and peptide hormones of the adrenal medulla, pituitary gland, parathyroid, thyroid C-cells, pancreatic islets, endocrine cells of the gastrointestinal tract and sympathetic nerves; PYY: PYY is localised in endocrine cells in the ileum and large intestine; Serotonin: Serotonin is a monoamine that is localised in the enterochromaffin cells throughout the entire gastrointestinal tract. It also occurs also in the enteric nervous system and acts as a hormone and a neurotransmitter.

Peer review

This is an excellent paper which shows new light on lymphocytic colitis. The study was performed to identify the endocrine cell types in the colonic epithelium of LC by immunostaining using representative 5 antibodies against serotonin, PYY, pancreatic polypeptide, somatostatin, and glucagon. The results were that serotonin and PYY cell densities were increased in both the right and left colon of patients with LC, when compared with controls. They concluded that the high density of serotonin cells in LC patients were caused by the interaction between immune cells and serotonin cells, which occurs in the epithelium and submucosa of LC patients, and that the increase in PYY density is secondary to the increase in serotonin cell density.

Abstract

AIM: To observe the curative effect of galactosylated chitosan (GC)/5-fluorouracil (5-FU) nanoparticles in liver cancer mice and its side effects.

METHODS: The GC/5-FU nanoparticle is a nanomaterial made by coupling GC and 5-FU. The release ex-

periment was performed *in vitro*. The orthotopic liver cancer mouse models were established and divided into control, GC, 5-FU and GC/5-FU groups. Mice in the control and GC group received an intravenous injection of 200 μ L saline and GC, respectively. Mice in the 5-FU and GC/5-FU groups received 200 μ L (containing 0.371 mg 5-FU) 5-FU and GC/5-FU, respectively. The tumor weight and survival time were observed. The cell cycle and apoptosis in tumor tissues were monitored by flow cytometry. The expression of p53, Bax, Bcl-2, caspase-3 and poly adenosine 50-diphosphate-ribose polymerase 1 (PARP-1) was detected by immunohistochemistry, reverse transcription-polymerase chain reaction and Western blot. The serum blood biochemical parameters and cytotoxic activity of natural killer (NK) cell and cytotoxicity T lymphocyte (CTL) were measured.

RESULTS: The GC/5-FU nanoparticle is a sustained release system. The drug loading was $6.12\% \pm 1.36\%$, the encapsulation efficiency was $81.82\% \pm 5.32\%$, and the Zeta potential was 10.34 ± 1.43 mV. The tumor weight in the GC/5-FU group (0.4361 ± 0.1153 g *vs* 1.5801 ± 0.2821 g, $P < 0.001$) and the 5-FU (0.7932 ± 0.1283 g *vs* 1.5801 ± 0.2821 g, $P < 0.001$) was significantly lower than that in the control group; GC/5-FU treatment can significantly lower the tumor weight (0.4361 ± 0.1153 g *vs* 0.7932 ± 0.1283 g, $P < 0.001$), and the longest median survival time was seen in the GC/5-FU group, compared with the control (12 d *vs* 30 d, $P < 0.001$), GC (13 d *vs* 30 d, $P < 0.001$) and 5-FU groups (17 d *vs* 30 d, $P < 0.001$). Flow cytometry revealed that compared with the control, GC/5-FU caused a higher rate of G0-G1 arrest ($52.79\% \pm 13.42\%$ *vs* $23.92\% \pm 9.09\%$, $P = 0.014$) and apoptosis ($2.55\% \pm 1.10\%$ *vs* $11.13\% \pm 11.73\%$, $P < 0.001$) in hepatic cancer cells. Analysis of the apoptosis pathways showed that GC/5-FU upregulated the expression of p53 at both the protein and the mRNA levels, which in turn lowered the ratio of Bcl-2/Bax expression; this led to the release of cytochrome C into the cytosol

from the mitochondria and the subsequent activation of caspase-3. Upregulation of caspase-3 expression decreased the PARP-1 at both the mRNA and the protein levels, which contributed to apoptosis. 5-FU increased the levels of aspartate aminotransferase and alanine aminotransferase, and decreased the numbers of platelet, white blood cell and lymphocyte and cytotoxic activities of CTL and NK cells, however, there were no such side effects in the GC/5-FU group.

CONCLUSION: GC/5-FU nanoparticles can significantly inhibit the growth of liver cancer in mice *via* the p53 apoptosis pathway, and relieve the side effects and immunosuppression of 5-FU.

INTRODUCTION

Hepatocellular cancer (HCC) is one the most prevalent malignancies^[1,2]. Liver transplantation remains the most effective therapeutic option for HCC; however, due to the lack of donors and the relatively high cost, a substantial number of patients die while waiting for a donor liver^[3,4]. The disadvantages of most anti-cancer drugs that are currently available include low bioavailability, poor selectivity because they can act on both tumor cells and healthy cells, and immunosuppression that can cause complications and even patient death^[5]. However, targeted therapy for HCC may be useful because it is relatively less expensive compared with the current therapies and it also produces fewer side effects^[6,7]. 5-fluorouracil (5-FU) is a pyrimidine anticancer drug. Since its development by Heidelberg in 1957, 5-FU has occupied an important position in the cancer chemotherapy field. Because 5-FU is highly effective against a broad spectrum of malignancies, it is widely used in chemotherapy regimens against cancers such as hepatocellular, gastric,

pancreatic and breast cancers; 5-FU is very important in the management of liver cancer. 5-FU belongs to the cell cycle specific drugs and can be converted into fluorouracil deoxynucleotide to bind with thymidine synthase, which leads to the disruption of RNA, DNA and protein biosynthesis. However, because of the similarity of the nucleic acid metabolism pathways between tumor and normal tissues, 5-FU can also target normally proliferating tissues, leading to bone marrow suppression and gastrointestinal reactions. Other disadvantages of 5-FU include irregular absorption, a short half-life, and rapid turnover, which require lengthy, high-dose intravenous administration to maintain its effective *in vivo* concentration for a suitable period^[8,9]; these disadvantages can significantly restrict the clinical application of 5-FU. The emergence of a novel, sustained-release formulation of 5-FU is of clinical significance because it has fewer side effects compared to the regular 5-FU formulation^[10-12]. Galactosylated chitosan (GC) is a galactose ligand, with chitosan modifications on the molecular structure^[13-15]. Asialoglycoprotein receptor (ASGPR) is a receptor found on the membrane of hepatocytes facing the sinusoids, with specificity for glycoproteins with galactose or acetyl galactosamine at the end. Each hepatocyte contains approximately two million binding sites for ASGPR^[16]. The binding of the galactose ligand with ASGPR induces liver-targeted gene transfer. Our lab previously synthesized a GC nanoparticle as a gene carrier and showed that the GC nanoparticle can successfully transfer genes into the liver *in vitro* and *in vivo*. We also confirmed that this nanoparticle material has a high selectivity to the liver and a low cytotoxicity^[17]. In the present study, we synthesized GC/5-FU nanoparticles by combining the GC material with 5-FU, and tested its effect on liver cancer *in vitro* and *in vivo*. We found that the GC/5-FU nanoparticles can specifically target the liver and that the addition of GC increases the cytotoxicity of 5-FU and apoptosis mediated by the p53 pathway. GC/5-FU nanoparticles can ameliorate the side effects and immunosuppressive action of 5-FU.

MATERIALS AND METHODS

Reagents

Chitosan (deacetylation degree > 85%) GC was synthesized and stored by our group. HCl was from Shanghai Medpep, AR. LC-10A HPLC (Shimadzu, Japan), flow cytometry (FACS Calibur, United States). The immunohistochemistry kit was from GBI, United States. Caspase-3 and poly ADP-ribose polymerase 1 (PARP-1) antibodies were from Santa Cruz, CA, United States; Bax and Bcl-2 antibodies were from Temecula, CA, United States; and p53 antibody was from Beverly, MA, United States.

Mice and cell lines

The mouse liver cancer cell lines (H22) were purchased from the Cancer Institute of Fudan University, China. Female BALB/c mice, 7 wk of age and weighing 25 g, were

obtained from the Department of Experimental Animals of Fudan University, China. All mice were housed in specific pathogen-free level B animal facility and animal experiments were conducted following the guidelines of the Animal Research Ethics Board of Fudan University.

Synthesis of GC/5-FU

The 5-FU/GC was mixed at a mass ratio of 10:1 in solution, using vortex oscillator (2500 r/min) for 30 s; the final concentration of 5-FU was 1.857 g/L. The product was kept at room temperature for 30 min to assess for further particle formation. The final product was kept at 4 °C. The drug loading and encapsulation efficiency were calculated according to the following equations: drug loading = the amount of 5-FU within nanoparticle/nanoparticle mass × 100%; encapsulation efficiency = the amount of 5-FU within nanoparticle/total amount of 5-FU added × 100%.

In vitro release experiment

GC/5-FU nanoparticles (20 mg) were mixed with 30 mL of simulated body fluid (pH 7.4) in dialysis bags and incubated at 37 °C using a shaker with a fixed speed of 60 r/min. Samples were taken at 0.5, 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10 d after mixing. The optical density (*A*) was measured at 265 nm by an automated microplate reader (Bio-Rad Inc, California, United States). The amount of 5-FU released at different time points was calculated according to a standard absorbance curve. The concentration and cumulative release rate were calculated according to the standard curve equation. Each experiment was performed in triplicate.

Animal model

The subcutaneous liver cancer mouse model was established using the mouse HCC cell line H22. After euthanasia and dissection, fresh fast-growing tumor tissues were minced and made into a tumor cell suspension at a density of 6×10^4 /L. Recipient mice were anesthetized by 20% urethane, followed by an injection of 50 μ L of tumor cell suspension into the left liver lobe capsule. Approximately two min after completion of the procedure, when there was no leaking, the abdomen was sutured and the orthotopic liver cancer mouse model was established successfully^[18].

Curative effect of GC/5-FU in the orthotopic liver cancer mouse model

Five days after the establishment of the orthotopic liver cancer mouse model, the tumor reached a size of about 4–6 mm in diameter (Figure 1). The mouse models were randomly assigned into 4 groups labeled as control, GC, 5-FU and GC/5-FU. Mice in the control group received an intravenous injection of 200 μ L saline. GC group received 200 μ L GC nano-material. 5-FU and GC/5-FU groups received 200 μ L (containing 0.371 mg 5-FU) 5-FU and GC/5-FU, respectively. The drugs were given continuously for 5 d starting from day 5 after the tumor

Figure 1 Establishment of the hepatic cancer mouse model. A: Liver cancer; B: Normal mouse liver.

was established. At day 15, 10 mice were sacrificed and the tumor growth was monitored. The remaining 15 mice in each group were kept for survival analysis.

Cell cycle and apoptosis analysis by flow cytometry

The cell suspension was made of 1–2 mL tumor tissues from each individual group. Cells were washed three times by 0.1 mol/L phosphate buffered solution (PBS) and fixed by 70% ethanol. Cells were then incubated with 50 mg/L propidium iodide (Zhengzhou Sigma Chemical, Zhengzhou, China), 1.0% Triton X-100 and 10 mg/L RNaseA for 30 min at 4 °C in dark. Cell cycle distribution was analyzed by flow cytometry. Proliferation index (PI) = (S + G2/M)/(G0/G1 + S + G2/M). Apoptosis was determined by staining cells with annexin V-FITC (Pharmingen, San Diego, CA, United States) and propidium iodide because annexin V can identify the externalization of phosphatidylserine during the progression of apoptosis and therefore can detect early apoptotic cells. To quantify apoptosis, cells were washed twice with cold PBS and resuspended in binding buffer at 1×10^3 cells/L. A quantity of 100 μ L of this suspension was transferred to a 5 mL culture tube with 5 mL of annexin V-FITC and 10 mL of 20 mL/L propidium iodide, and analyzed using the flow cytometry.

Immunohistochemistry

The 4 μ m sections were deparaffinized by incubation at 65 °C. Sections were soaked in 3% H₂O₂ for 10 min at room temperature to deactivate endogenous peroxidases. Antigen retrieval was performed using a microwave. The primary antibody was incubated at 37 °C for 1 h in a humidified chamber; the secondary antibody was incubated at 37 °C for 30 min. After washing, the sections were developed using diaminobenzidine, and counter stained with hematoxylin. After dehydration, the sections were analyzed under a light microscope^[19]. p53 staining was mainly observed in the nucleus, which appeared brown and granular with little background. Caspase-3 staining was mainly present in cytoplasm, showing a brown granular staining pattern. PBS was used instead of primary antibody for a negative control. The Image-pro plus 6.0

system was used to analyze five fields randomly chosen from each slide. The images were amplified 200-fold, converted into gray-scale so as to distinguish the positive staining area from background. The positive-stained area and the total area of the field were measured by the system and the area ratio was calculated using the following equation: staining area/total area \times 100%. The stained area of each individual slide was determined by averaging the area ratio.

Reverse transcription-polymerase chain reaction

Primers were purchased from Shanghai R and S Biotechnology Co., Ltd. The oligonucleotide primers used were: Bcl-2: 5'-CGGGCTGGGGATGACTTCTCT-3' (sense), 5'-GCATCCCAGCCTCCGTTATCC-3' (antisense); Bax: 5'-AGACACCTGAGCTGACCTTGGAG-3' (sense), 5'-AGACACCTGAGCTGACCTTGGAG-3' (antisense); PARP-1: 5'-TCCCAAGGACTCCCTCCGCATGG-3' (sense), 5'-CTTTGCCTGCCACGCCTCCAGCC-3' (antisense); Caspase-3: 5'-TTGGAACAAATGGACCTG-3' (sense), 5'-ACAAAGCGACTGGATGAA-3' (antisense); P53: 5'-GTGGCCTCTGTCATCTTCCG-3' (sense), 5'-CCGTCACCATCAGAGCAACG-3' (antisense); glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal control: 5'-ACCGCAAAGACTGTGGATGC-3' (sense), 5'-TGAGCTTGACAAAGTGGTCG-3' (antisense). Tissue total RNA was extracted by TRIZOL (Invitrogen, California, United States). Total RNA (1 μ L) was used to reverse transcribe into cDNA using 0.5 μ L AMV reverse transcriptase. Polymerase chain reaction (PCR) was performed using 2.5 μ L cDNA, 0.1 μ L Ex Taq HS, 0.1 μ L forward primer and 0.1 μ L reverse primer. The PCR reaction conditions were as follows: 94 °C for 2 min, 35 cycles of 94 °C for 40 s, 50 °C to 6 °C for 40 s and 72 °C for 1 min, followed by 72 °C for 5 min. PCR products were kept at -20 °C^[20]. GAPDH was used as internal control. The PCR product (6 μ L) was resolved in 2% agarose gel for 30 min at 120 V, 100 mA, stained with ethidium bromide solution for 5 min, imaged by a ultraviolet gel imaging system, and analyzed by Quantity One software (Bio-Rad Inc, California, United States). The expression of target genes was presented as the ratio of target to internal control GAPDH.

Western blotting analysis

After the concentration was determined, the samples were loaded onto the 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) gel and resolved at 80 V followed by 120 V. Methanol-pretreated polyvinylidene difluoride (PVDF) membrane was then soaked in transfer buffer (pH 8.3, 25 mmol/L Tris-HCl, 192 mmol/L glycine, 20% methanol) for 10 min. Proteins on the SDS-PAGE gel were then transferred onto the PVDF membrane under 100 volts (V) for 70 min. The membrane was blocked by 5% FBS/PBS at 4 °C overnight. Primary antibodies were diluted at 1:2000 and incubated with a membrane for 3 min at room temperature. The membrane was then washed three times for 10

min each with PBS containing 0.05% Tween 20. Goat-anti-mouse immunoglobulin G secondary antibody (1:8000) was added to incubate with the membrane for 3 h at room temperature, followed by washing three times using the same washing solution. The membrane was then developed for 1 min using an enhanced chemiluminescence kit with equal volumes of A and B solution^[21]. After imaging, Image J version 1.44 software (National Institutes of Health) was used to analyze the average density values.

Analysis of blood biochemical parameters

The animals were sacrificed by day 10 after treatment. Blood chemistry including the measurement of alanine aminotransferase (ALT), aspartate aminotransferase (AST), blood urea nitrogen and creatinine was examined by a Fuji Drychem 3500 automated analyzer (Fuji Medical System Co. Ltd., Tokyo), the blood routine such as hemoglobin (Hbg), platelet (PLT), white blood cell (WBC), lymphocyte and neutrophil was detected by a Sysmex XS-800i automated analyzer (Sysmex Shanghai Ltd, Shanghai, China) .

Cytotoxic assay for natural killer cell and cytotoxicity T lymphocyte

Natural killer cell (NK) and cytotoxicity T lymphocyte (CTL) cytotoxic activity was measured by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) colorimetry assay (Sigma, United States) as reported previously^[17]. 1×10^4 YAC-1 as target cells were seeded in a 96-well plastic plates. Spleen cells used as effector cells were prepared from the mice and were simultaneously seeded in a 96-well plate at a 50:1 ratio of effector to target (E:T) in CTL assay. The effector cells from spleen cells were incubated with H22 target cells at a 50:1 ratio of E:T. All cytotoxic activity assays were performed in triplicate.

The activities of CTL and NK were calculated using the following formulas: CTL activity (%) = $[1 - (A_{E+T} - A_E)/A_T] \times 100\%$; NK activity (%) = $[1 - (A_{E+T} - A_E)/A_T] \times 100\%$, where A_E indicates the mean A value of effector cells, A_T indicates the mean A value of target cells, and A_{E+T} indicates the mean A value of effector cells + target cells.

Statistical analysis

All data was collected and expressed as mean \pm SD. Analysis of variance (ANOVA) was used to analyze data within the same group, one-way ANOVA was used to analyze data between groups, while the least significant digit method was used for pairwise comparison between groups. A value of $\alpha = 0.05$ and $P < 0.05$ was considered statistically significant.

RESULTS

Synthesis and characterization of GC/5-FU nanoparticles
5-FU/GC nanoparticles were successfully synthesized,

Figure 2 Particle size and scanning electron microscope image of galactosylated chitosan/5-fluorouracil. A: Particle size graph showing the diameter of galactosylated chitosan/5-fluorouracil (GC/5-FU) (35.19 ± 9.50 nm); B: Scanning electron microscope image of GC/5-FU. The particles show spherical structure with a smooth surface and no adhesion between nanoparticles.

Figure 3 The *in vitro* release curve of nanoparticles in simulated body fluid (37 °C, pH 7.4, $n = 3$). A rapid release was observed from time 0 h to 12 h, with a cumulative release percentage of 32.4%; a smooth slow-release occurred between day 1 and day 8, with a cumulative release percentage of 93.50%. During days 8 to 10, the release reached a plateau, with a cumulative release percentage of 95.70% at day 10.

and the radius of the nanoparticles was 35.19 ± 9.50 nm, which had a normal distribution (Figure 2A). Electron microscopy showed that the particles were in regular spherical shape, with a smooth surface, a uniform size, and no adhesion between nanoparticles (Figure 2B). The drug loading was $6.12\% \pm 1.36\%$, the encapsulation efficiency was $81.82\% \pm 5.32\%$, and the Zeta potential was 10.34 ± 1.43 mV. Figure 3 shows the *in vitro* release curve of nanoparticles in simulated body fluid (37 °C, pH 7.4). A rapid release was observed from 0 h to 12 h, with a cumulative release percentage of 32.4%, presum-

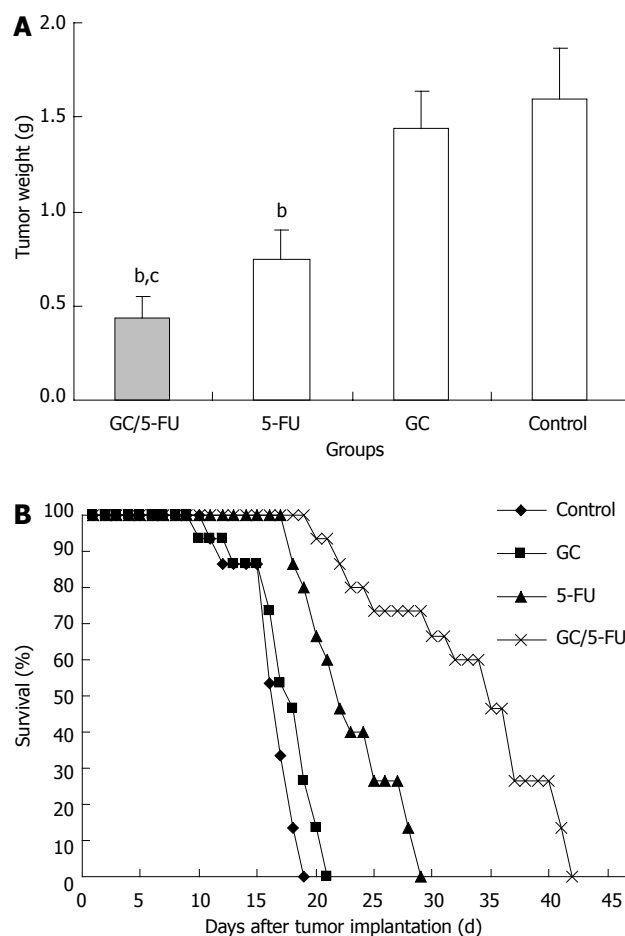

Figure 4 The curative effect of galactosylated chitosan/5-fluorouracil on liver cancer in the orthotopic transplant model of hepatocellular carcinoma. A: Five days after the tumor was established, galactosylated chitosan/5-fluorouracil (GC/5-FU), 5-FU, GC or phosphate buffered solution was given to the mice. Tumor weight was measured at day 15; B: Treatment was given as described previously and the survival was monitored. The median survival for control, GC, 5-FU and GC/5-FU groups were 12, 13, 17 and 30 d, respectively. ^b $P < 0.01$ vs control group; ^c $P < 0.05$ vs 5-FU group.

ably due to the diffusion of surface 5-FU into the solution; a smooth slow-release occurred between day 1 and day 8, with a cumulative release percentage of 93.50%, indicating that the GC/5-FU nanoparticles have a sustained release effect from days 1 to 8. From days 8 to 10, the release reached a plateau, with a cumulative release percentage of 95.70% at day 10.

Effect of GC/5-FU on tumor mass and survival in the mouse model

The tumor samples were harvested and weighted 15 d after treatment (Figure 4A). The weight of the tumor was 0.4361 ± 0.1153 g in GC/5-FU group, 0.7932 ± 0.1283 g in 5-FU group, 1.3989 ± 0.2125 g in GC group and 1.5801 ± 0.2821 g in control group. The differences between the groups was statistically significant ($P < 0.01$). The tumor weight in the GC/5-FU and the 5-FU groups were significantly lower than in the GC group and control group ($P < 0.01$) while tumor weight in the GC/5-FU group was significantly lower than in the 5-FU group ($P < 0.01$);

however, the tumor weight in the GC group and the control group was not different ($P > 0.05$). After the model was developed, the mice were randomly assigned to four groups with 15 mice each, and treated as described above. The survival of the mice was monitored, and there was a 100% mortality in all groups. The Kaplan-Meier survival curve (Figure 4B) showed that mice all the mice in the control group died between day 6 and day 14, with a median survival time of 12 d. In the GC group, all mice died between day 5 and day 16, the median survival time being 13 d. There was no statistical difference in the survival time between the control and the GC groups ($P > 0.05$). Mice treated with 5-FU also all died between day 13 and day 24, with a median survival of 17 d. All mice in the GC/5-FU group died between day 15 and day 37, with a median survival time of 30 d. The median survival time of mice treated with either 5-FU or GC/5-FU was significantly longer than that of mice in the GC or control groups; the longest median survival time was seen in the GC/5-FU group ($P < 0.01$ compared with the control, GC and 5-FU groups).

Effect of GC/5-FU on cell cycle, proliferation and apoptosis of H22 cells

Flow cytometry was used to analyze the liver cancer samples harvested 15 d after beginning the treatment. As shown in Figure 5A and B, the percentage of cells in the G0-G1 phases was significantly higher in the GC/5-FU- and 5-FU-treated tumors ($P < 0.01$), while the PI was lower than that in the GC and control groups ($P < 0.01$), suggesting that GC/5-FU and 5-FU had an overt anti-proliferative effect and arrested the tumor cells in the G0-G1 phases. The percentage of apoptotic cells in the GC/5-FU and 5-FU groups was significantly increased when compared with that in the control and GC groups ($P < 0.01$). Also, the percentage of apoptotic cells of GC/5-FU group was higher than that in the 5-FU group ($P < 0.01$), suggesting that GC is able to enhance the cellular influx of 5-FU, thereby improving the pro-apoptotic effect of 5-FU (Figure 5C).

GC/5-FU induced hepatic cancer cell apoptosis via activating the p53 pathway

To understand which pathway(s) mediated the GC/5-FU-induced apoptosis, we examined the expression of p53 at both protein and mRNA levels. Compared with the control and GC groups, the expression of p53 was increased in the 5-FU and GC/5-FU groups, with the highest increase seen in the GC/5-FU group ($P < 0.01$, Figures 6, 7A and B). The ratio of Bcl-2/Bax showed a decreasing tendency from control to GC to 5-FU to GC/5-FU groups ($P < 0.01$, Figure 7D); specifically, the ratio in 5-FU and GC/5-FU was significantly lower than that in the control and GC groups, with a lowest ratio observed in the GC/5-FU group ($P < 0.01$). GC/5-FU can also significantly induce the expression of caspase-3 in the tumor tissues ($P < 0.01$, Figures 6, 7A and B). The expression of PARP-1 also displayed a decreasing ten-

dency from control to GC to 5-FU to GC/5-FU groups ($P < 0.01$, Figure 7C), with the most significant reduction seen in the GC/5-FU group. Therefore, it is likely that GC/5-FU was involved in upregulating the genes in the p53 pathway.

Side effects of GC/5-FU

In order to understand the side effect of liver and kidney function and blood cells, we examined the blood of the mouse model by day 10 after treatment. The levels of AST and ALT in 5-FU group were obviously higher than those in control group ($P < 0.01$), while those in GC/5-FU group were lower compared with 5-FU group ($P < 0.01$), there were no differences among control, GC and GC/5-FU groups ($P > 0.05$). The numbers of PLT, WBC and lymphocyte in 5-FU group were decreased more obviously as compared with the control, GC and GC/5-FU groups ($P < 0.05$ or < 0.01), however, there were no differences among these three groups ($P > 0.05$). The levels of blood urea nitrogen, creatinine, Hbg and neutrophil were approximate in different groups ($P > 0.05$), as shown in Table 1.

Cytotoxic activities of CTL and NK in mice

We evaluated whether the GC/5-FU could affect the activity of CTL and NK *in vivo* in mouse model. The harvested splenocytes were washed with PBS. The activity of CTL and NK was detected by MTT colorimetry. Figure 8 shows that the cytotoxic activities of CTL and NK cells were significantly decreased in 5-FU group compared with other three groups ($P < 0.01$), while the crosscurrent was found in GC group compared with 5-FU group ($P < 0.05$). There were no differences between control and GC/5-FU groups. These results thus demonstrate that the GC/5-FU nanoparticles could ameliorate the decreased cytotoxic activities of CTL and NK in 5-FU group.

DISCUSSION

The utilization of nanotechnology and nano-materials in the pharmaceutical field gave rise to the drug-nanoparticle carrier-release system, which is a drug delivery system using nanoparticles as the drug carriers. A particle ranging from 0.1 nm to 100 nm is considered to be a nanoparticle^[22]. The size of a nanoparticle is very important for drug delivery, as the spaces between the cells in various tissues are different: it is now known that the aperture of vascular endothelial within most normal tissues is 2 nm, the aperture of the postcapillary venule is 6 nm, while that of non-continuous tumor blood vessels ranges from 100 nm to 780 nm^[23,24]. The size of the nanoparticles used in this study was approximately 35.19 nm (Figure 2A), which is smaller than most nanoparticles reported^[25], allowing them to enter the space within tumor cells but restricting them from penetrating the normal tissues. Scanning electron microscopy revealed a spherical structure with a smooth surface and no adhe-

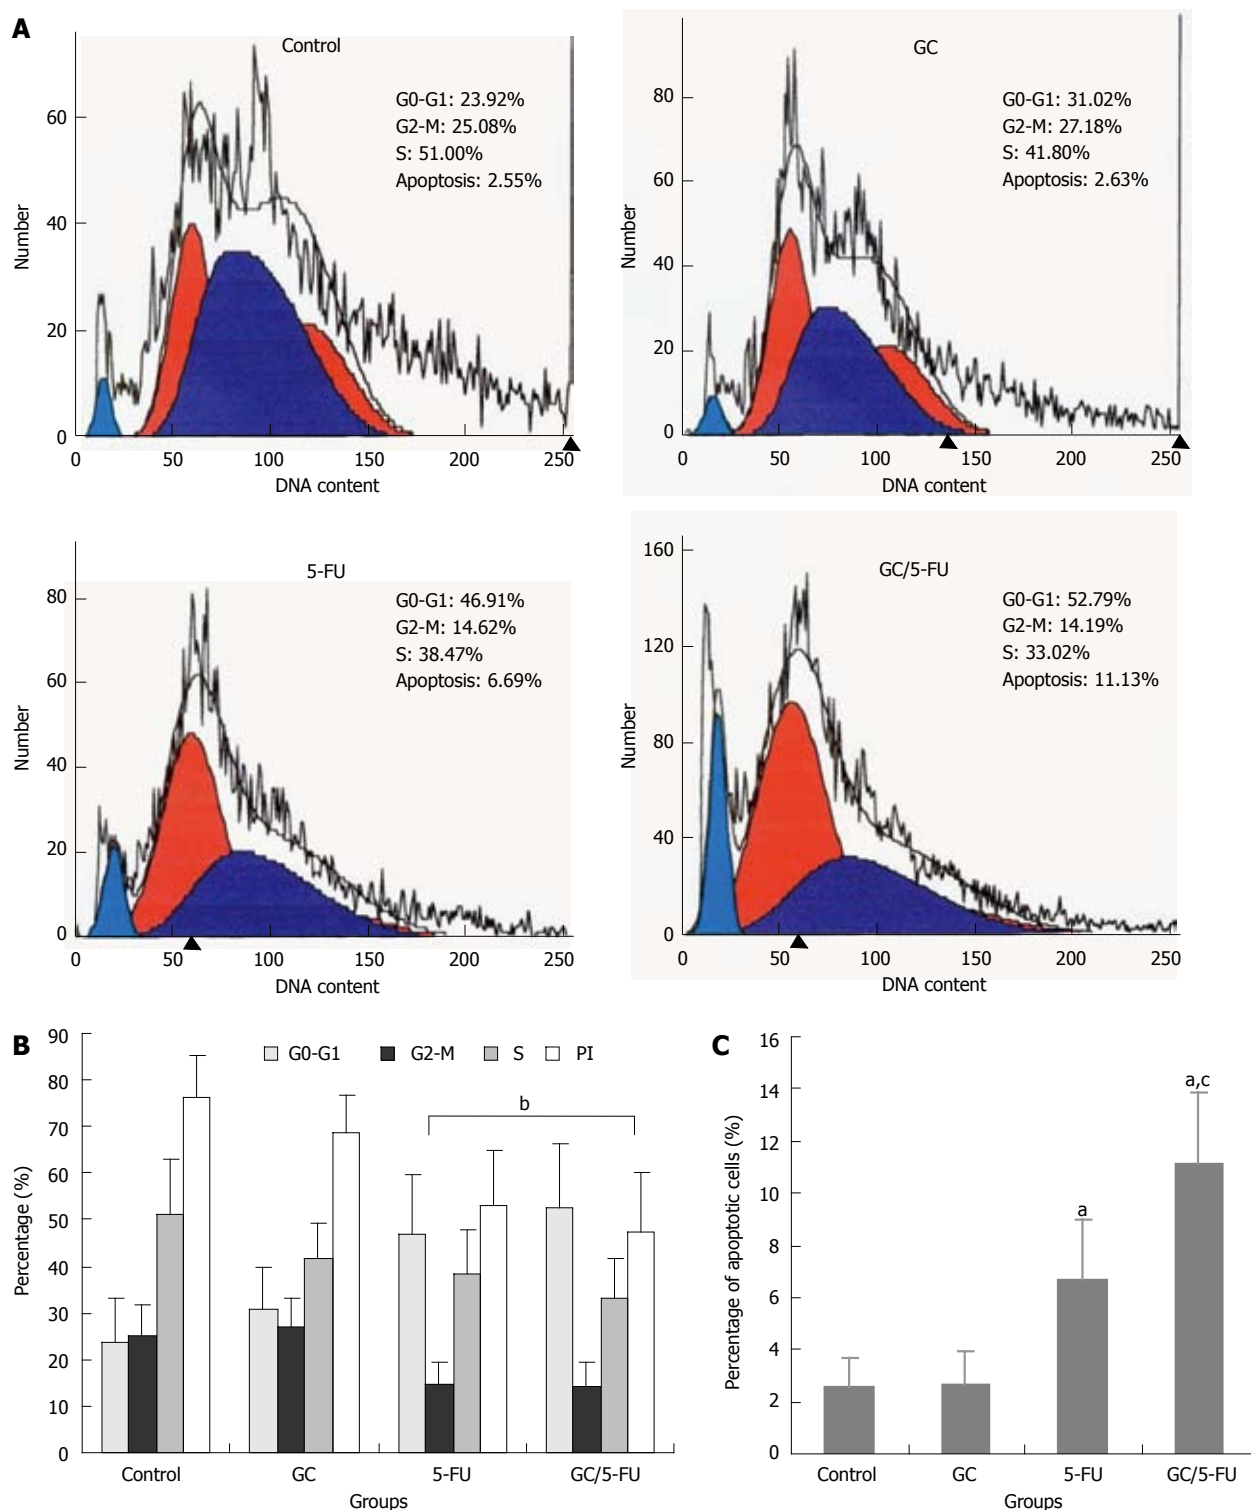

Figure 5 The effects of different treatments on cell cycle, proliferation index and apoptosis index. A: Flow cytometry analysis of cell cycle distribution of mouse liver cancer cell line (H22) cells; B: Quantification of cell cycle distribution and proliferation index of H22 cells. Percentage of cells in G0-G1 in the galactosylated chitosan/5-fluorouracil (GC/5-FU) and 5-FU groups was higher than that in control and GC groups, while the proliferation index (PI) decreased significantly ($P < 0.01$); C: Quantification of apoptosis of H22 in different treatment groups. ^a $P < 0.05$, ^b $P < 0.01$ vs control group; ^c $P < 0.05$ vs 5-FU group.

sion between nanoparticles (Figure 2B), which is consistent with previous reports^[25,26]. In order to confirm the sustained release effect, we performed an experiment on GC/5-FU. The *in vitro* release curve of GC/5-FU in simulated body fluid showed that the sustained release of the nanoparticle lasted 1-8 d. Such sustained release

effect makes the drug evenly distribute in the body, thereby increasing the half-life of GC/5-FU in the circulation system and decreasing the toxic effects of 5-FU on normal tissues^[27].

In order to evaluate the curative efficiency of intravenously injected GC/5-FU in a liver cancer mouse model,

Figure 6 Immunohistochemistry of p53 and caspase-3 in the tumor sections from mice with different treatments. A: p53 staining in the control and galactosylated chitosan (GC) groups showed a scattered nuclear distribution pattern, in dark yellow or dark brown; while in 5-fluorouracil (5-FU) and GC/5-FU groups, p53 showed a sheet staining pattern, which was more dramatic; B: Caspase-3 staining in the control and GC groups showed a scattered cytoplasmic distribution pattern, in dark yellow or dark brown; while in 5-FU and GC/5-FU groups, caspase-3 showed a sheet staining pattern, which was more dramatic in the GC/5-FU group.

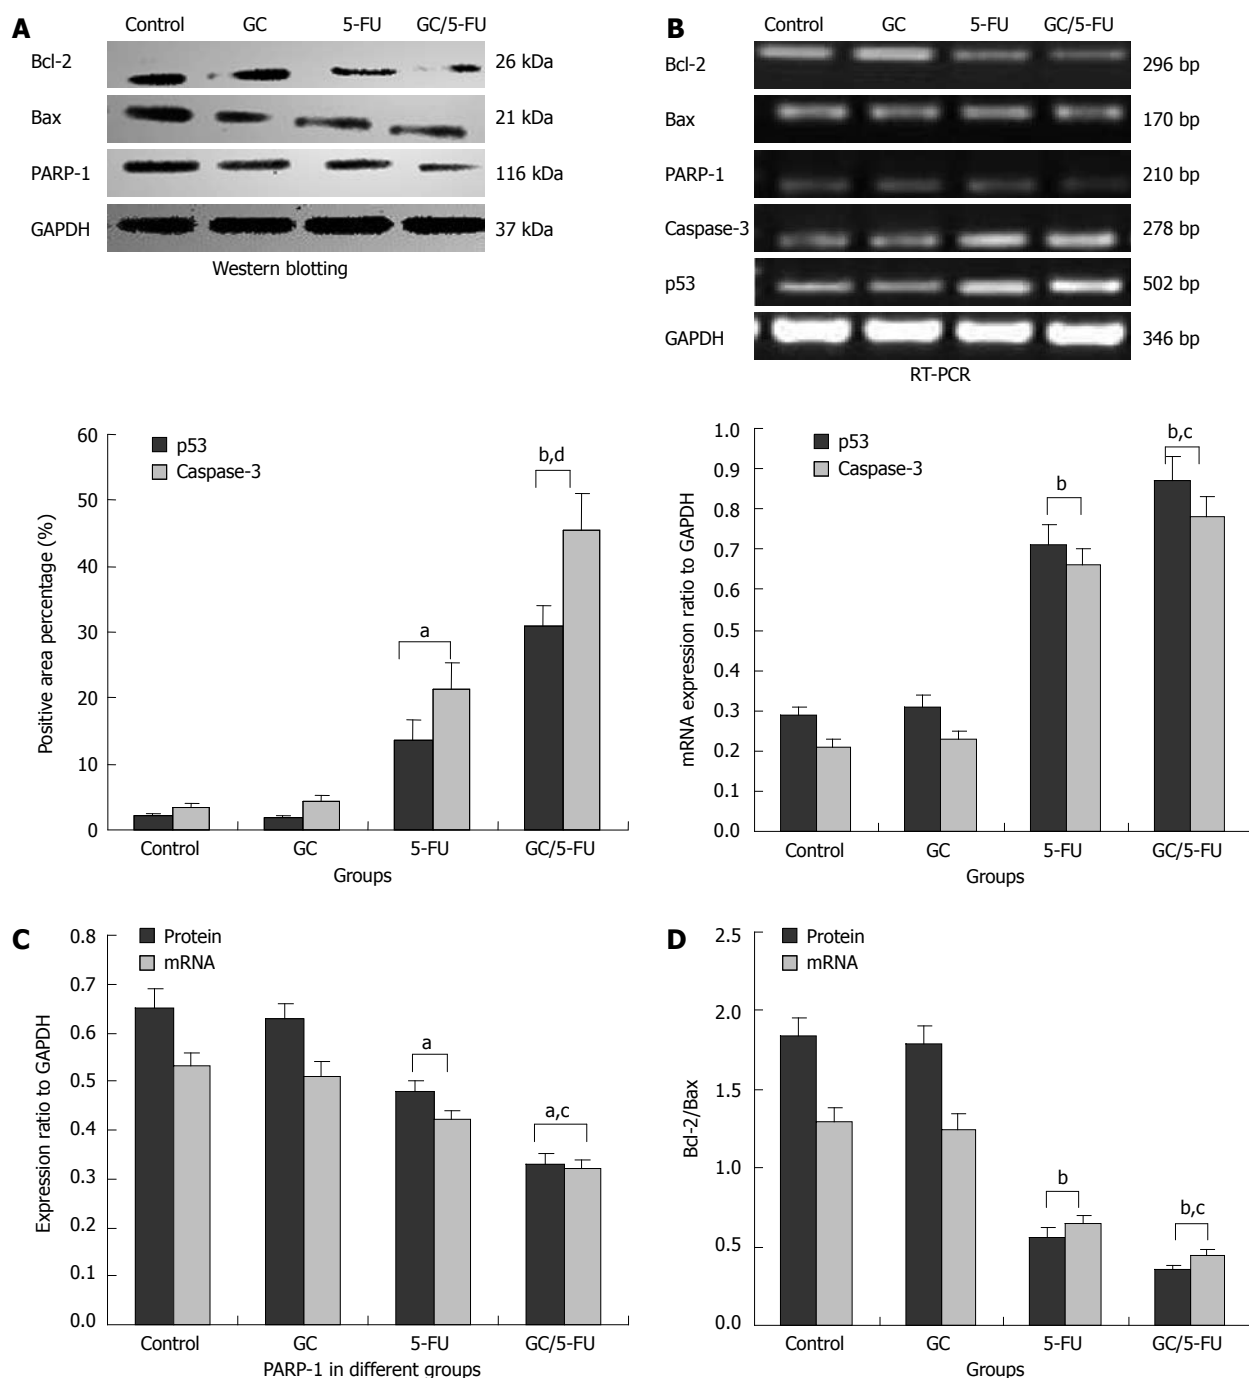

Figure 7 Expression of p53, caspase-3, Bax, Bcl-2 and poly adenosine 50-diphosphate-ribose polymerase 1 in the tumor tissues from mice with different treatments. A: Quantification of p53 and caspase-3 expression as detected by immunohistochemistry and shown pictorially in Figures 6 and 7; B: mRNA levels of p53 and caspase-3 in individual tissues was measured by reverse transcription-polymerase chain reaction (RT-PCR), and normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH); C: Poly adenosine 50-diphosphate-ribose polymerase 1 (PARP-1) expression in individual tumor samples was determined by both RT-PCR and western blot analysis; results were normalized to GAPDH; D: Expression of Bcl-2 and Bax was quantified by both RT-PCR and Western blotting; the ratio of Bcl-2/Bax was shown. ^a*P* < 0.05, ^b*P* < 0.01 vs control group; ^c*P* < 0.05, ^d*P* < 0.01 vs 5-fluorouracil (5-FU) group. GC: Galactosylated chitosan.

some of the mice were sacrificed and analyzed at day 15. As shown in Figure 4A, the tumor weight in mice treated with GC/5-FU and 5-FU was significantly less than that in the mice treated with GC or in the control; the weight of GC/5-FU-treated tumors was even lower than the 5-FU-treated tumors, while the GC- or control-treated tumors did not show any statistically significant difference. All mice died after treatment. In the control group,

mice died between day 6 and day 14, with a median survival of 12 d; in the GC group, mice died between day 5 and day 16, with a median survival of 13 d, showing no difference from the control group (Figure 4B, *P* > 0.05). Mice in the 5-FU group succumbed to a tumor-associated death between day 13 and day 24, with a median survival time of 17 d, while mice in the GC/5-FU group died between day 15 and day 37, with a median survival

Figure 8 The activity of cytotoxicity T lymphocyte and natural killer cell was detected by 3-(4, 5-dimethylthiazd-2-yl)-2,5-diphenyltetrazolium bromide in the orthotopic transplant model of hepatocellular carcinoma. The cytotoxic activities of cytotoxicity T lymphocyte (CTL) and natural killer (NK) cells were significantly decreased in 5-fluorouracil (5-FU) group compared with other three groups ($P < 0.01$), while, the crosscurrent was found in galactosylated chitosan (GC) group compared with 5-FU group ($P < 0.05$). ^a $P < 0.05$, ^b $P < 0.01$ vs control group; ^d $P < 0.01$ vs 5-FU group.

time of 30 d. The survival time of mice treated with either 5-FU or GC/5-FU was significantly longer than that of mice in the control and GC groups, with the longest survival time seen in the GC/5-FU group. This result suggested that although GC alone cannot affect tumor growth, the conjugation of GC to 5-FU improved the tumor suppressive effect of 5-FU. To determine the mechanism of effect of GC/5-FU nanoparticles on the hepatic cancer, we used flow cytometry to examine tumor cell apoptosis. The results revealed that both 5-FU and GC/5-FU enhanced apoptosis when compared with either control or GC, and compared with 5-FU alone, GC/5-FU further increased the apoptosis index, suggesting that GC improves the pro-apoptotic effect of 5-FU by promoting its entry into the cells. In addition, as shown in Figure 5A and B, compared with control and GC treatment, 5-FU and GC/5-FU can increase the percentage of cells in the G0-G1 phases, but lower the PI, suggesting 5-FU and GC/5-FU are cytotoxic to the proliferating cells by arresting them in the G0-G1 phases; this is consistent with previously reported research^[28,29]. Therefore, GC facilitates intracellular transport of 5-FU, improving the effects of 5-FU on tumor cell apoptosis and on inhibition of the cell cycle.

To further study whether the apoptosis induced by the GC/5-FU nanoparticles was mediated by the p53 pathway, we used immunohistochemistry, reverse transcription-PCR and Western blotting analysis to examine the expression of p53, Bax, Bcl-2, caspase-3 and PARP-1. We found that the addition of GC/5-FU and 5-FU induced p53 expression at both the protein and the RNA levels; the strongest induction of p53 was noted in the GC/5-FU group, and a moderate to strong induction seen in the 5-FU group (Figure 7A and B). The change of Bcl-2/Bax ratio also showed a similar pattern. Administration of GC/5-FU and 5-FU decreased the Bcl-2/Bax ratio, with the most dramatic reduction observed in the GC/5-FU group (Figure 7D). It is now known that Bax, belonging to the Bcl-2 family, is able to promote apoptosis. Although both Bax and Bcl-2 coexist in cells as dimers, each suppresses the function of the other. Physiologically, both Bax and Bcl-2 are present in cells in the same amounts, ensuring the normal growth of the cells. If Bcl-2 is overexpressed, the heterodimer Bcl-2/Bax is induced to suppress apoptosis, while if the level of Bax increases, the formation of Bax/Bax homodimer promotes apoptosis by antagonizing the anti-apoptotic effect of Bcl-2^[30]. Wild-type p53 induces Bax synthesis to mediate apoptosis, while mutant p53 can inhibit apoptosis leading to uncontrolled proliferation^[31]. We also found that GC/5-FU was able to significantly enhance the expression of caspase-3 ($P < 0.01$), which is known to be an important promoter of apoptosis. Caspase-3 can be activated by cytochrome c in the cytosol, which is released from mitochondria under the control of Bax and Bcl-2. Therefore, the ratio of Bax and Bcl-2 determines the activation of caspase-3^[32,33]. Figure 7C shows a tendency toward a decrease in PARP-1 expression from the control to the GC to the 5-FU to the GC/5-FU groups, with a most significant reduction in the GC/5-FU group. It has been reported that caspase-3 is a pivotal effector in apoptosis. Activation of PARP-1 after severe DNA damages results in depletion of cellular energy. In order to prevent the consumption of NAD⁺ and adenosine triphosphate, activated caspase-3 cleaves and inactivates PARP-1, leading to apoptosis^[34]. Taking into consideration all the above results, GC improved the apoptotic effect of 5-FU in hepatic cancer cells. The mechanism underlying GC/5-FU nanoparticle-induced apoptosis was

inducing the expression of p53 at the protein and mRNA levels. The elevated p53 level can significantly lower the Bcl-2/Bax ratio which in turn promotes the release of cytochrome c from the mitochondria into the cytosol, leading to the activation of caspase-3. Upregulation of the caspase-3 gene and protein contributed to the reduction of PARP-1 at both the protein and mRNA levels, thus triggering apoptosis. Therefore, GC/5-FU-induced apoptosis is p53 dependent.

5-FU is a common chemotherapy drug, and its common side effects are the suppression of bone marrow^[35], dysfunction of liver and kidney and suppression of immune function^[36-38], leading to a decreased efficacy and survival time of the patients with cancer. In this experiment, 5-FU increased significantly the levels of AST and ALT, decreased obviously the numbers of PLT, WBC and lymphocyte in tumor-bearing mice compared with the control group. The levels of ALT and AST, the numbers of PLT, WBC and lymphocyte, remained stable in GC/5-FU group compared with control group. It is indicated that GC nanoparticles can improve the damage of liver function caused by 5-FU and the suppression state of bone marrow. We found that the cytotoxic activities of CTL and NK cells by 5-FU were significantly inhibited, and the GC nanoparticles could relieve the suppression state of NK and CTL cells by 5-FU, which is consistent with our previously reported experiments which verified that GC nanoparticles can stimulate the cytotoxic activities of CTL and NK cells in tumor-bearing mice^[17]. So the GC/5-FU nanoparticles can alleviate the inhibition of 5-FU on the body's immunity.

In conclusion, we demonstrated that GC is a good carrier for nano-material, especially 5-FU. GC/5-FU nanoparticles had a sustained release effect. GC/5-FU nanoparticles can also significantly inhibit the tumor growth in the orthotopic liver cancer mouse model, and this *in vivo* effect was stronger than that of 5-FU alone. The mechanism underlying GC/5-FU nanoparticles may be the elevated G0-G1 arrest and apoptosis mediated by the p53 pathway. GC/5-FU nanoparticles can ameliorate the side effects and immunosuppressive action of 5-FU.

COMMENTS

Background

Biodegradable polymer nanoparticle drug delivery systems are characterized by targeted drug delivery, improved pharmacokinetic and biodistribution, enhanced drug stability and reduced side effects. These drug delivery systems are widely used for delivery of cytotoxic agents. The galactosylated chitosan (GC)/5-fluorouracil (5-FU) nanoparticle is a nanomaterial made by coupling GC, a polymer known to have the advantages described above, and 5-FU.

Research frontiers

5-FU can target normal, proliferating tissues, but with side effects of bone marrow suppression and gastrointestinal reactions. Targeted therapy for hepatocellular cancer may be useful because it is relatively less expensive compared with the current therapies and it also has fewer side effects. The emergence of a novel, sustained-release formulation of 5-FU is of clinical significance because it has fewer side effects compared with the regular 5-FU formulation.

Innovations and breakthroughs

In this paper, the authors examined the effects of GC/5-FU nanoparticle on liver cancer mouse model. As a result, GC/5-FU treatment could significantly lower

the tumor weight and increase the survival time of mice when compared with 5-FU treatment alone. In addition, it was suggested that the abovementioned effects of GC/5-FU was associated with G0-G1 arrest and apoptosis of tumor cells mediated by p53 pathway. GC/5-FU nanoparticles can relieve the side effects and immune-suppressive action of 5-FU.

Terminology

The effects of GC/5-FU nanoparticle on liver cancer mouse model. GC is a galactose ligand, with chitosan modifications on the molecular structure. Asialoglycoprotein receptor (ASGPR) is a receptor found on the membrane of hepatocytes facing the sinusoids, with specificity for glycoproteins with galactose or acetyl galactosamine at the end. The galactose ligand with ASGPR in GC/5-FU nanoparticle induces liver-targeted 5-FU transfer.

Peer review

The significance of this study is evident because the improvement of chemotherapy for liver cancer is an important subject in the clinical setting. In addition, the animal experiments were generally performed appropriately.

Abstract

AIM: To compare computed tomography enteroclysis (CTE) vs small intestine contrast ultrasonography (SICUS) for assessing small bowel lesions in Crohn's disease (CD), when using surgical pathology as gold standard.

METHODS: From January 2007 to July 2008, 15 eligible patients undergoing elective resection of the distal

ileum and caecum (or right colon) were prospectively enrolled. All patients were under follow-up. The study population included 6 males and 9 females, with a median age of 44 years (range: 18-80 years). Inclusion criteria: (1) certain diagnosis of small bowel requiring elective ileo-colonic resection; (2) age between 18-80 years; (3) elective surgery in our Surgical Unit; and (4) written informed consent. SICUS and CTE were performed ≤ 3 mo before surgery, followed by surgical pathology. The following small bowel lesions were blindly reported by one sonologist, radiologist, surgeon and histopathologist: disease site, extent, strictures, abscesses, fistulae, small bowel dilation. Comparison between findings at SICUS, CTE, surgical specimens and histological examination was made by assessing the specificity, sensitivity and accuracy of each technique, when using surgical findings as gold standard.

RESULTS: Among the 15 patients enrolled, CTE was not feasible in 2 patients, due to urgent surgery in one patients and to low compliance in the second patient, refusing to perform CTE due to the discomfort related to the naso-jejunal tube. The analysis for comparing CTE vs SICUS findings was therefore performed in 13 out of the 15 CD patients enrolled. Differently from CTE, SICUS was feasible in all the 15 patients enrolled. No complications were observed when using SICUS or CTE. Surgical pathology findings in the tested population included: small bowel stricture in 13 patients, small bowel dilation above ileal stricture in 10 patients, abdominal abscesses in 2 patients, enteric fistulae in 5 patients, lymphnodes enlargement (> 1 cm) in 7 patients and mesenteric enlargement in 9 patients. In order to compare findings by using SICUS, CTE, histology and surgery, characteristics of the small bowel lesions observed in CD each patient were blindly reported in the same form by one gastroenterologist-sonologist, radiologist, surgeon and anatomopathologist. At surgery, lesions related to CD were detected

in the distal ileum in all 13 patients, also visualized by both SICUS and CTE in all 13 patients. Ileal lesions > 10 cm length were detected at surgery in all the 13 CD patients, confirmed by SICUS and CTE in the same 12 out of the 13 patients. When using surgical findings as a gold standard, SICUS and CTE showed the exactly same sensitivity, specificity and accuracy for detecting the presence of small bowel fistulae (accuracy 77% for both) and abscesses (accuracy 85% for both). In the tested CD population, SICUS and CTE were also quite comparable in terms of accuracy for detecting the presence of small bowel strictures (92% vs 100%), small bowel fistulae (77% for both) and small bowel dilation (85% vs 82%).

CONCLUSION: In our study population, CTE and the non-invasive and radiation-free SICUS showed a comparable high accuracy for assessing small bowel lesions in CD.

INTRODUCTION

Accurate assessment of the lesions is mandatory for a proper pre-operative evaluation in Crohn's disease (CD). Diagnostic imaging of the small bowel traditionally included the small bowel follow through (SBFT) or small bowel enteroclysis^[1]. A comparable accuracy for assessing small bowel lesions in CD has been shown in referral centres^[2]. More recently, magnetic resonance enterography (MRE) and computed tomography enterography or enteroclysis (CTE) showed to accurately assess the presence, site and extent of small bowel lesions in CD, including stenosis, bowel dilation above stenosis and accurate measurement of the lumen diameter^[3-6]. These techniques also provide detailed extraluminal findings, including the bowel wall thickness (BWT), fis-

tulas, abscesses and phlegmons not detected by barium studies^[7-9]. For these reasons, MRE and CTE currently represent the standard techniques for assessing small bowel lesions in CD^[10]. The major limit of CTE is represented by the high radiation exposure for the patient^[5-11]. However, CTE has a greater availability and is less time-consuming than MRE^[10]. Therefore, as CTE and MRE show a comparable sensitivity for assessing small bowel lesions in CD, their use is also related to the local feasibility and availability of an experienced radiologist^[10].

Transabdominal ultrasonography also has been proposed for detecting small bowel lesions in patients with suspected or known CD, showing a sensitivity and specificity of 67%-84% and 81%-95%, respectively^[12-14]. The use of oral contrast significantly increases the sensitivity of ultrasonography for assessing small bowel lesions in CD (by more than 95%)^[10,15-19]. In particular, small intestine contrast ultrasonography (SICUS) performed by an experienced sonographer may visualize both established CD lesions (i.e., stenosis with possible pre-stenotic dilation) and minor changes of the small bowel^[10,15-20]. In experienced hands, SICUS may detect lesions in suspected small bowel diseases with a high (> 95%) sensitivity and specificity, when compared with SBFT and enema^[10,15-19]. The use of SICUS has also been proposed in the follow-up of CD patients after ileo-colonic resection, in order to avoid radiation exposure or the more invasive ileocolonoscopy^[19].

To our knowledge, only one retrospective study compared CTE and surgical pathology findings in patients with small bowel CD^[21]. A detailed information of the small bowel lesions is mandatory before elective surgery in CD^[10]. Moreover, surgical indication in subgroup of patients with small bowel CD may also be related to characteristics of the lesions, including abscesses, marked lumen narrowing and/or strictures with prestenotic dilation. On the basis of these observations, in a prospective longitudinal study, we aimed to compare the sensitivity, specificity and accuracy of SICUS vs CTE for assessing the presence of small bowel lesions in patients with CD undergoing elective ileo-colonic resection, when using surgical pathology findings as a gold standard.

MATERIALS AND METHODS

Patients

From January 2007 to July 2008, 18 eligible patients undergoing elective resection of the distal ileum and cecum (or right colon) with ileo-colonic anastomosis were enrolled. Among these 18 patients, there were 15 patients with ileal CD (8 males, median age 44 years, range: 19-73 years) and, as a control group, 3 patients (2 males, mean age 69 years, range: 60-77 years), requiring ileal resection due to small bowel duplication, carcinoid or ischemic enteritis. All patients were under regular follow-up in our unit.

Inclusion criteria included: (1) Patients with a certain

Figure 1 The figure shows images from the distal ileum from one patient with Crohn's disease of the distal and neo-terminal ileum undergoing ileo-colonic resection, as assessed by small intestine contrast ultrasonography and computed tomography-enteroclysis. A: Small intestine contrast ultrasonography (SICUS) showed a stenosis of the terminal ileum, with a thickened bowel wall, with lumen narrowing. The lumen diameter did not change after the ingestion of poly-ethylen glycole; B: Computed tomography-enteroclysis (CTE) showed findings comparable with SICUS, including a marked narrowing of the distal ileum, associated with an increased bowel wall thickness; C: SICUS showed a stricture of the neo-terminal ileum presenting as a thickened bowel wall, with lumen narrowing associated with pre-stenotic dilation; D: CTE showed findings comparable with SICUS, including a marked narrowing of the distal ileum, associated with an increased bowel wall thickness, but no bowel dilation).

diagnosis of small bowel diseases including CD or other non-inflammatory bowel disease (IBD) related conditions, requiring elective ileo-colonic resection; (2) age between 18-80 years; (3) elective surgery in our Referral Surgical Unit; and (4) written informed consent.

Exclusion criteria included: (1) Low compliance to perform both SICUS and CTE, including the introduction of a naso-gastric tube; (2) patients requiring urgent surgery; (3) obesity (body mass index > 30) not allowing a proper assessment by SICUS; and (4) allergy to contrast agents. In patients with CD, the diagnosis was made according to standard clinical, endoscopic and radiological criteria^[10]. Clinical characteristics of each of the 16 patients studied are summarized in Table 1.

Study protocol

From January 2007 to July 2008, all patients fulfilling the inclusion criteria and requiring elective ileo-colonic resection in our Unit due to small bowel CD were prospectively enrolled. In all patients, ileal lesions were assessed by using both SICUS and CTE within 3 mo before surgery, followed by surgical pathology findings used as a gold standard. Histological assessment of the surgical specimen was performed. In order to compare findings by using SICUS, CTE, histology and surgery,

characteristics of the small bowel lesions were blindly reported in the same form by one gastroenterologist-sonologist (Calabrese E), radiologist (Fiori R), surgeon (Simonetti G) and anatomopathologist (Palmieri G). The following parameters detailing the characteristics of the small bowel lesions were blindly reported by each specialist: site of the lesions (ileum, ileum-colon, colon, others), extent of the lesions (< 10 cm *vs* > 10 cm), strictures (yes/no, number), fistulae (yes/no, number), abscesses (yes/no, number), bowel dilation above strictures (yes/no), lymphnodes enlargement > 1 cm (yes/no, number), mesenteric enlargement (yes/no) (Figure 1).

CTE

CTE was performed by one experienced radiologist unaware of SICUS findings, from the Department of Diagnostic Imaging from our university, as previously described^[22]. Colonic cleaning was performed the day before CTE by using polyethylen glycole (PEG) 4000 solution. A 20G needle was placed in the antecubital vein and an 8-F naso-jejunal catheter with a Teflon-covered guide wire was positioned under fluoroscopic guidance (Guerbetm Guerbet GmbH D65838, Sulzbach/Ts) and the distal tip was located in the distal duodenum. The patient was then taken into CT room and contrast material (1500 mL of PEG) was administered manually with

CD: Crohn's disease; M: Male; F: Female; NA: Not applicable (non-CD).

60-mL syringes, with a continuous injection rate of 150 mL/min followed by a flow rate of 200 mL/min until the maximum tolerance of the patient. Before the examination, a smooth muscle relaxant (N butyl-scopolamine) was administered. CTE was performed by a 64-slice multidetector (LightSpeed VCT, General Electric Medical System, Milwaukee, WI, United States). After PEG infusion, CT scan was performed before and after the administration of *iu.*, iodinated contrast material. The contrast-enhanced study was acquired 70 s after the administration of contrast material (Ultravist 370, Schering AG, Berlin, Germany) with a “double-bolus” technique (a first bolus of 60 cc at a flow rate of 1.5 mL/s and a second bolus of 80 cc at a flow rate of 2.0 mL/s).

SICUS

SICUS was performed as previously described^[15,18,19]. In particular, SICUS was performed after the ingestion of 375 mL (range: 250-500 mL) of oral contrast solution consisting of PEG (Promefarm, Milano, Italy), by using a convex transducer (frequency 3.5-5 MHz) and then with a high frequency linear-array transducer (5-12 MHz) (Hitachi, EUB 6500, Japan). All procedures were performed by the same expert EC (> 2000 examinations).

The following findings were considered compatible with CD^[16,18,19]: (1) increased BWT (> 3 mm); (2) “stiff loop”, identified by the presence of small bowel loop, with increased BWT not distended by contrast solution; (3) small bowel dilation, defined as a lumen diameter > 2.5 cm; (4) bowel stricture defined as lumen diameter < 1 cm, measured at the level of maximally distended loop, independently of the presence of pre-stenotic dilation; (5) fistulae defined as hypoechoic tract with or without hyperechoic content; (6) mesenteric enlargement and/or

masses; (7) lymphnodes enlargement (> 1 cm); and (8) abscesses identified as roundish anechoic lesions, with an irregular wall, often presenting internal echoes and posterior echo enhancement.

Surgical assessment

At time of intestinal resection, one single GS filled up the above reported form in order to assess the small bowel lesions. Findings at surgery were considered as the gold standard for assessing the small bowel lesions described by SICUS and CTE. The surgical specimen was fixed in formalin for histological examination.

Histological assessment

The surgical specimen was examined by the one single GP unaware of previous findings at SICUS, CTE and surgery. At this purpose, routine hematoxylin and eosin staining was performed and the GP filled up the same form used by the sonographer, radiologist and surgeon.

Statistical analysis

All results were expressed as median and range. Comparison between findings at SICUS, CTE, surgical specimens and histological examination was made by assessing the specificity, sensitivity and accuracy of each technique, when using surgical findings as a gold standard.

RESULTS

From January 2007 to July 2008, 15 CD patients undergoing elective ileo-colonic resection and fulfilling the inclusion criteria were prospectively enrolled. Among these 15 patients, 2 CD patients performed SICUS but were not able to perform CTE, as one patient required “urgent surgery”, and the second patient refused to perform CTE due to the discomfort related to the naso-jejunal tube. Therefore, among the initial 15 patients eligible for the study, only 13 patients were studied by both SICUS and CTE and were therefore considered for the analysis. No side effects were reported after SICUS and CTE procedures.

Among the 13 CD patients considered in the analysis, surgical pathology findings included: small bowel stricture in 13, small bowel dilation above stricture in 10, abdominal abscesses in 2, fistulae in 5 (associated with abscess in 2), lymphnodes enlargement (> 1 cm) in 7 and mesenteric enlargement in 9 patients (Table 2).

Small bowel assessment by CTE and SICUS vs findings at surgery

Site of the lesions: At surgery, lesions were detected in the distal ileum in all 13 patients, and also in the right colon in 5. Both SICUS and CTE also visualized ileal lesions in all 13 patients, while concomitant lesions in the right colon were detected in 3 out of the 5 patients by both SICUS and CTE (including the same patients in 2 cases) (Table 2). Histological findings were comparable to surgery in all CD patients.

Table 2 Characteristics of the lesions in the 13 Crohn's disease patients, as assessed by surgical pathology (considered as a gold standard), small intestine contrast ultrasonography, computed tomography-enterography and histology

¹Including the jejunum in 1 patient. CD: Crohn's disease; SICUS: Small intestine contrast ultrasonography; CTE: Computed tomography-enterography.

Extent of the small bowel lesions: In CD group (Table 2), histology detected ileal lesions of > 10 cm length in only 9 patients.

Small bowel strictures: Ileal strictures were detected at surgery in all 13 CD patients. Comparable findings were detected by using CTE and histology, while no strictures were detected in one CD patient by using SICUS (Table 2).

Bowel dilation above strictures: Dilation above ileal strictures was detected by both surgery and SICUS in 10/13 CD patients, by CTE in 11/13 patients and by histology in 5/13 patients (Table 2). However, discrepant findings *vs* surgery were observed by using SICUS in 4/13 CD (dilation not detected in 2; dilation detected only by SICUS in 2), by using CTE in 5/13 CD (dilation not detected in 2; dilation detected only by CTE in 3) and by histology in 5/13 patients (dilation not detected in 5, discrepant findings *vs* surgery but comparable with SICUS in 2 and with CTE in 1) (Table 2). In the same 2 CD patients, both SICUS and CTE concordantly reported dilation above strictures not detected at surgery. Findings at CTE and SICUS were comparable in only 8/13 patients, as dilation was detected only by SICUS in 2 (confirmed at surgery) and only by CTE in 3 CD patients (confirmed at surgery in 2).

Fistulae: The presence of enteric fistulae were detected in 5 out of the 13 CD patients at surgery, in 6 patients when using SICUS, in 4 patients by using CTE, while histology reported the presence of fistulae in 6 CD patients (Table 2). Findings different from surgery were detected by SICUS in 3/13 patients (fistulae detected by SICUS and not at surgery in 2 patients; fistulae de-

SICUS: Small intestine contrast ultrasonography; CTE: Computed tomography-enterography; TN: True negative; TP: True positive; FN: False negative; FP: False positive; Sens.: Sensitivity; Spec.: Specificity.

tected at surgery and not by SICUS in 1 patient) by CTE in 4/13 patients (fistulae detected only by CTE in 2; detected only at surgery in 2); and by histology in 3/13 patients (fistulae detected by histology and not at surgery in 2, and detected at surgery and not by histology in 1). In 3 patients, SICUS and CTE concordantly reported enteric fistulae not confirmed at surgery (detected histologically in 2). When comparing SICUS *vs* CTE, the presence of fistulae was concordantly detected in 9/13 patients, while fistulae were detected only by SICUS in 1 CD patient.

Abscesses: Abdominal abscesses were detected at surgery in 3/13 CD patients (surgically drained in 1), by using SICUS in 5, by CTE in 3 and by histology in 4 patients (Table 2). Findings different from surgery were reported by SICUS in 2 patients (abscess detected only by SICUS in both), by CTE in 2 patients (abscess detected only by CTE in 1, only at surgery in 1), and by histology in 3 patients (abscess detected only by histology in 2 and only at surgery in 1 patient performing surgical drainage). In one patient, abdominal abscess was detected by both SICUS and CTE but not by surgical pathology and histology. When comparing SICUS and CTE, the presence of abscesses was concordantly detected in 11 out of the 13 patients, while in 2 patients SICUS only reported the presence of an intestinal abscess (confirmed at surgery in one of them).

Sensitivity and specificity of SICUS *vs* CTE

When using surgical findings as a gold standard, sensitivity, specificity and accuracy of SICUS and CTE for assessing the presence of stenosis, dilation above stenosis and fistulae are reported in Table 3. As indicated, the two techniques showed the same sensitivity, specificity and accuracy for detecting the presence of small bowel fistulae (accuracy 77% for both) and abscesses (accuracy 85% for both). SICUS and CTE were also quite comparable for detecting the presence of small bowel strictures, fistulae and abscesses. Nevertheless, there was a

not significant trend for a higher sensitivity and accuracy of CTE *vs* SICUS for assessing small bowel strictures (accuracy 100% *vs* 92%; the observed 0% specificity related to the absence of true negative findings), while SICUS showed a not significantly higher accuracy *vs* CTE for detecting small bowel dilation (85% *vs* 82%).

DISCUSSION

Appropriate surgical treatment of CD involves an accurate knowledge of the characteristics of the lesions, including the site, extent and possible presence of complications (strictures, dilation above strictures, fistulae, abscesses). The development of a marked bowel dilation above stricture or abscesses may represent indication for surgery^[10]. Colonoscopy represents the gold standard technique for assessing colonic lesions, while small bowel lesions were previously assessed by SBFT or small bowel enteroclysis^[11,2]. More recently, CTE or MRE represent the gold standard techniques at this purpose^[10]. These techniques indeed provide not only an accurate assessment of the presence, site and extent of the lesions, but they also allow the visualization of extraluminal findings related to the disease (i.e., increased BWT, fistulae, abscesses, mesenteric enlargement)^[3-9]. The preferential use of CTE *vs* MRE is related to the feasibility and easy access to these techniques in each IBD referral centre. At this purpose, both appropriate radiologic instruments and an experienced radiologist with specific competence in the field are required^[10]. MRE shows the advantage of a radiation-free procedure.

SICUS also has also been recently suggested as a non-invasive technique able to assess, in experienced hands, the presence of small bowel lesions in CD, including the BWT, strictures, bowel dilation, fistulae and abscesses^[16,18,21]. Indication for surgery in CD may also be related to the characteristics of the small bowel lesions (i.e., marked dilation above strictures, abscesses). Whether CTE and SICUS provide a comparable definition of the small bowel lesions in CD is currently unknown. On the basis of these observations, in the present study we aimed to compare these 2 techniques in terms of assessment of the small bowel lesions in patients with CD undergoing elective ileo-colonic resection. The use of small bowel capsule endoscopy has also been shown to accurately visualize small bowel lesions in CD^[23-25]. However, the use of small bowel capsule endoscopy (SBCE) is limited by the impact risk in patients with intestinal stenosis^[23-25]. In our study, according to the inclusion criteria, all CD patients were undergoing elective ileo-colonic resection. Therefore, all the enrolled CD patients were by definition at high risk of SBCE impact, related to severe lesions requiring surgical resection. For this reason, this useful technique able to visualize the entire small bowel was not feasible in the present study aimed to compare findings using CTE *vs* SICUS. A comparative estimate of the costs of the current techniques able to assess small bowel lesions, including not only CTE and SICUS, but also MRE and SBCE, could

be of great interest. However, these cost may greatly differ in different hospitals, thus limiting the usefulness of this estimate. Nevertheless, among techniques tested in the present study, it appears conceivable to consider CTE more expensive than SICUS.

Limitations of the study include the limited number of tested patients ($n = 15$), related to difficulties to perform 2 consecutive small bowel examinations in patients with active CD undergoing surgical resection. Additional limitation include the absence of a control group, as the purpose of the study was to compare the accuracy of SICUS *vs* CTE for assessing small bowel lesions in patients with a certain diagnosis of CD. Results from our limited series suggest that SICUS and CTE are quite comparable techniques at this purpose. However, while the accuracy of these two procedures for assessing the presence of strictures was quite comparable, SICUS showed a slightly higher accuracy for detecting the presence of dilation above strictures. In our series, CTE and SICUS were absolutely comparable for assessing the presence of fistulae and abscesses. SICUS is not feasible in obese patients, due to inaccurate findings and may be less accurate than CTE for visualizing lesions in the deeper layer of the abdominal cavity^[12]. Nevertheless, it seems relevant to note that CTE could not be performed in 2 out of the 17 enrolled CD patients (11.7%) already studied by SICUS. These 2 patients were therefore excluded from the analysis, as CTE could not be performed due to low compliance in one patient refusing the naso-jejunal tube and to need of urgent surgery in the second patient. These observations therefore support that CTE may not be performed in a relatively high proportion of patients undergoing ileo-colonic resection for CD.

Nevertheless, differently from SICUS, CTE is an invasive procedure associated with a high radiation exposure for the patient^[11]. This issue assumes particular relevance when considering that small bowel assessment before surgery for CD is most often required in young patients already performing other diagnostic radiological procedures and treated with immunomodulatory drugs^[26-29]. These observations, together with findings from our study therefore suggest that in referral IBD centres with a feasible experienced ultrasonographer, SICUS may represent the procedure of choice when compared with CTE, for assessing small bowel lesions in patients undergoing elective ileo-colonic resection for CD.

COMMENTS

Background

Magnetic resonance enterography (MRE) and computed tomography enterography or enteroclysis (CTE) accurately assess small bowel lesions in Crohn's disease (CD), representing the standard techniques at this purpose. The major limit of CTE is represented by the high radiation exposure for the patient. Recently, small intestine contrast ultrasonography (SICUS) performed by an experienced sonographer has been shown to visualize CD lesions of the small bowel. These findings suggest that SICUS may be used for assessing CD lesions, although comparison with CTE when using surgical pathology as standard is unknown.

Research frontiers

Proper follow up of CD patients includes the assessment of the lesions in order to choose appropriate treatment strategies and the presence of complications. In this study, the authors compared the sensitivity, specificity and accuracy of SICUS vs CTE for assessing the presence of small bowel lesions in patients with CD undergoing elective ileo-colonic resection, when using surgical pathology findings as a gold standard.

Innovations and breakthroughs

Small bowel lesions in CD may be accurately detected by CTE or MRE. However, the use of CTE is associated with a high radiation exposure, while MRE shows a low availability. Moreover, the need of intestinal preparation, insertion of the naso-gastric tube may limit the use of both techniques. The authors performed a prospective longitudinal study in patients undergoing elective surgery, aimed to assess the accuracy of SICUS vs CTE for assessing small bowel lesions in CD, when using surgical pathology as gold standard.

Applications

This study provides the first evidence that SICUS and CTE show a comparable high accuracy for assessing small bowel lesions in CD. These results suggest that the radiation-free, non-invasive SICUS performed by an experienced sonographer may be used for assessing small bowel lesions in patients with CD.

Peer review

CTE and MRE may not be performed in patients with low compliance. Results from this study support that, differently from CTE, SICUS may be performed in all CD patients undergoing elective surgery. As SICUS and CTE showed a comparable high accuracy for assessing small bowel lesions in CD, the non-invasive SICUS should be used at this purpose in referral centres provided of an experienced and available sonologist.

Abstract

AIM: To investigate the variability of the main immunodominant motifs of hepatitis B virus (HBV) core gene by ultra-deep-pyrosequencing (UDPS).

METHODS: Four samples (2 genotype A and 2 genotype D) from 4 treatment-naïve patients were assessed for baseline variability. Two additional samples from

one patient (patient 4, genotype D) were selected for analysis: one sample corresponded to a 36-mo treatment-free period from baseline and the other to the time of viral breakthrough after 18 mo of lamivudine treatment. The HBV region analyzed covered amino acids 40 to 95 of the core gene, and included the two main epitopic regions, Th50-69 and B74-84. UDPS was carried out in the Genome Sequencer FLX system (454 Life Sciences, Roche). After computer filtering of UDPS data based on a Poisson statistical model, 122 813 sequences were analyzed. The most conserved position detected by UDPS was analyzed by site-directed mutagenesis and evaluated in cell culture.

RESULTS: Positions with highest variability rates were mainly located in the main core epitopes, confirming their role as immune-stimulating regions. In addition, the distribution of variability showed a relationship with HBV genotype. Patient 1 (genotype A) presented the lowest variability rates and patient 2 (genotype A) had 3 codons with variability higher than 1%. Patient 3 and 4 (both genotype D) presented 5 and 8 codons with variability higher than 1%, respectively. The median baseline frequencies showed that genotype A samples had higher variability in epitopic positions than in the other positions analyzed, approaching significance ($P = 0.07$, sample 1 and $P = 0.05$, sample 2). In contrast, there were no significant differences in variability between the epitopic and other positions in genotype D cases. Interestingly, patient 1 presented a completely mutated motif from amino acid 64 to 67 (E₆₄LMT₆₇), which is commonly recognized by T helper cells. Additionally, the variability observed in all 4 patients was particularly associated with the E₆₄LMT₆₇ motif. Codons 78 and 79 were highly conserved in all samples, in keeping with their involvement in the interaction between the HBV virion capsid and the surface antigens (HBsAg). Of note, codon 76 was even more conserved than codons 78 and 79, suggesting a possible role in HBsAg interactions or even in hepatitis B e antigen

conformation. Sequential analysis of samples from patient 4 (genotype D) illustrated the dynamism of the HBV quasiespecies, with strong selection of one minor baseline variant coinciding with a decrease in core variability during the treatment-free and lamivudine-treated period. The drop in variability seemed to result from a "steady state" situation of the HBV quasiespecies after selection of the variant with greatest fitness.

CONCLUSION: Host immune pressure seems to be the main cause of HBV core evolution. UDPS analysis is a useful technique for studying viral quasiespecies.

INTRODUCTION

Hepatitis B virus (HBV) infection is a global health problem. Around 350 million people are chronically affected with this pathogen, which confers a higher risk of developing liver disease, liver cirrhosis, and hepatocellular carcinoma. The course of HBV infection is closely related to the host immune response and genetic factors^[1], and disease progression is related to mutations in the HBV core gene^[2-4].

HBV core gene codes for two partially collinear proteins, the hepatitis B e antigen (HBeAg) and hepatitis B core antigen (HBcAg). These proteins, together with the surface antigen (HBsAg) are important targets for antiviral immunity, but HBcAg seems to be the most immunogenic^[5]. Several epitopes have been identified in the HBV core gene. Among them, two regions play a particularly important immunodominant role: the sequence from amino acid 50 to 69, which immunostimulates CD4+ T-helper lymphocytes (Th50-69)^[6] and the sequence from amino acid 74 to 84, which stimulates B lymphocytes (B74-84)^[7,8].

During chronic HBV infection, a large number of amino acid substitutions are seen in the core gene, mainly clustered in epitopic regions. These amino acid changes have been associated with viral persistence because of their impact on the host immune response and the

natural course of HBV infection^[7,9-14]. The largest number of core gene changes is associated with interferon (IFN) therapy^[10-12]. The effect of nucleoside/nucleotide analogues on the core gene has been little investigated, although some variability in a minor epitope (Th28-47) was recently reported^[11]. In another recent study, entecavir and adefovir were associated with an enhanced immune response^[13]. Selection of core gene amino acid changes might result in evasion of HBV from the host immune system, thereby lengthening the life of infected hepatocytes. For this reason, core gene baseline variability in chronic hepatitis B patients might be crucial for understanding the evolution of the viral quasiespecies in response to host immune pressure.

Next-generation sequencing technologies enable deep assessment of gene variability and are especially useful to study the dynamics of viral quasiespecies^[16-21]. Core gene variability can be studied with this technology, specifically, the 454 FLX platform, which analyzes fragments of 250- to 400-bp length. Although this length does not permit complete analysis of the gene, ultra-deep analysis of the main immunodominant regions of the core protein (Th50-69 and B74-84) is possible. The aim of this study was to analyze the variability of these main HBV core epitopes in chronic hepatitis B patients by ultra-deep pyrosequencing (UDPS).

MATERIALS AND METHODS

Patients and samples

Four chronic hepatitis B patients with complete clinical documentation were selected for the study; baseline characteristics are indicated in Table 1. All patients were diagnosed with active HBV replication and treated with lamivudine (LVD) 100 mg/d (Zeffix, Glaxo Wellcome, United Kingdom). After 18 to 24 mo, they all presented mutations conferring resistance to treatment. Owing to their similarities in LVD non-response, they were selected for inclusion in the study. To evaluate baseline variability, a sample taken at the time of the diagnosis (antiviral treatment naïve) was selected for each patient. HBV DNA was retested in all samples by TaqMan real-time polymerase chain reaction (PCR) (Roche) technology, and all presented values higher than 5 log₁₀ IU/mL.

Two sequential samples from patient 4 were additionally selected for UDPS analysis. HBV-DNA had been quantified using the branched-DNA (bDNA, limit of detection 5 logs IU/mL) technology available at that time, but the samples selected were retested with TaqMan technology for this study. At the time of the diagnosis (baseline sample), high HBV-DNA levels were detected by bDNA (retesting with TaqMan, 7 log₁₀ IU/mL). However, HBV-DNA spontaneously dropped below the limit of detection of bDNA technology and the patient remained untreated, according to the guidelines at that time. After 36 mo (treatment-free sample), bDNA significantly increased (> 8 logs₁₀ IU/mL on TaqMan retesting) and LVD was started. After an initial suboptimal response (HBV DNA decrease to 4 logs), viral breakthrough (7

Table 1 Baseline characteristics of the four patients included in the study

Patient	Sex	Age (yr)	ALT (IU/mL)	HBV DNA (log ₁₀ IU/mL)	Genotype	HBeAg status
1	Male	46	167	7.4	A	- ¹
2	Male	39	95	7.8	A	+
3	Male	31	392	8.3	D	-
4	Female	55	117	7.5	D	-

log₁₀ HBV-DNA) was observed after 18 mo, and the rtL180M and rtM204V HBV polymerase variants were selected. Ultimately, adefovir was added to LVD.

Epitopic region amplification and UDPS amplicon preparation

All the samples included in this study had HBV viral loads higher than 6 logs IU/mL. HBV-DNA was extracted from serum by QIAamp microspin columns (QIAamp DNA Mini Kit, QIAGEN, Hilden, Germany), according to the manufacturer's instructions. To obtain optimal amplification of HBV DNA, the process was optimized with two PCRs. To minimize the error rate of the PCR process (false nucleotide substitutions), high fidelity polymerase (Pfu Ultra-II, Stratagene, La Jolla, United States) was used. At the time the study was designed, the maximal amplicon length that could be analyzed by the FLX platform was 250 nucleotides; PCR primers were selected for amplification of a specific 210-bp HBV fragment, which included main epitopic regions (Th50-69 and B74-84). The first PCR primers were sense (position 1662-1681); 5'-C/τATAAG AGGACTCTTGGACT-3' and anti-sense primers (position 2912-2931); 5'-TGTTCCCA^A/GGAATA^A/τGGTGA-3'. The nested primers included the recognition site for UDPS, in *italics*. The sequence of the sense primer (position 1997-2016) was 5'-GCCTCCCTCGC-GCCATCAGACCGCCTCAGCTCT^C/τTAT CG-3', and the anti-sense primer (position 2178-2206) was 5'-GCCTTGC CAGCCCGCTCAGCCACA^A/GAGTT-GCCTGA^A/GCTT-3'. PCR products were isolated from 0.9% agarose gel and quantified using Quan-iT Picogreen sDNA reagent (Invitrogen). Before the sequencing reaction, each amplicon was pooled to obtain a concentration of 4×10^6 molecules of the HBV region. This working solution was enriched with the capture beads needed for sequencing. After optimal enrichment, clonal amplification in beads was performed in forward and reverse directions (emPCR kits II and III, 454 Life Sciences). UDPS was carried out in the Genome Sequencer FLX system (454 Life Sciences). The HBV region analyzed covered amino acids 40 to 95 of the core gene.

Bioinformatics filter

A total of 122 813 sequences was obtained. Reads were acquired with forward and reverse sequences and were

aligned according to the primer sequence (designed by our group). Initial raw data filtering was performed as previously reported^[16-18,20-22].

After applying the Poisson-based statistical filter validated in a study from our group^[21], the empirical distribution of mismatch errors determined by UDPS analysis of an HBV DNA clone from the same region yielded an average of 0.006%; however in 8 positions, errors were higher than 0.02% but lower than 0.05%. Therefore, the sensitivity of UDPS to detect mutations was primarily limited by the highest mismatch error rate in the HBV DNA clone of 0.05%, which is similar to the value recently obtained in UDPS amplicons including an internal sequence as a control^[20]. Thus, the measurements and biological conclusions in this study are based only on mutations present at a percentage above 0.05%.

Phenotyping, mutagenesis and cell culture

Cloning of a more than full-length HBV genome^[20] in pTriEx-mod vector was performed as described by Durrant *et al.*^[23]. The influence on HBV viral replication of the most conserved position observed in UDPS analysis, codon 76, was analyzed by site-directed mutagenesis (Agilent Technologies, Stratagene, United States) according to the manufacturer's instructions. The wild-type clone had an L in codon 76, which was changed to V or P to test the effect of maintaining or deeply altering the physical-chemical properties of core codon 76. The introduction of mutations was confirmed by direct sequencing, as previously described^[20].

Huh7 human hepatoma cells were cultured in Dulbecco's modified Eagle medium supplemented with 10% calf serum. Transfection of plasmids was performed as previously described^[20] using Fugene-HD (Roche, Germany). The supernatant was used to quantify HBsAg (Architect, Abbot), HBeAg (Vitros, Johnson and Johnson), and HBV DNA (CobasTaqman, Roche) production. The results were statistically analyzed with the Student *t* test. DNA was extracted from the supernatant (QiagenAMP DNA Mini Kit, Qiagen, Germany) following the manufacturer's instructions and used to evaluate HBV-DNA production. As has been previously described^[20], to confirm that HBV-DNA detected after transfection was the result of HBV replication and not due to contamination from the HBV genome in the pTriEx-mod vector of the transfection experiments, the supernatant extractions were used in 1/10, 1/10², 1/10³, and 1/10⁴ dilutions and PCR amplification of HBV-DNA and pTriEx-mod was performed.

Statistical analysis

To obtain the percentage of amino acid variability in each sample, the total number of amino acid substitutions was divided by the total number of amino acids analyzed. This value gave the theoretical variability for each position, and was used to estimate the expected variability for the regions studied (the theoretical variability was multiplied by the length of the epitope: 20

Italic numbers indicate the patient in whom the master amino acid (AA) was detected.

for Th50-69, 11 for B 74-84, and 25 for the remaining positions).

Fisher's exact test was used to evaluate possible rela-

tionships between the most variable codons (variability $\geq 1\%$) and their positions in the epitopic region or other regions. The Wilcoxon signed-rank test was used to compare the evolution of the codons in the sequential analysis.

RESULTS

Baseline variability of main epitopic regions of HBV core gene

The amplicon analyzed was limited to codons 40 to 95, which include the main Th50-69 and B74-84 epitopes. A total of 122 814 sequences corresponding to 4 baseline samples were analyzed, and 108 403 of them were validated by bioinformatics and Poisson filtering. A total of 61 499 sequences were from genotype A samples and the remaining from genotype D. Variability was analyzed attending to the percentage of changes in all codons of the amplicon, and the results obtained for each position are shown in Table 2.

In the two genotype A samples (patients 1 and 2), differences between the master sequences were found in ten codons (41, 45, 59, 64, 65, 66, 67, 77, 84 and 87, Table 2), seven of which were located in Th50-69 or B74-84. Of particular note, the master sequence of the motif delimited by codons 64 to 67, commonly defined by E₆₄LMT₆₇ and recognized by T-cells^[13], differed in patient 1. The sequence found, D₆₄VTN₆₇, was completely different from the consensus sequence of genotypes A and D. The amino acid variability detected in patient 1 (average, 0.1%), which ranged from 0.69% to values under the cut-off ($< 0.05\%$), was the lowest in all 4 samples. In this patient, the main epitopic regions contained 67.7% of the changes, a percentage 1.2 times higher than would be expected by the length of these regions, and the changes were equally distributed between the two epitopes. In contrast, patient 2 had higher variability (average, 0.35%), particularly in codons 41 (7.54%), 59 (4.75%) and 63 (1.93%). Only 53.1% of these changes were located in epitopic regions, a rate similar to the expected random percentage, but in the Th50-69 epitope the substitutions were 1.3 times higher than would be expected. Interestingly, two of the main substitutions detected in patient 2, S41 (A, 7.51%) and V59 (I, 4.21%), coincided with the master sequence of patient 1. The third main variant position was G63 (V, 1.62%).

The two genotype D baseline samples (patients 3 and 4) had the same master sequence, except in codons 64, 74, 80 and 93, which were also the most highly variable in patient 4. In patient 3, five codons with more than 1% variability were detected: A41 (1.58%), I59 (1.68%), A74 (2.1%), E77 (1.94%) and S87 (1.93%) (3 of them in epitopic regions). The average amino acid variability was 0.26%, and 57.8% of changes were located in the main epitopic regions. Overall, this percentage was not higher than expected; however, changes in B74-84 were 1.6 times higher than the expected random percentage (31.6% *vs* 19.7%). In patient 4, variability was higher

Figure 1 Variability of all codons analyzed from the 3 sequentially studied samples, corresponding to patient 4. Percentages higher than 2% are indicated at the top of the bars. 1: Master aminoacid different between treatment free and lamivudine samples.

than 1% in 8 codons - Q40 (36.27%), L55 (18.58%), D64 (29.96%), V74 (13.72%), E77 (3.03%), T80 (8.08%), T92 (18.93%) and V93 (18.89%) - 5 of which were in epitopic regions. Linkage analysis showed that some of the main variants seen in this patient (S at codon 41, V at 59, N at 74, E at 77 and N at codon 87) were located in the same viral strain (1.5% of quasiespecies). This observation seems to indicate possible selection by the effect of immune pressure on the core gene. Surprisingly, despite the high total amino acid variability detected in patient 4 (2.69%), only 49.8% of changes affected positions located in main epitopic regions, a value lower than was expected in both Th50-69 and B74-84.

Median baseline frequencies were compared between the epitopic and other positions. Only genotype A samples showed high variability approaching significance ($P = 0.07$, sample 1 and $P = 0.05$, sample 2) in epitopic positions. Regarding the median baseline variability (Table 2), 6 of the highest values were located in positions within the main epitopic regions (codons 55, 59, 64, 74, 77 and 80), and 4 positions outside the main epitopes (codons 40, 41, 92 and 93) accumulated high percentages of changes. The variability in positions 40, 92 and 93 was due to changes in patient 4, whereas the variability of codon 41 (median 2.3% of changes) was due to changes in patients 2 and 3. Interestingly, positions

64 and 66, corresponding to the E₆₄LMT₆₇ motif of Th50-69, showed significant variability in all 4 samples (0.69%, 0.5%, 0.41% and 29.96% in position 64 and 0.12%, 0.21%, 0.11% and 0.11% in position 66).

Attending to the conserved positions, 12 codons showed variability lower than the system error rate ($< 0.05\%$): positions 44, 52, 57, 68, 70, 75, 76, 78, 81, 85, 86 and 89. The most highly conserved was leucine in codon 76, with frequencies clearly below the system error rate (0.003-0.02%) and a median baseline error of 0.013% (Table 2). Based on this finding, codon 76 was analyzed by site-directed mutagenesis analysis.

HBV quasiespecies dynamics: The sequentially studied patient

Patient 4 was selected for sequential analysis, and 3 samples were processed (Figure 1): a baseline sample (also included in the *Baseline Study*), a sample following a treatment-free period of 36 mo, and a sample following 18 mo of LVD non-response. After application of the bioinformatic filter, 34 320 sequences from the treatment-free sample and 43 257 sequences from the LVD sample were obtained. The average amino acid variability of the baseline sample was higher than that of the treatment-free one (2.69% *vs* 0.34%, $P = 0.001$) and the average amino acid variability of the treatment-free sample was

Figure 2 Evolution of the most variable codons of the core region analyzed in the sequentially studied patient. The variable position and its corresponding master amino acid are shown on the X-axis. The main mutated amino acids are indicated at the top of the bars.

higher than that of the LVD treatment sample (0.34% *vs* 0.18%, $P = 0.001$). The main variants detected by sequential analysis are represented in Figure 2. Of note, 6 of these 11 variable positions (codons 55, 57, 64, 74, 77, 80) were located in main core epitopic regions.

Linkage analysis was performed to determine whether the most frequent amino acid substitutions were simultaneously present in the same viral sequence (Figure 3A). At baseline, 50.15% of sequences in the positions studied were wild type, and 38.88% were mutated sequences in the most variable positions (15 different mutated variants, Figure 3A); 10.97% showed mutations in other positions. The mutated sequences in highly variable positions detected at baseline were found to be decreased in the treatment-free period (1.85%, Figure 3B) and after LVD breakthrough (1.24%, Figure 3B).

Attending to these variable positions, the most common strain at baseline (7.5%) had only one mutated codon (E40Q), followed by a strain (6.84%) with 5 mutated codons (E40Q, D64E, V74G, T92N and V93M) and another strain (5.45%) with 3 mutated codons (E40Q, L55I and D64E). Surprisingly, the baseline strain that had been selected as master after the treatment-free period and maintained during LVD was a low-frequency baseline mutant strain (1.31%) with the following substitutions: E40Q, L55I, D64E, T80G, T92H and V93M (variant 12, Figure 3A).

The time period with an absence of therapy (between baseline and treatment-free sampling) represented the complete time of HBV infection, and the HBV core

quasispecies showed a tendency to decreased variability. This was reflected by a drop in the percentage of accumulated variability from baseline (38.88%) to the treatment-free sample (1.85%) and coincided with the change in the master sequence between the two samples, which could indicate a possible alternative immune escape mechanism. No significant differences were observed between samples from the treatment-free and LVD periods, which showed similar composition and percentages of mutated variant strains (Figure 3).

Evaluation of the conserved position, leucine 76, by site-directed mutagenesis

As is described above, leucine (L) at codon 76 was the most highly conserved position in all the samples analyzed (Table 2). Although there were other conserved positions (Q57, T70, D78 and S81), codon 76 focused our interest because it was a leucine (one amino acid coded by 6 different codons), because of its location in the core gene, and because it has never been described as essential. L76 was even more conserved than D78 (0.05%) or P79 (0.09%), both of which are reported to be involved in the core-HBsAg interaction^[24]. Mutagenic studies of L76 were performed to evaluate a possible essential role of this amino acid. The experiments included a change to valine (V), whose hydrophobicity is similar to that of L, and a change to proline (P), whose physical-chemical properties differ from those of L.

After transfection, HBsAg, HBeAg and HBV DNA were quantified in cell culture supernatants. The presence

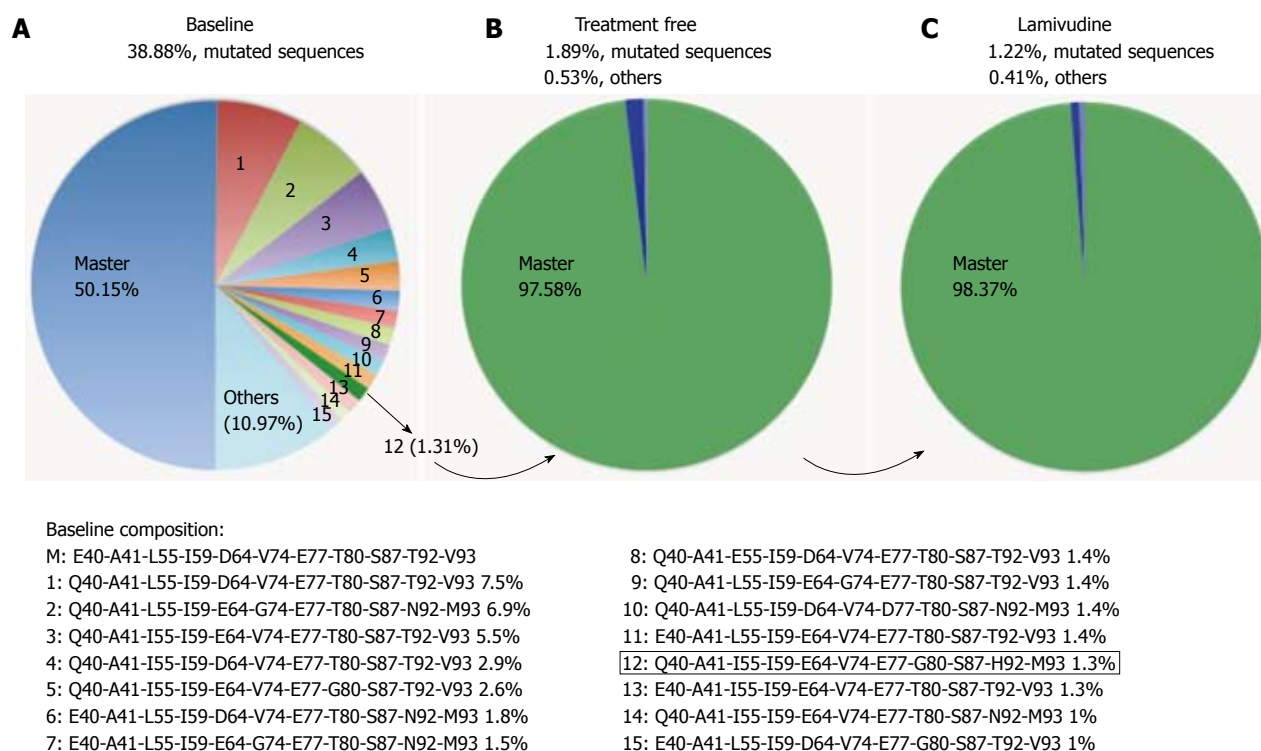

Figure 3 Quasispecies composition of the hepatitis B virus core region in the 3 sequentially analyzed samples. A: Baseline variants (1-15) in percentages $\geq 1\%$; B: Treatment-free variability; C: Lamivudine sample variability of the most frequent amino acid substitutions defined in Figure 2. Linkage analysis was also performed attending these most variable codons.

of P in position 76 significantly decreased production of HBsAg, HBeAg and HBV-DNA in comparison with the wild type (L76) (both, $P < 0.001$). However, when V was in position 76, a reduction was observed in HBsAg levels ($P < 0.001$), but not in HBV DNA. Surprisingly, the V substitution resulted in a four-fold increase in HBeAg production in comparison with L76 ($P < 0.001$).

DISCUSSION

Several epitopic regions have been described in HBV core gene. Core region variability under antiviral treatment has been extensively studied, particularly in relation to IFN therapy^[10,12]. However, differing patterns of amino acid substitutions under the effect of nucleotide/nucleoside analogues and during periods without treatment have been recently described^[11]. Some studies have used the classical clonal method to analyze the evolution and composition of the entire HBV core gene^[25-27]. However, in all these reports, only a small number of clones were processed and minor populations could not be studied. Thus, high-resolution clonal studies are needed to deeply analyze the composition of the HBV core gene quasispecies. To this end, the recently developed UDPS technology provides an opportunity to bypass the restrictions of the classical clonal method to determine the composition of viral quasispecies^[16,17,19-21].

When this study was designed, UDPS technology based on the 454 Life Science Platform (GS-FLX, Roche Applied Science) only allowed analysis of around 200

nucleotide sequences. Because of this limitation, the present work was focused on analysis of the main immunodominant core motifs, Th50-69 and B74-84^[6,7]. The high economic cost and complex computing analysis of UDPS strongly restrict the number of samples to be processed. For this reason, we were only able to study six selected samples: four samples to evaluate the baseline variability and two more samples to sequentially analyze one patient.

To achieve the main aim of UDPS analysis, a parallel analysis was needed to define the cut-off for analyzing the UDPS data. In our previous report of UDPS analysis of the HBV quasispecies^[20], inclusion of an internal control sequence within the analyzed amplicon enabled establishment of a cut-off percentage to define the limit of viral variability, which was set at 0.03%. In the present study, a Poisson computational model recently validated by our group was applied by processing an HBV-DNA clone^[21]; the percentage established to differentiate variability from UDPS error was set at 0.05%^[21].

In the study of baseline HBV quasispecies, the most variable codons (median baseline variability $\geq 1\%$) were 40, 41, 55, 59, 64, 74, 77, 80, 92 and 93, all of which have been previously described in a study using clonal methodology to analyze acute exacerbations in HBeAg-negative patients^[25]. Furthermore, some of these highly variable codons (codons 64, 74 and 77) were previously described as common changes in untreated chronic hepatitis B^[11]. Genotype A sequences showed fewer codons with variability $\geq 1\%$ and, consequently, lower over-

all median variability than genotype D. The statistical analysis of the median baseline frequencies showed that genotype A samples had higher variability in epitopic positions, approaching significance ($P = 0.07$, sample 1 and $P = 0.05$, sample 2). In contrast, in genotype D cases, no significant differences in variability were observed between the epitopic and other positions. These findings could be related to the high frequencies of mutations in codon 40, 87, 92 and 93 in genotype D samples (patients 3 and 4), which might be involved in the minor epitopic regions Th28-47 and Th82-101^[6,11]. These differences in HBV core gene variability seem to indicate an influence of genotype on immune activation.

Patient 1 showed the lowest variability, but interestingly, the codon 64 to 67 master sequence was defined by the sequence D₆₄VTN₆₇, which is completely different from the well-characterized E₆₄LMT₆₇ motif. This motif is commonly recognized by T-cells, and the simultaneous E₆₄D and T₆₇N change has been reported to reduce T-cell proliferation *in vitro*^[13]. Hence, we suggest that the changes observed in patient 1 might be the result of an alternative mechanism to escape from immune pressure, over the E₆₄LMT₆₇ motif. In fact, the finding that positions 64 and 66 of this motif showed significant variability in all 4 samples suggests that the motif could be a central target for immune pressure in HBV infection^[11]. The low variability observed in sample 1 (0.1% of total amino acid variability) could reflect attainment of a kind of “steady state” in the viral quasispecies, resulting from strong selection of an escape variant with the mutated motif D₆₄VTN₆₇, similar to that seen in the longitudinal study of patient 4.

Evolution of the HBV quasispecies was evaluated in a single patient and involved a baseline sample and two additional samples, one taken after a period without treatment and one taken after LVD treatment. During the treatment-free period, a decrease in quasispecies variability was observed, with a reduction in the number of viral strains. This change may have been a consequence of host immune pressure^[25]. One of the baseline viral strains present in a small percentage (variant 12, 1.31%, Figure 3) was strongly selected and became the master in the treatment-free and LVD samples, a fact suggesting that this variant might be an escape mutant, whose selection could be related to better fitness, regardless of its initial frequency.

Based on these results, we postulated that the HBV quasispecies achieved a kind of “steady state” after the treatment-free period that did not change with LVD treatment, because immune pressure could also be decreased during treatment. The significant differences in average variability in the two periods suggest that the equilibrium is dynamic. The structure of the HBV quasispecies in the three samples represents a complex reservoir of different minor variants, resulting from natural HBV evolution and likely affected by antiviral treatment^[28].

Several codons in our region were found to be highly

conserved (positions 57, 70, 76, 78 and 81). Position 76, located at the tip of the spike was of special interest, being next to the major immunodominant region and part of the B74-84 main epitope. Indeed, this position has never been described as essential, in contrast to the nearby positions 78 and 79^[24]. The HBV core sequence is involved in the process of capsid conformation by interacting with the surface antigens in viral particle assembly. However, the interaction between HBsAg and HBcAg in virions is still unclear^[29-31]. The core region analyzed in the present study is part of the assembly domain (amino acids 1-149); thus, the changes in this region might potentially modify the shell conformation.

Electrostatic interactions between core and HBsAg take place at the tip of the spike of the core antigen (codons 74-84)^[32,33]. Cryo-electron microscopy studies have shown that codon 78 and 79 are within the contact area of core with envelope proteins^[24]. This essential role might explain the high level of conservation of these positions (especially codon 78, 0.05%) observed in our UDPS analysis. However, surprisingly, the most conserved codon of the HBV core region in baseline and sequential samples was leucine at position 76.

To our knowledge, few studies^[30,31] have analyzed the effect of single core amino acid mutations on HBV replication *in vitro*. Only one such study conducted by Ponsel *et al.*^[31] evaluated the leucine 76 position (among others) by inducing a change to alanine; no significant reduction in nucleocapsid or virion production was observed. In the present study, we induced changes in the hydrophobic characteristics of position 76 and determined their effect on HBsAg, HBeAg and HBV DNA production. In contrast to the results of Ponsel *et al.*^[31], we found a significant reduction in HBsAg production with both the V and P changes, suggesting possible involvement of L76 of HBcAg in the HBsAg interaction. A significant decrease in HBV replication in the presence of P76 was detected, leading us to speculate that the hydrophobic characteristics of position 76, conferred by the presence of L or V, are needed for HBV replication. The increase in HBeAg production in the presence of the V mutation and the absence of increasing HBV DNA were surprising, particularly because some authors have reported a correlation between HBeAg and HBV DNA levels^[34]. Nonetheless, this correlation was not found by other authors^[35] and currently remains controversial. We suggest that this unexpected HBeAg increase may indicate alternative pathways between HBeAg and HBV replication, as has been indicated previously^[36]. Based on our *in vitro* results, it can be postulated that the amino acid changes induced in the core sequence are not as important as the structure adopted by the capsid and HBeAg.

Our study is mainly limited by the high cost of the UDPS process, which restricted the number of samples studied and created a risk that some results could be due to random chance. A larger number of samples, additional sequential studies, and duplicate UDPS experiments would have given more information about the

HBV core sites involved in quasispecies evolution and potentially related to HBV chronic infection and to treatment non-response. In addition, at the time of the study, the available UDPS methodology only allowed analysis of sequences up to 250 bp. For this reason, we limited the study to the widely described main epitopic regions included in the HBV core, previously investigated by conventional methodologies^[6,7,11,25].

In conclusion, this study validates application of UDPS to study the variability of the main core epitopes, substantiates the significant richness of the HBV baseline quasispecies, and suggests a relationship between core variability and HBV genotype. The highest variability was mainly detected in Th50-69 and B74-84, supporting their role as the main immune-stimulating core regions. The significant variability associated with well-characterized Th-cell motifs, such as E₆₄LMT₆₇, seems to indicate that the host immune system may be the main factor responsible for HBV core evolution. The relevant conservation of codon 76 may be related to possible interactions with the viral envelope. In the single longitudinally analyzed patient, a minor variant present in the baseline quasispecies was selected as the main variant in the absence of treatment and was maintained after lamivudine. These findings indicate the utility of UDPS to describe the dynamic behavior of the HBV quasispecies. More extended analyses with a larger number of samples must be performed to confirm the findings. The expected spread of this technology will probably allow a significant decrease in the cost, enabling processing a large number of samples. The UDPS application for diagnostic and routine analysis might serve for the quantitative estimation of the viral quasispecies, for defining mutant variants or for establishing the quasispecies complexity. All these parameters would be useful as prognostic factors for disease outcome or therapy efficacy.

COMMENTS

Background

Hepatitis B virus (HBV) infection is a global health problem, with more than 300 million HBV carriers. Viral distribution in individual infection is defined as a quasispecies, which means that variability can be accumulated along the HBV genome. The core gene is the least overlapped gene of the HBV genome and core antigen is the most immunogenic of all the viral peptides. Therefore, the region encoding the main core epitopes is useful to study the effect of the host immune response and to analyze the variability of HBV quasispecies composition.

Research frontiers

The distribution of viral infection as a quasispecies (in HBV, but also hepatitis C virus and human immunodeficiency virus) is an important advantage for the virus. It enables fast, easy establishment of infection and enables adaptation against changes in the viral environment. The study of viral quasispecies has been limited by the available methods, with which analysis of a significant number of clonal sequences was extremely difficult. The possibility of obtaining thousands of sequences in a single sample, provided by next-generation sequencing methods such as ultra-deep-pyrosequencing (UDPS), will allow

more in-depth study of the viral quasispecies. In the present study, the authors applied the UDPS to analyze HBV quasispecies variability and adaptability of the virus in single patient.

Innovations and breakthroughs

To date, few studies have used UDPS to study the HBV quasispecies, likely because of the current high cost of the technique for this purpose. However, the results presented in these recently published studies have shown clear advantages of UDPS for viral quasispecies analysis. Most of these studies have been mainly focused on the polymerase gene (treatment resistance variants). The present study is the first work analyzing the core gene by this method, to evaluate the effect of the host immune response and the variability of this little overlapped region of the HBV genome.

Applications

This study illustrates the value of deep quantitative analysis of the HBV quasispecies composition to investigate its clinical relevancy. The results provide an indication of the role of HBV core gene quasispecies structure in the natural host immune response and have prompted us to continue investigating HBV variability by UDPS, particularly the precore and core regions because of their relationship with the immune response.

Terminology

Viral quasispecies distribution in an infected patient refers to a group of viruses that are different, but highly related. This distribution results in competition between viruses from the same infection, but also confers plasticity and adaptability to environmental changes.

Peer review

The authors analyzed the quasispecies of HBV core epitopic regions by UDPS. They found that positions with highest variability rates, mainly clustered in the main core epitopes, showed some relationship with HBV genotype, and were particularly associated with the T-helper motif. The authors suggest that immune system pressure is the main cause of HBV core evolution.

Abstract

AIM: To compare program costs of chronic hepatitis B (CHB) screening and treatment using Australian and other published CHB treatment guidelines.

METHODS: Economic modeling demonstrated that in Australia a strategy of hepatocellular cancer (HCC) prevention in patients with CHB is more cost-effective than current standard care, or HCC screening. Based upon this model, we developed the B positive program to optimize CHB management of Australians born in countries of high CHB prevalence. We estimated CHB

program costs using the B positive program algorithm and compared them to estimated costs of using the CHB treatment guidelines published by the Asian-Pacific, American and European Associations for the Study of Liver Disease (APASL, AASLD, EASL) and those suggested by an independent United States hepatology panel. We used a Markov model that factored in the costs of CHB screening and treatment, individualized by viral load and alanine aminotransferase levels, and calculated the relative costs of program components. Costs were discounted by 5% and calculated in Australian dollars (AUD).

RESULTS: Using the B positive algorithm, total program costs amount to 13 979 224 AUD, or 9634 AUD per patient. The least costly strategy is based upon using the AASLD guidelines, which would cost 34% less than our B positive algorithm. Using the EASL and the United States Expert Group guidelines would increase program costs by 46%. The largest expenditure relates to the cost of drug treatment (66.9% of total program costs). The contribution of CHB surveillance (20.2%) and HCC screening and surveillance (6.6%) is small - and together they represent only approximately a quarter of the total program costs.

CONCLUSION: The significant cost variations in CHB screening and treatment using different guidelines are relevant for clinicians and policy makers involved in designing population-based disease control programs.

INTRODUCTION

Although hepatocellular cancer (HCC) remains relatively uncommon in Australia, its incidence has increased approximately fivefold since 1972, and based on current trends, a threefold increase is expected by 2020^[1]. HCC rates are highest in Southwestern Sydney, where its incidence (7.7 per 100 000 persons, 95% CI: 7.0-8.4) is significantly higher than the state average (5.2 per 100 000 persons, 95% CI: 5.0-5.5)^[1].

Nearly 90% of hepatitis-B-related HCC in NSW occurs in people born overseas, with approximately 70% affecting Australians born in countries of high hepatitis B prevalence^[2]. Migrants born in these countries are 6-12 times more likely to develop HCC than other Australians^[3], explained by the strong association between hepatitis B infection acquired early in life and the subsequent development of hepatic cirrhosis and HCC^[4]. In recent years, effective treatments for chronic hepatitis B (CHB) infection have achieved sustained suppression of viral replication and significant reductions in disease progression to cirrhosis, end-stage liver disease and HCC^[5-7]. This opens unique opportunities to reduce CHB-related morbidity and mortality among the 350 million chronically infected people worldwide^[8], provided that treatment costs are affordable at a population level. This is particularly relevant in the developing world, where the great majority of people with CHB reside^[4].

Our previous modeling work showed that in Asian populations with CHB residing in Australia (representing > 50% of people diagnosed with CHB in Australia^[9]), a strategy of HCC prevention is more cost-effective than HCC screening^[10]. For people with CHB, we defined HCC prevention as an intervention comprising regular (6-monthly) patient follow-up, the institution of antiviral therapy in those with active disease, and HCC surveillance. Following the confirmation of CHB diagnosis, general practitioners (GPs) order the relevant investigations and stratify participants into discrete risk categories, based upon hepatitis B virus (HBV) DNA and alanine aminotransferase (ALT) levels (Figure 1). Low-risk patients [those with low HBV DNA (defined as < 20 000 IU/mL for participants aged < 50 years and < 2000 IU/mL for those aged > 50 years) and normal ALT levels [defined as < 1.5 times upper limit of normal (ULN)]] are offered routine CHB surveillance, consisting of 6-monthly GP follow-up visits and testing for hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg), viral load and ALT levels. Patients with normal

ALT levels, but elevated viral loads (as defined above) are followed up by their local medical practitioners under a program of enhanced CHB surveillance (which in addition to routine blood tests also includes 6-monthly HCC surveillance using α fetoprotein (AFP) measurements and liver ultrasound (US) examinations. Patients with elevated ALT and viral load levels are referred to tertiary care for assessment and consideration of antiviral therapy (Figure 1). The general assumptions of the Markov model are summarized in Table 1.

These treatment strategies are at slight variance with those described in hepatitis B practice management guidelines, because they factor in age as a consideration for treatment initiation (program participants are aged ≥ 35 years and treatment criteria change at age 50 years) and ALT cutoff levels are $\geq 1.5 \times$ ULN. Additionally, HCC screening is being offered to groups deemed at higher risk, rather than to all Asian males over the age of 40 years and Asian women over the age of 50 years, as it is recommended by the American Association for the Study of Liver Disease (AASLD) guidelines^[11].

The modeling work informed the development of a program of CHB management targeting the area of Sydney with the highest burden of hepatitis-B-related HCC in Australia, located in Southwest Sydney. As the Gastroenterology Society of Australia uses viral loads > 2000 IU/mL as a cut-off for treatment initiation irrespective of age^[12], we subsequently modified the viral load cut-off for the B positive program, to avoid confusion among primary care providers participating in the program.

In order to inform hepatitis B management and provide data to policy makers, we estimated B positive program costs using the original B positive screening and treatment algorithm and compared them with those incurred using the modified B positive algorithm (viral load cutoff of 2000 IU/mL for treatment initiation, irrespective of patient age) and to costs incurred when applying guidelines published by the American, European and Asia-Pacific Associations for the Study of Liver Disease (AASLD, EASL and APASL)^[6,13,14] as well as those developed by an independent panel of hepatologists from the United States (referred to here as the United States Expert Group)^[15]. We also determined the relative proportion of program costs attributable to CHB screening, drug treatment, CHB surveillance and HCC screening and surveillance incurred by applying each of these algorithms. Costs were calculated in Australian dollars (AUD).

MATERIALS AND METHODS

The B positive project targets Asian migrant communities in Southwest Sydney, but is inclusive of all individuals who meet eligibility criteria. Eligibility criteria include: confirmed CHB, age ≥ 35 years, and attending a general practice in the target local government areas. To estimate the size of the eligible population, we used data provided by the Australian Bureau of Statistics 2006 National Cen-

Figure 1 B positive program for chronic hepatitis B screening and treatment protocol. Depicts the algorithm used to stratify participants aged > 35 years into routine surveillance [for those with viral loads below 2000 IU/mL and normal alanine aminotransferase (ALT)], enhanced hepatocellular cancer (HCC) surveillance (for elevated viral loads and normal ALT), and those at highest HCC risk (referred for specialist opinion and antiviral therapy). CHB: Chronic hepatitis B; HBeAg: Hepatitis B e antigen; HBsAg: Hepatitis B surface antigen; GP: General practitioner; HBV: Hepatitis B virus; AFP: α fetoprotein; LFTs: Liver function tests.

sus on the number of local residents born in China, Hong Kong and Vietnam aged ≥ 35 years. We applied HBV seroprevalence data on these numbers, based upon epidemiological estimates from the respective countries of birth^[16].

We estimated the proportion of people in different CHB-related disease stages over the 50-year timeframe [CHB without cirrhosis; CHB with cirrhosis; CHB with liver failure; CHB and HCC; spontaneous HBsAg clearance and death due to CHB-related causes (liver failure or HCC), or death from other causes], using the assumptions of our previously published Markov model^[10]. The model takes a health care funder perspective and discounts costs at 5% per annum. We estimated a program participation rate of 25%, informed by the experience of the New Zealand HBV screening program, which screened 27% of their eligible population^[17]. Table 1 summarizes the key assumptions of our model. We used an ALT level of $\geq 1.5 \times \text{ULN}$ to define high-risk patients and estimated that about 50% of the target population have ALT levels $< 1 \times \text{ULN}$, 12.5% have ALT levels of $1-1.5 \times \text{ULN}$, 12.5% between 1.5 and $2 \times \text{ULN}$ and 25% levels $> 2 \times \text{ULN}$, informed by a Hong Kong population-based study of CHB patients^[18].

We estimated the proportion of the target population receiving antiviral treatment based upon the cutoffs for ALT and viral load recommended by the different guidelines for patients who are HBeAg negative (Tables 2 and 3). Briefly, in this population group the AASLD guidelines recommend treatment to be initiated when viral load exceeds 20 000 IU/mL and ALT levels are $> 2 \times \text{ULN}$ ^[6]. The APASL guidelines use the same ALT level cutoff, but a lower threshold (2000 IU/mL) for viral load^[14], while the United States expert group and EASL

use the 2000 IU/mL cutoff for viral load, but recommend treatment for patients with ALT levels exceeding the normal range^[13,15].

The B positive program (unpublished) data suggested that 94% of those enrolled in the program were HBeAg negative at the time of enrolment (which corroborates the findings of Yuen *et al*^[9], that in an Asian population, HBeAg seroconversion occurs around 35 years of age); consequently we compared estimated CHB program costs using treatment guidelines developed for HBeAg-negative populations.

We factored in the costs of CHB screening and follow-up provided by specialists and/or primary care providers, the costs of HCC screening, and CHB and HCC treatment, but not recruitment costs, or the costs of immunization for those susceptible.

RESULTS

The CHB population targeted by the B positive program in Southwest Sydney was estimated at 5800 patients. Assuming a 25% enrolment rate, about 1500 patients (1451 patients) with CHB in Southwest Sydney would be enrolled in the program. Nearly two-thirds (63%) of these patients would be followed up by their GPs under a program of routine surveillance (Figure 1). Half of the patient population would receive this type of management if using the other guidelines, except for the AASLD guidelines, where 70% of all patients would be receiving routine surveillance. The proportion of patients under enhanced surveillance (which is 23% for B positive and 31% for the modified B positive) would range from a low of 23% using the AASLD guidelines to a high of 37% using

Table 1 General assumptions of the Markov model of the B positive hepatocellular cancer prevention program

Assumption	How addressed and rationale
Participant recruitment	Target population age ≥ 35 yr, HBsAg +ve for ≥ 6 mo, born in China, Hong Kong, Vietnam
Contact testing and immunisation	Not factored into the model
Seroprevalence in target populations	10.7% for people born in China 10.5% for people born in Vietnam 7.7% for people born in Hong Kong (Nguyen <i>et al</i> ^[16])
Initial testing to confirm chronic hepatitis B	Not factored in the GP consultation calculations
Program participation rates	Base case assumption: 25% of eligible people are enrolled
HCC screening	All participants have AFP and liver US at enrolment Participants receiving enhanced surveillance have 6-monthly AFP and US Participants receiving treatment also have liver biopsy
Follow up requirements	Routine surveillance arm: 2 GP appointments/yr Enhanced HCC surveillance arm: 2 GP appointments/yr Interferon treatment: 6 specialist appointments/yr Entecavir treatment: 4 specialist appointments/yr Patients with HCC: assumed two monthly follow up
Viral load distribution	Based upon Risk Evaluation of Viral Load Elevation and Associated Liver Disease study data (Chen <i>et al</i> ^[20])
ALT level distribution	Based upon Hong Kong data (Yuen <i>et al</i> ^[18])
Progression rates through different disease stages	Constant
Treatment protocol	30% receive first line interferon (weekly for 12 mo); 30% seroconvert and receive no further treatment; 70% commence entecavir the following year 70% receive entecavir as first-line treatment; 20% seroconvert in first year and receive no further treatment; 80% continue lifelong entecavir
Patients with liver failure	Receive lifelong entecavir

Lists the general assumptions used in building the model, including treatment protocols and follow up and other relevant elements and data sources. HBsAg: Hepatitis B surface antigen; GP: General practitioner; AFP: α fetoprotein; ALT: Alanine aminotransferase; HCC: Hepatocellular cancer; US: Ultrasound.

Table 2 Participant distribution by disease stage at initial enrolment and management pathways, according to the B positive algorithm and hepatitis B treatment published guidelines *n* (%)

Treatment guideline	B positive	Modified B positive	EASL, United States experts	APASL	AASLD
HBV DNA level to treat	> 2000 if > 50 > 20 000 if < 50	> 2000	> 2000	> 2000	> 20 000
ALT (ULN)	> 1.5	> 1.5	> 1	> 2	> 2
Number receiving interferon	61 (4)	81 (6)	108 (8)	54 (4)	33 (2)
Number receiving entecavir	143 (10)	190 (13)	253 (17)	126 (9)	76 (5)
Total on treatment	204 (14)	271 (19)	361 (25)	181 (12)	109 (8)
Total under enhanced surveillance	340 (23)	452 (31)	361 (25)	542 (37)	326 (23)
Total under routine surveillance	907 (63)	728 (50)	728 (50)	728 (50)	1016 (70)
Total	1451 (100)	1451 (100)	1451 (100)	1451 (100)	1451 (100)

Tabulates the estimated number of participants undergoing different monitoring strategies and treatment options, according to recommendations put forward by Australian, Asia-Pacific, United States and European chronic hepatitis B treatment guidelines. ULN: Upper limit of normal; HBV: Hepatitis B virus; EASL: European Associations for the Study of Liver Disease; APASL: Asia-Pacific Associations for the Study of Liver Disease; AASLD: American Associations for the Study of Liver Disease.

the EASL and United States Expert Panel guidelines. The proportion of patients receiving antiviral treatment (14% for B positive) ranges from a low of 8% under AASLD to a high of 25% under the more stringent EASL and United States Expert Panel Group guidelines (Table 2).

Overall, the lowest program costs are associated with the application of AASLD guidelines, because the 20 000 IU/mL viral load cutoff for treatment initiation and ALT levels $\geq 2 \times$ ULN make fewer patients eligible for treatment. Treatment costs are highest when applying EASL and United States Expert Group guidelines, because they recommend treatment for all patients with viral loads > 2000 IU/mL and ALT levels > 1 \times ULN.

The total B positive program costs would amount

to 13 979 224 AUD, or 9634 AUD per patient using the original B positive algorithm, ranging from a low of 6344 AUD for the AASLD guidelines to a high of 14 039 for the EASL and United States Expert Group recommendations (Table 3). The largest component of the cost structure relates to antiviral treatment, which represents over three-quarters (75.8%) of program costs if using EASL and United States Expert Group recommendations, approximately 70% (70.2%) for the modified B positive algorithm, 66.9% for the original B positive, 60% for the APASL guidelines, and just over 50% for the AASLD guidelines. Costs of CHB surveillance ranges from 17.5% for the modified B positive protocol to 30.1% of the program expenditure if using AASLD guidelines. The con-

Table 3 Calculated costs (in Australian dollars) of implementing a program of chronic hepatitis B management in hepatitis B e antigen-negative patients according to the B positive algorithms and published hepatitis B treatment guidelines, *n* (%)

Discounted costs of management strategies	B positive	Modified B positive	APASL	EASL, United States experts	AASLD
Cost/QALY (discounted)	13 465	15 770	11 746	19 622	8867
Total program cost (discounted)	13 979 224	16 372 320	12 194 905	20 371 117	9 205 680
Cost components					
Initial CHB screening cost	767 728 (5.5)	800 792 (4.9)	755 971 (6.2)	845 613 (4.2)	720 357 (7.8)
Drug treatment costs	9 347 662 (66.9)	11 493 535 (70.2)	7 360 940 (60.4)	15 447 510 (75.8)	4 951 419 (53.8)
CHB surveillance costs	2 827 093 (20.2)	2 866 053 (17.5)	2 866 053 (23.5)	2 866 053 (14.1)	2 767 073 (30.1)
HCC surveillance costs	917 783 (6.6)	1 092 983 (6.7)	1 092 983 (9.0)	1 092 983 (5.4)	647 874 (7.0)
Total cost per person in the program	9634	11 283	8404	14 039	6344
% change with equivalent unit costs/QALY	100	117	87	146	66

Tabulates the costs of chronic hepatitis B screening, surveillance and treatment as per Australian, Asia-Pacific, United States and European treatment guidelines scenarios. Costs are discounted by 5% and calculated in Australian dollars (AUD). EASL: European Associations for the Study of Liver Disease; APASL: Asia-Pacific Associations for the Study of Liver Disease; AASLD: American Associations for the Study of Liver Disease; HCC: Hepatocellular cancer; CHB: Chronic hepatitis B; QALY: Quality-adjusted life year.

tribution of the cost of HCC screening and surveillance remains relatively small in all scenarios, ranging from a low of 5.4% for the EASL and United States guidelines to 9% for the APASL guidelines.

Compared to the B positive algorithm, the lowest cost to achieve an equivalent unit cost/quality-adjusted life year is incurred by applying the AASLD guidelines (34% cost saving), followed by the APASL guidelines (13% cost saving); costs would be 17% higher with the modified B positive algorithm (because more patients aged 35-50 years would be in receipt of treatment) and 46% higher for the EASL and United States Expert Group recommendations.

DISCUSSION

This modeling exercise demonstrates that in a population-based CHB management program informed by current treatment guidelines, the majority of patients (ranging from 50 to 70%) have low viral loads (< 2000 IU/mL) and low ALT levels and may be effectively managed at the primary care level. Between a quarter and a third of patients have elevated viral loads and would benefit from more comprehensive follow-up, which we termed “enhanced surveillance”, which could still effectively be delivered at the primary care level and free up specialist resources. These calculations suggest that the proportion of patients requiring tertiary-level assessment for consideration of antiviral therapy is variable, ranging from a low of 8% if the AASLD guidelines are followed to a high of 25% if the more stringent EASL and United States Expert Group guidelines are used. Program costs range from approximately 9 million AUD (if AASLD guidelines are used) to more than double that figure (20 371 117 AUD) if the EASL or United States Expert Group recommendations are applied. Correspondingly, this leads to variations in costs per patient enrolled, ranging from 6344 AUD (for AASLD guidelines) to 14 039 AUD (for EASL and United States Expert Group guidelines). The B positive algorithm steers a mid-course with regards to total (13 979 224-16 372 320 AUD) and per patient costs (9634-11 283 AUD, depending on whether

the viral load cut-off is set at 2000 IU/mL for all patients, or only for those aged > 50 years.

The model assumes that all patients with elevated viral loads and ALT levels receive specialist assessment and liver biopsy to assess the degree of fibrosis prior to treatment initiation, although since November 2011, liver biopsy is no longer mandatory for treatment initiation.

In all modeled programs, the greatest contribution to cost is that of antiviral drug treatment (interferon or entecavir), accounting for 50%-75% of the program budget. By comparison, the costs of CHB surveillance are relatively low for a primary-care-based program (ranging from 14% to 30% of total costs); even lower are the costs associated with HCC screening and surveillance (ranging from 5% to 9%). The original B positive modeling did not include HCC surveillance in the subgroup presumed to have inactive disease; this is at variance with current published guidelines, which recommend HCC surveillance for all Asian men aged > 40 years or women aged > 50 years, irrespective of their disease stage or viral load^[11]. Although the original intention was to balance cost containment with ensuring that HCC cases are not missed, it appears that the contribution of HCC screening to costs would remain modest even if the program embraces the recommended screening guidelines. Sherman in a recent review concedes that it may be possible that, as more information about HCC risk stratification becomes available, patients with long-term inactive disease may not require the same intensive HCC surveillance^[11], something that is supported by the REVEAL data^[20].

Our model has a number of limitations related to our assumptions and the lack of clear data in some areas. For example, we used a 1.5 × ULN cut-off for the ALT levels prompting treatment. The different ALT cut-off levels in various guidelines indicate that there is no agreement about what level of ALT should prompt treatment initiation, and information to clarify this is keenly awaited. Similarly, we assumed that all patients with elevated ALT levels would require antiviral therapy, although in reality, ALT elevation may not always relate to disease reactivation, but to other factors, such as high

body mass index, non-alcoholic fatty liver disease, chronic alcohol consumption or coexisting hepatitis C infection^[21,22]. We also acknowledge that the rate of progression to HCC development is variable in different patient populations, being dependent on the degree of fibrosis, genotype, and other associated risk factors. Although the short-term goals of antiviral therapy have been achieved in recent clinical trials^[22], more answers are needed as to the extent to which this affects liver cancer incidence and the number of cancer deaths. As this is also the major assumption that underlies our analysis, more data confirming the impact of treatment on HCC risk reduction would strengthen the economic model findings.

Our original model factored in the cost of liver biopsy for all patients being considered for antiviral therapy, reflecting the recommendations of guidelines referred to in the paper, suggesting that a liver biopsy is helpful for determining the degree of necroinflammation and fibrosis. However the relatively low cost of a liver biopsy and the relatively small numbers of patients in this subgroup (we estimated that only about 12.5% of patients have ALT levels in that range and even fewer also have low-medium viral loads) means that this procedure will have a minimal impact on overall program costs, although it may influence the number of patients willing to accept drug therapy.

The effectiveness and cost-effectiveness of different interventions need to be corroborated by other types of studies and real-life outcomes data utilized to validate the economic models. We are currently collecting program data for this purpose.

Ideally our findings would need to be compared to those of other studies using decision models and against real-life data from clinical studies, but available data are limited. A recent European review^[23] identified only two studies addressing the cost-effectiveness of screening high-risk groups for CHB: both a United States^[24] and a Dutch study^[25] suggested that screening of migrant groups for HBV was both clinically effective and cost-effective findings that were corroborated by our Australian study^[10].

A clinical study estimating the efficacy and cost of HCC screening in a clinic population in Australia^[26] confirmed our model costs. We need to bear in mind however that direct comparisons between studies are of limited value, due to differences in study design, model assumptions, cut-offs used, and variable cost structures in different countries.

As the stated aim of this short paper was to examine the cost implications of utilizing different guidelines to treat patients with CHB, in order to assist funding decisions, we did not include a broader discussion of cost-effectiveness, effectiveness and efficacy of antiviral treatment, but agree that a more comprehensive review of effectiveness and cost-effectiveness may be warranted.

Although we incorporated a wide range of supporting evidence into our economic model, the relatively limited information available on the composition of cohorts of patients with CHB receiving treatment and the possible differences in treatment response in patients with

HBeAg-negative disease (which has been less extensively studied) may limit the generalizability of our findings. In the absence of relevant data, we assumed that the effectiveness and durability of current interventions can be extrapolated over a lifetime horizon, but acknowledge that the lack of long-term evidence precludes confident estimates of treatment outcomes.

From a policy perspective, the high cost of antiviral therapy makes population-based CHB screening and treatment unaffordable for all but well-resourced countries. For example, Hutton *et al.*^[27] published their analysis of the cost-effectiveness of interventions aiming to combat hepatitis B in the United States and China. They found that in an American setting it is cost-effective to screen adult Asian and Pacific Islanders (APIs) for CHB, with a view to providing them with appropriate treatment, as well as to vaccinate close contacts. This work led to a change in United States public health policy on hepatitis B screening, with a recommendation that all adult APIs and adults born in areas of intermediate HBV prevalence be screened for CHB. The authors found that in a Chinese setting catch-up adolescent vaccination is cost-effective, but that drug treatment costs would need to be halved (to about 1000 United States dollars/year) before the benefits of vaccination would be surpassed by those of instituting treatment^[27]. China's economic successes makes population level CHB screening and treatment a possibility in the future, but effective and inexpensive treatments are needed to reduce the burden of CHB in developing economies^[4].

Our original economic model assumptions attempted to reflect the Australian practice prevalent in 2006 and 2007, when entecavir was becoming first-line treatment for CHB. At that time interferon was still in common use, therefore, we modeled 30% of the cohort as receiving first-line interferon.

However, the therapeutic landscape has changed in recent years, with interferon being used now in only about 10% of patients as first-line treatment for CHB. We therefore repeated our calculations estimating that 10% of patients receive first-line interferon and found the incremental total cost was only about 1.5% higher (data not shown), as a result of interplay between a more intensive and more costly specialist follow-up during interferon treatment, a small proportion of patients who clear the infection, and the overall small number of patients affected.

As both available resources and local clinical preferences guide drug treatment, generic lamivudine may be the only affordable antiviral for low-income countries in Asia and Africa, where CHB is most prevalent, because replacing it with a more potent antiviral agent is associated with a more than 10-fold increase in drug costs^[28].

Consequently, we repeated the analysis, substituting lamivudine for entecavir and assuming that the cost of lamivudine represented only a tenth of the cost of entecavir. This led to significant reductions in drug costs (ranging from 75.3% to 77.6%) and in overall program costs (ranging from 40.5% to 58.9% - data not shown), which further emphasizes the important role played by

drug costing in program feasibility.

Our modeling has provided estimates of the cost of CHB management programs that could be useful for policy makers and health care providers in different settings, to inform program development. It would appear that population-based CHB management programs targeting at-risk groups are affordable in high-resource settings, but remain unattainable for many of the world's population with CHB, living in low- or middle-resourced countries. The high cost of antiviral therapies represents the largest cost component of a CHB management program. It is hoped that reductions in the cost of antiviral drugs will lead to more equitable access to treatment and address the global burden of chronic hepatitis B.

COMMENTS

Background

Chronic hepatitis B (CHB) is a leading cause of cirrhosis and hepatocellular carcinoma (HCC), and in Australia, HCC incidence has been rising faster than that of any other cancer, mostly related to changing migration patterns over recent decades. A population-level disease control is predicated upon early disease detection, regular monitoring and timely institution of antiviral treatment for people with active disease, but antiviral treatment is unaffordable for the great majority of people with CHB who live in resource-limited countries. Therefore the cost and cost-effectiveness of CHB management programs is an important consideration for program funders and needs to be factored in by those tasked with guideline development. The authors previously carried out modeling work that showed that screening and treating migrants born in high prevalence countries is cost-effective, which corroborated the findings of research groups in the United States and the Netherlands. This paper examines the cost of treatment of hepatitis B applied to a hypothetical population of people with CHB diagnosis, treated according to CHB screening and treatment guidelines in common use in Asia (issued by the Asia-Pacific Society for the Study of Liver Disease), Australia (issued by the Gastroenterological Society of Australia), Europe (issued by the European Association for the Study of Liver Disease, EASL) and the United States (issued by the American Association for the Study of Liver Disease, AASLD, as well as by an expert United States advisory group).

Research frontiers

This work builds the body of evidence suggesting the cost-effectiveness of screening high-risk groups for hepatitis B, by examining the implications of implementing a public health program of screening and treatment using different treatment initiation parameters, as recommended by different guideline developers. The proportion of patients in this hypothetical cohort requiring antiviral therapy ranges from 8% (if the AASLD guidelines are used) to 25% (if EASL guidelines are applied). The most substantial component of program cost relates to antiviral treatment (representing up to 75% of program costs), while screening for CHB and cancer surveillance account for a small part of total costs. Treatment with generic lamivudine (instead of entecavir) leads to substantially lower total program costs, although this must be balanced against the greater suppression of viral replication and lack of drug resistance associated with entecavir treatment.

Innovations and breakthroughs

Here the authors propose and cost a scheme for the diagnosis and subsequent monitoring of patients from countries with high prevalence of hepatitis B, resident in Australia. In the B positive algorithm, antiviral treatment is offered for patients with alanine aminotransferase (ALT) elevation above $1.5 \times$ normal, treating the "middle ground" between treating everyone with an elevated ALT level (which may have significant resource implications for countries with high disease prevalence, but limited resources) and treating only people with advanced disease (and running the risk of limiting the effectiveness of the program).

Applications

These findings are relevant for the design of interventions with the potential to make a significant impact on hepatitis B disease burden at a population level, in both well-resourced and low-resource settings. The authors hope that this type of work may be of interest to experts involved in CHB treatment guideline develop-

ment, policy makers and clinicians working in areas with a large hepatitis B load.

Peer review

This is a study on the cost of treatment of hepatitis B, using Markov models. The authors propose a scheme for the diagnosis and subsequent monitoring of patients from countries with high prevalence of hepatitis B, resident in Australia. They also compared the relative cost with the proposed guidelines from other major hepatology associations. They found that the AASLD recommendations were more cost-effective. This type of study is important in view of the increasing cost of drug treatment of HBV infection but also of the increasing cost of diagnostic tests related to HCC surveillance.

Abstract

AIM: To identify the incidence and etiology of anemia after gastrectomy in patients with long-term follow-up after gastrectomy for early gastric cancer.

METHODS: The medical records of those patients with early gastric adenocarcinoma who underwent curative gastrectomy between January 2006 and October 2007 were reviewed. Patients with anemia in the preoperative workup, cancer recurrence, undergoing systemic chemotherapy, with other medical conditions that can cause anemia, or treated during follow up with red cell transfusions or supplements for anemia were excluded. Anemia was defined by World Health Organization criteria (Hb < 12 g/dL in women and < 13 g/dL in men). Iron deficiency was defined as serum ferritin < 20 µg/dL. Vitamin B₁₂ deficiency was defined

as serum vitamin B₁₂ < 200 pg/mL. Iron deficiency anemia was defined as anemia with concomitant iron deficiency. Anemia from vitamin B₁₂ deficiency was defined as megaloblastic anemia (mean cell volume > 100 fL) with vitamin B₁₂ deficiency. The profile of anemia over 48 mo of follow-up was analyzed.

RESULTS: One hundred sixty-one patients with gastrectomy for early gastric cancer were analyzed. The incidence of anemia was 24.5% at 3 mo after surgery and increased up to 37.1% at 48 mo after surgery. The incidence of iron deficiency anemia increased during the follow up and became the major cause of anemia at 48 mo after surgery. Anemia of chronic disease and megaloblastic anemia were uncommon. The incidence of anemia in female patients was significantly higher than in male patients at 6 (35.4% vs 13.3%, $P = 0.002$), 12 (45.8% vs 16.8%, $P < 0.001$), 18 (52.1% vs 22.3%, $P < 0.001$), 24 (60.4% vs 20.9%, $P < 0.001$), 36 (62.5% vs 29.2%, $P < 0.001$), and 48 mo (66.7% vs 34.7%, $P = 0.001$) after surgery.

CONCLUSION: Anemia was frequent after gastrectomy for early gastric cancer, with iron deficiency being the major cause. Evaluation for anemia including iron status should be performed after gastrectomy and appropriate iron replacement should be considered.

Anemia after gastrectomy for early gastric cancer: Long-term follow-up observational study. *World J Gastroenterol* 2012; 18(42): 6114-6119 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i42/6114.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i42.6114>

INTRODUCTION

Gastric cancer is the most common malignancy in Korea and the second most frequent cause of cancer-related death worldwide^[1,2]. Curative resection has proven to be the only successful treatment modality for locally confined gastric cancer^[3]. Anemia is a frequent complication after gastrectomy and deficiencies of iron, vitamin B₁₂, or folate, either alone or in combination, have been reported after gastric surgery^[4-6]. However, these studies included relatively small numbers of patients, follow-up visits were not systematically scheduled, and the definition and biochemical markers of anemia were ambiguous or insufficient. There are limited reports concerning anemia in patients who undergo gastrectomy for early gastric cancer who have systematically scheduled serial follow-up visits, but do not receive supplements for anemia.

The incidence of gastric bypass surgery for morbid obesity is increasing, and anemia after bypass surgery has been reported^[7-11]. Dietary life after gastric surgery in patients with gastric cancer may differ from that in patients with morbid obesity: in contrast to patients with obesity, patients having gastrectomy for gastric cancer do not restrict their dietary intake for weight reduction. The aim of this study was to identify the natural history of anemia after gastrectomy in a cohort of patients undergoing gastrectomy for early gastric cancer who were systematically followed up in the long term.

MATERIALS AND METHODS

Study population

This study was a retrospective chart review of the registry of all patients who had undergone gastrectomy for early gastric cancer at Seoul St Mary's Hospital, Seoul, Korea between January 2006 and October 2007. Patients with anemia in the preoperative workup, cancer recurrence, undergoing systemic chemotherapy, with other medical conditions that can cause anemia, or treated during follow up with red cell transfusions or supplements for anemia were excluded from the study.

Follow-up program

Patients with early gastric cancer were followed up at 3, 6, 9, 12, 18, 24, 48 and 60 mo after surgery. The follow-up

program consisted of interim history taking, physical examination, imaging studies, endoscopic examination, hematology, and blood chemistry panels. Mean cell volume (MCV), serum iron, serum ferritin, total iron-binding capacity, serum vitamin B₁₂, and serum folate level were included in the follow-up program.

Definition of anemia and related conditions

Anemia was defined by World Health Organization criteria (Hb <12 g/dL in women and <13 g/dL in men)^[9]. Iron deficiency was defined as serum ferritin < 20 µg/dL. Vitamin B₁₂ deficiency was defined as serum vitamin B₁₂ < 200 pg/mL. Iron deficiency anemia was defined as anemia with concomitant iron deficiency. Anemia of chronic illness was defined as anemia with serum ferritin > 20 µg/dL. Anemia from vitamin B₁₂ deficiency was defined as megaloblastic anemia (MCV >100 fL) with vitamin B₁₂ deficiency.

Statistical analysis

Continuous data are presented as the mean ± SD and categorical data are presented as proportions. The data were analyzed using the paired *t* test to assess the differences in continuous data during follow up and a χ^2 test or Fisher's exact test to assess the differences according to sex and the type of gastrectomy. Differences were considered significant if the *P* value was less than 0.05. All statistical analysis were performed using SAS software (SAS Institute, Cary, NC, United States).

RESULTS

Four hundred fifty-eight patients with early gastric adenocarcinoma underwent curative gastrectomy in our institution during the study period. Of these, 297 were excluded from the analysis (anemia in preoperative workup in 45 patients, systemic chemotherapy in 79, other medical conditions that can cause anemia in 13, follow-up loss in 86, insufficient biochemical profile for anemia in 73, red cell transfusion during the follow-up in one). Finally, 161 patients undergoing gastrectomy for early gastric cancer were analyzed. No patient in the study population received iron or vitamin B₁₂ replacement therapy. Follow-up after surgery was possible at 3 mo in 159, 6 mo in 161, 12 mo in 161, 18 mo in 160, 24 mo in 158, 36 mo in 154, and 48 mo in 142.

The characteristics of the study population are shown in Table 1. The mean age was 56.2 ± 10.9 years (range, 23-78 years) and 113 patients were men (70.2%). Thirty-nine (24.2%) patients underwent Billroth I subtotal gastrectomy, 90 (55.9%) Billroth II subtotal gastrectomy, and 32 (19.9%) total gastrectomy.

The incidence of anemia was 24.5% at 3 mo after surgery and increased to 37.1% at 48 mo after surgery. The incidence of iron deficiency anemia increased during the follow-up and became the major cause of anemia at 48 mo after surgery (Figure 1). Anemia of chronic disease and megaloblastic anemia were uncommon. Only one

patient had a picture consistent with megaloblastic anemia with vitamin B₁₂ deficiency at 48 mo after surgery. The incidence of anemia, iron deficiency, and vitamin B₁₂ deficiency increased during follow-up after surgery (Figure 2). The incidence during follow-up of iron deficiency without anemia was considerable. Most vitamin B₁₂ deficiency occurred in patients who had total gastrectomy. At 48 mo after gastrectomy, the incidence of vitamin B₁₂ deficiency was 3.2% in patients with Billroth I subtotal gastrectomy, 7.5% in Billroth II subtotal gastrectomy, and 76.9% in total gastrectomy. The incidence of vitamin B₁₂ deficiency in patients with total gastrectomy was 0%, 16.1%, 50.0% and 76.9% at 12, 24, 36 and 48 mo after gastrectomy, respectively.

Serial follow-up hematology and blood chemistry data are shown in Table 2. Hemoglobin level, serum

ferritin level, and vitamin B₁₂ level decreased during the follow-up. The average serum albumin level was 3.3 ± 0.4 g/dL before surgery and recovered to 4.2 ± 0.3 g/dL at 3 mo after surgery.

The incidence of anemia in female patients was significantly higher than in male patients at 12 mo, 24 mo, 36 mo, and 48 mo after surgery (Figure 3A). Patients with total gastrectomy showed significantly higher incidence of anemia at 48 mo after surgery than patients with subtotal gastrectomy (60.7% *vs* 31.3%, *P* = 0.008) (Figure 3B). There was no significant difference in the incidence of anemia 48 mo after surgery between patients having Billroth I and Billroth II subtotal gastrectomy (18.8% *vs* 36.1%, *P* = 0.078). The incidence of iron deficiency was also significantly higher in female patients than in male patients at all times in the follow-up period except at 3 mo after surgery (Figure 3C). The incidence of iron deficiency was significantly higher in patients with total gastrectomy than those with in subtotal gastrectomy only at 36 mo after surgery (58.1% *vs* 35.0%, *P* = 0.024) (Figure 3D). There was no significant difference in the incidence of anemia and iron deficiency between patients with Billroth I and II subtotal gastrectomy at 48 mo after surgery (28.1% *vs* 45.8%, *P* = 0.095).

DISCUSSION

In this study, we identified the incidence and etiology of anemia after gastrectomy in a cohort of patients having gastrectomy for gastric cancer who were systematically followed up over the long term. We found that the incidence of anemia in the patients with gastrectomy increased during follow-up. Iron deficiency anemia became the major cause of anemia after gastrectomy, and megaloblastic anemia with vitamin B₁₂ deficiency was rare.

In this study, anemia was relatively frequent after gastrectomy for early gastric cancer. Anemia was detected shortly after surgery and increased during the follow-up period. The incidence of anemia was 24.5% at 3 mo after surgery and increased to 37.1% at 48 mo after surgery. Anemia has been reported to occur in up to 60% of

patients after partial gastrectomy^[12,13]. The incidence of anemia after bypass surgery has been reported as from 5% to 64%^[7-9,14-17]. A recent study of postsurgical anemia after gastrectomy reported that the incidence of anemia was 37.9%, 33.5% and 34.7% at 3, 6 and 12 mo after surgery, respectively^[18].

Our study showed that iron deficiency anemia increased during follow-up and was the major cause of anemia at 48 mo after surgery. Serial follow-up showed that serum ferritin gradually decreased from 70.8 μg/L to 30.1 μg/L during follow up and the incidence of iron deficiency gradually increased to 44% at 48 mo after gastrectomy. Our results are similar to those of a previous

study of patients after Roux-en-Y gastric bypass^[19]. Iron deficiency anemia was reported to be very common in post-gastrectomy patients at twenty five to thirty years after surgery^[20]. Iron deficiency after gastrectomy or bypass results from malabsorption of iron because of a surgically altered gastrointestinal tract. Inadequate oral intake or occult blood loss may also contribute to this condition. Iron is absorbed in the duodenum and proximal jejunum and its absorption is enhanced by gastric acid secretion. A lack of acidity results in impaired conversion of ingested ferric iron to absorbable ferrous iron^[21]. Duodenal bypass also contributes to iron deficiency in patients with gastrectomy or bypass surgery. Atrophic gastritis

and *Helicobacter pylori* infection were reported to play an important role in iron deficiency after gastrectomy for cancer of the stomach^[22]. In our study, the patients with Billroth I subtotal gastrectomy showed the lowest incidence of iron deficiency compared with all groups of patients with duodenal bypass (total gastrectomy and Billroth II subtotal gastrectomy) at 48 mo after surgery (28.1% *vs* 48.6%, $P = 0.045$). Our study showed a higher incidence of anemia and iron deficiency in patients with total gastrectomy than in those with subtotal gastrectomy. This difference may originate from the more depleted nutritional status of patients with total gastrectomy^[15,23,24]. In contrast to the subjects of other studies of severe obesity, our study population was patients with early gastric cancer and did not need weight reduction. They were recommended an adequate oral intake and serum albumin level was maintained at an adequate level. Therefore, our results show an etiology and natural course of postgastrectomy anemia that is close to reality.

The incidence of vitamin B₁₂ deficiency gradually increased to 20% of patients in our study at 48 mo after gastrectomy. The majority of the patients with vitamin B₁₂ deficiency at 48 mo were those with total gastrectomy. Vitamin B₁₂ deficiency causes megaloblastic anemia and neurological symptoms, and is known to develop within 5 or 6 years after total gastrectomy, a delay that reflects the time needed to exhaust cobalamin stores after cobalamin absorption ceases^[25]. Our study showed that 16.1%, 50.0% and 76.9% of the patients with total gastrectomy presented with vitamin B₁₂ deficiency at 24, 36 and 48 mo after gastrectomy, respectively. Although the incidence of vitamin B₁₂ deficiency at 48 mo after gastrectomy was high in our study, only one patient with vitamin B₁₂ deficiency presented with megaloblastic anemia. Because 70% of patients with vitamin B₁₂ deficiency at 48 mo after gastrectomy showed anemia and the majority of these were iron-deficient, the generation of macrocytosis by concomitant iron deficiency should be considered^[26]. Vitamin B₁₂ deficiency can develop within 2 years after total gastrectomy and vitamin B₁₂ replacement may be considered for post-gastrectomy patients with persistent anemia despite iron replacement or with neurological symptoms combined with vitamin B₁₂ deficiency.

Our study has some limitations. This study was a single-center retrospective study. The symptoms of anemia and other nutritional parameters such as body weight or body mass were not investigated. However, a strength of our study is the tightly controlled long-term follow-up of the patient cohort after gastrectomy for early gastric cancer, with systematically and prospectively scheduled serial follow-up visits and without any supplement for anemia. Our results enabled us to understand the development of post-gastrectomy anemia.

In conclusion, anemia was frequent after gastrectomy for early gastric cancer and iron deficiency was the major cause. Evaluation for anemia including iron status should be performed after gastrectomy and appropriate iron replacement should be considered.

COMMENTS

Background

Curative resection has proven to be the only successful treatment modality for locally confined gastric cancer. Anemia is a frequent complication after gastrectomy. The present study identified the natural history of anemia after gastrectomy in a cohort of patients undergoing gastrectomy for early gastric cancer who were systematically followed up in the long term.

Research frontiers

Anemia was frequent after gastrectomy for early gastric cancer, with iron deficiency being the major cause.

Innovations and breakthroughs

Anemia is a common complication of gastrectomy, particularly in female patients and it worsens as follow-up lengthens in a cohort with long-term follow-up for 48 mo. The incidence of iron deficiency gradually increased during follow up and became the major cause of anemia. Megaloblastic anemia is uncommon although the incidence of vitamin B₁₂ deficiency gradually increased after gastrectomy, particularly particularly after total gastrectomy.

Applications

The results of this study suggest that evaluation for anemia including iron status should be performed after gastrectomy and appropriate iron replacement should be considered.

Peer review

This study examined anemia in a large cohort of patients undergoing gastrectomy for early gastric cancer. The results of this study can serve as a benchmark in the follow up of patients undergoing partial or total gastrectomy for gastric carcinoma.

viral hepatitis B (CVHB) and insulin resistance (IR) in Korean adults.

METHODS: A total of 7880 adults (3851 men, 4029 women) who underwent a comprehensive medical examination were enrolled in this study. Subjects diagnosed with either diabetes mellitus, or any other disorder that could influence their insulin sensitivity, were rejected. Anthropometry, metabolic risk factors, hepatitis B surface antigen, hepatitis B surface antibody, hepatitis B core antibody, fasting plasma glucose and insulin were measured for all subjects. Homeostasis model assessment (HOMA), quantitative insulin check index (QUICKI), and Mf_{fm} index were used for determining insulin sensitivity. Each participant was categorized into a negative, recovery, or CVHB group. To compare variables between groups, a t-test and/or one-way analysis of variance were used. Partial correlation coefficients were computed to present the association between insulin resistance and other variables. Multiple logistic regression analysis was used to assess the independent association between CVHB and IR.

RESULTS: The mean age of men and women were 48.9 and 48.6 years, respectively. Subjects in the CVHB group had significantly higher waist circumference [(86.0 ± 7.7 cm vs 87.3 ± 7.8 cm, $P = 0.004$ in men), (78.3 ± 8.6 cm vs 80.5 ± 8.5 cm, $P < 0.001$ in women)], cystatin C [(0.96 ± 0.15 mg/dL vs 1.02 ± 0.22 mg/dL, $P < 0.001$ in men), (0.84 ± 0.15 mg/dL vs 0.90 ± 0.16 mg/dL, $P < 0.001$ in women)], fasting insulin [(5.47 ± 3.38 μU/mL vs 6.12 ± 4.62 μU/mL, $P < 0.001$ in men), (4.57 ± 2.82 μU/mL vs 5.06 ± 3.10 μU/mL, $P < 0.001$ in women)] and HOMA index [(1.24 ± 0.86 vs 1.43 ± 1.24, $P < 0.001$ in men), (1.02 ± 0.76 vs 1.13 ± 0.87, $P = 0.033$ in women)] compared to control group. The HOMA index revealed a positive correlation with body mass index (BMI) ($r = 0.378$, $P < 0.001$), waist circumference ($r = 0.356$, $P < 0.001$), percent body fat ($r = 0.296$, $P < 0.001$), systolic blood pressure ($r = 0.202$, $P < 0.001$), total cholesterol ($r = 0.134$, $P < 0.001$), triglycerides ($r = 0.292$, $P < 0.001$),

Abstract

AIM: To investigate the relationship between chronic

cystatin C ($r = 0.069$, $P < 0.001$) and uric acid ($r = 0.142$, $P < 0.001$). The QUICKI index revealed a negative correlation with BMI ($r = -0.254$, $P < 0.001$), waist circumference ($r = -0.243$, $P < 0.001$), percent body fat ($r = -0.217$, $P < 0.001$), systolic blood pressure ($r = -0.132$, $P < 0.001$), total cholesterol ($r = -0.106$, $P < 0.001$), triglycerides ($r = -0.205$, $P < 0.001$), cystatin C ($r = -0.044$, $P < 0.001$) and uric acid ($r = -0.096$, $P < 0.001$). For subjects identified with IR, the odds ratio of an accompanying diagnosis of chronic hepatitis B was 1.534 (95% CI: 1.158-2.031, HOMA index criteria) or 1.566 (95% CI: 1.124-2.182, QUICKI criteria) after adjustment for age, gender, BMI, and amount of alcohol consumption.

CONCLUSION: Our study demonstrates that CVHB is associated with IR. CVHB may need to be monitored for occurrence of IR and diabetes mellitus.

Association of chronic viral hepatitis B with insulin resistance. *World J Gastroenterol* 2012; 18(42): 6120-6126 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i42/6120.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i42.6120>

INTRODUCTION

Insulin resistance (IR) is the principal indication for development of metabolic syndrome and type 2 diabetes^[1,2]. IR appears as a consequence of the inability of insulin to induce the appropriate effect on glucose metabolism. Inordinately large amounts of insulin are required to achieve a normal response in a state of IR. A hyperinsulinemic state causes several clinical abnormalities to appear in the blood vessels, kidneys, and liver, and these represent the major features of metabolic syndrome^[3].

Metabolic syndrome generally refers to a combination of metabolic diseases such as abdominal obesity, high blood pressure, dyslipidemia and elevated blood glucose, that appear together in an individual patient^[1]. Because metabolic syndrome is recognized as a serious risk factor for cardiovascular disease, prevention and comprehensive management are important in treating this condition^[4].

Hepatitis B is one of the most common health problems and it is estimated that, of the world's total population, one third (over 2 billion people) have been infected with hepatitis B virus (HBV)^[5]. Approximately two thirds of chronic viral hepatitis B (CVHB) patients live in Asia

and the Pacific Islands. HBV infection may cause acute and/or chronic hepatitis and premature death from liver cirrhosis, liver failure or hepatocellular carcinoma^[6]. Moreover, CVHB infection is related to other diseases such as polyarteritis nodosa (PAN)^[7], glomerulonephritis (GN)^[8], serum sickness-like syndrome (prodrome)^[9], arthritis^[10], and acrodermatitis^[11].

Recently, an experimental study suggested that hepatitis B X protein (HBx) impairs the hepatic insulin signaling pathway, and that HBV infection is associated with IR^[12]. A previous clinical studies also suggest that hyperinsulinemia occurs in CVHB and hepatitis C^[13], and this association has been elucidated in hepatitis C virus (HCV) infection^[14,15]. HCV may disturb the insulin signaling pathway by activation of the tumor necrosis factor (TNF) system^[16]. IR has been proposed as an important risk factor in patients with chronic hepatitis C, mainly due to its relationship to steatosis development^[17] and fibrosis progression^[18], and non-response to peginterferon plus ribavirin^[19]. However, the effect of HBV infection on human insulin sensitivity remains unclear. In this study, we tested the hypothesis that HBV infection may associate with IR and metabolic syndrome, by comparing incidence of IR and prevalence of metabolic syndrome between HBV-infected study participants and a healthy control group.

MATERIALS AND METHODS

Study subjects

This consecutive study conducted at the Center for Health Promotion, Pusan National University Hospital in Busan, South Korea. Data for this study were obtained from 7880 Koreans (3851 men, 4029 women) who underwent a comprehensive medical examination between January 2007 and September 2008. The study participants were eligible if they met all of the following criteria: age ≥ 18 years, no history of diabetes and hypertension requiring medication, negative for anti-hepatitis C antibody, serum aspartate aminotransferase or alanine aminotransferase (ALT) < 80 IU/L, serum gamma-glutamyl transferase (GGT) < 80 mg/dL, serum creatinine < 1.5 mg/dL, prostate specific antigen < 5.0 ng/mL, α -fetoprotein < 10.0 IU/mL, carcinoembryonic antigen < 5.0 ng/mL (for smokers) or < 2.5 ng/mL (for non-smokers), WBC count $< 10\,000/\mu\text{L}$, and high sensitivity C-reactive protein (hs-CRP) < 1 mg/dL.

Measurements

The health checkup which provided our study data included a physical examination, anthropometric measurements and blood tests. Height and weight were measured to the nearest 0.1 cm and 0.1 kg using standard protocol with subjects wearing a light gown and without shoes. Body mass index (BMI) was calculated as weight (kg) divided by height squared (m^2). Waist circumference was measured at the narrowest point between the lower border of the rib cage and the iliac crest, at the end of a normal expiration of breath and to the nearest 0.1 cm.

Percentage of body fat and total fat mass were measured by bioelectric impedance analysis (Inbody 3.0, Biospace Co, Ltd, Korea). Blood pressure was measured using the right arm of subjects assuming a sitting position, and after they had rested for at least 10 min. By use of an automated blood pressure measurement device (BP-203RV II, Colin Corp, Aichi, Japan). Medication history, alcohol intake and smoking habits were obtained by patient interview. The questions relating to alcohol intake included descriptions of the type of alcohol beverage consumed, the weekly frequency of alcohol consumption, and the amount consumed daily. Smoking status was classified as either non-smoker or smoker (former or current). Blood samples were obtained from an antecubital vein after 12 h fasting, typically between 8 and 9 AM. The blood samples were subsequently analyzed at a certified laboratory at Pusan National University Hospital. Lipid profiles, uric acid, and GGT concentrations were measured using an autoanalyzer with the enzymatic colorimetric method (Hitachi7600, Hitachi Ltd, Japan). Cystatin C was measured by turbidimetric immunoassay (HBI Co, Ltd, Korea) using the Modular Analytics E170 (Roche Diagnostics, Switzerland). Hs-CRP was measured using a Behring Nephelometer (DadeBehring, Germany). Fasting plasma glucose was measured by the glucose oxidase method using a Synchron LX 20 (Beckman Coulter, Fullerton, CA, United States). Fasting insulin was measured using a radioimmunoassay (Diagnostic Product Corporation, Los Angeles, CA, United States) with antibody-coated tubes. The mean intra- and interassay coefficient of variation (CV) values were 4.2% and 6.3%, respectively.

Hepatitis B surface antigen (HBsAg), hepatitis B surface antibody, and hepatitis B core antibody were measured by enzyme-linked immunosorbent assay (Bio Focus Co, Ltd, Korea). Hepatitis B viral status was classified into three groups (negative/recovery/CVHB), according to serologic patterns. Insulin sensitivity was estimated using homeostasis model assessment (HOMA)-IR [fasting insulin (μ U/mL) \times fasting glucose (mg/dL)/405]^[20], quantitative insulin check index (QUICKI) $\{1/[\log \text{glucose (mg/dL)} + \log \text{insulin (}\mu\text{U/mL)}]\}$ ^[21,22] and Mf_{im} index $(\exp^{2.63 - [0.28 \times \ln(\text{insulin})] - [0.31 \times \ln(\text{triglycerides})]})$ ^[23].

Definition of metabolic syndrome

The prevalence of metabolic syndrome reported in this study was estimated using definitions proposed in 2005 by the American Heart Association/National Heart, Lung, and Blood Institute (AHA/NHLBI)^[24] and the International Diabetes Federation criteria^[25] for the diagnosis of metabolic syndrome. We defined central obesity as a waist circumference ≥ 90 cm in males and ≥ 85 cm in females, according to geography-specific cut points for waist circumference^[26].

Ethical approval

All participants gave informed consent, and this study was approved by the Institutional Review Board at Pusan National University Hospital and is in accordance with the Declaration of Helsinki (E2010-055).

Table 1 Baseline characteristics of study subjects

Variables	Men (<i>n</i> = 3851)	Women (<i>n</i> = 4029)
Age (yr)	48.9 \pm 10.7	48.6 \pm 10.4
BMI (kg/m ²)	24.5 \pm 2.8	23.5 \pm 2.9
Abdominal circumference (cm)	86.5 \pm 7.4	79.2 \pm 8.4
Percentage body fat (%)	22.7 \pm 5.1	30.1 \pm 5.7
Systolic BP (mmHg)	126.3 \pm 15.3	122.3 \pm 15.4
AST (IU/L)	23.8 \pm 8.6	20.9 \pm 10.5
ALT (IU/L)	26.8 \pm 16.6	19.0 \pm 11.5
GGT (IU/L)	38.0 \pm 20.1	20.0 \pm 12.6
Fasting plasma glucose (mg/dL)	91.6 \pm 14.7	88.3 \pm 14.1
Fasting insulin (μ U/mL)	5.48 \pm 3.49	4.64 \pm 2.78
Total cholesterol (mg/dL)	196.3 \pm 33.3	195.8 \pm 35.2
Triglycerides (mg/dL)	138.0 \pm 80.9	103.8 \pm 63.6
HDL-cholesterol (mg/dL)	50.8 \pm 12.5	59.8 \pm 14.1
LDL-cholesterol (mg/dL)	124.8 \pm 29.5	121.0 \pm 31.8
high-sensitivity CRP (mg/dL)	0.15 \pm 0.47	0.11 \pm 0.37
TSH (μ U/mL)	1.79 \pm 1.79	2.29 \pm 2.15
Uric acid (mg/dL)	5.88 \pm 1.25	4.20 \pm 0.91

Differences between men and women were statistically significant except for age and total cholesterol ($P < 0.05$ by *t* test). BMI: Body mass index; BP: Blood pressure; AST: Aspartate transferase; ALT: Alanine transferase; GGT: Gamma-glutamyl transferase; HDL: High-density lipoprotein; LDL: Low-density lipoprotein; CRP: C-reactive protein; TSH: Thyroid stimulating hormone.

Statistical analysis

To compare variables between groups, a *t* test and/or one-way analysis of variance followed by a Scheffé post hoc test or Kruskal-Wallis test were used as appropriate. Pearson partial correlation coefficients were computed to present the association between fasting plasma glucose concentration and other variables after adjustments for age, gender and alcohol consumption. Using multiple logistic regression analysis and adjusting for age, gender and alcohol intake, we estimated the existence of any independent association between IR and HBV status. Statistical analysis was performed using SPSS 12.0 for Windows. A *P* value of less than 0.05 was considered statistically significant. All statistical tests were two-sided.

RESULTS

Baseline characteristics of study subjects

The subjects were classified as men ($n = 3851$) and women ($n = 4029$), and their baseline clinical characteristics were compared (Table 1). The mean age of men and women were 48.9 years and 48.6 years, respectively. Age and total cholesterol level were not statistically different between men and women ($P > 0.05$). Men had significantly higher results for BMI, abdominal circumference, systolic blood pressure, aspartate aminotransferase, ALT, GGT, fasting plasma glucose, insulin, triglycerides, low-density lipoprotein-cholesterol, hs-CRP, and uric acid ($P < 0.001$).

Metabolic characteristics according to hepatitis groups

The metabolic data of study participants are shown in Table 2. In both men and women, subjects in the CVHB group were significantly older with larger waist circum-

Table 2 Means and frequencies of metabolic risk factors associated with hepatitis B virus status in men and women (mean \pm SD)

Mf _{im} index	-0.374	-0.366	-0.318	-0.199	-0.258	-0.628	0.386	-0.116	-0.203

BMI: Body mass index; WC: Waist circumference; BFP: Percent of body fat; SBP: Systolic blood pressure; TC: Total cholesterol; TG: Triglyceride; HDL: High-density lipoprotein; Cys-C: Cystatin-C; FPG: Fasting plasma glucose; HOMA: Homeostasis model assessment; QUICKI: Quantitative insulin check index. All correlation coefficients are statistically significant ($P < 0.001$).

ferences, and had higher percentages of body fat, cystatin C, fasting insulin, and HOMA index compared to other groups. There were significant differences between men in the CVHB group and negative group in terms of fasting plasma glucose, but no significant differences were observed for women. QUICKI ($P < 0.05$) and Mf_{im} index ($P < 0.01$) results were significantly lower for women in the CVHB group.

Correlation of insulin sensitivity index with metabolic factors

The HOMA index revealed a positive correlation with BMI ($r = 0.378$, $P < 0.001$), waist circumference ($r = 0.356$,

$P < 0.001$), percent body fat ($r = 0.296$, $P < 0.001$), systolic blood pressure ($r = 0.202$, $P < 0.001$), total cholesterol ($r = 0.134$, $P < 0.001$), triglycerides ($r = 0.292$, $P < 0.001$), cystatin C ($r = 0.069$, $P < 0.001$) and uric acid ($r = 0.142$, $P < 0.001$) (Table 3). QUICKI and Mf_{im} index produced a negative correlation with BMI, waist circumference, percent body fat, systolic blood pressure, total cholesterol, triglycerides, cystatin C, and uric acid ($P < 0.001$).

Association of insulin resistance and chronic hepatitis B

For the presence of IR, adjusted odds ratios for the CVHB group was 1.534 (95%CI: 1.158-2.031, HOMA index criteria) or 1.566 (95% CI: 1.124-2.182 in QUICKI

Table 4 Logistic regression analysis with insulin resistance as a dependent variable

Variables	Insulin resistance					
	HOMA index criteria			QUICKI criteria		
	β	SE	Odds ratio (95% CI)	β	SE	Odds ratio (95% CI)
Age (yr)	0.009	0.005	1.009 (0.999-1.019)	0.016	0.006	1.016 (1.005-1.028)

Recovery from hepatitis B	-0.027	0.112	0.974 (0.782-1.212)	-0.075	0.135	0.928 (0.712-1.210)
Chronic hepatitis B	0.428	0.143	1.534 (1.158-2.031)	0.449	0.169	1.566 (1.124-2.182)

HOMA: Homeostasis model assessment; QUICKI: Quantitative insulin check index.

criteria) (Table 4). Adjusting factors included age, gender, BMI and amount of alcoholic consumption.

DISCUSSION

In this study, CVHB was observed to be associated with IR in subjects free of prior diabetes mellitus. CVHB independently predicted a clinically significant increase in the odds ratio for the development of IR. These results indicate that patients with CVHB may need to be carefully monitored for occurrence of IR and diabetes mellitus. As the present study reports basic data on the association between CVHB and IR in a large community population, these findings support previous proposals that CVHB infection is related to IR.

HBV is the prototype member of a steadily growing family of viruses called hepadnaviruses^[27]. It is a partially double stranded virus that uses reverse transcriptase in its replication cycle. CVHB infection is a common health issue in Asia and the Pacific Islands. In Korea, approximately 3.7% of total population are affected in chronic hepatitis B^[28]. Most were infected directly from their mother during birth or through contact between children. CVHB infection may increase the occurrence of hepatic fibrosis, liver cirrhosis, and hepatocellular carcinoma^[29]. In addition, CVHB infection is related to diseases such as PAN, GN, and arthritis^[7-9]. Moreover, there is experimental evidence that CVHB infection increases the appearance of both IR and associated diabetes mellitus. A recent animal study suggested that HBx impairs the insulin signaling pathway^[12]. These findings provide the basis of a hypothesis for mechanism and are consistent with our study results.

IR is assumed to be caused by an inadequate glucose metabolism capacity which leads to more insulin to be secreted to achieve the same biologic response^[30]. Hyperinsulinemia may induce a large variety of abnormalities in blood vessels, kidneys, and muscles, and is the major pathogenesis associated with metabolic syndrome. Diabetes mellitus and metabolic syndrome are also independent risk factors for atherosclerotic disease^[31]. Thus,

early screening of high risk groups is very important to successful health promotion. The gold standard parameter for determining insulin sensitivity is the hyperinsulinemic euglycemic clamp technique. The HOMA model^[20], QUICKI^[21], and Mf_{im} index^[23] used in this study show good correlation with the clamp technique and are easily utilized in primary practice.

Previous studies have proposed association of HBV infection and IR. One previous, retrospective study proposed that maternal HBsAg carrier status was a risk factor for development of gestational diabetes^[32]. Sangiorgio *et al.*^[33] also reported increased frequency of HCV and HBV infection in type 2 diabetic patients. One study reported concordant results using the HOMA model that concluded that hyperinsulinemia occurs in chronic viral hepatitis B and hepatitis C^[13]. However, another previous study reported that HBV carriers were not associated with IR^[34]. But that study had limitations due to small number of study subjects and high prevalence of fatty liver disease in the subjects.

The mechanism IR plays in CVHB infection remains unknown. There are four proteins that originate from the HBV genome including polymerase, a surface protein, a core protein, and the HBx protein. Among these proteins, HBx may be most closely associated with hepatic steatosis, inflammation, and HBV-related disease^[34]. Previous reports proposed that hepatic steatosis and systemic inflammation are associated with IR^[35]. HBx protein can induce hepatic steatosis and inflammation, thus CVHB infection is possibly associated with an impaired insulin signaling pathway^[36]. A recent report concluded that chronic inflammation had effect on IR^[37]. HBV may induce activation of proinflammatory cytokines TNF- α , interleukin (IL)-6, and IL-1 β associated with fat accumulation^[29]. Hepatic steatosis has already been demonstrated to be related to IR, and this association has been clearly identified in HCV infection. HCV proteins present due to infection may also disturb the insulin signaling pathway. IR with chronic hepatitis C has also been related to steatosis development and fibrosis progression^[13-15].

The strength of this study was inclusion of healthy volunteers, which provided greater validity compared to hospital-based or institutional based populations. Other strengths included the large sample size, characterization of multiple confounders that influence IR, and the availability of 3 IR index or insulin sensitivity markers which are validated and widely used, and were also used for determining the degree of IR in previous studies.

This study had several limitations. Because of the cross-sectional nature of this study, it was difficult to prove a causal relationship between HBV infection and IR. Also, our results may not be able to be generalized to other ethnic groups because the present study was conducted exclusively using ethnic Koreans. A weakness in terms of clinical data is that daily variability of insulin within individuals is high, and a single, daily sample may not accurately characterize the actual level. Moreover, there are numerous other factors that influence IR such as condition of skeletal muscles, engagement in physical activity, and severity of liver injuries. Future studies that overcome these limitations are needed to confirm our findings.

In conclusion, CVHB may be associated with IR as identified by HOMA-index, QUICKI, and M_{fin} index results. These findings should be explored further.

COMMENTS

Background

Insulin resistance (IR) is the principal indication for development of metabolic syndrome and type 2 diabetes. Chronic viral hepatitis B (CVHB) is one of the most common health problems and previous clinical studies also suggest that hyperinsulinemia occurs in CVHB. However, the effect of hepatitis B virus (HBV) infection on human insulin sensitivity remains controversial. The authors therefore investigated the hypothesis that HBV infection may associate with IR and metabolic syndrome, by comparing incidence of IR between HBV-infected subjects and healthy group.

Research frontiers

There are four proteins that originate from the HBV genome including polymerase, a surface protein, a core protein, and the hepatitis B X protein (HBx) protein. Among these proteins, HBx may be most closely associated with hepatic steatosis, inflammation, and HBV related disease. Moreover, recent experimental study suggested that HBx impairs the hepatic insulin signaling pathway.

Innovations and breakthroughs

CVHB was observed to be associated with IR in subjects free of prior diabetes mellitus. CVHB independently predicted a clinically significant increase in the odds ratio for the development of IR. These results indicate that patients with CVHB may need to be carefully monitored for occurrence of IR and diabetes mellitus.

Applications

CVHB infection is a common health issue in Asia and the Pacific Islands. CVHB may need to be monitored for occurrence of insulin resistance and diabetes mellitus.

Terminology

Homeostasis model assessment index is calculated by equation of $[\text{fasting insulin } (\mu\text{U/mL}) \times \text{fasting glucose (mg/dL)} / 405]$, quantitative insulin check index is calculated by equation of $\{1/[\log \text{glucose (mg/dL)} + \log \text{insulin } (\mu\text{U/mL})]\}$, M_{fin} index is obtained by equation of $(\exp^{2.63 - [0.28 \times \ln(\text{insulin})] - [0.31 \times \ln(\text{triglycerides})]})$.

Peer review

This study investigated the association of insulin resistance and chronic viral hepatitis B. The authors evaluated a numerous population of HBV infected patients and compared their metabolic features with control group. This manuscript reinforce further evaluations on a real clinical impact of this association.

Abstract

AIM: To evaluate sertraline, a selective serotonin reuptake inhibitor in the treatment of patients with functional dyspepsia.

METHODS: Consecutive tertiary hospital patients with a clinical diagnosis of functional dyspepsia (FD) according to the Rome II criteria with a Hong Kong dyspepsia index (HKDI) of greater than 16 were recruited. Patients commenced enrolment prior to the inception of the Rome III criteria for functional dyspepsia. All patients were ethnic Chinese, had a normal upper endoscopy and were *Helicobacter pylori* negative prior to enrolment. Study patients were randomized to receive sertraline 50 mg or placebo daily for 8 wk. HKDI symptom scores, quality of life, hospital anxiety and depression (HAD) scale and global symptom relief were evaluated before, during and after treatment. Adverse effects were monitored during and after treatment.

RESULTS: A total of 193 patients were randomized in the intention to treat (ITT), and 150 patients were

included in the per protocol (PP) analysis. In both the ITT and PP, there was no difference in the primary outcome of global dyspepsia symptoms between the sertraline and placebo groups at week 8. In the ITT analysis, 98 and 95 patients were randomized to the sertraline and placebo groups respectively. A total of 43 patients withdrew from the study (22.3%) by week 8, with 23 of the 24 drop-outs in the sertraline group occurring prior to week 4 (95.8%). In contrast, in the placebo arm, 11 of 19 patients dropped out by week 4 (57.9%). Utilizing the last response carried forward to account for the drop-outs, there were no differences between the sertraline and placebo groups at baseline in terms of the HKDI, HKDI 26.08 ± 6.19 vs 26.70 ± 5.89 , $P = 0.433$; and at week 8, HKDI 22.41 ± 6.36 vs 23.25 ± 7.30 , $P = 0.352$ respectively. In the PP analysis, 74 and 76 patients were randomized to the sertraline and placebo groups respectively. At baseline, there were no statistically significant differences between the sertraline and placebo groups, HKDI 25.83 ± 6.313 vs 27.19 ± 5.929 respectively, $P = 0.233$; however by week 8, patients in the sertraline group demonstrated a statistically significant difference in their Hong Kong Dyspepsia Index compared to placebo, HKDI 20.53 ± 6.917 vs 23.34 ± 7.199 , $P = 0.02$, respectively). There was also no statistically significant difference in overall quality of life measures or the HAD scale related to treatment in either the ITT or PP analysis at week 8.

CONCLUSION: This pilot study, the first to examine sertraline, a selective serotonin reuptake inhibitor, for the management of FD, did not find that it was superior to placebo.

INTRODUCTION

Functional dyspepsia (FD) is defined as persistent or recurrent pain and/or discomfort centered in the upper abdomen for at least 12 wk in the preceding 12 mo according to the Rome II criteria in the absence of structural disease^[1]. The Rome III criteria, published in 2006, further refines FD into epigastric pain syndrome and/or postprandial distress syndrome with the criteria fulfilled in the last 3 mo with symptoms onset at least 6 mo prior to diagnosis, again in the absence of structural disease^[2,3]. The prevalence of dyspepsia in the Asia Pacific region varies from 10% to 20%, with a FD prevalence of 7.9%-12% which is lower than that seen in the west^[4-6]. FD or non-ulcer dyspepsia is a significant cause of morbidity and work-related productivity lost^[7]. The pathogenesis of FD is not known. A number of studies have shown an important role of psychological factors in the pathogenesis of this condition^[8-10]. We have demonstrated previously that anxiety and depression are important co-factors in its pathogenesis^[11]. There is no definitive treatment for this condition. Acid suppression therapy has been shown to be ineffective for the treatment of this condition in Chinese patients^[12] despite benefit of proton pump inhibitor therapy in patients with ulcer-like and reflux like dyspepsia^[13]. *Helicobacter pylori* (*H. pylori*) eradication confers only small benefit relative to placebo^[14] and studies of itopride, a dopamine D2 antagonist with acetyl cholinesterase effects although initially promising, conferred no benefit in a subsequent and larger study^[15,16]. Visceral hypersensitivity appears to be important in the pathogenesis of FD, as evidenced by a small study utilizing capsaicin to generate a desensitization of gastric nociceptive C fibers^[17]. Similarly, antidepressants were investigated in FD for their ability to modulate visceral hypersensitivity^[18]. Earlier antidepressant therapy studies demonstrated some effectiveness in the treatment of functional gastrointestinal symptoms, however a recent study utilizing venlafaxine (a selective serotonin and noradrenaline reuptake inhibitor) did not show any benefit^[19-23]. In terms of antidepressants studied in FD, tricyclic compounds are the class of antidepressants best studied for this application, however selective serotonin

reuptake inhibitors (SSRIs) are more commonly used in clinical practice because of their safer side-effect profile. The precise mechanism of action of SSRIs in the treatment of depression is not fully understood. However, long-term treatment with SSRIs has been reported to down regulate the serotonin transmitter responsible for serotonin reuptake as well as serotonergic receptors^[24], which may down regulate visceral hypersensitivity.

An open label study found that the SSRI, fluoxetine, was superior to no treatment in depressed patients with FD, however had methodological flaws including the open label nature of the study^[25]. To date, there are no published randomized controlled studies on the effect of sertraline for the treatment of FD. We performed a double-blind, randomized, placebo-controlled trial consisting of 8 wk of therapy in Chinese patients with FD. We aimed to assess the efficacy of SSRI in the treatment of FD and to identify potential responders to SSRI therapy in subgroups of patients with dyspepsia as their chief symptom.

MATERIALS AND METHODS

Patient enrollment

Consecutive patients referred to the Department of Medicine, Queen Mary Hospital, Hong Kong between June 2002 and June 2008 were screened for enrolment. FD was defined as persistent or recurrent dyspepsia (pain or discomfort centered in the upper abdomen) with no evidence of organic disease, chronic severe constipation, or irritable bowel syndrome to explain the symptoms, for at least 12 wk, which need not be consecutive, within the preceding 12 mo, in accordance with the Rome II criteria^[26]. The Rome III criteria for FD had not yet been conceived when the study was commenced^[3]. Patients aged 18-80 years with symptoms of dyspepsia within two weeks prior to the endoscopy visit were eligible for the study. Informed written consent was obtained from all patients. Patients were also required to have a dyspepsia score of greater than 16 by our validated questionnaire^[27] and have had no prior investigations performed for this episode of dyspepsia within the 6 mo prior to the study. All enrolled patients were ethnic Chinese. Exclusion criteria included patients who were pregnant or breast feeding, had a history of alcohol or drug abuse; recent malignancy or significant medical illnesses or concurrent medication, which may interact with or contra-indicate the use of sertraline. Patients with a history of or current anti-depressant use were excluded. Patients with classical heartburn or acid regurgitation as their only symptom without epigastric discomfort or pain were also excluded to avoid recruitment of patients with non-erosive gastro-oesophageal reflux disease. All patients had normal upper endoscopy. The study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West Cluster (EC 1774-02).

Study protocol

Patients were randomized to receive either sertraline 50

mg or placebo once daily for eight weeks. Randomization was performed by drawing a sealed envelope that contained a pre-assigned randomized treatment generated by computer on entry to the study. Both the investigators and patients were blinded to the assigned treatment throughout the study. The sertraline and placebo capsules were identical in appearance. Patients were given a diary in which they recorded side effects and symptoms during therapy. After enrolment by gastroenterologists, patients returned for follow up at four and eight weeks where one of two gastroenterologists assessed their symptoms and quality of life.

Dyspepsia symptoms were assessed by a locally validated dyspepsia questionnaire, the Hong Kong dyspepsia index (HKDI) which consisted of 12 questions (epigastric pain, upper abdominal bloating, upper abdominal dull ache, epigastric pain before meals, epigastric pain when anxious, vomiting, nausea, belching, acid regurgitation, heartburn, feeling of acidity in the stomach, loss of appetite) graded on a five point Likert scale as follows: 1 (none), no symptoms; 2 (mild), symptoms can be easily ignored; 3 (moderate), awareness of symptoms but easily tolerated; 4 (severe), symptoms sufficient to cause interference with normal activities; and 5 (incapacitating), incapacitating symptoms with an inability to perform daily activities and/or require days off work. Test-retest reproducibility and internal consistency were good, with an intra-class correlation coefficient of 0.89 and Cronbach's alpha coefficient of 0.90. A cut off score of ≥ 16 was discriminative between controls and dyspeptic patients. Moreover, the HKDI score was significantly correlated to patients who reported a subjective improvement in symptoms and those who reported no change or worsening after therapeutic intervention (Kendall's $\tau_{au} = 0.21$, $P = 0.02$)^[27]. Patients were then sub-classified into four dyspepsia subgroups according to their predominant symptoms: (1) ulcer-like dyspepsia-predominant epigastric pain; (2) dysmotility-like dyspepsia-predominant discomfort that may be characterised by upper abdominal fullness, early satiety, bloating, or nausea; (3) reflux-like dyspepsia-predominant reflux symptoms (heartburn or acid regurgitation); and (4) unspecified-symptoms do not fulfill the criteria for ulcer-like, dysmotility-like, or reflux-like dyspepsia. Although reflux-like dyspepsia was discarded in the Rome II criteria, we felt that a certain proportion of patients with FD still belong to that particular subgroup and there is considerable overlap between FD and non-erosive or negative endoscopy reflux disease^[28,29]. Furthermore, inclusion of reflux-like dyspepsia allows comparison with previous randomized controlled trials^[30].

Quality of life was assessed by a locally validated questionnaire [Chinese translated form of 36-item short-form (SF-36)]^[31]. The SF-36 consisted of 36 items to measure eight aspects of psychological general well being (physical functioning, role physical, bodily pain, general health, vitality, social functioning, role emotional, and mental health). A generic quality of life instrument was utilized to assess general well being as at the commence-

ment of this study, there were no dyspepsia specific quality of life questionnaires validated in the Chinese language. The symptoms pertaining to anxiety and depression were assessed by the hospital anxiety and depression (HAD) scale questionnaire which consists of 14 questions. Finally, subjective global symptom relief was graded by patients, from a scale of 1 to 5, representing the spectrum from complete resolution of symptoms to worsening of symptoms, respectively.

Study intervention: Sertraline

The SSRI utilized in this study was sertraline (Zoloft, Pfizer Corporation) at a dose of 50 mg orally daily. Study participants were provided with pre-sealed boxes containing either sertraline or placebo and were asked to take a capsule per day for 8 wk in total. Patients were provided with a 4 wk supply of capsules and were contacted weekly to ensure compliance with treatment. Patient compliance was checked by counting returned study medications. Subjects who took less than 75% of the study medication were excluded from the final per protocol (PP) analysis.

Statistical analysis

Mean dyspepsia score, the eight aspects of the SF-36 scores and the two HAD scores before and after treatment were collected on Excel (Microsoft) databases in the two treatment groups. The change in mean HKDI, SF-36 and HAD scores from baseline, at the four and eight week visit were calculated and compared between the sertraline and the placebo groups. Patient diaries, detailing the presence and severity of symptoms, were also compared between groups at weeks 4 and 8. The primary end point was defined as an improvement in clinical symptoms at week 8. Secondary endpoints included an improvement or resolution of the clinical symptoms, or an improvement in any of the scales including HKDI, SF-36 or HAD at week 8. Continuous variables were expressed as mean \pm SD, and categorical data expressed as percentages. Continuous variables were compared using Student's t tests. Categorical variables were compared using Fisher exact or χ^2 tests as appropriate. The Mann-Whitney test was used for data with a skewed distribution. The intention to treat (ITT) analysis included all patients who had taken at least one tablet. In the PP analysis, patients with poor drug compliance ($< 75\%$ intake of any study drugs) and drop outs (due to adverse effects) were excluded. Multiple logistic regression analysis was performed to determine independent factors (age, sex, *H. pylori* status, smoking, alcohol intake, dyspepsia duration, predominant symptoms, and type of treatment given) associated with treatment response.

All calculated P values were two-sided and P values < 0.05 were considered statistically significant. Statistical analysis was performed using SPSS Ver. 16.0 for Windows (SPSS Inc., Chicago, IL, United States).

Power of the study

This was a pilot study, so assuming a placebo response

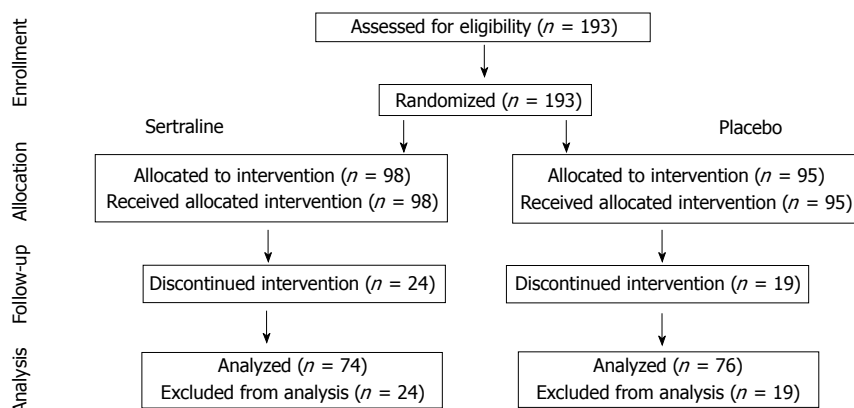

Figure 1 Study patient flow chart.

Table 1 Demographics of study patients

	Sertraline	Placebo	P value

H. pylori: *Helicobacter pylori*; NSAIDs: Non-steroidal anti-inflammatory drugs.

rate of 25%-30%, a drug response rate of 30 % above placebo and a drop out rate of 20%^[11], 166 patients will be needed to demonstrate 95% confidence interval with power of 0.8 and alpha of 0.05 (i.e., 166 patients with dyspepsia with 83 patients in each arm). It was aimed to recruit 190 patients.

RESULTS

Baseline demographics

We recruited 193 eligible patients (patients for the ITT analysis). A total of 98 patients were randomized to receive sertraline 50 mg and 95 patients were randomized to receive placebo (Figure 1).

All recruited patients were ethnic Chinese. Baseline characteristics of the patients in the two treatment groups are given in Table 1. 75.5% and 80% of patients took more than 75% of the medications in the sertraline and placebo groups, respectively. Poor compliance patients, those who refused follow up, and those who discontinued treatment because of adverse events were excluded from the PP analysis (*n* = 150).

Baseline characteristics of the patients and their dyspepsia subtypes are listed in Table 1. Mean age of these patients was 42.4 years (range: 18-71 years) with a median dyspepsia score of 26.5 (range: 17-46). There were 54 males (mean age 45.2 years) and 139 females (mean age

41.4 years). Mean age, sex distribution, smoking history, alcohol consumption and *H. pylori* positivity at baseline were similar between the treatment groups (Table 1). Baseline mean HKDI score, SF-36 and HAD scales in the PP analysis (Table 2) assessments were similar between the treatment groups.

Dyspepsia scores

In the PP analysis at week 8, 28.4% *vs* 27.6%, of patients experienced complete resolution of their dyspepsia symptoms, whilst 64.9% *vs* 59.2% of patients experienced no difference in their dyspepsia symptoms in the sertraline and placebo groups (*P* = 0.511 for difference between the two cohorts) respectively. Sub group analysis for complete response at weeks 4 and 8 was also unrevealing. Complete response was similar between the treatment groups at weeks 4 and 8.

In the PP analysis the baseline mean HKDI score was 25.83 (SD = 6.313) and 27.19 (SD = 5.929) for sertraline and placebo arms respectively (*P* = 0.233). Mean HKDI score improved in all groups at week 4 compared to baseline. HKDI score in the sertraline group improved the most but was not statistically significant. By week 8, the sertraline group had a mean HKDI score of 20.53 (SD = 6.917), whilst the placebo group's mean dyspepsia score was 23.34 (SD = 7.199), (*P* = 0.02). The change in HKDI between week 0 to 8 was 5.3 and 3.85 in the treatment and placebo groups respectively (*P* < 0.001 for both sertraline and placebo groups). There were no consistent significant differences in the parameters of the quality of life assessment and the HAD scale at week 8 (Table 2).

For the ITT analysis, where the method utilized was the last response carried forward, the mean HKDI at week 0 was 26.08 and 26.70 (SD = 6.19 and 5.89, *P* = 0.433) for sertraline and placebo cohorts respectively. Although improvement of the HKDI was seen at weeks 4 and 8, the results were not statistically significant at (HKDI week 8 = 22.41 and 23.25, SD = 6.36 and 7.30 for sertraline and placebo respectively, *P* = 0.352). Again, there was no consistent significant differences in the parameters of quality of life assessment, HAD scale or complete responses at week (data not shown).

HAD: Hospital Anxiety and Depression Scale; SF36: 36-item short-form.

Adverse events

At week 8, a total of 43 patients (24 on sertraline and 19 on placebo) discontinued treatment. The main reasons for discontinuation of the study medication were drug side effect (41.2%), no reason given (41.9%) or other reason which included the development of conditions for which sertraline could interfere with prescribed treatment (7%) (Table 3). Of particular interest is the pattern of withdrawal from the study, 23 of 24 patients withdrawing from the sertraline group did so before week 4, representing 95.8% of all drop-outs from the sertraline group. By contrast, in the placebo group, approximately half of the patients withdrew prior to week 4 (57.9%), whilst the other half withdrew prior to week 8. Patients experiencing drug adverse effect were noted to have multiple symptoms including insomnia, constipation and agitation, however there was no significant difference in the rate of adverse effects experienced by the two cohorts. Nine percent of all study patients withdrew from the study without explanation (were lost to follow up).

Table 3 Default patient profile *n* (%)

	Default week 4	Default week 8	Reason for default week 8		
			No reason given ¹	Adverse effect of drug ¹	Other ¹
Sertraline	23	24	7 (16.3)	14 (32.6)	3 (7)
Placebo	11	19	11 (25.6)	8 (18.6)	0 (0)

¹Represents percentage of all default patients; *P* = 0.259 for drug adverse effect between sertraline and placebo groups.

Factors associated with response

Age, sex, *H. pylori* status, smoking, alcohol consumption, and dyspepsia duration were not associated with response to sertraline. Multiple logistic regression analysis did not identify any independent predictors of favorable outcome.

A *post hoc* analysis comparing reflux like dyspepsia *vs* all other types of dyspepsia showed similar results to the PP analysis, in the non reflux like group the HKDI was 25.70 and 27.00 at week 0, whilst at week 8, HKDI was 20.85 and 23.42 respectively (*P* = 0.004). Similarly, the SF 36, HAD scales and complete response rates did not show any statistically significant differences (data not shown). In the reflux like group where *n* = 14, HKDI was 28.88 and 28.00 at week 0, and at week 8, HKDI was 21.00 and 23.80 (*P* = 0.426).

DISCUSSION

We have reported a double-blind, randomized, placebo-controlled pilot study of sertraline 50 mg *vs* placebo for the treatment of FD. We found that there was a statistically significant improvement in the mean HKID score at week 8 in the sertraline group compared to the placebo group in the PP but not the ITT analysis. There were also no differences in measures of quality of life, depression and anxiety and subjective global symptom resolution.

This study is a pilot study examining the effect on sertraline in patients with FD. The sertraline dose that was administered is a clinically relevant dose (the initial treatment dose for depression and obsessive-compulsive disorder and in some studies, depression)^[32]. The trial duration of 8 wk seems adequate given that a steady-state plasma sertraline level is expected after 1 wk with once daily dosing and the beneficial effects of antidepressants in functional gastrointestinal disorders are often observed after shorter treatment duration than in depression^[33]. However, longer term follow-up may yield more significant results given that individual responses to sertraline can vary and up to 12 wk may be required to see the full onset of action. Furthermore, although the dosage of sertraline utilized was appropriate for the reasons cited above, several studies have indicated that due to ethnic differences, Chinese patients may tolerate lower doses better^[33,34].

One of the limitations of the study is the drop out rate, 17.6% at week 4 and 22.3% at week 8. Our drop

out rates are similar to those observed when antidepressants are utilized in functional gastrointestinal disorders^[35]. There are many factors which could account for the drop out rate in our study. Sertraline's known side effects include sleep disturbance, headache, tremors, agitation and gastrointestinal upset^[24]. In our study, adverse drug effect was the cause of study withdrawal in 41.2% of cases. Interestingly, of the patients who dropped out, 41.9% withdrew from the study without giving a reason. Multiple studies have indicated a cultural bias in the Chinese population against a diagnosis of psychiatric or functional disorders^[36-38] and the authors hypothesize that the cultural stigma attached to treatment for a functional disorder with a known anti-depressant would contribute significantly to the drop out rate. Furthermore, the majority of the drop outs in the sertraline group occurred at week four, which could possibly be explained by the short term side effects of sertraline usually seen during the run in period of SSRIs^[39] which could be mitigated by more intensive support and education during the first few weeks of treatment.

Another limitation of the study is the failure to discern a difference in the generic quality of life measures utilized between the sertraline and placebo cohorts. This may ostensibly be a reflection of the fact that generic quality of life instruments are not sensitive enough to detect changes in overall well being in patients with FD particularly with treatment^[40]. This has been seen with other gastrointestinal disorders and has resulted in the development of disease specific quality of life instruments^[41,42].

Finally, the most important limitation of the study is the failure to find a difference in global symptom scores in the ITT analysis, and only a small difference in the HKDI, but not global symptoms score in PP analysis. The authors believe this small finding suggests a possible benefit of sertraline in patients with FD, but perhaps this study was under-powered to detect this difference due to the unexpectedly high dropout rate, particularly in the first 4 wk when SSRI adverse effects are at their maximal, and for this reason warrants further larger studies utilizing sertraline to clarify the issue. We assert that our findings are important given that clinicians not uncommonly are utilizing SSRIs to treat FD despite the fact that to date, our study included, there is no strong justification for its use^[43].

In conclusion, our data suggest that an SSRI, sertraline was not superior to placebo for the management of FD in Chinese patients. Further studies are warranted to confirm these results as this study was likely under powered to determine an effect in the context of a higher than expected drop out rate and there is a suggestion that with more support, a longer follow up period, and perhaps a reduction in the dose of sertraline in Chinese patients an effect may be seen.

COMMENTS

Background

Early studies with tricyclic antidepressants demonstrated efficacy in the treatment of functional dyspepsia yet there have been no double-blind, randomized, placebo-controlled trials examining the role of selective serotonin reuptake inhibitors (SSRIs) in this condition.

Research frontiers

SSRIs, the most commonly utilized antidepressant in clinical practice, may improve the symptoms of functional dyspepsia through modulation of visceral hypersensitivity. In this study, the authors examine the effects of sertraline, a SSRI, on global symptoms, a locally validated dyspepsia index, the 36-item short-form (SF-36) and the hospital anxiety and depression scale.

Innovations and breakthroughs

Tricyclic antidepressant medication has been shown to be efficacious in functional dyspepsia, however tricyclic antidepressant medications have significant side effects, prompting the study of the utility of newer antidepressants in this condition. Venlafaxine, a selective serotonin and noradrenaline reuptake inhibitor did not show any benefit in functional dyspepsia however an open label study of fluoxetine, a SSRI, found benefit. This is the first double-blind, randomized, placebo-controlled study examining an SSRI in the treatment of functional dyspepsia.

Applications

This study found that treatment with the SSRI, sertraline, improved the Hong Kong dyspepsia index score at week 8 compared to baseline but did not find overall improvement in global dyspepsia symptoms, SF-36 or the hospital anxiety and depression scale, possibly due to the higher than expected drop out rate in the sertraline group by week 4. Larger studies are warranted to further examine the effects of sertraline in functional dyspepsia.

Peer review

This is a nicely designed study showing that SSRI sertraline is of no benefit in functional dyspepsia. The authors acknowledge the main limitation of a negative study represented by the scarce numerosity and high drop out rate, based on the optimistic calculations adopted to evaluate sample size. A more realistic hypothesis will substantially raise the number of patients needed to be included.

Abstract

AIM: To evaluate the efficacy and safety of transcatheter arterial chemoembolization (TACE) for gastrointestinal stromal tumor (GIST) with liver metastases after the failure of tyrosine kinase inhibitors (TKIs).

METHODS: Patients with histologically confirmed CD117-positive GIST with liver metastases who were resistant and/or intolerant to prior imatinib and/or sunitinib and who received TACE for at least one treatment cycle or only best supportive care and TKI reintroduction were eligible for the study. The patients were divided into two groups: those in TACE group received TACE treatment containing 5-20 mL iodized oil and 40-80 mg doxorubicin hydrochloride and TKI reintroduction or best supportive care, those in control group only received TKI reintroduction or best supportive care. The primary end-point was overall survival

and the secondary end-points were, progression-free survival (PFS), response rates, and safety.

RESULTS: Sixty patients admitted between June 2008 and October 2011 were eligible for this study, including 22 in TACE group and 38 in control group. In the TACE group, 12 (54.5%) achieved liver partial response, 5 (22.7%) had stable disease, and 5 (22.7%) had liver progressive disease. Disease control rate of liver metastases was 77.3% in the TACE group and 39.5% in the control group. The median liver PFS in TACE group was 47.1 wk (95% CI: 23.9-70.3). The median PFS in TACE group was longer than in control group (30.0 wk, 95% CI: 20.1-39.9 vs 12.9 wk, 95% CI: 11.9-13.9) ($P = 0.0001$). The median overall survival in TACE group was also longer than in control group (68.5 wk, 95% CI: 57.4-79.6 vs 25.7 wk, 95% CI: 23.2-28.2) ($P = 0.0001$). TACE treatment significantly reduced the risk of death (hazard ratio: 0.109). Patients without extrahepatic metastases treated with TACE had significantly better prognosis. Most of the adverse events were of grade 1 or 2 and tolerable.

CONCLUSION: TACE is effective and well tolerated in GIST patients with liver metastases after TKI failure, and it may be an optional treatment for this disease.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the gastrointestinal (GI) tract and account for about 2% of gastrointestinal tract tumors^[1,2]. Tyrosine kinase inhibitors (TKIs) imatinib and sunitinib have demonstrated efficacy against GISTs, and are referred to as the first- and second-line therapeutic drugs^[3-5]. However, resistance to such kind of TKIs remains a substantial problem. Around 4%-5% patients showed evidence of primary resistance and nearly half of the patients will experience secondary resistance within two years^[4,6,7]. At present, there is still no standard treatment for metastatic GIST after imatinib and sunitinib failure. The National Comprehensive Cancer Network (NCCN) guideline (2010)^[8] recommended considering reintroduction of a TKI for palliation of symptoms in patients with GIST progression despite prior imatinib and sunitinib.

Liver is the most common site of metastasis from GISTs, with a reported incidence of 55%-72% in patients with recurrence, and metastatic liver disease is a major determinant of patient survival^[9,10]. Some studies^[11-14] have shown favorable results of transcatheter arterial chemoembolization (TACE) for GIST with liver metastases. However, there are few studies about the role of TACE in the treatment of GIST patients after TKIs failure, moreover, there is no control study comparing TACE with best supportive care (BSC) and/or TKI reintroduction. Herein we retrospectively analyzed the survival benefit of TACE, BSC and/or TKI reintroduction in the patients with liver metastatic GISTs treated in the Peking University Cancer Hospital when resistance and/or intolerance occurred to imatinib and/or sunitinib.

MATERIALS AND METHODS

Study design

It is an open, retrospective, controlled study to evaluate the efficacy and safety of TACE in Chinese GIST patients with liver metastases after TKI treatment failure. Patients with histologically confirmed CD117-positive GIST with liver metastases who were resistant and/or intolerant to prior imatinib and/or sunitinib and who received TACE for at least one treatment cycle or only BSC and TKI reintroduction were eligible for the study. Following a retrospective review of the medical records of the patients seen at our hospital between June 2008 and October 2011, a total of 60 patients were found to meet the study criteria. There were 22 in TACE treatment group and 38 in BSC/TKI reintroduction group, which served as control group.

Patient characteristics: The following demographic

and clinicopathological information was retrospectively obtained from the patient records: gender, age, extent of liver disease, and extrahepatic metastases.

Treatment: Data of TKI reintroduction and TACE treatment, including dose of TKI, interval between TKI and TACE, TACE procedure, and cycles of TACE, were collected.

Follow-up: Overall survival (OS) and progression-free survival (PFS) were acquired.

Study end-points

The primary end-point was OS and the secondary end-points were PFS, disease control rate (DCR) of liver metastases defined as a combination of complete response + partial response (PR) + stable disease (SD), and safety. Response rate was evaluated every 6 wk. OS was defined as the time from the first TACE or BSC/TKI reintroduction to the occurrence of death from any cause. The PFS was defined as the time from the first time of TACE or BSC/TKI reintroduction to the occurrence of disease progression or death from any cause. Disease control rate was assessed by Response Evaluation Criteria in Solid Tumors (RECIST 1.1). Adverse events were graded according to the National Cancer Institute Common Toxicity Criteria version 3.0.

Statistical analysis

All the statistical analyses were performed using the SPSS 15.0 (SPSS Inc., Chicago, IL, United States). PFS and OS curves were constructed by the Kaplan-Meier method and compared with log-rank test. In order to adjust for confounding variables, we used Cox proportional hazards models to estimate the simultaneous effects of prognostic factors on survival. Frequency and percentage descriptions were used for categorical variables and the χ^2 test was used to compare the incidence of different events. If the theoretical frequency was lower than 1, *F* test was conducted. Continuous variables were expressed as mean \pm SD and mean differences between two groups were compared using Student's *t* test.

RESULTS

Patient characteristics

There were 45 males and 15 females with a median age of 55.0 years (95% CI: 51.8-58.2). All the patients at registration were assessed to have the Eastern Cooperative Oncology Group (ECOG) performance status grade 0-2 and had received imatinib treatment. Among them, 35 took sunitinib after imatinib failure prior to TACE or BSC/TKI introduction treatment. Thirty-four (56.7%) had liver metastases and the others had extrahepatic metastases. Clinical features of the patients in the two groups are shown in Table 1.

In TACE group, 15 (68.2%) had an extent of liver involvement within 50%, 6 (27.3%) within 50%-70%,

TACE: Transcatheter arterial chemoembolization; ECOG PS: The Eastern Cooperative Oncology Group performance status; TKI: Tyrosine kinase inhibitors.

and 1 more than 70%. Eight patients (36.4%) had only 1 liver metastasis, 9 (40.9%) had 2-5 liver metastases, and the others had more than 5. The mean TACE treatment cycles received by all the patients in TACE group was 2.64, with 6 (27.3%) receiving only one TACE, and 16 (72.7%) received more than one TACE. Fifteen patients (68.2%) showed a good blood supply of liver metastases.

Treatment in TACE group

TACE protocol: Eligibility criteria for TACE included well-preserved hepatic and renal function, the Child-Pugh classification within A and B, adequate hematologic function, and ECOG performance status of 0-2. Patients with high-risk factors, such as portal vein occlusion, no hepatopetal flow, massive ascites, encephalopathy, or active cardiac failure, were excluded.

Local anesthesia was obtained with 1% lidocaine. After the introduction of a selective catheter through the femoral artery using the Seldinger technique, the localization of the hepatic arteries was checked with celiac and mesenteric arteriography. This was performed to define vascular anatomy. Next, indirect portography was performed to outline the portal circulation in the venous phase. A 5 French catheter was placed in the celiac trunk to identify the hepatic artery. Depending on the size, loca-

tion, and arterial supply to the tumor, a micro-catheter was advanced further into the segmental feeding arteries to perform embolization. An emulsion containing 5-20 mL iodized oil and 40-80 mg doxorubicin hydrochloride was used according to the tumor size. Additional embolization was performed using 1-2 mm diameter gelled sponge particles according to the status of blood supply. The ideal embolization end-point is the stasis of flow in tumor-feeding branches. Follow-up abdominal imaging (computed tomography) was generally performed two months after the first embolization. The follow-up images were assessed by two radiologists (Cao K and Cui Y) and compared with the baseline images to assess response.

TKI reintroduction: Ten patients received TKI reintroduction during the intermittent period of TACE. Among them, 6 patients took imatinib 400 mg/d and 4 patients took sunitinib 37.5 mg/d. The interval between TKI therapy and TACE was 2 wk.

Treatment in control group

All the patients in control group had GIST resistant to imatinib and 35 had tumor resistant to sunitinib. Among them, 9 patients received imatinib 400 mg/d and 15 received sunitinib 37.5 mg/d reintroduction, and the others only received best supportive care. Efficacy was evaluated every 6-8 wk according to the RECIST criteria.

Response rate: All the patients had measurable metastatic disease according to the RECIST criteria and tumor assessment was performed at least once. In TACE group, 12 (54.5%) achieved liver PR, 5 (22.7%) had SD, and 5 (22.7%) showed liver disease progression (PD) after TACE treatment. The DCR of liver metastases was 77.3%. In addition, 8 patients had PD when all the lesions were evaluated, and the DCR of all the lesions was 63.6%. In the control group, 12 patients receiving TKI reintroduction and 3 patients receiving BSC had SD, and the others had PD. The DCR in the control group was 39.5%.

PFS: As of May 2012, 19 (86.0%) patients in TACE group had liver metastasis progression. The median liver PFS of all 22 patients was 47.1 wk (95% CI: 23.9-70.3). In control group, all the patients had tumor progression. The median PFS in TACE group was longer than in control group (30.0 wk, 95% CI: 20.1-39.9 *vs* 12.9 wk, 95% CI: 11.9-13.9) ($P = 0.0001$, Figure 1A).

OS: As of May 2012, 4 patients in TACE group and 2 patients in control group were alive, and deaths occurred because of tumor progression. The median OS in TACE group was longer than in control group (68.5 wk 95% CI: 57.4-79.6 *vs* 25.7 wk 95% CI: 23.2-28.2) ($P = 0.0001$, Figure 1B). TACE significantly reduced the risk of death in GIST patients with liver metastases according to the Cox proportional hazards regression model [hazard ratio (HR): 0.109; 95% CI: 0.044-0.271].

Figure 1 The median progression-free survival (A) and overall survival (B) were longer in transcatheter arterial chemoembolization group than in control group ($P = 0.0001$). TACE: Transcatheter arterial chemoembolization.

Univariate and multivariate analysis

Results of the univariate and multivariate analysis are summarized in Table 2. The results showed the P value of number of liver metastases is 0.086. The patients without extrahepatic metastases and the patients treated with TACE were the two factors significantly associated with good survival. The two factors led to a reduction of death risk by 53.7% (HR: 0.463, $P = 0.007$) and 58.5% (HR: 0.415, $P = 0.005$), respectively.

In TACE group, univariate and multivariate analysis showed that absence of extrahepatic metastases, more than one session of TACE, and DCR of more than 3 mo after TACE were significantly associated with a good survival ($P = 0.006$, $P = 0.02$, $P = 0.012$).

Adverse events

Most patients in TACE group developed post-embolization complications, which included abnormal liver function, abdominal pain, fever and nausea. The incidence of fever, alanine aminotransferase increase and nausea in TACE group was higher than in control group ($P < 0.05$). However, the majority of adverse events were of grade

1-2, and in most cases, these symptoms were effectively resolved with supportive measures. No patient died within 1 mo after TACE. Other adverse events included anemia, neutropenia, thrombocytopenia, ascites, pleural effusion and hemorrhage (Table 3). No one discontinued treatment because of adverse events.

DISCUSSION

There is still no standard treatment for the GIST patients after imatinib and sunitinib failure. TKI reintroduction, BSC or drugs in clinical trial are recommended for these patients. Some studies^[15-19] reported that the novel TKIs had potential activity against metastatic GIST, but the efficacy remains to be validated in prospective randomized controlled trials. Liver is the most common metastatic site of GIST and some patients even have only liver metastases other than other diseases till death. Resection of liver metastases has improved the overall survival^[20-22], again the efficacy of resection should be further confirmed by prospective clinical trials. Some retrospective studies^[11-14] showed that TACE may be potentially effective for GIST resistant to TKI. In this study, the patients with liver metastatic GIST receiving TACE after imatinib and/or sunitinib failure gained better PFS and OS than the patients receiving TKI reintroduction or BSC. In the sunitinib phase III trial^[23], the median time to progression of the patients receiving placebo was only 6.4 wk. The results demonstrated that TACE may benefit the patients with liver metastases.

In TACE group, 68.2% patients had good blood

Table 3 Adverse events in the two groups

Adverse events	All grades (%)			Grade 3-4 (%)		
	TACE group (n = 22)	Control group (n = 38)	P value	TACE group (n = 22)	Control group (n = 38)	P value

TACE: Transcatheter arterial chemoembolization; ALT: Alanine aminotransferase; NA: Not applicable.

supply of liver metastases. Some suspensions such as iodized oil (lipiodol) can occlude small tumor vessels and cause obstruction in the vascular bed of liver metastases. Unresectable or metastatic GIST resists the conventional cyto-toxic chemotherapy^[9,24,25], so cyto-toxic drugs are not recommended in TACE. Further to a earlier report^[24] which showed that doxorubicin had slight efficacy in metastatic GIST, it has been reported recently that the chemo-embolization with doxorubicin elusion with the iodized oil demonstrated a potential efficacy^[11-14]. Lipiodol and microspheres concentrate and prolong the retention of the chemotherapeutic agent (doxorubicin) in the tumor^[26].

The results of this study showed that TACE significantly reduced death risk by 89.1%. In the subgroup analysis, DCR of more than 3 mo after TACE was correlated to good survival, indicating the benefit of TACE with regard to the overall survival. In the univariate and multivariate analysis, absence of extrahepatic metastases and TACE treatment were the independent prognostic factors. The similar results were seen in subgroup analysis in TACE group. These results showed that the patients without extrahepatic metastases can enjoy a longer survival after TACE. At the same time, a single session of TACE may not be adequate enough to control liver metastases. The results were consistent to the earlier report^[11]. However, bias of the patient selection may exist in this retrospective study. More prospective trials are expected to confirm the efficacy of TACE in this group of patients. In this study, all cases enrolled had advanced GIST with relatively larger liver lesions after the TKI failure. TACE still yielded a good control rate in this group of patients. Whether TACE procedure should be recommended earlier even before TKI failure warrants future studies.

NCCN guideline recommended considering reintroduction of a TKI for palliation of symptoms in patients with GIST progression despite prior imatinib and sunitinib. Does TKI reintroduction combining with TACE improve PFS and OS of GIST with liver metastases, especially for the patients with extrahepatic metastases? In this study it seemed that the patients receiving combined TACE and TKI reintroduction had longer overall sur-

vival than those receiving TACE alone, but there was no statistical significance ($P = 0.638$). This may be attributed to the small case number in this study. However, TKI reintroduction did not increase the incidence of complication during TACE treatment. The interval time of 2 wk between TKI and TACE is appropriate. For the patients without extrahepatic metastases, the combined TACE and TKI reintroduction may be an optional method of treatment.

Many patients in TACE group suffered from post-embolization complications, such as abdominal pain, fever and nausea. Most of them were of grade 1 or 2, and 22.7% patients were of grade 3. But all the adverse events were ameliorated within 1-2 wk with supportive measures. No adverse events out of expectation happened and no one discontinued treatment because of severe adverse events. The combined TACE and TKI reintroduction was well tolerated in the majority of the patients.

In summary, TACE may be an optional treatment for GIST with liver metastases after TKI failure. TACE can better benefit the patients without extrahepatic metastases.

ACKNOWLEDGMENTS

We would extend our sincere thanks to Professors Lin Shen and Xu Zhu for their encouragement, advice, constructive criticism and suggestions, which were most valuable in shaping this paper. We particularly thank our colleagues for their cooperation and assistance with the relevant information and document acquisition for this study and the individuals who willingly participated in the study.

COMMENTS

Background

There is still no standard treatment for metastatic gastrointestinal stromal tumor (GIST) after imatinib and sunitinib failure. Liver is the most common site of metastasis from GISTs and liver metastasis is one of the major causes of death in these patients. The authors evaluated the efficacy and safety of transcatheter arterial chemoembolization (TACE) in GIST with liver metastases after the failure of tyrosine kinase inhibitors.

Research frontiers

There are few studies about the role of TACE in the treatment of GIST patients after tyrosine kinase inhibitors (TKIs) failure, moreover, there is no control study comparing TACE with best supportive care (BSC) and/or TKI reintroduction.

Innovations and breakthroughs

This study is the first controlled report to evaluate the therapeutic effect of TACE combining with BSC and/or TKI reintroduction in GISTs with liver metastases after TKI failure. The results of the paper showed that TACE improved progression-free survival and overall survival of GIST patients with liver metastases after TKI failure as compared with those receiving only BSC and or TKI reintroduction.

Applications

This study provided some evidences that TACE may be an optional treatment for GIST with liver metastases after TKI failure. TACE can better benefit the patients without extrahepatic metastases.

Terminology

GIST is the most common mesenchymal tumor of the gastrointestinal tract and TKI is the standard treatment for metastases GIST. TACE is the abbreviation of transcatheter arterial chemoembolization. TACE is the use of vascular embolizing material combined with cytotoxic drugs to induce tumor ischemic necrosis and prolonged drug transit time, and often used in treatment of hepatocellular carcinoma.

Peer review

This is a nice review of a unique series of patients with metastatic GIST. The authors should specify what the chemotherapy in the TACE procedure actually is. It appears only to be lipid.

Abstract

AIM: To investigate the liver-protecting effect of parenteral nutrition (PN) support with omega-3 fatty acids in a randomized controlled clinical trial.

METHODS: Sixty-six patients with the diagnosis of end-stage liver disease or hepatic cellular carcinoma were admitted to the Affiliated Drum Tower Hospital, Nanjing University, China for orthotopic liver transplantation. The patients were randomly divided into two groups: PN group ($n = 33$) and polyunsaturated fatty acid (PUFA) group ($n = 33$). All patients received isocaloric and isonitrogenous PN for seven days after surgery, and in PUFA group omega-3 fish oil lipid emulsion replaced part of the standard lipid emulsion. Liver function was tested on days 2 and 9 after surgery. Pathological examination was performed after reperfu-

sion of the donor liver and on day 9. Clinical outcome was assessed based on the post-transplant investigations, including: (1) post-transplant mechanical ventilation; (2) total hospital stay; (3) infectious morbidities; (4) acute and chronic rejection; and (5) mortality (intensive care unit mortality, hospital mortality, 28-d mortality, and survival at a one-year post-transplant surveillance period).

RESULTS: On days 2 and 9 after operation, a significant decrease of alanine aminotransferase ($299.16 \text{ U/L} \pm 189.17 \text{ U/L}$ vs $246.16 \text{ U/L} \pm 175.21 \text{ U/L}$, $P = 0.024$) and prothrombin time ($5.64 \text{ s} \pm 2.06 \text{ s}$ vs $2.54 \text{ s} \pm 1.15 \text{ s}$, $P = 0.035$) was seen in PUFA group compared with PN group. The pathological results showed that omega-3 fatty acid supplement improved the injury of hepatic cells. Compared with PN group, there was a significant decrease of post-transplant hospital stay in PUFA group ($18.7 \text{ d} \pm 4.0 \text{ d}$ vs $20.6 \text{ d} \pm 4.6 \text{ d}$, $P = 0.041$). Complications of infection occurred in 6 cases of PN group (2 cases of pneumonia, 3 cases of intra-abdominal abscess and 1 case of urinary tract infection), and in 3 cases of PUFA group (2 cases of pneumonia and 1 case of intra-abdominal abscess). No acute or chronic rejection and hospital mortality were found in both groups. The one-year mortality in PN group was 9.1% (3/33), one died of pulmonary infection, one died of severe intra-hepatic cholangitis and hepatic dysfunction and the other died of hepatic cell carcinoma recurrence. Only one patient in PUFA group (1/33, 3.1%) died of biliary complication and hepatic dysfunction during follow-up.

CONCLUSION: Post-transplant parenteral nutritional support combined with omega-3 fatty acids can significantly improve the liver injury, reduce the infectious morbidities, and shorten the post-transplant hospital stay.

Liver-protecting effects of omega-3 fish oil lipid emulsion in liver transplantation. *World J Gastroenterol* 2012; 18(42): 6141-6147 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i42/6141.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i42.6141>

INTRODUCTION

Liver transplantation has dramatically improved the prognosis of end-stage liver disease. The progress made in the immunosuppressive regimens and surgical techniques has yielded a better outcome of the patients, and the 5-year survival after liver transplantation is 70%-80%^[1]. The liver recipients with liver insufficiency are in fact known to experience a higher incidence of severe protein/calorie malnutrition, which is associated with a greater risk of postoperative complications and mortality in patients undergoing liver transplantation^[2,3]. And ischemia/reperfusion (I/R) injury associated with liver transplantation often leads to hepatic dysfunction despite the improvement in surgical techniques and perioperative medication. I/R injury of the liver is an event involving multiple factors, such as hypoxia during inflow occlusion of the liver and inflammatory reactions after reperfusion^[4,5], and the mechanisms of the reperfusion injury, including the release of inflammatory cytokines, the generation of oxygen free radicals, Kupffer cell activation and leukocyte-endothelial cell interaction^[6,7]. Based on the pathophysiology of hepatic I/R injury, the current study particularly focused on various perioperative approaches to protect the liver from these inflammatory reactions and microcirculatory disturbances.

Omega-3 (N-3) fatty acids, which are derived from fish oil, are essential polyunsaturated fatty acids (PUFAs) for humans. Omega-3 fatty acids exert anti-inflammatory and immunomodulatory properties through their ability to modulate the synthesis of different eicosanoids^[8,9]. Perioperative administration of omega-3 fatty acids reduces plasma and tissue levels of the eicosanoids, specific leukotrienes, thromboxanes, and prostaglandins, all of which have pro-inflammatory effects^[10,11]. Recent studies described that supplementation with omega-3 fatty acids decreases the rate of inflammatory complications, the length of hospital stay, and the mortality after major abdominal surgeries^[12-14]. Their protective effects on hepatic I/R injury and inflammatory responses have been increasingly investigated.

In this study, we investigated the liver-protecting effects of parenteral nutrition (PN) supplemented with omega-3 fish oil lipid emulsion in patients undergoing liver transplantation.

MATERIALS AND METHODS

Ethics

This study was carried out in the Department of Hepatobiliary Surgery of the Affiliated Drum Tower Hospital, Medical School of Nanjing University, China according to the principles and guidelines of the Helsinki Declaration of 1975 revised in 2000. The protocol was approved by the Ethics Committee of the Affiliated Drum Tower Hospital. All patients fully understood the objective and adverse reactions of the study, and signed the written informed consent voluntarily prior to study enrollment.

Patients and randomization

From January 2006 to July 2010, we prospectively investigated 66 patients (45 men and 21 women; mean age, 51.6 years; range, 34-64 years) who underwent orthotopic liver transplantation in the Department of Hepatobiliary Surgery at the Affiliated Drum Tower Hospital of Medical School of Nanjing University. Recipients with manifest metabolic diseases (e.g., diabetes mellitus and hyperthyroidism) or severe renal abnormality were excluded. No acute rejection, primary transplanted liver dysfunction or second operation, which may affect the evaluation of liver function, were seen during the first 9 d after transplantation. The selection criteria for donors in this study included: (1) age < 50 years, matched ABO blood group and no history of chronic liver disease; (2) no evidence of malignant tumor, viral hepatitis or other viral infections; (3) no cirrhosis, mass or severe fatty degeneration of the donor liver seen during organ harvesting; and (4) liver biopsies of each donor liver taken before transplantation were reviewed by two pathologists. Donor livers with normal pathology or mild fatty change (10%-30%) were included in this study (Figure 1).

After transplantation, these patients were randomized into two groups based on the randomization chart generated by the Statistical Analysis System (SAS): (1) PN group (33 patients), without supplementation of omega-3 fatty acids in addition to routine treatment; and (2) PUFA group (33 patients), with PN supplemented with omega-3 fatty acids in addition to routine treatment.

This is a randomized controlled clinical study carried out in the Department of Hepatobiliary Surgery of our hospital. Nutrition Risk Screening 2002 (NRS 2002) scoring system was used, and the post-operative NRS 2002 score was ≥ 3 in all the patients, which meant that all the patients need nutritional support.

Treatment

The PN was given around the clock for seven days from the second day after operation. The two nutritional support groups were isonitrogenous and isocaloric. Nitrogen intake was 0.16 g/kg body weight per day, caloric intake was 104.5 kJ/kg per day, and lipid intake was 1.0 g/kg per day. The nonprotein calories were provided with dextrose (4.0 g/kg per day) and fat emulsion in a ratio of 2:1. The only source of lipids in PN group was

Figure 1 Pathology of liver biopsy of donor liver taken before transplantation. Mild steatosis was observed in donor liver. (Hematoxylin and eosin staining; paraffin-embedded 5 μ m thick sections; $\times 200$).

the standard lipid emulsion (20% emulsion, with a ratio of long-chain triglycerides to medium-chain triglycerides of 1:1, Huarui Pharmaceuticals, Jiangsu, China), and in PUFA group omega-3 fish oil lipid emulsion (Omegaven, 10%, 2 mL/kg per day, Fresenius Kabi Co., Austria) replaced part of the standard lipid emulsion. Both groups received 1.0 g amino acid/kg per day, and they were administered a commercially available branched-chain amino acid solution (Branched-chain amino acid solution 20%, Huarui Pharmaceuticals, Jiangsu, China). The ratio of nonprotein calories to nitrogen in both nutritional support groups was 653 kJ:1 g. The omega-3 fish oil lipid emulsion-containing solutions were prepared by the clinical pharmacist under aseptic condition and adjusted according to the weight of each individual patient. The amino acids, fat emulsion and dextrose mixture with electrolytes, vitamins, and trace elements were administered through a central venous catheter. As soon as the bowel function returned on days 3 or 4 after transplantation, all patients in the two groups were given liquid carbohydrate and cow's milk protein.

The surgical treatment was standardized, and modified piggyback orthotopic liver transplantation was performed by three groups of surgeons using the same approach. After operation, all the patients in the two groups were treated with the same antibiotics and antivirals, and 20 g of albumin was administered intravenously daily for five days to prevent any complications caused by hypoalbuminemia.

Assessment

Venous heparin blood samples were obtained on days 1 (the day before transplantation), 2 and 9 after surgery and liver function assessment was made. Serum total bilirubin (TB), direct bilirubin (DB), alanine aminotransferase (ALT), aspartate aminotransferase (AST), lactate dehydrogenase (LDH) and prothrombin time (PT) were measured by an automatic biochemical analyzer (HITA-CHI 7600, Japan).

Liver biopsy with fine needle was conducted after reperfusion of donor liver and on day 9 after surgery, re-

spectively. Hepatic specimens for light microscopy were fixed with formalin and embedded in paraffin. Sections were stained with hematoxylin and eosin for histological examination. Portal inflammation in the liver biopsy specimens was semiquantified by calculating inflammatory cells in portal tracts based on the Knodell histology activity index (HAI)^[15]. Portal inflammation was scored as 0, no portal inflammation; 1, mild (sprinkling of inflammatory cells in $< 1/3$ of portal tracts); 3, moderate (increased inflammatory cells in $1/3$ - $2/3$ of portal tracts); and 4, marked (dense packing of inflammatory cells in $> 2/3$ of portal tracts).

The assessment of clinical outcome was based on post-transplant investigations as shown by: (1) post-transplant mechanical ventilation; (2) total hospital stay; (3) infectious morbidities (pneumonia, intra-abdominal abscess, central line sepsis, wound infection, and urinary tract infection); (4) acute and chronic rejection; (5) mortality (intensive care unit mortality, hospital mortality, 28-d mortality, and survival at one year post-transplant surveillance period).

These post-transplant parameters were investigated and documented daily during the patients' post-transplant hospital stay and the period of one-year postoperative follow-up.

Statistical analysis

The results were expressed as mean \pm SD. Data were analyzed using the SAS. Differences between means were evaluated using Student *t* test when normal distribution was confirmed by Shapiro-Wilks test. When the hypothesis of normal distribution was rejected, differences between groups were tested by nonparametric statistics using Mann-Whitney test for unpaired samples and Wilcoxon criteria for paired samples. Fisher's exact test was used for analysis of categorical values when appropriate. A *P* value of < 0.05 was considered significant.

RESULTS

A total of 66 patients were enrolled in this study, including 33 patients in PN group and 33 patients in PUFA group. The mean age of the subjects was 51.6 years (range, 34-64 years). The clinical diagnosis of these patients included: hepatic cell carcinoma (27 cases), post-hepatitis B liver cirrhosis (35 cases), alcoholic liver cirrhosis (1 case), primary biliary liver cirrhosis (2 cases) and congenital polycystic liver (1 case). Demographic and clinical data (including age, sex, clinical diagnosis, Child-Pugh classification of hepatic function, warm ischemic time, cold ischemic time, operative time, anhepatic phase and post-operative immunosuppression) are summarized in Table 1. With respect to warm ischemic time, cold ischemic time, operative time, anhepatic phase, ratio of Child-Pugh classification, immunosuppression and clinical diagnosis, there were no significant differences between the two groups in any of these above param-

eters ($P > 0.05$).

Liver function assessment

No significant difference of pre-operative liver function was observed between the two groups. On days 2 and 9 after operation, a significant decrease of ALT ($299.16 \text{ U/L} \pm 189.17 \text{ U/L}$ *vs* $246.16 \text{ U/L} \pm 175.21 \text{ U/L}$, $P = 0.024$) and PT ($5.64 \text{ s} \pm 2.06 \text{ s}$ *vs* $2.54 \text{ s} \pm 1.15 \text{ s}$, $P = 0.035$) was seen in PUFA group compared with PN group. And there was no significant decrease of the following parameters tested on days 2 and 9: AST ($116.31 \text{ U/L} \pm 42.19 \text{ U/L}$ *vs* $121.09 \text{ U/L} \pm 53.14 \text{ U/L}$, $P = 0.682$), TB ($93.93 \text{ } \mu\text{mol/L} \pm 45.49 \text{ } \mu\text{mol/L}$ *vs* $87.20 \text{ } \mu\text{mol/L} \pm 61.12 \text{ } \mu\text{mol/L}$, $P = 1.439$), DB ($42.74 \text{ } \mu\text{mol/L} \pm 17.36 \text{ } \mu\text{mol/L}$ *vs* $36.22 \text{ } \mu\text{mol/L} \pm 21.63 \text{ } \mu\text{mol/L}$, $P = 0.815$) and LDH ($156.12 \text{ U/L} \pm 89.20 \text{ U/L}$ *vs* $119.10 \text{ U/L} \pm 69.72 \text{ U/L}$, $P = 1.112$) in PUFA group compared with PN group (Table 2).

Light microscopy

The histological examination after reperfusion revealed some swelling hepatocytes and inflammatory cell infiltration in the portal areas, and no significant difference of numerical score of portal inflammation was observed between the two groups.

Histological examination on day 9 in PN group revealed more inflammatory cells aggregating in hepatic sinusoid lumen, extensive swelling and some balloon-like degeneration of hepatocytes, extensive congestion, and bilirubin deposit in the hepatic plasma (Figure 2A). These were ameliorated markedly by parenteral nutritional support with omega-3 fatty acids (Figure 2B), and the numerical score of portal inflammation was significantly lowered in PUFA group (Table 3). There was no sign of acute rejection in both groups.

Clinical outcome

There was no significant difference of post-transplant

Figure 2 Histological appearance of the transplanted liver on day 9 after surgery. A: Extensive swelling, balloon-like degeneration and necrosis of hepatocytes, extensive congestion and bilirubin deposit were observed in the hepatic plasma in parenteral nutrition group; B: The results of histological examination were ameliorated markedly in the polyunsaturated fatty acid group. mechanical ventilation between the two groups ($P > 0.05$). Compared with PN group, the post-transplant hospital stay was significantly shortened in PUFA group ($P < 0.05$). Infectious complications occurred in 6 cases of PN group (2 cases of pneumonia, 3 cases of intra-abdominal abscess and 1 case of urinary tract infection), and in 3 cases of PUFA group (2 cases of pneumonia, 1 case of intra-abdominal abscess). No acute or chronic rejection and hospital mortality were found in the two groups. All patients were followed up, and the one-year mortality in PN group was 9.1% (3/33), one died of pulmonary infection, one died of severe intra-hepatic cholangitis and hepatic dysfunction and the other of hepatic cell carcinoma recurrence. Only one patient in PUFA group (1/33, 3.1%) died of biliary complication and hepatic dysfunction during follow-up (Table 4).

DISCUSSION

An impairment of nutritional status is a frequent finding in patients with end-stage liver disease. Malnutrition adversely affects the prognosis of these patients and is associated with the morbidity and mortality after liver transplantation^[16]. Malnutrition has been shown to be the only independent risk factor for the length of stay in the intensive care and the total number of days spent in the hospital, and the liver recipient's nutritional status

Table 2 Effect of parenteral nutritional support with Omega-3 fatty acids on liver function

	Normal value	Group	Day 1	Day 2	Day 9	Decrease (Day 2-Day 9)

also influences the incidence of post-transplant complications and may therefore increase the costs of liver transplant^[17,18]. After liver transplantation, surgical stress, postoperative fasting, and the possible occurrence of complications suggest the need for nutritional support. The primary goal of the nutrition support in the immediate post-transplant period is to provide adequate nutrition to promote recovery and replenishment of the depleted nutrient stores. Although most transplant centers use the similar post-transplant nutritional support as for other major abdominal operations, few studies have elucidated the role of postoperative nutritional support in the liver recipients.

Enteral nutrition is safer and less expensive than PN, and enteral nutrition has the potential advantage of maintaining intestinal trophism more effectively^[19]. This effect may help prevent bacterial translocation and enteric-origin infections in patients treated with transplantation^[20,21]. All patients in this study resumed their daily oral diet postoperatively as soon as bowel function returned to maintain intestinal trophism, but the recipients could not endure a large amount of liquid diet even with nasoenteric tube at the early phase after transplantation because of obvious abdominal pain, distention or diarrhea in our previous experience. The bowel function in all the patients in this study returned on day 3 or 4 after transplantation, and PN support discontinued on day 8 after surgery when the patients were able to maintain an adequate oral intake.

Omega-3 fatty acids mainly act as eicosapentaenoic acids (EPA) and docosahexaenoic acids (DHA), both

Table 4 Effect of parenteral nutritional support with Omega-3 fatty acids on clinical outcome

	PN group	PUFA group
Post-transplant mechanical ventilation (h)	12.1 ± 5.1	10.8 ± 5.4
Post-transplant hospital stay (d)	20.6 ± 4.6	18.7 ± 4.0 ^a
Infectious morbidities	6/33	3/33 ^a
Acute/chronic rejection	0/33	0/33
ICU mortality	0/33	0/33
Hospital mortality	0/33	0/33
28-d mortality	0/33	0/33
One-year mortality	3/33	1/33

PN: Parenteral nutrition; PUFA: Polyunsaturated fatty acid; ICU: Intensive care unit. ^a*P* < 0.05 *vs* PN group.

had anti-inflammatory effects. EPA and DHA reduce the release of arachidonic acid-derived pro-inflammatory eicosanoids, and generate a group of lipid mediators called resolvins (E- and D-series) and protectins with potent anti-inflammatory and inflammation resolution properties^[22,23]. Studies with experimental models of liver reperfusion injury have reported the beneficial actions of n-3 PUFA-derived resolvins and protectins in preventing liver DNA damage and oxidative stress, thus significantly ameliorating the necroinflammatory liver injury and hepatic steatosis^[24-26]. The liver-protecting effects of postoperative PN support supplemented with omega-3 fatty acids were evaluated in this study. Liver enzyme of ALT released after I/R was significantly suppressed by the supplements of omega-3 fatty acids. PT, as an important parameter in evaluating the synthesis function of liver, was significantly decreased in PUFA group. And the results of histological examination on day 9 revealed that the hepatocyte injury and inflammatory cell aggregation were ameliorated markedly in PUFA group. PUFA therapy could also decrease the infectious morbidities, and shorten the post-transplant hospital stay significantly. The possible mechanisms of omega-3 fatty acids include down-regulation of the inflammatory responses to surgery and immune modulation rather than a sole nutritional effect.

Some of the patients exhibited an obvious nitrogen accumulation disorder reflected by either encephalopathy or an excessive rise in blood urea nitrogen in the immediate postoperative period. Branched-chain amino acids were chosen for this study because it can promote protein synthesis in patients with chronic liver diseases and avoid the additional metabolic load of transplanted liver^[27]. Medium-chain triglycerides were included in the regimen to avert glucose intolerance and deposits in the transplanted liver. Based on the results of this study, we think that post-transplant nutritional support in the form of a solution enriched with branched-chain amino acids, dextrose, medium-chain triglycerides and omega-3 fatty acids might offer a benefit in terms of preserved liver function and better clinical outcome, including the decreased infectious morbidities and post-transplant hospital stay.

In conclusion, we have shown that omega-3 fatty acids-supplemented PN significantly improves the injury of transplanted liver, decreases the infectious morbidities, and shortens the post-transplant hospital stay.

COMMENTS

Background

The liver recipients with liver insufficiency are known to experience a higher incidence of severe protein/calorie malnutrition, and malnutrition is associated with a greater risk of postoperative complications and mortality in patients undergoing liver transplantation. And ischemia/reperfusion injury associated with liver transplantation often leads to hepatic dysfunction despite the improvements in surgical techniques and perioperative medication.

Research frontiers

Omega-3 fatty acids exert anti-inflammatory and immunomodulatory properties through their ability to modulate the synthesis of different eicosanoids. Recent studies have described that supplementation with omega-3 fatty acids decreases the rate of inflammatory complication, the length of hospital stay, and the mortality after major abdominal surgeries.

Innovations and breakthroughs

Although most transplant centers use the similar post-transplant nutritional support as for other major abdominal operations, few studies have elucidated the role of postoperative nutritional support in the organ recipient. Based on the results of this study, the authors have shown that post-transplant nutritional support in the form of a solution enriched with branched-chain amino acids, dextrose, medium-chain triglycerides and omega-3 fatty acids might offer a benefit in terms of preserved liver function and better clinical outcome, including the decreased infectious morbidities and post-transplant hospital stay.

Applications

This study has shown that omega-3 fatty acids-supplemented parenteral nutrition (PN) significantly improves the injury of transplanted liver, decreases the infectious morbidities, and shortens the post-transplant hospital stay. The nutritional support strategy is recommended in patients undergoing liver transplantation.

Peer review

The manuscript evaluates the potential for supplementation with polyunsaturated fatty acid to ameliorate hepatic injury associated with reperfusion and PN. It provides evidences about an efficient nutritional support strategy for liver transplanted patients.

Abstract

AIM: To investigate whether activated carbon nanoparticles suspension (ACNS) or methylene blue (MB) can increase the detected number of lymph nodes in colorectal cancer.

METHODS: Sixty-seven of 72 colorectal cancer patients treated at our hospital fulfilled the inclusion criteria of the study which was conducted from December 2010 to February 2012. Seven patients refused to participate. Eventually, 60 patients were included, and randomly assigned to three groups (20 in each group): ACNS group (group A), MB group (group B) and non-stained conventional surgical group (group C). In group A, patients received subserosal injection of 1 mL ACNS in a 4-quadrant region around the mass. In group B, the main artery of specimen was identified and isolated after the specimen was removed, and 2 mL MB was slowly injected into the isolated, stretched and fixed vessel. In group C, no ACNS and MB were injected. All the mesentery lymph nodes were isolated and removed systematically by visually inspecting and

palpating the adipose tissue.

RESULTS: No difference was observed among the three groups in age, gender, tumor location, tumor diameter, T-stage, degree of differentiation, postoperative complications and peritoneal drainage retention time. The total number of detected lymph nodes was 535, 476 and 223 in the three groups, respectively. The mean number of detected lymph nodes per patient was significantly higher in group A than in group C (26.8 ± 8.4 vs 12.2 ± 3.2 , $P < 0.001$). Similarly, there were significantly more lymph nodes detected in group B than in group C (23.8 ± 6.9 vs 12.2 ± 3.2 , $P < 0.001$). However, there was no significant difference between group A and group B. There were 50, 46 and 32 metastatic lymph nodes dissected in 13 patients of group A, 10 patients of group B and 11 patients of group C, without significant differences among the three groups. Eleven of the 60 patients had insufficient number of detected lymph nodes (< 12). Only one patient with T_{4a} rectal cancer had 10 lymph nodes detected in group B, the other 10 patients were all from group C. Based on the different diameter categories, the number of detected lymph nodes in groups A and B was significantly higher than in group C. However, there was no statistically significant difference between group A and group B. The metastatic lymph nodes were not significant different among the three groups. Similarly, tumor location, T stage and tumor differentiation did not affect the staining results. Body mass index was a minor influencing factor in the two different staining methods. The stained lymph nodes can easily be identified from the mesenteric adipose tissues, and the staining time for lymph nodes was not significantly different compared with unstained group. None of the patients in groups A and B had drug-related complications.

CONCLUSION: Both activated carbon nanoparticles suspension *in vivo* and methylene blue *in vitro* can be used as tracers to increase the detected number of lymph nodes in colorectal cancer.

INTRODUCTION

Colorectal cancer (CRC) is one of the leading causes of cancer-related death among men and women in the United States with an estimated 143 460 new cases and 51 690 deaths in 2012 according to the statistics of American Cancer Society^[1]. Accurate lymph node metastasis staging is of prognostic and therapeutic importance in patients with CRC. Previous researches have found that the number of lymph nodes evaluated after surgical resection was positively associated with the survival of CRC patients^[2,3]. However, population-based data suggest that lymph node evaluation is not adequate in the majority of patients with CRC^[4,5]. In addition, computed tomography (CT)^[6], even positron emission tomography^[7], are not efficacious enough in identifying nodal status. Therefore, a variety of techniques, including lymph node staining or radionuclide scan^[8], have been applied to make lymph nodes retrieval more efficient.

The biological application of nanoparticles is a rapidly developing area of nanotechnology^[9,10]. Particles have been observed passing through the lymphatic vessels but not the blood capillaries mainly due to the difference in permeability. Activated carbon nanoparticles suspension (ACNS), using smooth carbon particles at a diameter of 21 nm added with suspending agents, is a stable suspension of carbon pellets of 150 nm in diameter. ACNS is obviously inclined to the lymphatic system. After macrophage phagocytosis, ACNS quickly gathers in the lymph nodes and dyes them black. This unique selective bio-distribution is being extensively studied in recent years, such as sentinel lymph node staining, drug carriers and thermotherapy^[11-13].

In our previous study^[14], 62 patients with CRC were divided into two groups. The experimental group, using a simple lymphatic staining method, was injected with methylene blue (MB) into the regional main blood vessels immediately after specimens were resected *in vitro*. More and smaller lymph nodes could be detected, which significantly improved the lymph node harvest of resected colorectal specimens. However, the detection

sensitivity for lymph node metastasis was low and the staining could not be done *in vivo* before the destruction of the lymphoid structures. Therefore, we conducted a randomized controlled trial to test whether MB and ACNS as tracers can increase the detected number of lymph nodes in the systematic nodal dissected tissues from CRC resection and compare the staining effect of the two methods in order to choose the best one for further clinical application.

MATERIALS AND METHODS

Patient selection

This trial was performed in the Department of Surgical Oncology, Second Affiliated Hospital Zhejiang University College of Medicine, China from December 2010 to February 2012. The study was approved by the Ethics Committee of Zhejiang University. Informed consent was obtained from all the patients. Inclusion criteria were as follows: 18-80 years of age; endoscopic biopsy confirmed; performance status of 0-1 on the Eastern Cooperative Oncology Group scale; good compliance; able to tolerate radical resection; adequate hematologic function [white blood cell (WBC) count > 4000/mL, absolute neutrophil count > 1500/mL, platelet count > 100 000/mL, and hemoglobin > 10 g/dL]; normal hepatic function [bilirubin < 1.5 the upper-normal limits (UNL) and alanine aminotransferase or aspartate aminotransferase < 2.5 UNL]; and normal renal function (creatinine < 1.5 mg/dL). Exclusion criteria included: clinical stage IV CRC according to the American Joint Committee on Cancer (AJCC); patients received chemotherapy, radiotherapy or biological therapy prior to surgery; previous abdominal surgery; significant neurological or mental disorder. Of the 72 CRC patients, 67 fulfilled the inclusion criteria. Seven patients refused to participate. The enrollment was completed when 60 patients were included. The patients were randomly allocated to three groups (20 patients in each group): ACNS group (group A), MB group (group B) and non-staining conventional surgical group (group C).

Surgical technique

All surgical procedures were completed by the same team of surgeons. Each patient was administrated with 2 g cephalosporin for antibiotic prophylaxis within 30 min before surgery, and the same dose was repeated if the operation lasted more than 2 h.

In group A, patients received subserosal injection of 1 mL ACNS (Chongqing LUMMY Pharmaceutical Co., Chongqing, China) in a 4-quadrant region around the mass (Figure 1A). To avoid surgical destruction of the lymphatic system along the bronchi and vessels, we waited for 10 min after injection. In group B, MB was injected by the same methods (Jiangsu Jumpcan Medicines Group, Taixing, Jiangsu Province, China), however, staining effect was very poor partly because MB was quickly absorbed *in vivo* and then excreted with urine.

Figure 1 Activated carbon nanoparticles suspension *in vivo* is effective as a tracer in colorectal cancer lymph node detection. A: Subserosal injection of activated carbon nanoparticles suspension (ACNS) into a 4-quadrant region around the mass; B: Lymph nodes can easily be identified from the mesenteric adipose tissues, arrow points to the black dyed lymph nodes; C: ACNS migrating to the lymph node (hematoxylin and eosin, $\times 100$).

Figure 2 Methylene blue *in vitro* used as a tracer in colorectal cancer lymph node detection. A: The main artery of the specimen was isolated and methylene blue (MB) was injected into the vessel. Lymph nodes can easily be identified, arrow points to the blue dyed lymph nodes; B: MB migrating to the lymph node (hematoxylin and eosin, $\times 100$).

Therefore, we established a method for lymph nodes staining *in vitro*. After the specimen was dissected, we immediately identified the main artery of the specimen and isolated it at the root for 1 cm, and injected 2 mL MB slowly into the isolated, stretched and fixed vessel (Figure 2A). We also waited for 10 min after injection. In group C, neither ACNS nor MB was used for the staining.

All the mesentery lymph nodes were isolated and removed systematically by visually inspecting and palpating the adipose tissues. After identification and excision, all the black or blue nodes were collected for subsequent pathological examinations. Postoperative pain was relieved by intravenous opioid administration.

Statistical analysis

Statistical analysis was performed using the SPSS 17.0 for Windows (SPSS, Inc, Chicago, IL, United States). Factors considered to be possible determinants of the number of lymph nodes examined were first checked with the analysis of variance analysis and the influence of possible determinants was then tested in regression analysis. Kruskal-Wallis test was used when there was heterogeneity of variance. *P* value (two-tailed) of less than 0.05 was considered statistically significant.

RESULTS

Patient population

The 60 patients were randomly assigned to three groups. No difference was observed among the three groups in age, gender, tumor location, tumor diameter, T-stage and degree of differentiation. There was also no statistically significant difference in postoperative complications and peritoneal drainage retention time (Table 1).

Lymph nodes detected

The total number of detected lymph nodes was 535, 476 and 223 in the three groups, respectively. The mean number of detected lymph nodes per patient in group A was significantly higher than in group C (26.8 ± 8.4 *vs* 12.2 ± 3.2 , $P < 0.001$). Similarly, there were significantly more lymph nodes detected in group B than in group C (23.8 ± 6.9 *vs* 12.2 ± 3.2 , $P < 0.001$). However, there was no significant difference between group A and group B (26.8 ± 8.4 *vs* 23.8 ± 6.9 , $P > 0.1$) (Figure 3A). There were 50, 46 and 32 metastatic lymph nodes dissected in 13 patients of group A, 10 patients of group B, and 11 patients of group C, without significant difference among the three groups ($P > 0.1$). According to the

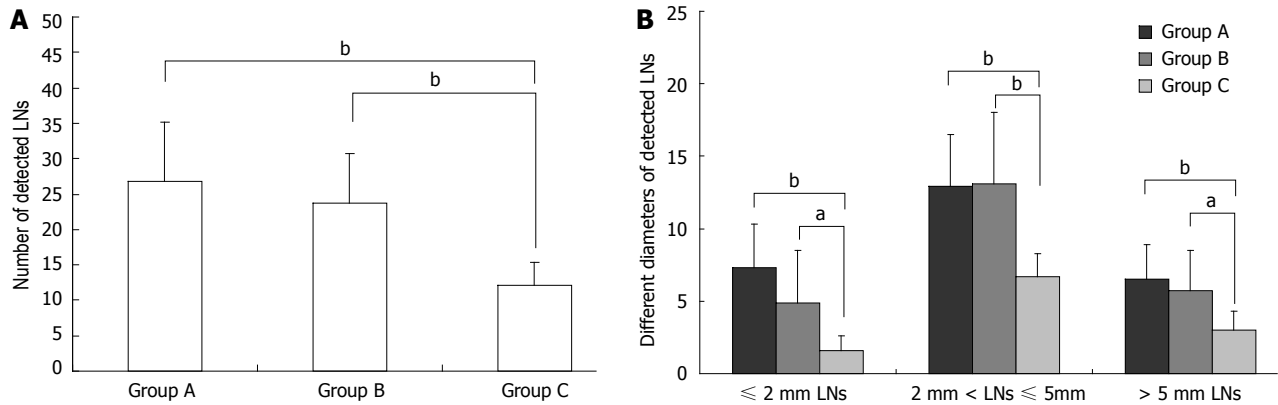

Figure 3 Lymph nodes detected in the three groups. A: The mean number of lymph nodes detected; B: Distribution of lymph node diameters. ^a $P < 0.05$, ^b $P < 0.01$ vs group A. LN: Lymph node.

Figure 4 Body mass index as an influencing factor in the two different staining methods. LN: Lymph node; BMI: Body mass index.

AJCC guideline, more than 12 detected lymph nodes are required for the accurate clinical staging. In this study, 11 of the 60 patients had insufficient number of detected lymph nodes. Among them, only one patient in group B with T_{4a} rectal cancer had 10 lymph nodes detected, the other 10 patients were all from group C ($P < 0.001$). According to the different diameter range, lymph nodes (LNs) detected were divided into three categories: LNs ≤ 2 mm, $2 \text{ mm} < \text{LNs} \leq 5$ mm, and LNs > 5 mm. We analyzed the different diameter categories of detected lymph nodes and metastatic lymph nodes in each group, and found that the number of detected lymph nodes was significantly higher in groups A and B than in group C. However, there was no statistically significant difference between group A and group B. Data is shown in Figure 3B. There was no significant difference in metastatic lymph nodes between each group ($P > 0.05$). Similarly, tumor location, T stage and tumor differentiation exerted no influence on the staining results ($P > 0.05$). Mesenteric hypertrophy may affect the lymph node detection by different staining methods^[15]. To explore whether the mesenteric hypertrophy affects the staining results in our trial, patients in the two staining groups were re-classified according to the Asian body mass index (BMI) criteria

Table 1 Clinicopathological details of the 60 patients in the three groups

	Group A	Group B	Group C
No. of patients	20	20	20
Age (yr)	57.5 \pm 11.5	58.9 \pm 17.8	64.9 \pm 7.4
Gender			
Male	14	14	13
Female	6	6	7

Transverse colon	1	1	1
Left colon	5	1	1
Sigmoid	5	4	4
Rectum	7	12	11
Tumor diameter (mm)	5.0 \pm 1.7	4.7 \pm 2.3	3.7 \pm 1.1
T-stage			
T1	0	1	0
T2	2	4	4
T3	6	7	7
T4	12	8	9
Degree of differentiation			
Well	7	7	8
Moderate	10	11	11
Poor	3	2	1
Postoperative complications			
Bleeding	1	0	0
Infection	0	1	0
Fistula	1	1	2
Abdominal tube drainage (d)	6.7 \pm 2.8	6.1 \pm 3.3	7.8 \pm 3.6

as BMI $\leq 23 \text{ kg/m}^2$, $23 \text{ kg/m}^2 < \text{BMI} \leq 25 \text{ kg/m}^2$ and BMI $> 25 \text{ kg/m}^2$. Statistical analysis showed that BMI was a minor influencing factor in the two different staining methods while mesenteric hypertrophy did not influence the staining results (Figure 4). Using either ACNS (Figure 1B) or MB (Figure 2A), stained lymph nodes can easily be visualized from the mesenteric adipose tissues, and the staining time for lymph nodes was not significant different compared with unstained group ($P > 0.05$). Hematoxylin and eosin stained micrograph confirmed that ACNS migrates to the lymph nodes (Figure 1C), so does the MB (Figure 2B). None of the patients injected with either ACNS or MB had drug-related complications.

DISCUSSION

Lymph nodes status of colorectal cancer played a vital role in tumor staging, classification, postoperative sequential treatment and prognosis. The number of detected lymph nodes is a significant prognostic factor in colon cancer patients^[16]. AJCC and College of American Pathologists recommend at least 12 lymph nodes detected for more accurate diagnosis of stage II CRC^[17]. However, recent studies indicated that lymph node detection rate was still low in CRC^[4], which can not accurately reflect the patient's disease status. There are many factors affecting the lymph node detection, including patient's age, gender, tumor grade, extent of surgical resection and the pathologist's expertise^[18]. Palpation is still the most important method for lymph node detection^[19]. Numerous studies have been conducted to improve the methods for lymph node detection. Cawthorn *et al.*^[20] used xylene alcohol clearance technique to facilitate the identification of lymph nodes (23.1 ± 1.18 *vs* 10.5 ± 0.6). Quadros *et al.*^[21] performed lymphoscintigraphy using technetium-99 m-phytate and patent blue to detect lymph nodes of rectal adenocarcinoma patients, which significantly increase the lymph nodes detection rate, particularly lateral pelvic lymph node metastasis. However, these techniques were not widely used in clinical practice because they are time-consuming, labor-intensive and toxic to doctors. This clinical trial used the novel nanomaterials ACNS and MB *in vivo* or *in vitro*. The results suggested that both staining techniques can significantly improve the lymph node detection compared with the conventional palpation method (26.8 ± 8.4 *vs* 23.8 ± 6.9 *vs* 12.2 ± 3.2). In our research, none of the patients had insufficient number of detected lymph nodes in ACNS stained group, only one patient in MB stained group, but 10 patients did so from unstained group C. Statistical results showed that in different diameter categories, the number of the detected lymph nodes was significantly higher in both the two stained groups than in the unstained group (Figure 4), especially in the ACNS group. This demonstrated the obvious advantages of the two staining methods in detecting the smaller diameter lymph nodes. Micrometastasis is defined as cohesive deposits of tumor cells of 2 mm or less, but larger than 0.2 mm. This definition has been extended in the AJCC 7th edition to include non-cohesive infiltrate of > 200 cells as micrometastasis^[22]. No definitive conclusions have been drawn about the role of sentinel lymph node biopsy and micrometastasis on the prognosis of CRC^[23,24]. Taking into account the advantage of the detection for lymph node micrometastasis in this study, our team will further study the effects of sentinel lymph node biopsy and micrometastasis in the prognosis of CRC patients. In this trial, we failed to find significant differences between the two staining methods with regard to the total number of detected lymph nodes, lymph node diameters or lymph node metastasis, which may be attributed to the limitations of sample size.

The biological application of nanoparticles is a rap-

idly developing area of nanotechnology that raises new possibilities in the diagnosis^[25] and treatment of human cancers^[26,27]. Nanoparticles are being developed for contrast at T1-weighted magnetic resonance imaging^[28], radionuclides for single photon emission computed tomography and positron emission tomography^[29], iodine for CT^[30] and gas-containing bubbles for ultrasonography^[31]. Several nanotechnologies have been used to improve the delivery of chemotherapeutic agents to cancer cells^[32,33], which promoted the microdosing clinical studies^[34]. A review by Schroeder *et al.*^[35] showed that nanoparticle therapies will improve the outcome for patients with metastatic cancer. Using ACNS combined with preoperative lymphoscintigraphy and intraoperative gamma probe detection, the detecting sensitivity was 100% for internal mammary sentinel node biopsy of breast cancer patients^[36]. A clinical trial from him^[37] showed that ACNS and MB both were effective as tracers in lymph nodes detection for non-small cell lung cancer. However, ACNS staining in colorectal cancer lymph nodes detection remains largely unexplored. MB is being widely used in clinical practice, however, when it was used in lymph nodes staining in CRC *in vivo*, it played a minor role in lymph nodes detection because it was absorbed and excreted too quickly. We thus used a modified method as described in the Surgical Technique, injected MB into the main blood vessels of the tumor drainage region *in vitro*, and achieved much better staining results in lymph node detection. An ideal tracer should possess the following properties: not influenced by external conditions, easy to perform, effective and free from side-effects. We found that T stage, degree of tumor differentiation, tumor location, and BMI had minor influence on the two staining methods. In this study, black-stained or blue-stained lymph nodes can be easily identified from the mesenteric adipose tissues, and no side-effect was found among patients, surgeons and pathologists. However, the results obtained in this study may be limited by the sample size. Further studies with a larger sample will be conducted.

In conclusion, both ACNS *in vivo* and MB *in vitro* are effective as a tracer in increasing the detected number of lymph nodes in CRC. They may play a key role in the studies of sentinel lymph nodes biopsy and micrometastasis in CRCs.

COMMENTS

Background

Accurate lymph node metastasis staging has important prognostic and therapeutic implications in patients with colorectal cancer (CRC). Activated carbon nanoparticles suspension (ACNS) is obviously inclined to lymphatic system. The unique selective biodistribution is being extensively studied in recent years, such as sentinel lymph node staining, drug carriers, and thermotherapy. Additionally, methylene blue (MB), as an efficacious and cost-effective tracer, was widely used in clinical practice.

Research frontiers

Numerous studies have been conducted to improve the methods of lymph node detection. The biological application of nanoparticles is a rapidly developing area of nanotechnology. However, ACNS as a tracer for lymph nodes detection

in CRC patients has not been reported. This study found that ACNS *in vivo* is effective in increasing the detected number of lymph nodes in CRC. Similarly, the authors used a modified method, injecting MB into the main blood vessels of the tumor drainage region *in vitro*, and achieved analogous clinical effects. Moreover, the two staining methods were mildly influenced by T stage, degree of tumor differentiation, tumor location, and body mass index.

Applications

This is the first research that compares the staining effects of ACNS and MB in colorectal cancer lymph nodes detection. Both ACNS *in vivo* and MB *in vitro* are effective as tracers in increasing the detected number of lymph nodes in CRC.

Terminology

ACNS is a stable suspension of carbon pellets with a diameter of 150 nm, which is obviously inclined to lymphatic system. After macrophage phagocytosis, ACNS quickly gathers in the lymph nodes and dyes them black.

Peer review

The topic is very interesting and is of great clinical importance as the number of removed and histologically analyzed lymph nodes does determine the prognosis of CRC patients. An easy, time- and cost-effective method to help the surgeons' work is needed.

Abstract

Meckel's diverticulum is a common asymptomatic congenital gastrointestinal anomaly, but rarely it can present with hemorrhage. Over the last few years inverted Meckel's diverticulum has been reported in the literature with increasing frequency as an occult source of lower gastrointestinal hemorrhage. Here, we report a case of a 54-year-old male, who was referred for surgical evaluation with persistent anemia and occult blood per rectum after a work up which failed to localize the source over 12 mo, including upper and capsule endoscopy, colonoscopy, enteroclysis, Meckel scan, and tagged nuclear red blood cell scan. An abdominal computed tomography scan showed a possible mid-ileal intussusception and intraluminal mass. During the abdominal exploration, inverted Meckel's diverticulum was diagnosed and resected. We review the literature, discuss the forms in which the disease presents, the diagnostic

modalities utilized, pathological findings, and treatment. Although less than 40 cases have been reported in the English literature from 1978 to 2005, 19 cases have been reported in the last 6 years alone (2006-2012) due to improved diagnostic modalities. Successful diagnosis and treatment of this disease requires a high index of clinical suspicion, which is becoming increasingly relevant to general gastroenterologists.

INTRODUCTION

Meckel's diverticulum is the most common congenital abnormality in the gastrointestinal tract, but is usually asymptomatic^[1]. When symptomatic it may present with hemorrhage in association with ectopic gastric and/or pancreatic mucosa, intestinal obstruction, intussusceptions, or inflammation. This abnormality can also present in the setting of an inverted diverticulum causing a lower gastrointestinal bleed. There is no role for non-operative

management in inverted Meckel's diverticulum, which mandates early surgical removal. Here, we present a case which first underwent an extensive diagnostic evaluation of persistent gastrointestinal hemorrhage over a 12-mo period before this entity was diagnosed and then appropriately treated. The aim of this report is to alert surgeons and gastroenterologists of this important source of persistent gastrointestinal hemorrhage which requires a high clinical suspicion to diagnose because of how difficult it is to detect. We conducted an extensive review of the previously reported cases in the literature, and discuss the presentations of this readily curable disease, the utility of various diagnostic modalities, pathological findings, and the appropriate management.

CASE REPORT

A 54-year-old male with no significant past medical history was seen by a gastroenterologist for anemia and stools positive for occult blood. An extensive diagnostic evaluation was undertaken over a 12-mo period before the patient was referred for surgical evaluation. He had a negative upper gastrointestinal and capsule endoscopy, and a negative colonoscopy, despite adequate bowel preparation. Enteroclysis revealed a polypoid lesion in the mid jejunum. The differential diagnosis at that point included tumor, lipoma, carcinoid, or sarcoma. He underwent a Meckel scan, which was negative. Given the continued anemia and occasional bright red blood per rectum, he underwent a tagged nuclear red blood cell scan, which failed to demonstrate an acute hemorrhagic source. An abdominal computed tomography (CT) scan was obtained, which demonstrated a possible mid-ileal intussusception and an intraluminal mass. The patient was referred for a surgical evaluation.

The patient underwent an exploratory laparoscopy which demonstrated a hard intraluminal mass in the mid-ileum. The remainder of the small bowel was normal to the level of the ligament of Treitz. A 5 cm mini midline-laparotomy was performed overlying the small bowel lesion. The lesion containing portion of the small bowel was delivered out of the abdomen and resected. Small bowel continuity was established *via* a stapled side-to-side anastomosis.

On gross examination, the specimen consisted of a segmental resection of the small bowel with a small dimple shaped defect penetrating through the bowel wall. This defect was proven to be patent by a probe. Opening of the specimen revealed a 5.0 cm × 1.8 cm × 1.5 cm polypoid lesion that terminated in a club-shaped head (Figure 1). The small bowel mucosa was contiguous with that of the stalk and extended to within 1.5 cm of the tip of the lesion. The dumbbell shaped tip was covered by attenuated mucosa that was granular in appearance. A small area of erythema was seen at the tip and appeared grossly consistent with an area of hemorrhage.

Microscopic sections revealed well-defined intestinal mucosa that surrounded the core of the lesion (Figure 2). The most internal component of the core consisted of

Figure 1 Gross specimen of the inverted Meckel's diverticulum arising in the segmental resection of the small bowel.

Figure 2 Histopathology reveals a central core consisting of serosa and muscle. The cross section reveals small intestinal mucosa lining the fragment.

the serosa and the muscle of the bowel wall. These layers were circumscribed by the intestinal submucosa and mucosa that became attenuated toward the tip of the specimen. The mucosa seen at the tip was that of intestinal-type with scattered paneth cells (exocrine serous cells) and goblet cells. No heterotopic gastric or pancreatic tissue was identified. The patient had an uneventful post-operative recovery. He was discharged on post-operative day three, and never had further episode of lower gastrointestinal hemorrhage nor any complications or sequelae during the subsequent two years of follow up.

DISCUSSION

Meckel's diverticulum is the most common congenital anomaly in the gastrointestinal tract^[1]. In an autopsy series, the incidence was reported as 1%-3%^[2]. Johann F Meckel, a famous anatomist, was the first to describe this entity. In 1808, he stated that the diverticulum comprised a remnant of the vitelline duct, the duct between the intestinal tract and the yolk sac^[3]. In normal human embryology, the vitelline duct closes by the 10th week of gestation. If it persists, presentations include incidental meckel's diverticulum, fibrous cord connecting the bowel to the anterior abdominal wall, persistent omphalenteric fistula, enterocystoma, torsion, and intussusception^[4]. Although the location of the diverticulum varies, they have been classically described on the antimesenteric surface of

Table 1 Clinical characteristics, diagnostic modalities, and pathological finding of patients with inverted Meckel's diverticulum

Clinical characteristics	n (%)
Gender ^[4,7,9-12,14-43]	
Male	41/59 (69)
Female	18/59 (30)
Signs and symptoms ^[4,7,9-12,14-34,36-43]	
Bleeding	48/59 (81)
Abdominal pain	41/59 (69)
Intussusception	23/59 (39)
Anemia	47/59 (80)
Diagnostic modalities ^[4,7-9,12,14-34,36-43]	
Positive upper endoscopy	2/58 (3)
Positive lower endoscopy	4/59 (7)
Positive abdominal ultrasonography	12/13 (92)
Positive tagged RBC scan	0/3 (0)
Positive Meckel's scan	0/3 (0)
Positive barium enema	0/0
Positive enteroclysis	7/7 (100)
Positive upper GI series with small bowel follow through	18/21 (86)
Positive abdominal CT scan	24/24 (100)
Pathologic findings ^[4,7-9,12,14-34,36-43]	
Ulceration	40/59 (68)
Ectopic gastric tissue only	18/59 (31)
Ectopic pancreatic tissue only	13/59 (22)
Ectopic gastric and pancreatic tissue	4/59 (7)
No ectopic tissue	24/59 (41)

the ileum within 100 cm of the ileocecal valve^[5]. Possible complications include hemorrhage, obstruction, diverticulitis, hernia, tumor, and inflammation, one of which an estimated 2% of those with Meckel's diverticulum will develop^[1,2]. The presentation of these complications often produces a complex constellation of recurrent symptoms consistent with obstruction, chronic abdominal pain and lower gastrointestinal hemorrhage which commonly delays diagnosis and definitive surgical treatment^[5].

An inverted Meckel's diverticulum is a condition where the Meckel's diverticulum literally inverts on itself; however, the pathophysiology underlying this rare phenomenon is not clearly understood. One theory is that there is abnormal peristalsis of the bowel segment in the proximity of the Meckel's diverticulum, possibly due to the tissue present at the base of the diverticulum itself, which causes the diverticulum to invert. Because of the inversion of the Meckel's diverticulum it may be difficult for diagnostic studies which rely on access to the lumen of diverticula, such as capsule endoscopy and colonoscopy, to identify this rare lesion. This inversion of the Meckel's diverticulum can then also lead to a complete intussusception of the bowel or to a compromise in blood flow to that bowel, ulceration and then gastrointestinal hemorrhage^[6].

Because of the clinical challenge of diagnosing this rare entity, inverted Meckel's diverticulum has been reported in less than 70 cases reported in the English literature. However, as diagnostic modalities have improved the reports of this disease as an occult source of hemorrhage

has increased from 40 cases from 1978 to 2005, to 19 cases reported in the last 6 years alone (Table 1). The largest series thus far reported included 18 cases, between 1971-1995 from the Armed Forces Institute of Pathology (AFIP)^[7], and the most recent systematic review was in 2005 before the surge in reports^[5]. Therefore, our report and review comprehensively reviews all these cases in the literature to further guide clinicians in the approach to the diagnosis and treatment of this readily curable disease (Table 1).

The median age of presentation of inverted Meckel's diverticulum is 27.7, slightly younger than reported by the AFIP, which was 33, with a male to female ratio of approximately 2.33:1. The most common presenting complaint was bleeding in 48 of 59 cases (80%), anemia 47 of 59 cases (78%), and abdominal pain (68%) (Table 1). With the most common presentation being lower gastrointestinal bleeding, it is not surprising that most reported cases included a thorough work up for the source of hemorrhage^[5]. In most cases involving bleeding and anemia, patients underwent an upper and lower endoscopy with negative results.

The first reported radiographic description of an inverted Meckel's diverticulum was by Fetterman *et al*^[8] in 1968 and there has been a great proliferation of diagnostic modalities available to clinicians^[5]. A Meckel's scan, a radionucleotide scan that detects gastric mucosa, can be a useful diagnostic tool, especially in the pediatric population. It has a high sensitivity but low specificity. Only 50% of cases are believed to be associated with ectopic gastric or pancreatic mucosa, but it is seen in 75% of those presenting with symptoms^[9]. Meckel scans were reported in only three cases^[4,10,11] which were negative. One of these actually had both ectopic gastric and pancreatic mucosa^[4]. This strongly suggests that a negative Meckel scan does not rule out the diagnosis, which was exemplified in our case.

Other radiologic diagnostic modalities include ultrasonography, which demonstrated positive or clinically influential findings in 12 of 13 cases (Table 1). These findings were often non-specific and only prompted surgical exploration in one case of a post-operative bowel obstruction caused by an intussusception from the inverted Meckel's diverticulum which was detected by ultrasound^[12]. Some of the nonspecific findings include "eggplant shaped mass within the bowel"^[13], fluid filled target^[14], and distended loops of bowel with free fluid^[15]. The use of a tagged nuclear red blood cell scan was reported in three cases with negative results, and barium enema has been of little use (Table 1). When a patient presents with massive hemorrhage, angiography may be useful, especially in a hemodynamically unstable patient. In a single reported case of angiography used for the diagnosis of Meckel's diverticulum, angiography revealed a vitelline artery centrally located in the ileal lumen^[10].

The three most useful tools employed for the diagnosis of inverted Meckel's diverticulum include small bowel follow-through, enteroclysis, and abdominal CT scans^[4,13,16]. When the scan reveals a mass, it often is as-

sociated with a central area of fat density^[5]. Small bowel follow-through was helpful in 18 of 21 cases. Findings include mass-like lesions, polypoid filling defects, and ulcerations. CT scans have been extremely helpful, especially recently with improving technology. CT scan was used in 24 of the reported cases, and all revealed useful information that ultimately led to an operation. They were especially useful when intussusceptions were found in association with the characteristic "target sign". In adults, intussusceptions with clinical symptoms are a clear indication for operation. In the pediatric population, however, even intussusceptions caused by an inverted Meckel's diverticulum can be treated non-surgically with barium enema reduction^[17]. When the small bowel is highly suspected as the source of hemorrhage, enteroclysis has been suggested as the single best study in the diagnosis of inverted Meckel's diverticulum. In 7 reported cases, all seven were useful, as they revealed filling defects and polypoid lesions (Table 1).

In the literature review of the specimens, the average length of the inverted segment was approximately 3.99 cm. Ulceration has been reported in the adjacent ileal mucosa, in the Meckel's segment, and in the tip. There appears to be no direct correlation with the presence or absence of ectopic tissue. The ulceration seen in cases without gastric mucosa may be explained by either ischemia and/or trauma^[5]. Fifty-eight percent of the reported cases were associated with ectopic mucosa of either gastric or pancreatic origin (Table 1).

The preferred treatment of any symptomatic Meckel's diverticulum is surgical. Whenever an inverted Meckel's diverticulum is diagnosed either pre-operatively or intra-operatively, the surgical procedure should be segmental resection with reestablishment of bowel continuity. Intussusception was noted in our case preoperatively. In our literature review, twenty three cases documented active intussusception at the time of operation (Table 1). There was one report of an endoscopic mucosal resection which resulted in iatrogenic perforation requiring emergent laparotomy^[18]. It has been the general consensus that intussusceptions in the adult should be treated with resection and primary anastomosis^[11]. Although most reports have described laparotomy, some minimally invasive techniques have been described in the literature. El-Dhuwaib *et al.*^[14] and Karahasanoglu *et al.*^[15] reported exploration and resection laparoscopically for an inverted Meckel's diverticulum. However, others have reported that manual palpation or laparoscopic inspection of the small bowel itself is not enough and may lead surgeons to miss the diagnosis^[17]. In our case, we planned on an initial abdominal exploration laparoscopically, and if unsuccessful, had planned on conversion to an open laparotomy with possible intra-operative endoscopy. Fortunately, we were able to find the lesion laparoscopically and performed the resection *via* a mini-laparotomy, which has the potential to provide less morbidity than a larger laparotomy incision. Our approach provided adequate exposure to achieve appropriate margins if the

lesion had been found to have been malignant. In cases where even open laparotomy fails to localize the lesion, the successful use of intra-operative endoscopy to localize the lesion and guide treatment of inverted Meckel's diverticulum has been reported^[19].

Bleeding seen in inverted Meckel's diverticulum cannot be attributed entirely to ulceration secondary to gastric mucosa, and it may be due to trauma or inversion induced mucosal ischemia^[5]. In fact, most cases did not have gastric cells present (Table 1). Trauma, due to its location within the lumen, is likely a primary source of bleeding in most cases reported in association with normal intestinal mucosa^[5,13,20-22].

There is some debate as to the treatment of incidentally discovered Meckel's diverticulum in the asymptomatic patient. Resection is generally recommended for patients younger than 40, diverticulum longer than 2 cm, divertula with narrow necks, fibrous bands, ectopic gastric tissue, and/or when the diverticulum appears thickened and inflamed. When a Meckel's diverticulum is discovered as the lead point to an intussusception, it is thought to be a primary pathologic process, and not a secondary process^[5,17]. The exact cause of the inversion is not yet understood. Intussusceptions are primarily seen in children under the age of 2, and only 5% of all intussusceptions are seen in adults^[1]. In children however, there is no lead point in 95% of the cases^[23].

Multiple diagnostic modalities have been described in the diagnosis of inverted Meckel's diverticulum. In instances of lower gastrointestinal hemorrhage, it is appropriate to first exclude an upper gastrointestinal source and a colonic source. Based upon a review of the literature, the studies recommended when inverted Meckel's diverticulum is suspected are CT scans and enteroclysis. However, to make this difficult diagnosis requires a high index of suspicion with an awareness of this important pathologic process and its unique presentation.

Although Meckel's diverticulum is usually an asymptomatic common congenital abnormality of the gastrointestinal tract, it can present with lower gastrointestinal hemorrhage^[35]. In the case of inverted Meckel's diverticulum, the bleeding may be due to the presence of ectopic gastric mucosa, but may also be commonly due to trauma or inversion induced ischemia. In a patient presenting with lower gastrointestinal bleeding, upper and lower endoscopy can be used to rule out a source. If these modalities are negative and Meckel's diverticulum is suspected, CT scan or enteroclysis may be more helpful in the diagnosis than other modalities, and its wider use may account for the increase in reports of this rare disease in the literature. Treatment usually provides a complete cure when it entails operative resection, either *via* an open or laparoscopic approach with possible intra-operative endoscopy. Because of the non-specific presentation of inverted Meckel's diverticulum as an occult source of lower gastrointestinal hemorrhage, it is important for gastroenterologists and surgeons to understand the pathophysiology, appropriate diagnostic approach and therapeutic management of this readily curable disease.

Abstract

Stasis of the flow of the intestinal contents, ingested material and unfavorable composition of the chylus can lead to the formation of enteroliths inside the bowel. Enterolithiasis represents a rare disorder of the gastrointestinal tract that can be associated with intermittent abdominal pain or more serious complications such as bleeding or obstruction. Enterolithiasis in Crohn's disease represents an extremely rare condition and usually occurs only in patients with a long symptomatic history of Crohn's disease. We report an unusual case of enterolithiasis-related intestinal obstruction in a young male patient with Crohn's disease (A2L3B1 Montreal Classification for Crohn's disease 2005) undergoing emergency laparotomy and ileocecal resection. In addition, we present an overview of the relevant characteristics of enterolithiasis on the basis of the corresponding literature.

INTRODUCTION

As enterolithiasis of the small bowel is a rare condition, only a few cases of enterolithiasis-related small bowel ileus in patients with Crohn's disease have been published. A PubMed database analysis showed 9 results published between 1972 and 2010 when searching for "enterolithiasis + crohn"^[1,2]. To date, about 20 cases of Crohn's disease-associated enterolithiasis have been reported in the literature. Here we present the case of a Crohn's disease patient with enterolithiasis-related small bowel obstruction and discuss the clinical and radiological features of this rare entity on the basis of the current literature.

CASE REPORT

A 46-year-old male patient (nonsmoker) presented with acute diffuse abdominal pain, constipation and vomiting at the emergency unit of the department of surgery. His past medical history included laparoscopic cholecystectomy for symptomatic cholecystolithiasis several years ago and a 12-year history of Crohn's disease. At the time of admission the patient was treated with budesonide, enteroclysm and 5-aminosalicylic acid (A2L3B1 Montreal Classification for Crohn's disease 2005). The clinical examination showed no fever, a soft, but distended abdomen without abdominal guarding. Blood investiga-

Figure 1 X-ray of the abdomen with two small radiopaque enteroliths in the lower abdomen. A: Overall picture; B: Enlarged detail. L: Left.

tion revealed a normal leucocyte count and a marginally increased level of C-reactive protein. On the abdominal X-ray, the typical imaging of an incipient small bowel ileus with dilated small bowel loops was apparent (Figure 1A), however, two conspicuous small shadows in the pelvis were also observed (Figure 1B). Consequently, a computed tomography (CT) scan of the abdomen was performed to confirm or exclude a mechanical obstruction. The CT scan showed a significant small bowel stricture and two adjacent intraluminal radiopaque, dense calcified enteroliths with a maximal diameter of 20 mm in the terminal ileum with significant wall thickening, acute inflammatory signs and prestenotic dilatation of the small bowel indicating a mechanical ileus (Figure 2). The patient underwent immediate emergency laparotomy: the intraoperative findings revealed a long (30 cm), dense narrowing of the terminal ileum with irremovable stony palpable masses, poststenotic emptiness and prestenotic dilatation of the bowel (Figure 3). An ileocecal resection of about 40 cm of the terminal ileum with a side to side ileoascendostomy reconstruction was conducted (Figure 4). Histopathological examination of the resected specimen confirmed the diagnosis of an acute inflammatory episode of Crohn's disease without any sign of malignant transformation or perforation. After an uneventful postoperative stay of 11 d, the patient was discharged home with Crohn's disease specific medication (metronidazole, azathioprine) recommended by the gastroenterologists to prevent postoperative bacterial infection and to control inflammatory activity.

DISCUSSION

The first description of enterolithiasis in the scientific literature can be traced back to 1917, when Pfahler *et al.*^[3] published a report on the radiological features of enterolithiasis. It was not until 1959 that Atwell *et al.*^[4] introduced the definition of enteroliths as “endogenous foreign bodies in the gastrointestinal tract”. According to a classification by Grettve *et al.*^[5], enteroliths can be divided into primary and secondary enteroliths. Primary enteroliths always develop inside the bowel, and can be caused by concretions of normal chylus components such as choleic acid, calcium phosphate and calcium carbonate (so called “true” primary enteroliths) or by ingested indigestible material such as hair (trichobezoar), vegetables (phytobezoar) or other exogenous substances such as barium sulfate (so called “false” primary enteroliths). In contrast, secondary enteroliths typically form outside the bowel and then pass into the bowel like gallstones which fistulate into the bowel causing peritonitis and/or mechanical obstruction. The most common localization of enteroliths is the colon including the appendix vermiformis (appendicoliths), however, enteroliths can occur throughout the entire gastrointestinal tract from the stomach to the rectum.

Stasis or decelerated motility of the gastrointestinal tract seems to be the crucial pathogenetic factor in the development of enteroliths, since an unimpaired continuous flow of the gastrointestinal content usually does not allow the formation of enteroliths^[5]. However, when stasis occurs, small particles have enough time to crystal-

Figure 3 Intraoperative illustration of the small bowel ileus with evident stenosis and prestenotic dilation.

Figure 4 Resected specimen of the cecum and small bowel with two fixed enteroliths causing small bowel obstruction.

lize and form accumulating stones. Stasis is always associated with anatomic alterations of the gastrointestinal tract such as harmless anatomic variations (diverticula, duplication cysts)^[6,7] or pathologic conditions (strictures) due to bowel diseases such as Crohn's disease or tuberculosis^[8-10]. In addition, stasis may also develop after bowel resection with a broad side to side enteroanastomosis with a big blind pouch allowing for continuous deposition of intestinal contents^[11]. Enteroliths can be asymptomatic and dissolve spontaneously passing slowly through the gastrointestinal tract until excretion. However, in most cases enterolithiasis is associated with recurrent signs of intestinal obstruction and intermittent abdominal pain. In addition, refractory chronic anemia and perforation have also been reported^[4,12]. Interestingly, the patient in our case report did not really suffer from any of these symptoms, although both enterolithiasis and Crohn's disease represent chronic disorders. Obviously, there was a moderate postinflammatory, quite asymptomatic stricture of the terminal ileum which permitted very slow but continuous development of enteroliths without significant alteration of intestinal passage. The actual inflammatory episode then led to complete intestinal obstruction due to thickening of the bowel wall. We suggest that the enteroliths developed primarily on site, since they were almost completely fixed in the diseased

Figure 5 Typical images of enteroliths. A: Long-standing enterolith with blank-looking polished surface; B: Emerging enterolith with a rough and fragile surface.

bowel segment. Additionally, the enteroliths stood out with a very hard consistency and blank-looking, polished surface (Figure 5A). About 20 cm proximal of the stricture another enterolith was detected in the resected specimen with completely different characteristics: this enterolith was morbid, fragile, rough and easily movable, potentially because there was no stricture (Figure 5B). We hypothesize that this additional enterolith represents the typical status nascendi of an enterolith which is usually not observable, since it is asymptomatic and potentially excreted.

The radiological diagnosis of enteroliths depends on their calcium content^[13,14]. In our case, two radiopaque enteroliths were clearly visible on abdominal X-ray, whereas the third mobile enterolith was not detectable. The differential diagnosis of radiopaque enterolith-like alterations includes gallstones, urolithiasis-calcified lymph nodes or pancreatic calcifications. Of note, enteroliths may change their localization on radiographs due to the mobility of the small bowel^[9].

Due to its typical strictures impairing the intestinal flow, Crohn's disease offers favorable conditions for the development of enteroliths. Nevertheless, enteroliths are a very rare condition in Crohn's disease, since most patients never become symptomatic or because symptoms are not attributable to enteroliths. Studies have proven that enterolithiasis in Crohn's disease occurs only in patients with a long history of the disorder and long duration of symptoms of between 7 and 40 years (median

15.7 years)^[9]. Additionally, a few cases of enterolithiasis-associated adenocarcinomata have been reported in the literature^[15]. In summary, there is no evidence for prophylactic treatment of asymptomatic enterolithiasis in Crohn's disease, although enteroliths represent clear indicators of a stenotic condition. Patients with intestinal obstruction require laparotomy with stricturoplasty or segmental bowel resection.

Abstract

Most primary aortoduodenal fistulas occur in the presence of an aortic aneurysm, which can be part of immunoglobulin G4 (IgG4)-related sclerosing disease. We present a case who underwent endovascular grafting of an aortoduodenal fistula associated with a high serum IgG4 level. A 56-year-old male underwent urgent endovascular reconstruction of an aortoduodenal fistula. The patient received antibiotics and other supportive therapy, and the postoperative course was uneventful, however, elevated levels of serum IgG, IgG4 and C-reactive protein were noted, which normalized after the introduction of steroid therapy. Control computed tomography angiography showed no endoleaks. The primary aortoduodenal fistula may have been as-

INTRODUCTION

A primary aortoenteric fistula (AEF) is a communication between the aorta and the intestines, and occurs in a setting without prior aortic surgery. It is a rare but potentially lethal condition with an incidence of 0.04% to 0.07%^[1]. Primary fistulas are in most cases (90%), the result of erosion of the bowel wall, caused by an abdominal aortic aneurysm (AAA)^[2]. The majority occur between the aorta and the duodenum^[3]. Primary aortoduodenal fistulas (ADF) have been reported in the presence of various conditions, including underlying atherosclerotic aortic aneurysm disease, gallstone erosion, foreign body ingestion, and invasive intra-abdominal malignancies^[4]. However, it has been reported that an aortic

antibiotics (imipenem in combination with vancomycin) preoperatively, and continued with the same medication for 4 wk after endovascular repair. The patient then continued taking an oral antibiotic for the next two months (ciprofloxacin 1000 mg per day for 4 wk then doxycycline 100 mg per day for another 4 wk). The post-operative course was without complications and without further blood loss. After the patient was introduced to *per os* food intake, control CT angiography showed no endoleaks and a reduction in thrombotic mass volume in the aneurysm with regression of the aneurysm diameter, however, the gas collection persisted (Figure 3A).

On the tenth day after endovascular repair, RBC and HCT values were normal (RBC 4.2 million per μL and HCT 35%). The patient had improved, but the laboratory tests showed a CRP serum level of 56 mg/L and a high serum IgG level of 20.2 g/L and IgG4 of 4.24 g/L, respectively. Autoantibodies against lactoferrin and carbonic anhydrase II were negative, and autoantibodies including anti-nuclear antibodies, antineutrophil cytoplasmic antibodies and rheumatoid factor were not found. Markers for viral hepatitis Bs infection, hepatitis C virus, hepatitis A virus, human immunodeficiency viruses 1 and 2 were negative. Due to lack of histopathological findings, but elevated serum levels of IgG, it could not

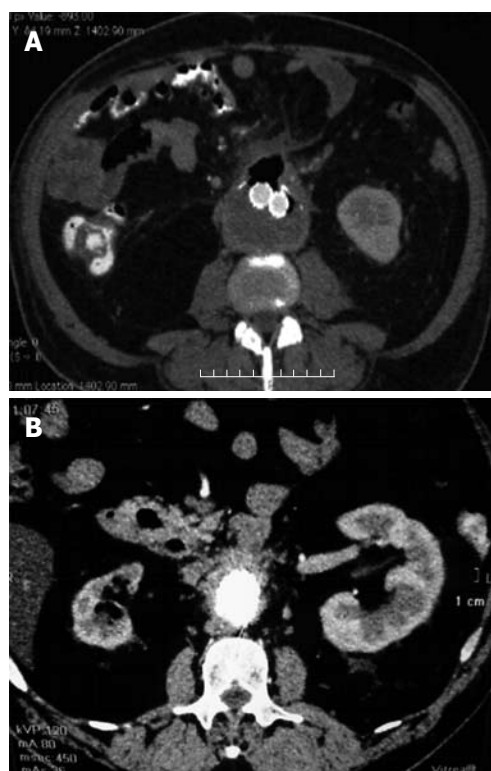

Figure 3 Control computed tomography angiography. A: Control computed tomography (CT) angiography shows no endoleaks and reduction of thrombotic mass volume in the aneurysmatic sac with persistence of gas collection; B: Control CT angiography after 6 mo showed no endoleaks and near total reduction of thrombotic mass in the aneurysmatic sac, without gas collection.

be determined with confidence that this was a systemic disease. It was decided that the patient should start steroid therapy with oral prednisolone at 40 mg per day for 4 wk, and then decrease the dosage by 5 mg every week. Four wk after initiation of steroid therapy, serum levels of IgG (16 g/L) and IgG4 (0.7 g/L) as well as CRP were normal. In the control examination conducted 6 mo after the patient's discharge from hospital (almost 3 mo after the end of steroid therapy), the levels of serum immunoglobulins and CRP were in the normal ranges and control CT angiography showed no endoleaks, near total reduction of the thrombotic mass in the aneurysmatic sac, and no gas collection (Figure 3B).

DISCUSSION

Primary ADF represents a serious condition and is much less frequent than a secondary ADF which occurs as a result of previous aortic aneurysm grafting. The first described case of primary ADF was more than a century ago, and since then about 250 cases have been reported. In the absence of treatment, the mortality rate is almost 100%. With surgical intervention, survival ranges from 18%-93%, but 40% of operated cases develop complications with an overall postoperative mortality rate greater than 30%^[12]. Diagnosis of primary ADF is also difficult. Only 33% to 50% of AEF are diagnosed preoperatively^[3]. Gastrointestinal bleeding and abdominal pain

have been described in all cases, but the classic trio of abdominal pain, palpable mass and gastrointestinal bleeding was found in only 6% to 27.8% of patients^[2,13,14]. Our patient only had gastrointestinal bleeding presenting as melena. Diagnostic procedures include EGDS, CT scan, and arteriography. Endoscopy is considered the modality of choice for initial evaluation of upper gastrointestinal bleeding, but has the potential risk of inducing massive hemorrhage by dislodging fresh thrombus in the fistula^[15,16]. In our case, EGDS findings were without signs of gastrointestinal hemorrhage. CT angiography was reliable in diagnosing AEF but may be somewhat challenging in unstable patients.

The surgical treatment of ADF consists of repairing the duodenal defect and performing a prosthetic repair of the aorta with graft. Where contamination is present, or in the case of mycotic aneurysm, an extraanatomical aortic graft is preferred and extensive debridement is required^[17]. Although the endovascular approach is increasingly utilized in the repair of secondary AEF, only a few primary AEF treated using this method have been reported^[4,11,12,18,19]. In the case of any applied vascular procedure, long-term broad spectrum antibiotic therapy is necessary^[11,12]. We believe that patients with persistent anemia who undergo laparotomy without diagnosis is hazardous.

Primary ADF is the result of inflammatory destruction of an aortic aneurysm arising from an atherosclerotic AAA. This is an etiological factor in 73% of all primary ADFs, while 26% are caused by traumatic or mycotic aneurysms^[2,17,20]. Rarer causes such as radiation, tumors, ulcers and ingestion of foreign bodies account of 1% or less^[4,12]. A very small number of AEF occur in the absence of an aortic aneurysm. In comparison to atherosclerotic AAA, IAAA occurs in only 2% to 10% of all AAA, and has different clinical characteristics, such as younger age of patients, non-specific symptoms, and large aneurysm diameter. Recent reports showed a close relationship between IgG4 and sclerosing lesions of various organs^[21]. IgG4-related sclerosing disease, which are also called IgG4-related sclerosing disease, was first reported with regard to autoimmune pancreatitis^[22]. The clinical characteristics of IgG4-related sclerosing disease are a frequent occurrence in adult male patients, and include elevation of serum IgG4 levels, and steroid sensitivity. In addition to affected organs in IgG4-related disease, elevated IgG4 levels have been described in atopic dermatitis, asthma, some parasitic diseases, pemphigus vulgaris, pemphigus foliaceus and pancreatic cancer^[23]. Our patient had no clinical signs of these diseases. The correct diagnosis of IAAA as part of IgG4-related disease is based on histopathological findings^[21]. According to these recommendations, the diagnosis of IAAA as part of IgG4-related disease in our patient could not be established due to lack of histopathological findings, as endovascular repair of AAA, was successful. If the AAA in our patient was an IAAA, this would be the first case with ADF in IgG4-related sclerosing disease. In addition, the patient had a positive response to steroid therapy. The

question remains as to how it is possible to make a diagnosis of IgG4-related IAAA in such cases where urgent minor surgery is the treatment of choice. In our case, endovascular repair of ADF was successful, and this may be an alternative treatment, especially in patients with high operative risk. Broad spectrum antibiotic therapy is as important as the endovascular treatment in ADF.

In conclusion, primary ADF is a rare complication of aortic aneurysms and is a rare cause of gastrointestinal bleeding. It can be associated with IgG4-related sclerosing disease, whether it occurs as a complication of IAAA or not. CT angiography is a good diagnostic test for an ADF. This case demonstrates that endovascular grafting of primary ADF as an effective, minimally invasive alternative to standard surgical repair. Other supportive therapy such as antibiotics are very important in the treatment of this condition. High serum IgG4 levels and a positive response to steroid therapy suggest the existence of an ADF in IgG4-related IAAA, without histopathological examination.

Abstract

Venous complications in patients with acute pancreatitis typically occur as a form of splenic, portal, or superior mesenteric vein thrombosis and have been detected more frequently in recent reports. Although a well-organized protocol for the treatment of venous thrombosis has not been established, anticoagulation therapy is commonly recommended. A 73-year-old man was diagnosed with acute progressive portal vein thrombosis associated with acute pancreatitis. After one month of anticoagulation therapy, the patient developed severe hematemesis. With endoscopy and an abdominal computed tomography scan, hemorrhages in the pancreatic pseudocyst, which was ruptured into the duodenal bulb, were confirmed. After conservative treatment, the patient was stabilized. While the rupture of a pseudocyst into the surrounding viscera is a well-known phenomenon, spontaneous rupture into the duodenum is rare. Moreover, no reports of upper gastrointestinal bleeding caused by pseudocyst rupture

INTRODUCTION

The vascular complications of pancreatitis are major causes of morbidity and mortality and are typically related to hemorrhage. Venous complications generally occur as a form of thrombosis in the splenic vein and less commonly in the portal or superior mesenteric vein^[1]. Although no randomized controlled trial regarding the use of anticoagulants in acute portal vein thrombosis has been conducted, the use of unfractionated heparin, with subsequent transition to oral warfarin, is the most common approach to anticoagulation^[2,3].

Pancreatic pseudocysts are common findings, but spontaneous rupture occurs infrequently. Pseudocyst rupture can occur in the free peritoneal cavity, stomach,

duodenum, colon, portal vein, pleural cavity, and abdominal wall. However, rupture into the duodenum is very rare^[4]. Furthermore, no reports of upper gastrointestinal bleeding caused by pseudocyst rupture in patients under anticoagulation therapy for venous thrombosis associated with acute pancreatitis have been published.

We describe herein a very rare and unique case of massive upper gastrointestinal bleeding due to pancreatic pseudocyst rupture into the duodenum, which developed during anticoagulation therapy for portal vein thrombosis associated with acute pancreatitis.

CASE REPORT

A 73-year-old man was transferred to our emergency department for the management of massive hematemesis. On arrival, his systolic blood pressure was 70 mmHg, and his blood hemoglobin level was 6.8 g/dL. He received a transfusion of two units of packed red blood cells. Seven weeks prior, he had initially developed acute alcoholic pancreatitis, and one month prior, he had been diagnosed with acute progressive portal vein thrombosis associated with non-necrotizing acute alcoholic pancreatitis. Since then, he had been receiving anticoagulation therapy. Computed tomography (CT) scans of the abdomen revealed not only thrombosis of the portal vein trunk but also thrombosis of the right and left portal veins (Figure 1A), and low perfusion areas were diffusely observed on the liver parenchyma. A 12 mm × 10 mm cystic lesion was found, suggesting the presence of a pancreatic pseudocyst and extensive fluid collection around the pancreatic head (Figure 1B). Endoscopic ultrasonography also demonstrated the absence of a color Doppler signal and thrombosis of the portal vein, superior mesenteric vein, and distal splenic vein. Arterial portography confirmed an occlusion and thrombosis of the portal vein, superior mesenteric vein, and distal splenic vein. The factors indicating a coagulation defect and tumor markers were normal. We decided to perform anticoagulation therapy because the patient complained of abdominal pain, and serial CT scans showed the progression of the acute portal vein thrombosis. He was treated with intravenous heparin and then switched to warfarin.

Endoscopy and abdominal CT scans were performed to evaluate the hematemesis. Emergency endoscopy (Figure 2A) revealed a 2 cm submucosal tumor-like lesion located just distal to the pylorus. The mucosa showed a central ulceration covered with dark blood clots, which was suggested as a cause of the upper gastrointestinal bleeding. Abdominal CT scans (Figure 1C) revealed a large, walled-in fluid collection of high attenuation around the pancreatic head, indicating a hemorrhagic pseudocyst of the pancreatic head that caused the displacement of the duodenum.

The patient was treated with a high dose of pantoprazole, a proton pump inhibitor, and the warfarin medication was stopped. The patient was hemodynamically

stabilized, and no recurrent bleeding occurred. On the seventh day following admission, follow-up endoscopy (Figure 2B) revealed a reduction of the bulging lesion and a fistula opening with clear discharge, which was suspected to be pancreatic fluid. A follow-up abdominal CT scan (Figure 1D) showed a small collapsed cyst without internal hematoma, and a fistulous tract was also observed between the duodenum and the pseudocyst, resulting in air pocket in the cyst. After only conservative treatment, the patient recovered without recurrent bleeding and was discharged without warfarin medication.

DISCUSSION

Pancreatitis may cause a spectrum of venous and arterial vascular complications. Of these complications, venous thromboses are typically reported in the splenic vein and less commonly in the superior mesenteric vein or portal vein^[5]. Thrombotic complications have been known to be more common in alcohol-induced, necrotizing, and chronic pancreatitis^[6,7]. It has been suggested that the pathogenesis of venous thromboses involves stasis, spasm, and mass effects from the surrounding inflamed pancreas and direct damage of the venous wall by liberated enzymes^[5]. Our case was associated with non-necrotizing, alcoholic pancreatitis. The portal vein was mainly involved, although venous thromboses also occurred in the distal splenic vein and superior mesenteric vein.

Specific therapeutic management for portal vein thrombosis seems to be mandatory to resolve portal vein obstruction, thereby preventing the development of chronic portal vein thrombosis and avoiding serious complications, such as portal vein hypertension, mesenteric ischemia, and infarction^[2,3]. However, randomized controlled studies on the efficacies of most forms of therapy for portal vein thrombosis are lacking. The use of unfractionated heparin, with subsequent transition to oral warfarin is the most common approach to anticoagulation^[2], while Gonzelez *et al*^[8] recently reported that recanalization is observed in almost one third of patients, irrespective of whether they receive systemic anticoagulation. The issue of warfarin dose has not been addressed in randomized trials, and the optimal duration of anticoagulation is controversial^[2]. What is certain is that the sooner the treatment is given, the better the outcome will be; the rate of recanalization is approximately 69% if anticoagulation is initiated within the first week after diagnosis, while it falls to 25% when initiated during the second week^[3].

In our case, anticoagulation therapy was not started at an earlier stage of portal venous thrombosis but began after the confirmation of thrombotic progression, which could explain why the patient achieved only partial portal vein recanalization. Fortunately, the patient did not develop mesenteric ischemia or infarction, and the portal vein thrombosis did not worsen further.

Gastrointestinal bleeding in the setting of pancreatitis arises from vascular complications or coexisting

Figure 1 Abdominal computed tomography images. A: A filling defect and intra-luminal hypoattenuation in the portal vein consistent with acute portal vein thrombosis; B: A 12 mm × 10 mm cystic lesion suggestive of a pseudocyst and extensive inflammatory fluid collections around the pancreatic head; C: A walled-in fluid collection with high attenuation, indicative findings of a hemorrhagic pseudocyst around the pancreatic head and compressed duodenum; D: Reduced hemorrhagic fluid collections and an air-filled cyst, indicative of a fistula between the duodenum and the pseudocyst.

Figure 2 Upper gastrointestinal endoscopy. A: Emergency endoscopy shows a 2 cm submucosal tumor-like bulging mass with central ulceration; B: A follow-up endoscopy image showing a decreased mass size and fistula orifice.

lesions^[9,10]. Major gastrointestinal bleeding is considered to be rare, but its exact incidence is not well established. According to a recent report of 1356 acute pancreatitis patients, spontaneous bleeding occurred in 10 patients, and 6 patients had gastrointestinal bleeding^[10]. The most frequent cause of severe bleeding in pancreatitis is a ruptured pseudoaneurysm, which accounts for approximately 60% of cases, and a hemorrhagic pseudocyst without a pseudoaneurysm and a capillary, venous, or small vessel hemorrhage each account for approximately 20% of cases^[7,11]. In a review of cases from 1987 to 1996, 31 patients were found to have developed vascular lesions either in

the form of hemorrhage into a pseudocyst (12 patients) or pseudoaneurysms (19 patients)^[12].

In the management of any hemorrhage, the early recognition and investigation of hemorrhagic episodes is imperative because accurate diagnosis and timely radiological interventional procedures can reduce mortality^[7]. Dynamic bolus CT and angiography are considered to be the most useful means of finding a hemorrhage^[13]. In particular, angiography can play an invaluable role both in locating the source of bleeding and in the embolization of the bleeding vessel^[14]. In the present case, the diagnosis of a ruptured bleeding pseudocyst was made

with CT scans and endoscopy, and the ruptured bleeding pseudocyst confirmed the presence of the fistula tract and the walled-in fluid collection with high attenuation around the pancreatic head, providing evidence supportive of a bleeding pseudocyst. Due to the hemodynamically stable clinical conditions and no evidence of pseudoaneurysm formation on CT scans, we did not perform angiography or surgical therapy and decided to pursue a “watchful waiting” policy.

The rupture of a pseudocyst into the gastrointestinal tract either results in no symptoms or leads to melena or hematemesis that typically requires urgent measures^[15]. Although rupture into the surrounding viscera is a well-known phenomenon, the spontaneous rupture of a pseudocyst into the upper gastrointestinal tract is very rarely reported^[4,16-21], and the spontaneous rupture of a pseudocyst into the duodenum most frequently occurs in the second portion of the duodenum^[21]. In the presented case, the first part of the duodenum was involved, and rupture into the duodenum led to hematemesis requiring transfusion.

In our case, the exact pathogenic mechanisms of the bleeding and rupture of the pancreatic pseudocysts were unclear. However, we can suggest some possibilities as to why massive bleeding due to pseudocyst rupture occurred. First, the pseudocyst may have been tensely distended because of intra-cystic bleeding caused by warfarin use and eventually ruptured into the duodenum; Second, the rupture of the pancreatic pseudocyst could have developed first, and severe bleeding of the ruptured duodenal mucosa followed due to the anticoagulation therapy. Consequently, we considered that the warfarin either initiated or aggravated the bleeding into the duodenum. Finally, in this case, it was not clear whether portal hypertension by portal vein thrombosis affected the bleeding risk itself and its severity.

In conclusion, we report a rare case of massive upper gastrointestinal bleeding due to pancreatic pseudocyst rupture into the duodenum, which developed during anticoagulation therapy for acute pancreatitis associated with portal vein thrombosis. Gastroenterologists should consider a pseudocyst rupture into the gastrointestinal tract as a bleeding source in patients with pancreatitis and should also keep in mind that anticoagulants used to manage portal vein thrombosis associated with acute pancreatitis can lead to serious bleeding.

Abstract

Desmoid tumor is a locally invasive, myofibroblastic, nonmetastatic tumor. Its pathogenesis remains unclear and it may involve genetic abnormalities, sex hormones and traumatic injury, including surgery. Postoperative intra-abdominal desmoid tumor is rare, especially in the retroperitoneum. We report a case of postoperative retroperitoneal desmoid tumor that developed 29 mo after the first excision of a gastrointestinal stromal tumor. Sporadic trauma-related intra-abdominal desmoid tumors reported in the English literature are also reviewed. Despite an extremely low incidence, postoperative desmoid tumor should be considered in the differential diagnosis when a recurrent neoplasm is found at least one year after operation. However, it is a clinical challenge to distinguish recurrent malignant neoplasms from desmoid tumors,

INTRODUCTION

Desmoid tumor (also known as aggressive fibromatosis or fibromatosis) is an infrequently occurring, locally invasive, nonmetastatic tumor. Desmoid tumors account for 0.03% of all newly diagnosed neoplasms and 3% of all soft tissue neoplasms^[1]. These tumors originate from musculoaponeurotic planes and are found intra- and extra-abdominally. The cause of desmoid tumor is unclear and it may be related to trauma, hormonal factors, or genetic associations^[2]. The occurrence of a surgery-related retroperitoneal desmoid tumor after the excision of gastrointestinal stromal tumor (GIST) is rare. However, despite its scarcity, desmoid tumor should be differentiated from recurrent neoplasm in diagnosis, especially those occurring near the previous operative site.

CASE REPORT

A 56-year-old man complained of epigastralgia for three weeks without symptomatic improvement after receiving medical treatment at another hospital in 2009, where a deep-seated gastric ulcer had been found by panendoscopy. Because there had been no symptomatic relief, he was referred to the in-patient department of our hospital. On physical examination, abdominal fullness with obvious rebounding pain was noticed. A perforated peptic ulcer was suspected and an abdominal computed tomography (CT) scan was performed. The abdominal CT scan revealed a 10-cm gastric mass with perforation (Figure 1A). In May 2009, the patient underwent an emergent explorative laparotomy with debulking of the intraperitoneal tumor and irrigation. A ruptured GIST, of intermediate risk category, with spreading intra-abdominal tumors was diagnosed pathologically (Figure 1B and C). He had no family history of familial adenomatous polyposis (FAP) or colorectal diseases among his close relatives. Because the abdominal CT scan had shown no signs of FAP, colonoscopy was not performed. His clinical course was uneventful and he was discharged on day 8 after admission. After the operation, imatinib (Glivec) 200 mg *b.i.d.* was prescribed. However, due to intractable diarrhea, the target therapy was discontinued. The follow-up abdominal CT scan showed no recurrent tumor two months after the operation. He was then lost to follow-up. The patient revisited our out-patient clinic 12 mo later after the previous operation. The abdominal CT scan showed a 4.7-cm hepatic tumor in segments 6 and 7 and an intra-abdominal 2.5-cm mass located in the upper greater curvature of the stomach (Figure 1D). The impression was metastatic GISTs. He received a second operation with a smooth course in June 2010 and metastatic GISTs were confirmed pathologically (Figure 1E). However, a 1.9-cm tumor between the pancreatic tail and splenic hilum was found in the follow-up abdominal CT scan 3 mo after the second operation. The tumor was located in the incision area of the first debulking operation. The patient refused another operation, and he was managed with target therapy with imatinib (Glivec) 200 mg *b.i.d.*, which was well tolerated. A series of follow-up abdominal CT scans were performed. Fifteen months after the second operation, CT scan revealed progressive enlargement of the splenic hilar tumor from 1.9 cm to 3.2 cm (Figure 1F). The patient continued to take imatinib (Glivec) regularly. Under the impression of a second recurrent GIST, he underwent a third operation in October 2011. Intraoperatively, the tumor was found in the retroperitoneum adhering to the peri-tumor vessels, nerves and the pancreatic tail. This tumor was resected *en bloc* with sacrifice of adjacent vessels and nerves. Grossly, the tumor measured 3.6 cm × 2.5 cm × 1.1 cm and was elastic with grayish-brown cut surface. Histologically, the tumor demonstrated proliferative spindle cells in fibrotic background with keloid-like, glassy, hyalinized collagen fibers, nodular fasciitis-like erythrocyte extravasation and infiltrative growth pattern.

Immunohistochemical staining of the tumor cells revealed positive nuclear stains for beta-catenin, but negative stains for CD117 and CD34 (Figure 1G). A desmoid tumor was diagnosed pathologically. The patient's clinical course was uneventful and no recurrent tumor was found 6 mo after the third operation.

DISCUSSION

Although desmoid tumor is locally aggressive with infiltrative growth behavior, it is considered to be a benign neoplasm for its bland cellular appearance, scant mitosis and lack of metastasis. The term “desmoid” originates from the Greek word “demos”, meaning band or tendon like, and was first named by Müller^[3] in 1838. Desmoid tumor accounts for 0.03% of all neoplasms and 3.0% of all soft tissue tumors^[1].

Although the actual cause of desmoid tumor is still being debated, its likely pathogenesis includes genetic abnormalities, sex hormones and trauma, including surgical trauma. Kulaylat *et al.*^[2] found that 10%-30% of all sporadic abdominal wall desmoid tumors occurred following surgical intervention and half of these tumors developed within 4 years after the surgery. Warren^[4] described the criteria for post-traumatic neoplasm, including prior integrity of the tumor site, injury severe enough to initiate reparative cell proliferation, reasonable latent period, and tumor compatible with the scar tissue and anatomic location of the injury. In the present case, the splenic hilar region was incised during the debulking operation for the ruptured GIST of the stomach, and the desmoid tumor occurred 29 mo after the surgery. The present case of postoperative retroperitoneal desmoid tumor was compatible with Warren's criteria^[4] and occurred within an appropriate latent period.

The English literature includes 12 cases, including the present case, of sporadic postoperative intra-abdominal desmoid tumor^[5-15] (Table 1). The male-to-female ratio was 8:3 (one case showed no gender datum) and the mean age was 49.6 years (range, 27-79 years). Five of the 12 cases were located on the mesentery, which is the most frequent site of this type of desmoid tumor to date. Tumor sizes ranged from 2.8 cm to 18 cm and the mean duration from previous operative insult to excision of desmoid tumor was 2.3 years (range, 11 mo to 7 years). It indicates that a reasonable latent period for this type of desmoid tumor is at least one year. None of the desmoid tumors was diagnosed preoperatively. This denotes the diagnostic challenge of this type of desmoid tumor. Ten of the 12 desmoid tumors were widely excised under the impression of recurrent malignant neoplasm. No recurrence was found in 8 cases followed up between 6 mo to 2 years. Up till now, only 3 postoperative desmoid tumors after resection of gastric GIST have been reported in the literature. Whether GIST is a risk factor for the development of desmoid tumors or just a coincidence should be further elucidated.

Recently, the Wntless/Wnt signaling pathway was hypothesized to be involved in the tumorigenesis of

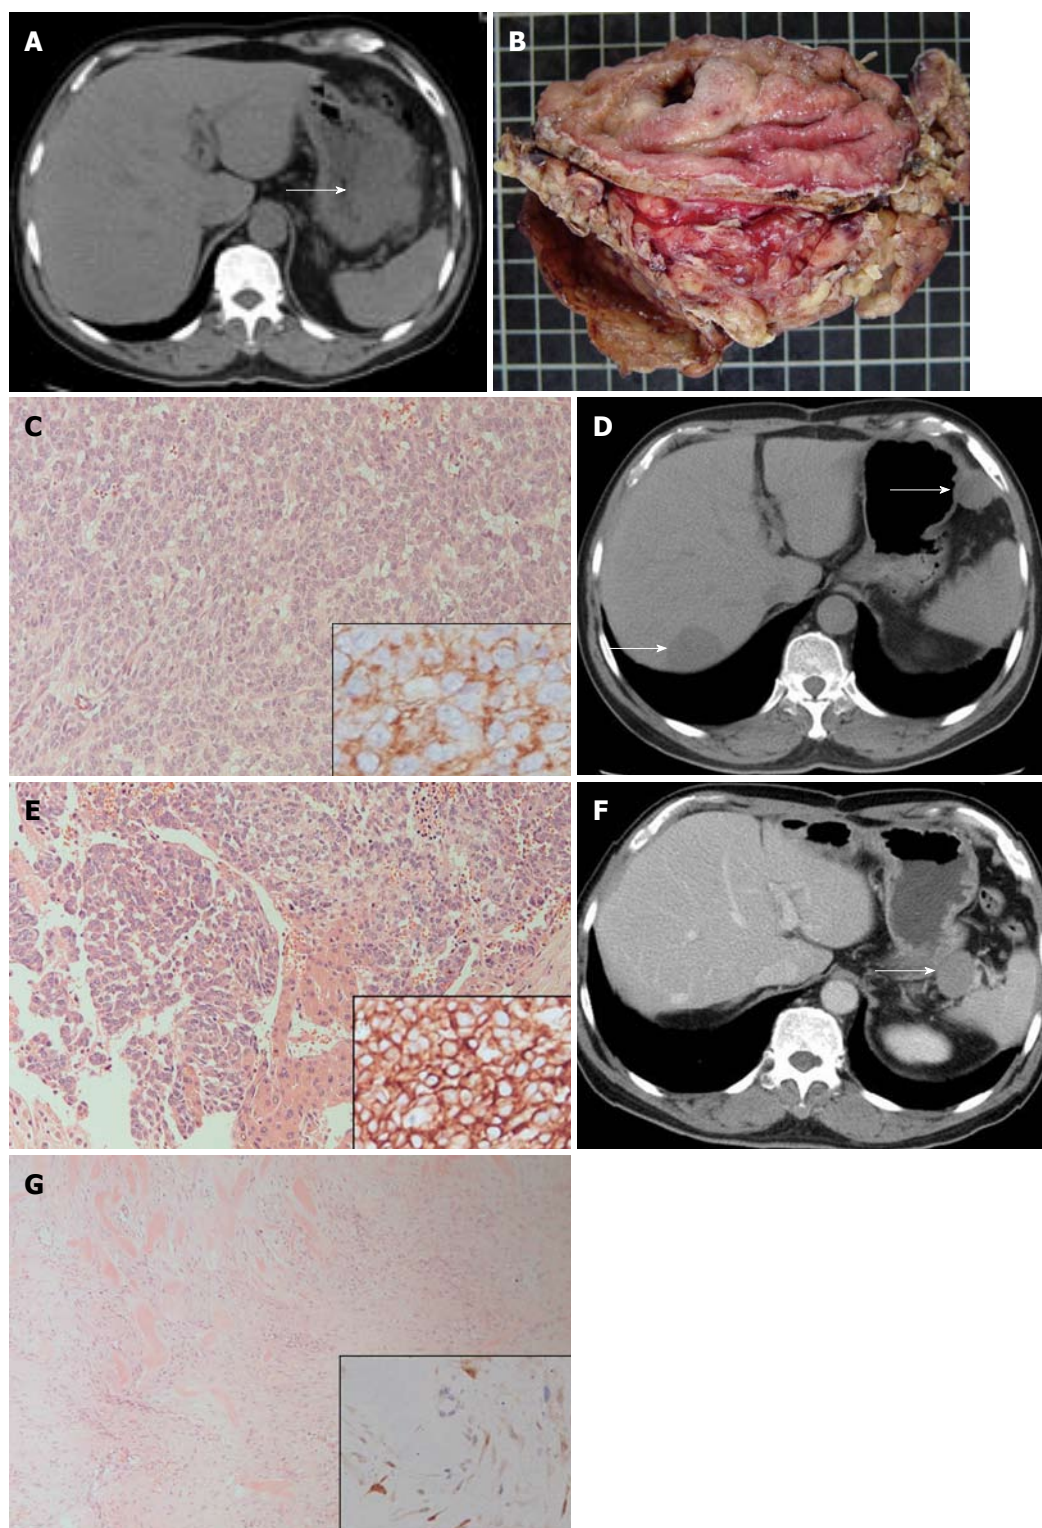

Figure 1 Abdominal computed tomography images and pathologic features of gastrointestinal stromal tumor, metastatic hepatic gastrointestinal stromal tumor and retroperitoneal desmoid tumor. A: Abdominal computed tomography (CT) scan reveals a 10-cm tumor (arrow) located at the greater curvature of the stomach; B: The excised specimen discloses a patch of gastric mucosa with a central deep-seated ulcer and the gastrointestinal stromal tumor adhering to the red yellow omental tissues; C: Histologically, the 10-cm gastric tumor demonstrated sheets of CD117-positive epithelioid cells after immunohistochemical (IHC) staining (right lower inset), hematoxylin and eosin (HE) stain, $\times 200$; D: The follow-up abdominal CT scan shows metastatic tumors in the liver (left lower arrow) and upper greater curvature of the stomach (right upper arrow); E: The histology of metastatic liver tumor demonstrated nests and sheets of CD117-positive epithelioid tumor cells (right lower inset, IHC stain). Entrapped hepatocytes are seen in the middle lower portion, HE stain, $\times 200$; F: Abdominal CT scan discloses a tumor neogrowth (arrow) located in the retroperitoneum between the pancreatic tail and splenic hilar region; G: Histologically, the retroperitoneal tumor demonstrated proliferative spindle cells with keloid-like bundles and erythrocyte extravasation, HE stain, $\times 200$. IHC staining reveals a positive nuclear beta-catenin in spindle cells (right lower inset).

desmoid tumors, especially the two key proteins, adenomatous polyposis coli (APC) and beta-catenin^[16]. APC is considered to be a tumor suppressor gene and beta-catenin an oncogene. Sporadic desmoid tumors typically present oncogenic mutation in beta-catenin. However, FAP-associated desmoid tumors are associated with germline APC mutation followed by somatic inactivation of the wild-type APC allele^[17,18]. Beta-catenin protein level is upregulated in desmoid tumors, due to either APC mutations and subsequent ineffective regulation of beta-catenin activation, or beta-catenin gene mutations that led to stabilization and constitutive activation of the beta-catenin. These pathways indicated that the expression of nuclear beta-catenin may play a role in the differential diagnosis of desmoid tumors from fibroblastic or smooth muscle neoplasms^[16].

Primary wide surgical resection with tumor-free margins is the treatment of choice for desmoid tumor. This surgical strategy made it essential to sometimes sacrifice the adhered normal vital tissues such as vessels and nerves. Resections with tumor-positive margins indicate a high risk of recurrence, and secondary resection, chemotherapy or radiotherapy may be performed consequently according to the patient's condition^[19]. Garbay *et al*^[20] treated 62 patients with cytotoxic chemotherapy for progressive or recurrent desmoid tumors, and 80%

of the patients had a clinical benefit (objective response plus stable disease) from the cytotoxic chemotherapy. Anthracycline-containing regimens appeared to be associated with a higher response rate. Radiotherapy for unresectable cases or local tumor control after surgery has been empirically applied in some instances^[21]. However, the efficacy of the adjuvant treatment still needs to be further elucidated. Recently, three discrete mutations (ACC41GCC, TCT45TTT and TCT45CCT) in two codons of CTNNB1 exon 3 were reported^[22]. Target therapy for desmoid tumor may be feasible and become another treatment option in the future.

Postoperative intra-abdominal desmoid tumor is exceptionally rare and is often overlooked by clinicians. Most clinicians believe that a tumor with locally infiltrative growth behavior in patients with a history of malignancy is a recurrent malignant tumor, and a wide excision with sacrifice of adjacent organs is usually done. However, despite an extremely low incidence, a postoperative desmoid tumor should be included in the differential diagnoses.

In conclusion, postoperative intra-abdominal desmoid tumor is rare and a correct preoperative diagnosis is a clinical challenge. Physicians should keep in mind the possibility that a postoperative desmoid tumor may appear as a so-called "recurrent" neoplasm, especially when the tumor presents at the previous surgical site.

ACKNOWLEDGMENTS

Acknowledgments to reviewers of World Journal of Gastroenterology

We acknowledge our sincere thanks to our reviewers. Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of our World Series Journals. Both the editors of the journals and authors of the manuscripts submitted to the journals are grateful to the following reviewers for reviewing the articles (either published or rejected) over the past period of time.

Dr. Leif Percival Andersen, MD, Department of Infection Control 9101, Copenhagen University Hospital, Rigshospitalet, Juliane Maries Vej 18, DK-2100 Copenhagen, Denmark

Ekaterini Chatzaki, PhD, Assistant Professor, Laboratory of Pharmacology, Faculty of Medicine, Dragana, Alexandroupolis, 68100 Thrace, Greece

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Biliary ductal changes are a common radiological finding in patients with portal hypertension, however only a small percentage of patients (5%-30%) develop symptomatic bile duct obstruction. The exact pathogenesis is not clear, but an involvement of factors such as bile duct compression by venous collaterals, ischemia, and infection is accepted by most authors. Although endoscopic retrograde cholangiopancreatography was used to define and diagnose this condition, magnetic resonance cholangiopancreatography is currently the investigation of choice for diagnosing this condition. Treatment is indicated only for symptomatic cases. Portosystemic shunts are the treatment of choice for symptomatic portal biliopathy. In the majority of patients, the changes caused by biliopathy resolve after shunt surgery, however, 15%-20% patients require a subsequent bilio-enteric bypass or endoscopic management for persistent biliopathy. There is a role for endoscopic therapy in patients with bile duct stones, cholangitis or when portosystemic shunt surgery is not feasible.

INTRODUCTION

The term portal biliopathy (syn. pseudosclerosing cholangitis) was first coined in the 1990s^[1], where it was used to describe abnormalities in the intrahepatic and extrahepatic biliary tract, gallbladder and cystic duct secondary to portal hypertension. However, jaundice and common bile duct (CBD) compression associated with portal hypertension had been, in fact, described by Fraser *et al*^[2] in 1944 and by Gibson *et al*^[3] in 1965. Hunt^[4], also in 1965, described the treatment of CBD obstruction secondary to distended venous collaterals.

Portal biliopathy is predominantly associated with extrahepatic portal venous obstruction (EHPVO). Studies in these patients using endoscopic retrograde cholangiopancreatography (ERCP) have shown that changes in the bile ducts occur in 81%-100% of them, although only 5%-30% have symptoms of biliary obstruction^[5-10]. The condition has also been described in patients who have non-cirrhotic portal fibrosis (NCPF) and cirrhosis, albeit in smaller numbers.

Portosystemic shunting as a decompressive treatment for portal biliopathy was first described in 1989

by Choudhuri *et al.*^[11]. However, subsequent studies have shown that in a subset of patients the biliary obstruction is not relieved by portosystemic shunts alone and requires an additional biliary drainage procedure. The characteristics of patients in whom the biliary obstruction is not reversed after a portosystemic shunt and the role of endoscopic management of the condition is still not clear.

In this article, we review the current data on portal biliopathy and outline the various controversies associated with its effective treatment.

The anatomical basis for the condition was suggested by the works of Petren^[12] and Saint^[13] who described the venous anatomy of the bile ducts in 1932 and 1971 respectively. An epicholedochal plexus (of Saint) forms a reticular network of veins (maximum size 1 mm) on the outer surface of the bile ducts. The paracholedochal network of Petren courses parallel to the CBD and is connected to the gastric, pancreaticoduodenal and portal veins below, and to the liver above.

PATHOGENESIS

There are three main theories for the pathogenesis of portal biliopathy; that it is the result of compression of the bile ducts, ischemia, or infection.

Compression theory

The first cholangiographic evidence of CBD varices compressing the bile duct was published by Williams *et al.*^[14] in 1982. In EHPVO, long standing obstruction of the portal vein leads to replacement of the portal vein by large collaterals along the CBD - the so-called cavernomatous transformation of the portal vein. These large collaterals compress the pliable CBD, leading to the changes seen on ERCP^[5-7]. Also, with increased duration of portal thrombosis, there is vascular neogenesis and formation of tumor-like connective tissue, which can encase the CBD or cause angulation of the bile ducts^[9]. In a study by Dilawari *et al.*^[5], 18 out of 20 patients had indentations suggestive of external compressions on ERCP. The reversibility of biliary tract changes after portal decompressive surgery^[11,15-17] or transjugular intrahepatic portosystemic shunts (TIPS)^[18,19], shown in various studies, further corroborates this mechanism.

Ischaemic theory

According to this theory, longstanding portal thrombosis leads to sclerosis of the veins draining the bile ducts, which in turn can lead to damage to the capillaries and arterioles. This interruption of the vascular supply can, in turn, lead to the development of ischaemic strictures in the bile duct which are not reversed after a portosystemic shunt or TIPS. In a study by Khuroo *et al.*^[7], strictures in the CBD, both short segment and long confluent, were the most common findings seen on ERCP suggestive of an ischemic pathology. Dhiman

et al.^[20] studied bile duct changes after shunt surgery in 5 patients by performing ERCP pre- and post-surgery and reported complete reversal in one patient, partial reversal in three and no reversal in one patient, postulating that ischemia or scarring may be the etiology behind persistence of bile duct changes.

Infective theory

Infection or cholangitis was postulated by some authors in earlier studies to be the cause of jaundice in patients with portal vein thrombosis^[15,21,22]. However, later cholangiographic studies have shown that changes in the biliary tract are seen even in asymptomatic patients, and cholangitis occurs late in its natural history. Cholangitis, once present, may lead to inflammation, neogenesis and deposition of fibrous tissue, along with persistence of strictures following shunt surgeries.

All the above mentioned mechanisms may be present simultaneously, resulting in the characteristic changes of portal biliopathy.

EPIDEMIOLOGY

Portal biliopathy is an uncommon presentation in patients with portal hypertension. In 1992, Dilawari *et al.*^[5] published a series of 20 patients with EHPVO in which ERCP was done prospectively, and found that changes in the biliary tract were seen in all of them. The left hepatic ducts were always involved, the right ductal system was involved in 56% and there were changes in the common bile duct in 90%. Sarin *et al.*^[6] found the incidence on ERCP to be 80%. Studies published by various authors utilising ERCP/magnetic resonance cholangiopancreatography (MRCP) found the frequency to be between 81%-100%^[5-10]. Portal biliopathy is also seen in patients with cirrhosis of the liver (0%-30%)^[1,23,24] and NCPF (9%-40%)^[1,24]. The natural history of portal biliopathy is not known. The majority of patients (70%-95%) do not manifest with any symptoms of biliary obstruction. However, patients with symptomatic portal biliopathy are normally older than patients presenting with EHPVO^[7,10], which is suggestive of long term obstruction. Patients with long term obstruction, or inadequate endoscopic or surgical management, may develop secondary biliary cirrhosis (2%-4%)^[1,9]. No evidence of malignant potential on long term follow-up exists in the literature.

CLINICAL FEATURES

In patients with EHPVO, 5%-38% develop symptomatic portal biliopathy^[5-10,25]. These symptoms may be secondary to bile duct obstruction like jaundice and pruritus, or to ductal stones like fever with chills and biliary colic. Dilawari *et al.*^[5] reported a 5% incidence of symptoms. Khuroo *et al.*^[7] reported a 38% incidence of symptoms ranging from jaundice, recurrent cholangitis

and biliary colic. All symptomatic patients in his study were adults and almost a decade older than the patients presenting with variceal bleeding. Sezgin *et al*^[10] studied 10 patients with portal biliopathy who presented with jaundice, cholangitis, pruritus and abdominal pain and their mean age at presentation was 36 years, whereas other patients with EHPVO generally presented with bleeding or splenomegaly during childhood. Their studies also suggest that portal biliopathy is a progressive condition which develops late in the course of portal hypertension and may progress to secondary biliary cirrhosis characterised by decreased serum albumin levels, ascites and a deranged coagulation time^[1,9].

INVESTIGATIONS

Most patients with EHPVO with biliary changes detected on ERCP are asymptomatic. However, because ERCP is an invasive procedure, its routine use in all patients with either EHPVO or NCPF is not justified. Liver function tests are the best initial investigations to identify patients who might benefit from imaging studies. A raised serum bilirubin level with a predominant increase in its direct component and an elevated serum alkaline phosphatase is an indication for performing biliary imaging. Serum albumin levels and prothrombin time abnormalities become abnormal only after prolonged biliary obstruction when secondary biliary cirrhosis develops.

Abdomen ultrasound with Doppler

Ultrasonography (USG) has a poor sensitivity in identifying the CBD in EHPVO as it is usually obscured by the portal vein collaterals. However, there is a role for USG in outlining the splenoportal axis before surgery and to identify gallbladder varices, which are seen in about 35% patients, if a cholecystectomy is planned^[26,27].

Endoscopic retrograde cholangiopancreatography

ERCP has been used by various authors to define portal biliopathy. The changes seen in the bile ducts include single or multiple smooth strictures of varying length and degree, saccular dilatations, indentations, dilated intrahepatic bile duct radicles, displacement of bile ducts, clustering and pruning of intrahepatic ducts, and filling defects in the CBD which may be due to stones or varices^[5-10,25]. These changes occur most commonly in the CBD and the left hepatic ducts. Although seen predominantly in EHPVO, patients with NCPF and cirrhosis also show these changes in 40% and 25% respectively^[1,23,24].

The differential diagnoses on cholangiography include sclerosing cholangitis, recurrent pyogenic cholangitis, CBD stones with stricture, and biliary ascariasis. Patients' history, clinical examination and ultrasound findings showing normal liver, portal cavernoma and echogenic shadowing suggestive of ascariasis may help in reaching a diagnosis^[1].

Figure 1 Magnetic resonance cholangiopancreatography showing common bile duct stricture with upstream dilatation of intra- and extrahepatic bile ducts. 1: Distance: 1.85 cm; 2: Distance: 2.57 cm; 3: Distance: 2.44 cm.

ERCP also has a therapeutic role in portal biliopathy. This includes removal of CBD stones, relief of cholangitis, and dilatation of dominant strictures with stenting. The latter is indicated only in patients not fit for surgery, or in whom shunt surgery is not feasible or has not reversed the biliopathy.

Presently, ERCP is indicated only if a therapeutic intervention is required and not for diagnosis.

Magnetic resonance cholangiopancreatography

Due to the invasive nature of ERCP and its attendant risks, magnetic resonance cholangiopancreatography (MRCP) with or without magnetic resonance (MR) portography has become the investigation of choice for portal biliopathy. The sensitivity of MRCP has been found to be similar to ERCP by various authors^[9,28]. Additional benefits of MR portography are that it differentiates choledochal varices from stones, images the splenoportal axis in surgical planning, and identifies portal collaterals (Figure 1).

Endoscopic ultrasonography

The additional information obtained from endoscopic ultrasonography (EUS) pertains to the differentiation between CBD varices^[29,30], stones, and tumours when other imaging modalities are not clear. EUS is not routinely recommended in the workup of a patient with portal biliopathy.

MANAGEMENT

Asymptomatic patients do not require any treatment if their liver function tests are within normal limits. Patients with persistently raised serum bilirubin and alkaline phosphatase levels need to be investigated by imaging (MRCP/ERCP/USG) to look for biliary tract changes^[1].

There is no consensus on the optimal treatment for symptomatic portal biliopathy. Endoscopic treatment is preferred in patients with CBD stones, cholangitis or if shunt surgery is not feasible^[1,17,31-34]. This includes use

of a balloon catheter or Dormia basket to clear CBD stones. Mechanical lithotripsy may be required for large stones. Endoscopic papillotomy with stenting or nasobiliary tube drainage may be necessary in patients with cholangitis^[1,34-37]. Balloon dilatation of dominant CBD strictures with stone extraction has also been described by various authors^[1,10,34].

The problems with endoscopic management are: (1) Filling defects seen on imaging may be due to varices and may lead to bleeding during attempted clearance. Stones usually move with a balloon catheter and varices appear as longitudinal defects on MRCP. Some authors prefer a balloon catheter over a Dormia basket for stone clearance as it is less traumatic^[34]; (2) Venous collaterals in the region of the ampulla of Vater may lead to bleeding during papillotomy, so this procedure should only be attempted in experienced centres which have a good surgical backup^[38,39]; (3) Balloon dilatation with stenting of dominant strictures may help to relieve biliary obstruction. However these stents become blocked frequently requiring multiple changes with their inherent risk of bleeding^[40]. Sezgin *et al.*^[10] reported long-term relief of portal biliopathy in only 3 out of 10 patients with endoscopic dilatation with stenting or nasobiliary drainage, whereas 7 out of 10 patients required repeated stent changes every 6 mo or earlier if cholangitis developed. Vibert *et al.*^[41] also reported long-term relief of biliary obstruction with percutaneous transhepatic biliary drainage with endobiliary stenting in only 3 out of 19 patients with symptomatic portal biliopathy. Furthermore, recurrent stent blockade with cholangitis may further decrease the chances of reversibility of the CBD obstruction following portosystemic shunt surgery; and (4) Multiple sessions require the patients to be compliant and have ready access to endoscopic expertise.

Therefore, although endoscopic extraction remains the preferred treatment in patients with CBD stones, most centres consider shunt surgery to be the first line of management for biliary obstruction secondary to bile duct strictures, unless complications like cholangitis or absence of a shuntable vein exist.

The role of ursodeoxycholic acid (UDCA) has not been evaluated for treatment or prophylaxis in portal biliopathy in any of the large studies. In a study by Condat *et al.*^[9], UDCA was effective in 3 out of 4 patients with portal biliopathy in relieving biliary symptoms and preventing recurrence. Most centres, however, rely on endoscopic extraction of biliary stones and experience in use of UDCA is limited.

Surgical management

The first published report of surgical treatment of portal biliopathy was by Hunt^[4] in 1965. He described separating the collaterals from the bile duct wall by dividing the fibrous adhesions between them and reported a relief from jaundice in the early postoperative period. However this technique has a high risk of intraoperative

hemorrhage as the collaterals are closely related to the wall of the CBD and attempting to separate them may cause torrential bleeding.

Choudhuri *et al.*^[11] in 1988 published the first case report of relief of CBD obstruction secondary to portal cavernoma after a proximal lienorenal shunt, in a patient with symptomatic portal biliopathy with EHPVO. Chaudhary *et al.*^[15] then published a series of 9 patients, out of whom 7 underwent proximal lienorenal shunts for symptomatic portal biliopathy. Five patients experienced reversal of their portal biliopathy with two patients requiring a biliary bypass (Roux-en-Y hepaticojejunostomy) for refractory bile duct strictures. Other authors have published similar results^[16,41].

In patients with non cirrhotic portal hypertension (EHPVO and NCPF) with portal biliopathy, portosystemic shunt surgery is the treatment of choice. The advantages of this approach are: (1) A successful portosystemic shunt not only prevents variceal bleeding but in a large number of patients may be the only treatment required for portal biliopathy^[11,15,16,41-43]; (2) Primary biliary bypass for portal biliopathy is associated with a risk of severe intraoperative bleeding due to the presence of large collaterals in the bile duct wall^[7,15,16,41,44,45], and (3) Even if a portosystemic shunt fails to completely revert the bile duct obstruction, a patent shunt decompresses the collaterals present in the region of the bile duct enough to render a later biliary bypass possible^[15,16].

Portosystemic shunt surgery is also the procedure of choice in patients with imaging features of portal biliopathy who are otherwise asymptomatic and are being operated on for other complications of portal hypertension like variceal bleeding or symptomatic hypersplenism, as these patients may develop significant bile duct obstruction later, even after splenectomy and devascularisation^[7,46]. A suggested algorithm for the management of portal biliopathy is shown in Figure 2.

In conclusion, although abnormalities in the biliary tract on imaging are seen in the majority of patients with EHPVO, symptomatic portal biliopathy is a late and uncommon presentation in the natural history of the condition. The exact pathogenesis of portal biliopathy is not clear, but compression by dilated collaterals, ischemia resulting from venous thrombosis, and infection may all have a role to play in its development. The diagnostic investigation of choice is an MRCP which is done based on clinical suspicion and biochemical abnormalities. Endoscopic management is indicated in the presence of CBD stones, cholangitis and dominant strictures without a shuntable vein. Portosystemic shunt surgery, if feasible, is indicated in most patients, as it causes reversal of portal biliopathy and also renders a subsequent biliary bypass easier if the biliary obstruction persists. Thus, in patients with portal biliopathy, both endoscopic and surgical management are complementary and should be used appropriately according to individual situations.

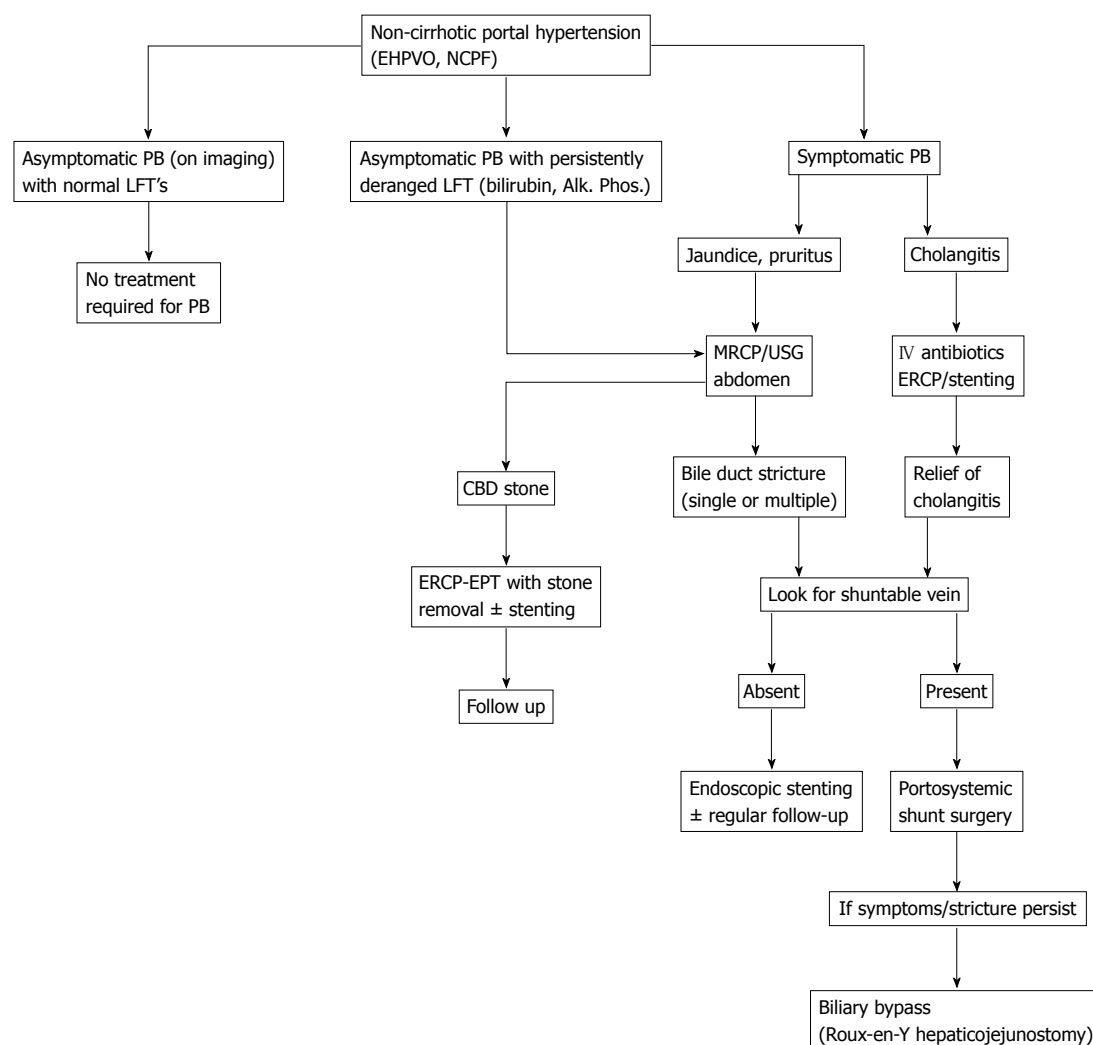

Figure 2 Algorithmic approach to management of portal biliopathy in patients with non-cirrhotic portal hypertension. EHPVO: Extrahepatic portal venous obstruction; NCPF: Non-cirrhotic portal fibrosis; LFT: Liver function test; PB: Portal biliopathy; ERCP: Endoscopic retrograde cholangiopancreatography; EPT: Endoscopic papillotomy; CBD: Common bile duct; MRCP: Magnetic resonance cholangiopancreatography; USG: Ultrasonography; Alk.: Alkaline; Phos.: Phosphatase.

Abstract

Hepatitis C virus (HCV) infects approximately 200 million people worldwide. Interferon-based therapies have dominated over the past two decades. However, the overall response rates remain suboptimal. Thanks to the tremendous effort from both academia and industry, two serine protease inhibitors telaprevir and boceprevir for treating chronic hepatitis C have finally reached the clinic. Although these compounds are only approved for combination use with interferon and ribavirin in genotype 1 HCV infected chronic patients, the management of HCV patients however is now evolving incredibly. Here, we overviewed a series of landmark studies, regarding the clinical development of telaprevir and boceprevir. We discussed the mechanism-of-action of telaprevir/boceprevir and their potential application in HCV-positive liver transplantation patients. We further emphasized some emerging concerns with perspective of further development in this field.

INVITED COMMENTARY ON HOT ARTICLES

Since the discovery of hepatitis C virus (HCV) in 1989^[1], the lack of good model systems has hampered the research at the early stages. Even though still little is known about the virus, interferon was found to be effective for treating chronic HCV and the first interferon- α (IFN- α) is approved by the United States Food and Drug Administration (FDA) to treat HCV in 1991^[2]. Interferons have a vital role for immune modulation of the host cells and involve the induction of a multitude of interferon-stimulated genes to establish an antiviral status^[3]. Through a series of optimizations, the current pegylated interferon (peg-IFN) in combination with ribavirin has dramatically improved the outcome, but still only approximately 50% of the patients can develop a sustained virologic response (SVR)^[4,5].

Thanks to the development of various cell culture models and the important involvement of biotechnology^[6], research in the HCV field has been flourishing both in academy and industry, over the past decade. This progress has enabled further improvement on the current interferon-based standard antiviral therapy and

the development of novel antivirals with distinct mechanism of action. A range of directly acting antiviral agents (DAAs), including protease and polymerase inhibitors, have been in various stages of clinical development^[7]. The serine protease inhibitors telaprevir and boceprevir are the most advanced in clinic. Both had been approved by FDA in May 2011 for treating chronic genotype 1 HCV infection and later were also approved by the European Medicines Agency^[7].

Mechanism-of-action of telaprevir and boceprevir

The HCV genome composes of a single open reading frame, encoding a polyprotein precursor of approximately 3000 amino acids, flanked by 5' and 3' non-coding region (NCR). Translation of the viral polyprotein is mediated by an internal ribosome entry site located within the highly conserved 5' NCR. The synthesized polyprotein is subsequently cleaved into four structural (core, E1, E2 and p7) and six non-structural (NS2, NS3, NS4A, NS4B, NS5A and NS5B) proteins^[8]. Processing of structural proteins, including the p7/NS2 junction, is carried out by at least two host signal peptidases and non-structural proteins and is matured by two viral proteases, NS2 and NS3/4A^[8,9].

The NS3/4A serine protease is a non-covalent, heterodimer complex formed by the catalytic subunit of the N-terminal serine protease domain of NS3 and the activation subunit of the NS4A cofactor. Unique to the NS3 protease is an extended polydentate substrate binding cleft, which ensures substrate specificity^[10]. It is responsible for the proteolytic cleavage of NS3/NS4A self cleavage, NS4A/NS4B, NS4B/NS5A and NS5A/NS5B. The multi-functional property of NS3/4A protease has attracted for targeted drug development. Current protease inhibitors can be divided into covalent and non-covalent peptidomimetic inhibitors. Telaprevir and boceprevir are covalent linear inhibitors, discovered by using structure-based drug design approach^[11,12]. Both act *via* formation of a reversible covalent interaction with serine-139. The assailment of electrophilic carbonyl of the ketoamide by the catalytic serine leads to tetrahedral formation which mimics the transition state of peptide bond cleavage. This is further stabilized by additional ionic interactions with the active site^[11,12]. However, telaprevir and boceprevir were designed to target the protease of genotype 1 HCV and therefore their activity varies among genotypes. Experimental data has shown that both were active against genotypes 2, 5 and 6, but not 3^[13]. Clinical evidence suggested that telaprevir was effective against genotype 2 but not genotype 3 and uncertain for genotype 4^[14,15].

Clinical efficacy

Two weeks monotherapy with telaprevir has demonstrated substantial antiviral activity in patients with genotype 1 HCV in a phase 1 trial (3 log drop in viral load in majority of patients). However, some patients showed resistance to telaprevir can be seen from viral break-

through during dosing and were associated with selection of the variants^[16]. Therefore, combination therapy with peg-IFN- α /ribavirin was required for the subsequent larger multicentre phase 2, PROVE 1^[17], PROVE 2^[18] and PROVE 3^[19] trials. Overall, telaprevir increased 20%-30% SVR rates in both naïve and genotype 1 treated patients (Figure 1). Ribavirin was an essential component of this triple therapy (Figure 1).

Phase 3 trials in the treatment of naïve or experienced patients were carried out in the ADVANCE^[20] and REALIZE^[21] studies, respectively. Superior SVR rates with treatment of telaprevir-based regimens were confirmed in both naïve and experienced genotype 1 patients. The illuminate phase 3 study supported the concept of response-guided telaprevir combination treatment (RGT) in naïve patients. This study summarized that treatment of telaprevir in combination with peg-IFN/ribavirin in the first 12 and 24 wk was noninferior to the same regimen for 48 wk in patients with undetectable HCV RNA at weeks 4 and 12^[22].

One week monotherapy with boceprevir resulted in an average HCV RNA load reduction of about 1.0 and 1.6 log₁₀ IU/mL in nonresponders of peg-IFN/ribavirin at dose of 200 mg and 400 mg, 3 times a day, respectively^[23]. However, during boceprevir monotherapy, resistance mutations at six positions within the NS3 protease were detected. All mutations were associated with reduced replicative fitness estimated by mathematical modeling with cross-resistance to telaprevir^[24]. Similarly, the successful clinical development of boceprevir treatment was used in combination with peg-IFN/ribavirin both in naïve and experienced genotype 1 patients, as demonstrated in the phase 2b SPRINT-1 trial (Figure 2)^[25], the phase 3 SPRINT-2 trial (Figure 2)^[26] and the phase 3 RESPOND-2 trial (Figure 2)^[27].

The most serious adverse effects of telaprevir were rash and anemia and of boceprevir were anemia, dysgeusia, neutropenia and anal discomfort.

The use of DAAs in liver transplant patients?

End-stage liver disease caused by chronic HCV infection is currently the leading indication for liver transplantation^[28]. However, HCV re-infection of the graft occurs universally and often results in accelerated recurrence of liver fibrosis and early development of cirrhosis^[29]. In general, peg-IFN/ribavirin is much less effective in transplant patients with approximate SVR rates of only 20%^[30]. An aggravated course of infection and more resistance to antiviral therapy have been attributed to several host and viral factors, in particular the application of specific immunosuppressive medication^[31].

The suppression of HCV viraemia in pre-transplant patients may attenuate the risk of viral recurrence. However, the tolerability and efficacy of peg-IFN/ribavirin antiviral therapy is compromised in decompensated cirrhosis patients^[32]. For telaprevir or boceprevir, a few patients with advanced fibrosis or compensated cirrhosis have been included in these phase 3 trials^[20-21,26-27]. How-

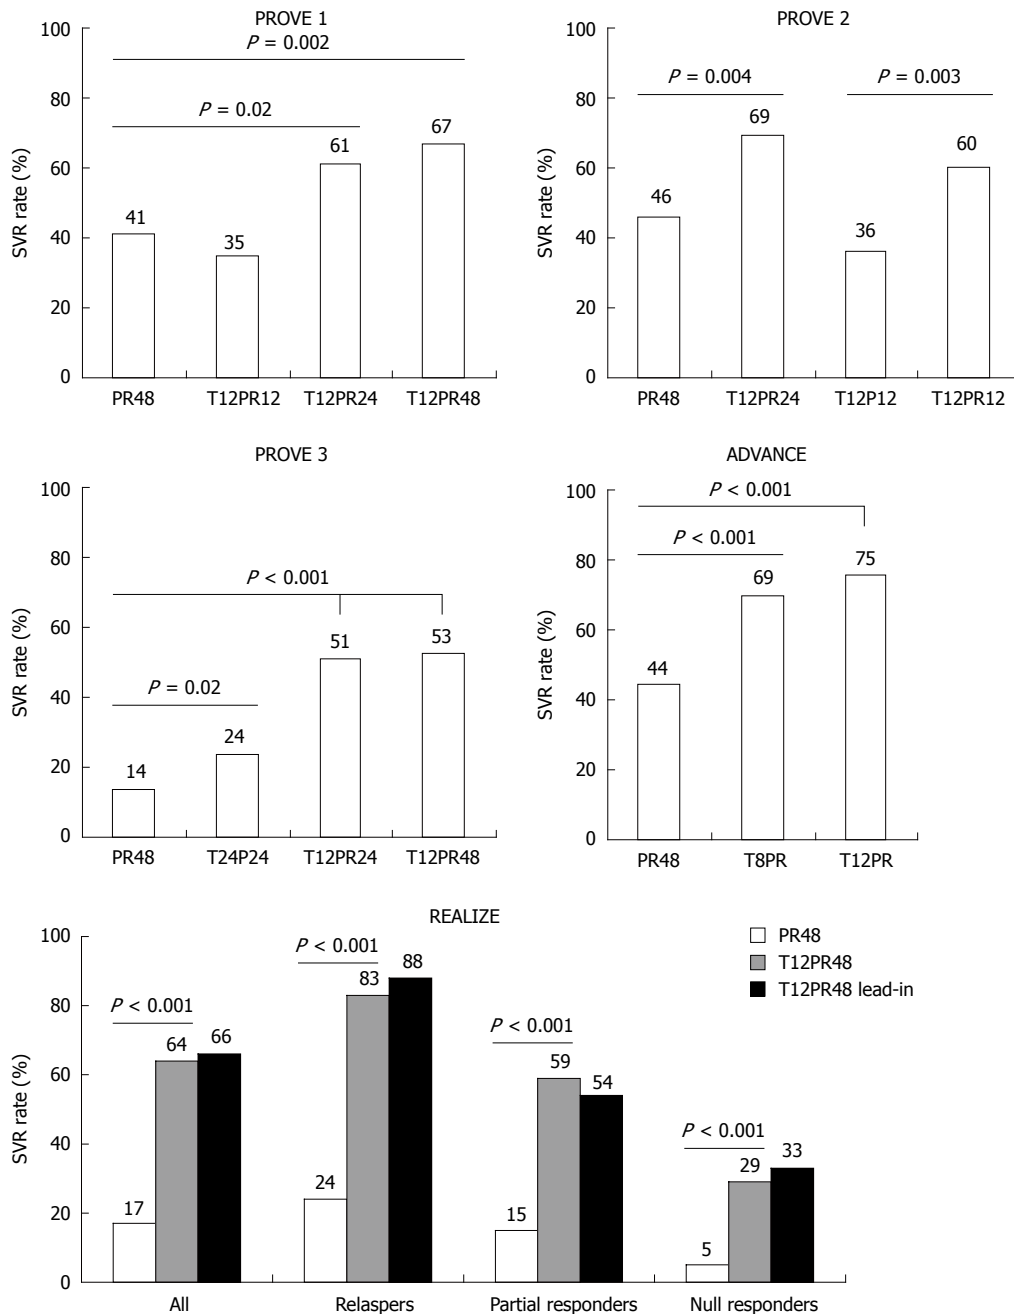

Figure 1 The outcome of the five landmark trials for telaprevir-based triple therapy in hepatitis C virus genotype 1 patients. Sustained virologic response rates are compared between groups. PROVE 1, PROVE 2 and ADVANCE trials were conducted in treatment-naïve patients. PROVE 3 and REALIZE trials were conducted in treatment-experienced patients. T: Telaprevir; P: Peg-IFN; R: Ribavirin; The numbers (8, 12, 24 or 48): Week of treatment; SVR: Sustained virologic response.

ever, the response rates in patients with advanced fibrosis were significantly lower than in patients with mild to moderate fibrosis but there is no experience in patients with decompensated cirrhosis so far.

Although prophylactic treatment, preemptive treatment or treatment of established HCV recurrence after transplantation with peg-IFN/ribavirin is common, its tolerability and efficacy remain unsatisfactory^[33]. Therefore, there is much expectation of telaprevir and boceprevir for improving the outcome in liver transplant patients. In the 18th annual congress of the International Liver Transplantation Society this year in San Francisco, United States, the first series of clinical data

of treating HCV recurrence using telaprevir or boceprevir in liver transplant patients were revealed, although these were rather small clinical studies. In a multicenter study of 7 patients, 2 patients had an undetectable viral load and 2 had viral load below 2 log at week 12 after treatment with boceprevir in combination with peg-IFN/ribavirin. However, all patients had severe anemia requiring erythropoietin and 4 patients required granulocyte colony stimulating factor. The dosage of peg-IFN and/or ribavirin was reduced in 4 patients and treatment was stopped prematurely in 3 patients^[34]. In one of the telaprevir-based triple therapy studies, 2 out of 9 patients achieved rapid viral response, however hematological ad-

Figure 2 The outcome of the three landmark trials for boceprevir-based triple therapy in hepatitis C virus genotype 1 patients. Sustained virologic response rates are compared between groups. The SPRINT-1 and SPRINT-2 trials were conducted in treatment-naïve patients. The RESPOND-2 trial was conducted in treatment-experienced patients. B: Boceprevir; P: Peg-interferon; R: Ribavirin; The numbers (4, 24, 28 or 48): Week of treatment; SVR: Sustained virologic response; RGT: Response-guided telaprevir combination treatment.

verse events were common, including anemia and leucopenia^[35]. In another telaprevir-based triple therapy study, 4 out of 5 patients were telaprevir tolerated but 1 patient stopped the treatment due to complications. Two out of these 4 patients obtained SVR after 5 wk of therapy. Another 2 patients achieved 2-log and 3-log viral reduc-

tions in the 1st week follow-up, respectively^[36]. Triple combination therapy has shown substantial antiviral efficacy but larger properly designed trials are definitely required to further evaluate the use of telaprevir and boceprevir in this setting. However, these studies have consistently raised the concerns of poor tolerability of these compounds in transplant patients. Clinical studies of additional DAAs peri-transplant are in progress and should be monitored closely.

In addition to the adverse events, potential interactions between telaprevir/boceprevir with immunosuppressive drugs are other concerns. As reported in a phase 1 study, telaprevir interferes the metabolism of both cyclosporin A (CsA) and tacrolimus by inhibition of cytochrome P450 3A enzymatic activity^[37]. Telaprevir caused a significant increase in blood concentrations of both immunosuppressants and could potentially lead to serious or even life-threatening adverse effects. McCashland *et al.*^[35] has specifically evaluated the drug level profile of CsA during telaprevir therapy in liver transplant patients, however no negative impact in achieving CsA target levels was observed. In fact, different immunosuppressive drugs can also have distinct effects on peg-IFN/ribavirin, such as CsA and MPA can promote the antiviral effects of interferon whereas tacrolimus does not^[31,38,39]. Thus, more attention from both basic and clinical perspective is needed, regarding drug to drug interaction with telaprevir/boceprevir.

The role of interferon and ribavirin?

Monotherapy with telaprevir or boceprevir not only been associated with resistance but also the antiviral potency is not sufficient for complete eradication of the virus^[16,24]. Therefore, combination treatment with peg-IFN/ribavirin has emerged as the ultimate solution to resolve these limitations. A specific issue which would be concerned is that whether the *IL28B* genetic variation as one of the important SVR prediction factors to peg-IFN/ribavirin, is still relevant to telaprevir/boceprevir-based triple combination therapy or not. In treatment of naïve patients, the *IL28B* rs12979860-CC genotype was a positive predictor to select appropriate candidates for RGT in the ADVANCE and SPRINT-2 trials^[20,26]. In treatment of experienced patients, the CC genotype however is less frequent than in general population, *IL28B* therefore is expected to be less important for response prediction. However, data remain limited to address the exact prediction value of *IL28B* genotype in telaprevir/boceprevir-based regimens. Another clear evidence from the PROVE and SPRINT trials suggested that the treatment regimens with low-dose or without ribavirin were associated with lower SVR rates, probably due to viral breakthrough and viral relapse after therapy^[18-19,25].

An emerging concept is the development of interferon-free regimens, which aims to limit the contraindications and adverse effects of peg-IFN. The combination of different reagents offers the potential for interferon-

free therapy including the development of various DAAs such as protease, NS4B, NS5A, polymerase inhibitors and host-targeting agents including cyclophilin inhibitors and anti-miR-122 oligonucleotides^[40]. In current clinical trials, different DAA combinations with or without ribavirin are the main scenario. It is not surprising that with or without interferon, a study of combining a non-nucleoside polymerase inhibitor with a protease inhibitor clearly showed the benefit of ribavirin^[41]. In spite of the mechanism of how ribavirin can synergize interferon that has been extensively extrapolated^[42-44], the mechanism of how ribavirin works with DAAs are poorly investigated. Notably, a recent study has shown that high SVR rate could be achieved with two DAAs (the NS5A inhibitor daclatasvir and the NS3 inhibitor asunaprevir) only, although higher SVR rates were achieved when combined with peg-IFN/ribavirin^[45]. Therefore, it remains an open question regarding the future of ribavirin in interferon-free-based DAA combination therapy. Further basic and clinical research will conceivably help to figure out this issue.

Summary and perspectives

The approval of telaprevir and boceprevir by FDA and the European Medicines Agency in last year (2011) has indeed changed the management of chronic HCV. From these series of clinical landmark studies, a 20%-30% increase of SVR rates were obtained with the additional telaprevir/boceprevir to the conventional standard peg-IFN/ribavirin therapy. Despite these exciting results, certainly there are several remaining concerns. An apparent limitation of telaprevir/boceprevir as well as most of the pipeline DDAs (such as protease inhibitors asunaprevir, BI 201335 and ABT-450) is genotype 1 specificity, whereas other HCV genotypes also prevail all over the world. Secondly, these compounds have very low genetic barrier to the development of resistant viral variants. Thirdly, although telaprevir/boceprevir are generally well tolerated, their adverse effects are still hampering the successful application in specific populations, particularly for liver transplant patients.

Perspectively, these issues could likely be minimized by further optimizing the clinical protocol. In addition, by the development of other compounds, more optimal combinations will be available. As being expected, the dream of achieving high SVR rates with all-oral interferon-free regimens will be no longer far from clinical reality.

Abstract

Cholangiopathies are a group of diseases primarily or secondarily affecting bile duct cells, and result in cholangiocyte proliferation, regression, and/or transformation. Their etiopathogenesis may be associated with a broad variety of causes of different nature, which includes genetic, neoplastic, immune-associated, infectious, vascular, and drug-induced alterations, or being idiopathic. miRNAs, small non-coding endogenous RNAs that post-transcriptionally regulate gene expres-

sion, have been associated with pathophysiological processes in different organs and cell types, and are postulated as potential targets for diagnosis and therapy. In the current manuscript, knowledge regarding the role of miRNAs in the development and/or progression of cholangiopathies has been reviewed and the most relevant findings in this promising field of hepatology have been highlighted.

INTRODUCTION

Cholangiocytes are the epithelial cells lining the bile ducts, and are key players in normal liver physiology^[1]. They participate in fundamental secretory processes by modifying the composition and flow of primary bile generated at the canaliculi of hepatocytes upstream of the biliary tree. Thus, transport of water, ions or solutes between the blood and the bile-duct lumen finally result in fluidization and alkalization of bile^[1-4]. Although cholangiocytes only represent 3%-5% of the total liver cell population, they may account for up to 30% of to-

tal bile flow^[1]. Cholangiocytes contain a single primary cilium extending from the apical membrane into the bile-duct lumen^[5]. This antenna-like organelle possesses sensory properties that detect physical and chemical changes in bile that are transmitted into the cell to activate signaling pathways and finally modify cellular functions. The primary cilium of cholangiocytes functions as a mechano- (detecting changes in bile flow)^[6], chemo- (interacting with different molecules^[7] and vesicles^[8]), and osmo- (identifying changes in osmolarity: hypo- and hyper-tonicity)^[9] sensor.

In addition, cholangiocytes are primarily or secondarily affected in a group of diseases termed cholangiopathies, whose etiopathogenesis is of diverse nature (genetic, neoplastic, immune-associated, idiopathic, infectious, vascular or drug-induced)^[10]. These biliary diseases may result in cholangiocyte proliferation, regression and/or transformation. Important advances are being achieved in understanding the molecular mechanisms involved in the development and progression of these disorders. In this regard, there is increasing evidence suggesting the role of miRNAs in the etiopathogenesis of cholangiopathies, which are postulated as potential targets for diagnosis and therapy.

miRNAs are small non-coding RNAs (approximately 22 nucleotides) that regulate the expression of multiple genes by binding to complementary sites of targeted mRNAs, causing translational repression (imperfect target duplexes) or degradation (perfect matches)^[11,12]. They participate in the regulation of multiple cell types under physiological and pathological conditions, and are fundamental in different cellular processes such as development, proliferation, apoptosis, metabolism, morphogenesis, and in diseases^[13,14]. In the current article, knowledge regarding the role of miRNAs in the development and/or progression of cholangiopathies has been highlighted.

CHOLANGIOCARCINOMA

Cholangiocarcinoma (CCA) is a malignant tumor affecting the biliary tree^[15,16]. The incidence of CCA (1:50 000) is increasing worldwide and the therapeutic options are very limited because of high chemoresistance. CCA accounts for up to 10%-15% of primary hepatobiliary malignancies and 3% of all gastrointestinal tumors, affecting individuals of both sexes. Owing to slow growth and late metastasis, this cancer is usually diagnosed in patients older than 65 years when it is at an advanced stage, thus reducing the success of surgical procedures. Complications of CCA include bile-duct obstruction, liver failure, metastasis to other organs, infections, and uncontrolled vomiting. Although the pathogenesis of CCA is poorly understood, the presence of primary sclerosing cholangitis, chronic biliary irritation, or choledochal cysts appears to predispose to the development of this cancer.

CCAs can be anatomically classified into extrahepatic or intrahepatic^[15,16]. Extrahepatic is more common than

intrahepatic CCA, accounting for up to 80%-95% of all CCAs. In addition, depending on the tumor location in the extrahepatic biliary system, extrahepatic CCA can be divided into proximal or perihilar (also frequently referred to as Klatskin tumor), and distal. On the other hand, intrahepatic CCA originates within the liver and accounts for up to 5%-20% of all CCAs.

Increasing evidence suggests the importance of miRNAs in the pathogenesis of CCA. Thus, global changes in the miRNA profile of malignant cholangiocytes has been reported^[17-21], which may alter different cholangiocyte features such as cell cycle, proliferation, migration and apoptosis (Table 1).

Cell cycle, proliferation and migration

Different miRNAs are able to act as onco-miRNAs by repressing the expression of tumor suppressor genes. In this regard, miR-421, upregulated in human CCA, was reported to modulate the expression of farnesoid X receptor (FXR), an event associated with cell proliferation, colony formation, and migration *in vitro*^[22]. FXR is a member of the nuclear receptor superfamily that plays crucial roles in bile acid, cholesterol, lipid and glucose metabolism^[23,24]. Likewise, FXR was shown to act as a tumor suppressor for hepatocellular carcinoma and breast cancer^[23,24]. Aberrant bile-acid secretion has been linked to CCA, therefore, further investigations will be needed to test the interplay between bile acids, FXR and miRNAs on biliary tract tumorigenesis.

Another miRNA involved in tumor proliferation is miR-21, which is reported to be overexpressed in human CCA due to upregulation of arsenic resistance protein 2 (Ars2)^[25]. This protein plays an important role in miRNA biogenesis, and hence its depletion reduces the levels of different miRNAs, including miR-21. Ars2 knock-down in CCA cells decreases miR-21 levels, inhibits cell proliferation, and prevents tumor formation in immunodeficient mice. It is suggested that miRNA-21 may negatively control the expression of tumor suppressor phosphatase and tension homolog (PTEN)^[18,21,25] leading to cell proliferation. Moreover, miR-21 is suggested to regulate the expression of the tissue inhibitor of metalloproteinase (TIMP)-3^[20], an inhibitor of cell-matrix TIMP activity downregulated in CCA, and could result in increased migration properties.

In addition, it has been recently reported that miR-NA-26a is overexpressed in human CCA promoting cell proliferation and migration *in vitro*, and tumor growth *in vivo*^[26]. This miRNA was demonstrated to downregulate directly the expression of glycogen synthase kinase (GSK)-3 β ^[26]. This enzyme phosphorylates the serine and threonine residues of β -catenin, leading to its degradation. Thus, miR-26a/GSK-3 β targeting results in intracellular accumulation of β -catenin that activates the expression of c-Myc, cyclin D1, and peroxisome proliferator-activated receptor δ ; three proteins involved in dedifferentiation, tumor growth, and migration^[26].

Induction of chronic cholestasis in a new murine model accelerates the progression of CCA by alter-

Table 1 Classification of miRNAs differentially expressed in cholangiocarcinoma regarding their action, expression and targets

miRNA	Expression	Disease	Target	Altered function	Ref.
miR-320	Down	Human-ICC	Mcl-1		[17]
miR-29b	Down	Human-CCA	Mcl-1		[21,30]
miR-204	Down	Human-ICC	Bcl-2	Apoptosis	[17]
miR-25	Up	Human-ICC	DR4		[29]
miR-21	Up	Human-CCA	PDCD4		[20,25]
miR-421	Up	Human-ICC	FXR		[22]
miR-34a	Down	Mouse-CCA	c-Myc		[27]
miR-210	Up	Mouse-CCA	Mnt	Proliferation	[27]
miR-21	Up	Human-CCA	PTEN		[18,21,25]
miR-26a	Up	Human-CCA	GSK-3 β		[26]
miR-421	Up	Human-ICC	FXR		[22]
miR-21	Up	Human-CCA	TIMP-3	Migration	[20]
miR-26a	Up	Human-CCA	GSK-3 β		[26]
miR-494	Down	Human-CCA	CDK-6	Cell cycle	[19]
miR-141	Up	Human-CCA	Gen CLOCK	Circadian rhythm	[18]
miR-370	Down	Human-CCA	MAP3K8, DNMT-1		[38]
miR-373	Down	Human-ECC	MBD2	Epigenetics	[36,37]
miR-148a	Down	Human-CCA	DNMT-1		[39]
miR-152	Down	Human-CCA	DNMT-1		[39]
miR-let7a	Up	Human-CCA	NF2		[41]
miR-21	Up	Human-CCA	PTEN	Chemoresistance	[18]
miR-200b	Up	Human-CCA	PTPN12		[18]

miRNA-15a/Cdc25A interplay participates in hepatic cystogenesis of polycystic liver diseases. miRNA-15a directly targets the cell cycle regulator Cdc25a. In polycystic rat and human cholangiocytes, miR15a is downregulated, thus resulting in Cdc25a upregulation, cell proliferation and cystogenesis. The Cdc25a inhibitor vitamin K3 was demonstrated to target Cdc25a, blocking the hepatorenal cystogenesis of several rodent models of polycystic kidney and liver disease. This suggests the therapeutic potential of vitamin K3 for polycystic kidney and liver diseases. CCA: Cholangiocarcinoma; ICC: Intrahepatic cholangiocarcinoma; ECC: Extrahepatic cholangiocarcinoma; CDK: Cell division kinase; Mcl-1: Myeloid cell leukemia sequence 1; Bcl-2: B-cell lymphoma 2; CDK: Cyclin-dependent kinase; DR4: Death receptor 4; PDCD4: Programmed cell death protein 4; FXR: Farnesoid X receptor; TIMP: Tissue inhibitor of metalloproteinase; GSK: Glycogen synthase kinase; MBD: Methyl-CpG-binding domain; MAP3K8: Mitogen-activated protein kinase 8; DNMT: DNA methyltransferases; NF2: Neurofibromatosis 2; PTEN: Phosphatase and tension homolog; PTPN12: Protein tyrosine phosphatase non-receptor type 12.

ing miRNA-34a, let-7a and miRNA-210 expression^[27]. Downregulation of miRNA-34a results in overexpression of its target c-Myc that mediates the upregulation of cyclin D1. In this regard, knockdown of c-Myc reduces progression of CCA. Moreover, in this animal model, the suppressor of miRNAs biogenesis LIN28B is found to be upregulated. LIN28B specifically binds to the family of let-7 miRNA precursors, inhibiting their processing, and inducing their degradation^[28]. These experimental data suggest that LIN28B upregulation in humans might also be associated with the inhibition of let-7a, a miRNA involved in the development of cystic hyperplasia, cystic atypical hyperplasia, cholangioma and CCA. On the other hand, the hypoxia inducible factor-2 α was shown to mediate miRNA-210 upregulation, which further inhibits Mnt (transcriptional repressor and antagonist of c-Myc-dependent transcriptional activation and cell growth)^[27].

Among those miRNAs reported to be downregulated in CCA based on miRNA arrays, miR-494 is involved in the control of the cell cycle by direct targeting cyclin-dependent kinase-6^[19]. Thus, it is suggested that miRNA-494 could be a potential therapeutic target for CCA because its overexpression decreases the growth of bile-duct cancer cells *in vitro* and *in vivo*^[19].

Apoptosis

Activation of anti-apoptotic pathways is a general event

involved in carcinogenesis. In this regard, CCA is often associated with alterations in the expression profile of miRNAs that regulate apoptosis. Thus, miRNA-25, which is overexpressed in CCA, may protect cholangiocytes from tumour necrosis factor-related apoptosis-inducing ligand-induced apoptosis through the inhibition of death receptor 4^[29]. Likewise, the overexpression of miRNA-21 in CCA is also able to downregulate the programmed cell death protein 4^[20,25].

On the other hand, several miRNAs that modulate proapoptotic mechanisms are downregulated in CCA. Among those downregulated miRNAs, both miR-320^[17] and miR-29b^[21,30] play a role in the expression control of the antiapoptotic effector myeloid cell leukemia sequence 1, thus promoting cell survival and proliferation. Moreover, miR-204, which is also downregulated in CCA, targets the antiapoptotic protein B-cell lymphoma 2^[17].

Epigenetics

Although genetic alterations have been widely associated with CCA, epigenetic modifications are poorly understood in this type of cancer. However, CCA has been associated with aberrant DNA methylation, which is an essential mechanism for gene expression regulation^[31,32]. This mechanism is mostly regulated by at least three DNA methyltransferases (DNMT-1, DNMT-3A and DNMT-3B). Once a DNA sequence becomes methyl-

ated, it can repress transcription by blocking the recognition of transcriptional activators to DNA sequences, or by recruiting methyl-CpG-binding domain (MBD) proteins to modify chromatin compaction. MBD proteins are transcription repressors that bind to methylated gene promoters, resulting in gene expression silencing. Interestingly, aberrant DNA methylation has been found in many types of cancers, indicating that hypomethylation or hypermethylation of gene promoter CpG islands may result in tumor cell genomic instability or tumor suppressor gene silencing, respectively^[33,34]. Moreover, both miRNAs and methylation are reversible regulators that can interact with each other^[35]. In this regard, miRNA-373, which was recently reported to be downregulated in hilar CCA, negatively regulates MBD2 protein expression through specific binding to its 3' untranslated region (3'-UTR)^[36]. As a result of miRNA-373 downregulation in CCA, MBD2 expression is upregulated, leading to hypermethylation and silencing of the tumor suppressor gene *RASSF1A*. Hence, miRNA-373 downregulation is associated with poor cell differentiation, advanced clinical stage, and shorter survival in hilar CCA. Interestingly, miRNA-373 expression can also be regulated by MBD2 in CCA^[37].

In addition, it has been demonstrated that interleukin-6 (IL-6) may epigenetically regulate the expression of selected miRNAs and contribute to CCA growth^[38]. IL-6, an inflammation-associated cytokine that induces mitogen and survival features in cholangiocytes, is overexpressed in human CCA and presumably contributes to tumor cell growth. In this regard, IL-6 overexpression in CCA cells stimulates the expression of different methyltransferases (DNMT-1 and HASJ4442) that further downregulate the expression of seven miRNAs; one of these downregulated miRNAs, miRNA-370, directly targets the oncogene mitogen-activated protein kinase mitogen-activated protein kinase 8 in both *in vitro* and in tumor cell xenografts *in vivo*^[38]. Moreover, IL-6 may also regulate the expression of other miRNAs, such as miR-148a, miRNA-152 and miRNA-301^[39]. These three miRNAs are downregulated in CCA cells and possess sequence complementarity to the 3'-UTR region of the DNMT-1 mRNA transcript. However, only miRNA-148a and miRNA-152 directly regulate DNMT-1 expression. Interestingly, DNMT-1 modulates the expression of the tumor suppressor genes *Rassf1a* and *p16INK4a* by promoter hypermethylation, leading to malignant cell transformation.

Chemoresistance

CCAs are tumors with a marked multidrug resistance phenotype that includes changes in the expression of genes involved in the apoptosis/survival balance^[40].

As mentioned above, miRNA-21 and miRNA-200b are highly overexpressed in malignant cholangiocytes^[18]. These two miRNAs are suggested to contribute to chemoresistance in CCA by modulating the chemotherapy-induced apoptosis. Thus, overexpression of oligonucle-

otides anti-miR21 and anti-miR200b in malignant cholangiocytes cell lines satisfactorily increases gemcitabine-induced cytotoxicity. Moreover, miRNA-21 targets the tumor suppressor PTEN, which through its phosphatase activity inhibits phosphatidylinositol 3-kinase-dependent growth and survival. In addition, miRNA-200b targets the protein tyrosine phosphatase non-receptor type 12 that is involved in cell growth, cell dedifferentiation and oncogenic transformation.

In contrast to the aforementioned data obtained using an experimental animal model of chemically induced CCA, other authors have reported that miRNA-let7a is overexpressed in human CCA^[41]. Thus, miRNA-let7a overexpression is able to target the tumor suppressor neurofibromatosis 2 (NF2), which modulates the signal transducer and activator of transcription 3 (STAT3)-activated survival mechanism^[41]. Interestingly, intratumor administration of oligonucleotides anti-miRNA-let7a increases NF2 and decreases p-STAT3 expression in CCA xenografts *in vivo*. Moreover, these effects increase gemcitabine toxicity, resulting in decreased tumor growth^[41].

Circadian rhythm

The circadian rhythm controls on a 24-h range many fundamental physiological features such as behavior, metabolism or cell proliferation. The suprachiasmatic nuclei located in the hypothalamus synchronizes the molecular clocks in most mammalian cells through different circadian physiological rhythms including rest-activity, body temperature, feeding patterns, and hormonal secretions. Therefore, circadian alterations have been suggested to affect carcinogenesis risk also in humans^[42]. In this regard, miRNA-141, overexpressed in intrahepatic CCA, was predicted by bioinformatics approaches to target CLOCK directly; a tumor suppressor that controls the cellular circadian rhythm^[18]. Indeed, CLOCK may inhibit cell cycle, both directly and indirectly, and increases apoptosis. Administration of oligonucleotides anti-miRNA-141 in CCA cells results in CLOCK protein downregulation. These data indicate that circadian rhythm and miRNAs may interact in physiological and pathological conditions.

POLYCYSTIC LIVER DISEASES

Polycystic liver diseases (PCLDs) are genetic disorders characterized by bile-duct dilatation and/or cyst development, which become progressively more severe and require liver transplantation as the only therapeutic option^[43]. The large volume of hepatic cysts causes symptoms such as abdominal distension, local pressure with back pain, gastroesophageal reflux, and dyspnea. The estimated prevalence of PCLDs is around 1:1000, and these patients often develop polycystic kidney disease. Different genetic mutations trigger the appearance and growth of cysts in PCLDs, and in some cases this phenomenon is also associated with hepatic fibrosis. Most of the proteins encoded by these genes are located in

Figure 1 miRNA-15a/Cdc25a interplay participates in hepatic cystogenesis of polycystic liver diseases. miRNA-15a directly targets the cell cycle regulator Cdc25a. In polycystic rat and human cholangiocytes, miR15a is down-regulated, thus resulting in Cdc25a upregulation, cell proliferation and cystogenesis. The Cdc25a inhibitor vitamin K3 was demonstrated to target Cdc25a, blocking the hepatorenal cystogenesis of several rodent models of polycystic kidney and liver disease. This suggests the therapeutic potential of vitamin K3 for polycystic kidney and liver diseases.
