Most PG effects are mediated *via* the monomeric 36 kDa form of the annexin II receptor (ANX II)^[29,30]. ANX II is a multi-functional protein that binds acid phospholipids and actin with similar affinity. It's expressed abundantly in rejuvenating cells, but not in quiescent cells; in addition, its expression is increased in many human cancer cells, including colon and pancreatic, and it's expressed in normal intestinal epithelial cells^[27,28]. ANX II is absent in the brain and liver, which supports that it is only expressed in proliferating cells.

The majority of effects of G-Gly and CTFP appear to be mediated by a cellular receptor distinct from CCKBR^[1,24,31-33]; yet, to date, the receptor or receptors remain unknown. Gly-G appears to be able to bind ANX II, but it is still unclear whether its action is mediated *via* this interaction^[1].

PPIs AND GASTRIN

PPIs are the most potent and widely used medications to reduce gastric acid secretion. These drugs are considered safe; although, some long-term side-effects have been identified, for example, all PPIs induce an increase in plasma gastrin levels. The reason for this increase remains unclear, but it may be due to the reduced activity in antral D-cells (shown by a three-fold decrease in antral somatostatin mRNA) in response to PPI-induced achlorhydria^[7]. There is also an increase in plasma gastrin levels with other antacids such as H₂ receptor antagonists, but only after long-term use^[34].

PPIs may induce a 2- to 4-fold increase in plasma gastrin^[35,36] (mainly G17-NH₂ and G34-NH₂) with short-term treatment, whereas, in long-term therapy, some patients will develop marked hypergastrinemia (often exceeding 400 pmol/L). The antral mucosa levels of amidated gastrins and G-Gly are not affected by PPI treatment, but

Table 1 Studies assessing expression levels and/or biological effects of gastrin through its interaction with cholecystokinin-B receptor

Ref.	Specimen	CCKBR expression	G17 expression	G17 effects
Haigh <i>et al</i> ^[4]	Esophageal biopsies from healthy, esophagitis, BE and EAC patients; <i>Ex vivo</i> culture of BE cells; OE33(E)GR cells	CCKBR is expressed in 3/9 of healthy, 5/7 esophagitis, 10/10 BE and 7/12 EAC samples	Not assessed	G17 stimulates cell proliferation through CCKBR
Konturek <i>et al</i> ^[46]	Tumor and plasma samples from CRC patients; Plasma and normal colonic mucosa biopsies from healthy subjects	All the tumor samples showed CCKBR expression	CRC patients showed normal G17 plasma levels, and higher progastrin levels than healthy subjects; Celecoxib diminished plasma gastrin and progastrin levels	Not assessed
Smith <i>et al</i> ^[49]	Healthy colonic mucosa and colonic polyps biopsies	Normal colonic mucosa didn't show CCKBR expression; Most of the polyps analyzed showed CCKBR expression	Most of the polyps showed higher expression of the gastrin precursors than amidated forms	Not assessed
Harris <i>et al</i> ^[70]	Healthy esophagus and BE biopsies; OE19 and OE33 cell culture; OE21 cell culture	All three esophageal cancer cell lines express CCKBR; BE biopsies show higher CCKBR expression levels than normal esophageal biopsies	BE samples express higher gastrin levels than healthy esophageal biopsies	G17 increases activation of the antiapoptotic factor PKB/Akt, through CCKBR

BE: Barrett's esophagus; EAC: Esophageal adenocarcinoma; CCKBR: Cholecystokinin-B receptor; G17: Amidated gastrin-17; CRC: Colorectal carcinoma; OE19 and OE33 cells: Esophageal adenocarcinoma cell lines; OE21 cells: Esophageal squamous carcinoma cell line; OE33(E)GR cells: Esophageal adenocarcinoma cells permanently transfected with the human CCKB receptor.

a 6-fold increase in the antral progastrin concentration was observed after PPI therapy^[57-59]. However, the gastrin levels in patients on PPIs are extremely variable, and not every subject will have a markedly increased plasma gastrin level after acid suppressive therapy.

PPIs rapidly stimulate antral gastrin secretion, but the overexpression of the gastrin gene, which is observed as increased gastrin mRNA concentrations in G-cells, is only seen after 24 h of achlorhydria^[7].

To date, circulating levels of gastrin precursors have not been evaluated in response to PPI intake.

GASTRIN AND CARCINOGENESIS

As mentioned above, gastrin is a major stimulant of acid secretion in the stomach mucosa, but it also has effects in different tissues promoting cell division and inhibiting apoptosis. There is now growing evidence suggesting that elevated gastrin levels could favor the development of certain neoplasias, especially in the gastrointestinal tract^[2,40-43]. To date, most of those studies have been focused on the possible relationship between elevated gastrin levels and colorectal and gastric cancers, but there is evidence that suggests a possible relationship with different tumors, even outside the gastrointestinal (GI) tract^[19,20,22,44,45].

CCKBR has been observed in several tumor types, but expression of the receptor in human gastrointestinal cancers is controversial. Although some groups found CCKBR expression in many GI neoplasias^[3,46], others found expression of the receptor in GI tumors only occasionally^[23,29] (Table 1).

It is well established that some tumors produce their own gastrin and that gastrin can promote tumor growth in an autocrine manner^[22,44,46-48], but there were conflicting findings from studies evaluating gastrin expression

in tumors. This may be because initial attempts focused only on the amidated forms of gastrin. We now know that certain tumors, such as colorectal carcinoma (CRC), produce high levels of gastrin intermediates while the amidated forms are not affected^[20,22]. Gastrin has been found in CRC extracts and also in adenomatous polyps^[49], but not in healthy colonic mucosa. A similar pattern was found with esophageal adenocarcinoma and Barrett's esophagus (BE) (a premalignant condition that is a major risk factor for esophageal adenocarcinoma), where gastrin and its receptor were expressed at higher levels than in normal epithelium^[4,50].

These observations suggest that activation of gastrin expression may be an early event in the adenoma-carcinoma or the metaplasia-carcinoma progression; thus, gastrin could favor neoplastic transformation.

Studies in animal models have demonstrated that a prolonged hypergastrinemic situation, such as in deep acid inhibition, is related to higher CRC rates and with gastric atrophy, metaplasia, gastric adenocarcinoma and carcinoid tumors^[34,41,43,51] (Table 2). *In vitro* studies demonstrated that gastrin and its derivatives increase the rate of cell proliferation and migration and reduce apoptosis, which are major steps in tumor development^[1,3,28,44,52]. Although both *in vitro* and *in vivo* animal model studies seem to demonstrate an association between a rise in gastrin levels and a higher risk of cancer development this is still unclear in human beings. While some epidemiologic studies showed an association between, elevated gastrin levels after use of PPIs and stomach ECL and argyrophil cell hyperplasia, but couldn't demonstrate that hypergastrinemia itself increases gastric adenocarcinoma rates^[35,53-55], others found higher cancer rates (gastric and gastrointestinal overall) in hypergastrinemic patients^[56,57] (Table 3).

Pernicious anemia could represent a human model

Table 2 Experimental studies in animal models exploring the impact of increased levels of gastrin peptides

Ref.	Animal model	Alteration on gastrin peptides levels	Hypergastrinemia effects
Cobb <i>et al</i> ^[2]	Fabp-wt mice; Fabp-mt mice	Fabp-wt mice express human PG in intestinal mucosa and Fabp-mt mice express a mutated form of human PG; Both mice show PG expression at similar levels as seen in hypergastrinemia	Mice overexpressing human PG (either the wild-type and the mutated form) are more likely to develop colonic tumors in response to AOM
Wang <i>et al</i> ^[5]	INS-GAS mice; hGAS mice	INS-GAS mice overexpress human amidated gastrin in the pancreatic islets; hGAS mice overexpress human PG in the liver	Both forms of gastrin showed similar proliferative effects on normal colonic mucosa
Havu <i>et al</i> ^[34]	Sprague-Dawley rats treated with ranitidine (2g/kg per day)	Rats showed a 3-fold increase in plasma gastrin levels	19/100 rats developed ECL carcinoids while no carcinoma was found in control animals
Watson <i>et al</i> ^[43]	APC ^{Mint/+} mice (model of multiple intestinal neoplasia) treated with omeprazole (75 mg/kg in a single oral dose)	Omeprazole increased only amidated gastrin plasma levels	PPI-induced hypergastrinemia reduced mice survival; Hypergastrinemia increased colonic adenomas proliferation; Hypergastrinemia did not increase the incidence of intestinal tumors
Ferrand <i>et al</i> ^[90]	MTI/G-Gly mice; hGAS mice	MTI/G-Gly mice overexpress human G-Gly throughout the gastrointestinal tract; hGAS mice overexpress human PG in the liver	Both G-Gly and PG strongly up-regulate Src, JAK2 and STAT3 activation; PG produced significantly great ERK and Akt pathways activation and TGF- α overexpression
Koh <i>et al</i> ^[95]	MTI/G-Gly mice	MTI/G-Gly mice overexpress human G-Gly throughout the gastrointestinal tract	Goblet cells hyperplasia and colonic hyperproliferation; Hypergastrinemia did not increase the incidence of GI tumors, but 3/10 mice developed bronchoalveolar carcinoma
Ottewell <i>et al</i> ^[98]	G ^{-/-} hg ^{+/+} mice; G ^{-/-} hg ^{-/-} mice	G ^{-/-} hg ^{+/+} mice express human PG and no murine gastrin; G ^{-/-} hg ^{-/-} mice do not express any forms of gastrin	PG increased colonic proliferation; PG exerts mitotic effects on colonic epithelia but does not seem to affect the small intestine epithelia

PG: Progastrin; AOM: Azoxymethane; ECL: Enterochromaffin-like cells; PPI: Proton pump inhibitors; G-Gly: Glycine-extended gastrins; JAK2: Janus-activated kinase 2; STAT3: Signal transducer and activator of transcription 3; ERK: Extracellular-signal regulated kinase; Akt: Protein kinase B; TGF- α : Transforming growth factor- α ; GI: Gastrointestinal.

to assess effects of long-term hypergastrinemia, since it causes a long-term hypergastrinemia as a consequence of sustained achlorhydria^[57]. Another human model of hypergastrinemia is Zollinger-Ellison syndrome. In this case, patients show higher rates of colonic proliferation^[58], but not a higher risk for developing CRC^[59].

Another study found a higher CRC incidence rate with higher serum gastrin levels^[60], while, one study found no association between PPI use and the risk of CRC^[61].

It has been suggested that the discrepancy between results observed in human studies could be explained by the variability of hypergastrinemia after use of PPIs among patients^[42], by differences in the duration of the follow-up period -since higher cancer rates have only been observed in long-time hypergastrinemic patients-, and by differences in the forms of gastrin being studied, given that most of the studies to date have been focused only on the amidated forms^[22,62].

GASTRIN, BE AND ESOPHAGEAL ADENOCARCINOMA

Gastroesophageal reflux disease (GERD) is a chronic state in which part of the acidic stomach contents backs up into the esophagus and may cause inflammation of its epithelium. In most patients, this damaged epithelium is

replaced by new squamous epithelium; however, in some subjects, this epithelium is substituted, through a metaplastic process, by an intestinal-type columnar epithelium. This condition is called BE, a premalignant state responsible for most esophageal adenocarcinoma cases (EAC). Patients with BE have a 30- to 40-fold higher risk for developing EAC than the general population^[63].

In the last few decades, the incidence rates for this tumor have increased significantly^[64], more than for any other type of cancer^[65] in developed countries.

BE may represent a good model to study the involvement of hypergastrinemia in carcinogenesis, because frequently high levels of gastrin can be observed in BE patients. PPIs are the main pharmacological treatment for BE and the sequence of neoplastic transformation is well known.

In the pathological state caused by the damaging effects of acid contents from the stomach in the esophagus, it seems that an increase in gastric reflux pH would have a potential benefit for the patient. However, the benefits of these drugs in the management of GERD and BE are not clear. Normalization of intraesophageal pH clearly relieves gastroesophageal reflux symptoms^[37], favoring differentiation and decreasing cell proliferation^[66]; yet, there has been an increasing incidence of EAC in BE patients in the last few decades, despite generalized use of PPIs^[67-69]. Studies addressing the potential

Table 3 Clinico-epidemiologic studies exploring the effects of proton pump inhibitors use in human beings

Ref.	Population studied	Treatment, dose and duration	Effects on gastrin levels	Physiopathological effects
Brunner <i>et al</i> ^[35]	143 patients with duodenal or stomach ulcer and GERD	Omeprazole 40 mg/d 1-5 yr	Plasma gastrin levels increased 4-fold after 4 mo of therapy	Hyperplasia of argyrophil cells from oxyntic mucosa; No increase in dysplasia or neoplasia rates was observed
Klinkenberg-Knol <i>et al</i> ^[37]	91 GERD patients	Omeprazole 20-40 mg/d 5 yr	Median serum gastrin levels increased from 60 to 162 ng/L and reached a plateau during maintenance treatment	Esophagitis symptoms ameliorated; Gastric hyperplasia rates increased from 2.5% at the beginning of the study to 20% at last biopsy
Nemeth <i>et al</i> ^[39]	10 patients with oesophagitis	Omeprazole 20 mg/d 6-8 wk	Plasma levels of amidated gastrins increased from 18 to 48 pmol/L; Antral levels of progastrin increased 6-fold while amidated gastrins and G-Gly remain unaltered	Not assessed
Wang <i>et al</i> ^[42]	82 BE patients; 13 GERD patients	All patients were on PPI therapy, once or twice daily during a median time of 74 mo	The median serum gastrin levels (40 pmol/L) was not related to the degree of dysplasia in BE	Higher serum gastrin levels were associated with high grade dysplasia and adenocarcinoma
Creutzfeldt <i>et al</i> ^[53]	74 patients with esophagitis or peptic ulcer	Omeprazole 40 mg/d 1-5 yr	Plasma gastrin levels increased 4-fold in 23% of patients	Patients with higher serum gastrin levels developed hyperplasia of the gastric argyrophil cells; This hyperplasia may not necessary be related to high gastrin levels
Kuipers <i>et al</i> ^[54]	177 GERD patients	105 patients treated with omeprazole 20-40 mg/d 5 yr; 72 patients treated with fundoplication	Not assessed	Patients treated with omeprazole and infected with H.pylori infection are at increased risk of atrophic gastritis
Lamberts <i>et al</i> ^[55]	74 peptic ulcer patients	Omeprazole 48 mo	Median gastrin levels moderately increased after 3 mo of therapy and reached a plateau during maintenance treatment	Significant argyrophil cell hyperplasia

GERD: Gastroesophageal reflux disease; G-Gly: Glycine-extended gastrins; BE: Barrett's esophagus; PPI: Proton pump inhibitors.

role of different molecular forms of gastrin in Barrett's carcinogenesis are discussed below.

AMIDATED GASTRINS

Amidated gastrins are, in healthy subjects, the final and most abundant product in the gastrin biosynthesis pathway. Through the interaction with their receptor, CCKBR, amidated gastrins might be involved in the neoplastic progression of BE.

Amidated gastrins and CCKB receptor expression in BE

Barrett's mucosa expresses its own gastrin. Patients with BE show higher levels of amidated gastrins than healthy subjects^[44], which might be a consequence of both PPI intake and autocrine gastrin production by Barrett's mucosa^[36,50]. This autocrine gastrin production diminishes with the progression to dysplasia and EAC^[44], and there is not a significant difference between serum gastrin levels in GERD and BE patients^[42]. The expression of its receptor increases in response to inflammation. In almost all BE biopsy samples studied, CCKBR mRNA and protein are detected; while, they are only occasionally present in healthy tissue and their presence in EAC is unclear^[4,36,50,70]. In addition, expression of the receptor increases cell proliferation^[26,31,44]; therefore, CCKBR may

have an important role in GERD ulcer healing^[36,44].

Biological effects of amidated gastrins

In vitro studies determined that amidated gastrins may promote cell proliferation and migration of BE and EAC cells, and those effects are mediated through the interaction with CCKBR^[4,26,36,44].

The effects of amidated gastrins are mediated, at least partially, by the induction of cyclooxygenases (COX)-2 expression and prostaglandins production^[3]. COX are membrane proteins that catalyze the limiting step in the prostaglandin synthesis pathway. Prostaglandins are molecules that may promote carcinogenesis through stimulation of cell division, induction of angiogenesis, and inhibition of apoptosis^[71,72]. As a consequence of the interaction between amidated gastrins and CCKBR, COX-2 is overexpressed in Barrett's mucosa, leading to an increase in prostaglandins synthesis and cell proliferation^[44,73].

COX-2 overexpression is related to the development of other GI cancers, and the use of COX-2 inhibitors, such as non-steroidal anti-inflammatory drugs is associated with a reduction in the frequency and mortality of those tumors^[74-78]. *In vitro* and *in vivo* studies have shown that COX-2 inhibitors decrease cell proliferation in BE^[79] and reduce the risk of developing EAC^[74], suggesting that COX-2 might be a key factor in Barrett's carcinogenesis.

COX-2 overexpression seems to be an early event in the neoplastic transformation of BE. Despite the great variability observed between subjects, COX-2 levels in biopsy samples are always higher in BE mucosa than in normal esophageal epithelium^[44,50,73,80].

Thus, amidated gastrins might have a role in the neoplastic progression of BE rather than in its initial development since BE cells express higher levels of gastrin, CCKB receptor and also COX-2 than EAC^[44] and normal esophageal cells.

GASTRIN SYNTHESIS INTERMEDIATES: PROGASTRIN, G-GLY AND CTFP

The biological activity of gastrin synthesis intermediates was unknown until 1994^[81]. Experiments carried out to determine their ability to stimulate gastric acid secretion showed negligible or less potency than fully processed amidated forms^[82,83]; therefore, those investigations concluded the intermediates were inactive peptides and focused mainly on the known bioactive forms. However, in the last few decades, numerous studies have demonstrated that these molecules are far from inactive precursors. Gastrin intermediates are secreted in higher proportions than their amidated forms in certain gastrin overexpression states^[39,84]; thus, knowledge of their recently known biological effects has led to several studies on these intermediates in the last few decades. To date, most of these studies have been focused on CRC; although the relative abundance of these precursors in other tissues supports that it is necessary to extend research to other organs as well.

PROGASTRIN

PG is the first gastrin synthesis intermediate after signal peptide cleavage. A study demonstrated that PG levels in antral biopsies from patients undergoing PPI treatment were up to 6-fold higher than in untreated patients^[39]; although, there are currently no studies showing PG plasma levels in response to PPI administration

Progastrin expression

Studies carried out on healthy colonic and CRC tissue have shown a higher proportion of products from the early stages of gastrin synthesis (PG above all) than those from later stages (G-Gly and amidated forms) in cancer samples^[20,85]. Plasma PG levels, but not amidated gastrin, are elevated in CRC patients compared with healthy subjects and those with colonic polyps, suggesting a possible tumor origin for this PG and an incomplete processing of the peptide in tumor cells^[22]. Other tumors, such as pancreatic, ovarian, and lung cancer, also overexpress PG^[45,47,48].

Biological effects of PG

Progastrin may exert greater proliferative effects than amidated gastrins on normal and tumor cells (CRC, pancreat-

ic) in culture^[28,86] and also has an antiapoptotic effect^[87]. *In vivo* studies using mice overexpressing both G17-NH₂ and PG showed increased colonic proliferation compared to wild-type control mice. At plasma concentrations similar to those observed in certain disease states, PG can act as a co-carcinogen and significantly increases the risk for colon carcinogenesis in response to azoxymethane^[2,5].

PG has negligible affinity for the receptor for amidated gastrins (CCKBR) and its effects are mediated by a different receptor: ANX II^[27-30]. This receptor is not expressed on quiescent cells and it is necessary to mediate at least 50% of exogenous PG effects on intestinal cells and more than 80% of the effects of autocrine gastrins on CRC cells^[29]. ANX II is overexpressed in human CRC and may be related to a poor prognosis^[88]. It is also overexpressed in a wide variety of tumors^[88,89]. The mitogenic and antiapoptotic effects of PG seem to be mediated through activation of several signaling pathways including nuclear factor- κ B (NF- κ B), Src, Janus-activated kinase 2 (JAK2)/signal transducer and activator of transcription 3 (STAT3), extracellular signal-regulated kinase (ERK), mitogen-activated protein kinase (MAPK) and phosphatidylinositol 3-kinase (PI3K)/Akt kinases^[86,90].

G-GLY

G-Gly are some of the last gastrin processing intermediates. They result from the cleavage of the C-terminal arginyl residues of progastrin by carboxypeptidase E, before the amidation step.

G-Gly expression

As with other gastrin intermediates, there are few studies focused on assessing possible changes in plasma or tissue levels of G-Gly in different situations. It seems that PPIs don't significantly affect its levels because antral mucosa levels of G-Gly remain unaltered after treatment with PPIs^[39]. In addition, CRC doesn't alter plasma G-Gly concentrations^[22]; while, tumor biopsies and cell lines derived from CRC show higher levels than healthy tissue^[20,22]. G-Gly levels are also increased in the gastric mucosa from patients with gastrinoma^[91]. Outside the GI tract, only a small proportion of lung cancer cases analyzed showed G-Gly overexpression, which was inversely related to survival rates^[45].

Biological effects of G-Gly

Even small variations in the levels of G-Gly may affect proliferation and apoptosis. G-Gly effects can be observed at concentrations at least one order of magnitude less than for amidated forms^[33,92]. G-Gly can act as a growth factor for many cultured cells, including gastric, pancreatic, colonic cancer cells, and non-transformed cells^[33,52,81,93,94]. It also decreases apoptosis in CRC and EAC^[1,92] cells and increases migration in CRC cells^[40]. *In vivo* experiments using transgenic mice overexpressing this intermediate demonstrated that higher G-Gly levels are related to colonic hyperproliferation, but were not

able to cause tumors alone^[90]. Surprisingly these experiments showed higher bronchoalveolar cancer rates in the animals overexpressing the molecule^[45,95].

The proliferative effects of G-Gly are dependant, at least partially, on COX-2 expression in EAC cells because the use of COX-2 inhibitors abolishes the proliferative effects of the molecule^[52].

To date, the G-Gly receptor remains unknown but the majority of its effects seem to be mediated *via* a different receptor than CCKBR^[1,33,96]. Although G-Gly has been shown to bind to ANX II, no effects were observed^[29]. The G-Gly interaction with a receptor distinct from CCKBR leads to JAK2/STAT3, Akt, NF- κ B, PI3k, and ERK activation^[52], increasing COX-2 expression. In contrast, the antiapoptotic effects of G-Gly occur independently from COX-2 expression^[1].

CTFP

CTFP is the gastrin synthesis intermediate generated after cleavage of progastrin into its dibasic residues, generating G-Gly and the 6-amino acid CTFP. After the discoveries that the gastrin intermediates PG and G-Gly are present in normal antrum and certain tumors^[20-22,48] and have effects enhancing cell proliferation and inhibiting apoptosis^[5,28,29,33,52], several studies focused on those molecules. However, little attention has been paid to CTFP.

CTFP expression

In plasma and human antral extracts from healthy subjects, CTFP is the most abundant peptide (four-fold higher than the next most abundant peptide in antral samples and 30-fold higher in plasma). In CRC patients, CTFP levels are elevated in tumor mucosa and remain unaltered in plasma^[32].

CTFP biological effects

CTFP effects have been tested on colonic and gastric cancer cell lines *in vitro*. CTFP showed higher potency in stimulating cell growth than G-Gly in colon tumor cells and a similar potency in gastric cancer cells. CTFP also stimulated cell migration in a non-transformed mouse gastric cell line and activated MAPK phosphorylation in colon cancer cells *via* a different receptor than CCKBR^[32]. CTFP also exerts anti-apoptotic effects^[97]. To date, only a few studies have focused on CTFP, but it has been determined that it is a biologically active molecule that is secreted in higher amounts than any other product of the gastrin gene. Thus, further experiments with this peptide should be carried out.

CONCLUSION

In summary, data derived from *in vitro* studies and animal models strongly suggest that high levels of gastrin may exert carcinogenic effects, on BE and colorectal epithelia, but also elsewhere. In addition, certain tumors produce their own gastrin, which might contribute to support

tumor growth. However, it is currently not clear if high gastrin levels have the same effects in human beings. Most studies have been focused on amidated gastrins. Although, intermediates of gastrin synthesis can exert even greater carcinogenic effects than the amidated forms and in certain situations they become the most abundant forms of gastrin. Therefore, more studies evaluating these molecules are needed to elucidate the potential role of gastrins in human carcinogenesis.

Abstract

Helicobacter pylori (*H. pylori*) is a Gram-negative bacterium that infects half of the human population. The infection is associated with chronic inflammation of the gastric mucosa and peptic ulcers. It is also a major risk factor for gastric cancer. Phylogenetic analysis of global strains reveals there are seven populations of *H. pylori*, including hpAfrica1, hpAfrica2, hpEastAsia, hpEurope, hpNEAfrica, hpAsia2 and hpSahul. These populations are consistent with their geographical origins, and possibly result from geographical separation of the bacterium leading to reduced bacterial recombination in some populations. For each population, *H. pylori* has evolved to possess genomic contents distinguishable from others. The hpEurope population is distinct in that it has the largest genome of 1.65 mbp on average, and the highest number of coding sequences. This confers its competitive advantage over other populations but at the cost of a lower infection rate. The large genomic size could be a cause of the frequent occurrence of the deletion of the *cag* pathogenicity island in *H. pylori* strains from hpEurope. The incidence of gastric cancer varies among different geographical regions. This can

be attributed in part to different rates of infection of *H. pylori*. Recent studies found that different populations of *H. pylori* vary in their carcinogenic potential and contribute to the variation in incidence of gastric cancer among geographical regions. This could be related to the ancestral origin of *H. pylori*. Further studies are indicated to investigate the bacterial factors contributing to differential virulence and their influence on the clinical features in infected individuals.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a Gram-negative bacterium which colonizes the human stomach. As a pathogen, *H. pylori* induces inflammation of the gastric mucosa^[1]. It plays a causal role in the ulceration and recurrence of peptic ulcer^[2]. Eradication of the bacterium heals ulcers and prevents recurrence of the disease. The infection is also associated with an increased risk of gastric cancer^[3,4].

The incidence of gastric cancer shows geographical variation. This is attributed in part to the difference in the prevalence of the *H. pylori* infection among geo-

graphical regions. In Africa and South Asia, however, the incidence of gastric cancer in these areas is much lower than in other countries in spite of the high prevalence of the *H. pylori* infection^[5]. Such a disparity has also been found in other local regions^[6]. Analysis of global strains reveals seven populations of *H. pylori* that are consistent with their geographical origin^[7-10]. These current populations derive from six ancestral populations^[7]. It appears that the ancestry, genomic contents and carcinogenic potentials are diversified among *H. pylori* populations. Studies at a population level have improved our understanding of gastric carcinogenesis associated with the *H. pylori* infection.

GENETIC DIVERSITY AND POPULATIONS OF *H. PYLORI*

There are three types of bacterial population structure: clonal, panmictic and endemic^[11]. If intra-species or inter-species recombination is rare, the genetic diversity of a bacterial species predominantly comes from evolution of the ancestry. This species has a clonal population structure. In a species with high frequency of recombination, introduction of foreign gene fragments into the genome occurs frequently in the evolution history. As foreign genes have a different evolution history, the evolution speed of individual genes is different. In this case, the species possess a panmictic structure. For a bacterial species with a panmictic structure, a temporal clonal structure may occur if it rapidly spread among naïve hosts. In this situation, a bacterial species has an endemic structure.

H. pylori shows great inter-strain variation in genetic content^[12]. None of the individual strains is identical as demonstrated by multiple fingerprinting methods^[13,14]. Sequence divergence is the main cause of this variation. Comparison of two sequenced genomes revealed occurrence of substantial silent mutation in the genetic loci^[15]. A number of mechanisms are involved in the generation of the sequence variation: *H. pylori* shows a higher mutation rate than *Escheria coli*^[16]. Approximately a quarter of strains possess a mutator-like phenotype. This is attributed to the lack of a functional DNA repair system^[16,17] and error-prone DNA polymerase in *H. pylori*^[18]. Recombination in *H. pylori* is more frequent than in any other organism studied to date^[19]. Foreign DNA from the same species or phage has been found in the bacterium^[15]. Strand slippage mispairing is another mechanism responsible for genetic diversity. A number of homopolymeric tracts and dinucleotide repeat regions are present in the *H. pylori* genome^[20,21], which may cause replication error and subsequently sequence variation. *H. pylori* has a specialized type IV system for uptake of foreign DNA from the same species or other species^[22]. Foreign DNA fragments are subsequently integrated into the genome by recombination. A high frequency of recombination and a high mutation rate in *H. pylori* result in a panmictic structure of the bacterium^[23].

Recombination is a rare genetic event in house-keeping genes. Phylogenetic analysis of highly conserved house-keeping genes (*atpA*, *efp*, *mutY*, *ppa*, *trpC*, *ureI* and *yphC*) has then been used to study populations of *H. pylori*^[24]. Examination of global strains of *H. pylori* reveals that it has seven populations: hpAfrica1, hpAfrica2, hpEastAsia, hpEurope, hpNEAfrica, hpAsia2 and hpSahul^[7-10,25,26]. Some populations could be further divided into subpopulations. For hpEastAsia, there are three subpopulations including hspEAsia, hspAmerind and hspMaori^[27], while hpAfrica1 is split into hspWAfrica and hspSAfrica^[28]. These populations and subpopulations reflect not only their geographical origin but also ethnic groups of their hosts. Spatial separation reduces bacterial recombination between different geographical regions. A weakly clonal population may thus be generated in strains from a particular geographical region^[29]. *H. pylori* spreads mainly through a mode of family transmission^[30,31], leading to a reduced chance of recombination between strains from different ethnic groups. Therefore, strains from different ethnic groups could be distinguished in the phylogenetic analysis. This is one of the features that allows phylogenetic analysis of *H. pylori* to be used to trace the history of human migration.

GENOMIC DIVERGENCE BETWEEN *H. PYLORI* POPULATIONS

H. pylori has been accompanying human hosts for more than 58 000 years^[10]. The genome of *H. pylori* is thus shaped by its human hosts due to the long co-existence^[32]. *H. pylori* strains differ in their affinity to bind blood group antigens expressed in the gastric mucosa^[33]. Strains from Europe bind all three blood group antigens, while Amerindian strains have higher affinity for O blood antigen as this antigen is predominant in Amerindians^[32]. Therefore, the genomic content of *H. pylori* may vary in different populations.

To date, a number of strains of *H. pylori* have been sequenced^[15,34-37]. Of these, the origin and other information of 30 strains are publicly available. These include 14 strains from hpEastAsia (7 from hspEAsia and 7 from hspAmerind subpopulations, respectively), 10 from hpEurope, 5 from hpAfrica1 and 1 from hpAfrica2^[38-41]. All, except for strain B38 from hpEurope, possess *cagA* and the *cag* pathogenicity island (*cag* PAI). The genomic size of *cagA*-positive *H. pylori* ranges from approximately 1.55 mbp to 1.71 mbp with an average of 1.61 mbp. For *cagA*-negative strains, their genome is generally smaller because of the lack of the *cag* pathogenicity island of about 40 kbp. We analyzed the average genomic size of *cagA*-positive *H. pylori* strains from different populations^[42-47]. The average genomic size of strains from hpEurope is approximately 1.65 mbp, which is significantly larger than that from hpEastAsia (1.60 mbp, $P < 0.05$) or hpAfrica1 (1.60 mbp). Consistent with this, strains of hpEurope have the highest number of coding sequences. There was a statistically significant difference between hpEurope and

hpEastAsia in the average genomic size and number of CDS. The size of bacterial genomes is primarily determined by two counteracting processes: the gain of new genes by gene duplication or by horizontal gene transfer; and the decay of non-essential genes^[15]. Both of these processes have been observed in *H. pylori*. Recombination, conjugation, insertion elements, mutation and slipped-strain replication lead to gene gain or loss^[34]. They may be involved in the variability of genomic size among *H. pylori* of different populations.

For bacteria, a larger genome requires more metabolic activities and consumes more energy^[48,49]. Therefore bacteria containing a larger genome may have a lowered capacity of growth, reducing its competitive ability with other bacteria in the same ecological niche. This leads to a decreased spread of bacteria. It is well known that *H. pylori* is less prevalent in Western countries than in other parts of the world^[50]. Hygiene, economical incomes and social status have been suggested to contribute to this differential prevalence^[51]. It is arguable that a larger genome of *H. pylori* strains in Western countries may also contribute to the low prevalence of the infection in this region.

Comparison of the genomic content of *H. pylori* from different populations revealed differences in the compositions of outer membrane proteins and central metabolism^[39]. Compared with hpEurope, strains from hpEastAsia tend to have fewer genes of these two categories. There are a total of 12 genes in *H. pylori* involved in molybdenum metabolism, including those encoding proteins for molybdenum transport and cofactor synthesis and a molybdenum-containing enzyme. A massive decay of molybdenum-related genes occurs in strains from hpEastAsia. At least five genes are fragmented due to mutations. The molybdenum-containing enzyme functions in electron transfer and responses to oxidative and acid stress^[52]. It is probable that in hpEastAsia populations, *H. pylori* use alternative pathways for the purpose^[39]. Outer membrane proteins consist of several paralog families interacting with the human host^[53,54]. In the hpEastAsia population, there is a tendency for a reduced number of these proteins resulting from mutations and recombination. Therefore it appears that *H. pylori* from hpEastAsia have evolved to possess a reduced genome.

The *cag* PAI is a 40-kb DNA fragment which contains 27 to 31 genes flanked by 31-bp direct repeats^[55]. It encodes CagA, the major virulence determinant of *H. pylori* and components of a type IV secretion system^[56,57]. The latter translocates CagA into host cells^[58]. Once inside the host cells, CagA binds to a number of host cell proteins disrupting intracellular signaling systems *via* tyrosine phosphorylation-dependent or -independent pathways^[59]. This causes elongation and loss of polarity of host cells, promoting proliferation and inflammation. The presence of the *cag* PAI in *H. pylori* is associated with increased risk of severe gastritis, atrophic gastritis, and distal gastric cancer compared with strains that lack the *cag* island^[60-62].

A marked difference lies between hpEurope and hpEast-

Asia in the prevalence of strains possessing the *cag* PAI. Approximately 60% to 70% of Western *H. pylori* strains express CagA^[61,63], indicating the presence of the *cag* PAI. In East Asia, however, almost 100% of strains possess the *cag* PAI irrespective of pathology^[64,65]. It is believed that the *cag* PAI is deleted in Western strains resulted from recombination between the repeats flanking the island^[66]. This results in a reduced genomic size by approximately 40 kbp. In addition, it has been demonstrated that the prevalence of strains with an intact *cag* PAI is the lowest in Western countries^[67]. As described above, strains from hpEurope are coincidentally 40 kbp larger than the average genomic size of *H. pylori*. Thus, the occurrence of *cagA*-negative strains in hpEurope is probably due to the evolution of the bacterium towards a smaller genome.

VARIATION IN THE CARCINOGENIC POTENTIAL OF *H. PYLORI* POPULATIONS

The incidence of gastric cancer varies in different geographical regions. It is higher in East Asian countries than in any other countries when age-standardized rates are considered^[68]. In some countries of West Africa and South America, there is also an increased incidence of gastric cancer^[69,70]. The geographic difference in the incidence of gastric cancer can be attributed partially to the difference in the prevalence of *H. pylori* infection^[71]. A high prevalence of virulent strains of *H. pylori* is another contributing factor to the high incidence of gastric cancer in East Asia. Virulent strains possess the *cag* PAI and express *VacA*. There is, however, a disparity between the prevalence of *H. pylori* or virulent strains and the incidence of gastric cancer. In Linqu County, China, the incidence of gastric cancer is extremely high, while in its neighboring county Cangshan the incidence is very low^[72,73]. The rate of *H. pylori* infection and the proportion of virulent strains in these two counties, however, show no significant difference^[74]. Similar results have been found when comparing two regions in Mexico with contrasting incidence of gastric cancer^[75]. These results indicate differential incidence of gastric cancer among different geographical regions is attributable to other bacterial factors.

To explore other bacterial factors related to carcinogenesis, the phylogeographical origin of *H. pylori* has been investigated^[76]. In the Andean mountain region of Colombia, habitants have a high incidence of gastric cancer (150 per 100 000 people per year)^[77,78], while habitants in the coastal line 200 kilometers away, have a very low incidence of gastric cancer (6/100 000)^[77,78]. The prevalence of the infection and virulent strains of *H. pylori* in these two regions are similar^[75]. All *H. pylori* strains isolated from the Andean region, however, are from hpEurope, in contrast to strains isolated from the coastal line which are mainly from hpAfrica1^[76]. Furthermore, strains from the Andean region caused more severe mucosal inflammation and more DNA damage in epithelial cells. This suggests that strains of hpEurope probably have an

increased carcinogenic potential compared with those of hpAfrica1^[76]. Ancestral origin of the bacterium could be an important factor contributing to gastric carcinogenesis. This conclusion is further supported from a study conducted in Malaysia^[7]. There are three ethnic groups in the country: Malay, Indian and Chinese. The infection rate of *H. pylori* in Malays is lower than that in Indian and Chinese subjects^[79]. The incidence of gastric cancer, however, is similar in Malays and Indians, but is much lower than in the Chinese^[80]. Analysis of the ancestral origin of *H. pylori* found that strains isolated from both Malay and Indian subjects belonged to hpAsia2, whereas those isolated from Chinese subjects belonged to hpEastAsia. This suggests a different potential for carcinogenesis between hpAsia2 and hpEastAsia. *H. pylori* populations generally reflect the geographical regions from which they are isolated. Differences in the incidence of gastric cancer among geographical regions could be in part attributed to different populations of *H. pylori*. Further study is required to investigate other bacterial factors involved in the carcinogenesis.

CONCLUSION

In summary, geographical separation reduces the frequency of recombination between *H. pylori* strains from a local area and those from outside. This leads to the formation of a clonal population structure of *H. pylori* in the local area. Thus, populations of *H. pylori* could be identified through examination of global strains. For each population, *H. pylori* have experienced relatively separate evolution processes, resulting in genomic diversity and differential potential for carcinogenesis. Further study to characterize these differences may help elucidate mechanisms involved in the development of gastric cancer induced by *H. pylori*.

Abstract

AIM: To investigate human epidermal growth factor receptor 2 (HER2)-phosphatidylinositol 3-kinase (PI3K)-v-Akt murine thymoma viral oncogene homolog signaling pathway.

METHODS: We analyzed 231 formalin-fixed, paraffin-embedded gastric cancer tissue specimens from Japanese patients who had undergone surgical treatment. The patients' age, sex, tumor location, depth of invasion, pathological type, lymph node metastasis, and pathological stage were determined by a review of the medical records. Expression of HER2 was analyzed by immunohistochemistry (IHC) using the HercepTest™ kit. Standard criteria for HER2 positivity (0, 1+, 2+, and 3+) were used. Tumors that scored 3+ were considered HER2-positive. Expression of phospho Akt (pAkt) was also analyzed by IHC. Tumors were considered pAkt-positive when the percentage of positive tumor cells was 10% or more. PI3K, catalytic, alpha polypeptide (PIK3CA) mutations in exons 1, 9 and 20 were analyzed by pyrosequencing. Epstein-Barr virus (EBV) infection was analyzed by *in situ* hybridization targeting EBV-encoded small RNA (EBER) with an EBER-RNA probe. Microsatellite instability (MSI) was analyzed by polymerase chain reaction using the mononucleotide markers BAT25 and BAT26.

RESULTS: HER2 expression levels of 0, 1+, 2+ and 3+ were found in 167 (72%), 32 (14%), 12 (5%) and 20 (8.7%) samples, respectively. HER2 overexpression (IHC 3+) significantly correlated with intestinal histological type (15/20 vs 98/205, $P = 0.05$). PIK3CA mutations were present in 20 cases (8.7%) and significantly correlated with MSI (10/20 vs 9/211, $P < 0.01$).

The mutation frequency was high (21%) in T4 cancers and very low (6%) in T2 cancers. Mutations in exons 1, 9 and 20 were detected in 5 (2%), 9 (4%) and 7 (3%) cases, respectively. Two new types of PIK3CA mutation, R88Q and R108H, were found in exon1. All PIK3CA mutations were heterozygous missense single-base substitutions, the most common being H1047R (6/20, 30%) in exon20. Eighteen cancers (8%) were EBV-positive and this positivity significantly correlated with a diffuse histological type (13/18 *vs* 93/198, $P = 0.04$). There were 7 cases of lymphoepithelioma-like carcinomas (LELC) and 6 of those cases were EBV-positive (percent/EBV: 6/18, 33%; percent/all LELC: 6/7, 86%). pAkt expression was positive in 119 (53%) cases but showed no correlation with clinicopathological characteristics. pAkt expression was significantly correlated with HER2 overexpression (16/20 *vs* 103/211, $P < 0.01$) but not with PIK3CA mutations (12/20 *vs* 107/211, $P = 0.37$) or EBV infection (8/18 *vs* 103/211, $P = 0.69$). The frequency of pAkt expression was higher in cancers with exon20 mutations (100%) than in those with exon1 (40%) or exon9 (56%) mutations. One case showed both HER2 overexpression and EBV infection and 3 cases showed both PIK3CA mutations and EBV infection. However, no cases showed both PIK3CA mutations and HER2 overexpression. One EBV-positive cancer with PIK3CA mutation (H1047R) was MSI-positive. Three of these 4 cases were positive for pAkt expression. In survival analysis, pAkt expression significantly correlated with a poor prognosis (hazard ratio 1.75; 95%CI: 1.12-2.80, $P = 0.02$).

CONCLUSION: HER2 expression, PIK3CA mutations and EBV infection in gastric cancer were characterized. pAkt expression significantly correlates with HER2 expression and with a poor prognosis.

Alterations in the human epidermal growth factor receptor 2-phosphatidylinositol 3-kinase-v-Akt pathway in gastric cancer. *World J Gastroenterol* 2012; 18(45): 6577-6586 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i45/6577.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i45.6577>

INTRODUCTION

Gastric cancer is one of the most common cancer types

and the second leading cause of cancer-related deaths worldwide^[1]. Genetic and epigenetic alterations play important roles in the development and progression of these tumors^[1,2]. Considerable attention has been given to the potential role of the phosphatidylinositol 3-kinase (PI3K)-Akt signaling pathway in gastric cancer^[3,4]. Various alterations, such as activation of growth factor receptors, PI3K, catalytic, alpha polypeptide (PIK3CA) mutations and inactivation of phosphatase and tensin homolog (PTEN) lead to activation of the PI3K-Akt signaling pathway. With regards to growth factor receptors, there is growing evidence that human epidermal growth factor receptor 2 (HER2) is a key driver of tumorigenesis and an important biomarker in gastric cancer. The amplification or overexpression of HER2 is observed in 7%-34% of these cases^[5-9].

PIK3CA is mutated in a wide variety of human tumor types^[10,11], including gastric cancers^[12-15]. Activating mutations in this gene up-regulate the PI3K-Akt signaling pathway, making it a potentially useful therapeutic target. For example, oncogenic mutations of PIK3CA reportedly render breast cancers more resistant to treatment with the anti-HER2 receptor antibody trastuzumab^[16]. Thus, this signaling pathway is thought to be one of the mechanisms underlying resistance to trastuzumab. Trastuzumab has recently been approved for treatment of advanced gastric cancers^[5,6].

Pyrosequencing-based methods facilitate the identification of low-frequency tumor mutations and allow a more accurate assessment of tumor mutation burden^[17]. PIK3CA mutations have been detected in 4%-25% of gastric cancers^[12-15]. However, in most previous studies, only exons 9 and 20 hot spot mutations in PIK3CA were analyzed by DNA sequencing. Moreover, the association between HER2 expression and PIK3CA mutations in gastric cancer has not been reported.

A significant correlation has been found between Epstein-Barr virus (EBV) and the methylation of multiple genes in gastric cancers^[18-20]. EBV infection reportedly induces PTEN expression loss through CpG island methylation of its promoter, leading to activation of the PI3K-Akt signaling pathway, in EBV-associated gastric cancer^[21].

The aim of our present study was to systematically characterize HER2 expression, PIK3CA mutations, and EBV infection, all of which are involved in the PI3K-Akt signaling pathway, in a large cohort of gastric cancers ($n = 231$). We wished to determine the prevalence of each of these factors with a high precision and thereby correlate them with clinicopathological and molecular features of gastric lesions, including microsatellite instability (MSI) and phospho Akt (pAkt) expression.

MATERIALS AND METHODS

Tissue samples

A total of 231 formalin-fixed, paraffin-embedded (FFPE) gastric cancer tissue specimens from Japanese patients who had undergone surgical treatment was analyzed in

this study. The patients' age, sex, tumor location, depth of invasion, pathological type, lymph node metastasis, and pathological stage were determined by a review of their medical records. Clinicopathological findings were determined according to the criteria of the Japanese Research Society for Gastric Cancer (Table 1). Our institutional review committee approved the study.

Immunohistochemistry

HER2 expression was analyzed using the HercepTest™ kit (DAKO, Carpinteria, CA) by manual sample processing in accordance with the manufacturer's instructions. Standard criteria for HER2 positivity (0, 1+, 2+ and 3+) were used. Tumors that scored 3+ were considered HER2-positive. For the immunohistochemical analysis of pAkt, FFPE specimens were processed using SignalStain Boost Detection Reagent (Cell Signaling Technology, Beverly, MA). Briefly, 5-μm-thick sections were dewaxed in xylene, rehydrated in ethanol, and heated with target retrieval solution (DAKO) in an autoclave for antigen retrieval. Endogenous peroxidase was blocked by incubation with 0.3% hydrogen peroxide in methanol for 10 min. The tissue sections were then washed twice with tris-buffered saline (TBS) and preblocked with 10% goat serum in TBS for 60 min. After washing with TBS, the sections were incubated with an anti-phospho-Akt (Ser473) polyclonal antibody (D9E, Cell Signaling Technology) at a dilution of 1:100 for 30 h at 4 °C. The sections were washed three times in TBS and incubated with SignalStain Boost Detection Reagent for 45 min. After three further washes in TBS, a diamino-benzidine tetrahydrochloride working solution was applied. Finally, the sections were

counterstained with hematoxylin. Tumors were considered pAkt-positive when the percentage of positive tumor cells was 10% or more^[22]. Only clear staining of the tumor cell nucleus and/or cytoplasm was considered positive.

Mutation analysis of the PIK3CA gene by pyrosequencing

Genomic DNA was extracted from tumor specimens and mutations in exon9 and exon20 of the *PIK3CA* gene were analyzed by pyrosequencing as described previously^[23,24]. We also developed a pyrosequencing assay to detect PIK-3CA exon1 mutations using the primer sets exon1-RS1 (5'-GGGAAGAATTTTGTGATGAAACA-3' for the biotinylated forward primer and 5'-GGTTGCCTACT-GGTTCAATTACTT-3' for the reverse primer) and exon1-RS2 (5'-CGGCTTTTTCACCCTTTT-3' for the forward primer and 5'-ATTTCTCGATTGAG-GATCTTTTCT-3' for the biotinylated reverse primer). Each polymerase chain reaction (PCR) mix contained the forward and reverse primers (each 10 μmol/L), a 25 mmol/L dNTP mix with dUTP, 75 mmol/L MgCl₂, 1 × PCR buffer, 1.0 U of exTaq, and 2 μL of template DNA in a total volume of 25 μL. PCR conditions were as follows: initial denaturing at 95 °C for 5 min; 50 cycles of 94 °C for 20 s, 50 °C for 20 s and 74 °C for 40 s; and a final extension at 72 °C for 1 min. The PCR products (each 25 μL) were sequenced using the PyroMark kit and Pyrosequencing PSQ96 HS System (Qiagen, Valencia, CA).

In situ hybridization for EBER1

The presence of EBV in the carcinoma tissues was evaluated by *in situ* hybridization (ISH) targeting of EBV-encoded small RNA (EBER-ISH) with an EBER-RNA probe (Dako Cytomation).

Microsatellite instability analysis

MSI was analyzed by PCR using the mononucleotide markers (BAT25 and BAT26). Based on the number of markers showing instability per tumor sample, cancers were divided into two groups; those with one or more of the two markers displaying MSI and those with no instability (microsatellite stable).

Statistical analysis

For all statistical analysis, the JMP program was used. All *P* values were two-sided and statistical significance was set at *P* ≤ 0.05. For categorical data, the χ^2 test was used. For survival analysis, Kaplan-Meier method and log-rank test were used. For analysis of cancer-specific mortality, we excluded surgery-related deaths (deaths within one month of surgery).

RESULTS

HER2 expression in gastric cancer tissues

HER2 expression levels of 0, 1+, 2+ and 3+ were found in 167 (72%), 32 (14%), 12 (5%) and 20 (8.7%) samples, respectively (Figure 1). HER2 overexpression (IHC 3+) significantly correlated with intestinal histological type

MSI: Microsatellite instability; LELC: Lymphoepithelioma-like carcinoma; HER2: Human epidermal growth factor receptor 2; PIK3CA: Phosphatidylinositol 3-kinase, catalytic, alpha polypeptide mutations; EBV: Epstein-Barr virus; pAkt: Phospho Akt; OS: Overall survival.

Table 3 Frequencies of phosphatidylinositol 3-kinase, catalytic, alpha polypeptide mutations detected in gastric cancer tissues

	Mutation	Overall frequency	Percent/ total cases	Percent/ mutated cases	Microsatellite instability
Exon1	R88Q	1	0.4	5	1
	R108H	4	1.7	20	1
	Total	5	2.2		2
Exon9	E542K	5	2.2	25	1
	E545K	2	0.9	10	1
	E545G	2	0.9	10	1
	Total	9	4.0		3
Exon20	H1047Y	1	0.4	5	1
	H1047R	6	2.6	30	4
	Total	7	3.0		5

(15/20 *vs* 98/205, *P* = 0.05, Table 2). Three-year survival rates were 29% in patients with HER2 overexpression and 59% in cases without HER2 overexpression, respectively [hazard ratio (HR) 1.73; 95%CI: 0.87-3.14, *P* = 0.24].

Mutations of the PIK3CA gene in gastric cancer tissues

PIK3CA mutations were present in 20 cases (8.7%) (Table 2 and Figure 2). The mutation frequency was high (21%)

in T4 cancers and low (6%) in T2 cancers. Mutations in exons 1, 9 and 20 of PIK3CA were detected in 5 (2%), 9 (4%) and 7 (3%) cases, respectively (Table 3). One case had multiple PIK3CA mutations (R108H and E542K). The exon20/exon9 prevalence ratio was 0.78 (7/9). Two new types of PIK3CA mutations, R88Q and R108H, were detected in exon1. All mutations were heterozygous missense single-base substitutions and the most common mutation was H1047R (6/20; 30%) in exon20. PIK3CA mutations were also found to significantly correlate with MSI (10/20 *vs* 9/211, *P* < 0.01) but not with other clinicopathological characteristics. The three-year survival rates were 57% in patients with PIK3CA mutations and 57% in cases without PIK3CA mutations, respectively (HR 1.37; 95%CI: 0.68-3.26, *P* = 0.59).

EBV infection

Eighteen samples in our cohort (8%) were EBV-positive and this positivity significantly correlated with diffuse histological type (13/18 *vs* 93/198, *P* = 0.04) (Table 2 and Figure 3). There were 7 cases of LELC and 6 of those cases were EBV-positive (percent/EBV: 6/18, 33%; percent/all LELC: 6/7, 86%). The three-year survival rates were 57% in patients with EBV infection and 57% in those without EBV infection (HR 0.81; 95%CI:

Original magnification, $\times 200$.

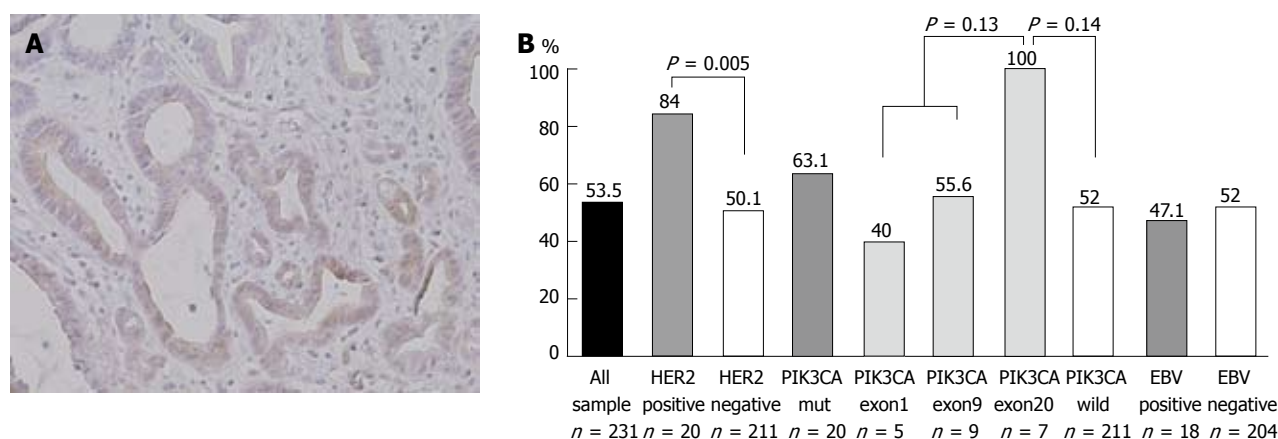

Figure 4 Immunohistochemical analysis and assessment of phospho Akt positivity based on molecular alterations in gastric cancer tissues. A: Gastric adenocarcinoma showing phospho Akt (pAkt) positivity. Original magnification, $\times 200$; B: pAkt expression significantly correlates with human epidermal growth factor receptor 2 (HER2) overexpression ($P < 0.01$) but not with phosphatidylinositol 3-kinase, catalytic, alpha polypeptide (PIK3CA) mutations ($P = 0.37$) or Epstein-Barr virus (EBV) infection ($P = 0.69$).

0.36-2.31, $P = 0.98$).

Association of HER2 overexpression, PIK3CA mutations and EBV infection

One of our cases showed both HER2 overexpression and EBV infection and 3 cases showed both PIK3CA mutations and EBV infection. However there were no cases showing both PIK3CA mutations and HER2 overexpression. Three of the 4 cases were positive also for pAkt expression. PIK3CA mutations were present in 3 EBV-positive cancers, including 2 cases of LELC (2/5, 40%). One EBV-positive cancer with a PIK3CA mutation (H1047R) was MSI-positive.

pAkt expression

pAkt expression was positive in 119 (53%) of our cases but this showed no correlation with clinicopathological characteristics (Figure 4A). On the other hand, pAkt expression was found to be significantly correlated with HER2 overexpression (16/19 *vs* 103/204, $P < 0.01$) but not with PIK3CA mutations (12/19 *vs* 107/204, $P = 0.37$)

or EBV infection (8/17 *vs* 103/198, $P = 0.69$) (Table 2). The frequency of pAkt expression was higher in cancers with exon20 mutations (100%) than in those with exon1 (40%) or exon9 (56%) mutations of PIK3CA, although this difference did not reach statistical significance (Figure 4B). The five-year survival rates were 37% in patients with pAkt expression and 59% in those without pAkt expression (HR 1.75; 95%CI: 1.12-2.80, $P = 0.02$) (Figure 5). Hence, pAkt expression significantly correlates with a poor prognosis in gastric cancer.

DISCUSSION

In our present study, we systematically characterized HER2 expression, PIK3CA mutations and EBV infection, all of which are involved in the PI3K-Akt signaling pathway, in a large cohort of patients with gastric cancer ($n = 231$). We aimed to determine the prevalence of these characteristics with a high level of precision and to correlate them with clinicopathological and molecular features, such as MSI and pAkt expression.

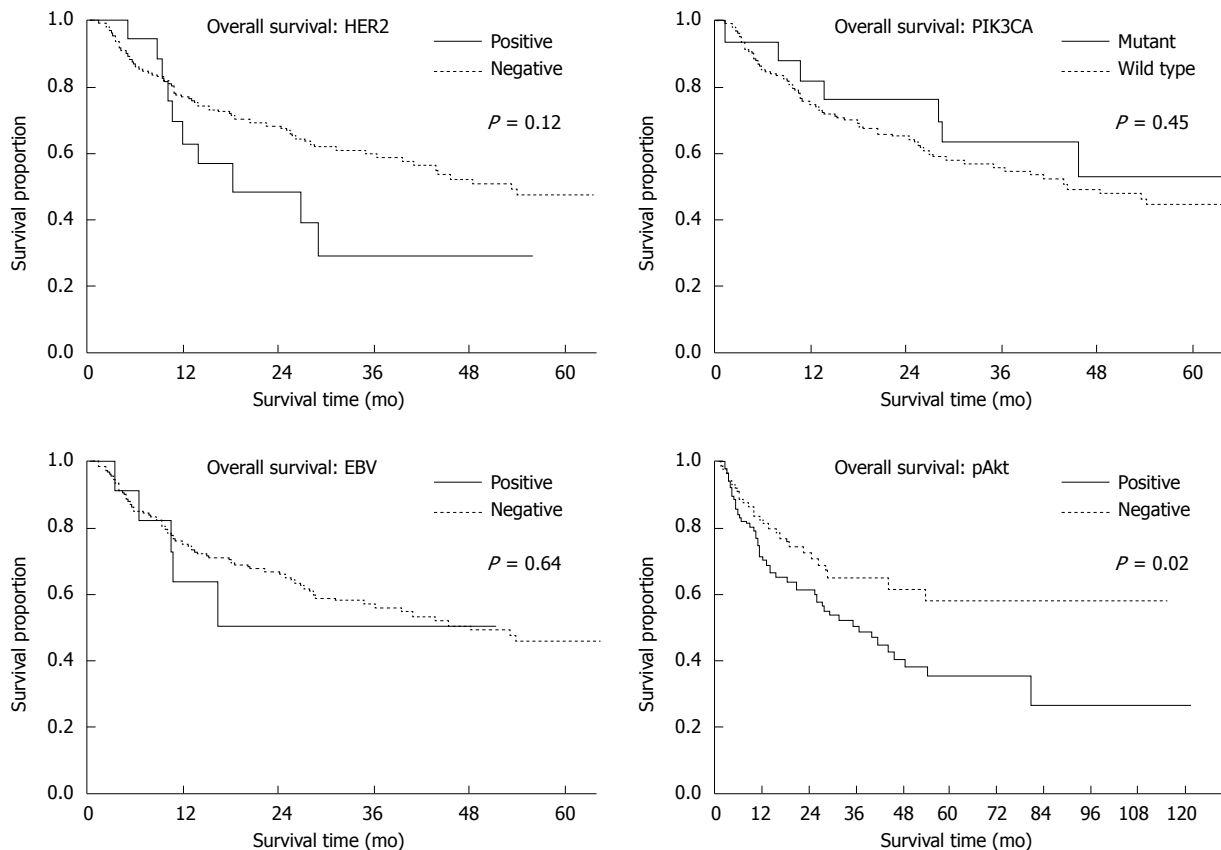

Figure 5 Survival analysis of gastric cancer patients. Three year survival of human epidermal growth factor receptor 2 (HER2)-positive vs HER2-negative, 29.1 mo vs 59.4 mo; Phosphatidylinositol 3-kinase, catalytic, alpha polypeptide (PIK3CA) mutation vs wild type, 63.7 mo vs 56.3 mo; Epstein-Barr virus (EBV)-positive vs EBV-negative, 51.3 mo vs 57.6 mo; And phospho Akt (pAkt)-positive vs pAkt-negative, 50.7 mo vs 64.8 mo. Five year survival of pAkt-positive vs pAkt-negative cases, 35.5 mo vs 58.1 mo.

HER2 overexpression (IHC 3+) was present in 20 samples (8.4%), a value that is within the range (7%-34%) reported in the current literature^[5-9]. HER2 overexpression was found to significantly correlate with the intestinal histological type. Hence, the frequency of HER2 expression may depend on, at least in part, the distribution of histology in a cohort of gastric cancer samples. Some studies have suggested that HER2 positivity in gastric cancer is associated with poor outcomes and aggressive disease, but the results are conflicting. We found for the first time in our present analyses that HER2 overexpression significantly correlates with pAkt expression in gastric cancer tissues. Moreover, pAkt expression correlated with a poor prognosis in these patients. Thus, the HER2-Akt axis may play an important role in gastric cancer.

Pyrosequencing-based methods facilitate the identification of low-frequency tumor mutations and allow a more accurate assessment of tumor mutation burden^[17,23,24]. We characterized PIK3CA mutations in gastric cancer tissues using pyrosequencing for the first time. The overall prevalence of PIK3CA mutations was found in our analysis to be 8.7%, a value that is within the previously reported range (4% to 25%)^[10,12-15]. The mutation frequency was found to be high (21.4%) in T4 cancers and low (6.4%) in T2 cancers in our sample cohort. Thus, PIK3CA mutations appear to be late events in gastric carcinogenesis,

leading to tumor progression. These patients might therefore be appropriate for targeted therapies directed against the PI3K pathway.

The most common PIK3CA mutation found in our analysis was H1047R, which was also found previously^[15]. Importantly, two new types of mutations were found in exon1. To our knowledge, PIK3CA mutations involving residues 88 and 108 (R88Q and R108H) have been never reported previously in gastric cancer, nor described in the COSMIC database, despite the large number of previous studies in which this region was investigated. These mutations have been detected in several other types of cancer tissues^[25]. Importantly also, these mutations have been reported to be gain-of-function^[26-28]. Our present results thus have potential clinical implications since the mutational status of PIK3CA could stratify patients for genotype-based molecular therapies targeting the PI3K pathway. Hence, exon1 of PIK3CA should be analyzed in gastric cancer patients in these clinical settings.

PIK3CA mutations were found to be significantly associated with the MSI phenotype in our experiments. An association between PIK3CA mutations and MSI has been reported, or at least suggested, for both gastric and colon cancers^[12,13,29]. We found in our present study that PIK3CA mutations in cancers with MSI are distributed in exon1, exon9 and exon20. These results further sup-

port the notion that PIK3CA is one of the most important oncogenes activated by missense mutations in MSI-positive gastric cancers.

The frequency of pAkt expression was found to be higher in cancers with exon20 mutations (100%) than in those with exon1 (40%) or exon9 (56%) mutations in PIK3CA. These results further support the notion that the functional significance of PIK3CA mutations depends on the mutation type and that the H1047R hotspot mutation has high oncogenic activity.

The previous ToGA study has shown that the addition of trastuzumab to the chemotherapeutic regimen improves survival in patients with advanced gastric or gastroesophageal junction cancer^[5,6]. PIK3CA mutation is one of the mechanisms underlying the resistance to trastuzumab in breast cancer^[30]. Trastuzumab is likely to be effective for HER2-overexpressing breast cancers with no PIK3CA mutations, with possible rescue using HER2-TKIs in cases of relapse^[31]. For HER2-overexpressing breast cancer with PIK3CA mutations, inhibitors against molecules of the PI3K pathway are possibly more effective than anti-HER2 agents, which are unlikely to be beneficial^[32]. In our present study, PIK3CA mutations were not found in gastric cancers with HER2 overexpression. Thus, it is unlikely that PIK3CA mutation is a major mechanism underlying the resistance to trastuzumab in gastric cancer.

HER2 overexpression was found in only one of the 18 EBV-positive gastric cancers in our sample cohort. This result can be explained, at least in part, by the fact that HER2 overexpression and EBV infection significantly correlate with intestinal and diffuse histological types, respectively. On the other hand, PIK3CA mutations were identified in 3 EBV-positive cancers, including 2 cases of LELC (2/5, 40%). Although not analyzed in our current study, EBV infection reportedly inactivates PTEN through the CpG island methylation of its promoter in EBV-associated gastric cancer^[21]. Thus, alterations in the PI3K-Akt signaling pathway in EBV-positive gastric cancers may differ from those in EBV-negative cancers.

Finally, pAkt expression was found to correlate with a poor prognosis in gastric cancer. A significant association between increased pAkt expression and poor prognosis has been reported previously in patients with T3/T4 gastric cancer but not in those with T1/T2 cancer^[33]. It has been reported also that pAkt expression is associated with increased resistance to multiple chemotherapeutic agents in gastric cancer patients, when chemotherapeutic sensitivities were tested using MTT assays^[34]. Thus, Akt activation appears to lead to a poor prognosis and resistance to chemotherapeutic agents in gastric cancer. A positive correlation between a decrease in the pAkt levels after gefitinib administration and tumor apoptotic index in gastric cancer has also been reported^[35]. Further analyses regarding the pAkt status in cancer tissues before and after chemotherapy and molecular targeted therapy will be necessary. Not all Akt activation events can be

explained by HER2 expression, PIK3CA mutations, and EBV infection in gastric cancer. We have reported previously that a dominant negative insulin-like growth factor (IGF)-1 receptor blocks the Akt-1 activation induced by IGF-1 and IGF-2 in gastric cancer cell lines^[36]. Thus, molecular alterations, such as the overexpression of IGF-1 receptor, might be involved in the activation of Akt in gastric cancer and this issue needs to be clarified in the near future.

COMMENTS

Background

Personalized therapy has begun also in advanced gastric cancer through the use of trastuzumab, an anti-human epidermal growth factor receptor 2 (HER2) antibody. Many drugs targeting the phosphatidylinositol 3-kinase (PI3K)-Akt pathway have now been developed and clinical trials are ongoing. An appropriate biomarker is necessary for successful molecular targeted therapy. The alterations of molecules in the PI3K-Akt pathway could be a good biomarker for such drugs.

Research frontiers

Various alterations, such as activation of growth factor receptors, PI3K, catalytic, alpha polypeptide (PIK3CA) mutations and Epstein-Barr virus (EBV) infection lead to activation of the PI3K-Akt signaling pathway. However, clinicopathological and molecular correlates among such alterations have not been clearly addressed. In the present study, the authors identify new clinicopathological and molecular correlations between HER2 expression, PIK3CA mutations, EBV infection and phospho Akt (pAkt) expression in gastric cancer.

Innovations and breakthroughs

This is the first study to systematically characterize HER2 expression, PIK3CA mutations and EBV infection, all of which are involved in the PI3K-Akt signaling pathway, in a large cohort of patients with gastric cancer. The prevalence of these characteristics was thereby determined with a high level of precision and correlations with the clinicopathological and molecular features of gastric cancers, such as microsatellite instability and pAkt expression, could be assessed accurately for the first time.

Applications

The results have potentially important clinical implications since the mutational status of PIK3CA can be used to stratify cancer patients for genotype-based molecular therapies that target the HERs-PI3K pathway.

Terminology

PI3K-Akt pathway: Akt is believed to transduce the major downstream PI3K signals in cancer. Akt regulates cell growth and survival pathways by phosphorylating substrates such as GSK3, forkhead transcription factors, and the TSC2 tumor suppressor protein; PIK3CA: PIK3CA encodes a key enzymatic subunit of PI3K. Gain of function mutations in PIK3CA occur frequently in several cancer types. Hotspots of PIK3CA mutations are located in exons 9 and 20.

Peer review

The authors investigated HER2 expression, PIK3CA mutations and EBV infection in patients with gastric cancer. The results demonstrated that pAkt expression significantly correlates with the prognosis and the HER2 expression status in gastric cancer. This article is important for the further development of molecular targeted therapy in patients with advanced gastric cancer.

Abstract

AIM: To assess the rate and risk factors for tumour seeding in a large cohort of patients.

METHODS: Over an 8-year period, 1436 hepatocellular carcinoma (HCC) patients with 2423 tumour nodules underwent 3015 image-guided percutaneous cryoablation sessions [1215 guided by ultrasonography and 221 by spiral computed tomography (CT)]. Follow-up CT or magnetic resonance imaging was performed every 3 mo. The detailed clinical data were recorded to analyse the risk factors for seeding.

RESULTS: The median follow-up time was 18 (range

1-90) mo. Seeding was detected in 11 patients (0.76%) at 1-24 (median 6.0) mo after cryoablation. Seeding occurred along the needle tract in 10 patients and at a distant location in 1 patient. Seeded tumours usually showed similar imaging and histopathological features to the primary HCCs. Univariate analyses identified subcapsular tumour location and direct subcapsular needle insertion as risk factors for seeding. Multivariate analysis showed that only direct subcapsular needle insertion was an independent risk factor for seeding ($P = 0.017$; odds ratio 2.57; 95%CI: 1.47-3.65). Seeding after cryoablation occurred earlier in patients with poorly differentiated HCC than those with well or moderately differentiated HCC [1.33 ± 0.577 mo vs 11.12 ± 6.896 mo; $P = 0.042$; 95%CI: (-19.115)-(-0.468)].

CONCLUSION: The risk of seeding after cryoablation for HCC is small. Direct puncture of subcapsular tumours should be avoided to minimise seeding.

INTRODUCTION

In patients with hepatocellular carcinoma (HCC) superimposed on cirrhosis, orthotopic liver transplantation, surgical resection and percutaneous ablation are considered radical treatments as they provide better survival rates compared with no treatment^[1]. Because of the poor acceptance of surgery and a severe shortage of donor organs, image-guided percutaneous ablation therapies play an important role in the management of HCC. Various local ablation therapies such as percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), microwave (MW) ablation and cryoablation have been developed for the treatment of unresectable HCC. All these procedures require the insertion of long, sharp needles into the liver parenchyma and tumours, which may cause various complications, although the complication rates are low. Tumour seeding is one of the most serious complications, especially in patients who are waiting for liver transplantation^[2]. The reported incidence of seeding after other ablation procedures varies widely: 0.2%-1.4% following PEI^[3,4], 0.005%-12.5% following RFA^[5,6] and 0.75% following MW ablation^[7].

Certain factors have been found to increase the likelihood of needle-tract seeding, including a superficial or subcapsular tumour^[8], high number of needle insertions^[9,10], large needle bore^[9,11], end-cutting needle^[8,9], absent or thin layer of normal liver parenchyma surrounding the needle tract^[9,10], high-grade HCC (moderately or poorly differentiated^[3,8,9], high serum alpha-fetoprotein (AFP) level^[2], tumour volumes > 2 cm³ and immunosuppression^[12].

Argon-helium cryoablation is a new local ablation modality. At one time, this technology caused some authors to question its use in HCC. Most of the bias against this percutaneous setting is based on a theoretical risk of post-procedure haemorrhage. However, the gradual downsizing of cryoprobe has fueled interest in percutaneous use, which offers several potential advantages versus the heat-based ablation modalities^[13]. First, multiple cryoprobes can be used simultaneously to generate a large zone of ablation. Second, the size and shape of the developing ice ball can be readily visualized using intra-procedural computed tomography (CT), magnetic resonance imaging (MRI) or ultrasound (US). Third, in contrast to heat-based ablation, percutaneous cryoablation is a relatively painless procedure. Recently, many studies have reported that imaging-guided percutaneous cryoablation is safe and effective for the treatment of HCC^[14-16]. In our previous study, the 1-, 2- and 3-year survival rates in patients with HCC < 5 cm in diameter who were treated with cryoablation were 92%, 82% and 64%, respectively, and the rate of serious complications was low^[13]. To our knowledge, tumour seeding after percutaneous cryoablation for HCC has not been described to date. The present study was conducted to evaluate the incidence and possible risk factors for seeding after percutaneous cryoablation, by reviewing the prospective database of HCC patients treated by cryoablation in our department.

MATERIALS AND METHODS

Patients

This study included 1436 consecutive patients with HCC who were treated at the Center of Therapeutic Research for Hepatocellular Carcinoma, 302 Hospital of PLA, between April 2003 and June 2011. HCC was diagnosed based on typical findings on MRI or CT (hyperattenuation in the arterial phase and hypoattenuation in the portal-venous phase) and serum AFP level. The diagnosis was confirmed by histopathological examination of US- or CT-guided biopsy specimens in 736 patients. Until 2007, we biopsied almost all tumours before treatment, and after 2007 we only biopsied cases in which we could not make a definite diagnosis using dynamic CT or MRI. Biopsy specimens for histological examination were obtained with 1-2 passes of a 19.5-gauge end-cutting needle (AutoVac; Angiomed, Karlsruhe, Germany). Histopathological grading of tumour differentiation was performed using the criteria described by Edmondson *et al*^[17]. Tumour stage was defined according to the Barcelona Clinic Liver Cancer (BCLC) classification^[18]. Performance status (PS) was defined according to the Eastern Cooperative Oncology Group criteria (ECOG). The 1436 patients had a total of 2423 tumours with a diameter of 1.2-15.0 cm (mean 4.5 ± 2.3 cm). The clinical characteristics of the patients are shown in Table 1. All cryoablation treatments were approved by the Research Ethics Committee at 302 Hospital of PLA. Written informed consent was obtained from all patients who met the inclusion criteria, before blood and tumour specimens were obtained, and before data were collected and analysed.

Inclusion and exclusion criteria

Inclusion criteria for cryoablation were as follows: contraindications to surgical resection or orthotopic liver transplantation, Child-Pugh class A or B liver function, total serum bilirubin level < 51.3 $\mu\text{mol/L}$, platelet count $\geq 20 \times 10^9/\text{L}$ and performance status ≤ 2 . Ascites was controlled before the procedure with diuretics. Patients with early HCC who were reluctant to undergo hepatic resection or transplantation were included. Patients were excluded for the following reasons: BCLC stage D (ECOG PS > 2, Child-Pugh C), tumour thrombosis at the main branch of the portal vein and the size of the thrombosis exceeded 50% of the diameter of the portal vein, extra-hepatic metastasis, tumours which were not accessible percutaneously, or a history of other ablation therapies. We generally performed percutaneous cryoablation in patients with up to three lesions, all of which were ≤ 5 cm in diameter, but we performed a combination of repeated cryoablation and transarterial chemoembolisation (TACE) in some patients who did not meet these criteria.

Technical terms

We defined a session as a single treatment consisting of one or more ablations performed on one or more tumours. To assess tumour depth, we categorised tumours

Table 1 Baseline characteristics of patients *n* (%)

¹Values are expressed as mean ± SD, *n* = 1436; ²Of 736 cases in which biopsy was performed. HBs-Ag: Hepatitis B surface antigen; HCV-Ab: Hepatitis C virus antibody; BCLC: The Barcelona Clinic Liver Cancer classification; AFP: Alpha-fetoprotein.

as subcapsular or deep. Tumours were defined as subcapsular when they were located adjacent to the surface of the liver, less than 0.5 cm of parenchyma between the tumour and the liver capsule, otherwise, they were defined as deep. Direct subcapsular needle insertion was defined as puncture of subcapsular tumours without traversing a sufficient portion of normal hepatic parenchyma. The number of needle insertions was defined as the total number of needle positions in all sessions.

Argon-helium cryoablation procedure

Argon-helium cryoablation was performed as described in our previous report^[16]. Briefly, an argon-helium gas-based CRYOcare system (EndoCare, Irvine, CA, United States) and cryoprobes were used to freeze the tumour with a dual freeze-thaw cycle under US or CT guidance.

After determining the most favourable percutaneous approach, we inserted the 3-mm cryoprobe into the tumour through the sheath introducer system under US or CT guidance, and advanced the tip to the distal margin of the targeted lesion. The number of probes used depended on the location and size of the lesions to be ablated. The dual freeze-thaw cycle comprised a 20-min freeze, a 10-min thaw and a further 15-min freeze. The dimensions of the frozen tissue were monitored by US or CT. The cryoprobe temperatures were reduced to $-135^{\circ}\text{C} \pm 2^{\circ}\text{C}$ within 1 min. After removal of the probes, all tracts were packed with Surgicel (Johnson and Johnson, Inc., Arlington, TX, United States) through the sheath introducer to control bleeding, and the sheath introducer was removed. We aimed to perform curative ablation of all tumours in each session by single or multiple cryoablation, particularly for tumours < 5 cm in diameter. Dynamic CT or MRI was performed 2-3 d after treatment to evaluate treatment efficacy. Complete ablation was defined as non-enhancement of the entire lesion on CT or MRI with a safety margin in the surrounding liver parenchyma. Patients underwent additional ablation sessions until complete ablation was confirmed in all nodules, to a maximum of three sessions. If ablation was incomplete after three sessions, we performed TACE. The cryoablation procedure was performed under conscious sedation. Echocardiography, ventilation and oxygen saturation levels were monitored throughout the procedure. Patients were kept warm during cryoablation with warming mats.

Follow-up and tumour seeding

All patients underwent MRI and CT at 1 mo after cryoablation. Patients were then assessed every 2-3 mo, including measurements of liver biochemistry and AFP level, and by CT or MRI. A newly detected tumour attached to the peritoneum or pleura was considered to be seeded, and the diagnosis was confirmed by biopsy and histopathological examination. Seeded tumours were treated with repeat cryoablation, PEI or TACE when feasible. The seeding rate was calculated based on the number of patients.

Statistical analysis

Potential risk factors for seeding were analysed. The following variables were recorded: age, sex, viral markers, tumour size, number of tumour nodules, tumour location, direct subcapsular needle insertion, tumour differentiation, number of cryoablation sessions, number of needle insertions, percutaneous biopsy prior to cryoablation and serum AFP level. Continuous variables were compared between patients with and without seeding using the Student's *t* test. The χ^2 test or Fisher's exact test was used to compare categorical variables between the groups. Variables with *P* < 0.1 were entered into a multivariate logistic regression model using stepwise selection of variables. Variables with *P* < 0.05 were considered statistically significant. All analysis were conducted using SPSS software version 13 (SPSS Inc., Chicago, IL, United States).

RESULTS

Clinical features of patients with tumour seeding

A total of 1436 HCC patients underwent 3015 cryoablation sessions (1215 guided by ultrasonography and 221 guided by CT; average 2.1 sessions per patient) for 2423 nodules. When a patient underwent more than one treatment session, the data from the initial session were used. During the follow-up period (median 18 mo; range 1-90 mo), seeding was diagnosed in 11 patients at an interval of 1-24 (median 6.0) mo after the first cryoablation. The seeding rate was 0.76% per patient (11/1436). The longest interval between the first cryoablation session and detection of seeding was 2 years. The cumulative seeding rates

were analysed using Kaplan-Meier estimates, and were 0.49% at 1 year and 1.0% at 2 years (Figure 1). Table 2 shows the baseline characteristics of the 11 patients with seeding. Eight of these patients were male, and the mean patient age was 56.5 ± 9.0 years. Ten patients were hepatitis B surface antigen positive and one patient was hepatitis C virus antibody positive. Eight patients were Child-Pugh class A and three were Child-Pugh class B. The mean tumour size was 4.5 ± 1.9 cm, and the mean number of tumours was 1.3 ± 0.6 . The mean number of needle insertions was 3.3 ± 1.7 . Direct subcapsular needle insertions were performed in eight patients with subcapsular tumours. Six patients underwent biopsy prior to cryoablation, of which three had poorly differentiated HCC. Four patients were classified as BCLC stage A, six as stage B, and one as stage C. The tumours were completely ablated in eight patients. The mean serum AFP level was 1182.9 ± 2668.6 ng/mL.

Seeding occurred along the cryoablation needle tract in 10 patients, and at a distant location in 1 patient (Figure 2). The seeding was intraperitoneal in seven patients, intraperitoneal and in the intercoastal muscles in one patient, pleural in one patient, and in the abdominal wall (subcutaneous fat) in one patient. One patient had distant seeding in the peritoneal cavity. In ten patients, the seeded tumours were < 3 cm in diameter, and in one patient the tumour was 3 cm in diameter. Nine (81.8%) patients had a single seeded tumour, and the other two (18.2%) patients had two and three seeded tumours, respectively, indicating that multiple seeding was not uncommon. One patient developed treatment-related liver haemorrhage 5 mo before the seeding was detected.

CT and MRI are the preferred imaging modalities for detecting needle-tract seeding. The seeded tumours are usually detected as one or a few round or oval-shaped

Figure 2 Locations of hepatocellular carcinoma and of seeding after cryoablation. A: Intrapertitoneal seeding (case 4); B: Intrapertitoneal and intercostal muscle seeding (case 6); C: Seeding in subcutaneous fat (case 3); D: Complete ablation of primary hepatocellular carcinoma (HCC) (case 11); E and F (case 11): Multiple, small, intraperitoneal seeding nodules 1 mo later; G: Complete ablation of primary HCC (case 5); H: Pleural seeding nodules 1 mo later (case 5). Arrowheads indicate primary HCCs, arrows indicate seeding.

enhancing nodules along the needle tract, with a few occurring at a distant location. Seeded tumours showed a similar imaging pattern to primary HCCs, with arterial phase hyperattenuation followed by portal-venous phase hypoattenuation (Figure 3).

Tumour biopsies performed before cryoablation in six patients who developed seeding showed that one patient had a well differentiated tumour, two patients had moderately differentiated tumours, and three patients had poorly differentiated tumours. The seeded tumours in the nine patients without distant or pleural seeding were confirmed by biopsy and histopathological examination. The seeded tumour showed similar differentiation features to the primary HCC in four of these patients (Figure 4).

Seeding was treated by PEI in four patients, resection in one patient, cryoablation in two patients, cryoablation plus sorafenib in two patients, and conservative treatment in two patients. Of the nine patients with seeding who were treated, recurrence of seeding after treatment occurred in five (55.6%), including three treated with PEI and two treated with cryoablation plus sorafenib. Three

of the patients with recurrent seeding were treated with RFA plus radiation and did not have further recurrence, and the other two patients were treated with sorafenib plus cryoablation and TACE (Figure 5).

At the end of the follow-up period, five patients with seeding had died. The causes of death were intrahepatic HCC progression and liver failure. No patient died of their seeded tumour nodules. In patients with seeding, the cumulative survival rates were 90% at 1 year, 68% at 2 years, 53% at 3 years, 32% at 4 years and 32% at 5 years. In patients without seeding, the cumulative survival rates were 86% at 1 year, 61% at 2 years, 51% at 3 years, 43% at 4 years and 34% at 5 years. There were no significant differences in survival rates between the two patient groups ($P = 0.942$) (Figure 6).

Risk factors for tumour seeding

Table 3 shows the results of the univariate analysis to identify risk factors for seeding. Direct subcapsular needle insertion ($P = 0.0043$) and subcapsular tumour location ($P = 0.0152$) were associated with seeding. There were no significant associations between seeding and age, sex,

Figure 3 Computed tomography showing tumour seeding in case 2 after cryoablation for hepatocellular carcinoma, with a history of transcatheter arterial chemoembolisation. A: Contrast-enhanced computed tomography (CT) image showing a 3-cm diameter hepatocellular carcinoma (HCC) in segment II before cryoablation (black arrow); B and C: Contrast-enhanced CT images during the arterial phase (B) and portal-venous phase (C) showing intrahepatic seeding (white arrow) at 2 mo after biopsy and percutaneous cryoablation. The tumour showed hyperattenuation during the arterial phase and hypoattenuation during the portal-venous phase, similar to the primary HCC. Histopathological examination of the seeded tumour showed a poorly differentiated HCC. Note that the intrahepatic tumour was completely ablated.

Figure 4 Computed tomography image and histopathology of primary and seeded tumours (case 10). The 58-year-old woman underwent biopsy and percutaneous cryoablation for a 2-cm diameter subcapsular hepatocellular carcinoma (HCC). A: The tumour was completely ablated (black arrow); B: Intrahepatic seeding at 18 mo after treatment (white arrow); C: Histopathological examination of the biopsy specimen from the primary tumour showed a well differentiated HCC; D: The seeded tumour was resected, and histopathological examination showed a well differentiated HCC. The patient was alive and tumour-free at 60 mo after cryoablation.

viral markers, Child-Pugh class, tumour size, number of nodules, number of sessions, number of needle insertions, tumour differentiation, biopsy prior to cryoablation, BCLC stage, incomplete ablation, or serum AFP level. Even though there was no significant association between seeding and tumour differentiation, seeding was detected earlier in patients with poorly differentiated HCC than in those with well or moderately differentiated HCC [1.33 ± 0.577 mo *vs* 11.12 ± 6.896 mo; 95%CI: (-19.115)-(-0.468); $P = 0.042$]. Multivariate analysis showed that the only significant risk factor for seeding was direct subcapsular needle insertion (odds ratio 2.57; 95%CI: 1.47-7.65; $P = 0.017$).

DISCUSSION

The new modality of imaging-guided percutaneous argon-helium cryoablation has been widely developed in China. Many studies have reported the safety and efficacy of this technique in the treatment of HCC^[14-16]. Although many complications have been reported, the majority are minor and can be treated conservatively. In carefully selected patients, the rate of serious complications is low^[16]. Because of its minimal invasiveness and resulting large ablation zone, percutaneous cryoablation is a useful treatment modality for HCC^[19].

However, occasional tumour seeding after percuta-

Figure 5 Patient treated with sorafenib plus cryoablation and transcatheter arterial chemoembolisation for hepatocellular carcinoma seeding (case 7). A: Complete ablation of the subcapsular hepatocellular carcinoma (arrowhead); B: Multiple, small, intraperitoneal seeded nodules (white arrows); C: Seeded nodules were treated with cryoablation (black arrows) plus sorafenib; D: Recurrence of seeding (white arrow); E: The recurrent seeding was treated with cryoablation (black arrows); F: The seeding was also treated with transarterial chemoembolisation (white arrow). Six months later, there was no further recurrence.

Figure 6 Cumulative overall survival in patients with and without tumour seeding. Survival curves are drawn according to the Kaplan-Meier method, using the log-rank test.

neous cryoablation for HCC remains unavoidable, as in other local ablation treatments such as PEI, RFA and MW ablation. In this study, we systematically searched for evidence of seeding using state-of-the-art imaging over a long follow-up period, and found seeding in 11 of 1436 patients treated with 3015 cryoablation sessions. The seeding rate was 0.76% per patient. The median interval between the first cryoablation session and detection of seeding was 6 (range 1-24) mo, with a median follow-up time of 18 (range 1-90) mo. At the end of the follow-up

period, 580 patients had died, and these patients had a median survival time of 15 (range 1 to 65) mo. All patients were under close observation, and no patients were lost to follow-up. Because of the duration and quality of follow-up, the likelihood of having missed a seeded tumour in this study is minimal.

Similar to other percutaneous interventions such as biopsy, PEI and RFA, the sites of seeding after cryoablation were the thoracic wall, abdominal wall, diaphragm and peritoneal cavity^[20-22]. Seeding usually occurred along the needle tract, but a few cases were at a distant location, with pleural and peritoneal cavity seeding in one patient each. Regular follow-up with contrast-enhanced CT or MRI from the chest to the pelvis is therefore very important.

The median time to diagnosis of seeding has been reported to be 13 (range 1-58) mo after biopsy^[21], 6 (range 2-48) mo after PEI^[21] and 28.5 (range 8.6-60.7) mo after RFA^[22]. In the present study, the median time to diagnosis was 6.0 (range 1-24) mo after cryoablation. The longest interval from the first cryoablation session to the diagnosis of seeding was 2 years. It can therefore be concluded that it is necessary to carefully monitor patients for at least 2 years after cryoablation for HCC. The reason for the longest interval to the diagnosis of seeding in the present study being shorter than in previous studies on biopsy, PEI and RFA is unknown. There are no reports of growth rates for seeded tumours after cryoablation, but it has been reported that the growth rate of needle-tract seeding after biopsy varies depending on the initial number of implanted tumour cells and the doubling time of the tumour, as well as the microenvironment surrounding the seeded tumour. The doubling time of seeded tumours after bi-

opsy is 112 (range 22–415) d^[8], which is comparable to that of primary HCC. Regarding differentiation features, Matsukuma *et al.*^[23] reported that peritoneal seeding can infrequently proliferate aggressively with more differentiated features. In the current study, four patients with seeding showed similar tumour differentiation features to the primary HCC, and only three patients had poorly differentiated HCC, so it is difficult to explain the shorter interval in terms of tumour differentiation. The available data report a median HCC diameter of 32.5 mm in patients who underwent PEI and 30 mm in patients who underwent RFA, and the use of 14- to 22-gauge needles for biopsies, 21- to 22-gauge needles for PEI and 14- to 17-gauge needles for RFA^[20,21]. The shorter interval to detection of seeding after cryoablation may be related to the use of larger needles (a 3-mm cryoprobe correlates to an 11-gauge needle) and larger nodule size (mean 45 ± 19 mm).

HCC is particularly prone to seeding, with higher seeding rates after biopsy (0%–5.1%)^[24] than other solid tumours such as pancreatic tumours (0.003%–0.017%) and other abdominal tumours (0%–0.03%)^[9,25].

In a recent review, several factors were suggested to contribute to seeding after percutaneous interventional procedures, which were listed as follows: poorly differentiated tumour, high serum AFP level, subcapsular tumour location, biopsy prior to RFA, high number of sessions and high number of electrode placements^[19]. However, only Shirai *et al.*^[22] and Imamura *et al.*^[26] have reported multivariate analyses of these factors. Imamura *et al.*^[26] reported that only poor tumour differentiation was an independent risk factor for seeding. Shirai *et al.*^[22] reported that only RFA was an independent risk factor. In

Figure 7 The sheath introducer system. The cryoablation needle (black arrow) is inserted and removed through the sheath introducer system (white arrow).

the present study, univariate analyses identified subcapsular tumour location and direct subcapsular needle insertion as risk factors. There were no significant associations between seeding and age, sex, viral markers, Child-Pugh class, tumour size, number of nodules, number of sessions, number of needle insertions, tumour differentiation, biopsy prior to cryoablation, BCLC stage, incomplete ablation or serum AFP level. Multivariate analysis showed that only direct subcapsular needle insertion was an independent risk factor for seeding.

Several studies have reported that subcapsular tumour location was a risk factor for seeding^[2,27–29]. In a study reporting a 12.5% seeding rate after RFA, all patients with seeding had a subcapsular tumour^[2]. This is consistent with the results of our univariate analysis. In our initial experience, percutaneous cryoablation of subcapsular tumours was also associated with liver haemorrhage^[16]. In the present study, treatment-related liver haemorrhage occurred in one patient with seeding. We therefore insert our cryoprobe across a portion of normal hepatic parenchyma, and avoid direct subcapsular needle insertion for subcapsular tumours whenever possible. This minimises both liver haemorrhage and needle-tract seeding. This may explain why multivariate analysis only identified direct subcapsular needle insertion as an independent risk factor.

There is still controversy regarding whether tumour biopsy prior to treatment or a poorly differentiated tumour increase the risk of seeding^[21–23,30]. In this study, biopsy and a poorly differentiated tumour were not associated with a higher rate of seeding. The current study also did not show a significant association between seeding and tumour size or incomplete cryoablation, which is consistent with the findings of other studies^[21,26]. Although the 3-mm cryoprobe was large, the risk of seeding after cryoablation was small. The risk of seeding may be reduced by the use of the sheath introducer system (Figure 7), through which cryoablation needles are inserted and removed. Similarly, Maturen *et al.*^[31] reported that no seeding occurred when they used a needle introducer that remained in position during multiple passes of a coaxial cutting needle for biopsies, which may protect the tissue along the needle tract and reduce seeding. Further studies should be conducted

to assess the effects of the sheath introducer system on the risk of seeding in percutaneous cryoablation for HCC. In addition, the low risk of cryoablation may be related to the mechanisms of cryoablation. Cryotherapy is believed to kill cells by several mechanisms, including intracellular ice formation, solute-solvent shifts that cause cell dehydration and rupture, small vessel obliteration causing hypoxia and specific anti-tumour immunoreactions that limit tumour growth^[32,33]. Several studies found that cryoablation resulted in both local tumour necrosis and necrosis and shrinkage of the tissues adjacent to the tumour, which was thought to indicate ectopic tumour suppression^[33]. Preclinical evidence of a cryo-immunologic response as well as some clinical data indicate that cryoablation may generate an anti-tumour response^[34,35]. Our previous study indicated that cryoablation not only directly destroys malignant tissues, but also has effects on the adjacent tissues^[36]. Cryotherapy resulted in reduced numbers of peripheral Treg cells and a lowering of the CD8-FoxP3+/CD8+FoxP3- ratio in malignant tissues^[37]. We therefore speculate that anti-tumour immunoreactions induced by cryoablation may limit seeding. This concept deserves further study.

Although poorly differentiated tumour did not increase the risk of seeding, we found that seeding occurred earlier in patients with poorly differentiated HCC than in those with well or moderately differentiated HCC. It is possible that poorly differentiated HCC lacks cohesiveness^[17] and grows more rapidly, allowing the seeding to be identified earlier.

It is not clear whether seeding affects prognosis. Shirai *et al.*^[22] and Imamura *et al.*^[26] investigated the prognosis of HCC patients with seeding after RFA. They reported that the survival rate was not particularly low in patients with seeding, and that seeding itself did not directly affect survival. The present study also did not find significant differences in the cumulative survival rates of patients with and without seeding. By the end of the follow-up period, five patients with seeding had died of intrahepatic HCC progression and liver failure. No patient died due to the growth of seeded nodules. Nevertheless, the survival rates of patients with seeding tended to be lower from the second year onwards. The reasons for the lack of significant differences in survival rates may be as follows: First, the number of patients with seeding was very small compared with the number without seeding. Second, seeded tumours were treated radically, which may improve outcome^[7,38]. It is therefore impossible to claim that seeding does not affect prognosis, and seeded tumours should be treated with the aim of achieving local cure. It is essential to recognise that seeding is difficult to treat successfully. In the present study, the recurrence rate after local radical treatment of seeding was 55.6%.

In conclusion, the relatively low rate of tumour seeding after cryoablation for HCC is considered an acceptable clinical risk. Direct puncture of subcapsular tumours was found to be a risk factor for seeding. Although seeding is sometimes unavoidable, strict attention to detail

and knowledge of seeding and its risk factors are helpful for minimising its occurrence.

COMMENTS

Background

Imaging-guided percutaneous argon-helium cryoablation is widely used in China, and this technique has been found to be safe and effective for the treatment of hepatocellular carcinoma (HCC). However, details of tumour seeding after this procedure have not been reported to date, even though seeding is one of the most important complications.

Research frontiers

This study reports the rate of tumour seeding after percutaneous cryoablation and analyses the risk factors for seeding in a large cohort of HCC patients who were treated with cryoablation sessions over an 8-year period.

Innovations and breakthroughs

Seeding occurred in 11 (0.76%) of 1436 patients treated with percutaneous cryoablation in this study. Only direct puncture of a subcapsular tumour was an independent risk factor for seeding.

Applications

This study indicates that the risk of seeding after percutaneous cryoablation for HCC is small and is considered an acceptable clinical risk. This procedure is minimally invasive and results in a large ablation zone, making it a useful treatment modality for HCC. However, direct puncture of a subcapsular tumour should be avoided. The small risk of seeding may be due to the use of an introducer sheath, or to the mechanisms of cryoablation, and further research is warranted.

Terminology

Percutaneous cryoablation requires the insertion of needle into the liver parenchyma and tumour, which may cause tumour seeding. However, the incidence of HCC seeding after the procedure is low.

Peer review

The authors analyzed the incidence of HCC tumour seeding after percutaneous cryoablation. It is very interesting study and has a great scientific value for physicians who take care of patients with this pathology. The study is well designed and data is convincing.

Abstract

AIM: To investigate whether the expression of kallikrein 12 (KLK12) is related to the development of gastric cancer (GC) and to determine the role of KLK12 in gastric cancer cells growth, invasion and migration.

METHODS: Between September 2007 and March 2008, 133 patients with histologically confirmed GC were recruited for the study. Expression of KLK12 was detected in samples from GC patients by quantitative real-time reverse transcription polymerase chain reaction and immunohistochemistry. The relationship between KLK12 protein expression and clinicopathological features of GC was analyzed. The difference in 5-year survival rates between the high KLK12 protein expression group and the low KLK12 expression group was compared. Additionally, the expression of KLK12 was examined in various human GC cell lines, including MKN-28, SGC-7901 and MKN-45. Small interfering RNA (siRNA) was used

to inhibit KLK12 expression in MKN-45 cells. Cell clones stably transfected with KLK12 siRNA were tested for KLK12 expression by quantitative real-time reverse transcription-polymerase chain reaction and Western blotting. Furthermore, a series of functional assays were performed in this study to assess the biological features of transfected cells. Cell proliferation was assessed using the methylthiazolyltetrazolium assay. Finally, cell migration and invasion were assessed using transwell chamber assays.

RESULTS: Of the 133 GC patients included in the study, 126 (94.7%) showed a higher expression level of KLK12 mRNA when compared to noncancerous tissue specimens. Expression of KLK12 mRNA was significantly higher in GC tissues than in normal tissue ($P < 0.001$). KLK12 protein expression was detected in 96 of 133 (72.2%) GC samples with moderate or strong staining primarily in the cytoplasm. In contrast, negative immunostaining for KLK12 protein was observed in the corresponding normal gastric mucosal tissue. Overexpression of KLK12 protein was significantly associated with lymph node metastasis ($P = 0.001$), histological type ($P < 0.001$) and tumor-node-metastasis stage ($P = 0.005$), while no significant correlation was observed between expression of KLK12 protein and sex, age, depth of invasion, tumor size or lymphatic invasion. Furthermore, patients with high KLK12 expression had a significantly poorer 5-year survival rate than those with low KLK12 expression ($P = 0.002$). Expression of KLK12 mRNA was significantly higher in MKN-45 GC cells compared to normal mucosal cells or two other GC cell lines ($P < 0.01$). Expression of KLK12 in MKN-45 cells was downregulated after transfection with siRNA. Knockdown of KLK12 markedly decreased the proliferation of MKN-45 cells when compared with parent or mock-transfected cells ($P = 0.001$), especially from the 3rd to the 5th day of the assay. In migration assays, fewer KLK12 siRNA cells migrated through the chambers (22.00 ± 1.81) when compared to the parent (46.47 ± 2.42) or mock-transfected cells (45.40 ± 1.99); these differences were statistically sig-

nificant ($P < 0.001$). However, in the invasion assay, the number of KLK12 siRNA cells that invaded the chambers was 18.40 ± 1.12 , closely similar to both the parent (18.67 ± 0.98) and mock-transfected cells (18.53 ± 0.92). There was no significant difference between the three groups in the invasion assay ($P = 0.054$).

CONCLUSION: The *KLK12* gene is markedly overexpressed in GC tissue, and its expression status may be a powerful prognostic indicator for patients with GC. KLK12 might serve as a novel diagnosis and prognosis biomarker in GC.

INTRODUCTION

Gastric cancer (GC) is the fourth most common malignancy, and the second most common cause of cancer mortality worldwide^[1]. Although morbidity and mortality rates for GC are steadily decreasing steadily in many countries, the overall outcomes for patients with GC have not changed significantly in recent decades^[2]. Additionally, none of the potential biomarkers proposed throughout the years for GC have presented the desired properties to be incorporated into routine clinical practice. The human tissue kallikrein (*KLK*) genes are a newly identified subgroup of putative serine proteases, consisting of 15 genes located within approximately 256 kb on chromosome 19q13.3-4^[3-5]. Due to their protease activity and expression in many tissues and cell types, KLKs have been implicated in a wide range of physiological processes and the pathogenesis of human diseases^[6,7]. Over the last several decades, a steadily increasing number of studies have suggested that human KLKs are involved in human carcinogenesis and that several KLKs may be promising biomarkers of prostate, ovarian, testicular, and breast cancers^[8-10]. The most notable kallikrein protein biomarker is KLK3, also known as prostate specific antigen (PSA)^[11]. PSA is currently the only biochemical test for prostate cancer, although the specificity of the test is not optimal^[12]. Recently, a considerable amount of work has focused on identifying novel KLK-derived molecular markers of GC^[13-16]. The human *KLK12* gene is a member

of the KLK family, encoding human kallikrein 12 protein (hK12). Similar to other kallikreins, KLK12 is an enzyme with serine protease activity that participates in several biological processes^[17]. Moreover, some researchers have shown that KLK12 might also play a role in human carcinogenesis^[17-19]. However, no information is available regarding KLK12 expression in human GC.

To explore the vital role of KLK12 in the tumorigenesis and progression of GC, we examined expression patterns of KLK12 in GC tissues, analyzed the relationship between hK12 expression and clinicopathological factors of GC. Furthermore, a series of function assays utilizing small interfering RNA (siRNA)-mediated downregulation of KLK12 expression were performed.

MATERIALS AND METHODS

Patients and samples

Prior to operation, no patient had received any type of treatment. All research examinations were approved by the Ethics Committee Board of Renji Hospital. Moreover, participants in this study signed an informed consent form so that their samples could be used for research purposes from September 2007 to March 2008. A computerized database with the medical history of each patient was created for an extensive statistical analysis. Selection criteria included confirmation of GC diagnosis by histopathology and the availability of sufficient tumor tissue for RNA extraction. Tumor stage was defined according to the 7th edition of International Union Against Cancer tumor-node-metastasis classification. All specimens were snap-frozen in liquid nitrogen immediately after surgery, and then stored at -80 °C until analysis.

Cell lines and cell culture

The human GC cell lines MKN-28, SGC-7901 and MKN-45 and the normal gastric mucosal cell line GES-1 were obtained from Shanghai Institute of Digestive Disease (Shanghai, China). Cell lines were cultured in Dulbecco's modified Eagle's medium (Gibco, United States) with 10% fetal bovine serum (FBS, Gibco, United States).

Total RNA extraction and cDNA synthesis

Total RNA was extracted from the human tissues and GC cells using TRIzol Reagent (Invitrogen, United States) according to the manufacturer's instructions. The RNA concentration and purity were determined using the absorbance ratio at 260/280 acquired by a spectrophotometer. cDNA synthesis from 4 µg of total RNA was performed with a reverse transcription system kit (Promega, United States) according to the manufacturer's protocol. Briefly, samples were preincubated at 70 °C for 10 min, cooled on ice, then added to a reaction mixture consisting of 3 µL dNTP mixture, 2 µL M-MLV reverse transcriptase, 10 µL reverse transcription 5 × buffer, 1 µL Rnasin and 2 µL oligo-(dT)15 primer in a final volume of 20 µL. The reaction mixture was sequentially incubated at 95 °C for 15 min, 99 °C for 15 s and 62 °C for 40 s. The cDNA was

stored at -20 °C before use.

Quantitative real-time reverse transcription polymerase chain reaction assay

Quantitative real-time reverse transcription polymerase chain reaction (RT-PCR) was carried out in 96-well polypropylene microplates on an ABI Prism 7500 sequence detection PCR system (Applied Biosystems, United States) with the following primers: KLK12: 5'-GCCTCAACCTCTCCATC-GTC-3' (forward) and 5'-CTTGAAGGACTCCCCCA-CAC-3' (reverse); β -actin: 5'-CATGTACGTTGCTATC-CAGGC-3' (forward) and 5'-CTCCTTAATGTCACG-CACGAT-3' (reverse). The 20 μ L PCR reaction consisted of (2 \times) SYBR[®] Premix Ex Tag[™] (Takara, Japan), 2 μ L cDNA and 0.4 μ L of each gene-specific primer. The thermal cycling protocol included an initial denaturation step at 95 °C for 30 s followed by 45 cycles at 95 °C for 5 s for denaturation and 62 °C for 40 s for primer annealing and extension. After the last cycle, a melting curve analysis was performed. All PCR reactions were run in triplicate. KLK12 mRNA expression was calculated from the standard curve, and quantitative normalization in each sample was performed using β -actin gene expression as an internal control. Relative quantification was performed using the $2^{-\Delta\Delta C_t}$ method.

Immunohistochemistry analysis

Immunohistochemistry (IHC) studies of hK12 were performed on surgical specimens from patients with GC using the avidin-biotin-peroxidase method (KIT-9702, Maixin Bio, China) on formalin-fixed, paraffin-embedded tissue specimens. All sections were incubated with polyclonal sheep anti-human KLK12 antibody (AF3095, R and D Systems, United States) at a dilution of 1:50. Slides were counterstained with hematoxylin. All sections were evaluated independently and blinded to outcome data by a pathologist three times. A cutoff of more than 30% of the tumor cells with moderate or strong KLK12 cytoplasmic staining in a gastric tumor section was considered to be positive.

siRNA transfection

The expression vector pBSKH1 (SIBS, China) was used for expression of siRNA. The siRNA designed to target the *KLK12* gene (sense strand: 5'-AAACAGUGACAGC-CACGUATT-3', anti-sense strand: 5'-UACGUGGCUG UCACUGUUUGG-3') was inserted into the pBSKH1 vector according to the manufacturer's instructions, and then, the vector was transfected into the GC cells by the Lipofectamine[™] 2000 (Invitrogen, United States). A mock vector-transfected clone of the cell line was used as a control. Stably transfected cell clones were tested for KLK12 expression by quantitative real-time RT-PCR and Western blotting.

Western blotting analysis

Cells were harvested 72 h after transfection, and whole-cell lysates were prepared for protein extraction. The

protein concentrations of the samples were determined by the bicinchoninic acid protein assay. Proteins were separated in 10% sodium dodecyl sulphate polyacrylamide gels, electrophoretically transferred to polyvinylidene difluoride membranes and incubated in a blocking solution of 5% skim milk powder for 1 h at room temperature. Membranes were then incubated with polyclonal sheep anti-human KLK12 antibody (1:500, AF3095, R and D Systems, United States) and anti- β -actin antibody (1:1000, sc-47778, Santa Cruz, United States) overnight at 4 °C. The membranes were washed 3 times in tris-buffered saline tween-20 (TBST) and incubated for 1 h at room temperature with a 1:1000 dilution of secondary antibody conjugated to horseradish peroxidase (Invitrogen, United States). After incubation with a secondary antibody, the membranes were washed in TBST and developed using electrochemiluminescence according to the manufacturer's instructions.

In vitro cell proliferation assay

Cell proliferation was evaluated using the methylthiazolyltetrazolium (MTT) assay. Cells were grown in a monolayer culture and plated at a density of 4×10^3 cells/well into separate wells of a 96-well culture plate. The cells were incubated with MTT after 1, 2, 3, 4 or 5 d. Absorbance was measured at 570 nm using a microplate reader (SpectraMax 250, Molecular devices, United States). The experiments were performed in triplicate.

In vitro migration and invasion assays

The motility and invasiveness of plasmid-transfected cells were evaluated in 24-well transwell chambers with upper and lower culture compartments separated by polycarbonate membranes with 8- μ m pores (CytoSelect[™] 24 Well Cell Migration and Invasion Assay Combo Kit, 8- μ m, CBA100-C, Cell Biolab, United States). Prior to plating cells into the transwells, the 24-well migration plate was allowed to warm up to room temperature for 10 min. A cell suspension containing 1.0×10^6 cells/mL in serum-free media was plated into the top chamber. Five hundred microliters of media containing 10% FBS was placed into the bottom chamber to act as a chemoattractant. Then, 300 μ L of the cell suspension solution was added to the inside of each insert and incubated 24 h in a cell culture incubator. The cells that migrated through the 8- μ m pores and adhered to the lower surface of the membrane were transferred to a clean well containing 400 μ L of 0.09% crystal violet as a cell staining solution and washed several times in a beaker with water. The migratory cells were counted using light microscopy under high magnification, with 5 individual fields per insert. In a similar fashion, the invasiveness of plasmid-transfected cells was also evaluated using this kit (Invasion Chamber Plate, Cell Biolab, United States). Cells, media, experimental conditions, and the analysis performed were similar to those for the migration assays. Triplicate assays were performed for each group of cells in both the migration and invasion assays.

Figure 1 Upregulation of kallikrein 12 mRNA expression in gastric cancer. Quantitative real-time reverse transcription polymerase chain reaction showed that the mean expression value of kallikrein 12 (KLK12) mRNA in cancer tissues was significantly higher than the value in relevant normal tissues. Data are shown as mean \pm SD, using the Student's *t* test ($^bP < 0.01$ between tumor and normal group, horizontal bars represent medians).

Statistical analysis

Statistical analysis were performed using SPSS 11.0 software (Shanghai Jiaotong University, China). The data are expressed as the mean \pm SD. The Student's *t* test and one-way analysis of variance test were used to compare data between the different groups. The χ^2 test was used to assess the relationship between hK12 expression levels and clinicopathological characteristics of GC. Survival curves were drawn according to the Kaplan-Meier method, and the log-rank test was applied to compare the survival curves. Differences were considered significant at the $P < 0.05$ level.

RESULTS

KLK12 mRNA level is upregulated in GC patients

There were 133 GC patients included in the study. The age of the patients ranged from 18 to 87 years (median 61 years). Overall, 126 of the 133 patients (94.7%) showed a higher expression level of KLK12 mRNA in GC tissue specimens compared to noncancerous tissue specimens. The mean expression value of KLK12 mRNA in cancer tissues was significantly higher than the value in relevant normal tissues (2.75 ± 0.78 *vs* 1.10 ± 0.56 , $P < 0.001$, Figure 1).

Immunostaining demonstrates hK12 overexpression in GC tissues

To further validate the expression and localization of hK12 in surgical specimens, IHC was performed on paraffin-fixed GC tissues and matched noncancerous mucosa of 133 patients. Dark-brown immunostaining was most prevalent in cancer cells, whereas the staining levels were lower in stromal cells or fibroblasts of GC tissues. hK12 expression was detected in 72.2% (96/133) GC samples with moderate or strong staining (Figure 2A), primarily located in the cytoplasm (Figure 2A and B). In contrast, negative immunostaining for hK12 was observed in normal gastric mucosal sections (Figure 2C and D).

Table 1 Relationship between human kallikrein 12 protein expression and clinicopathological features in 133 patients with gastric cancer

Feature	<i>n</i>	hK12 expression		<i>P</i> value ¹

¹*P* value was determined by the χ^2 test. hK12: Human kallikrein 12 protein.

Clinicopathological significance of hK12 expression in GC

The clinicopathological factors analyzed in relation to hK12 expression in tumor tissues are shown in Table 1. The incidence of lymph node metastasis was significantly higher ($P = 0.001$) in the high-expression group (76 of 95, 80.0%) than in the low-expression group (20 of 38, 52.6%). The histological type and pathological stage also correlated with the groups. However, no significant difference was observed with regard to sex, age, depth of invasion, tumor size or lymphatic invasion. The 5-year actuarial overall survival rates in patients with high hK12 levels and patients with low hK12 levels were 62.2% and 31.3%, respectively (Figure 3). The difference in survival rates between these two groups was statistically significant ($P = 0.002$).

Expression of KLK12 mRNA in GC cell lines

Furthermore, three well-characterized GC cell lines, MKN-28, SGC-7901 and MKN-45, and the normal gastric mucosal cell line GES-1 were chosen to examine KLK12 mRNA expression due to their diverse differentiation features. MKN-45 cells expressed the highest level of KLK12 across the four cell lines (Figure 4). Therefore, MKN-45 cells were chosen to do a series of functional experiments involving knockdown of KLK12 expression.

KLK12 siRNA-transfected GC cell line stably suppresses both KLK12 mRNA and hK12

As shown in Figure 5A, MKN-45 cells transfected with siRNA targeting KLK12 showed a remarkable decrease

Figure 2 Expression of human kallikrein 12 protein in gastric cancer and non-cancerous mucosal tissues detected by immunohistochemistry. A: Strong positive human kallikrein 12 protein (hK12) immunostaining in gastric cancer (GC) tissues, hK12 staining was observed in the cytoplasm of cancer cells; B: Weak positive hK12 immunostaining in GC tissues; C: Negative hK12 immunostaining in relevant normal tissues; D: Negative hK12 immunostaining in GC tissues (original magnification A, B, D $\times 200$, C $\times 100$).

Figure 3 Overall survival of patients with gastric cancer according to human kallikrein 12 protein expression in the cancer tissues. Patients in the high human kallikrein 12 protein (hK12) expression group had a significantly poorer prognosis than those in the low hK12 expression group. Survival curves are drawn according to the Kaplan-Meier method, using the log-rank test to compare the survival rates ($P = 0.002$).

in the level of KLK12 mRNA compared to mock-transfected or parent MKN-45 cells, as determined by quantitative real-time RT-PCR. Furthermore, we performed Western blotting analysis to verify the efficiency of the KLK12 siRNA. The stable KLK12-suppressed clone was confirmed to express markedly lower levels (about one fourth) of hK12 than the MKN-45 parental cells (Figure 5B), confirming that KLK12 siRNA decreased KLK12 expression, consistent with the quantitative real-time RT-PCR results.

Figure 4 Expression of kallikrein 12 mRNA in gastric cancer cell lines and normal gastric mucosal cell line. Gastric cancer cell lines show higher levels of kallikrein 12 (KLK12) mRNA expression than normal gastric mucosal cell line, while MKN-45 cells expressed the highest level of KLK12 across the four cell lines. Data are shown as mean \pm SD, using the one-way analysis of variance test (^b $P < 0.01$ vs other cell lines).

Knockdown of KLK12 affects the proliferative ability of MKN-45 GC cells

We analyzed whether suppressing the KLK12 expression would alter the growth rate of MKN-45 GC cells. As shown in Figure 6, transfection with KLK12 siRNA remarkably decreased the proliferative ability of MKN-45 cells when compared with the parent and mock-transfected cells ($P = 0.001$), especially from the 3rd to 5th days of the assay.

Knockdown of KLK12 affects the migratory ability of MKN-45 GC cells

We evaluated whether suppression of KLK12 expression could alter the ability of *in vitro* migration and invasion

Figure 5 Efficiency of small interfering RNA in silencing the kallikrein 12 mRNA, and protein expression in MKN-45 cells. A: MKN-45 cells transfected with small interfering RNA targeting human kallikrein 12 (*KLK12*) gene showed a remarkable decrease in the level of *KLK12* mRNA compared to mock-transfected or parent MKN-45 cells. Data are shown as mean \pm SD, using the one-way analysis of variance test ($^bP < 0.01$ vs other cell lines); B: Western blotting analysis showed a reduced protein expression in *KLK12* small interfering RNA (siRNA) transfected cells. The protein levels are measured by Image J software (National Institutes of Health, United States) with β -actin protein normalization.

of MKN-45 cells. As shown in Figure 7, fewer *KLK12* siRNA-transfected cells migrated through the chambers (22.00 ± 1.81) when compared to the parent (46.47 ± 2.42) or mock-transfected (45.40 ± 1.99); these differences were statistically significant ($P < 0.001$, Figure 7A and B). However, in the invasion test, the number of *KLK12* siRNA-transfected cells that invaded the chambers in 18.40 ± 1.12 , closely similar to both the parent (18.67 ± 0.98) and mock-transfected cells (18.53 ± 0.92). There was no significant difference between the three groups in the invasion assay ($P = 0.054$).

DISCUSSION

The *KLK12* gene is a new member of the *KLK* gene family, some members of which are implicated in the initiation and progression of cancer^[20-22]. *KLK12* is encoded by 5 coding exons, and is structurally similar to serine proteases and other known *KLKs*. *KLK12* is expressed in a variety of tissues including the salivary gland, stomach, uterus, lung, thymus, prostate, colon, brain, breast, thyroid, and trachea. Initially, it was reported that expression of *KLK12* is downregulated at the mRNA level in breast cancer tissues and is upregulated by steroid hormones in breast and prostate cancer cell lines^[17]. Memari *et al*^[19] demonstrated that more than 95% of prostate cancers were *KLK12* positive in a tissue microarray study. To the best of our knowledge, this study is the first investiga-

Figure 6 Reduction of cell proliferation by methylthiazolyltetrazolium assay after silencing the kallikrein 12. The proliferative ability significantly decreased in MKN-45 cells after transfection with kallikrein 12 small interfering RNA (siRNA), especially from the 3rd to 5th days of the assay. Data are shown as mean \pm SD, using the one-way analysis of variance test ($P = 0.001$). MTT: Methylthiazolyltetrazolium.

tion to analyze *KLK12* expression in GC. We performed quantitative real time RT-PCR, IHC and a series of functional assays utilizing siRNA-mediated downregulation of *KLK12* expression to determine the role and explore the mechanism of *KLK12* in GC. Our results showed a drastic difference in *KLK12* expression between GC and normal mucosal tissues. Substantially elevated expression of the *KLK6* gene has been observed in clinical tissue samples and several GC cell lines^[13], while other authors have reported that cancerous stomach tissues were found to present significantly decreased levels of *KLK11* and *KLK13* mRNA transcripts in comparison with their normal counterparts^[15,16]. Moreover, our study showed that high hK12 expression was significantly correlated with the lymph node metastasis ($P = 0.001$), histological type ($P < 0.001$) and pathological stage ($P = 0.005$) of GC. High expression of hK12 was also associated with a poor prognosis for patients with GC. These findings suggest that enhanced expression of *KLK12* might play an important role in various pathological processes of GC. MKN-45, a poorly differentiated GC cell line, was chosen for functional experiments because *KLK12* mRNA expression was higher in MKN-45 cells compared to other cell lines. Additionally, hK12 expression was significantly higher in undifferentiated GC. In our experiments, we established clones with suppressed *KLK12* expression by gene silencing using RNA interference (RNAi) techniques. RNAi is mediated by siRNAs that are produced from long double stranded RNAs of exogenous or endogenous origin by an endonuclease of the RNase-III type called Dicer^[23]; this technique has emerged as a powerful tool for understanding gene functioning. As quantitative real-time RT-PCR and Western blotting revealed, *KLK12* siRNA remarkably reduced *KLK12* expression of MKN-45 cells. MTT proliferation assays showed with *KLK12* siRNA dramatically decreased the proliferation of MKN-45 cells when compared with MKN-45 parent and mock-transfected cells. The differences were significant, especially from the 3rd day to the 5th day after transfection, which is in accor-

Figure 7 Effect of cell migration by kallikrein 12 knockdown. A: 24-well transwell chambers with upper and lower culture compartments separated by polycarbonate membranes with 8- μ m pores were used for migration or invasion assay. The chambers were stained by 0.09% crystal violet and cells were counted using light microscopy under high magnification (magnification $\times 10$); B: The migration or invasion cells were counted in 5 individual fields per insert. Values were the number of cells. Data are shown as mean \pm SD, using the one-way analysis of variance test ($^aP < 0.05$ vs other cell lines).

dance with the Western blotting data showing knockdown of KLK12 expression was greatest 72 h after transfection. Metastasis and local recurrence are known to be the primary causes of death after radical surgery of GC patients. Tumor metastasis is a complicated process and involves many steps including migration of cancer cells to, and invasion through, the basement membrane^[24]. In our experiments, significantly fewer KLK12-suppressed cells migrated across polycarbonate membranes when compared to MKN-45 parent and mock-transfected cells ($P < 0.001$). The invasiveness of all three cell lines was comparable, and the KLK12-suppressed cells displayed no difference in the invasion assay compared to parent or mock-transfected cells. Other KLKs have been shown to degrade components of the extracellular matrix. Magklara *et al*^[25] reported that hK6 can degrade fibrinogen and collagen type I, basic constituents of the extracellular matrix, as well as collagen type IV, a major component of the basement membrane *in vitro*. The lysis of certain components of the extracellular matrix is linked with an altered regulation of tumor metastasis. However, Memari *et al*^[26] reported that KLK12 is secreted as an inactive pro-enzyme, which is able to autoactivate to gain enzymatic activity. However, active KLK12 quickly loses its activity due to autodegradation, and its activity can also be rapidly inhibited by zinc ions and by alpha2-antiplasmin through covalent complex formation. According to these results, it is reasonable to conclude that the increased KLK12 expression may not play an important role in metastasis. In

conclusion, we present an early report that KLK12 was remarkably overexpressed in GC tissues and that high KLK12 expression levels were associated with the lymph node metastasis, histological type, pathological stage and poor patient prognosis. Our findings also demonstrate that knockdown of KLK12 expression leads to reduced proliferation and migratory ability with little effect on invasiveness in MKN-45 GC cells. Consequently, KLK12 might serve as a novel diagnostic and prognostic biomarker, as well as a potential therapeutic target, in GC.

COMMENTS

Background

Gastric cancer (GC) is the fourth most common malignancy and the second most common cause of cancer mortality worldwide. Although morbidity and mortality rates for GC are decreasing steadily in many countries, the overall outcome for patients with GC has not changed significantly in recent decades. It is necessary to find a reliable biomarker for GC to be incorporated into routine clinical practice.

Research frontiers

The human kallikrein 12 (KLK12) gene is a new member of the KLK gene family. Similar to other kallikreins, KLK12 is a proteolytic enzyme with serine protease activity, and participates in several biological processes. Moreover, KLK12 may also play a role in human carcinogenesis of cancers such as breast and prostate cancer. However, little is known about KLK12 in human GC.

Innovations and breakthroughs

The results of this study provide strong evidence suggesting that KLK12 expression is upregulated in GC tissue and correlated with lymph node metastasis, poor histological type, advanced clinical stage and decreased overall survival rate. Furthermore, the authors found that knockdown of KLK12 markedly

decreased the proliferative and migratory abilities of MKN-45 GC cells.

Applications

These results demonstrate that KLK12 might serve as a novel diagnostic and prognostic biomarker in GC. This study may represent a future strategy for therapeutic intervention in the treatment of patients with GC.

Terminology

The KLK genes are a newly identified subgroup of putative serine proteases, consisting of 15 genes located within approximately 256 kb on chromosome 19q13.3-4.

Peer review

This is a good descriptive study in which the authors investigate expression of KLK12 in GC tissues. The biological effects of KLK12 knockdown in the GC cell line MKN-45 were also studied. The results are interesting and suggest knockdown of KLK12 overexpression in GC may be a potential therapeutic target. The study was well designed and the data are convincing.

baicalein in promoting hepatocyte proliferation. Serum interleukin (IL)-6, IL-1 β and tumor necrosis factor- α (TNF- α) levels were measured by enzyme-linked immunosorbent assay and liver *IL-6*, *TNF- α* , transforming growth factor- α (*TGF- α*), hepatocyte growth factor (*HGF*) and epidermal growth factor (*EGF*) genes expression were determined by quantitative real-time polymerase chain reaction.

RESULTS: CCl₄-induced acute liver failure model offers a survival benefit in baicalein-treated mice. The data indicated that the mRNA levels of IL-6 and TNF- α significantly increased within 12 h after CCl₄ treatment in baicalein administration groups, but at 24, 48 and 72 h, the expression of IL-6 and TNF- α was kept at lower levels compared with the control. The expression of TGF- α , HGF and EGF was enhanced dramatically in baicalein administration group at 12, 24, 48 and 72 h. Furthermore, we found that baicalein significantly elevated the serum level of TNF- α and IL-6 at the early phase, which indicated that baicalein could facilitate the initiating events in liver regeneration.

CONCLUSION: Baicalein may be a therapeutic candidate for acute liver injury. Baicalein accelerates liver regeneration by regulating TNF- α and IL-6 mediated pathways.

Abstract

AIM: To investigate the hepatoprotective effect of baicalein against carbon tetrachloride (CCl₄)-induced liver damage in mice.

METHODS: Mice were orally administered with baicalein after CCl₄ injection, and therapeutic baicalein was given twice a day for 4 d. The anti-inflammation effects of baicalein were assessed directly by hepatic histology and serum alanine aminotransferase and aspartate aminotransferase measurement. Proliferating cell nuclear antigen was used to evaluate the effect of

INTRODUCTION

Liver is an important organ which plays a central role in metabolic homeostasis^[1]. It also has an amazing regenerative capability after liver mass loss, as demonstrated by Higgins *et al.*^[2] in 1931. Carbon tetrachloride (CCl₄)-induced hepatic injury is a very classic model widely used for hepatoprotective drug screening^[3,4]. The acute hepatotoxicity of CCl₄ lies in its biotransformation to trichloromethyl free radical (CCl₃) or trichloroperoxy radical (CCl₃O₂[•]) produced by the mixed-function cytochrome P450 oxygenase system of the endoplasmic reticulum, which causes oxidative stress and membrane damage^[5]. These free radicals cause lipid peroxidation which results in hepatocellular damage and enhances formation of inflamed tissues. The advantage of this model is that CCl₄ can fulminate hepatitis within a few hours, which specifically leads to necrosis and fatty liver, in a similar way as what happens in the cases of acute hepatitis. Meanwhile, following an inflammatory response launched by resident inflammatory cells, CCl₄-induced acute liver injury also involves an intricately regulated process of hepatocyte regeneration when the dosage of CCl₄ is below lethal level which would lead to irreversible liver damage^[6,7].

Baicalein (5, 6, 7-trihydroxyflavone, BAE, C₁₅H₁₀O₅) is a flavonoid extract from the root of *Scutellaria baicalensis* Georgi, a plant used in traditional Chinese medicine. Previous studies reported that baicalein has multiple functions. It acts as an anti-bacteria and anti-inflammation agent, inhibits the aggregation of blood platelets, decreases the production of endotoxin, and alleviates the reperfusion injury in ischemic tissues^[8,9]. Baicalein was indicated to suppress the growth of human hepatoblastoma cells^[10,11], human breast cancer cells^[12,13], human lung fibroblasts and peripheral lymphocytes^[14] and human leukemia HL-60 cells^[15]. Baicalein has beneficial effects against the cytotoxicity and genotoxicity to hepatocytes by tert-butylhydroperoxide *via* quench free radicals. Moreover, baicalein could protect animals from *D*-galactosamine/lipopolysaccharides induced acute liver failure in murine models, and especially reduce apoptosis (even hepatic necrosis) *via* cellular FLICE-like inhibitory protein and mitogen-activated protein kinase pathway^[16,17]. However, the antihepatotoxic mechanism of baicalein remains vague so far. The aforementioned investigations for liver diseases on the role of baicalein in selectively inducing apoptosis of cancer cells and inhibiting normal hepatocyte apoptosis, prompted us to study whether baicalein would increase the secretion of various inflammatory cytokines and facilitate regeneration of liver cells. The aim of this study is to assess whether baicalein could prevent acute liver injury induced by CCl₄ in mice and to investigate the possible mechanism of its protective role.

MATERIALS AND METHODS

Animals and chemicals

Specific pathogen-free male C57 BL/6 mice (8 wk old) were obtained from Shanghai Slac Laboratory Animal Corporation. The mice were maintained in a conventional clean facility in accordance with the National Animal Care and Use Committee. CCl₄ and baicalein were purchased from Sigma-Aldrich Biotechnology (St Louis, MO, United States). Assays kits for the detection of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were purchased from Jiancheng Biological Technology, Inc. (Nanjing, China). Mouse monoclonal antibody against proliferating cell nuclear antigen (PCNA) and the SABC Staining Kit were from Boster Biological Technology (Wuhan, China). Serum levels of interleukin (IL)-1 β , IL-6 and tumor necrosis factor- α (TNF- α) were measured by enzyme-linked immunosorbent assay (ELISA) kits for IL-1 β , IL-6 and TNF- α from R and D system (Minneapolis, MN, United States). All other chemicals were of the highest grade commercially available.

Induction of liver injury and baicalein administration

Acute liver injury in mice was induced by intraperitoneal injection of CCl₄ at a dose of 1 mL/kg body weight (1:3 diluted in corn oil). A lethal dose was administered by intraperitoneal injection of CCl₄ at 2.6 mL/kg (1:1 diluted in corn oil). At the indicated time points, serum and liver specimens were collected. Mice were orally administered with baicalein (80 mg/kg) dissolved in CMC-Na to 200 mg/L 1 h after CCl₄ injection, and the same dose of baicalein was given twice a day for 4 d, and control mice were treated with same dosage CMC-Na.

Serum AST and ALT

Serum AST and ALT levels were determined with a commercial assay kit (Nanjing Jiancheng Biological Technology, Inc., China). Enzyme activities were presented in international unit per liter (IU/L).

Histology-injury grading

Formalin-fixed, paraffin-embedded liver sections were stained with hematoxylin-eosin for the histological studies. To evaluate the degree of necrosis after acute liver injury, we created an injury grading score (Grades I-IV) based on severity of necrotic lesions in the liver parenchyma (Table 1).

Proliferating cell nuclear antigen staining

For PCNA immunohistochemical staining, de-paraffinized sections of liver blocks were used. Liver tissues were fixed for 24 h in neutral buffered formalin, processed routinely and embedded in wax. Immunohistochemical staining was performed as previously described^[18]. The sectioned liver tissues were stained using a mouse monoclonal antibody against PCNA and the SABC Staining Kit (Wuhan Boster Biological Technology, Wuhan, China) according to the

¹Days after CCl₄ treatment at the sacrifice point. Injury grading with respect to severity of necrosis in liver parenchyma. Grade 0: Normal histology; Grade I: Presence of degenerated hepatocytes with only rare foci of necrosis; Grade II: Mild centrilobular necrosis around the central vein, occupying only a part of Rappaport's zone III; Grade III: Established necrosis limited to zone III; Grade IV: Extensive, confluent centrilobular necrosis involving Rappaport's zone III and II.

manufacturer's protocol, then subjected to photomicroscopic observation (NIS-Elements Basic Research, Nikon Eclipse 50i, Kanagawa, Japan).

ELISA

Serum IL-1 β , IL-6 and TNF- α levels were measured by ELISA kit (RD system, Minneapolis, MN, United States) according to the manufacturer's instructions. Cell lysates were generated by adding 1 mL fresh medium to 100 mg liver specimen or 1×10^7 cells followed by three freeze-thaw cycles. Transforming growth factor- α (TGF- α), hepatocyte growth factor (HGF) and epidermal growth factor (EGF) and ELISA kits were used to determine protein concentrations^[19,20]. ELISA was performed in triplicate for each sample of lysate.

Real-time quantitative polymerase chain reaction

Total RNA was obtained from the liver of mice and was prepared using TRIzol reagent (Invitrogen, Carlsbad, CA, United States). The quantification and qualification of RNA were performed using ultraviolet absorbance assay and electrophoresis in 1.2% agarose. RNA quality was satisfactory for the 28s rRNA band on gel and had twice the intensity of the 18s rRNA band without significant smearing of rRNA. Real-time quantitative polymerase chain reactions (PCRs) were performed with the MJ chromo 4 reverse transcription-PCR detection system (Bio-Rad Laboratories, Hercules, CA, United States). Specific primers were designed using Primer 5.0 software (Premier Biosoft International, Palo Alto, CA, United States) and their sequences are listed in Table 2. As an internal control, the expression of the housekeeping gene β -actin was measured and remained constant at all the experimental conditions studied.

Figure 1 Baicalein increased probability of survival after a lethal dose of carbon tetrachloride (2.6 mL/kg). Mice ($n = 15$) were administered with or without baicalein twice a day for 5 d. Survivals were scored twice a day, and the results were analyzed using the log-rank test and expressed as the Kaplan-Meier survival curves. $P = 0.009$ between control and baicalein groups.

Statistical analysis

Student's t test (unpaired, two-tailed) was used for comparisons between data from specified different conditions. Results from survival experiments were analyzed using the log-rank test and presented as Kaplan-Meier survival curves.

RESULTS

Baicalein reduces mortality after a lethal dose performance

In a previous experiment to observe the dosage-dependent effect of CCl₄, we found that 2.6 mL/kg CCl₄ was a median lethal dose (a mortality of 50%, data not shown) within 24 h. Oral baicalein administration offers a survival

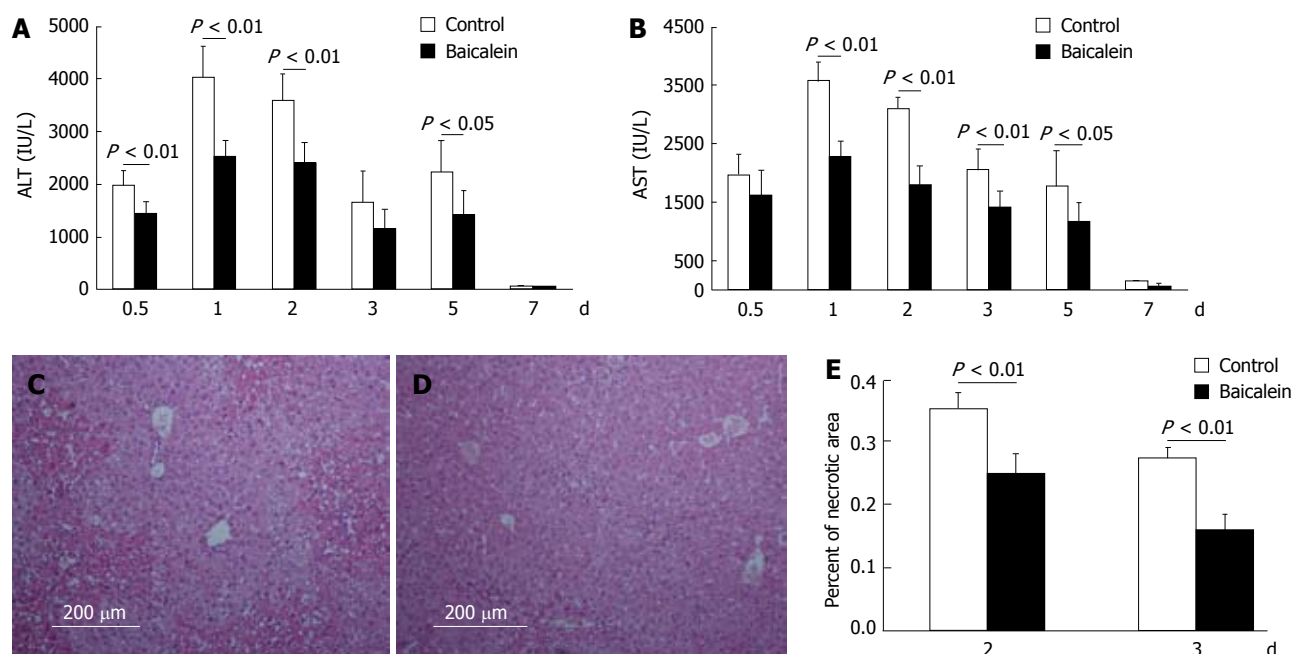

Figure 2 Baicalein protects liver against carbon tetrachloride induced acute liver injury. A: Serum alanine aminotransferase (ALT); B: Serum aspartate aminotransferase (AST); C: Hematoxylin and eosin (HE) stained liver sections of control group 3 d after carbon tetrachloride (CCl₄) treatment; D: HE stained liver sections of baicalein group 3 d after CCl₄ treatment; E: Percent of necrotic areas in control group and baicalein group 2 and 3 d after CCl₄ treatment. Mice received intraperitoneal CCl₄ at the dosage of 1 mL/kg body weight (1:3 diluted in corn oil). Mice in baicalein group were orally administered baicalein (80 mg/kg) 1 h after CCl₄ injection, twice a day for 4 d (original magnification, $\times 100$). Necrosis with clusters of inflammatory cells around central vein was seen in control group; and histological recovery with only inconspicuous necrosis remaining around central vein, and very few inflammatory cells were present in the baicalein group. Control mice were treated with an equal volume of CMC-Na. Values represent mean \pm SE ($n = 6$). $P < 0.05$, $P < 0.01$ between control and baicalein groups.

benefit for mice, increasing the probability of survival significantly one d after CCl₄ injection ($P = 0.009$, Figure 1).

Baicalein protects mice from acute hepatocellular damage

To confirm the effect of baicalein in protecting mice from hepatic damage, we used serum ALT and AST levels as indicators for liver injury. In the control group, the serum level of ALT and AST rapidly reached the peak level at day 1, and decreased thereafter, while baicalein significantly inhibited the elevated ALT and AST from day 1 to day 5 ($n = 6$) (Figure 2A and B). The attenuated increase of serum AST and ALT indicated that baicalein plays a direct protective role in hepatocytes. To evaluate the effect of baicalein on hepatocellular necrosis and inflammation, histological changes in the liver after CCl₄ administration with or without baicalein treatment were examined by histology-injury grading (Table 1). Liver sections from the baicalein-treated mice demonstrated only moderate necrosis involving the centrilobular areas, maintaining a rather normal architecture. The necrotic areas were significantly diminished around the central vein and centrilobular regions in baicalein-treated mice at day 3 (Figure 2C-E). These findings indicated that baicalein has potential anti-hepatotoxic activity.

Baicalein promotes hepatocyte proliferation from an early phase

To confirm whether baicalein has the potent advantage

of accelerating hepatocyte proliferation from an early phase, we investigated the proliferation of hepatocytes using immunostaining of PCNA in sections of liver tissue at days 2 and 3. The PCNA staining confirmed that baicalein administration increased the number of positive staining cells more significantly at day 2 compared with the control group (Figure 3A and B). A great number of PCNA⁺ hepatocytes could be detected in the liver sections of baicalein-treated mice at day 3 (Figure 3C and D), which demonstrated that baicalein significantly increased the number of PCNA⁺ cells. Numbers of PCNA⁺ cells in at least 12 mm² tissue sections were counted for each mouse, and data showed that baicalein could accelerate hepatocyte proliferation (Figure 3E).

Serum levels of IL-1 β , IL-6 and TNF- α

To evaluate the hepatoprotective mechanism of baicalein, serum IL-1 β , TNF- α and IL-6 levels were determined by ELISA kit. Serum IL-1 β was found to be elevated after CCl₄ treatment^[21], whereas baicalein administration resulted in significant attenuation of the elevation (Figure 4A). CCl₄-induced acute liver injury could activate hepatic non-parenchymal cells (including Kupffer cells and stellate cells) and increase the production of TNF- α and IL-6^[22]. In our study, we found that serum TNF- α and IL-6 were rapidly increased and reached the peak level within 12 h in baicalein administration group as compared with the control group, and then decreased within 24 h (Figure 4B and C).

Figure 3 Proliferation status of carbon tetrachloride induced mice after treated with or without baicalein. A, B: Immunostaining of proliferating cell nuclear antigen (PCNA) in liver sections from control (A) and baicalein (B) groups 2 d after carbon tetrachloride (CCl₄) treatment; C, D: Immunostaining of PCNA in liver sections from control (C) and baicalein (D) groups 3 d after CCl₄ treatment; E: Numbers of PCNA⁺ cells in CCl₄ induced mice after treated with or without baicalein. At least six 12-mm² tissue sections were counted for each mouse. Values represent mean \pm SE ($n = 6$). $P < 0.01$ between control and baicalein groups.

Expression of *TNF- α* and *IL-6* in liver

Real-time quantitative PCR was used to quantify the expression of *TNF- α* and *IL-6* in mouse liver. Data showed that in baicalein administration group, the production of *TNF- α* and *IL-6* mRNA reached a peak level, which was even higher than in the control group, and then decreased rapidly in 24 h (Figure 5A and B).

Expression of *TGF- α* , *HGF* and *EGF* in liver

Real-time quantitative PCR was used to quantify the levels of *TGF- α* , *HGF* and *EGF* mRNA in liver. Data showed that the production of *TGF- α* , *HGF* and *EGF* mRNA was upregulated more rapidly in the baicalein administration group during the early phase and kept at a generally higher level within the process of liver regeneration (Figure 5C-E).

DISCUSSION

The model of acute intoxication with CCl₄ has been used

for decades to investigate the response of acute liver injury, because the elementary lesions caused by this hepatotoxin replicate those seen in most cases of human liver diseases, which makes it a good model to study both signal transduction and cell cycle events *in vivo*^[23,24]. Using this delicate model, we have identified the protective effect of baicalein against the typical acute liver injury.

Oral administration of baicalein to mice which have received a LD₅₀ dosage of CCl₄ resulted in a significantly reduced mortality rate. Since the pathological effect of CCl₄ in the animals has been proved to be mainly restricted to the liver and lethality of high-dose CCl₄ is mostly related with organ failure following acute liver failure instead of direct injury to other organs, it is reasonable to hypothesize that administration of baicalein can reduce animal mortality mainly through attenuating acute liver damage by CCl₄, and facilitating the preservation and restoration of liver functions.

It has been proved that baicalein administration indeed attenuated acute liver damage. The indicators for

Figure 4 Levels of interleukin-1 β , interleukin-6 and tumor necrosis factor- α in serum in control and baicalein groups after CCl₄ (1 mL/kg) treatment. A: Serum interleukin (IL)-1 β ; B: Serum tumor necrosis factor- α (TNF- α); C: Serum IL-6. A, B and C were determined by enzyme-linked immunosorbent assay kit. Values represent mean \pm SE ($n = 6$). $P < 0.05$, $P < 0.01$ between control and baicalein groups.

the liver damage we have utilized are serum aminotransferase activities, including AST and ALT. They are commonly referred to as “liver enzymes”, because the levels of these enzymes are released from damaged hepatocytes into the blood, and their levels in the serum have been widely recognized as a very important indicator to judge the severity of acute hepatic injury^[25]. In our experiment, administration of baicalein attenuated the elevated serum ALT and AST induced by CCl₄ in mice, which indicated that the proportion of damaged hepatocytes was reduced as a direct result of baicalein administration. Elevated ALT level was found to be significantly attenuated 12 h after CCl₄ treatment, while similar phenomenon appeared at 24 h after CCl₄ treatment for AST. Both time points are defined as the early-stage liver damage in which cell apoptosis and necrosis dominate the process. When the liver damage progresses over time, the speed of cell damage as a result of either cell apoptosis or necrosis is reduced, as indicated by the relative decrease of AST/ALT levels at later time points of days 3 to 5. On the other hand, regeneration of liver gradually took place from the middle to late stages of liver damage, during which cell proliferation rate would naturally increase till the original weight and shape of the liver and its functions, is restored. We used another statistical index to measure the possible role of baicalein in the regeneration of liver tissue. It is the density of positive cells in a certain area of tissue section immunostained with PCNA antibody. The index strongly indicated that baicalein treatment contributes to a faster liver recovery after CCl₄-induced liver injury by promoting the endogenous regeneration

process from the middle stage of the entire liver damage process. We also used histological methods as supportive means to reveal the degree of cell necrosis and inflammation. Data also showed that oral baicalein administration inhibited inflammation, necrosis, and destruction of liver architecture.

To investigate the underlying mechanism, we evaluated the effects of baicalein treatment on the serum level of certain key cytokines tightly related to inflammation and cell proliferation. IL-1 β , IL-6 and TNF- α , as acute-phase proteins, are considered to be the special biomarkers that reflect inflammatory status^[26]. IL-1 β plays a key role in inflammation, usually leading to tissue destruction. Furthermore, IL-1 β has been previously shown to antagonize hepatocyte proliferation^[27,28]. Serum IL-1 β can increase dramatically during different inflammatory and non-inflammatory processes. In the present study, we observed that baicalein administrated mice demonstrated a significantly lower serum level of IL-1 β at days 1, 2, 3 and 5, compared with the control group. The decreased level of inflammatory cytokines may explain the accelerated liver regeneration observed in baicalein administrated mice. IL-6 and TNF- α expression has been identified as attractive targets for liver regeneration. The release of TNF- α , as a pro-inflammatory mediator in liver apoptosis, is also linked to cytotoxicity induced by CCl₄^[17,29]. Kupffer cells (macrophages in liver) produce TNF- α in rapid response to tissue injury, which then up-regulates the expression of IL-6. TNF- α and IL-6 together activate the neighboring hepatocytes, leading to signal transducer and activator of transcription STAT3 activation and

Figure 5 The microRNA levels of tumor necrosis factor- α , interleukin-6, transforming growth factor- α , hepatocyte growth factor and epidermal growth factor in liver of control and baicalein groups after carbon tetrachloride (1 mL/kg) treatment. Total RNA was isolated from liver tissue using TRIzol methods and quantified spectrophotometrically at 260 nm. The mRNA levels of tumor necrosis factor- α (TNF- α) (A), interleukin-6 (IL-6) (B), hepatocyte growth factor (HGF) (C), epidermal growth factor (EGF) (D) and transforming growth factor- α (TGF- α) (E) genes were quantified using reverse transcription polymerase chain reaction and normalized to β -actin housekeeping gene. Values represent mean \pm SE ($n = 6$). $P < 0.05$, $P < 0.01$ between control and baicalein groups.

the production of several other proteins that are shared within the growth-factor-mediated pathway network. In previous studies, pretreatment with IL-6 before CCl₄ reduces acute CCl₄-mediated cell apoptosis, and accelerates regeneration in both wild-type and IL-6/- livers^[30]. The mechanism of IL-6 and TNF- α in protecting the liver against injury has not been fully clarified^[31-33]. Previous studies showed that liver regeneration and hepatoprotection require the cytokine IL-6 immediately after liver injury^[34,35]. But overexpression of IL-6 inhibits hepatocyte growth and causes liver injury^[36,37]. In the present study, the expression of TNF- α and IL-6 in baicalein administrated mice reached a high level at day 0.5 and then was kept at a relatively lower level at days 1, 2, 3 and 5 compared with the control. We consider that the lower

levels of TNF- α and IL-6 which are cell death mediators from days 1 to 5 may facilitate liver regeneration. In term of the mechanisms, we found that gene expression of IL-6 and TNF- α in treated liver was enhanced in a similar pattern as the level of corresponding proteins, leading to the conclusion that baicalein could indeed alter the expression of certain cytokines to affect the liver damage process.

Another group of molecules we have investigated are growth factors such as HGF, TGF- α and EGF. They promote hepatic survival by stimulating liver regeneration and providing hepatoprotection in various models of liver injury, such as toxic damage caused by CCl₄^[38]. It has been proven that HGF, TGF- α and EGF are the main growth factors secreted after hepatic injury^[39]. HGF is the most

potent mitogen for mature hepatocytes and acts as a hepatotropic factor. HGF level is increased markedly in mouse liver after various liver injuries such as hepatitis, ischemia, physical crush and partial hepatectomy. HGF acts as a trigger for liver regeneration and strongly enhances EGF expression. Previous studies indicated that the liver regenerative response is blocked if antibodies to HGF are administered at the same time as CCl₄ treatment^[40]. HGF administration to rodents was confirmed to reduce the level of CCl₄-induced injury. HGF has been shown to regulate DNA synthesis partially through upregulation of other growth factors in hepatocytes *in vivo* and *in vitro*, which indicates that all of them are crucial for liver regeneration^[41,42]. In our study, a significant increase of HGF, EGF and TNF- α expression occurred in livers from baicalein-treated groups during the proliferation phase (from days 1 to 3). Such expression reached a lower level in baicalein-treated mice at day 5 compared with the control, which indicated that the liver regeneration was terminated at an earlier phase.

In conclusion, we found baicalein from the Chinese herbal medicine possesses strong beneficial effects in a mouse model against acute liver injury caused by CCl₄. The expression of inflammatory cytokines IL-6 and TNF- α are markedly increased at the very early stage, which activate crucial signal transducers, including signal transducer and activator of transcription 3 and trigger certain signal cascades related to liver regeneration. During the middle stage, the expression level of such cytokines was significantly lowered to reduce inflammation cell apoptosis. The subsequent elevation of HGF, TGF- α and EGF may promote hepatic survival by stimulating hepatocyte regeneration. The protective effect of baicalein represents a clinical potential in the development of novel therapeutic agents for acute liver injury.

COMMENTS

Background

Baicalein is one of the bioactive compounds of *Scutellaria baicalensis* Georgi which has been shown to have anti-inflammatory, anti-bacteria and anti-hepatotoxic effects. However, the underlying mechanisms by which baicalein protects the liver from drug-induced injury still remain speculative.

Research frontiers

Previous investigations of liver diseases on the role of baicalein in selectively inducing apoptosis of cancer cells and inhibiting normal hepatocyte apoptosis, have prompted studies whether baicalein would increase the secretion of various inflammatory cytokines and facilitate regeneration of liver cells. This study assessed whether baicalein administration could prevent acute liver injury induced by carbon tetrachloride in mice and investigated the possible mechanism of its protective role.

Innovations and breakthroughs

The authors found that baicalein significantly elevated the serum level of tumor necrosis factor- α (TNF- α) and interleukin (IL)-6 at the early phase, which indicated that baicalein could facilitate the initiating events in liver regeneration. This study supports the possibility that baicalein may be a therapeutic candidate for acute liver injury, and indicates that baicalein could accelerate liver regeneration by regulating the TNF- α and IL-6 mediated pathways.

Applications

All these results support the possibility of baicalein being a therapeutic candidate for acute liver injury, and indicate that baicalein accelerates liver regeneration by regulating the TNF- α and IL-6 mediated pathways.

Peer review

The authors concluded that baicalein could facilitate the initiating events in liver regeneration. The experiments were well done and the results were clearly shown. This study is well designed and performed, and is of great interest for its novelty and impact in the field.

colorectal cancer (CRC) and polyps in a single referral center in Rome, Italy, during two periods.

METHODS: CRC data were collected from surgery/pathology registers, and polyp data from colonoscopy reports. Patients who met the criteria for familial adenomatous polyposis, hereditary non-polyposis colorectal cancer syndrome or inflammatory bowel disease were excluded from the study. Overlap of patients between the two groups (cancers and polyps) was carefully avoided. The χ^2 statistical test and a regression analysis were performed.

RESULTS: Data from a total of 768 patients (352 and 416 patients, respectively, in periods A and B) who underwent surgery for cancer were collected. During the same time periods, a total of 1693 polyps were analyzed from 978 patients with complete colonoscopies (428 polyps from 273 patients during period A and 1265 polyps from 705 patients during period B). A proximal shift in cancer occurred during the latter years for both sexes, but particularly in males. Proximal cancer increased > 3-fold in period B compared to period A in males [odds ratio (OR) 3.31, 95%CI: 2.00-5.47; $P < 0.0001$]. A similar proximal shift was observed for polyps, particularly in males (OR 1.87, 95%CI: 1.23-2.87; $P < 0.0038$), but also in females (OR 1.62, 95%CI: 0.96-2.73; $P < 0.07$).

CONCLUSION: The prevalence of proximal proliferative colonic lesions seems to have increased over the last decade, particularly in males.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignancies worldwide, the etiology of CRC involves environmental and genetic factors. In most cases, the cancer develops according to the classic adenoma-carcinoma sequence^[1], as supported by epidemiological, clinical-pathological and molecular genetic studies. Thus, early detection and removal of adenomatous polyps are essential for cancer prevention. In fact, the risk of developing CRC within six years of a polypectomy is reduced by 75%-90%. However, not all CRC cases are preceded by adenomatous polyps, and some cancers have been shown to develop directly from aberrant crypts or flat lesions^[2]. These alternative carcinogenetic pathways are relatively more frequent on the right side of the colon, making the efficacy of preventative strategies very challenging. In this regard, one of the topics of particular interest in CRC is the possible change in site distribution observed in recent decades. In fact, recent data from different studies report a change in the site distribution of CRC (proximal shift) related to gender, race^[3,4] and older age^[5]. Many factors are potentially involved in this phenomenon, and most of them are not easily evaluated. However, the crucial issue is to establish if and how much of these changes are due to a real biological event or related to multiple diagnostic biases. Indeed, the question is not theoretical, but rather implies important decisions related to strategies for screening, surveying and treating millions of people worldwide, with health and economic implications. In fact, proximal colon cancer represents a great challenge for physicians, both due to the technical limitations of screening strategies in the detection of right-sided colon lesions and to the peculiar behavior of these tumors^[6]. Data on CRC location have been reported from different sources, such as cancer registries, colonoscopy reports, retrospective clinical analyses or autptic data^[5,7-9]. All of these sources have biases that could potentially under- or over-estimate the specific issue of the cancer location. However, data concerning a possible increase over time of right-sided colon cancers have been reported recently in large population studies^[10,11]. The possible changes in the location of polyps over time have been less investigated, but a possible proximal shift in these lesions has been described by some studies^[12-14]. Few studies have addressed the possible "right shift" of CRC in the Italian popula-

tion^[15,16], and only two studies have analyzed the changing distribution of both CRC and polyps over time^[17,18], thus data are scarce and not conclusive.

The present study aims to address this issue retrospectively by analyzing records from a large set of patients, either operated on for CRC or diagnosed with colon polyps by colonoscopy, during two distinct periods of time at an Italian single referral center.

MATERIALS AND METHODS

We performed a retrospective, observational study of CRC and polyps at a single referral center ("Sapienza" University Hospital - Rome, Italy) for two periods of time: from 1989 to 1993 (period A) and from 2003 to 2007 (period B). The aim of the study was to compare the location of CRC and polyps and to study the differences in the age and gender distributions between the two periods.

The age and gender of the patients and the location, histology, morphology and dimensions of their lesions were recorded. For discrimination between the proximal and distal colon, the boundary was situated at the juncture of the splenic flexure, as was performed in previous studies^[16,19].

Overlap of patients in the two groups (CRC and polyps) was carefully avoided. The study was approved by the institutional University review board; because this study was a retrospective analysis of an existing data set, written informed consent was not obtained from the participating subjects.

During the two periods, endoscopic examinations were performed using Olympus videocolonsopes (CF100I in period A, CFQ145I in period B).

Colorectal cancer data

CRC data were obtained from surgery registries, and the diagnoses were all confirmed by histological examination of surgical resections. Overall, 768 consecutive patients diagnosed with cancer who underwent surgery were analyzed. Of these, 352 were operated on from 1989-1993 (period A) and 416 from 2003-2007 (period B).

Polyp data

Polyp data were obtained from colonoscopies. Only complete colonoscopy examinations with adequate bowel preparation were considered. Subjects with uncompleted examinations or unsatisfactory cleansing were excluded, unless a second complete colonoscopy was performed within three months. Only patients with sporadic polyps were included, and patients who met the criteria for familial adenomatous polyposis, hereditary non-polyposis colorectal cancer syndrome or other polyposis syndromes, or who had been diagnosed with or suspected to have inflammatory bowel disease (ulcerative colitis or Crohn's disease), were excluded from the study.

Four senior gastroenterologists, each with more than 10 years of endoscopic experience, performed 4176 colonoscopies (1030 and 3146 for periods A and B, re-

Table 1 Characteristics of the 768 patients with colorectal cancer *n* (%)

	Period A (1989-1993)	Period B (2003-2007)	<i>P</i> value
	352 patients	416 patients	
Male	202 (57.4)	253 (60.8)	0.335
Female	150 (42.6)	163 (39.2)	
Age (yr)			
< 50	49 (13.9)	27 (6.5)	< 0.0001
50-59	70 (19.9)	55 (13.2)	
60-69	121 (34.4)	95 (22.8)	
70-79	90 (25.6)	180 (43.3)	
≥ 80	22 (6.2)	59 (14.2)	

spectively). Polyps were detected in 27% and 23% of colonoscopies in periods A and B, respectively.

A total of 978 patients were analyzed, and 1693 polyps were found.

The data obtained from each polyp were included in the descriptive analysis. For patients with more than one polyp, the most advanced lesion, either in the proximal or in the distal segment of the colon, was taken into consideration in the multivariate analysis.

Statistical analysis

Proportions were calculated for the categorical data, and means and standard deviations were calculated for the quantitative data. χ^2 and *t* tests were used to assess the differences between periods A and B. Multivariate logistic regression was used to estimate the relative risk of finding a proximal CRC and polyp, adjusting for age, sex and the diagnosis period (A *vs* B) as independent variables. The limit of statistical significance for all tests was set at 0.05.

RESULTS

Colon cancer

As shown in Table 1, a higher percentage of cancers was recorded in men than in women, and there was no statistically significant difference between the periods. Patients were older in period B than in period A. In particular, there were fewer patients with CRCs in period B than in period A in all age groups less than 70 years.

From period A to B, proximal CRC incidence increased by an absolute 14.3% (from 18.2% to 32.5%, *P* < 0.0001). In particular, the increase was observed in the cecum and in the ascending colon (12.0% *vs* 28.4% in periods A and B, respectively), whereas in distal CRC cases, a consistent reduction was noted in the rectum, with a decrease from 54.5% to 31.5% in periods A and B, respectively (*P* < 0.0001) (Figure 1).

In the multivariate analysis, the risk of finding a proximal CRC, after adjusting for age and sex, showed a statistically significant interaction term between period B and gender. Thus, two regression equations were run. For men, the risk of developing a proximal cancer in period B was more than 3 times greater than that in period A, adjusting for age [odds ratio (OR) 3.31, 95%CI: 2.00-5.47; *P* = 0.0001], whereas for females, there was an

Figure 1 Relative distribution of colorectal cancer according to colon segment in periods A and B. The relative percentage of colorectal cancer cases are indicated next to the corresponding tract of the colon. Total proximal and distal colorectal cancer percentages, with the splenic flexure as the boundary, are also reported.

increased risk, but this increase was not statistically significant (OR 1.21, 95%CI: 0.72-2.04; *P* = 0.4637). There was no significant evidence of an effect of age in males (OR 1.34, 95%CI: 0.86-2.11; *P* = 0.1999) or in females (OR 1.23, 95%CI: 0.74-2.07; *P* = 0.4272).

Polyps

As shown in Table 2, polyps were more frequently found in males than in females, with no statistically significant difference between the periods (*P* = 0.0892). We evaluated 428 polyps from 273 patients in period A and 1265 polyps from 705 patients in period B. The mean number of polyps per patient increased from 1.6 in period A to 1.8 in period B (*P* = 0.01).

No univocal trend in age distribution between the two periods was observed. With regard to the percentage of patients with polyps in period A to period B, a decrease was observed for age groups < 50 years and 60-69 years, whereas an increase was observed for the age groups 50-59, 70-79 and ≥ 80 years (*P* < 0.0015). A similar trend was observed in both males and females (data not shown).

From period A to B, the incidence of proximal polyps increased by an absolute 12.7% (from 22.8% to 35.5%, *P* < 0.00005). In analyzing the anatomical segments separately, an increase in incidence of proximal polyps was observed in the ascending colon (from 7.9% to 13.2%) and in the transverse colon (from 7.2% to 14.7%). In the distal colon, a reduction in polyps was observed in the descending colon (from 21.6% to 9.1%) and in the rectum (from 32% to 25.4%), whereas an increase was noted in the sigmoid colon (from 23.6% to 30%) (*P* < 0.00005) (Figure 2).

In the multivariate logistic regression analysis, after adjusting for age, a male's risk of developing a proximal polyp in period B was almost 90% greater than his risk in period A (OR 1.87, 95%CI: 1.23-2.87; *P* = 0.004), whereas for females, there was an increase of more than 60% in the risk, which was close to statistical significance (OR 1.62, 95%CI: 0.96-2.73; *P* = 0.07). When considering age groups stratified by greater or less than 70 years, no differences in proximal polyp detection was demonstrated for either gender.

The size and histopathological pattern of the polyps were also analyzed.

Table 2 Characteristics of the 978 patients with polyps *n* (%)

	Period A (1989-1993) 273 patients	Period B (2003-2007) 705 patients	<i>P</i> value
Male	178 (65.2)	418 (59.3)	0.0892
Female	95 (34.8)	287 (40.7)	
Age (yr)			
< 50	50 (19.2)	91 (12.9)	< 0.0015
50-59	44 (16.9)	154 (21.9)	
60-69	103 (39.5)	226 (32.1)	
70-79	57 (21.8)	185 (26.3)	
≥ 80	7 (2.7)	48 (6.8)	
Total No. of polyps	428	1265	
No. of polyps, mean ± SD	1.6 ± 1	1.8 ± 1.3	0.0102
No. of polyps, median	1	1	
Range	1-6	1-14	
Dimensions			
< 5 mm	114 (26.6)	530 (41.9)	< 0.00005
5-9 mm	228 (53.3)	454 (35.9)	
10-19 mm	44 (10.3)	191 (15.1)	
20-29 mm	23 (5.4)	52 (4.1)	
30-39 mm	9 (2.1)	25 (2)	
40+ mm	10 (2.3)	13 (1)	
Histopathological pattern			
Hyperplastic	91 (33.6)	438 (38.7)	< 0.00005
Mild/moderate dysplasia ¹	151 (55.7)	597 (52.7)	
Severe dysplasia ²	27 (10)	87 (7.7)	
Others ³	2 (0.7)	10 (0.9)	

¹Tubular, mixed or villous adenoma with mild or low grade dysplasia;

²Tubular, mixed or villous adenoma with severe dysplasia or cancer in situ or serrated adenoma; ³Lymphatic lump, hamartoma, leiomyoma, anal human papilloma virus.

There was a statistically significant increase in the percentages of micropolyps (< 5 mm) from 26.6% to 41.9% and from 10.3% to 15.1% for polyps of 10-19 mm in size, whereas the percentage of large polyps (40 mm) diminished from 2.3% to 1.0% in period B *vs* A ($P < 0.00005$).

Histopathology data were available for 63.3% and 89.5% of polyps in period A and B, respectively. No statistically significant differences in the overall number of hyperplastic polyps and adenomas with mild/moderate and severe dysplasia were observed between periods A and B. Nonetheless, when the histopathological pattern was analyzed according to polyp location, from period A to B, adenomas with mild/moderate dysplasia in the proximal colon increased significantly from 21.8% to 41.2% ($P < 0.001$), whereas adenomas with severe dysplasia decreased from 37% to 23%, which was not statistically significant.

DISCUSSION

In recent decades, screening strategies for early diagnosis and/or prevention of CRC have been consistently implemented. Nonetheless, colon malignancies still remain the third most common cancer and an important cause of death in Western countries^[20]. Thus, many efforts have been made in order to improve the efficacy of screening strategies, which often differ even regionally in the same country. Colonoscopy is considered the “gold standard” for the diagnosis and removal of pre-malignant colon

Figure 2 Relative distribution of polyps according to colon segment in periods A and B. Relative percentage of polyp detection are indicated next to the corresponding tract of the colon. Total proximal and distal colonic polyp percentages, with the splenic flexure as the boundary, are also reported.

lesions, even though a careful risk stratification strategy is required in order to optimize resources for screening purposes. In this setting, the presumed right-side increase in pre-malignant lesions and CRC may represent a further stimulus to perform high-quality endoscopic examination of the right side of the colon, which is often difficult to explore carefully (especially the cecum)^[6]. Moreover, even though in the last year colonoscopies have increased in number and quality, it has been demonstrated that a relatively high proportion of cases of CRC may develop without macroscopic evidence of pre-malignant lesions, introducing further challenges to prevention strategies. Despite the consistent number of studies that analyze differences in the location of colon CRC and polyps, data are still not univocal and indeed remain difficult to interpret. As already mentioned, results are often difficult to compare due to the different sources from which the data are collected. Another important reason concerns the length of the observation, which varies from a few years to decades according to different studies.

This study retrospectively evaluated the differences in the site distribution of CRC and polyps between two 5-year periods over a period of 10 years, analyzing data from surgical registries and from endoscopic reports in a single referral center. The relatively short interval time between the two periods (10 years) could have, at least in part, influenced the observed differences, which may be more striking with a wider interval time.

Bearing in mind the aforementioned limitations for data interpretation, many recent large studies have reported a trend for “proximalization” of CRC in different geographic areas^[10,15,21,22]. Conversely, other studies have questioned the possible “right shift” in CRC location^[23,24] or have observed the phenomenon only in specific subgroups^[3,25,26]. Moreover, some other authors have explained that the putative increase in proximal CRCs is mainly consequent to the decrease in rectal cancer cases^[8,16]. In this study, we confirmed the proximal shift in CRC over time and observed a 3-fold increase in the risk of finding proximal cancer in males in period B *vs* period A. In line with previous findings in Italian populations^[16], the single anatomical segments analysis emphasized that the relative increase in proximal CRC cases over time was partly due to a reduction in the number of rectal cancer cases (54.5% *vs*

31.5% in periods A and B, respectively). In fact, excluding rectal cancers, the trend for a proximal shift in CRCs over time, although maintained, showed less of a difference (data not shown). This relatively small, but homogeneous study from a single referral center, confirmed the trend of a proximal shift in CRC location during recent years, and is thus further confirmation of the phenomenon previously described in large cohorts of patients from different areas.

Published data on polyp prevalence are scarce and less consistent than are data for CRC, and the related studies mainly concern advanced adenomas^[27]. However, some studies have suggested a proximal shift in those lesions over time^[12-14,17,18]. In this study, we observed a proximal shift in polyps between periods A and B, albeit less consistent than that observed for CRC. As already observed for CRC, the proximalization of lesions was more evident in males (90% increase in period B *vs* A). The increase in total polyps, and in particular in proximal lesions, refers mainly to micropolyps and low-grade dysplastic polyps, that could be partially explained by the increase in colonoscopies for cancer prevention in period B *vs* period A, and to the “see and sampling” strategy that has become more popular in recent years. Notably, the present data on polyp dimensions and histopathological patterns need to be interpreted with caution, both due to the high rate of missing histological data [157 (36.7%) and 133 (10.5%) polyps with missing histological reports in periods A and B, respectively] and due to the fact that the two variables (size and histology) are not independent.

Besides possible biological explanations of increased proliferative right-sided colon lesions over time, many confounding factors related to the global technical and behavioral medical changes throughout the years could have partially contributed to this location shift. With regard to the latter, the most important consideration concerns the impact of increased sensibilization for CRC prevention in the last decade that could have potentially influenced either CRC or polyp presentation in our population during period B. In fact, the older age of CRC patients in that period could be at least partially due to the preventive effect of the screening approach, and the same “proximal shift” could be an effect of better prevention of distal lesions (which are more easily detected by screening methods such as sigmoidoscopy). Considering polyps, the modifications of colonoscopy indications, particularly due to an increased trend to cancer prevention, may have influenced the different findings in the two periods, even though only a slight decrease in the proportion of colonoscopies with polyp detection was found between the two periods (23% in period B *vs* 27% in period A). Regarding technical progress, the right-sided CRC increase could be a result of the recent different surgical treatment options for right-sided CRC, in particular the laparoscopic approach, that in many centers has made surgery much more possible in elderly patients compared to previous years. This detail is particularly true considering that for CRC evaluation, we included

exclusively surgical registry data without considering the surgical approach. Moreover, procedural improvements (i.e., standardization of retraction time) and the amelioration of bowel cleansing could have potentially influenced the observed difference in polyp detection between the two time periods. Nonetheless, no substantial improvements in technical equipment occurred between the two periods, since high definition endoscopes were not available in both periods.

Nonetheless, even if the precise amount and specific causes of the right shift in pre-malignant and malignant colon lesions remain to be established, the present retrospective analysis appears to confirm, albeit with some limitations and possible confounding factors, a trend of an increase in such lesions over time. As a consequence, endoscopists and clinicians in daily clinical practice, as well as future strategies for screening campaigns, should take into account the possible increase in proximal colonic proliferative disorders. In this regard, the whole colon should be considered as a potential target for neoplastic changes, and partial colon examinations should be avoided or limited to particular conditions. Novel endoscopic instruments with higher resolution power could result in an improvement *per se* in the detection of colonic lesions. However, besides the technical devices, better bowel preparation (cecum cleaning), the constant improvement of endoscopists’ skills, and a standardized technical endoscopic approach^[28] are all fundamental basic tools that can improve the endoscopic examination quality in order to obtain a more accurate observation of the whole colon.

COMMENTS

Background

Proximalization of colorectal cancer during the last decades has been variously reported. Data for the right shift in polyps are scant and controversial.

Research frontiers

Data from large cohorts of patients followed for decades and relatively short studies suggest a change in colonic proliferative disease during recent years, with an increase in right-sided lesions.

Innovations and breakthroughs

The data show a proximalization of proliferative colonic lesions (cancers and polyps), in a single referral center, in two different periods of time with a ten-year interval between these periods.

Applications

These results should be interpreted with caution, due to many possible unavoidable biases that may interfere when undertaking this type of study, either for different endoscopic/surgical approaches or for biological factors. However, the authors suggest that this phenomenon that may have important implications either for improvement of endoscopic accuracy or for screening programs.

Peer review

The study involves a single institution but covers 2 separate 5 year periods 10 years apart. The authors compared data regarding the anatomic location of both colorectal cancers and colonic polyps found by colonoscopy during each period. The data suggest that proximal proliferative lesions have increased in prevalence, particularly in males. That proximal colonic premalignant and malignant conditions have increased in prevalence over the last 2 decades has also been shown in other studies. In order to be sure that comparisons between 2 separate periods are valid, even within a single institution, the procedures in question should be as identical as possible, allowing for changes in technology, operator experience, etc.

Abstract

AIM: To analyze the prognostic value of adipokines in predicting the course, complications and fatal outcome of acute pancreatitis (AP).

METHODS: We performed the search of PubMed database and the systemic analysis of the literature for both experimental and human studies on prognostic value of adipokines in AP for period 2002-2012. Only the papers that described the use of adipokines for

prediction of severity and/or complications of AP were selected for further analysis. Each article had to contain information about the levels of measured adipokines, diagnosis and verification of AP, to specify presence of pancreatic necrosis, organ dysfunction and/or mortality rates. From the very beginning, study was carried out adhering to the PRISMA checklist and flowchart for systemic reviews. To assess quality of all included human studies, the Quality Assessment of Diagnostic Accuracy Studies tool was used. Because of the high heterogeneity between the studies, it was decided to refrain from the statistical processing or meta-analysis of the available data.

RESULTS: Nine human and three experimental studies were included into review. In experimental studies significant differences between leptin concentrations at 24 and 48 h in control, acute edematous and acute necrotizing pancreatitis groups were found ($P = 0.027$ and $P < 0.001$). In human studies significant differences between leptin and resistin concentrations in control and acute pancreatitis groups were found. 1-3 d serum adiponectin threshold of 4.5 $\mu\text{g/mL}$ correctly classified the severity of 81% of patients with AP. This threshold yielded a sensitivity of 70%, specificity 85%, positive predictive value 64%, negative predictive value 88% (area under curve 0.75). Resistin and visfatin concentrations differ significantly between mild and severe acute pancreatitis groups, they correlate with severity of disease, need for interventions and outcome. Both adipokines are good markers for parapancreatic necrosis and the cut-off values of 11.9 ng/mL and 1.8 ng/mL respectively predict the high ranges of radiological scores. However, the review revealed that all nine human studies with adipokines are very different in terms of methodology and objectives, so it is difficult to generalize their results. It seems that concentrations of the leptin and resistin increases significantly in patients with acute pancreatitis compared with controls. Serum levels of adiponectin, visfatin and especially resistin (positive correlation with Acute Physiology and Chronic

Health Evaluation II, Ranson and C-reactive protein) are significantly different in mild acute pancreatitis and severe acute pancreatitis patients, so, they can serve as a markers for the disease severity prediction. Resistin and visfatin can also be used for pancreatic and parapancreatic necrosis prediction, interventions needs and possible, outcome.

CONCLUSION: High levels of adipokines could allow for prediction of a severe disease course and outcome even in small pancreatic lesions on computed tomography scans.

Karpavicius A, Dambraszkas Z, Sileikis A, Vitkus D, Strupas K. Value of adipokines in predicting the severity of acute pancreatitis: Comprehensive review. *World J Gastroenterol* 2012; 18(45): 6620-6627 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i45/6620.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i45.6620>

INTRODUCTION

Acute pancreatitis (AP) is a common disease with a wide spectrum of severity. Its incidence is about 30-113 cases per 100 000 individuals, with the overall mortality rate of 10%-15%^[1-4]. Most episodes of AP are mild and self-limiting, but up to 10%-20% of patients develop severe AP with mortality ranging from 29% to 43%^[5,6]. Over past two decades mortality rate in early phase of AP associated with the systemic inflammatory response syndrome decreased significantly, but mortality in the late phase remains high. It is believed that the cause of death in late phase is predominantly linked to the development of infected necrosis and septic complications^[7], thus resulting in multiple organ failure and severe sepsis^[8,9]. Because of the systemic complications and high mortality, a considerable interest in the early prediction of the disease course and severity remains.

Pancreatic enzyme levels poorly correlate with the severity of AP, thus prognosis is commonly based on clinical scores. The first disease specific prognostic score was proposed by Ranson in 1974, which later was complemented by a number of pancreatitis specific and organ failure scores, including Glasgow/Imrie (1984), Acute Physiology and Chronic Health Evaluation (APACHE) II (1985), Multiple Organ Dysfunction Score (1995), Sequential Organ Failure Assessment (1998), Pancreatitis Outcome Prediction (2007), Bedside Index of Severity in Acute

Pancreatitis (2009), and many others. Although, the accuracy of such scores is high enough (Table 1)^[10-14], all of them are multifactorial and rather uncomfortable for everyday use, so a great attention is still given for seeking a single prognostic marker. The most widely explored and described single predictor is C-reactive protein (CRP), which remains very useful, because it is accurate, cheap, and widely available. However, its concentration reaches a peak on third day of the disease, so it has a greatest prognostic value approximately 48 h after the onset of the symptoms. Optimal cut-off value recommended by almost all societies for disease course prediction is 150 mg/L. CRP has sensitivity of 80%, specificity of 84% with area under curve (AUC) 0.84 in predicting severity of the disease 48 h after admission with a cut-off of 150 mg/L^[15]. There is little data on the value of CRP on prediction of development of pancreatic necrosis. Some studies demonstrated that a cut-off of as low as 71 mg/L is sufficient to predict development of clinically significant (volume > 30%) necrosis with a sensitivity of 78.79%, specificity of 71.43% and AUC 0.766^[12].

The main problem remains, that neither prognostic scores nor single predictors can't accurately predict the disease course and severity, development of pancreatic or peripancreatic necrosis, and outcomes during the first hours or even days of hospitalization. Therefore, there is a great stimulus for seeking new accurate and easy to use predictors. Perhaps, the least studied group of predictors in AP is adipokines, including adiponectin, leptin, resistin and visfatin.

Adiponectin is being produced exclusively in adipocytes and plays an important role in the inhibition of the inflammatory response^[16,17]. Adiponectin depresses nuclear factor kappa B signaling in endothelial cells and adipocytes, induces the anti-inflammatory cytokine interleukin (IL)-10 and IL-1 receptor antagonist in leukocytes^[18-20].

Leptin is an adipocyte-derived hormone that acts centrally in the hypothalamus to regulate body waste and peripheral energy expenditure^[21]. The presence of leptin and expression of its receptors have been detected in other tissues, also in pancreas^[22]. This suggests, that leptin may modulate pancreatic function and inflammatory response in pancreatitis.

Resistin and visfatin are the adipohormones, produced by neutrophils, macrophages, bone marrow and WAT^[23,24]. They can induce the synthesis of pro-inflammatory cytokines, such as IL-6, IL-1 β , tumor necrosis factor alpha, that is why their role in inflammatory response has been suggested^[24-27].

It is now widely accepted, that white adipose tissue is an active endocrine organ, which is also involved in pathogenesis of AP. Peripancreatic fat cells necrosis might cause a massive release of cytokines (IL-1, IL-6, tumor necrosis factor) and adipokines, that possibly cause multi-organ dysfunction and whole body metabolic changes. It is hypothesized that the extent of peripancreatic fat-cell necrosis determines the severity of pancreatitis, and an early increase of adipocyte-specific marker proteins might serve as predictor of the clinical course^[28].

The aim of this study is to analyze and review the available information about the prognostic value of adipokines in predicting the course of AP, development of pancreatic and peripancreatic necrosis, infectious complications, need for interventional treatment, and fatal outcome. The main objective of the study is to compare the prognostic value of adipokines with already well established single predictors and multifactorial scores in the clinical context.

MATERIALS AND METHODS

We performed the search of PubMed database (service of the United States National Library of Medicine that includes citations from MEDLINE and other life science journals for biomedical articles) and the systemic analysis of the literature for both experimental and human studies on prognostic value of adipokines in AP for period 2002-2012. Keywords (keywords and textwords) for the search were adipokines, adipocitokines, visfatin, resistin, adiponectin, leptin, acute pancreatitis, pancreatic necrosis, peripancreatic necrosis. Further we searched the references of identified articles to find additional sources of information. Only articles in English language were

included in the analysis. Dual publications were excluded. All identified papers (title, abstract and subsequently full text) were independently evaluated by two investigators. Only the papers that described the use of adipokines for prediction of severity and/or complications of AP were selected for further analysis. To be included in the systematic review, each article had to contain information about the levels of measured adipokines, diagnosis and verification of AP, to specify presence of pancreatic necrosis, organ dysfunction and/or mortality rates. All disagreements were resolved by discussion with other two investigators. From the very beginning study was carried out adhering to the PRISMA checklist and flowchart for systemic reviews.

To assess quality of all included human studies the Quality Assessment of Diagnostic Accuracy Studies tool was used^[29]. Quality assessment was performed independently by three researches and all disagreements were resolved by review and discussion with the fourth investigator. The result of the human studies quality assessment is shown in Table 2. Based on the judges' evaluation 8 of 9 studies got seven or more "yes", so the overall quality of included studies was good. However, all studies were very different. Four of them analyzed only one adipo-

Figure 1 Selection of the studies for systematic review (PRISMA flow-chart). Records identified through database search, $n = 28$.

kine, two adipokines were analyzed in three studies, and the remaining two studies analyzed three adipokines. In two studies adipokines concentration was measured only in control and AP groups, without distinction of mild and severe acute pancreatitis.

Statistical analysis

Because of the high heterogeneity between the studies, lack of the uniform diagnostic criteria and high variation of the assessed adipokines profile it was decided to refrain from the statistical processing or meta-analysis of the available data.

RESULTS

Through database search 28 records were identified. After screening the titles and abstracts, 16 records were removed, because adipokines were not used for prediction of the disease course. One record was removed because of the language. In reference search one additional study was found. So, nine human and three experimental studies were further analyzed (Figure 1).

All three experimental studies were performed on rats. The only one adipokine leptin was analyzed. In all studies significant differences between leptin concentrations in control and acute pancreatitis groups was found^[30-32], one study analyzed leptin concentrations in control, acute edematous pancreatitis (AEP) and acute necrotizing pancreatitis (ANP). Significant difference at 12 h was found between controls and ANP group. At 24 and 48 h significant difference was found between controls and both AEP and ANP groups^[32] (Table 3).

All nine human studies (Table 4) with adipokines are very different in terms of methodology and objectives, so it is difficult to generalize their results. It seems that concentrations of the leptin and resistin increases significantly in patients with AP compared with controls. Serum levels of adiponectin, visfatin and especially resistin (positive correlation with APACHE II, Ranson and CRP) are significantly different in severe acute pancreatitis (SAP),

Table 3 Summary of the experimental studies on the prognostic value of adipokines in rats

Study	Groups	n	Leptin, ng/mL	P value
Konturek <i>et al.</i> ^[30]	AP	6-8	7.5 (4.3-18.4)	$P < 0.01^1$
	Controls	6-8	2.1 (1.0-11.8)	
Yavuz <i>et al.</i> ^[31]	AP	10	1.92 ± 0.1	$P < 0.001$
	CP	10	1.86 ± 0.13	
Kerem <i>et al.</i> ^[32]	Controls	10	0.78 ± 0.12	$P < 0.001^2$
	AEP	30		
	ANP	30		
	Controls	30		

AP: Acute pancreatitis; CP: Chronic pancreatitis; AEP: Acute edematous pancreatitis; ANP: Acute necrotizing pancreatitis; CIP: Caerulein-induced pancreatitis. ¹The induction of CIP resulted in a significant increase of plasma levels of leptin; ²At 12 h leptin levels in ANP was higher than in controls, at 24 and 48 h leptin levels in AEP and ANP were higher than in controls.

mild acute pancreatitis (MAP) patients, so, they can serve as a markers for the disease severity prediction. Resistin and visfatin can also be used for pancreatic and parapancreatic necrosis prediction, interventions needs and possible, outcome.

DISCUSSION

Human studies (Table 4) began in 2002, when Konturek *et al.*^[30] found, that median plasma leptin levels in AP were significantly increased as compared with controls. In 2007, Leśniowski *et al.*^[33] found a significant differences between resistin concentrations in AP and control groups.

In study of Duarte-Rojo *et al.*^[34] there was no significant independent association between leptin serum levels and severity of AP or fatal outcome. The similar results are published from Tukiainen *et al.*^[35]: on admission plasma leptin levels do not correlate with AP severity. This study also did not confirm correlation between adiponectin levels and severity of AP. Despite of this, in 2009, Sharma *et al.*^[36] has shown, that 1-3 d serum adiponectin threshold of 4.5 $\mu\text{g/mL}$ correctly classified the severity of 81% of patients with AP. This threshold yielded a sensitivity of 70%, specificity 85%, positive predictive value 64%, negative predictive value 88% (AUC 75%).

Promising results are published from Schäffler *et al.*^[37-39] group. They began their trial in 2006 and finished in 2011 with 41 SAP and 9 MAP patients. This study has shown, that resistin and visfatin concentrations has significant differences between MAP and SAP groups, they correlate with severity of disease, need for interventions and outcome. Both adipokines are good markers for parapancreatic necrosis and the cut-off values of 11.9 ng/mL and 1.8 ng/mL respectively allow to predict the high ranges of radiological scores. These results are consistent with Daniel *et al.*^[40] study in 2010, which demonstrates, that resistin and visfatin may be possibly used for AP prognosis and disease monitoring.

Although Schäffler group provides some cut-off values of adipokines, which are associated with high radiological

Table 4 Summary of the human studies on the prognostic value of adipokines

Study	Patients and methods	Results	Conclusions
Konturek <i>et al</i> ^[30]	Prospective observational study (<i>n</i> = 45) Diagnosis of AP based on Atlanta criteria Adipokines studied: leptin Adipokines evaluated between 48-72 h of illness onetime AP (<i>n</i> = 15) <i>vs</i> controls (<i>n</i> = 30)	Leptin: AP/controls- 7.5 (4.3-18.4) ng/mL/2.1 (1.0-11.8) ng/mL	Median plasma leptin levels in AP were significantly increased as compared with controls
Duarte-Rojas <i>et al</i> ^[34]	Prospective observational study (<i>n</i> = 52) Diagnosis of AP based on typical clinical manifestations with at least a 3-fold increase of serum amylase and/or lipase Whenever uncertainty about diagnosis existed, CT-scan was performed to confirm/rule out AP Severe AP was considered when patients developed one or more local or systemic complications according to the Atlanta classification of AP Adipokines studied: leptin Adipokines evaluated onetime during the 1 d of hospital stay MAP (<i>n</i> = 38) <i>vs</i> SAP (<i>n</i> = 14)	There was no statistically significant association between leptin serum levels and severity of AP There was no difference in leptin measurements between patients favorable and fatal outcomes (<i>P</i> = 0.34) Time of evolution from onset of pain did not alter leptin values There was a positive correlation of BMI and leptin (<i>r</i> = 0.476, <i>P</i> < 0.001) in the whole group Predicted severity by modified Ranson's criteria correlated with Atlanta criteria (<i>r</i> = 0.414, <i>P</i> = 0.002); however, it did not correlate with leptin levels	Results do not support human leptin as a major pro-inflammatory signal involved in AP, nor as a protective and anti-inflammatory mediator It seems neither to be the link between obesity and a higher rate of complications in AP; nor a prognostic marker
Tukiainen <i>et al</i> ^[35]	Prospective observational study (<i>n</i> = 24) AP and SAP defined by Atlanta criteria Adipokines studied: leptin, adiponectin Adipokines evaluated on admission, on days 2-4, and on days 5-7 MAP (<i>n</i> = 12) <i>vs</i> SAP (<i>n</i> = 12)	In patients with SAP highest value of CRP was 349 mg/L (284-476 mg/L), with MAP 119 mg/L (11-367 mg/L) Leptin on admission SAP/MAP [6.1 (1.6-72.9) ng/L]/[9.0(2.5-36 .5) ng/L], (<i>P</i> > 0.05); on days 2-4, 7.7 (1.6-13.9) ng/L/3.8(1.6-12.9) ng/L, (<i>P</i> > 0.05) Adiponectin on admission SAP/MAP, [5642 (1201-19 400) ng/L]/[6314 (1980-24 340) ng/L], (<i>P</i> > 0.05)	Plasma levels of adiponectin and leptin do not correlate with AP severity on admission and during the first week of the disease
Schäffler <i>et al</i> ^[37]	Pilot prospective observational study (<i>n</i> = 23) Diagnosis of AP was based on clinical, laboratory and radiological findings during CT and/or ultrasound examination Adipokines studied: leptin, adiponectin, resistin Adipokines evaluated daily for 10 d after admission SAP (<i>n</i> = 20) <i>vs</i> MAP (<i>n</i> = 3) and patients with high points <i>vs</i> low points on radiological scores	Balthazar score: 4 (1-5), Schroeder score: 5 (1-7), Necrosis score: 2(1-4) Ranson: 3 (0-7), Apache II: 12 (4-37) Resistin has a significant positive correlation with Ranson score (<i>r</i> = 0.6, <i>P</i> = 0.002) and with Apache II score (<i>r</i> = 0.5, <i>P</i> = 0.019) Resistin: intervention group/no intervention, 32.4 ± 10.7 ng/L/15.8 ± 5.1 ng/L, <i>P</i> = 0.026 Leptin and relative changes in leptin values were positively and significantly correlated with CRP levels (<i>r</i> = 0.6, <i>P</i> = 0.007 and <i>P</i> = 0.003, respectively) Resistin cut-off value of > 9.2 ng/mL (10 d mean value) can provide a PPV of 91.9% in predicting Schroder score of > 3 (specificity 85%, sensitivity 75%, AUC 0.9, <i>P</i> < 0.0001) Leptin cut-off value of 15.0 ng/mL can provide a PPV of 88% in predicting Schroder score of > 3 (specificity 85%, sensitivity 50%, AUC 0.72, <i>P</i> < 0.0001) Day 1 resistin proved to predict a Schroder score > 3 with a PPV of 93.3%, cut-off 6.95 ng/mL, specificity 87.5%, sensitivity 93.3%; AUC 0.9, <i>P</i> = 0.002)	Serum adipokines might be the new useful early markers of disease severity in AP
Leśniowski <i>et al</i> ^[33]	Prospective observational study (<i>n</i> = 79) All AP was classified as grade B according to Balthazar CT score Adipokines studied: adiponectin, resistin Adipokines evaluated onetime during the first day of hospitalization AP (<i>n</i> = 39) <i>vs</i> controls (<i>n</i> = 40)	Resistin: AP/controls, 8.38 ± 4.87 ng/mL/3.58 ± 1.51 ng/mL, <i>P</i> < 0.05 Adiponectin: AP/controls, 119.38 ± 61.75 ng/mL/133.77 ± 55.38 ng/mL, <i>P</i> > 0.05 CRP: AP/controls, 23.21 ± 8.75 ng/mL/3.95 ± 1.06 mg/L, <i>P</i> < 0.01 Weak positive correlation between serum resistin and CRP was observed (<i>r</i> = 0.57, <i>P</i> < 0.05) No correlation between selected adipocytokines and BMI was noticed	Serum concentrations of resistin may possibly represent the useful early marker of inflammatory response in AP
Sharma <i>et al</i> ^[36]	Prospective observational study (<i>n</i> = 60) Diagnosis of AP based on Atlanta criteria SAP was defined as the presence of cardiovascular, pulmonary, and/or renal system dysfunction during the initial hospital admission during for at least 48 h Adipokines studied: adiponectin Adipokines evaluated on admission and subsequently up to 30th hospital day MAP (<i>n</i> = 27) <i>vs</i> SAP (<i>n</i> = 33)	Serum adiponectin levels from days 1 to 3 were significantly lower for patients with SAP [median 3.74 (0.83-8.92) µg/L] than those with MAP [6.58 (1.31-15.37) µg/L], <i>P</i> = 0.02 Serum adiponectin levels from days 4 to 7 were lower for patients with SAP [median 4.53 (0.94-18.2) µg/L] than those with MAP [8.06 (2.11-17.72) µg/L], <i>P</i> = 0.01 1-3 d serum adiponectin threshold of 4.5 µg/mL correctly classified the severity of 81% of patients with AP This threshold yielded a sensitivity of 70%, specificity 85%, PPV 64%, NPV 88%, AUC 0.75	Serum adiponectin levels are significantly lower in patients with SAP than those with MAP and could serve as inverse marker of systemic inflammatory response to pancreatic injury

Daniel <i>et al</i> ^[40]	Prospective observational study (<i>n</i> = 62) Diagnosis of AP was based on at least threefold elevated serum amylase level, as well as ultrasonography and CT In all cases AP was classified as C according to Balthazar's CT score and as severe according to Ranson's criteria (3 points) Adipokines studied: resistin Adipokines evaluated on 1, 2, 3 and 5 d of hospitalization SAP (<i>n</i> = 32) <i>vs</i> controls (<i>n</i> = 30)	On first day of observation, the median serum CRP level was 51.9 ± 46.1 mg/L, significantly higher than in control group (3.44 ± 3.04 mg/L, <i>P</i> = 0.01), and further increased at third day of hospitalization (102.6 ± 55.1 mg/L, <i>P</i> < 0.05), slightly decreasing on fifth day of hospitalization (78 ± 47.7 mg/L) The values observed at third and fifth day of hospitalization were significantly higher than in the control group (<i>P</i> < 0.001) One day of admission and third day of the hospitalization the mean serum resistin concentration was 12.9 ± 6.38 ng/mL and 17.4 ± 4.23 ng/mL, respectively Both values were significantly higher than in the control group (4.06 ± 2.63 ng/mL, <i>P</i> < 0.05) At fifth day of hospitalization serum resistin concentration increase further to 25.8 ± 8.14 ng/mL, which was significantly higher than at first and third day (<i>P</i> < 0.05) of hospital stay Significant correlation between CRP and resistin (<i>r</i> = 0.43, <i>P</i> < 0.05) during the hospital stay was found	Resistin may be useful early marker in edematous form of AP
Schäffler <i>et al</i> ^[38,39]	Prospective observational study (<i>n</i> = 50) Diagnosis of AP was based on clinical, laboratory and radiological findings during CT and/or ultrasound examination All patients were divided into three groups: first - with higher radiological score's points, second - with lower radiological score's points and third - no CT scan (mild pancreatitis) Adipokines studied: leptin, adiponectin, resistin, visfatin Adipokines were measured daily from admission till 10 d of hospital stay SAP (<i>n</i> = 41) <i>vs</i> MAP (<i>n</i> = 9) and patients with high points <i>vs</i> low points on radiological scores	Balthazar score: 4.0 (1-5), Schroeder score: 4.5 (1-7), Necrosis score: 1.5 (1-4), Ranson: 3 (0-8), Apache II: 12 (0-45) Admission resistin levels has positive an significant correlation with Apache II score (<i>r</i> = 6, <i>P</i> < 0.001) and with Ranson score (<i>r</i> = 0.4, <i>P</i> = 0.013) Admission resistin cut-off value of > 11.9 ng/mL can provide a PPV of 89% in predicting Schroeder score of > 3 (specificity 80%, sensitivity 70%, AUC 0.8, <i>P</i> < 0.002) Admission resistin cut-off value of > 11.9 ng/mL can serve as a positive predictor of a Balthazar score > 3 and Necrosis score > 2 Admission visfatin cut-off value of > 1.8 ng/mL can provide a PPV of 93.3% in predicting Schroeder score of > 3 (specificity 81.8%, sensitivity 93.3%, AUC 0.89, <i>P</i> < 0.001, likelihood ratio 5.1, post-test probability 93.0%) Admission visfatin concentration can also predict Necrosis score > 2 (PPV 48.3, specificity 40.0%, sensitivity 93.8%, AUC 0.77, <i>P</i> < 0.004, likelihood ratio 1.5, post-test probability 70.0%) and Balthazar score > 3 (PPV 79.3, specificity 57.1%, sensitivity 88.9%, AUC 0.74, <i>P</i> < 0.011, likelihood ratio 2.1, post-test probability 55.0%)	Resistin and visfatin levels are highly elevated in patients with SAP when compared to patients with MAP Both adipokines levels are positively correlated with clinical severity, clinical end points and needs for interventions A single measurement of serum resistin or visfatin on the day of admission is a highly significant and positive predictive marker in predicting peripancreatic necrosis

AP: Acute pancreatitis; SAP: Severe acute pancreatitis; MAP: Mild acute pancreatitis; BMI: Body mass index; CRP: C-reactive protein; AUC: Area under curve; PPV: Positive predictive value; NPV: Negative predictive value; CT: Computed tomography.

scores ranges, there is no precise cut-off values in order to predict disease severity on admission, development of pancreatic and parapancreatic necrosis, infectious complications, need for interventional treatment and fatal outcome. Therefore it is difficult to compare the prognostic value of adipokines with other prognostic systems.

It is clear, that obesity complicates the course of acute pancreatitis and it is associated with higher incidence of local complications, organ failure and increased mortality risk^[41,42]. Adipose tissue doesn't accumulate contrast, making it difficult to evaluate it's necrosis on computed tomography (CT) scans. Thus, adipokines could be a useful markers for adipose tissue necrosis. High levels of adipokines could allow for prediction of a severe disease course and outcome even in small pancreatic lesions on CT scans, but further research is needed. Therefore, it is appropriate to initiate a multicenter study, with a sufficient number of AP patients and controls. All patients must be evaluated with the same clinical score, adipokines should be investigated all at once and CT scans should be standardized in time. We believe, that such a study could provide a more definitive answer about the value of the

adipokines in predicting the course and the outcomes of AP in a clinical setting.

COMMENTS

Background

Acute pancreatitis (AP) is a common disease with a wide spectrum of severity. The main problem remains, that neither prognostic scores nor single predictors can't accurately predict the disease course and severity, development of pancreatic or peripancreatic necrosis, and outcomes during the first hours or even days of hospitalization. Therefore, there is a great stimulus for seeking new accurate and easy to use predictors. Perhaps, the least studied group of predictors in AP is adipokines. The aim of this study was to analyze the prognostic value of adipokines in predicting the course, complications and fatal outcome of AP.

Research frontiers

It is now widely accepted, that white adipose tissue is an active endocrine organ, which is also involved in pathogenesis of AP. Peripancreatic fat cells necrosis might cause a massive release of and adipokines, that possibly cause multi-organ dysfunction and whole body metabolic changes. It is hypothesized that the extent of peripancreatic fat-cell necrosis determines the severity of pancreatitis, and an early increase of adipocyte-specific marker proteins might serve as predictor of the clinical course.

Innovations and breakthroughs

It seems that concentrations of the leptin and resistin increases significantly in patients with AP compared with controls. Serum levels of adiponectin, visfatin

and especially resistin (positive correlation with Acute Physiology and Chronic Health Evaluation II, Ranson and C-reactive protein) are significantly different in mild and severe AP patients, so, they can serve as a markers for the disease severity prediction. Resistin and visfatin can also be used for pancreatic and parapancreatic necrosis prediction, interventions needs and possible, outcome.

Applications

Adipokines could be a useful markers for adipose tissue necrosis. High levels of adipokines could allow for prediction of a severe disease course and outcome even in small pancreatic lesions on computed tomography scans, but further research is needed.

Terminology

AP: Acute inflammatory process of the pancreas with variable involvement of other regional tissues or remote organ systems; Mild AP: Associated with minimal organ dysfunction and an uneventful recovery; Severe AP: Associated with organ failure and/or local complications such as necrosis, abscess or pseudocyst; Adipokines: Cytokines secreted by adipose tissue.

Peer review

In the current review, the authors have presented the current knowledge on the role of adipocytokines in predicting severity of AP. The search criteria were scientific and the data has been presented in an easily comprehensible manner.

Abstract

AIM: To evaluate the trends in the eradication rate of *Helicobacter pylori* (*H. pylori*) over the past 11 years in a single center.

METHODS: This retrospective study covered the period from January 2000 to December 2010. We evalu-

ated 5746 patients diagnosed with gastric ulcers (GU), duodenal ulcers (DU), GU + DU, or nonpeptic ulcers associated with an *H. pylori* infection. We treated them annually with the 2 wk standard first-line triple regimen, proton pump inhibitor (PPI) + amoxicillin + clarithromycin (PAC; PPI, clarithromycin 500 mg, and amoxicillin 1 g, all twice a day). The follow-up test was performed at least 4 wk after the completion of the 2 wk standard *H. pylori* eradication using the PAC regimen. We also assessed the eradication rates of 1 wk second-line therapy with a quadruple standard regimen (PPI *b.i.d.*, tripotassium dicitrate bismuthate 300 mg *q.i.d.*, metronidazole 500 mg *t.i.d.*, and tetracycline 500 mg *q.i.d.*) after the failure of the first-line therapy. Statistical analysis was performed with 95%CI for the differences in the annual eradication rates.

RESULTS: A total of 5746 patients [2333 males (58.8%), 1636 females (41.2%); mean age of males *vs* females 51.31 ± 13.1 years *vs* 52.76 ± 13.6 years, $P < 0.05$, total mean age 51.9 ± 13.3 years (mean \pm SD)] were investigated. Among these patients, 1674 patients were excluded: 35 patients refused treatment; 18 patients ceased *H. pylori* eradication due to side effects; 1211 patients had inappropriate indications for *H. pylori* eradication, having undergone stomach cancer operation or chemotherapy; and 410 patients did not undergo the follow-up. We also excluded 103 patients who wanted to stop eradication treatment after only 1 wk due to poor compliance or the side effects mentioned above. Finally, we evaluated the annual eradication success rates in a total of 3969 patients who received 2 wk first-line PAC therapy. The endoscopic and clinical findings in patients who received the 2 wk PAC were as follows: gastric ulcer in 855 (21.5%); duodenal ulcer in 878 (22.1%); gastric and duodenal ulcer in 124 (3.1%), erosive, atrophic gastritis and functional dyspepsia in 2055 (51.8%); and other findings (e.g., MALToma, patients who wanted to receive the therapy even though they had no abnormal endoscopic finding) in 57 (0.5%).

The overall eradication rate of the 2 wk standard first-line triple regimen was 86.5%. The annual eradication rates from 2000 to 2010 were 86.7%, 85.4%, 86.5%, 83.3%, 89.9%, 90.5%, 88.4%, 84.5%, 89.1%, 85.8%, and 88.3%, sequentially ($P = 0.06$). No definite evidence of a significant change in the eradication rate was seen during the past eleven years. The eradication rates of second-line therapy were 88.9%, 82.4%, 85%, 83.9%, 77.3%, 85.7%, 84.4%, 87.3%, 83.3%, 88.9%, and 84% ($P = 0.77$). The overall eradication rate of 1 wk quadruple second-line therapy was 84.7%. There was no significant difference in the eradication rate according to the *H. pylori* associated diseases.

CONCLUSION: This study showed that there was no trend change in the *H. pylori* eradication rate over the most recent 11 years in our institution.

INTRODUCTION

Helicobacter pylori (*H. pylori*) has been one of the most common human infections worldwide and is associated with a number of gastrointestinal diseases, including chronic gastritis, peptic ulcer disease, and gastric malignancy^[1]. In multicenter studies, it has been shown that triple therapy with a proton pump inhibitor (PPI), clarithromycin 500 mg and either amoxicillin 1000 mg or metronidazole 500 mg, all taken twice daily, is one of the most effective treatments for *H. pylori* eradication^[2]. However, there is no consensus on the length of treatment among the various management guidelines, including the Asia-Pacific consensus guideline^[3] and the consensus statements from North America^[4] and Europe^[5]. European guidelines recommend 1 wk of treatment, whereas in the United States, it is recommended that the triple standard regimen be given for 10-14 d. The second Asia-Pacific consensus guideline recommends a 7-14 d standard regimen; however, it mentions that 14 d triple therapy confers a limited advantage

over 7-d triple therapy in *H. pylori* eradication rates. In recent years, a decrease in the eradication success rate of 1 wk of triple therapy has been reported due to antibiotic resistance, especially to clarithromycin^[6]. Although clarithromycin resistance is increasing year by year, the current recommended first-line therapy for *H. pylori* infection is PPI, amoxicillin, and clarithromycin for 7-14 d in Korea^[7]. The aim of this retrospective observational study was to investigate the trend in the 2 wk PPI-based standard regimen, which included amoxicillin and clarithromycin, under the unfavorable conditions of increasing antibiotic resistance. In addition, we also studied the trend in the eradication success rate of 1 wk second-line therapy that consisted of bismuth-containing quadruple therapy including PPI, metronidazole, and tetracycline.

MATERIALS AND METHODS

Patients

We retrospectively investigated the annual *H. pylori* eradication success rate of patients who visited our hospital from January 2000 to December 2010 and who had been diagnosed as *H. pylori*-infected by at least one positive result from an *H. pylori* culture test, microscopy of a biopsy specimen, or ¹³C-urea breath test. Patients were excluded due to the following reasons: patient refusal of treatment, abandonment of *H. pylori* eradication treatment, inappropriate indications for *H. pylori* eradication because of a stomach cancer operation or chemotherapy, or follow-up loss after *H. pylori* eradication treatment. We also excluded patients receiving 1 wk PPI + amoxicillin + clarithromycin treatment (PAC; PPI: omeprazole, lansoprazole, pantoprazole, rabeprazole, or esomeprazole, clarithromycin 500 mg, and amoxicillin 1 g, all twice a day) that exhibited poor compliance or adverse effects. We evaluated the success rate of *H. pylori* eradication for all patients who received the 2 wk, first-line standard *H. pylori* eradication PAC regimen. We also evaluated the success rate of eradication of 1 wk bismuth-containing quadruple therapy (PPI *b.i.d.*, tripotassium dicitrate bismuthate 300 mg *q.i.d.*, metronidazole 500 mg *t.i.d.*, and tetracycline 500 mg *q.i.d.*) of patients who failed *H. pylori* eradication treatment by the standard PAC regimen. Among these, patients who did not want treatment, patients who ceased *H. pylori* eradication treatment, and patients lost to follow-up after *H. pylori* eradication treatment were excluded. In the end, we evaluated the success rate of *H. pylori* eradication for a total of 399 patients who received a 1 wk, second-line bismuth-containing quadruple therapy *H. pylori* eradication regimen. This study was approved by the institutional review board of Hallym University Chuncheon Hospital.

Diagnosis of *H. pylori* infection and assessment of *H. pylori* eradication

H. pylori infection was defined according to at least one of the following three tests: (1) a positive rapid urease test (CLO test, Delta West, Bentley, Australia) by gastric mucosal biopsy from the lesser curvature of the mid-antrum or

Figure 1 Flow of the study. ¹Inappropriate indications for *Helicobacter pylori* (*H. pylori*) eradication: Stomach cancer operation or chemotherapy. PAC: Proton pump inhibitor *b.i.d.* + amoxicillin 1 g *b.i.d.* + clarithromycin 500 mg; PBMT: Proton pump inhibitor *b.i.d.* + tripotassium dicitrate bismuthate 300 mg *q.i.d.* + metronidazole 500 mg *t.i.d.* + tetracycline 500 mg *q.i.d.*

mid-body; (2) histological evidence of *H. pylori* by modified Giemsa staining in the lesser and greater curvature of the mid-antrum or mid-body, respectively; or (3) a positive C-urea breath test. *H. pylori* eradication was defined as a negative ¹³C-urea breath test or a combination of the rapid urease test, Giemsa staining, and culture when follow-up endoscopy was necessary. The follow-up test was performed at least 4 wk after the completion of the 2 wk standard *H. pylori* eradication using the PAC regimen.

Statistical analysis

Statistical analysis was performed with 95%CI for the differences in the annual eradication rates from January 2000 to December 2010. Continuous variables were analyzed by Student's *t* test, and categorical variables, by the χ^2 test or Fisher's exact test. A *P* value of < 0.05 was considered to be statistically significant.

RESULTS

A total of 5746 patients [2333 males (58.8%), 1636 fe-

males (41.2%); mean age of males *vs* females 51.31 ± 13.1 years *vs* 52.76 ± 13.6 years, *P* < 0.05, total mean age 51.9 ± 13.3 years (mean \pm SD)] were retrospectively investigated for the period of January 2000 to December 2010 in this study. The retrospective assessment flow is summarized in Figure 1. Among these patients, 1674 patients were excluded: 35 patients refused treatment; 18 patients ceased *H. pylori* eradication treatment due to side effects, such as abdominal discomfort, diarrhea, taste disturbance, or nausea; 1211 patients had inappropriate indications for *H. pylori* eradication therapy, having undergone a stomach cancer operation or chemotherapy; and 410 patients did not undergo the follow-up assessment for *H. pylori* eradication after the 2 wk PAC treatment. We also excluded 103 patients who wanted to stop the eradication treatment after only 1 wk due to poor compliance or the side effects mentioned above. Finally, we evaluated the annual eradication success rates in a total of 3969 patients who received 2 wk PAC therapy. Demographic characteristics are summarized in Table 1. Of the patients included in the study, 735 (18.5%) were current smokers, and 28.7%

Table 1 Baseline characteristics of the *Helicobacter pylori* eradication population

Baseline characteristics	Data n (%)
Sex	
Male	2333 (58.8)
Female	1636 (41.2)
Age (yr, mean \pm SD)	51.9 \pm 13.3
Current smoker	735 (18.5)
Alcohol intake	1140 (28.7)
Endoscopic and clinical diagnosis	
GU	855 (21.5)
DU	878 (22.1)
GU + DU	124 (3.1)
Non-ulcer dyspepsia ¹	2055 (51.8)
Other ²	57 (1.4)

¹Functional dyspepsia, erosive gastritis, atrophic gastritis; ²Gastric cancer, MALToma. GU: Gastric ulcers; DU: Duodenal ulcers.

were alcohol drinkers. Endoscopic and clinical findings in patients who received the 2 wk PAC were as follows: gastric ulcer in 855 (21.5%); duodenal ulcer in 878 (22.1%); gastric and duodenal ulcer in 124 (3.1%), erosive, atrophic gastritis and functional dyspepsia in 2055 (51.8%), and other findings (e.g., MALToma, patients who wanted to receive the therapy even though they had no abnormal endoscopic finding) in 57 (1.4%). When endoscopy is not indicated, C¹³ urea breath tests (3030, 76.3%), biopsies (22, 0.6%), and CLO test (503, 12.7%) are accepted to determine the outcome of *H. pylori* eradication therapy. In some cases, biopsy + CLO test (329, 8.2%) or CLO test + C¹³ urea breath test was used for the diagnosis of *H. pylori* eradication therapy. Successful eradication rates for each year were follows: 2000, 86.7%; 2001, 85.4%; 2002, 86.5%; 2003, 83.3%; 2004, 89.9%; 2005, 90.5%; 2006, 88.4%; 2007, 84.5%; 2008, 89.1%; 2009, 85.8%; and 2010, 88.3% ($P = 0.06$). Figure 2 summarizes the annual eradication rates year by year from 2000 to 2010. The overall eradication rate was 86.5%, that is, 3435 of 3969 patients who received the 2 wk PAC (95%CI: 85.4% to 87.6%). The P value was 0.09. The annual eradication rates of the 2 wk PAC regimen revealed a relatively constant rate over the years. According to endoscopic and clinical findings, the eradication rates were not significantly different by year. We also investigated the eradication rates of 1 wk bismuth-containing quadruple therapy for 555 patients who failed the *H. pylori* eradication treatment using the 2 wk PAC therapy. Among the 555 patients, 156 patients were excluded for the following reasons: 23 patients declined treatment, 43 patients ceased *H. pylori* eradication treatment due to poor compliance or side effects such as diarrhea, nausea, vomiting, or stool color change, and 90 patients were lost to follow-up after *H. pylori* eradication treatment. Finally, we found the rates of successful eradication in 399 patients who received 1 wk bismuth-containing quadruple second-line therapy for each year to be as follows: 2000, 88.9%; 2001, 82.4%; 2002, 85.0%; 2003, 83.9%; 2004, 77.3%; 2005, 85.7%; 2006, 84.4%; 2007, 87.3%; 2008, 83.3%; 2009, 88.9%; and 2010, 84.0% ($P =$

Figure 2 Efficacy of 2 wk first-line (a dotted line) proton pump inhibitor b.i.d. + amoxicillin 1 g b.i.d. + clarithromycin 500 mg and 1 wk second-line (a solid line) bismuth-containing quadruple therapy for the eradication of *Helicobacter pylori* by year.

0.77). Figure 2 summarizes the annual eradication rates year by year from 2000 to 2010. The overall eradication rate was 84.7%, and the rate among those who received 1 wk second-line therapy was 338 of 399 patients (95%CI: 80.9% to 87.9%). The P value was 0.07. The annual eradication rates of the 1 wk second-line therapy revealed a relatively constant rate over the years.

DISCUSSION

The PAC regimen is one of the most widely used therapies for the first-line treatment of *H. pylori* infection. A recent study reported the eradication rate of *H. pylori* with one wk standard triple therapy to be 75% in Korea^[8]. There is still no general consensus regarding the optimal duration of triple therapy for *H. pylori* eradication, as mentioned above. A recent large, multicenter, double-blind, randomized study concluded that the 1 wk and 2 wk standard triple regimens for *H. pylori* eradication are similar in terms of efficacy, safety, and patient compliance^[9]. Two meta-analyses have reported that 2 wk triple therapy achieves considerably better results than 1 wk therapy^[10,11]. Recently, many studies have reported that the efficacy of the standard triple regimen has decreased^[12-14] because of the increased antibiotic resistance rate; that is, the standard triple regimen of PPI, amoxicillin, and clarithromycin administered to patients infected with the clarithromycin-resistant strain was not successful^[15]. Although the general consensus is that a 1 wk PAC is preferable, we have treated patients infected by *H. pylori* with the 2 wk PAC to overcome increasing antibiotic resistance. Our data on the 2 wk PAC regimen shows a relatively constant rate over the year from 2000 to 2010. A recent chronological analysis of the results of meta-analyses performed between 1998 and 2010 showed that first-line standard triple regimens achieved eradication rates of around only 80% (intention-to-treat)^[16]. Given that the overall eradication rate in this study was 86.5% (3435 of 3969 patients who received the 2 wk PAC), we concluded that the 2 wk PAC regimen had an accept-

able efficacy for *H. pylori* eradication. Many investigators have commented that the decreasing eradication rate using standard triple therapy is due to increasing antibiotic resistance. However, a number of factors, including resistance, which varies widely, influence the success of antibiotic regimens. The resistance rates of antibiotics that are widely used in eradication therapy, including amoxicillin and tetracyclines, are relatively lower than clarithromycin and metronidazole^[15]. Therefore, the true challenge for clinical practice lies mainly in resistance to metronidazole or clarithromycin. In Korea, the rates of resistance to clarithromycin and metronidazole were reported from 1.6% up to 29.7% and from 35.7% up to 49.6 % from 1996 to 2006, respectively^[17]. This is a major factor in the reduced effectiveness of triple regimens containing clarithromycin^[18]. Clarithromycin must bind to ribosomes to kill *H. pylori*. Resistance is associated with failure to bind to ribosomes, such that resistance cannot be overcome by increasing the dose or duration^[15]. However, patients do not always have perfect compliance. Because *H. pylori* treatment failures may also occur independently of resistance, that is, treatment may fail but the organism remains susceptible to the antibiotic^[19], we concluded that the 2 wk standard PAC regimen may be fit for use in eradicating *H. pylori*. Bacteria oscillate between a phenotypically resistant and a phenotypically susceptible state, during which they can be eradicated. To extend the duration of treatment such that the antibiotic will be present during at least one period of susceptibility may be an alternative option to overcome antibiotic resistance^[20]. Consistent with the results from Korea in this study, several authors have reported an increasing trend in clarithromycin resistance rates in other areas, such as the United States^[21], Turkey^[22], *etc.* Nevertheless, exceptional cases where clarithromycin resistance rates have remained stable have also been reported^[23]. These results strongly suggest that there is an institutional and geographical difference in the antibiotic resistance of *H. pylori*. This fact and our results in this study suggest that the 2 wk PAC regimen may be effective in eradicating *H. pylori* in some countries or limited geographical areas. In a recent review, the eradication rates of quadruple therapy were 75%-95%^[24]. In Korea, where the resistance to metronidazole is high, the eradication rates of second line quadruple therapy have been reported to be 54.5%-76.7% and 70.4%-83.9% in intention to treat and per protocol analysis^[25,26], respectively, based on studies in which the therapeutic durations varied from 7 to 14 d. Metronidazole is a prodrug that is activated by *H. pylori* enzymes to become active within the cell. There are a number of different enzyme pathways that can accomplish this task, and clinically, by increasing the dose and duration, it is possible to overcome, at least partially, metronidazole resistance^[2,27]. Thus, there is the possibility that quadruple therapy might be more effective with after a treatment duration of longer than 1 wk. However, some studies have shown the benefit of eradication with prolonged treatment durations^[28], while

others have not^[29,30]. We previously reported that 1 wk bismuth-containing quadruple therapy can be as an effective as 2 wk therapy after the failure of the first-line eradication therapy. In this study, the eradication rates of 1 wk bismuth-containing quadruple therapy have no significant differences from the consecutive, annual eradication rates, in spite of increasing metronidazole resistance in Korea. Therefore, although 1 wk bismuth-containing quadruple therapy is not effective up to more than 90% yet, we concluded that 1 wk bismuth-containing quadruple therapy can be used to treat patients who failed the first *H. pylori* eradication. To raise the eradication rate of *H. pylori*, when the clarithromycin resistance rate is higher than 20%, it is recommended that drug sensitivity tests be carried out prior to eradication^[5]. However, there are several limitations to performing a culture before the first-line treatment for *H. pylori* infection. Cultures are expensive, owing to the costs of the endoscopic procedures, and they are time-consuming. Therefore, cultures are not always available on a routine basis. Until now, cultures for *H. pylori* have mainly been used to perform epidemiological and pharmacologic research. Because extending the duration of the first line PAC regimen from 1 wk to 2 wk may improve the efficacy of the *H. pylori* eradication rate, the 2 wk PAC regimen is preferable for treating *H. pylori*. However, this study does have limitations. One is that it is a retrospective, observational study. Therefore, there was some bias, such as an uneven diagnostic method for the determination of the outcome of *H. pylori* eradication therapy in each year. The other endoscopic findings were not even taken in each year. Additionally, we could not obtain the data on antibiotic resistance including amoxicillin, clarithromycin, metronidazole, and tetracycline in accordance with the eradication rate.

In conclusion, we show the efficacy of a 2 wk PAC regimen and 1 wk bismuth-containing quadruple therapy has not changed across the 2000 to 2010 period in South Korea. The efficacy of 2 wk PAC and 1 wk quadruple second line therapy is by no means acceptable and satisfactory.

COMMENTS

Background

In recent years, a decrease in the eradication success rate of 1 wk of triple therapy has been reported due to antibiotic resistance, especially to clarithromycin. Although clarithromycin resistance is increasing year by year, the currently recommended first-line therapy for *Helicobacter pylori* (*H. pylori*) infection is proton pump inhibitor (PPI), amoxicillin, and clarithromycin for 7-14 d in South Korea. This retrospective, observational study intended to investigate the trend in the 2 wk PPI-based standard regimen including amoxicillin and clarithromycin under the unfavorable conditions of increasing antibiotic resistance.

Research frontiers

The overall eradication rate of the 2 wk standard first-line triple regimen from 2000 to 2010 was 86.5%. No definite evidence of a significant change in the eradication rate was seen during the past eleven years. The overall eradication rate of 1 wk bismuth-containing quadruple, second-line therapy from 2000 to 2010 was 84.7%. The annual eradication rates of the 1 wk second-line therapy revealed a relatively constant rate over the year.

Innovations and breakthroughs

Authors show that the efficacy of 2 wk PPI + amoxicillin + clarithromycin (PAC)

regimen and 1 wk bismuth-containing quadruple therapy did not change over the period from 2000 to 2010 in South Korea. The efficacy of the 2 wk PAC and 1 wk quadruple second line therapy is by no means acceptable and satisfactory.

Applications

Authors conclude that the 2 wk standard PAC regimen may be fit for use in eradicating *H. pylori*. Bacteria oscillate between a phenotypically resistant and a phenotypically susceptible state, during which they can be eradicated. To extend the duration of treatment such that the antibiotic will be present during at least one period of susceptibility may be an alternative option to overcome antibiotic resistance.

Peer review

In this study, the authors retrospectively evaluated the eradication rate of *H. pylori* in a single center in the Republic of Korea for the period of January 2000 to December 2010. In 3969 patients who received a two weeks standard first-line triple therapy, an overall eradication rate of 86.5% has been found, with no significant ($P = 0.09$) difference in the annual eradication rate during the eleven years. Furthermore, in the 399 patients who failed *H. pylori* eradication and received a 1-wk second-line therapy, an overall eradication rate of 84.7% has been found, with a relatively constant rate over the years. The authors conclude that there was no trend of change in the *H. pylori* eradication rate over the last 11 years in their institution and that a 2-wk first-line and a 1-wk second-line therapy can still be used in Korea.

Abstract

AIM: To evaluate effects of UDP-glucuronosyltransferase 1A1 (*UGT1A1*) and thymidylate synthetase (*TS*) gene polymorphisms on irinotecan in metastatic colorectal cancer (mCRC).

METHODS: Two irinotecan- and fluorouracil-based regimens, FOLFIRI and IFL, were selected as second-

line therapy for 138 Chinese mCRC patients. Genomic DNA was extracted from peripheral blood samples before treatment. *UGT1A1* and *TS* gene polymorphisms were determined by direct sequencing and restriction fragment length polymorphism, respectively. Gene polymorphisms of *UGT1A1**28, *UGT1A1**6 and promoter enhancer region of *TS* were analyzed. The relationship between genetic polymorphisms and clinical outcome, that is, response, toxicity and survival were assessed. Pharmacokinetic analyses were performed in a subgroup patients based on different *UGT1A1* genotypes. Plasma concentration of irinotecan and its active metabolite SN-38 and inactive metabolite SN-38G were determined by high performance liquid chromatography. Differences in irinotecan and its metabolites between *UGT1A1* gene variants were compared.

RESULTS: One hundred and eight patients received the FOLFIRI regimen, 29 the IFL regimen, and one irinotecan monotherapy. One hundred and thirty patients were eligible for toxicity and 111 for efficacy evaluation. One hundred and thirty-six patients were tested for *UGT1A1**28 and *6 genotypes and 125 for promoter enhancer region of *TS*. Patients showed a higher frequency of wild-type *UGT1A1**28 (TA6/6) compared with a Caucasian population (69.9% vs 45.2%). No significant difference was found between response rates and *UGT1A1* genotype, although wild-type showed lower response rates compared with other variants (17.9% vs 24.2% for *UGT1A1**28, 15.7% vs 26.8% for *UGT1A1**6). When *TS* was considered, the subgroup with homozygous *UGT1A1**28 (TA7/7) and non-3RG genotypes showed the highest response rate (33.3%), while wild-type *UGT1A1**28 (TA6/6) with non-3RG only had a 13.6% response rate, but no significant difference was found. Logistic regression showed treatment duration was closely linked to clinical response. In toxicity comparison, *UGT1A1**28 TA6/6 was associated with lower incidence of grade 2-4 diarrhea (27.8% vs 100%), and significantly reduced the risk of grade 4 neutropenia compared with TA7/7 (7.8% vs 37.5%).

Wild-type *UGT1A1**6 (G/G) tended to have a lower incidence of grade 3/4 diarrhea *vs* homozygous mutant (A/A) genotype (13.0% *vs* 40.0%). Taking *UGT1A1* and *TS* genotypes together, lower incidence of grade 2-4 diarrhea was found in patients with non-3RG *TS* genotypes, when TA6/6 was compared with TA7/7 (35.3% *vs* 100.0%). No significant association with time to progression (TTP) and overall survival (OS) was observed with either *UGT1A1* or *TS* gene polymorphisms, although slightly longer TTP and OS were found with *UGT1A1**28 (TA6/6). Irinotecan PK was investigated in 34 patients, which showed high area under concentration curve (AUC) of irinotecan and SN-38, but low AUC ratio (SN-38G / SN-38) in those patients with *UGT1A1**28 TA7/7.

CONCLUSION: A distinct distribution pattern of *UGT1A1* genotypes in Chinese patients might contribute to relatively low toxicity associated with irinotecan and 5-fluorouracil in mCRC patients.

INTRODUCTION

The current management of metastatic colorectal cancer (mCRC) uses fluorouracil-based regimens in combination with either oxaliplatin or irinotecan. These regimens mainly differ in their toxicity profiles with neutropenia and late diarrhea being associated with irinotecan-based therapy versus neurotoxicity with oxaliplatin-based treatment.

In our previous studies on the relationship of UDP-glucuronosyltransferase1A1 (*UGT1A1*) polymorphisms and irinotecan-related diarrhea, we found that *UGT1A1**28 genotype was significantly associated with the occurrence of diarrhea, while the polymorphisms of *UGT1A7* and *UGT1A9* variants were found to be unrelated. Mutated *UGT1A1**28 genotype was seen infrequently in the Chinese population, therefore, this might explain the lower

incidence of late diarrhea in our patients treated with irinotecan compared to that in the Caucasian population^[1,2]. However, the role of *UGT1A* in clinical response to irinotecan- and 5-fluorouracil (5-FU)-based treatment, non-diarrhea toxicities and prognosis remains unclear. In addition, thymidylate synthetase (TS), the enzyme targeted by 5-FU, deserves more attention because most patients that receive irinotecan are treated with irinotecan and 5-FU in combination.

UGT1A polymorphisms have become the focus of irinotecan pharmacokinetics and toxicity research because they are involved in metabolism of cytotoxic SN-38 (an active metabolite of irinotecan) to inactive SN-38 glucuronide (SN-38G) (Figure 1). Di Paolo *et al*^[3] have demonstrated that *UGT1A1* polymorphisms are closely correlated with glucuronidation rates, and patients with higher concentration of SN-38G are less susceptible to irinotecan-induced toxicity. Although, several clinical trials have confirmed that patients carrying different genotypes of *UGT1A1* had varied degrees of tolerance to irinotecan, it is still unclear whether *UGT1A1* has any influence on treatment efficacy. Three studies tested if *UGT1A1* isoforms had any impact on treatment outcome, however, their conclusions were inconsistent^[4-6].

Irinotecan is often combined with 5-FU in mCRC treatment, therefore, 5-FU should be taken into consideration for response and toxicity evaluation as well. *In vivo*, the active metabolite of 5-FU inhibits TS activity by forming complexes with TS and 5, 10-methylene-tetrahydrofolate (Figure 1)^[7]. Evidence supports the determinant role of TS promoter region polymorphism in 5-FU treatment efficacy and tolerance^[8,9]. Given higher accuracy and consistency in testing polymorphisms, tremendous efforts have been put into using TS polymorphism as a genetic marker for predicting clinical response, toxicity and prognosis in mCRC patients treated with 5-FU^[10-13].

This study aimed to evaluate the effects of *UGT1A1*/*TS* polymorphisms in Chinese mCRC patients treated with irinotecan and fluorouracil including toxicity and clinical outcome.

MATERIALS AND METHODS

Drug administration

Two regimens were selected for this study: (1) FOLFIRI: irinotecan (Camptosar; Pfizer, United States) 180 mg/m² 90-min *i.v.* infusion on day 1; leucovorin 200 mg/m² *i.v.* infusion on days 1 and 2; followed on days 1 and 2 by 5-FU 400 mg/m² *i.v.* bolus, then 600 mg/m² *i.v.* over 22 h continuous infusion; repeated every 2 wk; (2) IFL: irinotecan 125 mg/m² as a 90-min *i.v.* infusion on days 1, 8, 15 and 22; leucovorin 20 mg/m² *i.v.* infusion on days 1, 8, 15 and 22; 5-FU 500 mg/m² *i.v.* bolus on days 1, 8, 15 and 22; every 6 wk.

Patient eligibility

The criteria for inclusion were: at least 18 years old; histologically confirmed mCRC; failed or intolerant to oxalipl-

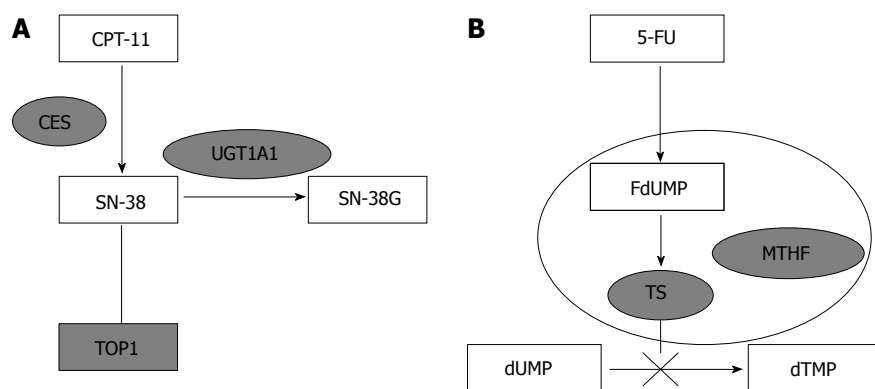

Figure 1 Schematic diagram of UDP-glucuronosyltransferase1A1 and thymidylate synthetase. **A:** UDP-glucuronosyltransferase1A1 (UGT1A1) is the main enzyme involved in the glucuronidation of SN-38 (SN-38G). Single-nucleotide polymorphisms (SNPs) of UGT1A1 are the key factor in irinotecan metabolism; **B:** Thymidylate synthetase (TS) is the main target of 5-fluorouracil (5-FU). The ternary complex of TS, active metabolite of 5-FU (FdUMP) and methyl-tetra-hydrofolic acid (MTHF) inhibits DNA synthesis. SNP of TS affects the expression of enzyme and 5-FU efficacy. CES: Carboxylesterases; TOP1: Topoisomerase-1.

atin-based regimens; the Eastern Cooperative Oncology Group (ECOG) performance status 0-2; no chemotherapy at least 4 wk before study enrollment; life expectancy > 3 mo; neutrophil count $\geq 1.5 \times 10^9/L$, platelet count $\geq 8 \times 10^{10}/L$, serum creatinine ≤ 1.25 upper limit normal (ULN), total bilirubin ≤ 1.25 ULN, alanine aminotransferase and aspartate aminotransferase ≤ 2.5 ULN (≤ 5 ULN with liver metastasis); normal electrocardiogram. Written informed consent was required and the study was performed in accordance with the Declaration of Helsinki and Good Clinical Practice guidelines. All patients' information and samples were collected from trial participating centers.

Evaluation of response and toxicity

Tumor response was assessed by RECIST 1.0^[14] based on the results of computed tomography. Time to progression (TTP) was defined as the time from the start of treatment to the date of progression. Overall survival (OS) was defined as the time from the start of the treatment to the date of death. Toxicity was assessed according to the NCI-CTC 3.0^[15].

Genomic DNA extraction, polymerase chain reaction and genotyping assay

Two-milliliter peripheral blood samples were collected before starting treatment and frozen at -20°C . Genomic DNA was extracted from these samples using the Peripheral Blood Extraction Kit (Tiangen, China). The fragments of UGT1A1*28 and UGT1A1*6 were amplified by polymerase chain reaction (PCR). The Primer 5.0 software was used to design the sense primer (5'-GC-CAGTTCAACTGTTGTTGC-3') and antisense primer (5'-GTCCGTCAGCATGACATCAA-3'). Each 25- μL PCR reaction mixture included 5 ng DNA template, 1 mmol/L dNTPs, 0.4 mmol/L MgSO_4 , 0.25 $\mu\text{mol/L}$ primers, 0.5 U KOD-plus polymerase (TOYOBO, Japan) and 10 \times KOD plus buffer. The PCR profile included 2.5 min denaturation at 94°C , 35 cycles of 30 s at 94°C , 60 s at 57°C , 60 s at 68°C , with a final 7-min extension at 68°C . The PCR products were sequenced by ABI-3730 DNA analyzer and all single-nucleotide polymorphisms (SNPs) were analyzed by Polyphred 5.04 with additional manual proofreading.

Restriction fragment length polymorphism testing for promoter enhancer region of TS

Promoter enhancer region of 2R or 3R and G>C SNP in 3R were selected for testing. PCR-based restriction fragment length polymorphism was applied to detect these variants. The PCR conditions were same as described above with sense primer of 5'-GTGGCTCCTGCGTTTCCCC-3' and antisense primer of 5'-GCTCCGAGCCGCCACAGGCATGGCGCGG-3'. The PCR profile included initial 15 cycles with annealing temperature at 63°C , and another 30 cycles with annealing temperature at 62°C . The PCR products were electrophoresized in 3% agarose gel to differentiate 215-bp 2R genotype and 243-bp 3R genotype. 3R gene polymorphism was detected *via* electrophoresis after enzyme digestion. After *Hae*III treatment, 3RG genotype was separated to fragments of 66, 47, 45, 44, 28 and 13 bp, whereas 3RC genotype was separated to fragments of 94, 47, 45, 44 and 13 bp. The 20- μL reaction system contained 1 μL *Hae* III Takara, 2 μL 10 \times M buffer, 17 μL purified PCR products for 37°C overnight incubation.

Pharmacokinetics study

Five-milliliter heparinized blood samples were collected before administration of irinotecan, 1 and 1.5 h during infusion, and 0.25, 0.5, 1, 2, 4, 6, 8, 12, 24, 36, 48, 60 and 72 h after termination of infusion. Plasma samples were obtained by 3000 r/min centrifugation for 10 min and kept at -40°C . The concentrations of the drug and its metabolites were determined by high performance liquid chromatography with postcolumn fluorescence derivatization (HPLC-FLD). Two hundred microliters plasma was added to 50 μL 1 ng/mL camptothecin, 150 μL methanol, and 200 μL acetonitrile, and vortexed for 2 min. The mixture was then centrifuged at 15 000 r/min for 10 min. Supernatant (200 μL) was placed with 100 μL 1 mol/L HCl before HPLC analysis. Agilent 1100 chromatographic system consisted of quaternary pumps, an automatic sample injection system, fluorescence detector, and Znerstisil ODS-C18 Column. The mobile phases were eluted through the column and contained acetonitrile-sterile water (75:75 by volume) and phosphate buffer at pH 4. Irinotecan was kindly donated by Pfizer and camptothecin was provided by National Institute for the Control of Pharmaceutical and Biological Products. SN-38 was synthesized by Shanghai Zhangjiang Biochemical

Company. Blank human plasma was obtained from Blood bank of 307 Hospital. The lowest limit of quantification of irinotecan, SN-38 and SN-38G were 50 ng/mL, 1.25 ng/mL and 5 ng/mL, respectively, with within-day and between-day imprecision < 15%. C_{max} and T_{max} were observed values. $AUC_{0 \rightarrow t}$ was acquired by linear trapezoidal approximation. $AUC_{0 \rightarrow \infty} = AUC_{0 \rightarrow t} + Ct/ke$.

Statistical analysis

The χ^2 test was used to determine if the allele frequencies were matched to Hardy-Weinberg equilibrium. Associations between genotypes, clinical response and toxicity in Chinese and Caucasian populations were assessed by using Fisher's exact test and Cochran-Armitage trend test. Kaplan-Meier estimates and the log-rank test were used in TTP and OS analysis. Cox regression and logistic regression models were examined in multivariate analysis with and without time variables, respectively. The linkage between genotypes and pharmacokinetic parameters was analyzed by Mann-Whitney *U* and Kruskal-Wallis tests. Two-sided tests were used to determine statistically significant *P* values ($P < 0.05$) using SPSS 13.0 software.

RESULTS

Between September 2005 and April 2009, 138 mCRC patients were enrolled. Of these, 130 patients were eligible for toxicity evaluation and 111 qualified for treatment efficacy evaluation. Of 138 patients, 108 received the FOL-FIRI regimen, 29 the IFL regimen, and one irinotecan monotherapy. The median age of patients was 52 years (range: 26-81 years) with 63% being male. One hundred and eleven patients were followed until cancer progression or death. The overall response rate (complete + partial response) was 19.5%. The median TTP was 5.6 mo (95%CI: 3.9-7.3) and the median OS was 17 mo (95%CI: 11.9-22.1). The incidence of grade 3/4 neutropenia was 29.5%, and 17.4% participants developed grade 3/4 late diarrhea. However, the incidences in the FOLFIRI regimen were decreased, with 21.8% grade 3/4 neutropenia

(95%CI: 13.7%-29.9%) and 10.9% grade 3/4 late diarrhea (95%CI: 4.8%-16.9%).

UGT1A1 and TS polymorphisms correlation with clinical response

We tested UGT1A1 genotypes in 136 patients and TS promoter enhancer region in 125 (Figure 2). We observed that the response rates of UGT1A1*28 alleles TA6/6 and TA6/7 + TA7/7 were 17.9% and 24.2%, respectively, and those of UGT1A1*6 alleles G/G and G/A + A/A were 15.7% and 26.8%, respectively, without statistical significance observed.

Based on mRNA transcriptional activity, TS was categorized into 3RG/3RG homozygous group with highest activity, 3RG heterozygous group (3RG/3RC and 3RG/2RG) with median activity, and non-3RG group (3RC/3RC, 3RC/2RG and 2RG/2RG) with lowest activity. Although not statistically significant, 3RG/3RG homozygous group was found with lowest response rate (17.6%) (Table 1). Taking UGT1A1 and TS genotypes together, the subgroup with TA7/7 and non-3RG genotypes showed the highest response rate of 33.3%. Furthermore, under the same non-3RG background, no significant difference in response rate was found between TA6/6 and TA7/7 (13.6% *vs* 33.3%, $P = 0.154$) (Table 2). A multivariate logistic regression model was fitted to our data. The covariates included: chemotherapy regimen, treatment duration, ECOG performance status, sex, age, UGT1A1 genotypes, and TS promoter enhancer region, but only treatment duration (odds ratio 1.268, 95%CI: 1.027-1.565, $P = 0.027$) was closely linked to clinical response.

UGT1A1 polymorphisms correlation with toxicity

The enzyme activities of UGT1A1*28 alleles from highest to lowest were TA6/6, TA6/7 and TA7/7. TA7/7 showed the highest incidence of grade 2-4 late diarrhea ($P < 0.0005$). Compared with TA6/6, the risk ratio of TA6/7 and TA7/7 was 2.6 (95%CI: 1.20-5.63). Although not statistically significant, a trend of higher incidence of grade 3/4 diarrhea was observed in patients with lower activity genotypes. A similar finding was obtained in the UGT1A1*6 study. G/G with the highest activity was associated with lowest incidence of grade 3/4 diarrhea (trend

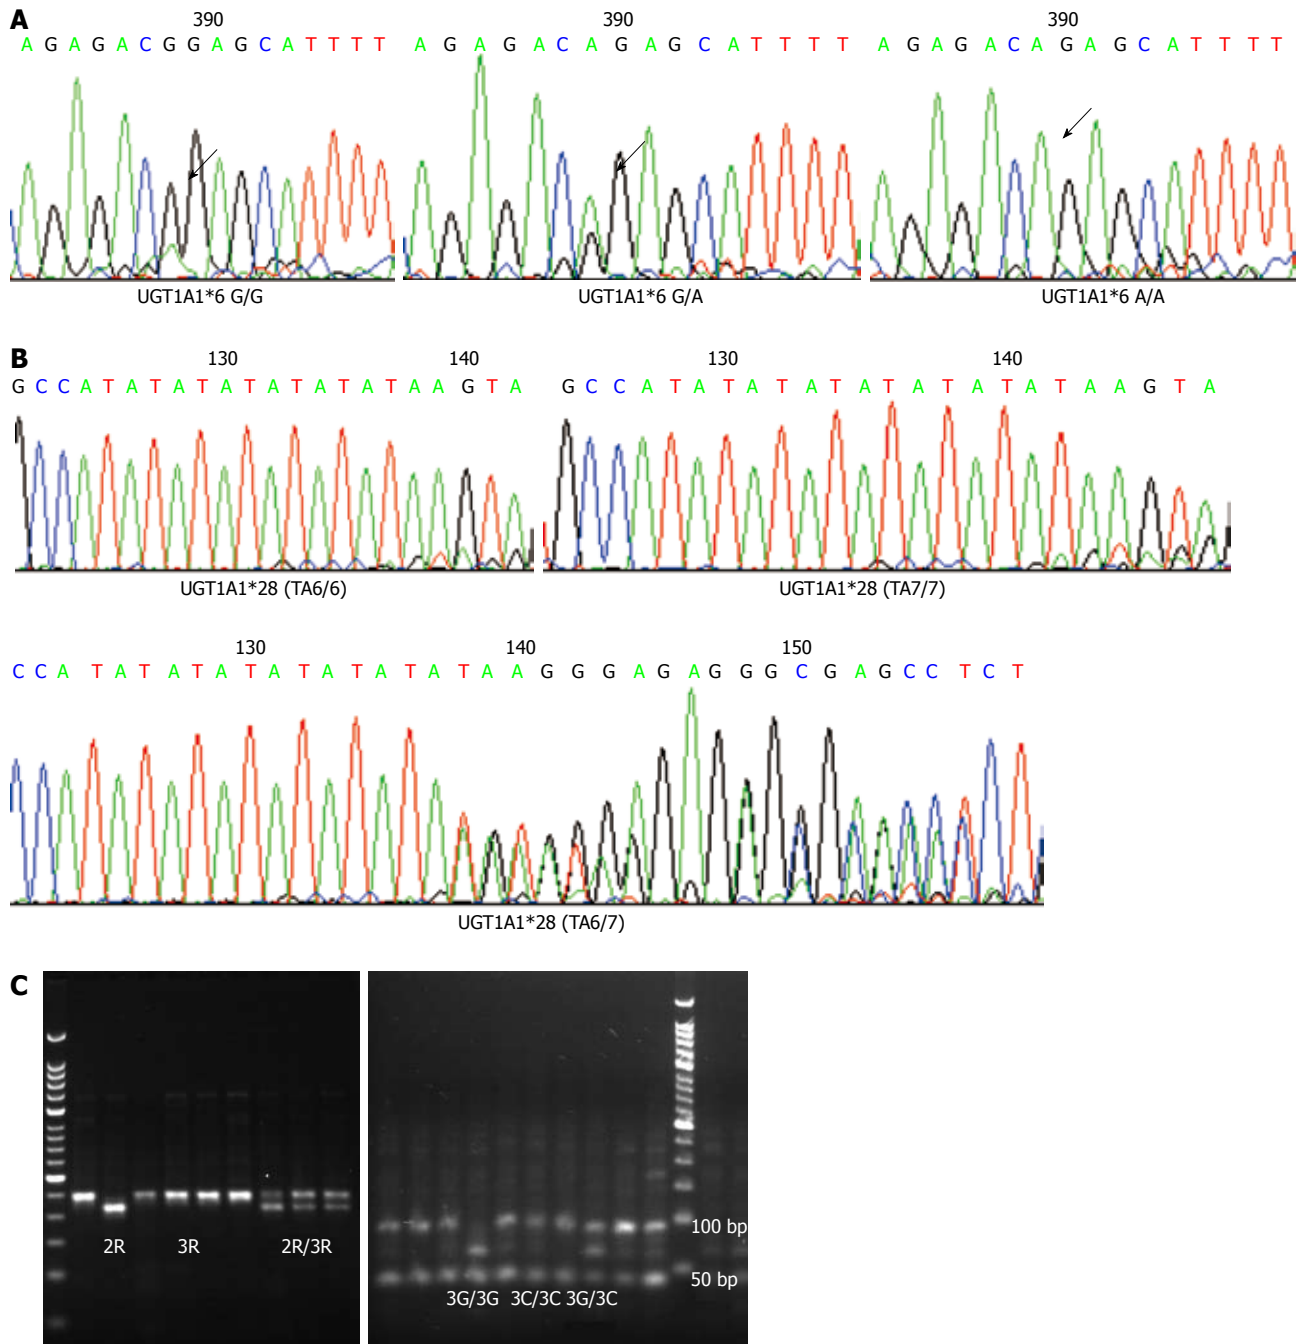

Figure 2 Analysis of UDP-glucuronosyltransferase1A1*28 and *6 by DNA sequencing and thymidylate synthase by restriction fragment length polymorphism. test $P = 0.057$). Compared with G/G, the risk ratio of grade 3/4 diarrhea in patients with G/A and A/A was 2.18 (95%CI: 0.87-5.42) (Table 3). In addition, UGT1A1*28 showed a similar correlation pattern with neutropenia. Grade 4 neutropenia was dominantly observed in TA7/7 patients ($P = 0.043$, trend test, $P = 0.017$). Compared with TA6/6, the risk ratio of grade 3/4 neutropenia in patients carrying TA6/7 and TA7/7 was 1.75 (95%CI: 0.79-3.88). By contrast, no association between UGT1A1*6 and grade 3/4 neutropenia was found (Table 3). Among three

TS groups, homozygous 3RG/3RG showed least incidence of grade 3/4 late diarrhea (15.8%) and neutropenia (26.3%), although not significantly different from the other two groups ($P > 0.05$). Further subgroup analysis of non-3RG TS genotypes found that patients with TA6/6 were less prone to grade 2-4 late diarrhea than TA7/7 (35.3% *vs* 100.0%, $P = 0.019$). Meanwhile, a trend of lower incidence of grade 3/4 neutropenia was observed in patients with TA6/6, although the association was not statistically significant (29.4% *vs* 50.0%, $P = 0.582$).

¹Fisher's exact test for all genotype; ²Exact test of Cochran-Armitage trend test across genotypes. Toxicity grade by National Cancer Institute Common Toxicity Criteria version 3.0. A total of 130 patients were assessable for toxicity. Significant differences were found on grades 2-4 delayed diarrhea and grade 4 neutropenia for UGT1A1*28 genotypes. UGT1A1: UDP-glucuronosyltransferase1A1.

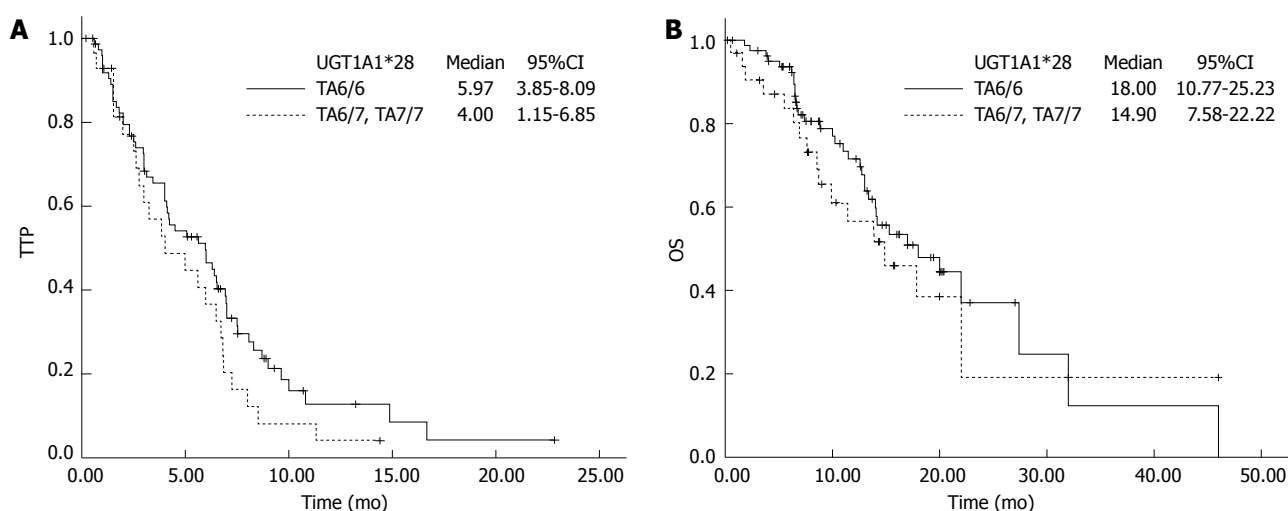

Figure 3 Time to progression and overall survival according to UDP-glucuronosyltransferase1A1*28 genotypes. A: Time to progression (TTP): Patients with TA6/6 were 5.97 (95%CI: 3.85-8.09), patients with TA6/7 and TA7/7 were 4.00 (95%CI: 1.15-6.85), $P = 0.154$; B: Overall survival (OS): Patients with TA6/6 were 18.00 (95%CI: 10.77-25.23), patients with TA6/7 and TA7/7 were 14.90 (95%CI: 7.58-22.22), $P = 0.444$. No significant difference was found between TA6/6 (wild type) and mutated genotypes. UGT1A1: UDP-glucuronosyltransferase1A1.

UGT1A1 polymorphisms correlation with TTP and OS

In 111 patients available for survival outcome analysis, no significant association with TTP and OS was observed with either UGT1A1*28 or UGT1A1*6, although slightly longer TTP and OS were found with UGT1A1*28 (TA6/6) (Figure 3). An additional study of 108 patients on TS revealed that there was no significant association between TS genotype and TTP/OS.

We further examined if the length of treatment duration was related to genotype. Patients with UGT1A1*28 (TA6/6) had a relatively longer treatment time compared with TA6/7 + TA7/7 genotype; near to statistical significance [9.57 ± 6.82 wk (range: 2-32 wk) *vs* 6.76 ± 5.05 wk (range: 1-19 wk), $P = 0.078$]. Although the 3RG homozygous group had longer treatment duration, it failed to display a significant correlation [3RG *vs* non-3RG, 9.03 ± 6.78 wk (range: 1-23 wk) *vs* 8.55 ± 6.16 wk (range: 2-32 wk), $P = 0.895$]. The longest TTP (6.9 mo) and OS (20 mo) were

found in the subgroup with TA6/6 and 3RG genotypes, but the differences were still insignificant compared with other subgroups ($P = 0.46$ and 0.37 , respectively). Independent variables that might affect OS were tested *via* Cox regression model analysis. These variables were ECOG performance status, age, sex, chemotherapy regimen, UGT1A1 and TS polymorphisms. Only chemotherapy regimen and ECOG were independent prognostic factors affecting OS. Higher ECOG score increased the death risk > 3 times [hazard ratio (HR): 3.325, 95% CI: 1.913-5.777, $P < 0.0005$]. Compared with IFL, FOLFIRI showed a 69% decline in death risk (HR: 0.312, 95%CI: 0.132-0.738, $P = 0.008$). For TTP, the Cox model suggested that chemotherapy regimen and sex were independent prognostic factors. Treatment with FOLFIRI lowered the risk of disease progression by 78% (HR: 0.217, 95%CI: 0.104-0.451, $P < 0.0005$). Female sex reduced the progression risk to 60% (HR: 0.608, 95%CI: 0.387-0.968, $P = 0.036$).

¹Kruskal-Wallis test; ²Mann-Whitney *U* test. 34 patients were assessable for pharmacokinetics parameters. CPT-11: Irinotecan; UGT1A1: UDP-glucuronosyl-transferase1A1; AUC: Area under concentration curve.

Figure 4 Area under concentration curve ratios of SN-38G/SN-38 comparison according to UDP-glucuronosyltransferase1A1*28 genotypes and UDP-glucuronosyltransferase1A1*28 + *6 group. A: Area under concentration curve (AUC) ratios comparison by UDP-glucuronosyltransferase1A1 (UGT1A1)*28: The AUC ratio of TA7/7 was less than half of the TA6/6 ratio (1.488 vs 3.178, $P = 0.158$); B: AUC ratios comparison by UGT1A1*28 + *6 group: Lower AUC ratio was found in the double mutation group (TA6/7 + G/A and TA7/7 + G/G), compared with the other two groups [wild type or single mutation group (1.488 vs 3.177, $P = 0.078$)].

UGT1A1*28 and UGT1A1*6 correlation with pharmacokinetics

Thirty-four patients were enrolled in a pharmacokinetics study. Among UGT1A1*28 alleles, there were 22 with TA6/6, 10 with TA6/7, and two with TA7/7. Among UGT1A1*6 alleles, there were 25 with G/G and nine with G/A. Among them, two participants were found with a double heterozygous genetic profile; TA6/7 + G/A. The pharmacokinetic parameters showed that the area under concentration curve (AUC) values of irinotecan and SN-38 had an increasing trend among UGT1A1*28 alleles, and TA7/7 appeared to have the highest AUC values, although the AUC values of SN-38G in these three alleles showed no significant difference. Another indicator of SN-38 metabolic rate, the AUC ratio of SN-38G

to SN-38 demonstrated that, compared with the other two alleles, the AUC ratio of TA7/7 was lower and close to statistical significance ($P = 0.057$). Due to no A/A allele being identified in UGT1A1*6, we were unable to study the effect of A/A on AUC. The combinations of UGT1A1*28 and UGT1A1*6 were divided into three groups: group 1 with wild type (TA6/6 + G/G); group 2 with one- mutated site variants (TA6/6 + G/A, TA6/7 + G/G); and group 3 with two-mutated site variants (TA6/7 + G/A, TA7/7 + G/A, TA7/7 + G/G). The higher AUC values of irinotecan and SN-38 and lower AUC ratio were found in group 3, and compared with the other two groups, the difference was near to statistical significance ($P = 0.061$ and 0.078 , respectively) (Table 4). The plot of AUC ratios (Figure 4) clearly illustrated that

group 3 had lower AUC ratio than the other two groups. Regarding UGT1A1*28, the AUC ratio of TA7/7 was less than half of the TA6/6 ratio (1.488 *vs* 3.178, $P = 0.158$).

DISCUSSION

Many western studies on the relationship of UGT1A polymorphisms and irinotecan toxicity and response have suggested that UGT1A1*28 is significantly associated with irinotecan-induced toxicity^[16-18]. In particular, patients bearing UGT1A1*28 (TA7/7) have a high possibility to experience severe neutropenia and diarrhea. Based on this, a warning is labeled on irinotecan that patients with UGT1A1*28 (TA7/7) should start with a reduced dose of irinotecan, although the details of how to adjust the dose have not been specified^[19]. By contrast, research in Asian countries has shown a lower incidence of UGT1A1*28 (TA7/7), while UGT1A1*6 (A/A) is more often found and may replace UGT1A1*28 as a key regulator in UGT1A1 expression^[20-22].

Our early studies have found that few carrying UGT1A1*28 (TA7/7) might be the reason that less than expected diarrhea was observed in Chinese patients treated with irinotecan-based chemotherapy. Nevertheless, other UGT1A members, such as UGT1A1*6, UGT1A7*3 and UGT1A9*1 have a trend towards a high incidence of toxicity, and this association is racially different^[1]. Although, recent data have implicated that UGT1A7 and UGT1A9 might be useful in predicting irinotecan-related toxicity^[7], it might not be applicable for Asian patients because UGT1A1*6 is highly linked with UGT1A7 and UGT1A9 in the Asian population. In addition, Fujita *et al*^[4] and Toffoli *et al*^[5] have proposed that the homozygous UGT1A1*28 (TA7/7) is a predictive marker for better treatment outcome and longer survival time. The results of our study confirmed that only 6.6% of Chinese patients had UGT1A1*28 (TA7/7), whereas a higher frequency of TA6/6 was identified compared with that in Caucasians (69.9% *vs* 45.2%, $P = 0.002$). The allele distribution difference might account for lower incidence of severe late diarrhea and grade 3/4 neutropenia in Chinese patients treated with irinotecan. At the same time, we discovered that the association between UGT1A1*6 and grade 3/4 late diarrhea was close to statistical significance. Furthermore, we did not find that treatment efficacy was discounted by either UGT1A1*28 or UGT1A1*6 variants. Besides that, multivariate logistic regression analysis failed to show that UGT1A1/TS polymorphisms and chemotherapy regimen had any effect on clinical response, but indicated that longer treatment time increased response rate by 26%. No OS benefit was obtained in patients with high incidence of toxicity. This could be caused by shorter treatment duration due to drug intolerance.

Several studies have indicated that TS polymorphism is associated with 5-FU toxicity and prognosis. Although the results are inconclusive, it is well accepted that the allele 3RG/3RG is correlated with long OS and low

toxicity^[23,24]. We introduced TS polymorphism into treatment outcome and toxicity evaluation of irinotecan/5-FU chemotherapy and found that patients carrying UGT1A1*28 (TA6/6) and 3RG/3RG seemed to experience mild toxicity, but relatively low tumor response. Similar to UGT1A1*28, the OS of patients with 3RG/3RG was extended because therapy was well tolerated and its duration was prolonged. However, these observed differences did not reach statistical significance. We conjectured that the differences of treatment response and toxicity between TS genotypes could be narrowed by the synergistic effect of 5-FU combined with irinotecan regimen.

Unfortunately, the combination of two genetic markers was unable to increase the predictive accuracy. In our study, blood samples were used for polymorphism testing. Possibly, examining TS polymorphism and expression level in tumor tissues might yield more convincing data.

The *in vivo* metabolism of irinotecan is complicated. Our data showed that the plasma concentrations of irinotecan and its metabolites varied significantly in each patient. These variations are strongly related to the polymorphisms of many metabolic enzymes and transport proteins. We found that the AUC values of irinotecan and SN-38 were gradually elevated from TA6/6 to TA7/7, whereas the AUC ratios of SN-38G/SN-38 were decreased from TA6/6 to TA7/7 ($P = 0.057$). A similar trend was found for UGT1A1*6. If UGT1A1*28 and UGT1A1*6 were taken together, the AUC ratios of group 1 (wild type), group 2 (one-mutated site) and group 3 (two mutated sites) were shifted from the highest to the lowest. Clearly, both alleles had effects on irinotecan metabolism.

Toffoli *et al*^[5] concluded that for Caucasians, UGT1A1*28 not only affected irinotecan-related toxicity, but also changed the drug metabolic rate. On the contrary, reports from Asia suggested that UGT1A1*6 was involved in irinotecan pharmacokinetics and toxicity. Han *et al*^[21] discovered that few UGT1A1*28 variants were found in the Korean population, while more UGT1A1*6 variants were observed. They claimed that the role of UGT1A1*28 in predicating irinotecan pharmacokinetics and toxicity could be replaced by UGT1A1*6 for Koreans. The research from Jada *et al*^[24] also downplayed the role of UGT1A1*28 in the irinotecan metabolic pathway. However, Minami *et al*^[20] contradicted this hypothesis by showing that both UGT1A1*28 and UGT1A1*6 were involved in irinotecan pharmacokinetics. Thus, for the Japanese population, the homozygous (UGT1A1*28/*28 and UGT1A1*6/*6) and the heterozygous (UGT1A1*6/*28) reduced the AUC ratios of SN-38G/SN-38. Our data favored Minami's conclusion that both UGT1A1*28 and UGT1A1*6 participated in glucuronidation.

Derived from the AUC ratios of UGT1A1*28 and UGT1A1*6 variants, we estimated that genetic alterations could inactivate the metabolic efficiency of SN-38 by 50%. Therefore we recommend a 50% dose reduction of irinotecan to treat group 3 patients with double-site mutations. Minami *et al*^[20] described that the ratio of SN-38 AUC to irinotecan dose was 2.4 in group 3, while the ratio was 1.4

in group 1. Based on their findings, it would be rational to lower the initial dose of irinotecan by 50% for group 3 patients. Another study by Innocenti *et al.*^[25] investigated the association between the pharmacokinetics of UGT1A1*28 variants and neutropenia. They recommended that a 20% decrease in drug dose should be considered in patients with UGT1A1*28 (TA7/7).

To date, no clinical trial has used genotypes for determining the proper dose for initial irinotecan-based therapy. We recommend a 50% dose reduction of irinotecan for patients with double-site mutations to avoid severe toxicity, and ensure better efficacy with sufficient treatment given. However, accurate dose modification for patients with different *UGT1A1* genotype is difficult. The limitations of our pharmacokinetics study were lack of UGT1A1*6 A/A information and small sample size. A large-scale prospective trial focused on dose modification of irinotecan will be our next work.

COMMENTS

Background

Irinotecan is a prodrug that is hydrolyzed by carboxylesterase *in vivo* to form an active metabolite SN-38. SN-38 is further conjugated and detoxified by UDP-glucuronosyltransferase (UGT) to yield its β -glucuronide. Remarkable inter-individual variations in the pharmacokinetics and clinical outcomes have been reported. Genetic polymorphisms of UDP-glucuronosyltransferase 1A1 (UGT1A1), especially UGT1A1*28 and UGT1A1*6 are important determinants of individual variations in Asian patients. 5-Fluorouracil (5-FU) is a fundamental component of all chemotherapeutic combinations for treatment of colorectal cancer (CRC). Thymidylate synthetase (TS) is the main intracellular target of fluoropyrimidines. The TS gene polymorphisms are known to influence the activity of TS, which are related to 5-FU clinical response. The allele containing the triple repeat (3R) in 5'-UTR of the TS is associated with 3-4-fold translational efficiency compared with the double repeat allele (2R), and a G>C base change in 3R alleles makes the transcriptional activity of the 3R allele as low as that of the 2R allele.

Research frontiers

Current studies have revealed the relationship of UGT1A polymorphisms and irinotecan related toxicity and pharmacokinetics. The polymorphisms of UGT1A1*28 are considered to be important in the Caucasian population, while UGT1A1*6 seems to be more important than UGT1A1*28 in Asian studies. It is still unclear whether UGT1A1 has any influence on treatment efficacy. Three studies tested if UGT1A1 isoforms had any impact on treatment outcome, however, their conclusions were inconsistent. TS polymorphisms are of the most broadly studied genetic variants in CRC. It is accepted that the 3R allele is associated with increased expression levels of TS and poorer outcome in patients treated with 5-FU-based regimens. However, the role of gene polymorphisms of UGT1A1 and TS on clinical response to irinotecan and 5-FU-based treatment, non-diarrhea toxicities and prognosis remains unclear.

Innovations and breakthroughs

Only 6.6% of Chinese patients had UGT1A1*28 (TA7/7), whereas higher frequency of TA6/6 was identified compared with that in Caucasians (69.9% vs 45.2%, $P = 0.002$). Mutant variants of UGT1A1*28 and UGT1A1*6 were associated with increased toxicity and decreased SN-38 disposition, but the response rate did not increase accordingly, although this group of patients surely had a trend towards a better response. This probably related to shorter treatment time in patients carrying double-site mutations. Derived from the area under concentration curve ratios of UGT1A1*28 and UGT1A1*6 variants, authors estimated that genetic alterations could inactive the metabolic efficiency of SN-38 by 50%.

Therefore, the authors recommend a 50% dose reduction of irinotecan to treat patients with double-site mutations.

Applications

To date, no clinical trial has used genotypes for determining the proper dose for initial irinotecan-based therapy. The authors recommend a 50% dose reduction of irinotecan for patients with double-site mutations to avoid severe toxicity, and ensure better efficacy with sufficient treatment given. However, accurate dose modification for patients with different *UGT1A1* genotypes is difficult. A large-scale prospective trial focusing on dose modification of irinotecan will be next work.

Peer review

Polymorphisms predict response and toxicity in patients with metastatic CRC treated with irinotecan and 5-FU. This study is interesting, and the manuscript is worthy of publication.

Abstract

AIM: To evaluate the safety of lamivudine (LAM) treatment for chronic hepatitis B in early pregnancy.

METHODS: A total of 92 pregnant women who received LAM treatment either before pregnancy or in early pregnancy were enrolled in this study. All of the pregnant women volunteered to take lamivudine during pregnancy and were not co-infected with hepatitis C virus, human immunodeficiency virus, cytomegalovirus, or other viruses. All infants received passive-active immunoprophylaxis with 200 IU hepatitis B immunoglobulin and three doses of 10 µg hepatitis B vaccines (0-1-6 mo) according to the guidelines for the prevention and treatment of chronic hepatitis B. Adverse events were observed throughout the entire pregnancy and perinatal period, and the effectiveness of lamivudine treatment for blocking mother-to-infant transmission of hepatitis B virus (HBV) was evaluated. All adverse events in mothers and infants during pregnancy and the perinatal period and the HBV mother-to-infant transmission blocking rate were compared with the literature.

RESULTS: Among the 92 pregnant women, spontaneous abortions occurred in 11 cases, while 3 mothers had a second pregnancy after the initial abortion; 72 mothers delivered 73 live infants, of whom 68 infants were followed up for no less than 6 mo, and 12 mothers were still pregnant. During pregnancy, the main maternal adverse events were vaginitis (12/72, 16.7%), spontaneous abortion (11/95, 11.6%), and gestational diabetes (6/72, 8.3%); only one case had 1-2 degree elevation of the creatine kinase level (195 U/L). During the perinatal period, the main maternal adverse events were premature rupture of the membranes (8/72, 11.1%), preterm delivery (5/72, 6.9%), and meconium staining of the amniotic fluid (4/72, 5.6%). In addition, 2 infants were found to have congenital abnormalities; 1 had a scalp hemangioma that did not change in size until 7 mo, and the other had early cerebral palsy, but with rehabilitation training, the infant's motor functions became totally normal at 2 years of age. The incidence of adverse events among the mothers or abnormalities in the infants was not higher than that of normal mothers or HBV-infected mothers who did not receive lamivudine treatment. In only 2 cases, mother-to-infant transmission blocking failed; the blocking rate was 97.1% (66/68), which was higher than has been previously reported.

CONCLUSION: Lamivudine treatment is safe for chronic HBV-infected pregnant mothers and their fetuses with a gestational age of less than 12 wk or throughout the entire pregnancy.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is a global health problem; about two billion people have a past or present HBV infection, of whom 350 million are chronic HBV carriers. Each year, about one million people die of liver failure, cirrhosis, or primary hepatocellular carcinoma, all of which are associated with HBV infection. Lamivudine (LAM) is the first approved oral nucleoside analog (NA) used to treat HBV infection (100 mg/d), and the appearance of LAM marked a new era in the treatment of chronic HBV infection. However, treatment duration is very long, and some patients may become pregnant during that time. Although some studies have previously reported on the safety of LAM treatment for chronic HBV infection in late pregnancy^[1-3], there are very few reports about the safety of LAM treatment in early pregnancy^[4-6]. The objective of this study was to evaluate the safety of LAM treatment for chronic hepatitis B in early pregnancy or throughout the entire pregnancy, to provide information about how to block mother-to-infant transmission of HBV in chronic HBV-infected fertile women.

MATERIALS AND METHODS

Patients

All patients were chronic HBV-infected fertile women from our outpatient department who either intended to become pregnant or were already in early pregnancy (with a gestational age of less than 12 wk). Three groups of patients were considered: (1) those who were on NA treatment and could not stop treatment; (2) those who had never taken any NA treatment, with alanine aminotransferase (ALT) > 2 times the upper limit of normal (ULN) for the reference range, HBV DNA > 1×10^5 copies/mL, but failed the traditional liver protection and enzyme reducing treatment; and (3) those who had received NA treatment, but later had virological breakthrough and liver function rebound without LAM drug-resistance. If patients from the above groups planned to become pregnant or had an accidental pregnancy and agreed to LAM treatment after thorough communication and consideration, they were included in this study after providing their written, informed consent.

All participants took screening tests before or in early pregnancy to rule out infection with hepatitis C virus, hepatitis delta virus, human immunodeficiency virus (HIV), syphilis, toxoplasmosis, rubella, cytomegalovirus, and herpes simplex. In this way, these tests helped to exclude any potentially hereditary diseases and any other diseases that needed to be treated. Furthermore, all participants routinely took folic acid before or during early

pregnancy to prevent embryonic neural tube defects.

Methods

All participants undertook routine screening tests, and additionally liver function and HBV serology (HBV markers and HBV DNA) were measured every 12 wk. All adverse events that occurred during pregnancy and all neonatal abnormalities were recorded. The rate of blocking vertical transmission of HBV was also determined.

All infants received passive-active immunoprophylaxis with 200 IU hepatitis B immunoglobulin (HBIG) and three doses of 10 µg hepatitis B vaccines (0-1-6 mo) according to the guidelines for the prevention and treatment of chronic hepatitis B^[7]. One month later, after all vaccinations (7-8 mo), liver function and HBV serology were measured again to evaluate the blocking rate. All infants underwent routine physical examination, hearing screening, and tests for congenital phenylketonuria and hypothyroidism. All neonatal abnormalities were observed for up to 2 years.

Laboratory tests

Liver function and HBV serology were tested in the hospital's clinical laboratory. HBV DNA was detected with an HBV real-time PCR amplification kit from Kehua Biological Company (Shanghai, China), which can detect HBV DNA at levels as low as 500 copies/mL. HBV markers were detected by enzyme-linked immunosorbent assay kits (Abbot Labs, North Chicago, IL, United States) on an ARCHITECT i2000 automatic immunoassay analyzer (Abbott) according to the manufacturer's instructions. Hearing screening was performed with the ECHO-SCREEN from Madsen Company (Germering, Germany). Heel blood was taken on filter paper from the infants after 72 h of breastfeeding, and specimens were sent to the Beijing Neonatal Diseases Screening Center to rule out congenital phenylketonuria and hypothyroidism.

RESULTS

Mothers' basic information

From January 1, 2007 to December 31, 2011, 92 HBV-infected women took LAM treatment before or during early pregnancy. Of these, one mother underwent *in vitro* fertilization with the transfer technique and later delivered twin infants. By the end of 20 wk' gestational age, 11 fetuses aborted, and 3 mothers had a second pregnancy after initial abortion. Ultimately, 72 mothers delivered 73 live infants, of whom 68 infants were followed-up for more than 6 mo, 47 were followed-up for more than 1 year, and 16 were followed-up for more than 2 years. At the end of follow-up, 12 mothers were still pregnant (Figure 1).

Table 1 summarizes the clinical information for the mothers who chose lamivudine treatment before or in early pregnancy, including their demographic characteristics, HBV infection status, and treatment history. All participants were chronic hepatitis B patients, except

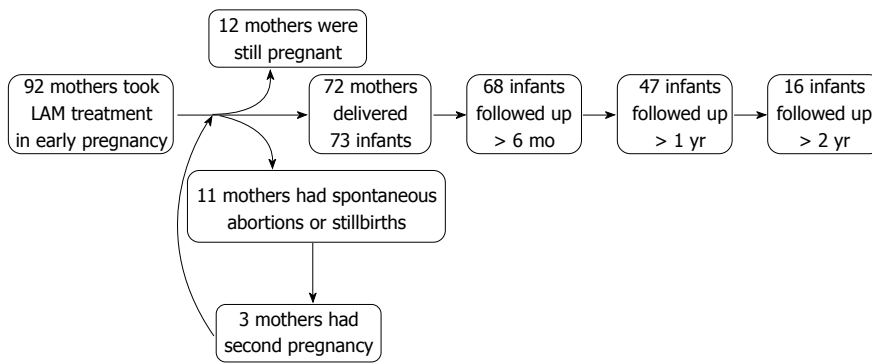

Figure 1 Basic information of mothers and follow-up times for mothers and infants. LAM: Lamivudine.

for 2 cases with compensated cirrhosis, and none of the participants were HBV carriers with normal liver function. Most cases had a history of NA treatment before pregnancy; therefore, only 16 cases (17.4%) had HBV DNA > 10⁵ copies/mL in early pregnancy. Of these 2 cirrhosis patients, one had refused to take any antiviral treatment despite a long history of abnormal liver function due to her concerns about the safety of NA drugs during pregnancy. However, when she later developed cirrhosis, she started to take LAM treatment and became pregnant; the other patient had concomitant autoimmune hepatitis and was taking ursodesoxycholic acid in addition to adefovir dipivoxil, and was later switched to LAM treatment before pregnancy. In early pregnancy, she ceased ursodesoxycholic acid treatment. In addition, 2 cases had previous peripheral neuropathy or myopathy when they took interferon and telbivudine (LdT) combination treatment; both switched to LAM treatment and later became pregnant.

Adverse events in mothers and infants during pregnancy and the perinatal period

Fetal monitoring during pregnancy: Among the 92 women who took LAM treatment in early pregnancy, there were 95 pregnancies. Before 20 wk' gestational age, 4 cases had a threatened abortion, but symptoms of miscar-

riage disappeared following aggressive treatment; 11 had developmental arrest or natural abortion, with an abortion rate of 11.6%. Ultimately, 72 mothers delivered 73 live infants; 3 had developmental retardation monitored with ultrasound but development later normalized after improving the mothers' nutritional status and intravenous hydration. There were no other fetal developmental abnormalities reported and no stillbirths.

Monitoring mothers during pregnancy and the perinatal period:

All maternal adverse events and laboratory abnormalities during pregnancy and the perinatal period are summarized in Table 2. The top 3 adverse events for mothers during pregnancy were vaginitis (16.7%), gestational diabetes (8.3%), and arrhythmia or abnormal electrocardiogram (5.6%). Only one case had 1-2 degree elevation of the creatine kinase (CK) level (195 U/L), and none of the other adverse events could be associated with LAM treatment. Abnormal ALT levels ($\geq 2 \times$ ULN) occurred in 16 cases (22.2%). Of these, 15 cases were in naïve patients without previous antiviral treatment who took LAM treatment only due to abnormal liver function in early pregnancy. The other case stopped LAM treatment before pregnancy and later developed severe hepatitis in early pregnancy, after which LAM was restarted, and her ALT level soon became normal, with her HBV DNA below 500 copies/mL.

However, another patient who took LAM treatment in early pregnancy decreased her HBV DNA by only 1.32 log in 12 wk, after which she was switched to LdT treatment from week 26. In addition, 6 cases had HBV DNA breakthrough with a LAM resistance rate of 8.3%; of these, 3 cases had HBV DNA rebound to above 10⁶ copies/mL, and ADV was added from week 28. For the other 3 cases, ADV was added postpartum. The top 3 adverse events for mothers during the perinatal period were premature rupture of the membranes (11.1%), preterm delivery (6.9%), and meconium staining of the amniotic fluid (5.6%). There were no cases of postpartum hemorrhage or perinatal mortality. In addition, HBV DNA was monitored in mothers antepartum, and 63 cases (87.5%) had HBV DNA below 500 copies/mL.

Postpartum infant monitoring

Of the 92 mothers who took LAM treatment before or

ECG: Electrocardiogram; Hb: Hemoglobin; ALT: Alanine aminotransferase; ULN: Upper limit of normal; HBV: Hepatitis B virus; CK: Creatine kinase.

in early pregnancy, 72 delivered 73 live infants. Only 3 infants (4.1%) were low birth weight (birth weight < 2500 g); all the other infants had normal weights. None of the infants had abnormal hearing, congenital phenylketonuria, or hypothyroidism on testing. Of the 73 infants, 68 were followed-up for no less than 6 mo, while 47 were followed-up for more than 1 year, and 16 were followed-up for more than 2 years. Two infants were found to have abnormalities postpartum: 1 had 2 scalp hemangiomas (1.5 cm × 1.5 cm and 1.5 cm × 2.0 cm, respectively), which did not change in size until 7 mo, when the parents planned to arrange surgery for the infant; the other infant had early cerebral palsy at 8 mo, but with rehabilitation training, the infant's motor functions became totally normal at 2 years of age. Sixteen babies were followed up for 2 to 4 years, and showed no signs of abnormal intelligence or growth.

Monitoring the mother-to-infant transmission blocking rate

Of the 73 live infants, 68 completed all of the examinations required for evaluating if there was mother-to-infant transmission. Vertical transmission was successfully blocked in 66 infants, for a blocking rate of 97.1%. One mother took LAM every other day by herself because she was concerned about LAM's influence on the infant. She later developed virological breakthrough with HBV DNA increasing to 6.38×10^7 copies/mL. The other mother, who had HBV DNA of 3.6×10^3 copies/mL antepartum, experienced HBV-S mutation during treatment, resulting in blocking failure (the infant had HBsAg(-), HBV DNA(+) and abnormal ALT levels at both 7 mo and 1 year).

DISCUSSION

HBV infection is a serious public health problem worldwide. According to WHO statistics, about 5% of mothers are chronic HBV carriers^[8], and the hepatitis B surface antigen positivity rate among fertile women in some high epidemic areas, such as Africa and South Asia, can be as high as 9.2%-15.5%^[9-11]. About one-third of HBV-infected women enter into the immune clearance phase before or during pregnancy, with a high HBV DNA load and abnormal ALT levels. They are not only faced with a high risk of mother-to-infant transmission, but they also have an increased chance of hepatic disease exacerbation during pregnancy, threatening the safety of both mother and infant^[12-14]. It is currently not recommended for chronic HBV-infected fertile women who are not pregnant to take interferon or NA treatment, in line with the guidelines for the prevention and treatment of chronic hepatitis B^[7]. The antiviral efficacy of interferon is limited, and several side effects hinder its use, resulting in treatment failure. NA treatment alone results in only 20% of hepatitis B e antigen (HBeAg)-positive patients achieving HBeAg seroconversion, with only 12% able to stop treatment with a sustained virological response^[15]. Therefore, many chronic HBV-infected fertile women become pregnant during treatment.

It is very dangerous for pregnant women to stop taking antiviral treatment during pregnancy when they have not met the withdrawal standard, as it may exacerbate liver disease, threatening the safety of both mother and infant. However, the safety of infants exposed to antiviral drugs in utero throughout the entire pregnancy is of particular concern, especially in early pregnancy, which is vital for fetal development. Although LAM is already approved as an optional antiviral drug for use in pregnancy, and several studies have reported its safety in late pregnancy^[1-3], all of the studies regarding its safety before or during early pregnancy come from HIV-infected pregnant women^[16]. Furthermore, most of these patients received combination therapy. So far, there have been very few reports about the safety of LAM treatment in chronic HBV-infected women before or during early pregnancy, and systematic observations have been scarce^[4-6,17].

The present study showed that the abortion rate for HBV-infected women who took LAM treatment in early pregnancy was 11.6%, which was not higher than that of non HBV-infected mothers or HBV-infected mothers according to previous reports (11%-16% and 16.7%-21.9%, respectively)^[6,18,19]. Overall, 72 mothers delivered 73 live infants; none were stillborn. Three fetuses had developmental retardation during pregnancy monitoring, although their development later normalized after treatment; no other fetal developmental abnormalities were reported. Only 4.1% of infants had low birth weight, which was similar to that of women without or with HBV infection according to previous reports (2.7%-7.8% and 5.0%-10.4%, respectively)^[20]. None of the infants had abnormal hearing, congenital phenylke-

tonuria, or hypothyroidism on testing. Two infants were found to have abnormalities (scalp hemangiomas and early cerebral palsy), with a congenital abnormality rate of 2.7%, which is similar to the data from HIV-infected women (3.1%) who took antiretroviral treatment (including LAM) in early pregnancy from 1989 to 2011^[16]. According to the literature, the congenital abnormality rates for infants born to mothers without or with HBV infection were 5.1%-6.3% and 7.2%-10%, respectively^[6,20,21]. The present report suggests that it is safe for fetuses to be exposed to LAM in utero for the entire pregnancy or in early pregnancy, and it does not affect fertilization or fetal development or result in congenital abnormalities. Neither does it affect postnatal development.

The most common adverse event for mothers during pregnancy and the perinatal period was vaginitis (16.7%), among which 7 were vulvovaginal candidiasis (9.7%) and 5 were bacterial vaginosis. However, vaginitis is a common genital infectious disease in pregnant and non-pregnant women and the incidence of vaginitis in our study group was similar to that reported in the literature; it has been reported that the detection rate of candidal vaginitis in pregnant women is about 10%^[22,23], and the incidence of bacterial vaginosis among Asian women is 6.1%^[24]. Other adverse events included gestational diabetes, gestational hypertension, nausea and vomiting of pregnancy, oligohydramnios, polyhydramnios, placenta previa, anemia, pre-eclampsia, premature rupture of the membranes, and preterm delivery. The incidence of the above adverse events was not higher than that of mothers without or with HBV infection according to previous reports^[25-29]. Only one patient had 1-2 degree elevation of serum CK levels, and none of the other adverse events could be associated with LAM treatment. These results suggest that it is safe for HBV-infected pregnant women to take LAM treatment in early pregnancy or throughout the entire pregnancy.

Pregnancy can not only increase the burden on the liver, but it can also increase adrenal cortical hormone levels, boosting HBV replication and activation of hepatitis B. Therefore, for HBV-infected women, the average increase in the HBV DNA level was 0.4 log in late pregnancy or postpartum, and 25% of HBeAg(-) pregnant women had an increase of HBV DNA > 1 log, accompanied by elevation of ALT levels in late pregnancy or postpartum^[13,29]. The incidence of severe hepatitis during the perinatal period (in late pregnancy and one month postpartum) was much higher than in nonpregnant women^[12-14,30]. In the present study, all mothers without previous antiviral treatment maintained normal ALT levels throughout the entire pregnancy, and none of them had severe hepatitis. Fifteen mothers who took NA treatment previously had abnormal ALT levels in early pregnancy, but ALT normalized after LAM treatment, and the pregnancy continued. Interestingly, one mother stopped LAM treatment before pregnancy and later developed severe hepatitis in early pregnancy. However, all symptoms later disappeared, liver function normalized

and the HBV DNA load became undetectable when she restarted LAM. In addition, 87.5% of patients had HBV DNA below 500 copies/mL antepartum, and the LAM resistance rate was only 8.3% during pregnancy. This suggests that LAM can effectively suppress HBV DNA replication in HBV-infected pregnant women, maintain normal liver function, and lower the incidence of hepatic disease during pregnancy, improving the prognosis of HBV-infected pregnant women.

According to previous reports, for infants born to HBeAg-positive mothers, even after they received passive-active immunoprophylaxis with HBIG and three doses of hepatitis B vaccines, vertical transmission was not blocked in 7%-16.3%^[31]. For mothers with an increased HBV DNA load, vertical transmission was not blocked in as many as 23.4%-32% of infants^[32]. In the present study, 80.4% of mothers was HBeAg-positive, and all of them had a high HBV DNA load before LAM treatment. However, 63 (87.5%) mothers had HBV DNA below 500 copies/mL antepartum, and the blocking rate was 97.1%; blocking failed in only 2 cases. The first mother had poor compliance, resulting in HBV DNA breakthrough, while the other had an HBV-S mutation during treatment, resulting in failure of vaccine immunization. These results suggest that LAM treatment could increase the vertical transmission blocking rate in HBeAg-positive mothers.

This study suggests that it is safe and effective for chronic HBV-infected pregnant women to take LAM treatment in early pregnancy. Treatment does not increase complications or adverse events for mothers during pregnancy or the perinatal period, has no effect on fertilization or embryonic development, and does not increase the incidence of congenital abnormalities in infants. Furthermore, it increases the blocking rate of mother-to-infant transmission. In conclusion, the benefits of taking LAM treatment in early pregnancy outweigh the risks. However, the sample size of this study was small, and the follow-up time was limited; both need to be optimized in later studies to provide greater insight.

COMMENTS

Background

Chronic hepatitis B virus (HBV) infection is prevalent throughout the world; 2 billion people have been or are infected with HBV worldwide, with 350 million people having chronic infections. Each year, more than 1 million people die of HBV-related liver failure, cirrhosis, or primary hepatic carcinoma. Interferon and nucleos(t)ide analogs (NAs) are available for the antiviral treatment of hepatitis B. However, the efficacy of interferon is suboptimal, and interferon is associated with scores of adverse effects, so that many patients fail or cannot tolerate treatment. Treatment with NAs requires long-term persistence, as in the case of human immunodeficiency virus; stopping the medicine frequently leads to relapse of the disease. As women undergoing treatment cannot halt the medicine at will, pregnancy often occurs during the on-treatment period. However, the safety profile of NAs has not been verified. The goal of this study was to observe the safety profile of lamivudine for the mother and fetus throughout the entire pregnancy.

Research frontiers

In recent years, with many studies evaluating the efficacy and safety profile, the administration of lamivudine and other NAs during the third trimester to block HBV transmission has been a hot topic. However, studies regarding lamivudine

treatment during the first trimester or the entire period of pregnancy are scarce.

Innovations and breakthroughs

This study observed adverse events throughout the entire period of pregnancy in women taking lamivudine, including abortion, ectopic pregnancy, and complications related to pregnancy. The study also observed intrauterine deformations of the fetus and abnormalities after birth in detail and maintained long-term follow-up of some neonates.

Applications

The study provides preliminary evidence of the safety profile for pregnant women taking lamivudine. It also sets an example for further studies exploring the safety profile of NAs in pregnant women.

Peer review

The manuscript describes safety of lamivudine treatment in early pregnancy. They compared maternal and infant abnormality, HBV DNA level and mutations, and blocking rates of mother-to infant transmission between cases with and without lamivudine treatment. They concluded that lamivudine treatment in early treatment is safe. The study is important, because patients with HBV infection often show elevation of HBV DNA levels and may have alanine aminotransferase flare.

Abstract

AIM: To investigate the clinicopathological features and prognostic value of lysine specific demethylase 1 (LSD1) in hepatocellular carcinoma (HCC).

METHODS: We examined LSD1 expression in 60 paired liver cancer tissues and adjacent noncancerous tissues by quantitative real time polymerase chain reaction (qRT-PCR) and Western blotting. In addition, we analyzed LSD1 expression in 198 HCC samples by immunohistochemistry. The relationship between LSD1 expression, clinicopathological features and patient survival was investigated.

RESULTS: Immunohistochemistry, Western blotting,

and qRT-PCR consistently confirmed LSD1 overexpression in HCC tissues compared to adjacent non-neoplastic tissues ($P < 0.01$). Additionally, immunostaining showed more LSD1-positive cells in the higher tumor stage (T3-4) and tumor grade (G3) than in the lower tumor stage (T1-2, $P < 0.001$) and tumor grade (G1-2, $P < 0.001$), respectively. Moreover, HCC patients with high LSD1 expression had significantly lower 5-year overall survival rates ($P < 0.001$) and lower 5-year disease-free survival rates ($P < 0.001$), respectively. A Cox proportional hazards model further demonstrated that LSD1 over-expression was an independent predictor of poor prognosis for both 5-year disease-free survival [hazards ratio (HR) = 1.426, 95%CI: 0.672-2.146, $P < 0.001$] and 5-year overall survival (HR = 2.456, 95%CI: 1.234-3.932, $P < 0.001$) in HCC.

CONCLUSION: Our data suggest for the first time that the overexpression of LSD1 protein in HCC tissues indicates tumor progression and predicts poor prognosis.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, especially in Asia^[1]. In China, HCC ranks behind gastric and esophageal cancer with the third highest mortality rate among all malignant carcinomas, leads to approximately 110 000 deaths every year, and accounts for 45% of total HCC deaths worldwide^[2]. Multiple risk factors have been associated with the initiation and development of HCC; these include chronic infection with hepatitis B, C or D virus, aflatoxin, alcohol abuse, hereditary metabolic liver diseases, and diabetes mellitus^[1,3]. Like most other cancers, hepatocarcinogenesis is a multistep process that involves multiple genetic alterations that may activate oncogenes and/or inactivate tumor suppressor genes, ultimately leading to the malignant transformation of hepatocytes.

Histone demethylase lysine specific demethylase 1 (LSD1), the first histone demethylase that was discovered as a nuclear homolog of amine oxidases, removes the methyl groups from mono- and dimethylated lysine (Lys) 4 of histone H3 (H3K4me1/2) and Lys9 of histone H3 (H3K9me1/2). LSD1 is essential for mammalian development and is involved in many biological processes, including cell-type differentiation, gene activation and gene repression^[4]. A recent study indicated that LSD1 might promote cell phase transition (deficiency in LSD1 led to partial cell cycle arrest in G2/M) and cell proliferation, suggesting that its over-expression might promote tumorigenesis^[5]. The expression of LSD1 has been associated with tumor recurrence during therapy in various cancers, further implicating LSD-1 as a tumor promoter^[6-8]. A tissue cDNA microarray analysis also demonstrated the presence of LSD1 transactivation in lung and colorectal carcinomas^[7]. LSD1 knockdown with small interfering (si) RNAs resulted in the suppression of proliferation of various bladder and lung cancer cell lines^[7]. To the best of our knowledge, there is little available data regarding the involvement of *LSD1* genes in hepatic tumorigenesis. In this study, we investigated LSD1 expression in HCC and its correlation with the clinicopathological features of patients with HCC, including patient survival.

MATERIALS AND METHODS

Patients and tissue samples

The study was approved by the Research Ethics Committee of Xinhua Hospital, which is affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China. Informed consent was obtained from all of the patients. All specimens were handled and made anonymous according to accepted ethical and legal standards.

A total of 198 patients who presented with primary HCC and later underwent curative liver resection at Xinhua Hospital affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China, were included in this retrospective study. The tissue samples used in this study were retrieved from the tissue bank of the Depart-

ment of Pathology in the Xinhua Hospital affiliated with Shanghai Jiaotong University School of Medicine. The patients had been diagnosed with HCC between 2001 and 2006. None of the patients recruited in this study had undergone preoperative chemotherapy or radiotherapy. HCC diagnosis was based on World Health Organization criteria. Tumor differentiation was defined according to the Edmondson grading system. Liver function was assessed using the Child-Pugh scoring system. Tumor staging was determined according to the sixth edition of the tumor-node-metastasis (TNM) classification of the International Union against Cancer. The clinicopathological features of 198 patients are summarized in Table 1. In addition, 60 self-pairs of HCC specimens (10 TNM stage I, 16 TNM stage II, 24 TNM stage III, and 10 TNM stage IV) and adjacent non-neoplastic liver tissues were snap frozen in liquid nitrogen and stored at -80 °C following surgery for quantitative real time polymerase chain reaction (qRT-PCR) assay and western blot analysis. The median follow-up period was 8.6 years. Postoperative surveillance included routine clinical and laboratory examinations every third month, computed tomography scans of the abdomen, and radiographs of the chest every third month. After 5 years, the examination interval was extended to 12 mo.

Immunohistochemistry analysis

Immunohistochemical staining was carried out follow-

ing the protocol of our previous study^[9-11]. The primary antibody against LSD1 was a rabbit polyclonal antibody (Santa Cruz Biotechnology, Inc., United States) at a dilution of 1:50. The specificity of the primary antibody has been validated by the previous studies of Müller *et al*^[12] and Lü *et al*^[13]. The secondary antibody for the detection of primary antibody was anti-rabbit immunoglobulin G (Sigma, St. Louis, MO, United States). The negative controls were processed in a similar manner with phosphate-buffered saline instead of primary antibody. Further, positive LSD1 expression, as confirmed by western blotting, was used as a positive control for immunostaining. Following hematoxylin counterstaining, immunostaining was scored by two independent experienced pathologists who were blinded to the clinicopathological parameters and clinical outcomes of the patients. The scores of the two pathologists were compared, and any discrepant scores were re-examined for staining by both pathologists until a consensus score was obtained. The number of cells that stained positive for nuclear LSD1 in ten representative microscopic fields was counted, and the percentage of positive cells was calculated. The percentages of cells that were immunoreactive were converted to scores as follows: 0 (0%), 1 (1%-10%), 2 (11%-50%) and 3 (> 50%). Staining intensity was visually scored and stratified as follows: 0 (negative), 1 (weak), 2 (moderate) and 3 (strong). A final score was obtained for each case by multiplying the percentage score and the intensity score. Multiplied scores exceeding 5 (median of total scores for LSD1) were considered to indicate low levels of LSD1 expression, while all other scores were considered to indicate high levels of LSD1 expression.

Western blotting

The Western blotting protocol and semiquantitative analysis were carried out following the protocol of Xu *et al*^[14]. LSD1 antibody (rabbit polyclonal antibody, dilution 1:50, Santa Cruz Biotechnology, Inc., United States) was used, and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) antibody (CW0266, dilution 1:1000, CoWin Biotech) was used as an internal control.

Quantitative RT-PCR

To measure the mRNA expression levels of LSD1, total RNA was extracted from frozen liver tissues using TriZol reagent (Invitrogen) according to the manufacturer's instructions. The extraction was followed by RT-PCR using the TransStart Green qPCR SuperMix (TransGen Biotech). The primer sequences for LSD1 amplification were 5'-CGAACGCACATCAAGACGA-3' for the forward primer and 5'-AGGTGAAGGTGGAGTAGAGGC-3' for the reverse primer. The transcription of GAPDH was used as an internal control for normalization. LSD1 expression levels were calculated relative to GAPDH using the delta-delta computed tomography method^[15].

Statistical analysis

SPSS version 13.0 for Windows (SPSS Inc, IL, United

Figure 1 Lysine specific demethylase 1 expression in hepatocellular carcinoma and adjacent non-neoplastic liver tissues. A: High expression of lysine specific demethylase 1 (LSD1) in hepatocellular carcinoma (HCC) samples; B: Low expression of LSD1 in HCC samples (original magnification, 200×).

States) and SAS 9.1 (SAS Institute, Cary, NC) were used for statistical analysis. A Fisher's exact test and χ^2 test were performed to assess associations between LSD1 expression and clinicopathological parameters. A Kaplan-Meier method was used for survival analysis, and differences in survival were estimated using the log-rank test. A multivariate survival analysis was performed for all parameters that were significant in the univariate analyses using a Cox regression model. Differences were considered statistically significant when *P* was less than 0.05.

RESULTS

Expression of LSD1 protein and mRNA in HCC

Immunohistochemical analysis revealed that LSD1 staining was mainly localized to the nucleus of noncancerous and malignant epithelial cells (Figure 1). In addition, we found that 112 (56.6%) of 198 HCC tissues had high LSD1 expression, and 86 (43.4%) of 198 HCC tissues had low LSD1 expression. Additionally, 52 (26.3%) of 198 adjacent non-neoplastic liver tissues had high LSD1 expression, and 146 (73.7%) of 198 adjacent nonneoplastic liver tissues had low LSD1 expression. Thus, the LSD1 immunostaining in HCC tissues was significantly higher than the staining in the adjacent non-neoplastic liver tissues (*P* < 0.01). To confirm LSD1 protein expression by an independent method, Western blotting analysis was performed using 60 self-pairs of HCC and adjacent

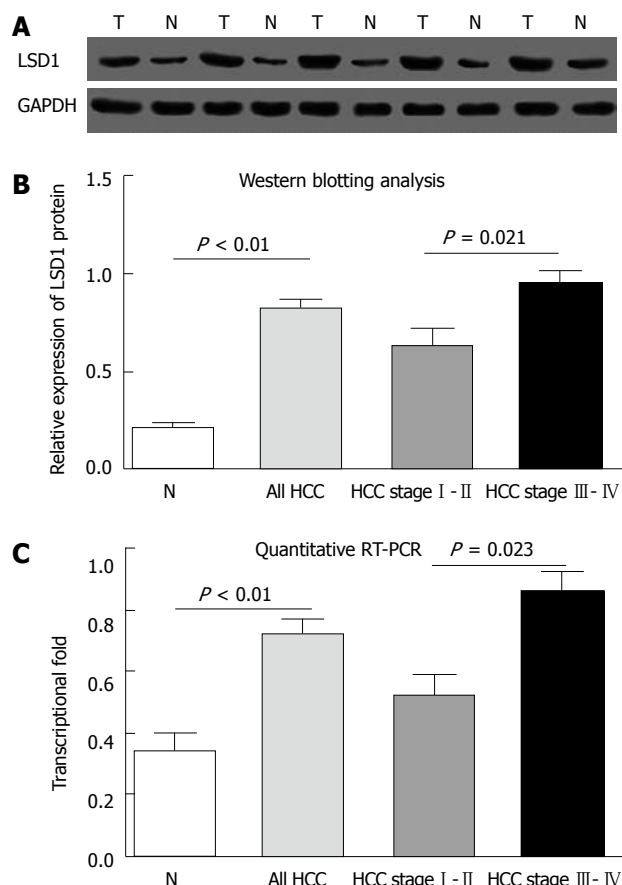

Figure 2 Increased lysine specific demethylase 1 protein and mRNA levels in hepatocellular carcinoma with different tumor node metastasis stages and adjacent non-neoplastic liver tissues. A: Representative Western blotting of lysine specific demethylase 1 (LSD1) protein levels in hepatocellular carcinoma (HCC) tissues (T) and adjacent non-neoplastic liver tissues (N); B: Semiquantitative Western blotting showed that the expression levels of LSD1 protein were significantly higher than those in adjacent non-neoplastic liver tissues ($P < 0.01$). Additionally, the expression levels of LSD1 protein increased with ascending tumor node metastasis (TNM) stages. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal control. P values, mean and SD were given (t test); C: Quantitative reverse transcription-polymerase chain reaction (RT-PCR) assay showed significantly increased LSD1 mRNA levels in HCC tissues compared with adjacent non-neoplastic liver tissues ($P < 0.01$). Additionally, the expression levels of LSD1 mRNA were increased with ascending tumor TNM stages. GAPDH was used as the internal control. P values, mean and SD were given (Mann-Whitney test).

non-neoplastic liver tissues. Overexpression of LSD1 protein in HCC tissues was compared with adjacent non-neoplastic liver tissues ($P < 0.01$, Figure 2A and B) using this method, and significantly increased LSD1 mRNA levels were detected by qRT-PCR ($P < 0.01$, Figure 2C). The expression levels of LSD1 protein and mRNA in high stage (III-IV) HCC tissues were both significantly higher than the levels of LSD1 protein and mRNA in low stage (I-II) HCC tissues (for protein: $P = 0.021$; for mRNA: $P = 0.023$; Figure 2B and C).

Association of LSD1 expression with the clinicopathological features of HCC

To evaluate whether LSD1 protein expression was associated with clinicopathological features of patients with

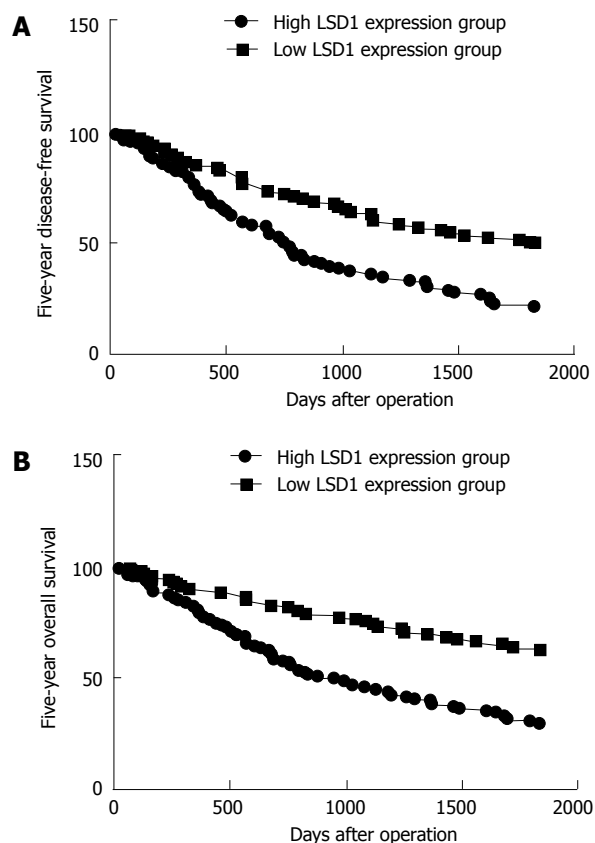

Figure 3 Kaplan-Meier survival curves for lysine specific demethylase 1 expression in hepatocellular carcinoma patients. A: The hepatocellular carcinoma patients with high lysine specific demethylase 1 (LSD1) expression showed significantly shorter disease-free survival ($P < 0.001$); B: Overall survival ($P < 0.001$) rates than those with low LSD1 expression.

HCC, we correlated immunohistochemical LSD1 staining results with T stage, tumor grade, presence of cirrhosis, underlying liver disease, including alcohol abuse, viral hepatitis B and C, sex and age (Table 1). We found more LSD1 positive cells in tissues with higher tumor stages (T3-4) and higher tumor grades (G3) than in the lower tumor stages (T1-2, $P < 0.001$) and tumor grades (G1-2, $P < 0.001$), respectively.

Prognostic values of LSD1 expression in HCC

The 5-year disease-free survival in the group with high LSD1 expression was significantly poorer than the disease-free survival in the group with low LSD1 expression ($P < 0.001$, log-rank test; Figure 3A). A Kaplan-Meier plot of 5-year overall survival curves stratified by LSD1 expression is shown in Figure 3B. There was a significant relationship between LSD1 expression and 5-year overall survival ($P < 0.001$, log-rank test; Figure 3B). In a multivariate Cox model that included tumor size, tumor stage, tumor grading, presence of cirrhosis, gender, age, and LSD1 staining, we found that LSD1 expression independently indicated poor prognosis for both 5-year disease-free survival [hazards ratio (HR) = 1.426, 95%CI: 0.672-2.146, $P < 0.001$; Table 2] and 5-year overall survival (HR = 2.456, 95%CI: 1.234-3.932, $P < 0.001$; Table

Table 2 Multivariate survival analysis of five-year overall and disease-free survival in 198 patients with hepatocellular carcinoma

Parameter	Five-year overall survival			Five-year disease-free survival		
	P value	HR	95%CI	P value	HR	95%CI
Age	0.775	0.867	0.463-1.452	0.714	1.174	0.883-1.853

2) in patients with HCC.

DISCUSSION

Genetic alterations are a hallmark of human cancer. In recent years, the field of cancer genomics has made significant advances in the area of cancer-associated genetic lesion identification. Furthermore, the importance of epigenetic changes that occur during HCC development has also been recognized^[16]. Epigenetic changes can take the form of DNA methylation or histone modification^[17]. Histone modifications in the form of selective acetylation, phosphorylation, and methylation serve as switches that alter chromatin structure, allowing posttranscriptional activation or repression of downstream proteins^[18]. Understanding these epigenetic changes will lead to the identification of novel cancer-related genes that may represent attractive targets for cancer treatment and provide new insights into the biology of hepatic cancers. Thus, an integrative approach to hepatic cancer research that combines epidemiological, genetic and epigenetic information has emerged as an important paradigm for cancer therapy^[19]. The methylation status of histone methyltransferases and histone demethylases plays a pivotal role in the regulation of gene expression^[20]. LSD1, the first histone demethylase that was discovered as a nuclear homolog of amine oxidases, removes methyl groups from mono- and dimethylated H3K4me1/2 and H3K9me1/2^[21].

Epigenetic changes in LSD1 have been shown to play a key role in carcinogenesis^[22]. LSD1 can prevent the accumulation of the dimethyl groups of p53, repressing p53-mediated transcriptional up-regulation, preventing apoptosis, and contributing to human carcinogenesis *via* a chromatin modification mechanism. To date, a few studies have indicated that LSD1 may promote cell phase transition (deficiency in LSD1 led to partial cell cycle arrest in G2/M) and cell proliferation, suggesting that LSD1 over-expression might promote tumorigenesis^[5]. The expression of LSD1 has been associated with tumor recurrence during therapy in various cancers, further implicating LSD-1 as a tumor promoter^[6-8]. Tissue cDNA microarray analysis also revealed LSD1 transactivation in lung and colorectal carcinomas^[7]. Knocking down LSD1 with small interfering RNAs resulted in suppression of proliferation of various bladder and lung cancer cell

lines^[7]. However, the association between LSD1 and the survival of HCC patients was not well defined. In this study, we investigated the associations between LSD1 expression levels and clinical features of HCC patients.

In order to demonstrate that the epigenetic changes were associated with genetic changes in lung cancer, we first investigated the expression of LSD1 in HCC clinical samples. Previous studies have demonstrated that LSD1 protein and mRNA levels could act as biomarkers for the identification of patients with more aggressive breast cancer, prostate cancer, lung cancer and neuroblastoma^[23-26]. In our study, we detected LSD1 by immunohistochemistry analysis, Western blotting, and qRT-PCR. Our results showed that LSD1 immunoreactivity was significantly increased in HCC compared with adjacent non-neoplastic liver tissue in a substantial proportion of cases. The over-expression of LSD1 was observed in tumor tissues with higher tumor stage and higher tumor grade. Additionally, our investigation revealed that high LSD1 expression is associated with a significant trend toward both poorer disease-free survival and poorer overall survival. Our study further confirms that high LSD1 expression independently predicts a higher risk of disease relapse or death after multivariate adjustment for other prognostic factors. These observations support the hypothesis that LSD1 may function as an oncogene in HCC and suggest that LSD1 may play an important role in the tumorigenesis of HCC. However, the role of LSD1 in HCC remains to be elucidated. Our data may offer new insight into LSD1 as a potentially important contributor to the progression of HCC and as a new prognostic factor for HCC. As the 198 cases of the present study were all obtained from the Chinese population, the results reported here should be further confirmed in other populations.

In conclusion, our study suggests that LSD1 is over-expressed in HCC tissues compared with their benign counterparts. To the best of our knowledge, this is the first study evaluating the expression levels of LSD1 mRNA and protein in HCC tissues and the association between these expression levels and clinicopathologic parameters. The most important finding of this study is that LSD1 expression may predict a poorer prognosis for HCC patients after surgery. Further studies are needed to investigate the precise function of LSD1 in the progression of HCC.

COMMENTS

Background

Lysine specific demethylase 1 (LSD1) is essential for mammalian development and is involved in many biological processes, such as cell-type differentiation, gene activation and gene repression. Knocking down LSD1 with small interfering RNAs suppressed the proliferation of various bladder and lung cancer cell lines. To be known, little data has been generated with regard to the involvement of LSD1 genes in hepatic tumorigenesis. In this study, the authors investigated LSD1 expression in hepatocellular carcinoma (HCC) and its correlation with clinicopathological features, including the survival of patients with HCC.

Research frontiers

The data suggest for the first time that the overexpression of LSD1 protein in HCC tissues may help predict tumor progression and poor prognosis.

Innovations and breakthroughs

The authors examined LSD1 expression in 60 paired liver cancer tissues and adjacent noncancerous tissues by quantitative real time polymerase chain reaction and Western blotting. In addition, authors analyzed LSD1 expression in 198 HCC samples by immunohistochemistry. The relationships between LSD1 expression and both clinicopathological features and patient survival were investigated.

Applications

These findings provide evidence that the overexpression of LSD1 serves as a biomarker for poor prognosis in HCC. Thus, authors speculate that LSD1 may be a potential target of anti-angiogenic therapy for HCC.

Terminology

LSD1, the first histone demethylase that was discovered as a nuclear homolog of amine oxidases, removes the methyl groups from mono- and dimethylated Lysine (Lys) 4 of histone H3 and Lys9 of histone H3.

Peer review

The authors investigated the expression of LSD1 in HCC and determined its correlation with tumor progression and prognosis. The authors claim that the expression levels of LSD1 protein in HCC tissues correlates with tumor progression and prognosis.

Abstract

AIM: To conduct a meta-analysis to determine the safety and efficacy of laparoscopic liver resection (LLR) and open liver resection (OLR) for hepatocellular carcinoma (HCC).

METHODS: PubMed (Medline), EMBASE and Science Citation Index Expanded and Cochrane Central Register of Controlled Trials in the Cochrane Library were searched systematically to identify relevant comparative studies reporting outcomes for both LLR and OLR

for HCC between January 1992 and February 2012. Two authors independently assessed the trials for inclusion and extracted the data. Meta-analysis was performed using Review Manager Version 5.0 software (The Cochrane Collaboration, Oxford, United Kingdom). Pooled odds ratios (OR) or weighted mean differences (WMD) with 95%CI were calculated using either fixed effects (Mantel-Haenszel method) or random effects models (DerSimonian and Laird method). Evaluated endpoints were operative outcomes (operation time, intraoperative blood loss, blood transfusion requirement), postoperative outcomes (liver failure, cirrhotic decompensation/ascites, bile leakage, postoperative bleeding, pulmonary complications, intraabdominal abscess, mortality, hospital stay and oncologic outcomes (positive resection margins and tumor recurrence).

RESULTS: Fifteen eligible non-randomized studies were identified, out of which, 9 high-quality studies involving 550 patients were included, with 234 patients in the LLR group and 316 patients in the OLR group. LLR was associated with significantly lower intraoperative blood loss, based on six studies with 333 patients [WMD: -129.48 mL; 95%CI: -224.76-(-34.21) mL; $P = 0.008$]. Seven studies involving 416 patients were included to assess blood transfusion requirement between the two groups. The LLR group had lower blood transfusion requirement (OR: 0.49; 95%CI: 0.26-0.91; $P = 0.02$). While analyzing hospital stay, six studies with 333 patients were included. Patients in the LLR group were found to have shorter hospital stay [WMD: -3.19 d; 95%CI: -4.09-(-2.28) d; $P < 0.00001$] than their OLR counterpart. Seven studies including 416 patients were pooled together to estimate the odds of developing postoperative ascites in the patient groups. The LLR group appeared to have a lower incidence of postoperative ascites (OR: 0.32; 95%CI: 0.16-0.61; $P = 0.0006$) as compared with OLR patients. Similarly, fewer patients had liver failure in the LLR group than in the OLR group (OR: 0.15; 95%CI: 0.02-0.95; $P =$

0.04). However, no significant differences were found between the two approaches with regards to operation time [WMD: 4.69 min; 95%CI: -22.62-32 min; $P = 0.74$], bile leakage (OR: 0.55; 95%CI: 0.10-3.12; $P = 0.50$), postoperative bleeding (OR: 0.54; 95%CI: 0.20-1.45; $P = 0.22$), pulmonary complications (OR: 0.43; 95%CI: 0.18-1.04; $P = 0.06$), intra-abdominal abscesses (OR: 0.21; 95%CI: 0.01-4.53; $P = 0.32$), mortality (OR: 0.46; 95%CI: 0.14-1.51; $P = 0.20$), presence of positive resection margins (OR: 0.59; 95%CI: 0.21-1.62; $P = 0.31$) and tumor recurrence (OR: 0.95; 95%CI: 0.62-1.46; $P = 0.81$).

CONCLUSION: LLR appears to be a safe and feasible option for resection of HCC in selected patients based on current evidence. However, further appropriately designed randomized controlled trials should be undertaken to ascertain these findings.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common primary cancer worldwide^[1], and the third most common cause of cancer-related deaths with about 600 000 patients dying from the disease annually^[2]. The potential treatment options for HCC include: surgical resection^[3], liver transplantation^[4], chemotherapy and local ablative therapy^[5]. Surgery, either through hepatic resection or liver transplantation, is the best hope for a cure, but is not suitable for those patients who also suffer from significant background cirrhosis^[5]. Liver transplantation should be considered in any patient with cirrhosis and a small (5 cm or less single nodule or up to three lesions of 3 cm or less) HCC. Hepatic resection, on the other hand, should be considered as a primary therapy in every patient with HCC and a non-cirrhotic liver (including fibrolamellar variant). Resection can also be carried out in highly selected patients with hepatic cirrhosis and well preserved hepatic function (Child-Pugh A) who are unsuitable for liver transplantation^[6].

Open liver resection (OLR) has traditionally been accepted as the preferred treatment for resectable HCC in patients with adequate liver reserves^[7]. However, most patients with HCC have significant underlying co-morbidities, including liver diseases such as chronic hepatitis and liver cirrhosis, and hence are at very high risk of developing significant postoperative complications. Laparoscopic surgery is considered to be a safe alternative to open surgical intervention in numerous surgical procedures. Since the first successful report of laparoscopic liver wedge resection in 1992^[8], improvement in surgical instrumentation and experience in laparoscopic treatment for the majority of surgical gastrointestinal conditions, including benign liver diseases, have led to a growing interest in its application for HCC. Recent studies have suggested that the laparoscopic liver resection (LLR) has a number of advantages such as reduction of postoperative pain, operative morbidity, and length of hospitalization, especially for cirrhotic patients with HCC^[9-12]. However, the current literature on LLR for HCC exists in the form of few comparative studies. General application of this approach for treating this disease is still a matter of debate because it is new and data regarding long-term oncologic outcomes (e.g., recurrence) are not robust.

Three published meta-analysis^[13-15] have investigated the advantages and disadvantages of the LLR for HCC. These meta-analyses have reported that LLR was associated with decreased blood loss and requirement for blood transfusion, lower overall postoperative morbidity and shorter hospital stay compared with the OLR. In addition, there was no difference between groups in oncologic outcomes such as positive resection margins and tumor recurrence. Since these meta-analysis included a limited number of studies with fewer cases, data reported were not sufficient to derive conclusions with regards to the overall efficacy and safety of LLR. In the interim, several high-quality studies^[16-20] with more participants have been published. We have therefore undertaken an analysis of 15 studies including 1105 hepatic resections to provide an update on the efficacy of LLR vs OLR for HCC.

MATERIALS AND METHODS

Study selection

PubMed (Medline), EMBASE and Science Citation Index Expanded and Cochrane Central Register of Controlled Trials in the Cochrane Library were searched systematically for all articles published from January 1992 to February 2012 comparing LLR and OLR for HCC. The following medical search headings and keywords were used: “laparoscopy” or “laparoscopic” or “minimally invasive surgery” and “hepatectomy” or “liver resection” or “hepatic resection” and “primary liver carcinoma” or “hepatocellular carcinoma” or “HCC”. Only human studies published in English language as full text articles were considered for inclusion. Reference lists of selected articles were also examined to find relevant studies which were not identified during the initial data-

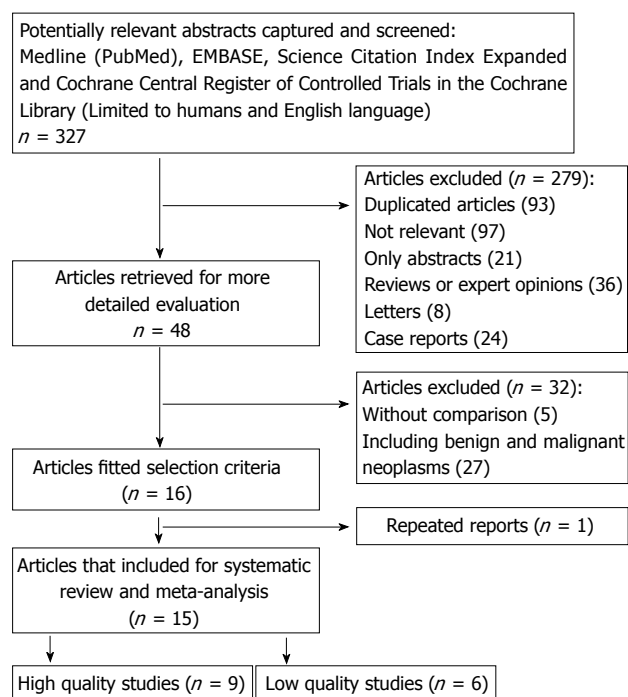

Figure 1 Flow diagram depicting the process of identification and inclusion of selected studies.

base searches. Final inclusion of articles was determined by consensus from two authors; when this failed, a third author adjudicated.

Inclusion and exclusion criteria

Two authors identified and screened the aforementioned databases for potentially eligible studies.

Inclusion criteria: (1) Clear documentation of the operative techniques as “laparoscopic” or “open”; (2) Studies with at least one of the outcomes mentioned; and (3) Where multiple studies came from the same institute and/or authors, either the one of higher quality or the most recent publication was included in the analysis.

Exclusion criteria: (1) Abstracts, letters, editorials, expert opinions, case reports, reviews and studies lacking control groups; (2) Studies with no clearly reported outcomes of interest; (3) Studies dealing with HCC recurrence after hepatectomy; and (4) Studies including patients with benign lesions or other types of malignant liver tumors.

Outcomes of interest

The following outcomes were evaluated in the two approaches.

Operative outcomes: Operative time, intraoperative blood loss and requirement for blood transfusions.

Postoperative outcomes: Hospital stay, liver failure, cirrhotic decompensation/ascites, bile leakage, postoperative bleeding, pulmonary complications (including pleural

effusion and pneumonia), intra-abdominal abscess and mortality.

Oncologic outcomes: Positive resection margins and tumor recurrence.

Data extraction and quality assessment

Data were extracted by two independent observers using standardized forms. The recorded data included patient and study characteristics and surgical details. The quality of studies was assessed using the Newcastle-Ottawa Scale^[21], by examining three factors: patient selection, comparability of the study groups and assessment of outcome. Studies were matched for age, American Society of Anesthesiologists status, presence of cirrhosis, size of tumor and type of hepatic resection undertaken. The maximum numbers of stars in the selection, comparability, and outcome categories were four, two, and three, respectively. Studies achieving six or more stars were considered to be of higher quality^[22]. Only these were included in the final analysis to have the best estimate of the outcome measure.

Statistical analysis

Meta-analysis was performed using Review Manager Version 5.0 software (The Cochrane Collaboration, Oxford, United Kingdom). For continuous variables, treatment effects were expressed as weighted mean difference (WMD) with corresponding 95%CI. For categorical variables, treatment effects were expressed as odds ratio (OR) with corresponding 95%CI. Heterogeneity was evaluated using the χ^2 test, and a P value < 0.1 was considered significant^[23]. The fixed-effects model was initially calculated for all outcomes^[24]. If the test rejected the assumption of homogeneity of studies, random-effects analysis was performed^[25]. Sensitivity analysis were performed by removing individual studies from the data set and analyzing the effect on the overall results to identify sources of significant heterogeneity. Subgroup analysis were also undertaken by including low-quality studies to present cumulative evidence. Funnel plots were constructed to evaluate potential publication bias^[26] based on the operative time, hospital stay and tumor recurrence.

RESULTS

Description of included trials in the meta-analysis

The search strategy initially generated 327 relevant clinical trials. Finally, 16 articles^[10-12,16-20,27-34] were selected for further investigation. Of these, two studies^[12,30] were published by the same institute and had overlapping patient populations; therefore, the higher-quality study^[30] was included. In total, 15 non-randomized comparative studies were identified for final inclusion, out of which 9 were found to be of high quality^[10,11,17,18,20,28,30,32,33]. These were included in the final analyses. Figure 1 shows the process of selecting comparative studies included in our meta-analysis.

Study and patient characteristics

The characteristics and quality assessments of included studies are shown in Table 1. A total of 550 patients were included: 234 patients in the LLR and 316 patients in the OLR group. The characteristics of patients and surgical details are summarized in Table 2. The sample size of the included studies varied from 21 to 89 patients. The rate of conversion, from laparoscopic to open procedure, ranged from 0% to 19.4%. Patients in most of studies had concurrent hepatitis B infection.

Meta-analysis results

Results of the analyses are shown in Figure 2 and summarized in Table 3.

Operative outcomes: Six high-quality studies^[10,11,18,28,30,33] reported mean operation time, analysis of which showed no statistically significant difference between the two groups (patients 354; WMD: 4.69 min; 95%CI: -22.62-32 min; $P = 0.74$). Similarly, six high-quality studies^[10,18,20,28,30,33] provided detailed data for estimation of blood loss between the two groups. We found that LLR had significantly less intraoperative blood loss compared to OLR [patients 333; WMD: -129.48 mL; 95%CI: -224.76-(-34.21) mL; $P = 0.008$]. Furthermore, the rate of blood transfusions requirement was identified to be significantly lower in the

LLR group as opposed to OLR (trials: 7; patients 416; OR: 0.49; 95%CI: 0.26-0.91; $P = 0.02$). Addition of low-quality trials to these groups did not affect the results.

Postoperative outcomes: Six high-quality studies^[10,18,20,28,30,33] reported on length of hospital stay. Pooled outcome measure favored LLR [patients 333; WMD: -3.19 d; 95%CI: -4.09-(-2.28) d; $P < 0.00001$]. A lower incidence of liver failure was observed in patients undergoing LLR (trials 2, patients 116; OR: 0.15; 95%CI: 0.02-0.95; $P = 0.04$). The incidence of postoperative ascites in seven high-quality trials (patients 416; OR: 0.32; 95%CI: 0.16-0.61; $P = 0.0006$) was found to be significantly lower in LLR group. Six high-quality trials^[10,17,18,20,28,30] revealed no statistically significant difference in the incidence of pulmonary complications between the two groups (patients 384; OR: 0.43; 95%CI: 0.18-1.04; $P = 0.06$). However, when two low-quality trials^[27,31] were also pooled together to get a cumulative result, LLR group seemed to have a lower incidence (patients 460; OR: 0.43; 95%CI: 0.19-0.96; $P = 0.04$).

No significant differences were observed between two operative techniques in terms of other postoperative complications, such as bile leakage (trials 3; patients 205; OR: 0.55; 95%CI: 0.10-3.12; $P = 0.50$), postoperative bleeding (trials 5; OR: 0.54; 95%CI: 0.20-1.45; $P = 0.22$) and mortality (trials 5; patients 474; OR: 0.46; 95%CI:

0.14-1.51; $P = 0.20$).

Two high-quality trials^[20,30] reported intra-abdominal abscess formation in their patient populations. However, one of these did not have any events in both the groups and was subsequently excluded. A subgroup analysis was therefore undertaken including a low-quality study, which also did not show an association of intra-abdominal abscess formation with the type of operative technique (patients 122; OR: 0.72; 95%CI: 0.12-4.54; $P = 0.73$).

Oncologic outcomes: We did not find any significant differences in the rate of positive margins (trials 4; patients 287; OR: 0.59; 95%CI: 0.21-1.62; $P = 0.31$) and tumor recurrence (trials 6; patients 416; OR: 0.95; 95%CI: 0.62-1.46; $P = 0.81$).

Sensitivity and subgroup analysis

Sensitivity analyses were carried out by excluding each in-

dividual study from each outcome measure. These exclusions did not alter the results obtained from cumulative analyses. Additionally, the pooled result of included outcomes was not affected, when either fixed effects or random effects models were used. Subgroup analyses were undertaken for all outcome measures by including low-quality studies as well. These are summarized in Table 3.

Publication bias

The funnel plot was based on the operation time, hospital stay and tumor recurrence, which is shown in Figure 3. As no study lies outside the limits of the 95%CI, there was no evidence of publication bias.

DISCUSSION

LLR is a challenging technique for surgeons as the liver has unique anatomical features which present technical difficulties for parenchymal transections-massive hemorrhage and bile leak from intrahepatic vessels^[11,29]. Presence of cirrhosis in patients undergoing LLR makes parenchymal transection an even more delicate and demanding procedure^[11]. Rare but fatal complications such as a gas embolism caused by the pneumoperitoneum through hepatic venous branches on the hepatic stump during parenchymal division of the liver have also been reported^[27]. On the contrary, increased experience, technical refinement and improvement in surgical equipment have increased the safety of liver resection as a curative treatment for benign or malignant liver lesions^[35-38]. In spite of these advancements, LLR has not been very popular for HCC, partly because of the controversies related to resection margins, tumor seeding, incision related metastasis, and long-term survival^[32]. However, the difference in outcomes between LLR and OLR in HCC has not been evaluated in a randomized controlled trial. Most reported studies are retrospective, single-institution series with a small number of patients, which makes it difficult to interpret outcomes appropriately. In order to overcome these limitations, we have endeavored to pool all the relevant available data and perform a meta-analysis. Although our result is similar to previously reports^[13-15] in some aspects, such as operative blood loss, blood transfusion requirement, length of hospital stay and tumor recurrence, our analysis included more high-quality case-matched studies as well as more patients and therefore, provides an up to date and high-quality evidence regarding the perioperative and long-term outcomes of patients with HCC undergoing LLR *vs* OLR.

We found no significant difference in the 30-d mortality between the two groups. The results from this analysis indicate that LLR was successfully completed in most patients, with a rate of conversion to open surgery ranging from 0% to 19.4%. These results point towards the feasibility of LLR for patients with HCC.

There was no significant difference in operative time between the two techniques, based on our analysis, which can be explained by current advances in surgical instru-

mentation and technology, as well as surgeons' experience and learning curve^[39]. Our results demonstrate that LLR is associated with significantly less intraoperative blood loss and blood transfusion requirement, which can partly be explained by the hemostatic effect of pneumoperitoneum on the hepatic vein branches^[30,40] and also image magnification during LLR^[33]. There have been some re-

ports in literature indicating that significant intraoperative blood loss and blood transfusion are associated with recurrence and survival rates after resection of HCC^[41-43]. Hence reduced blood loss in LLR is favorable. Results from this meta-analysis also reveal a significant reduction in the postoperative hospital stay in the LLR group. These findings are consistent with laparoscopic procedures

where patients have faster ambulation, early oral intake and reduced analgesic requirements^[11,33].

There is growing evidence to suggest that LLR is associated with less postoperative morbidity particularly with regards to developing postoperative ascites and liver failure. The reduction in the incidence of postoperative ascites in LLR might be due to preservation of the abdominal wall collateral circulation, by avoiding long abdominal incisions and preservation of the round ligament, which may contain significant collateral veins, thereby reducing portal hypertension and intraoperative fluid requirements^[44]. Other favorable factors associated with LLR include less frequent mobilization and manipulation of the liver, reduced fluid requirements, decreased blood loss, early ambulation and oral food intake and reduced third space accumulation leading to hyperaldosteronism^[28,30,45-47].

Incomplete tumor resection with positive resection margins is perceived to be a potential disadvantage in LLR^[33]. However, our results reveal no significant difference in the margin positive rate between the LLR and OLR groups. Further analysis revealed no difference in recurrence between the two groups. These findings can be attributed to the use of intraoperative ultrasonography in LLR or OLR. Intraoperative ultrasonography is a sensitive tool for accurate identification of lesions and orientation of borders for non-tumorous tissue^[48,49]. The other consideration for laparoscopic resection of malignancies is the potential of peritoneal dissemination, or port-site metastasis^[50-52]. However we did not encounter any case of peritoneal dissemination or port-site metastasis in our analysis.

Although our analysis shows apparent advantages of LLR over OLR for HCC, it is important to highlight that most of the patients included in our meta-analysis underwent segmentectomy or subsegmentectomy for peripheral lesions located in the anterolateral segments of the liver. Although it is encouraging that our results have been consistent throughout the sensitivity analyses, this meta-analysis also has some limitations which should be considered when interpreting its results and warrants a discussion. Firstly, all of the studies included were non-randomized, retrospective trials, which inevitably add a degree of selection bias to the results and can lead to over/under estimation of the measured effect. Since factors such as tumor location, extent of liver cirrhosis and tumor size are important determinants of outcome, we matched the two groups based on these important factors to eliminate bias and improve the validity of our results^[53].

Secondly, we observed some heterogeneity in certain outcome measures. This might be explained by differences in surgical techniques, retrospective nature of the studies, and limited blinded outcome assessment in some of the trials. However investigation of heterogeneity using meta-regression was not possible due to small number of studies.

Thirdly, there was inconsistency in the definition of some outcomes in different studies, making it difficult

to pool the results together. Using standardized guidelines to report outcomes can potentially overcome this problem and would allow more studies to be included in meta-analyses, leading to more reliable conclusions.

Finally, it is important to note that surgeons' experience and volume of cases operated in a particular hospital may affect these outcome measures tremendously. Unfortunately, none of the studies included in this analysis provided details of these factors and therefore, we were unable to assess the effect in such settings. Future trials should carefully consider such stratification while designing their studies and interpreting their data.

In conclusion, the results of this comprehensive, high-quality up to date meta-analysis indicate that LLR is feasible and safe for the treatment of HCC. LLR should be performed in selected patients by expert surgeons in high volume centers. Further research by undertaking well designed, prospective randomized controlled trials can confirm the advantages of LLR for the management of HCC.

COMMENTS

Background

Laparoscopic liver resection (LLR) is an attractive treatment for liver benign tumor comparing with open liver resection (OLR) because of good cosmetic results and less trauma, but its role remains controversial when LLR is applied to hepatocellular carcinoma (HCC) because of a lack of high-quality randomized controlled trials in this area.

Research frontiers

In order to compare the safety and effectiveness between the LLR and OLR, the meta-analysis was used to evaluate operative, postoperative and oncologic outcomes of these two surgical methods for HCC in this study.

Innovations and breakthroughs

Although previous meta-analysis had compared the outcomes of these two surgical methods, which included a limited number of studies with fewer cases, many high-quality studies with more participants have been published since. Therefore, it is important to provide an up to date analysis of these outcomes. This meta-analysis reported that LLR had significant advantage over OLR in terms of intraoperative blood loss, blood transfusions requirement, hospital stay, postoperative ascites and liver failure compared with OLR for HCC. Meanwhile, incidences of operation time, bile leakage, postoperative bleeding, pulmonary complications, intra-abdominal abscess, mortality, positive resection margins and tumor recurrence were similar between LLR and OLR.

Applications

The results of this meta-analysis show that LLR appears to be a safe and feasible option for HCC in selected patients based on current evidence. Therefore, LLR may be an alternative treatment for HCC. However, the experience of the operating surgeon and volume of operated cases in a particular centre has to be taken into consideration.

Terminology

HCC is the fifth most common primary cancer worldwide with high malignant potential.

Peer review

The paper investigates the safety and effectiveness of LLR on HCC. The statistical analysis used in the study is appropriate and the results suggest that there are some advantages in LLR. This paper should be of interest to surgeons in the field of the hepato-biliary-pancreatic surgery worldwide.

Abstract

We report 2 cases of pancreatic endocrine tumors that caused obstruction of the main pancreatic duct (MPD). A 49-year-old asymptomatic man was referred to our institution because dilation of the MPD was revealed by abdominal ultrasonography (US). No tumor was detected by endoscopic ultrasonography, computed tomography (CT), and magnetic resonance imaging (MRI). The diameter of the MPD was > 20 mm at the body, and no dilation was noted at the head. Although malignancy was not confirmed through cytology or imaging, pancreatic cancer was strongly suspected. Pancreaticoduodenectomy was performed. Pathologi-

cal and immunohistochemical examination revealed a 5 mm × 3 mm serotonin-positive endocrine tumor. Fibrosis was present around the MPD and seemed to cause stricture. A 32-year-old asymptomatic man had elevated serum amylase, and US demonstrated dilation of the MPD. No tumor was detected by CT and MRI. Pancreatic cancer was suspected due to stricture and dilation of the MPD. Pancreatectomy of middle part of pancreas was performed. Pathological and immunohistochemical examination revealed a serotonin-positive endocrine tumor sized 5 mm × 4 mm. We report 2 cases of serotonin-positive pancreatic endocrine tumors that caused stricture of the MPD in spite of the small size of the tumor.

INTRODUCTION

Pancreatic endocrine tumors, also known as islet cell tumors, are rare neoplasms and occur in approximately

1 of 100 000 people, representing 1% to 10% of all pancreatic neoplasms^[1-3]. Some pancreatic endocrine tumors release hormones into the blood stream that cause clinical syndromes, whereas others are non-syndromic and present as mass lesion^[4,5]. The overall prevalence of functional pancreatic endocrine tumors is reported to be approximately 10/1 000 000. In contrast, the prevalence of pancreatic endocrine tumors reported by autopsy studies is higher (0.5% to 1.5%)^[6]. Multi-detector row computed tomography (CT) plays an important role in the diagnosis and staging of both syndromic and non-syndromic pancreatic endocrine tumors. In general, syndromic pancreatic endocrine tumors are less than 3 cm in size. They are typically strongly enhanced and usually best seen on CT scans obtained during the arterial phase. Compared to syndromic pancreatic endocrine tumors, non-syndromic pancreatic endocrine tumors tend to be larger at presentation and are more likely to be cystic or necrotic^[7]. In previous studies, endoscopic retrograde pancreatography (ERP) has been used to detect main pancreatic duct (MPD) stenosis and dilation of the upstream pancreatic duct caused by pancreatic endocrine tumors^[8,9]. In addition, pancreatic endocrine tumors with serotonin production is suggested to be associated with prominent stromal fibrosis, which can extend to the MPD, causing ductal stenosis and upstream dilatation of the duct and/or upstream pancreatic atrophy^[10,11]. We recently encountered 2 cases of small pancreatic endocrine tumors that revealed serotonin-positive by immunohistochemical staining causing obstruction of the MPD.

CASE REPORT

Case 1

A 49-year-old asymptomatic man was referred to our institution because dilatation of the MPD was revealed by abdominal ultrasonography (US). However, no tumor was observed by endoscopic ultrasonography (EUS), CT, and magnetic resonance imaging (MRI). The diameter of the MPD was > 20 mm at the body and no dilation was noted at the head. Endoscopic retrograde cholangiopancreatography (ERCP) was performed; the MPD showed crab-like appearance (Figure 1). Cytology was benign. Although we could not confirm malignancy through cytology or imaging, pancreatic cancer was strongly suspected. Pancreaticoduodenectomy was performed, and pathological examination revealed a 5 mm × 3 mm tumor. Fibrosis was present around the MPD and seemed to cause stricture (Figure 2).

Immunohistochemical staining of tumor samples was positive for chromogranin A, synaptophysin, and serotonin (Figure 3). The MIB-1 (Ki-67) labeling index was less than 1%. We made the diagnosis of neuroendocrine tumor of grade 1 (NET G1).

Case 2

A 32-year-old man with no symptom had elevated serum amylase, and US demonstrated dilation of the MPD. No

tumor but MPD stenosis and dilatation was revealed by MRI. EUS demonstrated presence of a small pancreatic tumor. ERCP revealed MPD stenosis and upstream dilatation (Figure 4). Cytology was benign.

Pancreatectomy of middle part of pancreas was performed and pathological examination revealed an endocrine tumor sized 5 mm × 4 mm. Tumors with stromal fibrosis can cause stenosis of the pancreatic duct. Immunohistochemical staining of the tumor cells was positive for chromogranin A, synaptophysin, and serotonin (Figure 5). The Ki-67 labeling index was less than 1%, and we made the diagnosis of NET G1.

DISCUSSION

Pancreatic endocrine neoplasms that produce serotonin, including carcinoid tumors, account for only a small portion of pancreatic endocrine neoplasms. Compared with other well-differentiated endocrine neoplasms of the pancreas, pancreatic carcinoid tumors are associated with a higher rate of malignant behavior^[12]. These pancreatic neoplasms may have the poor prognosis since they are usually found at an advanced stage, after distant metastases have occurred, and the patient has developed carcinoid syndrome. The problem is that the mass lesion is often asymptomatic and indistinct at early stages. In addition, Shi *et al.*^[11] reported that in serotonin-producing tumors, the neoplasm was subtle or unapparent on CT images; only marked dilatation of the upstream pancreatic duct or marked atrophy of the upstream pancreas was visible. Isolated reports of an association of pancreatic carcinoid tumor with dilatation of the pancreatic duct have been described before. Nagai *et al.*^[10] reported a case of pancreatic carcinoid tumor with obstructive pancreatitis. ERP revealed MPD stenosis and dilatation of the upstream pancreatic duct. They suggested that the pancreatic carcinoid tumor obstructing the pancreatic duct might have arisen from argentaffin cells located in the MPD. However, no clear relationship between pancreatic endocrine neoplasms and pancreatic duct stenosis has been described. Takaji *et al.*^[13] reported that 3 of 4 cases showed MPD dilatation upstream of the tumor. Our 2 cases were similar to these reports; the tumors were subtle on CT or MRI images and a markedly dilated MPD was noted, and they had no symptoms as carcinoid syndrome. We decided to perform the pancreatic resection because there was a possibility of pancreatic duct dilation was caused by a tumor. As a result, we could treat the pancreatic endocrine tumor in early stage. We observed that the serotonin immunoreactivity correlated with the degree of stromal fibrosis and that stromal fibrosis caused MPD stenosis. Carcinoid tumors of the midgut, in which serotonin is the predominant hormone secreted by neoplastic cells, are usually associated with extensive fibrosis^[14]. In addition, serotonin has been shown to stimulate fibroblast mitosis in cell cultures^[15]. Recently, serotonin has been shown to play a crucial role in the progression of liver fibrosis by enhancing

the production of transforming growth factor β *via* selective activation of the 5-HT_{2A} serotonin receptors^[16]. Shi *et al*^[11] reported that a small portion of pancreatic endocrine neoplasms produces serotonin. Serotonin production may be associated with stromal fibrosis, and fibrosis, in turn, can cause stenosis of the pancreatic duct. In clinical practice, imaging findings of pancreatic duct stenosis that is out of proportion to the size of the causative strongly enhanced mass or that does not have an associated distinct mass are indicative of a pancreatic neoplasm. Recently, it was reported that many pancreatic NETs express high levels of somatostatin receptors, so somatostatin-receptor scintigraphy (OctreoScan) can be imaged with a radiolabeled form of the somatostatin analog octreotide. Somatostatin receptor scintigraphy has proven particularly effective for visualizing gastrinomas, glucagonomas, and nonfunctioning pancreatic tumors. However, in another study of 37 patients with a NET, MRI and CT were substantially superior to SRS for detection of liver metastases. The sensitivity of Oc-

treoScans was found to be particularly poor (< 35 percent) in lesions smaller than 1.5 cm in diameter^[17].

In conclusion, we report 2 cases of serotonin-positive pancreatic endocrine tumors that caused stricture of the MPD in spite of the small size of the tumor. It is necessary to consider that the MPD stenosis and upstream dilatation caused by the tiny pancreatic endocrine tumor as the differential diagnosis in addition to chronic pancreatitis and pancreatic cancer.

Abstract

Endoscopic intervention is less invasive than percutaneous or surgical approaches and should be considered the primary drainage procedure in most cases with obstructive jaundice. Recently, therapeutic endoscopic retrograde cholangiopancreatography (ERCP) using double-balloon enteroscopy (DBE) has been shown to be feasible and effective, even in patients with surgically altered anatomies. On the other hand, endoscopic partial stent-in-stent (PSIS) placement of self-expandable metallic stents (SEMSs) for malignant hilar biliary obstruction in conventional ERCP has also been shown to be feasible, safe and effective. We performed PSIS placement of SEMSs for malignant hilar biliary obstruction due to liver metastasis using a short DBE in a patient with Roux-en-Y anastomosis and achieved technical and clinical success. This procedure can result in quick relief from obstructive jaundice in a single session

INTRODUCTION

Endoscopic intervention is less invasive than percutaneous or surgical approaches and should be considered the primary drainage procedure in most cases with obstructive jaundice. Recently therapeutic endoscopic retrograde cholangiopancreatography (ERCP) using double-balloon enteroscopy (DBE) has been shown to be safe and feasible, even in patients with surgically altered anatomies^[1-4]. On the other hand, the placement of biliary stents is effective for the palliation of unresectable malignant hilar biliary obstruction in conventional ERCP^[5-8]. In particular, as we previously described, endoscopic partial stent-in-stent (PSIS) placement of self-expandable metallic

stents (SEMSs) for malignant hilar biliary obstruction has been shown to be feasible, safe and effective^[7,8], but it can be technically challenging. We report a case of a postoperative surgical patient who was managed successfully with a PSIS placement of SEMSs for malignant hilar biliary obstruction using a short DBE.

CASE REPORT

A 63-year-old male underwent total gastrectomy with Roux-en-Y reconstruction and sigmoidectomy due to simultaneous gastric and sigmoid colon cancer. Despite treatment with adjuvant chemotherapy, the patient's liver and lymph node metastases increased and caused obstructive jaundice, but no cholangitis. Computed tomography imaging showed dilation of the left intrahepatic bile duct due to liver metastasis, which occupied the right lobe (Figure 1A). For endoscopic biliary drainage, endoscopic retrograde cholangiography with a short DBE, EC-450BI5 (Fujifilm, Tokyo, Japan), was performed. The cholangiography revealed hilar biliary obstruction and a dilated left intrahepatic bile duct with tumor invasion extending to the bifurcation of the left lateral sectional bile duct branches (Figure 1B). After needle-knife sphincterotomy, a 0.035-inch guidewire was passed selectively into the left lateral superior bile duct branch (B3). The first uncovered SEMS (Zeostent 10 mm × 80 mm; Zeon Medical Inc., Tokyo, Japan) was deployed, with the proximal end in B3 and the distal end in the common bile duct. The guidewire remained in place, and the delivery system was removed. Subsequently, the wire was passed by catheter into the left lateral inferior bile duct branch (B2) through the mesh of the initial SEMS. Following balloon dilation (8 mm) at the stricture (Figure 2A), the second uncovered SEMS (Zeostent 10 mm × 100 mm) was smoothly deployed, with the proximal end in B2 through the mesh of the initial SEMS, forming a PSIS (Figure 2B). The patient was immediately relieved of jaundice and left our hospital in 7 d. He recovered enough to receive another round of chemotherapy on an outpatient basis.

DISCUSSION

In patients with surgically altered anatomy and long afferent limbs, ERCP by gastroenteroscopy, colonoscopy, or standard duodenoscopy is technically challenging and often unsuccessful because of an inability to reach the papilla or bilioenteric anastomosis. Recently, the use of a DBE or single-balloon enteroscopy has made therapeutic ERCP-including sphincterotomy, stone extraction, dilation of bilioenteric anastomotic stricture, and biliary stent placement-feasible and effective, even in patients with surgically altered anatomies^[1-4].

According to a recent report on endoscopic intervention for the relief of malignant hilar biliary obstruction, the placement of SEMSs offers advantages over plastic endoprostheses in terms of stent patency and the number of reinterventions needed^[5]. In addition, endoscopic PSIS

Figure 1 The hilar biliary obstruction due to liver metastasis occupying the right lobe and a dilated left intrahepatic bile duct with tumor invasion extending to the bifurcation of the lateral bile duct branch. A: Computed tomography image; B: Cholangiography.

placement of SEMSs for malignant hilar biliary obstruction has been shown to be feasible, safe and effective in conventional ERCP^[5-8]. We previously reported that this procedure is safe and effective even in cancer patients receiving chemotherapy^[8].

Therefore, in this case of a cancer patient with Roux-en-Y anastomosis, we used a short DBE to perform PSIS placement of SEMSs for malignant hilar biliary obstruction and achieved technical and clinical success. Almost all conventional accessories, including uncovered SEMS, were available, as we used a short DBE with a working channel of 2.8 mm in diameter and a 152 cm in length.

Percutaneous stent insertion for malignant obstructive jaundice had significantly higher 30-d mortality than the endoscopic method (33% *vs* 15%, $P = 0.016$) in a randomized trial^[9]. Complications related with percutaneous transhepatic biliary drainage (PTBD), including intraperitoneal hemorrhage, hemobilia, bile leakage, and pleural complications, can be avoided by using endoscopic drainage^[10]. In our cases, 2 PTBD routes would have been required for the placement of 2 SEMSs at B2 and B3, respectively. In addition, 2 sessions would have been required for the placement of the SEMSs, that is, the SEMSs are usually placed one week after the initial PTBD. The endoscopic procedure could protect our patient from the risks associated with more invasive drainage procedures, such as PTBD and surgical drainage, the latter of which is associated with high morbidity and mortality rates. Furthermore, the patient needed no further long-term hospitalization

Figure 2 A partial stent-in-stent placement of biliary metallic stents using a short double-balloon enteroscopy. A: Following the placement of the first self-expandable metallic stent (SEMS), balloon dilation was performed at the stricture; B: The second SEMS was deployed through the mesh of the initial SEMS.

for the treatment of obstructive jaundice for the duration of his life. We think that this procedure is also indicated for patients in whom PTBD cannot be performed for various reasons, such as patients with severe coagulopathy, thrombocytopenia, a large amount of ascites, or an anatomically inaccessible location, e.g., patients with Chilaiditi syndrome.

In conclusion, endoscopic PSIS placement of SEMSs for the treatment of malignant hilar biliary obstruction using a short DBE was proved to be feasible and effective

in a patient with Roux-en-Y anastomosis. This procedure can result in quick relief from obstructive jaundice in a single session and with short-term hospitalization, even in patients with surgically altered anatomies.

Abstract

Plasmablastic lymphoma (PBL) is a rare aggressive B-cell lymphoproliferative disorder, which has been characterized by the World Health Organization as a new entity. Although PBL is most commonly seen in the oral cavity of human immunodeficiency virus (HIV)-positive patients, it can also be seen in extra-oral sites in immunocompromised patients who are HIV-negative. Here we present a rare case of PBL of the small intestine in a 55-year-old HIV-negative male. Histopathological examination of the excisional lesion showed a large cell lymphoma with plasmacytic differentiation diffusely infiltrating the small intestine and involving the surrounding organs. The neoplastic cells were diffusely positive for CD79a, CD138 and CD10 and partly positive for CD38 and epithelial membrane antigen. Approximately 80% of the tumor cells were positive for Ki-67. A monoclonal rearrangement of the

kappa light chain gene was demonstrated. The patient died approximately 1.5 mo after diagnosis in spite of receiving two courses of the CHOP chemotherapy regimen. In a review of the literature, this is the first case report of PBL with initial presentation in the small intestine without HIV and Epstein-Barr virus infection, and a history of hepatitis B virus infection and radiotherapy probably led to the iatrogenic immunocompromised state.

INTRODUCTION

Plasmablastic lymphoma (PBL) is a distinct, aggressive B-cell neoplasm that shows diffuse proliferation of large neoplastic cells resembling B-immunoblasts with an immunophenotype of plasma cells^[1]. It was originally described in the oral cavity in the clinical setting of human immunodeficiency virus (HIV) infection, but may occur in other, predominately extra-oral sites, and these have been reflected in the current/revised 2008 World Health Organization classification^[2]. Extra-oral PBL has been reported in various locations^[3-6]; however PBL of

the small intestine was extremely rare. Here we present a rare case of PBL of the small intestine in an HIV-negative individual and review the literature.

CASE REPORT

A 55-year-old man presented with generalized abdominal pain, distension and vomiting for over a 1-mo period. He also described recent weight loss and anorexia. The above pathologic condition gradually became worse without relief of symptoms. Abdominal ultrasonography revealed multiple masses in the small intestine with extension to the bilateral adrenal glands. Radiographs and computed tomography (CT) scans of the chest, oral and peri-oral sites showed no abnormalities, and no peripheral lymphadenopathy was noted. Routine blood examination showed hemoglobin 106 g/L, white blood cell count 6.48×10^9 /L, neutrophils 64.4%, lymphocytes 15.3%, monocytes 10.2%. Serological testing demonstrated positivity for hepatitis B virus (HBV) surface antigen and HBV e-antigen, and negativity for HIV. The lactate dehydrogenase level (216 U/L) was in the normal range. Serum examination for Bence Jones' protein and rheumatoid factor were negative. The medical history was that he had a history of infection of HBV and underwent resection of squamous cell carcinoma in the maxillary sinus, followed by two courses of radiotherapy 7 mo previously.

During surgery, multiple tumor nodules were found in the intestinal wall and mesentery of the small intestine. Surrounding organs, including adrenal glands, liver, inferior vena cava and lumbar vertebrae were involved. Tumors were excised with adjacent portions of the small intestine and bilateral adrenal glands. A 55-cm long segment of the small bowel was obtained from the resection procedure. By gross examination, there was an irregular tumor nodule, volume 10 cm \times 8 cm \times 6 cm, in the intestinal wall surrounding the whole enteric cavity. Multiple tumor nodules ranging from 3.5 cm to 5.5 cm in diameter could be found in the adjacent mesentery. Tumor nodules in the left and right adrenal glands measured 8.5 cm \times 8 cm \times 4 cm and 8 cm \times 5 cm \times 2.5 cm respectively. The cut surface of these tumors was grey and soft. Selected tumor tissues were fixed in formalin and embedded in paraffin and cut into sections which were stained with the hematoxylin and eosin for routine histology. Additional sections of paraffin-embedded tissue were used for immunohistochemical staining and *in situ* hybridization analysis.

Histologically, the whole intestinal wall was diffusely infiltrated by malignant lymphocytes with abundant basophilic cytoplasm, eccentrically located pleomorphic nuclei, and single, centrally located prominent nucleoli (Figure 1A). The nuclei were round or oval or convoluted in shape and a large number of mitotic figures were apparent (Figure 1B). There were tumor emboli within the lymphatic vessels. Comprehensive necrosis of tumor cells was conspicuous. The tumor cells were scattered

throughout the small intestine wall into the peripheral soft tissue and adrenal glands forming tumor nodules of different sizes. Furthermore, tumor cell proliferation in lymph node sinuses was conspicuous in the mesenteric lymph nodes.

On immunohistochemistry, the neoplastic cells were diffusely positive for CD79a (Figure 1C), CD138 (Figure 1D) and CD10 (Figure 1E), and partly positive for CD38 and epithelial membrane antigen. These cells were negative for CD45, CD20, CD3, CD30, ALK-1, Bcl-2, Bcl-6, Mum-1, CD56, HMB45, S-100, CD34, CD117 and cytokeratin. The cells showed kappa light chain restriction (Figure 1F). Nuclear proliferation rate, as assessed by Ki-67 staining, was approximately 80% (Figure 1G). Epstein-Barr virus (EBV) infection was not detected by *in situ* hybridization for EBV-encoded RNA (Figure 1H) or immunohistochemistry for EBV latent membrane protein-1. On the basis of these morphologic and immunohistochemical characteristics, the pathological diagnosis of PBL was made.

After surgery, the patient was treated with two courses of a standard CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisone) chemotherapy regimen. Unfortunately, during the second course of chemotherapy, repeat CT scans and ultrasonography revealed tumor progression with an increase in swollen cervical lymph nodes and abdominal tumor load. The patient died of multiple organ failure due to further deterioration 1.5 mo later.

DISCUSSION

As a rare entity of non-Hodgkin B cell lymphoma, PBL was first described as a specific clinicopathologic entity by Delecluse *et al*^[7] as an aggressive B-cell lymphoma occurring in the oral cavity arising in the context of HIV infection. However, in recent years, several cases of PBL have been reported in patients without HIV infection, and several more have reported the occurrence of PBL in extra-oral sites, including the skin, subcutaneous tissue, stomach, anal mucosa or perianal area, lung, lymph node, and other regions^[3-6,8,9]. The small intestine is a rare extra-oral site of involvement in PBL patients, and only two cases in HIV-infected patients have been reported previously^[10,11]. In a review of the literature, this is the first case report of PBL with initial presentation in the small intestine and with multiple organ involvement in an HIV-negative individual.

As PBL is often associated with immunodeficiency, such as HIV infection, EBV plays an important role in the tumorigenesis of HIV-associated PBL. HIV infection creates a permissive environment for chronic EBV infection, with a subsequent latency that predisposes the EBV transformed B-cells to become malignant^[12]. There is likely a connection between HIV-induced immunosuppression and the development of EBV-associated PBL^[13]. However, recent investigation revealed that EBV infection was detected in only 17% of HIV-negative PBL cases, which suggest that this virus may not be a

Figure 1 Plasmablastic lymphoma of the small intestine.
 A: Diffuse infiltration in the mucosa of the small intestinal by monotonous large atypical lymphoid cells [hematoxylin and eosin (H and E), original magnification $\times 200$]; B: These atypical cells had a plasmablastic appearance, with abundant basophilic cytoplasm, eccentrically located pleomorphic nuclei, and single, centrally located prominent nucleoli (H and E, original magnification $\times 400$); C-F: The atypical cells were diffusely positive for CD79a (C), CD138 (D), CD10 (E) and immunoglobulin light chain κ (F) (immunoperoxidase stain, original magnification $\times 400$); G: Nuclear proliferation rate as assessed by Ki-67 staining was approximately 80% (immunoperoxidase stain, original magnification $\times 400$); H: Epstein-Barr virus (EBV)-encoded RNA *in situ* hybridization for EBV shows negative staining in the nucleus of these atypical cells (original magnification $\times 400$).

unique participant in the pathogenesis of PBL, especially in patients without HIV infection^[14]. Cases of HIV-negative PBL have been mostly described after solid organ transplantation, in association with steroid therapy for autoimmune disease and some other types of immunosuppression^[15,16]. The present patient was negative for HIV, and EBV infection was not detected by immunohistochemistry or *in situ* hybridization analysis, so an HBV infection and the history of radiotherapy probably

led to the iatrogenic immunocompromised state.

The pathological differential diagnosis of PBL in the present case mainly included poorly differentiated primary or metastatic carcinoma, malignant melanoma, gastrointestinal stromal tumor (GIST), diffuse large B-cell lymphoma (DLBCL), Burkitt's lymphoma, anaplastic large cell lymphoma (ALCL), and plasmacytoma^[3]. The characteristic morphology and immunophenotype of the tumor cells in conjunction with clinical features aid

in the differential diagnosis (Table 1). Poorly differentiated carcinoma may be differentiated from PBL according to its consistent immunological staining for cytokeratin. Malignant melanoma can be ruled out by using S-100 protein and HMB45. GIST is a common kind of mesenchymal tumor in the small intestine, usually characterized by expression of CD34 and CD117. In terms of negative expression for CD20 and morphological appearance, the present case of PBL can be clearly identified with other aggressive B-cell lymphomas, such as DLBCL and Burkitt's lymphoma. Histologically, the tumor resembled extranodal ALCL; however, tumor cells in ALCL are consistently immunoreactive for CD30 and usually immunoreactive for CD3 and ALK, which is different from our case. The differential diagnosis between PBL and poorly differentiated plasmacytoma is based mostly on clinical correlations, as both have similar morphological and phenotypic features^[14]. The negative presence of serum monoclonal proteins and a high Ki-67/MIB-1 proliferation index help in the differential diagnosis from plasmacytoma in the present case.

In terms of clinical behavior, PBL is highly aggressive, with most of the patients dying in the first year after diagnosis. Most patients are at an advanced stage (III or IV) at presentation^[15]. HIV-positive and HIV-negative patients with PBL have different clinicopathological characteristics, including a better response to chemotherapy and longer survival in HIV-positive patients. HIV-negative patients had a median overall survival of 9 mo *vs* 14 mo in HIV-positive patients^[13]. Furthermore, extra-oral PBL is more commonly disseminated (57% of the patients are at stage IV) at diagnosis. Meanwhile, the loss of CD20 associated with plasmacytic differentiation and very high Ki-67 index (> 90%) conveyed a worse prognosis^[9]. In our case, the primary PBL of the small intestine had in-

filtrated multiple organs, accordingly a clinical stage IV was assigned. The HIV-negative state, extra-oral location, absent expression of CD20 and relatively high nuclear proliferation index in tumor cells collectively contributed to the more aggressive clinical course and worse outcome of this case.

In summary, we report a rare case of extra-oral PBL involving the small intestine in a HIV-negative patient, and describe the histologic and immunophenotypic findings. A diffuse infiltrative growth, rapid mitotic rate, and necrosis are consistent with the classification of PBL as a high-grade malignant lymphoma. Because PBL does not express the more common lymphoid and/or B-cell markers, it is easy to mistake them for a poorly differentiated carcinoma or sarcoma. Thus, diagnosis of PBL is challenging, particularly when it arises in extraoral locations and in immunocompetent patients. Recognition of this entity by the pathologist and clinician is important in establishing the correct diagnosis and treatment of the patients.

Abstract

Neuroendocrine carcinoma (NEC) of the pancreas is rare. We report the case of a 34-year-old man with pancreatic NEC with soft tissue metastasis. The patient presented with right upper abdominal discomfort. Computed tomography revealed a low-density heterogeneous mass in the tail and body of the pancreas that encroached on the greater curvature of the stomach and spleen. We performed exploratory laparotomy and total pancreatectomy with splenectomy and total gastrectomy. Histopathological analysis showed spindle-shaped cells with scanty cytoplasm and hyperchromatic nuclei, confirming a primary pancreatic NEC. One month after the surgery, the patient experienced leg swelling. Positron emission tomography-computed tomography revealed high uptake of fludeoxyglucose in the left leg, and the leg was amputated. Histopathological analysis confirmed metastasis of pancreatic NEC. The patient was followed up and received chemotherapy (etoposide and cisplatin). One month after amputation, the level of tumor marker neuron-specific enolase was 142.70 $\mu\text{g/L}$ and computed tomography scan revealed an aggravated metastatic lesion. The patient suffered from unbearable

pain and we treated him with odynolysis. Four months postoperatively, the patient died of respiratory failure.

INTRODUCTION

Primary neuroendocrine carcinoma (NEC) of the pancreas is very rare, accounting for only 1%-1.4% of all pancreatic cancers^[1,2]. Almost all NECs of the pancreas are discovered when the tumor is fairly large (mean: 6.2 cm, range: 2.5-20 cm) and it has metastasized to several distant organs such as the liver, adrenal gland, and brain, which explains the dismal prognosis^[3]. We report a rare route of metastasis in this case.

CASE REPORT

We report a case of pancreatic NEC with soft tissue metastasis. The patient was a 34-year-old man who had no significant past medical history. He visited our hospital on January 1, 2012 with the symptom of right upper abdominal discomfort. A computed tomography (CT) scan revealed a low-density heterogeneous mass of 81

Figure 1 A computed tomography scan revealed a low-density heterogeneous mass of 81 mm × 68 mm in size in the tail of the pancreas (arrow) that invaded the greater curvature of the stomach and the spleen.

Figure 2 Pathology of the pancreas. A: Spindle-shaped cells with scanty cytoplasm and hyperchromatic nuclei (hematoxylin and eosin staining); B: Positively stained for chlorhexidine A; C: Approximately 80% of the tumor cells were positively stained for Ki67; D: Tumor cells were positively stained for synaptophysin (B, C and D: EnVision) (original magnification: ×200 and ×400).

mm × 68 mm in size in the tail and body of the pancreas that invaded the greater curvature of the stomach and the spleen (Figure 1). The laboratory findings were as follows: hemoglobin, 102 g/L; white blood cell count, 6.5×10^9 /L; platelets, 374×10^9 /L; aspartate aminotransferase, 18 U/L; alanine aminotransferase, 13 U/L; total bilirubin, 9.1 μ mol/L; direct bilirubin, 4.0 μ mol/L; serum creatinine, 59 μ mol/L; carcinoembryonic antigen, 0.86 ng/mL (normal, < 10.0 ng/mL); alpha-fetoprotein, 2.37 ng/mL (normal, < 13.40 ng/mL); and carbohydrate antigen 19-9, 101.7 U/mL (normal, < 27 U/mL). The serum neuron-specific enolase (NSE) level was 59.94 μ g/L (normal, < 17 μ g/L). Chest X-ray examination revealed no signs of primary lung cancer or metastasis. In addition, there was no evidence of liver metastasis; therefore, exploratory laparotomy was performed. During the abdominal exploration, a 1-cm mass was detected in the head of the pancreas, and an 8-cm mass was de-

tected in the pancreatic tail. The identified mass invaded the greater curvature of the stomach and the spleen. Consequently, we performed total pancreatectomy with splenectomy and total gastrectomy.

Histological examination revealed spindle-shaped cells with scanty cytoplasm and hyperchromatic nuclei. In addition, 9/12 lymph nodes were positive for metastasis. Hematoxylin and eosin staining (Figure 2) was performed on the paraffin-embedded sections. Immunohistochemical examination revealed chromogranin A and Ki-67 positivity.

One month after surgery, the patient exhibited leg swelling. Positron emission tomography-CT revealed high fludeoxyglucose uptake in the left leg and the relapse of carcinoma in both hila of the lungs (Figure 3). An orthopedist obtained a biopsy of the left leg, and the frozen section results indicated NEC. Therefore, the left leg of the patient was amputated below the knee. The

Figure 3 Positron emission tomography-computed tomography revealed high fludeoxyglucose uptake in the left leg and the relapse of carcinoma in both hila of the lungs.

Figure 4 Pathology of the leg. A: Tumor cells displayed infiltrative growth in the striated muscle of the left leg [hematoxylin and eosin (HE) staining, original magnification: ×100]; B: Tumor cells were homogeneous (HE staining, original magnification: ×400); C: Tumor cells were positively stained for synaptophysin (EnVision, original magnification: ×400).

postoperative pathology of the left leg was metastatic NEC of the pancreas (Figure 4). The patient was followed up, and he received chemotherapy consisting of etoposide and cisplatin.

One month after amputation, the level of the tumor marker NSE was 142.70 µg/L, and a CT scan revealed an aggravated metastatic lesion. The patient reported unbearable pain, and he was treated by odynolysis. Four months postoperatively, he died of respiratory failure.

DISCUSSION

In a review of all published cases of pancreatic NEC, 91% of patients had metastases at the time of the initial diagnosis. According to the report by Vos *et al*^[4], the most common sites of metastasis are the peripancreatic lymph nodes (62%), liver (38%), lungs (14%), bone marrow (14%), bone (10%), colon (10%), and adrenal gland (10%); rarer sites of metastasis include the spleen, gallbladder, kidneys, skin, and brain.

NSE can be considered a tumor marker that can be used in the diagnosis or assessment of treatment efficacy in patients with pancreatic NEC^[5,6]. In our case, NSE was continuously aggravated.

Pancreatic NEC is a rare type of pancreatic cancer that has a poor prognosis^[7]. The clinical course is typically aggressive, often characterized by disseminated disease at presentation and poor survival. In patients with

extensive disease, a median survival as short as 2 mo has been reported, whereas in patients with limited disease, a median survival of up to 34 mo has been described^[8]. Min Sung Chung reported a case of primary pancreatic NEC with unusually long-term survival after multimodal therapy. This patient remains in good health 36 mo after surgery^[9]. In our case, the tumor extended beyond the pancreas with regional lymph node involvement. Because there was extension beyond the locoregional boundaries (extensive disease), we could perform palliative surgery. The patient in our case survived 4 mo on combined chemotherapy.

Some trials have revealed improved oncologic outcomes when patients are treated with regimens similar to those used for small cell cancers of the lungs^[10]. The regimen of cisplatin, etoposide, and radiation is generally favored for pancreatic NEC^[11]. This is the first reported case of pancreatic NEC with soft tissue metastasis. As mentioned previously, pancreatic NEC is a rare type of pancreatic cancer that has a poor prognosis. These adjuvant approaches should be considered in addition to surgery.

Abstract

Sister Mary Joseph's nodule (SMJN) refers to a metastatic tumor of the umbilicus. It is a rare entity which arises from a malignancy in the intra-abdominal cavity. We herein describe a patient who presented with SMJN as his first sign of pancreatic cancer. It is an even more unusual case of SMJN. We therefore, suggest that pancreatic cancer should be included in the differential diagnosis when an umbilical mass is found. With the progress made in surgical procedures and other modalities, an early diagnosis will dramatically improve the prognosis of the patients.

INTRODUCTION

Umbilical tumors are rare and 30% of them are metastatic^[1]. Sister Mary Joseph's nodule (SMJN) refers to a metastatic lesion of the umbilicus originating from intra-abdominal or pelvic malignant diseases. The most common primary sites of the metastasis are stomach, ovaries, colon, rectum and pancreas. Pancreas accounts for 7%-9% of the SMJN cases^[2]. Almost 90% of the cases arise from the body and tail of the pancreas, but not the head^[2].

We herein describe a male patient with pancreatic cancer who presented with SMJN as his first clinical sign. We also reviewed the published literatures on this disease from PubMed. Only 20 cases (including our case) of SMJN with pancreatic cancer as the first symptom and sign have been reported in English. The aim of this report is to provide new insight into the identification of pancreatic cancer presenting as SMJN.

CASE REPORT

The patient is a 40-year-old man who presented with

Figure 1 Appearance and pathology of umbilical tumor. A: A red nodule without ulcer appears in the umbilical region; B: Hematoxylin and eosin stain shows adenocarcinoma cell infiltration ($\times 40$).

Figure 2 Abdominal contrast-enhanced multi-detector computed tomography scan. A: A mass in the neck of pancreas (arrow) is shown in arterial phase; B: The mass in venous phase.

Figure 3 Positron emission tomography-computed tomography showed increased fludeoxyglucose uptake of tumors. A: Significant enhanced signal showing increased fludeoxyglucose (FDG) uptake at the site of pancreatic mass; B: Increased FDG uptake at the site of umbilical nodule.

swelling, redness and induration at umbilicus. The patient was first diagnosed with eczema at a local hospital and was treated without improvement. After six months, the patient consulted a dermatologist at our hospital. Physical examination showed an inflamed umbilicus with a nodule of 2 cm \times 1.5 cm without ulcer (Figure 1A). An umbilical skin biopsy was taken and sent for pathologic examination. The pathology was suggestive of adenocarcinoma infiltrating dermis and epidermis (Figure 1B). Immunohistochemistry (IHC) showed cytokeratin (CK) (AE1/AE3) +++, carcinoembryonic antigen +++, and CK7 +. A metastatic adenocarcinoma was suspected based on all these findings.

Serum marker of carbohydrate antigen 19-9 (CA19-9) was elevated (202.1 U/mL). Other tumor markers were all in the normal range. An abdominal multi-detector

computed tomography (MDCT) revealed a tumor at the neck of the pancreas with retroperitoneal lymph nodes enlargement as well as an umbilical soft tissue mass (Figure 2). An abdominal computed tomography (CT) angiography also showed involvement of retroperitoneal lymph nodes, superior mesenteric artery and vein, celiac trunk, proximal splenic artery, splenic vein and part of portal vein. A fluorodeoxyglucose (FDG) positron emission tomography-CT (PET-CT) scan demonstrated a mass located at the neck and body of pancreas with increased FDG uptake, with a maximal standardized uptake value (SUV) of 3.69, and thus malignancy was suspected. The umbilical mass with a maximal SUV of 2.85 was also detected and a metastatic malignancy was diagnosed by PET-CT (Figure 3).

Preoperative abdominal CT angiography showed the

tumor encasing celiac trunk and superior mesenteric artery, which, however, did not cause the occlusion or the stricture of these arteries. According to our previous experience, the patient may still have a chance of resection. An exploratory laparotomy was then performed. Mild abdominal ascites was present. A hard mass of 8 cm at the neck and body of pancreas was discovered, with invasion of celiac trunk, superior mesenteric artery, superior mesenteric vein and portal vein. Several enlarged mesenteric lymph nodes and an umbilical mass of 2 cm × 1.5 cm as well as tiny diffused seeding nodules were observed. Diaphragmatic tumor invasion was visible. A biopsy was taken and a frozen section was sent for pathology. Adenocarcinoma infiltrating the striated diaphragmatic muscle tissues was confirmed. Surgical resection was abandoned because of distant metastasis of the cancer. The patient refused chemotherapy, and died four months later.

DISCUSSION

When a clinician observes an umbilical mass, his/her differential diagnosis should include both benign and malignant tumors. Benign tumors can be caused by a number of factors, including polyps, papilloma, myoma, fibroma, hemangioma, dermoid cyst, teratoma, pyogenic granuloma, omphalith, or endometriosis^[1]. Malignant lesions account for 38% of all umbilical tumors, including both primary and secondary cancers^[1]. These can be differentiated by means of biopsy collection and histopathological examination^[3]. Cytology can not distinguish between primary and secondary malignancies^[4].

The incidence of metastatic tumor originating from intra-abdominal malignancy to the umbilicus (SMJN) is very low. The most common primary sites of SMJN in men are stomach, followed by colon, rectum, pancreas and others^[3]. In women, the most common origins are the ovaries, followed by stomach, colon, rectum, pancreas and others^[2]. Pancreas is the fourth or fifth most common primary site of SMJN. The percentage of SMJN arising from pancreas ranges from 7% to 9%, among which SMJN presenting as the first sign of pancreatic cancer is even unusual^[2,5]. To our knowledge after literature review, only 20 such cases, including our case, have been reported in English^[6-11].

The metastatic routes of the pancreatic cancer to the umbilicus are thought to be by direct invasion from the peritoneum, through lymphatic or blood vessels and along embryonic remnants^[6]. Generally, the prognosis of pancreatic cancer with SMJN is poor. The mean survival is 6-11 mo^[6]. However, with early diagnosis and surgical intervention, a prolonged survival of 18 years was reported^[6]. Currently, with the improvement of surgery, the resection rate of advanced pancreatic cancer has been increased. Moreover, with advances made in multidisciplinary therapeutic modalities including chemotherapy, radiotherapy, targeted molecular therapy, immunotherapy, and others, the survival of the patients has

also been improved.

It has been reported that resection of SMJN and the primary cancer of pancreas combined with other therapeutic modalities has improved the prognosis of the patients^[9]. Therefore, an appropriate diagnostic algorithm is very important for early detection and rational treatment.

As mentioned above, for patients with umbilical nodules as the first clinical manifestation, biopsy should be performed first if the diagnosis is uncertain^[3,4]. Almost all the cases of SMJN from pancreatic cancer reported in the literature are adenocarcinomas^[4]. IHC staining for CK 7 and 19 are very important in diagnosing adenocarcinomas of pancreas^[5]. Serum tumor markers such as CA19-9 should be examined and elevation of CA19-9 is considered as a strong evidence of the disease. Once SMJN deriving from pancreatic cancer is suspected, contrast-enhanced MDCT or magnetic resonance imaging (MRI) on pancreas should be done. Contrast-enhanced MDCT or MRI is sensitive enough to display the pancreas mass and its involvement in the adjacent organs and vessels. PET-CT is also recommended to detect other distant metastasis^[12,13]. However, PET-CT is not sensitive to the identification of tiny seeding nodules in the intra-abdominal cavity. As in this case, PET-CT failed to display intra-abdominal diffusion.

An earlier diagnosis could have caught the tumor in its early phase, hence improving the prognosis of the patient. This paper is to remind physicians and surgeons of the importance of keeping in mind pancreatic cancer as one of their initial differential diagnosis when an umbilical nodule is presented. The recommended diagnostic algorithm is hopefully useful for the early detection of pancreatic cancer which appears as SMJN as its first sign.

Abstract

Malakoplakia is a rare granulomatous disease probably caused by infection and characterized histologically by Michaelis-Gutmann bodies. We report a more rarely seen case esophageal malakoplakia in a 54-year-old woman. She presented with coughing while eating and drinking. Gastroscopy showed yellow nodules in the esophagus, and endoscopic ultrasonography showed a space-occupying lesion in the substratum of the esophageal mucosa. All findings highly resembled esophageal cancer. Histopathological examination finally identified this space-occupying lesion as malakoplakia and not cancer. Immunohistochemistry showed that she had human papillomavirus (HPV) infection in the esophagus, which indicates that infection was responsible for the malakoplakia. This is believed to be the first case of malakoplakia in the esophagus, and more importantly, we established that HPV infection was the initiator of esophageal malakoplakia.

INTRODUCTION

Malakoplakia is a rare granulomatous disease that was first described by Michaelis and Gutmann^[1] in 1902, and is characterized by Michaelis-Gutmann bodies with cytoplasmic concentric laminated inclusions^[2,3]. Malakoplakia most frequently involves the urinary tract, and less frequently, the gastrointestinal tract^[4], and the esophagus is seldom involved. We report a case of esophageal malakoplakia in a 54-year-old woman.

CASE REPORT

Clinical findings

A 54-year-old woman was referred to the gastroenterology department with complaints of coughing while eating and drinking. Her past medical history included chronic atrophic gastritis, duodenitis and rheumatoid arthritis.

On clinical examination she was pale. Her chest X-ray, electrocardiogram, blood tests and serum α -fetoprotein results were normal. Gastroscopy showed soft yellow nodules in the right wall of the esophagus, which was 23.5-25.0 cm from the cutting tooth (Figure 1A). Endoscopic ultrasonography revealed a space-occupying lesion (8.1 mm \times 5.1 mm) in the substratum of the esophageal mucosa (Figure 1B). ¹⁴C-Urea breath tests were positive for *Helicobacter pylori* (*H. pylori*).

Figure 1 Soft yellow nodules protruding into the esophageal cavity. A: Gastroscopy presentation: soft yellow nodules protruding into the esophageal cavity; B: Endoscopic ultrasonography: a space-occupying lesion (8.1 mm × 5.1 mm) in the substratum sized 8.1 mm × 5.1 mm (dotted lines).

Figure 2 Michaelis-Gutmann bodies. A: Basophilic laminated inclusions in the cytoplasm (hematoxylin and eosin, ×200); B: Periodic acid-Schiff: targetoid appearance with a dense central core (×400); C: CD68 positivity by immunohistochemistry (×400); D: Esophageal squamous epithelium positive for human papillomavirus by immunohistochemistry, halo-shaped cells (×200).

Pathological findings

A local specimen of 1 cm × 1 cm was excision under gastroscopy for histopathological examination. Microscopic examination of hematoxylin and eosin stained sections showed a large amount of inflammatory cell infiltration in the substratum of the esophageal mucosa, mainly with lymphoid and histiocytic cells (Figure 2A). The presence of Michaelis-Gutmann bodies, with cytoplasmic concentric laminated inclusions of 5-15 mm confirmed the diagnosis. Follow-up examination supported this diagnosis. The Michaelis-Gutmann bodies were periodic acid-Schiff-positive (Figure 2B), and CD68-positive (Figure 2C) and human papillomavirus (HPV)-positive (Figure 2D) by immunohistochemistry, but negative for Eumycetes by hexamethylene diamine staining and *H. pylori* by Giemsa staining.

DISCUSSION

Malakoplakia is a chronic granulomatous inflammatory

disease characterized by accumulation of granular basophilic Michaelis-Gutmann bodies. These bodies are generated from histiocytes, which are positive for CD68 antibodies, as well as positive for periodic acid-Schiff stain, and exhibit a targetoid appearance with a dense central core under light microscopy^[4].

Malakoplakia has a worldwide distribution and does not have any racial, sex or age predilection^[5]. Malakoplakia most commonly affects the urinary tract, as well as the gastrointestinal system, regional lymph nodes, skin, liver, and spleen^[6-9].

The mechanism of malakoplakia is not well understood. Three postulates have been suggested. The first considers that microorganisms play a role in the pathogenesis. *Escherichia coli* infection is often found in the urinary tract^[10], *Rhodococcus equi* in the lungs^[11], and *H. pylori* in the stomach^[12]. However, there have been no previous reports of microbial infection in the esophagus. In the present case, HPV infection was identified by immunohistochemistry. We consider that HPV infection plays an important

role in development of esophageal malakoplakia. Another possibility is that abnormal immune responses are involved in the pathogenesis^[13]. Some immunosuppressive or chronic prolonged illnesses such as organ transplantation, acquired immunodeficiency syndrome, tuberculosis, sarcoidosis, and malignancy^[14] can be associated with malakoplakia. The woman in this case report suffered from rheumatoid arthritis whose pathogenesis is considered to be related to an abnormal immune response, which we consider may also have been related to her malakoplakia. The third hypothesis is an abnormal macrophage response caused by defective lysosomal function. This results in macrophages being unable to digest fully the phagocytosed bacteria, accumulation of partially digested bacteria, and generation of Michaelis-Gutmann bodies.

Malakoplakia typical presents as irregular nodules or plaque, but it also exists as widespread mucosal multinodular or polypoid lesions, or large mass lesions under endoscopy. In the present case, it presented as endoscopic nodules.

The clinical appearance of malakoplakia varies from silent nodules to various different presentations according to the organ involved. In the urinary tract it presents with lower tract irritative symptoms such as frequency, dysuria and hematuria^[15]. In the gastrointestinal system it can be clinically silent or can cause clinical symptoms such as diarrhea, abdominal pain, hemorrhage, or obstruction^[16,17]. In the respiratory system it can appear as silent nodules that mimic bronchogenic carcinoma or tuberculosis^[11]. Malakoplakia of the female genital tract usually presents with vaginal bleeding^[18]. In the present case, the patient presented with coughing while eating and drinking, which resembled esophageal cancer.

Malakoplakia is generally considered a chronic, self-limiting inflammatory disease that may undergo spontaneous regression^[19]. In the present case, despite the patient rejecting further treatment after receiving the pathological report, her symptoms disappeared and her condition did not develop. Follow-up endoscopic examinations 12 mo after resection revealed no changes in the patient's condition.

There are two therapeutic approaches to malakoplakia. Most cases have been successfully treated with antibiotics, for example, rifampicin, quinolone, and trimethoprim-sulfamethoxazole. The second approach is to attempt to correct the lysosomal defect by a cholinergic agonist, bethanechol chloride. Combination of antibiotic therapy and surgery provides satisfactory results. However, unnecessary radical surgical treatment should be avoided. The best choice depends on each specific patient. Our patient appeared to be cured by resection of the malakoplakia and showed no development during 1-year follow-up.

Acknowledgments to reviewers of World Journal of Gastroenterology

We acknowledge our sincere thanks to our reviewers. Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of our World Series Journals. Both the editors of the journals and authors of the manuscripts submitted to the journals are grateful to the following reviewers for reviewing the articles (either published or rejected) over the past period of time.

Elfriede Bollschweiler, Professor, Department of Surgery, University of Cologne, Kerpener Straße 62, 50935 Köln, Germany

Guang-Wen Cao, MD, PhD, Professor and Chairman, Department of Epidemiology, The Second Military Medical University, 800 Xiangyin Road, Shanghai 200433, China

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 ± 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

The gut flora plays an important role in the pathogenesis of the complications of cirrhosis. Hepatic encephalopathy (HE) represents a broad continuum of neuropsychological dysfunction in patients with acute or chronic liver disease and/or porto-systemic shunting of blood flow and it manifests with progressive deterioration of the superior neurological functions. The pathophysiology of this disease is complex, as it involves overproduction and reduced metabolism of various neurotoxins, particularly ammonia. Management of HE is diversified and requires several steps: elimination of precipitating factors, removal of toxins, proper nutritional support, modulation of resident fecal flora and downregulation of systemic and gut-derived inflammation. This review will provide an overview of gut barrier function and the influence of gut-derived factors on HE, focusing on the role of gut microbiota in the pathogenesis of HE and the recent literature findings on its therapeutic manipulation.

INTRODUCTION

Humans have been proposed to be a “meta-organisms” consisting of a huge number of bacterial cells that are metabolically and immunologically integrated with somatic cells^[1]. This interaction is especially important in the gastrointestinal tract, where the commensal bacteria, known as intestinal microbiota, are an integral component of human gut physiology and, together with the intestinal mucosa, form an important barrier against pathogens. Gut homeostasis and physiology are closely linked to the liver since it receives the intestinal blood content through the portal system and influences intestinal functions through bile secretion into the lumen^[2]. Thus, alterations of gut barrier seem to play an important role in the pathogenesis and progression of liver damage^[3]. Understanding of both partners in this normal gut-liver interaction is critical to the development of new therapeutic modalities to treat or prevent liver disease and its complications. This review will provide an overview of gut barrier function and the influence of gut-derived factors on hepatic encephalopathy (HE), fo-

cusing on the role of gut microbiota in the pathogenesis of HE and the recent literature findings on its therapeutic manipulation.

HOST-MICROBIOTA CROSS-TALK

The human intestine provides residence to more than 10^{14} bacteria, a number which is 10 times the number of somatic cells in the human body^[4,5]. Microorganisms start colonizing the gut immediately after birth and are characterized by a succession of different population until a stable, adult microbiota has been established. In this bacterial community anaerobes are more abundant than aerobes and the majority of the species are from the genera *Bacteroidetes* and *Firmicutes*^[6]. Bacterial density and types differ substantially from lower small intestine to distal colon, and are regulated by physiological conditions. The specific populations also vary among individuals and in the same individual during periods of illness or dietary changes^[7]. Microarray analysis of intestinal transcriptional responses and molecular taxonomic methodologies have greatly increased our understanding of the gut microbiota composition, activities and functions^[1,8,9]. In a healthy individual the host/microbiota relationship is characterized by a homeostatic symbiosis, in which the host provides nutrients and a stable environment and, in turn, the microbiota ensures optimal epithelial functioning.

GUT-LIVER AXIS

Receiving most of its blood supply from the intestine through the portal circulation, the liver is exposed to gut-derived toxins, including bacteria and bacterial products, and must be prepared to react against these potential systemic pathogens. For this purpose it contains a large number of resident immune cells including macrophages, dendritic cells, lymphocytes, natural killer cells. These cells act together with other non-parenchymal cells like endothelial and stellate cells to produce an organized response to these potentially highly inflammatory factors^[10,11]. The role of immune cells during inflammatory response or chronic liver injury and the potential impact of gut-derived toxins on these processes have been extensively studied^[2]. In particular bacterial overgrowth and altered intestinal permeability result in high plasmatic levels of bacterial endotoxins, such as lipopolysaccharide (LPS), peptidoglycan, and various lipopeptides also termed pathogen-associated molecular patterns. Endotoxemia could be responsible for initiation of the liver damage, through its interaction with specific recognition receptors, the toll like receptors on the surface of immune cells. These receptors contribute to adaptive immune response and regulation of inflammation and represent a link between intestinal flora changes, endotoxemia, and liver damage^[12]. Liver cirrhosis is characterized by several abnormalities of both the systemic and local immune systems and in particular by

reduced phagocytic activity of Kupffer cells^[13]. A great deal of evidence indicates that patients with cirrhosis could present increased intestinal permeability^[14]. This is related to structural changes that occur in the presence of portal hypertension and hypertensive enteropathy: an altered oxide-reductive state with consequent oxidative damage of the brush border membrane and the overproduction of nitric oxide resulting in tight junctions expansion and cytoskeleton destruction^[15]. Altered intestinal permeability, together with bacterial overgrowth and immune dysfunction are associated with the migration of bacteria or their products from the gut to mesenteric lymph nodes or to other organs, a process known as bacterial translocation (BT). This phenomenon, in association with the presence of vascular shunts, is responsible for increased circulating levels of LPS. Blood concentration of bacterial endotoxin directly correlates with the severity of liver disease and participates in the initiation of a complex series of mechanisms that lead to the development of cirrhosis complications^[16]. In particular, the main consequences of portal hypertension and BT are the occurrence of infections and HE.

Bacterial infections are present in about 15%-47% of patients with liver cirrhosis and are especially related to Gram-negative bacteria. The most frequent are spontaneous bacterial peritonitis (SBP), urinary tract infections, pneumonia, pleural empyema and sepsis. It has been shown that patients with SBP have a higher prevalence of small intestinal bacterial overgrowth (SIBO)^[17] and altered intestinal permeability^[18] than patients without SBP. Ammonia and other toxic substances derived from the gut, in the presence of portal and systemic shunts as well as of reduced liver clearance capability, represent the pathogenic mechanisms of HE as described in the following paragraph.

GUT MICROBIOTA AND HE

HE is a reversible neuropsychiatric disorder associated with liver dysfunction after exclusion of other potential causes of brain disease^[19] and is characterized by poor survival^[20]. Main features are disturbances in cognitive function, personality and behaviour with a wide spectrum of neuropsychiatric abnormalities that range from mild impairment of cognitive function and consciousness to coma. There are two types of HE named overt and minimal HE (OHE, MHE). The first is present in 30%-45% of patients with cirrhosis and in 10%-50% of patients with transjugular intrahepatic portosystemic shunt^[21]. OHE can be diagnosed clinically through a constellation of signs and symptoms by several scoring systems^[22]. The most widely used are the West-Haven criteria (Table 1) which are based on neurological examination and specific questionnaires to detect mental status changes. In addition, OHE can be further divided into episodic or persistent depending on time course and clinical behaviour: episodic HE remains below the clinical detection level among different episodes, whereas

Table 1 West-Haven criteria for hepatic encephalopathy

Stage	Consciousness	Intellect and behaviour	Neurological findings
0	Normal	Normal	Normal examination ¹
1	Trivial lack of awareness	Impaired attention span; altered sleep; euphoria	Mild asterixis
2	Lethargic	Disoriented; inappropriate behaviour depression	Asterixis; slurred speech
3	Somnolent but arousable	Gross disorientation; bizarre behaviour	Muscular rigidity/clonus hyper-reflexia
4	Coma	Coma	Decerebrate posturing

¹If impaired psychomotor testing, then minimal hepatic encephalopathy.

Figure 1 Pathophysiology of hepatic encephalopathy in liver cirrhosis. GABA: γ -aminobutyric acid.

persistent HE is always clinically evident^[23]. Prevalence for MHE ranges from 30% up to 80%, probably because there is still no accepted gold standard for diagnosis of MHE and the majority of the screening tests are time-consuming and cumbersome to perform^[23,24]. It is characterized by alterations of psychometric and neurophysiological tests in otherwise asymptomatic patients^[25]. This condition is considered a preclinical stage of OHE and is associated with poor quality of life, high risk of traffic violations and accidents and increased progression to OHE^[26-28]. The diagnosis of MHE aims to detect attention deficits and processing speed and is based on different batteries of tests. Among them, the portal systemic encephalopathy (PSE) syndrome test, that includes number connection test A (NCT A), number connection test B (NCT B), line tracing test errors and time, serial dotting test and digit symbol test, has been validated in different countries and is recommended by

the Working Group on HE^[29]. Although the pathogenesis of this disorder is not well understood, a key role is played by circulating gut derived toxins of the nitrogenous compounds with a resultant neuroglial injury in the setting of a systemic inflammatory milieu (Figure 1). In particular, the currently accepted hypothesis is that endogenous neurotoxic substances escape from catabolism by the liver, due both to the impaired function of the cirrhotic liver and to the presence of portal-systemic shunts. These substances circulate in the systemic blood flow, reach the brain through the blood-brain barrier and results in different severity of cerebral impairment^[30]. Several factors have been shown to precipitate HE, including gastrointestinal bleeding, electrolyte imbalances, infection, and medications such as sedatives and diuretics. They work by increasing the underlying inflammatory milieu, increasing toxins production or reducing the threshold for mental status decline, or a combination of

the above. Ammonia, mercaptans, phenols, short and medium-chain fatty acids and benzodiazepine-like compounds have all been found to be elevated in cirrhotic patients with HE. The majority of these toxic substances are produced in the intestine by the bacterial flora, and are absorbed into the portal venous flow. Thus, gut microflora contribute to the pro-inflammatory state of cirrhosis even in the absence of overt infection^[31]. In addition, cirrhotic patients have a substantial alteration of the gut microecology with a high prevalence of SIBO and delayed oro-cecal transit time (OCTT)^[17,32-36]. The latter has a multifactorial etiology. First, it could be due to the presence of autonomic neuropathy that has been demonstrated as an independent predictor of reduced intestinal motility in this kind of patients^[37]. Moreover, patients with autonomic dysfunction were found to have a higher incidence of new onset of HE^[38]. Second, a delayed OCTT may be associated with metabolic alterations that occur in patients with portal hypertension and portal-systemic venous shunting. Finally, SIBO itself may lead to delayed OCTT since it has been shown a significant improvement of intestinal motility after antibiotic therapy^[36]. There might be also a link between the cognitive impairment in cirrhosis with inflammation and specific bacterial taxa. For example, recent evidence showed how interleukin (IL)-23 system and innate immune response were highly correlated with several bacterial families in patients with cirrhosis and HE, and how there was a direct correlation between cognition, Porphyromonadaceae and Alcaligenaceae families^[39]. Based on these considerations, the manipulation of gut flora could be useful in the treatment of HE.

MODULATION OF GUT MICROBIOTA FOR THE MANAGEMENT OF HE

Treatment goals and options are dependent on the stage and acuity of HE^[23]. Once the diagnosis of OHE is confirmed, an extensive search for potential precipitating factors should be instituted along with treatment of OHE. As previously described, the leading causes are gastrointestinal bleeding, sepsis, dehydration resulting from diuretics, diarrhoea or vomiting, transjugular intra hepatic porto systemic shunting, constipation and the use of sedative and narcotic drugs. Their treatment can reverse OHE in most cases. However, when it is not possible to identify a precipitating factor despite an exhaustive search, specific treatment for OHE should be instituted. Most therapies for HE focus on treating episodes as they occur and are directed at reducing the nitrogenous load in the gut, an approach that is consistent with the hypothesis that this disorder results from the systemic accumulation of gut-derived neurotoxins in patients with impaired liver function and portosystemic shunting^[40]. Therefore, the majority of therapeutic options currently in use are directed towards the gut. Prebiotics are non-digestible food ingredients that act by directly stimulating the growth of bacterial strains potentially beneficial to

the host like *Bifidobacteria* and *Lactobacilli*, thereby indirectly reducing the influence of potentially more harmful resident flora (i.e. urease-producing species). They come in the form of indigestible fibers and have shown benefit for the management of HE, particularly MHE, both as prebiotics and when used in combination with probiotics (in which case they are termed synbiotics)^[41,42]. Probiotics are living non pathogenic microorganisms that are thought to exert an effect in HE by reducing intestinal ammonia production by enterocyte glutaminase and reduce BT, modulate gut permeability and modulate pro-inflammatory responses. Furthermore, probiotics bypass the small bowel and get fermented by colonic bacteria to form lactic, acetic, and butyric acids, and gas (mainly hydrogen); any resultant prokinetic effect may increase the expulsion of ammoniagenic bacteria^[43]. Probiotics have been studied for the treatment of HE and have shown some benefit, mostly in the setting of minimal disease^[24,44,45]. The bacterial species that appear to be most successful include *Lactobacilli* and *Bifidobacteria*. Probiotics may also improve overall liver function, perhaps by reducing translocation and subsequent endotoxemia and by ameliorating the hyperdynamic circulation^[41]. To quantify unambiguously the beneficial and harmful effects of any probiotics at any dosage, a recent meta-analysis identified seven randomized trials for the treatment of acute or chronic HE. The authors of this Cochrane review assessed a range of outcomes including death, recovery, adverse events, and quality of life. There was no benefit of probiotics shown for any of the primary outcomes including mortality. On the other hand, there was a significant difference in secondary outcomes such as lowering of plasma ammonia concentration compared with no treatment. The authors concluded that this finding is of questionable importance, not recommending the use of probiotics for patients with HE until further randomized clinical trials are undertaken^[46]. Non-absorbable disaccharides, such as lactulose and lactilol, have traditionally been considered the first-line drug therapy for lowering the production and absorption of ammonia^[47]. These substances are metabolized by the intestinal bacteria to acetic and lactic acid. The consequent acidification of the colonic contents creates a hostile environment for the survival of intestinal bacteria involved in the production of ammonia and facilitates the conversion of NH₃ to non-absorbable NH₄⁺. Moreover, their cathartic effects cause an increased in faecal nitrogen excretion^[48]. The non-absorbable disaccharides have been used for decades with anecdotal and clinical trial experience^[49]. However, side effects of lactulose therapy, including cramping, diarrhoea and flatulence, result in frequent noncompliance^[40]. Overdosage may also result in severe diarrhoea, electrolyte disturbances and hypovolaemia that, if severe enough, may itself precipitate encephalopathy symptoms. In spite of their anecdotal usefulness, in the last years the true efficacy of the disaccharides for this indication has been questioned. As the use of lactulose pre dated randomized controlled trials, a comprehensive meta-analysis

endorsed by the Cochrane Collaboration did not find any significant difference in outcomes in patients treated with and without lactulose^[50]. Based on a critical analysis of available published literature, Als-Nielsen *et al.*^[50] concluded that the evidence in favour of utilizing non-absorbable disaccharides in HE did not meet the current minimum criteria for adequacy. In fact, although in some cases the administration of lactulose was associated with improvement in mental status, it is difficult to assess the reason for improvement since precipitating factors were simultaneously being corrected. On the other hand newer clinical studies suggest benefits with lactulose conferring improved neuropsychometric and quality of life scores^[47]. Also, two recently published meta-analysis on the clinical efficacy and safety of lactulose in patients with MHE, provide substantial evidence for the beneficial effects of non-absorbable disaccharides^[51,52]. Therefore, at the present time, there is a lack of sufficient evidence to completely dismiss the use of non-absorbable disaccharides for the treatment of HE, while compliance and cost effectiveness should be carefully balanced against clinical outcomes. Antimicrobial agents have long been utilized as an alternative treatment option for patients intolerant or unresponsive to non-absorbable disaccharides due to their ability to inhibit ammonia production by intestinal bacteria. Neomycin is the most commonly used antimicrobial for HE, but despite the legitimate theoretical rationale for its use, there is a paucity of clinical data to support this practice^[48,53]. Moreover, the occurrence of serious adverse effects such as nephrotoxicity and ototoxicity limit their use to relatively short periods of time. Other antimicrobials, including metronidazole and vancomycin, have been studied to a more limited extent than neomycin^[48]. However, long-term use of metronidazole has been associated with neurotoxicity in patients with cirrhosis, whereas the risk for enteric bacteria resistance preclude the routine use of vancomycin for HE. Thus, with the potential for serious adverse effects and the lack of demonstrated clinical benefit, the routine management of HE with conventional antibiotics should be questioned. Rifaximin is a poorly absorbed synthetic antibiotic with a broad spectrum of antibacterial activity, against aerobic and anaerobic Gram positive and Gram-negative organisms^[54]. As a derivative of rifamycin, it similarly works by blocking bacterial RNA synthesis. However, rifaximin has an additional pyridoimidazole ring that allows for high concentrations in the gastrointestinal tract and minimal systemic drug absorption.

Due to its low rate of systemic bioavailability, the safety profile of rifaximin appears to be superior to that of systemic antibiotics, particularly for patients with liver disease, making it suitable for long-term use. Moreover, the risk of bacterial resistance appears to be lower with rifaximin than with systemic antibiotics because bacteria outside the gastrointestinal tract are not exposed to appreciable selective pressure^[55]. The safety and efficacy profiles of rifaximin as treatment of overt HE have been extensively explored in several clinical trials^[48]. The results of controlled double-blind studies demonstrated

that rifaximin was more effective than non-absorbable disaccharides in the treatment of acute HE: mental state, electroencephalogram irregularities and PSE-index were all significantly improved in the rifaximin group^[56-59]. While rifaximin was well tolerated, adverse events, including flatulence, diarrhoea, nausea and anorexia, were reported by patients in the disaccharides group. A recent study found a reduced hospitalization rate during rifaximin therapy compared with that of lactulose^[60]. Once again, the HE grade was significantly lower and patients compliance was significantly higher in the rifaximin group. Further data suggest that rifaximin is at least as effective as neomycin in decreasing plasma ammonia levels and in improving the clinical symptoms related to HE with fewer clinically significant adverse events during a 21 d treatment period^[61]. Based on these findings, the Cochrane review recommends the use of rifaximin in the treatment of acute HE^[50]. Until recently, there has not been any conclusive evidence to support routine use of pharmacological prophylaxis to prevent future recurrence in patients who have recovered from an acute episode of HE. However, the prevention of episodes of HE is an important goal in the treatment of patients with liver disease, especially since symptoms of overt encephalopathy are debilitating and decrease the ability for self-care, leading to frequent hospitalizations, and a poor quality of life. A recent clinical trial has been conducted to evaluate the efficacy of rifaximin as secondary prophylaxis of overt HE^[62]. This double blind, placebo controlled, multicentre trial randomized 299 patients with a recent history of recurrent, overt HE to receive either rifaximin or placebo for a period of 6 months. The majority of the patients in both groups were also maintained on concomitant lactulose therapy. During the study period, an acute episode of HE occurred in a significantly lower percentage of patients in the rifaximin group (22.1%) than in the placebo group (45.9%), with a hazard ratio (HR) of 0.42.

Furthermore, there was a significantly reduced risk of hospitalization in the rifaximin group when compared with placebo: 13.6% *vs* 22.6% of patients respectively with a corresponding HR of 0.50. No significant difference in the incidence of adverse events was found between the two groups. The authors concluded that the addition of rifaximin to a standard lactulose regimen may offer advantages in terms of decreasing risk of both acute HE episodes as well as hospitalizations when compared with lactulose alone. Overall, this pivotal study expands previously reported findings of the efficacy of rifaximin in the treatment of overt HE and demonstrates a clinically relevant benefit of rifaximin as pharmacological prophylaxis of HE. The protective effect of rifaximin was confirmed by an extension trial performed on the same patients to assess the efficacy of rifaximin in maintaining remission over time^[63]. The results of this preliminary study support a possible long-term protective pharmacological effect. In addition, an ancillary analysis of data from the same trial to assess the effect of rifaximin on health-related quality of life

(measured *via* the Chronic Liver Disease Questionnaire) provided evidence that rifaximin improves perception of daily well being and quality of life outcomes in all domains adversely affected by underlying liver diseases^[64]. Therefore at this time, both lactulose and rifaximin can be used to prevent recurrent episodes of OHE. Ambivalence remains as concerning the treatment of MHE. It is clear that MHE has a major impact on quality of life and should be promptly diagnosed and treated. However, for many years, various treatment modalities including lactulose, probiotics and dietary manipulation, have been studied with unconvincing evidence. Limits on the use of antibiotics have been exceeded by the results of the randomised ischaemic mitral evaluation trial^[65], which showed unequivocally that rifaximin improves psychometric test performance scores as early as after 2 wk of treatment. The same patients experienced, also, a significant improvement in health related quality of life, which was strongly correlated with the improvement in cognitive functions. The authors speculated that there are two possible mechanisms by which rifaximin could lead to an improvement in MHE: first by reducing the ammonia-producing bacteria in the gut^[61], second by decreasing BT and inflammation.

The results of the RIME trial represent an important step in the establishment of rifaximin as an effective and safe treatment for MHE and are in agreement with the findings of a more recent study which demonstrates improved driving skills following rifaximin treatment in patients with MHE^[66]. In this double-blind placebo controlled trial, patients randomized to rifaximin had a significant reduction in the number of total driving errors, and specifically speeding tickets and illegal turns, on a driving simulator, compared with those on placebo. Driving requires balance and integration of different cognitive functions, such as attention, adequate reaction time, visuo-motor coordination and can be considered a practical interpretation of the cognitive domains affected in MHE^[67]. Since patients on rifaximin presented increased plasmatic levels of the anti-inflammatory cytokine IL-10, the authors speculated that rifaximin could act by regulating local intestinal immunity and inflammation. The same authors provide in another paper a cost effective analysis based on a Markov model of progression from cirrhosis without MHE, to MHE and to OHE focused on motor vehicle crashes as an objective endpoint. The results of this analysis indicate that diagnosis of MHE followed by lactulose therapy could result in substantial societal cost savings by preventing major motor vehicle crashes among MHE patients. In contrast, because of its high monthly cost, treatment with rifaximin is unlikely to generate overall cost savings unless the rifaximin monthly cost is substantially reduced^[68].

CONCLUSION

Different chronic liver diseases are associated with alterations of the intestinal microbiota, gut barrier dysfunction

and translocation of bacteria or bacteria-derived antigens into the systemic circulation. The same processes, in turn, exacerbate liver disease leading to enhanced tissue damage and development of complications such as systemic infections, phosphate buffered saline, hepato renal syndrome and portal-systemic encephalopathy. Modulation of the gut microbiota may represent a good therapeutic target for the prevention and treatment of different complications associated with liver cirrhosis. In particular, due to its low rate of systemic bioavailability and a good tolerability profile, the non-absorbable antibiotic rifaximin could be an 'ideal' antimicrobial for selective targeting at the gastrointestinal tract in this kind of patients. As reviewed, at present this antibiotic is recommended for the treatment of acute HE. Furthermore, recent literature appears to support a favourable benefit-risk ratio for rifaximin both in the prevention of overt HE and in the treatment of minimal HE.

However, additional high-quality clinical trials are needed to more clearly define the effectiveness of long-term or periodic treatment with rifaximin on gut microbiota modulation in cirrhotic patients with HE.

Abstract

Glycogenotic hepatocellular carcinoma (HCC) with glycogen-ground-glass hepatocytes has recently been described as an allegedly "novel variant" of HCC, but neither the historical background nor the heuristic relevance of this observation were put in perspective. In the present contribution, the most important findings in animal models and human beings related to the emergence and further evolution of excessively glycogen storing (glycogenotic) hepatocytes with and without ground glass features during neoplastic development have been summarized. Glycogenotic HCCs with glycogen-ground-glass hepatocytes represent highly differentiated neoplasms which contain subpopulations of cells phenotypically resembling those of certain types of preneoplastic hepatic foci and benign hepatocellular neoplasms. It is questionable whether the occurrence of glycogen-ground-glass hepatocytes in a glycogenotic HCC justifies its classification as a specific entity. The typical appearance of ground-glass hepatocytes is due to a hypertrophy of the smooth endoplasmic reticulum, which is usually associated with an excessive storage of glycogen and frequently also with an expression of the hepatitis B surface antigen. Sequential studies in animal models and observations in humans indicate that glycogen-ground-glass hepatocytes are a facultative, integral part of a characteristic cellular sequence commencing with focal hepatic glycogenosis potentially progressing to benign and malignant neoplasms. During this process highly differentiated glycogenotic

cells including ground-glass hepatocytes are gradually transformed *via* various intermediate stages into poorly differentiated glycogen-poor, basophilic (ribosome-rich) cancer cells. Histochemical, microbiological, and molecular biochemical studies on focal hepatic glycogenosis and advanced preneoplastic and neoplastic lesions in tissue sections and laser-dissected specimens in rat and mouse models have provided compelling evidence for an early insulinomimetic effect of oncogenic agents, which is followed by a fundamental metabolic switch from gluconeogenesis towards the pentose-phosphate pathway and the Warburg type of glycolysis during progression from preneoplastic hepatic glycogenosis to the highly proliferative malignant phenotype.

Glycogenotic hepatocellular carcinoma with glycogen-ground-glass hepatocytes: A heuristically highly relevant phenotype. *World J Gastroenterol* 2012; 18(46): 6701-6708 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i46/6701.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i46.6701>

INVITED COMMENTARY ON HOT ARTICLES

The glycogenotic hepatocellular carcinoma (glycogenotic

HCC) with glycogen-ground-glass hepatocytes has recently been described as a “novel variant” of HCC by Callea *et al*^[1]. Relating the excessive storage of glycogen (glycogenosis) to a complete absence of glucose-6-phosphatase activity as measured by a microbiobiochemical approach, the authors referred to the long known finding of a focal hepatic glycogenosis (FHG) as an early event in experimental hepatocarcinogenesis^[2], continuing “however, ground-glass cells have not been reported in FHG”. In contrast to this statement, the characteristic hepatocellular phenotype addressed was not only explicitly described for the first time in preneoplastic and neoplastic lesions in rodents^[3,4] and in humans^[5,6] (Figure 1) decades ago but has also been proven to be heuristically highly relevant in numerous publications since then. Glycogenotic ground-glass hepatocytes (GGH) predominate in subpopulations of many focal precancerous hepatocellular lesions, particularly in preneoplastic FHG and benign hepatocellular neoplasms such as hepatocellular adenomas and focal nodular hyperplasia, but may also occur in more or less extended subpopulations of HCC as observed in various species, including non-human primates and human beings^[7,8]. However, glycogen-GGH hardly ever account for whole neoplasms. This also applies to the glycogenotic HCC depicted by Callea *et al*^[1] in which the GGH are mixed with “clear” (glycogenotic) cells without ground-glass features. It is, hence, questionable whether glycogenotic HCC with glycogen-GGH should be considered a specific entity as proposed by Callea *et al*^[1]. Extensive investigations in models of chemical, viral, and hormonal hepatocarcinogenesis and some observations in humans suggest that FHG with and without GGH indicates a critical early metabolic aberration in the pathogenesis of benign and malignant hepatocellular neoplasms^[7,8].

Animal models of hepatocarcinogenesis

The observations in humans were preceded by several seminal findings in animal models of hepatocarcinogenesis as repeatedly reviewed^[2,9]. In their pioneering electron microscopic investigations in rats continuously exposed to 3-methyl-dimethylaminoazobenzene, Porter *et al*^[10] detected a hypertrophy of the smooth endoplasmic reticulum in many hepatocytes, and addressed its light microscopic counterpart as “hyaline degeneration”^[11]. The authors related this characteristic subcellular change to a decreased rather than an increased storage of glycogen and felt “that only cells which, through mutation, loose the normal tendency to differentiate for glycogenesis will survive and so will be selected out for continued growth and differentiation”^[10]. However, investigations in other models of rat hepatocarcinogenesis, employing both continuous or limited (stop model) exposure to N-nitrosomorpholine at various dose levels and time schedules^[3,4], or ethionine for up to approximately 20 wk^[12] revealed that hypertrophy of the smooth endoplasmic reticulum is often associated with an excessive storage of glycogen, the smooth membranes forming either a typical network or peculiar lamellar complexes which often

Figure 1 Light micrographs of portions from human hepatocellular neoplasms with and without glycogenosis. A: Clear-cell hepatocellular adenoma consisting predominantly of glycogenotic cells. In some cells (arrows) there is a reduction of glycogen and focal increase in cytoplasmic basophilia; B: Highly differentiated hepatocellular carcinoma (HCC) composed of a mixed population of clear (glycogenotic) cells, acidophilic cells (ground-glass hepatocytes, arrows), and some glycogen-poor, basophilic cells; C: Poorly differentiated, glycogen-free, basophilic HCC. All: Hematoxylin and eosin stain, x 460, from Bannasch *et al*^[6].

show a close spatial relationship with glycogen particles (Figure 2) but may also be free of glycogen forming “fingerprints”^[4]. Steiner *et al*^[12] designated the complexes of the smooth endoplasmic reticulum associated with glycogen as “glycogen-bodies”, and speculated that these formations indicate a “resistance” to the carcinogen, reflecting a reactivation of the glycogen-storing ability after an early loss of glycogen in response to toxicity. In contrast to both of these considerations, many studies on experimental hepatocarcinogenesis in different species revealed that FHG composed of glycogenotic clear and/or acidophilic cells, the latter showing a pronounced hypertrophy of the smooth endoplasmic reticulum (corresponding to glycogenotic GGH), regularly occur in a multi-centric fashion in early stages of neoplastic development induced in small rodents by a variety of chemicals^[3,4,9,13]. More recently, typical glycogenotic GGH were also found after chronic infection of woodchucks with hepadnaviridae^[14-16], in hepatitis B virus (HBV)-transgenic mice^[17], and during hormonal hepatocarcinogenesis in

Figure 2 Portion of a glycogenotic acidophilic hepatocyte (corresponding to glycogen-ground-glass hepatocyte) induced in rat liver by N-nitrosomorpholine. Note abundant α - and β -glycogen particles (G) in close spatial relationship with large network complexes of proliferated smooth endoplasmic reticulum (SER). diabetic animals after intrahepatic transplantation of pancreatic islets in rats and mice^[18,19].

As demonstrated particularly in stop models of hepatocarcinogenesis in rats exposed to N-nitrosomorpholine or thioacetamide, glycogenotic hepatocytes with and without hypertrophy of the smooth endoplasmic reticulum may persist for weeks and months after withdrawal of the carcinogen, and may persist as almost entire populations of hepatocellular adenomas (“hyperplastic nodules”, “neoplastic nodules”) and in subpopulations of highly differentiated HCCs^[4,20,21]. These observations are neither compatible with the idea of a preferential cellular survival by loss of differentiation for glycogenesis^[10] nor with the notion of a “resistance” of these cells to carcinogen^[12,22,23]. The functional significance of the persistent hypertrophy of the smooth endoplasmic reticulum has remained obscure, but many findings suggest that the organelle represents a metabolic compartment whose increase is a facultative consequence of the disturbed carbohydrate metabolism characterizing the acquired hepatocellular glycogenesis^[4,24].

Independent of the observation of an acquired FHG produced in rat liver by N-nitrosomorpholine^[5], Gössner *et al*^[25] described a focal reduction in the activity of glucose-6-phosphatase in rats exposed to N-nitrosodiethylamine. A causal relationship between this enzyme deficiency and the accumulation of glycogen in preneoplastic FHG and “hyperplastic liver nodules” has been suggested by a number of authors^[3,4,26,27]. This conclusion

appears to be supported by the well known high risk of children suffering from an inborn hepatic glycogenosis type I, especially type I a (von Gierke), due to a genetically fixed deficiency of the glucose-6-phosphatase, to develop hepatocellular adenomas and carcinomas when passing through adolescence^[2,9,28]. This interpretation is in line with the recent finding that the targeted deletion of liver glucose-6-phosphatase in a knock-out mouse model results in hepatic glycogenosis and steatosis, and eventually also in multiple hepatocellular adenomas in all animals beyond 18 mo of age^[29].

It is important to realize, however, that correlative cytochemical studies in rodent models of hepatocarcinogenesis have shown that the focal decrease of glucose-6-phosphatase activity in FHG is regularly combined with decrease or increase in the activity of many other enzymes^[7,8,30], especially enzymes of the carbohydrate metabolism^[2,24,31]. In addition, over-expression of the key enzyme of *de novo* fatty acid synthase has been described in FHG in the N-nitrosomorpholine stop-model^[32]. In rats exposed to N-2-fluorenylacetylamide, Williams *et al*^[33] demonstrated that the preneoplastic glycogenotic clear cell foci are resistant to the storage of iron.

For a long time the cause of these complex metabolic alterations in FHG remained elusive. More recently, however, histochemical, microbiological and molecular biochemical studies on FHG and advanced preneoplastic and neoplastic liver lesions in tissue sections and laser-dissected specimens obtained from small rodents exposed to chemical carcinogens or oncogenic viruses provided evidence for an early insulin-like (insulinomimetic) effect of these agents^[7,24,34-36]. This notion has been corroborated by a number of studies on hormonal hepatocarcinogenesis induced in diabetic rats and mice by local hyperinsulinemia^[18,19,32,37-39].

The phenotype of preneoplastic FHG is not stable, but undergoes dramatic changes during progression to the benign and/or malignant neoplastic phenotype^[3,4]. Collectively, all types of specific focal hepatocellular lesions appearing during the preneoplastic phase in rodents have been termed foci of altered hepatocytes, and have been widely used as early indicators of neoplastic development in toxicologic pathology^[40-42]. The characteristic sequence of cellular changes starting with FHG follows an ordered pattern, passing through intermediate or mixed cell foci composed of glycogenotic, intermediate, and glycogen-poor basophilic (ribosome-rich) cell types, the latter corresponding to the typical cell type in poorly differentiated HCCs^[2,4,24]. Detailed morphological analysis of intermediate cell types at the light- and electron microscopic level has suggested that the hypertrophied smooth endoplasmic reticulum is usually transformed into rough endoplasmic reticulum by the addition of ribosomes during this phenotypic conversion^[4,9,20]. Frequently, the intermediate cells show an accumulation of neutral fat, often leading to a combination of glycogenosis and steatosis^[2,20]. Evidence of this sequence of cellular changes was originally provided by light- and electron-microscopic studies in rats

exposed for the lifetime or for limited time periods to N-nitrosomorpholine^[3,4]. And it has since been substantiated by a series of morphometric studies^[43-45] and by similar observations in other rodent models of hepatocarcinogenesis elicited by several “genotoxic” and “non-genotoxic” chemicals^[7,41], by local hyperinsulinemia^[18], by hepadnaviridae^[14,15], and by oncogenic transgenes^[17,46]. Most recently, multiple FHG, more advanced types of foci of altered hepatocytes, hepatocellular adenomas and HCC indicative of such a sequence, including an intermediate steatosis, were also observed in a knock-out mouse model with a reduced expression of the mitochondrial protein frataxin, which is responsible for the inherited neurodegenerative disease Friedreich’s ataxia in humans^[47].

The conversion of the highly differentiated glycogenotic clear or acidophilic to the de-differentiated glycogen-poor, basophilic (ribosome-rich) phenotype is associated with a fundamental metabolic switch characterized by a reduction in gluconeogenesis, an activation of the pen-

tose phosphate pathway and the Warburg type of glycolysis as detailed elsewhere^[7,8,24], and by an ever increasing cell proliferation which is inversely related to the gradual reduction of the glycogen initially stored in excess^[48]. Based on these observations, Kopp-Schneider *et al*^[49] developed the so-called color-shift model of hepatocarcinogenesis considering epigenetic changes in parenchymal colonies rather than multiple successive genomic mutations in single cells as the main cause of neoplastic cell conversion induced in the liver by exogenous oncogenic agents. The importance of epigenetic events in chemical hepatocarcinogenesis has been discussed by several authors previously^[7,50], and has been emphasized in recent years by Pogribny *et al*^[51,52].

Human hepatocarcinogenesis

In human pathology, the predominance of clear (glycogenotic) cells (Figure 1A and B) in a minor proportion of HCCs^[6,53], comprising about 8% in 150 cases studied by Buchanan *et al*^[54], and in many hepatocellular adenomas^[6,53-56] is well known. A favorable prognosis of the clear-cell variant of HCC has been reported^[57]. Sasaki *et al*^[58] described two cases of clear-cell HCC associated with hypoglycemia and hypercholesterolemia, and postulated a disturbed glucose metabolism of the tumor tissue, directed to lipogenesis and/or glucogenesis. Acquired FHG has been considered a preneoplastic condition in humans^[6]. This idea was supported by the fortuitous observation of FHG (clear-cell foci) in HCC-bearing livers of children suffering from different disorders^[59,60], in women after long-term use of oral contraceptives^[61], in about 12% of 95 males studied in a consecutive autopsy series in Finland^[62], in patients with Crohn’s disease treated over years with azathioprine which is apparently also responsible for associated HCC development^[63-67], and in a variety of other chronic liver diseases prone to develop HCC^[8,24,53,68,69]. Special cases are patients with genetic hemochromatosis endowed with a high risk of developing HCC, which frequently show FHG excluding iron similar to the iron-resistant FHG observed in experimental hepatocarcinogenesis in rodents^[8,53,69-73].

Particularly relevant are systematic histochemical and histological investigations on the phenotype and proliferation kinetics of foci and nodules of altered hepatocytes in more than 150 explanted and resected human livers with and without HCC^[68,74,75]. The results suggest that foci of altered hepatocytes are proliferative preneoplastic lesions, mixed cell foci (frequently with “small cell change”) being more advanced than FHG (Figure 3), potentially transforming into nodules of altered hepatocytes, highly differentiated HCC containing glycogenotic clear and ground-glass hepatocytes (Figure 4), and eventually also glycogen-poor, basophilic HCC (Figure 1C)^[68]. In keeping with these findings, clear-cell change, steatosis and small cell change have been considered histological features predicting malignant transformation in non-malignant hepatocellular nodules^[76]. Analysis of clonality and chromosomal aberrations in nodules of altered hepatocytes microdissected from cirrhotic livers revealed

Figure 4 Portion of a human trabecular hepatocellular carcinoma with mixed populations, including clear (glycogenotic) cells (small upper white circle), acidophilic (glycogenotic) ground-glass cells (somewhat larger white circle at the bottom, left), transitions from ground-glass hepatocytes into basophilic cell populations (largest white circle in the middle, right), and basophilic cell populations in the middle and at the bottom right (not marked by circles). Hematoxylin and eosin.

a loss of chromosomal inactivation mosaicism in three large “regenerative” nodules and in all (12) nodules of altered hepatocytes with small cell change, indicating their neoplastic nature^[77]. Even among 60 nodules of altered hepatocytes without small cell change, almost 50% (29) were shown to be monoclonal, whereas FHG and 14 “regenerative” nodules were found to be polyclonal. Interestingly, Cai *et al*^[78] using a similar approach to analyze focal nodular hyperplasia, the pathogenesis and neoplastic nature of which has been debated for decades^[53], found that this lesion, as a whole, is polyclonal, but represents a cluster of nodules of altered hepatocytes, some of which are monoclonal harboring chromosomal aberrations as in hepatocellular adenomas. The lack of genomic alterations in fatty and clear-cell changes in HCC and precursor nodular lesions in cirrhotic livers emphasized by some authors^[79] is in line with the polyclonal nature of many of these lesions^[77], but in view of the increasing evidence for a decisive role of epigenetic events in the development and progression of human HCC^[80] the findings by Laurent *et al*^[79] do not argue against a preneoplastic nature for these cellular changes.

A pronounced hypertrophy of the smooth endoplasmic reticulum was discovered in biopsies from cirrhotic livers and liver cell carcinomas at the light and electron microscopic level (Figure 1B) almost half a century ago, and related to aberrations of glycogen metabolism including glycogenesis from the very beginning^[5,6]. The altered hepatocytes (Figures 1B and 4) were designated as “acidophilic” (or “eosinophilic”). Later on, Popper *et al*^[81,82] found frequent association of this phenomenon with the expression of the hepatitis B surface antigen (HBsAg) localized in the lumen of hypertrophied smooth endoplasmic reticulum (Figure 5), and coined the term “ground glass hepatocyte” which has become an important diagnostic entity in chronic liver diseases elicited by HBV and has dominated the literature since

Figure 5 Portion of a ground-glass hepatocyte from a human liver with hepatitis B virus-associated cirrhosis, showing an accumulation of glycogen granules (long arrow) in the nucleus (N) and abundant smooth endoplasmic reticulum containing filamentous hepatitis B surface antigen (short arrows). M: Mitochondria; P: Peroxisome. Transmission electron microscopy, lead citrate. Bar: 1 μ m.

then^[83]. Wills^[84] described HBsAg-free “ground glasslike hepatocytes” exhibiting “glycogen bodies” in liver biopsies from an immunosuppressed (azathioprine, prednisone, clonidine, frusemide) renal transplant patient, similar to those observed in experimental chemical hepatocarcinogenesis^[4,12].

Irrespective of the expression of HBsAg, glycogenotic hepatocytes showing hypertrophy of the smooth endoplasmic reticulum (corresponding to GGH) have often been observed in human FHG, hepatocellular adenomas, and HCC and considered preneoplastic or highly differentiated neoplastic phenotypes^[6,53,68]. In 30 specimens of HBV-associated cirrhosis, GGH were identified in 17 of 25 showing HBsAg expression^[85] (Figure 5). Without mentioning any particular relationship to glycogen, others described GGH containing pre-S mutants in chronic HBV infection, postulating that they represent preneoplastic lesions^[83]. Wisell *et al*^[86] depicted partially persisting “glycogen pseudoground glass hepatocytes” in 12 patients immunosuppressed for numerous indications, but detected neither viral particles nor hypertrophy of the smooth endoplasmic reticulum under the electron microscope. Similar observations were reported by Bejarano *et al*^[87] but no efforts were made in either of these studies to directly compare GGH in serial sections of defined focal lesions at the light and electron microscopic level. Different types of altered hepatocytes, which superficially resemble glycogenotic GGH appearing during hepatocarcinogenesis, have also been observed in several other diseases but will not be further discussed in this context^[83,86,87].

An intriguing form of acquired hepatic glycogenesis was discovered by Mauriac *et al*^[88] in a child with poorly controlled insulin-dependent diabetes type 1. The excessive storage of glycogen resulted in hepatomegaly and was associated with growth retardation, delayed puberty, and a cushingoid face (named after Harvey Williams Cushing). Many additional cases resembling Mauriac’s

syndrome, especially with respect to hepatic glycogenosis, have subsequently been described^[89-91]. Torbenson *et al*^[91] emphasized that this “glycogenic hepatopathy” is an underrecognized complication of diabetes mellitus. In addition to children with insulin-dependent diabetes, hepatomegaly due to glycogen storage has also been recognized in adults afflicted by non-insulin-dependent diabetes type 2 with poor glycemic control^[91-93]. To the best of my knowledge neither GGH nor a relationship of glycogenic hepatopathy to the evolution of HCC in patients suffering from diabetes mellitus has hitherto been described, but it might be timely to take a closer look into this possibility.

The high risk of diffuse glycogenosis characterizing inborn hepatic glycogen storage diseases, particularly glycogen storage disease type I due to glucose-6-phosphatase deficiency, developing into hepatocellular adenomas potentially progressing to HCC has been well established^[2,9,28,94] since the first description of a case by Mason *et al*^[95]. In the meantime, hepatocellular neoplasms are now known to also be occasionally found in other types of glycogen storage disease, namely glycogenoses type III (amylo-1,6-glucosidase deficiency), type IV (α -1,4-glucan: α -1,4-glucan-6-glycosyl transferase deficiency) and type VI (phosphorylase deficiency, Hers disease)^[94,96-99]. I am not aware of any explicit report of GGH in inborn glycogenoses, but from the findings outlined it is obvious that a more detailed comparison of the molecular, metabolic, and morphological aspects of hepatocarcinogenesis in inborn and acquired (focal) hepatic glycogenosis should help to further elucidate the pathogenesis of hepatocellular neoplasms, and facilitate development of appropriate measures for the prevention and therapy of this frequently fatal disease. From a diagnostic point of view it appears to be of great advantage to use the characteristic changes in hepatocellular glycogen content during hepatocarcinogenesis as simple “superficial” histochemical markers of complex basic aberrations at the molecular and metabolic level.

Abstract

Hepatocellular carcinoma (HCC) is a dreadful cancer and a major cause of death among patients with chronic liver disease and cirrhosis. The apparent alterations in a diversity of intracellular pathways found in HCC has set the rational for developing molecular-directed drugs that simultaneously inhibit multiple pathways, such as the multi-kinase inhibitor Sorafenib. However, recently this concept has been challenged by showing that HCC is heavily dependent on a single oncogene designated late SV-40 factor (LSF), a transcription factor that is over-expressed in liver cancer cells and that its expression is strongly correlated with tumor grade and aggressiveness. Furthermore, using an intensive screening for drugs that inhibit LSF activity, Grant *et al* have found a molecule designated factor quinolinone inhibitor 1 that can specifically block the ability of LSF to bind its target promoters, resulting in a massive death of HCC cells both *in vitro* and *in vivo*. The innovative findings of HCC representing "oncogene addiction" to LSF and the ability of a single molecule to block the activity of this oncogene resulting in tumor abolishment are encouraging and provide us with the hope that the "Achilles heel" of HCC has been found.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in men and the seventh in women, and its incidence has been sharply rising during the last two decades^[1]. Whereas patients with localized disease can benefit from curative therapeutics modalities, such as liver resection, liver transplantation or radiofrequency ablation, until recently little could be offered to patients with advanced disease, whose survival was often measured in a few months^[2].

MULTIPLE PATHWAYS ARE DISTORTED IN HEPATOCELLULAR CARCINOMA

Disruption of a variety of cellular pathways, as well as mutations in tumor suppressors and oncogenes have been described in patients with HCC^[3]; mutations in the genes encoding for *TP53* and β -catenin, amplifications of the vascular endothelial growth factor (VEGF) and Cyclin D1 (*CCDN1*) genes, silencing of E-Cadherin tumor suppressor and activation of the myelocytomatosis viral oncogene are a partial list. Indeed, the more effort

invested in elucidating molecular mechanisms underlying HCC, the clearer it became that the complexity and diversity of such mechanisms make the development of potential gene-targeted drugs a highly complicated task.

SORAFENIB-THE FIRST APPROVED MOLECULAR-DIRECTED DRUG FOR HEPATOCELLULAR CARCINOMA

In 2008, Llovet *et al*^[4] have published the results of a phase 3 multi-center placebo control trial showing that the multi-kinase inhibitor Sorafenib prolongs survival in patients with advanced HCC. The rationale for using a multi-kinase inhibitor that simultaneously blocks Raf, VEGF, platelet-derived growth factor and c-Kit signaling is to “cover” as much diverse signaling pathways involved in hepatic carcinogenesis as possible. However, although the introduction of this first molecular-directed drug is a major breakthrough in the field of HCC, the results are still far from optimal as reflected by the only modest improvement in life expectancy of 2.8 mo on average in the price of often-severe adverse events^[5,6].

LATE SV40 FACTOR-AN ESSENTIAL ONCOGENE IN HEPATOCELLULAR CARCINOMA

Recently, Yoo *et al*^[7] has recognized the Late SV40 factor (LSF) transcription factor as a central oncogene in HCC. LSF, which is induced in the liver via inflammatory cytokines, has a major role in DNA synthesis by transcriptionally activating the rate-limiting enzyme in pyrimidine synthesis, thymidylate synthase, as well as other target genes important for DNA synthesis and cell survival. LSF inhibition results in constraining DNA synthesis, which ultimately leads to cell death. Interestingly, Sarker's group has found that LSF protein is significantly over-expressed in HCC cells as compared to normal human liver cells. Furthermore, the degree of LSF expression revealed a significant correlation with the stage and grade of the tumor. Most importantly, whereas over expression of LSF pushed the tumor towards a more aggressive phenotype, LSF inhibition resulted in abrogation of tumor growth and its metastatic potential, both *in-vitro* and *in-vivo*. Interestingly, among the various genes induced by LSF following its binding to their promoters, *SPP1* gene encoding for the osteopontin (OPN) protein has been found to be induced to the greatest extent. Indeed, the importance of OPN in promoting hepatic carcinogenesis was recently emphasized by a study showing that OPN is much more sensitive than the traditional alpha-fetoprotein as a marker for early HCC^[8]. Whatsoever, Sarker's work as well as a later work by Fan *et al*^[9] strongly indicated that LSF is an essential oncoprotein required for the maintenance and propagation of liver cancer, making it a potentially ideal target for HCC treatment. Furthermore, the merit of these findings lies

in the fact that although multiple genes and signaling pathways are impaired in HCC, the cancerous liver cells are heavily dependent on a single oncogenic protein, the transcription factor LSF, for their survival. This phenomenon, designated “oncogene addiction”, has been recognized in various cancers in the last few years, making the oncogene to which a particular cancer is addicted to an ideal target for anti-cancer therapy^[10,11].

FACTOR QUINOLINONE INHIBITOR 1 SPECIFICALLY INHIBITS LATE SV40 FACTOR ACTIVITY RESULTING IN ABOLISHMENT OF HEPATOCELLULAR CARCINOMA

However, how can one translate experimental abolishment of LSF achieved mainly by dominant negative constructs or knockdown strategies to a drug that inhibits LSF function *in-vivo* and that can be easily delivered to the liver?

A study recently published in the PNAS provided an unexpected and exciting solution to this problem^[12]. By screening for small molecules that could block the interaction of LSF to its DNA binding sites along the genome, Grant *et al*^[12] have revealed a small molecule named factor quinolinone inhibitor 1 (FQI1) that inhibits LSF DNA binding activity both *in-vitro* and *in-vivo*. Functionally, treating HCC cells with FQI1 results in a massive apoptosis of HCC cells whereas normal hepatocytes remain intact. FQI1 treatment results in a robust activity *in-vivo*, as well, reflected by inhibition of tumor growth in mouse HCC xenografts. Importantly, no toxicity was observed in FQI1 treated animals, as evaluated by animals' general well being and by careful examination of various non-hepatic tissues that remained intact following treatment. Noteworthy is the observation that tumors from FQI1-treated animals expressed LSF at similar levels to those of control mice, whereas the expression of a central LSF target gene, OPN, as well the proliferative activity of the tumor were dramatically reduced. This observation reflects the inhibition of LSF activity as a transcription factor by blocking its binding to DNA, rather than reducing its level following FQI1 treatment. Furthermore, the close correlation between the concentrations of FQI1 required for inhibition of LSF transactivation and those required for proliferation inhibition strongly suggest that FQI1 specifically targets LSF and does not share a general non-specific anti proliferative activity.

FQI1 AS AN EMERGING ANTI HEPATOCELLULAR CARCINOMA DRUG-PROMISES AND CHALLENGES

The originality and the importance of the aforementioned studies are dual. First, the identification of a single oncogene serving as a cellular transcription factor to

which HCC is “addicted” and completely dependent on. This finding may completely change the current concept of using drugs inhibiting multiple alternated cellular targets^[5], to a strategy that specifically inhibits a particular target that is essential for HCC maintenance and propagation. Second, in contrast to what was formally considered as an almost impossible target for drug therapy, the efficiency of FQI1 strongly indicates that targeting the activity rather than the level of a transcription factor is an effective and specific mechanism for an anti-cancer drug.

Further studies should address potential caveats and open question remaining before implementing those findings to an efficient anti-HCC drug. The bioavailability of FQI1 in human subjects following treatment should be carefully checked and the long-term consequences in terms of adverse effects should be monitored. The potential for tumor resistance due to mutations in the LSF DNA binding domain is certainly there and should be taken into consideration. In this regard, the combination of the current molecular-targeted drug, Sorafenib, with LSF inhibitors has the potential to minimize the risk of cancer cells “escaping” their oncogene addiction to LSF. Last but not least, the validity of LSF role in HCC should be ascertained for the various etiologies of HCC, including viral, metabolic and toxic.

In summary, the introduction of a small molecule that specifically inhibits the activity of an oncogene on which HCC heavily depends seems as stimulating news to the field. Time will tell whether, similar to the Greek mythology, LSF represents the Achilles heel of HCC, an innovation that can ultimately lead to defeating this deadly cancer.

Abstract

The three surgical patient safety events, wrong site surgery, retained surgical items (RSI) and surgical fires are rare occurrences and thus their effects on the complex modern operating room (OR) are difficult to study. The likelihood of occurrence and the magnitude of risk for each of these surgical safety events are undefined. Many providers may never have a personal experience with one of these events and training and education on these topics are sparse. These circumstances lead to faulty thinking that a provider won't ever have an event or if one does occur the provider will intuitively know what to do. Surgeons are not preoccupied with failure and tend to usually consider good outcomes, which leads them to ignore or diminish the importance of implementing and following simple safety practices. These circumstances contribute to the persistent low level occurrence of these three events and to the difficulty in generating sufficient interest to resource solutions. Individual facilities rarely have the time or talent to understand these events and develop lasting solutions. More often than not, even the most well meaning internal review results in a new line to a policy and some rigorous enforcement mandate. This approach routinely fails and is another reason why these problems are so persistent. Vigilance actions alone have

been unsuccessful so hospitals now have to take a systematic approach to implementing safer processes and providing the resources for surgeons and other stakeholders to optimize the OR environment. This article discusses standardized processes of care for mitigation of injury or outright prevention of wrong site surgery, RSI and surgical fires in an action-oriented framework illustrating the strategic elements important in each event and focusing on the responsibilities for each of the three major OR agents-anesthesiologists, surgeons and nurses. A Surgical Patient Safety Checklist is discussed that incorporates the necessary elements to bring these team members together and influence the emergence of a safer OR.

Gibbs VC. Thinking in three's: Changing surgical patient safety practices in the complex modern operating room. *World J Gastroenterol* 2012; 18(46): 6712-6719 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i46/6712.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i46.6712>

INTRODUCTION

Operating rooms (ORs) used to be just complicated places, but the modern OR has changed. No place epitomizes the complexity of health care delivery better than the OR where there is the routine interface of heterogeneous, variously trained personnel using high technology

equipment while providing service to an unconscious, anesthetized patient. In fact it is most helpful to think of the modern OR as a complex adaptive system that consists of (1) heterogeneous interdependent decision making agents; (2) who interact frequently with each other; and (3) develop a characteristic called emergence which arises when the whole actually begins to perform better than the sum of its parts^[1]. That is through the learning and interdependence of the heterogeneous agents a larger, higher functioning system is created. Anyone who has worked in a highly functioning OR over time can understand how this entity can evolve but also how rare and difficult it is to achieve.

Today it is expected that the delivery of surgical care will be (1) knowledge-driven (safe, effective); (2) patient-centered; and (3) system-based (timely, efficient and equitable)^[2]. Hospitals and the surgeons who operate within them are also learning that if the care is not of high value, that is high quality surgical outcomes at low total costs of care, there will be low or no reimbursement for their effort^[3]. Thus begins another step in the journey to stimulate hospitals and surgeons to accelerate improvement in the quality of surgical care and increase efforts to prevent errors and treatment complications. Multiple stakeholders have begun to reengineer or design, adopt and implement new OR practices and refined communication methods in order to reduce errors and waste. The specific surgical patient safety events are uncommon but the effort needed for prevention requires innovative solutions and illustrate the difficulty in changing OR culture (e.g., shared customary beliefs, values and behaviors).

The three main preventable surgical patient safety events which occur within the OR are (1) the surgical wrongs; (2) retained surgical items (RSI); and (3) surgical fires. The incidence of all three combined may affect at most 5000 patients a year (approximately 2000 wrong surgery events, 2000 RSI, 500 surgical fires) in the United States. National sentinel event disclosure is disparate and depends on state-based and regulatory agency voluntary reporting. Data on close-calls, which are likely to be more frequent, remain sketchy. No matter the total number of events, we do know that the number is greater than zero and therefore these are still not “never events”.

It has been tempting to use a “person approach” (e.g., the forgetfulness, inattention, ignorance, carelessness of individuals) in the analysis of why these events occur but we know that a “system approach” (e.g., analysis of the conditions under which individuals work and how defenses failed) that incorporates human factors (e.g., the interaction of human abilities, expectations and limitations) while harder to design and implement is likely to be more successful^[4]. These safety problems are reflective of the culture of safety in the OR rather than on patient or case characteristics. The people who work in the OR make it safe and it is important to know that there are subtle behaviors that aren't well quantified

but are highly valued that arise from the development of expertise. Expertise is the result of knowledge and experience. The behaviors are intuitive and have been recognized as characteristics of “safe people”^[5]. These feelings and intuitions are very important to nurture and develop but do have a quality of mystery to them but it is highly desirable for an organization to value expertise and develop “safe people”. When hospitals address these safety issues and there is culture change there may be positive consequences which decrease or prevent other more common perioperative occurrences such as surgical infections and venous thromboembolic events. ORs have not yet been characterized as highly reliable organizations (akin to nuclear reactors or aircraft carriers) so there is much room for improvement.

The current projects developed to help hospitals take action to prevent wrong site surgery, RSI and surgical fires focus on specific OR practice and communication problems. Unsafe OR practices are usually highly variable and efforts to standardize multi-stakeholder processes of care and develop specific communication modes are shared core elements in prevention strategies. Practice change and communication improvements are often viewed disparagingly as “soft” approaches which lack rigorous data and experimental validation however making sense of the rare and unexpected requires different tools and approaches^[6]. Increasingly, event reporting and analysis of close calls have informed failure modes and collective learning on how to manage unsafe acts which is just as important as preventing them. To change OR culture requires change in the practices of the people who are engaged in the work. To change their practices you have to change the relationships with whom they work and the environment in which they work.

Finally, a surgical patient safety checklist which is a simple, widely applicable, inexpensive, unifying tool, can be used by all OR personnel to enforce the individual safe practices which have programmatically been developed and enhance inter-personnel communication^[7]. We describe how one can be used to teach and enforce safer practices and address serious and avoidable surgical complications^[8].

WRONG SURGERY

The three types of wrong surgery are (1) wrong patient surgery, where the performance of an operation or procedure is carried out on a person other than the one for whom the procedure was intended; (2) wrong procedure surgery, is the performance of a procedure other than that intended or indicated for a specific patient; and (3) wrong site surgery where a planned procedure is performed at the wrong place, part, level, side or site^[9]. Wrong site surgery is a type of wrong procedure surgery and is the most common occurrence of the three^[10]. All three of these events are usually the result of mistakes in correctly applying identification procedures.

The Joint Commission (TJC) has been at the fore-

front of the wrong site surgery issue since 1998 when the first Sentinel Event Alert newsletter on the subject was printed. Subsequently TJC published a follow-up alert in 2001, in 2003 the first Wrong-Site Surgery Summit was held and in 2004 the Universal Protocol was launched. In spite of all of these efforts, it has most recently been estimated that wrong site, wrong procedure and wrong patient cases still occur more than 40 times a week in the United States^[11].

The essential elements of the Universal Protocol mandate that OR teams must (1) complete a preoperative verification process; (2) mark the operative site; and (3) take a “time out” immediately before starting the procedure. The verification process is to ensure that the correct patient has been consented and is present for the operation and all relevant documents and studies are available before the procedure is performed.

The most important elements are that the three major primary operative sources: the history and physical, the consent, and the official OR schedule are in exact agreement. If there are discrepancies the patient is considered the primary source for rectification. Patient verification and identification practices are usually performed by nursing and anesthesia personnel with requirements that at least one of these stakeholders must remain in constant attendance with the patient while being brought into the OR once patient identification has been performed. The site marking is within the domain of the surgeon and must be performed before the patient is brought into the OR and should be visible while the patient is prepped and draped. The mark must be visible within the operative field and referenced during the time out. Recent alcohol based prep solutions frequently diminish the site mark and practices must be established to use different inks or have a process in place whereby the person who performed the prep can refresh the diminished mark with a sterile surgical marker to ensure that it will be able to be seen before an incision is made. The time out is truly a team based activity called by the surgeon, monitored and orchestrated by the circulating nurse with responses from anesthesia and any other providers. The time out is usually performed just before the incision is made and all team members have to stop all activities. At the time out the three questions are answered: (1) Who is this patient? (2) What operation is to be performed? and (3) Is this the correct site mark, using secondary confirmatory evidence present on an armband or on the operative consent and unanimity from all stakeholders is required. Many facilities have checklists and scripted procedures with hard stops (e.g., the scalpel isn’t passed until the time out is completed) to enforce compliance. All questions are supposed to be asked in a non-intimidating environment where all staff feel equal in their contribution to safe patient care. These conditions have been challenging to meet.

While the Universal Protocol as a directive was comprehensive and widely mandated the implementation and effectiveness of the protocol was variable^[12]. Review

of wrong site surgery cases reveal that multiple errors occurred along the OR journey and multiple defenses failed which might have caught the mistakes^[5]. Inadequate standardization of practices and poor training and enforcement of practices provide the latent factors which exist that sets OR personnel up for failure. More than just the directive to use the Universal Protocol appears to be needed and hospitals need guidance on how to effectively make the process work.

To meet this goal, in July 2009 TJC started an eight hospital demonstration project using a Robust Process Improvement method that is a fact based, systematic and data-driven problem solving methodology^[13]. Project teams are developed for observational audits looking to discover specific risk points and contributing factors that lead to close calls and wrong site surgery events. The timeframe begins at the time of scheduling a surgical procedure and ends with confirmation that the intended operation was correctly performed.

Preliminary results from TJC project have shown that in 39% of cases, errors were introduced in the verification step that increased the risk of a wrong site surgery event^[11]. Usually these errors involved inadequate information about the patient and scheduling confusion. Identifying this failure mode lead to the development of standardized ways of collecting and having the information accessible. Site marking and time out practices have been contributory but were not as frequent a source of errors as the initial verification process^[5]. Further refinements to improving this practice will be available at TJC Targeted Solutions Toolkit which will provide a step-by-step process to measure performance^[13].

RETAINED SURGICAL ITEMS

A RSI occurs when surgical material, usually a sponge, needle, instrument or miscellaneous small item or device fragment is inadvertently left inside a patient. Retained surgical item is the preferred term rather than retained foreign body or object since bullets, shrapnel or ingested objects can be retained but aren’t the result of surgical error. An RSI is a surgical patient safety problem and results from problems in unreliable surgical OR practices and problems with communication between OR stakeholders^[14].

Reports of RSI have relied on mandatory state and voluntary regulatory agency reporting requirements which vary as does the definition of what is considered retention. The National Quality Forum’s (NQF) definition is most frequently referenced and in 2011 all NQF Serious Reportable Events were reviewed which included the issue of surgical retention. The new directive excludes reporting of unremovable items intentionally left at the judgment of a surgeon and most importantly addressed the definition of when an item is considered retained after surgery. Many states construed “after surgery” to mean closure of the incision, which meant even in cases where the sponge or surgical item was

discovered to be missing while the patient was on the OR table, and was removed in the OR without delay or harm, if the wound had been closed these cases were reported as a RSI. With the new 2011 definition, this area has been corrected and the operation ends after all incisions or procedural access routes have been closed in their entirety, devices have been removed and if relevant, final surgical counts have concluded and the patient has been taken from the operating/procedure room^[15]. In 2011 an item is considered to be retained only if found after the patient is out of the OR or procedure room. This change alone may lead to decreased numbers of RSI cases.

The most common RSI is the cotton gauze surgical sponge which has been found in the abdomen/pelvis, chest and increasingly in the vagina. Retained sponges occur after any type of surgical procedure and the risk of retention is unrelated to the number of sponges used during an operation. Sponges have been retained when only 10 sponges were used and small biopsy or skin incision made. This finding has led to policy changes which should require that surgical sponges must be accounted for in all cases in which surgical sponges are used and an incision is made^[16]. There should be no determinates for case exclusion because of size of the incision or length of the case.

Traditional means of accounting for sponges has relied on the longstanding practice of counting. Observational audits and focused reviews of cases of retained sponges has shown that the practice of counting sponges is highly variable between ORs and even within rooms in the same OR suite. This variation leads to sources of error and with increased demands of the OR environment, frequent change of shift between nursing personnel and multiple diversions the common practice of counting has proven unreliable. Examination of cases of retained sponges have often revealed that the sponges were counted during the procedure but no one knows where the error occurred or how the sponge was retained. In fact, overall about 80% of retained sponge cases occur in the setting of a correct count^[17]. That is at the end of the case the counts were called correct. In about 20% of cases of retention there was a known incorrect count at the end of the case, something was missing, yet the patient still got out of the OR without finding the sponge. The missing item is subsequently discovered sometime later. This occurs because of knowledge and communication problems usually at the interface with radiology, the taking and interpretation of xrays or with inadequate follow-up at the next level of care to determine if a sponge has been retained. Because of these observations about the counting of sponges a revised manual sponge management practice was developed by the NoThing Left Behind® Surgical Patient Safety Project^[17]. The practice is called Sponge ACCOUNTing that uses the adjunct of plastic blue-backed hanging sponge holders and wall mounted dry erase boards posted in each OR on which to record in a standardized manner the surgical counts.

Sponge ACCOUNTing was developed to standardize and improve the transparency of the practice of sponge management. The guiding principles have outlined three important steps to ensure that all sponges used in the procedure have been accounted for with important unique actions for each OR stakeholder during the case and a team based “show me” step at the debriefing or end of the case. The nursing essence is (1) that all sponges are only used in groups of 10 and each plastic sponge holder contains 10 pockets; (2) at the natural pause point which occurs at the time wound closure begins, it is the job of the surgeon to perform a methodical wound exam (MWE), not just a swish or sweep of the wound, but to do the best job possible to look for and remove any sponges (or other items not intended to remain in the patient) and give them to nursing staff; and (3) the last step is at the end of the case when the skin is closed and all of the sponges (the used and unused sponges) must be off the field and in the pockets of the plastic hanging sponge holders. Since there are 10 pockets per holder and sponges are managed only in multiples of ten there should be one holder for each 10 sponges and there should be no empty holder pockets at the end of the case. The team based activity is for the surgeon to say “show me the holders” so they can see that there are no empty pockets or for the nurse to say to the surgeon “here let me show you”, there are no empty pockets. Who shows who doesn't matter, it's that there is a visual confirmation that all sponges have been accounted for.

There are now three technological adjuncts for sponge management (1) a device which counts 2D matrix labeled sponges; (2) a device which detects radiofrequency tagged sponges; and (3) devices which can count and detect RadioFrequency IDentification (RFID) chip embedded sponges. The essential components of each device are a distinct type of detection element attached to a surgical sponge and a distinct compatible electronic readout system.

The computer assisted sponge counting system consists of two-dimensional matrix labeled sponges and a scanning device that can read the labels^[18]. The matrix label is scanned in with a handheld or table mounted scanner as the sponges are put on the sterile field and then each sponge is scanned out when the sponges are removed from the table. The matrix labels are embedded onto surgical sponges of various sizes and each sponge has a unique identifier that enables the scanner to count different types of sponges. The sponges are counted maintaining “line of sight” for each sponge. In order to account for all sponges at the final count, the sponges must be removed from the patient and individually passed under the scanner. The scanner has no capacity to “read-through” the patient and detect the presence of a matrix labeled sponge. In the event of a missing sponge an X-ray is used to determine if it is in the patient. This system is in place in many hospitals and most recently the experience from the Mayo Clinic has been reported^[19]. After 18 mo of use the device accurately

counted all sponges in all cases throughout the hospital and there were no cases of retained sponges.

The radiofrequency detection system consists of sponges that have a small passive radiofrequency tag sewn into a pocket on each sponge and a handheld wand or mat which contain the antennae and detection system^[20]. The tag is 4 mm × 12 mm and is recognized as only a yes or no signal. The tag is detected when the handheld wand or mat is activated and the computer console presents a visual and audible signal that a sponge has been detected. The system does not distinguish between sponge types or number of sponges. The signal readout will be the same intensity if there are one or five sponges. In the event of a missing sponge the mat can be activated to determine if the sponge is in the patient or the wand can be used to wand the patient or scan the trash to find the sponge. This system does not count sponges so at this time is usually used in conjunction with a manual counting practice such as Sponge AC-COUNTing. Some hospitals have adopted mandatory wand protocols to be used for specific types of cases, others require wand in lieu of using xray to find a missing sponge. There is an early trial from the University of North Carolina in the assessment and safety of this device and after 24 mo they have not had any retained sponges^[21].

RFID systems have a unique RFID chip sewn into each type of sponge and a separate computer console with a scanning bucket into which used sponges are placed^[22,23]. Each sponge has a specific RFID chip and thus sponges of different types pooled together can be distinguished and counted. Unopened packages of sponges are placed on a front panel of the console to be electronically counted-in and the sponges are then opened and placed on the sterile field. Used sponges can be put directly into the bucket or into plastic-bag lined kick buckets and the entire plastic bag full of sponges then placed into the scanning bucket. The sponges will all be individually counted-out. If there is a missing sponge it can be detected with a wand. All of these devices are undergoing clinical assessments in different hospitals around the world.

With the continued improvement in the prevention of retained sponges, reports of retained miscellaneous small items and unretrieved device fragments are increasing^[17,24]. The preventive strategy for these types of items are not applicable only to the OR since retained guidewires, sheaths and catheters are found after interventional vascular, cardiac and radiological procedures performed in various sites throughout a hospital. In addition various types of providers now must develop standardized processes to account for all of the items and parts of devices at the conclusion of invasive procedures. This is new territory for interventional radiologists and cardiologists and practices originating in the OR can be shared with these other clinical groups to help speed accountability.

In the OR, small miscellaneous items or broken parts or pieces of tools and material used during an operation

when found to be missing may require a clinical decision to leave the item behind because the risk of removal may cause greater harm than leaving the object behind. If a small item or un-retrieved device fragment is intentionally left behind, the patient must be informed. Leaving fragments and small objects in patients can be prevented because often human factors are involved in why the devices or objects break or fracture. Identifying early when an item is missing or broken means best practices in the OR will involve the coordination of actions between the surgeon and the surgical technologists who must become the content experts on the equipment. If something is missing or broken the scrub person has to recognize the defect and speak up so actions to find the missing part can be undertaken. Retained whole instruments are exceedingly rare and previous reports that indicated instruments as the second most common item most certainly included small devices and fragments in this category rather than the separate class in which they are now considered. Inside or out of the OR, standardized practices have to be established that are transparent, widely applicable and simple to perform so multiple providers at the completion of every case, delivery or invasive procedure can be sure there is "NoThing Left Behind".

SURGICAL FIRES

OR fires occur near or around a patient but a surgical fire is a fire that occurs in or on a patient and includes airway fires^[25]. Surgical fires are the rarest of the three surgical patient safety events with an estimate from a 2009 study suggesting that between 500-600 fires a year occurred in the United States^[26]. This national estimate was based on data from the Pennsylvania safety event reporting system which is the best available evidence. Surgical fires are dangerous, lethal and preventable but are so infrequent that most surgeons are painfully unaware of what preventive measures need to be taken.

A surgical fire requires the classic constellation of three components, "the fire triad": (1) an oxidizer; (2) an ignition source; and (3) fuel. The breadth of elements and circumstances that exist in each of these components are underappreciated and make it difficult to easily standardize or develop simple practices^[27,28]. For example, possible fuels sources can include almost anything on the patient or in a surgical field: tracheal tubes, sponges, drapes, gauze, alcohol or other volatile compound containing solutions, oxygen masks, nasal cannulae, hair, fat, dressings, gowns, gastrointestinal tract gases, suction catheters, cable coverings, gloves and packaging materials. The ignition sources can be from almost any energy generating device and all differentially function or have the potential to cause injury based upon the oxidizer enriched atmosphere.

In 2007 the American Society of Anesthesiologists published a practice advisory for the prevention and management of OR fires which provides a complex algorithm that outlines a risk assessment approach and action plans for surgical providers^[25]. In 2009, further

recommendations were promulgated for oxidizer management and communication guidelines to follow for prevention^[26]. These efforts are thorough but the end results are still highly complex and detailed and because of the rarity of surgical fires it remains difficult to engage providers. Otolaryngology surgeons are the most familiar with surgical fire prevention measures because they frequently operate with ignition sources near the airway, within a highly oxidized atmosphere however all types of surgeons need to learn and adopt safer surgical fire preventive strategies because all types of cases actually provide risky conditions. To this end a provider oriented accountability approach for surgical fire management has been developed which assigns responsibility for action to specific stakeholders. This protocol teaches providers to know their role in preventing fires and respond quickly should a fire occur^[29,30]. The roles for prevention are based on the domains of control for each of the elements in the fire triad. Anesthesiologists have the control and direct ability to act on the management of oxidizers which includes oxygen and nitrous oxide. Nurses have control and direct ability to monitor the fuel sources and provide immediate remedy to extinguish flames with saline. The Surgeon has control over the ignition source and is responsible for assessing the environment before starting or using electrocautery.

Surgical fire prevention requires constant situational awareness because of the changing nature throughout an operation of the availability of different fuels, oxidizer status and ignition sources. Information exchange between the anesthesiologist, nurse and surgeon are key. If a fire breaks out rapid responses from all three stakeholders are important and some suggest fire drills should be conducted for high risk cases so team members are adequately primed to respond appropriately. If there is the risk of an airway fire the anesthesiologist must keep the surgeon aware of oxidizer concentrations and atmospheric conditions and be ready to stop all airway gases and remove the tracheal tube. The surgeon must have thoughtful control and use of cutting devices while nursing personnel in the scrub position must be ready with saline and wet sponges. All of these coordinated actions will have to take place in seconds in order to save the patient from extensive injury. To this end, surgical fire case-specific risk assessment strategies are useful activities and allow all providers to be primed at the time and ready to go rather than relying on memory or remote training. Surgical fire risk assessment can be incorporated into part of the operative briefing and safety checklist so each case can be assessed and necessary steps taken before the case starts to make sure all team members know what to do and are on the same page^[8].

SURGICAL PATIENT SAFETY OR CHECKLIST

Common to the prevention of surgical patient safety events and mitigation of harm is the need to have all

team members prepared to address events as they occur. The nature of preparedness involves having knowledge and the appropriate skills and tools available. Simulation training and drills are ways in which many industries maintain preparedness. The use of checklists as an adjunct to the pre-existing skill set of team members who come together has also been important to make sure all necessary tools and practices are performed correctly.

In 2009 a surgery safety checklist was first introduced which was beyond what was traditionally used by nursing services to make sure the patient was prepared for surgery. This 19 item checklist was divided into three parts: (1) sign in activities; (2) time-out activities; and (3) sign-out activities which covered the recommended practices the World Health Organization (WHO) had developed to ensure the intraoperative safety of surgical patients worldwide^[7]. The elements were simple and were intended to enhance inter-professional communication and prevent surgical events that may result from poor teamwork and inadequate surgical operative preparation. This checklist was adopted and disseminated by the Institute for Healthcare Improvement and has been in place in more than 3900 hospitals around the world^[31]. Each facility is encouraged to develop a surgical safety checklist that will conform to their site-specific conditions but at the minimum the original 19 points are strongly encouraged to remain. Many surgical subspecialties e.g., ophthalmology have customized the original WHO safety checklist to their needs and recent work has been started on the development of crisis checklists for the operating room which aim to guide providers to perform the correct actions in intraoperative crises^[32]. Implementation of some form of a surgical safety checklist has been widespread and the benefits of checklist use continue to be evaluated.

There is no one surgical safety checklist that is “the best” but there are many which provide the necessary information for all stakeholders to come together and make sure the correct patient is being operated on, the correct operation is known and the operating team is properly prepared to perform that operation safely. A surgical patient safety checklist should help surgical providers address the preventative solutions to prevent the wrongs, RSI and surgical fires at a minimum^[33]. An example of a surgical patient safety checklist that covers this territory is included in the reference section^[34]. The checklist is used three times during a patient’s operation (1) as an aid during a pre-operative briefing that is conducted when the patient is first brought to the OR; (2) during the time-out; and (3) as a reporting tool during the de-briefing that is held at the end of the case to discuss what problems occurred and also what went well.

During the pre-operative briefing patient elements are reviewed, such as procedure verification and imaging, antibiotic administration, venous thromboembolism prophylaxis management, beta-blocker use, allergy history and blood availability but more importantly the surgical team puts together a surgical fire risk assessment score.

If the fire risk is considered high, based on a simple 3 point scoring system, then each of the three stakeholders in fire prevention go over what they are supposed to do as outlined on the back of the checklist. In this way the circulating nurse and surgical technologist, the surgeon and the anesthesiologist discuss what maneuvers and actions will be taken during that specific high risk case. During the time-out the three essential questions are answered using the checklist as a memory jogger and confirming primary source information in the computer or on the patient's armband. These actions prevent the occurrence of a wrong site surgery. At the de-briefing, all surgical items are accounted for, pathology specimens are reviewed to determine that they are correct and labeled correctly and any equipment or instrument problems are noted with specific referral units noted who are to take action for remediation thus preventing RSI.

CONCLUSION

The three surgical patient safety events, wrong site surgery, RSI and surgical fires can be prevented and even if prevention strategies fail mitigation of patient harm can be accomplished with application of consistent safety practices and effective communication. Effective communication includes the use of a comprehensive surgical patient safety checklist which brings all surgical providers together for at least a few moments to have a shared mental model for the patient's surgical care. The three major stakeholders working together in our complex OR environment are nurses, surgeons and anesthesiologists who face ever increasing work demands and knowledge requirements. It is not humanly possible to master all the knowledge domains for all safe practices for these three events, let alone all the other things that are necessary for the performance of an uncomplicated procedure. However, thought modules, checklists and assignment of areas of expertise and responsibility can be helpful in getting humans to work effectively and efficiently together. Of the three surgical patient safety events, it is not a stretch to see that there are knowledge domains which can drive improved performance and the three domains of expertise are possessed by each of the three major stakeholders. The content experts for wrong site surgery are surgeons, for RSI it is nurses and for surgical fires it is anesthesiologists.

Prevention of wrong site surgery is highly dependent on preoperative practices of patient identification and patient preparation in which the surgeon's knowledge and preparation of the primary documents and materials falls within their care domain. It is the surgeon who has determined what operation is to be performed, has marked the operative site and has seen the patient at some time prior to their arrival in the OR. During the surgeon activated time-out confirmatory actions are conducted in concert with the use of a checklist to become the primary means of wrong site surgery preventive actions. The prevention of RSI strongly depends on actions under the control of the scrub person and

circulating nurse who track and account for all the surgical material which is used. The use of a reliable sponge management practice in concert with a MWE is essential to prevent retained surgical sponges. The nurse also provides the interface with other stakeholders such as radiology should intra-operative x-rays be needed. For prevention of surgical fires it is the anesthesiologist who monitors oxygen status and has the situational awareness to alert and direct actions of the other stakeholders in the event of a fire. This is not to say that the other stakeholders don't have roles and responsibilities but when providers of care come together to perform a surgical case there is a team leader. The role of team leader is actually not fixed and immutable. It will have to change as the circumstances of the operation change and the team leader interestingly enough should be the person who is the content expert of that situation as it arises.

It is not possible for everyone to know everything about all things. It is possible for the content experts of each of their domains to be present, willing and able to share their knowledge and communicate effectively with other personnel. Rather than thinking one person has to know it all and do everything, thinking in threes can help all providers put a vast amount of information into some useable context where it will be up to the three major stakeholders to work together consistently in every case to prevent the three major surgical patient safety events.

Abstract

Gastrointestinal stromal tumors (GIST) are rare mesenchymal smooth muscle sarcomas that can arise anywhere within the gastrointestinal tract. Sporadic mutations within the tyrosine kinase receptors of the interstitial cells of Cajal have been identified as the key molecular step in GIST carcinogenesis. Although many patients are asymptomatic, the most common associated symptoms include: abdominal pain, dyspepsia, gastric outlet obstruction, and anorexia. Rarely, GIST can perforate causing life-threatening hemoperitoneum. Most are ultimately diagnosed on cross-sectional imaging studies (i.e., computed tomography and/or magnetic resonance imaging in combination with upper endoscopy. Endoscopic ultrasonographic localization of these tumors within the smooth muscle layer and acquisition of neoplastic spindle cells harboring mutations in the *c-KIT* gene is pathognomonic. Curative treatment requires a complete gross resection of the tumor. Both open and minimally invasive operations have been shown to reduce recurrence rates and improve long-term survival. While there is considerable debate over whether GIST can be benign neoplasms, we believe that all GIST have malignant potential, but vary in their propensity to recur after resection and metastasize to distant organ sites. Prognostic factors

include location, size (i.e., > 5 cm), grade (> 5-10 mitoses per 50 high power fields and specific mutational events that are still being defined. Adjuvant therapy with tyrosine kinase inhibitors, such as imatinib mesylate, has been shown to reduce the risk of recurrence after one year of therapy. Treatment of locally-advanced or borderline resectable gastric GIST with neoadjuvant imatinib has been shown to induce regression in a minority of patients and stabilization in the majority of cases. This treatment strategy potentially reduces the need for more extensive surgical resections and increases the number of patients eligible for curative therapy. The modern surgical treatment of gastric GIST combines the novel use of targeted therapy and aggressive minimally invasive surgical procedures to provide effective treatment for this lethal, but rare gastrointestinal malignancy.

INTRODUCTION

Gastrointestinal stromal tumors (GIST) are rare mesenchymal tumors that occur throughout the smooth muscle layer of the gastrointestinal (GI) tract^[1]. GIST represent less than 1% of all GI tract malignancies. The most common location of these tumors is the stomach (70%), small bowel (20%-30%), small intestine and colon/rec-

tum (10%). Uncommonly, they can arise within the greater omentum, esophagus, appendix, and gallbladder. Most cases are sporadic, and affect men slightly more frequently than women (54% *vs* 46%)^[2]. The annual incidence in the United States has remained stable at 3000 to 4000 cases per year. The world-wide age-adjusted annual incidence rates range from 6.8 to 14.5 cases per million and vary between countries of origin. The median age at diagnosis is 58 years of age, but GIST have been reported in newborns and adolescents^[3]. GIST can range in size from several millimeters to over 30 cm in diameter. Tumor diameter appears to significantly influence biologic behavior, as small GIST may remain indolent for many years and large, “massive” GIST have higher rates of recurrence and associated metastases^[2].

Historically, smooth muscle sarcomas were classified as leiomyosarcomas^[4]. The development of malignant GIST requires the transformation of the interstitial cells of Cajal, pacemakers of the GI tract, to a malignant phenotype through activating or gain of function mutations in the *c-KIT* proto-oncogene^[5]. GIST are spindle cell neoplasms that usually retain the ultrastructural characteristics of smooth muscle cells, but have immunohistochemical staining for *c-KIT*, *CD-34*, smooth muscle actin, desmin and S-100^[6]. Approximately 70% of GIST are spindle cell type neoplasms; the minority are epithelioid (20%) or mixed cell type (10%)^[7]. Hirota *et al*^[5] first described the novel mutation in the *KIT* tyrosine kinase receptor gene in 1998. Since this landmark discovery, most “leiomyosarcomas” have been reclassified as GIST. *KIT* is located on chromosome 4q11-q12 and functions as a transmembrane receptor for its ligand, stem cell factor. In the non-cancerous state, this ligand binds to the extracellular portion of the receptor to induce homodimerization and downstream activation of its cell-signaling pathways^[8]. Wild-type *c-KIT* normally regulates cellular differentiation, growth, and survival. Approximately 80%-90% of GIST harbor mutations in the *KIT* genome. Mutations in the platelet-derived growth factor receptor (*PDGFR α*) occur in 5%-10% of *c-KIT*-wild type GIST. *DOG1* mutations may help identify GIST with wild type *c-KIT* and *PDGFR*^[9]. Mutated *KIT* receptors induce ligand-independent, unregulated activation of the downstream cell signaling pathways which collectively results in a loss of normal cell adhesion, differentiation, and proliferation to promote tumorigenesis. Exon 11 mutations in the *KIT* gene cause constitutively activated receptors leading to unregulated autophosphorylation of the intracytoplasmic tyrosine kinases^[10]. *KIT* mutations in exons 9, 13, 17 are less common and have been associated with more aggressive tumor behavior.

Biologically, gastric GIST tumors grow locally within the stomach (intra- or extraluminal expansion) and eventually obtain the capability to metastasize *via* hematogenous routes to the solid viscera (liver, small bowel, lungs) and peritoneal cavity. Tumors can also spread along the smooth muscle planes within the stomach or can rupture into the peritoneal cavity causing sarcomatosis. Complete surgical resection is thought to be the only curative

treatment for GIST. The recent use of cytostatic agents, such as imatinib mesylate, in patients with metastatic disease has been associated with durable recurrence-free survival^[11]. This important observation suggests that overall survival may not be the most important endpoint to consider when making treatment decisions. Radical gastrectomy is seldom required for extirpation of these tumors^[3]. In contradistinction to gastric adenocarcinoma, where it is essential to obtain at least five-centimeter proximal and distal margins, GIST tumors can be effectively treated by a complete gross resection of the tumor^[1]. Given the infrequency of lymphatic metastases, regional lymphadenectomy is not indicated. Minimally-invasive operations are now frequently used to treat gastric GIST. Retrospective series suggest that these techniques may reduce perioperative stress and are associated with lower rates of postoperative complications, shorter hospital stays and equivalent recurrence rates (Table 1)^[12-16].

EPIDEMIOLOGY AND DIAGNOSIS

Miettinen *et al*^[3] published the largest retrospective series of gastric GIST that reviews 1869 cases seen at the Armed Forces Institute of Pathology from 1970-1996. The vast majority of cases occurred in patients over 40 years of age and the median tumor diameter was 6 cm (range: 0.5-4.4 cm). Most gastric GIST had spindle-cell or epithelioid differentiation. Over 90% of these neoplasms had mutations in the *c-KIT* gene; *PDGFR* mutations were more frequently identified in epithelioid tumors. The metastatic potential of these tumors strongly correlated with their size and rate of mitotic activity. Unfavorable prognostic factors included proximal tumors (gastric cardia and gastroesophageal junction), the presence of coagulative necrosis, ulceration, and invasion deep to the mucosal layer.

Most GIST are incidentally diagnosed during evaluations for nonspecific GI symptoms, such as pain, nausea and vomiting, and weight loss^[2]. Tumor hemorrhage commonly occurs when large tumors develop an ischemic, punctate ulcer (Figure 1A). Usually, the bleeding can be temporized using endoscopic sclerotherapy or electrosurgical coagulation techniques. Seldom is it necessary to take patients urgently for surgical resection with intractable hemorrhage (Figure 1B and C). Often these patients can be stabilized with medical and endoscopic therapy and have elective operations to extirpate these tumors. Intraperitoneal tumor rupture with hemoperitoneum and tumor dissemination is a difficult clinical problem that is associated with a significant risk of intraperitoneal sarcomatosis.

Computed tomography (CT) scanning is the most widely used and effective staging modality^[2]. Multiphase detector can localize the tumor within the stomach and remains a very sensitive technique to detect distant metastasis (at least ≥ 1 mm in diameter) within the liver or lungs; small volume intraperitoneal disease is often only detected on diagnostic laparoscopy and is respon-

Figure 1 Clinical images of complicated gastrointestinal stromal tumors. A: Large intraluminal gastric gastrointestinal stromal tumors (GIST) with punctate central ulceration. The bleeding ulcer was treated endoscopically with sclerotherapy and electrocautery (cauterized tissue; white oval). The patient had an interval resection electively without additional hemorrhage from the tumor; B: Acute presentation of a patient with a ruptured gastric GIST with hemoperitoneum. These images represent contrast-enhanced computed tomography (CT) scan from a patient with a large extraluminal gastric GIST along the greater curvature of the stomach. B1 demonstrates axial CT images of the bi-lobed tumor with irregular borders (arrows); B2 shows additional axial images at the caudal extent of gastric tumor with layering of blood in the splenic recess (oval). He was diagnosed with hemoperitoneum and was resuscitated with packed red blood cells, fresh frozen plasma, and platelets; the patient was on antiplatelet therapy at the time of admission. He stabilized and had an upper endoscopy/ultrasonography for tissue diagnosis and to plan definitive treatment; C: Ruptured gastric GIST following conservative management. Contrast-enhanced CT images following a six-week period of conservative management of the patient with ruptured gastric GIST. C1 demonstrates the more organized bi-lobed tumor with distinct borders (arrows); C2 shows coronal images of the organized hemorrhagic component within the splenic recess after a period of observation (oval). Ultimately this patient had an interval open subtotal gastrectomy for a high-grade GIST.

Figure 2 Endoscopy ultrasound images with fine needle aspiration biopsy. A: A 3 cm × 3 cm submucosal intraluminal mass within the gastric cardia; B: This Endoscopy ultrasound image shows the fine needle aspiration biopsy needle (horizontal white line in upper right corner of image) puncturing the submucosal gastric gastrointestinal stromal tumors.

sible for the reported 10%-15% of false negative rate with dynamic CT. Magnetic resonance imaging (MRI) is an acceptable alternative to CT for patients with renal dysfunction or in whom the risk of cumulative ionizing radiation may be prohibitive. Positron emission tomography (PET) remains an experimental test that may be useful in confirming distant metastatic disease and de-

termining the response to neoadjuvant targeted therapy. PET scans usually indicate tumor responsiveness to imatinib mesylate within days to weeks of induction therapy.

Upper endoscopy (EGD) with ultrasonography (EUS) is an essential diagnostic modality to acquire tissue for diagnosis, usually by fine needle aspiration (FNA) or core-needle biopsy (Figure 2). In addition, EUS is accu-

rate in determining the depth of penetration and origin of these neoplasms and also allows one to potentially consider a hybrid endoscopy/laparoscopic resection^[17]. The published National Comprehensive Cancer Network (NCCN) guidelines outline the recommended principles of tissue sampling for GIST (<http://www.nccn.org>). Since most GIST are soft, fragile, well-encapsulated tumors, indiscriminate biopsies increase the risk of tumoral hemorrhage and rupture. This is associated with higher rates of tumor recurrence and/or intraperitoneal dissemination. The decision to perform a preoperative or pretreatment biopsy should be individualized and only performed when the results of the sampling would definitively influence the choice of treatment^[18]. Biopsy is mandatory for all locally-advanced gastric GIST that will be treated with pre-resection neoadjuvant targeted therapy. Careful review of the acquired tissue by experienced GI histopathologists and use of comprehensive immunohistochemical staining for c-KIT and other markers is essential to confirm the diagnosis. Given the accuracy and real time localization of these tumors, EUS-guided biopsy is generally preferable to CT- or ultrasound-guided FNA biopsy techniques^[2,19].

EGD/EUS can identify the key anatomic relation-

ships of the tumor to the gastric wall layers. GIST at the gastroesophageal junction (Figure 3), pylorus and along the posterior wall of the stomach represent unique surgical challenges and influence the required operation. EGD can also effectively be used to treat tumor hemorrhage and avoid the need for urgent gastric operations. EUS can determine the depth of penetration through the layers of the gastric wall and potentially identify tumors that can be extirpated using endoscopic resection techniques. Only intragastric GIST that arise from the superficial circular muscular layer or muscularis mucosa can be removed with endoscopic enucleation^[20]. These procedures are technically demanding and require considerable experience and skill. Some of these cases take place in the endoscopy suites, but are often coordinated with surgical specialists to assist with the management of hemorrhage or gastric perforation. Often these resections are best performed in surgical operating rooms using laparoscopic-assisted techniques with an experienced surgeon present for the operation.

SURGICAL TREATMENT

Surgical treatment of gastric GIST is the only known cu-

Figure 4 Locally-advanced gastric gastrointestinal stromal tumors. A: Representative contrast-enhanced computed tomography images show a large, proximal gastric gastrointestinal stromal tumors that invades into the splenic hilum (oval); B: On the coronal images the arrow indicates a heterogeneous mass invading into the spleen with areas of viable tumor and necrotic areas represented by calcifications.

rative therapy^[1]. It is essential to completely remove the entire tumor without violating the capsule of the mass. Tumor spillage or hemorrhage is associated with high locoregional recurrence rates and/or development of peritoneal sarcomatosis^[18]. Given the rarity of lymphatic dissemination, regional lymphadenectomy is not routinely performed. Since these tumors originate from the muscular layer of the gastric wall, enucleation is an option, but may be associated with higher recurrence rates unless the intramuscular pedicle can be clearly identified. Standard operations include both “open” and minimally invasive operations. Wedge or a “full-thickness” partial gastrectomy is an effective strategy for tumors that are located along the lesser or greater curvature of the stomach^[21]. Posteriorly-based gastric GIST often require transgastric resections through an anterior longitudinal gastrotomy; the tumor is everted and its pedicle divided with a linear stapling device^[22]. Anatomic gastrectomy (i.e., subtotal or total gastrectomy) is reserved for large tumors that involve a significant portion of the stomach. Endoscopic-assisted, laparoscopic gastric resections are cutting-edge operations that combine precise intraoperative localization of these tumors with gastric-volume preservation techniques.

NCCN guidelines suggest that small (< 1 cm) gastric GIST without high-risk endoscopic ultrasonographic features (i.e., irregular borders, cystic spaces, ulceration, echogenic foci and heterogeneity) may be followed with close endoscopic surveillance at 6-12 mo intervals (<http://www.nccn.org>). In the absence of biopsy-proven metastatic disease, patients with an acceptable performance status and GIST confined to the stomach should undergo complete surgical resection. In patients with marginally resectable tumors or in cases that GIST are potentially resectable, but the need for concomitant en bloc organ resection or total gastrectomy is likely, consideration should be given to neoadjuvant treatment with imatinib mesylate to cytoreduce or “downstage” tumors so that a less morbid or less extensive operation can be considered in the future (Figure 4)^[23-25].

Multiple single institutions highlight the increased use of laparoscopic or minimally-invasive operations for gastric GIST^[12-16]. Resection techniques include: (1) laparoscopic transgastric resections; (2) laparoscopic full-thickness or “wedge” resections; (3) laparoscopic extramucosal enucleation; and (4) combined laparoscopic, endoscopic resections^[26]. The five largest published reports of laparoscopy resections for gastric GIST are summarized in Table 1^[12-16]. Most of these retrospective series include non-GIST, benign submucosal tumors (leiomyomas). Although a formal meta-analysis was not performed given the small number of patients, general trends are evident. It appears that minimally-invasive operations for gastric GIST have been successfully used to treat patients with large tumors in difficult locations (i.e., proximal stomach and gastroesophageal junction). The data also suggest reasonable operative times, acceptable complication rates, and few conversions to open operations. Since none of the series had strict criteria for postoperative discharge to home, the reported postoperative length of stay is difficult to interpret, but was shorter than historic controls for open operations. Importantly, despite nearly one-third of the patients having intermediate to high-risk lesions, nearly 100% were completely removed and did not recur after 1-4 years of follow-up^[12-16]. We urge caution in broadly extrapolating these results to all patients with gastric GIST; most series had relatively short follow-up, involved a considerable selection bias, and most operations were performed by surgeons with considerable experience with these techniques^[27]. Our institutional experience with laparoscopic resection of GIST suggest that these techniques are both feasible and effective treatment for tumors less than eight centimeters in diameter. We advocate using a multidisciplinary approach with combined surgical oncology and minimally-invasive specialists to estimate the biologic behavior and determine the optimal method of resection. Cutting-edge modifications include the use of robot-assisted laparoscopic resections^[28], natural orifice surgery^[29], gasless laparoscopic resections^[30], single-port techniques^[31,32], and novel methods of removing posteriorly based tumors^[26]. One report described an experimental transgastric technique that utilized the retractable, metal-rimmed EndoCatch bags to elevate posterior wall GIST to facilitate laparoscopic stapled transection of the tumor pedicle^[33].

OUTCOMES AFTER SURGICAL RESECTION OF GASTRIC GIST

Since GISTs are rare neoplasms that demonstrate a spectrum of biologic behavior, outcomes following surgical resection are difficult to ascertain. Recurrence free survival appears dependent on tumor size, location, and mitotic rate^[6,34]. Prior to the use of imatinib mesylate as an adjuvant treatment following complete resection of gastric GIST, several large, retrospective reports suggest

local recurrence rates as high as 40% and five-year survival rates as ranging between 40%-90%^[1,35-38]. Dematteo *et al*^[11] published a series of 200 patients with GIST in 2000; more than half of these patients had gastric GIST. In the 93 patients with primary GIST, 80 (86%) had a complete resection with a median disease-specific survival of 54%. Fujimoto *et al*^[36] reported a series of 140 patients that had curative operations for gastric GIST. The five- and ten-year overall survival rates for the 129 patients with “curative” operations were 93% and 88%, respectively. Independent predictors of poor prognosis included male patients [hazard ratio (HR) = 0.469, $P = 0.013$], tumor size greater than or equal to 10 cm (HR = 20.98, $P = 0.001$), a mitotic index of 10+ (HR = 45.95, $P < 0.001$), and epithelioid cell histologic component (HR = 5.32, $P = 0.014$). Models to estimate the risk of recurrence have been created from large, retrospective data set of patients with verified GIST^[6,34]. Size (> 10 cm) and mitotic rates greater than five per 50 high-powered fields are the most significant variables that predict malignant behavior.

Conventional chemo- and radiation therapy are historically ineffective adjuvant treatments for GIST and do not significantly improve survival in patients with recurrent, metastatic or unresectable primary tumors^[18]. The evolution of targeted therapy has dramatically altered outcomes for patients with advanced GIST. Imatinib mesylate is an orally bioavailable, selective molecular inhibitor of cellular tyrosine kinases. First used to treat Philadelphia chromosome-positive chronic myelogenous leukemia, imatinib inhibits tyrosine receptor kinases such as PDGFR and KIT^[39]. The Federal Drug Administration (FDA) approved imatinib mesylate for use in patients with metastatic GIST in 2002. The American College of Surgeons Oncology Group (ACOSOG) phase II non-randomized Z9000 trial examined the use of adjuvant imatinib for one-year following complete resection of high-risk GIST (> 10 cm tumors or ruptured GIST). Imatinib-use was associated with decreased recurrence rates (*vs* historic controls)^[40]. The ACOSOG Z9001 was a randomized, double-blind, placebo-controlled, multicenter trial that conclusively showed a statistically significant reduction in the risk of recurrence with one-year of adjuvant imatinib mesylate therapy (400 mg daily dose; HR = 0.35, range: 0.22-0.53, $P < 0.0001$)^[41]. Seven hundred and thirteen patients with completely resected c-KIT positive GIST (greater than 3 cm) were randomized in an intention to treat analysis. At a median follow-up of 19.7 mo, the study was halted when it became evident that only 30 (8%) of patients in the imatinib group and 70 (20%) in the placebo arm had recurrent disease identified. Further maturation of this data is necessary to determine whether the adjuvant treatment improves overall survival in treated patients.

The FDA approved imatinib mesylate in 2008 as adjuvant therapy following complete resection of GIST for all patients without restrictions on time (to initiate therapy) or histopathologic criteria. The European Medicines Agency approved adjuvant imatinib in 2009

for adult patients with resected c-KIT-positive GIST at significant risk of relapse of disease. At least one year of postoperative imatinib mesylate therapy (400 mg daily) is now considered the standard of care for tumors greater than 3 cm with high-risk features (> 5-10 mitoses/50 high power field) per the results of ACOSOG Z9001^[2]. Several postoperative models of risk assessment have been used to estimate the likelihood of recurrence for patients who do not meet the aforementioned criteria^[6,34]. The optimal duration of imatinib and long-term survival benefit remains the subject of several ongoing randomized, controlled international cooperative group trials and industry-sponsored studies. Current protocols include the recently completed EORTC 62024 trial that randomized 900 patients with completed resected intermediate- and high-risk GIST to receive either two years of adjuvant imatinib mesylate *vs* observation. The primary endpoint of the EORTC trial was overall survival, so the final results will require approximately ten years for complete analysis. The Scandinavian Sarcoma Group phase II trial, (SSGXVII; one *vs* three years of adjuvant imatinib mesylate) and the non-randomized Novartis Pharmaceutical Trial (NCT00867113; five years of adjuvant imatinib) were both designed to test extended use of adjuvant imatinib mesylate following complete resection. Patients at a higher risk of recurrence may justify indefinite use of adjuvant therapy. Three recent cooperative group trials using imatinib in patients with locally-advanced, unresectable or metastatic GIST have suggested that the KIT mutation genotype may have prognostic value to estimate the duration of response and optimal dose of imatinib mesylate^[10,42,43]. Patients in these trials with exon 11-mutations had better treatment outcomes (improved tumor response, progression-free survival, and overall survival) when compared to patients with KIT exon 9-mutants and wild-type patients. At the American Society of Clinical Oncology annual meeting in 2010, it was reported that only deletions (all types) in the KIT exon 11 gene was associated with an increased risk of recurrence^[44]. Heinrich *et al*^[43] also reported that GIST with KIT exon 9-mutations had higher tumor response rates to neoadjuvant imatinib mesylate with daily doses of 800 mg (*vs* 400 mg).

POST-OPERATIVE SURVEILLANCE

NCCN guidelines suggest that following complete resection of gastric GIST; patients should be followed with comprehensive history and physical examinations every 3-6 mo for 5 years, then annually (<http://www.nccn.org>). Abdominal/pelvic contrast enhanced CT scans were recommended every 3-6 mo for at least three to five years postoperatively. Given the risk of renal insufficiency with iodinated contrast and the cumulative ionizing radiation exposure with frequent CT scans, we believe that less intensive surveillance programs should be advocated. MRI remains an acceptable alternative for suitable patients and avoids the deleterious radiation exposure that is associated with serial CT scans. It is reasonable to

Figure 5 Neoadjuvant treatment of a locally-advanced gastrointestinal stromal tumors with imatinib mesylate. A: This woman presented with abdominal pain and fullness. A computed tomography (CT) scan identified a massive (> 30 cm), homogeneous tumor in the gastric fundus that was exophytic and extending caudally towards the pelvic inlet; B: After tissue diagnosis confirmed a gastric gastrointestinal stromal tumor (GIST), the patient was treated with six months of low-dose imatinib mesylate (400 mg/d) until a maximal response was achieved. The coronal views of this interval CT scan demonstrated a much smaller, well-encapsulated, homogenous tumor (solid white arrowhead). She had a radical resection of the gastric GIST and was free of disease until 24 mo when she developed a metastatic lesion in the left lateral segment of the liver. Following complete metastectomy, she was treated with several targeted tyrosine kinase inhibitors until she ultimately succumbed from her metastatic disease 19 mo from her second operation and 43 mo from her initial operation.

consider an EGD at one-year after resection to rule out a local or anastomotic recurrence. Less frequent surveillance programs have been suggested for small (< 2 cm), low-risk tumors. Patients on investigational adjuvant protocols routinely are scanned more frequently to determine the efficacy of treatment.

NEOADJUVANT TREATMENT OF LOCALLY-ADVANCED GASTRIC GIST

Locally-advanced “unresectable” or borderline-resectable gastric GIST are often treated with neoadjuvant imatinib mesylate therapy prior to surgical resection (Figure 5)^[45]. Theoretically, the use of preoperative imatinib may “downstage” or substantially cytoreduce GIST preoperatively and diminish the need for concomitant, en bloc organ resections. Over the past five years, there have been several small, single-institution; retrospective reports documenting outcomes following neoadjuvant treatment of borderline or locally-advanced GIST (Table 2)^[25,44,46-51]. Approximately 75% of these highly selected patients with “unresectable” GIST were subsequently treated with R0/R1 resections. The duration of neoadjuvant therapy and best method of detecting maximal treatment effect have been the subject of two recent phase II trials^[52,53]. The RTOG 0132/ACRIN 6665 cooperative group trial prospectively administered “neoadjuvant” imatinib mesylate (600 mg/d) for eight weeks to patients with both potentially resectable ($n = 30$) and recurrent/metastatic GIST ($n = 22$)^[53]. The majority of patients had disease stabilization; only 12% had a partial tumor response to therapy. Patients were

resected with minimal morbidity and given an additional two years of adjuvant therapy. The patients without metastatic disease had estimated two-year progression-free and overall-survival rates of 83% and 93%, respectively. McAuliffe *et al*^[52] randomized 19 patients with locally-advanced GIST to receive “neoadjuvant” imatinib therapy; subjects were given 600 mg/d for 3 d, 5 d or 7 d prior to surgical resection. Seventeen of 19 patients had a subsequent resection without significant morbidity and were given two years of adjuvant therapy. Approximately 30% of these patients had an objective radiologic response to imatinib (CT/PET) and 12% of the resected tumors had an increase in apoptosis by terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling assay. These studies provide the proof of principle that neoadjuvant imatinib mesylate may be a safe and effective method of treating patients with locally-advanced GIST.

CONCLUSION

Gastric GIST are rare neoplasms that have traditionally required complete surgical resection to achieve cure. Both traditional and minimally invasive gastric resections can be used to remove these tumors with minimal morbidity and excellent perioperative outcomes. The revolutionary use of specific, molecularly-targeted therapies, such as imatinib mesylate, reduces the frequency of disease recurrence when used as an adjuvant following complete resection. Neoadjuvant treatment with these agents appears to stabilize disease in the majority of patients and may reduce the extent of surgical resection required for subsequent complete tumor removal. Importantly, tyrosine kinase inhibitors likely extend the progression-free survival of most patients with GIST. The optimal sequencing of therapies and incorporation of predictive genomic data highlight future challenges in this disease.

Abstract

Adult to adult living donor liver transplantation (AALDLT) was first preformed in the United States in 1997. The procedure was rapidly integrated into clinical practice, but in 2002, possibly due to the first widely publicized donor death, the number of living liver donors plummeted. The number of donors has since reached a steady plateau far below its initial peak. In this review we evaluate the current climate of AALDLT. Specifically, we focus on several issues key to the success of AALDLT: determining the optimal indications for AALDLT, balancing graft size and donor safety, assuring adequate outflow, minimizing biliary complications, and maintaining ethical practices. We conclude by offering suggestions for the future of AALDLT in United States transplantation centers.

INTRODUCTION

At the time of its initial introduction into clinical practice, many believed that adult to adult living donor liver transplantation (AALDLT) would be a panacea for the severe shortage of cadaveric donors that resulted in extensive times on the waiting list and high patient mortality. This belief was illustrated by multiple studies from the late 1990s that suggested that AALDLT was safe and claimed that it would significantly decrease mortality on the transplantation waiting list^[1,2]. The first United States AALDLT was performed in 1997, and over the next 3-5 years AALDLT was vigorously embraced by many United States transplantation surgeons. This enthusiasm was obvious in the documented increase from one to 38 United States AALDLT centers and from one to 266 United States AALDLT procedures between 1997 and 2000^[3]. However, despite rapid integration of this novel procedure into clinical practice, multiple questions remained unanswered. Little was known regarding the proper indications for AALDLT. Further, there was relatively limited data on how graft size impacted recipient and donor safety. Additionally, techniques to assure adequate outflow and minimize biliary complications

were only in their infancy. Finally, the multitude of ethical issues surrounding AALDLT had not been rigorously addressed. In 2002, possibly due to the first widely publicized death of a living donor, the number of living liver donors plummeted. The current number of annual living liver donors has now reached a relatively static plateau at about 250 donors per year, which is far below the initial peak of 524 donors in 2001 (Figure 1)^[4].

While there is a current climate of concern in the United States regarding the safety and appropriateness of AALDLT, multiple other countries (mainly Asian countries, Turkey and Egypt) have experienced a continued rise in AALDLT. Presumably, this contrast is the result of societal norms and logistic difficulties that impede cadaveric organ donation in these areas. Review of data from current United States and Asian transplantation centers along with critical review of the literature from United States surgeons who enthusiastically embraced AALDLT in its early years and then altered their practice as increasing risk became apparent, should be undertaken to help us determine how and if AALDLT can safely be reinstated as a more widely utilized procedure in United States transplantation centers. In this review, we draw upon these studies to address the current status of AALDLT. Specifically, we explore issues related to both the technical/scientific aspects of AALDLT as well as the ethical issues that surround AALDLT. We then offer suggestions for the future of AALDLT in the United States.

OPTIMAL INDICATIONS FOR ADULT TO ADULT LIVING DONOR LIVER TRANSPLANTATION HAVE NOT BEEN ESTABLISHED

Extensive efforts have been dedicated to determining the optimal indications for AALDLT. Review of the recent literature identifies two central issues: the appropriateness of AALDLT for patients with acute liver failure (ALF) and whether the Model for End-stage Liver Disease (MELD) score can be utilized to determine the suitability of AALDLT for a given patient. Here, we briefly highlight recent literature regarding these controversial topics.

In many Asian centers where socio-cultural norms drastically limit utilization of cadaveric liver donation, AALDLT is being increasingly relied upon to offer expedient transplantation to patients with ALF (Table 1)^[5]. Despite relatively widespread use of AALDLT for ALF in many Asian countries, issues regarding graft size and donor safety have prevented widespread acceptance of AALDLT for ALF in the United States. This reluctance to utilize AALDLT in the setting of ALF presumably increases the risk of death due to failure to quickly receive a graft for these critically ill patients. For example, we have found that even when patients with ALF are

Figure 1 Number of United States living liver donors per year^[4].

managed in large-volume, Western liver transplantation centers, the transplantation rate ranges from 41%-72%, and the median waiting time for a deceased donor graft is 3.5-5 d^[6]. These statistics clearly indicate the impressive need for more readily available liver grafts.

The issue of AALDLT for ALF also sparks an ethical debate among the transplant community regarding issues such as how to assure adequate informed donor consent in a relatively pressured setting or whether it is appropriate to ask donors to give an organ to a recipient who may not have a successful outcome. Based on our recent analysis of the current ethical issues with AALDLT for ALF, we feel that with adherence to rigorous informed consent efforts mediated by a donor advocate and recognition that most donors rate the experience of donating positively even if the recipient has a poor outcome, AALDLT can be offered to patients with ALF in a way that maintains the highest ethical standards for both the donor and the recipient^[5]. Thus, given the extreme need for more liver grafts and the precedent of successful AALDLT outcomes in many Asian centers, United States centers should consider broadening the indication for AALDLT to include ALF.

In addition to efforts to determine whether AALDLT is appropriate for ALF, extensive efforts have also been directed toward determining if the MELD score can help predict the suitability of AALDLT for a given patient. The MELD score, which is based upon creatinine, total bilirubin, and INR, was originally developed by Malinchoc *et al*^[7] to predict 3 mo survival in patients undergoing elective transjugular intrahepatic portosystemic shunt procedures. The MELD score has since been shown to be a valuable predictor of pre-transplantation survival, and in 2002 it became a critical tool in assigning priority to patients on the United Network for Organ Sharing (UNOS) transplantation waiting list. At the inception of this policy, little data regarding the predictive value of the MELD score in AALDLT existed thus promoting general concern among transplantation physicians that a higher MELD score (i.e. a sicker patient) may correlate with poor outcomes after AALDLT.

Table 1 Literature review of adult to adult living donor liver transplantation for acute liver failure^[5]

Park <i>et al</i> ^[44]	2010	South Korea	40	85	Both	24	100

This concern was based primarily upon the relatively poor early outcomes of AALDLT for critically ill patients. This issue was addressed in work by Testa *et al*^[8] that investigated the appropriateness of AALDLT for patients with decompensated end-stage liver disease. The authors highlighted several early studies of AALDLT that described a 1 year survival of about 50% for critically ill patients which was far inferior to the 77%-80% 1 year survival reported for patients with a more favorable clinical status. The authors also cited their own 1 year survival for AALDLT in patients with a MELD score > 30 as 43%, which although relatively low, was considered successful given the high likelihood of patient death before a cadaveric donor graft could be allocated to them^[8]. The relatively low survival rates reported in these studies led to a general consensus that critically ill patients should not be candidates for AALDLT. However, Testa *et al* advocated that rather than abandoning the procedure for these patients, the outcomes of AALDLT in the critically ill could be improved by gaining further experience in appropriate donor selection and working to overcome the technical difficulties of the operation^[8]. Recent data from various transplantation centers, especially those in Korea, that heeded this recommendation and continued working to overcome the technical issues that initially contributed to poor outcomes now demonstrate survival in critically ill patients that closely parallels survival of patients who are less ill. Additionally, Hwang *et al*^[9] and Bhangui *et al*^[10] have recently demonstrated the success of AALDLT for patients with hepatocellular carcinoma. These improvements in outcome across a variety of disease etiologies and recipient clinical status suggest that AALDLT is an appropriate procedure for even the most critically ill patients.

To further understand which critically ill patients would benefit most from AALDLT, several studies have since emerged to specifically investigate the predictive validity of the MELD score in AALDLT. For example, in a retrospective review of 62 AALDLT recipients by Hayashi *et al*^[11], MELD score failed to predict 1-year patient or graft survival. To further analyze the predictive capacity the MELD score and 23 other preoperative factors Morioka *et al*^[12] conducted a retrospective review of 335 cases of AALDLT in Japan between 1994 and 2003. The authors concluded that lack of pre-transplant encephalopathy, MELD score ≤ 30 (including points

for persistent ascites and low serum sodium), and donor age < 50 were the key factors for obtaining successful outcomes with AALDLT. This work was contrasted by Durand *et al*^[13] who conducted a retrospective review of 331 DDLT and 128 AALDLT cases to develop statistical models to determine the most efficacious means of organ allocation. This group determined that AALDLT is most advantageous when performed in patients at high risk of death. More simply, these authors demonstrated that the most critically ill patients will derive the most robust statistical benefit from AALDLT^[13]. The studies reviewed here offer slightly conflicting suggestions regarding which patients will benefit most from AALDLT. Further work must be performed to more clearly delineate the indications for the procedure and to establish a meaningful selection criteria for potential recipients.

However, it is our belief that current data generally suggests that the indications for AALDLT should be broadened. Reflection on the drastic improvements in survival for critically ill patients (including those with ALF) in many Asian centers illustrates how diligent refinement of surgical technique and increased procedural experience can result in drastically improved outcomes of AALDLT for even the most critically ill patients. Perhaps United States transplantation centers can call upon the wealth of knowledge generated by these centers to successfully incorporate AALDLT into the routine treatment of United States patients.

DELICATE BALANCE BETWEEN GRAFT SIZE AND DONOR SAFETY

In addition to determining the optimal indications for AALDLT, the transplantation community must advise on the delicate balance of assuring adequate graft size while maintaining donor safety. It is well accepted that AALDLT must be performed in careful balance between recipient needs and donor safety. For example, if acquiring adequate graft volume for the recipient equates to unacceptable risk for the donor, the transplantation must not be performed. Currently, a graft weight to body weight ratio of > 0.8% and a graft size of at least 40% of the standard liver volume is accepted as a minimum requirement for donation^[14]. It has been advocated by some that use of a right lobe graft as compared to a

left lateral lobe as is used in pediatric living donor liver transplantation (LDLT) may allow for larger graft size while still maintaining reasonable donor risk. While it is presumed that the increased graft size places donors at a higher risk following a right hepatectomy, no controlled studies substantiate this concern. Further, presumption that donor morbidity or mortality is directly and solely related to the extent of the liver resection is not reasonable given the numerous other factors that may contribute to poor donor outcomes. The Korean experience demonstrates that with increased operative experience, strict donor selection, and an institutional focus on AALDLT, complications and mishaps can be drastically minimized^[15].

Numerous studies have also been conducted in an effort to determine the safest selection criteria for donors. Authors at a prominent United States transplantation center reviewed the screening of 66 potential donors for 15 eventual AALDLT procedures^[16]. The group relied upon 3D helical imaging including hepatic lobe volume renderings, vascular anatomy, virtual resection planes, preoperative arteriography, and medical/psychological examination, and found that even with robust preoperative donor screening in an experienced hepatobiliary center, morbidity occurred in 67% of donors^[16]. A slightly more recent study of 893 AALDLT cases between 1994 and 2005 in Korea demonstrates how modification of graft size and careful donor selection can result in marked reduction in donor morbidity^[15]. Specifically, until 2001, this group reported an AALDLT donor complication rate of 6.7% which was predominantly due to complications in right lobe liver donors. In 2002, authors changed their donor selection procedure such that liver resection exceeding 65% of total liver volume was avoided except in young donors with no evidence of hepatic steatosis. This change resulted in a reduction of donor morbidity to 1.3% and prompted authors to conclude that a majority of major living donor complications are avoidable through strict selection of living donor/graft type (with cautious selection of the donor right liver if it appears to be larger than 65% total liver volume), intensive postoperative surveillance, and prompt feedback regarding surgical technique. Perhaps most interestingly the authors commented that the experience that they gained from implementation of AALDLT has actually optimized all hepatobiliary surgery practices at their institution^[15]. There is also an interesting body of work evaluating the accuracy of preoperative assessment of graft volume *via* 3D-CT volumetry in AALDLT. Both Hiroshige *et al*^[17] and Kayashima *et al*^[18] have demonstrated that 3D-CT volumetry may overestimate graft volume by as much as 13%, especially in donors under 30 yr old. Authors suggest that this may be due to graft dehydration secondary to University of Wisconsin solution. Studies such as these illustrate the difficulty in assuring accurate pre-operative assessment of graft volume. Given the obvious importance of assuring adequate graft

size, future work to further optimize pre-operative assessment of graft volume is certainly warranted. Clearly, the transplantation community will benefit from further study regarding how to safely balance donor safety and graft size; however, studies such as those discussed here suggest that we are beginning to develop a more robust understanding of how to address this critical issue. We suggest that implementation of strict policies regarding acceptable graft size is the best method for avoiding complications related to small for size grafts or resection of an unsafe donor graft volume.

However, surgical technique alone, even that delivered by expert surgeons, cannot substitute for the institutional organization at all levels of patient care that is mandatory to minimize complications. Any institution willing to offer AALDLT to its patients must invest in AALDLT. Specifically, in order to replicate the results of the best transplantation centers in the world, United States centers should focus on how the entirety of the operative experience, ranging from pre-operative donor evaluation to the number of capable transplant surgeons to the coordinated management of post-operative care, can be structured to provide the highest levels of success.

ISSUE OF OUTFLOW

The right lobe of the liver is increasingly being utilized to assure adequate graft volume in AALDLT. However, use of the right lobe brings with it a heightened risk of impaired graft outflow. Specifically, the right lobe graft carries an increased risk of early post-operative congestion of the paramedian segments 5 and 8 due to interruption of the venous drainage of the middle hepatic vein (MHV). Post-operative congestion has been shown to lead to congestive necrosis which has been reported to incite early post-operative graft failure and recipient death^[19-21]. Harvest of an extended right lobe graft with inclusion of the entire donor MHV is an effective means of preventing outflow obstruction; however, the larger graft size may increase the donor's risk of morbidity and mortality. The surgeon's decision to resect or not resect the donor MHV is thus a complicated one that rests upon several key factors. Donor residual liver volume, the importance of MHV in right lobe drainage, the ratio of graft weight to recipient body weight, and the MELD score must all be carefully evaluated prior to determining whether resection of the MHV is appropriate. Generally, it seems prudent to suggest that if the donor residual liver volume is marginal (ratio < 0.6) or the rest volume is < 30%, the MHV should remain with the donor and segments 8 and 5 should be re-anastomosed.

Several procedural modifications have been proposed to generate improved outflow in cases where the MHV must be interrupted. For example, in a review of 74 AALDLT patients, Malago *et al*^[22] observed that rapid regeneration of the graft in the first 10 post-operative days

resulted in medial displacement of the graft such that kinking, torsion, and compression/occlusion of the outflow tract resulted. By using a cadaveric iliac vein graft to create an interposition conduit that allowed drainage of all intrahepatic veins (diameter > 5 mm) draining segments 5 and 8 into the MHV, the authors devised a modification of the outflow tract that enlarged the caval orifice and assured better outflow^[22]. Successful use of this cadaveric vein outflow reconstruction procedure in patients undergoing AALDLT was also demonstrated by Dong *et al*^[19]. Continued efforts to develop procedural modifications that assure successful outcomes in recipients of AALDLT while maximizing donor safety are imperative. Additionally, it is good practice to remember that every donor-recipient pair presents a unique set of anatomical challenges, however, these challenges should not be considered separately. Favorable outcomes are a result of the safest and most feasible combination of donor and recipient need. Any compromise at the expense of either may result in serious complications and poorer outcomes. Procedural flexibility is ultimately the best policy to protect the donor and assure prompt, successful graft functioning in the recipient.

BILIARY COMPLICATIONS

In addition to issues of impaired outflow, reliance on right lobe grafts for AALDLT has brought with it an increased rate of biliary complications. Overall, since the introduction of AALDLT with right lobe grafts, biliary complications have been the leading cause of post operative complication and re-operation^[23-27]. The reported incidence of biliary complication in AALDLT ranges from 15%-60%^[25,28-31], which is substantially greater than that of cadaveric full-liver transplantation 5%-15%^[29,32,33], and pediatric LDLT with the left lateral lobe of 4%-6%^[34]. Presumably, anatomic differences between the left and right hepatic biliary systems are responsible for this differential complication rate. Specifically, reliance upon the left hepatic duct usually allows a relatively easy dissection due to straightforward ductal anatomy. However, use of the right lobe hepatic system is markedly complicated by the numerous anatomic variations of the right duct. Multiple technical modifications for biliary reconstruction have been published over the past decade (use of recipients right and left hepatic ducts, end-side reconstruction of donor ducts to native common hepatic bile duct, donor ductoplasty, stents, T-tubes, *etc.*), however none has provided a standardized, replicable method that consistently decreases the incidence of biliary complications^[24,30].

Although, biliary complications result in high recipient morbidity and occasionally mortality, early detection and prompt treatment offers a favorable rate of recovery in these patients. Perhaps most importantly, a high rate of success in non-operative management of biliary complications has been consistently demonstrated in

the literature. For example, in a review of 429 patients that underwent liver transplantation, the success rates for treatment of biliary complications by endoscopic retrograde cholangiopancreatography and percutaneous transhepatic radiologic procedures were 100% and 78% respectively^[35]. Given the consistently high rate of biliary complications despite over a decade of efforts to perfect the biliary anastomosis, assurance of robust non-operative treatment modalities is imperative. Thus while continued refinement of technique is critical, we have limited expectation of an easy fix for biliary complications in AALDLT. It is generally clear that while most of the other technical obstacles to AALDLT have found favorable solutions, we are still far from having developed a biliary anastomosis technique that will provide consistently positive results. While relying on continued advancement in minimally invasive procedures to remedy these frequent complications is currently an acceptable compromise, it is imperative that we continue significant efforts to construct a biliary anastomosis with equivalent or lower complication rates than that of deceased donor liver transplant.

ETHICAL ISSUES

The ethical issues surrounding AALDLT are complex and warrant thoughtful discussion prior to widespread implementation of the procedure. Overall, the majority of regulations on liver transplantation are guided by a simple reality: liver grafts are provided by a public supply, and the supply is insufficient to meet current societal demands. The introduction of AALDLT presumably alters this climate by increasing the available supply of grafts. This increase in supply offers the opportunity of transplantation to patients who previously had relatively minimal chances of obtaining a graft given that their clinical status was not critical enough to assure high priority listing on the transplantation waiting list or because the etiology of their disease precluded them from being a transplant candidate (hepatocellular carcinoma, polycystic liver disease, *etc.*). While introduction of AALDLT clearly expands the opportunity for many patients awaiting transplantation it carries with it multiple ethical questions.

Overall, the issue of whether AALDLT is ethically appropriate requires careful assessment of the risks and benefits to the individual donor-recipient pair. The benefits to the potential recipient are relatively obvious. AALDLT offers potential recipients decreased time on the waiting list or, in some cases, the opportunity to completely bypass the waiting list. Further, with AALDLT potential recipients are able to undergo transplantation as an elective rather than urgent surgery thereby allowing increased control of variables such as graft ischemic time. However, given the healthy status of the donor, the age old vow of physicians, “*primum non nocere*” (first do no harm), mandates that the risks and

benefits to the donor be the primary focus of a discussion of transplantation ethics. In our brief review of the literature, it is evident that donors experience a relatively high risk of morbidity and a realistic risk of mortality in even the most well-qualified transplantation centers with the most experienced transplantation surgeons. The risk of short and long-term medical morbidity is compounded by the financial burdens that may result due to ongoing medical bills and time lost from work. Currently, no system is in place to assure that donors are not excessively burdened by such issues. However, one must remember that while this risk may be of high concern for United States donors, it may be less of an issue in European countries where public health insurance typically covers all donor expenses. While substantial health and financial risk is obvious for the donor, great benefits may also be incurred by consenting to living liver donation. The psychological benefit from this altruistic decision is one of the primary benefits to donors. A vast body of literature exists that consistently supports the finding that even in cases of poor recipient outcome, undergoing donation helps donors feel as if they have done everything possible to help save the life of their loved one^[36]. Donation may also bring with it a decreased caregiver burden and increased participation of the recipient in subsequent household matters.

Several other issues are central to a thorough discussion of the ethics of AALDLT. First, there is great concern among the transplantation community that critical recipient status (especially in the setting of ALF) or familial pressure may limit the ability of potential donors to fully engage in an informed consent discussion. Many worry that donors may feel pressured to donate, and they encourage a robust donor evaluation process with inclusion of a donor advocate who assures donors the opportunity to make their decision with minimal pressure from family or members of the health care team. Additionally, many worry that performing an AALDLT in a setting in which recipients may have a poor outcome (e.g., ALF) may not be appropriate. However, multiple authors have determined that even in settings in which recipients die or suffer significant morbidity, most donors rate the donation experience positively as they feel as if it has allowed them to do all they can to help save the life of their loved one^[36]. Clearly, the ethical issues involved with AALDLT are complex and deserving of further discussion to assure the highest ethical standards are maintained when caring for the donor-recipient pair.

HAVE WE IMPROVED SINCE 1997?

Critical review of the success and failure of AALDLT over the past decade is imperative in assessing our current status. Improved transparency in outcomes reporting, development of uniform regulations, an increasing number of National Institutes of Health funded studies, and increasing procedural experience all suggest that our ability to safely and successfully perform AALDLT has

improved since the initial introduction of the procedure in 1997.

MOVING FORWARD

Critical review of AALDLT suggests that the Western world both embraced and dismissed AALDLT too quickly^[37]. A new framework for integration of AALDLT into United States medical practice that is rooted in clinical expertise, genuine need, and accurate reporting should be developed to create a new starting point for AALDLT in the United States. Focus upon the key factors of determining the appropriate indications, balancing graft size with donor safety, assuring adequate outflow, minimizing biliary complications, and mandating ethical rigor is imperative. Additionally, we offer several suggestions that we believe will assure thoughtful integration of AALDLT into United States practice. First, all AALDLT activity should be concentrated in centers with dedicated AALDLT staff and adequate field strength (capacity of surgical team to meet the technical demands of a relatively innovative procedure, proven success with all facets of hepatobiliary surgery, *etc.*). Next, we believe that proper training programs for staff along with validated criteria to demonstrate clinical competency should be developed. Further, incorporating knowledge from centers that are already world leaders in AALDLT to establish patient and graft survival that is superior to deceased donor liver transplantation must be the ultimate goal. Finally, working to improve the societal image of AALDLT is critical for assuring integration into current United States medical practice. It is our belief that careful attention to these key factors will help redefine the role of AALDLT in United States transplantation centers. And while this may not provide the panacea for long wait times and high recipient mortality that was originally assumed, we believe that robust integration of AALDLT into United States practice will offer significant improvements for patients awaiting liver transplantation.

Abstract

Patients with esophageal cancer have a poor prognosis because they often have no symptoms until their disease is advanced. There are no screening recommendations for patients unless they have Barrett's esophagitis or a significant family history of this disease. Often, esophageal cancer is not diagnosed until patients present with dysphagia, odynophagia, anemia or weight loss. When symptoms occur, the stage is often stage III or greater. Treatment of patients with very early stage disease is fairly straight forward using only local treatment with surgical resection or endoscopic mucosal resection. The treatment of patients who have locally advanced esophageal cancer is more complex and controversial. Despite multiple trials, treatment recommendations are still unclear due to conflicting data. Sadly, much of our data is difficult to interpret due to many of the trials done have included very heterogeneous groups of patients both histologically as well as anatomically. Additionally, studies have been

underpowered or stopped early due to poor accrual. In the United States, concurrent chemoradiotherapy prior to surgical resection has been accepted by many as standard of care in the locally advanced patient. Patients who have metastatic disease are treated palliatively. The aim of this article is to describe the multidisciplinary approach used by an established team at a single high volume center for esophageal cancer, and to review the literature which guides our treatment recommendations.

INTRODUCTION

Esophageal cancer is a growing epidemic with approximately 460 000 new diagnosis and 380 000 deaths annually worldwide^[1,2]. Adenocarcinoma has increased in incidence while the incidence of squamous cell esophageal carcinoma has decreased in the Western world. This seems to be linked to gastroesophageal (GE) reflux disease and Barrett's esophagus^[3-7]. The prognosis for these patients is generally poor because of the advanced stage at the time of presentation. The increase in use of pro-

ton-pump inhibitors over-the-counter has also decreased the impetus to seek physician assistance for reflux symptoms. Hence most of these patients will be diagnosed at a late stage, with approximately 50 percent of patients have advanced unresectable or metastatic cancer^[7]. Most patients are not considered curable at diagnosis and are treated with chemotherapy and radiation, mostly with palliative intent. In patients who are fortunate enough to have potentially resectable disease, the data are not clear as to the best approach. Patients with very early disease may only require endoscopic mucosal resection or surgical resection. Others are treated with a combination of chemotherapy plus radiation (chemoradiation) plus surgery if they are deemed resectable. Ideally, we would like to have large randomized trials that were powered properly to support our treatment plans. As these studies do not exist in the esophageal cancer world, we are left to rely mainly on meta-analysis, small randomized trials, and historical reports to make decisions for our patients. These treatments require specialists from surgery, medical oncology, radiation oncology, and gastroenterology. It is imperative that these individuals work in a multidisciplinary fashion in order to deliver comprehensive care. The goal of this paper is to discuss the approach of an established multidisciplinary team in the treatment of patients with locoregionally advanced disease.

EVALUATION OF THE PATIENT

To obtain an adequate volume of tissue for diagnosis, a minimum of 7 core/pinch biopsy specimens in addition to brushings are recommended at the time of endoscopy. This approach improves the accuracy of diagnosis to 98%-100%^[7]. In addition, it provides tissue for molecular marker analysis, as cancer therapy is beginning to focus on targeted therapies which may require tumor marker analysis. Staging studies should include a computed tomography of the chest and abdomen, a positron emission tomography (PET) scan and endoscopic ultrasound by a specialized gastroenterologist trained and proficient in this technique. Biopsies should be obtained from suspicious lymph nodes if accessible. An esophagram is also helpful in determining the degree of esophageal stricture. With the seventh edition American Joint Committee on Cancer Staging System, it is imperative to determine the histology of the tumor and number of lymph nodes involved. In patients who have respiratory symptoms, a bronchoscopy should be done to evaluate for tracheoesophageal fistula formation. In patients with other pulmonary or abdominal findings on imaging studies, one may wish to pursue thoracoscopy or laparoscopy. In addition, it is important to assess the performance status, the nutritional status and the patient's comorbidities of prior to determining an appropriate treatment plan.

TREATMENT APPROACHES

Treatment of cT1-2N0 disease

Surgery alone remains the standard of care for patients

with local disease (cT1N0 and some cT2N0 tumors). At our institution and other high volume institutions, patients with T1aN0 tumors are treated with minimally invasive techniques such as endoscopic mucosal resection. There is limited experience with the use of radiation or chemoradiotherapy in the curative setting for patients with cT1N0 disease^[8]. Thirty-four patients with either medically inoperable disease or refused surgery were treated with external beam alone (64 Gy) or external beam (52 Gy) plus 8 to 12 Gy with brachytherapy. The median follow-up was 61 mo, 5-year survival was 59%, 68% local relapse-free survival, and 80% cause-specific survival^[8].

For most cT2N0 tumors, surgery alone may not be sufficient since approximately 50% of patients may have lymph node metastasis^[9-12]. However, if the nodes are negative (pT2N0m0) there is no role for postoperative adjuvant chemotherapy or chemoradiation.

Treatment of cT3-4 and/or N positive disease

There remains much controversy in what is considered the current standard of care for patients with locally advanced esophageal cancer (cT3-4 and/or N positive)^[13-15]. Initially, surgical resection was the main modality for esophageal cancer treatment. Since the 1980's, studies have evaluated the utility for perioperative chemotherapy, postoperative and more commonly preoperative chemoradiation to improve outcome. These studies have been criticized for a variety of insufficiencies including inadequate power, the type of chemotherapy regimen, the dosing of chemotherapy, the radiation dose and fraction size, radiation delivery schedules, number of patients enrolled, initial staging, multiple organ sites and histologic subtype. At our institution, we advocate the use of neoadjuvant chemoradiotherapy based on the following data.

DO PATIENTS BENEFIT FROM NEOADJUVANT RADIATION?

There have been five phase III trials which evaluated neoadjuvant radiation in esophageal cancer. None of the studies have demonstrated an increase in overall survival or resectability of esophageal cancer patients treated with radiation alone^[16-20]. Nygaard *et al.*^[19] reported a 3-year overall survival benefit only after adding patients who also received chemotherapy to the statistical analysis. A meta-analysis of neoadjuvant radiation revealed a trend toward improved 5-year overall survival but failed to show a statistically significant survival advantage^[21]. Data do not support the use of radiation as a single modality in the neoadjuvant treatment of esophageal cancer (Table 1). The role of radiation alone should be limited to palliation.

DO PATIENTS BENEFIT FROM PERIOPERATIVE CHEMOTHERAPY?

Neoadjuvant or perioperative chemotherapy has also

Table 1 Randomized trials of neoadjuvant radiation in esophageal cancer

been evaluated in patients with locally advanced gastric and GE cancer. At least five phase III trials have compared cisplatin-based regimens to surgery alone in esophageal cancer and three studies showed a survival advantage (Table 2)^[22-26]. The Medical Research Council trial is the largest of these studies as it randomized 802 patients with esophageal adenocarcinoma or squamous cell carcinoma. There was a 5-year overall survival advantage of approximately 6%^[24]. The Magic trial randomized 503 patients, predominately gastric cancer patients, and demonstrates a 5-year overall survival advantage of 13%^[22]. The French Cooperative Group study randomized 224 predominately gastric cancers with a survival advantage of 14% at 5 years^[26]. All of these studies noted no evidence of increased morbidity or mortality in patients who received neoadjuvant chemotherapy. Many studies that evaluated perioperative chemotherapy have shown some overall survival benefit. This is evident in GebSKI's meta-analysis that evaluated 1724 patients who received chemotherapy and surgery versus surgery alone in 8 trials. Of note was a 7% absolute benefit in 2 years survival ($P = 0.014$) in adenocarcinoma patients only^[27]. These data are complicated because only 2 of the studies evaluate only esophageal cancer^[23,24]. While we feel there is some benefit to perioperative chemotherapy, we do not advocate its use as the data suggest neoadjuvant chemoradiotherapy to be superior in esophageal cancer.

DO PATIENTS BENEFIT FROM CONCURRENT CHEMORADIOOTHERAPY?

Chemotherapy combined with radiation enhances the effects of radiation by synergistically damaging the DNA following cell cycle synchronization^[28,29]. Chemotherapy theoretically also reduces the risk of distant metastatic disease by eradication of micrometastases^[30]. Chemoradiation is useful in both the neoadjuvant setting for all esophageal cancer patients or in the adjuvant setting for patients with GE junction tumors. Additionally, in patients who are not surgical candidates chemoradiation may be used as definitive treatment^[31]. Ideally, concurrent

chemoradiation should be done by a multidisciplinary group proficient in these procedures as many situations may result in a less favorable outcome. Situations which may occur include unnecessarily missed chemotherapy or radiation doses for complications which could be managed by groups more experienced in this technique. Additionally, the use of unconventional chemotherapy or radiation regimens or erroneous staging studies may also be problematic.

Initially, concurrent chemoradiation was evaluated as definitive treatment for patients who were not surgical candidates in the Radiation Therapy Oncology Group (RTOG) 85-01 trial^[31]. In this study 134 patients were randomized to cisplatin combined with infusional fluorouracil and concurrent radiation or to radiation alone. The patients predominately had esophageal squamous cell carcinoma. Interim analysis revealed that a statistically significant survival advantage favoring concurrent chemoradiotherapy hence changing the treatment paradigm in inoperable locally advanced esophageal cancer. The 5-year overall survival was 27% *vs* 0% with radiation alone^[31]. Despite the reduction in the risk of persistent disease or local recurrence with concurrent chemoradiotherapy compared to radiation alone, the incidence of locoregional failure was a dismal 47%^[31]. Hence, in an effort to reduce locoregional failure, radiation dose was then addressed by the INT 0123 trial^[32]. A total of 236 patients were randomized to high (68.4 Gy) or low (50.4 Gy) dose radiation all given with concurrent cisplatin and infusional fluorouracil per the RTOG 85-01 regimen. An interim analysis failed to reveal a local control or survival benefit with high dose radiation hence, 50.4 Gy has become standard of care for both neoadjuvant and definitive radiotherapy^[32].

Patients with esophageal cancer have unacceptably high locoregional failure rates of approximately 50% with chemoradiation and a dismal prognosis of 20%-25% at 5 years with surgery alone^[23,33-35]. Based on the limited success of these two approaches, a number of studies evaluating the combination of chemoradiation and surgery were developed.

DO PATIENTS BENEFIT FROM SURGERY?

Surgery has been considered an essential part of the treatment of patients with esophageal carcinoma^[36]. Past experiences showed that a nonsurgical approach was associated with mediocre survival results^[37]. However, the better survival achieved with surgical therapy may have a high price. In 1980, Earlam *et al*^[38] reviewed the literature and reported 29% mortality for esophagectomy. Today, some still quote these numbers as a justification for nonsurgical approach to esophageal cancer, stating if a patient with esophageal cancer may either die by the tumor or die by the knife. However, it is hard to believe that these numbers remain true after significant improvements in antibiotics, intensive care, surgical equipment, and technique. Additionally, developments in chemotherapy and radiotherapy have occurred as well.

What is the best surgical technique?

There are 3 different basic approaches for esophagectomy: (1) transhiatal; (2) transthoracic; and (3) *en bloc* or radical. The transhiatal approach has a theoretical advantage of a decreased morbidity and mortality due to the avoidance of a thoracotomy (and thus, a decreased operative time and pain). Even though concern has been raised about lesser oncologic radicality, several studies compared the outcomes for transhiatal versus transthoracic esophagectomy. Two meta-analysis in 2 different decades (2001 and 2011) showed no differences in survival comparing these two approaches^[39,40]. The transthoracic group; however, had significantly more respiratory complications, wound infections, and early postoperative mortality, whereas anastomotic leak, anastomotic stricture, and recurrent laryngeal nerve palsy rates were significantly higher in the transhiatal group. Population studies reached the same conclusions. Chang *et al*^[41] evaluated a pool of 868 patients from the American Surveillance, Epidemiology, and End Results-Medicare linked database (1992 to 2002) with similar results. Additionally, Connors *et al*^[42] consulted the registries of 17 395 patients from the American Nationwide Inpatient Sample database and found similar outcomes for both procedures.

The need for lymphadenectomy (radical esophagectomy) is an ongoing debate in esophageal surgery. Also, it is unclear if the patients that may benefit from these procedures are the ones with early cancer or locally advanced tumors. Moreover, the extent of the lymphadenectomy (1 field-thoracic, 2 fields- thoracic and abdominal, 3 fields-thoracic, abdominal and cervical) is a controversial topic. The lack of randomized trials addressing this issue increases the controversy. Although some studies showed better survival after *en bloc* esophagectomy others showed results similar to a transhiatal esophagectomy^[43,44]. Morbidity and mortality for this procedure is not always reported; however, it seems to be high, especially in 3-field^[45].

Minimally invasive surgery has the advantages of better cosmetic results, reduced operative stress, postoperative immobility, and pain. As far as we are aware, no randomized controlled trials have compared minimally invasive and open esophagectomy to date. Available data, including 3 recent meta-analysis suggests that minimally invasive esophagectomy is similar to conventional esophagectomy in terms of complications, oncologic radicality and survival^[46-49].

Modern outcomes for mortality and survival

Different studies from experienced centers show a rate of mortality close to 0 in patients with non-advanced or even advanced tumors^[50-53]. The application of standardized protocols with a multidisciplinary team improved significantly the outcomes of esophagectomy. It is not easy to access the survival related to esophagectomy only since most series of surgery alone are related to initial cancer and most surgeons refer patients to neoadjuvant

or adjuvant chemotherapy^[54]. However, patients with potentially resectable tumor not referred for surgery have a lower survival rate^[55].

Relationship between volume and outcomes

Different papers repeatedly reported better outcomes for esophagectomy in high volume centers^[42,56,57]. This better results may be attributable to surgeons' experience, since a decrease in more than 50% in the index of complications following esophagectomy is observed when the operation is performed by surgeons experienced in more than 100 esophagectomies^[58]. However, hospital volume is also important, since the preparedness of the multidisciplinary team and hospital services to attend esophagectomy patients is crucial to better outcomes. Even low volume hospitals with high nurse ratios, lung transplantation services, complex medical oncology services, bariatric surgery services, and positron emission tomography scanners have lower mortality rates compared with low-volume hospitals with none of these characteristics^[59]. Very interestingly, survival was not linked to volume^[60].

DO PATIENTS WHO UNDERGO SURGERY BENEFIT FROM NEOADJUVANT CHEMORADIATION?

To date, there have been eleven randomized trials performed evaluating the utility of neoadjuvant chemoradiotherapy added to surgery (Table 3). These trials have incorporated a variety of chemotherapy regimens, doses and fraction sizes of radiation and timing of both chemotherapy and radiation. Of these studies only 3 have shown a benefit with concurrent chemoradiotherapy. The CALGB 9781 study randomly assigned patients to cisplatin, infusional fluorouracil with concurrent radiation and surgery or to surgery alone. The study was unable to adequately accrue due to patient and investigator bias favoring the neoadjuvant arm. Despite the lack of accrual in this study there was an impressive five-year overall survival of 39% with multimodality treatment and 16% with surgery alone ($P = 0.002$)^[61]. The study performed by Walsh *et al*^[62] randomized 113 patients with adenocarcinoma to cisplatin, infusional fluorouracil and radiotherapy followed by surgery or to surgery alone. The median overall survival was 16 mo with multimodality treatment and 11 mo with surgery alone ($P = 0.01$). Three-year survival of 32% with multimodality treatment and 6% with surgery alone ($P = 0.01$). This study has been criticized for inadequate radiation dose, inadequate fluorouracil dose, survival in the control arm lower than historical controls, and lack of adequate staging prior to chemoradiotherapy^[62]. The CROSS trial has been reported in abstract form by van der Gaast *et al*^[63]. A total of 363 patients with adenocarcinoma or squamous cell carcinoma were randomized to preoperative paclitaxel/carboplatin plus 41.4 Gy *vs* surgery alone.

P: Cisplatin; BP: Bleomycin and cisplatin; NS: Not significant; PF: Cisplatin and 5-fluorouracil; AC: Adenocarcinoma; SCC: Squamous cell carcinoma; NR: Not reported; NS: Not significant; RT: Radiation; CRT: Chemoradiotherapy.

With a median follow-up of 32 mo patients who received chemoradiation had a significant benefit in 3-year survival (59% *vs* 48%, $P = 0.011$). There was also an increase in (RO) resection rates 67% *vs* 92%, 0.002 favoring chemoradiotherapy^[63].

Given the contradictory and inconclusive results in many of the trials evaluating neoadjuvant multimodality treatment based on disparate study populations, differing histology, differing chemotherapy and radiotherapy doses and regimens, and small numbers of patients, data have been pooled in an effort to synthesize the data into larger numbers to discover if a survival benefit exists^[64]. The first meta-analysis published by Urschel *et al*^[65], included nine randomized controlled trials and 1116

patients. A trend toward 3-year survival improvement favoring neoadjuvant chemoradiotherapy was noted with the most pronounced effect with concurrent chemoradiotherapy as compared to a sequential approach. There was a decreased risk of local-regional recurrence but concerning trend toward increased treatment mortality with multimodality treatment. There was no difference in the risk of distant recurrence. Fiorica *et al*^[66] noted an improvement in patients who received neoadjuvant chemoradiotherapy. Gebiski *et al*^[27] also evaluated neoadjuvant chemotherapy and chemoradiotherapy compared to surgery alone in a meta-analysis. This recent meta-analysis evaluated 1209 patients with both adenocarcinoma and squamous cell carcinoma of the esophagus in

ten trials. A statistically significant benefit was noted with neoadjuvant chemoradiotherapy compared to surgery alone with a 19% decrease in the risk of death corresponding to a 13% absolute difference in 2 year survival. An absolute survival benefit of 7% was noted for neoadjuvant chemotherapy as compared to surgery alone. The Preoperative Chemotherapy or Radiochemotherapy in Esophagogastric Adenocarcinoma Trial (POET) attempted to determine in a prospective, randomized fashion if neoadjuvant concurrent chemoradiotherapy is more beneficial than perioperative chemotherapy^[67]. There was a trend toward improved pathologic complete response with neoadjuvant chemoradiotherapy but the study was closed early due to lack of accrual^[67]. Given these data, we plan neoadjuvant chemoradiotherapy in our eligible patients.

DO PATIENTS WHO UNDERGO CHEMORADIATION BENEFIT FROM SURGERY?

Two randomized trials examine whether surgery is necessary after chemoradiation. In the FFCD 9102 trial, 445 patients with clinically resectable T3-4N0-1M0 squamous cell carcinoma of the esophagus received initial chemoradiation^[68]. Patients initially received 2 cycles of 5-fluorouracil (5-FU), cisplatin, and concurrent radiation (either 46 Gy at 2 Gy/d or split course 15 Gy weeks 1 and 3^[68]). The 259 patients who had at least a partial response were then randomized to surgery *vs* additional chemoradiation which included 3 cycles of 5-FU, cisplatin, and concurrent radiation (either 20 Gy at 2 Gy/d or split course 15 Gy). There was no significant difference in 2-year survival (34% *vs* 40%, $P = 0.56$) or median survival (18 mo *vs* 19 mo) in patients who underwent surgery *vs* additional chemoradiation. These data suggest that for patients who initially respond to chemoradiation, they should complete chemoradiation rather than stop and undergo surgery. The German Oesophageal Cancer Study Group compared preoperative chemoradiation followed by surgery *vs* chemoradiation alone^[69]. In this trial, 172 patients < 70 years old with uT3-4N0-1M0 squamous cell cancers of the esophagus were randomized to preoperative therapy (3 cycles of 5-FU, leucovorin, etoposide, and cisplatin, followed by concurrent etoposide, cisplatin, plus 40 Gy) followed by surgery *vs* chemoradiation alone (the same chemotherapy but the radiation dose was increased to 60-65 Gy +/- brachytherapy). In patients who underwent surgical resection, 35% had complete pathologic response and 33% had no evidence of lymph node involvement following neoadjuvant therapy^[69]. Despite a decrease in 2-year local failure (36% *vs* 58%, $P = 0.003$) there was no statistically significant difference in 3-year survival (31% *vs* 24%) for those who were randomized to preoperative chemoradiation followed by surgery *vs* chemoradiation alone. The practice at our institution is to closely observe patients with

esophageal squamous cell cancer who have a complete clinical response. Patients with adenocarcinoma continue to require surgical resection as these studies only evaluate patients with squamous cell cancer and studies to address adenocarcinoma have not been done.

DO PATIENTS WHO HAVE SURGERY BENEFIT FROM ADJUVANT TREATMENT?

In an effort to address locally advanced gastric and GE junction cancers adjuvant chemoradiotherapy was evaluated (MacDonald)^[70]. This trial (INT 0116) enrolled 556 patients with gastric and GE junction (approximately 20%) adenocarcinoma. Patients were randomized to surgery alone or surgery followed by adjuvant leucovorin-modulated fluorouracil with concurrent radiation (45 Gy) in cycle 2 of 4 total cycles. There was an improvement in median overall survival with adjuvant therapy 36 mo *vs* 27 mo in the observation group ($P = 0.005$)^[70]. Treatment related toxicity prevented completion of the treatment in 17% of patients^[70]. There are no data evaluating the utility of adjuvant therapy in patients with more proximal esophageal tumors. At our institution, we plan neoadjuvant chemoradiation in locally advanced esophageal cancer patients. If following surgery, the pathology upstages the cancer, we plan for adjuvant treatment only in cancers of the GE junction.

WHAT IS OUR PRACTICE AND RATIONALE?

In summary, although there is good rationale for its use, it is not clear that the combination of surgery and chemoradiation regardless of the sequence, improves the survival results of either treatment alone. The survival benefit is likely to be 5%-10% with multimodality therapy. Currently, the standard of care in treatment of locally advanced tumors at our institution is to place patients on neoadjuvant chemoradiotherapy provided that it is feasible. We take into account the tumor location, size of the radiation field, comorbidities, and performance status in determining what the best multimodality approach is. There are many institutions, especially in Europe, who use neoadjuvant chemotherapy only. It is our practice to use neoadjuvant chemoradiotherapy because of the findings of the CALGB 9781, Walsh study, multiple meta-analysis and more recently the POET study^[27,61,62,67]. The GebSKI meta-analysis quoted a 13% absolute benefit in 2 year survival with neoadjuvant chemoradiotherapy and a 7% absolute benefit with neoadjuvant chemotherapy^[27]. This is almost a doubling of the benefit conferred with perioperative chemotherapy alone. Additionally, the POET study, the only study which compares neoadjuvant chemotherapy to neoadjuvant chemoradiotherapy demonstrates a trend toward increased pathologic complete response at resection and survival with neoadjuvant chemoradiotherapy^[67]. This study was performed in patients with GE junction

tumors and was closed early due to poor recruitment.

Additionally, we feel surgery may not be required in patients with esophageal squamous cell carcinoma provided they have a complete response to neoadjuvant therapy. Given that squamous cell carcinomas often recur locally, observation alone may be acceptable in this small group of patients. For those patients who have adenocarcinoma, we feel resection is still standard of care.

WHAT IS BEING EVALUATED CURRENTLY IN ESOPHAGEAL CANCER?

Despite improvements noted with multimodality treatment in esophageal cancer, cure rates are consistently dismal^[27]. With new interest in targeted agents in cancer demonstrating benefit in malignancies of the head and neck, breast, lung, colon and pancreas have generated evaluation in the esophagus^[71-73]. Multiple molecular pathways have been evaluated at the molecular level with potential targets in esophageal cancer including cyclin dependent kinases, nuclear factor κ , matrix metalloproteinases, inhibition of cyclooxygenase-2, c-MET (a protooncogene that encodes a protein known as hepatocyte growth factor), epidermal growth factor receptor (EGFR) and vascular endothelial growth factor^[72].

Over-expression of EGFR proteins may occur in 30%-70% of both adenocarcinoma and squamous cell carcinoma of the esophagus. Over-expression is associated with increased aggressiveness of the malignancy and poor prognosis^[74-76]. Clinical trials have been initiated trying to take advantage of this protein. The Southwest Oncology Group initially targeted this protein by using single agent cetuximab as a second-line therapy with discouraging results^[77]. More recent studies have evaluated cetuximab or other monoclonal EGFR antibodies with chemotherapy appear to be more promising^[78-80]. Recently, EGFR-2 (Her-2-neu) has also been evaluated in gastric and esophageal cancers over expressing human EGFR-2 HER2 (ToGA trial) with promising results^[81]. These targeted agents are currently undergoing evaluation in a multimodality setting with chemoradiotherapy. Safran *et al*^[82] have evaluated 57 patients with esophageal cancer with weekly carboplatin, paclitaxel, cetuximab, and concurrent radiation (50.4 Gy). Complete clinical response was achieved in 70% of patients. Forty-nine of patients went on to surgery with a pathologic complete response rate of 27%. The RTOG 0436 is an ongoing phase III trial evaluating weekly carboplatin, paclitaxel, and concurrent radiation with or without cetuximab in locally advanced inoperable patients. Additionally, given the results on the ToGA trial trastuzumab is currently under investigation with cisplatin, paclitaxel, and concurrent radiation for locally-advanced, HER2 overexpressing adenocarcinoma of the esophagus^[83].

Survival benefits of neoadjuvant therapy appear small, but it should be noted this is similar to other treatments for other lethal malignancies^[84]. The need to treat approximately 8 patients with a toxic regimen to cure

one additional patient is not ideal, yet these odds must be discussed with a patient who is felt to be medically fit to withstand an esophagectomy^[64]. Additionally, patients will often question about adjuvant therapy. While appropriate, in patients who have GE junction tumors only this is poorly tolerated post surgically, involves a larger radiation field, and radiation doses are lower^[70]. Hence, our recommendations in the locally advanced resectable patient remain neoadjuvant chemoradiotherapy followed by esophagectomy. How targeted therapies will affect our approach in locally advanced esophageal carcinoma and is currently under investigation^[73,76]. Additionally, studies arrived at neoadjuvant concurrent chemoradiation regimens based on PET response to induction chemotherapy are underway.

Abstract

Large comparative studies and multiple prospective randomized control trials (RCTs) have reported equivalence in short and long-term outcomes between the open and laparoscopic approaches for the surgical treatment of colon cancer which has heralded widespread acceptance for laparoscopic resection of colon cancer. In contrast, laparoscopic total mesorectal excision (TME) for the treatment of rectal cancer has been welcomed with significantly less enthusiasm. While it is likely that patients with rectal cancer will experience the same benefits of early recovery and decreased postoperative pain from the laparoscopic approach, whether the same oncologic clearance, specifically an adequate TME can be obtained is of concern. The aim of the current study is to review the current level of evidence in the literature on laparoscopic rectal cancer surgery with regard to short-term and long-term oncologic outcomes. The data from 8 RCTs, 3 meta-analyses, and 2 Cochrane Database of Systematic Reviews was reviewed. Current data suggests that laparoscopic rectal cancer resection may benefit patients with reduced blood loss, earlier return of bowel function, and shorter hospital length of stay. Concerns that laparoscopic rectal cancer surgery compromises short-term oncologic outcomes including number of lymph nodes retrieved and circumferential resection margin

and jeopardizes long-term oncologic outcomes has not conclusively been refuted by the available literature. Laparoscopic rectal cancer resection is feasible but whether or not it compromises short-term or long-term results still needs to be further studied.

INTRODUCTION

Laparoscopic colon resection was introduced in 1991^[1,2]. Concern for port site metastasis and inadequate oncologic clearance initially hampered its adoption in the treatment of colon and rectal malignancy^[3-6]. However, recently large comparative studies and multiple prospective randomized control trials (RCTs) have reported equivalence in resection margin, lymph node collection, tumor recurrence, postoperative complications, and long-term outcomes between open and laparoscopic

resection for colon cancer^[7-12]. In addition, these studies demonstrated earlier recovery of bowel function, less postoperative pain, and decreased hospital stay with the laparoscopic approach which has heralded widespread acceptance for laparoscopic resection of colon cancer^[8,9,13-16]. In contrast, laparoscopic total mesorectal excision (TME) for the treatment of rectal cancer has been welcomed with significantly less enthusiasm.

While it is likely that patients with rectal cancer will experience the same benefits of early recovery and decreased postoperative pain from the laparoscopic approach, whether the same oncologic clearance, specifically an adequate TME can be obtained is of concern^[17-23]. Involvement of the circumferential resection margin (CRM) after TME is a prognostic factor for local recurrence^[24-28]. Marijnen *et al.*^[29] found that in the Dutch Rectal Cancer Trial, 13.1% of patients with a positive CRM developed a local recurrence within 2 years of follow-up, whereas patients with a margin > 2 mm had a local recurrence rate of 3.3% at 2 years ($P < 0.0001$). Postoperative radiation did not lead to a reduction in the local recurrence rate (17.3% *vs* 15.7% local recurrence in patients with CRM < 1 mm with and without adjuvant radiotherapy respectively, $P = 0.98$)^[29]. In addition, preoperative radiotherapy had no significant effect on the prevention of local recurrence in patients with positive CRM (9.3% in the irradiated group *vs* 16.4% in the surgery alone group, $P = 0.08$) highlighting the importance of adequate surgery. In conventional open resection of rectal cancer, considerable variation between surgeons in oncologic outcomes has been demonstrated^[30]. Differences in local recurrence and disease-free survival may be amplified by the technical challenges of laparoscopic proctectomy. While, the laparoscopic approach provides a magnified view compared to open surgery, TME and autonomic nerve preservation which are prerequisites for satisfactory oncologic and functional results require significant laparoscopic expertise^[31]. A number of studies have reported on the safety and feasibility of laparoscopic low anterior resection (LAR) and abdominoperineal resection (APR) with TME but there is no level one evidence supporting laparoscopic TME in terms of oncologic outcomes^[19,20,32-36]. The aim of this study is to provide a systematic review of the short-term and long-term oncologic outcomes of laparoscopic rectal cancer resection.

DATA SOURCE

Peer-reviewed papers published on laparoscopic rectal cancer resection were found by searching the following terms in the Ovid Medline, PubMed, and Cochrane Database of Systematic Reviews from 1993 to 2010: "laparoscopy", "laparoscopic surgery", and "rectal cancer". Review articles found using the search terms "colon cancer" or "rectal cancer" and "laparoscopy" were also reviewed to find pertinent articles. All relevant articles were assessed and inclusion and exclusion criteria applied.

Study designs included prospective RCTs, meta-analyses, and Cochrane Database of Systematic Reviews. Studies were included if short-term outcomes, morbidity and mortality, or oncologic data specifically, recurrence rates, number of lymph nodes retrieved, margin status, and overall survival for patients undergoing curative laparoscopic rectal cancer resection were reported. When more than one trial containing overlapping patient inclusion periods and data was reported from the same institution, the most recent publication was included. Studies were excluded if they (1) reported both colonic and rectal outcomes, but did not analyze rectal cancer outcomes individually; (2) were non-randomized comparative trials, descriptive trials, or case reports; (3) were not published in the English language; and (4) reported on patients undergoing palliative treatment (non-curative surgical intent).

The majority of data on laparoscopic resection for rectal cancer come from non-randomized comparative and descriptive studies. The literature review yielded a total of 79 studies published in the English language from 1993 to 2010. Sixty-five studies were excluded because they were non-randomized comparative trials or descriptive trials. One meta-analysis was excluded because individual studies were not analyzed according to the site of disease or the type of resection. The remaining 2 Cochrane reviews, 3 meta-analyses, and 8 RCTs comparing laparoscopic *vs* open TME for rectal cancer form the basis of this review. When assessing the data on laparoscopic resection of rectal cancer it is important to remember that results may vary greatly based on level of the tumor, APR *vs* LAR, use of neoadjuvant chemoradiation, and completeness of TME.

OUTCOMES OF INTEREST

Intraoperative outcomes include: duration of operation, blood loss, length of incision, and conversion rate. Short-term parameters of interest include: early postoperative complications (hemorrhage, anastomotic leak, wound complications, chest infection, prolonged ileus, incidence of pulmonary embolism or deep vein thrombosis, and urinary infection/retention), and mortality. Oncologic outcomes reviewed include: number of lymph nodes retrieved, margin status, completeness of TME, local recurrence, and overall survival.

Intraoperative results

The proven benefits of laparoscopy noted in colon cancer surgery including decreased intraoperative blood loss, smaller length of incision, less postoperative pain, faster recovery of intestinal function, and shorter length of hospital stay likely also apply to rectal cancer surgery^[37]. In RCTs (Table 1) the mean operative time for open surgical resection of rectal cancer ranged from 106 to 284 min compared to 120 to 245 min for laparoscopic resection (Table 2). As expected, duration of operation was significantly longer in the laparoscopic group com-

pared to the open group in 6 of the 8 RCTs^[7,22,31,38-40]. Similar results were reported in RCTs of open *vs* laparoscopic resection for colon cancer. Zhou *et al*^[35] reported both shorter open and laparoscopic operative times compared to other trials with no significant difference between the two operative approaches (120 min *vs* 106 min for laparoscopic *vs* open resection respectively, *P* = 0.051). However, no details were provided on tumor stage, conversion rate, or whether the analysis was performed on an intent-to-treat basis. Araujo *et al*^[34] was the only RCT to demonstrate significantly shorter operative times with laparoscopic compared to open resection (228 min *vs* 284 min respectively, *P* = 0.04). However, they attributed these results to fact that the surgical team performing laparoscopic APR was the same whereas open APR was often performed by different surgical teams. In addition, extraction of the specimen from the perineum likely decreased operative time because there was not an abdominal incision to close.

Two meta-analyses included operative time as an outcome of interest. Aziz *et al*^[41] included 22 studies compar-

ing laparoscopic *vs* open rectal cancer resection in 2071 patients and found that operative time was significantly increased with the laparoscopic group as compared to the open group with a weighted mean difference (WMD) of 40.18 (95% CI, 26.46-56.13). Gao *et al*^[42] performed a meta-analysis of short-term outcomes after laparoscopic resection for rectal cancer based on 11 studies and included 643 patients which reported no difference in operating time between open and laparoscopic approaches with a WMD of 1.59 (1.2-1.98).

Intraoperative blood loss was significantly less for the laparoscopic group compared to the open group in 4 of 6 RCTs and ranged from 20 mL to 321.7 mL and from 92 mL to 555.6 mL in the laparoscopic and open groups respectively (Table 2)^[31,35,38,40]. Araujo *et al*^[34] did not specifically report on the amount of intraoperative blood loss but there was no statistically significant difference in the need for blood transfusions between the two groups which was attributed to the fact that in an APR the majority of blood loss occurs during the perineal portion of the case which is the same regardless of surgical access.

LN: Lymph nodes; CRM: Circumferential resection margin; NA: Not available. ^a*P* < 0.05 vs Open.

A recent Cochrane review by Breukink *et al*^[43] evaluating the safety and efficacy of elective laparoscopic TME for the resection of rectal cancer found that in the majority of studies blood loss was reduced with the laparoscopic approach although this did not translate to fewer blood transfusions. Length of incision was measured in 3 of 8 RCTs and ranged from an average of 5 cm to 10 cm with the laparoscopic approach compared to an average of 19.1 cm to 22 cm with the open approach (Table 2)^[7,38,40].

Seven of the 8 trials reported a conversion rate which ranged from 0%-34% (Table 2)^[7,12,22,31,34,38-40]. Conversion to the open approach was commonly defined as length of incision greater than the size needed for tumor extraction or premature abdominal incision to allow improved mobilization. In the majority of studies conversion to open surgery was required because of local tumor invasion or difficult dissection in a narrow pelvis although bulky tumor, dilated small bowel, dense adhesions, bleeding, rectal perforation, difficulty mobilizing the splenic flexure, failure to identify or injury to the ureter, ischemia of the descending colon, and anastomotic failure were also cited. Breukink *et al*^[44] reported that 36 of 48 studies assessed conversion and showed a highly variable rate ranging from 0% to 33%. However, they report that the lack of consensus in the definition made results difficult to interpret. In addition, surgeon experience and patient selection criteria were often not mentioned.

Two trials reported particularly high rates of conversion. Ng *et al*^[45] had a conversion rate of 30.3% but they did not routinely perform preoperative staging with computed tomography scans and therefore frequently converted after diagnostic laparoscopy. Twelve of the 23 patients randomized to laparoscopic surgery were converted to open due to local tumor invasion, bulky tumor, or dilated small bowel which may have been recognized by preoperative imaging. In the CLASICC trial the conversion rate for laparoscopic resection of rectal cancer was reported at 34% and attributed to excessive tumor fixation and uncertainty of tumor clearance^[7]. Surgeon learning curve may account for this high rate of con-

version as evidenced by the fact that the overall rate of conversion dropped by year of study from 38% in year one to 16% in year six. However, consistent with several non-randomized reports, in the CLASICC trial patients converted to open resection had a higher operative mortality compared to patients in the laparoscopic or open groups (9% vs 1% vs 5% respectively)^[7]. Conversion was also associated with worse oncologic outcomes in non-randomized comparative and descriptive studies^[46].

Short-term oncologic outcomes

While the number of lymph nodes retrieved can vary based on age, gender, tumor site, use of pre-operative radiation, and tumor grade, the extent and quality of surgical resection can also have an impact on the number of nodes collected and is therefore often considered a surrogate marker of the oncologic completeness of the resection^[47-53]. The American Joint Committee on Cancer recommends that at least 12 lymph nodes be examined in patients with rectal cancer to confirm the absence of nodal involvement by the tumor^[54]. In addition, a number of studies have reported that the number of lymph nodes examined may be associated with patient outcome^[55,56]. Six of the 8 RCTs reported the mean number of lymph nodes retrieved with a range of 5.5 to 17 nodes in the laparoscopic group compared to 11.6 to 18 nodes in the open group (Table 3)^[22,31,34,38-40]. In 4 of the 6 trials the number of lymph nodes isolated was not significantly different based on surgical approach. Araujo *et al*^[34] reported a significantly lower yield of lymph nodes with laparoscopic rectal resection compared to open resection (5.5 vs 11.9 respectively, *P* = 0.04). However, the number of lymph nodes obtained in the study by Lujan *et al*^[31] was higher in the laparoscopic group (13.63 vs 11.57 in the laparoscopic vs open approach respectively, *P* = 0.026). They suggested that laparoscopy offered better dissection and accuracy due to better visualization and exposure of structures with less manipulation of the mesorectum especially in a narrow pelvis. Four of the 8 RCTs reported the use of pre-operative chemoradiation. In these trials, the mean number of lymph nodes retrieved ranged from 5.5 to 17 nodes in the laparoscopic group and from 11.6 to 18 nodes in the open group^[31,34,38,40]. Anderson *et al*^[57] found that in the 17 trials that reported the number of lymph nodes retrieved, the mean number of nodes was 10 for the laparoscopic group and 12 for the open group (*P* = 0.001) with the majority of trials reporting a median of 11 or fewer nodes obtained. In 9 of these 17 trials, both groups were treated with preoperative radiation therapy and reported a mean of 10 lymph nodes harvested in the laparoscopic group and 11 in the open group.

One of the greatest concerns of laparoscopic TME is that obtaining a complete oncologic resection will be more difficult. Involvement of the circumferential or distal margin is one of the most important prognostic factors in rectal resection with TME and can lead to an increase in local recurrence and a reduction in survival. Radial margins of less than 2 mm are associated with

a local recurrence rate of 16% compared to a significantly reduced local recurrence rate of 6% with margins greater than 2 mm^[27]. Six of the 8 RCTs reported the involvement of the CRM and no difference was found by surgical approach (Table 3)^[7,31,38-40,45]. In the majority of trials the rate of CRM involvement was less than 5%. Patients with positive radial margins often had tumor invading the pelvic side wall or adjacent structure and were frequently converted from a laparoscopic to an open procedure^[39]. In the CLASICC study, the only multi-center trial, a positive CRM was identified in 14 of 97 (14%) patients with open surgery and in 30 of 193 (16%) patients with laparoscopic rectal resection (*P* = 0.8)^[7]. Of patients undergoing anterior resection, the CRM was positive in 16 of 129 (12%) individuals in the laparoscopic group and in 4 of 64 (6%) individuals in the open group (*P* = 0.19). While there is a non-significant higher positivity of the CRM in the laparoscopic anterior resection group, this is once again likely due to the fact that the learning curve was not completed before the start of this study. Two RCTs reported on distal margin status and the incidence of distal margin positivity was not significantly different between the two surgical approaches and in fact was 0%^[31,38]. All 3 meta-analyses and the Cochrane review by Breukink *et al*^[44] found no difference in positive margins based on surgical access.

Postoperative course: Less postoperative pain, faster recovery of intestinal function, and shorter length of stay are important benefits of laparoscopic colorectal surgery. Only 3 of 8 RCTs compared the exact amount of post-operative pain medication and 2 of these studies reported a significant reduction in analgesic use in the laparoscopic group (Table 4)^[39,40,45]. Zhou *et al*^[35] did not quantify the exact usage of pain medication, but found no significant difference in the number of days parental analgesics were necessary (4.1 vs 3.9 in the open and laparoscopic groups respectively, *P* = 0.225).

Resumption of bowel function was usually reported on post-operative days 3 to 5 and ability to tolerate a solid food diet was reported on post-operative days 3 to 6^[7,31,35,39,40,45]. In the majority of RCTs earlier bowel

movements and diet advancement was reported with the laparoscopic approach. The return of bowel function and reduction in wound pain was thought to contribute to earlier discharge after laparoscopic surgery. While in a majority of trials, the length of stay was not significantly different between surgical approaches, there was a trend toward decreased length of stay with laparoscopic rectal surgery. Breukink *et al*^[58] found that laparoscopic TME resulted in earlier return of normal diet, less pain, less narcotic use and a shorter hospital stay.

Complications: Rectal cancer surgery is associated with a high rate of morbidity and mortality. Post-operative mortality in RCTs ranged from 1%-4% and demonstrated no statistically significant difference based on surgical approach (Table 4). The rate of post-operative complications ranged from 6% to 69% and with the exception of Zhou *et al*^[35] did not differ significantly between laparoscopic and open groups. Wound infection and urinary tract infection accounted for the majority of perioperative complications in both groups. There was a higher incidence of wound infection with the open approach however this did not reach statistical significance. Breukink *et al*^[58] found no difference in morbidity between the laparoscopic and open groups although there was a trend toward lower morbidity with laparoscopic TME. Aziz *et al*^[41] found no difference in perioperative morbidity between the 2 groups while Gao *et al*^[42] found that the overall morbidity rate of the laparoscopic group was significantly lower than that of the open group.

Anastomotic leak is the most serious complication after sphincter sparing rectal cancer resection especially with neoadjuvant chemoradiation. In addition, development of an anastomotic leak is reported to be associated with decreased long-term survival and higher rates of local recurrence after curative resection for colorectal cancer^[59-63]. Operative expertise and selective diversion in high risk patients has resulted in an anastomotic leak rate of 1%-17% in most published series studying laparoscopic resection for rectal cancer^[46,64,65]. Consistent with reports from non-randomized comparative trials, RCTs demonstrated no significant difference in the incidence

of anastomotic leak between the laparoscopic and open technique for the resection of rectal cancer (Table 4).

While the incidence of perioperative morbidity was not different based on surgical access, fewer patients had long-term complications with laparoscopic rectal cancer resection compared to the open approach. Adhesion related bowel obstruction was the most common long-term morbidity. With a median follow-up of greater than 9 years, Ng *et al*^[45] found that adhesion-related obstruction requiring hospitalization (18.9% *vs* 2.7%) and reoperation (6.8% *vs* 0%) was higher in the open group. They report a cumulative probability of adhesion-related bowel obstruction at 10 years of 20.5% in the open group and 3.9% in the laparoscopic group ($P = 0.001$)^[45]. Kuhry *et al*^[66] performed a systematic review including 12 trials (3346 patients) to evaluate the long-term outcomes of laparoscopically assisted *vs* open surgery for resectable colorectal cancer. Data on long-term complications was not separated by site of disease but the overall occurrence of incisional hernia (7.9% *vs* 10.9%, $P = 0.32$) and reoperation for adhesions (1.1% *vs* 2.5%, $P = 0.30$) was not statistically difference between laparoscopic and open resection. Long-term studies need to be done to determine if laparoscopy decreases the incidence of intra-abdominal adhesion formation by reduced surgical trauma, less tissue handling, and smaller incisions.

Long-term oncologic outcomes

A number of the clinical trials were performed to determine the safety and feasibility of the laparoscopic approach for rectal adenocarcinoma and therefore the data we have for long-term outcomes is limited (Table 5). Braga *et al*^[38] found no difference in local recurrence (4.0% in the laparoscopic group *vs* 5.2% in the open group, $P = 0.97$), overall five-year survival, or disease-free five-year survival based on surgical approach. With a median follow-up of 87.2 mo in the laparoscopic group and 90.1 mo in the open group, Ng *et al*^[39] demonstrated that after curative resection, the probability of five-year survival was 75.2% *vs* 76.5% for laparoscopic *vs* open APR respectively ($P = 0.20$). In addition, stage-by-stage comparison for the two groups showed no statistical difference. There were no port site recurrences and overall recurrence rates were not significantly different between

the two groups (laparoscopic 20% *vs* open 25%, $P = 0.60$). Despite the higher rate of circumferential margin positivity in patients undergoing laparoscopic anterior resection in the CLASICC trial, there was no difference in local recurrence, three- year overall or three-year disease free survival between the two approaches (open OS 66.7% and laparoscopic OS 74.6%, $P = 0.17$; open DFS 70.4% and laparoscopic DFS 70.9%, $P = 0.72$; open LR 7.0% and laparoscopic LR 7.98%, $P = 0.70$)^[12]. In addition, there was no significant difference in the rates of local recurrence, three-year overall survival, or three-year disease-free survival in patients undergoing laparoscopic *vs* open APR^[12]. However, the sample size is small and therefore larger studies are needed for conclusive results. Ng *et al*^[45] published results of a randomized trial of laparoscopic *vs* open anterior resection for upper rectal cancer with a median follow-up of 9 years. No difference in local recurrence, overall survival, or disease-free survival was reported. Although these studies suggest comparative oncologic outcomes between laparoscopic and open rectal cancer resection, they include small sample sizes and are almost all are single institution studies, highlighting the need for large, multi-center RCTs to provide confirmatory data.

In a meta-analysis by Anderson *et al*^[57] 18 of 24 studies reported recurrence rates. With a mean follow-up of 35 mo for both groups, overall local recurrence was not statistically different between the 2 groups (laparoscopic 7% *vs* open 8%, $P = \text{NS}$). Eleven studies provided sufficient data to compare overall survival. Overall survival was 72% for patients undergoing laparoscopic rectal cancer resection and 65% for open resection at an average of 4.4 years ($P = 0.5$). Subset analysis by Kuhry *et al*^[66] demonstrated no significant difference between laparoscopic and open rectal cancer resection in terms of local recurrence (laparoscopic 7.2% *vs* open 7.8%, $P = 0.46$), development of distant metastases (laparoscopic 13.5% *vs* open 9.1%, $P = 0.60$), or cancer-related mortality (laparoscopic 9% *vs* open 10%, $P = 0.16$). While, this data is encouraging, it is not conclusive.

CONCLUSION

The primary goal of this study was to outline and review

the short-term and long-term oncologic outcomes and complications of laparoscopic rectal cancer resection compared to the gold standard of conventional open resection currently available in the literature. Due to the heterogeneity in tumor stage, surgeon experience, and surgical technique, descriptive and non-randomized trials were not included in this review. However, because of the relatively few RCTs, information on the long-term outcomes is sparse and our conclusions are thus based on a small number of patients. A second limitation is that in a number of these trials data accrual started before the effectiveness of neoadjuvant therapy had been proven and thus the majority of patients did not receive pre-operative chemoradiation which is the current standard of care. Given these limitations, we found no difference in adequacy of oncologic resection, perioperative morbidity, recurrence rates, overall survival, or disease-free survival between open and laparoscopic rectal cancer resection.

In conclusion, RCTs have demonstrated that laparoscopy does not adversely affect cancer related survival in patients with adenocarcinoma of the colon. Concerns about the technical difficulty of TME may have contributed to the exclusion of rectal cancer patients from most of these large multicenter RCTs resulting in little data on oncologic outcomes with laparoscopic rectal cancer resection.

Laparoscopic rectal dissection is technically more demanding than open and constraints of a narrow pelvis may result in difficulty assessing and obtaining adequate surgical margins. However, there are several proposed benefits of laparoscopic rectal resection. A clear and magnified view of the pelvis provided by the improved optics of laparoscopy may aid sharp dissection for TME and assist in identification of vital pelvic structures including the ureters and autonomic nerves. In addition, pneumoperitoneum may separate the parietal and visceral fascia of the mesorectum facilitating dissection in this plane. Laparoscopic rectal cancer resection has a steep learning curve but increased experience with both open and laparoscopic TME will lead to shorter operating times and decreased morbidity^[67].

Current data suggests that laparoscopic rectal cancer resection may benefit patients because of reduced blood loss, earlier return of bowel function, and shorter hospital length of stay^[68,69]. Concerns that laparoscopic rectal cancer surgery may compromise short-term oncologic outcomes including number of lymph nodes harvested and CRM positivity do not appear to be supported by the available literature. However, there is a paucity of data concerning long-term oncologic outcomes and complications with laparoscopic rectal cancer surgery. There are two large, multicenter RCTs that are currently being conducted: the COLOR II trial in Europe and the ACOSOG-Z6051 trial in the United States^[70]. Both of these studies are comparing the laparoscopic and open approach for treatment of resectable rectal cancer. Results from these trials will provide information on the

long-term outcomes of laparoscopic rectal cancer resection and are eagerly awaited. In view of the lack of level one data on oncologic outcomes, laparoscopic TME for locally advanced, curable rectal cancer should only be performed within the confines of a RCT.

Abstract

Despite significant improvements in medical management of inflammatory bowel disease, many of these patients still require surgery at some point in the course of their disease. Their young age and poor general conditions, worsened by the aggressive medical treatments, make minimally invasive approaches particularly enticing to this patient population. However, the typical inflammatory changes that characterize these diseases have hindered wide diffusion of laparoscopy in this setting, currently mostly pursued in high-volume referral centers, despite accumulating evidences in the literature supporting the benefits of minimally invasive surgery. The largest body of evidence currently available for terminal ileal Crohn's disease shows improved short term outcomes after laparoscopic surgery, with prolonged operative times. For Crohn's colitis, high quality evidence supporting laparoscopic surgery is lacking.

Encouraging preliminary results have been obtained with the adoption of laparoscopic restorative total proctocolectomy for the treatment of ulcerative colitis. A consensus about patients' selection and the need for staging has not been reached yet. Despite the lack of conclusive evidence, a wave of enthusiasm is pushing towards less invasive strategies, to further minimize surgical trauma, with single incision laparoscopic surgery being the most realistic future development.

INTRODUCTION

The past 20 years have seen dramatic improvements in the treatment of inflammatory bowel disease (IBD)^[1]. Medical therapy, especially with the advent of biologics, has significantly increased efficacy of disease control, even if the actual reduction of the need for surgery is still debated, and concerns have been raised about po-

tential negative impact on postoperative outcomes^[2,3]. In this setting, the introduction and implementation of minimally invasive surgical techniques has substantially improved outcomes and quality of life in this particularly frail patient population^[4,5]. After the first description of laparoscopic colectomy about 20 years ago, laparoscopic surgery slowly has gained wide acceptance for the treatment of colorectal diseases, showing several advantages in short-term outcomes over open surgery in randomized trials and meta-analysis, with comparable safety and long-term results^[6-9]. However, the diffusion of laparoscopy for IBD is proceeding particularly cautiously, given the magnitude of the procedures required for the most complex cases and the difficulty in handling severely inflamed tissues, as proven by the high conversion rates observed even in the hands of surgeons with documented experience in IBD and laparoscopic surgery^[10,11]. Crohn's disease (CD) and ulcerative colitis (UC) represent real surgical challenges, due to thickened mesentery, strictures, abscesses, inflammatory masses, and enteric fistulae in CD, and intense inflammation leading to colonic distension and high risk of bleeding and accidental perforation in UC^[12,13]. The quest for further reduction of surgical trauma is ongoing, and if the natural orifice transluminal endoscopic surgery has unsolved issues related to the violation of uninvolved hollow viscera, costs and specific training, single incision laparoscopic surgery (SILS) seems to be a reasonable approach capable of minimizing the overall trauma and extent of incisions, with benefits in short term outcomes and cosmesis^[14-17].

The aim of this article is to provide a comprehensive review of the state of the art in minimally invasive approaches to IBD, highlighting the current standard of care, with a glance at the most promising future directions.

CD

Approximately 70% of patients with a diagnosis of CD will eventually require a surgical treatment, due to failure of medical therapy, septic complications, recurrent intestinal obstruction, and malnutrition^[18]. The treatment of CD has traditionally represented a challenge even in open surgery, with just two prospective randomized trials comparing laparoscopic *vs* standard approach published to date^[19,20], and with the long-term results of these studies only recently available^[21,22]. The panintestinal involvement and inflammatory complications, along with the additional risk for postoperative complication, increased by the aggressive medical management, make CD patients particularly poor laparoscopic candidates^[23]. Concerns have been raised about missing occult segments of disease and critical strictures due to the lack of tactile sensation, technical difficulty due to inflamed bowel mesentery and the presence of adhesions, fistulas, and abscesses^[24]. In order to overcome this issues, some authors have advocated the use of laparoscopic-assisted or hand-assisted laparoscopic surgery procedures, with the rationale that an incision is needed for specimen extraction, and the

handling of inflamed Crohn's tissue is easier and safer when an assisted method is used, while maintaining the advantages of a minimally invasive approach^[25]. The intrinsic difficulty of this surgery is further confirmed by a study by Hamel *et al*^[26], that showed no differences in morbidity or conversion between the earlier and the latter time periods of the experience, thus negating the effects of the learning curve. Alves *et al*^[27] looked at the risk factors of conversion in a prospective study on 69 patients undergoing primary laparoscopic ileocecal resection, observing a conversion rate of 30%, with recurrent CD, intra-abdominal abscess and fistula independent risk factors on multivariate analysis. Even if minimally invasive surgery for CD is technically complex, requiring specific training and longer operating time^[28], data in the literature confirm the safety and efficacy of this approach in terms of postoperative pain, cosmesis, return to normal activity, and, more importantly, surgical recurrence rates^[29]. Despite this evidence, in a recent study by Lesperance *et al*^[30] on 49 609 patients admitted for CD that required surgical treatment from the 2000-2004 Nationwide Inpatient Sample, only 2826 cases (6%) underwent a laparoscopic resection, demonstrating that the vast majority of CD patients are still undergoing open conventional surgery, with a minimal invasive approach mostly reserved for patients who are younger (< 35 years old), female, admitted to a teaching hospital, with ileocecal, uncomplicated disease. The increased adoption of the laparoscopic approach for the treatment of CD in teaching hospitals confirms the peculiar technical complexity of minimally invasive procedures in this setting, requiring more skilled colorectal surgeons, as can be found in referral centers where specific laparoscopic training programs are implemented.

Terminal ileal CD

The small samples size and selection bias explain the conflicting results in the initial published series of ileocolonic CD treated by laparoscopic surgery^[28,31-34]. In our series of selected consecutive patients with elective, complex and even recurrent terminal ileal CD, laparoscopic patients had faster postoperative recovery - partially related to less postoperative pain and consequent decreased need for intravenous narcotics - and similar operating times compared to the open cohort, without increased complication and recurrence rates, with potential overall cost savings^[35]. In regards to the issue of costs associated with laparoscopy, Young-Fadok *et al*^[36], in a case match study comparing 33 cases of laparoscopic ileocolic resections with 33 open, showed significantly lower direct and indirect costs in the laparoscopic group. The strongest evidence available comes from the only two prospective randomized trials present in the literature, both conducted on small samples of highly selected patients. Although such populations might be far from the reality of a tertiary referral center, it is the only way to randomize CD patients given the panintestinal, relentless nature and often unpredictable presentation of the disease. In the trial by Maartense *et al*^[19], patients with

a fixed palpable inflammatory mass, prior median laparotomy, earlier bowel resection, or pregnancy were excluded. In this study, the laparoscopic approach showed longer median operating time, shorter hospital stay, lower 30-d post-operative morbidity, but no differences in quality of life, the primary endpoint of this study. After a median follow-up of 6.7 year, there were no differences in recurrence rate and need for reoperation between open and laparoscopic group, with a 58% relapse free rate and no patients in the laparoscopic group requiring a reoperation for incisional hernia or adhesive small bowel obstruction^[21]. Even if a minimal invasive approach did not impact the overall quality of life, body image and cosmesis scores were significantly higher after laparoscopy^[21]. These data differ from the previous observation by Thaler and colleagues, that found long-term quality of life significantly reduced in patients with CD compared to general healthy population, irrespective of the surgical approach, with recurrence identified as the only significant predictor of poor quality of life^[37]. In the other randomized trial, Milsom *et al*^[20] included only patients with isolated Crohn's disease of the terminal ileum with or without cecal involvement. The results of this study demonstrated that laparoscopy offers faster recovery of pulmonary function, fewer minor complications, and a trend towards shorter length of stay compared with conventional surgery, even if no differences in the amount of morphine equivalents, return of bowel function and length of stay were found. After a mean follow-up of 10.5 years there were no significant differences between groups with regard to use of medications to treat CD and recurrence rates, both clinical and surgical. Furthermore, two laparoscopic patients underwent lysis of adhesions while none did in the open group, with an incidence of incisional hernia repair of 4% in the laparoscopic group *vs* 14% in the open (both differences were not statistically significant)^[22]. Recently, Dasari *et al*^[38] conducted a meta-analysis of the aforementioned trials, and found that laparoscopic patients had a trend towards less wound infection and shorter hospital stay, with comparable incidence of other postoperative complications, duration of postoperative ileus, incidence of anastomotic leak and intraabdominal abscess, 30-d reoperation rate, and actuarial disease recurrence rates. To date, three meta-analysis comparing laparoscopic and open surgery for ileocolonic CD have been conducted, all demonstrating that laparoscopic surgery is associated with prolonged operative time, shorter duration of postoperative ileus, shorter hospital stay and lower incidence of early postoperative complications^[39-41]. Other significant findings from these studies also include similar intraoperative blood loss and complications^[41], with a trend toward lower overall costs with laparoscopic surgery^[39], and no differences in the rate of disease recurrence^[40]. With regard to the long-term outcomes, the study from Washington University, comparing 63 CD patients treated laparoscopically with 50 open ileocolic resections, found that the two groups had a recurrence rate of 9.5% and

24%, respectively (difference not statistically significant), with the laparoscopic group having shorter mean follow-up, thus confirming the non-inferiority of the laparoscopic approach. Interestingly, 50% of the recurrences in the laparoscopic group and 33% in the open group were able to be retreated laparoscopically^[29].

Laparoscopy in complicated/recurrent CD

In complicated CD laparoscopy is even more challenging. Seymour and Kavic analyzed their series of 17 patients managed with laparoscopic approach for complicated CD (defined as for the presence of fistulas, multiple or long-segment disease, abscesses and previous operations). In this study, conversion to open procedures was not always required, but operative time and postoperative hospital stay were longer compared to laparoscopic ileocecal resections for uncomplicated disease, with major complications occurring in 18% of patients^[42]. In the literature, surgical recurrence rates are reported as high as 70% to 90%, and multiple procedures are required in more than 30%^[12]. In a recent study from France, of 62 reoperations for CD recurrence in 57 patients, 29 were performed laparoscopically. While no differences between the two groups were observed in terms of use of a temporary stoma, mean operating time, postoperative mortality (nil in both groups), overall morbidity rate, severe complications, median hospital stay, and conversion rates, a higher number of intraoperative intestinal injuries was reported in the laparoscopic group (5 *vs* 0) ($P = 0.01$). The occurrence of fistulizing disease was a risk factor for conversion, and conversion did not seem to affect complication rate^[43]. A study from Japan looked at 16 laparoscopic procedures for CD recurrence at the anastomotic site out of 61 attempted laparoscopically by experienced surgeons in 52 patients. The result of this study showed that while the operating time was significantly longer in the recurrent group, there were no differences in the rates of postoperative complications and hospital stay, with the repeated laparoscopic operations performed using the same small incision as that of the primary operation. The advantage of a minimally invasive primary approach are supported by the fact that the operating time was shorter and blood loss was less in patients who underwent the primary procedure laparoscopically^[44]. Finally, in the experience by Goyer *et al*^[45] on 54 complex CD (defined as recurrent or complicated by abscess and/or fistula) compared with 70 patients with uncomplicated CD, the complex group had increased operative time, conversion rates and use of temporary stoma. Conversely, no differences were noted in overall postoperative morbidity, including major surgical postoperative complications and hospital stay, leading to the conclusion that complex CD should not be considered an absolute contraindication to a laparoscopic approach in experienced hands.

Crohn's colitis

In contrast with the data available on minimally invasive

surgery for terminal ileal CD, very few series have been published on CD of the colon. The feasibility and safety of a laparoscopic approach to subtotal colectomy for CD was addressed by Hamel *et al*^[46], who observed a higher rate of intraoperative complications compared to ileocolic resection, while hospital stay and postoperative complication rate did not differ between the two groups. Contrasting results come from a recent case match study by the Cleveland Clinic group on 27 laparoscopic and 27 open cases, with a conversion rate of 26%. In this series, laparoscopic colectomies took longer with similar blood loss and postoperative complications, along with a trend towards shorter time to first bowel movement and length of stay, which became statistically significant in favor of laparoscopy when overall length of stay included 30-d readmissions^[47]. In our own personal experience on 125 patients who underwent colectomy for CD, 44% by a laparoscopic approach, the conversion rate was 10.9%, median operative time, blood loss, return of bowel function and length of post-op stay were reduced in the laparoscopic group, while postoperative complications and disease recurrence rates were similar, suggesting that a laparoscopic approach for CD of the colon is safe and feasible in the hands of experienced surgeons^[48].

Laparoscopy has a role also in creating diverting stomas for severe perianal CD, reducing the number of incisions to few trocars and the ostomy site. In a study by Liu *et al*^[49] on 80 patients who underwent laparoscopic stoma creation over a 10-year period (ileostomy 30, colostomy 49, conversion 1), the overall morbidity rate was 11% with five major complications requiring reoperation, and no further stoma complications recorded within a 1-year follow-up.

UC

Despite significant advances in the medical treatment of UC, surgery remains definitive cure for these patients after failure of medical management or diagnosis of neoplastic degeneration^[50,51]. A restorative procedure with the creation of an ileal pouch anal anastomosis (IPAA) is universally considered the standard of care. The earliest reports of a laparoscopic approach to ulcerative colitis was published in 1992 by Peters *et al*^[52], who described the technique of laparoscopic proctocolectomy for two UC patients. The same year, Wexner and colleagues reported the first case-controlled series on the outcome of laparoscopic-assisted proctocolectomy with IPAA, showing a longer operative time compared to open procedure, and comparable postoperative ileus and hospital stay, with no short-term benefits in favor of laparoscopy^[53]. Since then, numerous series have been reported both in the adult and pediatric patient populations^[54-56], but only from single institutions with short follow-ups^[5,57]. Universally, these initial studies showed that laparoscopy took longer, with the exception of the series published by Araki *et al*^[58]. In these studies only the colonic mobilization was performed laparoscopically,

with vessel transection and rectal mobilization carried out through a mini laparotomy^[53,58-61], with the exception of the series reported by Marcello *et al*^[55], where a totally laparoscopic techniques was adopted, reserving a mini laparotomy only for specimen extraction. Subsequently, in a study from the Netherlands, 60 patients were randomized for hand assisted or laparoscopic restorative proctocolectomy with IPAA. The results from this study failed to show statistically significant differences in terms of morbidity, postoperative stay, quality of life at 3 mo after surgery, and overall costs, but the operative time for laparoscopy was significantly longer^[62]. In a subsequent study, Polle *et al*^[63] observed that female patients reported higher body image and cosmesis scores compared to open group, while there were no differences in functional outcome, morbidity, and overall quality of life. Similarly, Dunker *et al*^[59] compared 16 patients who underwent restorative surgery with laparoscopic technique with 19 open patients. The authors found that laparoscopic patients showed significantly higher satisfaction with the cosmetic results and better body image, but once again functional outcome and quality of life were similar between groups. It seems evident, as it may have been expected, that laparoscopic IPAA offers significant advantages over the open conventional procedure in terms of body image and cosmesis, important factors in the acceptance of surgery in this young patient population, while conflicting results have been reported in terms of postoperative recovery. Faster return of bowel function after laparoscopy and decreased use of narcotics have been reported by some authors, not always translating into shorter hospital stay^[57,62]. On the other hand, concerns have been raised regarding the duration of surgery often noted to be longer than open surgery even by very experienced laparoscopic surgeons, often resulting in higher costs. In regards to long-term pouch function, quality of life and complications, very few studies are available with adequate follow-up^[5,57,62,63,59]. These observations were confirmed in a Cochrane review on 607 patients from 12 studies, only one randomized, which did not found any significant differences in complications, readmission, reoperation rates and mortality. However, once again, it showed that laparoscopic IPAA is associated with a significantly longer operating time, along with the inability to confirm conclusively the presumed short-term benefits of laparoscopy, with length of follow-up too short for evaluating long-term outcomes^[64]. Similar results were obtained in a subsequent meta-analysis on 16 studies, only one randomized, by Wu *et al*^[13]. Postoperative fasting time and hospital stay were shorter for laparoscopy, and overall complication rates were higher after open surgery. Once again, laparoscopy took significantly longer and no advantages were demonstrated in terms of recovery of bowel function, postoperative septic complications, anastomotic leakage, postoperative bowel obstruction, blood loss, and mortality^[13]. In our personal experience with 73 laparoscopic IPAA with a mean follow-up of 24 mo, the minimally invasive ap-

proach offered a statistically significant earlier return of flatus and resumption of diet, less intraoperative blood loss, and lower incidence of incisional hernias compared to 106 open IPAA, with no differences in overall complication rate, pouch function and quality of life^[65].

The controversy about the safety of a single-stage procedure has not been resolved yet. Since long-term functional outcomes after IPAA are threatened by the occurrence of pouch-related septic complications, every effort should be made to reduce such complications and to identify patients at risk for pouch-related sepsis^[66]. In a study by Marcello *et al*^[67] on 59 patients who underwent laparoscopic proctocolectomy for UC, where only 9 patients received a diverting stoma at the primary procedure, 9 patients, all on high dose immunosuppressors or elevated body mass index, required a secondary ileostomy for postoperative complications. Better results were reported by Ky *et al*^[68], with only one out 32 patients with an anastomotic leak requiring secondary diversion after one-stage laparoscopic restorative proctocolectomy. It is hard to analyze these data since these results can be influenced by patients' selection; pelvic sepsis is reported to occur in up to 23% of patients after IPAA for UC, especially after the introduction of biologic therapy for IBD, in most cases secondary to an anastomotic leak^[66,69-72]. In a recent study on 118 UC patients treated with a minimally invasive approach, we compared a 3-stage approach (laparoscopic abdominal colectomy followed by pouch surgery with a diverting loop ileostomy, 50 patients) with a 2-stage approach (laparoscopy colectomy with IPAA and diverting stoma at the initial operation, 68 patients). We observed a significant higher rate of septic complications in the 2-stage group (38.2% *vs* 21%, $P < 0.05$), despite 3-stage patients had been receiving a more aggressive medical therapy in the immediate preoperative period^[73].

The role of laparoscopy for the treatment of ulcerative colitis in the emergency setting has been investigated by two studies. In the study by Bella and Seymour, 18 patients underwent laparoscopic-assisted restorative proctocolectomy for fulminant colitis, reporting a postoperative complication rate of 33%, with a length of stay of 5.0 d, which was shorter compared to the 8.8 d reported for the 6 open cases analyzed in the study^[74]. The other study, by Marcello *et al*^[67], reviewed the data from 19 laparoscopic and 29 conventional total colectomies with end ileostomy and mucous fistula buried within subcutaneous tissue for acute, not fulminant, UC, demonstrating longer operative time (210 *vs* 120 min) but lower complication rates (16% *vs* 24%), earlier return of bowel function (1 *vs* 2 d) and shorter length of stay (4 *vs* 6 d) for the laparoscopic group.

SILS IN IBD

During the last few years an increasing number of reports and case series on SILS colorectal resections for both benign and malignant diseases have been reported. Few

studies have been published comparing SILS to standard laparoscopy, showing potential for improved short-term outcomes^[75-78]. Besides the obvious cosmetic advantage resulting from a reduced number and size of scars - particularly important in a young IBD patient population - limiting the incisions seems to result in less postoperative pain, less use of narcotic pain medications, with consequent faster recovery and earlier discharge, along with a lower incidence of wound-related complications^[17,76,78-80]. These data are still preliminary, with only few cases of SILS for UC published to date^[4,16,17,75-78,81-92]. We believe that particularly for total abdominal colectomy (TAC) the SILS approach is a very attractive option in this patient population, representing a true "scarless" procedure, with the only access to the abdominal cavity at the site of the future stoma. Our preliminary results with the adoption of a well-standardized SILS approach to TAC confirm the potential of this technique in improving the postoperative recovery in selected patients, without significant increases in operative time and costs^[93].

CONCLUSION

During the past three decades the evidence has been accumulating in favor of a minimally invasive approach to IBD. Crohn's disease is probably one of the most challenging diseases to treat laparoscopically for the colorectal surgeons, especially when the disease is located in the colon and involves multiple segments, thus explaining the fact that in the United States the majority of CD patients are still approached with open surgery. Laparoscopic IPAA for UC has been shown to be feasible, but to date the evidence present in the literature is still not conclusive. Current data suggest a shorter length of stay, shorter ileus, faster recovery and less postoperative pain, along with better cosmesis with minimally invasive surgery. On the other hand, significantly longer operative times with laparoscopy are universally reported. Our goal and responsibility is to explore new avenues for a true minimally invasive approach to IBD and to train the next generation of surgeons to facilitate wide spread acceptance of laparoscopy.

Abstract

Thanks to the development of minimally invasive surgery, the last 20 years have witnessed a change in the treatment algorithm of benign esophageal disorders. Today a laparoscopic operation is the treatment of choice for esophageal achalasia and for most patients with gastroesophageal reflux disease. Because the pathogenesis of achalasia is unknown, treatment is palliative and aims to improve esophageal emptying by decreasing the functional obstruction at the level of the gastro-esophageal junction. The refinement of minimally invasive techniques accompanied by large, multiple randomized control trials with long-term outcome has allowed the laparoscopic Heller myotomy and partial fundoplication to become the treatment of choice for achalasia compared to endoscopic procedures, including endoscopic botulinum toxin injection and pneumatic dilatation. Patients with suspected gastroesophageal reflux need to undergo a thorough preoperative workup. After establishing diagnosis, treatment for gastroesophageal reflux should be individualized to patient characteristics and a decision

about an operation made jointly between surgeon and patient. The indications for surgery have changed in the last twenty years. In the past, surgery was often considered for patients who did not respond well to acid reducing medications. Today, the best candidate for surgery is the patient who has excellent control of symptoms with proton pump inhibitors. The minimally invasive approach to antireflux surgery has allowed surgeons to control reflux in a safe manner, with excellent long term outcomes. Like achalasia and gastroesophageal reflux, the treatment of patients with paraesophageal hernias has also seen a major evolution. The laparoscopic approach has been shown to be safe, and durable, with good relief of symptoms over the long-term. The most significant controversy with laparoscopic paraesophageal hernia repair is the optimal crural repair. This manuscript reviews the evolution of these techniques.

INTRODUCTION

The last two decades have seen a shift in the treatment algorithm of benign esophageal disorders, largely due to the introduction and development of minimally invasive surgery. In the early 1990s, it became clear that a minimally invasive approach for esophageal achalasia, gastroesophageal reflux disease, and paraesophageal hernias, provided outcomes comparable to those achieved by open techniques but with less postoperative pain, shorter hospital stay and earlier return to work^[1-3].

The late 1990s and last 10 years saw the evolution of the laparoscopic approach thanks to better instrumentation and expertise. As more of these procedures were performed, more long-term data became available allowing improved analysis of the technique and the outcome. For example, in the early 1990s a left thoracoscopic Heller myotomy was considered the surgical procedure of choice for achalasia, yet now the standard of care is a laparoscopic Heller myotomy with partial fundoplication as this operation allows better relief of dysphagia and a lower incidence of postoperative reflux^[4-8]. In a similar fashion, both total fundoplication and partial fundoplication were initially considered equivalent for the treatment of gastroesophageal reflux disease, however, long-term follow-up indicates that a laparoscopic total fundoplication is superior^[9]. In addition, a laparoscopic approach to paraesophageal hernias offers fewer complications and shorter hospital stay than to the open approach^[10].

In this review, we focus on the impact of minimally invasive surgery on the treatment of achalasia, gastroesophageal reflux disease (GERD), and paraesophageal hernias.

ACHALASIA

Esophageal achalasia is a primary esophageal motility disorder characterized by lack of esophageal peristalsis and inability of the lower esophageal sphincter (LES) to relax properly in response to swallowing. The goal of treatment is to relieve the functional obstruction caused by the LES, therefore allowing emptying of food from the esophagus into the stomach by gravity. The treatment of this disease is based on a delicate balance between elimination of the functional obstruction caused by the LES and the need to prevent gastroesophageal reflux into an aperistaltic esophagus, with risk of developing complications such as strictures, Barrett's esophagus, and even adenocarcinoma^[11-14].

Open era

In 1913, Heller first described the simultaneous performance of two myotomies, on the anterior and posterior sides of the esophagus, to treat patients with achalasia. A decade later, Zaaier would restrict the procedure to a single anterior myotomy. For decades, Heller myotomy was the standard treatment for esophageal achalasia. In the 1970s and 1980s, pneumatic dilatation became the primary form of treatment as it was believed that the results were equivalent to those of a myotomy but this

approach avoided the postoperative pain and the long recovery time which followed surgery. Very few Heller myotomies were performed during this era, and they were mostly reserved for patients whose dysphagia did not improve with balloon dilatation or whose esophagus was perforated during a dilatation^[15].

During this era, the myotomy was performed by either a left thoracotomy or a laparotomy. Ellis described his results using a left transthoracic approach to perform a Heller myotomy^[6]. His myotomy extended for only 5 mm onto the gastric wall, the rationale being that a short myotomy relieved dysphagia but avoided reflux, therefore obviating the need for a fundoplication. His results showed relief of dysphagia in about 90% of patients and symptomatic reflux in 5%^[12]. However, when gastroesophageal reflux was objectively measured postoperatively by manometry and pH monitoring, abnormal esophageal acid exposure was found in 29% of patients^[16]. These findings underscored the importance of objective measurement of reflux in achalasia patients.

A trans-abdominal approach was used mostly in Europe and South America. Bonavina *et al*^[17] from Italy reported the results of trans-abdominal Heller myotomy and Dor fundoplication in 206 patients operated between 1976 and 1989. The operation yielded "excellent" or "good" results in 94% of patients. Abnormal postoperative gastroesophageal reflux, as measured by pH monitoring, was present in 8.6% of patients only.

Minimally invasive era

A shift in the treatment algorithm of achalasia has slowly occurred in the last decade due to the excellent outcome of minimally invasive techniques. In 1992, we reported our initial experience with a thoracoscopic approach^[1], following the technique first described by Shimi *et al*^[18]. Using the guidance provided by intraoperative endoscopy, we performed a left thoracoscopic myotomy which extended for only 5 mm onto the gastric wall. Like Ellis^[12], the rationale for a shorter myotomy was to relieve dysphagia while trying to avoid postoperative reflux. The hospital stay was short, postoperative discomfort was minimal, and the recovery was fast^[1]. Long-term follow-up showed relief of dysphagia in almost 90% of patients^[19].

Despite these good results, some shortcomings of the thoracoscopic technique soon became apparent. This approach required a double lumen tube for one lung ventilation and a chest tube. In addition, the exposure of the gastroesophageal junction was limited by the diaphragm. Most striking though was that a thoracoscopic myotomy was associated with reflux in up to 60% of patients when studied by postoperative pH monitoring^[19]. A significant amount of postoperative reflux after thoracoscopic Heller myotomy was also demonstrated by others^[20,21].

These limitations of the thoracoscopic approach were the key reasons for the switch to a laparoscopic approach.

Is a fundoplication necessary?

A laparoscopic Heller myotomy alone is also associated with a high incidence of postoperative reflux, with the

risk of severe esophageal damage. In several retrospective studies, objective evidence of reflux was demonstrated in about 60% of patients postoperatively^[22,23].

Subsequent randomized control trials confirmed this observation and suggested that a fundoplication decreases the incidence of this problem. In 2003, Falkenback *et al*^[24] reported the results of a prospective and randomized trial comparing myotomy alone *vs* myotomy with Nissen fundoplication. Using postoperative pH monitoring, they found abnormal reflux in 25% of patients who had a myotomy and fundoplication as compared to 100% of patients who had a myotomy alone. Twenty percent of patients in the myotomy alone group subsequently developed Barrett's esophagus^[24].

Another randomized trial compared Heller myotomy alone *vs* Heller myotomy and Dor fundoplication. Pathologic gastroesophageal reflux was demonstrated by pH monitoring in 48% of patients after Heller myotomy alone but in 9.5% only when a Dor fundoplication was added^[25]. Relief of dysphagia was similar in the 2 groups. Both the total (Nissen) and partial (Dor) fundoplications prevent reflux in the majority of patients. The above trials provide Level 1 evidence that a fundoplication should be performed at the time of a laparoscopic Heller myotomy.

Partial vs total fundoplication

In patients with gastroesophageal reflux, a laparoscopic total fundoplication is the procedure of choice, even when esophageal peristalsis is weak^[9]. In contrast, because of the absence of peristalsis in achalasia, a total fundoplication may cause too much resistance at the level of the gastroesophageal junction, therefore impeding the emptying of food from the esophagus into the stomach. This can eventually cause persistent or recurrent dysphagia.

There have been long-term studies demonstrating that postoperative dysphagia is initially significantly decreased after a Heller myotomy with a total fundoplication^[24,26,27]. Yet, most surgeons have abandoned the use of a total fundoplication and switched to a partial fundoplication based on other long-term data showing that dysphagia eventually recurs in most patients that have a total fundoplication. For example, Duranceau *et al*^[28] initially reported excellent results with a Heller myotomy and total fundoplication, as dysphagia improved in most patients and there was no symptomatic reflux. Ten years later, however, they noted that symptoms had recurred in 82% of patients probably due to complete decompensation during the follow-up period^[29].

A prospective, randomized trial comparing long-term results of laparoscopic Heller myotomy and Dor fundoplication *vs* laparoscopic Heller myotomy and floppy-Nissen fundoplication for achalasia recently demonstrated that there was a statistically significant difference in dysphagia rates (2.8% *vs* 15%, $P < 0.0001$). Although both techniques achieved long-term reflux control, the recurrence rate of dysphagia was significantly higher among patients who underwent a Nissen fundoplication^[30].

These data provide Level 1 evidence supporting the use of a partial fundoplication with a Heller myotomy as the preferred choice of fundoplication for achalasia.

Partial fundoplication: Anterior vs posterior

Currently, deciding between which partial fundoplication is best, either a posterior (Toupet) or an anterior fundoplication (Dor) after Heller myotomy, is controversial. Some groups favor a posterior fundoplication as it might be more effective in preventing reflux and because it might keep the edges of the myotomy separate^[4,5,31-33]. One retrospective study demonstrated a lower rate of recurrent dysphagia in the Toupet fundoplication group compared to the Dor fundoplication group (3% *vs* 17%). However, conclusions from this study are limited since the comparison groups were not equivalent: the follow-up period for the Dor fundoplication group was longer and the length of the myotomy was longer in the Toupet fundoplication group^[33].

Our preference is for a Dor fundoplication because it is simpler to perform, in that there is no need for a posterior dissection. In addition, it adds the advantage of covering the esophageal mucosa. It certainly is the procedure of choice if there is any suspicion of injury to the mucosa or if a perforation has occurred. Many studies have demonstrated that a laparoscopic Heller myotomy with anterior fundoplication significantly relieves the symptoms of achalasia in about 90%, while limiting gastroesophageal reflux^[6-8,32,34-37].

Recently presented at the Society of American Gastrointestinal and Endoscopic Surgeons annual meeting in 2011 were the findings of a prospective, randomized, and multicenter study comparing laparoscopic Heller myotomy and Dor fundoplication and laparoscopic Heller myotomy and Toupet fundoplication. Follow-up monitoring by pH monitoring at six months showed no statistical significance between a Dor fundoplication and Toupet fundoplication^[38].

The last two decades have witnessed a shift in the treatment algorithm for esophageal achalasia. The refinement of minimally invasive techniques accompanied by large, multiple randomized control trials with long-term outcome has allowed the laparoscopic Heller myotomy and partial fundoplication to become the treatment of choice for achalasia.

GERD

The pathophysiology of GERD is multifactorial and complex. It is well established that the lower LES plays a key role in the antireflux mechanism. This is evidence that the striated muscles of the crus fail to exert its synergistic action with the LES when a hiatal hernia is present, thus, causing reflux^[39]. In addition, esophageal dysmotility can also play a crucial role: 40% to 50% of patients with GERD have low amplitude of peristalsis or an abnormal propagation of peristaltic waves^[40]. As a consequence, acid clearance is impaired, potentially caus-

ing more mucosal injury. Furthermore, it has been demonstrated that a mixed reflux of both gastric and duodenal juices plays a role in the pathogenesis of GERD, particularly in patients with Barrett's esophagus. This has a profound impact on treatment considering that proton pump inhibitors only control acid secretion and not duodenal reflux^[41]. The pH of the refluxate is changed, yet the underlying problem has not been addressed: the competence of the lower esophageal sphincter. The laparoscopic 360° fundoplication addresses this very issue, which can block either type of refluxate.

Open era

Nissen^[42] first described an antireflux procedure with a 360° wrap in 1956. Reflux symptoms improved, yet there were problems with dysphagia and inability to belch. Multiple modifications and different types of partial funduplications were then introduced over the years. In 1986, DeMeester *et al*^[43] described several modifications to operative technique that would prove to be valuable. Increasing the bougie size seemed to reduce the incidence of postoperative dysphagia. Similar results were obtained by shortening the length of the fundoplication. Finally, a more extensive mobilization of the fundus increased the incidence of complete distal esophageal sphincter relaxation.

Laparoscopic 360° fundoplication

The laparoscopic 360° fundoplication (total) was initially described by Dallemagne *et al*^[44] in 1991. Despite some surgeons favored partial fundoplication in some settings, it was shown that laparoscopic partial fundoplication was not as effective in controlling reflux as a laparoscopic total fundoplication^[9].

A 360° fundoplication using minimally invasive techniques is associated with a low morbidity, a short hospital stay, and excellent outcomes^[45,46]. The operation controls reflux by improving esophageal motility, both in terms of LES competence and quality of esophageal peristalsis^[9,47]. Long-term studies have shown that fundoplication controls symptoms in 93% of patients after 5 years and 89% after 10 years^[48]. Postoperative dysphagia has been described in approximately 8% of patients. However, this usually resolves in most patients within a few months and rarely requires any intervention^[9].

Clarifying indications

The indications for surgery have changed in the last twenty years. Surgery was often considered for patients who did not respond well to acid reducing medications. However, the paradigm has changed. Today, the best candidate for surgery is the patient who has excellent control of symptoms with proton pump inhibitors^[49].

We feel that laparoscopic 360° fundoplication is indicated in the following circumstances: (1) when heartburn and regurgitation are not completely controlled by medication; (2) when it is thought that cough is induced by reflux. For instance, Mainie *et al*^[50] demonstrated that

patients resistant to proton pump inhibitors (PPIs) with non-acid or acid reflux demonstrated by multichannel intraluminal impedance-pH monitoring and with a positive symptom index, can be treated successfully by a laparoscopic 360° fundoplication); (3) poor patient compliance with medical treatment; (4) cost of medical therapy is prohibitive (most insurance companies in the United States will pay for one PPI pill per day only, with many patients prescribed more frequent dosing); (5) postmenopausal women with osteoporosis. It has been shown that PPIs and H2 blockers may increase the risk of hip and femur fractures because of decreased calcium absorption^[51]; and (6) young and very symptomatic patients in whom life-long medical treatment is not advisable.

Finally, in a recently published meta-analysis of medical *vs* surgical management for GERD, Wileman *et al*^[52] have shown that, in adults, laparoscopic fundoplication is more effective than medical management for the treatment of GERD in the short to medium term. Surgery, however, carries some risks and its application should be individualized as the decision to undergo fundoplication should be based on patient and surgeon preference.

The minimally invasive approach to antireflux surgery has allowed surgeons to control reflux in a safe manner without troublesome side effects. Long term outcomes are excellent and risk is minimal. Nonetheless, patients with suspected reflux need to undergo a thorough preoperative evaluation. After establishing diagnosis, treatment for gastroesophageal reflux should be individualized to patient characteristics and a decision about an operation made jointly between surgeon and patient.

PARAESOPHAGEAL HERNIA

Paraesophageal hernias are rare and only make up a small fraction of hiatal hernias. Yet because of their association with serious morbidity and potential mortality, knowing how to treat these patients is essential.

Open era

Like achalasia and gastroesophageal reflux, the treatment of patients with paraesophageal hernias has also seen a major evolution. Thanks to the advent of minimally invasive techniques, a laparoscopic repair has slowly replaced an open approach *via* a laparotomy or left thoracotomy.

In the 1980s, an open technique was standard of care and was shown to be effective. Ellis *et al*^[53] demonstrated an 88% benefit from an open paraesophageal hiatal hernia repair *via* laparotomy. Their technique commonly included an antireflux procedure and a Stamm gastrotomy. Average length of stay was 9.5 d and the complication rate was 24%.

Minimally invasive era

The last two decades have seen the emergence of laparoscopy for treatment of paraesophageal hernias. Though it is a technically challenging operation, the laparoscopic approach has been shown to be safe, durable, with good

relief of symptoms over the long-term, decreased post-operative pain, and a rapid return to normal activities. The majority of patients also undergo an antireflux procedure as well^[54,55]. The basic principles of the operation include excising the hernia sac, mobilizing the esophagus extensively in the posterior mediastinum, closing the hiatus, and a fundoplication.

Current status

Despite popularization of the laparoscopic approach, many controversies remain. The majority of surgeons advocate complete excision of the hernia sac for several reasons. A sac remnant could potentially act as a potential lead point for a recurrence or interfere with the crural repair or fundoplication. Others argue that removing the sac can potentially cause injury to the mediastinum and pleura and that it is not necessary. Aly *et al*^[56] showed that sac excision was not routinely performed and had no significant effect on quality of life measures and post-operative barium swallow radiographs.

The most significant controversy with laparoscopic paraesophageal hernia repair though is recurrence rate. In several large volume studies, hiatal hernia recurrence rate is reported as high as 28%-44% for the laparoscopic repair^[56-59]. These rates are significantly higher than for open repair. However, prior open series rarely measured outcomes objectively as they routinely do now.

When repairing paraesophageal hernias, there can be a significant amount of tension with a primary repair, which ultimately may lead to recurrence. Due to the significant use of synthetic mesh for tension free repairs inguinal hernias, these were soon applied to paraesophageal hernias repairs. One randomized control trial showed a significant reduction in recurrence rates at the one year follow-up period^[60]. However, there was a significantly higher rate of dysphagia and potential for erosion into the esophagus or stomach^[60,61]. Synthetic mesh is rarely used now.

In 2006, Oelschlager *et al*^[62] published a multicenter, prospective randomized trial assessing biologic prosthesis for paraesophageal hernias as a buttress with a primary repair. They used small intestinal submucosa (SIS), an acellular xenograft consisting primarily of porcine collagen. Their findings at six month follow up were promising. The primary outcome measure was a greater than 2 cm recurrent hernia on upper gastrointestinal (UGI) series. At six months, patients who had the biologic prosthesis buttress repair had a 9% recurrence rate compared to 24% in the group who had a primary repair alone of the hiatus.

The long-term data from that study were recently presented at the 2010 American College of Surgeons Annual Clinical Congress. Unlike the short-term data, there was no difference in recurrence in long-term follow up. With a median follow-up of 58 mo, there was no statistical difference in symptom control, quality of life measures or UGI recurrence rates between the primary repair alone *vs* primary repair with a SIS buttress.

They concluded that both types of repair gave long and durable relief, but the benefit of reducing hiatal hernia recurrence in the short term had diminished by the five year mark^[63]. There have been new biologic mesh materials and redesigning of existing materials that will need to be studied in the future.

CONCLUSION

Despite controversies for laparoscopic paraesophageal hernia repairs, there are clear advantages when compared to open repair. Hospital stays are usually around two days and much shorter than before, pain is improved, and patients have less complications. More long-term data will be needed to assess the optimal crural repair.

Abstract

Glucose and other carbohydrates are transported into cells using members of a family of integral membrane glucose transporter (GLUT) molecules. To date 14 members of this family, also called the solute carrier 2A proteins have been identified which are divided on the basis of transport characteristics and sequence similarities into several families (Classes 1 to 3). The expression of these different receptor subtypes varies between different species, tissues and cellular subtypes and each has differential sensitivities to stimuli such as insulin. The liver is a contributor to metabolic carbohydrate homeostasis and is a major site for synthesis, storage and redistribution of carbohydrates. Situations in which the balance of glucose homeostasis is upset such as diabetes or the metabolic syndrome can lead metabolic disturbances that drive chronic organ damage and failure, confirming the importance of understanding the molecular regulation of hepatic glucose homeostasis. There is a considerable literature describing the expression and function of receptors that regulate glucose uptake and release by hepatocytes, the most import cells in glucose regulation and

glycogen storage. However there is less appreciation of the roles of GLUTs expressed by non parenchymal cell types within the liver, all of which require carbohydrate to function. A better understanding of the detailed cellular distribution of GLUTs in human liver tissue may shed light on mechanisms underlying disease pathogenesis. This review summarises the available literature on hepatocellular expression of GLUTs in health and disease and highlights areas where further investigation is required.

INTRODUCTION

Provision of a regular supply of glucose and other carbohydrates for fuel is vital for human survival and these are transported into cells using members of a family of integral membrane glucose transporter (GLUT) molecules^[1]. To date 14 members of this family, also called the solute carrier 2A (SLC2A) proteins have been identified which can be divided on the basis of transport characteristics (intrinsic or inducible, specificities) and sequence similarities^[2] into several families (Classes 1 to 3)^[3,4]. The expression of these different receptor subtypes varies between different species, tissues and cellular

subtypes and each has differential sensitivities to stimuli such as insulin.

The liver is a contributor to metabolic carbohydrate homeostasis and is a major site for synthesis, storage and redistribution of carbohydrates. At its simplest, after a meal hepatocyte GLUTs take up glucose from the portal bloodstream and it is converted to glycogen for storage. In a glucose-depleted state, this glycogen can then be converted back to glucose for fuel with up to 70% of total hepatic glucose production arising *via* this route^[5]. Situations in which the balance of glucose homeostasis is upset such as diabetes or the metabolic syndrome can lead metabolic disturbances that drive chronic organ damage and failure, which confirms the importance of understanding the molecular regulation of glucose homeostasis. The liver is the major store of glycogen, regulates the availability of glucose and acute liver failure is associated with profound hypoglycemia. This has led to a large body of work investigating the expression and function of receptors that regulate glucose uptake and release by hepatocytes, the most import cells in glucose regulation and glycogen storage but there is less appreciation of the roles of GLUTs expressed by other cell types within the liver. Thus to date expression of GLUT-1, GLUT-2^[6,7], GLUT-9^[8] and GLUT-10^[9] has been documented on hepatocytes but little is known about their expression or function on other cell types. However all cells require carbohydrate to function and there is evidence that non-parenchymal cells may contribute to glucose disposal. For example sinusoidal endothelial cells bind insulin with high affinity, and endothelial insulin-responses may be rate-limiting for glucose uptake^[10]. Thus a better understanding of the detailed cellular distribution of GLUTs in human liver tissue may shed light on mechanisms underlying disease pathogenesis. We begin by discussing the extrahepatic expression and functions of these proteins.

EXTRAHEPATIC EXPRESSION AND FUNCTION OF CLASS I GLUCOSE TRANSPORTERS

This family contains the proteins GLUTs 1 to 4 and 14 (SLC2A1-4, 14). The gene for GLUT-1 (*SLC2A1*) the most ubiquitous transporter is located on chromosome 1p35-p31.3 and generates a 54 Kd protein in humans and rodents^[11]. It has a high K_m for glucose ($K_m = 1-2$ mmol/L) and is mainly responsible for basal glucose and uptake^[12], but can also transport other hexose carbohydrates including mannose, galactose, glucosamine, 3-O-methylglucose and 2-deoxy-d-glucose. GLUT-1 is, expressed in most cells^[13] at low levels, with highest expression reported on erythrocytes, the blood brain barrier, neuronal membranes, eye, placenta and lactating mammary glands^[14-16]. Murine embryonic expression also suggests a developmental role^[17,18]. Over expression of GLUT-1 has been documented in a variety of tumours^[19] and is associated with increased proliferation rates and

increased mortality^[20] leading to its use as a diagnostic/prognostic marker in some cancers^[21,22].

The GLUT-2 (*SLC2A2*) gene located on chromosome 3q26-1-q26.2 encodes a 524 amino acid protein. GLUT-2 can efficiently transport sugars due to its high V_{max} and K_m for glucose, and is well suited to managing large bi-directional fluxes of glucose in and out of cells^[23]. It also transports other dietary sugars such as galactose, mannose and fructose with a high affinity for glucosamine^[11,24,25]. GLUT-2 is highly expressed in the liver, pancreatic beta cells, and on the basolateral surface of kidney and small intestine epithelia^[26,27] with expression regulated by sugars and hormones^[23,28]. Glycogenosis in the rare autosomal recessive disorder Fanconi-Bickel Syndrome has been associated with mutations in GLUT-2^[29], and diabetes mellitus in patients with prolonged hepatitis C virus (HCV) infection has been linked to virally-induced reduction in hepatocyte expression of GLUT-2^[30].

GLUT-3 (SLC2A3) was initially identified from muscle cell cDNA^[31]. Expression localises to the membrane of slow twitch muscle fibres^[32] and it is implicated in muscle regeneration and cell fusion^[33]. However its major role is in neurons, supplying the high glucose demands in the brain^[11,34] and it is increased in brain tumour cells^[35]. The gene for GLUT-3 is located on chromosome 12p13.3 and encodes a 496aa protein^[12] which transports glucose with a high affinity ($K_m = 1.8$ mmol/L) and maltose, xylose, dehydroascorbic acid, mannose and galactose^[25]. It is also present in fat, kidney, heart, placenta and liver at lower levels^[36], and is vital for the supply of substrate to early post-implanted embryos^[37]. White blood cells, which need an increased supply of glucose to fuel immune functions, express several GLUTs including GLUT-3^[34] the expression of which is decreased in diabetes^[38].

GLUT-4 (SLC2A4) was cloned and sequenced by several groups in 1989^[39-41]. It is a 55kDa protein responsible for more than 50% of all body glucose uptake^[42]. In the absence of insulin it is sequestered in intracellular vesicles and rapidly translocated to the plasma membrane in response to insulin. GLUT-4 transports glucose ($K_m = 5-6$ mmol/L), dehydroascorbic acid and glucosamine^[11,24]. Highest levels of expression are detected in insulin sensitive tissues such as skeletal and cardiac muscle, brown and white adipose tissue^[11] and endothelial cells^[43]. Expression has also been documented in monocytes, and like GLUT-3 is reduced in insulin-resistant individuals^[44]. Mutations in the gene have been associated with diabetes.

GLUT-14 (SLC2A14) was identified and cloned by Wu X *et al*^[45] in 2002. It is located on chromosome 12p13.3, has a high sequence similarity to GLUT-3 and may have arisen as a result of gene duplication. The protein contains sugar transporter signature motifs predicted to exhibit glucose transport activity^[45]. Two splice variants have been identified in the testis^[45]. Mutations of GLUT-14 and its drosophila homologue have been associated with Alzheimers disease in genome wide as-

sociation studies in patients and insect models^[46,47] and may explain the reported brain-specific dysregulation of glucose metabolism seen in this condition.

EXTRAHEPATIC EXPRESSION AND FUNCTION OF CLASS II TRANSPORTERS

This family contains the transporters GLUT-5, GLUT-7, GLUT-9 and GLUT-11. GLUT-5 (SLC2A5) mRNA is detected mainly in the small intestine where it is found at both the apical and basolateral membranes and functions to absorb dietary fructose ($K_m = 6 \text{ mmol/L}$)^[11,48,49]. It is also expressed at lower levels in the human kidney, microglial cells, adipocytes, muscle, brain, and testes^[49,50], and in common with other transporters, expression is increased in human malignant tumours^[51]. The protein exhibits no activity for glucose transport in humans or mouse^[11,52] and its localization is not regulated by insulin^[50,53]. There is a growing interest in fructose consumption and its link with the metabolic syndrome, type 11 diabetes and obesity^[49] since consuming foods and beverages which contain excessive amounts of fructose has been linked to nonalcoholic fatty liver disease (NAFLD)^[54]. The thiazolidinedione drug pioglitazone^[55], which is used to treat type II diabetes, decreases GLUT-5 mRNA (52%) and protein (40%) in muscle fibres of type II diabetic subjects.

The GLUT-7 (SLC2A7), which was originally cloned from a human intestinal cDNA library^[56], has considerable sequence similarity to GLUT-5^[57] and is involved in uptake of sugars *via* facilitative diffusion mechanisms. Like GLUT-5 it has substrate specificity for both glucose and fructose and a key Ile-314 residue confers hexose specificity and is essential for fructose transport^[58]. GLUT-7 mRNA is detected in the small and large intestines at the brush border membrane of enterocytes^[11,49]; it is also detected in the prostate and testis^[56]. Interestingly, disparities between the localisation of expression within the small intestine and glucose and fructose substrate availabilities suggest that alternate ligands may exist^[57].

GLUT-9 (SLC2A9) shares sequence homology^[59,60] and substrate specificities^[58] with GLUT-5, GLUT-7 and GLUT-11 and, together with GLUT-2, is important for glucose-sensing by pancreatic B-cells^[61]. Expression is localised to liver, kidneys, leukocytes^[62], pancreas^[61], placenta, lung^[63], testis and adrenal gland. Two alternate isoforms have been identified, termed GLUT-9a and GLUT-9b^[64,65], and alternative splicing results in differential subcellular localisation. Both isoforms have also been reported to transport urate with high affinity^[66], and polymorphisms in the *GLUT-9* gene are linked with an increased predisposition to gout^[67]. Some polymorphisms have also been associated with an increased incidence of diabetes in Chinese populations^[68]. GLUT-9a expression increases in pregestational and gestational diabetes, and GLUT-9b is increased by insulin^[59]. In mouse, three isoforms of this transporter are reported,

and similarly elevated in diabetes^[8].

Three distinct isoforms of GLUT-11 (SLC2A11) have been identified in humans, with distinct but overlapping tissue expression patterns. Thus GLUT-11-A is expressed in skeletal muscle, kidney and heart, GLUT-11-B in adipose tissue, kidney and placenta, and GLUT-11-C in pancreas, heart, adipose tissue and skeletal muscle^[69-72]. Muscle expression is localised to slow twitch fibres^[73] and appears to be involved in myeloma cell viability and proliferation^[74]. All three variants of GLUT-11 exhibit transport activity for both glucose and fructose but not galactose when expressed in *Xenopus* oocytes^[58,70].

EXTRAHEPATIC EXPRESSION AND FUNCTION OF CLASS III TRANSPORTERS

This family constitutes the evenly numbered transporters GLUT-6, GLUT-8, GLUT-10, GLUT-12 and GLUT-13. GLUT-6 (SLC2A6)^[62] is widely expressed in normal and malignant tissue. mRNA has been detected in peripheral leucocytes, brain^[72] and spleen^[11] as well as in pancreas, testis, colon^[62] and adipose tissue^[75]. Subcellular protein expression varies with plasma membrane localisation in renal collecting tubule cells and cytoplasmic localisation in germinal cells of the testis and smooth muscle. GLUT-6 has significant sequence identity with GLUT-3 and may have arisen through insertion of GLUT-3 sequence into another gene on chromosome 5^[76].

GLUT-8 (SLC2A8) is a high capacity intracellular GLUT^[77] composed of 447 amino acids containing an N-terminal dileucine motif that permits trafficking *via* adaptor proteins to different organelles^[77,78]. Expression is highest in the testis and^[79], following insulin stimulation increases in the mid-piece of mature spermatozoa and translocates to the acrosome where the spermatozoa take up glucose to drive motility and the acrosome reaction. GLUT-8 may compensate for a lack of GLUT-4 in spermatozoa^[80,81] and the preimplantation blastocyst, which demonstrates insulin stimulated glucose uptake *via* GLUT-8 translocation^[82]. GLUT-8 is also found in some insulin receptive tissues including adipose tissue, muscle, brain, adrenal glands, spleen, heart and the liver^[62,83,84], but not adipocytes^[75] or neuronal cells^[85].

GLUT-10 (SLC2A10) is a 541aa protein in humans and 513aa in zebrafish^[11,86], which transports both glucose and galactose with high affinity^[87]. It is expressed in the brain, lungs, adipose tissue^[88], heart, placenta, and skeletal muscle with highest expression in the liver and pancreas^[9,87]. The *GLUT-10* gene, located on chromosome 20q12-13.1^[89] has been linked with type II diabetes^[9,90]. However other studies do not show any association with a diabetic phenotype^[91,92]. Development of the cardiovascular system and TGF β signalling are linked to GLUT-10 function^[93] and mutations are associated with altered angiogenesis and arterial tortuosity syndrome^[93,94] as a consequence of a loss of regulation of smooth muscle mitochondrial antioxidants production in the absence of functional GLUT-10^[89].

Table 1 Summary of reported hepatic expression of glucose transporters isoforms

Class	GLUT isoform	Hepatic expression	Subcellular expression/localisation	Protein/mRNA	Ref.
Class I	GLUT1	Yes	Sinusoidal membrane of hepatocytes, protein restricted to hepatocytes proximal to the hepatic venule, also expressed on endothelial cells, kupffer cells and cholangiocytes; hepatocyte expression in HCC	Both	[110,113,115,116,120]
	GLUT2	Yes	Hepatocytes	Protein	[124-126]
	GLUT3	Yes	Hepatocytes, bile canalicular membrane more enriched than sinusoidal membrane	Protein	[115,116,132]
	GLUT4	Yes	Stellate cells	mRNA	[115,116,134]
	GLUT14	No			
Class II	GLUT5	Yes	Normal liver tissue hepatocytes (cytoplasmic)	Both	[51,115]
	GLUT7	No			[140]
	GLUT9	Yes	Majority of expression in hepatocytes of normal liver and HCC with cytoplasmic expression in pericentral areas	Protein	[51]
Class III	GLUT11	Yes		mRNA	[115]
	GLUT6	Yes		mRNA	[76]
	GLUT8	Yes	Perivenous hepatocytes	Both	[115,143]
	GLUT10	Yes		mRNA	[86,115]
	GLUT12	Yes		mRNA	[98]
	GLUT13	No			

The table summarizes the evidence presented within this review to highlight the reported hepatocellular expression of glucose transporter (GLUT) isoforms at message and protein level. Pertinent references are cited in the extreme right hand column. mRNA: Micro RNA; HCC: Hepatocellular carcinoma.

GLUT-12 (SLC2A12) was originally identified in the MCF-7 breast cancer epithelial cell line^[95]. It is expressed in insulin sensitive tissues in humans and rodents including adipose tissue, skeletal muscle (major expression in type 1 oxidative fibres) and heart^[72,88,96-98] as well as human chondrocytes^[99]. GLUT-12 is also found in placenta, small intestine, heart and tumours with a high metabolic and capacity glucose utilisation^[100-103]. In normal human muscle GLUT-12 undergoes PI3 kinase dependent translocation from an intracellular region to the plasma membrane^[104]. Its expression in insulin sensitive tissues, and evidence that overexpression of GLUT-12 in mice improves glucose clearance rate and whole body insulin sensitivity^[105] confirm that this transporter is insulin-sensitive. The *GLUT-13 (SLC2A13)* gene encodes a 629 amino acid protein, located on chromosome 12q12. It is a H⁺/myo-inositol co-transporter^[11,106,107] also known as HMIT^[108] in neuronal cells^[106,108]. Although there are no known reports of glucose activity for GLUT-13^[11], the rat gene contains motifs which are important for glucose transport activity (<http://omim.org/entry/611036>).

LIVER SPECIFIC EXPRESSION OF GLUCOSE TRANSPORTER MOLECULES

The data reviewed above reveal the widespread distribution and diverse function of extrahepatic transporter proteins but much less is known about their expression and function in the liver. Surprisingly, there are few studies documenting changes in expression and function in disease. Defining local expression of GLUTs in tissue will shed light on disease pathogenesis. For example, diabetes is associated with altered expression of GLUT-1, GLUT-2, GLUT-3 and GLUT-8 and GLUT-9 (reviewed in^[8]) and abnormal GLUT-1 expression on tumour endothelium in HCC has prognostic and diagnostic

significance^[109-111]. A good example is the finding that diabetes in HCV is a consequence of virally induced downregulation of GLUT-1 and GLUT-2 on hepatocytes^[30]. Similarly, transport of key substrates such as fructose has been linked to NAFLD^[54]. Dysregulated glucose homeostasis and insulin resistance in NAFLD is associated with chronic organ damage affecting multiple hepatic cell types. The expression levels of transporters is not only regulated by insulin and glucose levels but also by cytokines including interleukin-6, which is increased in obesity and diabetes and can amplify insulin resistance *via* effects on GLUT-4^[112]. The hexose transporters also play important roles in the function of cholangiocytes^[113], endothelial cells and stellate cells^[114]. Thus we summarise the current state of knowledge regarding hepatocellular expression of the GLUT family of proteins, in order to highlight their potential role in tissue homeostasis and disease (Table 1).

HEPATIC EXPRESSION OF CLASS I TRANSPORTERS

The widespread expression of GLUT-1 includes the liver although the precise cellular distribution remains controversial. Because hepatocytes are capable of gluconeogenesis their need for glucose uptake is modest. GLUT-1 is expressed on the sinusoidal membrane of rat and porcine^[115,116] hepatocytes, and may be expressed to a greater extent than GLUT-2 during early post-natal development^[117]. Expression of both GLUT-1 and GLUT-2 by foetal hepatocytes allows for efficient glycogenesis at low plasma glucose concentrations^[118]. In adult animals, expression is strongest in the central acinar zones^[119]. Transcription and microsomal expression of GLUT-1 is detected in periportal and perivenular hepatocytes but membrane localisation is restricted to hepatocytes

Figure 1 Expression of glucose transporter glucose transporters 1-13 micro RNA in normal human livers. This figure contains unpublished data generated by the authors. Livers were collected from patients at the Liver Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom with appropriate informed written consent and local ethics committee approval. Micro RNA was extracted using standard protocols and integrity was confirmed using an Agilent 2100 Bioanalyser. Transcriptome analysis was carried out for all samples using Agilent Human Whole Genome Oligo Arrays (G4112F) in accordance with Agilent one colour microarray gene expression analysis protocol. Results are expressed as means of five normal livers \pm SE, and were run on triplicate plates. Data were normalized to pooled endogenous controls and differential expression is represented as power $2^{-\Delta\Delta CT}$. ^b $P < 0.01$ vs glucose transporters (GLUT) 2.

proximal to the hepatic venule^[120] under basal conditions. Our own microarray analysis of human normal livers confirms expression of GLUT-1 and GLUT-2 in total liver mRNA (Figure 1). In hepatocellular carcinoma, variable cytoplasmic GLUT-1 is detected and has been used to distinguish between cholangiocarcinomas and hepatocellular carcinomas (HCC)^[109] and has even been proposed as a therapeutic target for HCC^[110]. Exposure of rodents to alcohol and high fat feeding results in increased GLUT-1 and decreased GLUT-2 expression in hepatocytes which presumably reflects changes in energy metabolism in response to the dietary changes^[121].

Non-parenchymal cells, which cannot carry out gluconeogenesis, rely on glucose uptake rather than endogenous generation. GLUT-1 is the dominant receptor on both endothelial cells and Kupffer cells and levels increase in response to even brief exposure to LPS^[122]. Interestingly, acute liver failure has been associated with increased GLUT-1 expression on cerebral vasculature in response to elevated circulating ammonia levels^[123]. Cholangiocytes demonstrate basolateral expression of GLUT-1^[113] which facilitates absorption of glucose from bile.

GLUT-2 fulfils the major glucose transport role in hepatocytes^[36,124] (Figure 1). The protein localises to the sinusoidal plasma membrane of normal^[23,125] and malignant hepatocytes. Historical reports suggest a K_m for glucose transport of up to 66 mmol/L in intact rat hepatocytes^[126] although contribution from other transporters likely contributes in this study since others report lower values between 10 mmol/L and 20 mmol/L^[23]. GLUT-2 promotes rapid glucose efflux following gluconeogenesis. In the fasting state the liver produces glucose *via* glycogenesis or glycogenolysis with the conversion of glucose 6 phosphate into glucose preceding release *via*

GLUT-2^[23]. However in the fed state glucose and insulin levels rise and inhibit endogenous glucose production through effects on enzymes involved in gluconeogenesis. This is associated with removal of membrane GLUT-2 and a subsequent fall in GLUT-2 mediated release^[23]. Excess glucose is stored as glycogen or converted to lipids and hepatocyte GLUT-2 and the insulin receptor are internalised together into endosomes in response to insulin^[23,127,128]. In mice lacking GLUT-2 the rate of hepatic glucose production is not impaired indicating the presence of a facilitated diffusion-independent mechanism for glucose release^[129]. Thus the major role of hepatocyte GLUT-2 is to regulate efflux rather than uptake of glucose. However, in obesity insulin resistance drives an increase in GLUT-2 levels that may further exacerbate metabolic dysfunction in NAFLD^[130].

Much less is known about the hepatic expression and function of GLUT-3. GLUT-3 is expressed in porcine livers^[115] and localised to the plasma membrane of rat hepatocytes. Expression is focussed on the bile canalicular membrane rather than the sinusoidal membrane^[116]. Mice with GLUT-3 haploinsufficiency develop obesity and insulin resistance associated with hepatic steatosis, possibly as a consequence of foetal glucose insufficiency^[131]. GLUT-3 expression is increased on both primary and metastatic hepatic tumours, which might reflect an increased need for glucose uptake in cancer^[132]. Low levels of GLUT-3 have been reported in the human liver^[36] and are supported by our microarray analysis but detailed human studies are lacking and little is known about changes in disease.

Whilst the liver is generally considered to lack significant expression of GLUT-4^[133], a recent study reports expression of GLUT-4 mRNA in porcine liver^[115]. Al-

though there is little evidence for expression in hepatocytes, GLUT-4 has been detected in sinusoidal endothelial cells and stellate cells where it can mediate glucose uptake by semicarbazide sensitive amine oxidase mediated effects on insulin receptor signalling^[134] which explains our findings of expression at mRNA level in humans (Figure 1). Expression on stellate cells is enhanced by leptin signalling^[114] leading to HSC activation that may contribute to fibrogenesis in NAFLD. In contrast, in murine models of diet-induced obesity GLUT-4 mRNA is decreased in the liver^[135] and cirrhosis is associated with decreased extrahepatic GLUT-4 mRNA^[42]. Deletion of skeletal muscle GLUT-4 results in redirection of excess circulating glucose to the liver where it becomes fuel for conversion to lipid storage^[136-138]. Thus glucose homeostasis is maintained by a complex relationship between intra- and extra hepatic levels of GLUT-4 regulated by metabolic activity and dietary intake. To date there are no published reports concerning expression of GLUT-14 in the liver.

HEPATIC EXPRESSION OF CLASS II TRANSPORTERS

GLUT-5 protein has been detected in human hepatocytes^[51] although low to undetectable RNA levels in pigs^[115] imply species-specific differences in GLUT-5 expression. Hepatic metastases from lung and breast cancer are GLUT-5 positive^[132] but under normal conditions liver expression is minimal (Figure 1). A mechanistic link between elevations in GLUT-5 expression in small intestine and alterations in hepatic metabolism^[139] has been suggested.

GLUT-7 was initially reported as a hepatic microsomal GLUT found in the endoplasmic reticulum, which facilitated the release of glucose formed in the process of gluconeogenesis and glycogenolysis for export into the blood^[136,140]. However this has recently been challenged by studies showing that neither human nor rat livers contain GLUT-7 mRNA^[141] and our data in Figure 1, suggesting that the previous findings were due to a cloning artefact. Definitive studies need to be performed to clarify the situation.

GLUT-9 has been detected in the cytoplasm of pericentral hepatocytes in normal human liver and in HCC^[51]. The receptor appears to be functional for glucose transport because plasma membrane expression of GLUT-9 correlates with glucose influx in HepG2 cells^[142] and GLUT-9 inactivation in mouse hepatocytes leads to hyperuricosuria^[143]. Although GLUT-11 mRNA has been detected in porcine liver^[115], there are no studies documenting expression of GLUT-11 in the human liver.

HEPATIC EXPRESSION OF CLASS III TRANSPORTERS

Little is known about the hepatic expression of the

recently identified Class III transporters although our microarray data (Figure 1) is indicative of some degree of expression. Presence of mRNA for GLUT-6 has been described in hepatoma cell lines but has not been detected in normal human liver^[76]. GLUT-8 mRNA has been detected in perivenous hepatocytes in pig^[115] and mouse^[144] livers where it may regulate glycolytic flux. Mice with type I diabetes show decreased expression whereas expression increases in insulin resistance and type II diabetes suggesting that expression is regulated by insulin^[144]. Hepatic expression of GLUT-10 has been reported in pigs^[115] and zebrafish^[86] but we are unaware of any data in humans. GLUT-12 mRNA has been documented in all bovine tissues including the liver where levels are low compared to spleen and skeletal muscle^[98], but again detailed cellular expression data is currently lacking. There are no known reports of GLUT-13 expression in the liver.

CONCLUSION

Systemic carbohydrate homeostasis is maintained by a complex relationship between organs such as the pancreas, intestine, muscle and liver. Intra- and extra hepatic levels of GLUT molecules are regulated in part by metabolic activity, dietary intake, and disease state. For example, diabetes is associated with altered expression of GLUT-1, GLUT-2, GLUT-3 and GLUT-8 and GLUT-9^[8] and abnormal GLUT-1 expression on tumour endothelium in HCC^[109-111] permits efficient glucose uptake by tumour cells even at low blood glucose concentrations. Chronic fructose intake drives glucose and glycogen storage, lipogenesis and production of lipogenic intermediates as well as promoting production of very-low-density lipoproteins^[145]. This suggests that the reported hyperlipidaemic and hyperuricaemic effects of fructose, coupled with macrovesicular steatosis and lobular inflammation patterns^[146] characteristic of human NAFLD seen in rodents fed high fructose diets, may be enhanced in the context of altered expression of fructose transporters within the hepatic parenchyma and especially so for individuals with high fructose intake or pre-existing hyperlipidaemia or metabolic syndrome. New data is increasingly suggesting the merits of targeting members of the GLUT family therapeutically. Thus overexpression of GLUT-1 in tumours, particularly those with poor prognosis has been suggested as a possible means to selectively inhibit tumour cell metabolism^[147], although expression of GLUT-1 in red blood cells will likely preclude use therapeutically. Similarly targeting of GLUT-3, which is involved in neovascularisation in glioblastoma has been suggested to prevent resistance to conventional therapy^[148], and GLUT-4 is of particular interest in the context of diabetes and insulin resistance, with efforts underway to design therapeutics to enable appropriate glucose uptake independently of insulin stimulation^[149]. Alterations in hepatic expression of GLUT transporters have been described in response to

insulin resistance and hyperlipidaemia, alcohol consumption, viral infection and carcinogenesis, with diverse functions including biliary transport, fibrogenesis, urate transport and angiogenesis executed by family members in extraparenchymal cells. Combined with the central role of the liver in regulation of circulating carbohydrate therefore, future definition of the spatial, temporal and disease-specific expression of GLUTs within the liver microenvironment is key to understanding disease pathogenesis and potential hepatic complications of systemic inhibition.

Abstract

The inflammatory bowel diseases (IBD), Crohn's disease and ulcerative colitis, are chronic relapsing, remitting disorders. Diagnosis, along with assessment of disease activity and prognosis present challenges to managing clinicians. Faecal biomarkers, such as faecal calprotectin, are a non-invasive method which can be used to aid these decisions. Calprotectin is a calcium and zinc binding protein found in the cytosol of human neutrophils and macrophages. It is released extracellularly in times of cell stress or damage and can be detected within faeces and thus can be used as a sensitive marker of intestinal inflammation. Faecal calprotectin has been shown to be useful in the diagnosis of IBD, correlates with mucosal disease activity and can help to predict response to treatment or relapse. With growing evidence supporting its use, over the last decade this faecal biomarker has significantly changed the way IBD is managed.

INTRODUCTION

It is desirable to have simple diagnostic tests and disease markers for use in the assessment and follow up of chronic diseases such as inflammatory bowel disease (IBD). These markers should be easy to perform, acceptable to both patients and health workers, economical, ideally non-invasive and have a high sensitivity and specificity. Calprotectin, first described in 1980^[1], is a protein found in the cytosol of neutrophils and macrophages composed of two subunits S100A8 and S100A9. It can be detected in plasma, urine, cerebrospinal fluid, faeces, saliva, synovial fluid and colonic biopsies^[2]. It is stable in faeces for up to seven days at room temperature and has a homogenous distribution in faeces^[3], properties which lend it to testing spot faecal samples. There has been recent emphasis of the involvement of the innate immune system in the pathogenesis of IBD^[4]. Calprotectin is classed as a damage associated molecular pattern protein (DAMP) having antimicrobial protective properties. DAMPs are released by the innate immune system from damaged or activated cells, initiating and perpetuating the immune response. The extracellular release of calprotectin during times of cell stress/damage makes it an accurate marker of intestinal inflammation.

As early as 1992 it was shown that faecal calprotectin

is elevated in patients with both ulcerative colitis (UC) and Crohn's disease (CD)^[3] and this has been confirmed by subsequent studies^[5-9]. Calprotectin levels in faeces correlate with faecal excretion of 111-indium labelled leucocytes, deemed to be the gold standard for measuring intestinal inflammation ($r = 0.80$, $P < 0.0001$)^[5]. Disadvantages of this gold standard test compared with calprotectin are the exposure to radiation, cost and the three day collection of faeces. Faecal calprotectin levels have also been shown to correlate well with radiolabelled white cell scanning, another method of assessing intestinal inflammation, in adults with CD^[10]. Spot faecal samples of < 5 g have been shown to be as reliable as 24 h collection samples for measuring calprotectin levels^[3] indicating that calprotectin is evenly distributed throughout the faeces.

An elevated faecal calprotectin is not specific for IBD. Any inflammatory process within the gastrointestinal tract will result in the activation of the innate immune response and release of calprotectin. Faecal calprotectin concentration has been shown in studies to be elevated in many conditions including infection, colorectal cancer, untreated coeliac disease, microscopic colitis and diverticulitis^[11-13]. Non-steroidal anti-inflammatory drugs (NSAIDs) have been shown to cause significant increases in faecal calprotectin levels within seven days due to NSAIDs induced intestinal inflammation with endoscopic correlation^[14,15]. Proton pump inhibitors (PPIs) have been associated with significantly elevated faecal calprotectin levels, regardless of reason for PPI^[16].

Initially faecal calprotectin concentration was reported in mg/L, but more recent assays (post 2000) usually report faecal calprotectin concentration as $\mu\text{g/g}$. To compare these results, faecal calprotectin concentrations obtained using assays pre-2000 need to be multiplied by a factor of five.

USE OF FAECAL CALPROTECTIN IN DIAGNOSIS OF IBD

Diagnosis of IBD has historically been based on a combination of clinical history and examination, blood parameters, radiology and endoscopy. The addition of a faecal biomarker able to reduce the need for invasive endoscopic procedures or exposure to radiation is advantageous.

Limburg *et al.*^[12], in 2000, published a study of 110 patients attending for colonoscopy for the investigation of chronic diarrhoea showing that increased faecal calprotectin levels were significantly ($P = 0.0001$) associated with the presence of colorectal inflammation (CD, UC, microscopic colitis or diverticulitis). Within the colonic inflammation subgroup, calprotectin concentrations were highest amongst subjects with IBD. The negative predictive value of faecal calprotectin in this dataset was 93%.

IBD and irritable bowel syndromes (IBS) can present in a similar clinical fashion with symptoms such as diarrhoea and abdominal pain. Routine colonoscopy in these

patients is costly, invasive and has associated morbidity and mortality. Serum markers of inflammation such as C reactive protein (CRP) and erythrocyte sedimentation rate (ESR) in isolation are not sufficiently sensitive or specific for the diagnosis of IBD^[7]. The use of faecal calprotectin to distinguish between IBD and IBS has been analysed in several studies. In 2000 Tibble *et al.*^[7] presented results of a prospective study of 220 consecutive patients in whom the principal differential diagnosis was that of either IBS or CD. They excluded patients with UC on sigmoidoscopy and biopsy. A diagnosis of CD was made from a combination of radiological, endoscopic and histological investigations. A diagnosis of IBS was made on basis of normal investigations and a compatible history fulfilling the Rome criteria. All patients subsequently diagnosed with CD had significantly higher faecal calprotectin concentrations than those with IBS. The investigators found that using a cut-off point of 30 mg/L faecal calprotectin had a 100% sensitivity and 97% specificity in discriminating between active CD and IBS.

Schoepfer *et al.*^[17] looked at the accuracy of faecal biomarkers alone and in combination with the IBD antibodies, antineutrophil cytoplasmic antibody (ANCA) and anti-*Saccharomyces Cerevisiae* manna antibody (ASCA), in discriminating IBD from IBS. They found that the overall accuracy of faecal calprotectin for discriminating between IBD and IBS was 89% (sensitivity 83%, specificity 100%). There was only a marginal increase in overall accuracy when faecal calprotectin was combined with IBD antibodies to 91%.

Faecal calprotectin has been studied as a tool to predict abnormal small-bowel radiology^[18]. The study looked at 73 consecutive patients attending for small bowel follow through whose presenting symptoms were consistent with a possible diagnosis of IBD. The control group consisted of 25 patients with IBS, 25 normal volunteers and 25 patients with active CD. A faecal calprotectin level above 60 $\mu\text{g/g}$ predicted all abnormal barium follow through results. The negative predictive value of a single calprotectin result below 60 $\mu\text{g/g}$ of stool was 100% compared with 91% each for erythrocyte sedimentation rate cut off of 10 mm and C-reactive protein of 6 mg/L. Somewhat in contrast to this Sipponen *et al.*^[19] found that faecal calprotectin had a low utility for predicting the presence of small bowel CD on wireless capsule endoscopy, sensitivity was low at 59% with a moderate specificity of 71% using a cut-off of 50 $\mu\text{g/g}$.

A recent meta-analysis analysed 30 prospective studies comparing the diagnostic precision of faecal calprotectin against a histological diagnosis^[20]. Summary receiver operating characteristic curve analysis showed a sensitivity of 0.95 (95% CI: 0.93-0.97), specificity of 0.91 (95% CI: 0.86-0.91), and an area under the curve (AUC) of 0.95 for the diagnosis of IBD. The diagnostic precision of faecal calprotectin for IBD was higher in children than adults with better accuracy at a cut-off level of 100 $\mu\text{g/g}$ *vs* 50 $\mu\text{g/g}$. This meta-analysis also showed that faecal calprotectin was superior to CRP, ESR, ASCA, perinuclear anti-neutrophil cytoplasmic an-

tibodies and anti-*Escherichia coli* outer membrane porin C antibody in diagnosis of IBD.

Thus it can be stated that a normal faecal calprotectin result, in the absence of 'red flag' symptoms and in the context of positive Rome criteria, is associated with a high likelihood of subsequent non-organic diagnosis and further endoscopic or radiological evaluation may be avoided in such patients. A meta-analysis published in 2010 to assess whether the use of faecal calprotectin reduces the number of unnecessary endoscopic procedures in the investigation of suspected IBD showed that screening with faecal calprotectin would result in a 67% reduction in the number of adults requiring endoscopy. The downside of this screening strategy is delayed diagnosis in 6% of adults because of a false negative test result^[13].

Faecal calprotectin appears to better reflect disease activity in UC rather than CD^[21] but faecal calprotectin has not been found to be useful in distinguishing UC from CD. Quail *et al*^[22] looked at faecal calprotectin concentrations in Scottish children with a diagnosis of IBD; there was no statistical difference in calprotectin concentrations between CD and non-Crohn's patients (UC or IBD type unspecified).

FAECAL CALPROTECTIN IN DISEASE ACTIVITY AND RESPONSE TO TREATMENT

In IBD, the presence of active gut inflammation is associated with migration of leucocytes, including neutrophils, to the gut mucosa^[23]. As a result the faecal stream contains increased levels of these inflammatory proteins including calprotectin. Faecal calprotectin has been shown to differentiate quiescent from active disease in both patients with CD and UC^[10,24-26]. Correlation of faecal calprotectin tends to be higher with endoscopic activity than clinical activity indices^[24,27] and indeed some studies have demonstrated no significant correlation between faecal calprotectin and clinical indices^[10,28]. In general faecal calprotectin correlates better with colonic CD rather than ileal disease^[27-31] and an inflammatory rather than a structuring/penetrating phenotype^[27,31]. Sipponen *et al*^[24] showed that in active disease (CD endoscopic index of severity, CDEIS ≥ 3), faecal calprotectin concentrations were significantly higher in colonic than in ileal CD. Also, in limited ileal disease faecal calprotectin failed to correlate with endoscopic activity.

In UC Rikanek *et al*^[32] showed that the median faecal calprotectin concentration was higher in patients with extensive and left sided disease distribution compared with proctitis (740 $\mu\text{g/g}$, 2106 $\mu\text{g/g}$, 86 $\mu\text{g/g}$ respectively; $P = 0.007$ and $P = 0.009$). There was no significant difference in faecal calprotectin concentration between extensive and left sided disease distribution.

There have been several studies looking at the use of faecal calprotectin to predict or monitor response to

treatment. In a study looking at 11 patients with relapsing IBD^[33] (11 CD and 27 UC) faecal calprotectin was analysed at inclusion and after 8 wk of treatment (end of study). Treatment was individualised medical therapy. A normalised faecal calprotectin concentration at 8 weeks predicted a complete response in 100% patients. There was a significant decline in faecal calprotectin levels ($P < 0.001$) in patients with UC responding to treatment defined as normalisation of clinical and endoscopic scores. Within the small subgroup of patients with CD although 81% of patients achieved a complete clinical response defined clinically as a Harvey Bradshaw Index^[34] (HBI) ≤ 5 there was no significant decline in calprotectin levels. This study was limited by small numbers and also the lack of endoscopic evidence of disease activity or remission in CD patients, it is possible that these patients had ongoing subclinical inflammation. In fact it has been shown that in patients with steroid induced clinical remission faecal calprotectin levels can remain elevated^[35,36]. This finding is in keeping with earlier studies showing incomplete mucosal healing in patients treated with corticosteroids^[37]. Sipponen *et al*^[35] were able to show a significant decrease in faecal calprotectin ($P = 0.005$) in patients with CD who responded both clinically and endoscopically (using CDEIS) to an individualised escalation of treatment. There was no significant change in faecal calprotectin concentration in patients without endoscopic response.

Faecal calprotectin may be able to predict colectomy in patients with acute severe UC. Ho *et al*^[38] showed that in patients with acute severe UC requiring inpatient treatment with intravenous corticosteroids faecal calprotectin was significantly higher in patients who failed to respond to medical therapy and required colectomy than those who did not ($P = 0.04$). The AUC was 0.65 ($P = 0.04$) for faecal calprotectin to predict colectomy with a maximum likelihood ratio of 9.23 at a cut-off of 1922.5 $\mu\text{g/g}$ (specificity of 97.4%). Overall in the study faecal calprotectin concentrations were high with 86% of patients having levels of $> 500 \mu\text{g/g}$ (median 1020 $\mu\text{g/g}$).

Faecal calprotectin can be used to monitor response to biological therapy. Palmon *et al*^[39] showed that faecal calprotectin concentration decreases significantly at week 2 after an infliximab (IFX) infusion in 17 patients with CD on maintenance IFX therapy. Calprotectin levels were noted to rise back to baseline values by week 4 again despite a low median HBI. There was no endoscopic assessment of disease activity in this study. The rise in faecal calprotectin at week 4 may once again indicate a subclinical recurrence of mucosal inflammation. Sipponen *et al*^[40] assessed the role of faecal calprotectin in monitoring clinical, using the CD activity index (CDAI) and CDEIS response to anti-tumor necrosis factor- α (TNF- α) therapy (IFX or adalimumab) in 15 patients with CD. Following 12 wk of treatment faecal calprotectin levels declined significantly from baseline level ($P = 0.001$) and changes in faecal calprotectin correlated to endoscopic appearances as scored using CDEIS (Spear-

man's rank correlation $r = 0.561$, $P = 0.03$) suggesting that faecal calprotectin is a useful non-invasive marker of mucosal response to anti-TNF- α treatment.

PREDICTING MUCOSAL HEALING

Historically clinical practice has considered interpretation of symptoms and the use of scoring systems such as the CDAI, HBI and the Rachmilewitz UC activity index^[41] to determine treatment success in IBD. These indices however tend to reflect patient well-being and quality of life rather than the degree of mucosal inflammation^[10,28]. In both CD and UC there is evidence that mucosal healing is associated with sustained remission and reduced need for surgery^[42,43] and following ileal resection the endoscopic appearance of the neoterminal ileum mucosa at 1 year post surgery has been shown to predict symptomatic relapse^[44]. Thus mucosal healing is evolving into the new goal of IBD treatment.

Røseth *et al*^[45] have demonstrated that normalisation of faecal calprotectin concentration corresponds to endoscopic mucosal healing. Seventeen patients with CD and 28 with UC clinically in remission who had faecal calprotectin concentrations of < 50 mg/L underwent endoscopic assessment of their lower GI tract and macroscopic mucosal appearances were assessed. Biopsies were also taken to assess histological inflammation. All but one of these patients with faecal calprotectin < 50 mg/L had inactive mucosal disease on colonoscopy.

Several subsequent studies have went on to show that concentration of faecal calprotectin correlates with both histological and endoscopic disease activity in IBD and these are summarised in Table 1. Furthermore, several of the studies included in Table 1 show that correlation of faecal calprotectin with endoscopic appearances is stronger than correlation with clinical indices^[28,40].

In contrast to the evidence shown in Table 1, Denis *et al*^[46] failed to find a significant correlation between CDEIS and faecal calprotectin concentration. This was a small study of 28 patients with CD who had CDAI $>$

150 but a normal serum CRP. This lack of correlation may reflect the population studied as more than half of the patients had isolated ileal disease and overall disease activity was low (median CDEIS 3.4).

Interestingly one study in paediatric patients with IBD showed that calprotectin concentration correlated more closely with histological inflammation rather than endoscopic findings suggesting that faecal calprotectin may be more sensitive than macroscopic endoscopic appearances in evaluating disease activity status^[47].

USE OF FAECAL CALPROTECTIN TO PREDICT RELAPSE

Being able to identify patients at high risk of relapse, and those with sub-clinical intestinal inflammation, may allow adjustment of their treatment strategy thus preventing clinical relapse. A non-invasive method of identifying this would reduce cost and risk of morbidity and mortality to patients. As sensitivity and specificity of serum markers of inflammation correlate poorly with intestinal inflammation their ability to predict disease relapse is poor^[48,49]. Several studies have looked at the use of faecal calprotectin to predict relapse in patients with IBD and have demonstrated significant differences in faecal calprotectin concentration in relapsers compared with non-relapsers. A summary of these studies is shown in Table 2. Interestingly, faecal calprotectin appears less useful for predicting relapse in patients with ileal CD compared with patients with UC or colonic/ileocolonic CD^[29,30].

The major outlier in these datasets is the study by Laharie *et al*^[50] which looked at the use of faecal calprotectin to predict relapse specifically in 65 patients with CD treated with IFX induction regimen and then maintained on immunomodulator alone. There was no significant difference in faecal calprotectin concentration between those patients who relapsed by 14 wk post induction and those who did not even when the analysis was restricted to patients with pure colonic disease. No endoscopic

Table 2 The use of faecal calprotectin to predict relapse

Ref.	Patient population	Cut-off calprotectin level	Sensitivity for relapse (%)	Specificity for relapse (%)	Increased risk of relapse
Costa <i>et al</i> ^[21]	UC	150 µ/L	89	82	14 fold
	CD		87	43	2 fold
D'Incà <i>et al</i> ^[29]	UC	130 mg/kg	70	70	2.4 fold
	CD		65	62	1.7 fold
García-Sánchez <i>et al</i> ^[30]	CD + UC	120 µ/g	80	60	
	Ileal CD	223 µ/g	83	50	
Tibble <i>et al</i> ^[49]	CD + UC	50 mg/L (250 µ/g)	90	83	
Laharie <i>et al</i> ^[50]	CD post IFX	130 µ/g	61	48	
		250 µ/g	43	57	
		340 µ/g	80	90.7	18.8 fold
Kallel <i>et al</i> ^[70]	Colonic CD	340 µ/g	80	90.7	
Gisbert <i>et al</i> ^[71]	CD + UC	150 µ/g	69	69	

UC: Ulcerative colitis; CD: Crohn's disease; IFX: Infliximab.

evaluation was performed after IFX induction so although the study did show a median drop in faecal calprotectin concentration of 340 µg/g following induction there may have been ongoing subclinical inflammation. Another limitation of this study is that disease relapse was defined on clinical grounds alone.

Mao *et al*^[51] performed a meta-analysis of the predictive capacity of faecal calprotectin in IBD relapse. Analysing 6 studies they found a pooled sensitivity of 78% and specificity of 73%. Capacity to predict relapse was comparable between CD and UC. Due to the small number of patients the predictive value of faecal calprotectin in ileal only CD patients was not assessed.

FAECAL CALPROTECTIN POST-SURGERY

More than 80% of CD patients require surgery within 10 years of diagnosis and by 3-5 years after surgery around a third of patients will have had a clinical relapse^[44,52]. The role of faecal calprotectin in predicting post-surgical recurrence of CD has been assessed. One study assessed 39 patients with CD undergoing bowel resection^[53]. The majority of patients (67%) had ileocolonic disease. Measurements of faecal calprotectin, CDAI and ultrasound examination were performed at 3 mo post surgery. Endoscopy was performed at 1 year regardless of patient symptoms and was considered the 'gold standard' for recurrence of disease. All patients were clinically in remission at 3 mo. Using a cut-off level of 200 mg/L, in predicting endoscopic post-surgical recurrence, faecal calprotectin has a sensitivity of 63% and specificity of 75% leading the authors to suggest that patients with elevated faecal calprotectin levels at 3 mo post surgery should be assessed endoscopically for early recurrence.

Lamb *et al*^[54] prospectively followed 13 patients for 12 mo post ileocaecal resection for symptomatic CD. Faecal calprotectin was seen to normalise after uncomplicated surgery at 2 mo and remained within normal limits in 8 patients who remained clinically in remission. In the remaining 5 patients there was an increase in faecal calprotectin concentration after initial normalisation associated with disease recurrence or post operative

intra-abdominal collections. The authors' conclusion from this small number of patients was that patients with low levels of faecal calprotectin after resection who had symptoms were unlikely to have mucosal inflammation. It should be pointed out though that there was no scheduled endoscopic evaluation of the gut mucosa during the 12 mo follow up period.

Pouchitis is an inflammatory condition with significant associated morbidity common in patients post restorative proctocolectomy^[55]. Diagnosis can be difficult histologically due to the patchy distribution of inflammation. Faecal calprotectin has been shown to reliably differentiate between inflamed and non-inflamed pouches and correlates with severity of pouchitis^[55-57] thus may reduce the need for endoscopic evaluation of the pouch in some patients.

USE OF FAECAL CALPROTECTIN TO AID DECISIONS OF WITHDRAWAL OF TREATMENT

There has been focus of late on when and in which patients it is appropriate to withdraw anti TNF-α therapy driven by costs and concerns about long term safety. Faecal calprotectin levels may assist in this decision making. Louis *et al*^[58] published results of a prospective study (STORI) of CD patients who had been in steroid free remission on IFX for at least six months. Relapse after IFX withdrawal was associated with various risk factors including a faecal calprotectin concentration of ≥ 300 µg/g. Other risk factors for relapse identified on multivariate analysis included male sex, absence of surgical resection, leucocyte counts > 6 × 10⁹/L, haemoglobin ≤ 145 g/L and hsCRP ≥ 5.0 mg/L. Patients with no more than 2 of the above risk factors had a reduced risk of relapse within 1 year (15% compared with 43.9% overall).

POINT-OF-CARE FAECAL CALPROTECTIN TESTING

Faecal calprotectin concentration is most commonly

measured using an enzyme-linked immunosorbent assay (ELISA) technique in clinical laboratories and several ELISA kits are available. Recently point-of-care or bedside faecal calprotectin tests have become available which may be advantageous in clinical circumstances such as primary care or when a more rapid result is required. These tests can be performed in less than 30 min. Correlation between faecal calprotectin concentrations measured using an ELISA technique and a point-of-care test has been shown to be good in recent initial studies^[59-62].

CONCLUSION

Faecal calprotectin is now playing a major role in the investigation and diagnosis of patients presenting to the physician with lower gastrointestinal symptoms and can obviate the need for costly invasive investigations in selected patients.

Perhaps more excitingly faecal calprotectin is dramatically changing the way IBD is managed. There is a growing body of evidence that faecal calprotectin correlates well with mucosal disease activity and this in turn makes it useful in assessing activity, monitoring response to treatment, predicting relapse and aiding in the difficult decision of whether or not to withdraw biological therapy to a degree than clinical scoring indices or other non-invasive serological markers cannot.

Abstract

The purpose of this review was to highlight, in relation to the currently accepted pathophysiology of non-alcoholic fatty liver disease (NAFLD), the known exercise habits of patients with NAFLD and to detail the benefits of lifestyle modification with exercise (and/or physical activity) on parameters of metabolic syndrome. More rigorous, controlled studies of longer duration and defined histopathological end-points comparing exercise alone and other treatment are needed before better, evidence-based physical activity modification guidelines can be established, since several questions remain unanswered.

INTRODUCTION

Compared with our ancestors, Western societies today lead a lifestyle that is much more sedentary, probably as a result of cultural changes stemming from disregarded traditional customs and modern usages. Taking into account differences in body size, our energy expenditure per kilogram of body weight has been estimated to be 40% less than that of our prehistoric ancestors^[1]. Current estimates suggest that 7 out of 10 adults are inactive or lack adequate conditioning^[2], and this lack of adequate exercise, combined with dietary indiscretion, has contributed to the worldwide epidemic of obesity and non-alcoholic fatty liver disease (NAFLD). Within the United States, data suggest that 64.5% of the adult population is now overweight or obese, with a worldwide prevalence of 40%-60%^[3-5]. Obesity, combined with host factors such as diet, sedentary lifestyle and genetic predisposition, has been directly associated with increases in the prevalence of insulin resistance, type 2 diabetes (T2D) and the metabolic syndrome. The hepatic manifestation of the metabolic syndrome, NAFLD, has also increased in prevalence, and is now considered to be around 20%-30% in Western countries. Among

morbidly obese patients undergoing bariatric surgery, approximately 90% have NAFLD and 36%-37% have the more aggressive form of fatty liver, non-alcoholic steatohepatitis (NASH)^[6,7]. In patients with NAFLD, advancing age, increasing weight, the number of features of the metabolic syndrome and the degree of insulin resistance have all been independently associated with NASH severity^[8]. Evidence-based treatment options for NAFLD are currently lacking. Recent data suggest that the thiazolidinedione class of insulin sensitizers may be efficacious, but widespread utilisation of these agents awaits further investigation^[9]. Evidence also supports a role for weight loss, achieved through exercise.

HORMONAL AND NON-HORMONAL REGULATORS OF GLUCOSE, LIPID AND ENERGY METABOLISM IN NAFLD

The majority of NAFLD patients are overweight or obese and have underlying insulin, and probably leptin, resistance that results in dysregulated energy metabolism. The regulation of glucose and lipid metabolism involves a complex interplay between adipose tissue, skeletal muscle and the liver. While our knowledge of the pathogenesis of hepatic steatosis has undoubtedly increased over the last decade, many uncertainties remain, and it remains the subject of intense investigation. Hepatic steatosis derives from several possible sources including: (1) increased free fatty acid (FFA) delivery to the liver as a result of dietary fat intake and increased lipolysis within insulin-resistant adipose tissue; (2) increased hepatic *de novo* lipogenesis (DNL); (3) decreased FFA oxidation; and (4) decreased triacylglycerol export from the liver in the form of very low-density lipoprotein. The largest contributor to hepatic steatosis in patients with NAFLD is increased FFA influx to the liver (60%), followed by DNL (26%)^[10].

Increased hepatic lipid supply

In insulin-resistant states, principally obesity and T2D, adipose tissue hormone-sensitive lipase activity is not fully suppressed by insulin, resulting in enhanced lipolysis and non-esterified fatty acid flux into the systemic circulation (Figure 1). The precise mechanism of adipocyte insulin resistance in obesity remains a subject of controversy, but an emerging body of data suggest that an altered adipocytokine milieu in visceral fat resulting from macrophage infiltration is important^[11]. This milieu is characterised by increased expression of pro-inflammatory cytokines, such as tumour necrosis factor- α and interleukin-6 (IL-6), that can directly inhibit insulin, signalling, and decreased expression of adiponectin, an anti-steatosis and insulin-sensitising adipocyte-derived cytokine (adipocytokine) in both skeletal muscle and liver^[12].

Hepatic lipid synthesis and oxidation

Energy metabolism within the liver is tightly regulated.

Two transcription factors, sterol regulatory element-binding protein (SREBP-1) and carbohydrate response element-binding protein (ChREBP), are intimately involved in hepatic glucose and lipid metabolism, and their activity is increased in animal models of NAFLD^[13,14]. The former is induced by insulin and high-fat diets, and regulates glycolytic and lipogenic gene expression resulting in increased DNL and a concomitant decrease in FFA oxidation resulting from malonyl-CoA-induced inhibition of carnitine palmitoyl transferase-1 reducing mitochondrial FFA uptake^[15]. ChREBP exerts similar effects on glycolytic and lipogenic gene expression and also increases the expression of genes involved in triglyceride synthesis. In contrast to SREBP-1, ChREBP is up-regulated by glucose, which increases its nuclear translocation and its DNA binding/transcriptional activity^[16].

Inhibition of ChREBP in *ob/ob* leptin-deficient mice reduces hepatic steatosis by decreasing lipogenesis and enhancing FFA β -oxidation, with a concomitant decrease in circulating plasma triglycerides and FFA resulting in the restoration of hepatic, skeletal muscle and adipose tissue insulin sensitivity^[14]. This study provides further evidence linking fat accumulation to insulin resistance in both hepatic and non-hepatic tissues, principally skeletal muscle^[17,18].

Insulin resistance

Skeletal muscle is the primary site for glucose disposal *via* insulin-dependent pathways, accounting for about 75% of whole-body insulin-stimulated glucose uptake^[19]. Insulin binding to the insulin receptor on the myocyte plasma membrane results in autophosphorylation of the receptor, allowing insulin receptor substrate (IRS)-1 adaptor protein to bind and undergo tyrosine phosphorylation (Figure 2A). IRS-1-associated phosphatidylinositol 3-kinase (PI3K) activity is increased, which results in downstream activation of protein kinase B, leading to enhanced glucose uptake into the cell, *via* increased glucose transporter (GLUT)-4 translocation from the cytosol to the cell membrane, and up-regulation of glycogen synthesis and glucose oxidation^[18]. In obese individuals, there is reduced insulin-stimulated glucose disposal in skeletal muscle, most probably due to increased intramyocellular lipid content (Figure 2B)^[18]. The increased concentration of FFA (or more probably their esterification product, diacylglycerol (DAG), activates the serine/threonine kinase PKC α , which phosphorylates IRS-1 on critical serine sites, thereby inhibiting its tyrosine phosphorylation and subsequently the activation of PI3K and the resulting glucose uptake, glycogen synthesis and glycolysis. Other cytokine-regulated serine/threonine kinases including I κ B kinase-b (IKKb) and JNK-1 may also be involved since the inhibition of IKKb *via* exercise^[20] or salicylates results in improved insulin sensitivity^[21]. As discussed above, hyperglycaemia resulting from skeletal muscle insulin resistance in obesity leads to increased hepatic fat synthesis, reduced fat oxidation and steatosis *via* activation of ChREBP. Moreover, the accumulation of FFA/DAG in the liver results in hepatic

6792

portant factor in the pathogenesis of hepatic steatosis. The evidence for leptin resistance in NAFLD, though indirect, is compelling. Leptin exerts a number of anti-steatosis effects on the liver, including inhibition of lipid synthesis *via* reduced expression of stearoyl CoA desaturase (SCD)-1^[23] and enhanced FFA oxidation, *via* up-regulation of peroxisome proliferator-activated receptor- α (PPAR- α)^[24], and yet patients with NAFLD

Lack of response to the adipocytokine leptin (leptin resistance) rather than insulin resistance may be an im-

have increased serum leptin concentrations^[25]. Recent studies in genetically leptin resistant (ZDF) rats have dissociated the direct anti-steatotic effects of leptin from any indirect effects *via* improved hepatic insulin sensitivity^[26]. The mechanism of leptin resistance in obesity is unclear; however, it may be enhanced by the ingestion of fructose which leads to an inhibition of STAT-3, abrogating leptin-mediated PPAR- α activation resulting in decreased fatty acid oxidation, increased SREBP-1 expression and increased hepatic triglyceride content^[27]. Further inhibition of STAT-3 may occur as a result of up-regulation of suppressor of cytokine signalling-3 (SOCS-3) by adipose tissue or hepatocyte-derived inflammatory cytokines^[15,28].

AMP-activated protein kinase

Of particular relevance to modify NAFLD natural history, AMP-activated protein kinase (AMPK) has recently emerged as a key orchestrator of both hormonal and non-hormonal regulators of energy metabolism in liver, skeletal muscle and adipose tissue. Activated by an increase in the AMP/ATP ratio, AMPK activity is enhanced by physiological processes that induce metabolic stress and either decrease ATP production (ischaemia, hypoxia) or increase its consumption (exercise)^[29]. Once activated, AMPK acts to increase ATP-generating cellular events while turning off energy-consuming processes to restore energy balance. In the liver, the activation of AMPK by exercise^[30], starvation, adiponectin^[31], leptin (*via* inhibition of SCD-1), the biguanide metformin^[32] or the thiazolidinedione class of insulin sensitizers^[33] suppresses expression of SREBP-1^[34], ChREBP^[35] and acetyl-CoA carboxylase^[36] resulting in decreased DNL and increased FFA oxidation. Hepatic gluconeogenesis is also inhibited. Within skeletal muscle, exercise, leptin or drug related AMPK activation enhances glucose uptake *via* direct non-insulin-dependent GLUT-4 translocation, and increases pyruvate oxidation^[32]. In adipose tissue, hormone-sensitive lipase activation is suppressed, resulting in decreased lipolysis^[32].

ChREBP, a newly discovered transcription factor, plays an essential role in glucose-induced L-pyruvate kinase (L-PK)^[37] gene transcription by binding to the carbohydrate-responsive element of L-PK promoter^[38,39]. It is well known that glucose metabolism is inhibited by fatty acids, which serve as an alternative fuel source and thus conserve glucose. This phenomenon has been termed the fat sparing effect on glucose^[37,40].

Kawaguchi *et al.*^[41] investigated the mechanism by which feeding high fat diets results in decreased activity of ChREBP in the liver. It's strongly suggested that the fatty acid inhibition of glucose-induced L-PK transcription resulted from AMPK phosphorylation of ChREBP at Ser(568), which inactivated the DNA binding activity. AMPK was activated by the increased AMP that was generated by the fatty acid activation.

AMPK is a metabolic master switch mediating adaptation of the cell to variations in nutritional environ-

ment^[42]. Its activity is stimulated by increases in intracellular AMP-to-ATP ratio in response to stresses such as exercise, hypoxia, and glucose deprivation. AMPK has acute effects on energy metabolism pathways and long-term effects involving changes in gene expression.

AMPK is a major therapeutic target for the treatment of diabetes. The effect of a short-term overexpression of AMPK specifically in the liver by adenovirus-mediated transfer of a gene encoding a constitutively active form of AMPK α 2 (AMPK α 2-CA) has been investigated^[43]. The short-term overexpression of AMPK α 2-CA in the liver results in a metabolic switch from glucose to lipid metabolism. The lower plasma glucose concentrations in Ad AMPK α 2-CA-infected mice lead to an increase in hepatic lipid utilization, resulting in a decrease in white adipose mass. The concomitant accumulation of hepatic triglycerides leads to the generation of ketone bodies, which are required as alternative substrates to supply energy to peripheral tissues in conditions of low glucose availability.

Another study investigated the effects of fasting and refeeding on AMPK and ChREBP mRNA, protein and activity levels; as well as the expression of lipogenic genes involved in regulating lipid synthesis in broiler chicken (*Gallus gallus*) liver^[44]. In general, evidence was found for coordinate transcriptional regulation of lipogenic program genes in broiler chicken liver, but specific regulatory roles for AMPK and ChREBP in that process remain to be further characterized.

Moreover, thioredoxin-interacting protein (TXNIP) regulates critical biological processes including inflammation, stress and apoptosis. TXNIP is upregulated by glucose and is a critical mediator of hyperglycemia-induced beta-cell apoptosis in diabetes. In contrast, the saturated long-chain fatty acid palmitate, although toxic to the beta-cell, inhibits TXNIP expression. The mechanisms involved in the opposing effects of glucose and fatty acids on TXNIP expression are unknown. Shaked *et al.*^[45] showed that AMPK is an important regulator of Txnip transcription *via* modulation of ChREBP activity. The divergent effects of glucose and fatty acids on TXNIP expression result in part from their opposing effects on AMPK activity. In light of the important role of TXNIP in beta-cell apoptosis, its inhibition by fatty acids can be regarded as an adaptive/protective response to glucolipotoxicity. The finding that AMPK mediates nutrient regulation of TXNIP may have important implications for the pathophysiology and treatment of diabetes.

EFFECT OF EXERCISE ALONE ON OBESITY, VISCERAL FAT AND INSULIN RESISTANCE

Exercise physiology and the salutatory effects on weight loss, fat reduction and insulin sensitivity have been described in great detail. These beneficial effects are now considered to reflect, at least in part, the effect of exer-

cise on the activation of AMPK. In obese non-diabetics, exercise has been shown to reduce the risk of developing T2D by up to 46%^[33].

Physical training, consisting of 20 min cycling or running, 20 min swimming at submaximal heart rate, followed by 20 min of warm up/cool down three times per week for 4 wk, resulted in a significant reduction in body weight and percentage body fat, and this was associated with improved whole-body glucose uptake, decreased fasting insulin concentrations and increased circulating adiponectin and mRNA expression in muscle. Among patients with T2D, increasing exercise led to a reduction in fasting plasma glucose^[34].

The intensity of exercise needed to show improvement in metabolic profiles has been studied by several investigators. O'Donovan and colleagues evaluated the effects of 24 wk of moderate intensity exercise, defined as cycling three times weekly at 60% $\text{VO}_{2\text{max}}$ to burn 400 kcal, *vs* high-intensity exercise, defined as cycling three times weekly at 80% $\text{VO}_{2\text{max}}$ to burn 400 kcal, *versus* no exercise, on insulin sensitivity, triglycerides and glucose concentration^[35]. Training at 60% $\text{VO}_{2\text{max}}$ was as effective as training at 80% $\text{VO}_{2\text{max}}$ when 400 kcal were expended per session, suggesting that moderate exercise, expending 400 kcal per session, three times per week is sufficient to improve insulin sensitivity. The overall energy expenditure achieved per work-out session appears to be more important than the intensity of the exercise. This is supported by two recent studies performed in obese patients^[36,46]. Daily exercise for 12 wk, performed at not greater than 70% $\text{VO}_{2\text{max}}$ (about 80% maximum heart rate) on a treadmill to achieve 700 kcal energy expenditure (about 60 min) resulted in an 8% body weight loss and was associated with significant reductions in abdominal obesity, visceral fat, waist circumference and insulin resistance^[36]. Furthermore, this study showed that exercise without weight loss also reduced both abdominal and visceral fat. Ray *et al*^[46] also demonstrated that daily aerobic exercise for 50-60 min, starting at 60%-65% maximum heart rate and increasing to 80%-85% maximum heart rate (about 70% $\text{VO}_{2\text{max}}$) over 4 wk improved visceral fat content and this correlated with improved glucose metabolism and loss of insulin resistance. These encouraging results were seen with only a 3% weight loss over this time period.

The effects of aerobic *vs* restrictive exercise have also been debated. A Turkish study examined the effects of aerobic exercise, defined as walking briskly for 15 min and exercising on a stationary bicycle for 12-15 min three times per week the first month, exercising 20-30 min four times per week the second month, and 30-45 min five times per week the third month, in a group of 20 obese women compared with a restrictive exercise utilizing a stationary exercise unit in a similar group of women over a 3-mo period^[47]. While improvement in body mass index (BMI), fasting glucose and postprandial glucose were seen in both groups, reduced fat mass (as measured by bioelectric impedance), decreased

low-density lipoprotein and insulin resistance were seen only in the aerobic exercise group. In another study in 39 older obese men, aerobic or restrictive exercise training 3 d per week for 6 mo resulted in similar improvement in whole-body glucose disposal^[48].

Weight loss remains fundamental to the management of NAFLD, but is mistakenly perceived as the primary rationale for promoting physical activity (PA) participation. However, obesity management is not simply a function of weight loss. Outside the context of liver disease, it is well established that exercise enhances insulin sensitivity, reduces progression to T2D, and favorably modifies serum lipids independent of weight loss^[49,50]. When combined with the observation that high fitness and habitual PA are associated with improved functional capacity, quality-of-life measures, well-being, and reduced all-cause mortality^[51], the importance of incorporating PA therapy, beyond assisting weight loss, becomes apparent.

At present, there is an overall paucity of evidence concerning the benefits of PA as treatment for NAFLD, even though PA is certainly useful in NAFLD-associated diseases such as obesity, T2D and cardiovascular disease.

What is available shows a conclusive benefit of PA when coupled with energy restriction when weight loss is achieved, and it is encouraging for an independent benefit in the absence of weight loss. Although weight loss remains fundamental, patients should be counseled on the spectrum of benefits conferred by regular PA. Management should include assessment of cardiorespiratory fitness and PA levels, and the setting of lifestyle goals based on adoption of regular exercise, with a focus on the attainment of sustainable PA habits.

The dose (intensity and volume) of PA required to reduce liver fat remains unclear. Furthermore, from the present evidence, it is difficult to discern the relative importance of structured exercise and fitness *vs* less structured PA.

Although several examples of a hepatic benefit from low-dose PA therapy have been cited^[52-55], in the absence of robust data and knowledge of the long-term sustainability of such outcomes, it would seem reasonable to promote the current public health recommendations for health promotion, disease prevention, and weight management (Table 1). This recommends that individuals accumulate 20-60 min or more of moderate intensity (about 45%-70% of $\text{VO}_{2\text{max}}$) exercise on most days of the week^[51]. If weight loss is the goal, exercise confers a reduction in body weight in an apparent dose-response fashion with exercise volume, even when prescribed without associated restriction of energy intake^[56]. Greater amounts of exercise may be needed for most individuals to induce significant weight loss or prevent weight being regained in the long term. The consensus suggests that little weight loss is achieved with < 150 min of exercise per week, modest (2-3 kg) losses are attainable with > 150 min/wk (with an energy equivalent of 1200-2000 kcal/wk), and moderate weight loss (5-7.5 kg) often results from 225-420 min/wk (1800-3300 kcal) of aerobic

Table 1 Recommendations for physical activity in non-alcoholic fatty liver disease

Patients should be appropriately screened for contraindications prior to initiating exercise testing or therapy
Physical fitness assessment <i>via</i> exercise testing. Physical activity level assessment by subjective (questionnaire/ diary) or objective (e.g., accelerometer) means
Accumulate 20-60 min or more of moderate intensity rhythmic exercise using large muscle groups on at least 5 d/wk
Moderate intensity physical activity between 150 and 250 min/wk for preventing weight gain
Physical activity > 250 min/wk for clinically significant weight loss
Moderate-to-high intensity resistance training 3 d/wk for enhancing insulin sensitivity

activity^[56]. These targets can be achieved using a variety of exercise modalities, with the outcome of cardiorespiratory fitness being a reliable and easily quantifiable endpoint measure of structured aerobic exercise. Although there is currently no longitudinal evidence available concerning its benefit in NAFLD, progressive resistance training may be useful for the management of obesity-related comorbidities, particularly insulin resistance^[56]. The benefits of nonstructured leisure-time PA, including reduced sedentary time, are becoming increasingly recognized and have, in some studies, shown efficacy in improving cardiometabolic risk and promoting weight loss^[56,57]. Clear guidelines for such “lifestyle PA” are lacking, and reliable measurement, particularly of intensity, is more difficult. PA habits and adherence can be estimated by questionnaires, pedometers, and accelerometers (reviews of which can be found elsewhere)^[58], and the latter may further promote adherence to PA^[58].

Hybrid training of voluntary and electrical muscle contractions

“Hybrid exercise” is an exercise method that combines electrically stimulated and volitional contraction. This technique produces resistance against the motion of a volitionally contracting muscle by means of a force generated by an electrically stimulated antagonist^[59-62]. In particular, hybrid exercise resists utilizes electrically stimulated eccentric contractions and concentric volitional contractions with reciprocal limb movements. Both the volitionally activated agonist and the electrically stimulated antagonist contract during joint motion. The result is that both muscles are trained and that a longitudinal compressive load is placed on the bone. This technique requires minimal external stabilization as compared with conventional weight training. Matsuse *et al.*^[59] have shown that such hybrid exercise increased the extension torque of the elbow joint by about 30% and the cross-sectional areas (CSA) of the proximal upper extremity muscles by about 15% over a 12-wk period. In addition, Iwasaki *et al.*^[60] demonstrated that 6 wk of hybrid exercise effectively increased the extension of the knee joint by 19-33%. Takano *et al.*^[61] demonstrated that 12 wk of treatment increased extension torque by 39% and the CSA of quadriceps muscle by 9% in elderly subjects. However, the mechanism by which hybrid exercise achieves these increases in muscular strength and bulk is still unknown.

Muscle atrophy occurs as a consequence of denervation, injury, joint immobilization, bed rest, glucocorticoid treatment, sepsis, cancer and aging^[63]. Unfortunately,

there is no effective treatment for muscle atrophy. The maintenance of muscle mass is controlled by a balance between protein synthesis and protein degradation pathways, which is thought to shift toward protein degradation during atrophy^[63]. Recently, a signaling pathway that increases protein synthesis was shown to promote muscle hypertrophy, thereby overcoming muscle atrophy^[64,65].

The “Hybrid Training” (HYBT) method utilizing combined electrical stimulation and voluntary muscle contraction has been developed as a muscle training method^[66]. It has already been shown that the method is technically sound and clinically effective in healthy young subjects. The HYBT method increases muscle strength and mass and is as effective as the weight machine training (WMT), an effective method for improving muscle strength and hypertrophy in elderly people^[67,68].

However, a critical problem is that the equipment for WMT is large in size and takes space. In addition, unlike the WMT, the HYBT device, which is portable and not large in size, is so easy to handle that it can be placed at the bedside. Therefore, the HYBT may become a safe, effective method of muscle training for elderly people^[66].

Although skeletal muscle regulates glucose metabolism, partly by releasing IL-6, the effects of hybrid training on glucose metabolism remain unclear. Kawaguchi *et al.*^[69] showed the effects of hybrid training on glucose metabolism and serum IL-6 levels in elderly people. This study showed the safety and good adherence of hybrid training for lower extremities in elderly people. Furthermore, hybrid training decreased fasting blood glucose and serum IL-6 levels in elderly people.

Kawaguchi *et al.*^[70] investigated the therapeutic efficacy of hybrid training in patients with NAFLD. Physical inactivity is a risk factor for the development of NAFLD. HYBT of voluntary and electrical muscle contractions improved hepatic steatosis and reduced insulin resistance and serum IL-6 levels in NAFLD patients who are resistant to lifestyle counseling.

Possible role of myokine in patients with NAFLD

Skeletal muscle has recently been identified as an organ that produces and releases cytokines, which have been named “myokines”. Given that skeletal muscle is the largest organ in the human body, our discovery that contracting skeletal muscle secretes proteins sets a novel paradigm: skeletal muscle is an endocrine organ producing and releasing myokines in response to contraction which can influence metabolism in other tissues and organs. With the discovery that exercise provokes an in-

crease in a number of cytokines, a possible link between skeletal muscle contractile activity and immune changes was established.

For most of the last century, researchers sought a link between muscle contraction and humoral changes in the form of an “exercise factor”, which could be released from skeletal muscle during contraction and mediate some of the exercise-induced metabolic changes in other organs such as the liver and adipose tissue. It has been suggested that cytokines or other peptides that are produced, expressed, and released by muscle fibers and exert either paracrine or endocrine effects should be classified as “myokines”^[71]. The nervous, endocrine, and immune systems all contribute to the maintenance of homeostasis. Interestingly, although these individual systems operate independently to a certain degree, each with their own collection of highly specific cells and regulatory factors, they also depend on each other for normal development and function.

It appears that skeletal muscle has the capacity to express several myokines. To date the list includes IL-6, IL-8 and IL-15^[71]. Contractile activity plays a role in regulating the expression of many of these cytokines in skeletal muscle^[71]. The discovery that IL-6 is released from contracting skeletal muscle has generated much interest among the scientific community because this finding is somewhat paradoxical. On one hand, IL-6 is markedly produced and released in the postexercise period when insulin action is enhanced, but on the other hand, IL-6 has been associated with obesity and reduced insulin action. Given the controversy, this review focuses on the metabolic roles of IL-6.

Despite the fact that acute IL-6 treatment may enhance glucose uptake and fat oxidation in skeletal muscle, there are, nonetheless, a number of studies both *in vitro*^[72-75] and in rodents *in vivo*^[76-78] that demonstrate that IL-6 is capable of inducing insulin resistance. It appears that most, if not all, *in vivo* studies seem to suggest that IL-6 induces insulin resistance *via* adverse effects on the liver. Subjecting lean mice to chronically elevated IL-6 for 5 days causes hepatic insulin resistance^[75], while treating either *ob/ob* (leptin-deficient) mice^[77] or liver-inducible kappa kinase transgenic mice that display hepatic insulin resistance^[79] with IL-6 neutralizing antibodies improves hepatic insulin resistance. The IL-6-induced insulin resistance appears due to increased SOCS proteins (SOCS-3) expression^[75], since it is thought that SOCS-3 may directly inhibit the insulin receptor^[80]. However, even the negative effect of SOCS-3 on insulin action has recently been brought into question. Liver specific activator of transcription 3 (STAT3) knockout mice that express low levels of hepatic SOCS-3 protein, paradoxically are unable to suppress hepatic glucose production after intracerebral ventricular insulin infusion^[81]. Moreover, the prevention of IL-6 signaling either by neutralizing antibodies or by genetic deletion of IL-6 markedly reduces insulin-induced phosphorylation of hepatic STAT3^[81]. These results suggest that the local production of IL-6

is important for the phosphorylation of hepatic STAT3 induced by the brain insulin action. In a separate study, liver specific SOCS-3 knockout mice exhibited obesity and systemic insulin resistance with age^[82]. Furthermore, in this recent study, insulin signaling was reduced in skeletal muscle^[82], suggesting that deletion of the *SOCS-3* gene in the liver modulates insulin sensitivity in other organs. Possibly, the most convincing data to suggest that IL-6 may be antiobesogenic is the observation that IL-6 knockout mice develop mature onset obesity and glucose intolerance^[83]; however, even this observation is unclear^[84]. Whether IL-6 has positive effects on obesity and insulin action is clearly unresolved and requires further work. However, IL-6 unquestionably has a poor prognosis for certain inflammatory diseases^[85], and due to the immunoreactive nature of IL-6, it is clear that rhIL-6 treatment may not be a wise therapeutic treatment strategy in human disease. This is most likely due to the previously described trans-signaling of IL-6. The soluble IL-6 receptor controls the transition from the acute to the chronic phase in many proinflammatory diseases such as peritonitis^[86], a transition that can be inhibited by treatment with a soluble gp130 receptor fragment that neutralizes the trans-signaling process^[86]. Therefore, other cytokines that signal through the gp130 receptor, but which do not activate trans-signaling of IL-6, such as ciliary neurotrophic factor, show some therapeutic promise as an antiobesity therapy^[87].

NAFLD and its subsequent complications create a significant health burden, and currently there is no effective treatment strategy. The biochemical mechanisms that underlie NAFLD are unclear at this time, but there is evidence that insulin resistance is a major contributing factor. In addition, circulating concentrations of inflammatory cytokines - myokines (e.g., IL-6) as well as decreased antiinflammatory factors (e.g., adiponectin, IL-10) are not only implicated in the development of insulin resistance and T2D, but are also related to NAFLD. Such inflammatory mechanisms are fundamental in the progression of NAFLD toward higher risk cirrhotic states. Regular exercise can reverse insulin resistance, suppress low-grade systemic inflammation, and attenuate inflammatory markers associated with NAFLD. Thus, exercise has the potential to become an effective treatment and prevention modality for NAFLD and NASH.

CONCLUSION

Our knowledge of the pathological consequences of lack of adequate exercise on adipose tissue, skeletal muscle and the liver is improving, and this will help establish more specific guidelines for the proper exercise regimens that will improve underlying metabolic pathways and ultimately decrease the incidence and severity of NAFLD.

Moderate exercise, preferably a combination of aerobic and restrictive, performed 3-4 times per week, expending about 400 calories each time seems adequate to augment improvement in the metabolic profiles of patients with

NAFLD. PA has long been considered a cornerstone of a healthy lifestyle. Although its protective role in cardiovascular and metabolic diseases is well established^[88], its place and importance in NAFLD still requires scientific support and clarification. In a study, an inverse association was found between cardio-respiratory fitness categories and the prevalence of NAFLD. Whereas fitness and BMI were independent of each other in their associations with the prevalence of NAFLD, the addition of waist circumference to the regression model attenuated the association^[89]. This is in line with the fact that abdominal obesity has been shown to be a major risk factor for NAFLD, of greater importance than BMI^[90,91], and is consistent with previous studies demonstrating that exercise-induced weight loss is associated with a preferential reduction in abdominal fat^[92,93], and that, at any given weight, individuals who exercise more have less visceral fat than those who are sedentary^[94]. The suggested effect of PA on NAFLD may stem from other mechanisms as well. Exercise alone, in the absence of any change in body weight or composition, may enhance insulin sensitivity and glucose homeostasis^[95,96]. PA appears to result in insulin-receptor up-regulation in muscle tissue and hence increased delivery of glucose and insulin to the muscles^[97]. Exercise also has a beneficial effect on FFA metabolism by enhancing whole-body lipid oxidation^[98]. Hepatic triglyceride accumulation was shown to decrease with exercise intervention^[99] and hepatic FFA uptake was lower in trained compared with untrained subjects^[100]. From the perspective of NAFLD patients, weekly or daily performance of walking, swimming, or cycling might seem as simple as jumping of the cliff. Thus, it seems that among NAFLD patients, even small increments in regular PA can improve liver enzymes; encouraging information that can be provided to patients. Time spent sedentary, measured objectively by individually calibrated heart rate monitoring, predicted higher levels of fasting insulin, independent of the amount of time spent at moderate- and vigorous-intensity activity levels. This highlights the importance of reducing sedentary time in order to improve metabolic status, in addition to the benefits associated with a physically active lifestyle^[101].

Environmental factors that discourage PA include an environment that encourages automobile use rather than walking (like lack of sidewalks), and that has few cues to promote activity and numerous cues that discourage activity (television, computers, *etc.*)^[102,103]. It should be emphasized that associations between air pollution and a multitude of health effects are now well established. Given ubiquitous exposure to some level of air pollution, the attributable health burden can be high, particularly for susceptible populations affected by cardio-respiratory problems when walking, running at a slow or leisurely pace, or cycling^[104]. More rigorous, controlled studies, of longer duration and defined histopathological end-points comparing exercise alone and other treatment are needed before better, evidence-based PA modification guidelines can be established, since several questions remain unanswered. Does PA modification work equally

well in men *vs* women? Do younger patients respond better than older patients to PA modification? Is there a diversity of response among various ethnic groups or in patients with fatty liver alone compared with patients with more progressive disease? Finally, are there different lifestyle modification approaches, i.e., diet alone *vs* diet and aerobic exercise, that work better for different patient populations?

Abstract

AIM: To explore whether patients with a defective ileocecal valve (ICV)/cecal distension reflex have small intestinal bacterial overgrowth.

METHODS: Using a colonoscope, under conscious sedation, the ICV was intubated and the colonoscope was placed within the terminal ileum (TI). A manometry catheter with 4 pressure channels, spaced 1 cm apart, was passed through the biopsy channel of the colonoscope into the TI. The colonoscope was slowly withdrawn from the TI while the manometry catheter was advanced. The catheter was placed across the ICV so

that at least one pressure port was within the TI, ICV and the cecum respectively. Pressures were continuously measured during air insufflation into the cecum, under direct endoscopic visualization, in 19 volunteers. Air was insufflated to a maximum of 40 mmHg to prevent barotrauma. All subjects underwent lactulose breath testing one month after the colonoscopy. The results of the breath tests were compared with the results of the pressures within the ICV during air insufflation.

RESULTS: Nineteen subjects underwent colonoscopy with measurements of the ICV pressures after intubation of the ICV with a colonoscope. Initial baseline readings showed no statistical difference in the pressures of the TI and ICV, between subjects with positive lactulose breath tests and normal lactulose breath tests. The average peak ICV pressure during air insufflation into the cecum in subjects with normal lactulose breath tests was significantly higher than cecal pressures during air insufflation (49.33 ± 7.99 mmHg *vs* 16.40 ± 2.14 mmHg, $P = 0.0011$). The average percentage difference of the area under the pressure curve of the ICV from the cecum during air insufflations in subjects with normal lactulose breath tests was significantly higher ($280.72\% \pm 43.29\%$ *vs* $100\% \pm 0\%$, $P = 0.0006$). The average peak ICV pressure during air insufflation into the cecum in subjects with positive lactulose breath tests was not significantly different than cecal pressures during air insufflation 21.23 ± 3.52 mmHg *vs* 16.10 ± 3.39 mmHg. The average percentage difference of the area under the pressure curve of the ICV from the cecum during air insufflation was not significantly different $101.08\% \pm 7.96\%$ *vs* $100\% \pm 0\%$. The total symptom score for subjects with normal lactulose breath tests and subjects with positive lactulose breath tests was not statistically different (13.30 ± 4.09 *vs* 24.14 ± 6.58). The ICV peak pressures during air insufflations were significantly higher in subjects with normal lactulose breath tests than in subjects with positive lactulose breath tests ($P = 0.005$). The aver-

age percent difference of the area under the pressure curve in the ICV from cecum was significantly higher in subjects with normal lactulose breath tests than in subjects with positive lactulose breath tests ($P = 0.0012$). Individuals with positive lactulose breath tests demonstrated symptom scores which were significantly higher for the following symptoms: not able to finish normal sized meal, feeling excessively full after meals, loss of appetite and bloating.

CONCLUSION: Compared to normal, subjects with a positive lactulose breath test have a defective ICV cecal distension reflex. These subjects also more commonly have higher symptom scores.

Ileocecal valve dysfunction in small intestinal bacterial overgrowth: A pilot study. *World J Gastroenterol* 2012; 18(46): 6801-6808 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i46/6801.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i46.6801>

INTRODUCTION

The literature regarding the ileocecal valve (ICV) and its relationship to small intestinal bacterial overgrowth (SIBO) is limited^[1-3]. Surgical section of the ileocecal ligament in dog, a procedure that suppresses the ileocolonic angle and reduces sphincter competence, increases the amount of cecoileal reflux^[4,5]. Surgical removal of the ICV maximizes reflux ultimately leading to bacterial overgrowth^[6].

Dinning *et al*^[1] using temporary, side diverting, defunctioning ileostomies, recorded ICV pressures in a configuration close to that surgically produced by Quigley *et al*^[7] in dogs, hence allowing precise positioning of the manometric assembly across the ICV for prolonged periods. In these patients, a sustained pressure of about 10 mmHg is observed either using a pull-through or sleeve recording over a 4.8 cm distance.

In fasted humans, phasic activity of the ICV, unrelated to motor activity of more oral or aboral zones, is observed for 35% of the recording time^[1-3]. During these waves that occur at about four to eight waves per minute, the basal tone is doubled. On the contrary, ICV tone is reduced in humans and in dogs while prolonged propagated contractions are observed on the distal ileum^[1,8]. In dogs and to a lesser extent in humans, ileal motor events propagate across the ICV into the colon. For instance,

Quigley *et al*^[8] show that 50% of ileal discrete clustered contractions and 76% of ileal prolonged propagated contractions continued propagating in the proximal canine colon. Colonic distension is followed consistently by contraction of the ICV in dogs and in humans. This enhanced motility of the ICV comprises simultaneously an increase in tone together with larger amplitude ICV phasic pressure waves^[1-3] while the ileal contractions are unaffected^[7].

Using a technique in which radioactive tracer is instilled in the cecum it was found that backward flow from the cecum to the ileum is episodic. In dog, the volume of the refluxate is low accounting for about 7% of the total radioactivity injected to the cecum^[9]. This minimal reflux rate can be explained by the competence of the canine ICV towards reflux. Surgical section of the ileocecal ligament in dog, a procedure that suppresses the ileocolonic angle and reduces sphincter competence^[4,5], increases the amount of cecoileal reflux to 44% of the total radioactivity^[9].

In the current study, we aimed to explore whether patients with a positive lactulose breath test (indicative of SIBO) may have an incompetent ICV leading to reflux of colonic contents into the small intestine^[10]. To test this hypothesis we measured pressures within the ICV during cecal distension and compared these pressures with the results of lactulose breath tests.

MATERIALS AND METHODS

Study design and conduct

This research study was approved by the Temple University Institutional review board on 06/27/2007. This study is registered with clinicaltrials.gov ID: NCT01413945. Written Informed consent was given by all the participants prior to their inclusion in this study. All subjects filled out a symptom questionnaire on a scale of 0 to 5 with 0 being no symptom and 5 being very severe symptoms.

Eligibility requirements

Subjects undergoing screening colonoscopy were included in the study. Subjects who were currently on medications such as prokinetics, antibiotics and anticholinergics were excluded from the study. Subjects with history of gastroparesis, Crohn's disease, ulcerative colitis, diseases causing diarrhea, and long standing uncontrolled diabetes were also excluded from the study.

Assessments and outcome measurements

All subjects were sedated with Midazolam and Fentanyl. Colonic preparation was used in all subjects (polyethylene glycol preparation). A custom make water perfused manometry catheter (Mui Scientific, Mississauga, Canada) with 4 pressure measurement ports spaced one cm apart was passed through the biopsy channel of the colonoscope and placed across the ICV with at least one port in the terminal ileum and one port in the cecum (Figure 1). The simultaneous video endoscopy and pressure readings (30 Hz) were continuously recorded on a Medical

Figure 1 Schematic of the terminal ileum, ileocecal valve and colon. It shows the colonoscope and manometry catheter passing through the biopsy channel of the colonoscope. The 4 channel manometry catheter is placed across the ileocecal valve so that at least 1 channel is in the cecum and 1 channel in the ileum.

Measurement Solar System (MMS, Dover, NH) (Figure 2). Video endoscopy was used to make sure that the catheter remained in the correct position during the entire study. If the catheter position changed during the study, the catheter was repositioned according to markings on the catheter. All the air was removed from the cecum by suction through the biopsy channel of the colonoscope and baseline measurements were taken. After the baseline measurements, air was slowly and continuously instilled into the cecum through the air/water channel of the colonoscope with the air insufflation setting, set at low on endoscopy processor (Evis, Exera II, CLV-180, Olympus America Inc, Center Valley, PA). The peak pressures were measured in all the channels at a time when the pressure in ICV reached its peak between the start of air insufflation and the end of air insufflation. Only studies in which the video playback showed the catheter to be in the correct position were used for analysis. A threshold cecal pressure of 40 mmHg was used to avoid barotrauma. If the pressure exceeded 40 mmHg the air flow into the cecum was stopped. *In vivo* and cadaveric animal experiments have yielded data regarding intraluminal pressure that can lead to rupture of the colon^[11-16]. An adult human cadaveric cecum exposed to less than 40 mmHg of intraluminal pressure generally does not rupture, but cecum exposed to more than 150 mmHg of pressure always ruptures^[11-16]. The pressures needed for perforation of the right colon and cecum are lower than those needed for perforation of the sigmoid and descending colon^[12,13]. It is estimated that the upper limit of safe intraluminal human colonic pressure is 80 mmHg, because perforation can occur at pressures greater than 140 mmHg^[17]. The area under the pressure curve was measured within all the channels, from the time of the beginning of the upslope of the pressures within the cecum, after the start of air insufflation, to the time when the ICV reached its peak pressure, before the end of air insufflation.

All patients returned one month after the colonoscopy for a lactulose breath test using “Breath Tracker Digital Microlyzer”, QuinTron Instrument Company,

Milwaukee, WI, United States. All subjects presented for the lactulose breath test after an overnight fast. The subjects were given 10 g of lactulose in 120 mL of water to drink and instructed to breathe into a collection bag every 15 min for 3 h after a sample of their breath was collected at baseline. All breath samples were end-expiratory and analyzed immediately. The concentrations of breath hydrogen and methane were measured in parts per million (ppm). The measurements were then graphed and analyzed^[18-21].

Graphs of methane and hydrogen concentration were plotted against time. A positive lactulose breath test was defined as a double peak of hydrogen or a combination of both hydrogen and methane above 20 ppm within the first 2 h.

All subjects were given a gastrointestinal questionnaire which evaluated the following habitual symptoms: nausea, vomiting, stomach fullness, not able to finish normal sized meal, feeling excessively full after meals, loss of appetite, bloating, stomach or belly visibly larger, upper abdominal pain, upper abdominal discomfort, lower abdominal pain, lower abdominal discomfort, diarrhea, gas from above, and gas from below.

Statistical analysis

All pressures were calculated relative to baseline colonic

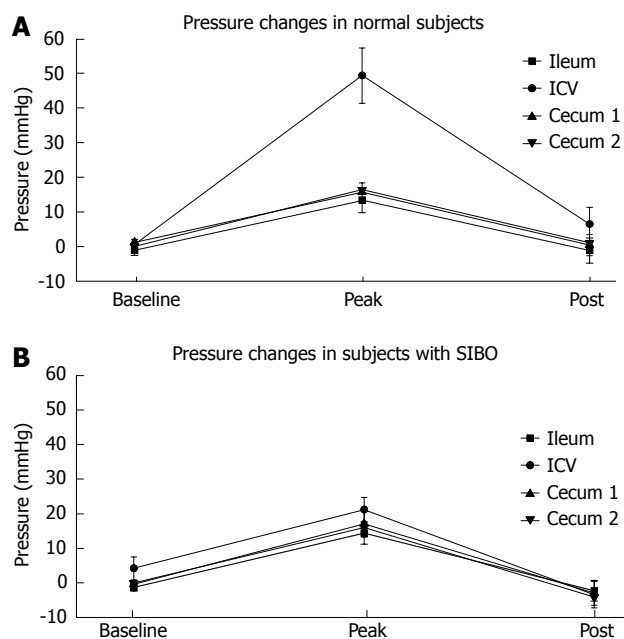

Figure 3 Average pressure changes (baseline, peak and post) in the colon, ileocecal valve and terminal ileum during and after air insufflation. A: The average response of the ileocecal valve during cecal distention by air insufflation in subjects with normal lactulose breath tests; B: The average response of the ileocecal valve during cecal distention by air insufflation in subjects with positive lactulose breath tests. ICV: Ileocecal valve; SIBO: Small intestinal bacterial overgrowth.

pressures. The analysis of pressures was performed using an unpaired Student's *t*-test, with a two tail distribution and equal variance. The questionnaires were evaluated using non-parametric tests (Mann Whitney *U*-test). The analysis was performed in a blinded manner. A Spearman correlation was used to compare ICV pressures to hydrogen and methane excretion.

RESULTS

Nineteen subjects (56.4 years, 7 male and 12 female) underwent colonoscopy with measurements of the ICV pressures after intubation of the ICV with a colonoscope. Cecal pressures before air insufflation were considered as baseline pressures and all the pressures noted were relative to cecal pressures. If the recorded pressures were less than the baseline cecal pressures, then they were considered negative. The resting pressures in the subjects with normal lactulose breath tests were -1.14 ± 1.44 mmHg and 1.18 ± 0.73 mmHg in TI and ICV respectively. The resting pressures in the subjects with positive lactulose breath tests were -1.31 ± 1.07 mmHg and 1.70 ± 2.49 mmHg in TI and ICV respectively. Initial readings showed no statistical difference in the resting pressures of the TI or ICV between subjects with positive lactulose breath tests and normal lactulose breath tests.

Subjects with normal lactulose breath tests

Ten subjects (5 male and 5 female), (age: 55.8 ± 3.05 years, weight: 86.77 ± 7.29 kg). The average dose of Mid-

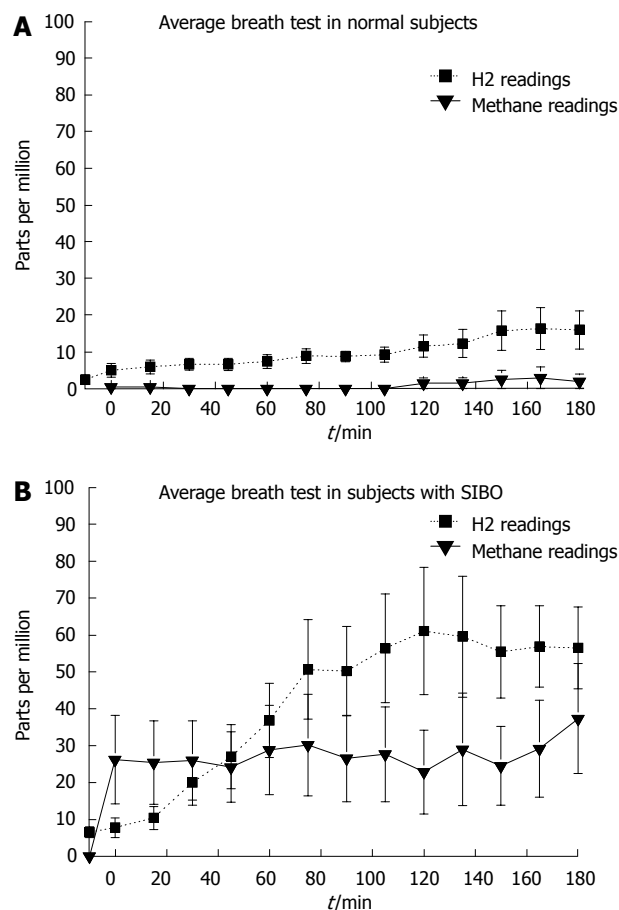

Figure 4 Average lactulose breath test results. A: Normal lactulose breath tests; B: Positive lactulose breath tests. ICV: ileocecal valve; SIBO: Small intestinal bacterial overgrowth.

azolam and Fentanyl per kg was 0.06 mg and 0.73 mg. The average peak ICV pressure during air insufflation into the cecum in subjects with normal lactulose breath tests was significantly higher than cecal pressures during air insufflation (49.33 ± 7.99 mmHg *vs* 16.40 ± 2.14 mmHg, $P = 0.0011$). The average percentage difference of the area under the pressure curve of the ICV from the cecum during air insufflations was significantly higher ($280.72\% \pm 43.29\%$ *vs* 100% ($P = 0.0006$)). The average symptom score for all subjects with normal lactulose breath tests was 13.30 ± 4.09 .

Subjects with positive lactulose breath tests

Nine subjects (2 male and 7 female), (age: 57 ± 4.92 years, weight: 84.35 ± 6.17 kg). The average dose of Midazolam and Fentanyl per kg was 0.08 mg and 0.50 mg. The average peak ICV pressure during air insufflation into the cecum in subjects with positive lactulose breath tests was not significantly different than cecal pressures during air insufflation (21.23 ± 3.52 mmHg *vs* 16.10 ± 3.39 mmHg). The average percentage difference of the area under the pressure curve of the ICV from the cecum during air insufflation was not significantly different ($101.08\% \pm 7.96\%$ *vs* 100%). The average total symptom score for all subjects with positive lactulose breath tests

Figure 5 Average percent change of the area under the pressure curve during air insufflation into the cecum, in normal subjects (normal lactulose breath tests) and in subjects with small bowel bacterial over growth (positive lactulose breath tests), with respect to the cecum. ICV: Ileocecal valve; SIBO: Small intestinal bacterial overgrowth.

was 24.14 ± 6.58 .

In some prior studies methane seems to influence smooth muscle function^[22]. Analyzing the breath test results, 3 of the subjects were methane producers' and one of these subjects was also positive for hydrogen. Six subjects were hydrogen producers. There was no significant difference in the peak ICV pressures between methane producers and hydrogen producers (23.7 ± 0.67 mmHg *vs* 26.8 ± 2.48 mmHg). There was only a weak correlation between the pressure measurements and the hydrogen excretion ($r = 0.19$) and the pressure measurements and the methane excretion ($r = 0.25$).

Comparison of subjects with normal lactulose breath tests to subjects with positive lactulose breath tests

There is no significant difference in age and weight between subjects with normal lactulose breath test and subjects with positive lactulose breath test. There is no significant difference in the drug dose/kg of Midazolam and Fentanyl between the two groups.

The ICV peak pressures during air insufflations were significantly higher in the subjects with normal lactulose breath tests than in the subjects with positive lactulose breath tests ($P = 0.005$) (Figures 3 and 4). The average percent difference of the area under the pressure curve within the ICV from cecum during air insufflations was significantly higher in subjects with normal lactulose breath tests than in subjects with positive lactulose breath tests ($P = 0.0012$) (Figure 5). The cecal peak pressures during air insufflations were not significantly different in the subjects with normal lactulose breath tests compared to the subjects with positive lactulose breath tests. The total symptom scores were not significantly different in subjects with normal lactulose breath tests than in subjects with positive lactulose breath tests. However, significantly higher symptom scores were observed in the subjects with positive lactulose breath tests in the individual symptoms of: "not able to finish normal sized meal" (P

$= 0.036$), "feeling excessively full after meals" ($P = 0.029$), "loss of appetite" ($P = 0.018$) and "bloating" ($P = 0.0536$).

DISCUSSION

In this study we explored whether patients with positive lactulose breath tests have an incompetent ICV. We tested this hypothesis by measuring ICV pressures during cecal distension in subjects with positive and negative lactulose breath tests.

In designing this study consideration was given to using a sleeve sensor to measure ICV pressures. However, this was rejected in favor of a four port pressure transducer because a sleeve sensor would have measured the peak pressure recorded and would not have been able to distinguish between the terminal ileum, the ICV or the cecum. Consideration was also given to using a barostat to distend the cecum. However, it was decided that a barostat would be very cumbersome to use during routine colonoscopy and would not distend the cecum in the correct position to reproducibly increase ICV pressure. We felt that insufflation of air, into the cecum, was closer to the actual physiology of gas being produced in the colon causing distension of the cecum. We did not use the same volume of gas in each subject. Rather we used a cutoff cecal pressure. We did this for safety purposes since we did not want to go above a certain threshold pressure and risk barotrauma to the subjects. A cutoff pressure of 40 mmHg was used during cecal distension. Finally consideration was given to collection of fluid from the small intestine to assay for SIBO. However, the colonoscopies were performed after a bowel preparation, which flushes bacteria out of the small intestine and this would have resulted in false negative results. In addition the colonoscope needs to pass through the colon before it can enter the small intestine and this could have contaminated the colonoscope with bacteria and could have resulted in false positive results for SIBO.

Yu *et al*^[23] have recently published an important study in which they combined oro-cecal scintigraphy and lactulose hydrogen breath testing demonstrating that breath testing may detect oro-cecal transit, not small intestinal bacterial overgrowth in patients with irritable bowel syndrome (IBS). Thus the lactulose hydrogen breath test may measure small intestinal transit rather than SIBO in IBS-patients. However, the patient population in that study was different than in the current study and the lactulose breath test is still used around the world to diagnose SIBO. Since the results of the lactulose breath test are dependent on motility within the stomach, the small intestine and the colon, we attempted to control for variability in motility between subjects by eliminating patients with known motility disorders, such as gastroparesis and small bowel motility disorders. We eliminated subjects who were taking any medications that would affect motility, such as prokinetics, anticholinergics and narcotics. The dosages of medications given during the colonoscopies were not significantly different between

the two groups, so as not to influence motility during the colonoscopy.

We found that the baseline pressure measurements showed no difference in the pressures of the TI, and ICV between the two groups. These findings are similar to the findings of Quigley *et al*^[24], “because ileocecal muscle behaves as a sphincter, we were surprised by the absence of clear tonic pressures across the ICV”. However, when tested for the ICV cecal distension reflex using air insufflation into the cecum, we recorded an increase in the pressure within the ICV in subjects with normal lactulose breath tests which were significantly higher than in subjects with positive lactulose breath test. Subjects, with a positive lactulose breath test commonly had a common cavity effect (equalization of the pressures across all of the compartments) during cecal air insufflation.

When the lactulose breath test is evaluated against the gold standard of jejunal aspiration with bacterial culturing for the diagnosis of SIBO the sensitivity and specificity of the breath test is much lower. We suggest a number of potential explanations for these results. First, perhaps not all SIBO is due to an incompetent ICV. For example, in cases of scleroderma in which there are diverticulum in the small intestine it has been suggested that SIBO is due to bacteria growing within the diverticulum. Second and probably more important is the fact that these cultures were taken from the jejunum which is a great distance from the ICV and TI. Reflux of colonic contents would not be expected to wash backwards beyond the ileum due to the propulsive motion of peristalsis within the small intestine, which is presumably normal in these subjects. Normal peristalsis should keep the jejunal bacterial count relatively low even when refluxing colonic contents into the ileum^[14]. Although we did not design this study to determine if subjects undergoing screening colonoscopy with a positive lactulose breath test have gastrointestinal (GI) symptoms, we did find that many of the subjects in our study had GI symptoms. While these symptoms were more common in the group with positive lactulose breath tests, they were not uncommon in the group with negative lactulose breath tests and we found that there was no significant difference in the overall symptom scores between the two groups. On the other hand, significantly higher symptom scores were demonstrated in the subjects with positive lactulose breath tests for the individual symptoms of, “not able to finish a normal sized meal”, “feeling excessively full after meals”, “loss of appetite” and “bloating”.

The Initial studies evaluating the treatment of IBS patients with poorly absorbed antibiotics, were based on the hypothesis that a significant proportion of these patients actually had occult SIBO^[25]. A number of studies have suggested that there are beneficial effects when poorly absorbed antibiotics are used to treat patients with IBS^[26,27]. Initial studies reported the presence of SIBO in up to 80% of IBS patients, on the basis of a rapid rise in breath hydrogen during lactulose breath testing. In a recent issue of the *New England Journal of*

Medicine, Pimentel *et al*^[28] reported the results of two large, double-blind, placebo-controlled trials of rifaximin, in patients with IBS without constipation. They found that patients in the group treated with rifaximin had adequate relief of IBS symptoms or bloating. Similarly significant results were obtained in an analysis of relief of symptoms during the 10-wk period after the end of the double-blind treatment phase. Harder *et al*^[29] showed that gas is less well tolerated in the small intestine than in the large bowel. Based on these studies the most likely mode of action of rifaximin is a reduction in overall small bowel bacterial load or a decrease in colonic flora. This may lead to decreased bacterial fermentation and less bloating, possibly in combination with decreased secretion of bacterial products or host responses to bacterial products that contribute to the generation of symptoms. In the future, we plan to perform a study on subjects with documented irritable bowel syndrome, by the Rome III criteria. In order to determine if a subgroup of patients with IBS symptoms is due to a defective ileocecal valve/cecal distension reflex with reflux of fecal flora or gas into the small intestine.

The results of our study suggest that some GI symptoms may be due to a defective ICV cecal distension reflex which either allows gas from the colon to distend the small intestine or lead to reflux of colonic contents into the small intestine, the colonization of the small intestine with fecal flora and the development of SIBO.

We hypothesize that even though a course of non-absorbable antibiotics may clear the small intestine or the colon of colonic flora, the symptomatic effect may not be durable because the underlying defect, the defective ICV cecal distension reflex, is still present and colonic flora or colonic gas may eventually reflux back into the small intestine. The results of the current study suggest that a restoration of the demonstrated dysfunction (pharmacological, endoscopic or surgical) by preventing coloileal reflux may have a more durable effect than antibiotic therapy. Indeed, prevention of coloileal reflux by constructing an artificial ileocolonic valve was suggested by Kellogg in 1913. Bakkevold^[30] demonstrated that the nipple valve anastomosis may prevent recurrence of Crohn's disease, after ileocolic resection.

Pimentel *et al*^[28] suggested that some IBS like symptoms, afflicting many millions of patients, might be due to SIBO and might respond to antibiotic treatment usually used to treat SIBO. In summary, the current study demonstrates that subjects with a positive lactulose breath test have a defective ICV cecal distension reflex. In addition it demonstrates that subjects with a defective ICV cecal distension reflex more commonly have certain GI symptoms. We propose that this pathophysiologic mechanism (defective ICV/cecal distension reflex) which may cause SIBO and IBS like symptoms due to reflux of fecal flora and the production of gas within the small intestine and/or the production of gas within the colon, with reflux of the gas into the small intestine.

ACKNOWLEDGEMENTS

We would like to thank Dilek Yazar for her contribution for this project.

COMMENTS

Background

Small intestinal bacterial overgrowth (SIBO) refers to a condition in which abnormally large numbers of bacteria are present in the small intestine and the types of bacteria in the small intestine resemble the bacteria of the colon. Irritable bowel syndrome (IBS) is a disorder that leads to abdominal pain and cramping, changes in bowel movements, and other symptoms. SIBO and some forms of IBS may be due to the distension of the small intestine with gas produced by bacteria within the small intestine and/or colon. Recent studies strongly suggest that some IBS like symptoms, afflicting many millions of patients, might be due to small intestinal bacterial overgrowth SIBO.

Research frontiers

A percentage of patients with IBS like symptoms have relief of their symptoms when they are treated with non-absorbable antibiotics which suppress the intestinal microbiota. It is thought that suppression of the microflora, within the colon or the small intestine is the mechanism of this therapy.

Innovations and breakthroughs

The initial studies evaluating the treatment of IBS patients with poorly absorbed antibiotics, were based on the hypothesis that a significant proportion of these patients actually had occult SIBO. A number of studies have suggested that there are beneficial effects when poorly absorbed antibiotics are used to treat patients with IBS. Initial studies reported the presence of SIBO in up to 80% of IBS patients, on the basis of a rapid rise in breath hydrogen during lactulose breath testing. The current study is the first study to evaluate the role of ileocecal valve (ICV)/cecal distention reflex in patients suffering with small bowel bacterial overgrowth.

Applications

These findings imply that repair of the ICV (pharmacologic, endoscopic or surgical) or restoration of the ICV/cecal distension reflex may be used to treat patients with SIBO and in patients with IBS like symptoms in the future.

Terminology

The ileocecal valve is a sphincter muscle situated at the junction of the ileum (last portion of your small intestine) and the colon (first portion of your large intestine). Its function is to allow digested food materials to pass from the small intestine into your large intestine. The ileocecal valve also blocks these waste materials from backing back up into your small intestine. It is intended to be a one-way valve, only opening up to allow processed foods to pass through.

Peer review

The authors examined the ICV/cecal distention reflex in patients with positive lactulose breath test and in subjects with negative lactulose breath test. The authors found that subjects with a positive lactulose breath test have a defective ICV/cecal distention reflex. This defective ICV/cecal distention reflex may cause SIBO and IBS like symptoms due to reflux of fecal flora and the production of gas within the small intestine and/or the production of gas within the colon, with reflux of the gas into the small intestine.

Abstract

AIM: To explore the bioactivity of an ethanolic extract of *Schizandra arisanensis* (SA-Et) and isolated constituents against interleukin-1 β and interferon- γ -mediated β cell death and abolition of insulin secretion.

METHODS: By employing BRIN-BD11 cells, the effects of SA-Et administration on cytokine-mediated cell death and abolition of insulin secretion were evaluated by a viability assay, cell cycle analysis, and insulin assay. The associated gene and protein expressions were also measured. In addition, the bioactivities of several peak compounds collected from the SA-Et were tested against cytokine-mediated β cell death.

RESULTS: Our results revealed that SA-Et dose-de-

pently ameliorated cytokine-mediated β cell death and apoptosis. Instead of suppressing inducible nitric oxide synthase/nitric oxide cascade or p38MAPK activity, suppression of stress-activated protein kinase/c-Jun NH2-terminal kinase activity appeared to be the target for SA-Et against the cytokine mix. In addition, SA-Et provided some insulinotropic effects which re-activated the abolished insulin exocytosis in cytokine-treated BRIN-BD11 cells. Finally, schiariisanrin A and B isolated from the SA-Et showed a dose-dependent protective effect against cytokine-mediated β cell death.

CONCLUSION: This is the first report on SA-Et ameliorating cytokine-mediated β cell death and dysfunction *via* anti-apoptotic and insulinotropic actions.

INTRODUCTION

The onset of type 1 diabetes occurs when approximately 60%-90% of insulin secreting cells are lost and/or are dysfunctional due to β -cell directed autoimmunity^[1].

During the progression of autoimmunity, heavy infiltrations of mononuclear cells lead to substantial damage to β cells by generating locally high concentrations of pro-inflammatory cytokines, perforin, and FasL-Fas interactions within the micro-environment of islets^[2,3]. As a result, deleterious outcomes include excessive proinsulin secretion, the abolition of glucose-induced insulin secretion, and ultimately β cell death^[4].

Currently, scientists have developed a wide range of approaches to prevent or intervene in type 1 diabetes by stimulating β -cell proliferation, attenuating the cytotoxic effects of inflammatory agents, or modulating autoimmune response, and so on^[1]. While many clinical trials are ongoing, the application of herbal medicine remains to be fully explored.

In cell culture systems, exposing β cells to an interleukin (IL)-1 β and interferon (IFN)- γ mixture can mimic the consequences of an immune attack in type 1 diabetes, which affects pro-insulin secretion^[5] and induces β cell death^[6]. By employing such a platform, potential β cell protective herbal material can be identified. *Schizandra arisanensis* (SA-Et) is one of the schizandraceous plants from Taiwan. This plant also contains various C₁₈ dibenzocyclooctadiene lignans and C₁₉ homolignans^[7,8]. The indications for this herb in traditional Chinese medicine include diabetes, hepatitis, immunomodulation, and cancer^[7,9-11]. Therefore, in the present study, we investigated the potential β cell protective bioactivity of the ethanol extract of SA-Et, including its isolated constituents against cytokine-mediated β cell cytotoxicity and dysfunction.

MATERIALS AND METHODS

Plant material and reagents

Stems of SA-Et were collected and authenticated by Dr. Kuo YH in October 2005 in Chiayi County, Taiwan. A voucher specimen (No. NRICM20051003) was deposited at the National Research Institute of Chinese Medicine. The following were used as positive controls in the various biological assays performed; recombinant cytokines (IL-1 β and IFN- γ ; PeproTech, NJ, United States); epigallocatechin gallate (EGCG; Fluka, MO, United States); nitro-L-arginine methyl ester (L-NAME), glucose, KCl and CaCl₂ (Sigma-Aldrich Corp., MO, United States). These reagents were obtained at the highest purity available (> 97%) from the suppliers indicated.

Preparation of the ethanol extract of SA-Et

Dried stems of SA-Et were ground and then extracted with 95% (v/v) EtOH at 45 °C three times for 48 h each time. Under reduced pressure, the combined ethanol extracts were concentrated to an ethanolic extract residue of SA-Et. DMSO was employed as the dissolving reagent, and aliquots were prepared and stored at -20 °C before the biological assays were carried out.

High-performance liquid chromatographic analysis of the SA-Et

A filtered volume (100 μ L) of the SA-Et solution (1.0

mg/mL in methanol) was prepared and injected into a reverse-phase high-performance liquid chromatography (HPLC) system. The HPLC analysis was performed using a WatersTM HPLC (cont 600 Pump, 996 photodiode array detector, 600 controller, and 717 plus autosampler; Milford, Massachusetts, United States), using a reverse-phase RP-18 column (4.6 mm \times 250 mm *i.d.*). The solvent system used was a gradient of water and CH₃CN. The gradient system was as follows: 0-60 min, 45%-60% CH₃CN, and 60-70 min, 60%-75% CH₃CN; with elution performed at a solvent flow rate of 1 mL/min. The detection chromatogram was recorded at 215 nm.

Isolation of C₁₉ homolignan and C₁₈ lignan compounds

Peak compounds including schiariisanrin A (peak 5), schiariisanrin B (peak 1), schiariisanrin C (peak 4), schiariisanrin E (peak 3), and macelignan (peak 6) were obtained from the SA-Et followed by the procedures described below. Isolation of taiwanschirin A (peak 2) was based on a previous method^[12].

Five grams of SA-Et was partitioned with water and *n*-hexane, to give the *n*-hexane residue (SA-Et-H). Further separations of SA-Et-H (100 mg) were performed on a WatersTM HPLC, using a preparative Cosmosil 5C₁₈ AR-II column (250 mm \times 10 mm *i.d.*; Nacalai Tesque, Kyoto, Japan), employing a gradient system [water (A) and CH₃CN (B), mobile phase was as follows: 0-2 min, 45%-50% (B); 2-20 min, 50%-55% (B), 20-55 min, 55%-60% (B), 55-60 min, 60%-70% (B), and 60-70 min, 70%-100% (B)], at a flow rate of 3 mL/min, under 215 nm UV, to yield schiariisanrin A (4.6 mg), schiariisanrin B (4.1 mg), schiariisanrin C (5.6 mg), schiariisanrin E (6.3 mg), macelignan (11.5 mg), and schizanrin A (3.6 mg), which were identified by comparison with authentic samples and reported spectroscopic data (UR, infrared, and nuclear magnetic resonance) in the literature^[8,12]. Their purity was over 75% as analyzed by HPLC.

Cytotoxicity test

BRIN-BD11 cells were routinely cultured in RPMI-1640 containing 10% (v/v) fetal bovine serum and 2 g/L glucose^[13]. For the cytotoxicity test, BRIN-BD11 cells were seeded into 24-well plates at the density of 5×10^4 cells/well. After overnight attachment, cells were incubated with cytokines according to the figure legends. The viability at the end of treatment was measured by a neutral red assay as described previously^[14]. The absorbance under control conditions was set to 100% viability.

Cell cycle analysis

At the end of treatment, cells were trypsinized and collected by centrifugation. Following a phosphate-buffered saline (PBS) wash, cell pellets were resuspended in ethanol overnight at -20 °C. Fixed cells were then washed with PBS before being resuspended in 1% (v/v) Triton X-100 and incubated for 15 min. The cells were then resuspended in propidium iodide (PI) staining solution, consisting of 20 μ g/mL PI, 50 μ g/mL RNase A, and 0.0001% (v/v) Triton X-100 in PBS, and incubated at 4 °C for 30 min

with protection from light. Finally, the cells were passed through a mesh prior to cell cycle analysis by employing FACSsan (BD Bioscience, San Jose, California, United States).

Western blot analysis

This procedure followed a previous methodology^[15]. In brief, cells were washed with ice-cold PBS and scraped into ice-cold lysis buffer. Cell debris was removed by centrifugation. Equal amounts of protein (40 μ g) were subjected to separation on sodium dodecylsulfate 10% polyacrylamide gels. Following transfer to nitrocellulose membranes, blots were blocked with 5% (w/v) non-fat milk in Tris-buffered saline containing 0.1% (v/v) Tween 20 for 1 h, and incubated with primary antibodies at 4 °C overnight prior to incubation for 1 h at room temperature with the secondary antibody. Finally, results were visualized after development of films with the aid of an enhanced chemiluminescence kit (Amersham Biosciences, Uppsala, Sweden).

Measurement of gene expression

Total RNA was extracted using the TRI-reagent according to the manufacturer's instructions. Total RNA (1 μ g) was reverse-transcribed to generate templates. Complementary (c) DNA at 50 ng was employed for the polymerase chain reaction (PCR). The sequences of primers are listed in Table 1. The annealing temperatures for amplification of β -actin (57 °C), glucokinase (57 °C), insulin (52 °C), and inducible nitric oxide synthase (iNOS) (55 °C) were employed to generate respective sequences of 349 bp, 130 bp, 187 bp, and 441 bp. Once the reaction was complete, PCR products were separated by gel electrophoresis, visualized, photographed using a digital camera, and quantified with Genetools 3.06 (Syngene, Cambridge, United Kingdom). When iNOS mRNA was determined by real-time reverse transcription-PCR, 1 μ g of total RNA was reverse transcribed into cDNA using the RevertAid™ First Strand cDNA Synthesis Kit (Fermentas, Maryland, United States) before being applied to the StepOnePlus™ Real-Time PCR System (Applied Biosystems, Warrington, United Kingdom). Each reaction was carried out based on the description of the TaqMan®

Gene Expression Assay kit with pre-designed probes for iNOS (Rn00561646_m1) and β -actin (Rn00667869_m1). Data were ct values (i.e., cycle number where logarithmic PCR plots cross a calculated threshold line). For comparative quantification, Δ ct values were firstly calculated using the formula: Δ ct = (ct of iNOS) - (ct of β -actin). Then the $\Delta\Delta$ ct value was determined using the following formula: $\Delta\Delta$ ct = (Δ ct of each sample) - (average Δ ct of control samples). Fold increase in iNOS level under each condition was presented as $2^{-\Delta\Delta$ ct}.

Acute insulin-secretion test

The acute insulin-secretion test was as previously described^[14]. In brief, the culture medium was discarded and the cells were washed twice with 1 mL Krebs-Ringer bicarbonate (KRB) buffer. The cells were then pre-incubated in KRB for 40 min at 37 °C. Pre-incubation buffer was then poured off followed by the addition of 1 mL of test medium per well at a constant rate. After 20 min, the test medium was collected at a constant rate and stored at -20 °C prior to insulin determination by a rat insulin enzyme-linked immunosorbent assay (ELISA) kit (Linco Research, St. Charles, Missouri, United States). The limit of sensitivity of the assay was 0.2 ng/mL (35 pmol/L) insulin using a 10 μ L sample. The appropriate range of the insulin assay was 0.2 ng/mL to 10 ng/mL insulin (10 μ L sample size). Samples with results greater than this range were diluted with sample buffer in order to fit the range of the standard curve.

Determination of nitrite production

Test samples at 100 μ L were mixed with 1.32% sulfanilamide (50 μ L) in 60% acetic acid and 0.1% N-(1-naphthyl) ethylenediamine dihydrochloride HCl (50 μ L) in distilled water. After 10 min incubation, the absorbance was read on a spectrophotometer at 540 nm. Actual concentrations were calculated from an absorbance vs nitrite (μ mol/L) standard curve.

Statistical analysis

The significance of various treatments was determined by the Student's unpaired *t*-test under non-parametric statistical conditions. Results are expressed as the mean \pm SE. Differences were considered significant at $P < 0.05$.

RESULTS

As shown in Figure 1, HPLC analysis of the ethanolic extract of SA-Et was carried out, and seven major peaks were obtained and identified as schiarsanrin B, taiwanschirin A, schiarsanrin E, schiarsanrin C, schiarsanrin A, macelignan, and schizanrin A, respectively, by matching them to authentic samples. In addition, the model of cytokine-mediated β cell destruction was established using BRIN-BD11 cells. As shown in Figure 2A, a synergistic effect on cytotoxicity was only observed when IL-1 β was mixed with IFN- γ . Maximum cell death occurred at 48 h when cells were treated with IL-1 β (2 ng/mL) and IFN- γ (100 ng/mL). As shown in Figure 2B, the pres-

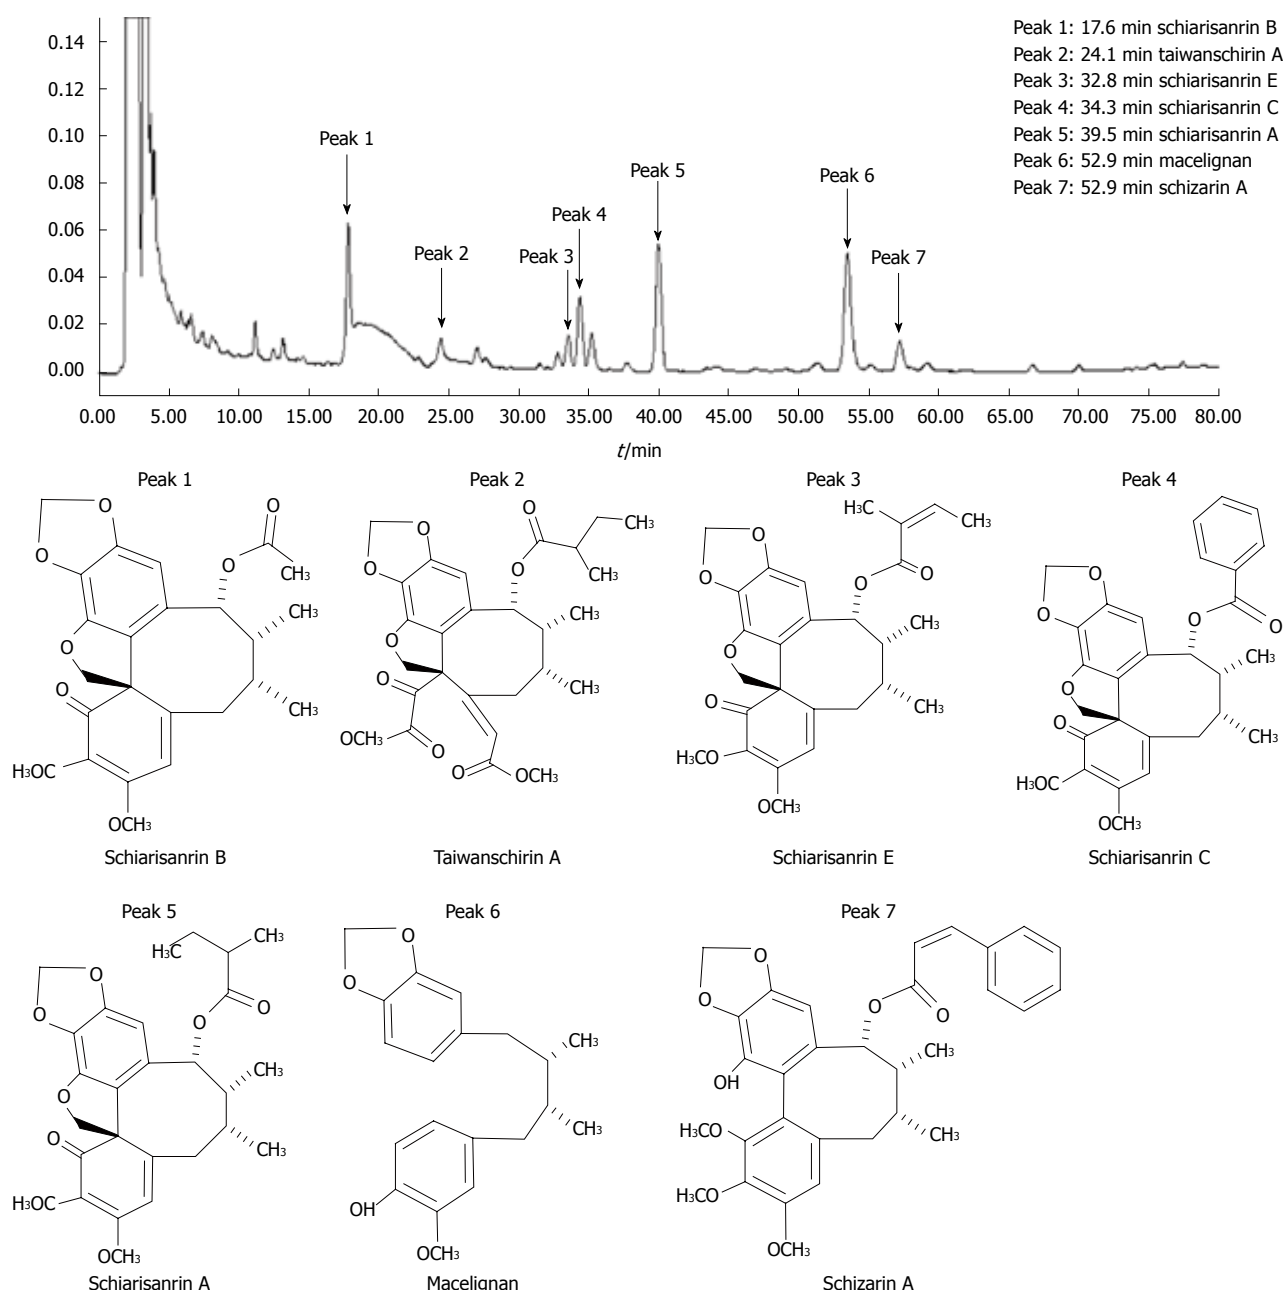

Figure 1 Chemical fingerprinting of the ethanolic extract of *Schizandra arisanensis*. The ethanolic extract of *Schizandra arisanensis* (SA-Et) (1.0 mg) was subjected to a high-performance liquid chromatography system to obtain chemical fingerprints. According to the retention times, the chemical identities and structures of seven major peaks are listed.

ence of IFN- γ alone resulted in significant G₁ arrest ($P < 0.05$). In contrast, the presence of IL-1 β alone caused significant inhibition at S phase. However, when IFN- γ was combined with IL-1 β , the accumulated G₁ arrested cells appeared to have progressed into the subG₁ phase ($P < 0.01$) at the end of cytokine treatment. By affecting the mechanisms of IL-1 β + IFN- γ using various inhibitors, our results showed that IL-1 β + IFN- γ -mediated cytotoxicity could be attenuated by SP600125 and SB203580. On the other hand, the presence of U0126 and L-NAME had no beneficial effects on cell viability. Moreover, the viability of cytokine-treated cells was worse in the presence of wortmannin (Figure 2C).

By employing our cell model, as shown in Figure 3A,

the SA-Et at 20 μ g/mL provided β cell protective activity as shown by an increase of approximately 1.3-fold ($P < 0.01$) in the viability in the cytokine treated condition. Consistently, induction of the subG₁ phase in the presence of IL-1 β + IFN- γ was attenuated by the SA-Et (Figure 3B). Finally, full-length caspase-3 degradation in the presence of IL-1 β + IFN- γ was observed and was parallel to the increase in cleaved caspase-3 (active form) of about 1.2-fold at 24 h post-treatment with IL-1 β + IFN- γ (Figure 3C). However, while SA-Et alone reduced the cleaved form of caspase-3 by 30%, the protease-mediated caspase-3 activation by IL-1 β + IFN- γ was also ameliorated by SA-Et.

Following determination of the protective effect of

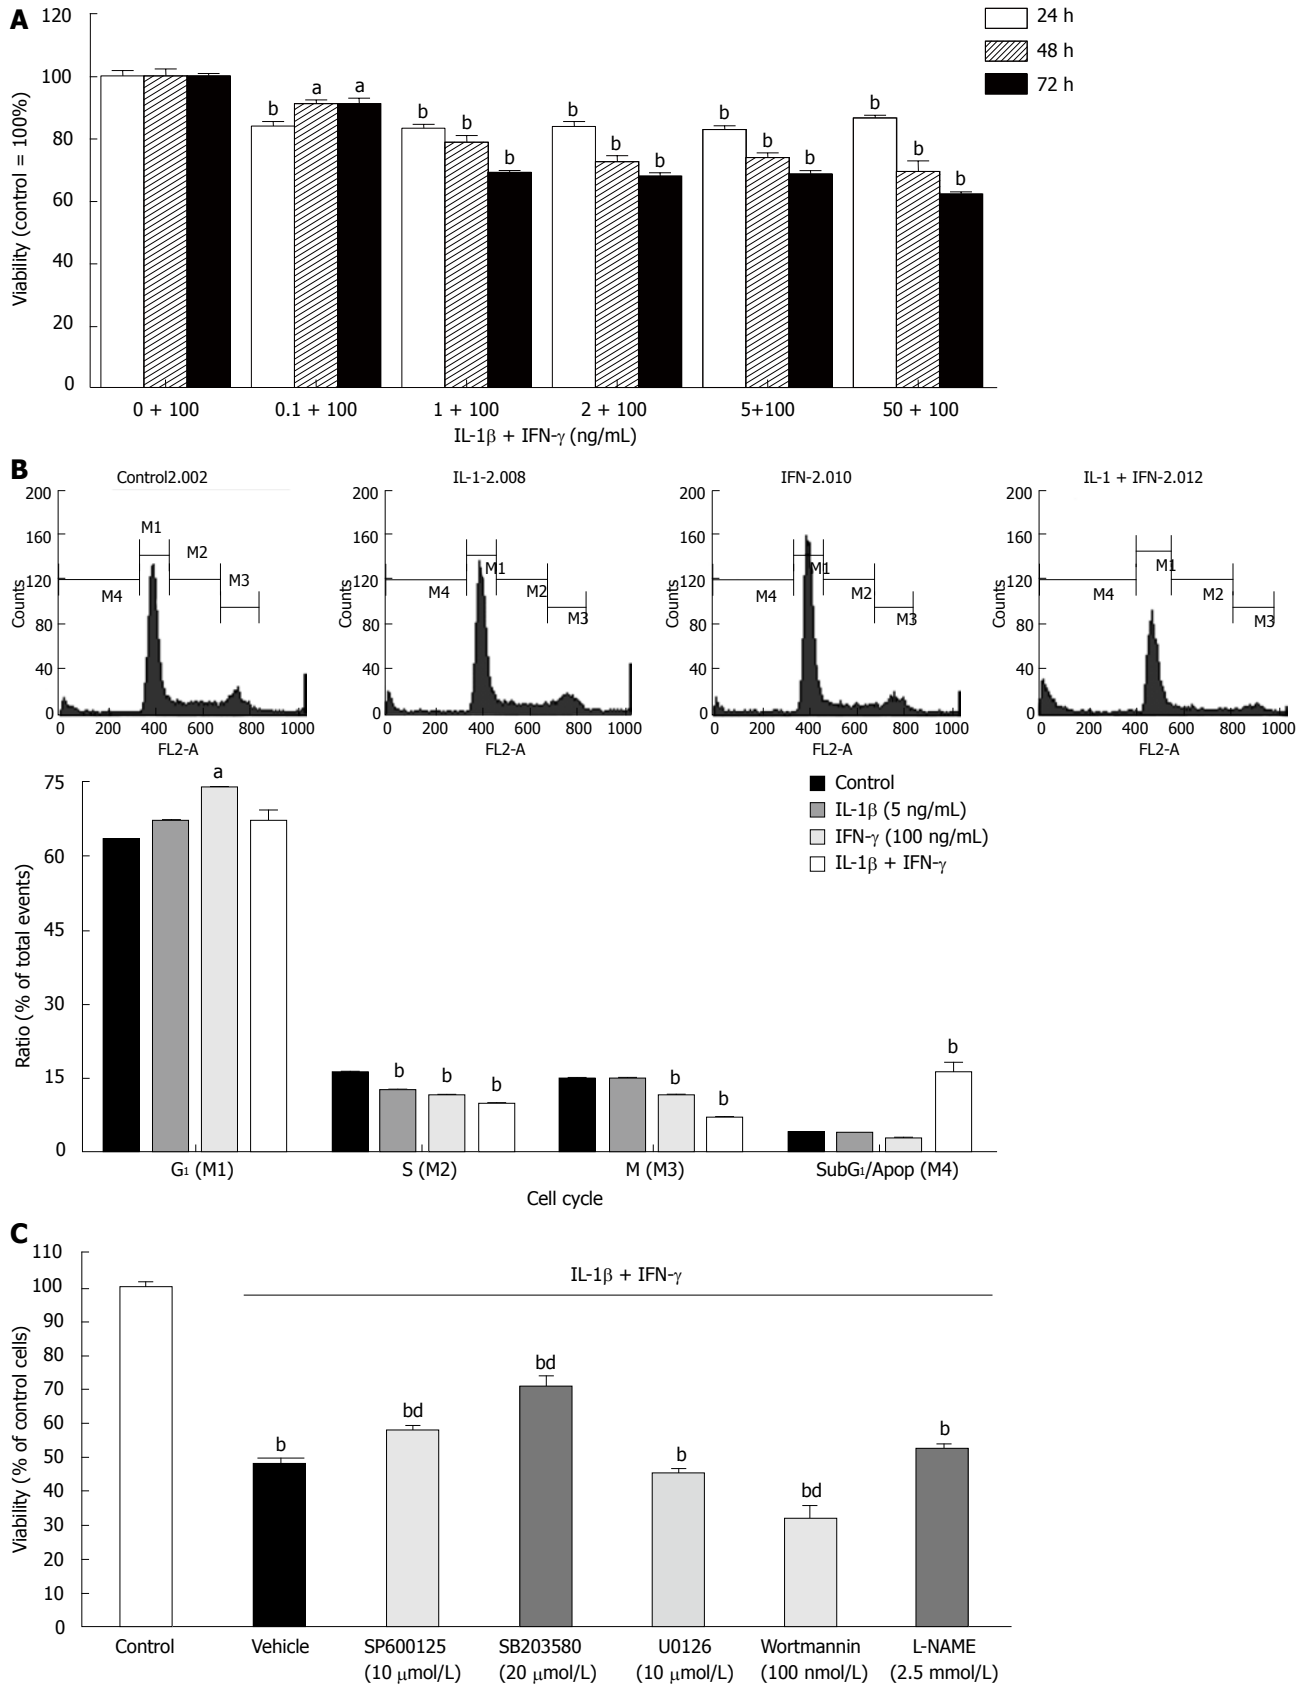

Figure 2 Interleukin-1 β and interferon- γ -mediated BRIN-BD11 cell apoptosis is attenuated by p38MAPK and stress-activated protein kinase/c-Jun NH2-terminal kinase inhibitors. **A:** The viability of interferon (IFN)- γ (100 ng/mL)-treated cells in the presence of various concentrations of interleukin (IL)-1 β for 24 h, 48 h and 72 h was measured. Data are presented as the mean \pm SE, $n = 4$. $^aP < 0.05$, $^bP < 0.01$ vs the viability of untreated cells; **B:** Cell cycle analysis was carried out at 48 h post-treatment with IL-1 β (5 ng/mL), IFN- γ (100 ng/mL), or a mixture of the two. Data are presented as the mean \pm SE, $n = 4$. $^aP < 0.05$, $^bP < 0.01$ vs the control; **C:** The viability of cytokine-treated BRIN-BD11 cells in the presence of inhibitors was measured. Data are presented as the mean \pm SE, $n = 4$. $^bP < 0.01$ vs the viability of untreated cells; $^dP < 0.01$ vs the viability of cells with the cytokine mix.

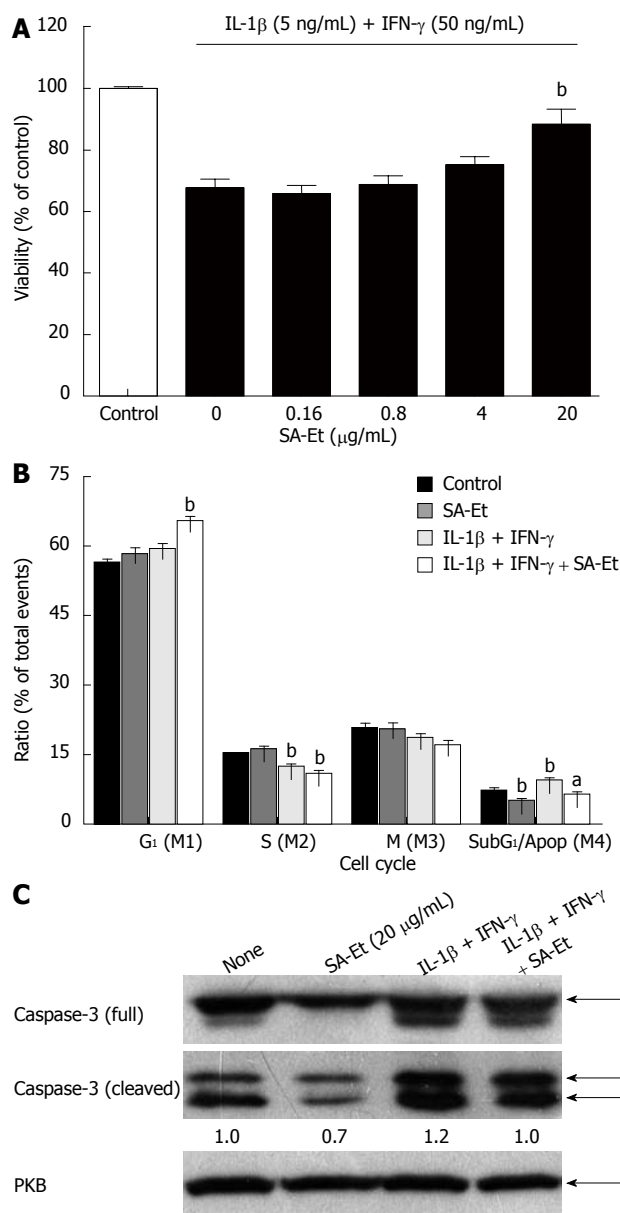

Figure 3 The anti-apoptotic effect of the ethanolic extract of *Schizandra arisanensis*. **A**: The viability of BRIN BD11 cells was determined after 48 h of cytokine treatment in the presence or absence of the ethanolic extract of *Schizandra arisanensis* (SA-Et); **B**: Cell cycle of BRIN BD11 cells was determined after 48 h of cytokine treatment in the presence or absence of the SA-Et. Data are presented as the mean \pm SE, $n = 4$. $^aP < 0.05$, $^bP < 0.01$ vs the control; **C**: Both full and cleaved forms of caspase-3 protein were analyzed by Western blot after 24 h of cytokine treatment in the presence or absence of the SA-Et. A representative from three experiments is shown. IL-1 β : Interleukin 1 β ; IFN- γ : Interferon- γ .

SA-Et, we further examined the impact of SA-Et on signal transduction of IL-1 β + IFN- γ . As shown in Figure 4A, stress-activated protein kinase/c-Jun NH2-terminal kinase (SAPK/JNK), p38MAPK, and STAT-1 α activation in cytokine-treated cells was evident, while ERK1/2 was not activated. In the presence of SA-Et, the phosphorylation of SAPK/JNK (at T183/Y182) and its substrate c-Jun (at S63) was attenuated by this treatment, while other pathways appeared to be unaffected by SA-Et.

In addition, cytokine treatment also promoted I κ B α degradation which was unaffected by the addition of SA-

Et (Figure 4B). Consistently, the presence of SA-Et (20 μ g/mL) was unable to inhibit cytokine-mediated iNOS mRNA through cytokine induction (Figure 4C and D). Interestingly, SA-Et administration up to 20 μ g/mL provided minor, but significant inhibition of cytokine-mediated NO formation. However, such inhibition did not reach the level of the known iNOS inhibitor, L-NAME, which provided $> 50\%$ of the inhibition of cytokine-mediated NO production (Figure 4E).

In terms of SA-Et treatment on β -cell function with or without cytokine challenge (Figure 5A), SA-Et treatment enhanced the insulinotropic effects of glucose and extracellular Ca $^{2+}$, and modestly but significantly affected the insulinotropic effect of extracellular K $^{+}$. As shown in Figure 5B, glucose responsiveness of BRIN-BD11 cells was unaffected by SA-Et alone. On the other hand, a detectable amount of secreted insulin under a basal or high concentration of glucose was not detected in surviving BRIN-BD11 cells following cytokine treatment. In contrast, we detected partial secretion of insulin from cytokine-treated BRIN-BD11 cells in the presence of SA-Et ($P < 0.01$).

When determining the insulin level in BRIN-BD11 cells under the indicated conditions, there was a modest reduction in insulin mRNA expression in the presence of SA-Et or the cytokine mix 48 h post-treatment (Figure 5C). In addition, insulin protein expression and the intracellular insulin content of BRIN-BD11 cells were consistent with each other (Figure 5D). Cellular insulin protein level appeared to be similar regardless of the addition of SA-Et. In contrast, cellular insulin contents in cytokine-treated cells were significantly elevated ($P < 0.001$). Interestingly, insulin content in cytokine-treated BRIN-BD11 cells with SA-Et treatment was significantly reduced ($P < 0.05$) compared with that in untreated cells.

Finally, we compared the biological activities of four major peaks as shown in Figure 6. Epigallocatechin gallate (EGCG) was employed as a reference drug which has been shown to protect against cytokine-mediated β cell death^[16]. Our results indicated that both peak 1 (schiarisanrin B) and peak 5 (schiarisanrin A) provided β cell protective bioactivity similar to EGCG (20 μ g/mL). The protective potency of schiarisanrin B reached its maximum at a concentration of 5 μ g/mL, and higher concentrations led to a deleterious outcome. On the other hand, schiarisanrin A provided a dose-dependent protective effect starting at a concentration of 5 μ g/mL ($P < 0.01$). Peak 4 (schiarisanrin C) led to cell death in a dose-dependent manner. Different from C $_{19}$ homolignans, the C $_{18}$ lignan, peak 6 (macelignan), played no role in cytokine-mediated cytotoxicity at any concentration.

DISCUSSION

Conventional therapy in patients with type 1 diabetes does not allow minute-to-minute control of blood glucose and does not prevent complications associated with the disease. Whole pancreas or islet transplantation facilitates glucose control on a real-time basis but the lack of

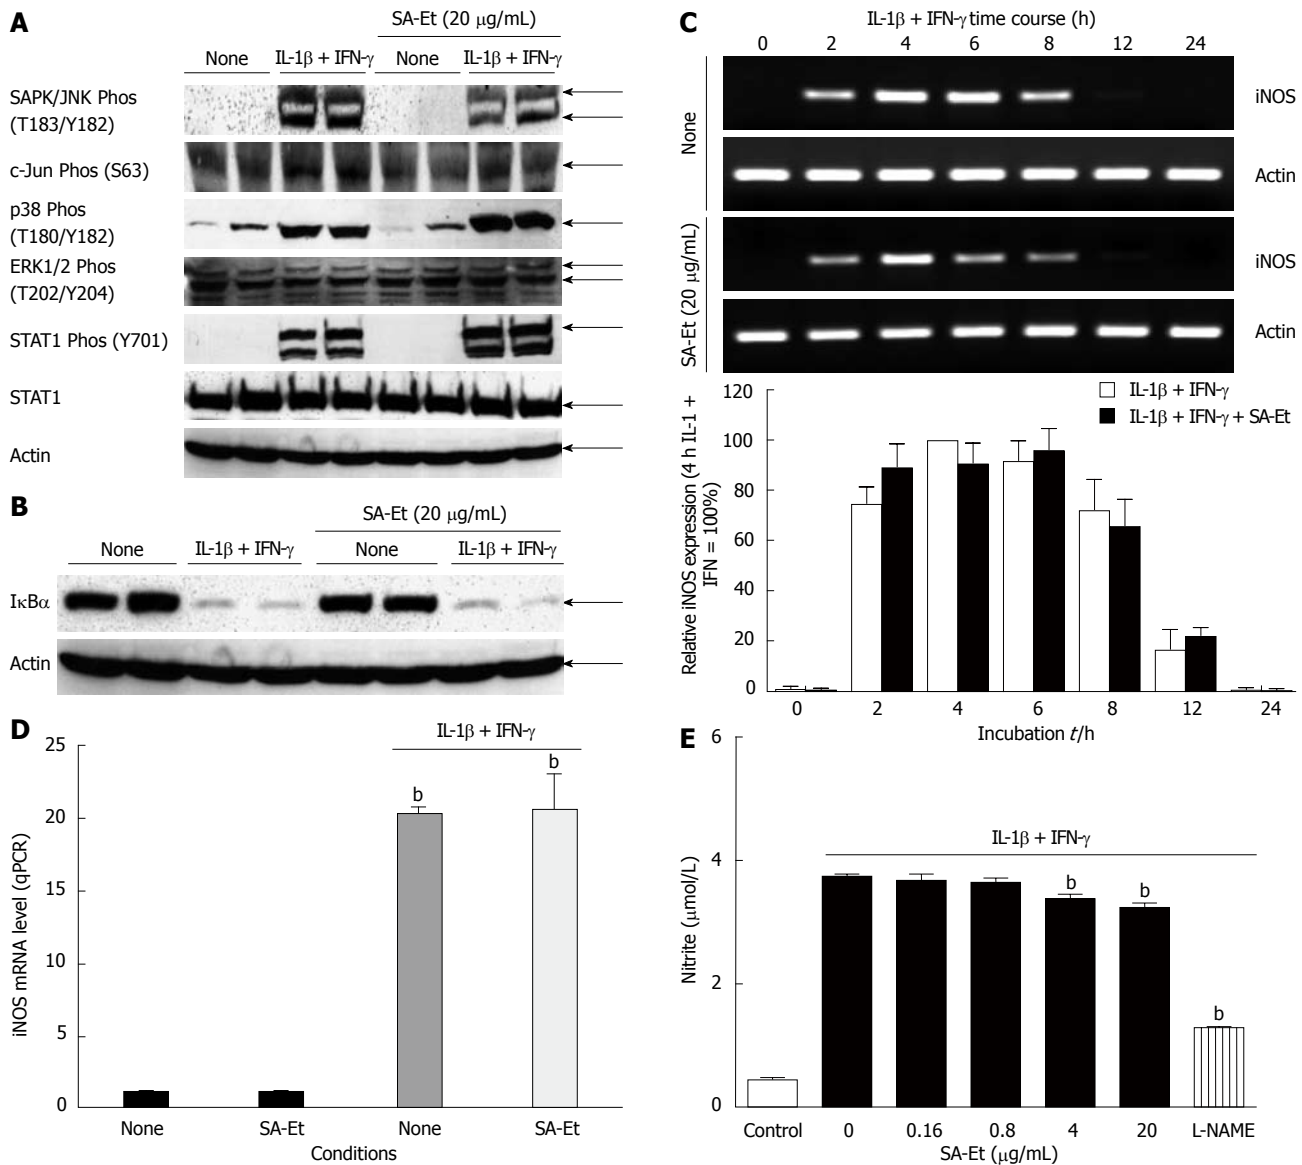

Figure 4 Characterizing the impact of ethanolic extract of *Schizandra arisanensis* (SA-Et) (20 μ g/mL) on cytokine signal transduction. A: BRIN-BD11 cells stimulated with the cytokine mix in the presence or absence of ethanolic extract of *Schizandra arisanensis* (SA-Et) (20 μ g/mL) were harvested after 30 min treatment for Western blot with the indicated antibodies. A representative Western blot from three experiments is shown; B: BRIN-BD11 cells stimulated with the cytokine mix in the presence or absence of SA-Et were harvested after 60 min treatment to measure I κ B α protein level. A representative Western blot from three experiments is shown; C: Cytokine-induced inducible nitric oxide synthase (iNOS) mRNA levels in BRIN-BD11 cells during 24 h were determined by an reverse transcription-polymerase chain reaction. Relative iNOS gene expression was calculated by employing endogenous β -actin mRNA level as an internal control. The maximum iNOS gene expression at 4 h post-treatment with the cytokines alone was set to 100%. Data are presented as the mean \pm SE, $n = 4$; D: Changes in cytokine-induced iNOS mRNA levels in BRIN-BD11 cells at 4 h in the presence or absence of the SA-Et (20 μ g/mL) were also determined by real-time reverse transcription-polymerase chain reaction. β -actin was used as an internal control. The relative quantification of iNOS mRNA was presented as $2^{-\Delta\Delta Ct}$. Data are presented as the mean \pm SE, $n = 3$. $^bP < 0.01$ vs cells under control conditions; E: Nitric oxide production in cytokine-treated BRIN-BD11 cells in the presence or absence of the SA-Et (0-20 μ g/mL) or nitro-L-arginine methyl ester (L-NAME) (0.5 mmol/L) was determined. Data are presented as the mean \pm SE, $n = 4$. $^bP < 0.01$ vs cells treated with the cytokine mixture alone. IL-1 β : Interleukin 1 β ; IFN- γ : Interferon- γ .

sufficient organs for transplantation is a major obstacle. Employing toxin-resistant cells for type 1 diabetes therapy is another developing approach in cell-based therapies. However, disassociation between toxin resistance and insulin-secretory functions may occur during the induction of toxin resistance^[17]. Moreover, to our knowledge, no “master” toxin-resistant cells have been created so far^[17-19]. As a result, supplementation with β cell protective phytochemicals to enhance the survival rate and secretory functions of cell-based therapeutics for curing type 1 diabetes is an interesting and flexible approach^[20,21].

To pursue this objective, we created a simple platform by employing BRIN-BD11 cells. The use of a cytokine mix successfully promoted β cell death and abolished glucose-stimulated insulin secretion after 48 h of treatment. Through cell cycle analysis, it was apparent that only the combination of IL-1 β and IFN- γ elicited apoptosis as judged by caspase 3 cleavage and a significant increment of the subG₁ population in BRIN-BD11 cells under such conditions. In the present investigation, the anti-apoptotic effect of SA-Et against cytokine-mediated β cell death was clearly demonstrated. Consistent with the restoration

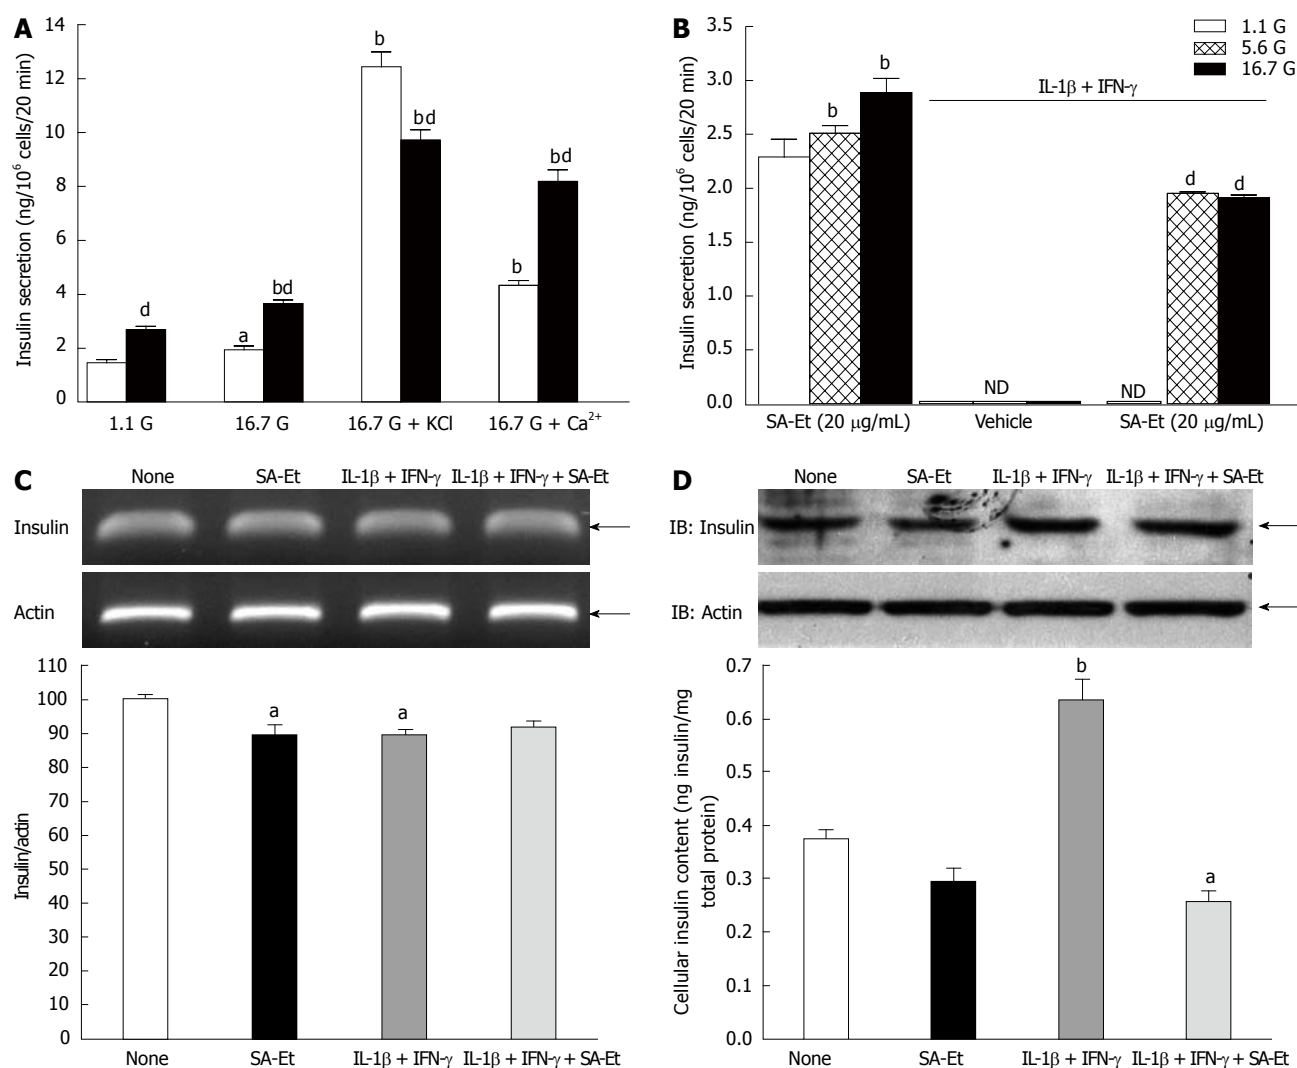

Figure 5 Ethanolic extract of *Schizandra arisanensis* treatment partially rescued the abolished insulin secretion in cytokine-treated BRIN-BD11 cells. **A:** Acute insulin release in response to glucose, KCl and Ca²⁺ in the presence or absence of the ethanolic extract of *Schizandra arisanensis* (SA-Et) was evaluated. Data are presented as the mean \pm SE, $n = 4$. ^a $P < 0.05$, ^b $P < 0.01$ vs insulin released from cells treated with 1.1 mmol/L glucose; ^d $P < 0.01$ vs control cells under the same conditions; **B:** Cultured BRIN-BD11 cells were treated with the cytokine mixture in the presence or absence of the SA-Et. At 48 h post-treatment, treated cells were evaluated for glucose responsiveness. Data are presented as the mean \pm SE, $n = 4$. ^b $P < 0.01$ vs insulin released from cells treated with 1.1 mmol/L glucose; ^d $P < 0.01$ vs SA-Et-treated cells under the same glucose conditions. **C:** In addition, a portion of the treated cells was harvested to measure insulin mRNA level using reverse transcription-polymerase chain reaction. Relative insulin gene expression was calculated by employing endogenous β -actin mRNA level as an internal control. ^a $P < 0.05$ vs control conditions (none); **D:** Protein level and cellular insulin content were independently measured by Western blot and enzyme-linked immunosorbent assay. Data are presented as the mean \pm SE, $n = 4$. ^a $P < 0.05$, ^b $P < 0.01$ vs control conditions (none). IL-1 β : Interleukin 1 β ; IFN- γ : Interferon- γ ; ND: Not determined.

of cell viability, the ratio of the subG₁ phase and protein level of cleaved caspase-3 in the cytokine-treated condition was blocked or reduced by SA-Et.

According to previous research, NF κ B, p38MAPK, and SAPK/JNK pathways all play a role in cytokine-mediated cytotoxicity in β cells. Interestingly, unlike other cell lines, NF κ B downstream iNOS/NO induction is not responsible for apoptosis of BRIN-BD11 cells. Instead, insulin secretion in response to glucose was significantly affected by NO production in BRIN-BD11 cells^[22]. Our results are consistent with previous findings and further demonstrated that p38MAPK and JNK/SAPK play important roles in cytokine-mediated BRIN-BD11 cell death.

Using this cell model, we screened several anti-diabetic herbal extracts and discovered that SA-Et has

protective bioactivity. According to the HPLC profile of the SA-Et, seven major peaks were identified: five C₁₉ homolignans (schiarisanrins) and two C₁₈ lignans (schizanrin A and macelignan). Through bioactivity screening, it was evident that some C₁₉ homolignans could account for the β cell protective effects of the SA-Et against the cytokine challenge. To our knowledge, this is the first report to reveal such bioactivity in C₁₉ homolignans. The results also implied that C₁₉ homolignans which possess an acetoxyl group at C-5 exhibited more-potent bioactivity than did those with the benzoic acid ester at C-5, regardless of the different C₁₉ homolignan skeletons as shown in Figure 1. Notably, schiarisanrin C exhibited dose-dependent negative protection activity, which was consistent with a previous report which found that schiarisanrin C exhibited cytotoxicity against other cell lines^[8]. The structure-

Figure 6 Identification of bio-active compounds isolated from *Schizandra arisanensis*. After major peak compounds were collected, BRIN-BD11 cells were treated with cytokine mix in the presence of each peak compounds for 48 h. The viability of cells was then measured by neutral red assay. Epigallocatechin gallate (EGCG) is used as reference drug. Data are presented as the mean \pm SE, $n = 8$. ^b $P < 0.01$ vs the viability of cells with no treatment.

activity relationship will likely be more obvious when more types of C₁₉ homolignan derivatives are compared.

To further elucidate the potential drug target of SA-Et, we evaluated the effects of SA-Et on key players in each pathway involved in cytokine-mediated β cell death. The results indicated that SA-Et appeared to impact on JNK/SAPK kinase activities and downstream substrate, i.e., c-Jun, to facilitate its protective activity against the cytokine mix. Recent research discovered that the JNK/c-Jun cascade could transactivate the expression of Bcl-2 homology 3 (BH3)-only member death protein 5 (DP5)/harakiri (Hrk) leading to β cell apoptosis^[23]; therefore, our results suggest that SA-Et treatment might intervene in such a cytokine pathway to facilitate β cell protection.

Interestingly, our results also demonstrated that SA-Et treatment had no inhibitory effect on cytokine-mediated NF- κ B release judged by a similar pattern of cytokine-mediated I κ B degradation and iNOS mRNA expression in the presence of SA-Et. NF- κ B is an important player in abolishing glucose-stimulated insulin secretion (GSIS) by affecting the glucose-induced influx of Ca²⁺^[24,25]. In addition, IL-1 β -mediated NO production also plays a negative role in insulin secretion in BRIN-BD11 cells^[22]. Therefore, whether SA-Et can not only preserve the viability of cytokine-treated BRIN-BD11 cells, but also rescue the impaired insulin secretion of the cytokine-treated cells was our next question.

In terms of the insulinotropic action of SA-Et, our results indicate that SA-Et acutely enhanced both glucose- and calcium-stimulated insulin secretion, although K⁺-stimulated insulin secretion appeared to be slightly reduced by SA-Et. As a result, we speculated that the insulinotropic effect of SA-Et might be associated with calcium-mediated insulin exocytosis, an overall proximal step in insulin secretion. In contrast, under cytokine treatment, insulin exocytosis rather than insulin mRNA expression appeared to be affected in BRIN-BD11 cells. This was based on the observations that insulin secreted by cytokine-treated BRIN-BD11 cells was undetectable using the insulin ELISA kit; however, the insulin mRNA

and intracellular insulin content (protein level) of BRIN-BD11 cells remained intact. When SA-Et was present, the abolished insulin exocytosis by the cytokine mix might be counteracted; therefore, resulting in partial recovery of glucose-stimulated insulin secretion and relief of accumulated insulin content in cytokine treated BRIN-BD11 cells.

In conclusion, the current investigation revealed, for the first time, that C₁₉ homolignans isolated from SA-Et possessed protective bioactivity against cytokine-induced β cell death. The cytokine-impaired insulin secretory function was also partially restored. However, iNOS/NO inhibition appeared to be an important factor if intact β cell insulin secretory function is to be preserved after cytokine challenge. In the future, continued research on potent β cell-protective phytochemicals should substantially contribute to the development of islet/stem cell transplantation or cell-based therapies for type 1 diabetes.

COMMENTS

Background

Conventional therapy (i.e., insulin injection) in patients with type 1 diabetes does not allow minute-to-minute control of blood glucose and does not prevent complications associated with the disease. However, the employment of whole pancreas or islet transplantation suffers from a lack of sufficient organs for transplantation. Therefore, the application of cell-based therapeutics for curing type 1 diabetes is an interesting and hot topic in the field.

Research frontiers

Employing toxin-resistant cells for type 1 diabetes therapy is a developing cell-based approach for curing type 1 diabetes. At least 5 toxin resistant β cell lines have been generated and investigated for defensive mechanisms. However, disassociation between toxin resistance and insulin-secretory functions may occur during the induction of toxin resistance. To our knowledge, no "master" toxin-resistant cells have been created so far. As a result, employing β -cell protective agent(s) including phytochemicals from traditional Chinese medicine to protect cell-based transplants has become an alternative and practical approach in the field.

Innovations and breakthroughs

By employing the glucose-responsive, insulin-secreting cell line, BRIN-BD11 cells, the authors successfully established a platform mimicking hormonal part of immune-attack in type 1 diabetes. In addition, the authors noted disassociation not only between cytokine-mediated nitric oxide and cell death, but also

between cell survival rate and secretory function. Moreover, the NF κ B-induced inducible nitric oxide synthase-nitric oxide pathway is not necessarily a master regulator for cell viability and function. *Schizandra arisanensis* (SA-Et) is one of the schizandraceous plants from Taiwan. The indications for this herb in traditional Chinese medicine include diabetes, hepatitis, immunomodulation and cancer. The current investigation is likely to be the first report on C₁₉ homolignans from SA-Et which possess β -cell protective effects. Different to previous β cell protective phytochemicals, such as epigallocatechin gallate and silymarin, the action of C₁₉ homolignans is not due to the blockage of NF κ B-inducible nitric oxide synthase-nitric oxide.

Applications

By employing this glucose-responsive, insulin-secreting cell line to generate several platforms which represent key steps in autoimmune mediated β -cell destruction. The authors will be able to design a formulation which can be used to enhance the survival rate and maintain secretory functions in cell-based therapeutics to achieve needle-free control of type 1 diabetes in the future.

Terminology

Type 1 diabetes (T1D) is an autoimmune disease which occurs when approximately 60%-90% of insulin secreting cells are lost and/or are dysfunctional due to β -cell directed autoimmunity. During the progression of T1D, heavy infiltrations of mononuclear cells lead to substantial damage to β cells by generating locally high concentrations of pro-inflammatory cytokines, perforin, and FasL-Fas interactions within the micro-environment of islets. As a result, deleterious outcomes including excessive pro-insulin secretion, the abolition of glucose-induced insulin secretion, and ultimately β cell death are observed.

Peer review

The article is very interesting and shows novel findings in insulin secreting cells. The article is well written. Furthermore, it correctly cites the most important articles in the field.

testinal flora and release of interleukin-12 (IL-12) and tumor necrosis factor- α (TNF- α) from the colon in rat with ulcerative colitis (UC).

METHODS: A rat model of UC was established by local stimulation of the intestine with supernatant from colonic contents harvested from human UC patients. A total of 40 male Sprague-Dawley rats were randomly divided into the following groups: normal (sham), model (UC), herb-partition moxibustion (HPM-treated), and positive control sulfasalazine (SA-treated). Rats treated with HPM received HPM at acupuncture points ST25 and RN6, once a day for 15 min, for a total of 8 d. Rats in the SA group were perfused with SA twice a day for 8 d. The colonic histopathology was observed by hematoxylin-eosin. The levels of intestinal flora, including *Bifidobacterium*, *Lactobacillus*, *Escherichia coli* (*E. coli*), and *Bacteroides fragilis* (*B. fragilis*), were tested by real-time quantitative polymerase chain reaction to detect bacterial 16S rRNA/DNA in order to determine DNA copy numbers of each specific species. Immunohistochemical assays were used to observe the expression of TNF- α and IL-12 in the rat colons.

RESULTS: HPM treatment inhibited immunopathology in colonic tissues of UC rats; the general morphological score and the immunopathological score were significantly decreased in the HPM and SA groups compared with the model group [3.5 (2.0-4.0), 3.0 (1.5-3.5) vs 6.0 (5.5-7.0), $P < 0.05$ for the general morphological score, and 3.00 (2.00-3.50), 3.00 (2.50-3.50) vs 5.00 (4.50-5.50), $P < 0.01$ for the immunopathological score]. As measured by DNA copy number, we found that *Bifidobacterium* and *Lactobacillus*, which are associated with a healthy colon, were significantly higher in the HPM and SA groups than in the model group (1.395 ± 1.339 , 1.461 ± 1.152 vs 0.045 ± 0.036 , $P < 0.01$ for *Bifidobacterium*, and 0.395 ± 0.325 , 0.851 ± 0.651 vs 0.0015 ± 0.0014 , $P < 0.01$ for *Lactobacillus*). On the

Abstract

AIM: To investigate the effect of moxibustion on in-

other hand, *E. coli* and *B. fragilis*, which are associated with an inflamed colon, were significantly lower in the HPM and SA groups than in the model group (0.244 ± 0.107 , 0.628 ± 0.257 vs 1.691 ± 0.683 , $P < 0.01$ for *E. coli*, and 0.351 ± 0.181 , 0.416 ± 0.329 vs 1.285 ± 1.039 , $P < 0.01$ for *B. fragilis*). The expression of TNF- α and IL-12 was decreased after HPM and SA treatment as compared to UC model alone (4970.81 ± 959.78 , 6635.45 ± 1135.16 vs 12333.81 ± 680.79 , $P < 0.01$ for TNF- α , and 5528.75 ± 1245.72 , 7477.38 ± 1259.16 vs 12550.29 ± 1973.30 , $P < 0.01$ for IL-12).

CONCLUSION: HPM treatment can regulate intestinal flora and inhibit the expression of TNF- α and IL-12 in the colon tissues of UC rats, indicating that HPM can improve colonic immune response.

INTRODUCTION

Ulcerative colitis (UC) is a chronic inflammatory disease of the gastrointestinal tract characterized by increased stool frequency, bleeding and abdominal pain, and ulceration limited to the colon mucosa. The role of immunological pathogenesis in UC has been widely recognized^[1,2]. In recent years, the involvement of pathogen-mediated immune dysfunction has received extensive attention. Studies have shown that UC patients have altered intestinal flora species. For example, *Bifidobacterium*, *Lactobacillus* and fusobacterium *Escherichia coli* (*E. coli*) desulfovibrio were significantly decreased, while *Bacteroides fragilis* (*B. fragilis*), were significantly increased^[3-6]. In hosts with altered intestinal flora, the immune system recognizes intestinal flora and its metabolites as pathogenic antigens that can cause an abnormal immune response and stimulate bowel epithelial cells in UC patients with genetic susceptibility. This activity then destroys the structure and function of colonic mucosa, leading to the ongoing pathology associated with UC^[7]. Alteration of the intestinal flora has been considered to be the initiating and continuous factor in the onset of UC^[7-10]. Therefore, the modulation of intestinal flora has been suggested as a potential approach to treat UC.

Previous studies have shown that herb-partition moxibustion (HPM) can be anti-inflammatory^[11]. It can also improve symptoms in mild-to-moderate UC patients, such as relieving abdominal pain and decreasing bloody diarrhea^[12-14]. Experiments have also demonstrated that HPM can down-regulate the protein and mRNA expression of interleukin (IL)-8 and intercellular adhesion molecule-1 in colon tissues of UC patients, indicating that HPM can inhibit chemotaxis and cell migration into inflamed tissues^[14]. HPM can also promote neutrophil apoptosis and down-regulate cytokines, such as IL-1 beta, IL-6, and tumor necrosis factor-alpha (TNF- α), further suggesting an anti-inflammatory role for HPM treatment^[15]. Moreover, a recent report shows that intestinal injury was decreased and TNF- α was also found to be decreased after HPM treatment in a Crohn's disease model^[16]. Taken together, these results indicate that HPM can regulate immune function in UC. However, whether HPM can also alter the intestinal flora composition is still unknown.

A large number of bacteria comprise the human intestinal flora, outnumbering host cells by a ratio of 10:1. Various types of bacteria constitute the gut flora, including symbiotic and pathogenic bacteria whose pathogenicity is hidden from the immune system from various barrier and immune-mediated mechanisms. For this study, we observed the relative proportions of both the symbiotic - and most prevalent - bacteria, such as bifidobacteria and lactobacilli, and the conditioned pathogenic flora, such as *E. coli* and *B. fragilis*, as readouts to explore the effects of HPM on modulating the intestinal flora of rats in a model of UC. We also investigated whether HPM regulates the expression of pro-inflammatory cytokines, such as TNF- α and IL-12, in colon tissues of UC rats. This study would aid in understanding the mechanisms of how HPM can alleviate symptoms of UC.

MATERIALS AND METHODS

Animals

Sprague-Dawley rats were obtained from the Department of Experimental Animal Science of Shanghai Medical College at Fudan University [No. SCXK(SH)2009-0019]. All protocols were performed in strict accordance with the Guidance Suggestions for the Care and Use of Laboratory Animals, formulated by the Ministry of Science and Technology of the People's Republic of China^[17]. This study received permission from the Ethics Committee in Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, which is affiliated with Shanghai University of Traditional Chinese Medicine, China.

Establishment of the UC rat model

Forty neonatal, male Sprague Dawley rats weighing 183 ± 10 g were randomly divided into the following experimental groups: normal, model, HPM, and sulfasalazine (SA). The UC rat model was established according to an

immunological method and local stimulation^[15,18-20]. In brief, fresh human colonic mucosa was obtained from surgical colonic specimens, homogenized in normal saline and centrifuged for 30 min at 3000 rpm in order to remove cells and bacteria. The supernatant, containing antigens released from UC colon patients, was diluted into an appropriate protein concentration and mixed with Freund's adjuvant (Shanghai Chemical Reagent Company, Shanghai, China). One mL of the antigen plus adjuvant mixture, containing a total of 6 mg protein, was injected into the front footpad at day 0. Following this initial dose, the same mixture was then injected into the back footpad, dorsa, inguina, and abdominal cavities on days 10, 17, 24 and 31, respectively. On day 38, rats were anesthetized intraperitoneally with 2% pentobarbital sodium (30 mg/kg) and 3 mL enema of 3% formalin were administered to the rats - in order to stimulate the colon immune response - for 1 h following a saline wash after a 2 mL enema of antigen fluid (without Freund's adjuvant) for 2 h following a saline wash.

Treatment

After the UC model was established in the rats, HPM was performed during days 39-46 of UC model in the treatment groups. Moxa cones (0.5 cm in diameter and

0.6 cm high) (Nanyang Hanyi Moxa Co., Ltd. China) were placed vertically on a medicinal formula composed of radix aconite, cortex, radix, carthami and salviae miltiorrhizae. The medicinal formula was then placed on acupoints ST25 (located on a horizontal line 2 cun laterally to the midline and 5 cun above the symphysis pubis, a point of hand Yangming, the mu point of the large intestine meridian, and it regulates the function of the intestine and stomach)^[21,22] and RN6 (located on ventral midline 3.5 cun above the symphysis pubis and 1.5 cun below the navel, a point of the conception meridian, and it strengthens original qi and improves immune function); the moxa cones were then ignited and each acupoint was treated twice in 15 min increments. This treatment was repeated once daily for a total of 8 d^[23]. As a positive control for inhibition of UC symptoms, the immunosuppressant SA was used. For the SA treatment group, salicylazosulfapyridine solution (0.25 g/tablet) was intragastrically administered to rats (Sanwei Pharmaceutical, Shanghai, China; Batch No. 200807C30) twice daily for a total of 8 d. The salicylazosulfapyridine solution concentration was 20 mg/mL with a daily dose of 100 mg/kg, which is equivalent to 0.1 g/kg in a human patient^[24].

Morphological observation of fixed colon samples

Following treatment and sacrifice by cervical dislocation, samples were collected from the descending colon (5 cm above the anus), cleaned with normal saline, and general morphology was then scored (Table 1). The samples were fixed in 10% formalin, dehydrated, embedded in paraffin, and sectioned into 4 µm thick slices. These sections were then stained by hematoxylin-eosin for pathological observation and the histological grade was scored with the bland method^[25,26] (Table 2).

TNF-α and IL-12 immunohistochemistry

Paraformaldehyde-fixed and paraffin-embedded samples were sliced into 4 µm slices. Paraffin slides were deparaffinized in xylene I, xylene II, and xylene III; dehydrated in 95%, 90% and 70% ethanol; and then incubated with primary rabbit antibodies at 4 °C for 18 h (anti-TNF-α was diluted to 1:150; IL-12 was diluted to 1:200) (Abcam Co., United Kingdom). The tissues were then visualized with 0.5 g/L diaminobenzidine and 0.3 g/L H₂O₂ in distilled water, and rinsed in phosphate buffered saline for 10 min. A known positive sample was used as a positive control for all slices, and phosphate buffered saline was substituted for the primary antibody and isotype controls as negative controls. All the samples were analyzed by a Motic Med 6.0 image analysis system (Motic Group Co., Ltd.). Three fields were randomly selected under an optical microscope (Olympus Co., Ltd.) at 400 × magnification to calculate the positive target value of the integral optical density.

**Figure 1** Herb-partition moxibustion inhibits tissue damage in colonic tissues of rats with ulcerative colitis. The general morphological score of the colonic tissue in the model control (MC) group was significantly higher than the normal control (NC) group ($P = 0.000$). After treatment, the scores were lower in both the herb-partition moxibustion (HPM) group ($P = 0.01$) and the control sulfasalazine (SA) group ($P = 0.002$).

into 5-10 mL of nutrient broth and was shaken and cultivated overnight at 37 °C. To extract DNA, 50 μ L of the bacterial culture fluid was placed in a 1.5 mL sterile centrifuge tube, and 50 μ L of DNA extract was added. This was mixed well at a constant temperature of 100 °C for 10 min. It was then centrifuged at 12 000 rpm for 5 min and saved for later use. For the quantitative reverse transcription-polymerase chain reaction, the 7500 Sequence Detection System was used (ABI Co., USA). The sequence of the forward primer (F) and reverse primer (R) are shown in Table 3. DNA was prepared for PCR amplification in the following way: 10 μ L 5 \times PCR buffer, 0.5 μ L forward primer F, 0.5 μ L reverse primer R, 0.5 μ L dNTPs, 0.5 μ L TaqMan fluorescent probe, 1 μ L Taq enzyme, 32 μ L dH₂O water, and 5 μ L cDNA template. We used the following amplification conditions: (1) 50 °C 2 min, (2) 95 °C 5min, (3) 95 °C 15 s, and (4) 60 °C 45 s, for 40 cycles.

Statistical analysis

All data were analyzed using SPSS 10.0 statistical software (SPSS Inc., United States), and all data were expressed as mean \pm SD for normally distributed continuous variables and as median (QL-QU) for abnormal variables. A one-way analysis of variance was used for normal

distributions, LSD/SNK-q for homogeneity of variance, and Dunnett's T3 for heterogeneity of variance. A non-parametric test was used for when the data did not follow Gaussian distribution, and the Spearman method was used for correlation analysis. A value of $P < 0.05$ was considered statistically significant.

RESULTS

HPM inhibits tissue damage in colonic tissues of UC rats

When the colonic tissues were observed for morphological changes upon treatment, we observed that our UC model group exhibited edematous colonic mucosa and there was serious congestion, erosion, and ulcer formation as compared to the normal group, which exhibited a smooth colonic mucosa surface, clear vascular texture, and no erosion or ulcers. Interestingly, HPM treatment was able to decrease the observed changes in UC treated rats and return the colon to a more normal state, as the colonic mucosa surface of these rats was smooth, there was accidental edema, the vascular texture was clear, and congestion, edema and erosion were significantly reduced compared to the model group. As shown in Figure 1, the general morphological score of the colonic tissue in the model group was significantly higher than the normal group [6.0 (5.5-7.0) *vs* 0.0 (0.0-0.0), $P = 0.000$]. After treatment, the scores were lower in both the HPM group [3.5 (2.0-4.0) *vs* 6.0 (5.5-7.0), $P = 0.01$] and the control SA group [3.0 (1.5-3.5) *vs* 6.0 (5.5-7.0), $P = 0.002$]. This data suggests that HPM is able to dampen the tissue-damaging effects of UC.

HPM inhibits immunopathology in colonic tissues of UC rats

To evaluate whether HPM was also able to regulate the inflammatory cell infiltration that causes tissue damage in UC, we evaluated the extent of immunopathology by looking for inflammatory cell tissue infiltration by HE staining. As shown in Figure 2A-D, the colonic mucosa and mucosa villi were damaged or missing in the UC model group, and large mononuclear cell and macrophage infiltration appeared in the mucosa or submucosa with congestion, edema, and ulceration as compared to the normal group, where the colonic mucosa epithelium was complete and the colonic gland was regularly arranged with inconspicuous inflammatory cell infiltration. However, HPM treatment decreased the inflammatory

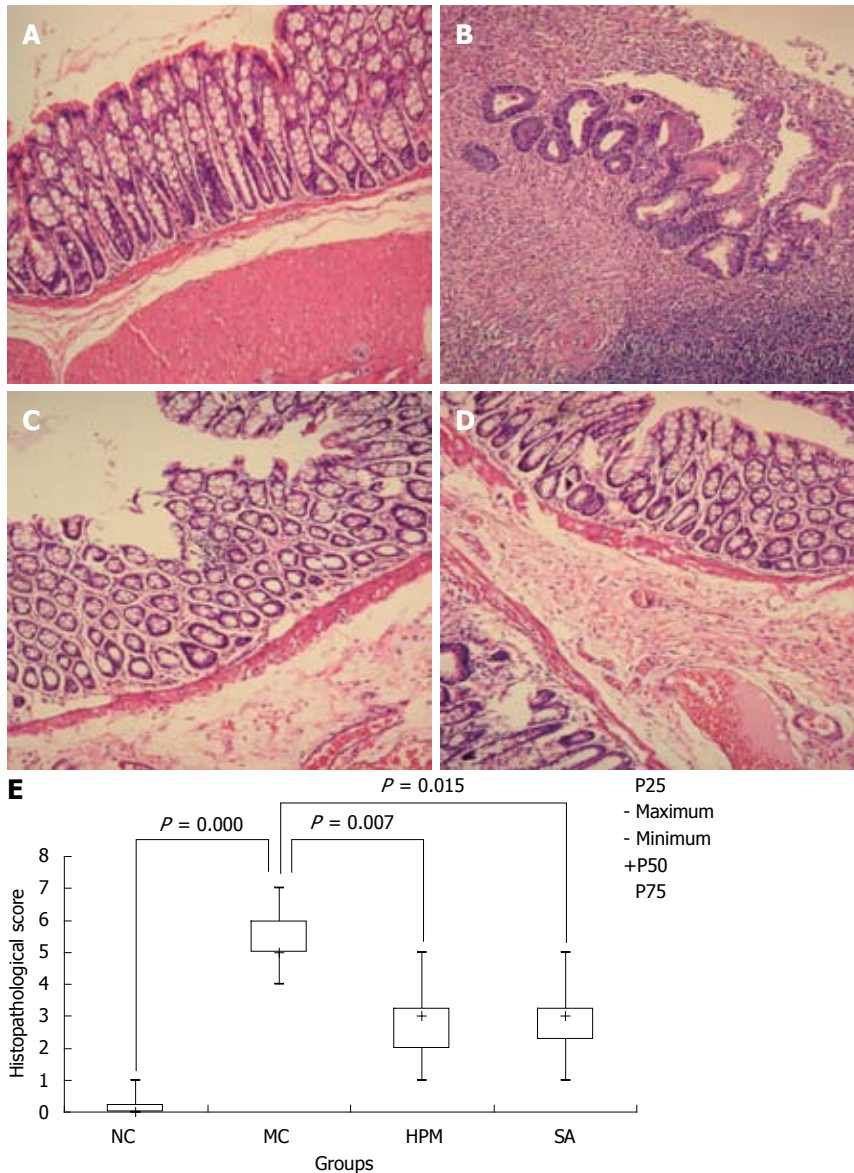

Figure 2 Herb-partition moxibustion inhibits immunopathology and decreases the histopathological scores in colonic tissues of rats with ulcerative colitis. A: Normal; B: Ulcerative colitis (UC); C: Herb-partition moxibustion (HPM); D: Sulfasalazine (SA); E: The histopathological scores for the colonic tissue in the UC model control (MC) group were significantly higher than the normal control (NC) group ($P = 0.000$). After treatment, the scores were lower in both the HPM group ($P = 0.007$) and SA group ($P = 0.015$). The colonic mucosa was damaged in the UC model group with cell infiltration, congestion, edema, and ulceration. After HPM treatment, there are only slight submucosal edema and inflammatory cell infiltration, and the colonic mucosa epithelium and the colonic gland were more regularly arranged than in the model group, new epithelial cells were observed to be covering the ulcers. Positive control SA treatment showed similar recovery of the UC model as the HPM group.

cell infiltration and the ensuing immunopathology, as we observed only slight submucosal edema and inflammatory cell infiltration, and the colonic mucosa epithelium and the colonic gland were more regularly arranged than in the model group. Additionally, new epithelial cells were observed to be covering the ulcers that developed under UC conditions, indicating that HPM treatment could induce recovery of these ulcers. Positive control SA treatment showed similar recovery of the UC model as the HPM group. As shown in Figure 2E, the histopathological scores for the colonic tissue in the model group were significantly higher than the normal group [5.00 (4.50-5.50) *vs* 0.00 (0.00-0.50), $P = 0.000$]. After

treatment, the scores were lower in both the HPM group [3.00 (2.00-3.50) *vs* 5.00 (4.50-5.50), $P = 0.007$] and SA group [3.00 (2.50-3.50) *vs* 5.00 (4.50-5.50), $P = 0.015$]. Taken together, these data indicate that HPM treatment can inhibit inflammatory cell infiltration under UC conditions and therefore limit the resulting immunopathology in the colon tissue.

HPM treatment rebalances the colonic intestinal flora of UC rats

Because the deregulation of intestinal flora is now understood to be a major component of UC pathogenesis, we tested whether HPM could restore the balance of

Figure 3 Herb-partition moxibustion treatment increases the colonic *Bifidobacterium* and *Lactobacillus* of rats with ulcerative colitis. The DNA copies of the symbiotic groups *Bifidobacterium* and *Lactobacillus* were both significantly decreased in the ulcerative colitis (UC) group compared to the normal control (NC) group ($P = 0.000$). After herb-partition moxibustion (HPM) treatment, the DNA copies of *Bifidobacterium* and *Lactobacillus* were both significantly increased in the HPM group ($P = 0.001$ and $P = 0.000$) and sulfasalazine (SA) group ($P = 0.000$ and $P = 0.000$) compared with the UC model group.

the bacteria species back to normal by using the readout of the levels of symbiotic and pathogenic bacteria. To do this, we tested the levels of species-specific bacterial DNA by detecting 16S RNA from rat feces among the different groups. As shown in Figure 3, DNA copies of the symbiotic groups *Bifidobacterium* and *Lactobacillus* were both significantly decreased in the UC group compared to the normal group ($0.045 \pm 0.036 \times 10^5$ vs $6.707 \pm 1.595 \times 10^5$ for *Bifidobacterium*, $0.0015 \pm 0.0014 \times 10^7$ vs $3.254 \pm 1.395 \times 10^7$ for *Lactobacillus*, $P = 0.000$). After HPM treatment, the levels were restored, because DNA copies of *Bifidobacterium* and *Lactobacillus* were both significantly increased in the HPM group and SA group compared with the model group (1.395 ± 1.339 , 1.461 ± 1.152 vs $0.045 \pm 0.036 \times 10^5$, $P = 0.001$ in HPM group and $P = 0.000$ in SA group for *Bifidobacterium*, and 0.395 ± 0.325 , 0.851 ± 0.651 vs $0.0015 \pm 0.0014 \times 10^7$, $P = 0.000$ for *Lactobacillus*). As shown in Figure 4, the DNA copies of the pathogenic bacteria *B. fragilis* and *E. coli* were both significantly increased in the UC rats compared to the normal rats (1.285 ± 1.039 vs $0.097 \pm 0.063 \times 10^5$ for *B. fragilis*, 1.691 ± 0.683 vs $1.691 \pm 0.683 \times 10^5$ for *E. coli*, $P = 0.000$). After HPM treatment, the DNA copies of *B. fragilis* and *E. coli* were both significantly decreased in the HPM group and SA group compared with the UC model group ($0.351 \pm 0.181 \times 10^5$, $0.416 \pm 0.329 \times 10^5$ vs $1.285 \pm 1.039 \times 10^5$, $P = 0.001$ for *B. fragilis* and $0.244 \pm 0.107 \times 10^5$, $0.628 \pm 0.257 \times 10^5$ vs $1.691 \pm 0.683 \times 10^5$, $P = 0.000$ in HPM group and $P = 0.003$ in SA group for *E. coli*). These data indicate that HPM treatment can rebalance the intestinal flora toward more normal levels after alteration under UC conditions.

Figure 4 Herb-partition moxibustion treatment decreases the colonic pathogenic bacteria *Bacteroides fragilis* and *Escherichia coli* of rats with ulcerative colitis. The DNA copies of the pathogenic bacteria *Bacteroides fragilis* (*B. fragilis*), and *Escherichia coli* (*E. coli*) were both significantly increased in the ulcerative colitis (UC) rats compared to the normal control (NC) rats ($P = 0.000$). After herb-partition moxibustion (HPM) treatment, the DNA copies of *B. fragilis* and *E. coli* were both significantly decreased in the HPM group ($P = 0.001$ and $P = 0.000$) and sulfasalazine (SA) group ($P = 0.001$ and $P = 0.003$) compared with the UC model group.

HPM inhibits the secretion of the pro-inflammatory mediators TNF- α and IL-12 in the colon tissue of UC rats

To determine whether the HPM-induced reduction of inflammation was due to an effect of HPM on the secretion of pro-inflammatory cytokines, we measured TNF- α and IL-12 levels in colon tissue by immunohistochemistry. As shown in Figure 5A1-E1, TNF- α expression was significantly increased in the UC model group compared to the normal group ($650\,313.82 \pm 65\,996.76$ vs $48\,384.84 \pm 9\,438.98$, $P = 0.000$). After treatment, TNF- α expression was significantly decreased in both the HPM group and SA group compared with the UC model group ($231\,783.33 \pm 50\,222.65$, $283\,668.65 \pm 44\,978.06$ vs $650\,313.82 \pm 65\,996.76$, $P = 0.000$). There was a difference in TNF- α expression between the HPM group and positive control SA group ($231\,783.33 \pm 50\,222.65$ vs $283\,668.65 \pm 44\,978.06$, $P = 0.034$). As shown in Figure 5A2-E2, IL-12 expression was significantly increased in the model group compared to the normal group ($901\,708.26 \pm 215\,867.35$ vs $76\,799.88 \pm 15\,270.78$, $P = 0.000$). HPM treatment inhibits IL-12 expression because it was significantly decreased in both the HPM group and positive control SA group compared with the model group ($333\,652.88 \pm 121\,428.18$, $512\,202.17 \pm 95\,369.17$ vs $901\,708.26 \pm 215\,867.35$, $P = 0.001$ in the HPM group and $P = 0.012$ in the SA group). There was a difference in IL-12 expression between the HPM group and the SA group ($333\,652.88 \pm 121\,428.18$ vs $512\,202.17 \pm 95\,369.17$, $P = 0.033$). This data indicates that HPM treatment exerts its anti-inflammatory effects through the inhibition of pro-inflammatory cytokine secretion, such as TNF- α and IL-12.

Figure 5 Herb-partition moxibustion inhibits the secretion of the pro-inflammatory mediators tumor necrosis factor- α and interleukin-12 in the colon tissue of rats with ulcerative colitis ($\times 400$). A1, A2: Normal control; B1, B2: Ulcerative colitis (UC); C1, C2: Herb-partition moxibustion (HPM); D1, D2: Sulfasalazine (SA). A1-E1: Tumor necrosis factor- α (TNF- α) expression was significantly increased in the UC model group compared to the normal group ($P = 0.000$). After treatment, TNF- α expression was significantly decreased in both the HPM group ($P = 0.000$) and SA group ($P = 0.000$) compared with the UC model group. There was a difference in TNF- α expression between the HPM group and positive control SA group ($P = 0.034$); A2-E2: Interleukin-12 (IL-12) expression was significantly increased in the model group compared to the normal group ($P = 0.000$). HPM treatment inhibits IL-12 expression because it was significantly decreased in both the HPM group ($P = 0.001$) and positive control SA group ($P = 0.012$) compared with the model group. There was a difference in IL-12 expression between the HPM group and SA group ($P = 0.033$). IOD: Integrated optical density per dye.

DISCUSSION

In normal physiological conditions, the overgrowth of pathogenic microorganisms is kept in check by the balance of gut flora species as well as the interaction between microbes and the host's immune system. These mechanisms limit the pathogenic microorganisms from sticking to the intestinal mucosa and act as a biological barrier to the host^[7,27,28]. Altered bacterial composition and function of the gut flora in UC results in increased immune stimulation, epithelial dysfunction, and enhanced mucosal permeability^[7]. Moreover, this barrier dysfunction leads to increased recognition of pathogens and their metabolites by the immune system and cause an abnormal intestinal immune response^[7] that constantly stimulates intestinal epithelium cells, among other effects. This immune response leads to the production of a large amount of cytokines, such as TNF- α , IL-12 and IL-6, that further aggravate the local immune response of the intestinal mucosa and cause continual damage of the intestinal mucosa^[29,30]. In recent years, studies have widely focused on the relationship between intestinal bacteria and UC. Changes in gut flora have been considered as key in the initiation and maintenance stages of the inflammatory processes in UC^[7,10,31-35]. There is evidence to support that UC patients undergo alterations in intestinal flora: the amount of *Enterobacter*, *Enterococcus*, and small-bowel *Clostridium* increased significantly, while *Bifidobacteria* and *Lactobacilli* decreased significantly in acute UC. In patients undergoing remission from UC, bacteroid and *Bifidobacteria* were increased markedly and small-bowel *Clostridium* was decreased significantly^[36,37]. In some studies, bacteroids were significantly increased^[38] and *Bifidobacteria* and *Lactobacilli* in the gut were both decreased in acute and remission UC^[39]. Other studies have indicated that *Bifidobacteria*, *Lactobacilli*, and *Fusobacterium* in the gut of UC patients decreased significantly, while *Bacteroides*, *E. coli*, and *Desulfovibrio* increased remarkably^[3-6]. The results of the present study showed that *Bifidobacteria* and *Lactobacilli* decreased significantly, while *E. coli* and *B. fragilis* significantly increased by testing the bacterial DNA copy numbers in the stool of UC rats as compared to normal rats. These results indicate that gut flora alterations also occur in the rat model of UC used in these studies and provide further evidence that alterations in gut flora play an important role in the pathogenesis of UC.

In recent years, modulation of gut flora has been suggested as an approach to treat UC. The balance between beneficial and detrimental bacterial species determines homeostasis *vs* inflammation. This balance can be manipulated by antibiotics, probiotics, and prebiotics to treat and prevent relapses of UC^[40]. Additionally, alternative treatments or complementary therapy, such as the use of probiotics, have been considered good candidates for treatment of UC because there are less problems with resistance, it means less risk for the development of bacterial resistance to antibiotic treatment, and there are less potential side effects and fewer ecological concerns

than using antibiotic drugs^[41]. Our previous studies in humans have indicated that HPM treatment is safe and has a therapeutic effect on UC patients^[12-14]. To determine the mechanism of how HPM might control UC, the aim of this study was to analyze whether HPM can modulate the gut flora in a rat model of UC. The results shown here demonstrate that HPM treatment does indeed alter the intestinal flora bacterial composition, as *Bifidobacteria* and *Lactobacilli* increased significantly, while *E. coli* and *B. fragilis* decreased remarkably in the stool of HPM-treated UC rats as compared to the stool of UC rats without treatment. Damage to the colonic mucosa was also remarkably improved after HPM treatment of UC rats, which indicated that the alteration of the gut flora back towards normal rat flora correlated with increased recovery of gut pathology in the UC rats treated with HPM. Therefore, HPM could modulate the alteration of gut flora in the UC rat model, recover intestinal micro-ecological balance, and inhibit the development and/or maintenance of gut pathology. The resultant modulation of gut flora by HPM is similar to that of probiotic supplements^[29], and therefore deserves further study as an alternative treatment for UC symptoms.

IL-12 and TNF- α are pre-inflammation factors and play an important role in the pathology of intestinal bowel disease (IBD). IL-12 from dendritic cells induces the differentiation of CD4⁺ T cells to Th1 cells. IL-12 also stimulates natural killer cells and T cells to secrete γ -interferon and TNF- α cytokines to mediate the inflammation. TNF- α cooperates with γ -interferon and can change the function of the intestinal barrier; it can also enhance the permeability of the mucous membrane or induce apoptosis of bowel epithelial cells. This tissue damage is the key process in the colonic inflammatory response in UC^[3,39] and is closely related to the pathogenesis of UC^[4,5]. Studies have revealed that IL-12 protein and mRNA expression is increased and correlates with the active index score of UC^[5,6]. IL-12 and TNF- α are significantly increased in the peripheral blood of patients with IBD^[40-43]. These previous studies indicate the relevance of IL-12 and TNF- α cytokines in the initiation and maintenance of UC pathogenesis.

Previous studies showed that HPM could rectify abnormal mucosal immune responses^[43], regulate the expression of IL-1 and IL-1 β ^[44,45], and improve intestinal mucus damage by down-regulating the expression of TGF- β 1 and IGF-1 in the inflamed tissue of UC^[46,47]. The results of the present study indicate that TNF- α and IL-12 are expressed at low levels in the colonic mucosa and the submucosa of normal rats. However, in UC rats, TNF- α and IL-12 were expressed at high levels that correlated with the observed higher morphological and histopathological scores. After HPM treatment, however, the expression of TNF- α and IL-12 decreased and the general morphological and histopathological scores were lower than those of the UC group, indicating that HPM treatment had an anti-inflammatory effect and improved the UC-mediated pathology. These results further support the previous reports that suggest that HPM can

improve the inflammatory response induced by UC, and that the mechanism may be regulation of the expression of inflammatory cytokines IL-6, IL-1 β , TNF- α , and IL-12 in the colon mucosa of UC rats.

Additionally, the intestinal flora and their products have been found to trigger cytokine expression, such as inducing TNF- α in macrophage and epithelial cell systems of inflammatory bowel disease^[48]. In addition to restoring beneficial intestinal flora, probiotics may enhance host protective immunity such as down-regulation of pro-inflammatory cytokines, IL-12 and TNF- α in colitis^[49,50]. Rifaximin administration decreased the protein and mRNA levels of IL-12 and TNF- α , and caused a significant reduction of colon bacterial translocation towards mesenteric lymph nodes, in colon of 2, 4, 6-trinitrobenzene sulfonic acid-induced colitis in mice^[51]. The results of this study showed that HPM can modulate intestinal flora towards a more normal flora and inhibit the expression of TNF- α and IL-12 in UC rats. These indicate that there may be a relationship between the release of IL-12 /TNF- α and the modulation of bacterial flora.

In conclusion, we suggest that HPM can modulate intestinal flora towards a more normal flora and inhibit the expression of the pro-inflammatory mediators TNF- α and IL-12 in UC rats. Therefore, whether HPM can improve the intestinal inflammation response of UC by modulating intestinal flora deserves further study as a treatment for patients suffering with UC.

COMMENTS

Background

Intestinal flora plays an important role in human health. Previous studies indicated that herb-partition moxibustion (HPM) has a beneficial effect on ulcerative colitis (UC), not just to relieve the symptoms, but also to improve the stool property, but whether the effect of HPM is related to intestinal flora remains unknown.

Research frontiers

More and more data show that the key role of bacteria in the pathogenesis of inflammatory bowel disease, which has become a hot spot of study.

Innovations and breakthroughs

This study is the first to report on the effects of HPM on intestinal flora of UC. HPM treatment can regulate intestinal flora of the UC model rat.

Applications

The experimental data can be used in the further study of moxibustion therapy in the treatment of inflammatory bowel disease.

Peer review

This is a good original study in which authors observed the relative proportions of both the symbiotic and most prevalent bacteria, and the conditioned pathogenic flora to explore the effects of HPM on modulating the intestinal flora of rats in a model of UC. They also investigated whether HPM regulates the expression of pro-inflammatory cytokines in colon tissues of UC rats. They concluded that HPM treatment regulates intestinal flora and inhibit the expression of interleukin-12 and tumor necrosis factor, indicating that HPM can improve colonic immune response.

Abstract

AIM: To systematically review these minimally invasive approaches to infected pancreatic necrosis.

METHODS: We used the MEDLINE database to investigate studies between 1996 and 2010 with greater than 10 patients that examined these techniques. Using a combination of Boolean operators, reports were retrieved addressing percutaneous therapy (341 studies), endoscopic necrosectomy (574 studies), laparoscopic necrosectomy *via* a transperitoneal approach (148 studies), and retroperitoneal necrosectomy (194 studies). Only cohorts with at least 10 or more patients were included. Non-English papers, letters, animal studies, duplicate series and reviews without original data were excluded, leaving a total of 27 studies for analysis.

RESULTS: Twenty-seven studies with 947 patients total were examined (eight studies on percutaneous approach; ten studies on endoscopic necrosectomy; two studies on laparoscopic necrosectomy *via* a transperitoneal approach; five studies on retroperitoneal necrosectomy; and two studies on a combined percutaneous-retroperitoneal approach). Success rate, complications, mortality, and number of procedures were outcomes that were included in the review. We found that most published reports were retrospective in na-

ture, and thus, susceptible to selection and publication bias. Few reports examined these techniques in a comparative, prospective manner.

CONCLUSION: Each minimally invasive approach though was found to be safe and feasible in multiple reports. With these new techniques, treatment of infected pancreatic necrosis remains a challenge. We advocate a multidisciplinary approach to this complex problem with treatment individualized to each patient.

INTRODUCTION

Most cases of acute pancreatitis are self-limited and resolve without serious complications. However, severe acute pancreatitis is associated with the development of potentially life-threatening complications including pancreatic necrosis and pancreatic abscess. The 1992 international consensus conference held in Atlanta established uniform terminology for acute pancreatitis and its complications. According to the Atlanta Classification, pancreatic necrosis refers to diffuse or focal areas of nonviable pancreatic parenchyma, typically associated with peripancreatic fat necrosis, whereas pancreatic abscess is defined as a circumscribed intra-abdominal col-

lection of pus, usually in proximity to the pancreas arising as a consequence of acute pancreatitis or pancreatic trauma^[1]. Treatment for pancreatic necrosis has evolved considerably over the past decade with respect to both the timing of intervention and the development of alternatives to traditional open necrosectomy.

Pancreatic necrosis may be sterile or infected. The prognosis (with or without intervention) is much worse for infected than sterile necrosis. Historically, early surgical intervention was considered mandatory for cases of suspected infection. The 2002 International Acute Pancreatitis (IAP) guidelines recommended early fine-needle aspiration to discriminate between sterile and infected pancreatic necrosis, with continued non-operative management for stable or improving patients with sterile necrosis but surgical intervention for those with documented infection^[2]. The traditional surgical approach to infected necrosis was open necrosectomy with the goals of wide drainage of all infected compartments and complete removal of all necrotic tissue with the placement of drains for continuous postoperative closed lavage. Frequently, repeat laparotomy was needed to ensure complete debridement^[2]. Historically, open necrosectomy was associated with substantial morbidity and rates of perioperative mortality that exceeded 50% in some reports^[3,4], although mortality in some contemporary series has been 11% or lower^[5,6].

Because various studies showed high mortality with early operation for severe necrotizing pancreatitis, the IAP recommended avoidance of surgical intervention within the first 14 d after onset unless there was progressive multiple organ failure and clinical deterioration. Subsequent studies suggested that morbidity and mortality can be further reduced if operation is delayed beyond 28–30 d^[7], presumably because the extended interval allows sufficient demarcation between normal and necrotic tissue, thereby reducing the risk of inciting overwhelming postoperative septic and systemic inflammatory responses, as well as the risk of intraoperative injury to surrounding organs and hemorrhage.

In addition to the open approach for pancreatic necrosis and abscess, the last two decades have brought about alternative “minimally-invasive” techniques. Percutaneous drainage of infected pancreatic necrosis has been shown to be safe and effective in highly-selected patients^[8,9], but multiple procedures are often needed, and adjunctive treatment is often required.

Gagner^[10] first described minimally invasive surgical treatment of necrotizing pancreatitis in 1996, including laparoscopic retrocolic, retroperitoneoscopic, and transgastric procedures. Over the past 15 years, a number of other minimally invasive surgical, endoscopic, and radiological approaches to drain and debride pancreatic necrosis have been described. These alternatives appear to be feasible and safe, although comparisons among approaches have been difficult due to small numbers, lack of uniform reporting criteria, and varying degrees of operator dependence. The advent of some of these

alternatives has led to reconsideration of some of the fundamental tenets of open surgical necrosectomy, particularly with respect to the timing and completeness of debridement. In this report, we review current techniques of minimally invasive pancreatic necrosectomy.

MATERIALS AND METHODS

A literature search was performed of the MEDLINE database from April 1996 to November 2010 for each of four techniques well described for minimally invasive necrosectomy: percutaneous therapy (341 studies), endoscopic necrosectomy (574 studies), laparoscopic necrosectomy *via* a transperitoneal approach (148 studies), and retroperitoneal necrosectomy (194 studies). Only cohorts with at least 10 or more patients were included. Non-English papers, letters, animal studies, duplicate series and reviews without original data were also excluded.

For percutaneous drainage, a search was conducted using subject headings: “percutaneous”, “drainage”, “pancreatic necrosis”, and “necrotizing pancreatitis” with the aid of Boolean operators. There were 341 initial hits in MEDLINE. After exclusion using the above-mentioned criteria, eight studies were included in this review.

For endoscopic necrosectomy, a search was conducted using subject headings: “endoscopic”, “endotherapy”, “drainage”, “pancreatic necrosis”, and “necrotizing pancreatitis” with the aid of Boolean operators. There were 574 initial hits in MEDLINE. After exclusion using the above-mentioned criteria, ten studies were included in this review.

For laparoscopic necrosectomy *via* a transperitoneal approach, a search was conducted using subject headings: “laparoscopic”, “minimally invasive”, “necrosectomy”, “pancreatic necrosis”, and “necrotizing pancreatitis” with the aid of Boolean operators. There were 148 initial hits in MEDLINE. After exclusion using the above-mentioned criteria, two studies were included in this review.

For retroperitoneal necrosectomy, a search was conducted using subject headings: “laparoscopic”, “minimally invasive”, “retroperitoneal”, “necrosectomy”, “pancreatic necrosis” and “necrotizing pancreatitis” with the aid of Boolean operators. There were 194 initial hits in MEDLINE. After exclusion using the above-mentioned criteria, five studies were included in this review.

RESULTS

Percutaneous therapy

The results of the literature search for percutaneous therapy for pancreatic necrosis are summarized in Table 1. Technique was similar throughout the studies, access to the area of necrosis was obtained utilizing ultrasound and/or computed tomography to place percutaneous drains ranging in size from 10 to 28 French drains. Afterward, saline flushes were often used every 8 h.

NA: Not available.

Eight studies included 286 patients ranging from 10 to 80 patients. There were six retrospective case series, one prospective case series^[15], and one randomized control trial^[11]. In the randomized control trial, percutaneous drainage was used as part of the minimally invasive “step-up” approach, in which a retroperitoneal necrosectomy was necessary in 65% of patients. This technique is further described later in the Results section under “combined approach”.

One hundred and twenty seven of 286 (44%) patients had successful percutaneous therapy and did not subsequently require surgical necrosectomy. Mortality was reported in 58 of 286 patients (20.2%). Complications were reported in 80 of 286 patients (28%) and included multiple organ failure^[8,11], colonic perforation^[16], intrabdominal bleeding^[8,11-13], gastrointestinal fistula^[8,11,12,14,15], biliary obstruction^[8], respiratory failure^[8], renal failure^[8], pancreatic fistula^[11,14], new-onset diabetes^[17], pseudocyst^[17], and use of pancreatic enzymes^[11].

Endoscopic necrosectomy

The results of the literature search for endoscopic necrosectomy for pancreatic necrosis are summarized in Table 1. Ten studies, all retrospective, included 352 pa-

tients ranging from 13 to 93 patients.

Two hundred and seventy four of 352 (78%) patients had successful endoscopic necrosectomy therapy and did not subsequently require surgical necrosectomy. Mortality was reported in 20 of 352 patients (5.6%). Complications were reported in 100 of 352 patients (28%) and included bleeding, fever^[20,23,24], gallbladder puncture^[23], hypotension^[23], deep-vein thrombosis/ pulmonary embolism^[23], peritonitis^[23], *Clostridium difficile colitis*^[25], perforation of necrosis into abdominal cavity^[18,22], pneumoperitoneum^[21,24,27], migration of stent into cyst^[21,23], post-endoscopic retrograde cholangiopancreatography pancreatitis^[24], fistula^[18,23], bowel obstruction^[23], and air embolism^[18]. Median follow up was reported as 5.7 mo to 43 mo.

The specific technique varied among the reports. Usually, a therapeutic or pediatric gastroscope or a viduodendoscope was used. Endoscopic ultrasound was used often to locate the necroma cavity and guide initial access. Transmural drainage was then usually performed followed by dilation and irrigation of the debris. This was accomplished most often *via* the stomach, although the duodenum was used in approximately 10%-50% of these patients. The size of the endoscopic cystgastros-

tomy was typically 1.5 cm to 2.0 cm. Endoscopic biopsy forceps and baskets was used to remove solid debris into the stomach, allowing it to be eliminated by digestion and peristalsis. Multiple pigtail stents were left in place to maintain cystgastrostomy patency, and often a nasocystic tube was left in place for post-procedure irrigation. On average, 3.2 endoscopic debridement procedures were necessary to achieve resolution of necrosis.

Laparoscopic necrosectomy

The results of the literature search for laparoscopic necrosectomy for pancreatic necrosis are summarized in Table 1. Two studies included 29 patients ranging from 10 to 19 patients^[28,29]. Each was a retrospective study.

Twenty-three of 29 (79%) patients had successful laparoscopic necrosectomy therapy and did not subsequently require open necrosectomy. Mortality was reported in 3 of 29 patients (10.3%). Complications were reported in only the study by Parekh^[28] and included *Clostridium difficile* infection, reintubation, central line infection, delirium tremens, pseudomonas pneumonia, and minor wound complications. The study also notes 11 patients were diagnosed with a pancreatic fistula. Thus the complication rate was calculated as 11 of 19 patients (58%). Zhu *et al*^[29] did not report complications of the procedure, only mortality. Median follow up was not available for either study.

Parekh^[28] described using three ports for access: a hand access device and two standard laparoscopic ports. Access to the retroperitoneum was obtained either through an infracolic approach or through the greater omentum between the stomach and colon. Gentle finger dissection was used for debridement and several drains were left for postoperative drainage. Four patients that were referred to the service were not considered for a laparoscopic approach because two patients had ileus and anasarca, and two patients had gastrointestinal perforations from prior interventions at other hospitals.

Zhu *et al*^[29] described using at least four standard ports, and going through the gastrocolic ligament to approach the pancreas. A fan retractor was used to elevate the stomach for exposure. Four to six drainage tubes were used for postoperative lavage. Selection criteria were not described.

Retroperitoneal necrosectomy

The results of the literature search for endoscopic necrosectomy for pancreatic necrosis are summarized in Table 1.

Five studies included 197 patients ranging from 10 to 137 patients^[17,30-33]. There were three retrospective studies^[17,30,31] and two prospective case series^[32,33]. 173 of 197 (88%) patients had successful retroperitoneal necrosectomy therapy and did not subsequently require open necrosectomy. Mortality was reported in 33 of 197 patients (17%). Complications were reported in 90 of 197 patients (46%) and included colonic fistula^[17], gastric perforation^[31], duodenal perforation^[31], enteric fistula^[30],

bleeding^[17,30,33], pseudocyst^[17,30,33], pancreatic fistula^[17], incisional hernia^[17], myocardial infarct^[30], cerebrovascular event^[30], biliary stricture^[30], pulmonary embolus^[30], colonic necrosis^[30], hepatic portal/superior mesenteric/splenic vein thrombosis^[30], *Clostridium difficile* infection^[30], residual abscess^[31], pneumonia^[31], respiratory and liver failure^[33], and gastric ileus^[33].

Technique varied among the five studies. Gambiez *et al*^[17] described using a short lumbotomy (6 cm in length) centered on the 12th rib. The spleen and descending colon (or ascending colon if on right side) were mobilized anteriorly and pancreas was accessed without violating the peritoneum. A 23 cm mediastinoscope was used for direct vision. Necrotic areas were removed with blunt dissection using a suction metal tube. A tube drain was left to facilitate later drainage. Similarly, Castellanos *et al*^[32] described a left translumbar approach. However, the group used a flexible endoscope for access followed by flushing and aspiration under direct guidance.

Chang *et al*^[31] described using a 5 cm skin incision below the costal margin, followed by blunt dissection. A Yankauer sucker was then used for probing the abscess cavity and/or removing necrotic discharge.

Raraty *et al*^[30] described first placing a 12F pigtail catheter under CT-guidance. After moving the patient to the operating room, the catheter was exchanged over a guide wire with serial dilators to 30F size. A nephroscope was then used for access, and a metal forceps used for piecemeal removal. Two drains were placed for irrigations. Carter *et al*^[33] used a similar technique with the nephroscope but also used a flexible endoscope for direct access.

Combined approach

Based on anecdotal success of percutaneous radiological and endoscopic necrosectomy used as primary therapy with avoidance of open necrosectomy, an increasing number of reports have utilized combinations of non-surgical approaches to treat pancreatic necrosis. A prospective randomized multicenter trial called the Minimally Invasive Step Up Approach Versus Maximal Necrosectomy in Patients with Acute Necrotising Pancreatitis (PANTER) was recently performed in the Netherlands^[11]. After the diagnosis of necrotizing pancreatitis or infected pancreatic necrosis was made, patients were randomly assigned to either a “step-up” approach or open necrosectomy. The step-up approach consisted of percutaneous drainage or endoscopic drainage, followed by a minimally invasive retroperitoneal necrosectomy if necessary. A video-assisted retroperitoneal debridement (VARD) with postoperative lavage was then performed three days after if there was no clinical improvement. Major complications or death occurred in 31 of 45 patients after open necrosectomy (69%) *vs* 17 of 43 patients after the step-up approach (40%) (risk ratio with the step-up approach, 0.57; 95% CI, 0.38 to 0.87; *P* = 0.006). About 35% of patients in the step up group were successfully able to be managed with percutaneous drainage only^[11].

Similar to the PANTER Trial, there is also a recent, prospective multicenter, single-arm study based out of the University of Washington. Percutaneous drainage was used as initial treatment for infected pancreatic necrosis. If there was a 75% reduction in size based on follow-up scan 10 d later, the remainder of their treatment would be percutaneous drains alone. If patients did not have a 75% reduction they were treated with a VARD. Twenty-three percent of patients were treated with percutaneous drains only. Sixty percent of patients were treated with a “minimally invasive intervention” (drains with or without VARD). Mortality at 30 d was 2.5%.

The results of these two studies are summarized in Table 1.

DISCUSSION

Infected pancreatic necrosis and pancreatic abscess are serious complications of severe acute pancreatitis. However, the last two decades have demonstrated much innovation and variety in minimally invasive techniques. These new techniques can potentially lower the significant morbidity and mortality of these complications. The less invasive approach can potentially keep an infection compartmentalized, specifically avoiding contamination of virgin spaces, such as the peritoneal cavity. It may reduce systemic inflammatory and septic response as a consequence of a major open operation and release of infected necrosis.

The percutaneous approach to infected pancreatic necrosis has been shown to be safe and feasible in multiple retrospective case series. It is significant to note, 44% of patients in the studies reviewed did not need surgical therapy. Conclusions are limited, however, since the studies are retrospective and small. We limited our review to include only studies that examined 10 or greater patients. Selection criteria was also not often reported and thus, it may be difficult to predict which subset of patients would most benefit from percutaneous drainage alone. In addition, repeat procedures were often needed, ranging from 1 to 12 procedures in the above-mentioned studies. What has become increasingly popular is the combination of percutaneous technique combined with a VARD as mentioned in the PANTER trial and the Horvath study^[11,34]. These studies not only confirmed that there is a subgroup of patients that can benefit from percutaneous drainage alone but also examined a combined technique in a prospective fashion with a relatively larger amount of patients.

The endoscopic approach to necrosectomy has also been shown to be safe and feasible with an acceptable procedure-related morbidity. The endoscopic ultrasound has allowed this approach to evolve allowing a better definition of the fluid collection and surrounding vasculature. The approach can also be used in poor risk surgical candidates. However, this technique though is not available at all institutions and often there is a need for repeated procedures for maximal drainage. Furthermore, not all pancreatic abscesses and pancreatic necrosis are

accessible *via* a transgastric or transduodenal approach. Like percutaneous drainage alone, often repeat procedures are needed.

Laparoscopic necrosectomy may provide better access to fluid collections not amenable to endoscopic approach. This may facilitate a more thorough debridement of the cavity. The laparoscopic approach has also been demonstrated to be safe in several small case series. In the two studies reported 23 of 29 (79%) patients did not require an open necrosectomy. As previously discussed, these are highly selected patients: these were likely stable patients that were able to tolerate pneumoperitoneum. Morbidity still exists in this approach including enterocutaneous and pancreatic fistulas.

Similar to the laparoscopic approach, retroperitoneal necrosectomy has been shown to be effective in select patients: 173 of 197 (88%) patients did not need an open necrosectomy. The approach has the theoretical advantage of not having transmission of intraperitoneal infection from the necrotic area compared to laparoscopy. This technique allows access to areas not accessible *via* endoscopy and the potential to remove all necrotic tissue from the area.

Because of their relatively rare presentation, reports on these minimally invasive approaches to pancreatic necrosis and abscess have mostly small numbers of patients and are mostly retrospective in nature. Selection and publication bias is inherent in these studies and the low morbidity and mortality demonstrated in these studies have to be interpreted as such. There is also a significant amount of heterogeneity and variety of technique within each type of different approach.

In addition, several studies utilize a combined technique using percutaneous drainage first followed by endoscopic, laparoscopic, or retroperitoneal necrosectomy. Percutaneous drainage likely temporizes the patient in early phases of infected necrosis.

In the future, we look for more prospective studies that use definitions as laid out clearly by the Atlanta classification. Several of the above studies do not strictly adhere to those classifications. Furthermore, complications, specifically major ones including pancreatic or enteric fistula and major hemorrhage should separately be reported. Additionally, some studies do not report the amount of days from presentation to time of necrosectomy. It is well-accepted now that a delay of 28 d between onset of symptoms and intervention can potentially lower morbidity and mortality^[7].

Up until recently, there has been no comparison of results between open necrosectomy and these minimally invasive techniques. The only randomized control trial to date comparing a minimally invasive approach versus an open approach is the PANTER trial recently published. The minimally invasive approach is actually a “step-up” approach in which the first step is either a percutaneous or endoscopic transgastric approach. A VARD procedure was then performed if those approaches were unsuccessful or if the patient did not clinically improve in 72 h. The step-up approach reduced the rate of the

composite end point of major complications or death. In addition, the step-up approach yielded less incisional hernias and new-onset diabetes. The authors hypothesize that in open necrosectomy, there is potentially viable pancreatic parenchyma that is unintentionally debrided leading to diabetes as a late complication. This is potentially the reason why other minimally invasive techniques have shown good outcomes.

It is important to note, that the PANTER trial is not a direct comparison between open necrosectomy and minimally invasive necrosectomy, rather a comparison between treatment strategies. Perhaps this is a better model moving forward in contrast to doing direct comparisons between open necrosectomies or among the different types of minimally invasive approaches. It is likely that these pancreatic fluid collections are amenable to multiple approaches.

Complications of severe acute pancreatitis remain a complex problem to treat. We advocate a multidisciplinary approach with interventional radiologists, gastroenterologists, intensivists, and hepatobiliary surgeons at tertiary care centers. Since comparison data is limited, the minimally invasive approach should be based on location of lesion and individual patient presentation. Challenges moving forward will be learning curves, technology improvements, and product cycles of new techniques. This report provides a brief overview of the evolving minimally invasive approaches as alternatives to open necrosectomy.

COMMENTS

Background

A variety of minimally invasive approaches have been described for treatment of infected pancreatic necrosis and pancreatic abscess.

Research frontiers

Early, open necrosectomy for infected pancreatitis was the traditional mainstay of surgical therapy for these critically ill patients. Current practice has shifted toward, with intervention ideally delayed for a minimum of two and preferably four weeks from the onset of illness. Moreover, various minimally invasive surgical, endoscopic, and percutaneous drainage/debridement strategies have emerged as alternatives to open operation.

Innovations and breakthroughs

This systematic review summarized studies published between 1996 and 2010 with greater than 10 patients. The quality of these published reports is limited by their retrospective design, selection bias, and possible publication bias.

Applications

Treatment algorithms for infected pancreatic necrosis should be multidisciplinary, reflective of local expertise and experience, and tailored to the individual presenting circumstances of each patient.

Terminology

Pancreatic necrosectomy refers to the debridement and drainage of necrotic pancreatic and peripancreatic tissue.

Peer review

An exhaustive review of the literature leading to the best summary of minimally invasive surgical approaches to infected pancreatic necrosis.

Abstract

AIM: Evaluation of the wide range of normal findings in asymptomatic women undergoing dynamic magnetic resonance (MR) defecography.

METHODS: MR defecography of 10 healthy female volunteers (median age: 31 years) without previous pregnancies or history of surgery were evaluated. The rectum was filled with 180 mL gadolinium ultrasound gel mixture. MR defecography was performed in the supine position. The pelvic floor was visualized with a dynamic T2-weighted sagittal plane where all relevant pelvic floor organs were acquired during defecation. The volunteers were instructed to relax and then to perform straining maneuvers to empty the rectum. The pubococcygeal line (PCGL) was used as the line of reference. The movement of pelvic floor organs was mea-

sured as the vertical distance to this reference line. Data were recorded in the resting position as well as during the defecation process with maximal straining. Examinations were performed and evaluated by two experienced abdominal radiologists without knowledge of patient history.

RESULTS: Average position of the anorectal junction was located at -5.3 mm at rest and -29.9 mm during straining. The anorectal angle widened significantly from 93° at rest to 109° during defecation. A rectocele was diagnosed in eight out of 10 volunteers showing an average diameter of 25.9 mm. The bladder base was located at a position of +23 mm at rest and descended to -8.1 mm during defecation in relation to the PCGL. The bladder base moved below the PCGL in six out of 10 volunteers, which was formally defined as a cystocele. The uterocervical junction was located at an average level of +43.1 mm at rest and at +7.9 mm during straining. The uterocervical junction of three volunteers fell below the PCGL; described formally as uterocervical prolapse.

CONCLUSION: Based on the range of standard values in asymptomatic volunteers, MR defecography values for pathological changes have to be re-evaluated.

INTRODUCTION

As a result of the complex anatomy and synergism of pelvic organs and their muscular structures, there is a wide variety of static and functional disorders. Outlet obstruction, anism, dyskinesia of the puborectal muscle, intussusception, prolapse of the anus and rectum, vaginal prolapse, rectocele, cystocele, and enterocele represent common diagnoses in proctology, urology and gynecology. Besides constipation, fecal or urinary incontinence is the most common symptom, with serious problems for the patients that have a major negative impact on quality of life. Women are affected at a significantly higher rate with a ratio of 9:1^[1]. Patients usually attend gynecologists, urologists and proctologists. Therefore, a comprehensive interdisciplinary approach for diagnosis and therapy is the most promising strategy.

A systematic medical history as well as a thorough proctological examination (inspection, palpation, rectoscopy, and proctoscopy) along with manometry and endosonography is the basic diagnostic approach for complex pelvic floor disorders. Furthermore, radiological imaging with evacuation proctography can give important additional information^[2].

With the development of magnetic resonance imaging (MRI) technology, dynamic MRI of the pelvic floor has become an important alternative for the diagnosis of complex combined pelvic floor disorders. Since its first introduction by Yang *et al.*^[3] and Krut *et al.*^[4] in 1991, MRI has increasingly replaced evacuation proctography, which was first described in 1952 by Walldén^[5], for evaluation of outlet obstruction.

For the evaluation of extraluminal pelvic disorders such as enterocele or utero-vaginal prolapse, MRI of the pelvic floor is favorable in several aspects compared to clinical examination and conventional evacuation proctography, which does not depict extraluminal structures^[3,4,6-10]. Additionally, MRI examination can be repeated because of the total lack of ionizing radiation. This may increase the chances of detecting pathological findings in some patients^[9]. The horizontal position of the patient during MR defecography may be a disadvantage, because it could influence the pelvic floor physiology as well as the dynamic defecation process. Therefore, some authors consider that videoproctography is still superior to MRI for assessment of an enterocele or rectocele^[11,12].

So far, patient preparation, examination technique, as well as reference lines for the evaluation of MRI are still not standardized and findings differ widely in the current literature. Most of the previously performed studies did not examine the defecation process itself. Normal find-

ings and values were defined in small control groups and therefore were only applicable within the particular study setting.

The aim of the present study was to show the wide range of normal findings in asymptomatic female volunteers and therefore the necessity of obtaining common standards not only in terms of patient preparation, but also in the evaluation of numeric values for the definition of pathological and normal dynamic MR examinations of the pelvic floor.

MATERIALS AND METHODS

Volunteers

Ten healthy female volunteers (median age: 31 years, range: 22-40 years) without previous pregnancy or history of any gynecological, urological or proctological surgery were evaluated by dynamic pelvic MRI. The volunteers had no symptoms of incontinence, constipation or other stool evacuation problems. None of the volunteers had any contraindications for MRI. Informed consent was obtained from all volunteers. We applied a uniform admission questionnaire for standardized documentation of patient history. The study was approved by the local ethics committee.

Dynamic MRI of the pelvic floor

All healthy volunteers were asked to empty their bladder 3 h before the examination to achieve a medium filling of the urinary bladder during MRI. The rectum was filled with 180 mL ultrasound gel mixture (1% Gd-DTPA-GEL-Mixture). MRI (1.5 Tesla MRI, Magnetom Symphony; Siemens, Erlangen, Germany) was performed in the supine position with hips and knees bent at 45°. The pelvic floor was visualized in three planes (transversal, coronal, sagittal, T1 and T2) to find the appropriate sagittal plane in which all relevant pelvic floor organs were acquired during defecation over 55 s at a frequency of one shot per 1.1 s [True FISP (True Fast Imaging with Steady State Precession), TR: 5.8 ms, TE: 2.8 ms). Slice thickness was 7 mm (field of view: 270 mm × 270 mm, matrix 256 × 256). During the examination, healthy volunteers were instructed via headphones. They first were asked to relax and then to perform straining maneuvers to empty the rectum as completely as possible. The sequences were acquired digitally and analyzed cinematographically.

MRI evaluation

The pubococcygeal line (PCGL) was defined as the line of reference (Figure 1). Movement of pelvic floor organs was measured as the vertical distance with reference to this line. The location of structures above the PCGL were marked with positive values (+), structures located below this line were marked negative (-).

Data were recorded in the resting position as well as during the defecation process with maximal straining. All data represents mean values with corresponding SD.

Figure 1 The pubococcygeal line (black) according to Yang *et al*^[3] from the most inferior part of the pubic symphysis to the last coccygeal joint; furthermore, gray dots show (from left to right) bladder base, uterocervical junction, and anorectal junction.

The anorectal junction was defined as the intersection point of the central axis of the anal canal and a line along the posterior rectal wall. The anorectal angle was measured between these two lines^[3,7,9].

According to the current literature, based on different evaluation techniques, a rectocele is defined as a bulge of the anterior rectal wall of > 20 –30 mm^[11,13]. For our data analysis we applied the method described by Delemarre, who defined the distance from the anorectal junction to the tip of the protrusion of the anterior rectal wall as the correct measurement^[11].

MRI revealed data about the position of the bladder base, the uterocervical junction and the vagina. Additionally the location of small bowel in relation to the PCGL was assessed.

A cystocele and a uterovaginal prolapse were diagnosed if the bladder base or the uterocervical junction fell below the PCGL during defecation^[9,10]. Widening of the rectovaginal space or a descent of mesenteric parts, small bowel or sigmoid colon beyond the PCGL during defecation was defined as an enterocele^[8,10].

All examinations were performed and evaluated in consensus by two experienced board-certified abdominal radiologists without any knowledge of the volunteers history or age.

RESULTS

All 10 volunteers were able to hold the rectal enema and perform defecation within the MR scanner according to the examination protocol. The average position of the anorectal junction was located at -5.3 mm (± 9.9 mm) at rest and descended to -29.9 mm (± 10.3 mm) during maximal straining. The average anorectal angle widened significantly from 93° ($\pm 4.8^\circ$) at rest to 108.7° ($\pm 14.7^\circ$) at maximal straining during defecation. A rectocele based on the current definition of an anterior bulging of the anterior rectum wall of at least 20 mm was diagnosed in eight of 10 volunteers, showing an average size of 26 mm (± 6 mm).

The bladder base was located at an average position

Figure 2 Dynamic magnetic resonance imaging of a 36-year-old healthy female volunteer. At the end of defecation, a rectocele, cystocele and uterovaginal prolapse were visualized.

Table 1 Results of magnetic resonance defecography of 10 healthy asymptomatic volunteers

Anatomic structure	Rest	Straining	Relative movement
Anorectal junction (mm)	$-5.3 (\pm 9.9)$	$-29.9 (\pm 10.3)$	-24.6
Anorectal angle ($^\circ$)	$93.0 (\pm 4.8)$	$108.7 (\pm 14.7)$	15.7
Bladder base (mm)	$23.0 (\pm 4.6)$	$-8.1 (\pm 11.1)$	-14.9
Uterovaginal junction (mm)	$43.1 (\pm 7.8)$	$7.9 (\pm 16.5)$	-35.2

A positive value represents the lowest position of the pelvic structure above the pubococcygeal line, a negative value marks structures located below the pubococcygeal line. The values represent the median measured distance in millimeters; the numbers in brackets represent the range.

of $+23$ mm (± 4.6 mm) at rest and descended to -8.1 mm (± 11.1 mm) during defecation. The bladder base moved below the PCGL in six of 10 healthy volunteers during maximal straining, which is defined as a cystocele (Figure 2).

The uterocervical junction or vaginal vault was located at an average level of $+43.1$ mm (± 7.8 mm) at rest and at $+7.9$ mm (± 16.5 mm) during maximal straining. The uterocervical junction of three volunteers descended below the PCGL at maximal straining during defecation, described as uterocervical prolapse according to the common definition in the literature (Figure 2). No enterocele or other additional pathological findings were detected in any volunteers. Table 1 shows an overview of all results and findings of the dynamic MRI examinations.

DISCUSSION

Dynamic MRI of the pelvic floor, also known as MR defecography, is increasingly used for the diagnosis of complex pelvic floor disorders and replaces conventional videoproctography. Different medical specialties such as radiology, urology, gynecology and surgery are involved in the interpretation and evaluation of findings and therefore need an accepted definition of normal values and clinical practical reference lines for image assessment.

Back in 1991, Kruyt *et al.*^[4] were the first authors using MRI to study functional aspects of the anorectal region. In their study, the anatomy of the anorectum and the anorectal angle was examined in 10 healthy volunteers placed in the prone position within the MRI scanner. The symphysiosacral line reaching from the most superior part of the pubic symphysis to the lower part of the sacrum, was taken as the reference line to evaluate the mobility of the pelvic organs. Dynamics were measured during contraction and relaxation of the pelvic floor and during straining. In this study, the defecation process itself was not visualized because no contrast medium or enema was applied to the rectum.

Also in 1991, Yang *et al.*^[3] introduced dynamic MRI as a new method for the diagnosis of the descending perineum in women. They compared 26 patients with 16 asymptomatic women in the supine position. Values were documented with various degrees of straining maneuvers. Again, defecation itself was not because the rectum was not filled with contrast medium. The PCGL was taken as the reference line to evaluate the degree of descent of the pelvic structures.

Another study comparing clinical examination, videoproctography and dynamic MRI in the diagnosis of anterior rectoceles was published by Delemarre *et al.*^[11]. In this study patients were examined in the prone position without any rectal enema, which again made evaluation of the defecation process itself impossible. The pubosacral line reaching from the most inferior part of the pubic symphysis to the lower part of the sacrum was chosen as the reference line for MRI. Measurements were performed at rest and during straining for both imaging techniques.

The pubosacral line was also used by Goodrich *et al.*^[6] who examined five female patients with descending perineum syndrome pre- and postoperatively, as well as 10 asymptomatic female volunteers undergoing MRI. In contrast to the previous study, patients were placed in the supine position. The authors did not state whether the rectum, vagina or bladder had been contrasted.

Healy *et al.*^[8,14] have analyzed various aspects of pelvic floor disorders in patients and healthy volunteers comparing videoproctography with dynamic MRI with patients placed in the supine position. The defecation maneuver was not acquired. In contrast to other studies^[9,10,12], instead of contrast medium, a tampon was placed in the rectum. Measurements were performed during maximal straining, while the lower PCGL was the reference landmark.

Tacke^[15] has tested a new method of dynamic MRI with radial real-time imaging and a reduced image area for defecography. Patients in the supine position were asked to void a condom filled with a gadolinium-based contrast gel. The authors discussed this form of rectal filling critically as it may mask intussusception or latent incontinence.

Vanbeckevoort *et al.*^[12] compared colpocystoproctography (videoproctography with opacification of vagina

and bladder) and dynamic MRI in supine position. For MRI, the rectum was filled with 100 mL of ultrasound gel, which was not meant to be voided. Measurements were taken during maximal straining using the PCGL as a reference line.

Lienemann *et al.*^[10] compared colpocystoproctography and MRI for the diagnosis of enteroceles. In MRI, patients and healthy volunteers were placed in a supine position and the rectum was filled with 200 mL of ultrasound gel, which was to be defecated during imaging. The study does not reveal data on frequency and completeness of the defecation process. Reference line was the PCGL.

In a technically equal approach, Lienemann *et al.*^[9] examined 44 female patients and five asymptomatic volunteers for descent of the pelvic floor. Patients and volunteers were asked not to void the gel. Additionally, there was no discussion of the findings of the healthy volunteers in this study.

Hilfiker *et al.*^[16] and Schoenberger *et al.*^[17] presented an “open system” MRI where patients were examined in an upright position analogous to videoproctography. In the study of Schoenberger *et al.*^[17], the findings of 15 patients examined with videoproctography and this new form of open configured MRI were compared. Five healthy volunteers were included for the definition of normal values, which are not mentioned in the paper.

This overview illustrates the problems arising with the introduction of a new examination technique. So far, dynamic MRI is widely accepted as a promising technique for the diagnosis of the pelvic floor^[3,4,6,9,10], particularly for functional aspects of pelvic floor disorders because pelvic organs and muscles can be visualized and evaluated without invasive opacification and without any exposure to ionizing radiation. Still, without standardization of patient preparation, examination technique and evaluation of the data according to standardized reference lines and landmarks, it may not yet replace a well-established technique like videoproctography or colpocystoproctography. We believe that a comparison of both procedures has to take place under standardized conditions. In this context, the documentation of the defecation process is most important for subsequent comparability of both techniques. Vanbeckevoort *et al.*^[12] have compared the results of 35 patients examined with colpocystoproctography with and without defecation with the findings of dynamic MRI without defecation. For colpocystoproctography the urinary bladder and the small bowel were filled with a contrast medium. In their analysis, colpocystoproctography including defecation was by far superior to the same technique without defecation. Based on the observation that the pelvic floor reached its maximum downward movement only during defecation, and supported by the fact that patients are placed in a horizontal position in MRI, the authors concluded that colpocystoproctography including defecation may also be superior to MRI without defecation. Our results also revealed that the formation of a rectocele and

a cystocele as well as the maximal descent of the anorectal junction and of the uterocervical junction was only completely visible at the end of the defecation process but not during straining alone.

In our study, the rectum was filled with 180 mL ultrasound gel with a gadolinium-based contrast medium. Ikenberry *et al.*^[18] have shown that varying viscosity of the contrast medium does not significantly influence the findings in videoproctography. Due to the natural differences in signal intensity of the urinary bladder, vagina, small bowel, and peritoneum, the procedure can be kept on a low level of invasivity.

The lower PCGL was used to visualize relative movements of the pelvic organs during defecation. The anorectal junction and anorectal angle were determined by the central axis of the anal canal and a line along the posterior wall of the rectum^[8-10,14]. According to Delemarre *et al.*^[11], rectoceles were measured from the anorectal junction to the tip of protrusion of the anterior rectum wall. Table 2 gives an overview of different techniques and normal values as described in other studies.

The position of the anorectal junction related to the PCGL at rest and during defecation is one parameter in the evaluation of a descent of the perineum. In the present study the anorectal junction moved 30 mm on average below the PCGL during defecation. In a previously published study by our group we evaluated symptomatic patients with pelvic floor disorders. In this study the anorectal junction moved an average 49 mm below the PCGL, while in patients suffering from a rectal incontinence, an average of 51 mm was measured^[19].

Besides the descent of the anorectal junction, changes in the anorectal angle are commonly used as an indicator for the functional status of the pelvic floor^[20]. A narrowing of the anorectal angle may indicate a disorder of the puborectal muscle^[21]. This may lead to constipation with subsequent straining leading to rectal intussusception, rectocele and mucosal prolapse with a solitary ulcer of the rectum^[21,22]. If the anorectal angle is already widened at rest, this may be a sign of weakness of the pelvic floor and is commonly observed along with incontinence and rectal prolapse^[23-25].

Standard values in the literature vary enormously. For

videoproctography, Hardcastle *et al.*^[26] described normal values between 60° and 105° at rest whereas the findings of other groups^[27-29] relying on control groups with up to 150 volunteers show values between 90° and 104° at rest and 103° to 137° during defecation. Comparing the data with our study we determined an average angle of 93° at rest and 108.7° during straining. Accordingly, the use of changes in the anorectal angle as a diagnostic parameter is difficult not only because data vary significantly but also because findings of patients and asymptomatic volunteers tend to overlap^[4,7,8,15,29].

A patient with an anterior rectocele often presents with symptoms of incomplete defecation and are observed along with a descent of the pelvic floor^[13]. However, a rectocele can also frequently be found in asymptomatic patients. Therefore, some authors assume that symptoms depend on the diameter of the rectocele^[9,29,30]. Due to different approaches in the attempt to measure the expansion of a rectocele, there are still no well-defined normal values available. Delemarre *et al.*^[11] used videoproctography and MRI to examine 38 patients in the prone position without rectal filling and without defecation. He concluded that videoproctography was superior to MRI for diagnosis of rectoceles. He postulated that a symptomatic rectocele > 20 mm needs to be operated. Lienemann *et al.*^[9] and Yoshioka *et al.*^[13] have defined a rectocele as a protrusion of the anterior rectal wall of > 30 mm. Yoshioka *et al.*^[13] have found that, in comparison to clinical examination, MRI was superior to colposcystoproctography in detecting rectoceles. Patients were examined in the supine position with rectal filling during maximal straining but without defecation. In contrast, Healy *et al.*^[8] rated videoproctography as superior to MRI. They have defined expansion of > 20 mm as pathological. In addition, they found that a rectocele < 13 mm measured by videoproctography was totally missed by MRI. MRI examination again was performed without defecation.

According to our observations the horizontal position does not seem to be a disadvantage because a rectocele was found in eight out of 10 healthy volunteers, with an average size of 26 mm (Table 1). This was in accordance with data from the literature^[9,14] where the

incidence of a rectocele in asymptomatic volunteers was about 80%, although these are described as “small” rectoceles.

Incidence and degree of a cystocele and an uterocervical prolapse is usually connected with the number of vaginal deliveries, preceding hysterectomy, and chronic constipation with increased straining maneuvers^[12]. Besides clinical examination, imaging techniques make quantification of findings possible^[9].

Yang *et al.*^[3], Lienemann *et al.*^[9], Vanbeckevoort *et al.*^[12] and Healy *et al.*^[7,14] have used normal values for the descent of the bladder base and uterocervical junction during straining in relation to the PCGL. These values were raised partly in healthy volunteers and partly determined at random.

Due to the natural differences in signal intensity of the urinary bladder and the vagina there was no necessity to apply additional contrast media^[16]. In our study, six of 10 asymptomatic healthy female volunteers without a history of previous delivery or surgery showed the finding of a cystocele, and in three of 10 a vaginal prolapse was diagnosed.

In the studies of Lienemann *et al.*^[31] and Sprenger *et al.*^[32], 20 and 39 healthy females were examined with dynamic MRI of the pelvic floor, including defecation. A cystocele or vaginal prolapse was detected in none of them.

An enterocele is defined as herniation of the peritoneum into the rectovaginal space^[33], which may contain small bowel loops or sigmoid colon. They are often accompanied by severe defecation disorders and a sensation of pressure as well as downward movement of the pelvic floor^[34]. The prevalence of an enterocele in women is between 18% and 37%^[35,36]. They often occur after hysterectomy^[33]. No enterocele was detected in any volunteer. Lienemann *et al.*^[10] examined 55 patients and 11 asymptomatic volunteers with colpocystoproctography and dynamic MRI, without application of contrast medium into the peritoneum or small bowel. MRI had a clear advantage because the peritoneum and contents of the enterocele were easily identified. He concluded that MRI may replace colpocystoproctography in the diagnosis of an enterocele.

It proved to be useful to acquire the complete defecation process after a rectal enema to detect potential pathological changes. A rectocele can easily be identified by dynamic MRI. The pelvic organs of healthy volunteers show a relatively high mobility, therefore, presently suggested normal values for the position of pelvic organs in relation to the PCGL have to be redefined. It is necessary to evaluate normal values under standardized investigation conditions and with large groups of healthy volunteers.

COMMENTS

Background

Pelvic floor disorders are commonly seen in proctology, urology and gynecology, and the patients are mostly women. Due to the complexity of anatomy and

physiology of the pelvic floor we have come across a wide variety of disorders.

Research frontiers

Imaging plays an important role in the diagnostic workup of complex combined pelvic floor disorders. Functional examinations like videoproctography provide valuable information but it has been increasingly replaced by dynamic magnetic resonance imaging (MRI) that can visualize intra- and extraluminal structures. Further strengths of MRI are excellent soft tissue contrast and the lack of ionizing radiation.

Innovations and breakthroughs

There have been several studies about the diagnostic value of dynamic MRI of the pelvic floor; most of them with symptomatic patients. This investigation is believed to be the first to document the range of normal findings in MR defecography of asymptomatic female volunteers.

Applications

The wide range of normal findings in this study emphasizes the necessity of obtaining common standards for the evaluation of MR defecography.

Terminology

MR defecography is a dynamic pelvic MRI examination. After optional application of a rectal enema, defecation is visualized by a series of fast MRI sequences.

Peer review

This is a good study but the authors should make some revision.

Abstract

AIM: To investigate the clinical outcome of double balloon enteroscopy (DBE)-assisted endoscopic retrograde cholangiopancreatography (DB-ERCP) in patients with altered gastrointestinal anatomy.

METHODS: Between September 2006 and April 2011, 47 procedures of DB-ERCP were performed in 28 patients with a Roux-en-Y total gastrectomy ($n = 11$), Billroth II gastrectomy ($n = 15$), or Roux-en-Y anastomosis with hepaticojejunostomy ($n = 2$). DB-ERCP was performed using a short-type DBE combined with several technical innovations such as using an endoscope attachment, marking by submucosal tattooing,

selectively applying contrast medium, and CO₂ insufflations.

RESULTS: The papilla of Vater or hepaticojejunostomy site was reached in its entirety with a 96% success rate (45/47 procedures). There were no significant differences in the success rate of reaching the blind end with a DBE among Roux-en-Y total gastrectomy (96%), Billroth II reconstruction (94%), or pancreatoduodenectomy (100%), respectively ($P = 0.91$). The total successful rate of cannulation and contrast enhancement of the target bile duct in patients whom the blind end was reached with a DBE was 40/45 procedures (89%). Again, there were no significant differences in the success rate of cannulation and contrast enhancement of the target bile duct with a DBE among Roux-en-Y total gastrectomy (88%), Billroth II reconstruction (89%), or pancreatoduodenectomy (100%), respectively ($P = 0.67$). Treatment was achieved in all 40 procedures (100%) in patients whom the contrast enhancement of the bile duct was successful. Common endoscopic treatments were endoscopic biliary drainage (24 procedures) and extraction of stones (14 procedures). Biliary drainage was done by placement of plastic stents. Stones extraction was done by lithotomy with the mechanical lithotripter followed by extraction with a basket or by the balloon pull-through method. Endoscopic sphincterotomy was performed in 14 procedures with a needle precutting knife using a guidewire. The mean total duration of the procedure was 93.6 ± 6.8 min and the mean time required to reach the papilla was 30.5 ± 3.7 min. The mean time required to reach the papilla tended to be shorter in Billroth II reconstruction (20.9 ± 5.8 min) than that in Roux-en-Y total gastrectomy (37.1 ± 4.9 min) but there was no significant difference ($P = 0.09$). A major complication occurred in one patient (3.5%); perforation of the long limb in a patient with Billroth II anastomosis.

CONCLUSION: Short-type DBE combined with several technical innovations enabled us to perform ERCP in most patients with altered gastrointestinal anatomy.

INTRODUCTION

Patients who have undergone bowel reconstruction have been considered unsuitable for endoscopic retrograde cholangiopancreatography (ERCP) using conventional endoscopy^[1-6]. This is because the endoscopic approach to the afferent loop, blind end, and the choledochojejunostomy site using a conventional endoscope is difficult because of the distance from the gastrojejunal anastomosis site, the unusual anatomical features of the intestine such as its winding form, and postoperative adhesions. Recently, double balloon enteroscopy (DBE) has been reported to be of significant benefit for the diagnosis and treatment of biliary and pancreatic diseases in such patients^[7-13]. DBE enables us to advance much deeper into the small intestine than using a conventional push-enteroscope^[14-16]. It is still difficult, however, not only to reach the papilla of Vater or the site of choledochojejunostomy, but also to cannulate selectively into the pancreatic and/or biliary duct in ERCP using DBE (DB-ERCP). Therefore, further contrivances including both instrumental and technical innovations have been required to improve the outcome of DB-ERCP. One of the most significant instrumental innovations is a short-type DBE, which has been recently developed, and contributes to increased success rates not only for reaching the papilla and blind end but also for ERCP-related interventions because of its short working length and the availability of various accessory devices^[17,18]. There has still been a need for developing the technical innovations to obtain more favorable outcome of the DB-ERCP. This study describes several technical innovations and tips in the use of a short-type DBE to improve clinical outcomes of DB-ERCP.

MATERIALS AND METHODS

Patient population

Between September 2006 and April 2011, 48 ERCP procedures were analyzed in 28 patients (10 female, 18 male; age 54-91 years, mean 74.0 years) with pancreatobiliary diseases who had previously undergone bowel reconstruction. The bowel reconstruction methods included Roux-en-Y total gastrectomy in 11 patients (26 procedures), Billroth II gastrectomy in 15 patients (18 procedures), and Roux-en-Y anastomosis with pancreaticoduodenectomy in two patients (three procedures). Patients with Roux-en-Y total gastrectomy or Billroth II gastrectomy had naïve papilla ($n = 26$), and those with pancreaticoduodenectomy had hepaticojejunostomy ($n = 2$). Twenty-eight consecutive postsurgical patients were included in this study after written informed consent was obtained.

Endoscope and accessories

We used short-type DBE, EC-450B15 (Fujifilm, Saitama, Japan). The DBE system is a high-resolution videoendoscope with a flexible overtube. The videoendoscope has a 2.8-mm working channel and a working length of 1520 mm, and a detachable balloon at its tip. It is used with a soft overtube measuring 1050 mm in length with another balloon at the distal end. The endoscope and overtube balloons are made from latex, which is 0.1 mm thick and very soft. The balloons can be inflated or deflated by a specially designed air pump controller with one-touch controls, while monitoring the air pressure. A soft transparent hood (DH-17EN; Fujifilm) was attached to the tip of a scope in all procedures.

DB-ERCP

All procedures were performed during conscious sedation by giving 35 mg pethidine hydrochloride and 0.5-2 mg of flunitrazepam intravenously. Scopolamine butylbromide was only used after reaching the end of the afferent loop. DBE was performed using a standard technique as described by Yamamoto *et al.*^[14], Kita *et al.*^[15] and May *et al.*^[16], and DB-ERCP was carried out as follows. When an endoscopist was not sure whether the endoscope was in the afferent loop, selective contrast enhancement in the intestine was performed with a balloon inflated on the endoscope tip, allowing the endoscopist to confirm the direction of the afferent loop under fluoroscopy^[17,18]. Although formerly we used standard air insufflations during the procedure, since April 2009 we have used CO₂ instead of standard air insufflations to improve intubation depth during DBE, as well as to reduce postprocedural pain^[19]. In the first procedure, the beginning of the Roux limb was marked by submucosal tattooing (Indian ink) in patients with a Roux-en-Y anastomosis (Figure 1). The time taken for this procedure and the whole procedure was recorded.

Once the endoscope reached the papilla or ductal anastomosis, appropriate stabilization of the enteroscope with the overtube and/or enteroscope balloon

Figure 1 In the first procedure, the beginning of the Roux limb was marked by submucosal tattooing in patients with a Roux-en-Y anastomosis.

Figure 2 A soft transparent hood (DH-17EN; Fujifilm) was attached to the tip of a scope in all procedures.

was often required prior to ERCP. Using DBE, the endoscopist could stabilize the endoscope by the deep insertion of an overtube, and immobilize the intestine in a position that allowed the bile duct to run in the 11

o'clock direction, as in the conventional ERCP view. A soft transparent hood was attached to the tip of a scope in all procedures. The attachment hood was useful to fix the ampulla (Figure 2). Selective biliary cannulation

Figure 3 A sphincterotome with rotatable tip (Autotome RX49; Boston Scientific) was also useful for cannulation in some cases, in which biliary cannulation was unsuccessful with a standard cannula.

was achieved using a standard cannula or, if necessary, a sphincterotome (Autotome RX49; Boston Scientific, Tokyo, Japan) with a tip rotatable through 360° (Figure 3). Guidewire (Jagwire 0.035; Boston Scientific) was preloaded into the cannula or sphincterotome, and was placed in the bile duct after successful cannulation for the following procedure. Endoscopic sphincterotomy (EST) was performed using a sphincterotome with rotatable tip or a precutting knife (Single Use 3-Lumen Needle knife V KD-V441M; Olympus, Tokyo, Japan). When EST was difficult, endoscopic papillary balloon dilation was performed with an 8- or 10-mm balloon dilation catheter (Hurricane RX 4594; Boston Scientific). When the opening of the choledochojejunostomy was stenotic, balloon dilation using either an 8-10-mm balloon dilation catheter or 12-mm balloon catheter (CRE Wireguided Balloon Dilatation Catheter 5842; Boston Scientific) was performed.

Stone extraction was performed with a six-wire basket (MTW) or a mechanical lithotripter (Xemex crusher catheter; Zeon Medical, Tokyo, Japan). After the stones were removed, a retrieval balloon catheter (Extractor; Boston Scientific) was used with a guidewire to confirm that no small stones remained.

In patients with the bile duct winding at sharp angles where the mechanical lithotripter could not be inserted, and in patients with a bulky stone that could not be extracted in one attempt, a 7-Fr plastic stent (Flexima Biliary Stent System 3920; Boston Scientific) was positioned.

Statistical analysis

All data are expressed as mean \pm SE, if applicable. Statistical analyses were performed with JMP statistical software (Version 9.0). Pearson's χ^2 test was performed to compare the success rate of DB-ERCP among Roux-en-Y total gastrectomy, Billroth II reconstruction, and pancreatoduodenectomy. An analysis of variance followed by Tukey's multiple comparison test was carried out to determine statistical significance among these three groups. A value of $P < 0.05$ was considered statistically significant.

Table 1 Success rate of double balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography *n* (%)

	Reaching the papilla of Vater	Contrast enhancement of target bile duct	Treatment of pancreatic and/or biliary duct
Roux-en-Y reconstruction	24 (96)	21 (88)	21 (100)
Billroth II gastrectomy	18 (95)	16 (89)	16 (100)
Pancreatoduodenectomy	3 (100)	3 (100)	3 (100)
Total	45 (96)	40 (89)	40 (100)

RESULTS

Reaching the blind end with a DBE

Twenty-eight patients had a total of 47 sessions of DBE. Deep insertion of an endoscope to the papilla of Vater was successful in 24 out of 25 procedures (96%) in patients with Roux-en-Y total gastrectomy, in 18 out of 19 procedures (94%) in patients with Billroth II reconstruction, and in all three procedures in patients with pancreatoduodenectomy (Table 1). There were no significant differences in the success rate of reaching the blind end with a DBE among Roux-en-Y total gastrectomy, Billroth II reconstruction, and pancreatoduodenectomy ($P = 0.91$). DBE can be a very useful modality for patients with altered gastrointestinal anatomy irrespective of surgical procedures.

Cannulation and contrast enhancement of the target bile duct in patients in whom the blind end was reached

Overall, the rate of successful cannulation and contrast enhancement of the target bile duct was 40 out of 45 (89%) in patients in whom the blind end was reached; this was made up of 21 out of 24 procedures (88%) in Roux-en-Y total gastrectomy patients, 16 out of 18 procedures (89%) in Billroth II patients, and all three procedures in patients with pancreatoduodenectomy. Again, there were no significant differences in the success rate of cannulation and contrast enhancement of the target bile duct in patients whom the blind end was reached with a DBE among Roux-en-Y total gastrectomy, Billroth II reconstruction, and pancreatoduodenectomy ($P = 0.67$).

Treatment of the pancreatic and/or biliary duct

Treatment was achieved in all 40 procedures (100%) in patients in whom contrast enhancement of the bile duct was successful. The 40 treatment procedures are listed in Table 2, and the details of treatment are given in Table 3. The most common endoscopic treatment was endoscopic biliary drainage (24 procedures), which was done by placement of plastic stents. Extraction of stones (14 procedures) was done by lithotomy with the mechanical lithotripter followed by extraction with a basket or by the balloon pull-through method. EST was performed with a needle precutting knife using a guidewire (14 procedures). The choledochojejunostomy site was dilated by balloon in three procedures.

BD: Balloon dilation; SE: Stone extraction; EST: Endoscopic sphincterotomy.

Time of the procedure

The mean total duration of the procedure was 93.6 ± 6.8 min. The mean time required to reach the papilla was 30.5 ± 3.7 min. For a subanalysis, the time required to reach the papilla of Vater was 37.1 ± 4.9 min in Roux-en-Y total gastrectomy, 20.9 ± 5.8 min in Billroth II reconstruction, and 33.3 ± 13.4 min in pancreatoduodenectomy. It tended to be shorter in Billroth II reconstruction than that in Roux-en-Y total gastrectomy but there was no significant difference ($P = 0.09$). DB-ERCP seemed to be technically more difficult in patients with Roux-en-Y total gastrectomy than those with Billroth II reconstruction.

Complications

A major complication occurred in one patient (3.5%); perforation of the long limb in a patient with Billroth II anastomosis. Perforation occurred during insertion of DBE in this patient's second session. The perforation was successfully resolved surgically. No post-ERCP pancreatitis occurred.

DISCUSSION

The invention of DBE has dramatically changed the endoscopic management of pancreatobiliary diseases in patients who have undergone bowel reconstruction^[8-12]. DBE has made it possible to reach the papilla or bilio-pancreatoenteric anastomosis site even in patients with Roux-en-Y surgical reconstruction. Although patients who have undergone Billroth II reconstruction are considered capable of undergoing ERCP with a conventional endoscope, the endoscopic approach to the afferent loop, blind end, and the site of hepaticojejunostomy is difficult in cases where there are severe adhesions or a long afferent loop. In such patients with Billroth II reconstruction, DB-ERCP is effective.

DB-ERCP has three major steps; the first step is intubation to the papilla or the site of hepaticojejunostomy, the second is cannulation into the bile and/or

Table 3 Detailed treatment procedures for double balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography

pancreatic duct, and the third is therapeutic manipulation such as sphincterotomy and/or stone extraction. There have been several reports of DB-ERCP. Although the success rates of reaching the papilla or of cannulation for intact papilla are high (50%-100%, 67%-100%, respectively)^[17,18,20-22], they are still lower than for conventional ERCP. Therefore, technical difficulties or instrument limitations are considered likely. Some useful techniques or endoscopic accessories have been reported for conventional endoscopy or DBE, however, there are few reports which describe in detail the technique or the instruments for each step of DB-ERCP. We describe these things in detail, because they may contribute to improving the outcome of DB-ERCP.

For the first step, intubation to the papilla or the site of hepaticojejunostomy, short-type DBE may be recommended. Originally, double balloon enteroscopes were 200 cm long, which did not cause a problem with insertion into the papilla, but limited the number of devices for the ERCP procedure^[17,18,20,21]. Short-type DBE, which was originally developed for colonic insertion, has resolved this problem^[17,18]. Shimatani *et al*^[18] have reported that because of its short working length and the availability of various accessory devices, short-type DBE increases the success rates for reaching the papilla and blind end, and for ERCP-related interventions. Cases in which double balloon enteroscope insertion may be difficult are patients who have jejunojunostomy such as Roux-en-Y anastomosis or pancreatoduodenectomy. Selective contrast enhancement in the intestine with a balloon inflated on the endoscope tip is useful to confirm the direction of the afferent loop^[17,18]. Once the correct way is confirmed, submucosal tattooing at the beginning of the Roux limb may be useful for later sessions (Figure 1)^[12,17,21,23,24].

In our series, the blind end was reached in 45 out of 47 procedures (95.7%) with short-type DBE, comprising 18 out of 19 procedures in Billroth II patients, all three in pancreatoduodenectomy, and 24 out of 25 procedures in Roux-en-Y patients. One procedure in Billroth II patients was aborted because of perforation of the long limb, and one in the Roux-en-Y group failed because of

strong adhesion. We have used CO₂ instead of standard air insufflations since April 2009 to improve intubation depth during DBE, as well as to reduce postprocedural pain^[19]. The mean duration for reaching the blind end using CO₂ insufflation in Roux-en-Y patients tended to be shorter than that using air insufflation, although the difference was not significant ($P = 0.18$, 40.9 min *vs* 29.4 min, air *vs* CO₂, respectively). CO₂ insufflation could be useful especially in patients with Roux-en-Y total gastrectomy where DB-ERCP seems to be technically difficult compared to Billroth II reconstruction.

The second step, deep cannulation into the bile and/or pancreatic duct, is an important precondition for later therapeutic manipulations. In patients with Roux-en-Y reconstruction, the position of the papilla may vary and may be observed by moving the screen in various directions. The manipulation of both the overtube and the endoscope makes it possible to change the position of the papilla in the view field. Double balloon enteroscopes are not provided with an elevator, therefore, cannulation may be difficult, but the attachment hood is useful to fix the ampulla and to align the axes of the cannula and the bile duct, enabling safe endoscopic procedures and selective pancreatic and/or biliary cannulation (Figure 2). We usually use a normal ERCP catheter. If the biliary axis does not fit, we use a sphincterotome with a rotatable tip (Figure 3). Needle-knife precut papilotomy was performed when the conventional biliary cannulation promised to be difficult, as described by Fukatsu *et al.*^[25]. In this study, cannulation was successful and contrast enhancement of the target bile duct was achieved in 40 out of 45 (89%) patients in whom the blind end was reached. There were difficult cases in Roux-en-Y patients (21/24, 88%) and in Billroth II patients (16/18, 89%). It was easy in all three patients with pancreatoduodenectomy.

The third therapeutic step is the endpoint of the DB-ERCP procedure. Deep insertion and placing the guidewire into the biliary and/or pancreatic duct is indispensable for the following procedures. Guidewire stabilizes the papilla and makes it easy to perform sphincterotomy or insert the devices into the duct. Treatment was achieved in all 40 procedures in patients in whom contrast enhancement of the bile duct and guidewire placement were successful. Endoscopic biliary drainage by placement of plastic stents was not difficult. However, the diameter of the stents was limited to < 7 Fr. Sphincterotomy using a sphincterotome is sometimes difficult in DB-ERCP. A rotatable sphincterotome or needle precutting knife may be useful in such cases. If sphincterotomy is impossible or insufficient, balloon dilation should be performed. Extraction of stones was done by lithotomy with the mechanical lithotripter followed by extraction with a basket or by the balloon pull-through method. A few types of mechanical lithotripters and baskets that can go through the DBE working channel are commercially available at the present time. However, most of them do not have the wire-guided mechanism,

which means it is sometimes difficult to insert into the duct.

DB-ERCP complications in patients who have undergone bowel reconstruction have featured in a limited number of reports. Perforations or emphysema at the time of insertion of an endoscope or endoscopic sphincterotomy have been reported in 2.3%-11.1% of cases. Raithel *et al.*^[21] have reported post-ERCP pancreatitis in 2.3% and post-interventional bleeding in 1.1% of patients. In our study, complications occurred in only one patient (3.5%); perforation of the long limb in a patient with Billroth II anastomosis^[17,18,21]. With regard to the insertion of an endoscope and shortening of the intestinal tract, attention should be paid to avoid forced insertion or shortening, which may cause perforation.

In conclusion, short-type DBE combined with several technical innovations enabled us to perform ERCP and ERCP-related interventions in a number of patients for whom it was previously impossible. Endoscopic tattooing at the beginning of the limb, using an attachment hood, and CO₂ insufflation might facilitate intubation of the papilla and reduce the duration of the procedure. Cannulation into the bile or pancreatic duct is the most difficult part of DB-ERCP. Using an attachment hood and/or a rotatable sphincterotome may facilitate the procedure. Further instrumental improvements such as the widening of the DBE working channel or development of the accessories for use in balloon enteroscope systems are necessary to improve the outcome of DB-ERCP.

COMMENTS

Background

Patients who have undergone bowel reconstruction have been considered to be difficult for endoscopic retrograde cholangiopancreatography (ERCP) using conventional endoscopy. Double balloon enteroscopy (DBE) has brought a significant benefit for performing ERCP in patients with such an altered gastrointestinal anatomy. However, there are still some technical difficulties to be resolved.

Research frontiers

Recently developed short DBE contributes to increased success rates for reaching the papilla and for ERCP-related interventions in DBE-assisted ERCP (DB-ERCP). In the area of DB-ERCP, the research hotspot is how to improve its results for completing therapeutic interventions such as stone extraction and stent insertion of the pancreatobiliary system.

Innovations and breakthroughs

Although a short DBE is more useful than a conventional long DBE, clinical outcomes of DB-ERCP are still unsatisfactory compared to conventional ERCP. DB-ERCP has three major steps: intubation to the papilla or the site of hepaticojunostomy, cannulation into the bile and/or pancreatic duct, and therapeutic manipulation. To improve intubation, the authors used CO₂ instead of standard air insufflations, selective contrast enhancement in the intestine with a balloon inflated on the endoscope tip to confirm the right direction, and submucosal tattooing in patients with Roux-en-Y anastomosis for the next session. To improve cannulation, we attached a soft transparent hood to the tip of a scope, and used a sphincterotome with a rotatable tip. To improve therapeutic manipulation, we performed guidewire placement into the biliary/pancreatic duct, and needle-

knife precutting and/or balloon dilation to make a large enough opening of the orifice.

Applications

In this study, the authors showed the possibility that short-type DBE combined with several technical innovations enabled us to perform ERCP and ERCP-related interventions more efficiently in a number of patients with altered gastrointestinal anatomy for whom it was previously impossible.

Terminology

DBE has been developed for visualization of and intervention in the entire small intestine. Currently, two types of double-balloon endoscope are available including a conventional type (200 cm working length) and a short type (152 cm). Short-type DBE has great practical use because of its short working length and the availability of various accessory devices. Roux-en-Y reconstruction of the small bowel is a general surgical technique in gastrointestinal oncology surgery, hepatobiliary and pancreatic surgery, and bariatric surgery. For the endoscopist, accessing the ampulla is technically difficult in a patient needing Roux-en-Y reconstruction, because of the long length of bowel that the endoscope must pass through, and the acute angle of the afferent limb and Roux limb anastomosis.

Peer review

This is an important paper describing difficult ERCP cases after gastric surgery. This is a useful report of DB-ERCP techniques. The authors' modifications of the technique are particularly helpful.

Abstract

AIM: To evaluate the safety and effectiveness of laparoscopy compared with laparotomy for diagnosing and treating small bowel injuries (SBIs) in a porcine model.

METHODS: Twenty-eight female pigs were anesthetized and laid in the left recumbent position. The SBI model was established by shooting at the right lower quadrant of the abdomen. The pigs were then randomized into either the laparotomy group or the laparoscopy group. All pigs underwent routine exploratory laparotomy or laparoscopy to evaluate the abdominal injuries, particularly the types, sites, and numbers of SBIs. Traditional open surgery or therapeutic laparoscopy was then performed. All pigs were kept alive within the observational period (postoperative 72 h). The postoperative recovery of each pig was carefully observed.

RESULTS: The vital signs of all pigs were stable within 1-2 h after shooting and none of the pigs died from gunshot wounds or SBIs immediately. The SBI model was successfully established in all pigs and definitively

diagnosed with single or multiple SBIs either by exploratory laparotomy or laparoscopy. Compared with exploratory laparotomy, laparoscopy took a significantly longer time for diagnosis (41.27 ± 12.04 min *vs* 27.64 ± 13.32 min, $P = 0.02$), but the time for therapeutic laparoscopy was similar to that of open surgery. The length of incision was significantly reduced in the laparoscopy group compared with the laparotomy group (5.27 ± 1.86 cm *vs* 15.73 ± 1.06 cm, $P < 0.01$). In the final post-mortem examination 72 h after surgery, both laparotomy and laparoscopy offered a definitive diagnosis with no missed injuries. Postoperative complications occurred in four cases (three following laparotomy and one following laparoscopy, $P = 0.326$). The average recovery period for bowel function, vital appearance, and food re-intake after laparoscopy was 10.36 ± 4.72 h, 14.91 ± 3.14 h, and 15.00 ± 7.11 h, respectively. All of these were significantly shorter than after laparotomy (21.27 ± 10.17 h, $P = 0.004$; 27.82 ± 9.61 h, $P < 0.001$; and 24.55 ± 9.72 h, respectively, $P = 0.016$).

CONCLUSION: Compared with laparotomy, laparoscopy offers equivalent efficacy for diagnosing and treating SBIs, and reduces postoperative complications as well as recovery period.

INTRODUCTION

The vast anatomic space occupied by the gastrointestinal tract predisposes it to penetrating injuries. In penetrating trauma, the small bowel is most frequently injured, followed by the large intestine and stomach^[1]. Small bowel injury (SBI) is seldom diagnosed preoperatively especially when there are no frank signs of hemoperitoneum or peritonitis^[2,3].

Laparotomy is considered the gold standard for evaluation of intra-abdominal injuries sustained from trauma^[4]. However, complications following negative or nontherapeutic laparotomy can be as high as 20%-40%^[5-7]. Therefore, it is advantageous to avoid a negative laparotomy while providing a reliable and accurate alternative diagnostic procedure^[8]. While laparoscopy has become a standard component of diagnosis and therapy for many conditions in general surgery, its role in trauma remains controversial. Many concerns about the safety, sensitivity, and specificity of laparoscopy have limited its application in abdominal trauma^[9-12], particularly in detecting SBIs^[13-15]. It was reported that laparoscopy in trauma initially resulted in a high rate of missed injuries (41%-77%) and considerable criticism of laparoscopy as a diagnostic tool^[9,10]. Studies in 1993 and 2006 showed little statistical change in its reliability; only 20% of SBIs were correctly identified by laparoscopy, and sensitivity was 25% for diagnosis of hollow viscus and retroperitoneal injuries^[16,17]. The high proportion of missed occult SBIs with laparoscopy in trauma (LIT) is a major reason why some surgeons still preclude LIT use today^[18]. These considerations conflict with the considerable advances that have been made in LIT.

In this present study we mimicked injuries to the small intestines by firing bullets into the abdomen of anesthetized pigs. We tried to provide a reproducible and hemodynamically stable porcine model with multiple SBIs. We also aimed to evaluate the safety and effectiveness of diagnostic and therapeutic laparoscopy compared with the laparotomy for SBI in the porcine model.

MATERIALS AND METHODS

Experimental design

The study protocol was approved by the Institutional Review Board of the Research Institute of Surgery (RIS), which was affiliated to the Third Military Medical University in Chong Qing (People's Republic of China). Animal welfare and experimental procedures were carried out strictly in accordance with the guide for the Animal Care and Use Committee of RIS.

A prospective, randomized, comparative study was conducted between February and July 2010. Enrolled in this research were 28 consecutive healthy pigs native to Chong Qing (all females). The pigs were provided and fed by staff from the Medical Animal Research Center of Da Ping Hospital (Affiliated to the Third Military Medical University).

After mastering the skilled techniques gained from previous experience in modeling and treating SBIs, we carried out this study to ascertain if laparoscopy alone could replace laparotomy in diagnosing and treating SBIs in this porcine model.

Preoperative preparation

All 28 pigs had free access to food and tap water without oral intake of antibiotics. After premedication with intramuscular administration of azaperone 4 mg/kg, ketamine 10 mg/kg, and atropine 0.02 mg/kg, general anesthesia was induced by 3% pentobarbital (1 mL/kg) *via* the left ear vein; an additional 3-5 mL of 3% pentobarbital was given if the pigs became restless. A 6.5-F endotracheal tube was applied, and pigs allowed to breathe spontaneously. They were ventilated with room air using a standard ventilator if necessary. Most of the animals were in the anesthetic plane between medium and deep anesthesia [muscles relaxed; most reflexes (palpebral, corneal) absent; pupillary light reflex slow or absent].

SBI modeling procedures: After anesthesia, the pigs were transferred to the shooting cabin to establish the model. Pigs were laid in the left lateral recumbent position; the right forelimb and hindlimb were abducted and suspended on the shooting shelf whereas the left forelimb and hindlimb were fixed horizontally. The entry point was 2 cm medial and 3 cm cephalad from the point of the right hip (this position was determined according to our previously experience). Once the entry point was defined, the location of the predicted exit point was obtained by ensuring that both points were in the right quadrant of the abdomen and the line between the two points was horizontal. The predicted exit point was equivalent to the entry point moving medially, and was 4 cm lateral to the abdominal midline (Figure 1).

The injury was inflicted by a 56-type military firearm. It fired 7.62-mm steel-core bullets weighing 7.9 g at a shooting distance of 5 meters. The military firearm was used after fine adjustment of the ballistic trajectory according to the position of animal. All devices and the professional marksman were provided by the RIS.

Surgical procedures: After shooting at the abdomen, pigs were rapidly transferred to the operating room. Immediately before surgery, all pigs were randomized to one of the two surgical approaches (laparotomy or laparoscopy). The interval between shooting and surgery was similar in each pig; approximately 70-80 min.

Laparotomy group: Pigs were placed in the supine

Figure 1 Animal model. The experimenters fixed the position of the anesthetized pig. The black arrows point at the entry and exit wounds of the abdomen.

position. Access to the abdominal cavity was gained through a midline incision ranging from approximately 7 cm above the umbilicus to approximately 9 cm below the umbilicus. The abdominal wall was drawn back with a metal retractor. Viscera (particularly the intestinal tract) were exposed manually. The sequence of exploration was from the major vessels, liver, spleen, the gyri centripetales and gyri centrifugales of the colon to the left kidney and left segment of the pancreas; this was continued from the sigmoid colon, rectum, bladder, and cecum to the ileum and jejunum; then continued from the stomach, duodenum, and the pancreatic head to the right segment of the pancreas and right kidney. After exploration, surgical treatment was performed for intra-abdominal injuries. Intestinal resection and anastomoses were undertaken if the diameter of the intestinal rupture was longer than 50% of the intestine circumference, otherwise simple repair with edge trimming was applied; end-to-end single-layer anastomoses were conducted with running number 0 silk sutures;

Laparoscopy group: A pneumoperitoneum of 13 mmHg with CO₂ insufflation was established after insertion of a Veress needle. A 10-mm camera access port was introduced 1 cm above the umbilicus. A 30° laparoscope connected to a camera allowed endoscopic visualization. Two additional 5-mm or 10-mm ports were inserted in the left lower quadrant of the abdomen in right-angled triangular fashion under laparoscopic guidance. Pigs were positioned in a Trendelenburg angle or

a reverse angle to facilitate free access to the intestinal tract and other viscera. The sequence of exploration and some of the specific rules of treatment during surgery were the same as those mentioned in the laparotomy. The small bowel was examined for traumatic injuries by two 5-mm atraumatic bowel graspers from the ileocecal valve to the ligament of Treitz (running the bowel). Once exploration was accomplished, effective therapeutic laparoscopic procedures were undertaken to treat the injuries. Larger bleedings were controlled through application of a laparoscopic clip or with bipolar forceps. If the intestinal injuries were not severe (injury scale lower than Grade II^[19]) with the exception of ruptures of the colon or rectum, single repair with single-layer interrupted sutures was undertaken entirely under the laparoscopic view (total laparoscopy). Otherwise, intestinal resection and anastomoses were performed through an extended 5-cm incision of the exit wound (video-assisted laparoscopy).

After anastomoses and debridement, the abdominal cavity was irrigated with approximately 2000 mL normal (0.9%) saline, and a drainage tube placed in the pelvic cavity. The exit wound was managed with sharp debridement and two layers of interrupted sutures for the deep fascia and skin and the surgical incision. Administration of anesthetics was stopped. Both laparoscopy and laparotomy were performed by the same surgeons in our study, all of whom trained at RIS and used similar techniques.

Postoperative management

Postoperatively, a clean dry dressing was sutured with the abdominal skin to prevent contamination of the incision. Each pig was transferred to the feeding room, kept in a single cage, and injected with 25 mg pethidine 3 h after surgery. All pigs received 500 mL 5% glucose solution containing 1 g cefradine and 0.5 g metronidazole per day through a peripheral vein. The eating habits and physical activities of the pigs were closely monitored three times daily to detect signs of peritonitis and generalized sepsis. The recovery of bowel function was recorded as the time of return of bowel sounds. At 72 h after surgery, all animals were sacrificed for a thorough exploration of the abdomen to check for missed injuries.

Statistical analysis

Statistical analysis were carried out with SPSS software (SPSS/PC + 16.0; SPSS, Chicago, IL, United States). Values are presented as mean \pm standard deviation; $P < 0.05$ was considered significant. Statistical comparisons of data were carried out by the Student *t*-test, the Chi-square test or repeated measures as appropriate. In addition, Fisher's exact test was applied if the sample was < 5 .

RESULTS

SBI model

The point of the entry wound was 2.1-2.9 cm medial (mean, 2.60 ± 0.19 cm) and 1.2-1.7 cm cephalad (mean,

Figure 2 Porcine model with gastrointestinal injuries. A: Multiple ruptures of the small intestine; B: Injuries to the sigmoid colon.

1.5 \pm 0.12 cm) from the point of the right hip. The exit wounds were located in the right lower quadrant of the abdomen, and 3.2–5.8 cm (mean, 4.53 \pm 0.51 cm) lateral to the midline.

The vital signs of all pigs were stable within 1–2 h after shooting. None of the pigs died from gunshot wounds (GSW) to the abdomen. All 28 pigs underwent routine exploration of the abdominal cavity. All had single or multiple injuries to the small bowel, one (3.57%) with sigmoid ruptures (Figure 2), and one (3.57%) with cecum ruptures. Injuries to the liver, spleen, the gyri centripetales and gyri centrifugales of the colon, crucial vessels and retroperitoneal organs were not observed. The details of the SBIs are listed in Table 1; the organ injury scale was based on that of Moore *et al.*^[19]. In addition, the severity of SBIs in the two groups was also compared. We considered injury numbers of Grade II SBIs < 3 as minor injuries, and injury numbers of Grade III or more SBIs ≥ 1 as severe injuries. In the laparoscopy group, 5 cases were found with minor injuries and 9 cases with severe injuries, while in the laparotomy group, 4 cases were diagnosed with minor injuries and 10 cases with severe injuries. There was no significant difference between the groups concerning the severity of SBIs.

Perioperative outcomes

All 28 pigs were randomized into either the laparotomy group or the laparoscopy group (14 in each group). According to the operative findings, both laparotomy and laparoscopy offered a definitive diagnosis with no

missed injuries (all confirmed by the final post-mortem examination). Compared with laparotomy, laparoscopy took a significantly longer time for diagnosis (41.27 \pm 12.04 min *vs* 27.64 \pm 13.32 min, $P = 0.02$), but the time of therapeutic laparoscopy was similar to that of open surgery (83.27 \pm 23.43 min *vs* 79.00 \pm 19.17 min, $P > 0.05$). Furthermore, according to our analysis, the overall operative (diagnostic plus therapeutic) time was slightly longer in the laparoscopy group, but the difference did not reach statistical significance ($P = 0.12$). In addition, the length of the incision was significantly reduced in the laparoscopy group compared with the laparotomy group (5.27 \pm 1.86 cm *vs* 15.73 \pm 1.06 cm, $P < 0.01$).

Although all 28 pigs survived during the 72 h of follow-up, the recovery was not uneventful. Three cases (3/14, 21.5%) in the laparotomy group developed post-operative complications (one small bowel volvulus, one gastric retention, and one abdominal cavity infection and abscess) while only one case (1/14, 7.14%) had a complication of incisional infection in the laparoscopy group. No complications related to the technique (e.g., leakage, obstruction due to tight anastomosis, bleeding) were found. Although the incidence of complications was slightly higher following laparotomy, the difference between groups was not significant ($P = 0.326$). The average recovery period for bowel function, vital appearance, and food re-intake after laparoscopy was 10.36 \pm 4.72 h, 14.91 \pm 3.14 h, and 15.00 \pm 7.11 h, respectively, following laparoscopy. All of these were significantly shorter than after laparotomy (21.27 \pm 10.17 h, $P = 0.004$; 27.82 \pm 9.61 h, $P < 0.001$; and 24.55 \pm 9.72 h, respectively, $P = 0.016$).

DISCUSSION

Few studies have been carried out focusing on the methodology of SBI in pigs arising from GSW^[20,21]. According to our experience, the entry and exit points were extremely critical in establishing a purely SBI model. Through our work on intra-abdominal anatomy, we found that the distribution pattern was considerably regular in pigs. The small bowel had a centralized distribution in the right abdomen, and the gyri centripetales and gyri centrifugales of the colon were located in the left upper quadrant in a circular fashion. The cecum was approximately 20 cm in length with no obvious mesentery; it was mainly located in the left lower quadrant with its end pointing towards the pelvic cavity. Therefore, we assumed that if both the entry and exit wounds were located on the right lower quadrant of the abdomen, avoiding bony structures such as right ribs, right hip and pubis, there would be injuries only to the small intestine. As predicted, in the present study, all 28 pigs were diagnosed with SBIs.

One of the greatest concerns about LIT has been its unreliability in detecting SBIs^[13,14], a major reason why some surgeons still preclude LIT today. However, according to the results of the final post-mortem ab-

¹Based on the reference of Moore *et al*^[19]. IH: Hematoma, contusion or hematoma without devascularization; IL: Laceration, partial thickness, no perforation; II: Laceration, laceration < 50% of circumference; III: Laceration, laceration > 50% of circumference without transaction; IV: Laceration, transection of small bowel; V: Laceration, transection of small bowel with segmental tissue loss vascular, devascularized segment; SB: Small bowel.

dominal examination, the present study demonstrated that laparoscopy could also offer equivalent efficacy for diagnosing SBIs compared with laparotomy, with no missed injuries. According to our experience, the systematic approach for diagnostic laparoscopy exploration of the gastrointestinal tract was very important for avoiding missed SBIs^[15], and mainly consisted of all the principles of open exploratory laparotomy for trauma and the technique of running the small bowel. During the exploration, we initially lifted an 8-10-cm segment of the small bowel with two 5-mm atraumatic bowel graspers at the ileocecal valve, and one side of the bowel and mesentery was observed. The graspers were then turned 180 degrees, and the other side of the bowel was visualized. This sequence was repeated until the ligament of Treitz was reached. Therefore, after using this systematic approach, we could correctly identify SBIs, minimizing the potential of a missed injury. Although diagnostic laparoscopy was time-consuming, and took approximately 45 min to diagnose intestinal injuries in each case, which was significantly longer than the laparotomy exploration, the safety and sensitivity of diagnostic laparoscopy for

SBIs was good according to our research.

While surgeons disputed the disadvantages of laparoscopy for SBIs, the benefits of laparoscopy were evident^[22]. First, by directly visualizing the abdominal cavity, laparoscopy allowed the surgeon to exclude the presence of other associated intra-abdominal injuries, and was also able to eliminate the blind zone of visual fields when using a 30° laparoscope. Secondly, following the laparoscopic guidance, the SBIs could be treated directly using a laparoscopic technique, or using a notably shorter incision, which was near the injuries. In the current study, five pigs in the laparoscopy group were diagnosed with simple SBIs, and received total laparoscopy for treatment. In addition, video-assisted therapeutic laparoscopy, which utilized a 6-7 cm incision, was successfully carried out in nine pigs with relatively severe SBIs. Therefore, laparoscopy would also be a reliable and accurate alternative therapeutic procedure for severe SBIs^[23]. Thirdly, compared with the laparotomy group, the length of incision was significantly shortened in the laparoscopy group. The length of incision is an important factor affecting surgical stress^[24]. Thus, given the minimally invasive nature of laparoscopy, there is good reason to assume that laparoscopy is advantageous over conventional laparotomy in reducing surgical trauma. Another benefit of laparoscopy was the significantly reduced recovery period after surgery. The almost 50% reduction in recovery periods of bowel function, vital appearance, and food re-intake in the present research was not surprising considering the less invasive nature of the procedure. Therefore, laparoscopy could be a promising minimally invasive approach for treating SBIs^[25,26].

Limitation

One overwhelming limitation of this study was that a major proportion of patients with GSW to the abdomen would have significant injuries involving not only the small intestines, but also many other kinds of abdominal organs, which would make the conditions of the patients very complicated. Thus, therapeutic laparoscopy might not be the first choice for patients with GSW. However, we believe that, in the hemodynamically stable patient with abdominal penetrating injury and without extensive intra-abdominal adhesions, a thorough laparoscopic examination is possible and feasible. The results of diagnostic laparoscopy would be a useful guidance, and directly influence the modality of further treatment. Moreover, we aimed to evaluate the feasibility and validity of diagnostic and therapeutic laparoscopy for SBI, which was the chief objective of our study, and we did obtain convincing evidence supporting the use of laparoscopy for SBIs.

In conclusion, our research indicates that laparoscopy could be a minimally invasive approach for diagnosing and treating SBIs. Compared with laparotomy, laparoscopy could offer equivalent efficacy for SBIs, and reduces postoperative complications as well as recovery period.

COMMENTS

Background

While laparoscopy has become a standard component of diagnosis and therapy for many conditions in general surgery, its role in abdominal trauma remains controversial. Many concerns about the safety, sensitivity, and specificity of the laparoscopy have limited its application in abdominal trauma, particularly in detecting small bowel injuries (SBIs).

Research frontiers

One of the greatest concerns about laparoscopy in trauma (LIT) has been its unreliability in detecting SBIs, a major reason why some surgeons still preclude LIT today. This study aimed to evaluate the safety and effectiveness of diagnostic and therapeutic laparoscopy compared with laparotomy for SBIs in a porcine model.

Innovations and breakthroughs

Few studies have been carried out focusing on the value of laparoscopy for SBIs due to gunshot wounds in pigs. To the best of the authors' knowledge, the present study was the most detailed and systematic study establishing a purely SBI porcine model. Furthermore, the study also provided a comprehensive picture of the safety and effectiveness of laparoscopy and laparotomy in trauma.

Applications

In the hemodynamically stable patient with abdominal penetrating injury, a thorough diagnostic and therapeutic laparoscopy was possible and feasible. Compared with laparotomy, laparoscopy offers equivalent efficacy for diagnosing and treating SBIs, and reduces postoperative complications as well as recovery period.

Peer review

The author compared the safety and efficacy of laparoscopy for diagnosing and treating small bowel injuries in a trauma model using pigs. The study is well designed, and the article is also important and interesting.

Abstract

AIM: To study the polymorphisms of toll-like receptor 4 (TLR4) gene *Asp299Gly*, *Thr399Ile* and TLR2 gene *Arg753Gln*, *Arg677Trp* and susceptibility to inflammatory bowel disease (IBD) in the Zhuang population from Guangxi, China.

METHODS: A case-control study was performed from February 2007 to October 2011 which included 146 Zhuang patients with IBD in the experimental group and 164 healthy Zhuang subjects who acted as the control group. All patients and healthy subjects were from the Guangxi Zhuang Autonomous Region of China. Genomic DNA was extracted from intestinal tissue by the phenol chloroform method. TLR4 gene *Asp299Gly*, *Thr399Ile* and TLR2 gene *Arg753Gln*, *Arg677Trp* were amplified by polymerase chain reaction (PCR), and then

detected by PCR-restriction fragment length polymorphism (RFLP).

RESULTS: The TLR4 gene *Asp299Gly* was digested using *Nco* I restriction enzyme, and a single band of 249 bp was observed which showed that it was a wild type (AA). The TLR4 gene *Thr399Ile* was digested using *Hinf* I restriction enzyme and only the wild type (CC) was detected. In addition, the TLR2 gene *Arg677Trp* was digested using *Aci* I restriction enzyme and only the wild type (CC) was detected. The TLR2 gene *Arg753Gln* was digested using *Pst* I restriction enzyme. Only the wild type (GG) as a single band of 254 bp was observed during RFLP. Overall, no heterozygous or homozygous single nucleotide polymorphism mutations were found in patients with Crohn's disease and ulcerative colitis both in the TLR4 gene *Asp299Gly*, *Thr399Ile* and the TLR2 gene *Arg677Trp*, *Arg753Gln* in the Zhuang population from the Guangxi Zhuang Autonomous Region of China.

CONCLUSION: The TLR4 gene *Asp299Gly*, *Thr399Ile* and TLR2 gene *Arg753Gln*, *Arg677Trp* polymorphisms may not be associated with IBD in the Zhuang population from the Guangxi Zhuang Autonomous Region of China.

Analysis of TLR4 and TLR2 polymorphisms in inflammatory bowel disease in a Guangxi Zhuang population. *World J Gastroenterol* 2012; 18(46): 6856-6860 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i46/6856.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i46.6856>

INTRODUCTION

Inflammatory bowel disease (IBD) is a chronic disorder caused by multiple factors in genetically susceptible hosts, and includes ulcerative colitis (UC) and Crohn's disease (CD). The molecular basis of the pathogenesis is not completely clear, but involves a complex interaction of factors such as genetics, immunology, environment and infection. The incidence of IBD in Western populations has increased with an estimated incidence of 0.10%-1.00% for UC and 0.35%-1.00% for CD during the past few decades^[1]. NOD2/CARD15 was the first verified predisposing gene for CD, where three NOD2/CARD15 polymorphisms, *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC*, were found to be significantly associated with CD in Caucasian populations^[2,3]. Nevertheless, these single nucleotide polymorphisms (SNPs) were not reported to be associated with CD in Japanese, and Hubei, Zhejiang, or Hong Kong populations in China^[4-7], thus, their exact role in CD is controversial. Recently, genome wide association studies, provided evidence for several determinants including Toll-like receptor 2 (TLR2) and TLR4^[8]. TLR4 is upregulated in intestinal epithelial cells, macrophages, and dendritic cells in patients with UC and CD. In contrast, the expression of TLR2 is unchanged. The *Asp299Gly* and *Thr399Ile* polymorphisms of the *TLR4* gene were shown to be associated with lipopolysaccharide hyporesponsiveness and with both CD and UC in some studies^[9,10]. The *TLR2* gene *Arg753Gln* polymorphism frequency is approximately 1%-4% in the Caucasian population, significantly higher than that in Indian patients with IBD^[11].

In view of the discrepant data regarding the association between key regulatory genes and IBD susceptibility, the purpose of our study was to investigate whether the known gene polymorphisms in TLR2 and TLR4 determine susceptibility to IBD in the Guangxi Zhuang population from the Guangxi Zhuang Autonomous Region. Guangxi has a large Zhuang population, where genetic diseases and gene polymorphisms are unique. Therefore, research on the relation between TLR2 and TLR4 polymorphisms and IBD in Chinese Zhuang patients from the Guangxi Zhuang Autonomous Region is needed.

MATERIALS AND METHODS

Patients

The study group consisted of 146 IBD Zhuang patients without genetic kinship enrolled in the Gastroenterology Department, First Affiliated Hospital of Guangxi Medical University, from February 2007 to October 2011. The control group included 164 healthy Zhuang subjects without genetic kinship who were healthy individuals or patients with functional dyspepsia, and did not have liver or gastrointestinal diseases. All patients had a well-established diagnosis of UC or CD, according to standard clinical criteria based on endoscopic and histopathological examinations. There were no significant differences

in age and sex between the study group and the control group. All patients and healthy controls gave informed consent and the study was approved by the ethical committee of the institute.

DNA extraction and genotyping of the *TLR4* and *TLR2* polymorphisms

Genomic DNA was extracted according to the modified protocol of Taggart. The primers used to amplify the *TLR4* gene (*Asp299Gly*, *Thr399Ile*) were designed according to the National Center for Biotechnology Information gene database, NM_138554, and the *TLR2* gene (*Arg677Trp*, *Arg753Gln*) with NM_003264 shown in Table 1 (primers were synthesized in SHENGGONG Biological Technology Co., Ltd., Shanghai, China).

Amplification was performed using H_2O_2 10.5 μL , 2 \times Taq polymerase chain reaction (PCR) Master-mix 11.5 μL (TIANGEN), DNA 1 μL , and 1 μL in addition to 10 $\mu\text{mol/L}$ of each primer in a total volume of 25 μL . For *Asp299Gly* and *Arg753Gln*, cycle conditions were an initial denaturation for 5 min at 95 $^\circ\text{C}$, followed by 28 cycles of denaturing at 95 $^\circ\text{C}$ for 40 s, annealing at 58 $^\circ\text{C}$ for 30 s, primer extension at 72 $^\circ\text{C}$ for 50 s, followed by a final extension at 72 $^\circ\text{C}$ for 10 min. For *Thr399Ile* and *Arg677Trp*, cycle conditions were an initial denaturation for 5 min at 95 $^\circ\text{C}$, followed by 28 cycles of denaturing at 95 $^\circ\text{C}$ for 40 s, annealing at 62 $^\circ\text{C}$ for 40 s, primer extension at 72 $^\circ\text{C}$ for 50 s, followed by a final extension at 72 $^\circ\text{C}$ for 10 min (Thermo Electron Corporation, Waltham, MA, United States). All the PCR products were electrophoresed on a 1.5% agarose gel, with 1 \times tris-borate-EDTA buffer, $V = 100\text{V}$ for 30 min, and visualized under ultraviolet illumination (Bio-Rad Gel Doc-2000, United States).

Five μL PCR products of *TLR4* gene (*Asp299Gly*, *Thr399Ile*) and *TLR2* gene (*Arg677Trp*, *Arg753Gln*) were digested at 37 $^\circ\text{C}$ overnight with 0.5 μL (10 U) *Nco* I, *Hinf* I, *Aci* I, and *Pst* I restriction enzymes (Fermentas), respectively. After enzymatic digestion, the fragments were separated and visualized by gel electrophoresis (2% Yito Bio-Instrument Company Ltd., Shanghai, China).

PCR products of each SNP were purified with a PCR purification kit (QIAGEN, Hilden, Germany) and were sequenced using an ABI Prism 377 DNA sequencer (LIU HE HUA DA GENE Technology Co, Ltd., Beijing, China).

Statistical analysis

The genetic equilibrium was tested using Hardy-Weinberg. Allele and genotype frequencies in patients and in controls were compared using the χ^2 test with SPSS 13.0, and P values were considered significant at a level of < 0.05 .

RESULTS

RFLP analysis was performed to assess the status of SNPs in our samples after digestion with restriction enzymes (Figure 1).

Table 1 Specific polymerase chain reaction primers and restriction enzymes for each single nucleotide polymorphism

Gene	Amino acid substitution	Sequence of primers(5'→3')	Fragments (bp)	Enzymes
TLR4	Asp299Gly	F-GATTAGCATACTTAGACTACTACCTCCATG R-GATCAACTTCTGAAAAAGCATITCCCAC	249	Nco I

A: Electrophoresis of *Asp299Gly* restriction fragment length polymorphism (AA type); B: Electrophoresis of *Thr399Ile* restriction fragment length polymorphism (CC type); C: Electrophoresis of *Arg677Trp* restriction fragment length polymorphism (CC type); D: Electrophoresis of *Arg753Gln* restriction fragment length polymorphism (GG type). M: Marker; 1: Ulcerative colitis; 2: Crohn's disease; 3: Control.

TLR4 gene *Asp299Gly* PCR-RFLP

Nco I restriction enzyme identified the sequence of CCATGG. For the heterozygous type (AG), this could be generated when digested with *Asp299Gly* and three bands of 249 bp, 223 bp and 26 bp, where one chain was cut, and the others were not. For the homozygous type (GG), a transite to G, *Nco* I identified the mutated site, and the mutated DNA was visible as a double band of 223 bp and 26 bp, whereas a single band of 249 bp was observed in the wild type (AA), as the site was not cut. In this study, only the wild type (AA) was detected, and no other types (Figure 1A).

TLR4 gene *Thr399Ile* PCR-RFLP

Hinf I restriction enzyme identified the sequence of GANTC. For the heterozygous type (CT), this could be

generated when digested with *Thr399Ile* and three bands of 406 bp, 377 bp and 29 bp, where only one chain was cut, and the others were not. For the homozygous type (TT), C transite to T, *Hinf* I identified the mutated site, and the mutated DNA was visible as a double band of 377 bp and 29 bp, whereas a single band of 406 bp was observed in the wild type (CC), as the site was not cut. In this study, only the wild type (CC) was detected, and no other types (Figure 1B).

TLR2 gene *Arg677Trp* PCR-RFLP

Aci I restriction enzyme identified the sequence of CCGC. For the heterozygous type (CT), this could be generated when digested with *Arg677Trp* and three bands of 199 bp, 124 bp and 75 bp, where one chain was cut, and the others were not. For the homozy-

gous type (TT), C transite to T, the site was not cut by *Aci* I restriction enzyme, and a single band of 199 bp was observed, for the wild type (CC), it identified the site, and the DNA was visible as a double band of 124 bp and 75 bp. In this study, only the wild type (CC) was detected, and no other types (Figure 1C).

TLR2 gene *Arg753Gln* PCR-RFLP

Pst I restriction enzyme identified the sequence of CTGCAG. For the heterozygous type (GA), this could be generated when digested with *Arg753Gln* and three bands of 254 bp, 214 bp and 40 bp, where one chain was cut, and the others were not. For the homozygous type (AA), G transite to A, *Pst* I identified the mutated site, and the mutated DNA was visible as a double band of 214 bp and 40 bp, whereas a single band of 254 bp was observed in the wild type (GG), as the site was not cut. In this study, only the wild type (GG) was detected, and no other types (Figure 1D).

DISCUSSION

UC and CD are multifactorial diseases of unknown etiology. Despite being disorders of the gastrointestinal tract, an abnormal immune response directed against the gut microflora has been postulated as a possible explanation in genetically susceptible hosts^[12].

Numerous studies have been performed on the frequency of NOD2/CARD15 mutations in IBD populations in Western Europe and Northern America. In CD patients from Northern America or Western Europe, allele frequencies ranged from 9.1%-12.9%, 6.6%-16.0% and 3.3%-6.0% for *Arg702Trp*, *1007fsC*, and *Gly908Arg*, respectively^[13]. Interestingly, a recent study reported lower allele frequencies in Finnish IBD patients for all three NOD2/CARD15 variants in CD patients compared with the above-mentioned studies and similar frequencies in patients with UC^[14]. Additionally, in Asian IBD populations, NOD2/CARD15 variants were not detected at all^[4,5]. Thus, there is a need for more studies in different populations with IBD. Human TLRs participate in the innate immune response and signal the activation of adaptive immunity. Therefore, these TLRs may be important in autoimmune diseases such as IBD, rheumatoid arthritis and systemic lupus erythematosus^[15].

This is the first study to report the *TLR4* (*Asp299Gly*, *Thr399Ile*) and *TLR2* (*Arg677Trp*, *Arg753Gln*) gene mutations in patients with IBD from the Guangxi Zhuang population of China, where the ethnic background is heterogeneous, and includes Han, Zhuang and Rao. In this study, the mutation genotypes of the *TLR4* gene *Asp299Gly*, *Thr399Ile* and *TLR2* gene *Arg677Trp*, *Arg753Gln* were not found in the Zhuang population with IBD. Our results are in agreement with those from studies on Asian patients from Hong Kong, Hubei, Zhejiang, Shanghai and Japan^[4,7].

In recent years, several studies have reported divergent results^[16]. The allele frequency of the *Asp299Gly* variant ranges from 0%-10% in UC, from 8%-13% in

CD and from 3%-15% in healthy controls^[17]. Franchimont *et al*^[10] reported that the *TLR4* SNP was associated with UC and CD in a Belgian study. This association was in accordance with Dutch, Greek, Australian and German populations with CD, and an association with colonic disease has been described^[18-21]. In one German cohort, an association between the *TLR4* *Thr399Ile* SNP and UC was demonstrated^[22]. However, because of substantial heterogeneity between populations, no association was noted in Scottish CD patients^[23]. The *TLR2* gene *Arg753Gln* variant frequency was 9.4% in Germany, and 1% in Spain^[24], the *TLR2* gene *Arg677Trp* was 30.3% in Tunisia^[25], where the difference was significant. In addition, Pierik *et al*^[26] reported that an association was found between non-synonymous variants and extensive colonic disease with UC and CD in the *TLR2* genes.

In our study, we did not find mutations in *TLR4* gene *Asp299Gly*, *Thr399Ile* and *TLR2* gene *Arg677Trp*, *Arg753Gln* in the Zhuang population with IBD. These findings were different from those in Tunisia, Germany and Spain. Our results showed that the *TLR4* gene *Asp299Gly*, *Thr399Ile* and *TLR2* gene may not be associated with IBD patients from the Guangxi Zhuang Autonomous Region of China. This is possibly due to the existence of racial and geographic differences.

The present study supports the notion that genetics, immunology, environment and infection may be vital in the pathogenesis of IBD. However, the heterogeneity in the small number of available studies limited the ability to draw conclusions. Further studies using a larger cohort of patients with IBD are warranted to identify the risk factors and genetic susceptibility to IBD.

COMMENTS

Background

The pathogenesis of inflammatory bowel disease (IBD) is not completely clear, however, contributing factors may include immunology, genetics, environment and infection. It has been reported that the *NOD2/CARD15* polymorphisms (single nucleotide polymorphisms, SNPs) were found to be associated with Crohn's disease (CD) in Caucasian populations. However, the SNPs were not found to be associated with CD in Japan and China. In addition, the *TLR2* and *TLR4* were reported to provide evidence for several determinants. The study assessed whether the known gene polymorphisms in the toll-like receptor 2 (*TLR2*) and *TLR4* genes determined susceptibility for IBD in the Guangxi Zhuang population. Since Guangxi has a large Zhuang population, genetic diseases and gene polymorphisms are unique.

Research frontiers

TLR4 (*Asp299Gly*, *Thr399Ile*) and *TLR2* (*Arg677Trp*, *Arg753Gln*) were found to be associated with IBD in Tunisia, Germany and Spain, but not in Hong Kong, Hubei, Zhengjiang, Shanghai and Japan. This is possibly due to the existence of racial and geographic differences. This study determined whether the *TLR4* (*Asp299Gly*, *Thr399Ile*) and *TLR2* (*Arg677Trp*, *Arg753Gln*) were associated with IBD in the Guangxi Zhuang population from the Guangxi Zhuang Autonomous Region of China.

Innovations and breakthroughs

Only a few studies have investigated the *TLR2* and *TLR4* gene polymorphisms in China. Moreover, all the subjects in these studies were from the Han population. This is the first study to report that *TLR4* gene *Asp299Gly*, *Thr399Ile* and *TLR2* gene *Arg753Gln*, *Arg753Gln* polymorphisms may not be associated with IBD in the Zhuang population from the Guangxi Zhuang Autonomous Region of China.

Applications

TLR2 and TLR4 variants may be rare or non-existent in the Zhuang population from the Guangxi Zhuang Autonomous Region of China.

Terminology

TLRs play a key role in microbial recognition in innate immunity and control the adaptive immune responses. Among the TLRs, TLR2 recognizes bacterial components such as lipoprotein, lipoteichoic acids, peptidoglycan and zymozan. TLR4 requires CD14 to form the lipopolysaccharide (LPS) receptor. LPS, found in the outer membrane of Gram-negative bacteria, is opsonized by LPS-binding protein, and recognized by CD14. The LPS-LPS binding protein-CD14 complex activates TLR4, which results in the activation of NF- κ B. TLR2 and TLR4 gene mutations or deletions can induce abnormal immune responses.

Peer review

This study demonstrates no association of TLR2 and/or TLR4 polymorphism with IBD in a patient cohort within a restricted Chinese population. Although this is a "negative" result, it adds to the impact of genetic and/or ethnical predisposition to IBD.

Abstract

Hepatocellular carcinoma (HCC) is difficult to eradicate due to its resilient nature. Portal vein is often involved in tumors of large size, which exclude the patient from surgical resection and local ablative therapy, such as percutaneous ethanol injection (PEI) and radiofrequency ablation (RFA) because they were considered neither effective nor safe. Currently, there is almost no effective treatment for HCC of such condition. As a unique antitumor agent in form of lipophilic fluid for local injection, para-toluenesulfonamide (PTS) produces mild side effects while necrotizing the tumor tissues quickly and efficiently. Being largely different from both PEI and RFA therapies, PTS can disseminate itself in tumors more easily than other caustic agents, such as alcohol. So PTS may offer additional benefit to HCCs with vascular involvement. We herein describe a 70-year-old HCC patient who was treated with the combination of PTS injection and transcatheter arterial chemoembolization, resulting in a significantly improved clinical prognosis.

INTRODUCTION

Transcatheter arterial chemoembolization (TACE) has become the standard treatment for unresectable hepatocellular carcinoma (HCC). Nonetheless, clinical outcomes are often unsatisfactory, especially for recurrent cases. As a novel anticancer agent, para-toluenesulfonamide (PTS) is completely different from genetic, classical chemical and molecular targeted drugs, and has shown amazing antitumor effect in animal HCC experiment^[1,2]. Primary pharmacological studies suggest that PTS inhibits tumor growth by acting as a tumor necrotizing agent^[1,2]. PTS may strengthen the effect of TACE in advanced HCC. We herein report a patient with refractory HCC who was treated with PTS injection after TACE, which resulted in a very good clinical prognosis.

CASE REPORT

The patient was a 70-year-old man. A mass was found in his right lobe of the liver in May 2004. He refused

to receive further diagnosis and treatment until January 2006 when he began to suffer from anorexia and dull abdominal pain. Computer tomography (CT) detected a large mass (about 9.5 cm × 8.5 cm × 8.5 cm) in the right lobe of the liver with significant enhancement (Figure 1A). Alpha-fetoprotein (AFP) level was > 1210 ng/mL. He was diagnosed with a histologically proven HCC. Due to the large tumor size and invasion to the portal vein, the patient underwent two rounds of TACE with an interval of one month. The drugs used were 5fluoro2deoxyuridine (1.0 g), epirubicin (40 mg) and lipiodol (10 mL). In May 2006, three months after the second TACE, a routine postoperative CT scan found a minimal decrease in tumor size with necrosis < 25% (Figure 1B), while the AFP level was still > 1210 ng/mL. The second angiography revealed hepatic artery-portal vein fistula and hepatic arteriovenous fistula. Although additional gelfoam pieces were used and the fistula disappeared after embolization, a poor prognosis was still predicted. Consequently, PTS (Beijing Vision Drugs Development Ltd., Beijing, China) was used to enhance the effect of TACE after informed consent was obtained from the patient.

The mass was punctured percutaneously with a fine needle under CT guidance. After the tip of the needle was manipulated into the mass, about 10 mL of PTS was injected intratumorally in a multi-point fashion. This injection was repeated four times. The interval between each procedure was between three and seven days according to the patient's clinical condition. When all five injections were completed, the AFP level dropped to 1106 ng/mL. Two months later, a routine follow-up CT showed moderate improvement, no blood being supplied to the tumor (Figure 2A), and the AFP level dropped further down to 185 ng/mL. In an attempt to investigate the increased efficacy, PTS injections were repeated three more times. Following a routine check two months later, a CT examination of the abdomen demonstrated complete deposit of oil and no signs of recurrence or tumor embolism (Figure 2B). Furthermore, the AFP was within the normal reference range (4.44 ng/mL).

The only side effect of this therapy was abdominal pain, which occurred after the first two procedures, but subsided shortly thereafter in approximately 10 min. No other discomfort was noted post-procedurally. Four years following the last PTS treatment, the patient exhibited no evidence of recurrence and no other abnormal liver function serum values, and he had a normal serum AFP level. The AFP level changes in the course of the treatment are summarized in Table 1.

DISCUSSION

Despite the fact that TACE has become the standard treatment for unresectable HCC, it is frequently unsuccessful. Rate of local recurrence following tumor resection is also unacceptably high^[3-6]. In addition, TACE alone fails to control the tumor completely, often leading

Table 1 Changes of alpha-fetoprotein in the course of therapy

Time (yr-mo)	APF (ng/mL)	TACE	PTS injections
2005-4	533.8		
2006-1	> 1210	Yes	
2006-2	> 1210	Yes	
2006-5	> 1210	No	5 times
2006-6	1106	No	
2006-8	185	No	3 times
2006-10	4.44	No	
2008-6	2.69	No	
2009-3	3.84	No	
2010-4	3.86	No	

A sharp decrease in alpha-fetoprotein (AFP) levels occurred right after para-toluenesulfonamide (PTS) injections. The initial series of transcatheter arterial chemoembolization (TACE) failed to control the tumor (although the TACE's effect on fistula embolization was irreplaceable). PTS treatment appeared to be effective and well-tolerated. A 4-year follow-up showed no sign of recurrence.

to a poor prognosis. In this report, the patient had received two sessions of TACE and embolized the fistula successfully before admission. Although little effect was got on HCC, the TACE did restrict the tumor's growth and metastasis that made it possible for PTS to eradicate the tumor later. Due to the large tumor size and involvement of the portal vein, this lesion was inoperable, and other local ablative therapies, such as percutaneous ethanol injection, microwave coagulation therapy and radiofrequency ablation (RFA) were considered neither effective nor safe. Complications caused by these modalities may result in a high mortality rate. Therefore, we attempted to treat the patient with the combined administration of PTS and TACE. Consequently, the patient's condition was significantly improved with satisfactory tumor control and without severe complications.

Para-toluenesulfonamide (P-TSA) is the active ingredient in PTS. The P-TSA is a white, odorless, crystalline substance that has a very low solubility in water. The molecular formula is C₇H₉NO₂S. The injection solution is a clear, colorless, oil liquid with a characteristic odor and contains 330 mg/mL P-TSA. PTS has been approved for clinical trial injection in both 3 mL ampoule and 5 mL ampoule. Recommended storage temperature is 25 °C (77°F), although a range of 10-35 °C (50-90°F) is acceptable. Long-term exposure to light should be avoided.

PTS produces mild side effects while necrotizing the tumor tissues effectively and thoroughly. However, PTS is still in the phase of clinical trial, and the mechanism of the antitumor activity of PTS is still unclear. Primary pharmacological studies suggest that PTS inhibits tumor growth by acting as a tumor necrotizing agent^[1,2].

It has been shown that PTS does not cause serious side effects that have been observed frequently in conventional chemotherapy and locoregional therapy (e.g., RFA, alcohol injection, *etc.*), such as fever, bone marrow suppression, stomach discomfort, hemorrhage, needle-track seeding, lesion abscess, liver failure, biloma, biliary

Figure 1 Transcatheter arterial chemoembolization had little effect on the hepatocellular carcinoma, but restrict the size of tumor mass. A: Contrast computer tomography (CT) before the procedure showed a huge hypodense mass with remarkable enhancement and portal vein embolus; B: Two months after the initial 2 series of transcatheter arterial chemoembolization, contrast CT still found a hypodense nodule with partial contrast enhancement and portal vein invasion.

Figure 2 The following para-toluenesulfonamide injections resulted in a significantly improved clinical prognosis. A: Contrast computer tomography (CT) after the first 5 para-toluenesulfonamide (PTS) injections demonstrated a decreased nodule with partial retention of lipiodol. Remarkable necrosis and no blood supply were found in the rest part of the tumor; B: Two months after the last 3 PTS injections, contrast CT revealed homogeneous dense retention of lipiodol within the entire tumoral mass and no recurrent lesion was identified.

stricture, portal vein thrombosis, and hemothorax^[7-9]. Because most anticancer drugs are corrosive and extremely toxic, they will destroy both cancer cells and normal cells when given locally at high concentrations. PTS is a local therapeutic drug that is injected directly into the tumors and has been shown to cause selectively necrosis in a variety of cancers with minimal damage to normal tissues^[2,10].

Local ablative therapies share similar difficulties with surgical resection. The size, site and number of tumors, vascular and extrahepatic involvement as well as liver function of the patient pose a relatively minor effect on the usage of PTS^[8,9]. PTS is a more readily available alternative to the local ablative therapies.

PTS, in form of lipophilic fluid, kills tumor cells by a rodent mode. Local and intratumoral injection is the optimal route of PTS delivery. Being largely different from both alcohol and RFA therapies, PTS can disseminate itself in tumors more easily than other caustic agents, such as alcohol. Therefore, a successful PTS administration is to approach to the anatomically dangerous or hard-to-reach areas and diffuse to the target area and induce injury to the tumor tissues. This might be the mechanism as to why PTS combined with TACE could effectively treat the HCC with vascular invasion. As a locoregional antitumor agent, PTS is safe^[11,2,10]. But up to date, PTS

is still only a locally-used antitumor agent. It is intended mainly for the treatment of a limited number of detectable tumors. PTS is not suitable to be used alone for the treatment of multifocal HCCs.

This case report demonstrated that PTS is effective in treating liver cancers by intratumoral injection, which was hypothesized to enhance the effect of TACE. This combined therapy may prove to be useful in the treatment of patients with refractory and recurrent HCC. Therefore, subsequent large, multi-center, randomized controlled studies are needed to facilitate the introduction of PTS as a novel modality for the treatment of cancers.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomerybissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 ± 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings

ABOUT COVER Dr. Jing-Yun Ma, a renowned expert in biomedical editing and publishing, worked as the editorial director and senior editor of *World Journal of Gastroenterology* (1996-2005) and other major national and international medical journals (1976-1995). She is now the Editor-in-Chief of Jing-Yun Ma Expert Office for Biomedical Editing and Publishing.

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-IX Editorial Board

Abstract

NR4A2 is a transcription factor belonging to the steroid orphan nuclear receptor superfamily. It was originally considered to be essential in the generation and maintenance of dopaminergic neurons, and associated with neurological disorders such as Parkinson's disease. Recently, NR4A2 has been found to play a critical role in some inflammatory diseases and cancer. NR4A2 can be efficiently trans-activated by some proinflammatory cytokines, such as tumor necrosis factor- α , interleukin-1 β , and vascular endothelial growth factor (VEGF). The nuclear factor- κ B signaling pathway serves as a principal regulator of inducible NR4A expression in immune cells. NR4A2 can trans-activate Foxp3, a hallmark specifically expressed in regulatory T (Treg) cells, and plays a critical role in the differentiation, maintenance, and function of Treg cells. NR4A2 in T lymphocytes is pivotal for Treg cell induction and suppression of aberrant induction of Th1 under physiological and pathological conditions. High density of Foxp3⁺ Treg cells is significantly associated with gastrointestinal inflammation, tumor immune escape, and disease progression. NR4A2 is produced at high levels in CD133⁺ colorectal carcinoma (CRC) cells and significantly upregulated by cyclooxygenase-2-de-

rived prostaglandin E₂ in a cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA)-dependent manner in CRC cells. The cAMP/PKA signaling pathway is the common pathway of NR4A2-related inflammation and cancer. NR4A2 trans-activates osteopontin, a direct target of the Wnt/ β -catenin pathway associated with CRC invasion, metastasis, and poor prognosis. Knockdown of endogenous NR4A2 expression attenuates VEGF-induced endothelial cell proliferation, migration and *in vivo* angiogenesis. Taken together, NR4A2 emerges as an important nuclear factor linking gastrointestinal inflammation and cancer, especially CRC, and should serve as a candidate therapeutic target for inflammation-related gastrointestinal cancer.

INTRODUCTION

A quarter of cancer-related deaths worldwide are currently associated with chronic inflammation^[1]. Most malignancies in the digestive system such as colorectal carcinoma (CRC), gastric cancer and hepatocellular carcinoma belong to the inflammation-related cancers^[2-5]. The type of inflammation related to these cancers is chronic inflammation, or more precisely, nonresolving inflammation. The development and progression of these tumors

in the digestive system are accompanied by angiogenesis, release of inflammatory cytokines and/or chemokines, and recruitment of immune cells in the tumor microenvironment. Apart from some infectious agents such as hepatitis B virus and *Helicobacter pylori*, inflammation-related molecules and their related inflammatory networks play important roles in the development of this group of cancers. However, it is clear that a single or even a few molecules are unable to represent the inflammatory predisposition of a given cancer. In the inflammation-related cancers, inflammatory molecules do not function in isolation, but interact with one another to form inflammatory networks. A small number of highly connected protein nodes (known as hubs) in the inflammatory network may have high probabilities of engaging in essential biological functions. In our previous work on screening hub genes associated with liver metastasis of gastric cancer, we identified NR4A2, one of the hub genes related to gastric cancer malignant phenotype^[6]. Here, we summarize the role of NR4A2 in inflammation and cancer.

NR4A2 (also known as NOT, TINUR, RNR-1, HZF-3 and Nurr1) maps to chromosome 2q22-23 and is a transcription factor belonging to the steroid nuclear hormone receptor superfamily. This superfamily also includes two other members, NR4A1 (also known as HMR, N10, TR3, NP10, GFRP1, NAK-1, NGFI β and Nur77) and NR4A3 (also known as CHN, TEC, CSMF, MINOR and NOR1)^[7]. Their ligand-binding pockets are hidden by bulky amino acids, therefore, the three nuclear factors belong to an orphan receptor subfamily. All three subfamily members bind to a consensus sequence AAAGGTCA as monomers or to palindromic DNA binding motif sequence TDATAITTTX \times AAATGCCA as homodimers. Expression of each family member alone is sufficient to activate the above sequence-directed transcriptional activities, indicating that the family members are constitutive orphan steroid receptors that do not require ligands for activation^[8]. The three nuclear receptors have also been implicated in cell cycle regulation, energy metabolism, apoptosis, inflammation and carcinogenesis. They are important for apoptosis in lymphocytes and other cell types^[9-12] and for the differentiation of dopaminergic neurons^[13]. NR4A1 and NR4A3 have been shown to be involved in apoptosis-related pathways. NR4A1 has been reported to play either an antiapoptotic or proapoptotic function depending on cell types. NR4A3 has been reported to play a partly redundant functional role with NR4A1 in inducing T-cell apoptosis^[9]. Knocking out both NR4A1 and NR4A3 in mice leads to rapid postnatal development of acute myeloid leukemia (AML), indicating that they function as potent tumor suppressors^[14,15]. Meanwhile, the three NR4A receptors are transcriptional regulators of hepatic glucose metabolism and lipid metabolism. NR4As function as novel branches of cyclic adenosine monophosphate (cAMP)-dependent regulators of hepatic glucose production under healthy and diabetic conditions. Activated NR4A1 and NR4A3 elevate the production of blood glucose^[16]. NR4As inhibits adipo-

cyte differentiation, leading to repressed adipogenesis^[17]. NR4A1 and NR4A2 can form heterodimers with retinoic acid receptor and influence retinoid signaling and Th17 cell differentiation^[18,19].

NR4A2 has been previously linked to neurological diseases because of its essential role in the generation and maintenance of dopaminergic neurons in the brain. Gene encoding NR4A2 may be susceptibility gene for neurological diseases such as Parkinson's disease, schizophrenia, and manic depression. Homozygous NR4A2 knockout mice have severe impairments in midbrain neuronal development and dopamine expression, and die soon after birth^[20]. However, the horizontal and vertical movement of the heterozygous NR4A2 knockout mice is impaired by the reduction in brain dopamine^[21]. The most important event in downregulating NR4A2 expression in brain tissues is mutations, such as missense mutations in exon 3, and point mutations in exon 1 of NR4A2 have been reported in disorders related to dopaminergic dysfunction such as schizophrenia, manic depression, and familial Parkinson's disease^[22-24]. In recent years, however, more researches have focused on the relationship between NR4A2 and inflammation.

NR4A2 AND INFLAMMATION

NR4A2 and immune cells

Immune cells are essential in controlling the inflammatory response. T and B lymphocytes, macrophages, neutrophils, and mast cells are all important in the maintenance of chronic inflammation and play active roles in the initiation and progression of inflammation-related cancers. Cytotoxic CD8⁺ T lymphocytes and CD4⁺ T helper lymphocyte subpopulations [Th1, Th2, Th17, and regulatory T (Treg) cells] play key roles in balancing cancer-promoting inflammation and antitumor immunity in the tumor microenvironment. Imbalances in Th1/Th2, neutrophil/CD8⁺ T cells, and CD8⁺ T cell/Treg cell in tumors or adjacent tissues, high density of intratumoral macrophage infiltration, as well as high circulating neutrophil-to-lymphocyte ratio are associated with the prognosis of cancer patients^[25]. Recently, NR4A2 has been found to function as a critical regulator in T lymphocytes, macrophages, mast cells and even fibroblasts.

Treg cells (CD4⁺CD25⁺Foxp3⁺) inhibit immune responses by suppressing CD8⁺ T cell or Th1 cell function, playing an important role in maintaining immune homeostasis. Foxp3, a hallmark of Treg cells, is specifically expressed in Treg cells and plays a critical role in the differentiation, maintenance and effector functions of these cells. Foxp3 has recently been identified as a direct target of NR4A2. The -209 to +12 promoter region of Foxp3 encoding region has been confirmed to be the minimal responsive region to NR4A2. NR4A2 regulate CD4⁺ T cells by inducing Foxp3 and strongly repressing Th1 cytokine production, such as interleukin (IL)-2 and interferon (IFN)- γ . NR4A2 in T cell is pivotal for Treg cell induction and suppression of aberrant induction of

Th1 under physiological and pathological conditions. Deletion of NR4A2 in T cells attenuates the induction of Treg cells and causes aberrant induction of Th1, leading to exacerbation of colitis. Both IFN- γ and IL-17 are apparently repressed under Th1 and Th17 conditions, respectively, and Foxp3 can be induced under Th1 and Th17 conditions by NR4A2^[26]. Thus, NR4A2 is crucial in lineage maintenance and effector functions of Treg cells and in regulation of the Th1/Treg balance, contributing to immune homeostasis (Figure 1A).

Macrophages can be divided into two main classes: M1 and M2. M1 macrophages (classically activated) originate upon encounter with IFN- γ and microbial stimuli and are characterized by IL-12 production and consequent activation of a polarized type I T cell response, fighting against tumors, producing high amounts of inflammatory cytokines, and activating adoptive immunity. M2 macrophages are responsible for angiogenesis, remodeling and repair of wounded tissues, and promote carcinogenesis and downregulate M1 function. NR4As are highly inducible in macrophages by diverse inflammatory stimuli. Treatment of macrophages with lipopolysaccharide, cytokines, or oxidized lipids triggers the transcriptional induction of NR4A expression. NR4A2 is an intermediate maker for macrophage activation^[27]. The nuclear factor (NF)- κ B signaling pathway is a principal mediator of inducible NR4A expression in macrophages^[28]. NR4A2 is a target of macrophage migration inhibitory factor (MIF) signaling and plays an active role in regulating mitogen-activated protein kinase (MAPK) phosphatase 1, a critical MAPK signaling inhibitor^[29]. NR4A2 may serve as a potential transcriptional mediator of inflammatory signals in activated macrophages. However, it is necessary to define the difference in NR4A2 expression between M1 and M2; the two functionally different macrophages.

NR4A2 and autoimmune diseases

NR4A2 plays either a proinflammatory or anti-inflammatory role. The conflicting roles of NR4A2 depend on the type of immune disorders. Multiple sclerosis (MS) is an autoimmune disease mediated by Th17 and Th1 cells in the central nervous system (CNS). In an animal model of MS, NR4A2 is selectively upregulated in T cells isolated from the CNS, while forced expression of NR4A2 augments promoter activities of IL-17 and IFN- γ genes, leading to excess production of these cytokines^[30]. In contrast, NR4A2 can also exert anti-inflammatory and neuroprotective effects by docking to NF- κ B/p65 on target inflammatory gene promoters in an NR4A2/CoREST transrepression pathway in microglia and astrocytes, leading to protection of dopaminergic neurons from inflammation-induced death^[31]. Furthermore, NR4A2 is a key downstream mediator of cAMP response element-binding protein (CREB)-induced neuroprotection after insults leading to excitotoxic and oxidative stress^[32].

Chronic inflammation is a hallmark of rheumatoid arthritis and osteoarthritis. The arthritis is a well-established

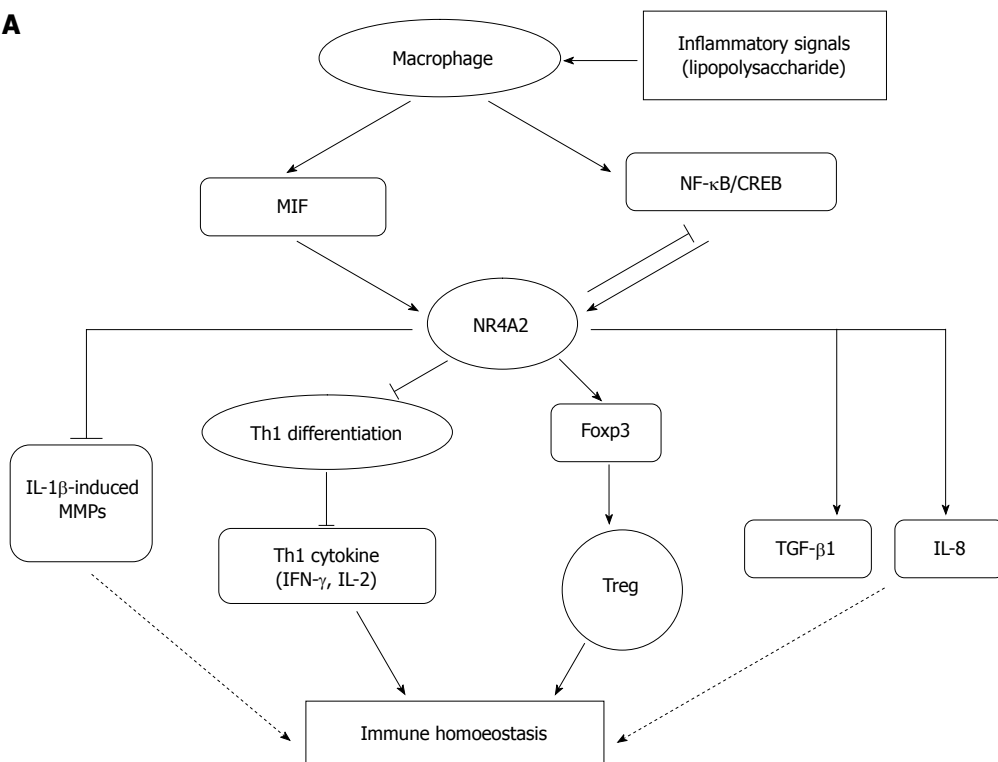

disease model to study the mechanism by which NR4A2 is involved in the process of chronic inflammation. NR4A2 expression is markedly higher in synovial tissue of patients with rheumatoid arthritis compared with normal subjects. The high expression of NR4A2 is caused by the stimulation of some proinflammatory cytokines, such as tumor necrosis factor (TNF)- α , IL-1 β and prostaglandin E₂ (PGE₂). Ectopic expression of NR4A2 induced by TNF- α in normal synoviocytes significantly increases cell proliferation and survival, promotes anchorage-independent growth, and induces migration and invasion^[33]. The trans-activation of NR4A2 by these cytokines and molecules depends on distinctive subunit binding to the NR4A2 promoter. IL-1 β and TNF- α trans-activate the NR4A2 *via* a proximal promoter region that contains a consensus NF- κ B DNA-binding motif. IL-1 β - and TNF- α -induced NF- κ B binding to this site is due predominantly to p65-p50 heterodimer and p50 homodimer complexes^[34]. NR4A2 robustly promotes IL-8 expression *via* co-operating with the NF- κ B/p65 subunit in the presence of TNF- α in human inflammatory disease^[35]. NR4A2 and TNF- α also synergistically induce matrix metalloproteinase (MMP)-13 protein which is a critical enzyme for the degradation of type II collagen molecules^[36]. NR4A2 trans-activates MMP-13 by directly targeting the proximal region of the MMP-13 promoter^[33]. PGE₂ signaling leads to the phosphorylation of CREB transcription factors, which can, in turn, bind to the NR4A2 promoter region -171/-163 and activate transcription. PGE₂ can repress IL-1 β -induced MMP-1 and activate NR4A2 expression. Meanwhile, NR4A2 antagonizes the progression of IL-1 β -induced MMP-1 in osteoarthritic cartilage^[37]. In human synovial tissue, corticotropin-releasing hormone (CRH) also can induce the expression of NR4A2, which in turn upregulates CRH gene expression. NR4A2 is a downstream effector molecule in the modulation of endothelial function by CRH signaling^[38]. Thus, NR4A2 as a mediator of an autocrine inflammatory cascade to amplify the inflammatory response participate in the CRH-receptor-mediated signaling in synovial tissue *via* the cAMP/CREB pathway. Figure 1B depicts the potential role of NR4A2 on the development of autoimmune diseases (MS and rheumatoid arthritis) and neurodegenerative diseases like Parkinson's disease.

NR4A2 AND GASTROINTESTINAL CANCER

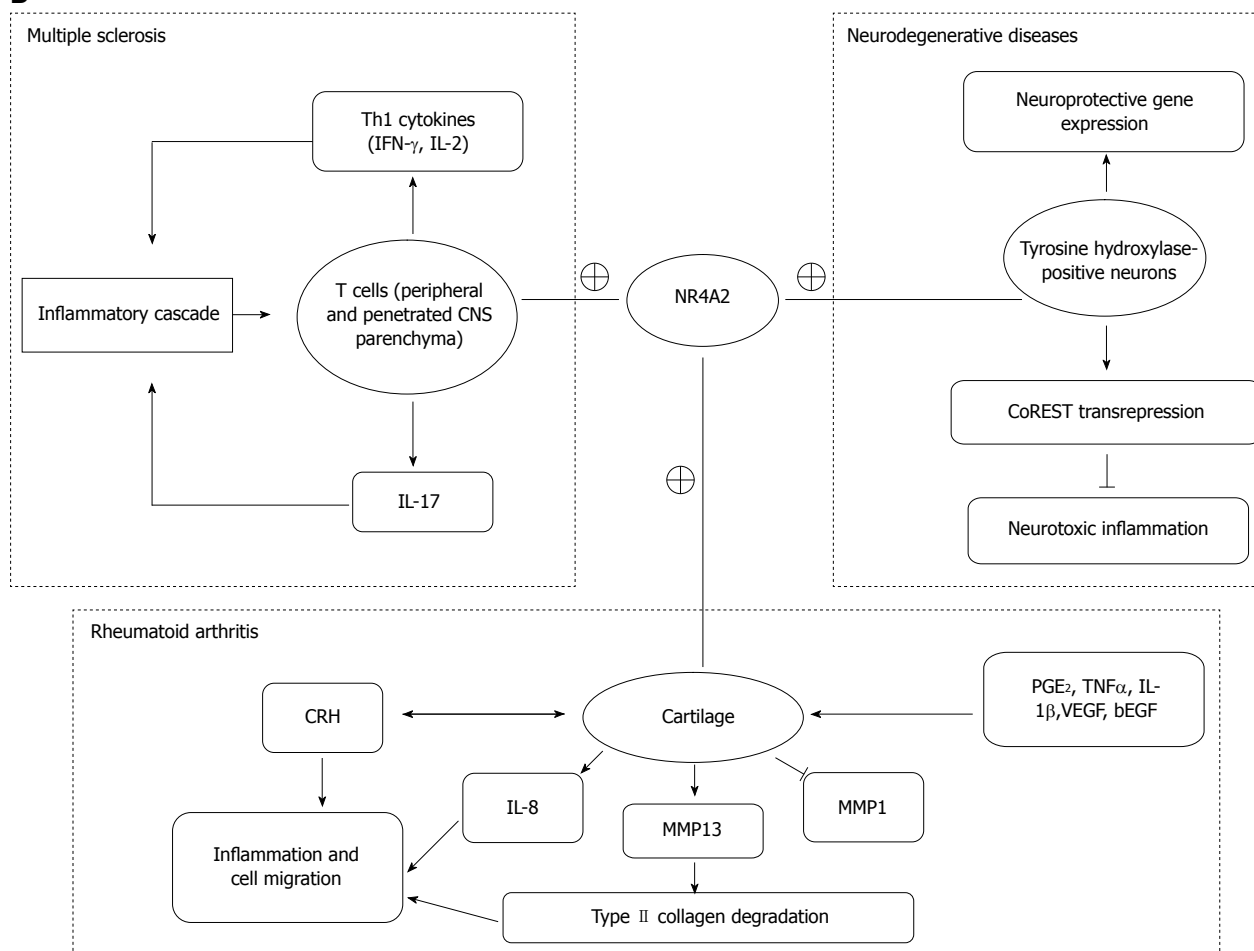

NR4A2 promotes proliferation of cancer cells

NR4A2 and endothelin-1 are expressed at a significantly higher level in the CD133⁺ fraction than the CD133⁻ fraction of colon cancer cells. The overexpression of CD133, NR4A2, and endothelin-1 is also evident in human colon cancer specimens compared to normal tissues. Furthermore, effective knockdown of CD133 protein is associated with a parallel reduction of NR4A2 and endothelin-1 protein, indicating the existence of a functional

relationship between CD133, NR4A2 and endothelin-1 expression in colon cancer cells^[39]. NR4A2 is involved in anchorage-independent growth of cancer cells and plays a significant role in mediating thromboxane A₂ receptor induced cell proliferation and transformation in several cancer cell lines^[11,40]. NR4A2 also plays a key role as a transcriptional integration point between the eicosanoid and fatty acid metabolic pathways involving in energy utilization *via* fatty acid oxidation, thus facilitating CRC cell survival and growth^[41]. These results indicate that NR4A2 expressed in cancer cells might play an active role in promoting the initiation and progression of CRC.

NR4A2-related inflammatory pathways in gastrointestinal cancers

CRC is closely related to inflammation, because regular use of nonsteroidal anti-inflammatory drugs (NSAIDs) reduces relative risk of developing CRC by 30%^[42]. NSAIDs inhibit cyclooxygenase (COX) enzymes and prostaglandin synthases, which are key components in the arachidonic acid metabolism pathway. The main mechanism of action of NSAIDs on CRC is to inhibit COX-2, the inducible isoform of the COX enzyme. COX-2 is upregulated in inflammation and cancer, resulting in the production of PGE₂ which binds to and activates G-protein-coupled prostaglandin E receptor 1 (EP1)^[43]. COX-2-derived PGE₂ is produced at high levels

in CRC. Some evidence indicates that PGE₂ plays a pro-oncogenic role in CRC progression. PGE₂ stimulation of the human EP1 receptor upregulates the expression of NR4A2 by a mechanism involving the sequential activation of the Rho, protein kinase A (PKA), CREB and NF-κB signaling pathways^[44]. NR4A2 is an immediate early gene induced by PGE₂ in a cAMP/PKA-dependent manner in CRC cells. NR4A2 can stimulate progression of CRC downstream from COX-2-derived PGE₂^[45]. The common pathway of NR4A2-related inflammation and cancer is the cAMP/PKA signaling pathway. The cAMP/PKA signaling pathway plays a critical role not only in inflammation but also in carcinogenesis^[46-48]. It has been proven that cAMP/PKA can activate CREB-dependent reporter gene expression in gastric cancer cell lines^[49]. Through cAMP/PKA activation, PGE₂ stabilizes the complex of PI3K/Ras to inhibit cell apoptosis in colon cancer cell lines^[50]. The proximal promoter region of NR4A2 contains a CREB-binding site by which this transcriptional factor participates in cAMP-mediated induction^[32]. However, the cAMP/PKA pathway is not the only way by which NR4A2 participate in the progression of CRC. PGE₂ either modulates the β-catenin signaling axis, a key pathway for colorectal tumorigenesis, or act via NR4A2^[51]. PGE₂ can induce the expression of NR4A2 and two target genes of Wnt/β-catenin: vascular endothelial growth factor (VEGF) and cyclin D1. NR4A2

protein can be regulated by Wnt signaling^[52]. Meanwhile, NR4A2 and Wnt signaling are sequentially repressed after blockade of COX-2 activity, with NR4A2 inhibition occurring in the first few hours of the treatment, whereas repression of the Wnt/ β -catenin pathway happens a few days later. This change might be associated with COX-2 inhibitor-induced downregulation of osteopontin (OPN) whose high expression level significantly correlates with advancing tumor stage in human CRC^[53]. OPN, a marker of colon cancer progression, is a direct target of Wnt/ β -catenin pathway. Furthermore, NR4A2 trans-activates OPN by directly binding to the NR4A2 response element at the OPN promoter^[54]. OPN is involved in the development of various inflammatory conditions^[55] and also play a pivotal role in carcinogenesis and metastasis of digestive system cancer, such as gastric cancer and hepatocellular carcinoma. High expression of OPN in tumors is associated with tumor invasion, metastasis, and poor prognosis in gastric cancer and CRC^[53,56]. Downregulation of OPN, probably through blockade of NR4A2 and Wnt signaling, is an important component of the antitumor activity of COX-2 inhibitors^[57]. VEGF potently and rapidly induces expression of NR4A2 mRNA, protein and its promoter activity in endothelial cells. Deletion of the putative CREB site in the proximal region of the NR4A2 promoter markedly reduces VEGF-induced promoter activity. VEGF also stimulates the binding of nuclear CREB protein to its site in the NR4A2 promoter. Knockdown of endogenous NR4A2 expression attenuates VEGF-induced endothelial cell proliferation, migration and *in vivo* angiogenesis^[58]. The growth and metastasis of cancer cells rely on angiogenesis, and VEGF is an important angiogenic factor. It has been reported that VEGF is highly expressed in gastrointestinal cancers and plays a pivotal role in tumor angiogenesis, tumor growth, and metastasis^[59-61]. The correlation among the expression levels of OPN, COX-2 and VEGF in gastric cancer indicates that OPN, COX-2, and VEGF synergistically promote angiogenesis and metastasis^[62]. The three molecules are all closely related to NR4A2. The NF- κ B signaling pathway serves as a principal regulator of inducible NR4A expression in some chronic inflammation, while NF- κ B pathway plays a major function in CRC development and progress^[63]. These results indicate that aberrant expression of NR4A2 provokes several inflammation-related signaling pathways and promotes the development and progression of gastrointestinal cancers. Figure 1C depicts the potential role of NR4A2 on the development of CRC.

NR4A2-related lymphocytes in gastrointestinal inflammation and cancers

Foxp3⁺ Treg cells are significantly increased in gastric mucosa of patients with gastritis, peptic ulcer, and those with gastric cancer, as compared with healthy controls^[64]. An imbalance of colitogenic Th1 cells and Treg cells facilitates the development of aggravated chronic enterocolitis^[65]. Although NR4A2 has not been implicated in

predicting CRC prognosis, the NR4A2-related Th lymphocytes are closely linked to adverse outcome of CRC patients. Foxp3⁺ and CD3⁺ T-cell densities are increased in CRC tissues compared with autologous normal mucosa. Furthermore, a low CD3⁺/Foxp3⁺ cell ratio and low numbers of CD3⁺ T cells in tumors predict shorter disease-free survival and are stronger prognostic variables than tumor stage or number of lymph node metastases^[66]. The density of Foxp3⁺ Treg cells in tumor draining lymph nodes (TDLNs) is dramatically higher than that in peripheral blood lymphocytes, but significantly lower than that in tumor-infiltrating lymphocytes. Foxp3⁺ Treg cells in TDLNs are more correlated with disease progression and potentially influence CD8⁺ T-cell functions^[67]. A new Treg cell population, CD8⁺CD25⁺Foxp3⁺ cells, has been found in CRC tissues. IL-6 and transforming growth factor- β 1 can synergistically induce the generation of these new Treg cells that may contribute to tumor immune escape and disease progression^[68]. The CRC patients with high expression of the Th17 cluster have a poor prognosis, whereas patients with high expression of the Th1 cluster have prolonged disease-free survival, thus functional Th1 and Th17 clusters yield opposite effects on patient survival in CRC^[69]. Th17 and Treg cells accumulate in the tumor microenvironment of early gastric cancer and then infiltration of Treg cells gradually increases according to disease progression, in contrast to Th17 cells^[70]. Significantly more Foxp3⁺ Treg cells accumulate in gastric tumors. The elevated Foxp3 expression in tumor-infiltrating Treg cells correlates with expression of COX-2 and PGE₂ and is associated with the TNM stage in gastric cancer patients. Tumor-infiltrating Treg cells with increased Foxp3 expression can mediate immune suppression *via* COX-2/PGE₂ production in the gastric cancer microenvironment^[71]. NR4A2 trans-activates the transcription factor Foxp3, while Foxp3 plays a key role in Treg cell function. Furthermore, NR4A2 is highly expressed in the CD133⁺ CRC cells and also pivotal for Treg cell induction and suppression of aberrant induction of Th1 cells^[26,39]. NR4A2 is a target of MIF/MAPK signaling, while MIF expression in tumors is inversely associated with the prognosis of hepatocellular carcinoma^[25,29]. Thus, it can be inferred that NR4A2 expression in lymphocytes and/or tumor cells might promote gastrointestinal inflammation and carcinogenesis and also indicate poor prognosis of CRC and gastric cancer.

QUESTIONS CONCERNING NR4A2 FUNCTIONS IN HUMAN CANCER

There are conflicting data concerning the oncogenic or tumor suppressive function of the three NR4A family members. Several lines of evidence mentioned above indicate that NR4A2 plays an important role in promoting inflammation and gastrointestinal cancers. Downregulation of NR4A2 results in reduced anchorage-independent growth that is largely attributable to increased

anoikis, furthermore, downregulation of NR4A2 as well as NR4A1 promotes intrinsic apoptosis in several other experimental cancer cells such as cervical cancer^[11]. Thus, NR4A family members exhibit oncogenic functions with regard to cell proliferation and anti-apoptosis. However, knocking out both NR4A1 and NR4A3 in mice leads to rapid postnatal development of AML, indicating they function as critical tumor suppressors^[14]. NR4A2 also exhibits tumor suppressor function in bladder cancer. Chemical-induced activation of NR4A2 results in bladder cancer cell apoptosis and suppresses bladder cancer growth, as reported by the research group of Kamat^[72]. However, this group also reported that cytoplasmic dislocation of NR4A2 in bladder cancer was associated with poor prognosis, and silencing of endogenous NR4A2 attenuated the migration of bladder cancer cells, indicating that NR4A2 functions as a tumor-promoting factor^[73]. NR4A2 is a nuclear factor, therefore, cytoplasmic dislocation might indicate loss of function of NR4A2. Thus, NR4A2 is more likely to function as a tumor suppressor in bladder cancer. These conflicting data can be explained by the hypothesis that NR4A2 functions differently in different tissues. More studies using cancer of different origins are necessary to elucidate the functions of NR4A2 in human cancers.

In summary, NR4A2 plays a pivotal role in some inflammatory diseases and cancers. NR4A2 functions as an inflammatory mediator primarily *via* at least two distinct signaling pathways, cAMP/PKA and NF- κ B, suggesting an important common role for this transcription factor in mediating multiple inflammatory signals. NR4A2 trans-activates the transcription factor Foxp3, while Foxp3 plays a key role in Treg cell function. Treg cells contribute significantly to tumoral immune escape and disease progression. NR4A2 trans-activates OPN while OPN is a direct target of Wnt/ β -catenin pathway. There is a crosstalk between NR4A2 and Wnt/ β -catenin signaling pathways in human gastrointestinal cancers such as CRC. Taken together, the aberrant expression of NR4A2 in the tumors and tumor-infiltrating lymphocytes might facilitate gastrointestinal inflammation, carcinogenesis and cancer metastasis. NR4A2 emerges as an important nuclear factor linking gastrointestinal inflammation and cancers, especially CRC, and might serve as a candidate therapeutic target for the inflammation-related gastrointestinal cancers.

INTRODUCTION

In quality of Guest Editor, I am delighted to introduce this special issue of *World Journal of Gastroenterology (WJG)* focusing on regenerative medicine and gastroenterology.

The term “regenerative medicine” (RM) was coined only in 1999 and refers to the field of health sciences which aims to replace, regenerate or bioengineer *ex novo* human cells, tissues, or organs to restore or establish normal function^[1]. Its main trait is the multidisciplinary approach required to reach its goals. As a corollary, RM investigations are made possible by synergistic contributions of researchers with different backgrounds, namely physicians, veterinarians, cell biologists, extracellular matrix experts, bioengineers, chemists and biochemists, physicists, molecular biologists, biomaterial scientists, mathematicians and statisticians, immunologists, physiologists, geneticists, and others. For this reason, in 2006, the United Nations Educational, Scientific and Cultural Organization defined RM as a super discipline whose contours are still being defined^[2]. It should be noted that the term “(bio)engineering” is often, yet erroneously, used as synonymous to RM. In fact, the process of regenerating cells, tissues and organs can occur *in vivo* or *ex vivo*, and may require cells, natural or artificial scaffolding materials, growth factors, or combinations of all three elements, whereas the term bioengineering is narrower in scope and strictly defined as manufacturing body parts *ex vivo* by seeding cells on or into a supporting scaffold.

The past decade has been marked by numerous ground-breaking achievements in the field of RM. Researchers have developed sophisticated, cutting-edge technologies to manufacture functional substitutes of relatively simple organs such as vessels, bladders, segments

Abstract

This special issue of *World Journal of Gastroenterology* has been conceived to illustrate to gastroenterology operators the role that regenerative medicine (RM) will have in the progress of gastrointestinal (GI) medicine. RM is a multidisciplinary field aiming to replace, regenerate or repair diseased tissues or organs. The past decade has been marked by numerous ground-breaking achievements that led experts in the field to manufacture functional substitutes of relatively simple organs. This progress is paving the ground for investigations that aims to the bioengineering and regeneration of more complex organs like livers, pancreas and intestine. In this special issue, the reader will be introduced, hand-in-hand, to explore the field of RM and will be educated on the progress, pitfalls and promise of RM technologies as applied to GI medicine.

Key words: Regenerative medicine; Gastroenterology

Orlando G. Regenerative medicine technology applied to gastroenterology: Current status and future perspectives. *World J*

of upper airways and urethras^[1,3]. These organs were engineered from patients' own cells and successfully implanted to replace diseased or damaged tissue. At the same time, stem cells treatments are being developed and tested in seminal clinical trials for treatment of various diseases^[4-6].

This special issue of *WJG* has been conceived to illustrate to gastroenterology operators how RM may impact gastrointestinal (GI) medicine. The manuscript by Carbone *et al*^[7] stigmatizes the unmet clinical needs in gastroenterology and paves the ground for the following papers which show the fields and clinical settings where RM has the potential to meet those needs. In particular, Domínguez-Bendala *et al*^[8] from the Diabetes Research Institute of the University of Miami, FL, review the most promising avenues of research aimed at generating a potentially inexhaustible supply of insulin-producing cells for islet regeneration. These avenues include the differentiation of pluripotent and multipotent stem cells of embryonic and adult origin along the beta cell lineage, and the direct reprogramming of non-endocrine tissues into insulin-producing cells. Dufrane *et al*^[9] from the Pôle de Chirurgie Expérimentale et Transplantation, Université Catholique de Louvain, Brussels, Belgium, complete the session on RM applied to diabetes sciences by drawing state of the art of investigations aiming to produce a bio-artificial pancreas to treat diabetes, with emphasis on islet encapsulation technology and immunoisolation.

Four papers are focused on the bioengineering and regeneration of different segments of the gastrointestinal tract. Koch *et al*^[10] from the Wake Forest Institute of Regenerative Medicine, Wake Forest University, Winston Salem, United States, report on the most recent developments in the bioengineering of sphincteric units of the GI tract, while Londono *et al*^[11] from the McGowan Institute for Regenerative Medicine, University of Pittsburgh, Pittsburgh, United States, focus on the esophagus. The group at the Child Health and Great Ormond Street Hospital, University College London, London, lead by Totonelli *et al*^[12] complements the view on the bioengineering and regeneration of the esophagus by presenting it from the perspective of the pediatric surgeon. This session is completed by a seminal review from the Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Tokyo, Japan, lead by one of the pioneers of the field, Takagi *et al*^[13]. This manuscript^[13] reports on the most recent progress and clinical translation of one of the most cutting-edge bioengineering technologies, namely cell-sheet, which will certainly fascinate readers. Finally, the special issue is completed by a review paper on the state of the art liver bioengineering by our group at Wake Forest University, Winston Salem, United States^[14].

I do believe that readers will enjoy to be introduced, hand-in-hand, to this field, RM, which has the potential to change the way we approach diseases and how we

strategize treatments. I am very grateful to the publisher and the Editor-in-Chief for granting the great opportunity to guest edit the special issue in question. Importantly, the success of this issue has been made possible by the outstanding contribution of the above mentioned authors who are among the biggest names in the field.

Abstract

If only at a small scale, islet transplantation has successfully addressed what ought to be the primary endpoint of any cell therapy: the functional replenishment of damaged tissue in patients. After years of less-than-optimal approaches to immunosuppression, recent advances consistently yield long-term graft survival rates comparable to those of whole pancreas transplantation. Limited organ availability is the main hurdle that stands in the way of the widespread clinical utilization of this pioneering intervention. Progress in stem cell research over the past decade, coupled with our decades-long experience with islet transplantation, is shaping the future of cell therapies for the treatment of diabetes. Here we review the most promising avenues of research aimed at generating an inexhaustible supply of insulin-producing cells for islet regeneration, including the differentiation of pluripotent and multipotent stem cells of embryonic and adult origin along the beta cell

INTRODUCTION

Type 1 diabetes is an autoimmune disease characterized by the targeted destruction of the insulin-producing beta cells within the pancreatic islets. This is a chronic condition that requires daily insulin administration to maintain blood glucose levels within acceptable limits. However, because of the impossibility of exogenous insulin to accurately mimic islet function in the long run, diabetes often progresses with the development of debilitating complications, including kidney failure, blindness and vascular degeneration. Whole pancreas transplantation is an effective means to permanently correct hyperglycemia, but because of the risks inherent to any major surgery is rarely indicated as a treatment for diabetes. Islet transplantation is a less invasive procedure based on

the isolation of islets from their surrounding tissue and subsequent implantation in the recipient's liver^[1-8]. The method entails the enzymatic and mechanical separation of the islets from the rest of the organ. Since islets have a different density than acinar tissue, centrifugation can be used to enrich for layers of high purity that are infused intraportally into the liver of the patient, where they lodge and revascularize in a matter of weeks^[9-13]. The evolution of this technology has followed a typical pattern of innovation^[14] in which the hype elicited by an early milestone (the invention of the isolation method^[9]) ballooned with a technical achievement (the development of an steroid-free immunosuppression protocol that allowed for long-term graft survival^[15]), only to burst with the realization that the long-term outcome was not nearly as good as expected (only 20% of the patients remained insulin-independent five years after the procedure^[16]). As it is also commonly seen in most innovations, a dry "trough of disillusionment" ensued, during which researchers had to struggle with a hostile scientific and financial environment fed by the perception that islet transplantation was a therapeutic *cul-de-sac*. This has been so until very recently, when new developments (such as reports of novel T-cell depleting strategies that prolong graft survival and support function at rates that stand comparison to those seen when transplanting the entire organ^[17]) have shifted the perception again. Of course, the expectations have now been adjusted to the reality, and few would contend now that this therapy represents the future treatment of choice for diabetes. However, the advent of stem cells in the clinical arena has helped refocus the goals of islet transplantation, which is now seen as an invaluable testing ground for the next generation of cell therapeutics rather than as the next breakthrough in the fight against diabetes. Indeed, it is expected that stem cell-derived insulin-producing cells will take over islets in the near future, making this therapy available to millions (as opposed to hundreds) of patients. It is reasonable to expect that the transition to stem cells, if not seamless, will be easier and faster than for other conditions for which there is no cell therapy today. From adult and embryonic stem cells to somatic tissue engineering and islet regeneration, this review will describe the best positioned candidates to lead this transition in the next decade.

MESENCHYMAL STEM CELLS

Mesenchymal stem cells (MSCs) are ubiquitously found throughout the entire body. Tissues from which they can be commonly isolated and expanded include the stroma of the bone marrow, the adipose tissue and the umbilical cord^[18]. Whether or not MSCs from disparate sources are one and the same is still subject to debate. Indeed, to be considered MSCs they must share a number of characteristics such as adherence to plastic, capacity to differentiate along the bone, cartilage and fat lineages, presence of some surface markers (CD73, CD90 and CD105) and absence of others (chiefly those of the hematopoietic

lineage). However, some MSCs express markers of pluripotency (Oct4, Nanog) whereas others do not. Proliferation rates vary greatly between clones even if obtained from the same tissue, as evidenced by a recent example in which division rates of umbilical cord blood-derived MSCs ranged anywhere from 36 h to nearly 9 d^[19]. To complicate things even more, clones not only from the same tissue, but also from the same donor, also exhibit substantial variability^[20]. While these lines of evidence would suggest that MSCs comprehend a far too diverse collection of cell types to make common assumptions about their true identity and therapeutic potential, these differences ultimately reside in epigenetic signatures that -as shown time and again after the advent of reprogramming techniques- are anything but irreversible. From this perspective, even if some subsets of MSCs (such as those residing in the umbilical cord blood) would appear to be more adept than others at acquiring beta cell characteristics, considerations such as the ease of procurement and expansion or the ability to derive them from the prospective recipient (as would likely be the case when considering fat-derived MSCs) may ultimately weigh more than their apparent developmental potential at the time of isolation. This same consideration applies to what many perceive as an ontological limitation of MSCs to become pancreatic islets, since beta cells and MSCs arise from different embryonic germ layers. While this is true, the epigenetic landscape has proven in recent years to be much more pliable than previously thought. Be it by direct reprogramming into pancreatic endocrine tissues or by de-differentiation followed by re-education into insulin-producing cells, there is a growing consensus in the field of diabetes that MSCs may after all be of more use than that of providing a beneficial immunomodulatory^[21] and pro-angiogenic^[22] microenvironment for other cells.

Most approaches described until now to coax MSCs into beta-like cells are based on the sequential addition to their culture medium of soluble factors known to have an effect on the progression of pancreatic development. Partial success has been reported in recent years with MSCs derived from a wealth of different sources, including pancreatic ductal and acinar tissues^[23-25], fat^[26,27], amniotic fluid^[28], umbilical cord blood and placenta^[19,29-33], bone marrow^[34-37], endometrium^[38,39], and even from the very islets of Langerhans^[40-44]. However, unlike for human embryonic stem (hES) cells^[45-47], researchers in the field of MSCs still have failed to define a "gold standard" method of differentiation that results in bona fide, mature or otherwise, beta cells. Efforts may have been dispersed by the parallel pursuit of many different MSC sources, each one purportedly superior to the others, with an overall lack of focus on the description of robust protocols that may result in successful beta cell differentiation from all of them. Only recently have steps been taken to adopt the strategies developed for hES cells to the differentiation of primitive populations of MSCs^[19]. These caveats aside, the use of MSCs seems to be solidly ingrained in the pipeline of cell therapies diabetes. As

mentioned earlier, even in the unlikely case that all our efforts at converting them into cells with the ability to regulate glucose *in vivo* were to fail, MSCs are known for their ability to foster a favorable microenvironment for other cells to engraft. They do this by secreting a plethora of trophic agents such as nerve growth factor, basic fibroblast growth factor, vascular endothelial growth factor, brain-derived neurotrophic factor, insulin-like growth factor-1, and hepatocyte growth factor^[48]. There is no reason why the favorable results observed when co-transplanting islets with MSCs^[49-53] could not be extended to stem cell-derived beta-like cells.

NON-MESENCHYMAL ADULT STEM CELLS

Because of their shared provenance, hematopoietic cells from the bone marrow and umbilical cord blood cell are often mistaken with MSCs. Although some studies have shown that there are multipotent stem cells in the hematopoietic compartment of these tissues, in most cases the use of stromal (or mesenchymal) cells would be for non immune-related regeneration (see above), whereas hematopoietic cells would be primarily used to treat immune-related disorders. Examples of the latter are the decades-old practice of bone marrow transplantation or the recent attempts to reset the immunological clock of diabetes by autologous transplantation of bone marrow-derived stem cells^[54,55]. More recently, some groups have tested the administration of bone marrow-derived hematopoietic cells directly into the pancreas of the subject, an approach that has yielded promising results in type 2 diabetic patients when combined with hyperbaric oxygen therapy^[56]. Local injection of hematopoietic stem cells has also been tested clinically for the treatment of limb ischemia and diabetic neuropathy^[57]. In general, the mechanism by which these cells might exert their action is likely related to their ability to stimulate vascular regeneration (which may in turn result in enhanced islet function when injected in the pancreas) rather than to their direct differentiation into beta cells.

As for potential stem/progenitor cells residing in the pancreas, the ongoing debate about their existence is beyond the scope of this manuscript and has been already reviewed in^[58]. Whether or not they exist and have an active role on the physiological regeneration of the organ, to this date the only evidence that true pancreatic progenitors can be isolated and expanded *in vitro*^[59,60] is very preliminary and needs independent confirmation. The findings by Cardinale *et al.*^[61] on stem cell populations in the adult extrahepatic biliary tree can be propagated *ex vivo* and give rise to hepatocytes, cholangiocytes or pancreatic islets are also very promising but warrant similar caution.

EMBRYONIC STEM AND INDUCED PLURIPOTENT STEM CELLS

Mouse embryonic stem (ES) cells have been a staple of

developmental biology laboratories for the most part of the thirty years since they were first isolated^[62,63]. Their human counterparts, however, are a much more recent addition^[64]. When cultured according to very precise specifications, these unique cells proliferate at high speeds (typical population doubling times are in the range of 24-48 h) and in an indefinite manner, while retaining the potential to differentiate into derivatives of all three embryonic layers (endoderm, ectoderm and mesoderm). It is not difficult to appreciate in the evolution of this technology, as applied to human therapy, the same pattern previously described for islet transplantation: (1) a technology trigger, namely the initial characterization of ES cells by the team of James Thomson in 1998: A field whose main pursuit for more than two decades had been to perfect ES cell isolation techniques from non-murine species with the goal of generating higher animal models of human disease, suddenly became the new, potentially most powerful weapon to combat it; (2) The peak of inflated expectations, coincident with the description of what appeared to be a most simple method, easy to translate from mouse to human cells, to obtain insulin-producing beta cells^[65]; (3) The trough of disillusionment, which came about with the realization that such method was in reality generating not beta but neuroectodermal cells and that their purported insulin staining obeyed to an artifactual uptake of insulin from the culture medium rather than to its synthesis and secretion^[66]; (4) The slope of enlightenment, a methodical path of research that ended up with the unraveling of the perfect combination of factors leading to the specification of definitive endoderm, the first and critical step along the beta cell lineage^[67,68]; and (5) The current plateau of productivity, in which protocols that elaborate upon that initial milestone^[45,46,69,70] have reached the pre-clinical level^[47]. Normoglycemia is now routinely attained when transplanting hES cell-derived beta cell progenitors into immunodeficient diabetic mice. The approach of transplanting cells halfway their differentiation course is based on the observation that beta cells differentiate better and acquire full functionality when allowed to mature *in vivo*, due to factors that remain largely unknown. The well documented risk of tumorigenesis posed by hES cells (heightened when transplanting non-terminally mature derivatives) is currently being addressed as part of the strict controls required by regulatory agencies prior to the approval of their use in clinical trials. These include the separation of pancreatic progenitors from the rest of the population^[47] and the also antibody-based selective ablation of tumorigenic cells^[71]. The leading company pushing for hES cell-based clinical trials for diabetes (Viacyte, Inc.) complements the above strategies with that of encapsulating the cells inside an immunoisolation device that would double as a physical barrier to contain potential tumor-forming escapees. In fact, if this barrier allowed for the total elimination of immunosuppression in the recipient, in theory such escapees would be recognized as allografts by the host and thus promptly rejected.

Induced pluripotent stem (iPS) cells are a much newer

addition to the regenerative medicine armamentarium - one that has been saluted by many as an ethically sounder alternative to hES cells^[72-79]. The incredible pace at which this field of research progresses is evidenced by the fact that, merely four years after the first report on the simple reprogramming technology that allowed us to make cells “go back in time” to pluripotency without the need of destroying human embryos^[72-77,79-82], iPS cells have had time not only to rise to the heights of the Pantheon of therapeutic candidates, but also to start falling^[80,83]. Seen at first as a combination of the best features of adult and embryonic stem cells (pluripotency coupled to the potential for autologous isolation), it is now that we are starting to see some worrisome signs that even the most drastic reprogramming may leave traces of the original epigenetic memory of the cell^[84] or cause the iPS derivatives to age faster^[85]. Much worse than that, reprogramming can also induce mutations or activate oncogenes^[86-88] regardless of the method used, i.e., the effect is not necessarily associated to viral insertional mutagenesis. In this context, the successful adaptation to iPS cells of a beta cell differentiation protocol originally designed for hES cells^[89] represents only a preliminary proof of concept that it does not in any way get us closer than we are with hES cells to clinical therapies. Moreover, the potential advantages of using patient-derived iPS cells for type 1 diabetes is dubious inasmuch as, this being an autoimmune disorder, the recipient's immune system would be expected to swiftly reject any neogenic beta cells derived through this means.

LATERAL REPROGRAMMING

While “vertical” reprogramming would cause a terminally differentiated cell to go back in time and re-acquire full pluripotency, the notion of lateral reprogramming is based on the observation that the epigenetic signature of any differentiated cell can also be overridden in a manner that ultimately leads to the adoption of another terminally differentiated phenotype. In this sense, the older term “transdifferentiation” might be more appropriate to describe this type of horizontal reprogramming. As with iPS cell reprogramming, this young field started using DNA-integrating approaches (chiefly by means of viral vehicles), but is expected to follow the steps of the former in the use of non-integrative methods such as protein transduction^[90,91], episomal constructs^[78], DNA minicircles^[92], synthetic mRNAs^[93] and even small molecules identified through high-throughput screening^[94].

Earlier attempts at using reprogramming to obtain beta cells used the liver as a substrate. The choice of this organ is hardly surprising, since numerous studies confirm that liver and pancreas are susceptible of inter-conversion under multiple experimental, physiological or pathophysiological circumstances, including dietary depletion of copper^[95-97], spontaneous tumoral processes or administration of chemicals such as diethylnitrosamine^[98] or dexamethasone^[99]. In fact, fully differentiated hepatocytes and pancreatic beta cells share common molecular

mechanisms for glucose sensing^[100,101], with glucokinase being a prominent marker or both. From an evolutionary perspective, the existence of a single hepatopancreas in many invertebrates indicates that the two organs started as one. In vertebrates, liver and pancreas arise from the same progenitor cell pool^[102-110], and their separation is dictated by signals secreted by the developing heart^[103,104,111,112]. More to the point, in adult mice and humans alike, the extrahepatic biliary tree harbors progenitor cells with the ability to differentiate into hepatic and pancreatic tissues^[61,113].

The systemic delivery of the master pancreatic regulator Pdx1^[114,115] to mice was arguably the experiment that inaugurated the field of lateral reprogramming at the beginning of the century^[116,117]. The authors of those pioneering studies reported the appearance of insulin-positive cells in the liver of the animals, in sufficient amounts as to restore normoglycemia when the recipients were diabetic. Of even higher significance was the ulterior finding that reprogramming was not contingent to the ectopic expression of the gene, but persistent in time long after the expected clearance of the adenovirus used to deliver it^[118]. Similar results were independently confirmed by other groups, using either Pdx1 alone or in combination with other genes, such as NeuroD or MafA, known to act synergistically with the former^[119-126]. These reports were received with a mixture of expectation (the total liver-to-pancreas transdifferentiation described in transgenic frogs that expressed Pdx1 under the control of an early liver promoter^[127] was nothing short of extraordinary) and vague disappointment. This is because with the exception of the above transgenic setting (which obviously did not have any clinical applicability), none of the other strategies had yielded cells that could unequivocally be defined as true beta cells. When conducted *in vitro*, transdifferentiation resulted in cells that, at best, had a hybrid hepatocyte-beta cell phenotype and were incapable of regulating insulin secretion according to changes in glucose concentration. And when done *in vivo*, the observation that the inflammation elicited by the use of adenoviruses could be as important to induce reprogramming as the actual genes -if not more-, was a troubling discovery that caused legitimate concerns about how “clean” the strategy actually was^[120].

After an impasse of a few years, during which the excitement that first welcomed the advent of this new technology had started to wane, the impact of a recent report^[128] renewed the enthusiasm of the scientific community. The choice of genes (Pdx1, Ngn3 and MafA) was not particularly novel, as comparable combinations of factors had already been assayed on liver^[101,103,121,129-131] with all the aforementioned limitations. What was novel was the use of pancreatic acinar tissue as the substrate for reprogramming. Perhaps because of the even closer developmental ties between the beta cells and the surrounding acinar parenchyma that engulfs the islets in the native organ, the observed transdifferentiation to beta cells upon direct injection of these genes in the pancreas

of recipient mice was convincing enough to reawaken excitement about the clinical prospects of reprogramming.

CONCLUSION

Upon reviewing the diversity of options potentially available to us in the near future, one may get the impression that current efforts are somewhat dispersed. Clinicians and patient advocates alike often voice their concern that such dispersion may stand in the way of an effective allocation of manpower and resources to the strategy that has the highest translational potential. But who is to say which strategy this is at this early stage of the game? Indeed, based on the trends observed in the field, it is plausible that the approach with the highest chance of success will be a multi-pronged one, possibly involving more than one cell type and addressing both replacement and immunomodulation.

hES cells are well positioned from the standpoint of the robustness of the described differentiation methods and the heavy private and public investment bestowed upon the team that leads these efforts. ViaCyte received last year more than \$20 million from the California Institute for Regenerative Medicine to speed up pre-clinical studies that could lead in the very near future to an Investigational New Drug application to the FDA. However, unlike other prospective therapies based on the use of adult stem cells (heavily represented in clinical trials), hES cell-based ones still have to break ground from a regulatory perspective. The recent withdrawal of Geron's phase I clinical trials for spinal cord injury (which pioneered the use of hES cells in the clinical arena) represents an unfortunate turn of events that is not likely to help foster a more favorable climate for new trials. Fortunately, recent advances at immunoisolation^[132,133], coupled with refinements at enriching for the fraction of cells with therapeutic potential^[47,71] are likely to surmount the main concerns posed by regulatory agencies. Despite the initial impression that iPS cell-based protocols could be largely swapped with those designed for hES cells, developments already discussed in the relevant section urge caution about their clinical use, which, if ever realized, will undoubtedly lag behind that of hES cells. The potential advantage of using autologous cells for type 1 diabetes is dubious at best and logistically impractical. In fact, even if autoimmunity was not a consideration and we still wanted to obtain pluripotent cells as closely matched to the recipient as possible, an alternative is human leukocyte antigen (HLA)-homozygous hES cells, which have been derived by parthenogenesis. One of these cell lines is reported to carry the most widespread HLA haplotype in North America^[134,135].

Adult stem cells, especially those with known ontogenic potential to become definitive endoderm, have been remarkably difficult to identify - let alone isolate and expand. The recent discovery of such potential populations in the adult extrahepatic biliary tree^[61,113] or the islets themselves^[60] may open promising avenues of research,

but until these early results are validated, MSCs are likely to keep the lion's share of attention and funding. Easy to derive, characterize and expand, their apparent genealogic disconnect with the endoderm from which organs such as the liver or the pancreas arise has not been an obstacle for those who champion them in the context of diabetes. Progress at developing methods to coax these cells into insulin-producing cells, albeit slow, is starting to pick up speed with the description of more primitive MSC populations and better differentiation methods. The burgeoning field of reprogramming is also likely to have a say on whether the developmental potential of MSCs is intrinsically limited to mesodermal lineages. Although none of the 11 currently listed MSC-based clinical trials for the treatment of either type 1 or type 2 diabetes makes use of MSCs previously differentiated into beta-like cells *in vitro* (www.clinicaltrials.gov), their immunomodulatory and niche-forming properties are now widely acknowledged and could be the basis of both combination (such as islets and MSCs^[49]) and stand-alone therapies in the short term.

Lateral transdifferentiation, finally, may not necessarily take a backseat to the above approaches, provided that non DNA-based reprogramming techniques are refined to the extent required for the process to be efficient. Indeed, progress in this direction may effectively leapfrog years of research on stem cell differentiation, and end up in contention to become the therapy of choice for type 1 diabetes. While *ex vivo* reprogramming of acinar tissue may not represent a viable strategy in the long run (pancreatic biopsies from the prospective patients would be risky, and the use of acinar tissue from deceased donors would present the same scarcity problems that afflict organ donation in general), recent advances in "DNA-free gene therapy"^[136,137] may soon change the perception that *in vivo* reprogramming of cell fate is a clinical implausibility. More so, because one commonly cited shortcoming of these approaches -i.e., the fact that reprogramming is seldom complete, invariably leaving traces of the original fate- might in fact work in our benefit if the autoimmune response seen in type 1 diabetes is elicited only by true beta cells, but not the reprogrammed ones. While this is only a speculation at this point, the potential therapeutic implications of such finding would be incommensurable. Finally, it is necessary to emphasize that most of the approaches herein listed could also be potentially applied not only to type 1 diabetes, but also to all types of insulin-dependent conditions resulting in glycemic dysregulation, including type 2 diabetes.

In the next few years, we expect to see a progressive shift from islet transplantation to the transplantation of hES cells in an immunoisolation setting. Parallel efforts will be made at using MSCs and hematopoietic stem cells for immunomodulation, which will be accompanied by an emphasis on the exploration of endogenous regeneration pathways. A cure is likely to ultimately arise from a combination of many, if not all, of the above approaches.

Abstract

Although allogeneic islet transplantation can successfully cure type 1 diabetes, it has limited applicability. For example, organs are in short supply; several human pancreas donors are often needed to treat one diabetic recipient; the intrahepatic site may not be the most appropriate site for islet implantation; and immunosuppressive regimens, which are associated with side effects, are often required to prolong survival of the islet graft. An alternative source of insulin-producing cells would therefore be of major interest. Pigs represent a possible alternative source of beta cells. Grafting of pig islets may appear difficult because of the immunologic species barrier, but pig islets have been shown to function in primates for at least 6 mo with clinically incompatible immunosuppression. Therefore, a bioartificial pancreas made of encapsulated pig islets may resolve issues associated with islet allotransplantation. Although several groups have shown that encapsulated pig islets are functional in small-animal

models, less is known about the use of bioartificial pancreases in large-animal models. In this review, we summarize current knowledge of encapsulated pig islets, to determine obstacles to implantation in humans and possible solutions to overcome these obstacles.

INTRODUCTION

Type 1 diabetes has been treated successfully by transplanting islets of Langerhans, the endocrine tissue that releases insulin^[1]. Despite the clinical efficacy of islet transplantation, serious issues preclude its broad clinical application, including the side effects of chronic immunosuppressive regimens and a shortage of human donors. For example, it was recently estimated that only one pancreas is available per 333 patients with type 1 diabetes in the United States^[2]. This situation is aggravated by the need of each recipient undergoing transplantation

for 2-4 pancreases^[1,3]. This shortage of pancreas donors therefore justifies the search for alternative sources of insulin-producing cells. Swine appear to be the major candidates for islet procurement because: (1) humans have been treated with porcine insulin for > 40 years (pig and human insulin differ by only one amino acid); (2) pigs have large litters with offspring that rapidly attain adult size and are therefore amenable to genetic engineering; (3) pig pancreases contain large islets that respond to glucose stimulation; and (4) since pigs are widely bred and slaughtered for food, the use of their islets to restore human health may be an option that could satisfy sociocultural and ethical concerns^[4-6].

Unlike primarily vascularized organs, pancreatic islets are implanted without direct connection to the host vascular network, with 7 to 14 d needed to re-establish blood flow^[7-12]. Thus, it was thought that pig islet xenografts could escape typical hyperacute rejection and acute vascular rejection^[13]. *In vivo*, however, pig islets in non-immunosuppressed nonhuman primates are rejected by both humoral and cellular immune reactions^[14-16]. Diffuse, presumably nonspecific IgG deposits were observed within islet-associated accumulations of platelets 12 h after transplantation. Deposits of large amounts of IgM and moderate to large amounts of C3, C5, and C9 were present on islet surfaces 2 to 3 d after xenografting^[15-17]. Anti-galactosyl (anti-Gal) and non-Gal^[18,19] IgM antibodies bind to islet surfaces soon after transplantation and activate the classical complement pathway, as well as promoting neutrophil infiltration. These humoral immune responses to pig islets are consistent with early T-cell-independent immune system activation and are reminiscent of mechanisms that operate during the hyperacute rejection of solid-organ xenografts^[20]. Humans and nonhuman primates have preformed anti-pig antibodies that rapidly recognize the Gal epitope on islet endothelial cells. During pig islet-to-primate xenotransplantation, however, the expression of Gal epitopes is influenced by the age of the pig. Gal residues are present on 20% of fetal, but on only 5.1% of adult, islet β cells^[21-23]. Since Gal expression persists after islet isolation^[24,25], Gal remains a target for humoral xenorejection.

Islet xenografts that survive immediate blood-mediated inflammatory reactions and additional humoral damage will be subject to acute cellular xenograft rejection. Following transplantation of fetal pig islets under the kidney capsule, the cellular infiltrate in primates has been found to consist mainly of CD8 T cells (implicating the indirect pathway), whereas the cellular infiltrate in rodents was dominated by macrophages. T-cell infiltration precedes macrophage influx, with small numbers of CD3⁺ T cells observed 12 h after transplantation^[14]. After 24 h, equal numbers of CD3⁺ T cells and neutrophils were observed, and after 72 h, CD3⁺ T cells dominated, representing 50% to 80% of all infiltrating cells. After 72 h, large numbers of macrophages were observed, with T cells localized at the periphery of and within transplanted islets. In addition, increased E-selectin expres-

sion on portal vein endothelial cells correlated with the infiltration of neutrophils, which caused tissue damage by releasing enzymes, active oxygen intermediates, and proinflammatory cytokines, and produced chemokines that attracted dendritic cells and T lymphocytes. Pig islet xenorejection seems theoretically easier to overcome, but because hyperacute and acute vascular rejections do not occur, the rapid destruction of pig islets within 72 h of transplantation into nonhuman primates demonstrates the strength of xenorejection.

Thus, an immunosuppressive regimen is mandatory for the long-term survival of pig islets in primates^[26,27]. Although several immunosuppressive strategies have successfully suppressed alloimmune responses, T-cell-mediated xenoimmune responses have proven more resistant to immunosuppressive therapy^[28,29]. This may be due to the greater molecular incompatibility between donor and recipient, which activates particularly the innate immune response^[30].

Until recently, the maximum reported duration of pig islet survival (insulin-positive cells, no function) following transplantation under the kidney capsule in non-diabetic cynomolgus monkeys and immunosuppression with anti-thymocyte globulin, anti-interleukin-2R mAb, cyclosporine, and steroids was 53 d^[31]. In March 2006, however, two studies reported that neonate or adult pig islets xenotransplanted into primates survived and functioned for > 180 d^[26,27]. More recently, the transgenic expression of a human complement-regulatory protein (hCD46) on porcine islets was shown to enhance the survival of islets xenotransplanted into cynomolgus monkeys with streptozotocin (STZ)-induced diabetes for > 12 mo^[32]. In addition, transplantation of galactosyl knock-out neonate pig islets was found to significantly enhance normoglycemia rates in diabetic primates, likely due to the decreased susceptibility of these xenografts to innate immunity mediated by complement and preformed xenoantibodies^[33]. These results, however, required treatment with a heavy immunosuppressive regimen, in particular an anti-CD154-specific mAb, an antibody that induced thromboembolic events precluding its clinical use^[34]. Despite the unacceptability of these immunosuppressive regimens in humans, these results are very encouraging since an alternative, nontoxic regimen combined with xenotransplantation of pig islets may induce normoglycemia in diabetic patients.

A bioartificial pancreas, in which islets of Langerhans are encapsulated within a semipermeable membrane, may be an alternative therapeutic device for patients with insulin-dependent (type 1) diabetes mellitus. It may constitute a safe and simple method of transplanting islets without the need for immunosuppressive therapy. Since the semipermeable membrane protects the islets from the host immune system, the islets are likely to survive and release insulin for a long period of time, thereby controlling glucose metabolism in the absence of immunosuppressive medication. Nevertheless, several important questions are associated with the transplanta-

Table 1 Bioartificial device configurations for encapsulation of pig islets

	Macroencapsulation	Microencapsulation	Conformal coating
Type of pig islets tested	Adult/neonate	Adult/neonate	Adult
Suitable material with biocompatibility	Alginate	Alginate with/ without PLL/PLO over-layer	PEG
Implantation site	Intraperitoneal	Intraperitoneal	Into the liver <i>via</i> the portal vein
	Subcutaneous	Kidney subcapsular space	
Proof of concept in preclinical studies in diabetic primates	+	+	–
Maximum survival of pig islets and diabetes correction	Mean 24 wk correction of glycated hemoglobin < 7% after transplantation of the MCD into subcutaneous tissues	Max 804 d but never reproduced; Biocompatibility confirmed under the kidney capsule up to 6 mo after transplantation	ND
Clinical study	+	+	ND
Clinical efficacy	No insulin-independence	No insulin independence	ND
	Glycated hemoglobin improvement; porcine insulin detected in recipient sera up to 4 yr after transplantation with insulin positive cells into hollow-fiber devices.	Survival up to 9.5 yr with insulin-positive cells after transplantation into the peritoneum and detection of urinary porcine C-peptide up to 11 mo after transplantation	
Advantages for large-scale clinical application	Easy procedure for transplantation into subcutaneous tissue	Easy procedure for transplantation by simple injection into the peritoneum	- Capability of transplantation into the liver
	Simple procedure to remove the graft from subcutaneous tissue	Large scale encapsulation of large number of islets	- Reduction of graft size
Limitations for large-scale clinical application	Limited islet oxygenation	Large volume of encapsulated islets limiting transplantation into the peritoneum	- No stability for long-term islet immunoprotection
	Difficulty to transplant into the peritoneal cavity	Islet survival limited by absence of biologic interaction with encapsulation material	
		No ability to remove the graft after transplantation	

PLL: Poly-lysine; PLO: Poly-ornithine; MCD: Monolayer cellular device; ND: Not determined; PEG: Polyethylene glycol.

tion of immunoisolated adult pig islets as a “bioartificial pancreas”^[35] (Table 1).

VARIATIONS IN CAPSULE SIZE: MACROENCAPSULATION OR MICROENCAPSULATION

Macroencapsulation

In the first reports of encapsulation, a large number of islets were immunoisolated between flat-sheet double membranes^[36,37]. This type of single macroencapsulation device could be implanted with minimal surgery at different sites, including the peritoneal cavity, subcutaneously, or under the renal capsule. Although several types of biomaterial have been used to produce microcapsules, including nitrocellulose, alginate, acrylonitrile, and agarose, these devices usually had some toxicity and activated nonspecific foreign body reactions, resulting in fibrotic overgrowth with subsequent necrosis of the encapsulated tissue^[35]. A subcutaneously transplanted microdevice (TheraCyte device, Baxter Healthcare), 4 cm in length, shaped like a teabag, and made of a bilayered polytetrafluoroethylene membrane, was recently found to be biocompatible^[38,39]. Neonatal pig cells inside the graft (i.e., cells immunohistochemically positive for insulin and glucagon) remained viable for up to 8 wk after xenotransplantation into nondiabetic cynomolgus

monkeys, with no evidence of reaction with adjacent subcutaneous tissue^[40]. Moreover, one of 12 non-immunosuppressed adolescents became insulin independent and 5 children had reduced insulin requirement after transplantation of porcine islets encapsulated in hollow-fibers with porcine Sertoli cells, which likely have immunomodulating properties^[41,42].

A “monolayer” configuration of macroencapsulated pig islets (monolayer cellular device) implanted subcutaneously (see below) has been found to significantly improve diabetes control (glycated hemoglobin < 7%) in primates for 6 mo without any immunosuppression^[43]. In this encapsulation system, islets were seeded as a monolayer on an acellular collagen matrix, enhancing their interactions with a biologic membrane and increasing islet concentration per unit surface area. In addition, diabetes was controlled for up to 1 year in 2 diabetic primates after retransplantation with new monolayer cellular devices. Unfortunately, the lifespan of adult pig islets limited long-term graft function. Diabetic control was completely maintained for > 32 wk after the cotransplantation of adult pig islets and adipose mesenchymal stem cells^[44]. A phase 1 clinical study is currently ongoing to assess the safety and efficacy of this device for allotransplantation of encapsulated islets into humans.

Microencapsulation

Another approach consists of the microencapsulation

of 1-3 islets per semipermeable immunoprotective capsule. The spherical configuration of these microcapsules resulted in a higher surface-to-volume ratio than did the tube or disk geometry of microcapsules, resulting in a higher diffusion rate^[45]. Furthermore, microcapsules can be injected in large numbers, are durable and are difficult to disrupt mechanically^[46,47].

Two recent studies describing transplantation of microencapsulated neonatal pig islets in an alginate matrix confirmed their biocompatibility in nondiabetic monkeys as well as their capacity to partially regulate diabetes^[39,40]. Several protocols must be followed to increase the survival of alginate microencapsulated pig islets for up to 6 mo without immunosuppression in nondiabetic primates^[25]: (1) Before transplantation, the islets should be cultured in medium containing 1.8 mmol CaCl₂; (2) Animal serum should be omitted from the culture medium; and (3) The graft should be composed of > 90% well-shaped capsules. Some of these islets survived for > 6 mo and were able to respond *in vitro* to glucose challenge 135 and 180 d after implantation. In addition, the implantation site (peritoneum, kidney capsule, or subcutaneous space) must be suitable^[48,49], with the subcutaneous space considered a good choice for clinical applications^[50].

Following transplantation of microencapsulated adult pig islets into spontaneously diabetic cynomolgus monkeys, blood glucose became normalized and the monkeys became insulin independent for periods ranging from 120 to 804 d^[51]. Although these results were encouraging for the clinical application, they may have been dependent on the diabetic status of the recipient, the exact formulation of the capsules, and the immune response against pig islets (see below). To date, these results have been confirmed by only two casuistic manuscripts describing xenotransplantation in primates of microencapsulated neonatal pig islets^[39,40]. One study confirmed the biocompatibility, for up to 8 wk, after transplantation of encapsulated pig islets in nondiabetic animals, and the second demonstrated that these microcapsules could regulate the diabetic state of diabetic recipients. Although the latter showed that daily exogenous insulin requirements were reduced by a mean of 43% compared with control animals transplanted with empty capsules, neither group showed changes in weekly blood glucose levels^[39]. The absence of solid consistent data on glucose metabolism (e.g., changes in glycosylated hemoglobin concentration, glycosuria, intravenous glucose tolerance testing) renders this casuistic study difficult to interpret.

Living cell technologies (LCT) showed that porcine islet cells had survived and insulin production was maintained in a human patient 10 years after transplant of pig islet cells^[52]. These findings demonstrated the long-term safety, viability, and functionality of encapsulated porcine islets in a human patient, without the use of immunosuppression. In 1996, a 41-year-old patient with diabetes was injected with pig islet cells to help regulate his blood glucose levels and control his diabetes. This

patient's insulin requirement was reduced by 34% for over one year. Ten years later, the patient was still obtaining benefit from the transplant, and laparoscopic examination revealed living and functioning pig islet cells in his abdomen.

Two phase 1 trials have shown that intraperitoneally infused microencapsulated human islets can be considered safe for up to 3 years^[53,54]. Although insulin independence was not achieved, glycemic control was improved, with a reduction in insulin daily requirement. In 2007, LCT launched a phase 1/2a study in Moscow of encapsulated neonatal insulin-producing porcine pancreatic islet cells (commercially called DIABECCELL[®]). Seven patients with insulin-dependent diabetes have received between one and three implants of DIABECCELL[®] (5000 and 10 000 IEQ/kg), with none showing marked adverse events 18 to 96 wk after transplantation. At last follow-up, the blood glucose concentrations in 5 patients were within the normal range (5.8-8.2 mmol/L). Two patients have shown excellent responses and do not require exogenously administered insulin. All recipients showed improvements in diabetes control, with lower glycated hemoglobin (% HbA1c) concentrations.

Following the successful completion of this phase 1/2a clinical trial in Russia, LCT launched phase 2b clinical trials, which are currently underway in New Zealand and Argentina. In contrast, although diabetes control was achieved by repeated injections of encapsulated islets (up to 4 infusions and up to 779 000 islets equivalent), a humoral response was induced, with cytotoxic antibodies found in the recipient sera 4 to 8 wk after transplantation, and necrosis of the islets at 16 mo^[54].

Conformal coating of cell surfaces

A serious issue remains in using microcapsules as bioartificial pancreases, namely, the increase in total volume of the implant after microencapsulation. The average diameter of islets is roughly 150 μ m, making the average diameter of capsules about three times as large and the total volume of microcapsules about 27 times as large. In clinical settings, the volume of islet suspensions is 10 mL, making it > 270 mL after microencapsulation. A site to implant such a large volume is difficult to find.

Much effort has been made to reduce the size of the capsules. For example, smaller microcapsules, about 300 μ m in diameter, could result in a reasonable total volume for clinical application^[55]. In clinical allotransplantation programs, islets are transplanted into the liver through the portal veins, and capsules of diameter larger than the islets themselves may plug larger blood vessels, resulting in severe thrombosis of the liver. The diameter of the encapsulated islets should therefore be much smaller than at present, to allow for their transplantation through the portal veins. A technique to coat islets with a very thin membrane or with conformal coating may reduce the diameter of these microcapsules, allowing their transplantation into the liver through the portal veins.

Several types of coating have been tested to im-

munoisolate islets from the host immune systems. For example, the surface of islets has been modified with thin membranes made of amphiphilic polymers, such as polyethylene glycol (PEG)-conjugated phospholipid (PEG-lipid) and polyvinyl alcohol carrying long alkyl chains^[56-59]. The thickness of the PEG layer formed on the cell surface was several nanometers, but depended on the molecular weight of the PEG.

Surface modification did not change the morphology or viability of the islets^[60]. Transplantation of 5000 porcine islets modified with PEG-N-hydroxysuccinimide (NHS) ester into the livers of NOD-severe combined immunodeficiency mice through the portal vein resulted in the transient normalization of blood glucose concentrations, but these concentrations later increased. The surface of islets covered with PEG reacted with the amino groups of the collagen layer remaining on the islet surface^[61]. Although transplantation of islets covered with a PEG-NHS-modified surface into recipient rats treated with low-dose cyclosporine resulted in the maintenance of normoglycemia for 1 year, normoglycemia was maintained for only 11 d in the absence of cyclosporine despite the surface modification with PEG.

Although a conformal PEG layer may form on the cells or islet surfaces at the nanometer level and this method enables a drastic reduction in total graft volume compared with conventional microcapsules, the PEG layer on the islets was not stable and disappeared from the cell surface over 3 d.

Use of a layer-by-layer method may enhance the stability of PEG-lipid membranes on the cell surface. Various functional groups, such as maleimide and biotin, can be easily introduced to the end of the PEG chain of PEG-lipids^[58] and can be used as reaction points to form multilayer membranes on the cell surface. A layer-by-layer membrane can also be formed by the reaction between biotin and streptavidin. Biotin-PEG-lipids are anchored to the cell membranes of islets and are further covered by streptavidin. The modified islets can be alternatively exposed to a biotin-bovine serum albumin conjugate solution and a streptavidin solution to form 20 layers. The thickness of the membrane is approximately 30 nm. A glucose stimulation test demonstrates the ability of the modified islets to control insulin release in response to changes in glucose concentration. After intraportal transplantation of modified islets with PEG-lipid into STZ-induced diabetic mice^[59], most islets were not damaged and remained intact in the blood vessels of the liver for 1 h to 1 d after transplantation.

VARIATION OF MATERIALS

The choice of material to use for cellular encapsulation is a crucial parameter because failure of microencapsulated islet grafts is usually regarded as a consequence of insufficient biocompatibility, inducing a nonspecific foreign body immune reaction against the microcapsules and resulting in progressively fibrotic overgrowth of the

capsules. This overgrowth interferes with adequate nutrition of the islets and consequently causes islet cell death. There are major distinctions between water-soluble polymers, such as alginate, and water-insoluble polymers, such as poly (hydroxyethyl methacrylate-methyl methacrylate)^[35]. However, a major obstacle in using water-insoluble polymers for encapsulation of cells is the requirement for an organic solvent, which usually interferes with cellular function^[62]. Despite their solubility in aqueous solutions, alginate-based capsules have been shown to remain stable for several years in small and large animals as well as humans^[51,63-67]. The method of alginate capsule formation is based on the entrapment of islets in alginate droplets, which are transformed into rigid beads by gelification in a divalent cation solution, mostly Ca^{2+} . In most studies to date, alginate beads were coated with a second layer to reduce the porosity of the capsule membrane^[35,68]. In the pig-to-primate model, alternating layers of poly-L-lysine and a polyornithine were used to surround the alginate core^[40,51]. The latter type of layer, however, has been associated with polyamino acid cytotoxicity and mechanical instability of the microcapsules, limiting their application^[35,69,70]. Several groups have recently reported that encapsulation in simple alginate microbeads can protect pig pancreatic cells against xenorejections in diabetic mice^[46,47,71]. Although several chemical formulations of alginate (e.g., high-mannuronic/guluronic; high/low viscosity, with or without additional peptide sequences) have been proposed for islet immuno-isolation, we found that high-mannuronic alginate was the most suitable to obtain selective impermeability for molecules over 150 kDa (as an IgG) before and after transplantation, and optimal biocompatibility to avoid nonspecific inflammatory response associated with surrounding angiogenesis, resulting in sufficient oxygen tension (about 40 mmHg) for the survival and function of encapsulated islets^[72]. This type of alginate was biocompatible not only in a small-animal model (Wistar rat recipients) but also in a pig-to-primate model of xenotransplantation under the kidney capsule and skin for up to 6 mo (see below)^[25,43,48].

VARIATION OF IMPLANTATION SITES

The lack of revascularization of the encapsulated islets interferes with both the functional performance and the longevity of the grafts. Apparently, a site in which encapsulated islets are in close contact with the bloodstream is obligatory for clinical application. Unfortunately, it is difficult to find such a site because it must be of sufficient size to bear a large graft volume and be near blood vessels. Sites reported to allow successful nonencapsulated islet transplantation, such as the liver and spleen, do not meet these requirements because these sites are unable to tolerate the large volumes (> 16 mL) of capsules (of diameter > 600 μm) required for transplantation into primates. Therefore, most transplantations of encapsulated pig islets into primates were

intraperitoneal^[39,39,51]. Although this technique seemed relatively easy, the peritoneal site was not optimal. Indeed, recent studies in mice found that macrophages and lymphocytes are involved in the rapid degradation of encapsulated pig islets after their transplantation into the peritoneum^[71,73-76]. The peritoneum is, indeed, a preferential site for inflammation and immunologic reactions^[77] and peritoneal mesothelial cells facilitate the action of powerful innate immune mechanisms^[77]. Studies in mice showed that immunosuppression had beneficial effects, improving the biocompatibility and prolonging the survival of encapsulated pig islets transplanted into the peritoneum^[73,74,78]. This method of combining encapsulation and immunosuppression, however, remains incompatible with clinical applications. The biocompatibility of alginate-encapsulated pig islets depends on the implantation site. Encapsulated pig islets transplanted under the kidney capsule and under the skin demonstrated better biocompatibility than capsules transplanted into the peritoneum^[48]. Indeed, a cellular reaction essentially composed of macrophages was observed 7 d after transplantation into the peritoneum. This finding is in good agreement with results showing that macrophages are recruited 7 d after transplantation of encapsulated pig islets into the peritoneum of mice and rats^[73,74]. In addition, severe fibrosis surrounding intraperitoneally implanted capsules was observed 30 d after transplantation and was correlated with the loss of porcine C-peptide 7 d after implantation. In contrast, subcutaneous and kidney capsule implantation resulted in very weak cellular immune reactions against encapsulated pig islets, along with improved porcine islet viability; porcine C-peptide was detected in the sera of rats for 30 d after transplantation of encapsulated pig islets at both sites. These findings indicate that implantation into the subcapsular kidney and subcutaneous spaces improves the biocompatibility and *in vivo* survival of encapsulated pig islets, as well as enhancing pig islet function during the first 7 d after transplantation. The loss of the *in vivo* function activity of encapsulated pig islets transplanted into the peritoneum correlated with significant alterations in islet viability, a loss of insulin content, and significant reductions in insulin secretion after glucose stimulation. These findings may be associated with macrophage overgrowth of the area surrounding the capsules, creating a micro-environment of stress, with low oxygen tension, for pig islets^[75,76]. Indeed, macrophage activation, as shown by NO production and the release of the cytokines L-1 β and tumor necrosis factor- α , had a deleterious effect on islet function and viability^[73,75,76]. We found that implantation into kidney subcapsular and subcutaneous spaces improved the biocompatibility of encapsulated pig islets and significantly reduced macrophage recruitment. This reduction in pig islet stress and improved islet viability maintained insulin level per islet and insulin secretion after glucose stimulation^[48]. Subcutaneous tissue was recently shown to provide oxygen tension (20-40 mmHg) compatible with the function and survival of

encapsulated islets^[72]. Among the sites being tested for islet transplantation, with or without encapsulation, to improve the survival, engraftment and function of islets, are the brachioradialis muscle^[79], striated muscle^[80], the greater omentum^[81], and the anterior chamber of the eye^[82].

CONCLUSION

Immunosuppression remains the major limitation of allotransplantation or xenotransplantation of islets for type 1 diabetes. Extended survival of transplanted pig islets has recently been observed in primate models, but several questions and problems associated with immunosuppression remain to be resolved in terms of adjustment before clinical trials. A bioartificial pancreas made of encapsulated pig islets may overcome the two major hurdles to islet transplantation: the shortage of human organ donors and the requirement for immunosuppressive regimens.

The development of a bioartificial pancreas for preclinical/clinical studies requires the conjunction of integrated parameters such as the choice of a biocompatible material for encapsulation to maintain selective permeability. The encapsulation device should be designed to maintain mechanical properties and stability at an implantation site compatible with the viability and physiology of the encapsulated islets to control glycemic homeostasis.

Of the three major types of bioartificial pancreases (macroencapsulation, microencapsulation, and conformal encapsulation), the macroencapsulation system is the only method that has demonstrated the capacity to control diabetes in large animals and in preliminary clinical studies.

Several improvements must be made to reduce the size of the implant (by increasing islet concentration relative to the surface or volume of the implant), to improve oxygenation of islets (to limit islet death), and to develop a simple clinical procedure for bioartificial transplantation and easy access to a device allowing "re-alimentation" of the islets.

to be effective for the reconstruction of small patch defects, anastomosis reinforcement, and the prevention of stricture formation after endomucosal resection (EMR). More so, esophageal cancer patients treated with ECM scaffolds have shown complete restoration of a normal, functional, and disease-free epithelium after EMR. These studies provide evidence that a regenerative medicine approach may enable aggressive resection of neoplastic tissue without the need for radical esophagectomy and its associated complications.

Abstract

In addition to squamous cell carcinoma, the incidence of Barrett's esophagus with high-grade dysplasia and esophageal adenocarcinoma is rapidly increasing worldwide. Unfortunately, the current standard of care for esophageal pathology involves resection of the affected tissue, sometimes involving radical esophagectomy. Without exception, these procedures are associated with a high morbidity, compromised quality of life, and unacceptable mortality rates. Regenerative medicine approaches to functional tissue replacement include the use of biological and synthetic scaffolds to promote tissue remodeling and growth. In the case of esophageal repair, extracellular matrix (ECM) scaffolds have proven

INTRODUCTION

The default tissue response to injury in adult mammals is characterized by hemostasis, inflammation, and subsequent deposition of dense collagenous connective tissue (i.e., scar tissue)^[1-5]. The deposited scar tissue serves as a partial volume replacement for the missing native tissue and maintains the structural integrity of the tissue, albeit at a loss of normal function in many instances. This mechanism is adequate in most, but not all, tissues.

Some tissues in adults retain the ability to regenerate either as part of normal physiologic events or in response to injury. For example, the epidermis is com-

pletely replaced approximately every 40 d^[6-9]. The bone marrow sustains a regenerating population of cells to continuously replenish the hematopoietic cell population^[10-13], and the intestinal epithelium regenerates from a well described crypt stem cell population^[14-16]. The liver can respond to injury by a nonblastemal epimorphic regenerative mechanism^[17] and can replace most if not all of its lost hepatocellular mass if the native stroma remains intact^[18-20]. Skeletal muscle has limited regenerative potential and can respond to mild or repetitive injury with full return to structure and function^[21,22]. However, volumetric muscle loss (i.e., loss of greater the 20% of the muscle mass) results in deposition of scar tissue^[23]. Therefore regenerative potential is encoded into the genome of adult mammals but only functionally expressed in selected tissues or to a limited extent. It should also be noted that all of these examples of tissue/organ regeneration involve the participation of a reserve stem/progenitor cell population.

Those tissues with the inability to regenerate functional mass following injury are the cause of significant morbidity, aesthetic deformity, mortality, and are causally associated with a large fraction of the health care burden worldwide. For example, the inability to regenerate functional myocardium following ischemic coronary artery disease^[24-27], the dysfunctional central nervous system tissue following ischemic stroke or spinal cord injury^[28-35], and the lack of functional pancreatic beta cells following immune mediated destruction^[36-39] are the cause for a group of diseases that affects a large percentage of the aging population. Esophageal pathology, especially neoplasia, affects a rapidly increasing number of individuals in North America^[40,41] and worldwide^[42]. The lack of regenerative ability in the esophagus relegates this tubular structure to an inflammation/scarring response following injury, which in turn results in stricture and loss of function. Therefore, the standard of care for many esophageal diseases, especially overt cancer and its' precursor Barrett's disease with high grade dysplasia (HGD) involves esophagectomy; a procedure associated with a complication incidence approaching 50%^[43-46]. A regenerative medicine approach which can recreate functional esophageal tissue, preserve the integrity of the esophagus, and avoid the necessity for esophagectomy would offer a significant advancement in the arsenal of treatment methods available to affected patients.

PROBLEM

There are 5000 to 10 000 patients identified annually with non-neoplastic esophageal disease^[47] including congenital anomalies such as esophageal atresia, tracheoesophageal fistulas^[48], and corrosive injuries^[49,50]. The incidence of Barrett's esophagus (BE) and esophageal adenocarcinoma has increased dramatically and esophageal cancer now represents the world's sixth leading cause of cancer death with 300 000 new cases each year^[41,42,51]. The management of Barrett's disease with HGD and intramucosal

adenocarcinoma remains controversial. Esophagectomy has been the standard of care for HGD based on the high incidence of progression to subsequent neoplasia^[52,53]. However, the majority of patients in which esophageal neoplasia is diagnosed have disease limited to the mucosa and the involvement of regional lymph nodes is unlikely. Because esophagectomy is associated with high morbidity rates and a marked compromise in quality of life, there has been a great deal of interest and success in minimally invasive endoscopic approaches which involve esophageal preserving techniques in patients with superficial malignancy^[54].

STANDARD OF CARE

There are several endoscopic ablation techniques for BE with HGD and for superficial adenocarcinoma. Radiofrequency ablation (RFA) has become accepted as a viable treatment for BE, especially flat BE, in light of a recent sham controlled randomized trial^[55]. RFA has been shown to effectively ablate BE with very low rate of stricture formation. For BE with nodularity, endomucosal resection (EMR) with or without ablation therapy has been shown to be safe and effective to eradicate BE and prevent the recurrence of BE with minimal complications^[56]. Excellent survival has been found in long term follow up studies in which endoscopic approaches were used to treat HGD and intramucosal adenocarcinoma^[57,58].

However, the development of metachronous lesions is common (21.5%) with risk factors that include piecemeal resection, no ablation therapy of flat BE after EMR, long-segment BE, multifocal neoplasia, and the prolonged time required for complete eradication of the lesions^[59]. Currently used techniques invariably include one or more of the stated risk factors. These risk factors are compounded by the inability to remove all affected tissue as an *en bloc* specimen by endoscopic techniques; thus less than optimal specimens are available for histopathologic examination of the removed tissue.

A stepwise radical endoscopic resection (SRER) has been proposed to treat BE refractory to RFA and/or EMR. A recent multicenter randomized trial^[60] has demonstrated encouraging results of SRER but the technique involved a greater number of therapeutic sessions and complications such as esophageal stenosis requiring dilation in up to 50% of cases.

In summary, the limitations of currently used endoscopic techniques include the necessity for numerous interventions, the high incidence of metachronous lesions, the absence of a suitable tissue specimen for histologic assessment, and the unavoidable sampling error that occurs especially in patients with long segment Barrett's. Ideally, *en bloc* resection of the entire abnormal epithelium in a single procedure without any compromise of tissue specimens collected for histopathologic examination would be possible. A regenerative medicine strategy that would facilitate restitution of the resected esophageal tissue without concomitant stenosis would represent a significant

Figure 1 Replacement of esophageal mucosa with extracellular matrix device after endoscopic resection for treatment of high grade dysplasia. A: High grade dysplasia before treatment; B: Esophagus after circumferential resection; C: Regenerated neoeplithelium without stricture 3 mo post operatively.

advancement in the treatment of esophageal disease.

REGENERATIVE MEDICINE STRATEGIES FOR THE TREATMENT OF ESOPHAGEAL DISEASE

Classic tissue engineering and regenerative medicine approaches involve either cell based therapies, utilization of a scaffold material, and/or use of bioactive molecules such as growth factors, cytokines and chemokines. In reality, the goal of all approaches is to alter or avoid the default inflammatory/scar tissue response to esophageal injury, and either replace the missing tissue with engineered normal tissue or stimulate the endogenous formation of new, site appropriate functional tissue.

Although an esophageal epithelial stem cell population located in the basal layer of the esophagus has been identified^[61-65], their use in a cell based approach to functional esophageal reconstruction has not been described. Sheets of esophageal epithelial cells can be cultured^[66-68], but practical application of such cell sheet technology to resurface the esophageal lumen following ablative procedures has not been successful. An approach which involves the placement of xenogeneic extracellular matrix (ECM) showed that full thickness defects that included approximately 40%-50% of the circumference and 5 cm of length could facilitate a constructive, non-stenotic healing response with formation of all layers of the esophageal wall in a preclinical dog model^[47]. However, when reconstruction of complete circumferential full thickness defects was attempted with the same ECM scaffold approach, there was the uniform occurrence of severe stricture^[69]. Of note however, if the complete circumferential defects were not full thickness in nature and lesions were limited to the mucosa, then placement of the ECM scaffold upon the subjacent muscularis externa supported the endogenous regeneration of a functional mucosa without clinical stricture^[47,69-71].

These results suggested that a combination of the biologic scaffold material in contact with a native esophageal cell population (i.e., skeletal and smooth muscle plus

adventitial cells) was required for a constructive remodeling response to occur. Further studies showed that as little as 30% of the normal esophageal muscle tissue was required to support the constructive type of esophageal remodeling outcome which allowed for normal dietary habits and absence of any signs of esophageal disease^[69].

The promising results of these preclinical studies were the basis of successful endoscopic treatment for five patients with esophageal adenocarcinoma^[72]. All patients had long segment disease limited to the mucosa. Complete circumferential *en bloc* mucosal resection, ranging from 8 cm to 14 cm in length, was performed on these patients with subsequent placement of a xenogeneic ECM scaffold (SurgiSis™, Cook Biotech, Lafayette, IN) held in place by an expandable stent. The stent was removed within 9-17 d during which time the ECM scaffold integrated with the underlying muscular wall of the esophagus and supported complete epithelialization and formation of a new submucosal layer. All patients required transient post operative dilation for mild stricture but were able to then eat a normal diet without recurrence of disease. Several of these patients have had subsequent reflux surgery and require no further treatment (unreported data). In the context of classic approaches to regenerative medicine, one could consider the successful approach in these patients as a combination of scaffold plus the bioactive factors inherent in the ECM, plus the required endogenous host cells in contact with the scaffold.

Using a similar approach, three additional patients recently were subjected to endoscopic, circumferential *en bloc* resection of Barrett's with HGD, followed by fundoplication (Figure 1). The results support the findings from the previous study and provide further evidence for the use of this procedure as a feasible alternative to surgery for the treatment of HGD and intramucosal adenocarcinoma.

Alternative regenerative medicine approaches to creating esophageal tissue have been explored. Grikscheit *et al*^[73] adapted a technique previously used in intestinal engineering whereby organoid units, mesenchymal cores surrounded by epithelial cells, were isolated from neonatal

and adult rats, labeled with green fluorescent protein (GFP), and paratopically transplanted on biodegradable polyglycolic acid tubes before implantation within the omentum of syngeneic hosts. Four weeks later, the engineered esophageal tissue was either harvested or anastomosed as an onlay patch or total interposition graft^[73]. Histologic examination of these organoids showed a complete esophageal wall including mucosa, submucosa, and muscularis propria. These findings were confirmed with immunohistochemical staining for actin smooth muscle. Furthermore, the tissue-engineered esophagus architecture was maintained after interposition or use as a patch, and animals gained weight on a normal diet. GFP-labeled tissue-engineered esophagus preserved its fluorescent label, proving the donor origin of the tissue-engineered esophagus. The maximal amount of esophageal tissue that could be replaced by this method remains to be explored and the application of this technique to full circumferential lesions has not been investigated.

Similar cell based and/or scaffold based approaches to construct functional esophageal tissue have been investigated by others. In 2006, Marzaro *et al.*^[74] used esophageal ECM seeded with smooth muscle cells (SMCs) to repair a 2 cm defect in the tunica muscularis in a porcine model. They reported the ingrowth of SMCs with early organization into small fascicles. Two years later, Nakase *et al.*^[75] explored replacement of a full circumference esophageal defect with polyglycolic acid scaffolds seeded with epithelial cells. Good distensibility of the construct following implantation was reported although peristaltic activity of the new tissue was absent. The thickness of both the squamous epithelial layer and the smooth muscle layer of the engineered esophagus were similar to that of the native esophagus. These results confirmed the concept of biomaterials seeded with cells, either differentiated cells or stem/progenitor cells, as a potentially viable approach for the repair of damaged esophageal tissue.

The mechanisms by which ECM bioscaffolds alter the default proinflammatory esophageal healing response and instead promote a more constructive remodeling response are only partially understood. However it is known that degradation of the ECM releases a variety of growth factors including vascular endothelial growth factor and basic fibroblast growth factor, among others^[76]. The critical amounts of active growth factor and the specific factors required to support constructive tissue remodeling are unknown. ECM scaffold degradation *in vivo* occurs rapidly based upon results of preclinical studies in non-esophageal sites^[77-80] and the endoscopic procedures to remove the temporary stents in the patients treated for esophageal cancer suggests that degradation is also very rapid in this location. Scaffold degradation is considered important because it removes a persistent foreign material against which the host can mount a chronic inflammatory reaction and, perhaps more importantly, scaffold degradation results in the generation of bioactive cryptic peptides from component structural

molecules of the ECM such as collagen^[81]. These cryptic peptides, typically no larger than 10-12 amino acids in length, have been shown to have potent chemotactic and mitogenic activity for selected stem and progenitor cells *in vitro*^[81-84]. The role of this chemotactic phenomenon in constructive remodeling is not fully understood but logically it provides a method for supporting a regenerative type of response.

It is also known that the host response to the presence of a xenogeneic ECM scaffold includes local modulation of the innate immune response from proinflammatory M1 macrophage mediated events toward more dominant constructive tissue remodeling M2 macrophage mediated processes^[77,85-87]. However, it is unknown which, if any, of these mechanisms occur or are important in the esophageal location.

CONCLUSION

Esophageal disease is an increasingly important problem and has very limited satisfactory treatment options. The default inflammatory and scarring response of the non-regenerating esophageal tissue not only creates severe morbidity from the disease process itself, but also limits the therapeutic options since manipulation and tissue injury are unavoidable sequelae of either invasive or minimally invasive endoscopic techniques. Regenerative medicine strategies that utilize cell based, scaffold based, and bioactive molecule based approaches potentially provide a viable alternative for both physicians and the affected patients. Preliminary early results of a bioactive ECM scaffold based approach have been promising.

Abstract

A number of congenital and acquired disorders require esophageal tissue replacement. Various surgical techniques, such as gastric and colonic interposition, are standards of treatment, but frequently complicated by stenosis and other problems. Regenerative medicine approaches facilitate the use of biological constructs to replace or regenerate normal tissue function. We review the literature of esophageal tissue engineering, discuss its implications, compare the methodologies that have

been employed and suggest possible directions for the future. Medline, Embase, the Cochrane Library, National Research Register and ClinicalTrials.gov databases were searched with the following search terms: stem cell and esophagus, esophageal replacement, esophageal tissue engineering, esophageal substitution. Reference lists of papers identified were also examined and experts in this field contacted for further information. All full-text articles in English of all potentially relevant abstracts were reviewed. Tissue engineering has involved acellular scaffolds that were either transplanted with the aim of being repopulated by host cells or seeded prior to transplantation. When acellular scaffolds were used to replace patch and short tubular defects they allowed epithelial and partial muscular migration whereas when employed for long tubular defects the results were poor leading to an increased rate of stenosis and mortality. Stenting has been shown as an effective means to reduce stenotic changes and promote cell migration, whilst omental wrapping to induce vascularization of the construct has an uncertain benefit. Decellularized matrices have been recently suggested as the optimal choice for scaffolds, but smart polymers that will incorporate signalling to promote cell-scaffold interaction may provide a more reproducible and available solution. Results in animal models that have used seeded scaffolds strongly suggest that seeding of both muscle and epithelial cells on scaffolds prior to implantation is a prerequisite for complete esophageal replacement. Novel approaches need to be designed to allow for peristalsis and vascularization in the engineered esophagus. Although esophageal tissue engineering potentially offers a real alternative to conventional treatments for severe esophageal disease, important barriers remain that need to be addressed.

INTRODUCTION

Recent years have witnessed great interest in regenerative medicine, the replacement, repair and regeneration of tissues and organs^[1,2]. Particular interest has focused on the potential for this new field to offer new solutions for failing tissues and organs, and alternatives to transplantation, implants and reconstructive surgery, all of which have limitations.

Several conditions, both congenital and acquired, may require esophageal tissue replacement. In the pediatric population the primary indication for esophageal replacement is long-gap esophageal atresia (EA) with insufficient length for primary anastomosis. Patients with long-gap EA, which fail a primary repair, receive a denervated gastric pull-up or interposition graft using either jejunum or colon, with many associated early and late post-operative complications, such as stricture formation and the potentially carcinogenic effect of acid reflux^[3,4]. In children, gastric transposition and intestinal interposition can also be used in esophageal strictures not responsive to dilatation following failed EA repair or caustic ingestion, or for rare neoplastic conditions such as inflammatory pseudotumor, leiomyosarcoma and teratoma^[5]. By contrast, the commonest indication for esophageal replacement in adults is cancer, a condition whose incidence is escalating^[6], whilst colon interposition is sometimes indicated for diffuse Barrett's esophagus, a premalignant condition. Unfortunately, all of these methods of esophageal replacement severely impair the quality of life of recipient adults and children^[7,8] and present problems related to donor site morbidity. Even recent developments in endoluminal resection, which removes the diseased inner layers of the esophagus through an endoscope, whilst reducing morbidity, still results in a high rate of stenosis and consequent dysphagia^[9]. Despite its 60-year history, conventional organ transplantation is not a solution for the failure of every organ, due to technical and ethical issues, and is specifically unable to address the unmet needs of esophageal replacement. Thus, regenerative medicine techniques, which extend the boundaries of reconstruction and do not, in most applications, require immunosuppression, present attractive alternatives^[10].

Regenerative medicine has been used to describe the use of natural human substances, such as genes, proteins, cells, and biomaterials to regenerate diseased or damaged human tissue^[11,12] in order to restore normal function^[2].

Tissue engineering with the end-point of organogenesis has been successful through a combination of appropriate cells with a scaffold^[13-17] as well as the use of only one of these two components, for example in the repair of urethra^[18] and skin^[19] (Figure 1).

We review the literature relating to esophageal tissue engineering and suggest areas where research may lead to the most rapid clinical gains.

INFORMATION COLLECTION

We searched Medline, Embase, the Cochrane Library, National Research Register and ClinicalTrials.gov databases, using the search terms stem cell and esophagus, esophageal replacement, esophageal tissue engineering, esophageal substitution. The reference lists of papers identified in this way were searched and further papers identified. All full-text articles in English of potentially relevant abstracts were reviewed. Finally, acknowledged experts in this field were contacted for information on gaps in our review and information on unpublished studies.

TWO BROAD CATEGORIES OF INTERVENTION

Seventy-four papers were identified and are reviewed in this manuscript. Two broad categories of intervention were identified: the use of scaffolds alone, and a combination of cells and scaffolds.

Acellular scaffolds

The majority of identified studies transplanted acellular scaffolds with the aim that host epithelial and smooth muscle cells will migrate to repopulate the new conduit. Acellular scaffolds studied to date conform to one of three categories: synthetic, collagen alone and decellularized matrix.

Synthetic scaffolds: Acellular synthetic scaffolds such as polyethylene plastic^[20-22] and silicon^[23,24] have been used for esophageal replacement, but the nature of the materials did not allow cellular migration and led to poor results in animal models. When polyvinylidene fluoride (PVDF) and polyglactin-910 (Vicryl[®]) were compared for the regeneration of patch defects in rabbits, PVDF was shown to lead to improved results with an absence of strictures and neo-epithelialization^[25]. However, in a different study, the combination of Vicryl[®] and collagen brought about positive results both for patch and tubular defects in dogs, with a low mortality of 8.3%^[26]. The successful use of synthetic polymers in other organs such as the trachea^[27], suggests that this approach may appear attractive and further development of appropriate materials is needed.

Collagen scaffolds: In a series of experiments performed by a research group in Japan, porcine dermal collagen scaffolds were used to produce porous tubular structures (Table 1)^[28-33]. The general methodology involved the use of these

Figure 1 Esophageal tissue engineering. A tissue-engineered esophageal construct may be created by the combination of a scaffold and cells, grown in a bioreactor and transplanted in patients. A three-dimensional scaffold may be created from synthetic material, collagen or a decellularized matrix. Cells for the use of tissue engineering are derived from a number of sources such as the adult, fetus and the embryo. Additionally, non-seeded scaffolds may be transplanted with the aim of being repopulated by host cells. ESC: Embryonic stem cells; IPS: Induced pluripotent stem cells.

scaffolds to replace 5-10 cm tubular defects in the cervical or intra-thoracic portion of the esophagus in dogs. A silicon tube was used as a stent to support the scaffold until repopulation occurred. Aiming to avoid complications such as stenosis^[28,29], the research group compared whether this was related to the time for which the scaffold was supported by the stent. In an experiment where three groups of dogs had a 5-cm cervical surgically created defect, the stent was removed at either 2, 3 or 4 wk. With increasing stent duration, it was observed that greater epithelial and muscle cell densities were achieved in the collagen scaffold, and this correlated with decreased stenosis and mortality^[31]. However, when the collagen scaffold replaced 10-cm portions of the esophagus there was poor cellular migration in the muscular layer, suggesting that there are limitations to the size of defect that may be replaced by this methodology^[30]. Moreover, when the same methods were used to replace intra-thoracic portions of the esophagus in dogs, muscular regeneration was completely absent, something the authors attributed to the lack of a vascular supply in the thorax^[32]. In an attempt to address this, the scaffold was wrapped in omentum^[33], as has been successfully applied to tracheal tissue engineering^[34,35]. However, muscular regeneration remained absent, whilst an increase in mid-portion stenosis and mortality was observed^[33].

Decellularized matrix: Decellularized matrices are derived from human and animal organs and tissues that have been treated to remove cells and immunogenic material^[36]. Importantly, however, they retain the macro- and micro-architecture of the tissue of origin, and the molecular components of its natural extracellular matrix^[37-40]. They have the added hypothetical advantages over synthetic scaffolds of not producing potentially toxic degradation products or inducing inflammation characteristics that may be important in the prevention of stenosis^[20,41,42]. Decellularized scaffolds that have been used for esophageal organs originated from the esophagus

as well as from other tissues such as the small intestinal submucosa (SIS)^[28-31,43-47].

Significant heterogeneity exists among studies, both with respect to the type of scaffold, extent of surgery and species used, which partly explains the range of results reported. Thus, regeneration of the muscularis propria layer is seen to take place in some studies^[43,44,48], but not others^[49]. Studies that have attempted tube-interposition with SIS report the development of esophageal stenosis and increased mortality^[44,50,51]. By contrast, studies applying SIS as a patch repair demonstrated encouraging results^[44,50-53]. Badylak *et al.*^[45] laid sheets of SIS onto the raw internal surface of esophagus following endoscopic submucosal resection in five patients with superficial cancers. With a follow-up of 4 to 24 mo, the scaffold promoted physiological remodelling as evident by endoscopy and histological characterisation following biopsy. Strictures still formed, but only at areas outside those lined by SIS, suggesting that possible technical improvements in scaffold delivery could ameliorate this. In fact, when SIS was used to completely cover a 3 cm × 5 cm mucosal defect in the cervical esophagus, there was no stenosis and endoscopy at 4 wk demonstrated good integration of the scaffold^[46].

Hypothetically, decellularized esophageal tissue should retain the signals, both chemical and structural, that will direct the appropriate migration and differentiation of host cells, in a way unlikely to occur with scaffolds originating outside the esophagus, such as SIS. Ozeki *et al.*^[54] compared two methods of decellularization of adult rat esophagus based on deoxycholate and Triton X-100 respectively and assessed the resulting scaffolds using routine histology and biocompatibility. Those treated with deoxycholate showed superior mechanical properties, maintenance of the extracellular matrix and a lower DNA content than those treated with Triton X-100. Bhrany *et al.*^[55] found a combination of 0.5% sodium dodecyl sulphate and Triton X-100 to be effective in decellularization, albeit with a loss of tensile strength as measured by burst pressure studies. Our experience with the detergent-enzymatic treatment in the decellularization of the intestine^[39] allowed us to use the same methodology in the esophagus (Figure 2), leading to an improved preservation in microarchitecture^[56].

Cell-seeded scaffolds

To reduce complications arising from acellular approaches, some authors have seeded the scaffolds prior to transplantation. As mentioned, the two main cell types that are important for esophageal tissue engineering are those that will reconstitute the epithelium and the muscle layer on the luminal and extra-luminal sides respectively. Also important in the formation of a functional esophagus are the vascular and neuronal cell components but we could locate no studies that have studied these in engineered esophagus.

A number of *in vitro* experiments have examined the seeding and culture of esophageal epithelial cells and different scaffolds to assess the optimal combination. When a matrix composed of decellularized human skin was

Table 1 Overview of *in vivo* transplantation of acellular matrices

Animal model (<i>n</i>)	Scaffold type	Size	Scaffold regeneration	Results		Ref.
				Clinical course		
Canine (19)	Collagen with silicon stent (not removed)	5 cm circumferential gap, cervical esophagus	Partial epithelial regeneration	26% mortality		[28]
Canine (26)	Collagen with silicon stent (removed between 2 and 8 wk)	5 cm circumferential gap, cervical esophagus	Epithelial regeneration, no stenosis	0% mortality when stent dislodged after 4 wk (<i>n</i> = 4)		[29]
Canine (7)	Collagen with silicon stent (removed at 6 wk)	10 cm circumferential gap, cervical esophagus	Epithelial and partial muscular regeneration, no stenosis	29% mortality		[30]
Canine (43)	Collagen with silicon stent (removed either at 2, 3 or 4 wk)	5 cm circumferential gap, cervical esophagus	Epithelial and muscular regeneration, no stenosis	0% mortality when stent was removed at 4 wk (<i>n</i> = 16)		[31]
Canine (9)	Collagen with silicon stent (removed at 4 wk)	5 cm circumferential gap, thoracic esophagus	Epithelial but no muscular regeneration, mid-portion stenosis	11% mortality		[32]
Canine (14)	Collagen with silicon stent (removed at 4-8 wk) +/- OMPx	5 cm circumferential gap, thoracic esophagus	Epithelial regeneration, mid-portion stenosis	11% mortality in control group, 80% in OMPx group		[33]
Canine (15)	Extracellular matrix scaffold from either small intestine (<i>n</i> = 12) or urinary bladder submucosa (<i>n</i> = 3)	5 cm semi-circumferential or 5 cm circumferential, cervical esophagus	Mucosal and muscular regeneration. Stenosis in case of complete circumferential defects	0% mortality		[44]
Pigs (10)	Elastin based acellular biomaterial patch (from porcine aorta)	2-cm circular defect, abdominal esophagus	Mucosal and muscular regeneration	0% mortality. No complications reported in treatment groups		[43]
Canine (12)	Urinary bladder matrix scaffold	Complete transection with replacement of endomucosa with matrix	Mucosal and muscular regeneration	0% mortality. No complications reported in treatment groups		[48]
Rats (67)	Small intestinal submucosa patch graft	Semi-circumferential defect, cervical or abdominal esophagus	Mucosal and muscular regeneration at 150 d	94% survival at 150 d		[50]
Rats (85)	Small intestinal submucosa patch graft, or tube interposition	Semi-circumferential defect or segmental esophageal excision	Tube interposition unsuccessful. Mucosal and muscular regeneration at 150 d in patch-group	100% survival for patch-group (and no complications reported), 0% survival for tube interposition group at 28 d		[52]
Rats (27)	Gastric acellular matrix scaffold	Patch defects, abdominal esophagus	Mucosal regeneration seen at 2 wk. No muscular regeneration seen up to 18 mo	11% complication rate		[49]
Pigs (14)	Small intestinal submucosa (tubular)	4-cm defect, cervical esophagus	Prosthesis not found either macroscopically or histologically	Only 1 pig survived the full 4 wk study. The other pigs have to be sacrificed prematurely due to severe stenosis		[51]
Human (5)	Porcine small intestinal mucosa	8-cm to 13-cm en-bloc resection of mucosa and submucosa for superficial carcinoma	Restoration of normal mucosa as early as 4 mo	Strictures; perforation in one patients		[45]
Human (1)	Porcine small intestinal mucosa	5 cm × 3 cm defect cervical esophagus	Intact esophagus with normal calibre	No complications encountered		[46]

Figure 2 Production of esophageal natural acellular matrices. Decellularization involves treatment of fresh esophageal tissue with a combination of solutions that will remove the cells but maintain the structural characteristics of the native extracellular matrix. The optimal methodology of esophageal decellularization is currently under investigation. Our experience with the detergent enzymatic treatment is illustrated here with hematoxylin and eosin staining of a representative decellularized esophagus demonstrating preservation of the native architecture (Scale bar 100 μ m).

compared to synthetic scaffolds *in vitro* for the capacity to support cultured epithelial cells, the decellularized scaffold exhibited cell differentiation and surface confluence similar to native esophagus, whereas synthetic scaffolds demonstrated a discontinuous epithelial lining^[57]. Another study compared the growth of human esophageal squamous cells on human decellularized esophagus, porcine decellularized esophagus, human decellularized dermis, and collagen^[58]. Interestingly the porcine matrix and collagen gave better results leading to the formation of a mature stratified epithelium. When rat esophageal epithelial cells (EEC) were seeded onto 3-dimensional (3-D) collagen scaffolds they were shown to be viable for up to 8 wk *in vitro* but did not fully integrate within the scaffold, remaining on the surface as individual cells or small clusters^[59]. Seeding of sheep EEC on the same 3-D collagen scaffold resulted in the absence of epithelium sheet for-

mation, which was attributed to cellular penetration into the scaffold and loss of cell-to-cell contact^[60]. However, when the same cells were seeded on the 2-D collagen scaffolds a single layer of epithelium was evident following 3 wk of *in vitro* culture that remained viable up to 6 wk. The same group has also performed *in vivo* studies of vascularization of the EEC-scaffold construct by omental transplantation in lambs for 8-12 wk^[61]. Positive selection of the epithelial population could increase proliferative capacity as demonstrated by Kofler *et al.*^[62], who selected ovine EEC for expression of pancytokeratin (PCK) using fluorescence activated cell sorting. The PCK-negative sub-population had minimal cell attachment on the collagen scaffolds, whereas the PCK-positive cells had a uniform distribution.

In vivo experiments using EEC-scaffold constructs, similarly to results in acellular approaches, have shown more promise for regeneration of partial rather than circumferential defects in rats and dogs^[63-65]. An innovative approach recently described seeded cells on a temperature-responsive dish that became hydrophilic at 20 °C and allowed harvesting of a single-cell sheet^[63]. When the cell sheets were transplanted in dogs that had undergone endoscopic submucosal resection, complete wound healing was observed at 4 wk with no signs of stricture and an intact epithelium. Wei *et al.*^[64] obtained mucosal epithelial cells from oral biopsy, or esophageal organoid units created following digestion of rat esophagi^[65]. These were seeded onto scaffolds and implanted as complete esophageal substitutes, but histology of the resultant muscle layers showed poor architecture.

To overcome the limitations of using EEC in isolation, esophageal constructs prepared using EEC-seeded collagen scaffolds were placed on the latissimus dorsi muscle of athymic mice with the intention to harvest and tubularize the muscle once the epithelial side has matured^[66,67]. Miki *et al.*^[68] found an increase in the number of epithelial layers from 2 when EEC seeded alone, to 18 when co-seeded with fibroblasts. A more recent study by Hayashi *et al.*^[69] cultured both epithelial and fibroblast cells on a bed of smooth muscle cells (SMC) embedded in a collagen gel *in vitro*, prior to transplanting them on the latissimus dorsi of athymic rats. Nakase *et al.*^[70] also aimed to combine different cell lines and scaffolds into one tubular structure in dogs. They used oral keratinocytes and fibroblasts cultured on human amniotic membrane and SMC seeded on poly (glycolic acid). These two scaffolds were then rolled together and implanted into the omentum for 3 wk, following which they were transplanted into a 3-cm intrathoracic esophageal defect. Both muscular and epithelial layers were present at 420 d of follow-up, although no peristaltic activity was observed.

FUTURE PERSPECTIVES

Based on the above literature, it is clear that although tissue engineering has been proposed as a solution for the current treatments of esophageal defects, currently, there

is no clear strategy for recreating all the portions of the esophagus in man^[71,72]. The problems that need to be solved are related to the optimal scaffold, the cell sources for the epithelial and muscular components, peristalsis and vascularization (Table 1). The stenotic changes that are the main complication encountered with esophageal constructs are likely related to poor regeneration of natural architecture.

The recent trend in organ tissue engineering has been to use decellularized scaffolds. It has been suggested that they would be an advantageous choice due to their enhancement of cellular proliferation, migration and differentiation. However, the lack of positive results when trying to replace a tubular defect, confirms that the use of biomaterials alone as a means of esophageal repair is unsuccessful. We envisage a point where “smart polymers” may replace scaffolds of biological origin and facilitate an “off-the-shelf” approach to esophageal tissue-engineering. Our group and collaborators in Sweden have used poly-hedral oligomeric silsesquioxane-poly (carbonate-urea) urethane, a synthetic material used in clinical trials of vascular grafting, as an alternative to biologic scaffolds in the generation of tracheal scaffolds^[73]. These have the added advantages of being tailor-made and retain biomechanical properties indefinitely, whilst there is no need for an organ donor, with all the attendant convenience, infection and ethical issues of the latter. However, early experience shows that these scaffolds do not epithelialize or vascularize easily^[27]. The study of cell-scaffold interactions is likely to substantially inform the development of better biomaterials for organ and tissue regeneration. Ritchie *et al.*^[74] found that esophageal muscle cells seeded onto collagen membranes required mechanical stimulation to retain normal contractile properties in a bioreactor, showing the importance of a multidisciplinary engineering approach to this problem, but we could find no other references to the application of bioreactors to esophageal tissue-engineering. *Ex vivo* models, such as bioreactors and microfluidic organotypic chambers, are urgently required in order to explore the effects of varying stem cell/cell-scaffold-signaling combinations in the generation of functional esophageal tissue pre-implantation.

The general consensus indicates a significant advantage in repopulating scaffolds with cells prior to implantation. Studies that have seeded EEC have had positive results in repopulating the epithelial layer, both as an onlay patch^[63,64] and as a total interposition graft^[65]. Nevertheless, as with cell-free approaches, in cases in which only the lumen was seeded, there was a poor regeneration of the muscular layer, indicating a need for co-seeding with SMC. This is not a surprise, since esophageal strictures can be managed clinically easily with an intestinal patch (free graft) as partial substitution while they have very high chance of recurrence when such material is used to repair the whole circumference. Studies are required to identify the optimal cell types and sources to repopulate esophageal scaffolds. Ideally, cell sources should be autologous, easy to harvest, highly proliferative, and should have the

ability to differentiate into many specialized cell types.

Equally important to muscular regeneration is the challenge of replicating peristaltic contractility and a vascular supply in an artificial esophagus. Watanabe *et al*^[75] developed nickel-titanium, shaped-memory, alloy coils, which were placed in an annular manner on a Gore-Tex vascular graft for esophageal replacement. Interestingly, low-voltage electrical current passing through the coils generated peristaltic movements in the artificial esophagus implanted in a goat model, suggesting that re-provision of appropriate muscular stimuli, either by enhanced neural regeneration or by electrical means, may be a profitable route for investigation if functionally normal swallowing is to be achieved. What is more, we propose that the physiological contribution of neural crest cells is a prerequisite for functional peristalsis.

Regarding the vascular component, the esophagus holds an additional challenge due to the tenuous intrinsic vascular anatomy of the esophagus in man and the association of stenosis with poor vascularization. Wrapping the engineered esophagus in the omentum prior to thoracic transplantation is one potential solution, as proposed by Nakase *et al*^[70]. However, results in this instance as well as in our use of omental wrapping for transplantation of tissue-engineered tracheas in humans^[35] were sub-optimal. More preclinical work on revascularization strategies is required. The use of intraluminal stents is another solution to avoid stenosis. Where collagen scaffolds were used in the above studies, the stenosis and mortality was inversely correlated to the length of stay of the intraluminal stent^[29,31]. The use of stents allows time for epithelial and muscular migration onto the cell-free scaffolds. In our recent pediatric tissue engineered trachea transplant^[35] we also used bio-absorbable stents, which were engineered using large mesh that allows epithelial ingrowth and persists for about 6 wk before complete degradation^[76,77].

CONCLUSION

In the near future, tissue engineering may represent a valid therapeutic alternative to treat severe congenital or acquired esophageal disorders. We present possible lines for investigation that could indicate what such products will look like, but propose that, in the short- to medium-term, a combination of decellularized scaffolds with muscle and epithelial cells of autologous (including autologous stem cell) origin are likely to be the most expeditious route. Major questions of vascularity, cell-cell and cell-scaffold interaction, and motility remain outstanding, however, before the bioengineered neo-esophagus becomes an established, effective treatment for complex congenital and acquired malformations in adults and children.

Abstract

The increasing shortage of donors and the adverse effects of immunosuppression have restricted the impact of solid organ transplantation. Despite the initial promising developments in xenotransplantation, roadblocks still need to be overcome and this form of organ support remains a long way from clinical practice. While hepatocyte transplantation may be effectively correct metabolic defects, it is far less effective in restoring liver function than liver transplantation. Tissue engineering, using extracellular matrix scaffolds with an intact but decellularized vascular network that is repopulated with autologous or allogeneic stem cells and/or adult cells, holds great promise for the treatment of failure of organs within gastrointestinal tract, such as end-stage liver disease, pancreatic insufficiency, bowel failure and type 1 diabetes. Particularly in the liver field, where there is a significant mortality of patients

awaiting transplant, human bioengineering may offer a source of readily available organs for transplantation. The use of autologous cells will mitigate the need for long term immunosuppression thus removing a major hurdle in transplantation.

INTRODUCTION

Failure of abdominal organs is a significant cause of morbidity and mortality (Table 1). Patients with organ failure may benefit from non surgical therapies, such as insulin for endocrine pancreatic failure, parenteral nutrition for bowel failure and renal replacement therapy for renal failure. Until now, solid organ transplantation, and less convincingly cellular transplantation, represent the only way to provide a definitive treatment for organ fail-

ure, although the long-term impact is limited.

SOLID ORGAN TRANSPLANTATION

Over the last half a century, there have been major advances in the field of transplantation because of improved surgical techniques, anaesthesia, immunosuppression and peri-operative care. All these elements substantially improved patient and graft survival. Five-years patient and graft survival rates of 73% and 68.4% can nowadays be achieved in liver transplantation (LT), but still relatively poor long-term results are obtained for intestinal and pancreas transplantation with five-year patient and graft survival rates of 47% and 38%, and 82% and 52%, respectively^[1].

The major limitation to the widespread use of transplantation is the scarcity of organs. The gap between available organs and potential recipients increases every year, giving rise to serious ethical and practical dilemmas of equity and utility when allocating the organs. In March 2011, the United Network for Organ Sharing reported a solid organ transplant waiting list of 110 600; 16 133 patients were listed for liver, 1389 for pancreas and 262 for intestine transplants. The absolute numbers of transplants in 2010, in contrast, was 6291, 351 and 151 for liver, pancreas and intestine, respectively. These figures clearly illustrates that many patients will never benefit from transplantation and die on the waiting list^[1]. The problem is even greater than these figures suggest as not all those who might benefit from transplantation are listed. In the United Kingdom, patients with chronic liver disease are listed only when estimated likelihood of death without transplant is greater than likelihood of death following transplantation. This estimation of survival is calculated based on validated models using objective laboratory data incorporated in scores such as developed by the Model for End-Stage Liver Disease (MELD) or United Kingdom End-stage Liver Disease (UKELD). The UKELD score includes, besides the MELD parameters, serum creatinine, bilirubin and INR, also serum sodium. The latter score seems to have an improved predictive accuracy. A UKELD score of over 49 predicts a > 9% 1-year mortality without liver transplant; this is the minimum criteria for entering the waiting list in the United Kingdom^[2]. In the United States, survival benefit starts when MELD score exceeds 17, unless the patient has other co-morbid factors, such as liver cancer, affecting prognosis or unacceptable quality of life because of liver disease. In the United Kingdom, candidates for LT must also have a greater than 50% probability of surviving for 5 years post transplant with a quality of life acceptable to the patient^[3].

Although not used as a direct criterion for selection or allocation, development of the concept of transplant survival benefit, i.e. the extra years of life attributable to transplant, might facilitate more effective use of scarce organs and restrict access to those whose lives will be

Table 1 Deaths in United Kingdom¹ and United Kingdom Transplant Activity²

Note: Overall deaths include all causes and all ages so many of those who died would not be suitable for transplantation. NA: Not available.

extended minimally or not at all. However, it has proved very difficult to develop robust modelling on which to base such a benefits based approach to liver allocation.

In case of diabetes mellitus, numbers on waiting lists also underestimate the need for transplantation as this therapeutic modality is primarily applied to patients in need for a combined pancreas-kidney transplantation. Transplantation for diabetes alone is restricted, in many centers, to some patients, with hypoglycemia unawareness and brittle diabetes. The adverse consequences of immunosuppression, such as the increased risk of some infections and malignancies need to be balanced against the potential benefits of improved glycemic control so it is not clear which patients with diabetes mellitus might benefit from transplantation.

In part because of cultural and logistic issues, deceased donor rates vary considerably between countries, ranging from 2 per million population in Greece to 35 per million population in Spain^[4]. The success of public health initiatives, leading to better awareness for vascular diseases such as hypertension and reduction in fatal road accidents, resulted in a fall in the number of “traditional ideal” (young post-traumatic) organ donors and an increase in the use of “high risk” donors, such as older and obese donors and donors after circulatory arrest^[5]. The increasing donor risk profile partly negates the benefits made by better surgery and peri-transplant care.

To increase the number of available organs, several technical advances and policies have been adopted. Using extended criteria donors (ECD) and donation after circulatory death (DCD) [also referred to as non-heart beating donors (NHBD)] and implementing split LT (SLT), domino or living donor LT can contribute to enlarging the donor pool. All these techniques and policies are however not free from additional risk and therefore their use raises medical and ethical concerns as welfare of both the living donor and recipient may be compromised. Indeed all these allografts from deceased donors carry an increased risk of primary non-function, early or delayed dysfunction and possibly a greater risk trans-

mission of infection and cancers^[6]. It has been clearly shown that ECD organs, defined as organs originating from donors dying from cerebrovascular catastrophe, DCD, longer ischemia time, older age and steatosis compromise outcome. Severe allograft steatosis, defined as > 60% fatty infiltration, is associated with a greater risk of primary graft dysfunction and lower patient and graft survival^[7]. Grafts with more than 30% steatosis have been reported to be safe in low-risk recipients but associated with more risk in recipients with MELD scores greater than 30^[8]. Clinical estimation of the degree of fatty infiltration correlates poorly with histologic assessment.

Guarrera *et al.*^[9] have undertaken a pilot study designed to evaluate the safety and feasibility of liver preservation with hypothermic machine perfusion (HMP), a technique widely used in kidney transplantation^[10] although its potential has been shown in animal models of LT. Compared to standard cold preservation in human LT, HMP appears safe, may improve graft function and is reported to be associated with a reduction in preservation injury (PI). This strategy is likely to be most beneficial in older, steatotic and DCD grafts, which are most susceptible to PI.

Models investigating the interaction between donor and recipient risk profiles have been developed to predict the likelihood of graft and patient survival after LT. Feng *et al.*^[11] recently identified, in a large donor cohort study, nine factors (age, height, DCD donors, split liver grafts, black race, cause of death from cerebrovascular accident, regional sharing and cold ischemia time) which were associated with graft failure. As a corollary, a donor risk index predicting the effect of these variables on graft survival was developed^[11]. It is clear that it will become more and more important to match donor risk score with recipient risk score in order to assure an acceptable outcome for the recipient.

SLT has been developed as a strategy to increase the number of liver grafts by creating 2 grafts from 1 donated liver. The bipartition of a liver is especially important in the small group of pediatric patients for whom size-matched whole liver allografts are scarce. Indeed the use of split grafts has been associated with a reduction in the risk of death on the pediatric waiting list; although some centers have reported an increased risk of graft failure, the split procedure for adult-pediatric pair is now accepted as a valuable technical variant in pediatric LT^[11,12]. Donor selection for splitting, technical and logistic expertise to decrease total ischemia time are all important factors for a successful outcome of the procedure. This technique is much less successful in the adult-adult split constellation.

In order to expand further the donor pool, organs from DCD donors are increasingly used in liver and pancreas transplantation, especially in the United Kingdom and the Netherlands. Liver and pancreas grafts are usually restricted to those originating from controlled

donors - those donors in Maastricht category III (awaiting cardiac arrest)^[13]. However in Europe, legal constraints do not allow use of NHBD in all countries^[14]. Although, DCD LT can have good outcome, their use is associated with a significantly higher risk of graft failure^[13-16], severe biliary complications and higher costs^[17-19]. However, increasing understanding of the pathophysiology of the events surrounding DCD and better selection and timing may improve outcome in the future.

Several reports described successful islet isolation and transplantation from DCD donors^[20-24]. These donors could provide an important resource for islet transplantation if used under strict criteria and in multiple transplantation, particularly in countries where heart-beating donors are not readily available.

The use of DCD organs has not been deemed suitable to intestinal recipients because of concerns about organ quality.

With respect to transplantation of organs of the gastrointestinal system, living donation is essentially confined to LT. Better understanding of the anatomy and increasing surgical skills has allowed living donor liver transplants (LDLT) to become a routine procedure in some, especially Asian, centres. LDLT has been widely adopted in Asia because of the very low rates of deceased organ donation and because of the very high incidence of liver cancer. LDLT accounts for over 95% liver transplants in Asia. In 2008, a Chinese series of 234 right-liver living donor liver transplants showed 1-, 3-, and 5-year overall survival rates of 93.2%, 85.7%, and 82.4%, respectively, comparable with deceased donor liver transplant outcomes^[25]. Good outcomes have been shown even when using grafts with a graft-to-recipient weight ratio (GRWR) < 0.8%, with a rate of small-for-size syndrome similar to those receiving graft with a GRWR > 0.8%, provided the recipient is receiving the graft from a young donor^[26].

In the Western world LDLT is practised much less frequently because of the greater availability of deceased donors but also because of major concerns with donor mortality, especially when transplanting the right lobe which is associated with an estimated risk of donor death of 0.08% and a morbidity around 20%. The reported morbidity and mortality data underestimate the real risk. There have been anecdotal reports of donors requiring a transplant for hepatic failure. The outcome of LDLT is good with a 1-, 5- and 10-years graft survival of 81%, 70% and 68%, respectively^[27-30]. The survival rates after LDLT are better than full size deceased donor LT in children but somewhat lower in adults^[29].

However, not all liver transplant candidates have suitable donors. Altruistic (non-directed) liver donation is done very rarely although the number of altruistic kidney donations, while still small, is increasing slowly.

Living donor bowel transplantation has been reported as an additional resource for patients with intestinal failure with total parenteral nutrition-related life-

threatening complications^[31]. However the very limited data from the Intestinal Transplant Registry do not demonstrate a clear advantage of living donor intestine donation over deceased donor intestine transplant^[32-34]. The early outcomes of combined intestinal and LT using living donors are promising and the elimination of the high mortality on the cadaver waiting list (30%) for this category of patients represents a substantial advantage^[35].

Limitations of solid organ transplantation

Transplantation is associated with a significant improvement in both quality and quantity of life for most organ recipients but does not reach normal values^[36]. Patient and graft survival is limited by many factors including recurrent disease, immune mediated graft damage, technical problems and long-term infectious, malignant and cardiovascular consequences of immunosuppression. It is noteworthy that recurrent hepatitis C virus (HCV) allograft infection is almost universal and associated with a worse outcome compared with most other indications, yet HCV related cirrhosis is one of the leading indication for LT in the Western world^[37].

Although operational tolerance is found in a small proportion of highly selected liver allograft recipients, most patients will require life-long immunosuppression. Attempts to induce tolerance strategies which are successful in the laboratory, have yet to be reliably achieved in man^[38].

Transmission of donor-related disease, especially some infections and cancers, can be mitigated but not abolished^[39].

XENOTRANSPLANTATION

Research in xenotransplantation has grown in the last decades^[40,41]. The use of knock-out pigs with multiple gene modifications reduced the frequency of hyperacute rejection which was a major problem in earlier models^[42,43]. Many physiological restraints, as evidenced by a systemic inflammatory response involving the innate immune system, by platelet, leucocyte and complement activation, by coagulation dysfunction associated with coagulation-anticoagulation incompatibilities of primates and pigs, remain. The transplantation of porcine organs has been carried out in non-human primates with better outcomes with pig hearts or kidneys compared with pig livers, the main problems being in the latter a coagulation dysfunction with thrombocytopenia leading to spontaneous bleeding^[44]. However, pig livers may provide sufficient function to maintain short term support and might so be used in patients with acute liver failure, either until the native liver recovers or as a bridge to liver allograft. Only one clinical pig-to-human LT has been reported so far by a surgical team in Los Angeles headed by Leonard Makowka, in a patient with fulminant hepatitis. The patient underwent preoperative plasmapheresis to remove

circulating xenoantibodies and the porcine liver graft was placed in a heterotopic position. The pig liver was rejected in few hours and the patient died before a human liver became available^[45].

Significant roadblocks, such as the immunologic hurdle of cross species transplantation and transmission of infections, particularly endogenous retroviruses, need to be overcome before pig organ xenotransplantation can become a clinical reality. Furthermore, the physiological impact of xenotransplantation remains unclear as shown by the immunogenicity and uncertain physiological functioning of pig proteins in the maintenance of homeostasis.

Progress is being made in this difficult field of transplantation as shown by the report of encouraging outcome of pig hepatocyte xenotransplantation with the benefit of the lack of an acute humoral xenograft rejection, the immediate restoration of the liver function and the resistance to specific human viruses^[46]. Are equally encouraging the results of xenotransplantation of encapsulated pig islet cells with the aim to prevent antibody or T-cell contact with islets, allowing though insulin to reach the systemic circulation^[47]. However, this xenotransplantation remains illegal at this time.

CELLULAR TRANSPLANTS

Cellular transplants are being used in a very limited number of indications, such as use of pancreatic islets for diabetes mellitus^[48] and hepatocytes for some metabolic liver diseases and parenchymal liver diseases^[49]. The Collaborative Islet Transplant Registry reports that the majority of islet transplant procedures are performed in the islet transplantation alone setting, with Islet-after-Kidney-Transplantation representing only a small fraction of all islet transplants performed^[50].

Islet transplantation is limited to a highly selected group of patients with type 1 diabetes (T1DM) and aims to achieve adequate glycemic control and removal of need for exogenous insulin^[48] (Table 2). Islet transplantation is associated with short-term benefits of insulin independence, normal or near normal HbA1C levels, sustained marked decrease in severe hypoglycemic episodes and a return of hypoglycemia awareness. However the long-term efficacy is disappointing. In 2006, an international, multicenter trial reported on 36 subjects with T1DM; insulin independence with adequate glycemic control at 1 year after the final transplantation was achieved in only 44% of patients and 31% remained insulin-independent at 2 years^[51]. Follow-up of a larger cohort of 65 patients showed that insulin independence was achieved in 69% at 1 year, 37% at 2 years and only 7.5% at 5 years^[52].

A successful islet transplantation can effectively reverse and stabilize the risk of secondary diabetic complications. The Vancouver group compared islet recipients to best medical therapy and found that islet transplanta-

tion had a better impact upon risk of secondary complication^[53].

In contrast to the time consuming and expensive islet isolation from donor pancreas, islet transplantation is minimally invasive and carries a low morbidity and mortality compared to whole pancreas transplantation because the islets can be infused percutaneously into the hepatic portal vein. However, its use is limited because of the shortage of high quality donor pancreases, the high cost of the isolation procedure, the maintenance of a specialised human islet isolation laboratory, the need for life-long immunosuppression and the need of multiple organs to obtain enough islets. The ability to achieve single-donor islet transplantation would provide many more islet grafts and also increase the number of recipients with T1DM. Although Matsumoto *et al*^[54] recently published a protocol describing successful single-donor islet transplantation, further studies are needed to confirm the benefit of this protocol. Recipients of IT are also exposed to a wide range of human leukocyte antigens from multiple donors due to repeated islet infusions, which are still, in many units, matched for ABO blood group only. The development of antibodies may be an important issue in end stage diabetic patients also requiring a kidney transplant, as their appearance possibly limits the chance to find a compatible kidney^[55]. It may therefore be difficult to resolve the competing requirements of islet and renal transplantations.

The research in hepatocyte transplantation (HT) has shown encouraging results in particular in the treatment of some inherited metabolic disorders, and have raised expectations for a new therapeutic approach as a pos-

sible alternative to LT (Table 2)^[56]. About 30 patients had HT for liver-based inborn errors of metabolism; the main indication was urea cycle defects. About 5% of newly formed, exogenous-derived, cells natively expressing the gene involved in the disease, suffice to significantly alleviate the consequences of many congenital liver metabolic diseases^[57]. The procedure seems to be safe and results are encouraging; however, as seen in the field of islet transplantation, cell function often declines within 1 year ending finally up in LT.

A new approach of gene targeting technology has been recently proposed with the potential of combining human induced pluripotent stem cells with genetic correction to generate clinically relevant cells for autologous cell-based therapies for the treatment of some inherited metabolic disorders^[58].

HT in patients with chronic liver failure has been associated with dismal results^[59-63]. This might be related, at least in part, to the presence of fibrosis, which may impair cell engraftment in the liver^[62]. HT has also been applied in patients with acute and acute-on-chronic liver failure, in the former with the aim to support the liver function as a bridge to LT. More than 40 patients with acute liver failure have been treated worldwide; a part from an improvement in bilirubin levels and hepatic encephalopathy, there was no significant impact on outcome^[59]. Two large clinical trials assessed the effectiveness of bio-artificial liver devices including both a biological component and an artificial scaffold, and both failed to have a beneficial effect on survival^[63,64].

HT is also limited by the availability of livers for cell isolation. The recipient's cirrhotic liver as a source for donor hepatocytes, would be an easily available option, but it is uncertain whether these cells behave *in vivo* as they do in culture.

Establishing banks of cryopreserved hepatocytes is challenging, because isolated liver cells are very sensitive to damage. Furthermore, cryopreserved hepatocytes engraft less efficiently than freshly-isolated cells. Another major issue is their time-limited efficacy, which may limit the use of HT as a bridge to LT. In contrast, the use of stem/precursor cells is associated with relatively easy procurement and as they proliferate well *in vitro*, such cells may provide sufficient cell mass available for transplantation. A further issue in this field is related to the mechanism of parenchymal integration and repopulation of exogenous hepatocytes^[65]. "Making space" is a prerequisite in order to provide an initial regenerative stimuli; partial hepatectomy, partial embolization and irradiation of the liver all represent effective regenerative stimuli in animal models, but their efficacy in humans requires further investigation. Moreover, the exogenous cells should have a proliferative advantage with respect to autologous liver parenchymal cells; in order to proliferate some authors suggest that this problem may be overcome with the use of foetal hepatic progenitors cells that exhibit an intrinsic biological advantage^[66].

REGENERATIVE MEDICINE AND TISSUE ENGINEERING

The manufacturing of bioengineered organs in the laboratory starting off from autologous differentiated cells and/or stem cells is undoubtedly ground-breaking and exciting for the transplant community. As there will always be more potential recipients than donors, many researchers are working in the field of artificial tissue engineering (TE) and regenerative medicine (RM).

In 2006, Atala *et al.*^[67] of the Wake Forest Institute for Regenerative Medicine in Winston-Salem, North Carolina, implanted bladders engineered *ex vivo* from the seeding of autologous cells onto artificial supporting scaffolds; in 2008 the same group implanted a trachea manufactured from human components^[68]. However, solid organs with lots of blood vessels, such as liver, pancreas and bowel are harder to grow.

Progresses in the development of clinically feasible liver TE approaches, has been hampered mainly by insufficient cell-to-cell contact of the engrafted hepatocytes. Ohashi *et al.* developed a method of cell sheet technology to engineer a uniformly continuous sheet of hepatic tissue using isolated primary hepatocytes cultured on temperature-responsive surfaces. Sheets of hepatic tissue transplanted into the subcutaneous space resulted in efficient engraftment to the surrounding cells, with the formation of two-dimensional hepatic tissues that stably persisted for longer than 200 d and showed several characteristics of liver-specific functionality.

Decellularization-recellularization technology has done steps forward in order to manufacture liver organoids. Uygun *et al.*^[69] decellularized rat livers and repopulated them with rat primary hepatocytes, showing hepatic function. Atala's group implemented the technique by bioengineering livers with human cells^[70,71].

Extracellular matrix (ECM) scaffolds might provide the desired natural environment to enhance current cell-based approaches aimed at producing large quantities of functional pancreatic endocrine cells^[72,73]. However, compared to islet transplantation, whole organ transplantation using ECM scaffolds is clearly more invasive, requiring revascularization and possibly even exocrine drainage.

Primary hurdles to intestinal bioengineering are the functional regeneration of diverse motility patterns and the complexity of intestinal anatomy.

The implantation of organoid units of intestine has been successful in rats and pigs; however, this technology is time consuming and expensive, as several centimetres of bowel are needed to obtain a sufficient number of organoid units able to repopulate just a few centimetres of engineered intestine. Moreover, organoid units cannot be cultured and grown easily *in vitro*^[74,75]. Decellularization-recellularization technology has been used to engineer less complex gut structures such as the esophagus. A 10-cm segment of porcine jejunum was decellularized

and repopulated with autologous cells. After maturation, the construct was implanted in the arm of a patient suffering from a major esophago-tracheal defect and retrieved after 7 d; the construct showed patent vessels and viable cells, showing that sustained the implantation^[76].

The attraction of a failing organ being replaced by a bioengineered organ generated from a decellularized scaffold and seeded with autologous stem cells is obvious but not without limitations. It will take time to isolate and grow such organs or sufficient cells to provide adequate function so this approach would not be an option for those with acute liver failure where liver replacement is required within some days and liver assist devices have yet to demonstrate an effective role. Similar time constraints may also preclude the use of such organs in patients with primary liver cancer. The use of autologous stem cells, able to differentiate into the kind of required cells and with the potential to expand without limitation, may resolve the issue of rejection and long-term immunosuppression requirement, even though very little is understood regarding the host immune response to bio-engineered constructs.

However, organs derived from autologous stem cells may be subject to the same risk of damage from virus or immune mechanisms that result in the failure of the native organ. Recurrent HCV allograft infection remains a major cause of graft failure despite major advances in antiviral treatments and recurrent autoimmune diseases such as diabetes or autoimmune hepatitis, contribute to graft loss despite associated immunosuppression. Without genetic modification, autologous stem cell derived organs or cells will not correct the disease resulting from metabolic conditions that result in cirrhosis and so leading to organ failure, such as is seen in Wilson's disease or tyrosinosis. Organs or cells derived from allogeneic stem cells would provide an alternative to deceased donor organs and so mitigate against the organ shortage and allow greater access to life-saving care. The application of bone marrow-derived stem cells has shown good results in small groups of patients however in the absence of control groups^[71,72,77,78].

In addition to supplementing or replacing the traditional abdominal organs from living or deceased donors, RM could be of help in other patient groups such as those with inflammatory bowel disease and selected small bowel disease refractory to treatment. Non-responding patients frequently require surgery to control symptoms, although such interventions will not necessarily resolve their disease. An approach based on new findings of RM could drive major changes in management and treatment of such diseases. RM therapy can become effective either in repairing damaged intestinal tissue and correcting immunological underlying disorders. Therefore, RM should not only be considered as a potential therapy for patients with inflammatory disease refractory to standard medical and biological therapy but, hopefully, as a curative treatment that allows achievement of long-lasting

remission.

RM could also have a great impact in the area of gastrointestinal motility disorders, particularly those associated with the aganglionic gut or Hirschsprung's disease and other congenital or acquired enteric nervous system disorders, and may obviate the need for surgical therapies that, although life-saving, are associated with an unsatisfactory long-term prognosis for many.

RM and TE have the enormous potential to help not only those patients who would otherwise be candidates for liver, pancreas or bowel transplantation but also those who would not, under current restrictions, be eligible for listing. Despite promising pre-clinical results^[69,73-75,79-83], many critical aspects of cell therapy and TE need to be further addressed, including long-term safety, tolerability and efficacy in the clinical setting, and last but not least the development of an European Medicines Agency/Food And Drug Administration approved product, before they become protagonists of a new scientific era. Doubts whether such aspirations can be fulfilled in the near future remain, despite the significant advances already made, uncertain. Lessons from other technologies, such as gene therapy, suggest that expectations must be managed carefully.
