NEUROMUSCULAR FUNCTION OF THE GUT: NEUROMUSCULAR TUBES AND SPHINCTERS

The digestive tract is designed for the optimal processing of food that nourishes all organ systems. The esophagus, stomach, small bowel, and colon are sophisticated neuromuscular tubes with specialized sphincters that transport ingested food-stuffs from one region to another. Peristaltic contractions move ingested solids and liquids from the esophagus into the stomach^[1]; the stomach mixes the ingested nutrients into chyme and empties chyme from the stomach into the duodenum^[2]. The to-and-fro movement of the small bowel maximizes absorption of fat, protein, and carbohydrates^[3]. Peristaltic contractions are necessary for colon function and defecation^[4].

Sphincters of the digestive tract, on the other hand, have intrinsic muscle tone that produces sustained (tonic) pressure zones. The sphincteric pressures regulate movement of luminal content produced by the peristaltic contractions. Relaxation of the lower esophageal sphincter (LES), for example, allows the entry of esophageal content into the stomach^[5]; contraction and relaxation of the pyloric sphincter regulates movement of gastric content

Abstract

The digestive tract is designed for the optimal processing of food that nourishes all organ systems. The esophagus, stomach, small bowel, and colon are sophisticated neuromuscular tubes with specialized sphincters that transport ingested food-stuffs from one region to another. Peristaltic contractions move ingested solids and liquids from the esophagus into the stomach; the stomach mixes the ingested nutrients into chyme and empties chyme from the stomach into the duodenum. The to-and-fro movement of the small bowel maximizes absorption of fat, protein, and carbohydrates. Peristaltic contractions are necessary for colon function and defecation.

Key words: Neuromuscular disorders; Gastrointestinal tract; Dysfunction; Esophagus; Stomach; Small bowel; Colon

into the duodenum^[6]. The ileocecal valve regulates flow of content from the ileum into the cecum^[7]. The internal anal sphincter (IAS) regulates the elimination of rectal-sigmoid content^[8]. Sphincters not only provide resistance to flow in the areas distal to the sphincter but also limit the retrograde movement of intraluminal content into the areas proximal to the sphincter. Thus, normal neuromuscular function of the esophagus, stomach, small bowel, and colon requires the coordination of the tubular neuromuscular structures and the relevant sphincters. Symptoms such as dysphagia, nausea and vomiting, diarrhea, constipation, or incontinence may occur if neuromuscular function of the esophagus, stomach, intestine, and colon is disturbed, resulting in neuromuscular disorders such as achalasia, gastroesophageal reflux, gastroparesis, intestinal pseudo-obstruction, colonic inertia, and fecal incontinence, respectfully^[1-4,9,10].

The wall of gastrointestinal tract organs contains circular and longitudinal smooth muscle layers, the enteric nervous system including the myenteric plexus, and the interstitial cells of Cajal (ICCs) which control the rhythmicity of contractions^[11,12], all of which are targets for tissue bioengineering^[13]. The gastrointestinal tract wall is innervated by vagal afferent and efferent fibers and inputs from the sympathetic nervous system. Thus, neuromuscular disorders of the gastrointestinal tract may involve damage to the smooth muscle, enteric nerves, ICCs, extrinsic neurons, or all cell types. Neuromuscular diseases such as achalasia, gastroparesis, intestinal pseudo-obstruction, and colonic inertia represent the most severe forms of neuromuscular diseases of the gastrointestinal (GI) tract^[14-17]. These disorders are very difficult to treat, and very few drugs are designed to improve GI neuromuscular function. Table 1 shows a summary of the human neuromuscular disorders from selected areas of the GI tract, the key neuromuscular abnormalities, the clinical neuromuscular diagnosis, and the medical and surgical treatments currently available for these diseases.

In the most severe neuromuscular diseases, surgery is often required to improve symptoms. For example, a myotomy of the LES may be necessary to treat severe dysphagia due to achalasia. Partial resection of the colon and pull-through operations may also be necessary to treat drug-refractory, severe constipation or marked colonic dilation. Colectomy may be needed to correct aganglionic segments of colon as seen in Hirschsprung's disease. While a surgical approach may relieve one set of symptoms, the consequence is often secondary neuromuscular disorders. After myotomy is performed for achalasia, for example, gastroesophageal reflux may occur and require drug treatment or fundoplication. Problems with fecal incontinence may also occur after colonic resection.

In this review, the normal neuromuscular function and disorders of neuromuscular function of the digestive organs in humans are discussed. We will focus on advances in regenerative medicine as an innovative and potential cure for GI neuromuscular diseases. The goal of this novel technology is restoration of the neuromus-

cular function of the bowel wall. A regenerative medicine approach aims to bioengineer "functional" circular and longitudinal smooth muscle, enteric neurons, ICCs, and mucosa in the correct anatomical configurations in order to produce normal physiologic gut functions. GI neuromuscular disorders are particularly suited to regenerative medicine approaches because drug and surgical therapies are extremely limited.

ESOPHAGUS: NEUROMUSCULAR FUNCTION AND DYSFUNCTION

The esophagus is a neuromuscular tube with an upper esophageal sphincter formed by the cricopharyngeus muscle, the esophageal body, and the lower esophageal sphincter at the esophagogastric junction. Peristaltic waves in the esophageal body move ingested solid and liquid foods from the proximal esophagus to the distal esophagus and into the stomach during relaxation of the lower esophageal sphincter (The upper esophageal sphincter is striated muscle and disorders will not be addressed). Neuromuscular disorders of the esophagus involve the esophageal body, the lower esophageal sphincter, or both and are listed on Table 1. For example, peristaltic esophageal contractions with abnormally high amplitudes are associated with chest pain and dysphagia and are termed the "nutcracker esophagus"^[18]. On the other hand, low amplitude and simultaneous contractions of the esophageal body are associated with achalasia and scleroderma^[19]. High amplitude contractions of the nutcracker esophagus may be treated with nitrates, but there are no medical or surgical treatments for low-amplitude simultaneous contractions of the esophageal body.

Neuromuscular disorders also occur in the LES. Increased LES pressure and decreased LES relaxation after swallows are the key neuromuscular features of achalasia^[19]. The hypertensive lower esophageal sphincter may be treated with nitrates, Botox injections, balloon dilation, or surgical myotomy. In contrast, a low amplitude LES pressure is associated with gastroesophageal reflux. There are no specific drug treatments available to increase LES pressure, but radiofrequency ablation^[20] and augmentation of the LES are device-related treatments that increase LES pressure^[21].

Regenerative medicine methods to produce patches or segmental portions of the esophageal wall have been studied in dogs. In a study by Nakase *et al.*^[22], keratinocytes and fibroblasts (KF+ group) were cultured on human amniotic membrane opposed to smooth muscle tissue on a polyglycolic acid scaffold which was rolled around a polypropylene tube. Three weeks after implantation of this construct in the omentum, the KF (+) constructs had developed into tubes with stratified squamous epithelium and smooth muscle-like tissue. The KF (-) constructs lacked keratinocytes and fibroblast layers and developed luminal obstructions 2-3 wk after implantation into the esophagus. On the other hand, the 3 cm

Table 1 Neuromuscular disorders of the gastrointestinal tract, current treatments and future regenerative medicine approaches

	Disorder	Neuromuscular diagnosis	Medical treatment	Surgical treatment
Esophagus				
Body	↑ Contraction	Nutcracker	Nitrates	Myotomy
	↓ Contraction	Scleroderma	None	None
Lower esophageal sphincter	↑ Contraction	Achalasia	Botox	Myotomy
	↓ Relaxation	GERD	Nitrates	Fundoplication, RFA
	↓ Contraction		None

↑: Increase; ↓: Decrease; CIPO: Chronic intestinal pseudo-obstruction; GERD: Gastroesophageal reflux disease; IBS: Irritable bowel syndrome; RFA: Radiofrequency ablation; STN: Somatostatin.

length KF (+) constructs showed distensibility, but no peristaltic contractions, when implanted in the esophagus. Shrinkage of the keratinocytes and smooth muscle also resulted in a shorter segment of restored esophagus that was durable up to 420 d in some dogs. Two of the six KF (+) dogs eventually developed esophageal structures. Scar formation and shrinkage of tissue engineered oral mucosa epithelial sheets were also major problems in bioengineered esophageal constructs^[22].

Takimoto *et al.*^[23] used 5 cm silicone tubes to shape a collagen sponge matrix into an artificial esophagus. The construct was implanted in 43 dogs. Strictures occurred in 27 dogs if the Teflon support tube was removed 2-3 wk after implantation; but, the regenerated esophageal tissue replaced the esophageal defect if the stent was removed 4 wk after implantation. These regenerated tissues showed stratified epithelium, glands, and striated muscle, suggesting that cervical esophageal muscle had grown into the implant area, not smooth muscle of the esophageal body.

Regenerative medicine approaches to bioengineering the LES have been reported. In canine studies, the baseline LES pressure increased after skeletal muscle derived stem cells were injected into the LES area. The cells integrated within the native GI smooth muscle, but no differentiation of the cells into smooth muscle genotypes was noted^[24]. Regenerated lower esophageal sphincters need adequate myogenic tone to prevent gastroesophageal reflux, but also need to relax in response to swallows and the arrival of food boluses in the distal esophageal body. Furthermore, the LES must relax in response to

distension of the fundus to allow physiological venting of stomach air. At this time, functioning neuromuscular constructs to restore animal or human esophageal body or sphincter functions are not available.

STOMACH: NEUROMUSCULAR FUNCTION AND DYSFUNCTION

Fundus and corpus-antrum

The key functional neuromuscular regions of the stomach are the fundus, body/antrum, and pylorus. In healthy subjects, the fundus relaxes through vagal mediated nitric oxide pathways in response to swallowing and in response to solids and liquids entering the gastric fundus from the esophagus^[2]. Ingested solids are triturated by the corpus/antrum until appropriate particle size is achieved. In humans, peristaltic activities are controlled by 3 cycle per minute gastric myoelectric activity or gastric slow waves^[2]. The triturated food is termed “chyme” and is emptied through the pylorus into the duodenum by body/antral peristaltic contractions.

Patients with paralysis of the stomach (or gastroparesis) may have neuromuscular dysfunction of the fundus, body/antrum, pylorus, or all of these areas. Symptoms of gastroparesis include early satiety, prolonged fullness, nausea, and the vomiting of undigested food^[25]. Table 1 summarizes major gastric neuromuscular defects and the associated clinical diagnoses and treatments in gastroparesis. In patients with gastroparesis, the fundus fails to relax appropriately in response to ingestion of meals;

other patients have excessive relaxation of the fundus. Abnormalities of fundic relaxation affect the ability of the stomach to accommodate ingested food. There are no established medical or surgical treatments for fundic dysfunction.

Low amplitude contractions of the corpus and antrum and abnormalities of gastric slow waves (e.g., presence of tachygastrias) results in disturbed peristalsis and gastroparesis^[2,26]. There are few medications available to treat gastroparesis^[27]. Gastric electrical stimulation is a device used to treatment for the nausea and vomiting symptoms of severe gastroparesis^[28].

Regenerative medicine approaches for the development of gastric tissues are evolving. Araki *et al.*^[29] implanted a 5 cm collagen scaffold with silicone layers on the mucosa side and fabric on the serosa side. The scaffold was soaked in blood or bone marrow aspirate before implantation. Seven dogs were implanted. During the 16-wk study, the construct developed ulcers that healed, showed 59%-77% shrinkage in length, and developed alpha-smooth muscle actin positive cells, but no calponin staining cells. Maemura *et al.*^[30] used rat stomach epithelium organoid cells, a preparation of minced rat stomach wall that was centrifuged, washed, and placed onto a tubular mesh. The organoid cells were wrapped in omentum *in vivo*, harvested after 3 wk, and used to replace the resected stomach in the same rat. Barium studies showed emptying from the neo-stomach, but weight in these rats was no better than rats with total gastrectomy. Histology showed neo-mucosa and smooth muscle orientation similar to the normal stomach. In the study by Hori *et al.*^[31], mucosal and smooth muscle layers of the canine stomach were bioengineered, but the construct exhibited no contractions. Ultimately, bioengineered constructs need to restore peristaltic contractions in the corpus/antrum for restoring gastric mixing and emptying of food.

Pylorus

On the other hand, dumping syndrome results when ingested foods are emptied exceedingly rapidly from the stomach into the duodenum^[32]. Increased antral contractions or decreased pyloric resistance to emptying are putative underlying mechanisms of dumping syndrome. Dumping syndrome may develop after resection of the antrum-pylorus for treatment of ulcers or cancer. Thus, pyloric function affects gastric emptying rates. Hypotensive pylorus is another mechanism that may underlie the dumping syndrome. There are no medical approaches to increasing pyloric pressure at this time. On the other hand, a hypertensive pyloric sphincter which does not relax (example: pylorospasm) is associated with gastroparesis^[33]. Medical approaches to the treatment of pylorospasm include injection of Botox or balloon dilation of the pylorus^[34]. In some patients, a myotomy may be performed to reduce pyloric pressure and increase gastric emptying.

Micci *et al.*^[35] described transplantation of neural stem cells to the pylorus and results showed improved

relaxation of pylorus muscle strips and improved gastric emptying in neural nitric oxide synthetase (nNOS) deficient mice. Results suggested the stem cells restored nNOS function regarding relaxation of the pylorus. The pylorus is a target for stem cell and regenerative medicine treatments. At this time, the bioengineered stomach and pylorus have not reached development for clinical deployment.

SMALL INTESTINE: NEUROMUSCULAR FUNCTION AND DYSFUNCTION

The small intestine is a hollow neuromuscular tube that comprises the duodenum, jejunum, and ileum^[36]. In the small intestine, chyme is broken down into smaller nutritional fragments: amino acids, carbohydrates, and fatty acids. Normal small intestinal motility and digestive enzymes from the pancreas and bile from the gallbladder are needed for normal digestion and absorption of nutrients. The ileum has special features for absorption of bile salts^[37]. The ileocecal valve is positioned between the distal ileum and the cecum, controls emptying of ileal effluent into the cecum, and prevents the reflux of cecal contents into the ileum. The regulation of this process is poorly understood because the ileocecal valve area is difficult to study in humans. Normal small intestinal motility includes phase 3, the interdigestive migrating motor complex, which consists of strong peristaltic contractions that move distally from the duodenum to the ileum in a cycle every 90 min during fasting^[38]. These contractions transport indigestible fibers from the small bowel into the colon.

Neuromuscular disorders of the small intestine are uncommon in adults. Scleroderma is associated with low amplitude, poorly organized small intestinal contractions and idiopathic chronic intestinal pseudo-obstruction involves disorders of the enteric nervous system and smooth muscle of the small bowel. In disorders with poor small intestinal peristaltic contractions, as seen in chronic intestinal pseudo-obstruction, bacterial overgrowth of the small bowel occurs and leads to malabsorption and diarrhea. There are no treatments for hypocontractility of the jejunum and ileum; however, small bowel bacterial overgrowth is treated with antibiotics and somatostatin which may increase the incidence of phase 3 migrating motor complexity. Jejunal diverticula can be resected surgically if they are thought to be the cause of symptomatic bacterial overgrowth. Short bowel syndromes occur in adults when the jejunum is resected due to ischemia and in neonates with severe enterocolitis that required resection^[39].

In regards to the ileocecal valve, a narrow nipple-like structure is positioned between the distal ileum and the cecum^[7]. Specific neuromuscular disorders have not been described. Mechanical obstructions due to tumors such as adenocarcinoma of the ileum or cecum may cause ileal obstruction and are treated with appropriate operations. Dysfunction or loss of the ileocecal valve may lead to

“backwash ileitis”.

Regenerative medicine approaches to small bowel neuromuscular diseases include studies to increase the length of the small bowel to treat short bowel syndromes. Kim *et al.*^[40] used polyglycolic tubes seeded with intestinal fragments (epithelial organoid units) which were implanted in the omentum of rats. These constructs developed into neointestinal cysts that were well vascularized, had a neomucosa with crypts, and some areas had smooth muscle^[40]. Anastomosis of the constructs with native small intestine was successful and no stenoses or obstructions developed^[41].

The small intestinal submucosa (SIS) was used to form a scaffold for bioengineered small intestine in dogs^[42]. SIS sheets were wrapped around glass tubes to form segments which were used to patch defects, approximately 7 cm × 3 cm in size, or for tubular implants in the small intestine. Most dogs with tubular implants had obstructions, anastomotic leaks, or appeared ill. Dogs with patch implants survived, but the implants shrunk approximately 35% in size, the mucosal layers were not well organized, and the amount of smooth muscle was variable or absent. Hori *et al.*^[43] used autologous mesenchymal stem cells (MSC) from bone marrow seeded onto a collagen scaffold to induce smooth muscles to regenerate small intestine. A 5 cm area was resected and replaced with scaffold and a silicone tube stent to prevent contraction and stenosis. All six dogs survived. Although mucosa developed, no smooth muscle layers regenerated. Grikscheit *et al.*^[44] used intestinal organoid units loaded into polymer tubes to form intestine-like segments. The units were implanted into the omentum. Four weeks later, small bowel resections were performed and the regenerated cysts and the native small bowel were connected with anastomoses. The regenerated cysts contained villi, crypts, ganglion cells, and some muscularis. Transit time was 1825 min in animals with regenerated cysts *vs* 982 min in those without implants, but weight gain was better in the former group. Nakase *et al.*^[45] seeded a collagen scaffold with autologous smooth muscle cells isolated from the canine stomach. After implantation in the ileum, mucosal villi and circular smooth muscle cells developed in orderly alignment at 12 wk in animals with ileal reanastomosis at 8 wk after implantation. Scaffolds coated with basic fibroblast growth factor enhanced smooth muscle growth and angiogenesis, but distinct smooth muscle layers and contractions were not seen in these constructs^[46]. Some smooth muscle cells differentiated into fibroblast-like cells. More recently, Koga *et al.*^[47] showed that the porcine small bowel was successfully lengthened with a hydraulic-lengthening device. The elongated jejunum retained near normal motility and absorption when implanted in the native jejunum.

No studies using human tissue have been reported for small bowel regeneration, although there is an extensive clinical need for small intestine segments as therapies for short gut syndromes. In adults with short bowel syndrome, increased length of small bowel would help

ongoing problems with malabsorption and dehydration.

COLON: NEUROMUSCULAR FUNCTION AND DYSFUNCTION

The anatomical regions of the colon include the cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and anorectum. The cecum and ascending colon receives up to 1.5 L of ileal effluent each day and absorbs 90% of the effluent. Subsequently, approximately 200 g of semi-solid stool are normally eliminated by defecation each day. Evacuation of the rectum requires coordination between peristaltic waves in the rectal-sigmoid area of the colon and relaxation of the anal sphincter and the pelvic floor muscles^[4,8].

Neuromuscular diseases related to the colon include irritable bowel syndrome in which increased and decreased contractility of the colon produces alternating constipation and diarrhea. Treatments for irritable bowel syndrome are confined to fiber supplements, cholinergic agents, and tricyclic antidepressants. There are no surgical options for irritable bowel syndrome. Colonic inertia is a disorder with weak contractions throughout the colon resulting in severe constipation. For patients with colonic inertia, there are very few medications other than laxatives and lubiprostone. In severe cases of colonic inertia, a colectomy may be performed. The colectomy (with ileo-sigmoid or ileo-rectal anastomosis) often results in loose stools four to six times per day. In some patients, the recto-sigmoid segment has significant neuromuscular dysfunction and constipation persists despite the colectomy^[48,49]. Similarly, functional constipation with associated fecal incontinence, often due to colonic dilation and megarectum, generally responds poorly to medical management. Surgical approaches such as cecostomy or appendicostomy (ACE) have been widely used in the treatment of refractory constipation. However, some patients are unable to have a bowel movement on their own despite the use of the cecostomy/ACE, while others demonstrate recurrent symptoms after discontinuation of antegrade enemas^[50]. When this occurs, further surgical intervention including placement of a diverting colostomy or colonic resection becomes an option^[51].

Regenerative medicine approaches to the colon have been explored in rats. A bioengineered colon segment, colonic mucosa, and smooth muscle was produced by seeding colon organoid units from autologous sigmoid colon onto polymer scaffolds. After implantation for 12 wk, the regenerated cysts showed correct colon microarchitecture^[52]. Hecker *et al.*^[53] bioengineered colon tissues with normal three dimensional smooth muscle orientation around a central lumen; the tissue exhibited peristalsis. These experiments suggest that multiple smooth muscle rings may be an alternative method compared to regenerating long segments of the colon organ itself. There is much work remaining to be done to prepare the way for human studies related to the regeneration of the colon.

IAS: NEUROMUSCULAR FUNCTION AND DYSFUNCTION

The IAS is a smooth muscle that is under anonomic nervous system control, whereas the external sphincter is striated muscle under voluntary control^[54]. A hypertensive IAS with poor relaxation results in rectal outlet obstruction associated with severe constipation^[4,8]. Medical treatments include physical therapy, laxatives, Botox injections, and myotomy of the sphincter^[55]. On the other hand, a hypotensive or weak anal sphincter results in fecal incontinence. Fecal incontinence results in significant psychosocial issues and poor quality of life. Treatments of fecal incontinence include stool bulking agents, sphincteroplasty, injection of the sphincter with bulking agents, and sacral nerve stimulation^[56].

Neuronal disorders of the gut such as Intestinal Neuronal Dysplasia and Hirschsprung's disease involve a developmental or degenerative loss of enteric neurons^[57]. Aganglionosis results in serious motility problems due to lack of adequate peristalsis. Symptoms include painful abdominal distention, stool retention, and fecal incontinence. Currently, surgical excision of the aganglionic segment is the most effective treatment strategy. Despite technical advances in surgery, the complications in Hirschsprung's patients after corrective surgery include fecal incontinence (10%-16%) and enterocolitis (10%)^[58,59].

Considerable progress has been made using regenerative methods to bioengineer an internal anal sphincter that has properly aligned circular smooth muscle, and importantly, neural innervation. Hecker *et al.*^[53] showed that IAS smooth muscle cells in fibrin-based gels developed into three dimensional smooth muscle rings which showed relaxation and contraction in response to 8-bromo-c AMP and acetylcholine, respectively. Somara *et al.*^[60] used human IAS cells to form bioengineered three dimensional smooth muscle rings which exhibited basal myogenic tone that was dependent on prokinase C (PKC) pathways not rho kinase. Bioengineered mouse IAS constructions were grown for 28 d after implantation in the backs of mice. The harvested rings developed basal tone, responded normally to vascularization, had no ICCs, but smooth muscle cells (smooth muscle actin and h-caldesmon positive cells) were present and responded normally to stimulating and relaxing drugs^[61]. Thus, the implanted IAS constructions had traits of the native IAS. Raghavan *et al.*^[62] reported the successful implantation of the bioengineered IAS comprised of human smooth muscle cells and immortalized fetal enteric neurons. The harvested construct, implanted into RAG1-1-mice for 25-28 d developed neovascularization, myogenic tone, and normal contraction and relaxation characteristics in response to testing. These advances in bioengineering the IAS reflect increasing sophistication in combining the enteric nerve and GI smooth muscle components that will be critical in providing treatment for clinical neuromuscular diseases such as fecal incontinence.

CONCLUSION

Neuromuscular disorders of the GI tract are excellent but complex targets for regenerative medicine approaches designed to restore function. In many of these human diseases, the symptoms are severe, but treatments are extremely limited. Many challenges for regenerative medicine approaches remain: identifying sources for cells, construction of scaffolds that result in the proper three-dimensional growth of the selected cells into the desired organ, physiological orientation of the component layers of the wall of the GI organs, and the functional integration of the key cells (smooth muscle, enteric nerves, ICCs). Implantation, integration, and growth of the regenerated patches, grafts, and organs require growth factors, vascularization of the bioengineered tissues, and restoration of neuromuscular function. Many challenges must be overcome to bioengineer functional regions of the GI tract, but the needs and the opportunities are great.

Abstract

The present review aims to illustrate the strategies that are being implemented to regenerate or bioengineer livers for clinical purposes. There are two general pathways to liver bioengineering and regeneration. The first consists of creating a supporting scaffold, either synthetically or by decellularization of human or animal organs, and seeding cells on the scaffold, where they will mature either in bioreactors or *in vivo*. This strategy seems to offer the quickest route to clinical translation, as demonstrated by the development of liver

organoids from rodent livers which were repopulated with organ specific cells of animal and/or human origin. Liver bioengineering has potential for transplantation and for toxicity testing during preclinical drug development. The second possibility is to induce liver regeneration of dead or resected tissue by manipulating cell pathways. In fact, it is well known that the liver has peculiar regenerative potential which allows hepatocyte hyperplasia after amputation of liver volume. Infusion of autologous bone marrow cells, which aids in liver regeneration, into patients was shown to be safe and to improve their clinical condition, but the specific cells responsible for liver regeneration have not yet been determined and the underlying mechanisms remain largely unknown. A complete understanding of the cell pathways and dynamics and of the functioning of liver stem cell niche is necessary for the clinical translation of regenerative medicine strategies. As well, it will be crucial to elucidate the mechanisms through which cells interact with the extracellular matrix, and how this latter supports and drives cell fate.

INTRODUCTION

With the many recent advances in the general area of liver regenerative medicine, there have been a multitude of significant improvements regarding the technology of liver bioengineering and regeneration. The purpose of the present review is to illustrate the two main strategies that are currently being implemented to manufacture liver organoids for clinical purposes.

DECELLULARIZATION-RECELLULARIZATION TECHNOLOGY

Several studies have provided evidence that this technology offers a valuable platform for liver bioengineering through the repopulation of an acellular liver with appropriate fresh cells.

The first report addressed the methodology for the decellularization of rodent livers^[1]. Livers were cannulated through the inferior vena cava, with the portal vein severed and the superior vena cava clamped. The decellularization process began with rinsing of the liver with 100 mL of phosphate buffered saline (PBS) to clear the blood followed by perfusion of three 300 mL isotonic solutions of 1%, 2%, and 3% Triton X-100 at a rate of 5 mL/min. This was followed by perfusion of a 300 mL PBS solution containing 0.1% sodium monododecyl sulfate (SDS) and a 300 mL PBS wash. The disruption of the lipid membranes cleared most of the cellular components of the organ except for intact nuclear cages containing DNA, which was further removed by a solution of SDS. Hematoxylin and eosin staining of the intact decellularized liver showed a fine web of matrix remaining in the acellularized liver, which was further analyzed by immunohistochemical staining of collagen IV and laminin. The stains showed the presence of collagen within the matrix and that laminin was present within the basement membrane of the vessels. After the decellularization process, the scaffold remained intact and strong enough to maintain further cannulation for the perfusion of cells. 10^6 cells of the rat liver progenitor cell line WB344 in Roswell Park Memorial Institute medium were infused into the decellularized liver through the cannulated inferior vena cava. Further histological analysis of the center of the intact recellularized scaffold indicated that the intrahepatic vasculature was able to traffic cells from the inferior vena cava. This report demonstrated the necessary process of using SDS in the decellularization process to truly remove any cellular components, specifically DNA.

Another similar subsequent report that used a similar decellularization method showed vascular patency through portal vein dye^[2]. The decellularization process was performed by sequential perfusion of different concentrations of detergents through the portal vein at a flow rate of 1 mL/min. The livers were perfused for 72 h with SDS in distilled H₂O: 0.01% SDS for 24 h, 0.1% SDS for 24 h, and 1% SDS for 24 h. The livers were then perfused with distilled H₂O for 15 min and with 1%

Triton X-100 for 30 min to cleanse the livers of any remaining SDS. After rinsing the decellularized livers with PBS for 1 h, only the median lobe was sterilized in 0.1% peracetic acid in PBS for 3 h and kept for recellularization after further extensive PBS washing. The decellularized scaffolds were histologically analyzed to demonstrate that the scaffolds were acellular and functionally similar to an intact normal liver, in order for recellularization to be possible. Histological analysis showed that there were no nuclei or cytoplasmic staining in the decellularized liver compared to a normal rat liver. Immunohistochemical analysis of four extracellular matrix (ECM) proteins (collagen type I, collagen type IV, fibronectin and laminin- β 1) showed that the structural and basement membrane components of ECM remained intact similarly to the normal liver. DNA analysis of the decellularized scaffold showed that less than 3% of residual DNA remained after the decellularization process. They also reported intact functional vascular beds and microvasculature through the perfusion of the Allura Red dye. The dye flowed through the vasculature just as expected in a functioning liver. The acellular translucent scaffold was then infused with rat-derived hepatocytes through perfusion of the portal vein at 15 mL/min. The perfusion system consisted of a peristaltic pump, bubble trap, and oxygenator from a donors-after-cardiac-death organ resuscitation perfusion system. They introduced approximately 12.5 million cells during each of the four steps in ten-minute intervals, which showed superior engraftment efficiency when compared to a single-step infusion. The recellularized grafts were maintained in a perfusion chamber for up to 2 wk *in vitro*, with histological staining of the recellularized sections at 4 h, 1 d, 2 d, and 5 d of perfusion. At 4 h, the majority of the cells remained in and around the vessels; however, at 1 d and 2 d, the cells leave the vessels and become distributed throughout the matrix.

It should be emphasized that this is the first report that contains data showing the level of function exhibited by the hepatocytes grown on the decellularized matrix. They report that hepatocyte viability was maintained during culture and that cell death was kept to a minimum. They were also able to determine that the cells migrated beyond the matrix barrier to reach decellularized sinusoidal spaces through scanning electron microscopy (SEM) and histological analysis. They also determined that albumin synthesis was not increased in the recellularized matrix compared to an intact liver; however, urea synthesis was significantly higher in the recellularized liver than the hepatocyte sandwich during culture. The analysis of the expression of drug metabolism enzymes showed that the levels of Cyp2c11, Gstm2, Ugt1a1, and Cyp1a1 that were expressed in the recellularized grafts were similar to those of the sandwich hepatocyte cultures. The recellularized liver grafts were then transplanted into recipient rats that underwent unilateral nephrectomy for auxiliary liver graft transplantation. The recellularized liver grafts were perfused quickly with blood and the appropriate efflux

occurred only after 5 min. The graft was maintained *in vivo* for 8 h, and then harvested for further Tdt-mediated dUTP Nick-End Labeling staining analysis. This staining demonstrated that the cells were minimally damaged and further histological staining showed that the hepatocytes reserved normal morphology and parenchymal positions.

While it is extremely important to have these previous promising reports on liver decellularization and recellularization, the ultimate necessary technology that needs to be expanded upon is the decellularization and recellularization of whole organs—specifically human organs, and subsequently human derived cell lines—in order to create a transplant graft for possible human functioning. The report by Baptista *et al.*^[3] demonstrated the potential for the colonization of human hepatocyte progenitors on a decellularized liver matrix. This is one of the first reports to show the decellularization and recellularization process with a whole liver instead of thin slices or lobes of the liver, as well as the first report to recellularize successfully with human liver cells. They attempted to decellularize whole livers from multiple species as well, including mice, rats, ferrets, rabbits, and adult pigs.

All of the dissected livers were cannulated with different gauged cannulas, depending on the species, through the inferior vena cava and the portal vein, which were then hooked up to a Masterflex peristaltic pump in preparation for decellularization. There was approximately 40 times the volume of the liver perfused with distilled water at a flow rate of 5 mL/min. The decellularization process was performed by perfusion of approximately 50 times the volume of the liver with 1% Triton-X 100/0.1% Ammonium Hydroxide. The approximate perfusion times for the decellularization process were 1 h for mice, 2 h for ferret, 3 h for rat, and 24 h for pig livers. It was visibly clear after the perfusion period that the parenchyma became transparent and the vascular tree was visible under low magnification microscopy (Figure 1).

Spectrophotometric and agarose gel DNA analysis showed the removal of approximately 97% of the DNA from the tissue, indicating efficiency of the decellularization process. SEM was performed to determine that that ultrastructure was preserved. The SEM analysis showed that reticular collagen fibers that support the hepatic tissue were present and the “portal triad” structures remained intact, as well as the lack of any cells. Histological analysis of acellular ECM was performed to further characterize the scaffold composition. The staining showed that there was no cellular nuclear material or any other cellular material present. The staining also showed that collagen layers with vascular channels were present, along with collagen fibers, elastin fibers, and glycosaminoglycans (Figure 2).

Quantification of the ECM components showed higher levels of collagen and glycosaminoglycans in the decellularized scaffold compared to native tissue, which can be explained by the absence of cellular components, while there was no difference in elastin presence. The localization of the specific extracellular matrix proteins

collagen I, collagen III, collagen IV, laminin, and fibronectin were all observed around the vascular structures, specifically denser around the larger vessels, and the parenchymal areas of the acellular liver, as well as the fresh tissue. Vascular preservation and patency was demonstrated by the ability of the network of vascular remnants to retain labeled dextran that had a similar molecular weight to that of blood proteins.

The recellularization methods used in this report show that perfusion through the vena cava or the portal vein (preferred) both allow the green fluorescent protein-labeled MS1 endothelial cells to line the vascular network, including the larger vessels to the capillary sized vessels. Portal vein-seeded endothelial cells were primarily deposited in the periportal regions of the liver lobule while the vena cava-seeded endothelial cells were primarily concentrated in the regions of the central veins and in smaller branches and vessels. Through fluorescent microscopy and transmission electron microscopy they were able to determine that the lumens of the acellular vascular remnants could be colonized by endothelial cells that were able to actively spread and cover the vessel basement membrane while forming appropriate cell-cell junctions. They also determined that the surface of the vascular lumen was non-thrombogenic, which was confirmed by the lower quantification of platelets in the bioscaffold compared to the fresh tissue. The reseeding experiments performed in this report utilized the coseeding of human umbilical vein endothelial cells and freshly isolated human fetal liver cell's, while using similar recellularization protocols previously mentioned. Immunohistochemical analysis was used to assess the proliferation and analyze the presence of hepatocytic lineage markers. Staining of Ki67 to assess proliferation showed a high number of positive cells throughout the bioscaffold, which was 3 times higher than the number of apoptotic cells present. The staining also showed that the hepatocytic markers α -fetoprotein, CYP2A, and CYP3A were expressed in the parenchyma. Cytokeratin 19 was strongly seen throughout the bioscaffold in biliary tubular structures while clusters of albumin-expressing hepatocytes were distributed in the parenchyma. The small amount of co-expression of these specific markers implies that there are specific niches within the bioscaffold for bile duct and hepatocytes. Immunohistochemical staining also detected CK19+/CK18-/ALB-tubular structures and clusters of ALB+/CK18+ cells in the parenchyma, which suggests that the bioscaffold is able to support the differentiation of the fetal hepatoblasts into biliary or hepatocytic lineages. The ability of cells with immunophenotypes consistent with hepatocytes, cholangiocytes, and endothelial cells to form discrete pockets in the bioscaffold suggests that some of the micro-architectural “blueprint” was retained within the scaffold. This suggests that not only does the bioscaffold provide a three-dimensional vascularized scaffold (previously described) but it also retains the necessary environmental cues, further explained by the retention of the glycosaminoglycans that serve as

Figure 1 Gross and microscopic anatomy of acellular ferret livers. Upper row: The liver on the left is almost entirely decellularized, however it remains a segment still cellular (interrupted line); on the right, instead, the liver is fully acellular as expression of successful decellularization; Middle row: Scanning electronic microscopic ruling out the presence of any cell remnant and showing the triad completely acellular (arrow); Lower row: Hematoxylin and eosin confirms the lack of cellular element within the remaining liver extracellular matrix (arrow).

active binding sites for growth factors that regulate cell phenotype, for progenitor hepatic and endothelial cells to grow, differentiate, and maintain functionality.

A related study reports on a refined decellularization procedure. This study demonstrated the ability of liver progenitor cells to differentiate to both the hepatocyte and cholangiocyte lineages while seeded on the decellularized scaffold^[4]. The strategy for recellularizing the bioscaffold was aimed at creating a more rapid and efficient differentiation of the stem cells using tissue-specific extracts enriched in extracellular matrix and a hormonally specific defined medium using associated growth factors and cytokines. They reseeded the scaffold with human hepatic stem cells in a hormonally defined medium specific for adult liver cells. The stem cell markers were expressed in the cells after the reseeded process and the

cells differentiated into mature functional parenchymal cells in approximately one week. These cells remained viable and presented stable mature phenotypes for more than 8 wk.

Similar results have been obtained by other groups^[5,6]; however in all the above reported investigations liver ECM was produced from rodent livers. Instead, Barakat *et al.*^[7] recently developed a method to decellularize porcine livers, which were eventually repopulated with human cells^[8,9]. The goal was to produce a clinically relevant model of liver bioengineering. Livers from Yorkshire pigs were decellularized with SDS. The ECM of the posterior segment of the right liver lobe was used as scaffold for cell seeding. Fetal hepatocytes co-cultured with fetal stellate cells were expanded, collected, resuspended in appropriate medium supplemented with hepatocyte growth factor and seeded

Figure 2 Movat-Pentachrome staining of acellular liver sections shows yellow staining for collagen and dark staining for elastin surrounding the vascular structures.

within the ECM. The so-obtained constructs were perfused for 3 d, 7 d and 13 d. During perfusion, pH, PO₂, PCO₂, lactate, glucose, urea nitrogen and albumin were measured to assess metabolic and synthetic functions. Of note, some constructs were implanted *in vivo* and perfused for 2 h to determine the behavior of the matrix *in vivo* and its ability to withstand the shear stress produce by the blood flow in physiologic conditions. Results were encouraging. Liver organoids showed active metabolism and preserved capability to synthesize albumin, and were able to sustain blood pressure without harm. Notably, immunohistochemical analysis revealed cell differentiation into mature hepatocytes. This latter finding provides evidence that ECM is essential in that it supports cells and may drive the differentiation of progenitor cells into an organ-specific phenotype^[10]. Badyalak's group confirmed this information in an elegant model of liver hepatectomy in rats^[11], in which he demonstrated that liver ECM implanted in intact and amputated livers enhances hepatocyte proliferation and ultimately liver regeneration.

While the primary goal for the majority of the research pertaining to decellularizing and recellularizing an organ is the functional transplantation of a bioengineered organ into a recipient host, there are the possibilities of using this technology in *in vitro* studies for advanced preclinical drug development^[12]. This report provided a 60-min rapid natural decellularization method for a 3-dimensional scaffold prepared from a rat liver that maintained the microvascular system and was able to withstand fluid flowing through all three hepatic circular systems. The method utilized two thirty-minute perfusion periods; a 1% Triton-X 100 solution followed by a 1% SDS solution. The development of a novel *in vitro* 3-dimensional model that closely represents the *in vivo* liver could present the potential for toxicity testing of key compounds in preclinical drug developments since the liver is the main metabolizing organ that is usually the target of toxicity.

CELLS FOR LIVER REGENERATION

The liver is able to regenerate itself with the ability to

maintain adequate volume and function after undergoing up to 70% resection. However, the way the liver regenerates after a more or less extended amputation is not a true recapitulation of liver ontogenesis. In fact, resumption of the original volume is accomplished by cellular hyperplasia of the remaining liver rather than true regeneration of the amputated portion whose original anatomy will not be resumed^[13]. Therefore, from an evolutionary perspective, liver hyperplasia is a mechanism of repair that has developed to restore normal function, not normal anatomy. Unfortunately, the actual system that regulates the hepatic regeneration after injury remains mostly obscure. When the liver regenerates after amputation, cellular hyperplasia occurs spontaneously through a complex cascade of events and pathways. This cascade of regulation involves the inflammatory signaling, the recruitment of inflammatory cells, the stimulation of hepatobiliary cell proliferation, and the ultimate aim of cell migration and neo-angiogenesis. The restoration of the tissue mass is thus carried out by the division of mature hepatocytes. If the mature hepatocytes are unable to maintain sufficient proliferative potential to restore the organ, or if there is complete inhibition of this process, intervention occurs from the liver progenitor cells, known as oval cells^[14-18].

There are many techniques that address regenerating the liver, without actually fully regenerating and replacing the organ, by attempting to enhance the natural regeneration of the injured liver. The basic idea behind this technique is to enhance the liver's natural ability to regenerate itself through the transplantation and mobilization of liver progenitor cells that are isolated from bone marrow. The studies that address this technique base the idea off the fact that it has been found that the cells resident to the bone marrow are able to aid in liver regeneration by differentiating into fully functional hepatocytes^[19-22]. While these studies have yet to fully characterize these cells, it has been clearly established that there are bone marrow populations that could have the ability to increase the quality of the clinical conditions regarding patients that have chronic liver disease or injury. In these clinical trials the initial goal was to determine whether or not the infusion of autologous bone marrow cells, through perfusion of the peripheral vein or the hepatic artery, into patients who have liver cirrhosis, was safe. Some of these studies were able to achieve more than just safety results, and showed that there was statistically significant clinical improvement in the patients^[23-25].

More recent studies have attempted to determine the clinical safety of administering patients with the hematopoietic stem cell mobilizing cytokine, granulocyte colony stimulating factor (G-CSF), which has been shown to improve the functioning of the liver in patients with liver disease. It is thought that the function of the G-CSF is to primarily activate cells that are within the bone marrow that have hepatocyte lineage differentiation potential. G-CSF not only interacts with the bone marrow cells, but it has also been shown to increase the ability of resident progenitor cells that have the receptor for the cytokine to respond to injuries. In these studies it has been deter-

mined that the G-CSF is able to maintain the ability to mobilize cells from the bone marrow and the peripheral circulation, while there is an increase in the circulating hepatocyte growth factor that plays a major role in liver regeneration^[26-29]. The bone marrow and peripheral blood are great sources for this because they are easily accessible while having a large source of stem cells and progenitor cells that are able to proliferate *in vitro*. Since these studies primarily aimed to focus on the safety potential for administering the cytokine, there have been two large studies that have been conducted in order to actually determine the therapeutic treatment potential of this technique. These trials were performed by administering G-CSF to the patient with liver disease, which was then followed by the isolation of stem cells from both the peripheral circulation and the bone marrow. These isolated cells were then infused back into the patient through the already established perfusion methods. The trials clearly showed significant improvement in the serum bilirubin and the liver enzyme levels, while there was no improvement noticed in the untreated control group^[30,31].

As previously mentioned, despite the clearly seen therapeutic potential for bone marrow cells to help the regenerative process of a diseased liver, the findings from these trials have yet to be able to determine the specific cell in the bone marrow that is actually aiding in the regeneration. There have been a few *in vivo* animal models that have demonstrated the ability for bone marrow derived mesenchymal stem cells and hematopoietic stem cells (CD34⁺/Lin) to have ability to differentiate into hepatocytes^[32-36]. Fetal liver progenitor cells have also been shown to improve the condition of cirrhotic patients^[37,38]. Therefore, the use of these cells with the previously described isolation and infusion techniques presents multiple advantages for creating a potential therapy. This presents the possibility of having an easily obtainable source of cells that are from the isolated G-CSF mobilized bone marrow cells. The concern of the patient having a rejection to the treatment would be absent because all of the cells used in the therapy are autologous. A portion of these cells used could also possibly carry a progenitor phenotype following infusion, which could help participate in the liver repopulation over time when the damage to the native hepatocyte population is chronic. The corrective gene could therefore be slowly increased in the native cells with as little as a repopulation of 10% of the cells expressing the factor^[39].

Other cell sources are also available, namely fetal hepatoblasts and stem cells from adult or fetal tissue. As reported above, Baptista *et al.*^[3] used fetal liver hepatoblasts to recellularize liver ECM scaffolds. Once in this three-dimensional environment, these liver progenitors were able to expand and differentiate into biliary and hepatocytic lineages. In the fetal liver, these cells are the main parenchymal cell type and are identified by their expression of α -fetoprotein (AFP). These cells are rare in the normal adult liver, except in livers with severe injury or disease^[40,41]. Because these cells are able to originate the

two hepatic cell lineages, hepatocytes and cholangiocytes, they are named bipotential progenitors.

AFP-negative hepatic stem cells are the precursors to hepatoblasts that can mature into AFP-positive hepatoblasts^[42-44]. Human fetal hepatoblasts are then the putative transient amplifying progenitors in the liver lineage and can be cultured long-term and clonally, contributing to liver parenchyma when transplanted into SCID mice^[45]. Hepatoblasts express biliary and hepatocyte markers such as CK19, CK14, α -GT, glucose-6-phosphatase, glycogen, albumin, AFP, E-cadherin^[46], α -1 microglobulin, Hep-Par1, glutamate dehydrogenase, and DPP-IV^[42,47]. These progenitors do not express mesenchymal or hematopoietic markers like CD90, vimentin, and CD34^[46]. The therapeutic potential and safety of these cells has already been successfully tested in human patients with end-stage chronic liver disease^[48]. In these patients, there was significant clinical improvement in terms of biochemical and overall clinical parameters. Moreover, mean MELD score decreased ($P < 0.01$) over the following 6 mo after stem cell therapy. Thus, fetal derived stem/progenitor cells have the potential to provide supportive therapy to organ transplantation in the management of end-stage liver diseases^[18,48-54].

This notwithstanding, it is the authors' conviction that cell transplantation alone may not be appropriate. In fact, clinical transplantation provides incontrovertible evidence that the outcome of cell transplantation is very poor when compared to whole organ transplantation. Therefore, it cannot be proposed as an alternative to whole organ transplantation, rather it should be considered still an experimental treatment, as it has been proposed by Cravedi's^[55] in the case of islet transplantation and by from a regenerative medicine perspective, the poor outcome may be attributed to the fact that cells welfare is dramatically impaired when cells are extrapolated by their natural niche—namely the ECM—despite encapsulation. Therefore, research should direct efforts to bioengineer a suitable supporting scaffold, which would recapitulate the same characteristics of the natural environment.

Interestingly, some authors have proposed a different bioengineering method, which does not require any supporting scaffolds. However, cells are not manipulated alone but are grown in order to produce cell sheets. Hara-guchi's group^[56] employs temperature-responsive culture surfaces onto which poly (N-isopropylacrylamide) is covalently immobilized to control cell adhesion/detachment with simple temperature change. Cells adhere, spread, and proliferate on temperature-responsive surfaces at 37 °C, which is the normal temperature for mammalian cell culture. By reducing temperature below 32 °C, cells spontaneously detach from the surfaces without requiring proteolytic enzyme such as trypsin, since the grafted polymer becomes hydrophilic. When temperature is reduced after cells reach confluency, all the cells are harvested as a single contiguous cell sheet. The advantage of this method is that, as trypsin is not used, all cell membrane proteins including growth factor receptors, ion

channels, and cell-to-cell junction proteins are intact after the harvest. Furthermore, the ECM deposited during cell culture is retained under cell sheets, and therefore, cell sheets easily integrate to transplanted sites. In a murine model, sheets of hepatic tissue transplanted into the subcutaneous space resulted in efficient engraftment to the surrounding cells, with the formation of two-dimensional hepatic tissues that stably persisted for more than 6 mo, while showing several liver-specific functions^[57].

FUTURE PERSPECTIVES

The need for improved treatment modalities for patients with diseased or absent tissues or organs is evident. Regenerative medicine holds the promise of regenerating tissues and organs by either stimulating previously irreparable tissues to heal themselves, or manufacturing them *ex vivo*^[58-64]. In the first scenario, cells with regenerative potential are targeted to the diseased bodily district. Given the multitude of available sources of these cells, it is still a mystery as to which are the most appropriate and best cell sources. Although this may vary depending on the tissue or organ of interest, it is important to fully understand the biological mechanisms controlling differentiation along a specific lineage of all cell types. Ideally, it is desirable to have the ability to harvest autologous cells and employ them with minimal *ex vivo* manipulation. Ultimately, the goal is to identify cells that can be easily harvested and differentiated consistently along the lineage of interest. At the same time, research should aim to in-depth understanding of all environmental stimuli that are required by liver SC niches to be activated and allow hepatocyte and/or biliary cell regeneration aiming to compensate tissue loss.

In the second scenario, differentiated, adult liver cells or SC are seeded on supporting scaffolds and allowed to mature in custom-made bioreactors. Human or animal-derived whole tissue ECM scaffolds are preferred, compared to artificial homogeneous materials, because they preserve an intact vascular network that will allow regeneration of the vascular system for optimal delivery of nutrients and oxygen. The utilization of autologous cells holds the theoretical potential to rule out immunological breakdowns and concerns, and limits the response of the immune system to a non-harmful inflammatory reaction.

In both cases, there are clearly a lot of gray areas that need to be colored in^[58,59,63,65-69]. There has been a greater understanding of the cell types and numbers of cells used for repopulation, but it is still lacking the perfected elements to produce optimal results. Even when this is fully understood and developed, there also needs to be an established standard or test on the bioengineered organ that would reveal the successful incorporation of all the necessary items that the organ requires in order to be fully functional *in vivo*. The actual functionality of the cells within the decellularized matrix and of the organoid as a whole, as well as the biocompatibility of the so-obtained construct, absolutely must be confirmed before

transplantation can ever be a feasible option. Importantly, it will be crucial to understand the mechanisms through which cells interact with the environment and in particular how the liver ECM drives and regulates cell fate and which additional molecules (namely growth factors) are essential to achieve this goal.

Abstract

AIM: To investigate the suppressive activity of MUTYH variant proteins against mutations caused by oxidative lesion, 8-hydroxyguanine (8OHG), in human cells.

METHODS: p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variants, which were previously found in patients with colorectal polyposis and cancer, were selected for use in this study. Human H1299 cancer cell lines inducibly expressing wild-type (WT) MUTYH (type 2) or one of the 4 above-mentioned MUTYH variants were established using the piggyBac transposon vector system, enabling the genomic integration of the trans-

poson sequence for MUTYH expression. MUTYH expression was examined after cumate induction using Western blotting analysis and immunofluorescence analysis. The intracellular localization of MUTYH variants tagged with FLAG was also immunofluorescently examined. Next, the mutation frequency in the *supF* of the shuttle plasmid pMY189 containing a single 8OHG residue at position 159 of the *supF* was compared between empty vector cells and cells expressing WT MUTYH or one of the 4 MUTYH variants using a *supF* forward mutation assay.

RESULTS: The successful establishment of human cell lines inducibly expressing WT MUTYH or one of the 4 MUTYH variants was concluded based on the detection of MUTYH expression in these cell lines after treatment with cumate. All of the MUTYH variants and WT MUTYH were localized in the nucleus, and nuclear localization was also observed for FLAG-tagged MUTYH. The mutation frequency of *supF* was 2.2×10^{-2} in the 8OHG-containing pMY189 plasmid and 2.5×10^{-4} in WT pMY189 in empty vector cells, which was an 86-fold increase with the introduction of 8OHG. The mutation frequency (4.7×10^{-3}) of *supF* in the 8OHG-containing pMY189 plasmid in cells overexpressing WT MUTYH was significantly lower than in the empty vector cells ($P < 0.01$). However, the mutation frequencies of the *supF* in the 8OHG-containing pMY189 plasmid in cells overexpressing the p.R154H, p.M255V, p.L360P, or p.P377L MUTYH variant were 1.84×10^{-2} , 1.55×10^{-2} , 1.91×10^{-2} , and 1.96×10^{-2} , respectively, meaning that no significant difference was observed in the mutation frequency between the empty vector cells and cells overexpressing MUTYH mutants.

CONCLUSION: The suppressive activities of p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variants against mutations caused by 8OHG are thought to be severely impaired in human cells.

INTRODUCTION

8-hydroxyguanine (8OHG) is an oxidatively damaged form of guanine^[1], and because 8OHG can pair with adenine as well as cytosine, the formation of 8OHG in DNA causes a G:C to T:A transversion mutation^[2]. To prevent such mutations, excision repair proteins, such as MUTYH (OMIM 604933), that act on 8OHG are present in human cells. The MUTYH protein is a DNA glycosylase that catalyzes the removal of adenine that is mispaired with 8OHG in double-stranded DNA^[3-7]. Two major MUTYH proteins, type 1 and type 2, are expressed in human cells as a result of multiple transcription initiation sites and the alternative splicing of mRNA transcripts^[4,7]. Because the type 1 protein contains a mitochondrial targeting signal (MTS) in its N-terminal, it is localized in the mitochondria. In contrast, the type 2 protein lacks the N-terminal 14 amino acids of type 1, and this absence leads to the destruction of the MTS; consequently, the type 2 protein is localized in the nucleus^[4,7].

Biallelic germline mutations in the *MUTYH* gene are responsible for MUTYH-associated polyposis (MAP) (OMIM 608456), which is a hereditary disease characterized by multiple colorectal adenomas and carcinomas^[8-12]. Most biallelic *MUTYH* carriers have between 10 and a few hundred colorectal polyps, meaning that MAP shows a phenotypic overlap with two other hereditary colorectal polyposis syndromes: familial adenomatous polyposis (FAP: OMIM 175100) and attenuated FAP (AFAP: OMIM 175100), both of which are caused by inactivation of the *APC* gene (OMIM 611731)^[13,14]. Therefore, screening for germline mutations in *MUTYH* and *APC* is important in candidate patients with multiple colorectal polyps. However, even when *MUTYH* gene variations are detected in the mutation screening, if information regarding the level of the repair activities of the MUTYH variants is lacking, a correct diagnosis of MAP is impossible to make. Thus far, 300 unique DNA variants of the

MUTYH gene have been reported in the Leiden Open Variation Database (http://www.lovd.nl/2.0/index_list.php)^[15], and the proportion of missense *MUTYH* variations in the database is larger than nonsense mutations or truncating mutations. For most of the genes, a functional analysis is needed to determine whether the activity of a protein encoded by a missense variant is severely reduced. Thus, the effect of *MUTYH* variations on repair activity should be examined; however, so far, only a small number of *MUTYH* variations has been investigated^[16-27]. In most of these studies, the DNA glycosylase activities of the variant recombinant proteins were analyzed using a DNA cleavage assay to test the abilities of the variants to cleave double-stranded oligonucleotides containing an A:8OHG mispair *in vitro*^[18,19,21,23-27]. However, because examining the repair activity of MUTYH variant proteins from multiple aspects would lead to a more definitive judgment of the pathogenicity of MUTYH variants and MUTYH has the ability to regulate the mutation frequency in human cells *in vivo*^[28-30], evaluating the mutation frequency in human cells is also valuable. However, at present, the activities of MUTYH variants in the regulation of mutation suppression in human cells *in vivo* have not been previously reported. Therefore, in this paper, we evaluated the suppressive activities of MUTYH variant proteins against oxidative mutagenesis in human cells. We recently determined the DNA glycosylase activities of 14 type 2 (nuclear form) MUTYH variants using a DNA cleavage assay^[27], and based on those results, p.R154H, p.M255V, p.L360P, and p.P377L type 2 proteins were chosen from the tested variants, and their abilities to suppress mutations caused by 8OHG in human cells were analyzed in this study. As far as we know, this is the first report to analyze the suppressive activities of MUTYH variants against oxidative mutagenesis in human cells.

The Human Genome Variation Society (<http://www.hgvs.org/>) recommends using the transcript variant $\alpha 5$ (NM_001128425.1), which encodes the longest isoform (549 amino acids), as a reference sequence. Therefore, the type 2 proteins p.R154H, p.M255V, p.L360P, and p.P377L used in this study correspond to the reference proteins p.R182H, p.M283V, p.L388P, and p.P405L, respectively.

MATERIALS AND METHODS

Cell line

The human cancer cell line H1299 was obtained from the American Type Culture Collection (Manassas, VA). Cells were maintained at 37 °C in RPMI1640 medium supplemented with 10% fetal bovine serum and penicillin/streptomycin under a 5% CO₂ atmosphere. The study design was approved by an institutional review board.

Construction of expression plasmid

Human wild-type (WT) and variant (p.R154H, p.M255V, p.L360P, and p.P377L) MUTYH type 2 cDNAs were polymerase chain reaction-amplified with *PfuUltra* Hot-

start DNA polymerase (Stratagene, La Jolla, CA) and the MUTYH-type 2/pET25b(+) expression vector^[27] as a template; the amplified sequence was then inserted into a piggyBac cumate switch inducible vector (System Biosciences, Mountain View, CA) at the *NheI* and *NotI* restriction enzyme sites. A WT MUTYH type 2 expression vector with a C-terminal FLAG tag was previously constructed using the pcDNA3.1 expression vector (Invitrogen, Carlsbad, CA)^[31]; in this study, the variants were generated using site-directed mutagenesis with a QuikChange Site-directed Mutagenesis kit (Stratagene). All of the vectors were confirmed using DNA sequencing with a BigDye Terminator Cycle Sequencing Reaction Kit (Applied Biosystems, Tokyo, Japan) and an ABI 3100 Genetic Analyzer (Applied Biosystems).

Transfection

A plasmid vector was transfected into H1299 cells using Lipofectamine 2000 reagent (Invitrogen) according to the supplier's recommendations.

Establishment of stable inducible cell lines

H1299 cells were transfected with the cumate switch inducible vector for MUTYH expression together with the piggyBac transposase vector (System Biosciences). To establish stable inducible cell lines, positively transposed cells were selected using puromycin (1 µg/mL). Because the inducible piggyBac vector features a tight cumate switch combined with the EF1-CymR repressor-T2A-Puro cassette to establish stable cell lines, the addition of cumate solution (System Biosciences) to the puromycin-selected cells led to the induction of MUTYH expression.

Western blotting analysis

Cells were harvested in lysis buffer containing 50 mmol/L HEPES (pH 7.5), 150 mmol/L NaCl, 0.1% sodium dodecyl sulfate (SDS), 1.0% Triton X-100, 0.5% sodium deoxycholate, 100 mmol/L sodium fluoride, 1 mmol/L sodium orthovanadate, and a protease inhibitor cocktail (Sigma-Aldrich, St. Louis, MO), and the whole-cell extracts were mixed with an equal volume of 2 × SDS sample buffer and boiled. The extract was then subjected to SDS-polyacrylamide gel electrophoresis, and the proteins obtained were electrophoretically transferred to a polyvinylidene fluoride membrane (GE Healthcare Bio-Science, Piscataway, NJ). The membrane was blocked with nonfat milk at room temperature (RT) for 1 h and incubated with an anti-MUTYH monoclonal antibody (clone 4D10; Abnova, Taipei, Taiwan) or an anti-β-tubulin monoclonal antibody (clone 2-28-33; Sigma-Aldrich) at RT for 1 h. After washing with PBS containing 0.05% Tween-20 (PBS-T), the membrane was incubated with an anti-mouse HRP-conjugated secondary antibody (GE Healthcare Bio-Science) at RT for 1 h. The membrane was then washed with PBS-T, and immunoreactivity was visualized using an ECL chemiluminescence system (GE Healthcare Bio-Science).

Indirect immunofluorescence analysis

Cells were fixed with 10% formalin at RT or 4% paraformaldehyde at 4 °C. The cells were permeabilized with 1% Nonidet P-40 in PBS for 5 min and incubated with 10% normal goat serum blocking solution (DAKO, Kyoto, Japan) for 30 min. The cells were then probed with mouse anti-MUTYH monoclonal antibody (4D10) or mouse anti-FLAG M2 monoclonal antibody (Sigma-Aldrich) at RT for 1 h. Indirect immunofluorescence labeling was performed by incubation with an Alexa Fluor 594-conjugated secondary antibody (Molecular Probes, Eugene, OR) at RT for 1 h, and the nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI) (Sigma-Aldrich). The immunostained cells were examined under a fluorescence microscope (Olympus BX-51-FL; Olympus, Tokyo, Japan) equipped with epifluorescence filters and a photometric CCD camera (Sensicam; PCO Company, Kelheim, Germany). The captured images were digitized and stored using an image analysis program (MetaMorph; Molecular Devices, Palo Alto, CA).

Shuttle vector plasmid and an indicator bacterial strain

The plasmid pMY189 and the indicator *Escherichia coli* (*E. coli*) strain KS40/pKY241 were used for the *supF* forward mutation assay, as reported previously^[30,32]. pMY189 is a shuttle vector containing the bacterial suppressor tRNA (*supF*) gene. KS40 is a nalidixic acid-resistant (*gyrA*) derivative of MBM7070 with genotype *lacZ* (*am*), *CA7070*, *lacY1*, *hsdR*, *hsdM*, Δ (*araABC-len*)7679, *galU*, *galK*, *rpsL*, *thi*. The pKY241 plasmid contains a chloramphenicol resistance marker and the *gyrA* (amber) gene. *E. coli* KS40/pKY241 cells carrying the active *supF* gene are sensitive to nalidixic acid and form blue colonies on LB plates containing ampicillin, chloramphenicol, isopropyl-β-D-thiogalactopyranoside (IPTG), and 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-gal), whereas cells carrying the mutated *supF* gene form white colonies on plates containing nalidixic acid, ampicillin, chloramphenicol, IPTG, and X-gal.

Construction of a shuttle vector plasmid containing an 8OHG residue

pMY189-8OHG, which is the shuttle plasmid pMY189 containing a single 8OHG:cytosine pair at nucleotide position 159 of the *supF* gene, was prepared according to a previously described method^[30]. Briefly, *E. coli* XL1-Blue MRF⁺ (Stratagene) and R408 Helper Phage (Stratagene) were used to prepare single-stranded pMY189 DNA, and 30 µg of the single-stranded pMY189 plasmid and a 5-fold molar excess of a 5'-phosphorylated 24-mer oligonucleotide with a single 8OHG at nucleotide position 159 of the *supF* gene [5'-CGA CTT CGA A (8OHG) G TTC GAA TCC TTC-3'] were annealed in a reaction mixture. Forty units of T4 DNA polymerase (New England Biolabs, Beverly, MA), 600 µmol/L of deoxynucleotide triphosphate (GE Healthcare Bio-Science), 36 Weiss units of T4 DNA ligase (New England Biolabs) and 1 mmol/L of ATP (Nacalai Tesque, Kyoto, Japan) were added to the

reaction mixture, and the mixture was incubated at 37 °C for 4 h. Closed circular pMY189-8OHG was isolated using cesium chloride-ethidium bromide density gradient centrifugation.

SupF forward mutation assay

Cells were cultured in the presence of cumate for 3 d for the induction of MUTYH expression, and they were then transfected with the shuttle plasmid pMY189 or pMY189-8OHG. After 48 h, the propagated plasmids were extracted from the cells using a QIAprep Spin Miniprep Kit (Qiagen, Valencia, CA) and digested with *DpnI* restriction enzyme (New England Biolabs) to eliminate unreplicated plasmids with the bacterial methylation pattern. After purification with Amicon Ultra Centrifugal Filter Units (Millipore, Bedford, MA), the plasmids were introduced into the KS40/pKY241 indicator *E. coli* strain using electroporation. The transformants were plated onto LB agar plates containing 50 µg/mL of nalidixic acid, 150 µg/mL of ampicillin, and 30 µg/mL of chloramphenicol together with IPTG and X-gal. White colonies on were counted as *supF* mutants. The mutation frequencies were calculated as the number of *supF* mutants per the total number of transformants, which were counted on LB plates containing ampicillin, chloramphenicol, IPTG and X-gal.

Statistical analysis

The statistical analysis was performed using an unpaired *t*-test and JMP software, version 9 (SAS Institute, Cary, NC). *P*-values less than 0.05 were considered statistically significant.

RESULTS

Establishment of human cells inducibly expressing MUTYH variants

To investigate the ability of MUTYH variants to suppress mutations caused by 8OHG in human cells, we used the piggyBac transposon vector system^[33] to establish human cells capable of inducibly expressing MUTYH variants and performed a *supF* forward mutation assay using the shuttle plasmid pMY189, which contains a single 8OHG in the *supF* gene. First, H1299 human cancer cells were transfected with a piggyBac cumate switch inducible vector for the expression of WT, p.R154H, p.M255V, p.L360P, or p.P377L MUTYH together with the piggyBac transposase vector; positively transposed cells were then selected with puromycin. We also transfected cells with an empty (parental) piggyBac cumate switch inducible vector and transposase vector. The expression of MUTYH protein after cumate induction was examined using Western blotting analysis using an anti-MUTYH monoclonal antibody (Figure 1A). MUTYH protein was abundantly expressed in cells in which a WT, p.R154H, p.M255V, p.L360P, or p.P377L MUTYH expression vector but not an empty vector was transposed. Immunofluorescence analysis also showed abundant MUTYH pro-

tein expression in cells in which a WT, p.R154H, p.M255V, p.L360P, or p.P377L MUTYH expression vector but not an empty vector was transposed (Figure 1B). In accordance with the previous finding that the MUTYH type 2 protein is the nuclear form^[4,7], WT MUTYH protein was localized in the nucleus. All of the MUTYH variants were also localized in the nucleus, suggesting that the amino acid changes in p.R154H, p.M255V, p.L360P, and p.P377L did not alter the subcellular localization of these proteins in human cells. With regard to endogenous MUTYH expression, low levels were detected in the immunofluorescence analysis, as shown in the panel of empty vector-transposed cells (Figure 1B). When the intensity of the MUTYH protein signal was enhanced with image-editing software, the signal was observed in both the nucleus and cytoplasm (Figure 1C), which is compatible with the existence of both the type 1 mitochondrial form and the type 2 nuclear form^[4,7]. Next, to confirm the nuclear localization of MUTYH type 2 variant forms, we constructed a vector to express MUTYH tagged with a FLAG peptide at the C-terminus and examined the localization of the MUTYH variants using immunofluorescence analysis with an anti-FLAG antibody (Figure 2). All of the variants showed nuclear localization, further suggesting that the amino acid changes in p.R154H, p.M255V, p.L360P, and p.P377L did not alter their subcellular localization in human cells. Together, the above findings indicate that human cells inducibly expressing the MUTYH variants (p.R154H, p.M255V, p.L360P, or p.P377L) and their control cells were properly prepared and were appropriate for evaluating the suppressive activities of MUTYH variants against oxidative mutagenesis in human cells.

Impaired activities of MUTYH variants in the suppression of oxidative mutagenesis in human cells in vivo

Next, mutation frequencies were compared for the empty vector-transposed human cells and the cumate-inducible stable cells expressing WT or variant MUTYH using a *supF* forward mutation assay with the shuttle plasmid pMY189. In this assay, we introduced a single 8OHG residue at position 159 of the *supF* gene in pMY189. The mutation frequency of *supF* was 2.2×10^{-2} in the 8OHG-containing pMY189 plasmid and 2.5×10^{-4} in WT pMY189 in empty vector-transposed cells (Figure 3), which was an 86-fold increase in mutation frequency with the introduction of 8OHG. The mutation frequency (4.7×10^{-3}) of *supF* in the 8OHG-containing pMY189 plasmid in cells overexpressing WT MUTYH was significantly lower than in the empty vector-transposed cells. However, the mutation frequencies of *supF* in the 8OHG-containing pMY189 plasmid in cells overexpressing the p.R154H, p.M255V, p.L360P, or p.P377L MUTYH variant were 1.84×10^{-2} , 1.55×10^{-2} , 1.91×10^{-2} , and 1.96×10^{-2} , respectively, meaning that no significant difference was observed in the mutation frequency between the empty vector-transposed cells and the cells overexpressing MUTYH variants. These results suggested that the suppressive activities of p.R154H, p.M255V, p.L360P,

Figure 1 Establishment of H1299 human cell lines inducibly expressing MUTYH variant proteins. A: Detection of MUTYH proteins in cumate-inducible stable cell lines expressing MUTYH in the presence of cumate using Western blotting analysis with an anti-MUTYH antibody. Lysates from empty vector-transposed cells and cells inducibly expressing wild-type (WT) MUTYH or p.R154H, p.M255V, p.L360P, or p.P377L MUTYH variants were analyzed. β-tubulin protein was also analyzed as an internal control; B: Immunofluorescence detection of MUTYH proteins expressed in the cell lines used in (A) in the presence of cumate. The MUTYH protein (red) was stained with anti-MUTYH as the primary antibody and Alexa Fluor 594-conjugated goat anti-mouse IgG as the secondary antibody. The nuclei were counterstained with 4',6-diamidino-2-phenylindole (DAPI) (blue); C: Immunofluorescence detection of endogenous MUTYH proteins in the empty vector-transposed cells as described in (B). The intensity of the signals of MUTYH protein (red) was enhanced with image-editing software to determine the subcellular localization of endogenous MUTYH protein. The nuclei were counterstained with DAPI (blue).

and p.P377L MUTYH variants against mutations caused by 8OHG were severely impaired in human cells.

DISCUSSION

In this study, human cell lines inducibly expressing MUTYH variants (p.R154H, p.M255V, p.L360P, or p.P377L) were established, and the abilities of these cells to suppress mutations caused by 8OHG were compared using a *supF* forward mutation assay with a shuttle vector containing an 8OHG residue in the *supF* gene. The assay showed that the suppressive activities of p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variants against mutations caused by 8OHG were severely impaired in human cells. To the best of our knowledge, this is the first analysis of the suppressive activities of MUTYH variants against oxi-

dative mutagenesis in human cells *in vivo*.

The type 2 protein is the nuclear form of MUTYH^[4,7], and somatic *APC* and *KRAS* (OMIM 190070) mutations occur in the nuclear DNA of MAP tumors^[8,9,12]; therefore, we believed that it would be more appropriate to investigate type 2 rather than type 1 and we established cell lines expressing the type 2 form in this study. In the *supF* forward mutation assay using a shuttle vector containing 8OHG, no significant difference was observed in the mutation frequencies between empty vector-transposed cells and cells expressing 1 of the 4 MUTYH variants, indicating the severe impairment of the suppressive activities of the MUTYH variants against mutations caused by 8OHG in human cells *in vivo*. We previously showed that the adenine DNA glycosylase activity of the p.M255V protein was 10.7% of the level of the WT protein and that the DNA

Figure 2 Nuclear localization of MUTYH variant proteins (p.R154H, p.M255V, p.L360P, and p.P377L). H1299 cells were transiently transfected with a vector expressing various types of MUTYH proteins tagged with FLAG, and MUTYH-FLAG protein (red) was stained with anti-FLAG M2 as the primary antibody and Alexa Fluor 594-conjugated goat anti-mouse IgG as the secondary antibody. The nuclei were counterstained with 4',6-diamidino-2-phenylindole (DAPI) (blue). WT: Wild-type.

Figure 3 Measurement of the mutation frequency of the *supF* gene in the pMY189 plasmid using a *supF* forward mutation assay in H1299 human cell lines inducibly expressing MUTYH variant proteins. Empty vector-transfected cells and cells inducibly expressing wild-type (WT) MUTYH or p.R154H, p.M255V, p.L360P, or p.P377L MUTYH variants in the presence of cumate were transfected with a pMY189 shuttle plasmid, and the mutation frequency of *supF* in these human cell lines was measured. "8-hydroxyguanine (8OHG)" indicates a pMY189 plasmid containing an 8OHG residue at position 159 of *supF*, while "G" indicates a pMY189 plasmid containing the WT *supF* gene. The data are shown as the means \pm SE.

glycosylase activities of the p.R154H, p.L360P, and p.P377L proteins were severely impaired^[27]. Thus, the results regarding the regulation of the mutation frequency in the present study are in agreement with DNA glycosylase activity in the previous study. A combination of the results of two distinct analyses, i.e., *in vitro* and *in vivo* analyses, would provide more definitive proof of the pathogenicity of the p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variants. Because the diagnosis of MAP depends on whether

(1) the clinical phenotypic characteristics of MAP are present in a candidate patient; and (2) the repair activities of the MUTYH variants encoded in the two *MUTYH* alleles of the patient are decreased, even when gene variations are found in the patient by *MUTYH* mutation screening, information on the levels of the repair activities of MUTYH variants is indispensable for properly diagnosing MAP. Regarding this point, our results are clinically useful.

Previous studies have provided contradictory results regarding the subcellular localization of MUTYH protein in MAP patients; one paper insisted that MUTYH protein was predominantly localized in the cytoplasm of colorectal tumor cells in MAP patients but not in non-MAP patients, while the other papers denied this localization^[34,35]. In the present study, the nuclear localization of the p.R154H, p.M255V, p.L360P, and p.P377L MUTYH type 2 variants was shown using two distinct experiments. Therefore, it seems that the amino acid changes of p.R154H, p.M255V, p.L360P, and p.P377L did not alter the subcellular localization of the MUTYH protein. Similarly, Molatore *et al.*^[26] recently reported that 3 missense MUTYH variants other than our variants were all localized in the nucleus.

In this paper, we successfully established cumate-inducible stable human cell lines by utilizing the piggyBac transposon vector system. Transposon technology is an attractive non-viral gene delivery model that allows for efficient genomic integration in a variety of cell types^[36]. Among the several transposon systems available, the piggyBac transposon, which was isolated from the genome of the cabbage looper moth (*Trichoplusia ni*), has been optimized for gene transfer into mammalian cells^[36,37]. In practice, the MUTYH expression status in our cell lines after puromycin selection in the presence of cumate clearly demonstrated abundant MUTYH expression in almost all of the cells. Because we performed transient transfection with a shuttle plasmid in the *supF* forward

mutation assay in this study, the genomic integration of the sequence for MUTYH expression using the piggyBac transposon system was well suited to our experiment.

In our experiments, the level of expression of exogenously introduced MUTYH was much higher than the level of expression of endogenous MUTYH. This scenario allowed us to effectively evaluate the activities of MUTYH variants to regulate the mutation frequency, and we believe that such an evaluation was successfully performed. However, we cannot completely exclude the possibility that the functional difference observed under experimental conditions of high MUTYH expression levels does not reflect a true functional difference.

The impaired activity of MUTYH variants was shown using H1299 human lung cancer cells in this study. We used this cell line because we believed that the ability of MUTYH variants to suppress mutations in H1299 cells is not different from their ability in human cells derived from the colorectum. If there are no organ type-specific systems to modulate MUTYH activity, then MUTYH activity is dependent on the MUTYH expression level and MUTYH variation. Moreover, we studied overexpressed and exogenous MUTYH variant proteins in this paper. Therefore, we believe our results can most likely be applied for colorectal cells. However, because it might be possible that the difference in organ type has an effect on the results of functional evaluation, we would like to evaluate this activity in human colorectal cells in the future.

Genetic screening for *MUTYH* mutations in the diagnosis of colorectal polyposis continues to be performed worldwide, and technological progress in genome sequencing analysis has contributed to efficient and rapid screening protocols. Therefore, increasing *MUTYH* nucleotide variants are likely to be detected in the future. For appropriate patient management, the levels of the repair activities of MUTYH variant proteins should be evaluated, and our system for determining the abilities of these variants to suppress oxidative mutagenesis in human cells *in vivo* may be of great use for such evaluations.

COMMENTS

Background

The *MUTYH* gene is responsible for MUTYH-associated polyposis (MAP), a relatively recently identified hereditary disease. Although 300 *MUTYH* variants have been found, only a small number of variants has been functionally characterized. Therefore, evaluations of the activities of MUTYH variant proteins are needed for the correct diagnosis of MAP.

Research frontiers

An *in vitro* DNA cleavage assay was performed to evaluate the repair activities of MUTYH variants. Despite the clinical importance of the multiplicity of functional analytical methods for evaluating the activities of MUTYH variant proteins, until now, the ability of MUTYH variants to suppress oxidative mutagenesis in human cells *in vivo* has not been previously analyzed.

Innovations and breakthroughs

Human cumate-inducible stable cell lines expressing various MUTYH variants were established using the piggyBac transposon vector system. This is the first report to utilize human cells expressing MUTYH variants encoded by an ectopically transposed gene. Moreover, this is the first report to analyze the suppressive activities of MUTYH variants against oxidative mutagenesis in human cells.

Applications

The results of the present study suggest that the suppressive activities of p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variant proteins against mutations caused by 8-hydroxyguanine (8OHG) are severely impaired in human cells. These *in vivo* results combined with results from our previous *in vitro* analysis provide definitive proof of the pathogenicity of p.R154H, p.M255V, p.L360P, and p.P377L MUTYH variants. This conclusion is valuable for the appropriate diagnosis of MAP.

Terminology

The base excision repair protein MUTYH is involved in the repair of the oxidative base lesion 8OHG in DNA. Patients with biallelic inactivating germline mutations in the *MUTYH* gene are predisposed to MAP, which is characterized by the development of multiple colorectal adenomas and carcinomas.

Peer review

This is a good study in which authors analyze the suppressive activity of MUTYH variant proteins against mutations caused by 8OHG in human cells. Towards understanding the impact of having so many missense mutations among MAP patients, the authors have steadily developed an infrastructure for serving the patients in the future. Through expression of MUTYH WT and 4 variants, subcellular localization, and mutation frequency counting, they suggested that anti-mutation activity of the four MUTYH variants were severely impaired in human cells.

data of CHB patients treated with clevudine 30 mg/d and compared their clinical outcomes with patients treated with entecavir 0.5 mg/d. The biochemical response, as assessed by serum alanine aminotransferase (ALT) activity, virologic response, as assessed by serum hepatitis B virus DNA (HBV DNA) titer, serologic response, as assessed by hepatitis B e antigen (HBeAg) status, and virologic breakthrough with genotypic mutations were assessed.

RESULTS: Two-hundred and fifty-four patients [clevudine ($n = 118$) vs entecavir ($n = 136$)] were enrolled. In clevudine-treated patients, the cumulative rates of serum ALT normalization were 83.9% at week 48 and 91.5% at week 96 (80.9% and 91.2% in the entecavir group, respectively), the mean titer changes in serum HBV DNA were -6.03 and -6.55 log₁₀ copies/mL (-6.35 and -6.86 log₁₀ copies/mL, respectively, in the entecavir group), and the cumulative non-detection rates of serum HBV DNA were 72.6% and 83.1% (74.4% and 83.8%, respectively, in the entecavir group). These results were similar to those of entecavir-treated patients. The cumulative rates of HBeAg seroconversion were 21.8% at week 48 and 25.0% at week 96 in patients treated with clevudine, which was similar to patients treated with entecavir (22.8% and 27.7%, respectively). The virologic breakthrough in the clevudine group occurred in 9 (7.6%) patients at weeks 48 and 15 (12.7%) patients at week 96, which primarily corresponded to genotypic mutations of rtM204I and/or rtL180M. There was no virologic breakthrough in the entecavir group.

CONCLUSION: In antiviral-naïve CHB patients, long-term treatment outcomes of clevudine were not inferior to those of entecavir, except for virologic breakthrough.

Abstract

AIM: To evaluate the treatment outcomes of clevudine compared with entecavir in antiviral-naïve patients with chronic hepatitis B (CHB).

METHODS: We retrospectively analyzed the clinical

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is a serious health problem worldwide and a major risk factor for the development of liver cirrhosis and hepatocellular carcinoma (HCC), two grave complications that have a high morbidity and mortality^[1,2]. Although the seroprevalence rate of HBV in the South Korean population has gradually decreased since the development of the HBV vaccine in the 1980s, the rate is still high compared to Western countries^[3,4].

Since the first oral antiviral agent against HBV, lamivudine, was introduced in 1997^[5-7], there has been a significant evolution in antiviral fields for patients with chronic hepatitis B (CHB).

Among HBV-targeted oral agents available in Korea, such as lamivudine, adefovir, clevudine, entecavir, and telbivudine, clevudine (CLV) and entecavir (ETV) are now prescribed to a large extent, and they were approved by the South Korean Food and Drug Administration in 2006 and subsequently marketed in Korea as a 1st-line treatment for patients with chronic HBV infection. CLV, which was developed in Korea, is a pyrimidine nucleoside analog with potent antiviral activity against HBV^[8]. CLV therapy for 24 wk showed durable off-treatment virologic suppression and excellent on-treatment virologic response in both hepatitis B e antigen (HBeAg)-positive CHB patients and HBeAg-negative CHB patients^[9,10]. However, CLV-related myopathy was found in a previous global clinical trial, which was controlled due to unfavorable safety profiles despite a tolerable, manageable, and self-limited level of adverse effects.

In contrast, after the clinical establishment of ETV, an analog of the deoxyguanosine nucleoside, as an antiviral agent against HBV, ETV has become the most frequently prescribed drug in clinical fields for the treatment of CHB patients both globally and in Korea, with advantages of potent HBV suppression and low geno-

typic resistance^[11-13].

This study was performed to evaluate the long-term treatment efficacy and safety of CLV in antiviral-naïve patients with chronic HBV infection on the basis of those of ETV as a comparative standard of the present study.

MATERIALS AND METHODS

Study subjects

The study subjects were CHB patients who were treated with CLV or ETV as a 1st-line treatment at six University Hospitals in Daejeon and Chungcheong provinces in Korea between January 2007 and March 2010. CHB was diagnosed either histologically or clinically. The clinical diagnosis of CHB was determined through the presence of hepatitis B surface antigen over at least a 6-mo period, a high titer of serum HBV DNA, and sustained or fluctuating elevations of serum alanine aminotransferase (ALT) activity at the corresponding times. In this study, we enrolled CHB patients with a serum ALT value ≥ 80 IU/L and serum HBV DNA titer $> 100\,000$ copies/mL who had been taking CLV 30 mg or ETV 0.5 mg daily. We followed the global guideline for ALT value, which is 2 times over the normal value. Patients with the following criteria were excluded: age less than 18 years; interferon therapy within 6 mo; HCC diagnosis prior to entrance to this study; alcohol consumption more than 80 g per week; elevated serum ALT value due to other causes, such as drugs, toxins, autoimmune-related or metabolic-related liver diseases, co-infection with hepatitis C virus or human immunodeficiency virus; creatinine clearance less than 50 mL/min; or severe systemic illnesses. During the treatment with antiviral agents, drug compliance was recorded, and patients who did not take the antiviral drug for more than 12 wk were also excluded from the study. The selection of antiviral drug was determined by the patients after they were provided with information on the drugs and their relative merits. The study was conducted in accordance and compliance with ethical guidelines of the 1975 Declaration of Helsinki.

Among the 352 total CHB patients treated with CLV or ETV, we analyzed the clinical data of 254 patients in this study after excluding 67 patients with serum ALT value < 80 IU/L and 31 patients with inadequate follow-up, poor compliance, or insufficient data (Figure 1).

Clinical variables for study evaluation

Clinical baseline characteristics, such as age, gender, history of alcohol consumption, presence of cirrhosis, history of prior antiviral therapy, and other medical history, were retrospectively reviewed and analyzed. Cirrhosis was diagnosed based on histologic evidence through liver biopsy or clinical manifestations of portal hypertension, such as gastroesophageal varices or other collaterals, ascites, encephalopathy, splenomegaly, thrombocytopenia, and radiologic features suggestive of cirrhosis on liver

Figure 1 Flow chart of patient enrollment. ALT: Alanine aminotransferase.

ultrasound or computed tomography.

Serum ALT, creatinine, HBeAg/anti-HBe, and HBV DNA titer were recorded approximately 3-mo interval following CLV or ETV administration, and if the examination times were missed, the latest results within a month were used for analysis.

Serum HBV DNA titers were determined by real-time polymerase chain reaction (PCR) with two types of detection indicators: one model with a minimum detection level of 316 copies/mL (Cobas Amplicor PCR, Roche Molecular Systems, United States) and the other model with a minimum detection level of 70 copies/mL (Cobas Taqman, Roche Diagnostics, United States). Mutant analysis of HBV DNA for detecting genotypic resistance was performed by polymerase chain reaction-restriction fragment length polymorphism or direct sequencing in patients showing virologic breakthrough.

Evaluation of treatment efficacy

We evaluated the biochemical responses, including the median change and cumulative normalization rate of the serum ALT value, the virologic responses, including the decrement degree and cumulative non-detection rate of the serum HBV DNA titer, the serologic responses, including the cumulative rates of HBeAg clearance and HBeAg seroconversion, and the antiviral resistance, including the cumulative rate of virologic breakthrough with genotypic mutation.

Non-detection of HBV DNA was defined as a serum HBV DNA titer less than 316 copies/mL. ALT normalization was defined as a serum ALT value less than 40 IU/L. HBeAg clearance was defined as a loss of HBeAg in a patient who was previously positive for HBeAg, and HBeAg seroconversion was defined as a loss of HBeAg and an acquisition of anti-HBe in a patient who was previously positive for HBeAg and negative for anti-HBe. Virologic breakthrough was defined as an increase in serum HBV DNA titer by $> 1 \log_{10}$ (10-fold) above nadir after achieving a virologic response during continued treatment. Genotypic resistance was defined as the detection of mutations that have been shown *in vitro*

to confer resistance to an antiviral agent. In this study, rtM204V/I and rtL180M were considered CLV-related mutations due to common profiles of genotypic mutation for CLV and lamivudine^[14,15]. We also defined no virologic response as a decrease $< 2 \log_{10}$ copies/mL in serum HBV DNA titer after 24 wk of drug administration.

Evaluation of adverse effects

When the patients experienced constitutional symptoms, such as weakness, fatigue, or muscle pain, during the administration of antiviral agents, the serum creatinine phosphokinase (CK) activity was measured for the detection of clinical myopathy. Clinical myopathy was defined as a presence of the above-mentioned symptoms with a simultaneous elevation of serum CK activity.

Statistical analysis

SPSS software (Windows version 15.0, Chicago, IL, United States) was used for statistical analysis for comparison. Student's *t*-test was applied for consecutive variables, and the χ^2 test or Fisher's verification was applied for categorical variables. Statistical significance was determined when the *P*-value was < 0.05 .

RESULTS

Baseline characteristics of the patients

Of the 254 patients with CHB enrolled in this study, 118 patients (70 men and 48 women) were treated with CLV, and 136 patients (86 men and 50 women) were treated with ETV (Figure 1). The mean age of the patients was 42 ± 11 years. None of the patients were previously treated with any antiviral drugs including interferon. No significant difference was noted in the number of patients with cirrhosis (12.7% in the CLV group *vs* 22.1% in the ETV group, $P = 0.052$), HBeAg positivity (74.6% in the CLV group *vs* 69.1% in the ETV group, $P = 0.322$), median serum ALT value [158 (107-263) IU/L in the CLV group *vs* 139.5 (101.5-288.5) IU/L in the ETV group, $P = 0.206$], and serum HBV DNA titer ($7.3 \pm 1.1 \log_{10}$ copies/mL in the CLV group *vs* $7.4 \pm 1.1 \log_{10}$ copies/mL in the ETV group, $P = 0.556$) between the CLV and ETV groups. The median follow-up period was similar in the two groups (74 ± 24 wk in the CLV group and 75 ± 21 wk in the ETV group, $P = 0.922$) (Table 1).

Biochemical responses assessed by serum ALT

The median values of serum ALT at weeks 24, 48, 72, 96, and 120 after treatment were 27, 27, 27, 26, and 16 IU/L in the CLV group and 29, 24, 23, 21, and 16 IU/L in the ETV group, respectively (Figure 2A). The cumulative rates of serum ALT normalization at the same points of time were 81.9% (95/116), 83.9% (99/118), 83.9% (99/118), 91.5% (108/118), and 94.1% (111/118) in the CLV group and 73.9% (99/134), 80.9% (110/136), 89.7% (122/136), 91.2% (124/136), and

Table 1 Baseline characteristics of the enrolled patients *n* (%)

Characteristics	Clevudine (<i>n</i> = 118)	Entecavir (<i>n</i> = 136)	<i>P</i> -value
Age ¹ , yr	42 ± 11	41 ± 11	0.358
Male gender	70 (59.3)	86 (63.2)	0.528
Cirrhosis	15 (12.7)	30 (22.1)	0.052

92.6% (126/136) in the ETV group, respectively (Figure 2B). No significant difference was noted in either the median value or cumulative normalization rate of serum ALT between the two groups.

Virologic responses assessed by serum HBV DNA

The titer decrements of serum HBV DNA were -5.83, -6.03, -5.66, -6.55, and -7.28 log₁₀ copies/mL in the

Figure 3 Decrement changes in serum hepatitis B virus DNA titer and cumulative rates of hepatitis B virus DNA non-detection during the on-treatment period. A: Hepatitis B virus (HBV) DNA decrement changes; B: HBV DNA non-detection rate.

CLV group and -5.70, -6.35, -6.74, -6.86, and -7.63 log₁₀ copies/mL in the ETV group at weeks 24, 48, 72, 96, and 120 after treatment, respectively. There was no significant difference between the groups, except for serum HBV DNA titer at week 72 (CLV group *vs* ETV group, *P* < 0.05)(Figure 3A). At the same time points, the cumulative non-detection rates of serum HBV DNA were 61.3% (68/111), 72.6% (85/117), 77.1% (91/118), 83.1% (98/118), and 85.6% (101/118) in the CLV group and 57.3% (71/124), 74.4% (99/133), 83.8% (114/136), 83.8% (114/136), and 83.8% (114/136) in the ETV group, respectively, showing no significant difference (Figure 3B).

Serologic responses assessed by HBeAg

In patients who were positive for HBeAg, the cumulative rate of HBeAg clearance was 19.5% (16/82), 33.3% (29/87), 37.5% (33/88), 40.9% (36/88), and 40.9% (36/88) in the CLV group and 20.2% (17/84), 28.3% (26/92), 34.0% (32/94), 40.4% (38/94), and 40.4% (38/94) in the ETV group at weeks 24, 48, 72, 96, and 120 after drug administration, respectively (Figure 4A). The cumulative rate of HBeAg seroconversion was

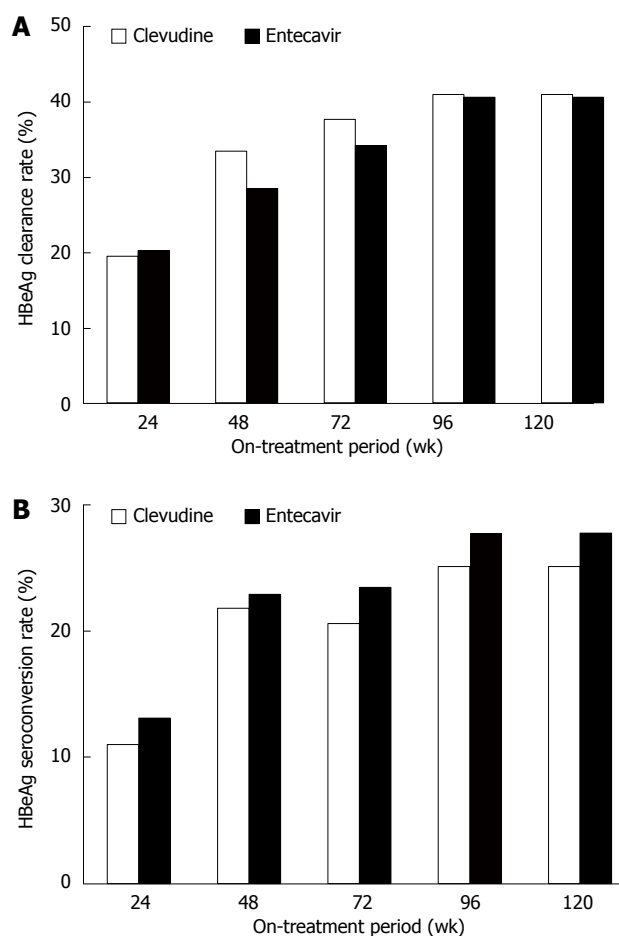

Figure 4 Cumulative rates of hepatitis B e antigen clearance and hepatitis B e antigen seroconversion during the on-treatment period. A: Hepatitis B e antigen (HBeAg) clearance rate; B: HBeAg seroconversion rate.

11.0% (9/82), 21.8% (19/87), 20.5% (18/88), 25.0% (22/88), and 25.0% (22/88) in the CLV group and 13.1% (11/84), 22.8% (21/92), 23.4% (22/94), 27.7% (26/94), and 27.7% (26/94) in the ETV group, respectively, at the same time points (Figure 4B). No significant difference was observed in the cumulative rates of HBeAg clearance or HBeAg seroconversion between the two groups.

Virologic breakthrough and adverse effects

Virologic breakthrough in the CLV group occurred in 7.6% (9/118) of the patients at 1-year after administration and 12.7% (15/118) of the patients at 2-years after administration, while no virologic breakthrough occurred in the ETV group throughout the treatment period (CLV group *vs* ETV group, $P < 0.05$). Most of the patients with virologic breakthrough showed a genotypic mutation at sites rt204 and rt180, either singly or combined, except for two patients, who showed mutation at site rt80. Only two patients (1.7%) in the CLV group experienced clinical myopathy, and they showed self-limited recovery with conservative management without dose reduction or discontinuation of CLV.

DISCUSSION

1-(2-deoxy-2-fluoro- β -L-arabinofuranosyl)thymine (CLV) is a nucleoside analogue with powerful antiviral activity against HBV; it inhibits DNA polymerase through the binding of clevudine-triphosphate to the polymerase^[16]. CLV is one of the currently available antiviral agents used as a 1st-line treatment for CHB patients in Korea, an HBV-endemic area. Although CLV was reported to be beneficial in virologic suppression on-treatment and off-treatment in CHB patients, these results were reported in a few clinical studies with small study populations and/or short follow-up periods^[9,10,17,18], and a large-scale, long-term comparative study should have been required for verifying the efficacy of CLV. With these considerations, the present study was conducted to assess relatively long-term (median follow-up period of 74 wk) clinical outcomes of CLV in antiviral-naïve CHB patients compared with ETV-treated patients during the same period, and this study was conducted in multiple regional institutes.

ETV is strongly recommended as a 1st-line treatment agent in the AASLD and EASL guidelines^[19,20], because it effectively suppresses HBV DNA and has a low genotypic resistance. Because of the globally established effects of ETV on HBV infection, the present study used clinical outcomes of ETV as a comparative standard for estimating the treatment efficacy of CLV in patients with CHB.

In this study, the cumulative rate of serum ALT normalization in CLV-treated patients increased from 83.9% at week 48 to 91.5% at week 96, which was similar to ETV-treated patients. Previous studies have reported that CLV showed a wide-range of ALT normalization (68.2% to 98.1% at week 24 and 77.3% to 87.5% at week 48)^[9,10,17,21-23]. The cumulative non-detection rate of serum HBV DNA in the CLV group also increased from 61.3% at week 24 to 72.6% at week 48 and 83.1% at week 96, which was similar to the ETV group. These rates seem to be slightly lower than previously reported HBV DNA non-detection rates^[17,21,24,25], most likely resulting from the use of a stricter detection assay of HBV DNA in our study. HBV DNA detection is mainly affected by the detection limit of the quantitation tool of HBV DNA. The real-time polymerase chain reaction method used in our study institutes is the most sensitive method for the quantitation of serum HBV DNA, and the lower limit of detection was 70 copies/mL.

CLV-treated patients showed excellent biochemical and virological responses during treatment and these response were not inferior to the responses shown in ETV-treated patients. Specifically, the titer decrement of serum HBV DNA was rapid and potent, as it was nearly at the 90% level of decrement at 96 wk after treatment for 24 wk. The rapid and potent suppression of HBV DNA is generally a significant indicator for maintaining an on-treatment virological response and sustained off-

treatment virological response^[26].

This study revealed that the HBeAg clearance rate in the CLV group increased from 33.3% at week 48 to 40.9% at week 96, and this pattern was similar to the ETV group and the results of previous CLV-related studies (11.1%-25.7% at 6 mo and 23.5%-48.0% at 12 mo)^[9,10,21,24]. The HBeAg seroconversion rate of CLV-treated patients, which was 21.8% at week 48 and 25.0% at week 96, was in agreement with ETV-treated patients and comparable to results from previous studies (7.6%-21.4% at 6 mo and 11.8%-16.9% at 12 mo)^[9,10,18,25]. Our study did not show a significant difference either HBeAg clearance or HBeAg seroconversion rates between the two groups treated with CLV or ETV.

In CLV-treated patients, the cumulative rate of virologic breakthrough increased from 7.6% at week 48 to 12.7% at week 96, while no virologic breakthrough occurred in ETV-treated patients during treatment. Most of the patients with virologic breakthrough had genotypic mutations of rtM204I or rtL180M, as previously reported in other CLV-associated studies. Rt204 of HBV DNA polymerase/reverse transcriptase is the main site relevant to CLV-associated genotypic mutation, with cross-resistance to other antiviral agents, such as lamivudine and telbivudine^[14]. The add-on or mono-switch to nucleotide analogs, such as tenofovir or adefovir, is a possible rescue therapy for CLV-resistant CHB patients; however, the choice of drug should be validated through further clinical studies. In addition to rt204, rt80, rt180, rt181, rt184, and rt270 have also been infrequently reported to be mutation sites conferring resistance to CLV. The cumulative rate of virologic breakthrough induced by CLV-associated genotypic mutation has been reported to be 0.7%-14.5% up to 12 mo^[18,21,27,28] and 24.4% up to 24 mo^[29], which is similar to the results of the present study. Biochemical breakthrough after virologic breakthrough may occur, but several months are required for ALT to increase^[30]. We did not compare the interval between biochemical breakthrough and virologic breakthrough because it only occurred in the CLV group. Most of the patients who showed virologic breakthrough were changed to or supplemented with another drug before ALT increased. The current treatment for virologic breakthrough for CLV is similar to that of lamivudine^[31].

The biologic mechanism of myopathy related to CLV has not been clearly identified, but mitochondrial dysfunction induced by mtDNA polymerase γ suppression of the phosphorylated CLV metabolite has been hypothesized to be involved^[32-34]. Although the incidence rate of myopathy has been reported to be variable (1%-14.6%)^[15,17,21,22,25,35], only 1.7% of CLV-treated patients in this study showed clinical myopathy to the tolerable extent of compliance without any modification of drug administration.

The present study has several restrictions. First, this is a retrospective study, which could not entirely escape

a non-intentional withdrawal of a number of study candidates prior to study analysis; therefore selection bias was not completely eliminated. This matter could be overcome through a comparative prospective study; Second, the detection limit of the serum HBV DNA titer was different in each institute that participated in this study, which could affect the cumulative non-detection rate of serum HBV DNA, despite the adoption of real-time PCR with a relatively sensitive quantitation indicator; Third, the analysis of clinical myopathy was insufficient because of irregular check-up for obtaining clinical information and data review only through medical records of the patients, which could not exclude the presence of myopathy of a subclinical nature; Fourth, the lack of off-treatment clinical responses suggests that an advanced clinical study sufficient to assess long-term outcomes, such as response maintenance, relapse, and disease progression after treatment, is needed.

In conclusion, we evaluated the clinical outcomes of CLV as a first-line treatment agent in antiviral-naïve CHB patients. The on-treatment biochemical, virologic, and serologic responses of CLV, except for genotypic resistance with virologic breakthrough, were as good as and not inferior to the responses of ETV up to a 96-wk period. In the future, clinical data for the rescue therapy of CLV-related antiviral resistance should be mandatory and should be acquired through a large-scale prospective study. A study to determine the conditions under which virologic resistance could be minimized should be performed.

COMMENTS

Background

Chronic hepatitis B virus (HBV) infection is a serious health problem worldwide and a major risk factor for the development of liver cirrhosis and hepatocellular carcinoma, two grave complications that have a high morbidity and mortality. Although the seroprevalence rate of HBV in the South Korean population has gradually decreased since the development of the HBV vaccine in the 1980s, the rate is still high compared to Western countries.

Research frontiers

Clevudine (CLV) is one of the currently available antiviral agents used as a 1st-line treatment for chronic hepatitis B (CHB) patients in Korea, an HBV-endemic area. Although CLV was reported to be beneficial in virologic suppression on-treatment and off-treatment in CHB patients, these results were reported in a few clinical studies with small study populations and/or short follow-up periods, and a large-scale, long-term comparative study should have been required for verifying the efficacy of CLV.

Innovations and breakthroughs

Authors evaluated the clinical outcomes of CLV as a first-line treatment agent in antiviral-naïve CHB patients. The on-treatment biochemical, virologic, and serologic responses of CLV, except for genotypic resistance with virologic breakthrough, were as good as and not inferior to the responses of entecavir up to a 96-wk period. In the future, clinical data for the rescue therapy of CLV-related antiviral resistance should be mandatory and should be acquired through a large-scale prospective study.

Applications

The study results suggest that long-term treatment outcomes of clevudine were not inferior to those of entecavir, except for virologic breakthrough in antiviral-naïve CHB patients.

Peer review

Authors reported that long-term treatment outcomes of clevudine in antiviral-

naive patients with CHB. This report has the important information. The data is appropriately treated and text is clear although the retrospective study.

Abstract

AIM: To investigate the effects of hexahydrocurcumin (HHC), and its combination with 5-fluorouracil (5-FU) on dimethylhydrazine (DMH)-induced colon cancer in rats.

METHODS: Male Wistar rats weighing 100-120 g were used as subject models. Aberrant crypt foci (ACF), early preneoplastic lesions of colon cancer, were induced

by subcutaneous injection of DMH (40 mg/kg) twice a week for two weeks. After the first DMH injection, rats were treated daily with vehicle ($n = 12$), curcumin (CUR) (50 mg/kg) ($n = 12$), HHC (50 mg/kg) orally ($n = 12$), and treated weekly with an intraperitoneal injection of 5-FU (50 mg/kg) ($n = 12$), or a combination of 5-FU plus CUR ($n = 12$) and HHC ($n = 12$) at the same dosage(s) for 16 wk. The total number of ACF and large ACF were assessed. Cyclooxygenase (COX)-1 and COX-2 expression were detected by immunohistochemistry in colon tissues. The quantitative data of both COX-1 and COX-2 expression were presented as the percentage of number of positive-stained cells to the total number of cells counted. Apoptotic cells in colon tissues were also visualized using the dUTP-biotin nick end labeling method. Apoptotic index (AI) was determined as the percentage of labeled nuclei with respect to the total number of nuclei counted.

RESULTS: The total number of ACF was highest in the DMH-vehicle group (1558.20 ± 17.37), however, the number of ACF was significantly reduced by all treatments, 5-FU (1231.20 ± 25.62 vs 1558.20 ± 17.37 , $P < 0.001$), CUR (1284.20 ± 25.47 vs 1558.20 ± 17.37 , $P < 0.001$), HHC (1086.80 ± 53.47 vs 1558.20 ± 17.37 , $P < 0.001$), DMH-5-FU + CUR (880.20 ± 13.67 vs 1558.20 ± 17.37 , $P < 0.001$) and DMH-5-FU + HHC (665.80 ± 16.64 vs 1558.20 ± 17.37 , $P < 0.001$). Interestingly, the total number of ACF in the combined treatment groups, the DMH-5-FU + CUR group (880.20 ± 13.67 vs 1231.20 ± 25.62 , $P < 0.001$; 880.20 ± 13.67 vs 1284.20 ± 25.47 , $P < 0.001$) and the DMH-5-FU + HHC group (665.80 ± 16.64 vs 1231.20 ± 25.62 , $P < 0.001$; 665.80 ± 16.64 vs 1086.80 ± 53.47 , $P < 0.001$) were significantly reduced as compared to 5-FU or each treatment alone. Large ACF were also significantly reduced in all treatment groups, 5-FU (111.00 ± 7.88 vs 262.20 ± 10.18 , $P < 0.001$), CUR (178.00 ± 7.33 vs 262.20 ± 10.18 , $P < 0.001$), HHC (186.60 ± 21.51 vs

262.20 ± 10.18, $P < 0.001$), DMH-5-FU + CUR (122.00 ± 5.94 *vs* 262.20 ± 10.18, $P < 0.001$) and DMH-5-FU + HHC (119.00 ± 17.92 *vs* 262.20 ± 10.18, $P < 0.001$) when compared to the vehicle group. Furthermore, in the DMH-5-FU + CUR and DMH-5-FU + HHC groups the formation of large ACF was significantly reduced when compared to CUR (122.00 ± 5.94 *vs* 178.00 ± 7.33, $P < 0.005$) or HHC treatment alone (119.00 ± 17.92 *vs* 186.60 ± 21.51, $P < 0.001$), however, this reduction was not statistically different to 5-FU monotherapy (122.00 ± 5.94 *vs* 111.00 ± 7.88, $P = 0.217$; 119.00 ± 17.92 *vs* 111.00 ± 7.88, $P = 0.619$, respectively). The levels of COX-1 protein after all treatments were not different from normal rats. A marked increase in the expression of COX-2 protein was observed in the DMH-vehicle group. Over-expression of COX-2 was not significantly decreased by 5-FU treatment alone (95.79 ± 1.60 *vs* 100 ± 0.00, $P = 0.198$). However, over-expression of COX-2 was significantly suppressed by CUR (77.52 ± 1.68 *vs* 100 ± 0.00, $P < 0.001$), HHC (71.33 ± 3.01 *vs* 100 ± 0.00, $P < 0.001$), 5-FU + CUR (76.25 ± 3.32 *vs* 100 ± 0.00, $P < 0.001$) and 5-FU + HHC (68.48 ± 2.24 *vs* 100 ± 0.00, $P < 0.001$) in the treated groups compared to the vehicle group. Moreover, CUR (77.52 ± 1.68 *vs* 95.79 ± 1.60, $P < 0.001$), HHC (71.33 ± 3.01 *vs* 95.79 ± 1.60, $P < 0.001$), 5-FU + CUR treatments (76.25 ± 3.32 *vs* 95.79 ± 1.60, $P < 0.001$) and 5-FU + HHC (68.48 ± 2.24 *vs* 95.79 ± 1.60, $P < 0.001$) markedly decreased COX-2 protein expression more than 5-FU alone. Furthermore, the AI in all treated groups, 5-FU (38.86 ± 4.73 *vs* 23.56 ± 2.12, $P = 0.038$), CUR (41.78 ± 6.92 *vs* 23.56 ± 2.12, $P < 0.001$), HHC (41.06 ± 4.81 *vs* 23.56 ± 2.12, $P < 0.001$), 5-FU + CUR (49.05 ± 6.75 *vs* 23.56 ± 2.12, $P < 0.001$) and 5-FU + HHC (53.69 ± 8.59 *vs* 23.56 ± 2.12, $P < 0.001$) significantly increased when compared to the DMH-vehicle group. However, the AI in the combination treatments, 5-FU + CUR (49.05 ± 6.75 *vs* 41.78 ± 6.92, $P = 0.192$; 49.05 ± 6.75 *vs* 38.86 ± 4.73, $P = 0.771$) and 5-FU + HHC (53.69 ± 8.59 *vs* 41.06 ± 4.81, $P = 0.379$; 53.69 ± 8.59 *vs* 38.86 ± 4.73, $P = 0.245$) did not reach significant levels as compared with each treatment alone and 5-FU monotherapy, respectively.

CONCLUSION: The combined effects of HHC with 5-FU exhibit a synergistic inhibition by decreasing ACF formation mediated by down-regulation of COX-2 expression.

INTRODUCTION

5-fluorouracil (5-FU) therapy is a conventional treatment for colorectal cancer and has been used for five decades. However, the toxicity of this agent to normal tissues is a major obstacle to successful cancer chemotherapy. To reduce its toxicity, combination treatment of 5-FU with minimally toxic substances derived from plants, such as genistein and geraniol, have been employed. While these are beneficial, they are also considered counterproductive in enhancing overall 5-FU efficacy^[1-3]. Curcumin (CUR), the major active substance in turmeric, which is derived from the rhizome of *Curcuma longa* L. may be an alternative^[4]. CUR is considered a suitable replacement for genistein and geraniol as it promotes higher 5-FU efficacy in the treatment of various cancer types, including colon cancer^[5,6]. The properties of CUR also highlight its usefulness, as it specifically inhibits the expression of cyclooxygenase (COX)-2, an enzyme highly expressed in a variety of human cancers, but does not suppress the expression of COX-1^[7,8]. CUR also has a low level of toxicity and is safe for the prevention/treatment of human colorectal cancer compared to other chemopreventive agents such as non-steroidal inflammatory drugs (NSAIDs)^[9]. Recently, Du *et al*^[3] showed that the synergistic effect of CUR combined with 5-FU inhibited the growth and reduced the level of COX-2 protein expression in HT-29 human colon cancer cells. However, while CUR is a very important agent in preventing and treating colorectal cancer, its characteristics-such as poor solubility, poor absorption in the gastrointestinal tract and rapid decomposition in human blood-make it unsuitable for pharmaceutical development^[10,11]. Therefore, CUR metabolites were synthesized in order to solve these problems^[12]. Hexahydrocurcumin (HHC) is one of the major metabolites of CUR. Previous studies found that HHC exhibited stronger antioxidant activity than CUR^[13]. Moreover, this compound inhibited the biosynthesis of prostaglandin (PGE₂) in lipopolysaccharide (LPS)-stimulated macrophages^[14]. PGE₂ is also a major product of COX-2 enzymes, which are involved in colorectal carcinogenesis. Interestingly, HHC decreased PGE₂ levels in phorbol ester-induced PGE₂ production in human colonic epithelial cells^[15]. Recently, our previous *in vitro* study showed that HHC markedly decreased the viability of HT-29 human colon cancer cells and down-regulated COX-2 mRNA production. Moreover, the combined effect of HHC with a low dose of 5-FU exerted a synergistic effect on the growth of HT-29 cells by markedly reducing cell viability and COX-2 mRNA to a greater degree than monotherapy^[16]. Therefore, the present study aimed to investigate the anti-colon carcinogenic effects of HHC in combination with 5-FU, with a focus on the expression of COX-2 in

dimethylhydrazine (DMH)-induced rat colon cancer.

MATERIALS AND METHODS

Animals

Male Wistar rats (National Animal Center, Salaya, Nakorn Pathom, Thailand) weighing 100-120 g were used. Animals were housed at $25 \pm 2^\circ\text{C}$ under a 12-h light/dark cycle. All procedures were carried out in accordance with the Guidelines of Animal Care described by the Animal Center, Faculty of Medical Science, Naresuan University, Phitsanulok, Thailand.

Preparation of tested chemicals

CUR and HHC were prepared from *C. longa* L. Briefly, the curcuminoid mixture obtained from the rhizomes of *C. longa* L. was subjected to silica-gel column chromatography, using hexane-dichloromethane, dichloromethane and dichloromethane-methanol as eluents to afford CUR as the major constituent. Recrystallization was accomplished by dissolving the evaporated eluate with a small quantity of dichloromethane and ethanol was then added. CUR crystallized out as yellow needles with a melting point (m.p.) of $181\text{--}183^\circ\text{C}$. HHC was synthesized from CUR by a catalytic hydrogenation reaction in ethanol for 5 h with palladium on charcoal as a catalyst. The product was isolated from tetrahydrocurcumin and octahydrocurcumin by silica-gel column chromatography followed by recrystallization with dichloromethane-*n*-hexane to provide a 45% yield of HHC as a white amorphous solid (m.p. $81\text{--}82^\circ\text{C}$). The spectroscopic (IR, ^1H -NMR and mass spectra) data of the synthesized HHC were consistent with those in a previous report^[17]. CUR and HHC were then separately dissolved in propylene glycol and were ready for use.

Experimental protocols

The animals were randomly divided into seven groups. The animals in group 1, designated the negative control (normal group, $n = 10$), were fed daily with propylene glycol (PG). Group 2 to 7 served as the carcinogenic groups. In these groups, the animals were subcutaneously injected with DMH (Sigma-Aldrich, St. Louis, MO, United States) (40 mg/kg) twice a week for two wk in order to induce aberrant crypt foci (ACF). In group 2, (vehicle group, $n = 12$) rats were fed daily with PG. Group 3 (5-FU group, $n = 12$) received an intraperitoneal injection (ip) of 5-FU at a dose of 50 mg/kg body weight weekly. Group 4 (CUR group, $n = 12$) and 5 (HHC group, $n = 12$), were treated daily with intragastric administration of CUR and HHC at a dose of 50 mg/kg, respectively, whereas group 6 (5-FU + CUR, $n = 12$) and 7 (5-FU + HHC, $n = 12$) were the combined treatment groups, and were treated with 5-FU plus CUR and 5-FU plus HHC, respectively. All treatments were started after the first DMH injection and were given daily until week 16.

ACF analysis

Colons were dissected and washed with cold normal saline. They were then fixed in 10% buffer neutral formalin for 24 h. The colon tissues were stained with 2% methylene blue for 2 min and placed on a microscope slide with the mucosal surface up. ACF were examined under a light microscope at $40\times$ magnification and distinguished from surrounding normal crypts by the following characteristics: (1) increased size; (2) large luminal openings; (3) thickened epithelia; and (4) larger than adjacent normal crypts^[18,19]. In this study, the number of ACF and large ACF defined as containing 4 crypts or more (> 3 crypts/ACF)^[20], which represent advancing preneoplastic states, were counted.

Immunohistochemical analysis

COX-2: Paraffin sections from the distal portion of the colon were dewaxed in xylene and rehydrated through a graded series of alcohol. Endogenous peroxidase activity was blocked with 3% hydrogen peroxide in methanol for 15 min at ambient temperature. After washing in water, nonspecific binding sites were blocked with 5% bovine serum in phosphate-buffered saline (PBS) for 30 min at ambient temperature. The primary polyclonal antibody COX-2 (Cayman Chemical, Ann Arbor, MI, United States) was diluted in 1% BSA/Tris-Cl (at a 1:500 dilution) and incubated at 4°C overnight. The slides were then gently rinsed with PBS and incubated with the secondary antibody (goat anti-rabbit immunoglobulins) conjugated with labeled polymer-horseradish (HRP) developed by the Envision system/HRP (DAKO cytometry, Glostrup, Denmark) as follows: the slides were incubated in peroxidase-labeled polymer for 30 min and substrate-chromogen for 10 min at ambient temperature. The nuclei were counterstained with Mayer's hematoxylin. COX-2 expression is presented as the percentage of the number of positive-stained cells to the total number of cells counted by image analysis (Image Pro[®]-plus).

COX-1: The paraffin sections were processed as in the COX-2 method up to the nonspecific binding sites step. The primary antibody COX-1 (Cayman Chemical, Ann Arbor, MI, United States) was diluted in 1% BSA/Tris-Cl (at a 1:1000 dilution) and incubated at 4°C overnight. The slides were then rinsed with PBS and incubated with the secondary antibody conjugated with biotin (biotinylated anti-mouse immunoglobulins) for 1 h at ambient temperature. The slides were incubated with the ABC reagent (Vectastain, Burlingame, CA, United States) for 30 min at ambient temperature and developed by DAB peroxidase substrate (Vectastain, Burlingame, CA, United States). The nuclei were counterstained with Mayer's hematoxylin. The positive stained cells were then counted by image analysis software (Image Pro[®]-plus). COX-1 expression is presented as the percentage of the number of positive-stained cells to the total number of cells counted.

Figure 1 Topographical view of colon tissue. A: Normal colon tissue; B: Aberrant crypt foci (ACF) with 2 crypts; C: Large ACF (crypt multiplicity containing more than 3 crypts per ACF). Scale bars = 25 μ m.

Table 1 Effect of curcumin, hexahydrocurcumin, 5-fluorouracil and their combined treatment on aberrant crypt foci formation in rats exposed to dimethylhydrazine

Groups	Total ACF	Large ACF
Vehicle	1558.20 \pm 17.37	262.20 \pm 10.18
5-FU	1231.20 \pm 25.62 ^b	111.00 \pm 7.88 ^b
CUR	1284.20 \pm 25.47 ^b	178.00 \pm 7.33 ^b
HHC	1086.80 \pm 53.47 ^b	186.60 \pm 21.51 ^b
5-FU + CUR	880.20 \pm 13.67 ^{b,d,f}	122.00 \pm 5.94 ^b
5-FU + HHC	665.80 \pm 16.64 ^{b,d,h}	119.00 \pm 17.92 ^{b,h}

Each value is represented by mean \pm SE. ^b P < 0.01 *vs* vehicle group; ^d P < 0.01 *vs* 5-fluorouracil (5-FU) monotherapy; ^e P < 0.01 *vs* curcumin (CUR) monotherapy; ^f P < 0.01 *vs* hexahydrocurcumin (HHC) monotherapy. ACF: Aberrant crypt foci.

Apoptotic analysis

Apoptotic cells in the distal colon were visualized using the terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick end labeling (TUNEL) method with the FragELTM DNA fragmentation Detection kit (Calbiochem, Darmstadt, Germany). The deparaffinized tissue sections were permeabilized by Triton-X-100 and inactivated by endogenous peroxidases with 3% H₂O₂ in methanol at ambient temperature for 5 min. The tissue sections were incubated with TUNEL reaction mixture containing the TdT at 37 °C for 60 min. Slides were rinsed twice in PBS for 10 min and dried around the sample. The labeled DNA was detected by DAB solution for 10-15 min at ambient temperature. The nuclei were counterstained immediately with methyl green solution. Finally, the slides were washed and analyzed under a light microscope. Apoptotic index (AI) was determined as the percentage of the labeled nuclei with respect to the total number of nuclei counted.

Statistical analysis

The differences in mean values among the different groups were tested and the values are expressed as mean \pm SE. All data were tested by analysis of variance followed by the LSD test. All statistical calculations were carried out using SPSS (version 11.5) and a P -value < 0.05 was considered significant.

RESULTS

Effects of 5-FU, CUR, HHC and their combined treatments on ACF formation

ACF were distinguished from the surrounding normal crypts by their increased size, darker epithelial lining than normal crypts and large luminal opening (Figure 1). We assessed ACF formation in the colonic epithelia of experimental models by recording two parameters of ACF: (1) number of aberrant crypts and (2) large ACF containing 4 crypts or more (> 3 crypts/ACF), which are found in advancing preneoplastic states. The results showed that all rats developed ACF in the colon after DMH induction. The total number of ACF was highest in the DMH-vehicle group (1558.20 \pm 17.37) as shown in Table 1. HHC treatment alone markedly reduced the total number of ACF as compared to the vehicle group (1086.80 \pm 53.47 *vs* 1558.20 \pm 17.37, P < 0.001). In addition, the total number of ACF in the 5-FU (1231.20 \pm 25.62 *vs* 1558.20 \pm 17.37, P < 0.001) and CUR treatment alone groups (1284.20 \pm 25.47 *vs* 1558.20 \pm 17.37, P < 0.001) were significantly decreased as compared to the DMH-vehicle group. Interestingly, the total number of ACF in the combined treatment group, the DMH-5-FU + HHC group, was significantly reduced as compared to 5-FU or HHC treatment alone (665.80 \pm 16.64 *vs* 1231.20 \pm 25.62, P < 0.001; 665.80 \pm 16.64 *vs* 1086.80 \pm 53.47, P < 0.001). Similarly, the total number of ACF in the DMH-5-FU + CUR group was significantly reduced as compared to 5-FU or CUR treatment alone (880.20 \pm 13.67 *vs* 1231.20 \pm 25.62, P < 0.001; 880.20 \pm 13.67 *vs* 1284.20 \pm 25.47, P < 0.001). The large ACF were significantly reduced in all treatment groups, 5-FU (111.00 \pm 7.88 *vs* 262.20 \pm 10.18, P < 0.001), CUR (178.00 \pm 7.33 *vs* 262.20 \pm 10.18, P < 0.001), HHC (186.60 \pm 21.51 *vs* 262.20 \pm 10.18, P < 0.001), DMH-5-FU + CUR (122.00 \pm 5.94 *vs* 262.20 \pm 10.18, P < 0.001) and DMH-5-FU + HHC (119.00 \pm 17.92 *vs* 262.20 \pm 10.18, P < 0.001) when compared to the vehicle group. Furthermore, the DMH-5-FU + CUR and DMH-5-FU + HHC groups significantly reduced the formation of the large ACF when compared to CUR (122.00 \pm 5.94 *vs* 178.00 \pm 7.33,

$P < 0.005$) or HHC treatment alone (119.00 ± 17.92 *vs* 186.60 ± 21.51 , $P < 0.001$), however, this reduction was not statistically different to 5-FU monotherapy (122.00 ± 5.94 *vs* 111.00 ± 7.88 , $P = 0.217$; 119.00 ± 17.92 *vs* 111.00 ± 7.88 , $P = 0.619$, respectively).

Effects of 5-FU, CUR, and HHC alone and their combined treatments on COX-2 expression

Immunohistochemical assays demonstrated that COX-2 protein was mostly localized in the cytoplasm in a diffuse-granular pattern. Positive staining was seen as a brown stain at a low-power field (20X), indicated by the arrows in Figure 2A. The COX-2 protein was not observed in normal colon mucosal tissue. The over-expression of COX-2 was most marked in DMH-vehicle rats (Figure 2A). CUR and HHC alone and their combined treatments attenuated the over-expression of COX-2. The quantitative data from image analysis showed that marked COX-2 expression was found in the vehicle group ($100\% \pm 0.00\%$) (Figure 2B). Over-expression of COX-2 was not significantly decreased by 5-FU treatment alone ($95.79\% \pm 1.60\%$ *vs* $100\% \pm 0.00\%$, $P = 0.198$). However, over-expression of COX-2 was significantly suppressed by CUR ($77.52\% \pm 1.68\%$ *vs* $100\% \pm 0.00\%$, $P < 0.001$), HHC ($71.33\% \pm 3.01\%$ *vs* $100\% \pm 0.00\%$, $P < 0.001$), 5-FU + CUR ($76.25\% \pm 3.32\%$ *vs* $100\% \pm 0.00\%$, $P < 0.001$) and 5-FU + HHC ($68.48\% \pm 2.24\%$ *vs* $100\% \pm 0.00\%$, $P < 0.001$) compared to the vehicle group. Moreover, CUR monotherapy ($77.52\% \pm 1.68\%$ *vs* $95.79\% \pm 1.60\%$, $P < 0.001$), HHC monotherapy ($71.33\% \pm 3.01\%$ *vs* $95.79\% \pm 1.60\%$, $P < 0.001$), 5-FU + CUR ($76.25\% \pm 3.32\%$ *vs* $95.79\% \pm 1.60\%$, $P < 0.001$) and 5-FU + HHC ($68.48\% \pm 2.24\%$ *vs* $95.79\% \pm 1.60\%$, $P < 0.001$) markedly decreased COX-2 protein expression more than 5-FU treatment alone.

Effects of 5-FU, CUR, and HHC alone and their combined treatments on COX-1 expression

COX-1 expression was observed in the cytoplasm of most cells in colonic crypts in all animals. The COX-1 protein-labeled cells were analyzed by image analysis. The data revealed that the level of COX-1 protein in all treated rats was not different from the normal group (data not shown).

Effects of 5-FU, CUR, and HHC alone and their combined treatments on apoptosis

Apoptotic cells showed a strong dark or brown stain in normal colon mucosa (arrows in Figure 2C). In contrast, apoptotic cells were very low in DMH-vehicle group. 5-FU, CUR, and HHC alone and their combined treatments induced an increment of apoptotic cells in colon tissue. The quantitative data, as shown by the AI was highest in normal colon tissue ($75.71\% \pm 3.59\%$). In Figure 2D, the results show that AI was very low in the DMH-induced colon cancer vehicle group ($23.56\% \pm 2.12\%$). The AI in all treated groups were as follows: 5-FU ($38.86\% \pm 4.73\%$ *vs* $23.56\% \pm 2.12\%$, $P = 0.038$),

CUR ($41.78\% \pm 6.92\%$ *vs* $23.56\% \pm 2.12\%$, $P < 0.001$), HHC ($41.06\% \pm 4.81\%$ *vs* $23.56\% \pm 2.12\%$, $P < 0.001$), 5-FU + CUR ($49.05\% \pm 6.75\%$ *vs* $23.56\% \pm 2.12\%$, $P < 0.001$) and 5-FU + HHC ($53.69\% \pm 8.59\%$ *vs* $23.56\% \pm 2.12\%$, $P < 0.001$) and were significantly increased when compared to the DMH-vehicle group. However, the AI in the combined treatments which were: 5-FU + CUR ($49.05\% \pm 6.75\%$ *vs* $41.78\% \pm 6.92\%$, $P = 0.192$; $49.05\% \pm 6.75\%$ *vs* $38.86\% \pm 4.73\%$, $P = 0.771$) and 5-FU + HHC ($53.69\% \pm 8.59\%$ *vs* $41.06\% \pm 4.81\%$, $P = 0.379$; $53.69\% \pm 8.59\%$ *vs* $38.86\% \pm 4.73\%$, $P = 0.245$) did not reach significant levels as compared with each treatment alone and 5-FU monotherapy, respectively.

DISCUSSION

This study aimed to determine the anti-colon carcinogenic effects of HHC, a major metabolite of CUR, in combination with 5-FU therapy with a focus on the expression of COX-2 in DMH-induced colorectal cancer in rats. DMH induces DNA damage in the colon, ileum, and liver, and thus is a carcinogen in colorectal tissue^[21]. Several studies have reported that ACF are recognized as early preneoplastic lesions of colorectal origin. In addition, crypt multiplicity may indicate a step in colon carcinogenesis promotion^[22,23]. This study thus assessed the formation of ACF in DMH-induced colorectal cancer in a rat model. The results showed that both the total number of ACF and large ACF were highest in the DMH-vehicle group. Moreover, over-expression of COX-2 protein was most marked in this group. These findings agree with a previous study where an over-expression of COX-2 was detected in ACF, adenomas and carcinomas in azoxymethane-induced rat colon cancer^[24]. Several studies reported that COX-2 over-expression and up-regulation of the prostaglandins play a crucial role in carcinogenesis and angiogenesis^[25-27]. COX-2 is also known to have an anti-apoptotic effect on colon cancer cells *via* the activation of different signal transduction pathways^[28-30]. Therefore, ACF induction of COX-2 promotes colon carcinogenesis, and blockage of these processes is a strategy for colon cancer prevention and treatment.

In the present study, we demonstrated that HHC treatment alone significantly reduced the total number of ACF and large ACF compared with the vehicle. This result suggests that HHC has the ability to inhibit the initiation and promotion of steps in colorectal carcinogenesis which is similar to the property of CUR^[31]. Furthermore, HHC together with 5-FU exhibited a synergistic effect, with inhibition of total ACF numbers being higher than either HHC or 5-FU treatment alone. Therefore, it is reasonable to assume that HHC augments the growth inhibitory effect of 5-FU chemotherapy by inhibiting the initiation of colorectal carcinogenesis. This result also correlates with the synergistic inhibitory effect of CUR combined with 5-FU on the growth of HT-29 human colon cancer cells^[3].

Figure 2 Effects of 5-fluorouracil, curcumin, and hexahydrocurcumin alone and their combined treatments on cyclooxygenase-2 protein expression and apoptosis. A: Immunohistochemical staining of cyclooxygenase-2 (COX-2) protein expression. Scale bars = 50 μ m; B: Quantitative data of COX-2 protein expression (%). Each value is represented by mean \pm SE. ^b $P < 0.01$ vs vehicle or 5-FU monotherapy; C: Apoptosis labeled using the dUTP-biotin nick end labeling method. Scale bars = 50 μ m; D: Apoptotic index (%). Each value is represented by mean \pm SE. ^c $P < 0.05$, ^d $P < 0.01$ vs vehicle group. 5-FU: 5-fluorouracil; HHC: Hexahydrocurcumin; CUR: Curcumin.

The anti-colorectal cancer mechanisms of HHC have not previously been reported. However, Shao *et al.*^[14]

reported that this compound inhibited the biosynthesis of PGE₂ in LPS-stimulated macrophages. Our study

found that HHC alone significantly decreased the COX-2 protein level compared to vehicle treatment which was similar to CUR treatment alone. The results support our recent report which showed that HHC is significantly responsible for the down-regulation of COX-2 mRNA synthesis, but does not alter the expression of COX-1 in HT-29 human colon cancer cells^[16]. Furthermore, HHC in combination with 5-FU has a higher level of potency against COX-2 mRNA expression when compared with cells treated with 5-FU or HHC alone. We therefore propose that HHC plays a significant role in inhibiting the expression of COX-2 protein in colorectal carcinogenesis, and when combined with 5-FU can lead to an overall decrease in the level of COX-2 protein and a reduction in the formation of ACF in the early stage of colorectal carcinogenesis through attenuation of COX-2 expression. When compared to the vehicle treatment group, this is an important distinction. Furthermore, this study found that the level of COX-1 protein after treatment with HHC alone and in combination with 5-FU was not different from normal rats. Therefore, HHC can be classified as a selective COX-2 inhibitor in contrast to some NSAIDs such as meloxicam, diclofenac, indomethacin which inhibit both COX-2 and COX-1 expression, causing injury to the gastric mucosa^[32,33]. We suggest that HHC treatment alone or in combination with 5-FU would not produce unwanted side effects in the colorectal cancer rat model, and thus HHC administration may be suitable for the long-term treatment and/or prevention of human colorectal cancer. However, we must consider that the relationship between COX-2 and carcinogenesis may involve several pathways, including conversion of procarcinogens into active carcinogens, inhibition of apoptosis, increase in tumor growth and invasiveness, and promotion of angiogenesis^[25-30,34]. Therefore, it is reasonable that COX-2 inhibitors may offer an important and powerful target for cancer prevention and treatment. In the present study, we also investigated whether HHC could induce colon cell apoptosis in DMH-induced colon cancer in rats. We showed that colon cell apoptosis in the DMH-injected group was significantly lower than that in normal rats and was very low in the vehicle-treated group, however, treatment with HHC alone resulted in greater levels of apoptosis. These results suggested that HHC may also suppress colorectal carcinogenesis through its ability to induce apoptosis, possibly by inhibiting COX-2 production. The combined treatment of HHC and 5-FU significantly increased apoptosis when compared to the vehicle group, but not when compared to the groups treated with HHC and 5-FU alone. These findings suggested that HHC combined with 5-FU did not have a synergistic effect on apoptosis induction in colorectal carcinogenesis in the DMH-induced rat model. Therefore, the combined effects of these agents on inhibition of ACF formation may be due to other modes of actions which need to be explored.

In summary, the evidence presented in this *in vivo* study gives new insight into the anti-carcinogenic activity

of HHC in this colorectal cancer model. Our findings indicate that the addition of DMH caused COX-2 over-expression resulting in resistance to apoptosis in colorectal tissues. HHC treatment alone and combined with 5-FU significantly suppressed the growth of colorectal cancer at the initiation step by down-regulating the expression of COX-2 and inducing apoptosis. Although the combined effect of HHC and 5-FU was similar to its progenitor, CUR, the greater bioavailability of HHC makes it more suitable for further pharmaceutical development in the prevention and therapy of colon cancer. Further studies should be encouraged to determine the mechanisms underlining these anti-cancer activities.

COMMENTS

Background

The toxicity of 5-fluorouracil (5-FU) chemotherapy in normal tissues is a major limitation of its treatment of colon cancer. To avoid the toxicity of chemotherapeutic agents, alternative treatments using chemopreventive natural medicine may be an option. The previous study showed that hexahydrocurcumin (HHC), a natural metabolite of curcumin (CUR), enhanced 5-FU in inhibiting the growth of HT-29 human colon cancer cells and down-regulated the expression of cyclooxygenase-2 (COX-2) mRNA *in vitro*. However, the effects of HHC combined with 5-FU *in vivo* have not yet been studied. The present study therefore aimed to investigate the anti-colon carcinogenic effects of HHC in combination with 5-FU on dimethylhydrazine (DMH)-induced colon cancer in rats, with a focus on the expression of the COX-2.

Research frontiers

This study involved testing the anti-colon carcinogenesis effect of HHC combined with the standard chemotherapeutic agent, 5-FU. Areas of this research included: studying the natural substance-HHC as an alternative or an adjunctive cancer therapy; testing the anti-carcinogenic effect against DMH-induced colon cancer in rats; measuring aberrant crypt foci (ACF) which are early preneoplastic lesions of colorectal cancer; measuring COX-2 protein, an important enzyme which promotes/initiates the colon carcinogenesis process; and detecting the apoptosis of colonic cells after these treatments.

Innovations and breakthroughs

In a previous study of 5-FU combined with CUR, it was found that this combined treatment had a synergistic effect on inhibiting the growth of a colorectal cancer cell line. However, the physical properties of CUR are unsuitable for pharmaceutical development. The authors thus synthesized HHC, a major metabolite of CUR, which shows greater bioavailability compared to CUR. In this study, HHC in combination with 5-FU was tested for the treatment of colorectal cancer. The authors found that HHC in combination with 5-FU suppressed the formation of ACF more than HHC or 5-FU treatment alone, which indicates that this combination shows a synergistic effect for anti-carcinogenic activity.

Applications

The results suggest that HHC combined with 5-FU can suppress the growth of colorectal cancer without any side effects. HHC plus 5-FU also showed a synergistic inhibitory effect to reduce ACF formation. Although the combined effect of HHC and 5-FU was similar to its progenitor, CUR, its greater bioavailability in colon cancer makes it more suitable for further pharmaceutical development in the prevention of colon cancer and its treatment.

Terminology

5-FU is a conventional cancer chemotherapeutic drug used to treat human colorectal cancer. Its toxicity to normal cells and long-term exposure to this drug shows higher resistance in cancer cells to treatment. CUR is the major yellow pigment in turmeric which is obtained from the rhizome of *Curcuma longa* L. HHC is one of the natural metabolites of CUR.

Peer review

This study examines the effects of HHC, a relatively low toxic CUR metabolite, on colonic ACF formation in a rat model induced by DMH to produce colorectal cancer. The authors suggest that HHC has similar effects to CUR and reduced ACF numbers by increasing apoptosis, inhibiting COX-2 protein expression but

no expression of COX-1. This is an interesting study that extends previous *in vitro* studies and suggests that HHC effectively reduced preneoplastic changes in an *in vivo* model of colorectal cancer.

Abstract

AIM: To investigate endoscopic findings in patients with Schatzki rings (SRs) with a focus on evidence for eosinophilic esophagitis (EoE).

METHODS: We consecutively approached all adult patients scheduled for elective outpatient upper endoscopy for a variety of indications at the German Diagnostic Clinic, Wiesbaden, Germany between July 2007 and July 2010. All patients with endoscopically diagnosed SRs, defined as thin, symmetrical, mucosal structures located at the esophagogastric junction, were prospectively registered. Additional endoscopic findings, clinical information and histopathological findings with a focus on esophageal eosinophilia (≥ 20 eosinophils/high power field) were recorded. The criteria for active EoE were defined as: (1) eosinophilic tissue infiltration ≥ 20 eosinophils/hpf; (2) symptoms of esophageal dysfunction; and (3) exclusion of other causes of esophageal

geal eosinophilia. Gastroesophageal reflux disease was excluded by proton pump inhibitor treatment prior to endoscopy. The presence of ≥ 20 eosinophils/hpf in esophageal biopsies in patients that did not fulfil the criteria of EoE was defined as esophageal hypereosinophilia.

RESULTS: A SR was diagnosed in 171 (3.3%; 128 males, 43 females, mean age 66 ± 12.9 years) of the 5163 patients that underwent upper gastrointestinal-endoscopy. Twenty of the 116 patients (17%) from whom esophageal biopsies were obtained showed histological hypereosinophilia (≥ 20 eosinophils/hpf). Nine of these patients (8 males, 1 female, mean age 49 ± 10 years) did not fulfill all diagnostic criteria of EoE, whereas in 11 (9%) patients with ≥ 20 eosinophils/hpf, a definite diagnosis of EoE was made. Three of the 11 patients (27%) with definite EoE had no suspicious endoscopic features of EoE. In contrast, in the 25 patients in whom EoE was suspected by endoscopic features, EoE was only confirmed in 7 (28%) patients. Patients with EoE were younger (mean age 41.5 ± 6.5 vs 50.5 ± 11.5 years, $P = 0.012$), were more likely to have a history of allergies (73% vs 29%, $P = 0.007$) and complained more often of dysphagia (91% vs 34%, $P = 0.004$) and food impaction (36% vs 6%, $P = 0.007$) than patients without EoE. Endoscopically, additional webs were found significantly more often in patients with EoE than in patients without EoE (36% vs 11%, $P = 0.04$). Furthermore, the SR had a tendency to be narrower in patients with EoE than in those without EoE (36% vs 18%, $P = 0.22$). The percentage of males (73% vs 72%, $P = 1.0$) and frequency of heartburn (27% vs 27%, $P = 1.0$) were not significantly different in both groups. The 9 patients with esophageal hypereosinophilia that did not fulfil the diagnostic criteria of EoE were younger (mean age 49 ± 10 years vs 58 ± 6 years, $P = 0.0008$) and were more likely to have a history of allergies (78% vs 24%, $P = 0.003$) than patients with < 20 eosinophils/hpf. Predictors of EoE were younger age, presence of dysphagia or food impaction

and a history of allergies.

CONCLUSION: A significant proportion of patients with SRs also have EoE, which may not always be suspected according to other endoscopic features.

INTRODUCTION

The prevalence of a lower esophageal Schatzki ring (SR) ranges from 4%-15%, depending on the diagnostic method and population investigated. In the majority of cases, it does not cause any symptoms, however, it is also one of the most common causes of intermittent dysphagia and food impaction^[1-3]. The etiology and pathogenesis still remain unclear. Gastroesophageal reflux disease has been suggested as an etiological factor^[4]. However, prospective studies have documented an association with gastroesophageal reflux disease (GERD) in less than two-thirds of patients^[5,6]. Therefore, additional pathogenetic factors should be considered.

More recently, an association of SRs with eosinophilic esophagitis (EoE) has been reported^[7,8], although the causal relationship between the two entities is under discussion^[9-11].

The aim of this study was to obtain additional endoscopic findings and assess the prevalence of EoE in patients with SRs.

MATERIALS AND METHODS

Patients

We consecutively approached all adult patients scheduled for elective outpatient upper endoscopy for a variety of indications at the German Diagnostic Clinic, Wiesbaden between July 2007 and July 2010. We recruited all patients in which we could endoscopically identify a lower esophageal SR. A SR was defined as a thin, symmetric, mucosal structure located at the esophagogastric junction (Figure 1A)^[12]. Data including sex, medical history, medications,

allergies, additional endoscopic findings and esophageal biopsy results were recorded.

After Institutional Review Board (IRB) approval was obtained (approved by the Gesellschaft zur Förderung der Forschung an der Deutschen Klinik für Diagnostik; GFF Approval No. IRB-2012-I), medical records were reviewed to assess symptoms, medical history, medications and endoscopic findings of all patients with SRs in whom esophageal biopsies were obtained to determine the prevalence of EoE. Patients with concomitant eosinophilic infiltration in the stomach or duodenum and patients with known Barrett's esophagus were excluded.

Endoscopy

Endoscopic findings for patients consenting to participate in the study were prospectively recorded in an electronic database (Clinic Win Data, E+L GmbH, Erlangen, Germany). All endoscopies were performed by senior gastroenterologists with a GIF 160 or GIF 180 Olympus upper endoscope (Olympus Corp., Hamburg, Germany) with an outer diameter of 9.5 mm. The internal diameter of the SR was estimated during endoscopy. A narrow ring was defined as being difficult to pass through with the endoscope and a wide ring was easy to pass through with the endoscope. A sliding hiatal hernia was diagnosed when gastric mucosa folds extended for more than 1.5 cm above the diaphragm^[13].

Erosive esophagitis was classified according to the criteria of the Los Angeles classification system^[14,15]. An esophageal web was defined as an eccentric, mucosal narrowing proximal to the esophagogastric junction having a maximum thickness of 1.5 mm^[16]. The diagnosis of a diverticulum was based on the presence of a pouch in the esophagus (Zenker's diverticulum: pouch in the pharyngo-esophageal area; midesophageal diverticulum: pouch in the mid esophagus; epiphrenic diverticulum: pouch just proximal to the diaphragm)^[16]. EoE was assumed with the presence of linear furrows, whitish exudates, trachealization or a small calibre esophagus^[17].

Following the standard procedure in our department, all patients in whom no otherwise obvious cause of their symptoms could be detected (e.g., reflux esophagitis, malignant or peptic strictures) and who had no recent exposure to anticoagulants had esophageal biopsies. This was done using a standard biopsy protocol, which included 2 duodenal biopsies, 2 gastric biopsies and a total of 4 esophageal biopsies (2 distal within 5-8 cm proximal to the esophagogastric junction, and 2 mid > 10 cm proximal to the esophagogastric junction).

Histopathological assessment

Biopsy specimens were submitted for routine processing and pathology evaluation with a request to evaluate for EoE. All histopathological analyses were performed by senior pathologists. The peak count of intraepithelial eosinophils/high power field ($\times 400$ magnifications on the Optiphot-2 microscope, ocular $\times 10$ with Plan $\times 40$ objective; Nikon, Japan) was determined in the area of

Figure 1 Endoscopic image and histological image of eosinophilic esophagitis. highest density of eosinophils using the most densely populated hpf. Histological suspicion of EoE was the presence of 20 or more eosinophils/hpf^[10,17]. In biopsy specimens with ≥ 20 eosinophils/hpf, a thorough histopathological review was performed by a second senior pathologist according to further histological features associated with EoE, including a particular affiliation of eosinophils to aggregate in the surface layers of the epithelium, the presence of microabscesses (defined by ≥ 4 eosinophils/cluster), findings of epithelial hyperplasia (basal-zone expansion of 30% and papillary height elongation of $> 70\%$) and lamina propria fibrosis^[18,19] (Figure 1B).

Definition of EoE

Criteria of active EoE were defined as: (1) eosinophilic tissue infiltration ≥ 20 eosinophils/hpf; this cut-off was chosen as the study was designed prior to the publication of the AGA guidelines^[17]; (2) symptoms of esophageal dysfunction (dysphagia, food impaction and PPI-resistant heartburn); and (3) exclusion of other causes of esophageal eosinophilia. Gastroesophageal reflux disease (GERD) was excluded by proton pump inhibitor treatment prior to endoscopy.

The presence of ≥ 20 eosinophils/hpf in esophageal

No symptoms of esophageal dysfunction	31 (27)

M/F: Male/female.

biopsies in patients that did not fulfil the criteria of EoE was defined as esophageal hypereosinophilia.

Statistical analysis

Numeric variables are described as the mean \pm SD and the number of observations (n). Categorical variables are described using frequencies (n) and percentages (%). In order to assess whether group differences were compatible with pure chance, we performed exploratory tests. Therefore, all reported P -values are descriptive. Association of age with categorical variables was assessed by the two-sample Wilcoxon test. Association of categorical variables was tested using Fisher's exact test. All statistical analyses were performed using SPSS 15.0 for Windows (SPSS Inc, Chicago, IL, United States).

RESULTS

During the study period, a total of 5163 patients underwent upper gastrointestinal-endoscopy in our department. A SR was diagnosed in 171 (3.3%) patients (128 males, 43 females, mean age 66 ± 12.9 years). Reflux esophagitis was present in 45 patients (who were then excluded from the analysis) and an additional 10 patients were excluded because of the presence of peptic stenosis ($n = 1$), Barrett's esophagus ($n = 6$), and esophageal malignancy ($n = 1$). Two patients were on anticoagulation therapy and therefore a biopsy specimen was not taken.

The clinical and demographic characteristics of the 116 patients enrolled are shown in Table 1.

The endoscopically estimated diameter of the lower esophageal ring was wide in 93 (80%) and narrow in 13 (11%) patients. The most frequent additional endoscopic finding was a sliding hiatal hernia in 95 (82%) patients. Sixteen (14%) of 116 patients showed esophageal webs and 3 (3%) patients had esophageal diverticula. One of the 3 patients with esophageal diverticula showed a Zenker's diverticulum and, in 2 patients, midesophageal diverticula were diagnosed. EoE was assumed in 25 (21%) patients because of the presence of specific endoscopic features.

In 20 (17%; 16 males, 4 females, mean age 39 ± 6 years) of the 116 patients, hypereosinophilia (≥ 20 eosinophils/hpf) could be shown in the esophageal biopsies. The results of the histopathological analysis of these

specimens are shown in Table 2. Biopsy specimens of the stomach and duodenum of these patients showed no evidence of eosinophilic gastroenteritis, Crohn's disease or infection.

Eleven of these 20 patients met the diagnostic criteria of EoE. Table 3 shows the baseline characteristics of the 11 patients with SRs and EoE. From the 25 patients in whom EoE was assumed because of the endoscopic features, EoE was confirmed in 7 (28%) patients. Three of the 11 patients (27%) with defined EoE had no suspicious endoscopic features of EoE.

When compared with the remainder of the 116 patients, the 11 patients with documented EoE were of younger age, more often showed an allergic predisposition, and complained to a larger degree of dysphagia and food impaction (Table 4). Whereas no gender difference (27% *vs* 28% females, $P = 1.0$) was demonstrated between both groups, EoE was diagnosed in 50% of the patients < 45 years of age *vs* 3% in patients 45 years or older (relative risk 10).

Endoscopically, additional webs were found significantly more often in patients with EoE than in patients without EoE (36% *vs* 11%, $P = 0.04$). Furthermore patients with EoE had a tendency to have narrower SR than patients without EoE (36% *vs* 18%, $P = 0.22$). Nine patients (8 males, 1 female, mean age 49 ± 10 years) showed ≥ 20 eosinophils/hpf in the histological examination, but did not fulfil the diagnostic criteria of EoE because gastroesophageal reflux disease could not be excluded prior to the esophageal biopsy sampling (6 patients) or the patients had no symptoms of esophageal dysfunc-

Demographics and clinical and endoscopic findings for patients with a Schatzki ring (SR) with and without eosinophilic esophagitis (EoE). M: Male; F: Female.

tion (3 patients had abdominal pain). Four (44%) of the 9 patients with esophageal hypereosinophilia complained of dysphagia and one of the 4 also had heartburn. One (11%) of the 9 patients had a history of food impaction and another (11%) had heartburn. The endoscopically estimated diameter of the lower esophageal ring was wide in 5 (56%) and narrow in 4 (44%) patients and 3 (33%) patients exhibited additional esophageal webs. EoE was assumed in 4 (44%) of those patients because of the endoscopic features.

Patients with esophageal hypereosinophilia were younger (mean age 49 ± 10 years *vs* 58 ± 6 years, $P = 0.0008$), were more likely to have a history of allergies (78% *vs* 24%, $P = 0.003$) and were more frequently found to have additional webs (33% *vs* 9%, $P = 0.009$) and more narrow SRs (44% *vs* 16%, $P = 0.05$) than patients with < 20 eosinophils/hpf. Furthermore, patients with esophageal hypereosinophilia had a tendency to complain less often of heartburn (11% *vs* 27%, $P = 0.23$). The number of males (89% *vs* 71%, $P = 0.4$), frequency of dysphagia (44% *vs* 33%, $P = 0.5$) and rate of food impaction (11% *vs* 5%, $P = 0.4$) were not significantly different in both groups.

Three of the 6 patients in whom GERD could not be excluded prior to biopsy sampling had relief of their symptoms after proton pump inhibitor treatment in standard doses for 4 wk following the endoscopy.

DISCUSSION

In this study, the prevalence of a lower esophageal SR was 3.3%, which is in the lower range of that reported in the literature^[20]. SRs are seen in up to 14% of routine barium radiographs^[2], however, similar to the presented data, symptomatic rings are less common and endoscopic examinations seem to be less accurate in diagnosing a ring^[21,22]. This might be because endoscopic visualization of mucosal rings depends on proper distension of the esophagogastric region beyond the caliber of the ring, which is often not accomplished. This is especially true for the detection of wider rings^[23].

SRs are frequently associated with erosive reflux esophagitis. Histologically, this might be reflected by increased tissue eosinophilia^[24]. Therefore, those patients were excluded from further analysis. In 17.1% of the patients in whom esophageal biopsies were obtained, an esophageal hypereosinophilia with ≥ 20 eosinophils/hpf was demonstrated. However, there also was significant overlap with EoE in more than half of those patients.

As was demonstrated in a previous study with a different cohort of patients, a SR is frequently associated with other esophageal disorders^[25]. In the current investigation, erosive esophagitis was found in a quarter of the patients. Because of the frequent association, gastroesophageal reflux has been discussed by some authors as the main etiological factor for the development of a SR ring^[4,25], while others have pointed out that GERD is only present in less than two-thirds of these patients and, therefore, might not be the only cause for the development of the ring^[5,6]. However, inflammation, as a main pathogenic factor in the development of a SR, might be supported by the fact that, in the present study, esophageal hypereosinophilia with ≥ 20 eosinophils/hpf was a common finding in patients in whom esophageal biopsies were obtained, but only half of them met the diagnostic criteria for EoE according to the AGA guidelines^[17].

In 6 of the 9 patients with esophageal hypereosinophilia, gastroesophageal reflux disease could not be excluded prior to the esophageal biopsy sampling and 3 patients complained of abdominal pain instead of symptoms of esophageal dysfunction. Because of this, they could not be diagnosed with EoE. Although some of these patients might have GERD, it is possible that some of these patients had early EoE. Particularly with regard to the fact that in 3 patients with an esophageal hypereosinophilia there was a surface layering of eosinophils, and in one a lamina propria fibrosis could be demonstrated, the findings were more typical of EoE than GERD^[19]. Therefore, it could be assumed that the prevalence of EoE might actually be higher than 9% in the presenting group of patients with SRs. The association

between SRs and EoE in children was first described by Nurko *et al*^[7]. In a further prospective study that evaluated the etiology of esophageal bolus obstruction in adults, SRs were diagnosed in 9 of 37 patients, five (55.5%) of whom also exhibited EoE^[9]. In contrast, such an association was not found in the investigation of Sgouros *et al*^[9]. These discrepancies were explained by differences in life style and the age distribution of the populations under investigation^[10]. Especially the latter argument could be supported by the results of Mackenzie *et al*^[8]. Although it remains under debate whether the association between SRs and EoE is merely a coincidental finding of two common diseases or whether they share a common pathophysiology, in our opinion these data support the latter.

In the last decade, EoE has been increasingly recognized as a cause of dysphagia and food impaction. It is a chronic, immune/allergen mediated clinic-pathological disease of the esophagus characterized by dense eosinophilic inflammation^[8]. The prevalence of EoE in an asymptomatic European population has been described as 0.4% and as 6.5% in a US population undergoing upper endoscopy for a variety of indications^[26,27].

However, similar to the SR, the etiology of EoE is not completely understood and the connection between GERD and SRs, as well as the connection between GERD and EoE is still under debate^[22,28]. Nevertheless, it is important to be aware of this association because biopsies should be taken from the esophagus in patients with symptoms of esophageal dysfunction despite the presence of a SR. This may be obvious in cases that present with endoscopic features suspicious of EoE, such as linear furrows, trachealization, white plaques or a narrow caliber esophagus^[18,29], but EoE may be present even in the absence of such features. Similar to other studies^[30,31], the current investigation demonstrated that one-third of the patients do not present endoscopic features suspicious of EoE. Thus, the presence of EoE would have been missed in those patients if no biopsies had been obtained. We therefore suggest that routine biopsies should be taken from the esophagus in all symptomatic patients even in the presence of a SR, because EoE might be additionally present, even in the absence of other suggestive endoscopic features.

On the other hand, among the 25 patients that had endoscopic features suggestive of EoE, the diagnosis was confirmed by means of biopsy in only 28%. Therefore, endoscopic findings might not be reliable for supporting a diagnosis of EoE.

In the present study, the patients with SRs and EoE presented with symptoms of dysphagia, food impactions, and heartburn, all of which have been described as leading symptoms in both clinical entities^[3,18,32]. Similar to previous observations of EoE, patients with SRs and EoE were younger and had a history of allergies more often than patients with SRs alone^[18,29,30]. However, EoE was diagnosed in patients with SRs older than 50 years, in whom EoE was of unclear significance. It could be spec-

ulated that these patients had a late onset of the disease or that it represents a late diagnosis of a long-standing disease. The latter explanation might be more reasonable, due to the fact that EoE in adults is chronic and often indolent, especially when patients adapt their chewing habits over time^[33].

In contrast to other studies of EoE^[29,34], there was no gender preference in cases with SR and EoE, in comparison to those with SRs alone. This observation, however, might be due to a male preponderance for patients with SRs in the current investigation.

Endoscopically, patients with EoE had a tendency to have narrower rings than patients without EoE. Additional webs could be found significantly more often in patients with EoE than in patients without EoE. Although, 5%-15% of patients presenting with dysphagia are found to have esophageal webs^[16], the etiology is often unknown. At least one study also showed a possible association with EoE^[35], which was not confirmed by others^[28,36]. However, in our opinion, narrow SRs and esophageal webs should raise the suspicion of EoE.

This study has its limitation in that 24 h esophageal pH monitoring was not available; therefore, we cannot exclude the possibility that some of the patients with esophageal hypereosinophilia might have had GERD instead of EoE. We attempted to overcome this limitation by administering PPI before the endoscopy.

In summary, the current data strongly suggest that the association of SRs and EoE in adults is not a chance finding but is a rather frequent coincidence that should be considered whenever one is confronted with a patient exhibiting a SR. Endoscopic findings might not be reliable for supporting a diagnosis of EoE. Therefore, it appears advisable to obtain esophageal biopsies, not only in the presence of typical endoscopic features of EoE, but also whenever a SR is detected in symptomatic patients, especially when a ring is narrow or patients are younger and have a history of allergies.

COMMENTS

Background

The Schatzki ring (SR) is the most common cause of episodic dysphagia to solid food, but its etiology and pathogenesis remain unknown. The most common theory as to its origin suggests inflammation, with gastroesophageal reflux disease (GERD) as the main cause of inflammation. However, an association with GERD could only be documented in less than two-thirds of the patients, suggesting that additional pathogenetic factors must be considered.

Research frontiers

Eosinophilic esophagitis (EoE) is an emerging inflammatory esophageal disorder that can cause fibrosis with thickening of the esophageal mucosa, submucosa and muscularis. Therefore, EoE as a pathogenic factor for the development of SRs would support the "inflammation theory". However, the causal relationship between SRs and EoE in adults is controversial.

Innovations and breakthroughs

Recent reports have demonstrated an association of SRs with EoE in children. The present study shows that a significant proportion of adult patients with SRs also exhibit EoE and that endoscopic findings are not reliable for supporting a diagnosis of EoE. Furthermore, predictors of an association of SRs with EoE were younger age, presence of dysphagia or food impaction, narrow rings and a history of allergies.

Applications

The study results suggest that esophageal biopsies should be obtained, not only in the presence of typical endoscopic signs for EoE, but also whenever a SR is detected in symptomatic patients, especially if the ring is narrow and if the patient is younger and has a history of allergies.

Peer review

This paper enrolled one hundred seventy-one patients with endoscopically diagnosed SRs who were prospectively registered and followed. EoE was diagnosed in 9% of the patients with SRs, some of whom did not present with typical endoscopic features of EoE. Therefore esophageal biopsies are warranted in patients presenting with SRs, not only in the presence of endoscopic findings suggestive of EoE, but also whenever a SR is detected.

Abstract

AIM: To analyze sex differences in adverse drug reactions (ADR) to the immune suppressive medication in inflammatory bowel disease (IBD) patients.

METHODS: All IBD patients attending the IBD outpatient clinic of a referral hospital were identified through the electronic diagnosis registration system. The electronic medical records of IBD patients were reviewed and the files of those patients who have used immune suppressive therapy for IBD, i.e., thiopurines, methotrexate, cyclosporine, tacrolimus and anti-tumor necrosis factor agents (anti-TNF); infliximab (IFX), adalimumab (ADA) and/or certolizumab, were further analyzed. The reported ADR to immune suppressive drugs were noted. The general definition of ADR used in clinical practice comprised the occurrence of the ADR in the temporal relationship with its disappearance upon discontinuation of the medication. Patients for whom the required information on drug use and ADR was not

available in the electronic medical record and patients with only one registered contact and no further follow-up at the outpatient clinic were excluded. The difference in the incidence and type of ADR between male and female IBD patients were analyzed statistically by χ^2 test.

RESULTS: In total, 1009 IBD patients were identified in the electronic diagnosis registration system. Out of these 1009 patients, 843 patients were eligible for further analysis. There were 386 males (46%), mean age 42 years (range: 16-87 years) with a mean duration of the disease of 14 years (range: 0-54 years); 578 patients with Crohn's disease, 244 with ulcerative colitis and 21 with unclassified colitis. Seventy percent (586 pts) of patients used any kind of immune suppressive agents at a certain point of the disease course, the majority of the patients (546 pts, 65%) used thiopurines, 176 pts (21%) methotrexate, 46 pts (5%) cyclosporine and one patient tacrolimus. One third (240 pts, 28%) of patients were treated with anti-TNF, the majority of patients (227 pts, 27%) used IFX, 99 (12%) used ADA and five patients certolizumab. There were no differences between male and female patients in the use of immune suppressive agents. With regards to ADR, no differences between males and females were observed in the incidence of ADR to thiopurines, methotrexate and cyclosporine. Among 77 pts who developed ADR to one or more anti-TNF agents, significantly more females (54 pts, 39% of all anti-TNF treated women) than males (23 pts, 23% of all anti-TNF treated men) experienced ADR to an anti-TNF agent [$P = 0.011$; odds ratio (OR) 2.2, 95%CI 1.2-3.8]. The most frequent ADR to both anti-TNF agents, IFX and ADA, were allergic reactions (15% of all IFX users and 7% of all patients treated with ADA) and for both agents a significantly higher rate of allergic reactions in females compared with males was observed. As a result of ADR, 36 patients (15% of all patients using anti-TNF) stopped the treatment, with significantly

higher stopping rate among females (27 females, 19% vs 9 males, 9%, $P = 0.024$).

CONCLUSION: Treatment with anti-TNF antibodies is accompanied by sexual dimorphic profile of ADR with female patients being more at risk for allergic reactions and subsequent discontinuation of the treatment.

INTRODUCTION

The existence of a sex dimorphic profile of adverse drug reactions (ADR) has been increasingly recognized in recent years. Several studies on various therapeutics pointed to differences between sexes in the incidence as well as character of ADR. In general, females seem to be more at risk for ADR to various medication, 70% of drug users with ADR in a large cohort of 2367 patients being women^[1]. In addition to this generally increased risk of ADR, female patients also differ from males in terms of types of ADR to a range of medication such as antiarrhythmics, antipsychotics, anti-retroviral drugs, and analgesics^[2,3].

A limited number of small size studies performed in the field of auto-immune diseases and transplant medicine suggested existence of a sexual dimorphic profile of ADR to immunosuppressive medication, but this has not been studied in depth. Male sex has been reported as a risk factor for nodular regenerative hyperplasia in inflammatory bowel disease (IBD) patients treated with azathioprine^[4]. In rheumatoid arthritis patients' population, males have been shown to be more at risk than females for methotrexate-associated interstitial pneumonia^[5] and to bacterial pneumonia complicating treatment with infliximab (IFX)^[6]. For females, a higher incidence of azathioprine-related alopecia has been reported in transplant recipients^[7]. In a pediatric population of Crohn's disease (CD) patients, female sex was one of the risk factors for infusion reactions to anti-tumor necrosis factor (anti-TNF) treatment^[8] and in an adult population of ankylosing spondylitis patients, females were more at

risk of discontinuation of anti-TNF agents^[9].

The sexual dimorphism of the immune responses is a generally accepted concept that has been studied predominantly in the context of the female predominance in autoimmune disorders^[10] with the most important factor determining this dimorphism being the immunomodulatory properties of sex hormones. Considering these differences between the two sexes in basic immune reactions, further modulation of immune response by the immunosuppressive medication might have sex-specific consequences, including the quantitative and qualitative differences in ADR to these agents.

The limitations resulting from ADR for further therapeutic strategy in patients with chronic inflammatory conditions such as IBD are important. The ADR occurring in up to 20% of IBD patients using immune suppressive and anti-TNF agents^[11,12] represent an important factor leading to the modulation or discontinuation of effective treatment. The thorough understanding of the underlying mechanism of ADR to these drugs, including the sex-related differences would help optimizing the therapy in these patients.

Therefore, in the present study we aimed to specifically determine the difference between male and female IBD patients in the occurrence and type of ADR to commonly used immunosuppressive agents, including 'classical' immune suppressive medication, i.e., thiopurines and methotrexate, as well as anti-TNF agents.

MATERIALS AND METHODS

Patients

All IBD patients attending the outpatient clinic of the Department of Gastroenterology and Hepatology of the Erasmus MC as of January 2009 were identified through the electronic diagnosis registration system. The medical records were reviewed with emphasis on details of drug treatment. Reported ADR to immune suppressive medication used for IBD were noted. Patients for whom the required information on drug use and ADR was not available in the electronic medical record and patients with only one registered contact and no further follow-up at the outpatient clinic were excluded.

Definition of ADR

All ADRs designated as such by the treating physician in the medical record were registered. The general definition of ADR used in clinical practice comprised the occurrence of the ADR in the temporal relationship with its disappearance upon discontinuation of the medication. In case of doubt about other concomitant factors contributing to the ADR a positive re-challenge was considered to be necessary for the event to be definitely categorized as ADR.

The ADR to immunosuppressive agents were divided into the following categories according to the type of symptom/event: gastro-intestinal, arthralgia and/or myalgia, cutaneous, infectious, malignancy, myelosuppression, hepatotoxicity, or pancreatitis. In case of anti-TNF

¹For each categorical variable number and percentage of males within the group is displayed; ²*P* values for test of the sex-related differences; two-sided χ^2 test for categorical variables and *t*-test for continuous variables. Anti-TNF: Anti-tumor necrosis factor agents; CD: Crohn's disease; UC: Ulcerative colitis.

agents, additional categories of allergic reactions, lupus-like syndrome, and injection-site reactions were used.

Gastro-intestinal ADR comprised abdominal pain recognized by the patient as different from the IBD-related pain, diarrhea, nausea, and vomiting. Cutaneous ADR were defined as any kind of reported skin abnormality that occurred in temporal relationship with the treatment and resolved after cessation of the medication. Remittent or opportunistic infections occurring during the immunosuppressive treatment were noted as infectious ADR. For malignancies, any malignancy that was revealed during the use of the treatment was categorized as ADR.

Myelosuppression was defined as leucopenia (leucocytes count < $4.0 \times 10^9/L$), and/or anemia (hemoglobin level < 8.5 mmol/L for males and < 7.5 mmol/L for females) and/or thrombocytopenia (thrombocytes count < $1.5 \times 10^{11}/L$). To categorize abnormal liver tests as hepatotoxic ADR, the increase of liver tests above 2 times upper normal value and absence of other causes, i.e., viral or autoimmune were required. Drug-induced pancreatitis was defined as a new abdominal pain and hyperamylasemia occurring during the treatment.

Any of the following symptoms occurring during or within one day after infusion alone or in combination were considered as allergic reactions: skin reactions, dyspnoea, chest pain, low blood pressure, angioedema, fever and/or chills. Dyspnoea, skin abnormalities and arthralgia/myalgia occurring later than two days after infusion were categorized separately as potential delayed allergic reactions. Any motoric or sensoric loss, paresthesia and/or seizures were categorized as neurological ADR. Lupus-like syndrome diagnosis was characterized as the combination of arthritis and/or flu-like symptoms or fever and presence of anti-nuclear and or anti-double strand DNA antibodies. Injection site reactions (appli-

cable for adalimumab-ADA) were defined as pain or local skin reaction after injection.

Non-specific ADR which could not be categorized according to these criteria were analyzed together and are further referred as others.

Demographic characteristics and the use of medication

In total, 1009 IBD patients were identified in the electronic diagnosis registration system. Out of these 1009 patients, 843 patients were eligible for analysis according to the exclusion criteria stated in the methods part. There were 386 males (46%), mean age 42 years (range: 16-87 years) with a mean duration of the disease of 14 years (range: 0-54 years); 578 patients with CD, 244 with ulcerative colitis and 21 with unclassified colitis. There were no differences between male and female patients with regard to age and disease duration; significantly more males suffered from ulcerative colitis (141 pts, 58% of all ulcerative colitis patients).

Seventy percent (586 pts) of patients used any kind of immunosuppressive agents during the disease course, the majority of the patients (546 pts, 65%) used thiopurines, 176 pts (21%) methotrexate, 46 pts (5%) cyclosporine and one patient tacrolimus. No differences between male and female patients were observed with regard to the frequency of use of immunosuppressive agents in general or of particular agent.

One third (240 pts, 28%) of patients were treated with anti-TNF, the majority of patients (227 pts, 27%) used IFX, 99 (12%) ADA and five patients certolizumab. There were no sex-related differences in the use of anti-TNF agents (Table 1).

Statistical analysis

The sex-related differences in categorical variable were analyzed statistically using two-sided χ^2 testing, for continuous variables a two-sided independent *t*-test was used. *P*-values < 0.05 were considered significant. The analysis was performed using SPSS PASW 17 software.

RESULTS

ADR to immune suppressive agents

In total 278 patients experienced ADR to immunosuppressive agents; of which 155 patients to thiopurines (28% of all thiopurine-treated patients), 44 to methotrexate (25%), 2 (4%) to cyclosporine, and 77 pts (32%) developed ADR to one or more anti-TNF agents. As the age may represent an important factor influencing the development of ADR, a subanalysis was performed to compare the mean age between the groups of patients with and without ADR to immune suppressive agents and to anti-TNF agents. The mean age between the patients with and without ADR did not differ neither in the groups with ADR to immune suppressive agents (mean \pm SEM, 41 ± 1 years in the group with ADR *vs* 40 ± 0.7 years in the group without ADR; *P* = 0.76) nor in the group with ADR to anti-TNF (mean \pm SEM, 37 ± 1.5 years in the group with ADR *vs* 40 ± 1 year in the group

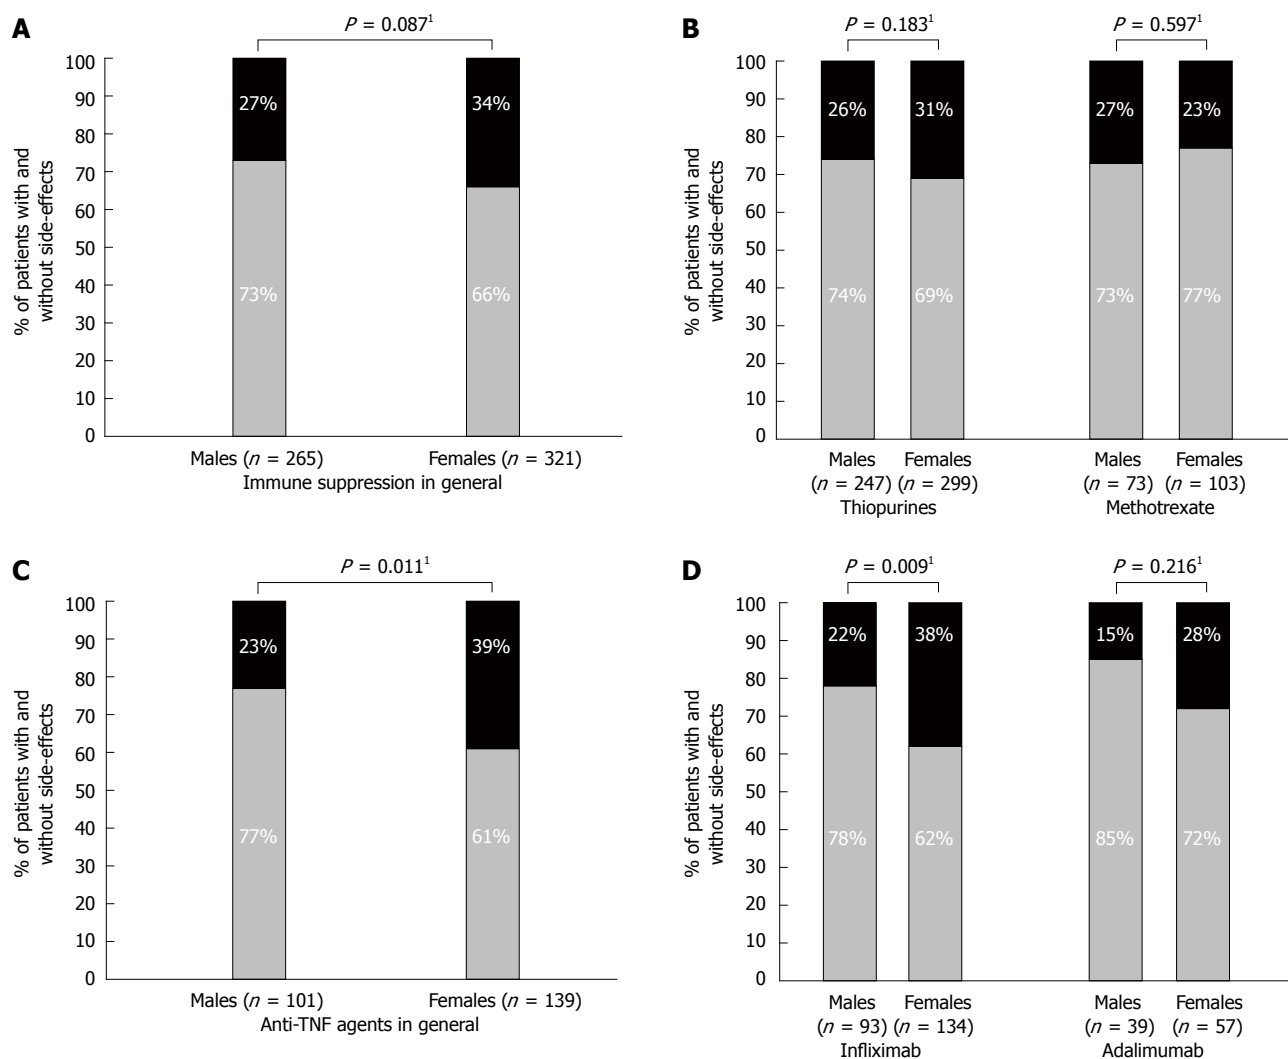

Figure 1 Relative percentages of male and female patients experiencing adverse drug reactions to “classical” immune suppressive agents (thiopurines, methotrexate, cyclosporine and tacrolimus) and anti-tumor necrosis factor agents. A: Adverse drug reactions (ADR) to immune suppressive agents in general; B: ADR to respective immunosuppressive agents; C: ADR to anti-tumor necrosis factor agents (anti-TNF) in general; D: ADR to respective anti-TNF agents. ¹Two-sided χ^2 test. Black bars: ADR present; Gray bars: No ADR.

without ADR to anti-TNF; $P = 0.79$).

Overall, there were no significant differences in the frequencies of the ADR to immune suppressive agents between males and females. In total, 27% of males (71 pts) experienced ADR to any kind of immune suppressive agent compared to 34% of females (108 pts; $P = 0.087$), (Figure 1A).

Among thiopurines users, 26% of males (63 pts) and 31% of females (92 pts) suffered from ADR to thiopurines ($P = 0.183$; Figure 1B). The most frequent ADR to thiopurines were myelosuppression, hepatotoxicity (both in 33 pts, 6%) and gastro-intestinal ADR (23 pts, 4%), (Table 2). No differences between male and female patients were observed with regard to specific type of ADR to thiopurines.

In the group of patients treated with methotrexate, 27% (20 pts) of males and 23% (24 pts) of females experienced ADR ($P = 0.597$; Figure 1B). The most frequent ADR to methotrexate were hepatotoxicity and gastro-intestinal ADR (both in 10 pts, 6%) (Table 2).

Out of 46 pts treated with cyclosporine, two female

patients experienced an ADR, one developed pseudo-membranous colitis following treatment but she was also treated with systemic steroids. The second patient had a cutaneous reaction to cyclosporine.

Among 77 pts who developed ADR to one or more anti-TNF agents, significantly more females (54 pts, 39% of all anti-TNF treated women) than males (23 pts, 23% of all anti-TNF treated men) experienced ADR to an anti-TNF agent [$P = 0.011$; odds ratio (OR) 2.2, 95%CI 1.2-3.8] (Figure 1C). In the subanalysis of respective anti-TNF agents, significantly more females (51 pts, 38% of all IFX-treated women) than males (20 pts, 22% of all IFX-treated men) suffered from ADR to IFX ($P = 0.009$; OR 2.2, 95%CI 1.2-4.1) (Figure 1D). Relatively more females than males experienced ADR to ADA (16 females; 28% vs 6 males; 15%), this difference was not significant though ($P = 0.216$) Figure 1D.

The most frequent ADR to both IFX and ADA were allergic reactions (15% of all IFX users and 7% of all patients treated with ADA) and for both agents a significantly higher rate of allergic reactions in females com-

pared with males was observed (Table 3). There were no other sex-specific ADR observed to anti-TNF agents.

Of 77 patients experiencing ADR to an anti-TNF agent, 36 pts stopped the treatment (47%; overall discontinuation rate 15%), 27 pts (35%) switched to another anti-TNF agent, and 14 pts (18%) continued the treatment. As a result of ADR, 27 females (19% of all anti-TNF-treated women) stopped the treatment compared with 9 males (9% of all anti-TNF-treated men; $P = 0.024$). Furthermore, significantly higher proportion of females (21 pts, 15% of all anti-TNF-treated women) switched to another anti-TNF agents compared with males (6 pts, 6% of all anti-TNF-treated men; $P = 0.026$) significantly more frequently than males.

In the subanalysis of the influence of disease type and the use of immune suppression as a co-medication with anti-TNF treatment, no differences were found between the group of patients with ADR to anti-TNF compared with patients without ADR. Overall, 138 patients (58%) were on the combo therapy. Out of these 138 patients, 43 patients (31%) developed ADR to anti-TNF vs 34 patients (33%) with ADR from the group not using combo therapy ($P = 0.78$).

DISCUSSION

In this large retrospective study, we studied sex differences in the frequency and types of ADR to immune suppressive medication in IBD patients. In contrast to thiopurines and methotrexate with similar rates of ADR in both sexes, we observed a sex dimorphic profile of ADR to anti-TNF agents with higher frequency of ADR among female IBD patients compared with male patients. With regard to particular types of ADRs, females experienced more often allergic reactions to the most frequently used anti-TNF agents, IFX and ADA. In addition, these ADR have led to discontinuation of treatment more frequently in females than males, thus substantially limiting the long term use of anti-TNF agents by female patients.

The landmark randomized controlled trials on IFX and ADA efficacy and safety did not reveal sex dimorphic profile of ADR to anti-TNF agents^[13-17]. However, the design of these studies with rather short follow-up might underestimate the overall incidence of ADR and immune-mediated ADR occurring at long term in particular. This would subsequently limit the sample size to study specific risk factors for the development of ADR.

Another source of information on ADR, the safety registry with inclusion of patients being at the physicians' discretion are difficult to interpret with regard to sex differences in ADR incidence due to the possible selection bias and also a rather short follow-up^[18]. Interestingly, in a large retrospective, real-life study on long-term safety of IFX for the treatment of IBD, female sex was shown to be an independent risk factor for the development of hypersensitivity reactions and dermatological ADR to IFX^[12]. In addition, one small size study with pediatric CD patients determined female sex as one of the risk factors for infusion reactions^[8]. Thus, our results, in line with previous reports, suggest that female IBD patients are at specific risk for hypersensitivity reactions to monoclonal anti-TNF antibodies.

For each drug group with sex dimorphic ADR profile specific considerations for underlying mechanisms are applicable. The basic pharmacokinetic differences between the genders were at first considered to cause the predominance of ADR to some drugs in females, but over the past years, it became evident that sex hormones interacted with the particular drugs' metabolism and mechanisms of action^[3]. The sex hormones greatly influence the immune responses which might also account for the sex differences in ADR to immune system modulating therapy. However, in the present study, only biological anti-TNF agents and no other immunosuppressive treatment showed a specific ADR sex dimorphic profile. In addition, the particular ADR presenting more frequently in females were hypersensitivity reactions, suggesting a female-specific immunogenic potential related to biological therapy.

ADR to monoclonal anti-TNF antibodies have been shown to be related to the development of antibodies against these agents. Anti-infliximab as well anti-adalimumab antibodies are found in the sera of patients with loss of response and/or ADR to IFX or ADA^[19-23], suggesting thus the humoral immune response as underlying mechanism of IFX- and ADA- related immunogenicity. Interestingly, some studies analyzing the sex differences in the humoral response to vaccinations showed higher antibody titers in females^[24,25] and more local and systemic adverse reactions to influenza and rubella vaccines have been observed in women compared with men^[26,27]. The underlying mechanism of these sex differences in humoral immune response in general is not elucidated thus far, but taken all these observational data together, it is tempting to speculate that the use of monoclonal antibodies against TNF- α might result in higher anti-anti-TNF antibodies formation rate in female patients which in turn would lead to the female-specific higher incidence of immune-mediated ADR.

This immunogenic potential of anti-TNF agents resulting in ADR has important consequences for the management of IBD patients using these drugs. In this study, up to 50% of patients experiencing ADR discontinued the treatment, with the overall discontinuation rate of all patients using anti-TNF agents being 15%. There

are thus considerable potential limitations of long term use of these otherwise effective drugs. Understanding the underlying mechanisms, one of which might be female-specific immunogenicity would subsequently help to identify patients at risk and modify the therapeutic strategy accordingly.

To our knowledge, this is the first report studying the sex differences in ADR profile to immunosuppressive medication in a large cohort of patients with immune-mediated disease. The main limitation of our study is its retrospective design in which reporting bias of ADR is inevitable due to the lack of a standardized protocol that would ensure a meticulous screening of every treated patient in a prospective study design. This might particularly affect a study dealing with sex-related differences due to the psychosocial specificities of the two sexes in reporting ADRs. On the other hand, we analyzed sex-related ADRs profile to several immunosuppressive drugs in this large cohort. We found the sex dimorphism specifically applying only for anti-TNF agents and no other medication which would be the case if this reporting bias ensuing from retrospective design was substantially to modify the findings.

In conclusion, female IBD patients are at increased risk of hypersensitivity reactions to anti-TNF agents compared with males. These ADR have important clinical consequences as they lead to the discontinuation of the treatment in half of the patients experiencing these reactions. Further research, with a specific consideration of sex dimorphism of the immunogenic potential of anti-TNF agents is warranted in order to improve the clinical management of patients at risk for ADR.

COMMENTS

Background

Adverse drug reactions (ADR) to immune suppressive agents used for inflammatory bowel disease (IBD) limit the treatment in up to 20% of patients. For various drugs, sex dimorphic profile of ADR has been documented but this has not been studied in depth in case of immune suppressive medication.

Research frontiers

Sex has great impact on the various physiological and pathophysiological processes including pharmacokinetics and pharmacodynamics. The immune responses differ between men and women and therefore, it is presumable that the response to immune suppressive treatment may have specific profile in male and female patients. This could specifically apply for the ADR that are immune-mediated, such as the reactions to biological therapy. With the current situation of immunogenicity of biologicals being the main limitation of this otherwise effective therapy, identifying patients with high immunogenic potential is one of the possible strategies to enhance the overall success of anti-tumor necrosis factor agents (anti-TNF) therapy.

Innovations and breakthroughs

In the present study, authors show that female IBD patients are more at risk for allergic reactions to infliximab and adalimumab compared with male patients. This sex-dimorphic profile of ADR seems to be specific to biological therapy and not a general feature of immune suppressive medication since no sex-specific ADR to thiopurines and methotrexate were observed. This increased risk for ADR to biological has been reported previously in small sample size studies of patients with various immune-mediated conditions but has not been studied as a particular phenomenon in IBD patients.

Applications

The described phenomenon of increased immunogenic potential of anti-TNF

agents in females compared to males has important consequences for the management of IBD patients using these drugs. In this study, up to 50% of patients experiencing ADR to anti-TNF discontinued the treatment, with the overall discontinuation rate of all patients using anti-TNF agents being 15%. There are thus considerable potential limitations of long term use of these otherwise effective drugs. Understanding the underlying mechanisms, one of which might be female-specific immunogenicity would subsequently help to identify patients at risk and modify the therapeutic strategy accordingly.

Peer review

This retrospective study in a cohort of 843 patients is aimed to specifically determine the difference between male and female IBD patients in the occurrence and type of ADR related to immunosuppressive agents (thiopurines, methotrexate, cyclosporine, tacrolimus), and anti-TNF agents (infliximab, adalimumab, certolizumab). The results indicate that IBD women are at increased risk for allergic reactions in the course of anti-TNF treatment.

Abstract

AIM: To investigate the utility of immunohistochemical (IHC) staining with an antibody to *Mycobacterium tuberculosis* (*M. tuberculosis*) for the diagnosis of intestinal tuberculosis (TB).

METHODS: We retrospectively identified 10 patients (4 males and 6 females; mean age = 65.1 ± 13.6 years) with intestinal TB. Clinical characteristics, including age, gender, underlying disease, and symptoms were obtained. Chest radiograph and laboratory tests, including sputum Ziehl-Neelsen (ZN) staining, *M. tuberculosis* culture, and sputum polymerase chain reaction (PCR)

for tubercle bacilli DNA, as well as Tuberculin skin test (TST) and QuantiFERON-TB gold test (QFT), were examined. Colonoscopic records recorded on the basis of Sato's classification were also reviewed, in addition to data from intestinal biopsies examined for histopathological findings, including hematoxylin and eosin staining, and ZN staining, as well as *M. tuberculosis* culture, and PCR for tubercle bacilli DNA. For the present study, archived formalin-fixed paraffin-embedded (FFPE) intestinal tissue samples were immunohistochemically stained using a commercially available species-specific monoclonal antibody to the 38-kDa antigen of the *M. tuberculosis* complex. These sections were also stained with the pan-macrophage marker CD68 antibody.

RESULTS: From the clinical data, we found that no patients were immunocompromised, and that the main symptoms were diarrhea and weight loss. Three patients displayed active pulmonary TB, six patients (60%) had a positive TST, and 4 patients (40%) had a positive QFT. Colonoscopic findings revealed that all patients had type 1 findings (linear ulcers in a circumferential arrangement or linear ulcers arranged circumferentially with mucosa showing multiple nodules), all of which were located in the right hemicolon and/or terminal ileum. Seven patients (70%) had concomitant healed lesions in the ileocecal area. No acid-fast bacilli were detected with ZN staining of the intestinal tissue samples, and both *M. tuberculosis* culture and PCR for tubercle bacilli DNA were negative in all samples. The histopathological data revealed that tuberculous granulomas were present in 4 cases (40%). IHC staining in archived FFPE samples with anti-*M. tuberculosis* monoclonal antibody revealed positive findings in 4 patients (40%); the same patients in which granulomas were detected by hematoxylin and eosin staining. *M. tuberculosis* antigens were found to be mostly intracellular, granular in pattern, and primarily located in the CD68⁺ macrophages of the granulomas.

CONCLUSION: IHC staining with a monoclonal antibody to *M. tuberculosis* may be an efficient and simple diagnostic tool in addition to classic examination methods for the diagnosis of intestinal TB.

INTRODUCTION

Tuberculosis (TB), a chronic granulomatous infectious disease caused by *Mycobacterium tuberculosis* (*M. tuberculosis*), is still a significant cause of morbidity and mortality worldwide. Due to the increasing prevalence of human immunodeficiency virus (HIV) infection and immunosuppressive therapy for various diseases, the global incidence of TB has increased^[1].

The gastrointestinal tract is a common site of extrapulmonary TB. The ileocecal region is frequently involved in most patients diagnosed with intestinal TB, although the diagnosis of intestinal TB is often difficult because of its diverse clinical manifestations and very low positivity using current diagnostic tests including Ziehl-Neelsen (ZN) staining and *M. tuberculosis* culture from intestinal tissue samples^[2]. More recently, detection of tubercle bacilli DNA by polymerase chain reaction (PCR) has been developed as a diagnostic tool with excellent sensitivity and specificity in respiratory specimens. However, diagnosis by PCR in clinical settings still requires validation^[3]. Therefore, diagnosis is generally made on the basis of the classical histopathological demonstration of a caseating epithelioid cell granuloma, which is suggestive of TB. However, it may be difficult to differentiate intestinal TB from Crohn's disease based on this technique due to the fact that intestinal TB and CD have similar clinical, colonoscopic, and pathological findings. Although it is well known that caseating granulomas are a feature of TB, and non-caseating granulomas are that of CD, the prevalence of caseation is low in clinical settings for intestinal tuberculous granuloma^[4,5].

mas^[4,5].

The present study was conducted to investigate the utility of immunohistochemical (IHC) staining with a species-specific monoclonal antibody to the 38-kDa antigen of the *M. tuberculosis* complex to diagnose intestinal TB in archived formalin-fixed paraffin-embedded (FFPE) intestinal tissue sections of suspected intestinal TB patients.

MATERIALS AND METHODS

Patients

We retrospectively identified 10 patients (4 males and 6 females; mean age, 65.1 ± 13.6 years) with intestinal TB between 1996 and 2011. All cases were obtained from the archives of the Department of Infectious, Respiratory, and Digestive Medicine at the University of the Ryukyus Hospital, Okinawa, Japan. The diagnosis of intestinal TB was made by at least one of the following criteria: (1) a positive culture of *M. tuberculosis* from the intestinal tissue; (2) histopathological demonstration of acid-fast bacilli (AFB) in the intestinal tissue; (3) histopathological demonstration of a caseating epithelioid cell granuloma in the intestinal tissue; (4) detection of tubercle bacilli DNA by PCR from the intestinal tissue; and (5) typical endoscopic features together with a favorable response to a trial of antituberculous therapy. These patients were all treated with a full course of anti-tuberculosis therapy (rifampicin, isoniazid, ethambutol, pyrazinamide) following diagnosis. The clinical and colonoscopic records of these patients were obtained, as well as archived FFPE intestinal tissue sections. This study was approved by the Ethics Committee of our institute.

Colonoscopy and histopathology

Colonoscopy was performed with standard colonoscopes (Olympus, Tokyo, Japan). All patients diagnosed with intestinal TB were examined from the rectum to terminal ileum after lavage bowel preparation with a polyethylene glycol electrolyte solution. Colonoscopic findings were recorded on the basis of Sato's classification^[6]. Open ulcers or erosions were classified into 4 types: type 1 (linear ulcers in a circumferential arrangement or linear ulcers arranged circumferentially with mucosa showing multiple nodules), type 2 (round or irregular-shaped isolated small ulcers arranged circumferentially without nodules), type 3 (multiple erosions restricted to the colon), and type 4 (small aphthous ulcers or erosions restricted to the ileum). Healed lesions in the ileocecal area were also recorded, including the patulous ileocecal valve (PV), pseudodiverticular deformity (PD), and atrophic mucosal area (AMA) with multiple ulcer scars^[6]. During colonoscopy, biopsy specimens were obtained in a routine fashion using standard forceps. The specimens were prepared for ZN staining, tuberculous culture, PCR for tubercle bacilli DNA, and hematoxylin and eosin (HE) staining.

Table 1 Clinical, laboratory and bacteriologic findings in patients with intestinal tuberculosis

Case	Age/gender	Underlying disease	Symptoms	Chest radiograph	Sputum ZN stain	Sputum culture	Sputum PCR	TST	QFT
1	38/F	Epilepsy	Fever	Active TB	+	-	+	+	ND
2	66/F	Lumber neuralgia	Diarrhea	Normal	-	-	-	+	ND
3	81/F	Cecal cancer	Diarrhea, weight loss	Active TB	+	-	-	ND	ND
4	72/M	Post-herpes neuralgia	Abdominal pain	Normal	-	-	-	+	+
5	43/M	Diabetes mellitus	Diarrhea	Normal	-	-	-	-	ND
6	76/M	Gout	Diarrhea	Normal	-	-	-	+	+

8	74/F	Gastric ulcer	Weight-loss	Active TB	+	-	-	+	+
9	74/F	Colonic polyp	None	Normal	-	-	-	ND	+
10	70/F	Rectal cancer	Diarrhea	Inactive TB	-	-	-	+	ND

TB: Tuberculosis; ZN: Ziehl-Neelsen; PCR: Polymerase chain reaction; TST: Tuberculin skin test; ND: Not determined; QFT: QuantiFERON-TB gold test; M: Male; F: Female.

IHC staining

IHC staining was performed using the IgG1 type mouse monoclonal antibody against the 38-kDa antigen of the *M. tuberculosis* complex (Vector Laboratories, Burlingame, CA, United States). 5 µm thick sections were prepared from formalin-fixed, paraffin-embedded tissue. IHC was carried out using the VECTASTAIN ABC kit (Vector Laboratories, Burlingame, CA, United States) as described elsewhere^[7-11]. Briefly, after deparaffinization and rehydration, the sections were exposed to antigen retrieval (Target retrieval solution pH 6.0, DakoCytomation, CA, United States) in high temperature water (98 °C) for 30 min, and then cooled for 20 min at room temperature. Endogenous peroxidase activity was inhibited by incubating the sections with hydrogen peroxide for 20 min. To prevent non-specific binding, these sections were incubated in normal mouse serum for 20 min. Primary antibody (anti-*M. tuberculosis* mouse monoclonal antibody in 1:80 dilutions) was applied to the sections overnight. This step was followed by washing and 40-min incubation with a biotinylated secondary antibody. These sections were then subjected to an avidin biotin-peroxidase complex for 40 min. Visualization was performed using ImmPACT DAB (Vector Laboratories, Burlingame, CA, United States), which was applied for 10 s. Sections were counter-stained with hematoxylin. A negative control in which the primary antibody was substituted with antibody diluent was used. IHC expression of the *M. tuberculosis* antigen was evaluated under light microscopy for the distribution of stain in the cytoplasm of epithelioid histiocytes and multinucleated giant cells. Additional IHC staining was performed to evaluate the relationship between *M. tuberculosis* antigen and macrophage distribution in the colonic specimens. These paraffin sections were stained with anti-*M. tuberculosis* rabbit antibody (Abcam, Cambridge, MA) at a 1:200 dilution, and the pan-macrophage marker CD68 antibody (Leica Microsystem, Buckinghamshire, United Kingdom) at a 1:80 dilution using the streptavidin-biotin peroxidase method as described previously.

RESULTS

Clinical features

Clinical features of the 10 patients are summarized in Table 1. No patients were immunocompromised, including immunosuppressive medication use and HIV infection. Primary symptoms were diarrhea and weight loss. Although no patients had respiratory symptoms, chest radiograph and sputum ZN staining in 3 patients revealed active pulmonary TB. Six patients (60%) had a positive Tuberculin skin test (TST) and four patients (40%) had a positive QuantiFERON-TB gold test (QFT), of which three patients had both a positive TST and QFT test.

Colonoscopic, bacteriological, and histopathological findings

Colonoscopic, bacteriological, and histopathological findings of the 10 patients are summarized in Table 2. All patients had type 1 findings (linear ulcers in a circumferential arrangement or linear ulcers arranged circumferentially with mucosa showing multiple nodules), all of which were located in the right hemicolon and/or terminal ileum (Figure 1A). Seven patients (70%) had concomitant healed lesions, including PV, PD, or AMA, in the ileocecal area (Figure 1B). No AFB was detected with ZN staining of the intestinal tissue samples. Tuberculous culture and PCR for tubercle bacilli DNA were negative in all intestinal tissue samples.

In the histopathological studies, tuberculous granulomas were identified in 4 cases (40%) (Figure 2A). IHC staining with anti-*M. tuberculosis* monoclonal antibody was positive in these same 4 patients (40%). The mycobacterial antigens were mainly detected as granular cytoplasmic staining in the epithelioid cells and giant cells within granulomas (Figure 2B). All samples in which granulomas were detected by HE staining were positive for TB by IHC staining. As for the relationship between *M. tuberculosis* antigens and macrophage distribution in the colonic consecutive specimens, the mycobacterial

Table 2 Colonoscopic, bacteriologic and histopathological findings in patients with intestinal tuberculosis

TI: Terminal ileum; C: Cecum; A: Ascending colon; T: Transverse colon; D: Descending colon; S: Sigmoid colon; PV: Patulous ileocecal valve; PD: Pseudodiverticular deformity; AMA: Atrophic mucosal area; AFB: Acid-fast bacilli; ZN: Ziehl-Neelsen; PCR: Polymerase chain reaction; IHC: Immunohistochemical; TB: Tuberculosis.

Figure 1 Typical colonoscopic views of intestinal tuberculosis. A: Colonoscopy shows a circumferential ulcer with edematous flared nodules in the ascending colon (patient 1); B: Colonoscopy shows a whitish mucosal area with an absence of the normal vascular pattern of healed ulcer scars in the ascending colon. Note the concomitant active ulcers in the proximal colon (patient 2).

antigens were seen predominantly as coarse granular immunopositive material in CD68⁺ macrophage cytoplasm (Figure 2C, D).

Clinical course and outcome

All patients were suspected to have intestinal TB on the basis of clinicopathologic findings. The regimen for TB was combined chemotherapy containing isoniazid, rifampicin, and ethambutol for six months and pyrazinamide for two months. All patients responded to antituberculous therapy and follow-up colonoscopies showed improvement of the colonic lesions.

DISCUSSION

This study has highlighted several important considerations. Most patients in this study had abdominal symptoms, and although no patients had respiratory symptoms, 4 (40%) had concomitant active or inactive pulmonary TB, consistent with prior reports in which pulmonary TB was apparent in less than 25% of patients with intestinal TB^[2,12]. Based on these findings, we should be aware of the possibility of tuberculous involvement in multiple organs despite apparent symp-

toms.

Although the TST has long been used as a reliable diagnostic examination, the recently developed QFT has been increasingly applied. There is controversy as to whether or not the QFT is effective for the diagnosis of extrapulmonary TB. Kim *et al*^[13] reported that in a prospective study of 128 patients, QFT was a limited but useful aid in combination with the TST in the diagnosis of intestinal TB. In agreement with their findings, the QFT and TST had a good agreement in our study.

In this study, the vast majority of cases were colonoscopically diagnosed with TB. Similar to previous studies^[6,14], all patients in our study had a type 1 appearance among colonoscopic findings. Although this type has been established as a reliable colonoscopic feature, recent studies have emphasized that healed lesions in the ileocecal area, including PV, PD, and AMA with multiple ulcer scars, can coexist with active tuberculous inflammation. Sato *et al*^[6] reported that 91% of patients in their study have AMA lesions, and so concluded that the AMA was the most frequently recognized endoscopic manifestation of intestinal TB. Our data, in which 60% of patients had these lesions, correlates strongly with their findings.

Figure 2 Histopathological views of tuberculous granuloma and localization of the mycobacterial antigen in the colonic lesion (patient 8). A: A granuloma, surrounded by inflammatory lymphocytes, is present in the lamina propria (hematoxylin and eosin, $\times 200$); B: Immunohistochemical staining view of the colonic specimen ($\times 200$). Note that the mycobacterial antigens (brownish granular matter) are present in the cytoplasm of epithelioid histiocytes and multinucleated giant cells in the granuloma; C: Cells stained with the pan-macrophage marker CD68 antibody are present in the granuloma ($\times 400$); D: The mycobacterial antigens (brownish granular matter) are present in the cytoplasm of the macrophages in the granuloma ($\times 400$).

Numerous studies have compared the diagnostic methods of intestinal TB^[15]. A study by Sekar *et al.*^[16] evaluated the role of PCR in the laboratory diagnosis of different forms of extrapulmonary TB in comparison with conventional bacteriologic techniques. They found an 18%, 22%, and 63% sensitivity for smear, culture, and PCR, respectively. A recent study clearly demonstrated that using real-time PCR technology with fluorescence resonance energy transfer probes has much higher sensitivity for the detection of tubercle bacilli DNA in tissue biopsy samples and FFPE surgically resected tissues of the gastrointestinal tract than traditional PCR^[17]. Our negative AFB and PCR tests may be due to a small biopsy sample size.

There have been several studies on IHC staining for the diagnosis of TB in which the most used polyclonal antibodies^[18,19] resulted in false-positive reactions. There are only two studies that have evaluated IHC staining with a species-specific monoclonal antibody to 38-kDa antigen of *M. tuberculosis* complex in archival FFPE tissue sections of intestinal TB. Goel *et al.*^[7] demonstrated that 2/2 samples tested had positive IHC staining (100%), whereas Ince *et al.*^[8] demonstrated IHC positivity in 6/8 (75%) intestinal tuberculous granulomas. Our results revealed 4 positive samples using IHC staining out of 4 tuberculous granulomas, whereas ZN staining for AFB was negative in all of these sections. Our results dem-

onstrating that granulomas detected with HE staining are all positive with IHC have confirmed these previous findings. It is important to note that this was a retrospective study on previously diagnosed TB; hence we cannot determine the false positivity rate of IHC staining for intestinal TB.

Granular cytoplasmic staining of *M. tuberculosis* in IHC staining is considered to be due to fragments or debris of the bacilli^[7]. Low positivity of AFB could be due to the fact that only the intact bacilli take up the stain. The fact that fragments or debris of *M. tuberculosis* can be detected easily using IHC staining may be a great advantage. To the best of our knowledge, this is the first report that demonstrates that *M. tuberculosis* antigens are located as coarse granular immunopositive material in the cytoplasm of CD68⁺ macrophages within human intestinal TB. This finding may help to uncover the unknown relationship between *M. tuberculosis* and macrophages^[20].

Distinguishing intestinal TB from CD is still challenging^[21-25], and the treatments of TB and CD are quite different. Corticosteroids, immunosuppressive and anti-tumor necrosis factor (TNF) agents are widely applied in the treatment of CD, whereas they may be harmful in TB. For example, anti-TNF agents can induce reactivation of TB; therefore differentiating TB from CD is extremely important. Histopathological features en-

countered frequently in intestinal TB include granulomas that are confluent, large ($> 200 \mu\text{m}$), and multiple in number (> 5 per section)^[26]. The classical histological picture of tuberculous granulomatous inflammation is not a diagnostic problem in tissue samples; however, when sections show non-caseous epithelioid granulomas mimicking TB as is the case in CD, it creates a diagnostic dilemma. In the present study, we did not conduct any experiments using intestinal samples of CD; however Ince *et al*^[8] concluded that positive IHC staining with species-specific antibodies to TB can rule out the diagnosis of CD with high sensitivity and specificity. We plan to conduct a large-scale study to confirm these findings in the future.

In conclusion, IHC staining using a monoclonal antibody to *M. tuberculosis* antigen, which is a novel translational implication, can potentially be an efficient and simple diagnostic tool to compliment classic clinicopathological examinations for the diagnosis of intestinal TB.

ACKNOWLEDGMENTS

We thank the clinical staff of the Department of Infectious, Respiratory, and Digestive Medicine, Faculty of Medicine, University of the Ryukyus for their aid in collecting clinical data.

COMMENTS

Background

The diagnosis of intestinal tuberculosis (TB) is often difficult because of its diverse clinical manifestations and very low positivity using current diagnostics, including acid-fast bacilli in Ziehl-Neelsen staining and culture of *Mycobacterium tuberculosis* (*M. tuberculosis*) from intestinal tissue samples.

Research frontiers

Detection of *M. tuberculosis* DNA by polymerase chain reaction has been established as a diagnostic tool with excellent sensitivity and specificity in pulmonary TB. However, the diagnosis of intestinal TB still requires validation.

Innovations and breakthroughs

In this study, the authors have shown that immunohistochemical (IHC) staining using a monoclonal antibody to *M. tuberculosis* antigen in archived formalin-fixed paraffin-embedded intestinal tissue samples, which is a novel translational implication, can be an efficient and simple diagnostic tool to compliment classic clinicopathological examinations for the diagnosis of intestinal TB.

Applications

Although further studies are needed, IHC staining may be beneficial to differentiate TB from Crohn's disease (CD) with similar microscopic features, including the presence of granulomas.

Terminology

Monoclonal antibodies are monospecific antibodies which have monovalent affinity. IHC staining is widely applied to investigate the distribution of antigens in biological tissues by using specific antibodies.

Peer review

In this manuscript, the authors have clearly illustrated the potential advantage for the diagnosis of intestinal tuberculous granuloma. The importance of the research and its significance show that this topic is an important issue. The differentiation between TB and CD is very important in gastroenterology.

Abstract

AIM: To clarify the association between a polymorphism -449 C>G (rs72696119) in 5'-UTR of *NFKB1* with ulcerative colitis (UC).

METHODS: The studied population comprised 639 subjects, including patients with UC (UC cases, $n = 174$) and subjects without UC (controls, $n = 465$). We employed polymerase chain reaction-single strand conformation polymorphism to detect the gene polymor-

phism.

RESULTS: The rs72696119 G allele frequencies in controls and UC cases were 33.4% and 38.5%, respectively ($P = 0.10$). Genotype frequency of the GG homozygote in UC cases was significantly higher than that in controls ($P = 0.017$), and the GG homozygote was significantly associated with susceptibility to UC [odds ratio (OR), 1.88; 95%CI, 1.13-3.14]. In male subjects, the GG homozygote was associated with an increased risk for UC (OR, 3.10; 95%CI, 1.47-6.54; $P = 0.0053$), whereas this association was not found in female subjects. In addition, the GG homozygote was significantly associated with the risk of non-continuous disease (OR, 2.06; 95%CI, 1.12-3.79; $P = 0.029$), not having total colitis (OR, 2.40; 95%CI, 1.09-3.80, $P = 0.040$), disease which developed before 20 years of age (OR, 2.80; 95%CI, 1.07-7.32, $P = 0.041$), no hospitalization (OR, 2.28; 95%CI, 1.29-4.05; $P = 0.0090$) and with a maximum of 8 or less on the UCDAI score (OR, 2.45; 95%CI, 1.23-4.93; $P = 0.022$).

CONCLUSION: Our results provide evidence that *NFKB1* polymorphism rs72696119 was significantly associated with the development of UC. This polymorphism influences the susceptibility to and pathophysiological features of UC.

INTRODUCTION

Ulcerative colitis (UC) is precipitated by a complex interaction of environmental, genetic, and immunoregulatory factors^[1,2]. UC affects the colon and rectum and typically involves the innermost lining mucosa, manifesting as continuous areas of inflammation, with no segments of normal mucosa^[3]. The pathogenesis of UC is only partially understood. Recently, the important role of innate immune response in the pathogenesis of UC has been reported^[4]. In addition, some genes are associated with UC itself^[5]. We have previously investigated the association between genetic polymorphisms in several genes and susceptibility to UC^[6-9].

One of the linkage regions for inflammatory bowel diseases (IBD) has been mapped to chromosome 4q^[10]. In this region, the *NFKB1*, encoding 2 subunits (p50 and p105) of nuclear factor κ (NF)- κ B, is located (4q24)^[11]. NF- κ B is a pleiotropic transcription factor involved in diverse immunologic processes including regulation of the intestinal immune system^[12]. Dysregulation of NF- κ B has been demonstrated in different inflammatory disorders, including UC^[13]. Recently, many studies have reported the association between polymorphism rs28362491 (-94 ins/del ATTG of *NFKB1*) and various inflammatory diseases^[14]. However, these studies have not always led to the same conclusions. Furthermore, a genetic variation, rs72696119 (-449 C>G in 5'-UTR of *NFKB1*), has been identified. We previously reported a close association between *NFKB1* polymorphisms (rs28362491 and rs72696119) and aberrant gene methylation in gastric mucosa^[15].

In this study, we attempted to clarify the association between the *NFKB1* polymorphism, rs72696119 (-449 C>G), and susceptibility to UC.

MATERIALS AND METHODS

Clinical samples

The studied population comprised 639 subjects, including patients with UC (UC cases, $n = 174$), who were enrolled in Fujita Health University Hospital, and subjects without UC (controls, $n = 465$). The diagnosis of UC was based on standard clinical, endoscopic, radiological, and histological criteria^[16]. The control subjects had no

lower abdominal symptoms, diarrhea or hematochezia. Genomic DNA was isolated from peripheral blood using the FlexiGene DNA Kit (QIAGEN GmbH, Hilden, Germany).

The Ethics Committees of Fujita Health University and Kanazawa Medical University approved the protocol, and written informed consent was obtained from all the participating subjects.

Classification

According to their clinical courses, UC cases were classified into continuous disease and non-continuous disease (relapsing and only one episode)^[17]. UC patients were also classified as having total colitis or not having total colitis (left sided, distal colitis and proctitis) according to the location and extension of the inflammatory lesions judged by endoscopic findings.

Genotyping of polymorphisms

The polymorphism was genotyped by polymerase chain reaction (PCR)-single strand conformation polymorphism (SSCP) as previously reported^[15,18]. To detect *NFKB1* rs72696119 C>G, using the primer pairs (449F: 5'-cgtgtgtccgtctgtctgtatgctc-3' and 449R: 5'-cgctgggtg-cactctctctcttctt-3'), was carried out in a volume of 20 μ L containing 0.1 μ g of genomic DNA. The DNA was denatured at 95 °C for 3 min, followed by 35 cycles at 95 °C for 30 s, 57 °C for 40 s, and 72 °C for 45 s, with final extension at 72 °C for 5 min. SSCP was carried out at 6 °C using a GenePhor DNA separation system with GeneGel Excel 12.5/24 (Amersham Biosciences Corp., United States), after which the denatured single strand DNA bands were detected using a DNA Silver Staining Kit (Amersham Biosciences Corp.).

Statistical analysis

Patient age was expressed as mean \pm SD. Mean age between the 2 groups was compared by Student's *t*-test. Allelic and genotype frequencies were calculated by direct counting. The allele counts and the distribution of genotypes were compared between the cases and the controls by a 2 \times 2 table using Fisher's exact test. Furthermore, the strength of the association between allele frequencies and the disease was assessed by calculating the odds ratio (OR) and 95%CI. For all analyses, the level of significance was set at $P < 0.05$.

RESULTS

Characteristics of subjects and the frequencies of genotypes

As shown in Figure 1, single strand DNA was clearly separated by SSCP. *NFKB1* rs2505901 was in Hardy-Weinberg equilibrium ($P = 0.26$). The mean age of the controls was significantly higher than that of UC cases (Table 1). The minor allele frequencies of rs72696119 were 33.4% and 38.5% in controls and UC cases, re-

Figure 1 Polymerase chain reaction-single strand conformation polymorphism images using clinical samples. Single strand DNA was clearly separated by single strand conformation polymorphism.

UC: Ulcerative colitis; NS: Not significant.

spectively ($P = 0.10$). The genotype frequencies of the rs72696119GG homozygote was significantly higher in UC cases than in controls ($P = 0.017$).

Association between rs72696119 and UC

The rs72696119GG homozygote was significantly associated with increased risk for UC (OR, 1.88; 95%CI, 1.13-3.14; $P = 0.017$, Table 2). This association was stronger in male subjects (OR, 3.10; 95%CI, 1.47-6.54; $P = 0.0053$), whereas it was not observed in female subjects.

Association between rs72696119 and phenotypes of UC

The rs72696119 was associated with UC cases with an onset age below 20 years (OR, 2.80; 95%CI, 1.11-7.14; $P = 0.041$, Table 3). In addition, the GG homozygote was significantly associated with non-continuous disease (OR, 2.06; 95%CI, 1.13-3.77; $P = 0.029$), not having total colitis (OR, 2.04; 95%CI, 1.10-3.78; $P = 0.040$), no hospitalization (OR, 2.28; 95%CI, 1.29-4.05; $P = 0.0090$), and with a maximum of 8 or less on the UCDAI score (OR, 2.45; 95%CI, 1.23-4.93; $P = 0.022$). This polymorphism was not associated with response to steroid treatment.

DISCUSSION

In the current study, we evaluated the association between the polymorphism rs72696119 (-449C>G) in

5'-UTR of *NFKB1* and the risk for developing UC. The rs72696119 GG homozygote was significantly associated with increased risk for UC, especially in male subjects. In addition, this genotype was associated with younger age at onset, non-continuous disease, not having total colitis, no hospitalization and with a UCDAI score below 8. These results suggest that this genotype may be associated with UC of comparatively mild or moderate severity. In our study, sample selection may have affected the outcome, as our controls included patients who came to hospital in order to have treatment for complaints other than diarrhea, bloody feces and lower abdominal discomfort, and were not completely healthy subjects. Moreover, the effect of type II error cannot be excluded in relatively small sample sizes. Another limitation of this study was that mean age was different between the controls and UC cases. However, it seems that this was not an obstacle in the analysis, as UC developed at a

relatively young age.

To the best of our knowledge, there have been no reports on the distribution of rs72696119 in Japanese subjects, including HapMap-JPT. In a previous study, we demonstrated that rs72696119 has a strong allelic association with rs28362491^[15]. It has been reported that the rs28362491 ATTG deletion variant in the promoter region destroys a transcription factor binding site, resulting in lower expression of NF- κ B^[19]. Therefore, NF- κ B expression is considered to be low in rs72696119 GG variants, as well as rs28362491 del/del variants. Due to their important role in inflammation, the lower expression of NF- κ B protein seems to suppress inflammation. However, several studies have shown that the rs28362491 ATTG deletion variant is associated with increased risk for the development of inflammatory or auto-immune diseases^[19,20]. Our results also indicated that the rs72696119 GG homozygote was associated with an increased risk for UC in Japanese.

NF- κ B names a number of different transcription factors that are homo- or heterodimers of p65, p50, p105, C-rel and relB^[21]. *NFKB1* encodes both the subunits p105 and p50 of the transcription factor NF- κ B by alternative splicing^[22]. NF- κ B is involved in both inflammatory and anti-inflammatory processes^[23]. The role of NF- κ B in inflammation is determined by subunit type. As part of the p65/p50 NF- κ B transcription factor complex, it is pro-inflammatory, controlling transcription of pro-inflammatory cytokines^[24]. Conversely, p50 has anti-inflammatory properties in the p50 homodimer by repressing transcription^[25]. The relative abundance of p65/p50 heterodimers and p50 homodimers may determine the magnitude of inflammation by balancing the pro-inflammatory and anti-inflammatory response^[21]. In fact, p50 deficient mice have an increased sensitivity to lipopolysaccharide (LPS) and have increased LPS-induced inflammation^[26,27]. In subjects with the del/del genotype, decreased p50 synthesis may lead to decreased repressive homodimers and increased active heterodimers of the NF- κ B complex. This balance may influence the susceptibility to inflammatory diseases, including UC.

The significant association between the rs28362491 ATTG deletion allele and UC was first reported by Karban *et al.*^[19]. Borm *et al.*^[28] also reported the same results. However, several studies did not find a significant association between this allele and UC^[29-32]. On the other hand, there have been no reports on the association between the *NFKB1* polymorphism and UC in Japan. In our study, the rs72696119 G allele, in linkage disequilibrium with the rs28362491 ATTG deletion allele, was significantly associated with susceptibility to UC using a recessive genetic model. In addition, this genotype was associated with patients who developed UC at a relatively young age, similar to Borm's report^[28]. These contrasting observations may be explained by differences in the genotypic composition of populations in different coun-

tries with different racial groups. Another explanation is that it is possible that the results may be controlled by the composition of the phenotypes in UC cases, as our results indicated that the *NFKB1* polymorphism was more closely associated with specific phenotypes of UC. Furthermore, the influence of rs72696119 has not yet been investigated. The association between rs28362491 and rs72696119 has not been described in the HapMap project. More studies will be necessary to clarify the influence of rs72696119 on susceptibility to UC.

It is difficult to evaluate the severity of UC at any one point, because it fluctuates with clinical period and medications. Thus, we assessed the association between rs72696119 and the severity of UC, when the cases with a history of hospitalization or with a maximum of 9 or more on the UCDAI score were considered to be severe cases. Our results suggested that this genotype might be associated with UC of comparatively mild or moderate severity. Moreover, a strong significant association between the rs72696119 GG homozygote and UC was found in male subjects. It is unclear why this genotype was associated with specific phenotypes and male UC cases. UC is a multifactorial disorder with both genetic and environmental etiological factors, and is considered a complex genetic disorder predicted to involve multiple genes of relatively low penetrance^[33]. In fact, Fisher *et al.*^[34] reported that several regions of male-specific linkage were found in the susceptibility to IBD. It may be no surprise that *NFKB1* polymorphism is more closely associated with specific phenotypes of UC. Further studies will be necessary in order to clarify how the *NFKB1* polymorphism influences susceptibility to UC.

In conclusion, the GG homozygote of rs72696119, which is located in *NFKB1* 5'-UTR and is in linkage disequilibrium with rs28362491, is significantly associated with susceptibility to UC, especially in Japanese male subjects. This genotype is associated with UC of mild or moderate severity.

COMMENTS

Background

The incidence of ulcerative colitis (UC) is currently rising in Japan although the pathogenesis of UC is only partially understood. Recently, variations in some genes have been associated with the development of UC.

Research frontiers

One of the linkage regions for inflammatory bowel diseases maps to chromosome 4q. In this region, the *NFKB1*, encoding 2 subunits (p50 and p105) of nuclear factor (NF)- κ B, is located (4q24). A certain genetic variation, rs72696119, has been identified at position -449 C>G in 5'-UTR of *NFKB1*. In this study, the authors demonstrate that rs72696119 GG genotype is associated with the development of UC in Japan.

Innovations and breakthroughs

Many studies have reported the association between polymorphism rs28362491 (-94 ins/del ATTG of *NFKB1*) and various inflammatory diseases. However, these studies have not always led to the same conclusions. In addition, there have been no reports investigating an association between rs72696119 and inflammatory diseases. This is the first study to report that rs72696119 is asso-

ciated with the development of UC in Japan.

Applications

The authors assessed how genetic variation contributes to the development of UC using a case-control study (174 cases and 465 controls). The genotype analysis was performed by polymerase chain reaction-single strand conformation polymorphism.

Terminology

NF- κ B activation is known to regulate cellular growth responses, including apoptosis, and is required for the induction of inflammatory and tissue-repair genes. NF- κ B names a number of different transcription factors that are homo- or heterodimers of p65, p50, p105, C-rel and relB. Subunits p105 and p50 of NF- κ B are encoded by *NFKB1*. A p65/p50 heterodimer is pro-inflammatory, and p50 has anti-inflammatory properties.

Peer review

It is suitable for acceptance to this journal. Authors compared the GG homozygote in UC patients between total colitis and not total colitis.

needed. The "switch/combination" group was then divided into two subgroups depending on whether participants followed (group A, $n = 30$) or violated (group B, $n = 45$) a proposed treatment strategy that determined whether to add lamivudine based on the serum hepatitis B virus (HBV) DNA levels (< 60 IU/mL or not) after 6 mo of treatment (roadmap concept).

RESULTS: The cumulative probability of virologic response (HBV DNA < 60 IU/mL) was higher in group A than in the "add-on" group and in group B ($P < 0.001$). In contrast, the cumulative probability of virologic breakthrough was lower in the "add-on" group than in group B ($P = 0.002$). Furthermore, the risk of virologic breakthrough in the multivariate analysis was significantly lower in the "add-on" group than in group A (hazard ratio = 0.096; 95%CI, 0.015-0.629; $P = 0.015$).

CONCLUSION: The selective combination of adefovir with lamivudine based upon early treatment responses increased the odds of virologic breakthrough relative to the use of uniform combination therapy from the beginning of treatment.

Abstract

AIM: To investigate retrospectively the long-term efficacy of various treatment strategies using adefovir dipivoxil (adefovir) in patients with lamivudine-resistant chronic hepatitis B.

METHODS: We included 154 consecutive patients in two treatment groups: the "add-on" group ($n = 79$), in which adefovir was added to ongoing lamivudine treatment due to lamivudine resistance, and the "switch/combination" group ($n = 75$), in which lamivudine was first switched to adefovir and then re-added later as

J Gastroenterol 2012; 18(47): 6987-6995 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i47/6987.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i47.6987>

INTRODUCTION

The aims of chronic hepatitis B (CHB) treatment are to achieve the sustained suppression of hepatitis B virus (HBV) replication and to prevent progression to cirrhosis, liver failure, and hepatocellular carcinoma^[1]. Lamivudine is a safe and effective nucleoside analog that has been approved by the United States Food and Drug Administration as the first oral therapy for CHB. Lamivudine suppresses HBV replication by inhibiting the activity of HBV DNA polymerase, which leads to the normalization of serum alanine aminotransferase (ALT) levels, hepatitis B e antigen (HBeAg) seroconversion, and histological improvement^[2-5]. However, some CHB patients who are treated with lamivudine over a long period of time develop resistance to the drug at a rate reaching approximately 70% after five years of administration^[6]. This resistance leads to virologic breakthrough, re-elevation of the serum ALT levels, hepatic failure, and even death in some patients^[3,4,7]. Despite the introduction of more potent antiviral agents for the treatment of CHB, lamivudine is still frequently used due to its lower cost.

Adefovir dipivoxil (adefovir) is a nucleotide analog that is effective against both wild-type and lamivudine-resistant forms of HBV^[8-13]. However, adefovir resistance mutations develop more frequently in lamivudine-resistant patients than in treatment-naïve patients^[14-17]. Several recent studies have reported that the combination of adefovir with lamivudine results in a lower incidence of resistance to adefovir and has higher efficacy than adefovir monotherapy in patients with lamivudine resistance^[18-21]. In reality, however, adefovir is frequently initiated as a monotherapy due to the high cost of combination therapy, and lamivudine is sometimes added later if needed. It has not yet been determined when and how to assess the appropriateness of the virologic response to adefovir monotherapy so that lamivudine can be added at the optimal time. In such situations, healthcare providers may consult the roadmap concept proposed by Keefe *et al.*^[22]. The roadmap concept uses the treatment response at 6 mo to individualize ongoing antiviral management to minimize resistance and improve long-term efficacy. Although this concept is primarily based on the results of previous studies on treatment-naïve CHB patients^[23-25], a recent study suggested that the roadmap concept might be useful as a means of increasing the therapeutic efficacy during adefovir monotherapy in patients with lamivudine-resistant HBeAg-positive CHB^[26].

To date, however, no studies have investigated whether treatment strategies based on the roadmap con-

cept (first initiating adefovir monotherapy and then adding lamivudine based on early treatment response) are as effective as *ab initio* combination therapy in patients with lamivudine-resistant CHB.

In this study, we retrospectively compared the long-term efficacies of various treatment strategies using adefovir in patients with lamivudine-resistant CHB and analyzed factors associated with treatment efficacy. In particular, we focused on whether the long-term efficacies differed between patients treated in accordance with the roadmap concept and those treated with combination therapy from the start of treatment.

MATERIALS AND METHODS

Study sample

We screened the medical records of 255 consecutive patients who were prescribed adefovir 10 mg daily for the treatment of lamivudine-resistant CHB and followed up for more than 12 mo at Korea University Anam Hospital from May 2004 to February 2010. Of these 255 patients, 14 were excluded from the study because they had already been prescribed adefovir at another hospital. 20 patients were excluded because they received other drugs (entecavir, remsofovir, or clevudine) prior to adefovir treatment. We also excluded another 67 patients with serum HBV DNA levels at month six that were below the detection limit (< 0.5 pg/mL) of the hybridization method and that were not measured with more sensitive quantitative techniques. The data were collected for the remaining 154 patients and analyzed retrospectively. Patients were divided into two groups depending on how adefovir was initiated: a “switch/combination” group and an “add-on” group. For the “switch/combination” group ($n = 75$), lamivudine was first switched to adefovir, and lamivudine was re-added later if necessary in cases of primary non-response and inadequate response ($n = 31$) or virologic breakthrough ($n = 6$). For the “add-on” group ($n = 79$), adefovir was added to ongoing lamivudine treatment due to lamivudine resistance.

Methods

Clinical information (including age, gender, duration of prior lamivudine treatment, body mass index, presence of liver cirrhosis, and Child-Pugh score) was obtained by reviewing the patient medical records. Data were also collected from laboratory tests that were performed prior to adefovir administration and every three months thereafter. These tests included routine complete blood counts; biochemical tests to measure the serum levels of ALT, aspartate aminotransferase, alkaline phosphatase, gamma glutamyl transpeptidase, albumin, total bilirubin, blood urea nitrogen, creatinine, and phosphorus; assays to determine the prothrombin time; and serologic studies to determine the HBeAg, anti-HBeAg antibody (anti-HBe), and HBV DNA levels.

The diagnosis of liver cirrhosis was based on liver

biopsy features or on clinical, laboratory, radiologic and endoscopic data. Lamivudine resistance mutations (rtM204V/I or rtL180M) were detected using direct sequencing assays or restriction fragment mass polymorphisms at baseline in all patients included in our study. In the same manner, testing for adefovir resistance mutations was also performed in patients who exhibited virologic breakthrough during adefovir treatment. Prior to July 2007, the quantitative analyses of serum HBV DNA levels were conducted using a polymerase chain reaction (PCR) assay (COBAS Amplicor HBV Monitor, Roche Diagnostics, Indianapolis, IN, United States), which has a lower detection limit of 60 IU/mL; thereafter, a real-time PCR assay (COBAS TaqMan HBV test, Roche Diagnostics, Indianapolis, IN, United States) with a lower detection limit of 20 IU/mL was used.

Definition

Virologic response was defined as a decrease in HBV DNA to undetectable levels (HBV DNA < 60 IU/mL). Biochemical response was defined as a decrease in the serum ALT level to within the normal range. HBeAg seroclearance was defined as the loss of HBeAg from the serum with a decrease in serum HBV DNA to undetectable levels (HBV DNA < 60 IU/mL) in patients who had been seropositive for HBeAg before the initiation of adefovir. We defined virologic breakthrough as a confirmed increase in HBV DNA levels of more than 1 log₁₀ IU/mL relative to the lowest HBV DNA levels observed during treatment. Biochemical breakthrough was defined as an increase in the serum ALT level above the upper limit of normal on at least two occasions after achieving normalization with treatment. Primary non-response was defined as a decrease of less than 2 log₁₀ IU/mL in the HBV DNA level from baseline after six months of treatment. Inadequate response was defined as HBV DNA levels of 2000 IU/mL or greater after six months of treatment.

We based our treatment strategy for the “switch/combination” group on the roadmap concept, in which clinicians decide whether to add lamivudine based on the early treatment response after six months of adefovir monotherapy. However, if serum HBV DNA levels at six months were lower than 60 IU/mL, patients were regarded as having early treatment response and continued to receive adefovir monotherapy. However, if serum HBV DNA levels at six months were 60 IU/mL or higher, the response was considered inadequate, and lamivudine was added to the treatment regimen. The “switch/combination” group was then divided into subgroups A and B, in which the treatment strategy based on the roadmap concept was either satisfied or not satisfied, respectively.

Statistical analysis

The serum HBV DNA levels were logarithmically trans-

formed for analysis. To evaluate differences in clinical aspects prior to adefovir treatment between the “switch/combination” group and the “add-on” group, continuous variables were compared using the two-sample *t* test, and categorical data were compared using the χ^2 test. The cumulative probabilities of virologic and biochemical responses, HBeAg seroclearance, and virologic and biochemical breakthroughs were evaluated using Kaplan-Meier analysis. The log-rank test was used to evaluate differences between the two groups. We identified independent factors associated with treatment outcomes using the Cox proportional hazard model. Variables with *P* values < 0.1 in the univariate analysis were included in the multivariate analysis. *P* values < 0.05 were considered statistically significant. All data were analyzed using the Statistical Package for the Social Sciences (SPSS) for Windows (version 18, SPSS Inc., Chicago, IL, United States).

RESULTS

Baseline characteristics of the patients prior to adefovir treatment

Of the 154 patients included in the study, 109 (70.8%) were male, and 45 (29.2%) were female. The mean (\pm SD) age of the entire sample was 45.5 \pm 11.8 years. 110 patients (71.4%) were seropositive for HBeAg, and 65 (42.2%) had liver cirrhosis. The mean levels of serum HBV DNA and ALT were 6.85 \pm 1.01 log₁₀ IU/mL and 200.1 \pm 179.3 IU/L, respectively. The mean duration of prior lamivudine treatment before the initiation of adefovir was 28.5 \pm 14.6 mo, and we conducted follow-up after the initiation of adefovir for an average of 33.8 \pm 14.1 mo (median, 33; range 12-66). The “switch/combination” group included 75 patients, and the “add-on” group included 79 patients. The median durations of follow-up in the “switch/combination” group and the “add-on” group were 42 mo (range, 12-66) and 24 mo (range, 12-36), respectively. At baseline, there were no significant differences in the clinical and laboratory features between groups except for age and the presence of liver cirrhosis (Table 1).

Treatment efficacy in the “switch/combination” group and the “add-on” group

After the initiation of adefovir, virologic response was achieved in 51 of 75 (68.0%) patients in the “switch/combination” group during the follow-up period. In the “add-on” group, 51 of 79 (64.6%) patients achieved virologic response. There were no significant differences in the virologic response rate between the two groups (*P* = 0.249), with cumulative probabilities at the first and third years of 41.3% and 68.2% in the “switch/combination” group and 48.1% and 73.5% in the “add-on” group, respectively. In the multivariate analysis, however, virologic response was found to be significantly more common in the “add-on” group [hazard ratio (HR) = 1.646; 95%CI,

¹P-values were calculated with the Cox's proportional hazard model; Variables with a *P* < 0.1 in the univariate analysis were included in the multivariate analysis; ²Inadequate response was defined as serum HBV DNA levels of 2000 IU/mL or greater at 6 mo of treatment; ³Patients were divided into two treatment groups: the "add-on" group, in which adefovir dipivoxil (adefovir) was added to ongoing lamivudine treatment due to lamivudine resistance, and the "switch/combination" group, in which lamivudine was first switched to adefovir and then re-added later as needed. HBeAg: Hepatitis B e Antigen; HBV DNA: Hepatitis B virus DNA; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; HR: Hazard ratio.

**Figure 1** Cumulative probabilities of virologic breakthrough in the two treatment groups.

= 0.214; 95%CI, 0.109-0.419; *P* < 0.001).

Virologic and biochemical breakthroughs during adefovir treatment were observed in 19 patients [17 of 75 (22.7%) in the "switch/combination" group and 2 of 79 (2.5%) in the "add-on" group] and 16 patients (20.0% *vs* 1.3%), respectively. Both breakthroughs were more common in the "switch/combination" group than in the "add-on" group, according to the Kaplan-Meier analysis (*P* < 0.05). The cumulative probabilities of virologic breakthrough at the first and third years were 2.7% and 23.2% in the "switch/combination" group and 0% and 3.8% in the "add-on" group (Figure 1). In the multivariate analysis, the risk of virologic breakthrough was significantly lower in the "add-on" group (HR = 0.130; 95%CI, 0.028-0.599; *P* = 0.009) and significantly higher in patients with inadequate response (HR = 5.251;

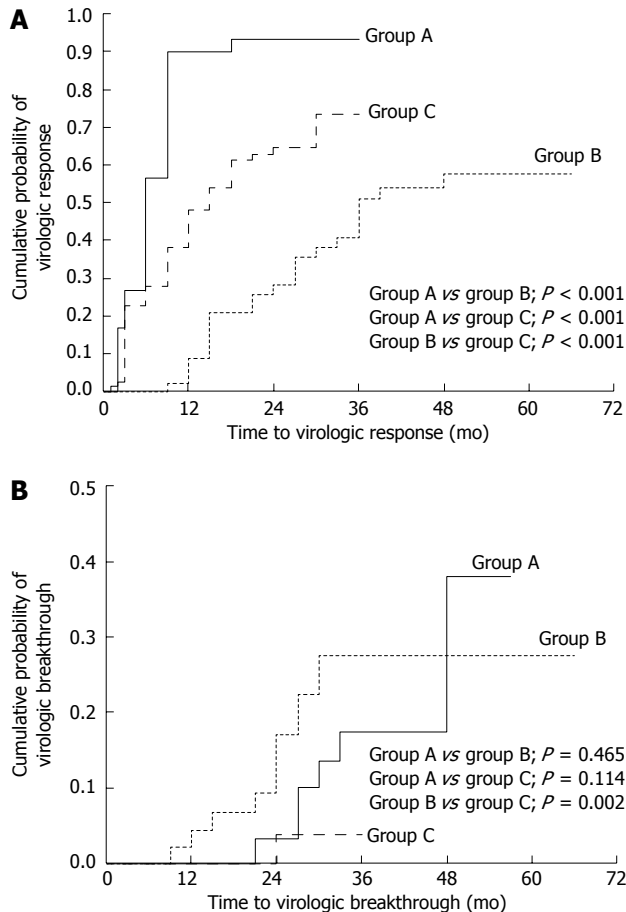

Figure 2 A comparison of the cumulative probabilities of virologic response and viral breakthrough according to different treatment strategies using adefovir dipivoxil in patients with lamivudine-resistant chronic hepatitis B. Groups A and B represent the patients who followed or violated the roadmap treatment strategy, respectively; Group C stands for those treated by adding adefovir dipivoxil in addition to ongoing lamivudine therapy. The roadmap treatment strategy was supposed to initiate adefovir monotherapy first and then add lamivudine when serum HBV DNA levels were ≥ 60 IU/mL at six months of treatment. A: There were significant differences in the cumulative probabilities of virologic responses between any two treatment groups ($P < 0.001$); B: The cumulative probability of virologic breakthrough was significantly lower in group C than in group B ($P = 0.002$) but not lower than group A ($P = 0.114$). However, there was a significant difference between groups C and A in the multivariate Cox's regression model (Table 3).

95%CI, 1.684-16.371; $P = 0.004$).

Treatment efficacy in the "switch/combination" group according to compliance with the treatment strategy based on the roadmap concept

As mentioned above, we used a roadmap concept-based treatment strategy, which recommends the addition of lamivudine based on an early treatment response after six months of adefovir monotherapy (< 60 IU/mL), for patients in the "switch/combination" group. group A included patients who were treated in accordance with the roadmap strategy. group B was made up of patients for whom the roadmap-dictated treatment strategy was not followed. Thirty patients were included in group A (27 maintained adefovir monotherapy, and 3 received

concomitant lamivudine), and 45 patients were included in group B.

Patients in "switch/combination" group A were more likely to experience virologic response than those in group B ($P < 0.001$) or those in the "add-on" group (group C) ($P < 0.001$) (Figure 2A). In contrast, the cumulative probability of virologic breakthrough was significantly lower in the "add-on" group (0% at the first year, 3.8% at the third year) than in "switch/combination" group B (4.4% at the first year, 27.5% at the third year) ($P = 0.002$) but was not lower than in "switch/combination" group A (0% at the first year, 17.4% at the third year, 38.0% at the fifth year) ($P = 0.114$) (Figure 2B). In the multivariate analysis, however, the risk of virologic breakthrough was significantly lower in the "add-on" group than in "switch/combination" group A (HR = 0.096; 95%CI, 0.015-0.629; $P = 0.015$) (Table 3).

In addition, patients with undetectable (< 60 IU/mL) serum HBV DNA levels after six months of adefovir monotherapy had cumulative probabilities of virologic breakthrough of 15.7% and 36.7% at three and five years of treatment, respectively, with continued adefovir monotherapy based on the roadmap concept strategy.

Mutations conferring adefovir resistance

Testing for mutations conferring adefovir resistance was performed in patients with primary non-response, inadequate response or virologic breakthrough during adefovir treatment. 28 (37.3%) and 6 (7.6%) patients were tested for genotypic resistance to adefovir in the "switch/

Table 4 Patterns of genotypic resistance to adefovir dipivoxil in patients with lamivudine-resistant chronic hepatitis B

combination" group and the "add-on" group, respectively. Among these patients, adefovir resistance mutations were detected in 10 and 2 patients in the "switch/combination" and "add-on" groups, respectively (Table 4). Adefovir resistance mutations were only identified in 6 (40%) of 15 patients with virologic breakthrough (5 of 13 in the "switch/combination" group and 1 of 2 in the "add-on" group).

Nephrotoxicity due to adefovir

After initiating adefovir therapy, increased serum creatinine levels (> 1.2 mg/dL and an increase of over 20% from baseline) were observed more than once in 9 of 154 patients (5.8%). Of 4 patients with elevated serum creatinine levels (> 1.2 mg/dL) at baseline, 2 showed a greater than 20% increase from baseline.

9 of 154 patients (5.8%) had hypophosphatemia at least once during adefovir treatment, and 5 experienced the condition at least twice. Of these 5 patients, 3 recovered from hypophosphatemia after taking oral KH₂PO₄. In 3 patients (1.9%), increased serum creatinine and hypophosphatemia were both observed, and one of the participants showed severe hypophosphatemia, with levels less than 1.5 mg/dL.

DISCUSSION

Despite the high incidence of resistance, lamivudine is still prescribed for the treatment of CHB because of its low cost relative to other available drugs. Therefore, the treatment of lamivudine-resistant CHB will remain a clinical challenge in the field of hepatology for the foreseeable future.

In South Korea, we are currently able to use adefovir or entecavir to treat patients with lamivudine resistance. Approximately 40% of patients with lamivudine resistance develop resistance to adefovir monotherapy after four years of treatment^[21]; patients receiving entecavir monotherapy exhibited resistance at a rate of 35.9% af-

ter three years^[27]. By contrast, when adefovir was added to ongoing lamivudine therapy, the rate of resistance to adefovir was just 0%-2% at two years and 4.4% at four years^[18,19,21]. In addition, as time passed, the proportion of patients who maintained undetectable serum HBV DNA levels and serum ALT levels within the normal range was greater in the combination therapy group than in the adefovir monotherapy group^[21]. Therefore, when lamivudine resistance was detected, we prescribed combination therapy as soon as possible. In patients already receiving adefovir monotherapy, we added lamivudine only when an incomplete response was observed.

In the present study, we found that the cumulative probability of virologic breakthrough at three years was just 3.8% in the "add-on" group compared with 23.2% in the "switch/combination" group. Upon multivariate analysis, we confirmed that the probability of virologic response (serum HBV DNA < 60 IU/mL) was significantly higher and that the risk of virologic breakthrough was significantly lower in the "add-on" group than in the "switch/combination" group. These results suggest that adding adefovir to lamivudine may be the most appropriate treatment currently available for patients with lamivudine resistance in Korea. However, many patients do not have access to combination therapy because of its cost. Therefore, from a cost-effectiveness point of view, a treatment strategy based on the roadmap concept is worth considering.

The roadmap concept was originally proposed for treatment-naïve patients after researchers realized that early virologic suppression during antiviral treatment was closely related to long-term therapeutic efficacy and the development of viral resistance to a drug^[22]. However, a recent study of the outcomes of adefovir rescue monotherapy suggested that the roadmap concept might also be applicable in patients with lamivudine resistance^[26]. Our study also found that early treatment responses (at six months) in patients with lamivudine-resistant CHB were strongly correlated with long-term therapeutic outcomes, such as virologic response, biochemical response and HBeAg seroclearance.

In this study, there was a significant difference in the rate of treatment response between the "switch/combination" and "add-on" groups. However, this result could not be interpreted to indicate that the add-on combination treatment was superior to a stepwise combination treatment based on the roadmap concept because the "switch/combination" group included many patients whose treatment was not based on the roadmap concept. To address this question, we divided the "switch/combination" group into two sub-groups depending on whether the participants received treatment based on the roadmap concept, and then we compared the treatment outcomes in these subgroups with those in the "add-on" group. We found that the cumulative probability of virologic response was significantly better in the subgroup whose treatment conformed to the roadmap concept

(group A) than in the “add-on” group. However, the multivariate analysis showed that the risk of virologic breakthrough was significantly higher in group A than in the “add-on” group, with three-year cumulative probabilities of 17.4% and 3.8%, respectively. Even if the serum HBV DNA became undetectable (< 60 IU/mL) following six months of adefovir monotherapy, the cumulative probability of virologic breakthrough reached 15.7% and 36.7% at three and five years of treatment, respectively, when adefovir monotherapy was continued based on the roadmap strategy. These results suggest that the roadmap concept-based treatment strategy, which initiates adefovir first and adds lamivudine back to the treatment regimen depending on the treatment response at six months, should not be recommended for patients with lamivudine-resistant CHB. Of course, because the longest follow-up duration in our “add-on” group was only 36 mo, the resistance rate in the “add-on” group might increase as time passes. However, that possibility appears to be very low, given that the resistance rate at 48 mo in the “add-on” group was just 4% in two previous studies^[18,21].

Adefovir resistance mutations were identified in only 40% of patients with virologic breakthrough in this study. This finding might be explained by the following: First, it is possible that virologic breakthrough developed following low drug compliance among patients without mutations. Second, lamivudine-resistant HBV may be decreased by the use of adefovir; at the same time, however, the wild-type HBV, which does not respond well to adefovir, might exhibit increased growth. These two processes may lead to virologic breakthrough. Third, these findings might be due to methodological problems regarding the analysis of genetic variations.

In this study, HBV genotyping was not performed because almost all patients with CHB (> 95%) in Korea are infected with HBV genotype C^[28-31]. In addition, previous studies have not shown any relationship between HBV genotype and response to nucleos(t)ide analogs^[32]. Therefore, the routine genotyping of HBV appears to be uninformative in predicting therapeutic outcome, and genotyping might be meaningless for Korean patients with CHB.

Nephrotoxicity is a well-known side-effect of adefovir. In the present study, we investigated two of the primary nephrotoxic side-effects that can be caused by adefovir. Serum creatinine levels were increased in 5.8% of patients after initiating adefovir in this study. This figure is similar to that reported in other studies^[13,17-19]. Some case reports have found that adefovir can induce Fanconi syndrome or hypophosphatemic osteomalacia^[33-35]. In this study, 5.8% of patients showed hypophosphatemia, and some of them required the administration of oral KH₂PO₄. Therefore, clinicians must monitor these side effects more thoroughly in case patients require further treatment. Although the mechanism of nephrotoxicity due to adefovir has not been clearly determined, it is thought to occur mainly in the proximal tubule of the

kidney. As a nucleotide analog, adefovir might serve as a substrate for DNA polymerase γ , which is responsible for the replication of mitochondrial DNA (mtDNA). Thus, adefovir is thought to inhibit mtDNA replication and impair cellular oxidative respiration^[36,37]. In addition, the over-expression of renal tubular transporters, which increases the intracellular concentration of the drug, is implicated in adefovir nephrotoxicity^[38-40].

In conclusion, our study reaffirmed that the *ab initio* combination of adefovir with lamivudine was more effective than switching to adefovir monotherapy in a stepwise fashion in patients with lamivudine-resistant CHB. Although early treatment response is closely related to long-term efficacy, stepwise combination therapy based on the roadmap concept carries a higher risk of virologic breakthrough than initiating combination therapy from the beginning of treatment.

COMMENTS

Background

Lamivudine is still being used in many patients with chronic hepatitis B (CHB) due to its lower cost, despite its higher risk of promoting viral resistance. Adefovir dipivoxil (adefovir) has been used to treat lamivudine-resistant CHB. It is known that the combination of adefovir with lamivudine results in a lower rate of resistance than adefovir monotherapy in patients with lamivudine-resistant CHB. Due to the high cost of combination therapy, however, adefovir is frequently initiated as a monotherapy, with lamivudine added back to the treatment regimen later as needed.

Research frontiers

A recent study suggested the potential usefulness of response-guided adefovir monotherapy based on the roadmap concept in patients with lamivudine-resistant CHB. However, no study has compared the effectiveness of response-guided stepwise combination therapy with that of *ab initio* combination therapy.

Innovations and breakthroughs

This study aimed to compare the long-term efficacies of various treatment strategies including adefovir in patients with lamivudine-resistant CHB, with a focus on whether long-term efficacy differs between patients treated in accordance with the roadmap concept and those treated with combination therapy from the start of treatment. The results suggest that, although an early virologic response helps to predict long-term efficacy, the treatment strategy conforming to the roadmap concept carries a higher risk of virologic breakthrough than does initiating combination therapy from the beginning of treatment.

Applications

For patients with lamivudine-resistant CHB, adefovir should be used *ab initio* in combination with ongoing treatment with lamivudine rather than switching to adefovir monotherapy with the later addition of lamivudine.

Terminology

The roadmap concept: The roadmap concept is a treatment strategy that is used to individualize ongoing antiviral management based on early treatment responses to minimize resistance and improve long-term efficacy.

Peer review

The authors present the results for 154 lamivudine-resistant CHB patients treated with adefovir and the long-term efficacies of various treatment strategies. The study is well designed, and the manuscript is well written.

Abstract

AIM: To evaluate the efficacy and safety of tenofovir disoproxil fumarate (TDF) for chronic hepatitis B (CHB) patients after multiple failures.

METHODS: A total of 29 CHB patients who had a suboptimal response or developed resistance to two or more previous nucleoside/nucleotide analogue (NA) treatments were included. Study subjects were treated with TDF alone ($n = 13$) or in combination with lamivudine (LAM, $n = 12$) or entecavir (ETV, $n = 4$) for ≥ 6 mo. Complete virologic response (CVR) was defined as an achievement of serum hepatitis B virus (HBV) DNA level ≤ 60 IU/mL by real-time polymerase chain reaction method during treatment. Safety assessment was based on serum creatinine and phosphorus level. Eleven patients had histories of LAM and adefovir dipivoxil (ADV) treatment and 18 patients were exposed to LAM, ADV, and ETV. Twenty-seven patients (93.1%) were hepatitis B e antigen (HBeAg) positive and the mean

value of the baseline serum HBV DNA level was $5.5 \log$ IU/mL $\pm 1.7 \log$ IU/mL. The median treatment duration was 16 mo (range 7 to 29 mo).

RESULTS: All the patients had been treated with LAM and developed genotypic and phenotypic resistance to it. Resistance to ADV was present in 7 patients and 10 subjects had a resistance to ETV. One patient had a resistance to both ADV and ETV. The cumulative probabilities of CVR at 12 and 24 mo of TDF containing treatment regimen calculated by the Kaplan Meier method were 86.2% and 96.6%, respectively. Although one patient failed to achieve CVR, serum HBV DNA level decreased by $3.9 \log$ IU/mL from the baseline and the last serum HBV DNA level during treatment was 85 IU/mL, achieving near CVR. No patients in this study showed viral breakthrough or primary non-response during the follow-up period. The cumulative probability of HBeAg clearance in the 27 HBeAg positive patients was 7.4%, 12%, and 27% at 6, 12, and 18 mo of treatment, respectively. Treatment efficacy of TDF containing regimen was not statistically different according to the presence of specific HBV mutations. History of prior exposure to specific antiviral agents did not make a difference to treatment outcome. Treatment efficacy of TDF was not affected by combination therapy with LAM or ETV. No patient developed renal toxicity and no cases of hypophosphatemia associated with TDF therapy were observed. There were no other adverse events related to TDF therapy observed in the study subjects.

CONCLUSION: TDF can be an effective and safe rescue therapy in CHB patients after multiple NA therapy failures.

Tenofovir rescue therapy for chronic hepatitis B patients after multiple treatment failures. *World J Gastroenterol* 2012; 18(47): 6996-7002 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v18/i47/6996.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i47.6996>

INTRODUCTION

Nucleoside/nucleotide analogues (NAs), which inhibit reverse transcription of hepatitis B virus (HBV) polymerase, are an important class of drugs that changed the treatment paradigm and prognosis of chronic hepatitis B (CHB). Oral NA therapy has advantages over interferon therapy due to its potent antiviral effects, good tolerance, lower side-effect profile, and convenience^[1,2]. However, the development of antiviral resistance to the drug is the major limitation of NA therapy and frequently leads to treatment failure. The development of drug resistance begins with mutations in the polymerase gene, followed by viral breakthrough, biochemical breakthrough, clinical deterioration, and even progressive liver failure. Favorable effects obtained by NA therapy are lost in patients who developed antiviral resistance. Today, an increasing number of patients experience multiple NA treatment failures, especially when they are sequentially treated with drugs that have similar characteristics^[3]. To achieve sustained suppression of HBV replication and remission of liver disease, successful management of CHB patients who developed treatment failure due to antiviral resistance or incomplete inhibition of viral replication is critical.

Tenofovir disoproxil fumarate (TDF) is an oral NA with the most potent activity against HBV and a high genetic barrier that has been approved in the United States and Europe for the treatment of CHB since 2009. In treatment-naïve patients, viral resistance to TDF was not detected after up to 144 wk of therapy, and persistent viremia through week 144 was only 0.8%, mostly due to poor compliance^[4]. TDF has also shown efficacy in NA experienced patients with various results. TDF monotherapy in patients with prior failure or resistance to two or more NAs showed a 79% viral suppression rate at 23 mo of treatment^[5]. In another study, TDF rescue therapy following lamivudine (LAM) and adefovir dipivoxil (ADV) treatment failure achieved a viral suppression rate of only 46% at 48 wk and 64% at 96 wk of treatment^[6]. However, experience with TDF in Asian countries, including Korea, is limited because this drug has not yet been approved for the treatment of CHB in this region of the world. A single report of six South Korean patients with prior LAM and ADV treatment failure stated that complete virologic suppression was achieved in all patients at

12 mo with TDF plus LAM therapy^[7].

Many CHB patients in Korea have undergone sequential treatment with LAM, ADV, and/or entecavir (ETV) at 1 mg to manage antiviral resistance or insufficient suppression of HBV DNA and they have begun to emerge as an important and difficult issue for clinicians^[8]. However, the efficacy of TDF treatment in such patients with previous treatment failures using multiple NAs, including ETV, is not well known. Multiple treatment failures of NAs in CHB patients are not limited to Korea; it is considered to be a global problem. In this study, we evaluated the efficacy and safety of a TDF containing treatment regimen in CHB patients after the failure of multiple NA therapies.

MATERIALS AND METHODS

Subjects

CHB patients with failures of two or more previous NA therapies were treated with TDF containing regimens for at least 6 mo. The TDF containing regimens included TDF monotherapy (300 mg/d), or combination therapy with LAM (100 mg/d) or ETV (1 mg/d). Failures of previous NA therapies included suboptimal viral suppression (serum HBV DNA level > 2000 IU/mL despite continued therapy for more than 1 year) or the development of resistance. Exclusion criteria were coinfection with human immunodeficiency virus or hepatitis C virus, and history of underlying renal problems. Since TDF is not approved for use with CHB patients in Korea, informed consent was obtained from all subjects. The study protocol was approved by the Institutional Review Board of Samsung Medical Center (IRB file number: 2011-06-027) and was conducted in accordance with the principles of the Declaration of Helsinki.

Laboratory and clinical assessment

Serum HBV DNA, hepatitis B e antigen (HBeAg), anti-hepatitis B e antibody, alanine aminotransferase, creatinine, and phosphorus levels were recorded every 3 mo. All data were collected from medical records and analyzed retrospectively.

Definition of treatment response

The mean reduction of HBV DNA levels was assessed during treatment. Complete virologic response (CVR) was defined as a decrease of serum HBV DNA \leq 60 IU/mL. The primary non-response was defined as a decrease in serum HBV DNA of less than 2 log IU/mL at 24 wk of therapy. Viral breakthrough (BT) was defined as an increase of HBV DNA > 1 log IU/mL from nadir during TDF treatment. HBeAg clearance included HBeAg loss or seroconversion to anti-HBe.

Safety assessment

The safety assessment was based on the development of renal toxicity or hypophosphatemia. Renal toxicity was defined when the estimated glomerular filtration

ADV: Adefovir dipivoxil; ALT: Alanine aminotransferase; ETV: Entecavir; HBeAg: Hepatitis B e antigen; HBV: Hepatitis B virus; LAM: Lamivudine; NA: Nucleoside/nucleotide analogue; TDF: Tenofovir disoproxil fumarate.

rate (eGFR) decreased by more than 20% from baseline. Calculation of eGFR was performed with this formula: $eGFR = (140 - \text{age}) \times \text{weight (kg)} (\times 0.85 \text{ if female}) / (72 \times \text{serum creatinine})$. Investigation of other adverse events was performed by review of medical records.

Virologic assay

Serum HBV DNA level was determined by real-time polymerase chain reaction (PCR) assay, using the COBAS TaqMan HBV quantitative test (Roche Molecular System Inc., Branchburg, NJ, United States), which has a lower limit of detection at 9 IU/mL. To identify mutations associated with resistance in the gene encoding HBV polymerase, PCR amplification and direct sequencing was performed in a single reference laboratory as previously described^[9].

Statistical analysis

To describe continuous variables with normal distributions, the mean \pm SD was used. Continuous variables without normal distributions were expressed as the median with range. Cumulative probability of CVR during the treatment period was calculated using the Kaplan-Meier method and comparison between groups was performed with a log-rank test. *P* values less than 0.05 were considered statistically significant. All data were analyzed using SPSS (version 15.0; Chicago, IL, United States).

RESULTS

Baseline characteristics of the study subjects

A total of 29 patients were included in the study. De-

tailed demographics of the patients are presented in Table 1. The median age was 56 years (range 22 to 63 years) and 72.4% were male. Twenty-seven patients were HBeAg positive (93.1%) and the mean baseline serum HBV DNA level was 5.5 log IU/mL \pm 1.7 log IU/mL. Eleven patients (37.9%) had been exposed to LAM and ADV, and 18 (62.1%) subjects had been additionally exposed to ETV. TDF treatment alone was used in 13 subjects (44.8%), with LAM in 12 (41.4%), or with ETV in 4 (13.8%). The median treatment duration of the TDF containing regimen was 16 mo (range 7 to 29 mo).

More detailed information about prior NA therapy history and genotypic resistance profiles is described in Table 2. All patients had been treated with LAM at first, and then developed a resistance to it. In LAM and ADV experienced patients, ADV was used as a sequential or add-on therapy in an attempt to suppress LAM resistant strains; however, the patients developed viral BT with or without genotypic resistance to ADV, or showed suboptimal viral response. In LAM, ADV, and ETV experienced patients, patients were moved to an 1 mg ETV regimen, due to the failure of sequential or add-on ADV therapy. 10 out of these 18 patients were confirmed to have genotypic resistance to ETV (Table 2).

Virologic response

The cumulative probability of CVR during the treatment period is presented as a Kaplan-Meier curve (Figure 1). The probability of CVR was 86.2% at 12 mo and 96.6% at 24 mo of treatment. In this study, only one patient did not achieve CVR with TDF treatment. The detailed clinical course of this patient is given in Figure 2. This patient underwent sequential therapy with LAM, ADV, and ETV at 1 mg; however, the development of resistance and suboptimal viral suppression led to treatment failure. TDF monotherapy was introduced and maintained for 24 mo. Even though the patient did not reach CVR, the patient's serum HBV DNA decreased to 85 IU/mL with a reduction of 3.9 log IU/mL, therefore becoming near CVR. No patient in this study developed primary non-response or viral BT during follow-up.

To define whether there is any difference in the rates of CVR according to prior exposures to antiviral agents, genotypic resistance profile, or TDF monotherapy *vs* combination therapy with LAM or ETV, the CVR rates were compared according to these variables using a log-rank test. There were no significant differences between patients with prior exposure to LAM and ADV *vs* LAM, ADV, and ETV (*P* = 0.93). Genotypic resistance to ADV (rtA181V/T or rtN236T) and resistance to ETV did not affect CVR rates (*P* = 0.99 and 0.14, respectively). TDF monotherapy, or in combination with other NAs, was not related to the achievement of CVR (*P* = 0.19).

Serologic response

Cumulative probability of HBeAg clearance was calculated with the Kaplan-Meier method. The rate of HBeAg clearance in the 27 HBeAg positive patients was 7.4%,

12%, and 27% at 6, 12, and 18 mo of treatment, respectively.

Safety analysis

No patient developed renal toxicity, defined as a decrease of eGFR more than 20% from baseline. No cases of hypophosphatemia associated with TDF therapy were observed. There were no other adverse events related to TDF therapy observed in the subjects.

DISCUSSION

The management of CHB has improved markedly over the last decade, primarily due to the availability of oral NA therapy. LAM was the first NA approved for CHB in 1998 and has been used extensively for treatment since that time. However, resistance to LAM occurs frequently and is observed in up to 80% of patients treated for 5 years^[10]. When sequential ADV monotherapy was introduced to these patients, ADV resistance was found in up to 21% of the patients after 1 to 2 years^[11-13]. Sequential

Figure 2 Detailed clinical course of a patient who did not achieve complete virologic response. The patient had undergone sequential therapy with lamivudine (LAM), adefovir (ADV), and entecavir (ETV) at 1 mg and developed sequential resistance and suboptimal viral suppression leading to treatment failure. Although tenofovir disoproxil fumarate (TDF) monotherapy was not able to result in complete virologic response (CVR), serum hepatitis B virus DNA levels were decreased to 85 IU/mL with a reduction of 3.9 IU/mL, accomplishing near CVR.

therapy with ETV, a newer generation NA, has been attempted to counteract LAM resistance. Despite good treatment efficacy and low levels of ETV resistance in treatment naive patients, rescue therapy in LAM resistance patients revealed that the treatment was less effective and had a higher rate of resistance^[14,15]. Sequential therapies with multiple NAs in this manner can promote selection for multidrug-resistant strains of HBV and frequently leads to viral BT or inadequate viral response^[3]. As a result, increased numbers of CHB patients with NA (mostly LAM and ADV, or ETV) treatment failures are becoming a global problem.

TDF is an oral NA that has been used for the treatment of human immunodeficiency virus infection and is approved for the treatment of CHB in the United States and Europe^[16]. Owing to its potent antiviral activity and high genetic barrier to the development of resistance for up to 3 years as determined in phase 4 clinical trials^[4,17], TDF is now recommended as a first-line therapy for HBV infected patients in recently published guide-

lines^[1,18].

The efficacy of TDF in the treatment of prior NA refractory HBV infection has also been evaluated. TDF showed an excellent antiviral activity on LAM resistant virus independently of the resistance mutation profile *in vitro*^[19]. In patients with LAM resistant CHB, treatment with TDF was well tolerated without significant adverse events such as renal toxicity. Treatment resulted in a median decline of 4.5 log copies/mL in HBV DNA levels after median treatment duration of 12 mo^[20]. TDF alone, or combined with LAM, exerted a greater viral reduction than ADV for LAM-resistant HBV infection without developing phenotypic resistance, and showed a high antiviral efficacy in patients with LAM resistance and an inadequate response during therapy with ADV^[21-23]. TDF plus LAM therapy improved the Child-Pugh score in decompensated liver cirrhosis patients with multiple NA treatment failures^[7].

This current study included 29 patients with a prior history of treatment failure with two or more NAs. Treatment with a TDF containing regimen in these subjects resulted in 86.2% of CVR at 12 mo and 96.6% at 24 mo of treatment. A distinctive feature of our study is that we included 18 patients who had failed treatment with ETV at 1 mg in addition to LAM and ADV. A retrospective multicenter study conducted by van Bömmel *et al.*^[5] included only 3 patients who had failed ETV therapy; two who had been only ETV experienced and one who had been treated with sequential LAM and ETV at 1 mg. ETV has an extremely high anti-HBV suppressive effect and very low chance of resistance emergence at only 1.2% after 5 years in treatment-naïve subjects^[24]. In this study, among the 18 patients who failed multiple NA treatments including LAM, ADV, and ETV, 17 patients achieved CVR and one patient showed a viral reduction of 3.9 log IU/mL, nearly reaching CVR. Genotypic resistance to ETV did not affect the probability of CVR. Based on these results, it can be suggested that the strong antiviral activity of TDF is also valid in ETV failed CHB patients.

Patterson *et al.*^[6] reported 64% of CVR rate at 96 wk of TDF rescue therapy in CHB patients following failures of both LAM and ADV treatment. 21 of the 60 patients had baseline ADV resistance (14 patients with the rtA181T/V mutation and 7 patients with the rtN236T mutation), and the authors concluded that the viral response was independent of mutations conferring ADV resistance. However, in another study, the presence of ADV resistance was considered to decrease the efficacy of TDF. During the observation period, the probability of achieving HBV DNA levels below 400 copies/mL was 52% for patients with ADV resistant variants and 100% for those without^[5]. In the current study, 6 patients had genotypic resistance to ADV. Although one patient with the rtA181V/T mutant strain did not reach CVR, resistance to ADV did not influence CVR during the treatment period. The effect of ADV resistance on the antiviral efficacy of TDF cannot be concluded from the results of this study because of the small sample size,

and is an area that should be explored in further research. However, considering that *in vitro* cross resistance of ADV and TDF has been described previously^[25-27], the possibility of altered response to TDF in CHB patients with genotypic resistance to ADV should be considered.

The ultimate goal of CHB therapy is to prevent cirrhosis, hepatic failure, hepatocellular carcinoma, and death. This goal can be achieved by the complete and sustained suppression of HBV replication. Therefore, the primary aim of treatment in chronic HBV infection is to suppress HBV replication to an undetectable level^[1,18,28], leading to decreased infectivity and pathogenicity of the virus and resulting in reduced hepatic necroinflammation^[29]. Viral BT resulting from resistance or insufficient suppression of HBV DNA due to the use of a less potent drug can result in failure to completely suppress HBV DNA. After the availability of ETV and TDF, NAs with potent antiviral activity and a high genetic barrier, insufficient viral suppression or resistance in treatment naïve patients is not common. However, in the era when these drugs with a high genetic barrier were not available, the majority of patients started therapy with LAM and subsequently received ADV and/or ETV to manage LAM resistance. Many of these patients developed resistance to ADV or ETV and remained viremic despite prolonged treatment^[11-15,22]. Multiple failures of NA therapies are a growing and global problem, especially in some parts of Asia, where the use of LAM remains common due to the high prevalence of CHB and generics are available at a low cost^[30]. In the present study, we have demonstrated the high efficacy of a TDF containing regimen in patients with sequential resistance to multiple NAs, and that TDF containing regimens are effective and safe rescue therapies for CHB patients after multiple failures with NAs.

Treatment efficacy, evaluated as CVR, did not differ in patients treated with TDF alone or in patients treated with combination therapy with LAM or ETV. Generally, combination therapy of drugs that are not in the same cross-resistance group is recommended for the management of resistant strains^[1,3,18]. However, since TDF monotherapy without other NAs was also effective without viral BT after approximately 2 years of follow-up^[5], it is questionable as to whether combination therapy with this strong antiviral agent is really necessary when considering the cost and potential adverse effects of combination therapy. As such, further studies are necessary to explore these results.

This study has some limitations. The number of subjects included was not large enough ($n = 29$) and the follow-up period was relatively short (median 16 mo). Nevertheless, the patients in this study represent the most difficult-to-treat population in the management of CHB. Further studies with larger sample sizes are necessary to remedy these shortcomings and to elucidate the long-term outcome of TDF treatment. Although the genotype of HBV could be a factor affecting the treatment efficacy of antiviral agents, we did not perform an analysis of the

genotype. However, previous studies have documented that almost all HBV infected patients in Korea have genotype C; constituting 98%-100% of HBV infected patients^[31-33]. Therefore these results could be applicable to our study patients, and can represent the genotype C HBV infected patients.

In conclusion, a TDF containing treatment regimen suppressed HBV DNA in CHB patients with multiple treatment failures of NA therapy, regardless of genotypic resistance or treatment regimen. TDF can be an effective and safe rescue therapy for these patients.

COMMENTS

Background

The excellent treatment efficacy of tenofovir disoproxil fumarate (TDF) in treatment naive chronic hepatitis B (CHB) has been documented in various clinical studies. However, data on its role in CHB patients with prior treatment failure to other oral anti-viral agent is insufficient.

Research frontiers

TDF has shown efficacy in nucleoside/nucleotide analogue (NA) experienced patients with various results outside of Asia. A single report including six South Korean patients with prior treatment failure to lamivudine (LAM) and adefovir stated that a complete virologic suppression was achieved in all patients at 12 mo with a TDF containing regimen, and this has been the only study of its type conducted in Asian country.

Innovations and breakthroughs

Many CHB patients in Asian countries develop sequential antiviral resistance to oral anti-viral agents or develop insufficient suppression of hepatitis B virus (HBV) DNA, which has begun to emerge as an important and difficult issue for clinicians. In this study, the authors documented the efficacy and safety of a TDF rescue therapy in Asian CHB patients after failure of multiple NA therapies. The efficacy was not affected by genotypic resistance or prior exposure to a specific agent.

Applications

After documenting the efficacy and safety of TDF regimen in CHB patients with multiple NA treatment failure, the authors suggest the possibility of using TDF as a rescue therapy for CHB patients, even those with prior entecavir therapy failure.

Peer review

The authors evaluated the efficacy and safety of a TDF treatment for CHB patients after failures of multiple NA therapies, and showed that TDF successfully suppressed HBV DNA levels in these patients. The study is very important, as the authors stated in the manuscript, in some countries where LAM treatment is still common due to financial problems.

Abstract

AIM: To investigate the association between *interleukin-28B* (*IL28B*) genotype and response to treatment and hepatic fibrosis in patients with hepatitis C virus (HCV) genotype 4.

METHODS: Two hundred and one HCV-genotype 4 patients were included. All patients were treated with Peginterferon alfa2a/Ribavirin for 48 wk. End of treatment response (ETR) was defined as loss of detectable serum HCV RNA at the end of treatment. Sustained viral response (SVR) was defined as loss of detectable serum HCV RNA at the end of 24 wk follow up. Genotyping of *IL28B* rs12979860 was performed using the TaqMan assay. We used logistic regression to estimate

the adjusted odds ratio (aOR) and 95%CI.

RESULTS: The study included 201 HCV-genotype 4 patients. The majority of patients were men (89.6%), with a median age of 47 years, inter-quartile range (40-51). Approximately 62.5% of patients had ETR, and 49.6% had SVR. Individuals who achieved SVR were more likely to be younger ($\chi^2 = 4.91$, $P = 0.027$), and less likely to have fibrosis ($\chi^2 = 15.54$, $P < 0.0001$), or inflammation ($\chi^2 = 7.58$, $P = 0.006$). The genotype distribution of rs12979860 was 36.2%, 49.0% and 14.8% for genotypes CC, CT, and TT, respectively. In these participants, rs12979860 genotype distribution did not differ by gender ($P = 0.466$), pretreatment viral load ($P = 0.600$), inflammation ($P = 0.435$), or fibrosis ($P = 0.291$). The frequencies of *IL28B* rs12979860 genotypes were TT (14.8%), CT (49.0%), and CC (36.2%). Compared to rs12979860 genotype TT, aORs (95%CI) for ETR and SVR were: CC genotype, [17.55 (5.34-57.69) and 5.92 (2.09-16.76), respectively]; CT genotype, [5.15 (1.80-14.78) and 2.48 (0.94-6.52), respectively]. In the current study, the patients who did not achieve ETR or SVR had a lower prevalence of rs12979860 CC (17.4% and 23.3%, respectively) than individuals who had ETR or SVR (47.9% and 47.2%, respectively). Individuals with rs12979860 CC genotype had approximately 6 times the odds of SVR compared to individuals with TT genotype (aOR = 5.92; 95%CI: 2.09-16.76). Similarly, patients with CT genotype had SVR more often than patients with TT genotype (aOR = 2.48; 95%CI: 0.94-6.52). Carrying at least one copy of the C allele (genotypes CT and CC) had almost 8 times the probability of ETR compared to those with genotype rs12979860 TT (aOR = 7.87; 95%CI: 2.84-21.82), and approximately 3 times the odds of SVR compared to those with genotype rs12979860 TT (aOR = 3.46; 95%CI: 1.37-8.74). In addition, data were consistent with a significant gene-dose relationship (aOR = 4.05/allele; 95%CI: 2.27-7.22). The association between rs12979860 genotype and SVR was

similar among those who achieved and those who did not achieve SVR.

CONCLUSION: In HCV-genotype 4 patients, rs12979860 is a sensitive predictor of viral clearance, independent of viral load, age, gender or fibrosis, with no similar relation to severity of fibrosis.

INTRODUCTION

Hepatitis C virus genotype 4 (HCV-G4) is the most common type of HCV in the Middle East and Africa, particularly in Egypt, which has the highest prevalence of HCV worldwide (15%), and HCV-G4 represents 90% of all HCV cases^[1]. Despite the development of new direct antiviral agents such as protease inhibitors, which have improved response in HCV genotypes^[1,2], unfortunately G4 has emerged as a resistant genotype to new treatment strategies. This raises the importance, both for patient care and the economic approach, of improving the prediction of response to standard pegylated interferon alfa (PEG-IFN) and ribavirin therapy.

Although the mechanisms leading to clearance of acute HCV infection are not completely understood, both innate and adaptive immune responses have been suggested to play crucial roles in viral eradication and response to treatment^[3]. Besides immune responses, other host factors have also been associated with treatment-induced viral clearance. Higher rates of viral resolution have been reported in women compared with men; however, other factors such as age, race, or route of transmission were not significantly associated with viral resolution^[4].

Recently, another host factor, a genetic variation in the *interleukin-28B* (*IL28B*) gene, was found to predict spontaneous clearance of HCV infection^[5]. A single nucleotide polymorphism (SNP) rs12979860 located 3 kb upstream of *IL28B*, the gene that encodes IFN- λ 3, has been strongly associated with resolution of HCV infection^[6]. Patients with C/C genotype were more likely

to eradicate HCV than those with T/T genotype^[7,8]. The same SNP has also been associated with treatment-induced viral clearance^[9,10]. Patients with the C/C genotype were twice as likely to achieve an sustained viral response (SVR) compared to patients with other *IL28B* SNP genotypes^[6]. These findings jointly suggest a role for IFN- λ in the innate control of HCV. Of note, the T/T genotype was shown to be more common among those with African ancestry^[5].

However, the association between *IL28B* genotype and response to treatment among individuals infected with HCV-G4 still needs further investigation among the ethnic group living in the Middle East. Therefore, we conducted the present study to assess the extent of the association between *IL28B* genotype and response to treatment in HCV-G4 and severity of liver fibrosis.

MATERIALS AND METHODS

Subjects

The study included 201 Egyptian patients with chronic HCV genotype-4 who were followed in the Hamad Medical Corporation outpatient clinic in the State of Qatar. Patients received HCV treatment between 2007 and 2010. This was a retrospective-prospective cohort study in which all patients who were treated between 2007 and 2010 and had finished their follow up to week 72 were invited to participate (retrospective aspect). In addition, all patients who were currently on treatment and had not completed 72 wk of follow up (thus their outcome was not known yet) were invited to participate in the study (prospective aspect) and were followed until week 72 to determine their outcome.

All patients provided written informed consent in accordance with the Declaration of Helsinki of 1979, and the ethics research committee of the Hamad Medical Corporation provided ethical approval.

Chronic HCV infection was diagnosed by a sustained increase in alanine aminotransferase (ALT), positive anti-HCV serology and active virus replication shown by the detection of HCV-RNA and histological pattern of chronic active hepatitis. Patients were excluded from treatment if they had: active alcohol consumption over 80 g/d, concurrent hepatic B virus, immunodeficiency viruses, autoimmune hepatitis, hemochromatosis, Wilson disease, or were on antiviral or corticosteroid therapy.

All patients were treated with 180 μ g of Peginterferon-2a (Pegasys[®], Hoffmann-La Roche, Basel, Switzerland) subcutaneously once weekly and Ribavirin (COPE-GUS[®]; Hoffmann-La Roche) 1000 mg (body weight \leq 75 kg) or 1200 mg (body weight \geq 75 kg) orally for 48 wk. End of treatment response (ETR) was defined as loss of detectable serum HCV RNA at the end of treatment (48 wk). SVR was defined as loss of detectable serum HCV RNA at the end of follow up (72 wk).

Laboratory assays

Viral assays: Testing for anti-HCV was carried out us-

Table 1 Demographic and clinical characteristics of the study participants

ing a commercial ELISA kit (AxSYM 3.0; Abbott Laboratories, Chicago, IL, United States). All patients were HCV-G4 as detected by the Inno-LiPA HCV II assay (Innogenetics Inc., Alphen aan de Rijn, The Netherlands). Serum HCV RNA level monitoring was by Amplicor (version 2.0; Hoffmann-La Roche) with a minimum detection limit of 50 IU/mL.

Liver histology: The necro-inflammatory and fibrosis scores were assigned based on the Scheuer scoring system from 0 to 4. The patients were further subdivided into mild fibrosis (stages I and II) and severe fibrosis (stages III and IV).

***IL28B* genotype assay:** Genomic DNA was extracted from EDTA whole-blood samples using the QIAamp DNA Blood Mini Kit # 51166 (Qiagen GmbH, Hilden, Germany). DNA concentration was measured using a Nanodrop Spectrophotometer to assess the quantity of the product. Polymorphisms of the studied SNP were carried out by the 5' nuclease assay using the TaqMan MGB probe. The reaction was performed using an ABI 7500 (Applied Biosystems, Foster City, CA, United States) in the Biomedical Labs-Health Sciences Department at Qatar University, Doha, Qatar. The primers and the TaqMan MGB probes of the SNP were provided by the Custom assay-on demand™ service (Applied Biosystems). The 5' nuclease assay was performed using 10-30 ng genomic DNA, 1 × TaqMan Universal polymerase chain reaction Master Mix (Applied Biosystems), and 1 × primer/probe mix using the correct conditions for amplifications according to the manufacturer's instructions. Negative controls as well as non-template controls were included in each run.

Statistical analysis

In the bivariate analyses we used the χ^2 test for categorical variables and ANOVA for continuous variables to compare the relevant characteristics by treatment response status. We conducted multivariable logistic regression to calculate adjusted odds ratio (aOR) and 95%CI of the association between treatment response and *IL28B* genotype. Only variables that were significantly associated with treatment response or *IL28B* genotype were included in the multivariable models. To test whether

the association between *IL28B* genotype and response to treatment was modified by gender, grade, viral load, inflammation or fibrosis, we employed logistic regression models with an interaction term (cross product) for *IL28B* genotype and the modifier of interest included. ORs were computed using the homozygous minor allele as the reference group. All analyses were performed using SAS program version 9.2 (SAS Institute, Cary, NC, United States).

RESULTS

Descriptive data

Table 1 presents the characteristics of the study population. The study included 201 patients. The majority of participants were males (89.6%). Median age was 47 years (inter-quartile range 40-51). We observed Rapid Virological response (RVR), ETR, and SVR in 52.5%, 62.5% and 54.2% of patients, respectively. The mean, median and range of viral load (log 10) over the duration of therapy among responders and non-responders, were (4.9, 2.2, 0.0-6.9 and 5.5, 3.9, 2.1-6.9) for RVR, (3.6, 1.0, 0.0-4.23 and 6.0, 4.9, 2.5-6.5) for ETR, respectively. There was no difference in gender, or pretreatment HCV viral load by RVR, ETR or SVR status. RVR was not associated with age, liver inflammation or fibrosis. Those who had ETR were less likely to have fibrosis ($\chi^2 = 12.54$, $P < 0.001$), or inflammation ($\chi^2 = 5.17$, $P = 0.023$). Only 62.5% of patients had an ETR and 49.6% had SVR. There was no difference in gender, or pretreatment HCV viral load by ETR or SVR status. In addition, individuals who achieved SVR were more likely to be younger ($\chi^2 = 4.91$, $P = 0.027$), and less likely to have fibrosis ($\chi^2 = 15.54$, $P < 0.0001$), or inflammation ($\chi^2 = 7.58$, $P = 0.006$).

The genotype distribution of rs12979860 was 36.2%, 49.0% and 14.8% for genotypes CC, CT, and TT, respectively. Among our participants, rs12979860 genotype distribution did not differ by gender ($P = 0.466$), pretreatment viral load ($P = 0.600$), inflammation ($P = 0.435$), or fibrosis ($P = 0.291$). In our study, the patients who did not achieve ETR or SVR had a lower prevalence of rs12979860 CC (17.4% and 23.3%, respectively) than individuals who had ETR or SVR (47.9% and 47.2%, respectively). Genotype distributions by HCV status are presented in Figure 1.

Figure 1 Genotype frequency in percentage of rs12979860 of the *interleukin-28B* gene under treatment with and without end of treatment response and with and without sustained virological response in chronic hepatitis C-genotype 4 patients. ETR: End of treatment response; SVR: Sustained viral response.

End of treatment response

The data revealed that adjusting for stage, patients with rs12979860 CC and CT genotypes had ETR more often than patients with TT genotype [aOR (95%CI) = 17.55 (5.34-57.69) and 5.15 (1.80-14.78), respectively]. Patients carrying at least one copy of the C allele (genotypes CT and CC) had almost 8 times the probability of ETR compared to those with genotype rs12979860 TT (aOR = 7.87; 95%CI: 2.84-21.82) (Table 2). In addition, data were consistent with a significant gene-dose relationship (aOR = 4.05/allele; 95%CI: 2.27-7.22). No significant interactions were detected by gender, fibrosis, inflammation, or pretreatment ALT levels ($P > 0.05$).

Sustained viral response

Individuals with rs12979860 CC genotype had approximately 6 times the odds of SVR compared to individuals with TT genotype (aOR = 5.92; 95%CI: 2.09-16.76). Similarly, patients with CT genotype had SVR more often than those with TT genotype (aOR = 2.48; 95%CI: 0.94-6.52). Carrying at least one copy of the C allele (genotypes CT and CC) had approximately 3 times the odds of SVR compared to those with genotype rs12979860 TT (aOR = 3.46; 95%CI: 1.37-8.74) (Table 2). Of note, we observed a significant gene-dose relationship (aOR = 2.42/allele; 95%CI: 1.47-3.99). We did not reveal any significant interactions by gender, fibrosis, inflammation, or pretreatment ALT levels ($P > 0.05$).

There were no significant interactions between the rs12979860 genotype and RVR indicating that the association between the rs12979860 genotype and SVR was similar among those who achieved RVR and those who did not achieve RVR.

DISCUSSION

Recent studies have suggested that SNPs within or ad-

OR: Odds ratio.

acent to *IL28B* are the most promising, host-related predictors of treatment-induced clearance in HCV genotype-1 patients^[11,12], however, in studies of individuals infected with genotypes 2 and 3, the association between *IL28B* genotype and outcome is less pronounced, including rs12979860 with treatment-induced clearance^[13,14]. The impact of genetic *IL28B* variability on viral elimination during therapy in G4 is still limited. Similar to HCV genotype-1, in the present study, we demonstrated that CC genotypes of rs12979860 significantly determined SVR in patients with HCV G4. Not only that, even carrying at least one copy of the C allele increased sensitivity to PEG-IFN/Ribavirin therapy, which was 3 times that of rs12979860-negative hosts. The mechanism and explanation behind the association between genetic variations in the *IL28B* gene and spontaneous clearance may be related to the host innate immune response. *IL28B* encodes IFN- λ 3, which is involved in viral control, including HCV. In vitro, IFN- α induces expression of IFN- λ genes, which inhibit HCV replication^[15]. *IL28A* and *IL29* are three closely related cytokine genes that encode proteins known as type III IFNs at chromosomal region 19q13. The three cytokines are induced by viral infection and have antiviral activity. In addition, an experimental genetic variant regulating *IL28* expression is important for PEG-IFN TLR-mediated antiviral protection.

HCV treatment should not be withheld based solely on *IL28B* genotype, as patients with the TT genotype can achieve SVR, as it was found that the association between rs12979860 genotype and SVR was similar between the patients regardless of their RVR status.

In contrast to Ge *et al*^[6] who reported higher viral load with the C allele, in our participants, rs12979860 genotype distribution did not differ by pretreatment viral load.

Rao *et al*^[16] reported a significant genetic polymorphism among women who responded to treatment, but Montes-Cano *et al*^[17] found that rs12979860 genotype distribution did not differ by gender in G4 patients. This can be explained simply, by the difference in tested SNPs, while Rao *et al*^[16] reported this gender-related difference with the rs8099917 TT genotype, in our study and in the study by Montes-Cano, we studied rs12979860.

The association between *IL28B* polymorphisms and liver fibrosis progression is still controversial^[18]. While, Barreiro *et al*^[19] reported that *IL28B* CC carriers might experience a more rapid progression of HCV-related

liver fibrosis, Marabita *et al*^[20] reported that IL28B polymorphisms had no impact on fibrosis progression. Some investigators found that the unfavorable rs12979860 T/T gene pattern was associated with worse liver fibrosis^[21], while others did not replicate this finding. In G4 patients, and similar to Asselah *et al*^[22], no significant differences and associations for genotype and alleles frequencies were detected between mild and severe fibrosis. Host genetic factors associated with the risk of liver disease progression in hepatitis C-G4 needs further investigation.

Few reports have studied the relation between IL28B and G4, particularly among patients in our area, where Egyptians represent the majority of cases with different ethnic and G4-subtypes^[23]. The overall frequency of the protective C allele in our study was 85%, which was higher than that found by Kurbanov *et al*^[24], who reported a frequency of 67% among the Egyptians studied. When the diploid genotype was considered, the overall frequency of the protective C/C genotype was 45%, which was close to our finding (36.2%). With regard to the association between genetic polymorphisms and response to treatment, Asselah *et al*^[22] reported that SNP rs12979860 was strongly associated with SVR in patients infected with HCV-G4 in 164 HCV-G4 patients who were from different ethnic groups (Egyptian, European, and Sub-Saharan African). Although Egyptians represented 67% (75/112) of the patients with G4 in the study by De Nicola *et al*^[25], the results were very similar to ours concerning IL28B genotype distribution and distribution of the C allele among the patients who achieved SVR. Our study re-enforces the importance of SNP rs12979860 of IL28B in G4, regardless of viral clearance by week 4 and confirmed the absence of its correlation with hepatic fibrosis.

This study specifically examined the relationship between IL28B rs12979860 CC genotype, rapid viral clearance, treatment response and severity of liver disease in patients with chronic HCV-G4 infection which included a large sample of patients from the same ethnic group.

In conclusion, in patients with HCV-G4, the IL28B single nucleotide polymorphism (rs12979860) is a sensitive predictor of viral clearance, independent of baseline viral load, age, gender or fibrosis. This polymorphism does not have a similar relation with rapid viral clearance or severity of hepatic fibrosis.

The authors wish to thank Mrs. Mooza Al-Khinji and Ms. Randa Saleh, Biomedical Labs, CAS, at Qatar University, Qatar for their technical support in the genotyping experiments.

COMMENTS

Background

Genotype 4 (G4) has emerged as a resistant genotype to new treatment strategies. This raises the importance, both for patient care and the economic approach, of improving the prediction of response to standard pegylated interferon

alfa and ribavirin therapy. Genetic variation in the *interleukin-28B* (IL28B) gene has been found to predict spontaneous clearance of hepatitis C virus (HCV) infection and response to treatment.

Research frontiers

The association between the IL28B genotype and response to treatment in individuals infected with HCV-G4 still needs further investigation, especially among the ethnic group living in the Middle East. The research focused on the sensitivity of this gene in the prediction of response and its importance in predicting liver histology progression.

Innovations and breakthroughs

In previous reports, a few G4 patients were studied which was mainly related to spontaneous clearance. This study provided information on the relation between IL28B and post-treatment viral clearance and its relation to hepatic fibrosis in G4.

Applications

The study results suggest that the IL28B single nucleotide polymorphism (rs12979860) is a sensitive predictor of viral clearance in G4 patients and may improve clinical prediction models for treatment and should be included as a test in pre-treatment investigations, providing an opportunity for clinicians to individualize treatment regimens for hepatitis C patients.

Peer review

The authors studied 201 G4 HCV infected patients. All patients were treated with Peginterferon/Ribavirin for 48 wk. They found in HCV-G4, IL28B single nucleotide polymorphism (rs12979860) is an independent predictor of viral clearance.

size, pathological type and adhesions were recorded prospectively. The order of treatment represented the experience of the operator. Univariate analysis and multivariate analysis were performed to evaluate the relationships between these factors and ESD procedure time.

RESULTS: Univariate analysis showed the ESD time was closely related to the gender ($P = 0.0210$), tumor size ($P < 0.0001$), location ($P < 0.0001$), gross type ($P < 0.0001$) and adhesion ($P = 0.0010$). The surgical proficiency level was associated with ESD time in unit area ($P < 0.0001$). Multivariate analysis revealed that the ESD time was positively correlated with tumor size ($P < 0.0001$), adhesion ($P < 0.0001$) and location ($P < 0.0001$), but negatively correlated with surgical proficiency level ($P = 0.0046$).

CONCLUSION: Large tumor size, adjacency to the cardia, and adhesion are predictors of a long ESD time, whereas high surgical proficiency level predicts a short ESD time.

Abstract

AIM: To identify the determinants of endoscopic submucosal dissection (ESD) operation time.

METHODS: This investigation was conducted as a single-center, prospective study in which ESD was performed by the same endoscopist at the Chinese PLA General Hospital. A total of 173 patients underwent ESD operations performed by Dr. Lu from July 2007 to December 2011, and 183 lesions were enrolled. Patient gender, age, tumor location, gross type, tumor

INTRODUCTION

Endoscopic submucosal dissection (ESD) has become a mature technique widely applied in the treatment of mucosal lesions. ESD has advantages compared with endoscopic mucosal resection. However, ESD is complex, and the associated high risk is another disadvantage of ESD that requires improvement^[1-7]. The time required to perform ESD is one of the best indicators of operation difficulty. Studies have demonstrated ESD time is closely related to bleeding, perforation and post-operative pneumonia^[8-12]. It is the goal of clinicians to overcome operation difficulty and reduce ESD time. Previous studies have reported on the determinants of ESD time, but these results reflected the operations conducted by several clinicians^[13,14]. In the present study, ESD was performed by the same endoscopist. A total of 183 lesions were collected, and the determinants of ESD time were analyzed.

MATERIALS AND METHODS

Patients

From July 2007 to December 2011, consecutive gastric superficial intraepithelial neoplasia (GIN) was treated by ESD that were performed by the same endoscopist at the Chinese PLA General Hospital. This study was approved by the medical ethical committee Chinese PLA General Hospital and the clinical study was registered with the Clinical Trial (NCT01378507). Partial resection, piecemeal resection and snare resection after circumferential cutting was excluded and complete *en bloc* resection was included in the study.

The morphology of the lesions of all patients was superficial intraepithelial neoplasia according to the Paris endoscopic classification^[15]. Adenoma, noninfiltrating carcinoma or intramucosal invasive carcinoma were confirmed by histologic evaluation of forceps biopsy specimens, which corresponding to criteria of no lymph node metastases^[16].

Patients were excluded from the study if they had a previous diagnosis of undifferentiated carcinoma, or Type 0-III or 0-I s adenocarcinoma. Systemic conditions were evaluated before each operation, and those with contraindications for anesthesia and endoscopy were excluded from the study. The existing strategies for the treatment of GIN and their advantages and disadvantages were explained to the patients and their family members before the operation. Written informed consent was obtained before ESD.

ESD procedure

The patients were sedated by intravenous injection of propofol (0.1-0.2 mg/kg per minute) (Xi'an Libang Pharmaceutical Co., Ltd. Xi'an, China). A gastroscope (GIF Q260J, Olympus Optical Co., Ltd, Tokyo, Japan) was used for the treatment, which was facilitated with a soft transparent front cap (Olympus Optical Co, Ltd.) and a high-

frequency surgical unit for cutting and coagulation (Erbotom VIO200; ERBE, Tübingen, Germany). A normal-saline solution of 10% glycerin and 5% fructose with epinephrine (0.025 mg/mL) was used for submucosal injections.

The first step was locating the lesion using gastroscopy with narrow-band imaging magnification to observe and distinguish the border between the lesion and normal mucosa. The border was marked with thermal coagulation markers at 0.5 cm intervals at a distance of 0.3 to 0.5 cm from the edge with a needle knife (KD-1L; Olympus Optical Co. Ltd., Tokyo, Japan). The glycerol fructose solution was then injected submucosally around the lesion to raise the mucosa thoroughly. Next, a pre-cut was made with needle knife to cut the mucosa through to the submucosa. Then insulation tipped (IT-2) knife (KD-610L; Olympus Optical Co, Ltd.) was inserted into the pre-cut incision to complete the incision around the lesion at 0.5 cm outside the markers (Endo cut Q 2). After the lesion was cut in a circle, submucosal injection was continued, and the mucosa was gradually dissected with an IT-2 knife (foced coag 40W) until the mucosa was completely excised. A needle knife or IT-2 knife was used for hemostasis of small blood vessels (foced coag 40W); an electric coagulation hemostat (FD-410LR; Olympus Optical Co., Ltd.) was used for hemostasis of large blood vessels (soft coag 80W). The ESD procedure is showed in Figure 1.

Definition

ESD time was defined as the time from circumferential marking around the lesion to the complete removal of GIN. The number of patients was used as the continuous numerical variable, which represented the proficiency level. The tumor size was calculated with two vertical maximum diameters.

Statistical analysis

The age, gender, number of patients, location, macroscopic appearance, tumor size, pathological type and adhesion were recorded as variables. Normally-distributed data were expressed as mean \pm SD, and data not conforming to a normal distribution were expressed as medians and inter-quartile ranges. The categorical variables were presented as constituent ratios. One way analysis of variance was employed to analyze the factors influencing procedure time. Simple correlation analysis was performed to investigate the association between numerical variables and procedure time. A rank sum test was used to investigate the association between categorical variables and procedure time. A value of $P < 0.05$ was considered statistically significant. Factors meeting the criteria for significance in the univariate analysis were included in the multivariate analysis. Multiple linear regressions were used to analyze the association between procedure time and factors influencing procedure time. The procedure time served as the dependent variable and those from univariate analysis as independent variables. Factors with a significant difference, as determined by multivariate analysis, were included

Figure 1 Procedure of endoscopic submucosal dissection: A male patient aged 56 years. A: Gastroscopy showed a type 0-IIa (2.5 cm × 1.8 cm) lesion in the greater curvature of the stomach and pathology revealed differentiated adenocarcinoma; B: Magnification was performed using narrow band imaging to determine the borderline; C: Point-like electric coagulation was done at 0.5 cm away from the borderline of lesion for marking; D: Following submucosal injection, a circumferential incision was made in the mucosa and submucosa at 0.5 cm away from the marks; E: The mucosae were dissected from submucosa using an insulation tipped-2 knife; F: Artificial ulcer following resection; G: The sample (4 cm × 3 cm) was unfolded and the marks were found in the sample; H: Pathological type was high-grade intraepithelial neoplasia (× 40).

in a step-forward linear regression model to compose a predictive formula of procedural time. In addition, 0.10 and 0.05 were applied for backward selection and forward selection, respectively. Statistical analysis was performed with SPSS version 13.0.

RESULTS

A total of 194 GIN lesions were treated by ESD, and 183 GIN lesions were completely removed (94.3%). In addition, 178 lesions met the criteria for curative resection (91.8%). In the present study, 173 cases were recruited, and a total of 183 lesions were collected. There were 126 males and 47 females, with a mean age of 62.0 years (29-82 years). The major diameter of the resected lesions was 3.0 cm (1.5-8.0 cm). The median area of resected mucosa was 7.0 cm² (1.5-33.25 cm²). The median procedure time was 41 min (8-221 min). Bleeding to different extents was observed during the operation but did not meet the criteria for bleeding as a complication^[17]. Delayed bleeding was observed in 7 cases, which resolved after endoscopic hemostasis ($n = 5$) or pharmacotherapy ($n = 2$).

Small muscularis propria resection was identified in 2 cases, but the serosa was intact and no pneumoperitoneum was observed. Because the defect was closed with the used of endoscopic clips after the *en bloc* dissection, the clip closure time was not including the ESD procedure time and was not analyzed as a risk factor.

Univariate analysis showed that the procedure time was related to tumor size, but not to age or the level of surgical proficiency. The procedure time was significantly different among groups in terms of gender, location, macroscopic appearance and adhesion. No marked dif-

ferences were noted among groups in terms of pathological types.

The irrelevance of some factors to ESD time may be attributed to small tumor size at early stage. For the same size lesion, the more experienced of the operator, the shorter of procedure time. Once ESD time per unit area was used as a factor, the influence of resection area was abolished. The ESD procedure time should be related to the proficiency of endoscopist because the resection size was increased as technical proficiency increased so the ESD procedure time was also increased although univariate analysis showed no correlation. If the ratio of procedure time to specimen area was transformed unit area, the ESD procedure time related to the proficiency of endoscopist and the number of procedure cases was conformed by univariate analysis because of elimination of interference of lesion area. So the number of procedure cases was independent predictors in multivariate analysis. (Tables 1 and 2).

Multiple linear regression analysis revealed that ESD time was positively correlated with tumor size, adhesion and location, but was negatively associated with surgical proficiency level. After comparison with the standardized regression coefficients, the correlation intensity was in the following order: tumor size, adhesion, lesions in upper stomach and proficiency level. Although multiple linear regression analysis showed the ESD procedure time was not correlation with the lesions in the middle of the stomach, the influence of lesions in the middle stomach should be used in prediction the time because ESD procedure time was related to the lesions in the upper stomach. Statistical analysis revealed tumor size and proximity to the cardia were positively correlated with longer ESD times. In addition, a submucosal adhesion could prolong

Table 1 Correlation analysis of numerical variables and endoscopic submucosal dissection time

Predictive factors	Data	ESD time (min) median (IQR)	Analysis method	P value

ESD time. With the increase of proficiency level, ESD time was reduced. The results of multiple linear regressions are displayed in Table 3.

DISCUSSION

In the present study, ESD was performed by a single endoscopist. The complete resection rate, curative resection rate, and incidence of complications were similar to those previously reported^[18-25]. The procedures of ESD by the same operator were identical among different patients. Thus, the influence of procedural differences on ESD time was excluded. We tried our best to reduce pre-operative confounding factors, and then performed univariate and multivariate analysis. The analysis of information from operations performed by the same operator can help to identify the association between proficiency level and ESD time.

The pre-operative predictable factors served as variables for analysis, and the results can serve as a reference for predicting ESD time. Although an adhesion is only found during surgery, the scar and the cushion following submucosal injection can be identified to determine the adhesion. In the recruitment of patients, the indications were restricted and the post-operative pathology only confirmed two lesions with submucosal invasion. The remaining lesions were only found in the tunica mucosa. Lesions confined to the tunica mucosa may not affect the procedure time regardless of tumor depth. Thus, tumor depth was not applied as a viable.

Studies have shown that ESD time is related to the location and size of tumors. However, some studies are

Table 2 Categorical variables and endoscopic submucosal dissection time

Predictive factors	<i>n</i> (%)	ESD time (min) median (IQR)	Analysis method	P value

ESD: Endoscopic submucosal dissection; IQR: Interquartile-range.

derived from empirical analysis, and some from univariate analysis^[26]. Goto *et al*^[13] investigated 222 early gastric cancers, which were resected with a Flex knife by four operators. Their results showed that location in the upper-third of the stomach, the presence of ulcerative findings, and > 20 mm in size was independent factors affecting ESD time. In the study by Ahn *et al*^[14] complete ESDs were performed by four experts, primarily using an IT knife, for 916 early gastric cancers. The results revealed that proximal location, tumor size greater than 20 mm, submucosal fibrosis, and perforation during the procedure were independent predictors of a longer ESD time. In the present study, the multivariate analysis indicated that ESD time was positively correlated with tumor size, location and adhesion, but negatively associated with proficiency level. The correlation intensity was in the following order: resection area, adhesion, location in the upper-third of the stomach and the proficiency level.

The factors identified by the multivariate analysis can be applied to predict ESD time. However, the determinants are numerous, and some are unpredictable before an operation, including unstable anesthesia, equipment failure, and heavy bleeding. Therefore, ESD time cannot be accurately determined according to the factors identified in the present study. These factors may only be used to predict ESD time and the level of difficulty. These findings suggest that lesions with small size and without adhesion are suitable for the training of inexperienced endoscopists. The resection of lesions with larger size located in the upper to middle stomach should be performed by experienced operators or in the presence of experienced operators. Once it is determined that the predicted ESD time is relatively long, preventive mea-

tures should be prepared before operating, with the aim of preventing skin compression and deep vein thrombosis of the lower extremities. With respect to anesthesia, intubation followed by general anesthesia is preferred. Maintaining an open airway helps to assure satisfactory anesthesia status.

Although analysis of clinical information from operations performed by the same operator can exclude the influence of other confounding factors, such as different instruments and operation habits, we only analyzed the data from a single center and therefore the sample size was relatively small. Our experience revealed that the time consumed maintaining hemostasis can affect ESD time. However, this period of time is unpredictable and cannot be accurately recorded. Therefore, it was not used as a variable for analysis.

Taken together, our results revealed that large tumor size, adjacency to the cardia, and adhesion predict a long ESD time, but high a proficiency level predicts a short ESD time. Our results provide reference for the prediction of operation difficulty and ESD time.

COMMENTS

Background

Endoscopic submucosal dissection (ESD) is a therapeutic technique for the treatment of gastrointestinal neoplasms with high *en bloc* resection rate. However, owing to its technical difficulty, longer procedure time and increase risk of perforation, ESD is not as widely used in China. The procedure time of ESD is the most direct indicator of operation difficulty. An investigation of the determinants of the time required for ESD will offer guidance in predicting operation difficulty.

Research frontiers

Many investigators have shown that ESD time is related to the location and size of tumors. In the present study, the multivariate analysis indicated that ESD time was positively correlated with tumor size, location and adhesion, but negatively associated with proficiency level.

Innovations and breakthroughs

In this study, 183 ESD procedures were performed by a single endoscopist. Analysis of clinical information from operations performed by the same operator can exclude the influence of other confounding factors, such as different instruments and operation habits.

Applications

This study revealed that large tumor size, adjacency to the cardia, and adhesion predict a long ESD time, but high a proficiency level predicts a short ESD time. The results provide reference for the prediction of operation difficulty and ESD time.

Terminology

The ESD technique was first introduced in Japan. ESD is an innovative technique that improves the rate of successful *en bloc* resection of gastrointestinal neoplasms.

Peer review

This is a study done in one center by a single endoscopist, which in this case is a strength. The manuscript is well presented and easy to read.

Abstract

AIM: To investigate the patterns and decisive prognostic factors for local recurrence of rectal cancer treated with a multidisciplinary team (MDT) modality.

METHODS: Ninety patients with local recurrence were studied, out of 1079 consecutive rectal cancer patients who underwent curative surgery from 1999 to 2007. For each patient, the recurrence pattern was assessed by specialist radiologists from the MDT using imaging, and the treatment strategy was decided after discussion by the MDT. The associations between clinicopathological factors and long-term outcomes were evaluated using both univariate and multivariate analysis.

RESULTS: The recurrence pattern was classified as follows: Twenty-seven (30%) recurrent tumors were evaluated as axial type, 21 (23.3%) were anterior type,

8 (8.9%) were posterior type, and 13 (25.6%) were lateral type. Forty-one patients had tumors that were evaluated as resectable by the MDT and ultimately received surgery, and R0 resection was achieved in 36 (87.8%) of these patients. The recurrence pattern was closely associated with resectability and R0 resection rate ($P < 0.001$). The recurrence pattern, interval to recurrence, and R0 resection were significantly associated with 5-year survival rate in univariate analysis. Multivariate analysis showed that the R0 resection was the unique independent factor affecting long-term survival.

CONCLUSION: The MDT modality improves patient selection for surgery by enabling accurate classification of the recurrence pattern; R0 resection is the most significant factor affecting long-term survival.

INTRODUCTION

Local recurrence of rectal cancer (LRR) has dramatically fallen to 4%-10% after widespread application of total mesorectal excision (TME)^[1-5]. Nevertheless, LRR re-

mains a significant clinical problem and is associated with severe morbidity, low quality of life, and poor survival in the majority of patients^[6]. Although radical (R0) resection is the most effective way to improve prognosis, it is only achieved in 10%-50% of LRRC, and in general, the 5-year survival rate remains unfavorable, varying from 18% to 58% according to different reports^[7-10]. One decisive factor for R0 resection is the pattern of recurrence^[3,4,11,12], since an accurate assessment of the recurrence pattern before treatment is critical for the selection of indicated patients as candidates for surgery.

Currently, the treatment of rectal cancer has evolved toward a multidisciplinary team (MDT) modality^[13], and this modality has been successfully delivered in our center for ten years^[14]. The MDT approach can optimize treatment strategy by enabling accurate and integrative evaluation *via* discussion by the MDT before treatment^[15]. However, whether the MDT approach can improve the R0 resection rate and long-term survival in patients with LRRC is still unknown. The aim of this study was to investigate the long-term outcome and its influential factors in LRRC under the MDT modality.

MATERIALS AND METHODS

Patients

A total of 1079 consecutive patients who underwent curative surgery at the Beijing Cancer Hospital between January 1999 and December 2007 were reviewed. In this study, LRRC was defined as the occurrence of recurrent tumors after prior radical resection located within the pelvis, either alone or in conjunction with metastases^[16]. Ninety eligible patients were ultimately included in the study according to the following criteria: (1) the initial surgery was R0 resection, and transabdominal surgery must be delivered strictly according to TME principles^[17], without bowel resection margin or circumferential resection margin involvement; (2) no synchronic distant metastasis outside the pelvis; (3) no history of other malignant tumors; and (4) no severe surgical or medical complications that were likely to affect the long-term outcome after initial surgery.

Diagnosis and evaluation of local recurrence by the MDT

Confirmation of LRRC by biopsy was obtained in 68 patients, and 10 patients were diagnosed with positron emission tomography. The remaining 12 patients were clinically diagnosed by assessing clinical symptoms, serum carcinoembryonic antigen (CEA) levels, and imaging, including computed tomography (CT), magnetic resonance imaging (MRI), and sonography.

Data for each patient was evaluated and discussed by a special MDT. Recurrence patterns were evaluated by senior radiologists of the MDT based on CT or MRI, using the Memorial Sloan-Kettering classification^[6,12],

namely, axial: recurrence at anastomotic, residual mesorectum, or perirectal soft tissue within the center of the pelvis or perineum following an abdominoperineal resection; anterior: involving the genitourinary tract; posterior: involving the sacrum and presacral fascia; and lateral: involving the muscles or soft tissue of the pelvic sidewall, major iliac vessels, sacral nerve plexus, and lateral bony pelvis.

Multimodality treatment surgery

Surgery for indicated patients was performed after discussion by the MDT, which included a group of experienced colorectal surgeons. Surgery for recurrent tumors was defined as curative (R0) if the area where resection was performed was grossly and microscopically free of residual cancer. Resections were considered palliative if either gross (R2) or microscopic (R1) cancer remained at the end of the procedure. For each patient, a thorough abdominal exploration was carried out to rule out extrapelvic metastasis after division of adhesions. Recurrent tumors were resected, along with any adjacent structures involved. Frozen-section analysis was not routinely performed, except for the suspicious resection margin.

Chemoradiotherapy and palliative treatment

Decisions regarding whether and when patients needed to undergo chemoradiotherapy were arrived at *via* discussion by the MDT. In principle, preoperative external beam radiotherapy was applied in patients 70 years of age and under with the possibility of curative resection. A radiation dose of 50 Gy in 25 daily fractions of 2 Gy was planned if no neoadjuvant radiotherapy for the primary tumor had been delivered. Three fields (1 posterior and 2 lateral) were used. Chemotherapy with fluorouracil (350 mg/m² per day) and leucovorin (20 mg/m² per day) was administered concurrently in two 5 d courses. Surgery was performed 6-8 wk after the end of the preoperative treatment. None of the patients in this study underwent intraoperative or postoperative radiotherapy. Palliative chemotherapy for unresectable tumors was delivered by oncologists, and the regimens were based on fluorouracil, oxaliplatin, and irinotecan. If the patients could not receive radio- or chemotherapy due to poor status, supportive care, including nutrition support, analgesic therapy, and other measures were given to improve quality of life.

Follow-up

All included patients underwent regular follow-ups. Physical examination and laboratory testing (blood count, liver enzymes, and CEA) were performed at the time of each follow-up visit, every 3 mo for 2 years, and every 6 mo thereafter. Abdominal ultrasonography, a chest X-ray, and abdominal and pelvic CT were performed every 6 mo. Colonoscopy was performed every 12 mo. The follow-up was repeated for at least 5 years.

Statistical analysis

Statistical analyses were performed using the SPSS 16.0 Statistical Software (SPSS Inc., Chicago, IL). Categorical variables were compared using Pearson's χ^2 test. Survival rates were estimated using the Kaplan-Meier curve, and comparisons of survival between groups were made using the log-rank method. Multivariate analysis was performed using the Cox proportional-hazard method. All statistical tests were 2-tailed, and statistical significance was set at $P < 0.05$.

RESULTS

Baseline characteristics of patients

Of the 90 included patients, 54 were male and 36 were female. The mean age was 59.4 years (median 57.5; range 27-76). Median follow-up was 68.5 mo (range 6-96). Ten patients (11.1%) were lost to follow-up and their data

Table 2 The association between recurrence pattern and resectability

Recurrence pattern	Resection rate (%)	<i>P</i> value	R0 rate (%)	<i>P</i> value
Axial	88.9 (24/27)	< 0.001	85.2 (23/27)	< 0.001
Anterior	33.3 (7/21)		33.3 (7/21)	
Posterior	25 (2/8)		25 (2/8)	
Lateral	21.7 (5/23)		4.3 (1/23)	

The values shown are the resection rate expressed in %, with the number of patients with successful resection/total number of patients with locally recurrent rectal cancer in parentheses.

were included in the survival analysis until the date of loss. The interval to recurrence was a median of 18.5 mo (3-102). Forty-one patients had recurrent tumors that were deemed resectable or potentially resectable; of these patients, 10 received preoperative chemoradiotherapy and 8 had R0 resection. Of the 41 patients who underwent surgery, 36 (87.8%) had R0 resection. In total, 9 patients underwent extended resection: 4 patients underwent total pelvic exenteration, 3 were R0 resection and 1 was R1 resection; 5 patients underwent combined organ excision, 3 were R0 resection, 1 was R1 resection, and 1 was R2 resection. Within the combined organ excision, 2 combined with uterus and vagina resection, 1 combined with partial prostate resection, and 2 combined with sacrum resection. The remaining 49 patients with unresectable tumors received conservative therapy: 18 received chemoradiotherapy and consequent chemotherapy, 25 received palliative chemotherapy alone, and 6 underwent supportive care. The demographic and clinicopathological characteristics are summarized in Table 1.

Recurrence pattern and its relationship to resectability

The pattern of local recurrence was classified by the MDT as axial type in 27 (30%) patients, anterior type in 21 (23.3%), posterior type in 8 (8.9%), lateral type in 23 (25.6%), and unclassifiable in 11.

The recurrence pattern had a strong association with resectability of the recurrent tumor, with the highest resection rate (88.9%) in the axial type and the lowest resection rate (21.7%) in the lateral type ($P < 0.001$) (Table 2). A significant difference in R0 resection percentage was also observed among the different patterns of recurrence: the R0 resection rates in axial, anterior, posterior, and lateral type were 85.2%, 33.3%, 25%, and 4.3%, respectively ($P < 0.001$; Table 2).

Prognostic factors for long-term survival

The 5-year overall survival rate of all patients was 31.1%. Univariate analysis of patient survival with locally recurrent tumors was performed according to clinicopathological and surgical factors. Twenty-seven patients with a long recurrence interval (> 24 mo) had a significantly higher rate of survival than the 63 patients with a short recurrence interval (≤ 24 mo) (48.1% *vs* 23.8%, $P < 0.05$; Table 3). A significant difference in survival was seen in

CEA: Carcinoembryonic antigen.

patients with different recurrence patterns: the 5-year survival rate was 63% in patients with the axial type, 28.6% in the anterior type, 12.5% in the posterior type, and 4.3% in the lateral type ($P < 0.001$). Univariate analysis also demonstrated that patients who underwent R0 resection had a significantly improved survival rate than those with palliative resection or conservative therapy (55.6% *vs* 14.8%, $P < 0.001$; Figure 1). Gender, age, primary surgery, pathological stage of primary tumor, and serum CEA were not associated with long-term survival (Table 3).

Multivariate analysis revealed that only the R0 resection independently influenced long-term survival of locally recurrent rectal cancer ($P < 0.05$). Although other factors, including the recurrence pattern, may associate

Figure 1 Survival after recurrence between the curative resection group and other groups. Patients who underwent curative resection ($n = 36$) had a significantly higher 5 year survival rate than those who underwent palliative resection or conservative treatment ($n = 54$) in both univariate and multivariate analysis (55.6% *vs* 14.8%, $P < 0.001$).

with overall survival, they were not as significant as R0 resection in prognosticating long-term survival (Table 4).

DISCUSSION

The aggressive use of multimodality therapy, including chemotherapy and perioperative or intraoperative radiotherapy, is being increasingly delivered in order to improve the outcomes of patients with LRRC^[8,18,19]. However, the prognosis of LRRC is far from satisfactory: the 5-year survival rate fluctuates between 18% and 58%, and only a minority of patients received curative surgery^[7-10]. To date, surgical resection with curative intent is still the most relevant prognostic factor for LRRC, and this was demonstrated in almost all reports published thus far^[7-10]. Unfortunately, the traditional pre-operative evaluation by surgeons does not allow for an accurate selection of patients as candidates for radical surgery, even though this selection is particularly important for prognosis. Nearly 30% to 65% of patients who underwent surgery did not achieve microscopically negative margins according to the majority of reports, which means that almost half of the patients would not benefit from surgery, whereas they still had to risk surgical morbidity^[8,9,20,21]. Therefore, the evaluation and treatment for LRRC needs more accurate and individualized strategies, and to this end, we propose the MDT approach.

MDT is a promising approach for identifying candidates who are most likely to benefit from surgical resection, since this modality concentrates the superiority of a series of colorectal cancer-associated disciplines, including imaging, radiology, surgery, and oncology^[13,22]. Our data revealed that an R0 resection rate of 87.8% could be achieved in patients who underwent surgery following MDT evaluation, which was significantly higher than that in previous reports^[8,9,20,21], and suggested that patient selection for surgery might be dramatically im-

proved *via* discussion by the MDT. Additionally, 8 out of 10 patients who were evaluated as marginally resectable gained R0 resection after preoperative chemoradiotherapy, based on the downsizing of the recurrent tumor; which suggested that the MDT approach may improve resectability by individual and multimodality treatment for LRRC. However, our findings need further studies to verify this, and our conclusion needs to be definitely proven by well-designed prospective cohort studies.

The basis of improved patient selection for surgery is the accurate evaluation of the recurrence pattern, which was also the main concern of the discussion by the MDT. Several studies have demonstrated that the recurrence pattern is a decisive factor for resectability^[3,4,11,12]. Moore *et al.*^[12] reported the axial and anterior type of recurrences had a R0 resection rate greater than 70%, whereas the lateral type had a R0 resection rate lower than 20%. Yamada *et al.*^[11] also reported that the involvement of the pelvic sidewall in LRRC is a dominant adverse factor for surgery and prognosis, with a 5-year survival rate lower than 5%. Our data revealed that the recurrence pattern was an optimal index to accurately select indicated patients for surgery, since the difference was dramatically significant in R0 resection and survival between each pattern, with a favorable outcome in the axial type and a poor prognosis in the lateral type. Therefore, based on the results of this study, we recommend including the recurrence pattern as an essential criterion in clinical decision making.

In terms of the independent prognostic factors of long-term survival, the conclusions from this study are in accordance with those of most current reports, in that R0 resection is the most critical factor compared to other clinicopathological variables^[3,4,10,11,20,21]. Although some studies have mentioned that elevated serum CEA, primary tumor stage, recurrence pattern, and other factors, may also have predictive value for long-term survival of LRRC^[5,9,10,23], these factors were demonstrated to be not as strong as radical surgery in their influence on the 5-year survival rate^[10]. Therefore, the most pragmatic and effective way to improve long-term survival is to enhance radical resection for indicated patients *via* an MDT discussion.

In summary, this study reveals that the MDT approach optimizes the treatment strategy of LRRC; and among all the clinicopathological factors, R0 resection is the most significant factor affecting long-term survival.

COMMENTS

Background

Local recurrence of rectal cancer (LRRC) remains a significant clinical problem. Although radical resection is the most effective way to improve prognosis, it is only achieved in limited patients. Currently, the treatment of rectal cancer has evolved toward a multidisciplinary team (MDT) modality, and this modality is expected to improve the R0 resection rate and long-term survival of patients with LRRC. The aim of this study was to investigate the long-term outcome and its influential factors in LRRC under the MDT modality.

Research frontiers

This study addresses the role and effectiveness of MDT in the treatment of LRRC, which was rarely reported in other studies. The results of this study suggest that among all the clinicopathological factors, R0 resection is the most significant factor affecting long-term survival, and MDT modality could improve R0 resection by optimize the treatment strategy.

Innovations and breakthroughs

This study demonstrated that the MDT approach could optimize the treatment strategy of LRRC; and R0 resection is still the most significant factor affecting long-term survival.

Applications

The MDT modality should be widely applied in the treatment of LRRC, since it could optimize treatment strategy and improve R0 resection.

Terminology

Local recurrence refers to the occurrence of recurrent tumors after prior radical resection located within the pelvis, either alone or in conjunction with metastases. A multidisciplinary team is a unit or working group composed of specialists from multiple disciplines which are associated with a certain disease.

Peer review

This is an excellent study in which the authors analyzed the associations between recurrence pattern and resectability, as well as the influential factors of long-term survival. All the pretreatment evaluation and therapy were made by a special MDT, which is a distinctive characteristic of this study. The results are interesting, and suggest that the recurrence pattern is a decisive factor of resectability, and that R0 resection is still the most significant factor affecting long-term survival. This study has important clinical significance for the identification of the indicated patients for surgery and those who had a better prognosis.

Abstract

AIM: To investigate the risk factors for postoperative liver insufficiency in patients with Child-Pugh class A liver function undergoing liver resection.

METHODS: A total of 427 consecutive patients undergoing partial hepatectomy from October 2007 to April 2011 at a single center (Department of Hepatic Surgery I, Eastern Hepatobiliary Surgery Hospital, Shanghai, China) were included in the study. All the patients had preoperative liver function of Child-Pugh class A and were diagnosed as having primary liver cancer by postoperative histopathology. Surgery was performed by the same team and hepatic resection was carried out by a clamp crushing method. A clamp/unclamp time of 15 min/5 min was adopted for hepatic inflow occlusion. Patients' records of demographic variables, intraoperative parameters, pathological findings and laboratory test results were reviewed. Postoperative

liver insufficiency and failure were defined as prolonged hyperbilirubinemia unrelated to biliary obstruction or leak, clinically apparent ascites, prolonged coagulopathy requiring frozen fresh plasma, and/or hepatic encephalopathy. The incidence of postoperative liver insufficiency or liver failure was observed and the attributing risk factors were analyzed. A multivariate analysis was conducted to determine the independent predictive factors.

RESULTS: Among the 427 patients, there were 362 males and 65 females, with a mean age of 51.1 ± 10.4 years. Most patients (86.4%) had a background of viral hepatitis and 234 (54.8%) patients had liver cirrhosis. Indications for partial hepatectomy included hepatocellular carcinoma (391 patients), intrahepatic cholangiocarcinoma (31 patients) and a combination of both (5 patients). Hepatic resections of ≤ 3 and ≥ 4 liver segments were performed in 358 (83.8%) and 69 (16.2%) patients, respectively. Seventeen (4.0%) patients developed liver insufficiency after hepatectomy, of whom 10 patients manifested as prolonged hyperbilirubinemia unrelated to biliary obstruction or leak, 6 patients had clinically apparent ascites and prolonged coagulopathy, 1 patient had hepatic encephalopathy and died on day 21 after surgery. On univariate analysis, age ≥ 60 years and prealbumin < 170 mg/dL were found to be significantly correlated with postoperative liver insufficiency ($P = 0.045$ and $P = 0.009$, respectively). There was no statistical difference in postoperative liver insufficiency between patients with or without hepatitis, liver cirrhosis and esophagogastric varices. Intraoperative parameters (type of resection, inflow blood occlusion time, blood loss and blood transfusion) and laboratory test results were not associated with postoperative liver insufficiency either. Age ≥ 60 years and prealbumin < 170 mg/dL were selected on multivariate analysis, and only prealbumin < 170 mg/dL remained predictive (hazard ratio, 3.192; 95%CI: 1.185-8.601, $P = 0.022$).

CONCLUSION: Prealbumin serum level is a predictive factor for postoperative liver insufficiency in patients with liver function of Child-Pugh class A undergoing hepatectomy. Since prealbumin is a good marker of nutritional status, the improved nutritional status may decrease the incidence of liver insufficiency.

INTRODUCTION

In spite of techniques such as local ablation, liver resection is still the accepted gold standard treatment for liver tumors. The aim of liver resection is to remove all macroscopic diseases (with negative resection margins), retain sufficient functioning liver^[1] and preserve vascular inflow and outflow. If too much healthy liver parenchyma is removed, patients may develop postoperative liver insufficiency or liver failure, which is a complication dreaded by surgeons.

The search for a method to categorically quantify the functional reserve of the liver and tailor surgical intervention has resulted in the development of a range of methods. These methods range from clinical scores such as the Child-Pugh classification, tests assessing complex hepatic metabolic pathways and radiological methods assessing functional reserve. Child-Pugh classification, a convenient and practical scoring system, has proven to be a useful tool in estimating the risks for both hepatic and nonhepatic surgery in patients with liver diseases^[2-4]. Liver resection is generally safe for patients with preoperative liver function of Child-Pugh class A, even for patients with cirrhosis. However, a minority of patients undergoing apparently safe resection still inexplicably develop postoperative liver insufficiency or liver failure despite seemingly sufficient liver remained preoperatively^[5].

The objective of this study is to determine the incidence of postoperative liver insufficiency in patients with preoperative liver function of Child-Pugh class A who underwent liver resection, and to clarify the risk factors for postoperative liver insufficiency in those patients.

MATERIALS AND METHODS

We reviewed the data of a single center database (De-

partment of Hepatic Surgery I, Eastern Hepatobiliary Surgery Hospital, Shanghai, China). This database comprises 427 patients undergoing partial hepatectomy with liver function of Child-Pugh class A observed during the period from October 2007 to April 2011. All the patients were diagnosed as having primary liver cancer by postoperative histopathology.

Before surgery, all patients had a chest X-ray, ultrasonography, esophagogastric endoscopy, and contrast computed tomography scan or magnetic resonance imaging of the abdomen. Laboratory blood tests included count of white blood cell and platelet, hepatitis B surface antigen, antibodies to hepatitis C, serum alpha-fetoprotein, carcinoembryonic antigen, carbohydrate antigen 19 to 9, serum albumin, serum prealbumin, serum total bilirubin, alanine aminotransferase (ALT) and prothrombin time (PT).

Surgery was performed through a right subcostal incision with a midline extension. As for hepatic inflow occlusion, normothermic intermittent interruption of the porta hepatis, with a clamp/unclamp time of 15 min/5 min, was adopted. Hepatic resection was carried out by a clamp crushing method, which has been reported previously^[6]. Blood loss was accurately recorded and blood transfusion was given when necessary. Serum albumin, serum prealbumin, serum total bilirubin, ALT, PT and ascites were monitored after surgery. Patients were discharged when the liver function was recovered (total bilirubin ≤ 34 $\mu\text{mol/L}$, ALT ≤ 40 IU/L, PT ≤ 15 s, no ascites on abdominal ultrasound and no appearance of hepatic encephalopathy).

We reviewed patients' records for demographic variables (age, gender, hepatitis background, liver cirrhosis and esophagogastric endoscopic findings), intraoperative parameters (type of resection, inflow blood occlusion time, blood loss and blood transfusion), pathological diagnosis and laboratory test results. Postoperative liver insufficiency and failure were defined as "prolonged hyperbilirubinemia unrelated to biliary obstruction or leak, clinically apparent ascites, prolonged coagulopathy requiring frozen fresh plasma, and/or hepatic encephalopathy"^[7], which was recommended by Mullin *et al*^[5].

Statistical analysis

Data were collected and analyzed with the SPSS statistical software (SPSS version 16.0, Chicago, IL, United States). The variable data were expressed as means and SDs or median and range. Categorical variables were compared using χ^2 or Fisher's exact test when appropriate, and continuous variables were compared using the independent sample *t* test. A multiple logistic regression analysis was used to determine predictors of postoperative liver insufficiency.

Variables with a $P < 0.05$ in the univariable analysis were added to the multi-variable model. In the multivariate analysis, a stepwise method was used to select variables for the final model: the conditional probabilities for stepwise entry and stepwise removal of a factor were 0.05 and 0.20, respectively.

RESULTS

Baseline data

The clinical features of the 427 patients included in the study are reported in Table 1. There were 362 males and 65 females, with a mean age of 51.1 ± 10.4 years. Most patients (86.4%) had a background of viral hepatitis (hepatitis B and/or hepatitis C), 234 (54.8%) patients suffered from liver cirrhosis, and 48 (11.2%) patients had controlled ascites before surgery. Indications for partial hepatectomy included hepatocellular carcinoma (391 patients), intrahepatic cholangiocarcinoma (31 patients) and combination of hepatocellular carcinoma and intrahepatic cholangiocarcinoma (5 patients). Hepatic resection of ≤ 3 and ≥ 4 liver segments was performed in 358 (83.8%) and 69 (16.2%) patients, respectively.

Liver insufficiency and its risk factors

There were 17 (4.0%) patients who had liver insufficiency after hepatectomy, of whom 10 patients presented with prolonged hyperbilirubinemia unrelated to biliary

obstruction or leak, 6 patients had clinically apparent ascites and prolonged coagulopathy requiring frozen fresh plasma, and 1 patient had hepatic encephalopathy and died on day 21 after surgery.

To determine the risk factors for postoperative liver insufficiency, 427 patients were classified into two groups: patients with liver insufficiency (17 patients) and patients without liver insufficiency (410 patients). Eighteen variables as listed in Table 2 were analyzed. On univariate analysis, age ≥ 60 years and prealbumin serum level < 170 mg/dL were found to be significantly correlated with the postoperative liver insufficiency ($P = 0.045$ and $P = 0.009$, respectively). On multivariate analysis using

a logistic regression, only prealbumin serum level < 170 mg/dL remained predictive (hazard ratio, 3.192; 95%CI: 1.185-8.601, $P = 0.022$).

Other complications

Twenty-five patients had one or more complications, one (0.2%) them died in the hospital because of multiple organ failure including liver failure, the other patients recovered after a longer hospital stay. These complications included pleural effusion (15 patients), abdominal hemorrhage (3 patients), wound infection (2 patients), acute renal failure (2 patients) and bile leakage (1 patient).

DISCUSSION

Child score, first proposed in 1964^[8] and modified as Child-Pugh score thereafter, was originally developed to predict the risk of mortality in patients undergoing shunting procedures for portal hypertension. Its role has been expanded to predict risk for a range of procedures, including hepatectomy, and liver resection is generally safe in patients with class A liver function^[9]. However, in the present study, the minority of patients (4.0%) with good liver function (Child-Pugh class A) still had postoperative liver insufficiency, one of them even developed undesirable liver failure.

Because of several apparent limitations in the assessment of risk of liver failure following hepatectomy, to improve the Child-Pugh classification system, many quantitative techniques have been developed to assess postoperative risk of liver failure in patients undergoing hepatectomy. Indocyanine green (ICG) elimination is the most widely used assessment for liver function and a number of retrospective studies have found some efficacy in predicting liver dysfunction and mortality following hepatectomy^[10-13]. Unfortunately, ICG elimination is not a routine test in our hospital and we could not present such data in this study. However, with the finite data in our study, we found that patients with postoperative liver insufficiency were correlated with elder age and lower serum level of prealbumin, and prealbumin serum level < 170 mg/dL remained predictive for liver insufficiency after hepatectomy.

Prealbumin, also known as transthyretin, is synthesized in the liver and serves as a transport protein throughout the body. Serum prealbumin differs from albumin, which has a relatively short half-life of 48 h and does not accumulate in the body to undergo redistribution^[14-17]. Therefore, it might be a better indicator to assess nutritional status than the widely used albumin serum level, and any fluctuations in nutritional status can be detected rapidly^[18,19]. Prealbumin has been considered an effective indicator of malnutrition in cancer patients^[15,16]. Nutrition is an important part of the management of surgical patients, and poor nutritional status in patients undergoing surgery is well known to increase postoperative morbidity and mortality by deteriorating various organ functions and the immune system of the host^[14,20-23]. Thus, we could infer that it was the poor nutritional status that caused the postoperative liver insufficiency, and prealbumin serum

level < 170 mg/dL was an indicator of malnutrition.

With regard to the Child-Pugh score, we noticed that the initial version of Child or Child-Turcotte score^[8], included nutritional status which was classified as good, fair and poor. One of the limitations which is argued by studies reported thereafter was that some values (ascites, encephalopathy and nutritional status) were determined subjectively by clinicians^[24,25]. There was no quantitative index for clinicians to give the substantial score. Due to its good representation of nutritional status, we think that prealbumin could be a quantitative variable to evaluate the patient's nutritional status, and possibly as a modification to the Child-Pugh classification system, which will make the score system more objective to assess the liver function.

Almost all the serum prealbumin is synthesized in the liver, thus, its level can be influenced by the liver condition. It has been reported that the prealbumin level could be lowered in patients with acute or chronic liver diseases and alcoholism^[16]. We think that the decreased prealbumin level may reflect the damage of liver function, which also indicates the risk of liver insufficiency after hepatectomy. More importantly, oral and parenteral steroids can falsely elevate the prealbumin levels. This elevation can make patients on steroids appear to be at a lower risk for surgery than they really are^[26]. For those patients, more attention should be paid and other variables can be taken into account to justify the liver function.

In summary, the present study exhibited that the minority of patients (4.0%) with good liver function (Child-Pugh class A) still had postoperative liver insufficiency, one of them even developed undesirable liver failure. Patients' age ≥ 60 years and serum level of prealbumin serum level < 170 mg/dL were found to be significantly correlated with the postoperative liver insufficiency, and prealbumin serum level < 170 mg/dL remained predictive for liver insufficiency after liver resection. Considering prealbumin has served as a good marker of nutritional status in cancer patients, the improved nutritional status may decrease the incidence of liver insufficiency. However, further studies with a larger number of patients are needed to confirm this hypothesis.

COMMENTS

Background

In spite of techniques such as local ablation, liver resection is still the accepted gold standard treatment for liver tumors. The aim of liver resection is to remove all macroscopic diseases (with negative resection margins) and retain sufficient functioning liver with preservation of vascular inflow and outflow. If too much healthy liver parenchyma is removed, patients may develop postoperative liver insufficiency or liver failure, which is a complication dreaded by surgeons. Liver resection is generally safe in patients with preoperative liver function of Child-Pugh class A, even in patients with cirrhosis. However, a small number of patients undergoing apparently safe resection still inexplicably develop postoperative liver insufficiency or liver failure although seemingly sufficient liver remained preoperatively.

Research frontiers

The search for a method to categorically quantify the functional reserve of the liver and tailor surgical intervention has resulted in the development of a range of methods. These methods include clinical scores such as the Child-Pugh clas-

sification, tests assessing complex hepatic metabolic pathways and radiological methods assessing functional reserve. Child-Pugh classification, a convenient and practical scoring system, has proven to be a useful tool in estimating the risks for both hepatic and nonhepatic surgery for patients with liver diseases.

Innovations and breakthroughs

In this study, the authors exhibited that a small number of patients (4.0%) with good liver function (Child-Pugh class A) still had postoperative liver insufficiency, one of them even developed undesirable liver failure. Patients' age ≥ 60 years and serum level of prealbumin serum level < 170 mg/dL were found to be significantly correlated with the postoperative liver insufficiency, and prealbumin serum level < 170 mg/dL remained predictive for liver insufficiency after liver resection. Prealbumin has been considered an effective indicator of malnutrition in cancer patients. Nutrition is an important part of the management of surgical patients, and poor nutritional status in patients undergoing surgery is well known to increase postoperative morbidity and mortality by deteriorating various organ functions and the immune system of the host. Thus, the authors inferred that it was the poor nutritional status that caused the postoperative liver insufficiency, and prealbumin serum level < 170 mg/dL was an indicator of malnutrition.

Applications

One of the limitations which is argued by previous studies was that some values (ascites, encephalopathy and nutritional status) were determined subjectively by clinicians. There was no quantitative index for clinicians to give the substantial score. Due to its good representation of nutritional status, the authors think that prealbumin could be a quantitative variable to evaluate the patient's nutritional status, and possibly as a modification to the Child-Pugh classification system, which will make the score system more objective to assess the liver function.

Peer review

This manuscript demonstrates that preoperative serum level of prealbumin is a predictor of postoperative liver insufficiency in patients with Child-Pugh class A. This manuscript is well written and attractive.

Abstract

AIM: To quantitatively assess the ability of double contrast-enhanced ultrasound (DCUS) to detect tumor early response to pre-operative chemotherapy.

METHODS: Forty-three patients with gastric cancer treated with neoadjuvant chemotherapy followed by curative resection between September 2011 and February

2012 were analyzed. Pre-operative chemotherapy regimens of fluorouracil + oxaliplatin or S-1 + oxaliplatin were administered in 2-4 cycles over 6-12 wk periods. All patients underwent contrast-enhanced computed tomography (CT) scan and DCUS before and after two courses of pre-operative chemotherapy. The therapeutic response was assessed by CT using the response evaluation criteria in solid tumors (RECIST 1.1) criteria. Tumor area was assessed by DCUS as enhanced appearance of gastric carcinoma due to tumor vascularity during the contrast phase as compared to the normal gastric wall. Histopathologic analysis was carried out according to the Mandard tumor regression grade criteria and used as the reference standard. Receiver operating characteristic (ROC) analysis was used to evaluate the efficacy of DCUS parameters in differentiating histopathological responders from non-responders.

RESULTS: The study population consisted of 32 men and 11 women, with mean age of 59.7 ± 11.4 years. Neither age, sex, histologic type, tumor site, T stage, nor N stage was associated with pathological response. The responders had significantly smaller mean tumor size than the non-responders (15.7 ± 7.4 cm vs 33.3 ± 14.1 cm, $P < 0.01$). According to Mandard's criteria, 27 patients were classified as responders, with 11 (40.7%) showing decreased tumor size by DCUS. In contrast, only three (18.8%) of the 16 non-responders showed decreased tumor size by DCUS ($P < 0.01$). The area under the ROC curve was 0.64, with a 95%CI of 0.46-0.81. The effects of several cut-off points on diagnostic parameters were calculated in the ROC curve analysis. By maximizing Youden's index (sensitivity + specificity - 1), the best cut-off point for distinguishing responders from non-responders was determined, which had optimal sensitivity of 62.9% and specificity of 56.3%. Using this cut-off point, the positive and negative predictive values of DCUS for distinguishing responders from non-responders were 70.8% and 47.4%, respectively. The overall accuracy of DCUS for therapeutic response assessment was 60.5%, slightly

higher than the 53.5% for CT response assessment with RECIST criteria ($P = 0.663$). Although the advantage was not statistically significant, likely due to the small number of cases assessed. DCUS was able to identify decreased perfusion in responders who showed no morphological change by CT imaging, which can be occluded by such treatment effects as fibrosis and edema.

CONCLUSION: DCUS may represent an innovative tool for more accurately predicting histopathological response to neoadjuvant chemotherapy before surgical resection in patients with locally-advanced gastric cancer.

INTRODUCTION

Neoadjuvant chemotherapy (NAC) is a particularly promising component of the current multidisciplinary model for treating locally-advanced gastric cancer. Recent studies have shown that pre-operative NAC can increase the likelihood of curative resection, thereby improving long-term survival^[1]. However, in cases where patients prove unresponsive to the pre-operative NAC regimen, the result is higher risk of tumor progression and death since the surgical treatment is delayed. Thus, in contrast to a post-operative NAC regimen, pre-operative NAC requires an accurate, non-invasive technique to assess short-term therapeutic response. Such a technique should not only identify unresponsive cases in a timely manner to initiate individualized treatment options but also provide alternative endpoints for identifying non-responders and prognostic parameters for assessing individual prognosis^[2].

Currently, computed tomography (CT) is a key method for evaluating chemotherapy response in patients with advanced gastric cancer. The parameters of CT imaging to assess tumor response to treatment are well defined and established in the standard workup for gastric cancer staging^[3]. The response evaluation criteria in solid tumors (RECIST 1.1) were developed in 2009 as a robust and standardized guideline for clinical assessment of tumor

response to treatment^[4]. Unfortunately, the morphologic imaging techniques, including CT, magnetic resonance image (MRI) and endoscopic ultrasonography (EUS), have limited accuracy for detecting residual tumorous tissue within chemotherapy-treated areas due to occlusion by chemotherapy-induced fibrosis^[3,4].

Double contrast-enhanced ultrasound (DCUS) was recently developed as a complementary tool for the existing imaging modalities to help improve assessment of gastric cancer^[5,6]. In clinical application of this technology, use of an oral ultrasound contrast agent reveals the three-layered structure of the gastric wall, while use of intravenous contrast reveals the dynamic features of tumor vascularity. Thus, patient evaluation with double contrast provides qualitative and quantitative measures by which changes in gastric cancer pathophysiology may be evaluated and used to determine a patient's prognosis or treatment responsiveness^[5]. In addition, DCUS is superior to the traditional staging methods for gastric cancer since it can assess the depth of tumor penetration and the presence of lymph node metastases. However, no study to date has systematically evaluated the DCUS parameters for differentiating histopathological responders from non-responders after NAC and prior to surgical treatment.

The purpose of this study was to determine whether DCUS parameters are able to differentiate histopathological responders from non-responders early in the NAC course of treatment. In addition, the predictive value of DCUS was compared with the routine CT imaging technique.

MATERIALS AND METHODS

Patients

Forty-five consecutive patients who underwent pre-operative NAC followed by curative resection at the Second Affiliated Hospital at Zhejiang University College of Medicine between September 2011 and February 2012 were enrolled in the study. NAC was recommended for patients according to the following criteria: (1) a diagnosis of histologically proven gastric adenocarcinoma; (2) clinical stage of T4a or greater, and/or any T stage with lymph node metastasis; (3) Eastern Cooperative Oncology Group performance status of 2 or less; (4) adequate organ function; and (5) no active concomitant malignancy. All patients underwent pre-operative staging by both CT and DCUS. During the NAC treatment period, one of the study participants developed an irresectable tumor and a second developed metastatic disease; both of these patients were removed from the study and excluded from analysis.

The response to chemotherapy was evaluated for each patient after two courses of chemotherapy had been completed, according to the RECIST criteria. For cases showing partial response (PR), one or two more courses were administered or the patient underwent surgical resection. The study was carried out with pre-approval by the institute's Medical Ethics Committee. All subjects provided written informed consent prior to study participation.

Pre-operative chemotherapy regimens

Two NAC regimens were randomly used: either fluorouracil + oxaliplatin (FOLFOX) or S-1 + oxaliplatin (SOX) were administered for 2-4 cycles (as noted above) over a period of 6-12 wk. The fluorouracil was given on day 1 of each cycle at 400 mg/m² IVP, followed by 2400 mg/m² IVCI over 48 h. The S-1 was given at 80 mg/m² per day for 14 d, and then repeated three weeks later. For both regimens, the oxaliplatin was given on day 1 of each cycle at 130 mg/m² IV over 2 h.

Evaluation of tumor therapeutic response by CT and DCUS

CT scanning and DCUS were performed before and after two courses of the pre-operative NAC (either FOLFOX or SOX). For contrast-enhanced abdominal CT (Somatom Definition AS scanner; Siemens Medical Solutions, Forchheim, Germany), patients were fasted for six hours and given a 450 mL bolus of pure water immediately before the CT scanning to induce gastric distention. Contrast medium [OmnipaqueTM (iohexol); GE Healthcare, Cork, Ireland] was delivered intravenously at a rate of 3 mL/s by using an automatic injector to achieve a total injection volume of 2 mL/kg. For DCUS, the Sequoia 512 Acuson sonographic system (Siemens Medical Solutions) equipped with CadenceTM contrast pulse sequencing visualization technology and a 4V1 vector transducer to deliver low acoustic pressure frequencies (1.0-4.0 MHz) was used. Oral contrast agent and intravenous contrast medium were administered sequentially, as previously described^[5,6]. Briefly, the patients drank the Xinzhang oral contrast agent (Huqingyutang, Zhejiang, China; <http://dazzy007.cn.makepolo.com/product/8891276.html>) diluted in 500 mL of warm water to distend the stomach immediately before the procedure. Each dose of the microvesicle intravenous contrast medium (SonoVue, Bracco, Italy) was dissolved in 5 mL of saline and a 2.4 mL bolus was injected into the patient's superficial elbow vein.

CT and DCUS images were interpreted and reviewed by two independent diagnostic specialists, each with more than 10 years of experience in gastric imaging. All specialists were blinded to the histological findings and the same-sample findings from the other technique for evaluating the therapeutic response. The therapeutic response indicated by CT assessment was classified using the RECIST 1.1 criteria^[4] as: complete response, PR, stable disease, or progressive disease. Tumor area was assessed by DCUS as enhanced appearance of gastric carcinoma due to tumor vascularity during the contrast phase as compared to the normal gastric wall. Thus, the DCUS detected NAC response was evaluated according to: (1) the static change of ultrasonic echo; and (2) the dynamic (real-time) assessment of tumor vascularity and lymph nodes.

Surgery

Surgery was performed between weeks 3 and 5 after the completion of pre-operative NAC. All surgical procedures were carried out using an open laparotomy approach.

The resectability of the tumors, the extent of lymph node dissection, and the type of gastrectomy procedure were determined according to the perioperative observations. The gastrectomy procedure (total or subtotal) was selected based on the location and extent of the primary lesion. For successful resection, the resection lines had to be at least 5 cm from the edge of the macroscopic tumor. D2 (extended) or D3/D4 (super-extended) lymphadenectomies were performed according to the guidelines of the Japanese Research Society for Gastric Cancer (14th ed).

Assessment of pathologic response to NAC

Pathological findings served as the reference standard for all patients. The pathological response to NAC was evaluated according to the criteria of Mandard's tumor regression grade, which was based on the percentage of viable residual tumor cells in relation to fibrosis/necrosis^[7]. Patients with TRG1-2 were defined as responders, while patients with TRG3-5 were defined as non-responders.

Statistical analysis

All statistical analysis were carried out using SPSS software (version 16.0 for Windows; Chicago, IL, United States). The χ^2 or Fisher's exact tests were used to determine the significance of associations between pathologic findings and categorical variables. Receiver operating characteristic (ROC) curves were constructed to evaluate the ability of DCUS to identify a histopathological therapeutic response, with the area under the curves and the corresponding 95%CIs being calculated. The effects of several cut-off points on diagnostic parameters were determined by the ROC curve analysis. To compare the CT and DCUS procedures, the summary accuracy measure of Youden's index (sensitivity + specificity - 1) was used. By maximizing Youden's index, the best cut-off for distinguishing pathological responders from non-responders was identified. All tests were two-sided with *P* values of < 0.05 considered as indicating statistical significance.

RESULTS

The study population consisted of 32 men and 11 women, with a mean age of 59.7 ± 11.4 years (range: 34-79 years). The baseline patient and tumor characteristics are summarized in Table 1, with patients stratified according to the status as histopathological responders or non-responders.

Neither age, sex, histologic type, tumor site, T stage, nor N stage was significantly associated with the pathological response (χ^2 test, *P* > 0.05). However, the mean tumor size was significantly smaller in the responders than in the non-responders (15.7 ± 7.4 cm vs 33.3 ± 14.1 cm, *P* < 0.01).

The individual patient data of change in tumor size showed that 40.7% (11/27) of the responders experienced a decrease in tumor size that was detected by DCUS. However, significantly less, only 18.8% (3/16), of the non-responders showed a decrease in tumor size, as detected by DCUS (*P* < 0.01).

Table 1 Patient's clinical data and pathological features (*n* = 43)

Characteristic	Assessable patients with Mandard's TRG		<i>P</i> value

TRG: Tumor regression grade.

The ROC curve analysis for identifying histopathologic responders based on DCUS-detected changes in tumor size is shown in Figure 1. The area under the receiver-operating characteristic curve (AUC) was 0.64 (95%CI: 0.46-0.81). Using ROC curve analysis with Youden's index maximization, the best cut-off for distinguishing the responders from the non-responders was identified, which showed optimal sensitivity of 62.9% and specificity of 56.3%. For this cut-off point, the positive and negative predictive values of DCUS for distinguishing the responders from the non-responders were 70.8% and 47.4%, respectively. The overall accuracy of DCUS for therapeutic response assessment was 60.5%, compared with the slightly lower overall accuracy (53.5%) of CT assessment with RECIST criteria (*P* = 0.663, Table 2).

Interestingly, we found that DCUS was able to identify decreased perfusion in the tumors of responders who showed no morphological changes by the CT imaging technique. We believe the false negative findings of CT were likely due to occlusion by chemotherapy-induced effects, such as fibrosis and edema.

DISCUSSION

Given the generally poor long-term survival (< 20%-30%) achieved in advanced gastric cancer patients who undergo

Table 2 Comparison between computed tomography and double contrast-enhanced ultrasound for neoadjuvant chemotherapy response assessment *n* (%)

	Sensitivity	Specificity	PPV	NPV	Accuracy	χ^2	<i>P</i> value
CT	13 (48.1)	10 (62.5)	13 (66.7)	10 (41.7)	23 (53.5)	0.427	0.663
DCUS	17 (62.9)	9 (56.3)	17 (70.8)	9 (47.4)	26 (60.5)		

Double contrast-enhanced ultrasound (DCUS) had an overall accuracy of 60.5%, with a positive predictive value (PPV) of 70.8%. NPV: Negative predictive value; CT: Computed tomography.

Figure 1 Receiver operator characteristics curve for the assessment of histopathologic response using double contrast-enhanced ultrasound. Area under the receiver-operating characteristic curve: 0.64 (95%CI: 0.46-0.81). The solid circle indicates the best cut-off point for distinguishing the responders from the non-responders.

surgery alone, clinicians and researchers have been actively pursuing methods to improve the survival rates of these patients. The approach of providing chemotherapy prior to the resection surgery (pre-operative/neoadjuvant) has proven beneficial for locally-advanced tumors^[8-10]. Patients receiving pre-operative NAC have shown increased likelihood of curative resection and improved overall survival. Although several studies have demonstrated the significant benefits of NAC, compared to surgery alone, for patients with resectable locally-advanced gastric cancer, the major clinical response rate has only reached 38%-69.7%^[11,12].

The current standard method for discriminating chemotherapeutic responders from non-responders is histopathologic analysis, which measures the extent of the residual tumor. This method, however, is applicable only in a post-operative setting and cannot be used for either the pre-operative design of personalized treatment or the planning of intra-operative strategies^[13]. Previous studies have revealed that the conventional imaging modalities (EUS, CT and MRI) to detect tumor volumetry lack reliability for predicting response to chemotherapy^[14,15]. Moreover, the response evaluation methods based on the

World Health Organization or RECIST criteria were reported to be highly inaccurate for gastric cancer^[16]. The recently developed technology of functional imaging, which detects or measures changes in metabolism, blood flow, regional chemical composition, and absorption, appears to be a promising alternative for monitoring chemotherapeutic effects in gastric tumors^[17]. In addition, the semi-quantitative approach of measuring glucose metabolism by means of positron emission tomography (PET) was shown to have clinical relevance in determining the response to chemotherapy for several tumor types, including gastric carcinomas^[18]. While both PET and PET/CT are well-established methods of molecular imaging, they are each limited by poor spatial resolution^[19]. In this regard, the CT and MRI technologies are preferable; however, these imaging technologies are restricted from widespread use due to their technical complexity and high cost which is often not amenable to smaller, underfunded clinics, especially those in rural areas.

Zhou *et al.*^[20] was the first to suggest that quantifying tumor perfusion with contrast-enhanced ultrasound may help detect changes in tumor perfusion after chemotherapy, based on their findings in an animal model. Our present study assessed the clinical value of a new functional imaging modality, DCUS, for non-invasive assessment of response to NAC in locally-advanced gastric cancer patients. The routine ultrasound techniques, US and EUS, rely purely on acoustic shadowing for visualization. As such, they are unable to differentiate conditions of inflammation and fibrosis in tumorous tissues, which leads to misinterpretation of the tumor depth^[3]. Chemotherapy-induced death of cancer cells results in reduced blood perfusion and decreased metabolic activity of the tumor. Since DCUS is capable of assessing the physiological blood flow within a tumor, it is also able to assess the depth of tumor penetration and lymph node metastasis^[21].

Quantitative assessment of tumor perfusion with contrast-enhanced ultrasound has already been successfully applied in both animal model^[22-24] and clinical^[25,26] studies. However, to the best of our knowledge, our study presented herein is the first to evaluate the efficiency of DCUS-detected tumor perfusion to monitor gastric cancer tumor response to chemotherapy. Although the indicated value of this technique in early assessment of tumor response to chemotherapy must be further tested in larger and more heterogeneous study populations, our preliminary results indicate that DCUS provides better diagnostic performance (AUC: 0.64) and accuracy (65.1%) for the assessment of a histopathological response than the standard CT imaging technique. Moreover, the results from the current study have clinical implications for customizing gastric cancer treatments to individual risk profiles, which should be explored in future studies.

In conclusion, in this study of patients with locally-advanced gastric cancer undergoing NAC, we found that DCUS may be as an innovative tool for predicting pathological response at an early stage of the NAC regimen

and prior to definitive resection. Because this technique is non-invasive and does not cause patient discomfort, it is particularly promising for repeated monitoring during the chemotherapy treatment period. Some limitations exist in the current study, however, that may impact the generalization of our findings. Despite the fact that the present study is the first to investigate the potential of DCUS response assessment during neoadjuvant chemotherapy in patients with gastric cancer, the total number of cases assessed was small ($n = 43$). We found that tumor size was affected by chemotherapy, and considered this a parameter of the assessment method, but we did not investigate any fluctuations in tumor size over time or in response to features of the chemotherapy regimen (doses, drug type, or cycle duration). Finally, our institute does not routinely use ultrasonography techniques as an evaluation modality for gastric cancer, so we were unable to draw conclusions about which analysis method is most useful (i.e., EUS *vs* DCUS). In order to determine whether DCUS can actually be used for accurate response prediction, a larger, multi-institute study is required.

COMMENTS

Background

Gastric cancer is currently the fourth most commonly diagnosed cancer worldwide, and it ranks second among cancer-related deaths. Currently, almost two-thirds of the gastric cancer cases occur in developing countries, with China alone accounting for 42%. Neoadjuvant chemoradiotherapy (NACRT) before surgery can improve survival in patients with locally-advanced gastric cancer, but not all patients respond to this treatment. An accurate method to assess short-term response to NACRT is critical for identifying responsive and non-responsive patients to design appropriate individualized treatment strategies.

Research frontiers

The criteria of computed tomography (CT) imaging for assessing tumor response to chemotherapy is well defined, and a well-established component of the standard workup for gastric cancer staging. However, CT imaging is usually not accurate for identifying the presence of residual tumorous tissues within areas with chemotherapy-induced effects, such as fibrosis. Their previous studies showed that double contrast-enhanced ultrasound (DCUS) is superior to the traditional CT-based gastric cancer staging methods to assess tumor penetration depth and lymph node metastases. In the current study, authors aimed to determine whether DCUS parameters are able to differentiate histopathological responders from non-responders in the early stage after neoadjuvant chemotherapy (NAC), and if so to compare the predictive efficacy of DCUS with that of CT imaging.

Innovations and breakthroughs

The results of the current study demonstrate that DCUS has optimal sensitivity and specificity for distinguishing histopathological responders from non-responders among NAC-treated gastric cancer patients. The overall accuracy of 60.5% was slightly higher than that of 53.5% for CT assessment with the response evaluation criteria in solid tumors criteria. Moreover, DCUS was able to identify decreased perfusion in cases of responders who showed no morphological changes by CT imaging, which had been likely occluded by treatment effects, such as fibrosis and edema.

Applications

DCUS is a feasible addition to the preoperative workup for NAC response assessment in gastric cancer patients. The results of DCUS may be beneficial and additive for formulating appropriate treatment plans for individual patients. Finally, ultrasound is a low-cost technique that is amenable to widespread application in small clinical setting with restricted funding and may prove a valuable technique for assessing the patients served by such clinics.

Terminology

Contrast-enhanced ultrasound is based on the traditional medical sonography

imaging technique but combined with contrast agents to enhance and differentiate various sections of an object under investigation. The substance composition of each of the various ultrasound contrast agents reflects sound waves in a distinctive manner. Neoadjuvant therapy is the administration of therapeutic agents prior to the main treatment regimen being initiated. The objective of neoadjuvant chemotherapy for gastric carcinoma is to reduce the size or extent of the cancer lesion prior to the curative resection surgery; smaller tumors are easier to resect and less extensive tumors have a higher chance of complete removal. Use of neoadjuvant chemotherapy is expected to reduce the potential risk and side effects of more radical surgical interventions required for larger and more extensive tumors.

Peer review

This is an interesting study in which authors evaluate the efficacy of double contrast-enhanced ultrasound for assessing tumor response to pre-operative chemotherapy in patients with gastric cancer. The results suggest that DCUS may represent an innovative tool for accurate predicting of histopathological response to neoadjuvant chemotherapy in patients with locally-advanced gastric cancer.

China Liver Transplant Registry retrospectively. PTHL was defined as serum triglycerides ≥ 150 mg/dL or serum cholesterol ≥ 200 mg/dL or the need for pharmacologic treatment at the sixth month after LDLT. Early renal dysfunction (ERD) was defined as serum creatinine ≥ 2 mg/dL and/or the need for renal replacement therapy in the first post-transplant week.

RESULTS: In 115 eligible patients, the incidence of PTHL was 24.3%. Recipients with PTHL showed a higher incidence of post-transplant cardiovascular events compared to those without PTHL (17.9% vs 4.6%, $P = 0.037$). Serum creatinine showed significant positive correlations with total serum triglycerides, both at post-transplant month 1 and 3 ($P < 0.01$). Patients with ERD had much higher pre-transplant serum creatinine levels ($P < 0.001$) and longer duration of pre-transplant renal insufficiency ($P < 0.001$) than those without ERD. Pre-transplant serum creatinine, graft-to-recipient weight ratio, graft volume/standard liver volume ratio, body mass index (BMI) and ERD were identified as risk factors for PTHL by univariate analysis. Furthermore, ERD [odds ratio (OR) = 9.593, $P < 0.001$] and BMI (OR = 6.358, $P = 0.002$) were identified as independent risk factors for PTHL by multivariate analysis.

CONCLUSION: Renal function is closely associated with the development of PTHL in LDLT. Post-transplant renal dysfunction, which mainly results from pre-transplant renal insufficiency, contributes to PTHL.

Abstract

AIM: To investigate the impact of renal and graft function on post-transplant hyperlipidemia (PTHL) in living donor liver transplantation (LDLT).

METHODS: A total of 115 adult patients undergoing LDLT from January 2007 to May 2009 at a single center were enrolled. Data were collected and analyzed by the

INTRODUCTION

Post-transplant hyperlipidemia (PHTL) is a common and serious complication in liver transplantation (LT). It is estimated that 45%-70% of LT recipients develop PHTL^[1-4]. Previous studies have shown that recipients with lipid metabolic disorders are approximately 3-4 times more likely to have cardiovascular events than recipients without lipid metabolic disorders^[5,6]. Therefore, PHTL is well recognized as one of the major risk factors for cardiovascular diseases, including myocardial infarction, ischemic stroke and peripheral arterial disease. Furthermore, cardiovascular complications after LT exert negative effects on the recipient's long-term survival and quality of life and are becoming the leading cause of non-graft related deaths in LT recipients^[7-9].

The pathogenesis of PHTL remains to be elucidated. Possible factors that may increase the risk of PHTL include overweight or obesity, advanced age, and the use of immunosuppressive agents^[2,10]. Immunosuppressive drugs were considered to have a major effect on the development of metabolic syndromes in previous years. Today, immunosuppressive drugs are known to have a reduced impact on glucose and lipid metabolism^[11]. Low toxicity immunosuppressive protocols (e.g., early withdrawal of steroids and low-dose calcineurin inhibitors) have decreased the impact of immunosuppressive drugs on PHTL. It is known that the liver plays an essential role in lipoprotein metabolism and is involved in almost every key step during lipid anabolism and catabolism. In living donor liver transplantation (LDLT), graft function can be influenced by reduced graft size, preservation and ischemia-reperfusion injuries. Early allograft dysfunction (EAD) may occur in more than 10% of LT recipients and result in an unfavorable prognosis^[12,13]. More importantly, renal insufficiency, which is common in liver transplant candidates, is closely associated with significant alterations in lipid metabolism. Early renal dysfunction (ERD), which is also common after LT, may indicate a prolonged recovery of kidney insufficiency and indicates a poor outcome^[14].

To date, it is still unknown whether impaired kidney or graft function can cause derangements in lipid metabolism after LDLT. To clarify these questions, we designed this retrospective study with the aim of evaluating the impact of renal and graft function on lipid metabolism after LDLT and to identify the possible risk factors for PHTL.

MATERIALS AND METHODS

Study population

All adult (age ≥ 18 years old) patients undergoing LDLT

from January 2007 to May 2009 at the First Affiliated Hospital, Zhejiang University School of Medicine, China were included in this retrospective study. Patients who died within 3 mo of LDLT were excluded. A total of 115 (96 male and 19 female) patients with a mean age of 44.7 ± 10.11 years (median: 46 years, range: 18-64 years) at transplantation were finally included. The indications for LT included cirrhosis ($n = 63$, 54.8%), acute liver failure ($n = 28$, 24.3%) and hepatocellular carcinoma ($n = 24$, 20.9%). Patient characteristics are shown in Table 1. Written informed consent was acquired from all donors and recipients before transplantation. Each organ donation and transplantation at our center was strictly carried out under the guidelines of the Ethics Committee of the First Affiliated Hospital, Zhejiang University, the regulation of Organ Transplant Committee of Zhejiang Province and the Helsinki Declaration of 1975. No prisoners were included in this study.

All patients received a triple immunosuppressive regimen incorporating tacrolimus, prednisolone, and mycophenolate mofetil as described previously^[15]. An interleukin (IL)-2 receptor blocker was used in some patients. Prednisolone was withdrawn within the first post-transplant month. A reduced dose of tacrolimus was given to patients who developed post-transplant renal impairment. All patients were routinely followed up at the out-patient clinic and the mean follow-up time was 2.66 ± 1.02 years (median: 1.98 years, range: 0.50-4.63 years).

Data collection

The data were extracted from the China Liver Transplant Registry (CLTR) database: age (donor/recipient), gender (donor/recipient), underlying liver diseases, cold ischemic time, graft-to-recipient weight ratio (GR/WR), graft volume to standard liver volume ratio (GV/SLV), donor's hepatic steatosis, recipient's pre-transplant metabolic status [history of smoking, alcohol abuse, diabetes mellitus, hypertension, hyperlipidemia, body mass index (BMI)], recipient's post-transplant liver function (bilirubin, alanine transaminase, aspartate transaminase, cholinesterase and international normalized ratio), recipient's pre/post-transplant renal function (serum creatinine), donor's and recipient's pre/post-transplant serum lipid profile (total triglycerides, total cholesterol), immunosuppressive regimen (agents and plasma levels), and recipient's post-transplant complications.

Hyperlipidemia was defined as serum triglycerides ≥ 150 mg/dL or serum cholesterol ≥ 200 mg/dL or the need for pharmacologic treatment^[16]. Patients were divided into the PHTL group ($n = 28$) and non-PHTL group ($n = 87$) according to their serum lipid levels at the sixth month after LDLT. EAD was defined by the presence of at least one of the following features: total bilirubin > 10 mg/dL, prothrombin time ≥ 17 s, or hepatic encephalopathy from day 2 to 7 post-transplantation^[17]. ERD was defined as serum creatinine ≥ 2 mg/dL and/or the need for renal replacement therapy in the first post-transplant week^[18]. Renal insufficiency was defined as pre-transplant serum creatinine > 1.5 mg/dL^[18].

Statistical analysis

Quantitative variables were presented as mean \pm SD or median with range. Categorical variables were expressed as numbers and percentages. The Student's *t* test or Mann-Whitney *U* test was used to compare quantitative variables and the χ^2 test was used to compare categorical variables. Pearson's correlation and scatter plot graph were used for correlation analysis. Logistic regression was used to identify the risk factors for PTHL. Variables that were statistically significant in univariate analysis were entered into multivariate analysis. The Kaplan-Meier method and log-rank test were used for survival analysis. SAS software version 9.2 (SAS institute, Cary, NC, United States) was used to complete all the analyses, and a *P* value of less than 0.05 was considered statistically significant. Data analysis was performed by the CLTR

Table 2 Comparison between patients with and without early renal dysfunction (means \pm SD)

Hypercholesterolemia <i>n</i> (%)	3 (18.8)	9 (9.1)	NS
PTHL <i>n</i> (%)	9 (56.3)	19 (19.2)	0.003

Hypertriglyceridemia was defined as serum triglycerides \geq 150 mg/dL; Hypercholesterolemia was defined as serum cholesterol \geq 200mg/dL. PTHL: Post-transplant hyperlipidemia; MELD: Model for end-stage of liver disease; ERD: Early renal dysfunction; NS: Not significant.

Statistical Department.

RESULTS

Prevalence and prognosis of hyperlipidemia

Of 115 eligible recipients, 19 (16.5%) had pre-transplant hyperlipidemia and 28 (24.3%) developed PTHL. Of the recipients with and without pre-transplant hyperlipidemia, the incidence of PTHL did not differ significantly (21.1% *vs* 25%, *P* = 0.714).

Of 115 donors, 13 (11.3%) were diagnosed with hyperlipidemia and 9 (7.8%) had hepatic steatosis. However, neither donor hyperlipidemia nor hepatic steatosis was found to be differently distributed between the PTHL group and non-PTHL group (both *P* > 0.05) (Table 1).

Nine recipients (7.8%) developed cardiovascular events, including four with nonfatal myocardial infarction, two with cardiac arrhythmia, one with cardiac arrest and two with stroke, with a mean onset time of 10.5 mo (median: 8 mo, range: 3-15 mo). Compared to the non-PTHL group, the PTHL group had a higher incidence of cardiovascular events after LDLT (*n* = 5, 17.9% *vs* *n* = 4, 4.6%, *P* = 0.037). The 1- and 3-year cumulative survival rates were 89.3% and 85.7% in the PTHL group, and 97.7% and 85.0% in the non-PTHL group, respectively.

Figure 1 Variation tendency of graft and renal function by post-transplant month 6 in all recipients. A: Alanine/aspartate transaminase; B: Total bilirubin; C: Cholinesterase; D: Serum creatinine. Data were presented as means ± SD.

There was no statistically significant difference between the two groups in cumulative survival ($P = 0.956$).

Graft function and post-transplant hyperlipidemia

As shown in Figure 1, alanine transaminase, aspartate transaminase and bilirubin, which indicate hepatic cellular injury, decreased sharply in the first post-transplant month and continued to decline to the normal range during the next two months. Cholinesterase, which represents hepatocellular synthetic function, remained at a low level during the first post-transplant month and gradually increased to an ideal level at post-transplant month 3. Of these parameters, cholinesterase had a significant positive correlation with serum cholesterol level at post-transplant month 1 ($r = 0.341$, $P = 0.001$) and month 3 ($r = 0.280$, $P = 0.003$), respectively (Figure 2A and B). However, cholinesterase was not associated with the development of PTHL following logistic regression analysis ($P > 0.05$).

EAD occurred in 18 (15.7%) of 115 recipients. At the third post-transplant month, EAD had resolved in 77.8% (14/18) of patients. Primary graft non-function was not observed. The incidence of PTHL did not differ significantly between patients with EAD and those without EAD (33.3% *vs* 20.6%, $P = 0.236$).

Renal function and post-transplant hyperlipidemia

Serum creatinine levels decreased during the first post-

transplant month (Figure 1) and were significantly related to serum triglyceride level at the first ($r = 0.440$, $P < 0.001$) and third ($r = 0.250$, $P = 0.007$) post-transplant month, respectively (Figure 2C and D). Serum creatinine levels at the first post-transplant month differed significantly between the PTHL and non-PTHL groups (1.10 ± 0.67 mg/dL *vs* 0.73 ± 0.25 mg/dL, $P = 0.001$).

ERD occurred in 16 (13.9%) of 115 post-transplant recipients. There was a statistically significant difference between ERD and non-ERD recipients in pre-transplant renal function (Table 2). Serum creatinine remained high during the first 6 post-transplant months in ERD recipients. Of the 16 recipients with ERD, 9 and 5 needed hemodialysis in the first and third post-transplant month, respectively. The prevalence of PTHL in ERD patients was significantly higher than that in non-ERD patients (56.3% *vs* 19.2%, $P = 0.003$), notably for hypertriglyceridemia (56.3% *vs* 12.1%, $P < 0.001$).

Risk factors for post-transplant hyperlipidemia

We postulated that donors' pre-transplant hyperlipidemia and hepatic steatosis, GR/WR (%) and GV/SLV (%); recipients' pre-transplant serum creatinine level, pre-transplant BMI and pre-transplant hyperlipidemia, post-transplant tacrolimus level, post-transplant diabetes within the first six months after LDLT^[15], post-transplant BMI at the sixth month after LDLT, EAD and ERD were poten-

Figure 2 Correlation between serum cholesterol and triglyceride level and cholinesterase at post-transplant. A: Correlation between serum cholesterol level and cholinesterase at post-transplant month 1; B: Correlation between serum cholesterol level and cholinesterase at post-transplant month 3; C: Correlation between serum triglyceride level and serum creatinine at post-transplant month 1; D: Correlation between serum triglyceride level and serum creatinine at post-transplant month 3.

tial risk factors for PTHL. Following univariate analysis, five variables were identified as significant risk factors for PTHL and were entered into the multivariate analysis (Table 3). We subsequently found that ERD [odds ratio (OR) = 9.593, $P < 0.001$] and BMI (OR = 6.358, $P = 0.002$) were independent risk factors for PTHL.

DISCUSSION

The most important finding in this study was the correlation between renal function and PTHL, which may be of great help in better understanding the pathogenesis of PTHL, and as much as possible, preventing its development. It was demonstrated that post-transplant serum creatinine had a significant positive correlation with serum triglycerides both in the first and third post-transplant month. More importantly, using multivariate regression analysis, ERD was found to be an independent risk factor for PTHL. Patients with ERD usually had a relatively long-term and severe renal insufficiency before transplantation, and impaired renal function resolved very slowly during the first six months after transplantation. Here, we provide the first evidence that delayed recovery of renal function after transplantation, which was probably due to chronic kidney injury before transplantation, can result in PTHL, especially hypertriglyceridemia.

In fact, it is well known that chronic kidney disease is associated with hyperlipidemia. In the kidney, the apical surface of proximal tubules has a high capacity for receptor-mediated uptake of filtered lipid-binding plasma proteins^[19]. Therefore, hyperlipidemia induced by impaired renal function is characterized by abnormal metabolism of plasma lipoproteins^[20,21]. The reduced catabolic rate of triglyceride-rich lipoproteins and the growing hepatic production of triglyceride-high lipoproteins may explain why hypertriglyceridemia is one of the most common quantitative lipid abnormalities in patients with chronic kidney disease^[22,23]. Consistent with previous findings, the impaired renal function and recovered liver synthetic function in patients with ERD during the early post-transplant period may explain the development of hypertriglyceridemia in this study. Therefore, more emphasis should be placed on this issue, as more and more patients are undergoing liver transplantation with higher serum creatinine levels in the era of MELD.

Another finding in this study was that graft function was associated with cholesterol metabolism after LDLT. Our results showed the smooth recovery of decompensated liver function during the early post-transplant period. Furthermore, elevated serum cholinesterase level, which represents the recovery of hepatic cellular synthetic function, was significantly correlated with an increase

in cholesterol level within the normal range. It is noteworthy that cholesterol plays an active role during liver regeneration. It is not only a structural component, but also a significant regulator in the control of the intermediate metabolism of different liver cell types^[24]. This implies that there may be mutual benefits between improved graft synthetic function and cholesterol homeostasis.

Since donor pre-transplant serum lipid level may play an essential role in the development of PTHL^[25], we also analyzed the association between pre-transplant donor serum lipid level and post-transplant recipient serum lipid level. No significant difference in the incidence of PTHL was found between the recipients receiving grafts from pre-transplant hyperlipidemic and non-hyperlipidemic donors. The pre-transplant serum triglyceride and cholesterol levels of donors in the PTHL group were not significantly higher than those in the non-PTHL group. Therefore, in this study, there was no obvious evidence to show that pre-transplant donors' serum lipid level or fatty liver exerted crucial effects on the development of PTHL.

High BMI was found to be another independent risk factor for PTHL in this study. As a main component of the metabolic syndrome, high BMI or obesity before LT has been reported to be associated with an increased prevalence of PTHL^[26]. It seems unlikely that dietary habits and unhealthy lifestyle can be changed and thus patients retain their obesity status, resulting in abnormalities in lipid metabolism. It was notable that some patients had pre-transplant hyperlipidemia, but did not have PTHL in this study. A possible reason for this is that pre-transplant hyperlipidemia, which resulted mainly from hepatorenal syndrome due to end-stage liver disease, could be improved or resolved by the recovery of liver and kidney function after liver transplantation.

A high blood concentration of tacrolimus has been reported to contribute to PTHL in LDLT^[27]. However, in the present study, we did not find an association between immunosuppressive drugs and PTHL. This may be due to the early steroid withdrawn and low tacrolimus concentration protocol. Furthermore, reduced-dose tacrolimus with or without an IL-2 receptor blocker was

given to patients who developed post-transplant renal impairment, which also minimizes the side-effects of immunosuppressive drugs on lipid metabolism.

There were some limitations in this study. Firstly, it was not a prospective study. The impact of graft and kidney function on the development of PTHL requires confirmation in prospective studies with larger samples. Secondly, a longer period of follow-up is necessary to identify the natural history of PTHL and to determine the influence of PTHL on a recipient's prognosis. Thirdly, a study at the molecular level should be performed as the donor's genotype may play a role in the development of metabolic diseases.

In conclusion, renal and graft function correlated with lipid metabolism after LDLT. Severe pre-transplant renal insufficiency may lead to long-term post-transplant renal dysfunction, and consequently cause PTHL, especially hypertriglyceridemia. Appropriate clinical treatment such as the prophylactic use of fibrates or statins may be considered to prevent PTHL in patients who develop ERD or have longstanding pre-transplant renal dysfunction. Well-designed and large-sample studies are needed to verify these results.

COMMENTS

Background

Post-transplant hyperlipidemia (PTHL) is a major and serious complication after liver transplantation. It is estimated that 45%-70% of recipients develop PTHL, which is well recognized as one of the major risk factors for cardiovascular diseases, including myocardial infarction, ischemic stroke and peripheral arterial disease, and exerts negative effects on the recipient's long-term survival and quality of life. It is well known that the liver plays an essential role in lipoprotein metabolism and is involved in almost every key step during lipid anabolism and catabolism. More importantly, renal insufficiency, which is common in liver transplant candidates, is closely associated with significant alterations in lipid metabolism. Therefore, it is necessary to determine the associations between both renal and hepatic function and PTHL.

Research frontiers

The pathogenesis of PTHL remains to be elucidated. Possible factors which may increase the risk of PTHL include overweight or obesity, advanced age, and the use of immunosuppressive agents. Immunosuppressive drugs were considered to have a major effect on the development of metabolic syndromes in previous years. Today, immunosuppressive drugs are known to have a reduced impact on glucose or lipid metabolism. Low toxicity immunosuppressive

protocols (e.g., early withdrawal of steroids and low-dose calcineurin inhibitors) have decreased the impact of immunosuppressive drugs on PTHL.

Innovations and breakthroughs

Over the past few years, most researchers have focused their attention on immunosuppressive protocols and obesity status. However, together with the application of lower toxicity immunosuppressive protocols, an increasing number of articles have shown that novel immunosuppressive therapy has less of an impact on glucose and lipid metabolism. Therefore, authors looked into the possibility that kidney and graft function may have a potential relationship with PTHL. From the results, renal and graft function were shown to correlate with lipid metabolism after living donor liver transplantation. Severe pre-transplant renal insufficiency may lead to long-term post-transplant renal dysfunction, and consequently result in PTHL, especially hypertriglyceridemia. Appropriate clinical treatment such as the prophylactic use of fibrates or statins may prevent PTHL in patients who develop early renal dysfunction or have longstanding pre-transplant renal dysfunction.

Applications

This study suggested that there was a correlation between renal function and PTHL, which may be of great help in better understanding the pathogenesis of PTHL, and as much as possible, preventing its development.

Peer review

This is a good retrospective study. There were some limitations in this study, but were reasonably explained by the authors. In my opinion, this study is original and it is acceptable for publication.

Abstract

AIM: To study the effect of salvianolate on tight junctions (TJs) and zonula occludens protein 1 (ZO-1) in small intestinal mucosa of cirrhotic rats.

METHODS: Cirrhosis was induced using carbon tetrachloride. Rats were randomly divided into the untreated group, low-dose salvianolate (12 mg/kg) treatment

group, medium-dose salvianolate (24 mg/kg) treatment group, and high-dose salvianolate (48 mg/kg) treatment group, and were treated for 2 wk. Another 10 healthy rats served as the normal control group. Histological changes in liver tissue samples were observed under a light microscope. We evaluated morphologic indices of ileal mucosa including intestinal villi width and thickness of mucosa and intestinal wall using a pathological image analysis system. Ultrastructural changes in small intestinal mucosa were investigated in the five groups using transmission electron microscopy. The changes in ZO-1 expression, a tight junction protein, were analyzed by immunocytochemistry. The staining index was calculated as the product of the staining intensity score and the proportion of positive cells.

RESULTS: In the untreated group, hepatocytes showed a disordered arrangement, fatty degeneration was extensive, swelling was obvious, and disorganized lobules were divided by collagen fibers in hepatic tissue, which were partly improved in the salvianolate treated groups. In the untreated group, abundant lymphocytes infiltrated the fibrous tissue with proliferation of bile ducts, and collagen fibers gradually decreased and damaged hepatic lobules were partly repaired following salvianolate treatment. Compared with the untreated group, no differences in intestinal villi width between the five groups were observed. The villi height as well as mucosa and intestinal wall thickness gradually thickened with salvianolate treatment and were significantly shorter in the untreated group compared with those in the salvianolate treatment groups and normal group ($P < 0.01$). The number of microvilli decreased and showed irregular lengths and arrangements in the untreated group. The intercellular space between epithelial cells was wider. The TJs were discontinuous, which indicated disruption in TJ morphology in the untreated group. In the treated groups, the microvilli in the intestinal epithelium were regular and the TJs were gradually integrated and distinct. The expression of ZO-1 decreased in the small intestine of the un-

treated cirrhotic rats. The high expression rate of ZO-1 in ileal mucosa in the untreated group was significantly lower than that in the medium-dose salvianolate group (21.43% *vs* 64.29%, $\chi^2 = 5.25$, $P < 0.05$), high-dose salvianolate group (21.43% *vs* 76.92%, $\chi^2 = 8.315$, $P < 0.01$) and normal group (21.43% *vs* 90%, $\chi^2 = 10.98$, $P < 0.01$).

CONCLUSION: Salvianolate improves liver histopathological changes, repairs intestinal mucosa and TJ structure, and enhances ZO-1 expression in the small intestinal mucosa in cirrhotic rats.

INTRODUCTION

In liver cirrhosis, disruption of the intestinal mucosal barrier function and increased mucosal intestinal permeability lead to bacterial translocation and endotoxemia^[1], which increase susceptibility to infection, the most frequent and severe of which is spontaneous bacterial peritonitis^[2,3]. Endotoxemia may affect liver function, contribute to systemic hemodynamic derangement in liver cirrhosis^[4,5], and result in severe complications^[6-8]. Therefore, restoring the integrity of the intestinal barrier is an important goal in preventing deterioration of liver function in patients with cirrhosis^[3,9].

The intestinal mucosal barrier includes both secretory and physical preventive measures against the penetration of microbes. The secretory mechanism is realized through mucus secretion, local immunoglobulins and bile salts. The physical mechanism is represented by the intestinal epithelium^[10,11], specifically its lack of permeability and active antimicrobial peptide production. The tight junctions (TJs) of the intestinal epithelium allow only the passage of very tiny molecules^[12], preventing the transport of bacteria or macromolecules (lipopolysaccharides)^[13]. Disruption of the intestinal TJ barrier results in a "leaky" TJ barrier, allowing paracellular permeation of toxic luminal substances. Altered intestinal TJ expression in patients is a molecular mechanism of intestinal hyperpermeability. It was demonstrated that patients with decompensated and compensated cirrhosis had signifi-

cantly reduced expression of TJ proteins, higher Child-Pugh score, and decreased liver function^[14]. As an important contributor to the development of liver cirrhosis, the physical barrier of the small intestine represents an ideal therapeutic target^[15]. However, there are no reports on an effective means of preventing disruption of the intestinal physical barrier in liver cirrhosis.

Radix *Salvia miltiorrhiza*, a traditional Chinese medicinal herb known as "danshen" has been widely used for the treatment of various cardiovascular diseases^[16,17]. *Salvia miltiorrhiza* (*S. miltiorrhiza*) extracts contain lipid-soluble diterpene quinones (tanshinones) and water-soluble phenolic acid derivatives such as salvianolic acid A and B and lithospermic acid B^[18]. Recent pharmacological research has shown that *S. miltiorrhiza* eliminates oxygen free radicals, enhances antioxidant activity, decreases serum cytokine levels, and inhibits endotoxemia^[19]. Moreover, *S. miltiorrhiza* can block the lethal toxicity of lipopolysaccharides in mice *via* suppression of tumor necrosis factor- α (TNF- α) release^[20] and help to maintain the integrity of the endothelial junction structure^[21]. Salvianolate is a new water-soluble phenolic compound and is one of the most bioactive compounds in *S. miltiorrhiza* Bge. However, in carbon tetrachloride (CCl₄)-induced cirrhosis in rats, the effect of salvianolate on the physical barriers of the small intestine is less clear. A previous study demonstrated that salvianolate can reduce the endotoxin level, ameliorate injury to the intestinal mucosa, and inhibit the expression of TNF- α and interleukin-6 (IL-6) mRNA in the small intestine of cirrhotic rats^[22]. Therefore, we used CCl₄-induced cirrhotic rats to evaluate changes in the epithelial barrier of the ileal mucosa and the effect of different doses of salvianolate on TJs and zonula occludens protein 1 (ZO-1) in microvillus cells of the small intestine mucosa.

MATERIALS AND METHODS

A previous study demonstrated that salvianolate can reduce endotoxin levels in the portal vein, ameliorate injury to the intestinal mucosa, and inhibit cytokine gene expression in rats with CCl₄-induced liver cirrhosis^[22]. To further explore the mechanism of salvianolate in enhancement of the intestinal mechanical barrier, in the present study, we evaluated liver histopathological changes and morphologic indices of ileal mucosa using light microscopy, analyzed the ultrastructural changes using transmission electron microscopy and the expression of ZO-1, a TJ protein, using immunocytochemistry. The results of this study may provide a new strategy for the treatment of liver cirrhosis.

Animals

Ninety male Sprague-Dawley rats (weight: 180-220 g) were provided by the Department of Animal Care, Zhejiang Traditional University, Hangzhou, China. Experimental animals were housed in individual cages at 22 °C to 25 °C under a 12-h light/dark cycle and fed a standard

laboratory diet and tap water *ad libitum*.

Experimental protocol

The rats were randomly divided into two groups: the normal control group ($n = 10$, group A) and the model group. All model group rats received a subcutaneous injection of 40% CCl₄ in a 2:3 mixture with olive oil (0.3 mL/kg) once weekly for 12 wk. Liver cirrhosis was successfully induced in 55 rats at the end of 12 wk as shown by liver histological evaluation. The 55 model rats were further randomly divided into four subgroups: the untreated group ($n = 14$, group B), low-dose salvianolate-treated group (12 mg/kg) ($n = 14$, group C), medium-dose salvianolate-treated group (24 mg/kg) ($n = 14$, group D), and high-dose salvianolate-treated group (48 mg/kg) ($n = 13$, group E). Group A was injected intraperitoneally with 5% glucose solution once daily for 2 wk. Groups C to E were treated intraperitoneally with different doses of salvianolate dissolved in 5% glucose solution once daily for 2 wk. 40% CCl₄ administration was continued for the 14-wk experimental period. At the end of the experimental period, all rats were anesthetized with 3% chloral hydrate and dissected. Blood samples from the portal vein and intestinal tissue were obtained for further analysis.

Assessment of histological changes in the liver and morphologic indices of ileal mucosa

At the end of the 14-wk experimental period, the abdominal cavity in each rat was opened by a horizontal incision along the mid-section and the liver and intestines were excised. Tissue samples were taken immediately and washed three times with cold physiological saline and fixed in 10% formalin solution. After fixation, tissue specimens were dehydrated and embedded in paraffin. Sections from each sample were cut at a thickness of 4 μ m and stained with hematoxylin and eosin (Olympus BX50; Tokyo, Japan). We evaluated morphologic indices of the ileal mucosa including intestinal villi width, and thickness of the mucosa and intestinal wall using a pathological image analysis system (Leica Qwinv3, Jiangsu, China).

Ultrastructure with transmission electron microscopy

Ileum samples in the five groups were separated and fixed immediately with 2% glutaraldehyde, post-fixed with 1% osmium tetroxide, and embedded in resin (EM-bed 812 Embedding Kit, Electron Microscopy Sciences Company, United States). Ultrathin sections were cut and stained with uranyl acetate and lead citrate. Samples were examined using a transmission electron microscope (Philips Tecnai 12, Holland) and analyzed by an electron microscope image analyzer (Erlangshen ES500W, Holland).

Immunohistochemistry

Immunohistochemical analysis was performed to study ZO-1 expression in the intestinal mucous membranes. In brief, slides were baked at 55 °C for 2 h, deparaf-

finized with xylene, and rehydrated. The sections were submerged in EDTA antigenic retrieval buffer and microwaved for antigenic retrieval, after which they were treated with 3% hydrogen peroxide in methanol to quench endogenous peroxidase activity. They were then incubated with 1% bovine serum albumin to block nonspecific binding. Sections were incubated with mouse anti-ZO-1 antibodies (Beijing Biosynthesis Biotechnology Co., Ltd., Beijing, China) overnight at 4 °C. Normal goat serum was used as a negative control. After washing, tissue sections were treated with secondary antibody. Tissue sections were then counterstained with hematoxylin, dehydrated and mounted. The cytoplasm and stroma containing ZO-1 were stained as the buffy coat. The degree of immunostaining was reviewed and scored independently by two observers based on the proportion of positively stained epithelium and intensity of staining^[23-25]. The proportion of ZO-1 expression-positive areas was scored as follows: 0 ($\leq 5\%$ positive area expression), 1 (6%-25% positive area expression), 2 (26%-50% positive area expression), and 3 ($> 51\%$ positive area expression). Staining intensity was graded according to the following criteria: 0 (no staining), 1 (weak staining, light yellow), 2 (moderate staining, yellow-brown), and 3 (strong staining, brown). The staining index was calculated as the product of the staining intensity score and the proportion of positive cells. Using this method of assessment, we evaluated ZO-1 expression in the intestinal mucous membranes by determining the staining index with scores of 0, 1, 2, 3, 4, 6, or 9. The cutoff value for high and low expression levels was chosen based on a measure of heterogeneity using the log-rank test with respect to overall survival. An optimal cutoff value was identified as follows: a staining index score of ≥ 6 was used to define high ZO-1 expression and a staining index score of < 6 was used to indicate low ZO-1 expression.

Statistical analysis

Statistical analysis was performed using SPSS version 13.0 (Chicago, IL, United States). Results of the mucosal morphologic indices were assessed by analysis of variance. Data were expressed as the means \pm SD. The expression rate of ZO-1 protein was compared using the χ^2 test. A P value of < 0.05 was considered statistically significant.

RESULTS

Liver histological evaluation

In the untreated group, hepatocytes showed a disordered arrangement, fatty degeneration was extensive, and swelling was obvious. Spotty necrosis and eosinophilic bodies appeared in the hepatic tissue. Disorganized lobules were divided by collagen fibers. Central veins disappeared and pseudolobules proliferated in the hepatic tissue. Abundant lymphocytes infiltrated the fibrous tissue with proliferation of bile ducts (Figure 1A). Collagen fibers gradually decreased and damaged hepatic lobules were partly repaired by salvianolate treatment. Fatty degeneration of

^b $P < 0.01$ vs group B.

hepatocytes was reduced and inflammatory cell infiltration decreased in the fibrous tissue, especially in the high-dose salvianolate group (Figure 1B-D).

Morphologic indices of ileal mucosa

Histological changes observed in ileal tissue under light microscopy were previously published^[22]. In that study, we found that salvianolate ameliorated injury to the intestinal mucosa. In the present study, we measured intestinal villi width and thickness of the mucosa and intestinal wall using a pathological image analysis system. There were no differences in intestinal villi width among the five groups ($P > 0.05$). Villi height was significantly shorter in group B than in groups C, D, E and the normal group (99.14 \pm 14.57 μm vs 126.43 \pm 22.12 μm , 128.71 \pm 20.33 μm , 147.10 \pm 19.48 μm and 221.82 \pm 37.97 μm , respectively; $P < 0.01$). Mucosal thickness was significantly less in the untreated group than in groups C, D and E (131.43 \pm

18.83 μm vs 179.02 \pm 26.99 μm , 181.10 \pm 30.71 μm and 230.28 \pm 20.67 μm , respectively; $P < 0.01$). The intestinal walls were significantly thicker in groups C, D and E compared with group B (226.37 \pm 40.66 μm , 229.95 \pm 42.08 μm and 278.94 \pm 39.94 μm vs 165.93 \pm 23.02 μm , respectively; $P < 0.01$) (Table 1). These results show that the intestinal mucosa was gradually thickened and repaired by salvianolate treatment.

Ultrastructural morphology of intestinal mucosa

In the normal group, regularly aligned microvilli and intact TJs were observed in the intestinal epithelium (Figure 2A). In the untreated group, the number of microvilli decreased and showed irregular lengths and arrangements. The intercellular space between epithelial cells widened. TJs were discontinuous, which indicated disruption in TJ morphology in the untreated group (Figure 2B). In the treated groups, the microvilli in the intestinal epithelium were regular and the TJs were gradually integrated and distinct (Figure 2C-E).

Expression of ZO-1 in ileal epithelial mucosa shown by immunohistochemistry

Ileal epithelial mucosa from the five groups was assayed for ZO-1 expression using immunohistochemistry. Normal mice showed expression of ZO-1 at the apical pole of epithelial cells^[26] and within the cytoplasm (Figure 3A). Nine (90%) rats in group A showed high expression of ZO-1. Staining of ZO-1 was less in group B; there was almost no expression at the apical pole of epithelial cells and slight expres-

Figure 2 Tight junction structural morphology in ileal mucosa. A: Normal control group; B: Untreated group; C: Low-dose salvianolate-treated group; D: Medium-dose salvianolate-treated group; E: High-dose salvianolate-treated group (transmission electron microscopy, $\times 26\,500$).

Figure 3 Immunohistochemical staining for zonula occludens protein 1 in ileal mucosa. A: Normal control group; B: Untreated group; C: Low-dose salvianolate-treated group; D: Medium-dose salvianolate-treated group; E: High-dose salvianolate-treated group ($\times 40$).

sion within the cytoplasm (Figure 3B). The expression of ZO-1 gradually increased in epithelial cells following salvianolate treatment. Group B showed a high expression rate of 21.43%, which was significantly lower than that in group A (21.43% *vs* 90%, $\chi^2 = 10.98$, $P < 0.01$) (Figure 4).

In the treated groups, brown grains again appeared at the apical pole of epithelial cells and within the cytoplasm of epithelial cells (Figure 3C-E). Groups C, D and E showed high ZO-1 expression rates of 57.14%, 64.29% and 76.92%, respectively. The expression rate in group B

Figure 4 Expression of zonula occludens protein 1 in ileal mucosa. A: Normal control group; B: Untreated group; C: Low-dose salvianolate-treated group; D: Medium-dose salvianolate-treated group; E: High-dose salvianolate-treated group. The staining index was calculated as the product of the staining intensity score and the proportion of positive cells. We evaluated zonula occludens protein 1 (ZO-1) expression in the five groups by determining the staining index with scores of 0, 1, 2, 3, 4, 6, or 9. An optimal cutoff value was identified as follows: a staining index score of ≥ 6 was used to define high ZO-1 expression and a staining index score of < 3 was used to indicate low ZO-1 expression.

was significantly lower than that in groups D (21.43% *vs* 64.29%, $\chi^2 = 5.25$, $P < 0.05$) and E (21.43% *vs* 76.92%, $\chi^2 = 8.315$, $P < 0.01$) (Figure 4).

DISCUSSION

Protection of the intestinal barrier function and decreased bacterial translocation are important in patients with liver cirrhosis^[27]. In our previous study^[22], a significant increase in plasma endotoxins and high mortality were observed in untreated cirrhotic rats. Endotoxemia was significantly reduced and intestinal histopathological changes were improved by administration of salvianolate in cirrhotic rats. We showed that salvianolate has a direct anti-inflammatory effect on the intestine by inhibiting the expression of TNF- α and IL-6 mRNA. These favorable effects of salvianolate on the intestine can be partially explained by direct protection of the integrity of the mucosal barrier.

In this study, we observed improvement in liver histopathological changes (Figure 1) as well as thickening and gradual repair of the intestinal mucosa with salvianolate treatment (Table 1). To further elucidate the mechanisms of salvianolate in protecting the mucosal barrier in cirrhotic rats, we investigated the effect of salvianolate therapy on ultrastructural analysis using transmission electron microscopy and ZO-1 expression changes using immunocytochemistry.

The physical intestinal barrier comprises an intact layer of epithelial cells, which are tightly connected by a surrounding system of TJ strands that seal the lateral intercellular space^[28]. The intercellular space between

epithelial and endothelial cells is bridged by a set of specialized structures: TJs, or ZO; zonula adherens (ZA); desmosomes; and gap junctions. The TJ is an essential component of this barrier. The junctional complexes of the plasma membrane are not simply epithelial barriers in paracellular transport or barriers preventing diffusion across the plasma membrane, but also contain proteins involved in signal transduction and maintenance of the physiological epithelial cell state^[29,30]. Increased permeability is caused by disruption of intercellular TJs in the intestine and plays an important role in the pathogenesis of chronic liver disease^[31]. Previous studies have shown that impaired intestinal permeability may increase the risk of endotoxemia and spontaneous bacterial peritonitis in liver cirrhosis^[14].

The intracellular complex of TJ-associated proteins includes ZO-1, ZO-2, ZO-3, cingulin, 7H6, symplekin and ZA-1^[32]. This complex appears to link TJs to a perijunctional actomyosin ring, which supports and regulates TJ permeability in epithelial cells. ZO-1, one of the plaque proteins, was the first TJ protein to be characterized. It is a 225-kDa membrane-bound protein that localizes to the TJ. It binds the occluding and claudin transmembrane proteins, linking them to cytoskeletal actin^[33]. ZO-1 may be the direct link between actin and the transmembrane proteins; it has its own specific function^[34] and is a particularly important molecule in terms of the formation of TJs^[35]. ZO-1 alterations may contribute to disturbances of the TJ barrier, which lead to enhanced intestinal permeability^[36]. Disruption of this structure could lead to an imbalance in the normal interaction between aggressive factors and mucosal defense, resulting in increased intestinal permeability and bacterial translocation.

Further investigations revealed that mucosal damage was accompanied by ultrastructural changes in TJs. TJ injury is associated not only with increased transcellular permeability, but also with increased paracellular permeability because of the rearrangement of TJ proteins. In this study, we found that the expression of ZO-1 was decreased in the small intestine of untreated cirrhotic rats. Administration of salvianolate may recover the TJ structure and enhance the expression of ZO-1 in the small intestine of cirrhotic rats. This may explain the effect of salvianolate on the epithelial barriers of the small intestine in cirrhotic rats.

In summary, the epithelial barriers of the small intestine were destroyed in cirrhotic rats. These changes may promote bacterial translocation and intestinal endotoxemia. Salvianolate administration caused reduced mucosal damage and maintained the epithelial mucosal barrier function in the small intestine of cirrhotic rats. Furthermore, salvianolate may be a potent traditional Chinese medicinal herb for reducing the incidence of spontaneous bacterial peritonitis and influencing the natural history of liver cirrhosis. These results indicate that salvianolate may be a new therapy for liver cirrhosis.

COMMENTS

Background

In liver cirrhosis, disruption of the intestinal barrier function increases intestinal permeability and bacterial translocation, which contribute to endotoxemia and derangement in liver cirrhosis. Abnormalities of the epithelial mucosal barrier represented by tight junction structure damage play an important role in the pathogenesis of altered intestinal permeability. Improving the epithelial mucosal tight junctions (TJs) and epithelium tight junction proteins is a key goal in preventing intestinal endotoxemia in patients with cirrhosis.

Research frontiers

Recent studies have shown that the physical barrier of the intestinal mucosa plays an important role in intestinal defense mechanisms in hepatic cirrhosis. Previous experiments confirmed that salvianolate can reduce the endotoxin level, ameliorate injury to the intestinal mucosa and inhibit the expression of tumor necrosis factor- α and interleukin-6 mRNA in the small intestine of cirrhotic rats.

Innovations and breakthroughs

Disturbance of the TJs and zonula occludens protein 1 (ZO-1) alterations lead to increased intestinal permeability and bacterial translocation in hepatic cirrhosis. This study showed, for the first time, that salvianolate can restore ultra-structural changes in the intestinal mucosa and significantly increase TJ protein expression in cirrhotic rats. The authors demonstrated that the pharmacological activities of salvianolate represent an important cellular mechanism for preventing intestinal epithelial barrier function damage in liver cirrhosis.

Applications

By demonstrating the effects of salvianolate in maintaining the mucosal physical barrier function in the small intestine of cirrhotic rats, this study provides a new strategy for the treatment of liver cirrhosis. Salvianolate can be applied in clinical practice due to its potential pharmacological activities.

Terminology

Radix *Salvia miltiorrhiza* is a traditional Chinese medicinal herb known as "dan-shen". Salvianolate is a water-soluble phenolic compound isolated from Radix *Salvia miltiorrhiza*.

Peer review

The authors have illustrated that the administration of salvianolate may recover the TJ structure and enhance the expression of ZO-1 in the small intestine of cirrhotic rats. This topic is of significant clinical importance and the results provide a new strategy for the treatment of spontaneous bacterial peritonitis.

Abstract

AIM: To retrospectively analyze the imaging features of hepatic focal nodular hyperplasia (FNH) in children on dynamic contrast-enhanced multi-slice computed tomography (MSCT) and computed tomography angiography (CTA) images.

METHODS: From September 1999 to April 2012, a total of 218 cases of hepatic FNH were confirmed by either surgical resection or biopsy in the Sun Yat-sen Memorial Hospital of Sun Yat-sen University and the Cancer center of Sun Yat-sen University, including 12 cases (5.5%) of FNH in children (age ≤ 18 years old). All the 12 pediatric patients underwent MSCT. We retrospectively analyzed the imaging features of FNH le-

sions, including the number, location, size, margin, density of FNH demonstrated on pre-contrast and contrast-enhanced computed tomography (CT) scanning, central scar, fibrous septa, pseudocapsule, the morphology of the feeding arteries and the presence of draining vessels (portal vein or hepatic vein).

RESULTS: All the 12 pediatric cases of FNH had solitary lesion. The maximum diameter of the lesions was 4.0-12.9 cm, with an average diameter of 5.5 ± 2.5 cm. The majority of the FNH lesions (10/12, 83.3%) had well-defined margins. Central scar (10/12, 83.3%) and fibrous septa (11/12, 91.7%) were commonly found in children with FNH. Central scar was either isodense ($n = 7$) or hypodense ($n = 3$) on pre-contrast CT images and showed progressive enhancement in 8 cases in the equilibrium phase. Fibrous septa were linear hypodense areas in the arterial phase and isodense in the portal and equilibrium phases. Pseudocapsule was very rare (1/12, 8.3%) in pediatric FNH. With the exception of central scars and fibrous septa within the lesions, all 12 cases of pediatric FNH were homogeneously enhanced on the contrast-enhanced CT images, significantly hyperdense in the arterial phase (12/12, 100.0%), and isodense in the portal venous phase (7/12, 58.3%) and equilibrium phase (11/12, 91.7%). Central feeding arteries inside the tumors were observed on CTA images for all 12 cases of FNH, whereas no neovascularization of malignant tumors was noted. In 9 cases (75.0%), there was a spoke-wheel shaped centrifugal blood supply inside the tumors. The draining hepatic vein was detected in 8 cases of pediatric FNH. However, the draining vessels in the other 4 cases could not be detected. No associated hepatic adenoma or hemangioma was observed in the livers of the 12 pediatric cases.

CONCLUSION: The characteristic imaging appearances of MSCT and CTA may reflect the pathological and hemodynamic features of pediatric FNH. Dynamic multi-phase MSCT and CTA imaging is an effective method for diagnosing FNH in children.

INTRODUCTION

Hepatic focal nodular hyperplasia (FNH) is the second most common benign liver tumor after hemangioma, occurring in approximately 3%-5% of the general population^[1]. The mechanism for the pathogenesis of FNH is unclear, although it may be caused by a proliferative response to local vascular abnormalities^[2]. FNH is most common in adult females, with a female to male ratio of 2-4:1^[1,3], whereas it is rare in children. If a focal hyper-vascular liver lesion is accidentally detected in children during imaging, it is important to differentiate FNH from other malignant lesions to avoid unnecessary surgical resection. Since FNH is a slow growing tumor without malignant transformation and is rarely accompanied by the complications of hemorrhage or rupture, conservative “wait and see” strategy is recommended for asymptomatic children^[4]. Surgical treatment would be considered only for symptomatic pediatric patients, patients with increasing size of FNH, or patients in whom malignancy cannot be ruled out confidently^[5-7].

Multi-slice spiral computed tomography (CT) technology has rapidly developed since the clinical application of 16-slice spiral CT was introduced in 2001. Multi-slice computed tomography (MSCT) (16 slices, 64 slices or 128 slices) features a fast scanning speed (the time required for a single tube rotation is sub-second) and is ideal for assessing pediatric patients. With MSCT, dynamic multi-phase scanning is allowed in a very short period of time, and increased detection and characterization of focal liver lesion can be achieved^[2]. In addition, the ability of MSCT to acquire data with “isotropic voxel” makes high-quality two- or three-dimensional vascular reconstruction images possible^[3]. To the best of our knowledge, there are few reports on the imaging features of FNH in children^[4,8,9]. The previous imaging procedure most often utilized for the assessment of the hemodynamic characteristics of FNH was angiography, which is invasive and labor-intensive. Studies that analyze the imaging characteristics of FNH in children on MSCT images and the angioarchitecture of pediatric FNH on computed tomography angiography (CTA) have not reported in the literature. This paper retrospectively reviewed the imaging features

of MSCT in 12 cases of FNH in children.

MATERIALS AND METHODS

Patients

The database of the Sun Yat-sen Memorial Hospital of Sun Yat-sen University and the Cancer Center of Sun Yat-sen University was searched from September 1999 to April 2012, and 218 cases of hepatic FNH confirmed by surgical resection or biopsy were identified. Out of the 218 cases, there were 12 cases (5.5%) of FNH in children (aged ≤ 18 years).

Out of the 12 pediatric cases, 8 were males and 4 were females. The age of the patients ranged from 2 years old to 18 years old, with an average of 12.1 ± 6.4 years. Four pediatric cases presented with abdominal pain, 2 cases presented with palpable abdominal masses, 1 case presented with upper abdominal discomfort, and the other 5 asymptomatic cases were discovered accidentally during imaging check-up for related reasons. In 1 patient, hemangiomas were found in the right shoulder and nasal alae when the diagnosis of hepatic FNH was established. All 12 cases were negative for hepatitis B surface antigen markers and for tumor markers, such as alpha-fetoprotein (AFP), carcinoembryonic antigen 125, and carbohydrate antigen 19-9. All the 12 pediatric patients did not have a history of malignancy or stem cell transplantation.

Imaging protocols

MSCT examinations were performed on either a 64-slice spiral CT scanner (Sensation 64, Siemens Medical Solutions, Erlangen, Germany) or a 16-slice spiral CT scanner (BrillianceTM 16, Philips Medical Systems, Best, The Netherlands) in all 12 pediatric patients. The CT scan parameters were as follows: a tube voltage of 120 kV, an effective tube current of 85-200 mAs, and collimation of $64 \text{ mm} \times 0.6 \text{ mm}$ or $16 \text{ mm} \times 0.75 \text{ mm}$. After pre-contrast scanning images were obtained, multi-phase contrast-enhanced CT scan was performed after intravenous administration of nonionic contrast material of Iopamidol (370 mgI/mL, Bracco, Milan, Italy) or Iopromide (370 mgI/mL, Schering, Erlangen, Germany) by using a power injector at a rate of 1.5-2.5 mL/s, and the dose of the contrast agents was 1.5 mL/kg. Images of the hepatic arterial phase, portal vein phase and equilibrium phase were acquired at 20, 60 and 120 s, respectively. Vascular reconstruction processing was performed using a commercially available workstation and software with interactive maximum-intensity-projection (MIP) and volume-rendering techniques. The slice thickness of reconstructed image for retrospective review was 3.0 mm.

Image analysis

Two experienced abdominal radiologists retrospectively reviewed the imaging features of FNH by consensus, who were unaware of the patient's clinical data and pathological results. The following imaging features were assessed: the number of FNH lesion, location, maximum

Table 1 The multi-slice computed tomography findings of the 12 pediatric focal nodular hyperplasia cases

Case	Sex/age (yr)	Location/size (cm × cm)	Margin	Central scar	Fibrous septa	Pseudocapsule	Precontrast/HAP/PVP/EP	Spoke-wheel pattern	Draining vein

HAP: Hepatic arterial phase; PVP: Portal venous phase; EP: Equilibrium phase; M: Male; F: Female.

axial diameter, margin, density of the lesions on the pre-contrast images and contrast-enhanced CT images, central scar, fibrous septa, pseudocapsule, the morphology of the feeding artery, and the presence of draining vessels (portal vein or hepatic vein). Other associated lesions in the liver were also recorded, such as hepatic adenomas and hemangiomas. Compared to the surrounding liver parenchyma, the density of FNH was classified as hypo-, iso-, or hyperdense on CT images. Homogeneous enhancement was considered if consistent enhancement was observed in all parts of the lesions, with the exception of the central scars and fibrous septa. The central scar was defined as the area in or near the center of the lesion that showed a significantly different density on pre-contrast or contrast enhanced CT images when compared to the surrounding component of the lesion. Fibrous septa were defined as the linear structures that radiated from the center to the periphery of the lesions.

RESULTS

The 12 cases of FNH were solitary lesions with a maximum lesion diameter of 4.0-12.9 cm and an average maximum diameter of 5.5 ± 2.5 cm. Out of the 12 cases of FNH, 2 cases (cases 3 and 5) had an exophytic growth. No hemorrhage, necrosis or calcification was observed in the FNH lesions. The detailed MSCT findings of the 12 FNH cases are listed in Table 1. Most FNH (10/12, 83.3%) had a well-defined margin. Central scar (10/12, 83.3%) and fibrous septa (11/12, 91.7%) were commonly detected in the pediatric cases of FNH (Figures 1-3). The central scar was found to be isodense ($n = 7$) or hypodense ($n = 3$) on pre-contrast CT images and was

hypodense in the arterial phase. The central scar showed progressive enhancement, and became isodense in the portal vein phase ($n = 2$) and in the equilibrium phase ($n = 8$). However, the central scar was still hypodense in other two cases in the equilibrium phase. Fibrous septa were isodense on pre-contrast CT images, hypodense in the arterial phase images, and isodense in the portal vein phase and equilibrium phase images. Pseudocapsule was very rare in the cases of pediatric FNH (1/12, 8.3%) and was confirmed pathologically as the surrounding displaced veins, showing a hyperdense rim enhancement in the equilibrium phase.

All 12 cases of FNH were hypodense on pre-contrast scans, and were homogeneously enhanced in all phases of the enhanced scans with the exception of the central scars and fibrous septa. FNH was significantly hyperdense in the arterial phase (12/12, 100%), and most of them were isodense in the portal vein phase (7/12, 58.3%) and equilibrium phase (11/12, 91.7%) (Figures 1A-D, 2A-D and 3A-D). The central feeding arteries in the FNH lesions were observed on CTA images in the arterial phase in all 12 cases of pediatric FNH (Figures 1B, 2B and 3C). However, no neovascularization of malignant tumors was observed. In 9 cases (75.0%), spoke-wheel shaped angioarchitecture of FNH was observed, with the feeding vessels radiating peripherally from the center and tapering gradually, suggesting a centrifugal blood supply of the tumors (Figures 1E, 2E and 3F). In 8 cases of FNH, the draining vessels of FNH entered the hepatic vein instead of the portal vein (Figures 1F and 2F). The draining vessels of the other 4 cases of FNH were not observed on CTA images in the portal vein phase or equilibrium phase.

Figure 1 Focal nodular hyperplasia in a 2-year-old boy. A: The lesion was hypodense on pre-contrast computed tomography scan; B: The lesion was significantly enhanced in the arterial phase with enlarged feeding arteries (arrows); C: The lesion was hyperdense in the portal vein phase with hypodense central scar (arrows) and fibrous septa; D: The lesion was isodense in the equilibrium phase, and the scar shows delayed enhanced; E: Computed tomography angiography (CTA) in the arterial phase showed that the enlarged feeding artery was distorted with a spoke-wheel shaped blood supply (arrows); F: CTA in the portal vein phase showed the draining vessels directly into the hepatic vein (arrows).

No associated hepatic adenoma or hemangioma was observed in the liver of the 12 pediatric cases of FNH. Only 1 case (case 3) was associated with hemangioma in other parts of the body.

DISCUSSION

Pediatric FNH is a rare entity, accounting for approximately 2% of hepatic tumors and 0.02% of all pediatric tumors^[10]. The exact pathogenesis of FNH is unclear; although it might be a proliferative response to intrahepatic vascular malformations^[2]. Many studies have shown that the incidence of FNH increases after chemotherapy or radiotherapy for the treatment of solid tumors in children, suggesting that anti-tumor therapy-induced intrahepatic vascular injury may be risk factor for the development of FNH^[4,11-13]. Current molecular pathological data revealed an activation of the β -catenin pathway, a marked upregulation of angiopoietin-1 and downregulation of angiopoietin-2 in FNH^[14].

Most of the studies show that FNH in children is more common in females^[4,6]. In a large series of 172 cases of pediatric FNH, Lautz *et al*^[6] found that 66% (113/172) of the cases occurred in females. However, the majority of our cases were males, with a male to female ratio of 2:1. The high male to female ratio may be due to the bias inherent in the choice of cases enrolled in our study. All cases enrolled in this study were instances of FNH that had been confirmed by surgical resection or biopsy, and cases that were diagnosed by imaging modali-

ties and close follow-up were not included. There are no specific clinical manifestations for FNH in children. The majority of the cases of FNH are usually discovered accidentally for unrelated reasons, with only 36% of cases showing symptoms^[6]. The common symptoms of pediatric FNH include palpable abdominal mass and abdominal pain. Tumor rupture and hemorrhage are rare^[4]. Laboratory test results often do not show clinical significance, and tumor markers such as AFP are usually in normal range^[4].

After review the clinical features of 172 cases of pediatric FNH, Lautz *et al*^[6] found an interesting result: pediatric FNH patients with a history of malignancy were significantly less likely to be symptomatic (12% *vs* 45%, $P < 0.0001$), were much smaller in size (2.8 ± 2.2 cm *vs* 8.0 ± 3.3 cm, $P < 0.0001$), and fewer patients required resection of the lesions (10% *vs* 78%, $P < 0.0001$) as compared with patients without a malignancy history. The pediatric FNH patients with a history of malignancy were more likely to have multiple FNH nodules and less likely to have central scars. In contrast, pediatric patients without a history of malignant lesions generally had larger FNH nodules and were more likely to have central scars^[15,16]. The 12 patients in this group had no history of malignancy and had the features mentioned above: solitary FNH nodule, relatively large size (an average of 5.5 ± 2.5 cm), and high proportion of central scars (10/12, 83.3%).

Adult FNH patients may have associated hepatic adenomas (3.6%-6%) and hemangiomas (17%-23%)^[2,3,17].

Figure 2 Focal nodular hyperplasia in a 16-year-old boy. A: The lesion was hypodense on pre-contrast computed tomography scan, and central scar with much lower density were identified (arrows); B: The lesion was significantly enhanced in the arterial phase with enlarged feeding arteries penetrating into the central scar (arrows); C: The lesion was slightly hyperdense in the portal vein phase; D: The lesion was isodense in the equilibrium phase with delayed enhancement of the central scar; E: Computed tomography angiography (CTA) in the arterial phase showed that the enlarged feeding arteries were distorted, and exhibited a spoke-wheel shaped blood supply (arrows); F: CTA in the portal vein phase showed the draining hepatic vein (arrows).

However, in our group of pediatric patients, there were no instances of associated hepatic adenomas or hemangiomas. More studies are needed to see whether FNH in adults and children differs in this respect.

The imaging appearances of FNH in pediatric patients on MSCT images reflect its pathological features. A typical case of FNH has the following pathological characteristics: well-differentiated hepatocytes forming nodules subdivided by fibrous septa, proliferation of ductules and malformed blood vessels in the central scars and fibrous septa, and no fibrous capsule^[4]. The fibrous septa are the linear structures that radiate from the central scar to the periphery of the lesions and can sometimes be detected in the absence of a central scar. The hypodense fibrous septa were clearly depicted by CT in the arterial phase, and become isodense with the surrounding component of nodules in the portal vein and equilibrium phases. The sign of fibrous septa is a characteristic finding of FNH, and has not been reported in other tumors of the liver. However, after analyzing 78 cases of FNH using an obsolete spiral CT scanner with thick slice thickness (slice thickness of 5-7 mm), Brancatelli *et al.*^[17] found that only 8% of the patients showed this feature. Our results showed that, by using thin-slice MSCT imaging (slice thickness of 3.0 mm), this feature can be commonly observed (11/12, 91.7%). Kamel *et al.*^[11] suggest that this finding is best seen on volume-rendered images of the portal venous phase, and frequently detected with fine manipulation of the degree of tissue opacity of the volume-rendered images. However, the subtle changes of fibrous septa on volume-rendered images are difficult to detect in our experience.

The vascular central stellate scar is another patho-

logical characteristic of FNH. The CT findings of the central scar in pediatric FNH are consistent with those of the central scar in adult FNH: compared to the surrounding nodules, the central scar was either hypodense or isodense on pre-contrast CT images, hypodense in the arterial phase (90%), and hypodense (68%) or isodense (22%) in the portal vein phase^[17]. Due to the retention of contrast material within the myxoid matrix of the central scar, the scars show delayed contrast enhancement in the imaging scans at 5-20 min^[17]. The central scar can be seen in 42.1%-50.0% of FNH nodules^[17-19]. However, it was more common in the 12 pediatric cases of FNH in our group (10/12, 83.3%). This discrepancy could be explained by the larger diameter of the lesions (average 5.5 ± 2.5 cm) observed in our group of FNH, since detection of a central scar is clearly related to the size of the FNH (central scars are identified in only 35% of FNH ≤ 3.0 cm but in 65% of FNH > 3.0 cm)^[17]. In addition to FNH, the central scar has also been described in fibrolamellar hepatocellular carcinoma (HCC) and large hemangiomas. A central scar width greater than 2 cm is helpful in differentiating between these three entities, since it is often detected in fibrolamellar HCC and sometimes in large hemangiomas, however never seen in FNH^[20]. The presence of delayed contrast enhancement of the central scar and radiating fibrous septa were not statistically significant for the identification of these three entities^[20].

With the development of CT software and hardware technology, the spatial and temporal resolutions of the images have significantly improved, which enables high-resolution CTA images possible. The post-processed high-resolution CTA images provide unique insights into the angioarchitecture of FNH. Although the hemodynamic

Figure 3 Focal nodular hyperplasia in a 14-year-old girl. A: The lesion was hypodense on pre-contrast computed tomography image; B, C: The lesion was significantly enhanced in the arterial phase with hypodense fibrous septa; D: The lesion was isodense in the portal vein phase; E: Immunohistochemical staining of CD34 revealed the abnormal blood vessels within fibrous septa ($\times 100$); F: Computed tomography angiography in the arterial phase showed that a spoke-wheel shaped blood supply of the focal nodular hyperplasia (arrow).

characteristics of FNH (such as one or more enlarged feeding arteries entering into the center of the tumor and radiating to the periphery, a spoke-wheel shaped centrifugal blood supply) could be observed through the use of the invasive and time-consuming process of transcatheter angiography, it can also be non-invasively depicted on three-dimensional CTA images. Liu *et al.*^[18] compared CTA in 28 cases of FNH and 75 cases of other hypervascular hepatic tumors (hepatocellular carcinoma, hemangioma, and hepatic adenoma), using 16-MSCT with the MIP imaging and volume rendering technology. They found that the centrifugal arterial supply pattern was only seen in FNH, and this finding will assist in differentiating FNH from other hypervascular hepatic tumors. The three-dimensional display of the feeding artery provided by CTA may be valuable in planning for embolization or ligation of vessels in symptomatic pediatric FNH patients.

CTA can clearly show the draining vessels of pediatric FNH. FNH lesion exclusively drains into the hepatic vein branches either directly or *via* perinodular sinusoids^[21,22]. HCC is drained almost always into the portal vein, only 1.8% of HCC draining into the hepatic vein. The identification of the draining blood vessels is therefore a reliable criterion for the differentiation between HCC and FNH^[22].

FNH has no fibrous capsule and shows a well-defined margin on contrast-enhanced CT images in arterial phase. However, pseudocapsules can be detected in 8%-36% of FNH on CT images, which appearing as hypodense rims in the arterial phase and hyperdense rims in the portal vein phase and the delayed phase. This sign is especially

obvious in large lesions, and may be a result of dilated surrounding vessels or sinusoids or compressed liver parenchyma^[1,2,17]. The sign of pseudocapsule is also visible on magnetic resonance imaging (MRI) (9% of FNH in pre-contrast scanning and 18% in contrast enhanced scanning)^[2]. Tumor capsule is a specific sign of HCC and is present in 60%-80% of cases. The capsule of HCC is mainly composed of fibrotic tissue and appears hypointense on both T1W and T2W images, whereas the pseudocapsule of FNH is hyperintense on T2W^[23]. This discrepancy might help to differentiate between these two entities.

The enhancement pattern of pediatric FNH on multi-phase CT images typically shows as early homogeneous enhancement (with the exception of the central scar and fibrous septa) in the arterial phase, hyperdense or isodense in the portal vein phase, and isodense in the equilibrium phase. These findings are consistent with the enhancement pattern of adult FNH reported in the literature^[17].

If all of the imaging characteristics of FNH are identified on CT images, FNH can be diagnosed with confidence. However, approximately 50% of FNH lesions lacking typical imaging manifestations, especially the small lesions, are reported in the literature, such as the absence of central scar, rapid washout of contrast agents in the portal vein phase, absence of delayed enhancement in the central scar, and presence of rim enhancement of the pseudocapsule^[3,4]. In these circumstances, it is necessary to distinguish FNH from other pediatric solid hypervascular tumor, and percutaneous fine needle biopsy

may be suggested when necessary. The malignant hepatic tumors, such as hepatoblastoma and hepatocellular carcinoma, manifest with elevated AFP, and heterogeneous density on CT images due to hemorrhage, necrosis and calcification, which are helpful for distinguishing these malignant tumors from FNH^[4]. MRI examinations with hepatobiliary-specific gadolinium-based contrast agents (specifically gadobenate dimeglumine, gadoxetate disodium or gadoxetic acid) may be valuable for the diagnosis of FNH, particularly on the delayed hepatobiliary phase of imaging where FNHs are usually iso- or hyperintense relative to the liver parenchyma but rarely hypointense, presumably because of the presence of functioning hepatocytes and focal abnormal biliary excretion^[24]. Hepatic adenoma in children is usually accompanied by glycogen storage disease and is prone to having multiple lesions and hemorrhage. Hepatic adenomas usually have no central scar and show heterogeneous density due to intratumoral hemorrhage. In the arterial phase, the CT attenuation values and relative enhancement of the lesion were significantly higher in FNH than in hepatic adenoma ($P < 0.05$). A threshold value of 1.6 for relative enhancement of the lesion in the arterial phase seems to be valuable to distinguish FNH from hepatic adenoma with an accuracy of 96%^[25]. FNH has a centrifugal and spoke-wheel shaped blood supply, whereas hepatic adenoma has centripetal and subcapsular feeding blood supply^[25]. Infantile hemangioendothelioma, or infantile hepatic hemangioma, is a benign vascular tumor that is unique to pediatric patients. Punctate calcification is seen in 50% of these cases^[4]. The enhancement features are similar to those of adult hepatic hemangioma: intense peripheral nodular or corrugated enhancement in the arterial phase, and progressive centripetal fill-in of contrast material in the portal venous and delayed phase, which are different from those of FNH^[4].

In summary, FNH in children manifests as solitary large nodule. The thin-slice MSCT images (slice thickness of 3.0 mm) facilitate in revealing the fibrous septa and central scar within FNH nodules. Multi-phase enhanced scanning has the capacity to demonstrate the enhancement characteristics of pediatric FNH: except for fibrous septa and central scars, FNH is homogeneously enhanced in the arterial phase, and it appears isodense or hyperdense in the portal vein phase and isodense in the equilibrium phase. CTA provides unique insight into the hemodynamic of FNH: the enlarged feeding arteries in the center of the nodules, the spoke-wheel shaped and centrifugal blood supply, and the drainage into the hepatic vein. For asymptomatic pediatric FNH patients with typical MSCT imaging findings, unnecessary surgical resection can be avoided and close follow-up may be suggested. For pediatric FNH patients who cannot definitely be diagnosed by MSCT, further invasive and expensive tests, such as biopsy or surgical resection, are required.

COMMENTS

Background

Hepatic focal nodular hyperplasia (FNH) is the second most common benign liver tumor after hemangioma in adult, whereas it is rare in children. It is important to differentiate FNH from other malignant lesions to avoid unnecessary surgical resection in pediatric patients. Since FNH is a slow growing tumor without malignant transformation and is rarely accompanied by the complications of hemorrhage or rupture, conservative "wait and see" strategy is recommended for asymptomatic children.

Research frontiers

Multi-slice computed tomography (MSCT) features a fast scanning speed and is ideal for assessing hepatic lesions in pediatric patients. With MSCT, dynamic multi-phase scanning is allowed in a very short period of time, and increased detection and characterization of focal liver lesion can be achieved. In addition, MSCT makes high-quality two- or three-dimensional vascular reconstruction images possible. There are few reports on the imaging features of FNH in children, especially the angioarchitecture of pediatric FNH on computed tomography angiography.

Innovations and breakthroughs

Twelve pediatric patients with FNH were reported in this study, and their MSCT features were reviewed. This study showed that central scar and fibrous septa were commonly found in children with FNH. Central scar was either isodense or hypodense on pre-contrast computed tomography (CT) images and showed progressive enhancement in the equilibrium phase. Fibrous septa were linear hypodense areas in the arterial phase and isodense in the portal and equilibrium phases. With the exception of central scars and fibrous septa within the lesions, pediatric FNH were homogeneously enhanced on the contrast-enhanced CT images, and usually isodense in the portal venous phase and equilibrium phase. Central feeding arteries inside the tumors and a spoke-wheel shaped centrifugal blood supply were usually observed on computed tomography angiography (CTA) images. The characteristic imaging appearances on MSCT and CTA could reflect the pathological and hemodynamic features of pediatric FNH.

Applications

The study results suggest that dynamic multi-phase MSCT and CTA imaging is an effective method for diagnosing FNH in children.

Terminology

MSCT features a fast scanning speed (the time required for a single tube rotation is sub-second), and allows dynamic multi-phase scanning in a very short period of time. The ability of MSCT to acquire data with "isotropic voxel" makes high-quality two- or three-dimensional vascular reconstruction images possible.

Peer review

This manuscript is well written, and the authors retrospectively analyze the imaging features of FNH in children by MSCT and CTA, and suggested that it is an effective method for diagnosing FNH in children.

Abstract

AIM: To investigate the therapeutic effect of radical treatment and palliative treatment in stage IV pancreatic cancer patients.

METHODS: 81 patients were enrolled in the study. Radical treatment was performed on 51 patients, while 30 patients were put under palliative treatment. The procedural safety and interval survival for stage IV pan-

creatic cancer (IS-IV) was assessed by almost 2.5 years of follow-ups. The IS-IV of patients under the two kinds of treatment, and the effects of treatment timing and frequency on IS-IV, were compared.

RESULTS: The IS-IV of patients who received radical treatment was significantly longer than those who received palliative treatment ($P < 0.001$). The IS-IV of patients who received delayed radical or palliative treatment was longer than those who received accordingly timely treatment ($P = 0.0034$ and 0.0415 , respectively). Multiple treatments can play an important role in improving the IS-IV of patients who received radical treatment ($P = 0.0389$), but not for those who received palliative treatment ($P = 0.99$).

CONCLUSION: The effect of radical treatment was significantly more obvious than that of palliative treatment, and multiple radical treatments may contribute more to patients than a single radical treatment.

Chen JB, Li JL, He LH, Liu WQ, Yao F, Zeng JY, Zhang Y, Xu KQ, Niu LZ, Zuo JS, Xu KC. Radical treatment of stage IV pancreatic cancer by the combination of cryosurgery and iodine-125 seed implantation. *World J Gastroenterol* 2012; 18(47): 7056-7062 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i47/7056.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i47.7056>

INTRODUCTION

Pancreatic cancer is the fourth-leading cause of cancer-related death in Western societies^[1]. The incidence almost equals the mortality rate, since pancreatic cancer has one of the worst prognoses of all human malignancies. Less than 20% of pancreatic cancers are curable on diagnosis^[2]. Without effective treatment, the overall survival for patients with advanced pancreatic cancer is usually less than 1 year, and for those with metastatic stage IV pancreatic cancer the median survival is only 3–4 mo^[3,4]. Chemotherapy is currently the standard treatment for stage IV pancreatic cancer^[5,6], but it cannot radically eliminate larger tumors. Radiofrequency ablation has been widely used in radical treatment of metastatic pancreatic cancer: in 2007, Spiliotis *et al.*^[7] reported the effect of radiofrequency ablation combined with palliative surgery on patients with stage IV pancreatic cancer; in 2010, Zou *et al.*^[8] reported the effect of intraoperative radiofrequency ablation combined with iodine-125 seed implantation on patients with stage IV pancreatic cancer. The median overall survival of patients in both reports was 10 mo, but laparotomy is necessary for this technique. Cryosurgery, which is widely accepted as an invasive technique for curing solid tumors, has emerged as a new therapy for pancreatic cancer. The combination of cryosurgery and the implantation of iodine-125 seeds (CandS), which eliminate residual tumors in the treatment of advanced pancreatic cancer, was first reported by us in 2008^[9,10]. In our reports, the median survival was 16.2 mo, with 26 patients (53.1%) surviving for 12 mo or more. Overall 6-, 12-, 24-, and 36-mo survival rates were 94.9%, 63.1%, 22.8%, and 9.5%, respectively.

Here we aimed to compare the effects of radical treatment (CandS for intrapancreatic and extrapancreatic tumors) and palliative treatment (seed implantation for intrapancreatic tumors, CandS for extrapancreatic tumors) on stage IV pancreatic cancer, and assess the influence of treatment timing and frequency on the survival time of patients. To concentrate on the survival time of patients with stage IV cancer, the interval survival of stage IV pancreatic cancer (IS-IV) was used as the main evaluation index.

MATERIALS AND METHODS

Ethics

This study protocol received ethical approval from the Regional Ethics Committee of Guangzhou Fuda Cancer Hospital. Written informed consent was obtained from each participant in accordance with the Declaration of Helsinki.

Patient selection

This was a retrospective study of patients treated for metastatic pancreatic tumors in our tumor hospital from November 2008 through to August 2010. Before hospitalization, 145 patients received a comprehensive

evaluation, with their tumors being considered unresectable. These evaluations were multidisciplinary decisions incorporating a radiologist, a gastrointestinal pancreatic surgeon, and an oncologist in our hospital. Their diagnoses were principally based on computed tomography (CT) imaging and CT-guided needle biopsy to obtain a definitive diagnosis as pancreatic adenocarcinoma histologically. An 18-gauge Tru-Cut (Baxter, Deerfield, IL, United States) biopsy needle was used percutaneously to obtain one to two cores of tissue from the solid pancreatic tumor. Patients received their final treatments in our hospital and almost 2.5 years of follow-ups were reviewed.

A patient was deemed unsuitable for surgery and chemotherapy due to any of the following reasons: (1) multifocal disease; (2) an unresectable primary tumor; (3) the patient refusing surgery and chemotherapy, or seeking further treatment after previous chemotherapy; (4) severe complications (e.g., hypertension, hydrothorax, and ascites); or (5) advanced age. Written informed consent was obtained from all patients. The inclusion criteria were as follows: (1) the Karnofsky performance status (KPS) score was ≥ 70 ; (2) the platelet count was $\geq 80 \times 10^9/L$, white blood cell count was $\geq 3 \times 10^9/L$, neutrophil granulocyte count was $\geq 2 \times 10^9/L$, or hemoglobin ≥ 90 g/L; (3) the prothrombin time international normalized ratio was ≥ 1.5 ; (4) the largest primary or metastatic tumor diameter was < 6 cm, as measured by preoperative CT; (5) the pancreatic tumor did not obviously invade the main pancreatic duct, postcava, duodenum or colon; (6) absence of level 3 hypertension, severe coronary disease, myelosuppression, respiratory system disease, acute and chronic infection; (7) the basic normal liver function and puncture release ascites $< 1L$; and (8) the patient was deemed incapable of cooperating during the procedure.

When the patient had primary or metastatic tumors with a diameter ≥ 6 cm, or obviously invading the main pancreatic duct, postcava, duodenum or colon, we preferentially performed the treatment in other ways^[11,12], and so these patients were not enrolled in this study.

Percutaneous cryosurgery and iodine-125 seed implantation

According to the patients' own selection, 51 patients were under radical treatment and 31 patients received palliative treatment. Their treatments had been reported by us^[9,10]. In the radical treatment group, the CandS treatment of the pancreatic tumor was performed under double row helical CT (Somatom Emotion Duo; Siemens, Germany) and color ultrasound device (ALOKA SSD-5500SA; Aloka, Japan) guidance. Before the cryosurgery, the patients were administered general or local anesthesia, and positioned for an upper abdominal incision. All cryosurgery were performed by Dr. Niu LZ and assistants (Zhou L and Zhang C). Based on the location of the pancreatic tumor, the cryoprobes were inserted percutaneously *via* the retroperitoneal, transhepatic, or transgastric approach. For tumors greater than 3 cm in length, more than two 1.7 mm cryoprobes (CRYO-42; Endocare, Irvine, CA,

United State) were used, in an attempt to avoid puncturing the main pancreatic duct and duodenum. A 1-3 cycle freeze/thaw procedure was used with an argon gas-based cryosurgical unit (Endocare, United State)^[9,10]. The iodine-125 seed (Syncor Pharmaceuticals, Shanghai, China) implantation was performed by PTC needle, either at the time of cryosurgery or after cryosurgery through the percutaneous approach under a 3D treatment planning system. The seeds (activity of a single seed 0.7 mCi, half-life period 1-6 mCi) were implanted at the tumor borderline. The number of seeds deployed depended on the tumor size (matching dose around 120Gy, usually ≤ 20 particles), with the seeds implanted at intervals of 0.5 cm. In the palliative treatment group, the iodine-125 seeds were implanted in all parts of the pancreatic tumor under ultrasound or CT guidance, and the planting density and quantity were both more than the radical treatment group. For extrapancreatic metastases in the two groups, the CandS treatment were performed percutaneously *via* the retroperitoneal or transabdominal approach at the same time, or after the treatment of the intrapancreatic tumor.

Postoperative treatment

Once cryoablation was completed, 1 mL of both fibrinogen and thrombin for each probe were injected into the sheath simultaneously. The patients were then observed in the intensive care unit for at least 6 h, and fasted for at least 24 h. Therapies of anti-infection and inhibition of pancreatic juice secretion were given for a few days. Patients under radical treatment received some special treatment: for patients under the transgastric approach of cryosurgery, antacid and stomach mucosa-protecting drugs were delivered for a few days; for patients under the transhepatic approach of cryosurgery, oppressing hemostasis, bellyband, and liver-protecting drugs were all administered for a few days.

Statistical analysis

Complications were recorded and classified in accordance with the Common Terminology Criteria of Adverse Events v4.0. Local tumor control and IS-IV were also evaluated. Radiographic local tumor control was assessed by image-guided tumor ablation criteria^[13]. A post-operative plain abdominal CT was performed immediately after the removal of the cryoprobes for verification as to whether any major complications, such as pancreatic fistula, bile leakage, or intestinal fistula, had occurred. Abdominal ultrasound was performed at both 1 d and 1 wk after the cryoablation procedure. Follow-up dynamic CT abdominal scans of patients were carried out at 1 mo, and then at 3 to 4 mo intervals. The revised RECIST criteria (version 1.1) were used to assess the basic response of the intrapancreatic and extrapancreatic cancer^[14]. Three diagnostic radiologists (Piao XH, Zhou Q, and Tang J) with 17, 20, and 13 years of clinical experience, respectively, determined whether progression or recurrence had occurred; reviewing CT scans in every

case. Diagnoses were made independently, and the radiologists discussed with each other when the results were different. The IS-IV was calculated from the date when a patient was first diagnosed as suffering stage IV pancreatic cancer, and compared using the Kaplan-Meier test with long-rank analysis. A significant difference was indicated by $P < 0.05$. All analyses were performed using GraphPad Software (San Diego, CA, United States).

RESULTS

Clinical data

Percutaneous cryoablation was performed on 81 patients (42-84 years of age, median age: 65 years; 43 male patients, 38 female patients). The patients of each treatment half were from both China (38 patients) and abroad (43 patients). Two-thirds of patients (54 patients) were treated in our hospital when diagnosed as having stage IV pancreatic cancer; one-third of patients were diagnosed and treated with chemotherapy (27 patients, 95 sessions) and/or radiation (9 patients, 24 sessions) in other hospitals first, and came to our hospital 2-14 mo later for further treatment. Liver metastases (75 lesions) were found in 47 patients, peritoneum and liver metastases (76 lesions) were found in 27 patients, and all other metastases (26 lesions) were found in seven patients. Diabetes (16 patients), hydrothorax/ascites (15 patients), and hypertension/coronary disease (8 patients) were common complications in these patients. Radical treatment was performed on 50 patients (79 sessions), and 31 patients (48 sessions) were put under palliative treatment. The therapeutic option of cryoablation was chosen according to the previously-stated criteria.

The mean intrapancreatic tumor diameter in the radical treatment group was 4.3 ± 0.9 cm (range: 3.2-5.7 cm). For the first treatment of the 50 lesions, 13 were treated by using 2 cryoprobes; 16 by 3 cryoprobes; and 21 by four cryoprobes. The mean intrapancreatic tumor diameter in the palliative treatment group was 4.5 ± 0.8 cm (range: 3.5-5.8 cm). For the first treatment of the 31 lesions, 6 were implanted by using about 20 iodine-125 seeds; 9 by about 30 seeds; and 16 by about 40 seeds.

The mean extrapancreatic tumor diameter in the radical treatment group was 3.5 ± 0.8 cm (range: 2.1-4.5 cm). For the first treatment of the 110 lesions, 46 were treated by using 2 cryoprobes; 43 by 3 cryoprobes; and 21 by four cryoprobes. The mean extrapancreatic tumor diameter in the palliative treatment group was 3.7 ± 0.9 cm (range, 2.3-5.0 cm). For the first treatment of the 67 lesions, 31 were treated by using 2 cryoprobes; 27 by 3 cryoprobes; and 9 by 4 cryoprobes.

Perioperative outcomes

All percutaneous cryoablations of primary and metastatic pancreatic tumors by ultrasound and CT monitoring were performed successfully. No severe complications, such as pancreatic fistula, bile leakage, and intestinal fistula were discovered post-cryoablation. In the radical treat-

Figure 1 IS-IV of patients under radical or palliative treatment. All 81 patients had suffered from stage IV pancreatic cancer and died before October of 2011. There were 51 patients in the radical treatment group, and 30 patients in the palliative treatment group. The median follow-up period was 8 mo. The IS-IV of patients was accumulated from the early diagnosis of stage IV pancreatic cancer in our own or other hospitals.

ment group, some common adverse effects were found and are shown below. Serum amylase, an important index of acute pancreatitis, increased in 25 sessions (31%) for 16 patients (32%) on the first day after the procedure, unaccompanied by ascites or leukocytosis, but returned to normal levels in the following 5 d after symptomatic treatment. Seven patients (14%) with diabetes after 12 sessions (15%) experienced a rise in fasting blood glucose levels up to 20–25 mmol/L on the first day post-cryoablation, which were well-controlled with insulin injections. A mild decrease in the platelet count occurred after 14 sessions (18%) for 10 patients (20%), which returned to normal within 8–13 d without any treatment. Abdominal distension and nausea occurred after 23 sessions (29%) for 14 patients (28%) on the first day post-cryoablation, and disappeared automatically the following day. Eight patients (16%) in 11 sessions (14%) complained of poor appetite after the cryosurgery and were found to have ascites by ultrasound, which improved the following 3–5 d without any treatment. Eleven patients (22%) in 17 sessions (22%) were found to have abdominal bleeding, 8 patients (16%) of whom developed fever and a mild increase in white blood cells, and neutrophil granulocytes; they improved in the following 7 d after symptomatic treatment. Similar adverse effects were also found in the palliative treatment group, and disappeared in 2 wk after symptomatic treatment. There were no treatment-related deaths or any conversions to chemotherapy.

Within 1 wk after the first CandS treatment, 64 patients (79%) experienced a $\geq 50\%$ reduction in pain score, 57 patients (70%) experienced a 50% decrease in analgesic consumption, and 43 patients (53%) experienced a ≥ 20 increase in KPS score.

Influence of therapies, treatment timing, and treatment frequency on IS-IV of patients

The median follow-up period was 8 mo. Up to the date of the last follow-up of each patient, the median IS-IV of all patients was 7.12 mo (95%CI: 3.79–13.37). The me-

Figure 2 IS-IV of patients under timely or delayed treatment. A: Comparison between patients in the radical treatment group: 32 patients under timely treatment and 18 patients under delayed treatment; B: Comparison between patients in the palliative treatment group: 22 patients under timely treatment and 9 patients under delayed treatment.

dian IS-IV of patients with radical treatment was 8 mo, and those with palliative treatment was 4 mo. The IS-IV of the two groups differed significantly by long-rank test ($P < 0.001$, Figure 1).

Two-third of patients received CandS treatment 2 mo after the diagnosis of stage IV pancreatic cancer, and one-third of patients received CandS treatment 2–14 mo after diagnosis. The influences of treatment timing on IS-IV of patients were detected: for the radical treatment group, the median IS-IV of patients under timely treatment was 6 mo, and 13 mo for those under delayed treatment ($P = 0.0034$, Figure 2A); for the palliative treatment group, the median IS-IV of patients under timely treatment was 3 mo, and 5 mo for those under delayed treatment ($P = 0.0415$, Figure 2B). In the two groups, the patients who received CandS treatment ≥ 2 mo after diagnosis were associated with a longer IS-IV, which was more obvious in the radical treatment group.

According to disease progression, tumor recurrence and individual intents of patients, 31 patients (39%) received repeated CandS treatment when re-examined. For the radical treatment group, the median IS-IV of patients under single treatment was 7 mo, and 11 mo for those under multiple treatments ($P = 0.0389$, Figure 3A); for the palliative treatment group, the median IS-IV of patients under single treatment was 3 mo, and 4 mo for

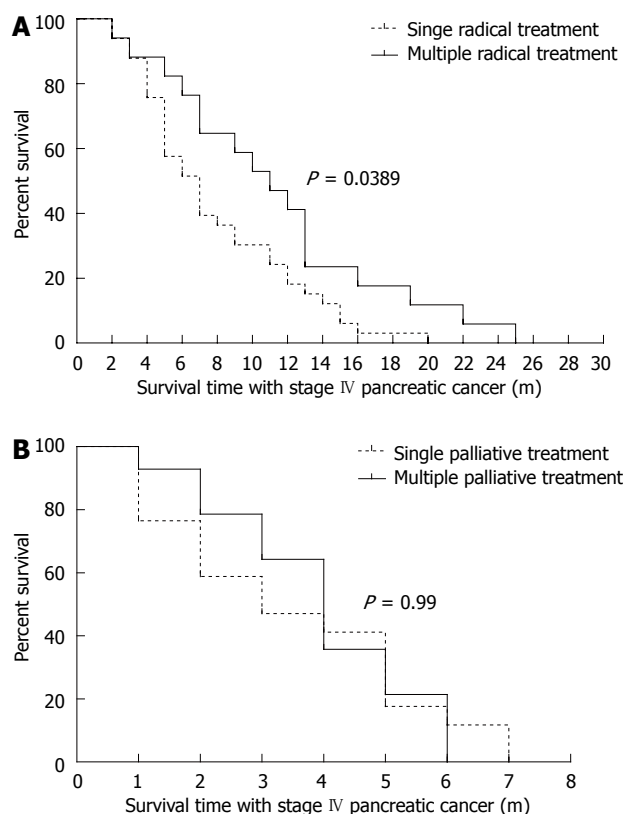

Figure 3 IS-IV of patients under different treatment frequency. A: Comparison among patients in radical treatment group, 17 patients under multiple radical treatment (2 times, by 10 patients; 3 times, by 4 patients; 4, 5 and 9 times, by 1 patient each) and 33 patients were under single radical treatment; B: Comparison among patients in palliative treatment group, 14 patients under multiple palliative treatment (2 times, by 11 patients; 3 times, by 3 patients) and 17 patients under single palliative treatment.

those under multiple treatments ($P = 0.99$, Figure 3B). Only in the radical treatment group did multiple treatments show a significant superiority in prolonging the IS-IV of patients.

DISCUSSION

Cryoablation has been performed for hepatic, renal, breast, and prostate cancer, and it has shown acceptable results. During cryoablation, the formation of an oversized ice ball increases the complication rate and can endanger a patient's life; an undersized ice ball can lead to the recurrence of the tumor at the edge of the frozen area^[15]. As the volumes of primary or metastatic tumors are sometimes large, adhesions to other organs or tissues and invasive growth are often present. Percutaneous cryoablation cannot guarantee complete ablation, and combination with brachytherapy might be a better choice^[16-20]. This combination of minimal invasive therapies (namely CandS treatment) can minimize the damage of radiotherapy and cryoablation, and increase the treatment response^[21,22].

In $\geq 80\%$ of patients with pancreatic cancer, the tumor is unresectable at time of diagnosis. Chemotherapy, palliative surgery, and radiofrequency ablation may be

the best options for patients with metastases. Along with advances in the cryosurgical system and imageology, percutaneous cryosurgery has been increasingly successful in the treatment of pancreatic cancer^[9,10]. This method avoids the risks of laparotomy, decreases the likelihood of complications^[23-25], and improves the quality of life, but the data is still lacking as to whether it can extend the IS-IV of patients. Cryoablation and chemotherapy have different effects on patients with stage IV pancreatic cancer. In 2010, Stathis *et al.*^[26] reported that the median survival for patients treated with single-agent 5-FU or gemcitabine were 4.41 and 5.65 mo, respectively. Combined applications of other agents with gemcitabine had been frequently attempted in order to get a better IS-IV, but the statistical indication for such a benefit failed to materialize until now^[4,27-30]. In our study, the IS-IV of patients under radical treatment was significantly longer than for those under palliative treatment ($P < 0.0001$), with a 4 mo extension of median IS-IV (8 mo *vs* 4 mo, respectively). The 1-year survival rate of patients in the radical treatment group was 32%, showing the greater superiority of radical treatment, as this was better than palliative treatment and chemotherapy. Interestingly, patients who delayed CandS treatment were associated with better IS-IV, regardless of radical or palliative treatment. For this reason we re-analyzed the data, and found that all the patients under delayed treatment had received chemotherapy before admission to our hospital, and so chemotherapy may be an important reason for the extension of IS-IV. It seems that if chemotherapy is delivered early in stage IV pancreatic cancer, it will change the systemic disease into local disease, and improve the benefit to survival time of patients. As for the frequency of CandS treatment, multiple treatments only showed a significant advantage in the radical treatment group (median survival: 11 mo *vs* 7 mo, $P = 0.0389$). Therefore, in order to get the best therapeutic effect, early chemotherapy, radical, and multiple treatments are all very important.

With regard to the complications associated with radical treatment, pancreatic fistula, bile leakage, and intestinal fistula were seldom observed in our study, maybe due to the evasion of patients with a high surgical risk when enrolling. Other minor complications associated with radical or palliative treatment were common after cryoablation of the pancreas and liver, including an increase of serum amylase and blood glucose, a decrease in the number of platelets, abdominal distension, ascites, fever, infection, and abdominal bleeding. All complications can be decreased to normal within 2 wk after symptomatic treatment. In effectively reducing tumors and removing obstructions, the physical strength and energy of patients in the two groups improved obviously and pains were reduced significantly. These achievements are inseparable with effective tumor reduction and close postoperative monitoring.

The present study represents an early experience, with a small number of patients. Hence, extrapolation of the results to clinical practice should be performed with cau-

tion. This was not a definitive study for assessing the effects of chemotherapy on IS-IV of patients, the effectiveness of CandS in the treatment of newly diagnosed stage IV pancreatic cancer, or for determining whether CandS treatment was as effective as surgery for pancreatic tumors.

In conclusion, percutaneous CandS treatment may have a useful role in the management of stage IV pancreatic cancer evading vital organs and those < 6 cm in diameter when surgery and chemotherapy are not options. To further increase the IS-IV of patients, close postoperative monitoring and multiple treatments will be needed for recurrent tumors.

COMMENTS

Background

Pancreatic cancer is the fourth leading cause of cancer-related death clinically. Less than 20% of pancreatic cancers are curable on diagnosis. Without effective treatment, the overall survival for patients with advanced pancreatic cancer is usually less than 1 year, and for those with metastatic stage IV pancreatic cancer, the median survival is only 3-4 mo. Treatment effects of radiation and chemotherapy are poor, and radiofrequency ablation can not be applied for patients percutaneously.

Research frontiers

This research concerns the field of ablation for pancreatic cancer. Currently, cryosurgery is the only useful method for *in situ* ablation of pancreatic cancer.

Innovations and breakthroughs

Three methods were used to treat different parts of the pancreatic cancer by percutaneous ablation, which increased the safety and efficiency of cryosurgery for patients. The relationship between treatment timing, treatment frequency, and survival time of patients with metastatic pancreatic cancer were analyzed.

Applications

Depending on the retrospective analysis of radical and palliative treatment on patients with stage IV pancreatic cancer, clinical evidence was provided concerning survival time, which will benefit the future application of this technology.

Terminology

Percutaneous cryosurgery: Under the guidance of B ultrasound or computed tomography (CT), cryoprobes are directly stuck into the tumor through skin, and cryoablation is performed *in situ* by the ultra-low temperature of the probe tip; Seed implantation: under the guidance of B ultrasound or CT, radioactive seeds are implanted into the tumor to act as brachytherapy; IS-IV: since the patients enrolled in this study were all suffered from metastatic tumors (stage IV pancreatic cancer), and many treatments had been carried out in other countries and hospitals before, the ideal evaluating method for survival time for our treatment is interval survival for stage IV pancreatic cancer.

Peer review

This study is the first retrospective analysis for the radical and palliative treatment of patients with stage IV pancreatic cancer, which clarified the benefits of percutaneous cryosurgery for this disease, along with the relationship between treatment timing, treatment frequency, and survival time of patients. These findings can provide important evidence for the clinical treatment of stage IV pancreatic cancer.

Abstract

AIM: To evaluate the protective role of AE-941, a matrix metalloproteinase (MMP) inhibitor, on ulcerative colitis (UC) in rats.

METHODS: Sprague Dawley (SD) rats were randomly divided into three groups: a control group, an AE-941 treatment group, and an UC model group. Rats were sacrificed on days 7, 21, or 56 following administration of treatment by enema and the disease activity index (DAI), colonic mucosa damage index (CMDI) and colonic expression of MMP-2 and MMP-9 were assessed.

RESULTS: DAI and CMDI scores in the UC model group increased significantly compared to the control group at all timepoints ($P < 0.001$), and also increased significantly at the 21- and 56-d timepoints compared to the AE-941-treated group (DAI: 21- and 56-d = 2.09

± 0.25 , 1.52 ± 0.30 vs 1.55 ± 0.28 , 0.59 ± 0.19 , respectively, $P = 0.040$ and 0.007 , CMDI: 21- and 56-d = 3.03 ± 0.42 , 1.60 ± 0.35 vs 2.08 ± 0.46 , 0.86 ± 0.37 , respectively, $P = 0.040$ and 0.005). Furthermore, the colonic expression of MMP-2 and MMP-9 in the UC model group increased significantly compared to the control group ($P < 0.001$), and also increased compared to the AE-941-treated group on the 21- and 56-d timepoints (MMP-2: 21- and 56-d = 0.6048 ± 0.0522 , 0.4163 ± 0.0330 vs 0.3983 ± 0.0218 , 0.1093 ± 0.0072 , respectively, $P = 0.010$; MMP-9: 21- and 56-d = 0.6873 ± 0.0472 , 0.4328 ± 0.0257 vs 0.5179 ± 0.0305 , 0.2673 ± 0.0210 , respectively, $P = 0.010$ and 0.040).

CONCLUSION: Expression of MMP-2 and MMP-9 increased significantly in rats with UC. AE-941 can reduce colonic mucosal damage by downregulating the expression of MMP-2 and MMP-9.

INTRODUCTION

Ulcerative colitis (UC) is a type of nonspecific inflammatory bowel disease for which the etiology and disease mechanism are not completely clear. It has recently

become apparent that the synthetic and degradative imbalance of the colonic extracellular matrix (ECM) may be associated with the progression of UC^[1,2]. The aberrant expression of matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs) can cause a synthetic and degradative imbalance of the ECM, which then leads to a series of pathological reactions such as colonic mucosa inflammation, erosion, and ulceration^[3,4]. TIMPs can inhibit the activity of MMPs, which are able to correct MMP-TIMP imbalances. Our previous research indicated that MMPs may be involved in the occurrence and development of UC.

Expression of MMP-2 and MMP-9 can be blocked by AE-941, a natural inhibitor of MMPs, which is a new and effective treatment of malignant tumors^[5]. In this study, we used a rat model of UC and administered AE-941 by gastric lavage. We then observed the therapeutic effect of AE-941. We will discuss the mechanism of AE-941 alleviation of UC to provide a theoretical basis for a novel treatment for UC.

MATERIALS AND METHODS

Materials

Healthy male Sprague Dawley (SD) rats weighing 180-220 g and aged 4-8 wk were supplied by the SPF laboratory animal center of Dalian Medical University. 2,4,6-trinitrobenzenesulfonic acid solution (TNBS) was purchased from Sigma. AE-941, MMP-2 and MMP-9 polyclonal antibodies were supplied by Bioworld Technology. The MaxPoly Plus Anti-Mouse/Rabbit horseradish peroxidase IHC Kit was supplied by the Fujian Maixin Biological Technology Co. Primers, DNA markers (DL 2000), Takara RNA polymerase chain reaction (PCR) kit3.0 (AMV) kit were from Dalian, Takara Co. Ltd.

Animal treatment

A total of 54 SD rats were randomly divided into three groups: a control group, an AE-941 group, and an UC model group; each group had 18 rats. The SD rat model of UC was established by administering a mixture of TNBS (100 mg/kg) and 50% ethanol (0.25 mL) by enema. The control group was subject to enema and gastric lavage with normal saline. For the AE-941 group, TNBS was administered by enema and AE-941 was administered by gastric lavage (10 mg/kg once a day). The UC model group was subjected to TNBS enema and the gastric lavage was composed of a saline control. Rats from all groups were sacrificed on days 7, 21 and 56. Six rats per group were sacrificed each day, after the enema and colonic tissue 2.0-10.0 cm from the anus was collected for reverse transcription polymerase chain reaction (RT-PCR) and immunohistochemical analysis.

Disease activity index and colonic mucosa damage index scoring

The rats were weighed and checked for behavior, stool

consistency and the presence of gross blood in the stools every day. The scores were assigned as follows: percentage of body weight reduction (0, no change; 1, 1%-5%; 2, 6%-10%; 3, 11%-15%; 4, > 15%); stool consistency (0, normal; 2, loose; 4, diarrhea); and the presence of fecal blood (0, normal; 2, positive occult blood test; 4, visible bleeding)^[6]. The disease activity index (DAI) was calculated as the sum of these scores.

Rats were sacrificed at the timepoints indicated and the entire colon was excised from the cecum to the anus and opened longitudinally. Macroscopic damage was evaluated using a validated [colonic mucosa damage index (CMDI)] scoring system with slight modifications^[7]. The numerical rating score was as follows: 0, no inflammation; 1, local hyperemia without ulcers, and/or stool consistency; 2, ulceration without hyperemia; 3, ulceration and adhesions at one site; 4, two or more sites of inflammation and ulceration extending > 1 cm; 5, ulceration extending more than 2 cm.

MMP-2 and MMP-9 mRNA expression

mRNA was extracted from colonic tissue samples using Trizol according to the manufacturer's protocols (Invitrogen) and RT-PCR was performed according to the instructions of the Takara RNA PCR kit 3.0 (AMV). An equal amount of cDNA from each sample was amplified using primers specific to each gene (Table 1). DNA amplification was done using a thermocycler under the following conditions: for MMP-2, 35 cycles of denaturation at 94 °C for 30 s, annealing at 58 °C for 45 s, and extension at 72 °C for 90 s; for MMP-9, 35 cycles of denaturation at 94 °C for 30 s, annealing at 59 °C for 30s, and extension at 72 °C for 90 s; for β-actin, 35 cycles of denaturation at 94 °C for 30s, annealing at 62 °C for 30s, and extension at 72 °C for 90s. RT-PCR products were measured by photodensitometry using a gel image analysis system after agarose gel electrophoresis and ethidium bromide staining.

Measurement of MMP-2 and MMP-9 protein expression

Immunohistochemistry was performed according to the Max Vision kit protocol. Image analysis software (Image-pro plus 6.0) was used to measure the light density

of positive control cells in which the cytoplasm was tan-yellow or brown after 3,3'-diaminobenzidine staining. For each section, the positive integrated optical density (IOD) and total area of five representative visual fields without overlap were observed under high-power microscope ($\times 400$). The ratio of IOD and total area represents the mean value of optical density, with a higher ratio indicating a higher level of protein expression.

Statistical analysis

All data were analyzed using the SPSS statistical package version 11.5. Data showed a normal distribution and are expressed as means \pm SD. The responses of different experimental groups were analyzed using one-way analysis of variance. A *P*-value of < 0.05 indicates a statisti-

cally significant difference between different groups.

RESULTS

Results of disease activity index and colonic mucosa damage index

The DAI and CMDI of the UC model group was significantly higher than that of the control group (*P* < 0.05) at all timepoints. Compared with the UC model group, the DAI and CMDI values of the AE-941 treatment group were reduced on day 7, although not significantly (*P* > 0.05). On days 21 and 56 after treatment, the DAI and CMDI scores of the AE-941 treatment group were significantly lower than that of the UC model group (*P* < 0.05; Table 2).

Figure 2 Colonic mucosal matrix metalloproteinase-2 and -9 protein expression in control, AE-941, and ulcerative colitis model groups at different time-points. The expression of matrix metalloproteinases (MMP)-2 (A) and MMP-9 (B) protein in the colonic mucosa of the ulcerative colitis model group was significantly higher than in the control group ($P < 0.05$). By days 21 and 56 expression of MMP-2 and MMP-9 in the AE-941 treatment group was significantly less than in the model group ($P < 0.05$).

^a $P < 0.05$ vs control group; ^c $P < 0.05$ vs model group. MMP: Matrix metalloproteinase.

Results of reverse transcription polymerase chain reaction

Expression of MMP-2 and MMP-9 mRNA in the colonic mucosa was significantly higher in the UC model group compared to the control group ($P < 0.05$). However, compared to the UC model group, MMP-2 and MMP-9 mRNA expression in the AE-941 treatment group was reduced by day 7, although not significantly ($P > 0.05$). On days 21 and 56, the two index values in the AE-941 treatment group were significantly lower than that of the model group ($P < 0.05$, Table 3, Figure 1).

Results of immunohistochemistry

The expression of MMP-2 and MMP-9 protein in the colonic mucosa of the UC model group was significantly higher than in the control group ($P < 0.05$). Compared with the model group, expression of MMP-2 and MMP-9 protein in the AE-941 treatment group was reduced, although not significantly, by day 7 ($P > 0.05$). In contrast, by days 21 and 56 expression of MMP-2 and MMP-9 in the AE-941 treatment group was significantly lower than in the model group ($P < 0.05$) (Figure 2, Table 4).

DISCUSSION

Our previous research indicated that MMPs may be involved in the occurrence and development of UC^[8,9]. MMPs are a family of calcium- or zinc-dependent proteolytic enzymes that can remodel the ECM^[10]. At least 28 different MMP enzymes have been identified to date^[11]. MMP-2 and MMP-9 are the main matrix metalloproteinases that function to degrade collagen subtypes, including type IV and V, in the matrix^[12]. The study of von Lampe demonstrated that MMP-2 was highly expressed in the mucosa of patients with UC^[13]. Pirlă *et al.*^[14] identified MMP-2 overexpression in the colonic mucous membrane surrounding areas of inflammation in patients with UC. Medina also found that the expression and activity of MMP-9 was upregulated in colonic mucosa in the UC rat model^[15]. These results suggest that overexpression of MMP-2 and MMP-9 is related to mucosal membrane injury, inflammation of the epithelium and tissue destruction. We therefore tested MMP-2 and MMP-9 expression levels in colonic mucosa using RT-PCR and immunohistochemistry. Our results showed that expression of two indices, DAI and CMDI were significantly higher in

UC model animals than in the control group, and that decreased MMP-2 and MMP-9 expression is associated with an improvement in both DAI and CMDI. These data suggest that overexpression of MMP-2 and MMP-9 is related to mucosal injury and is particularly important for inflammation.

TIMPs are endogenous secretory proteins that can regulate the activity of MMPs^[16]. A disequilibrium of MMPs and TIMPs can lead to a synthetic and degradative imbalance of the ECM, which induces a series of pathological reactions^[17]. Our previous research showed that hyperdegradation combined with insufficient synthesis of colonic ECM resulted in mucosal injury, necrosis and ulceration that were attributed to unbalanced colonic mucosal expression of MMPs and TIMPs in patients with UC^[18,19].

AE-941, also known as Neovastat, is a natural MMP inhibitor derived from shark cartilage, and is a potent inhibitor of MMP-2 and MMP-9 that can dissolve gelatin and elastic protein^[20,21]. Béliveau and Falardeau *et al.*^[22,23] have shown that the activity of MMP-2, MMP-9 and MMP-12 is strongly inhibited by AE-941. Neovastat is a naturally occurring anti-angiogenic compound with multiple mechanisms of action that provide a broad therapeutic potential for a number of diseases^[23]. This drug is currently in international Phase II trials for multiple myeloma, renal cell carcinoma, and non-small-cell lung cancer^[24-26], and its inhibitory function may represent an innovative approach to the treatment of these diseases. The potent inhibition of MMP-2 and MMP-9 by AE-941 was used in our study of TNBS-induced UC in rats. Compared to the UC model group, the DAI and CMDI in the colon of AE-941-treated rats were significantly decreased at the 21- and 56-d timepoints. We found that expression of MMP-2 and MMP-9 mRNA and protein in the colonic mucosa of AE-941-treated rats was significantly lower than in the UC model group. Our results indicated that AE-941 is a potent MMP-2 and MMP-9 inhibitor that can relieve the intensity of chronic inflammation by decreasing the activity and expression of MMP-2 and MMP-9. We found no significant difference in the DAI, the CMDI, and colonic mucosal expression of MMP-2 and MMP-9 between the UC model animals and the AE-941 treatment group by day 7. A possible reason for this is that rats suffering the worst reaction to the TNBS enema at the day 7 evaluation were included in the UC model group. However,

AE-941 did not achieve a response at the shorter (7-d) treatment time.

By comparing the colonic mucosa expression of MMP-2 and MMP-9 in UC model animals at different timepoints, we found that MMP-2 and MMP-9 expression decreased as the DAI and CMDI improved. Using Spearman analysis, we identified a positive correlation between the expression of both MMP-2 and MMP-9 and the severity of UC.

In conclusion, our study confirmed that colonic mucosa in UC expressed MMP-2 and MMP-9 excessively and this overexpression correlated with the severity of UC. Treatment with AE-941 decreased the DAI and CMDI of UC, as well as colonic mucosal expression of MMP-2 and MMP-9, which indicates that AE-941 can protect the colon by inhibiting the excessive expression of MMP-2 and MMP-9 in an UC model. Therefore, MMP inhibitors may become a new measure to treat UC.

ACKNOWLEDGMENTS

The authors thank Wan-Jing Zou for her excellent technical assistance for help with immunohistochemistry. We also thank the SPF laboratory animal center of Dalian Medical University.

COMMENTS

Background

Ulcerative colitis (UC) is a type of nonspecific inflammatory bowel diseases for which the pathogenesis is not completely clear and lacking of effective treatments. The aberrant expression of matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs) can cause a synthetic and degradative imbalance of the extracellular matrix, which then leads to colonic mucosa inflammation, erosion and ulceration. Therefore, in this study, AE-941, a natural MMP inhibitor (MMPI), was employed to verify its protective effect on the rat model of UC.

Research frontiers

In recent years, intense and extensive studies have shown that MMPs, TIMPs play an important role in the development of UC, while studies on the effects of exogenous MMPI on UC are not well documented. Therefore, studies are needed to verify the protective and therapeutic effects of MMPI on UC.

Innovations and breakthroughs

AE-941, a natural MMPI derived from shark cartilage, has been used in experimental and clinical treatment of tumors due to its potent inhibition of MMP-2 and MMP-9. However, its protective effects on UC remain largely unknown. Therefore, in this study, the authors verified the protective effects of AE-941 on UC in rats and provided a new therapeutic approach to UC.

Applications

Up till now, no satisfactory therapy for UC has been available. MMPI targeting MMPs may become a new and effective treatment modality for UC.

Peer review

This concise study reports interesting features on the role of metalloproteinase in ulcerative colitis. The study is well done, and the results are clearly presented.

Abstract

AIM: To determine the expression characteristics of connective tissue growth factor (CTGF/CCN2) in human hepatocellular carcinoma (HCC) in histology and to elucidate the roles of CCN2 on hepatoma cell cycle progression and metastasis *in vitro*.

METHODS: Liver samples from 36 patients (who underwent hepatic resection for the first HCC between 2006 and 2011) and 6 normal individuals were exam-

ined for transforming growth factor β 1 (TGF- β 1) or CCN2 mRNA by *in situ* hybridization. Computer image analysis was performed to measure integrated optical density of CCN2 mRNA-positive cells in carcinoma foci and the surrounding stroma. Fibroblast-specific protein-1 (FSP-1) and E-cadherin were examined to evaluate the process of epithelial to mesenchymal transition, α -smooth muscle actin and FSP-1 were detected to identify hepatic stellate cells, and CD34 was measured to evaluate the extent of vascularization in liver tissues by immunohistochemical staining. CCN2 was assessed for its stimulation of HepG2 cell migration and invasion using commercial kits while flow cytometry was used to determine CCN2 effects on HepG2 cell-cycle.

RESULTS: *In situ* hybridization analysis showed that TGF- β 1 mRNA was mainly detected in connective tissues and vasculature around carcinoma foci. In comparison to normal controls, CCN2 mRNA was enhanced 1.9-fold in carcinoma foci (12.36 ± 6.08 vs 6.42 ± 2.35) or 9.4-fold in the surrounding stroma (60.27 ± 28.71 vs 6.42 ± 2.35), with concomitant expression of CCN2 and TGF- β 1 mRNA in those areas. Epithelial-mesenchymal transition phenotype related with CCN2 was detected in 12/36 (33.3%) of HCC liver samples at the edges between carcinoma foci and vasculature. Incubation of HepG2 cells with CCN2 (100 ng/mL) resulted in more of the cells transitioning into S phase (23.85 ± 2.35 vs 10.94 ± 0.23), and induced a significant migratory (4.0-fold) and invasive (5.7-fold) effect. TGF- β 1-induced cell invasion was abrogated by a neutralizing CCN2 antibody showing that CCN2 is a downstream mediator of TGF- β 1-induced hepatoma cell invasion.

CONCLUSION: These data support a role for CCN2 in the growth and metastasis of HCC and highlight CCN2 as a potential novel therapeutic target.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide and the third most common cause of cancer death^[1]. Although HCC resection plays an important role in improving prognosis of HCC, short survival has been observed in these patients due to high rate of recurrence and metastasis after surgery^[2,3]. The mechanisms regulating tumor growth and metastasis of HCC are very complicated and still not fully understand.

HCC consists of a tumor parenchyma comprised of hepatoma cells and a surrounding microenvironment composed of various cell types such as hepatic stellate cells (HSCs), fibroblasts or inflammatory cells that produce a variety of tumor stroma components, including extracellular matrix (ECM) proteins, growth factors and cytokines^[4,5]. In normal liver, HSCs are typically located in the perisinusoidal space of disse which lies between endothelial cells of sinusoids and hepatocytes. Following liver injury, HSCs become activated, undergo a phenotypic transformation into fibroblast-like cells or myofibroblasts, and migrate to sites of injury where they produce a provisional ECM to support parenchymal repopulation. In settings of chronic injury, this process proceeds unabated, leading to deposition of excessive amounts of ECM proteins and fibrillar collagens, resulting in fibrosis and scarring. This fibrotic environment supports the growth of hepatoma cells and HCC progression is dependent on an intricate cross-talk between the tumor and its surrounding environment^[6-8]. Recent literature has highlighted a fundamental role of the tumor microenvironment in modulating the process of liver fibrosis, hepatocarcinogenesis, epithelial-mesenchymal transition (EMT), tumor invasion and metastasis^[9,10]. A growing body of evidence from animal models and *in vitro* studies suggests that growth factors and matricellular proteins as well as resident HSCs play a key role in this stromal-tumor interaction^[5,10-12].

Connective tissue growth factor (CTGF/CCN2) is a cysteine-rich matricellular protein that has been implicated in regulating diverse processes *in vivo*, including angiogenesis, embryogenesis, chondrogenesis, fibro-

genesis, and tumorigenesis^[13]. CCN2 is transcriptionally activated by transforming growth factor β 1 (TGF- β 1) through a mechanism that involves activation of Smad binding elements and a unique TGF- β response element in the CCN2 promoter. Enhanced expression of CCN2 by TGF- β 1 has been demonstrated in many cell types including HSCs and hepatoma cells^[7,14]. Numerous studies have demonstrated that CCN2 is a downstream mediator of TGF- β 1-induced ECM production in HSCs, pancreatic stellate cells and osteoblasts^[15-17]. Recently, down-regulation of CCN2 by either the TGF- β 1 inhibitor LY2109761 or CCN2 siRNA appeared to inhibit the growth of HCC in culture or xenograft models^[7,18].

In this study, we have characterized CCN2 expression in human HCC, its association with EMT, and its effects on hepatoma cell migration, invasion or cell cycle progression.

MATERIALS AND METHODS

Clinical data

Thirty-six HCC specimens were obtained by surgical resection from May 2006 to June 2011. Samples obtained from the peripheral areas of the tumors were selected for this study. The patients with HCC consisted of 26 men and 10 women, mean age 56.4 years (range: 27-71 years). According to Pittsburgh modified TNM criteria, the patients were classified as small hepatocellular carcinoma ($n = 20$), solitary large hepatocellular carcinoma ($n = 10$) and nodular hepatocellular carcinoma ($n = 6$). Six normal liver specimens were obtained from patients undergoing hepatic resection due to a single cavernous hemangioma and the normal liver tissues were taken at the greatest distance from the location of the angiocavernoma. The tissue samples used as controls were histologically analyzed and clearly shown to have no inflammation or fibrosis. All specimens were examined under a light microscope after haematoxylin and eosin (HE) staining or Masson's trichome staining.

In situ hybridization

ISH was performed using digoxigenin-labeled sense or anti-sense probes for CCN2 or TGF- β 1 (Boster Biotechnology Co. Ltd., Wuhan, China). In brief, liver samples from HCC patients were formaldehyde-fixed and paraffin-embedded. The tissue sections (5 μ m) were deparaffinized, rehydrated with phosphate buffered solution (PBS), digested with pepsin (30 μ g/mL) for 10 min at 37 °C, fixed in 4% paraformaldehyde in PBS and washed in 3 \times SSC. The samples were pre-hybridized at 42 °C for 2 h, and hybridization was performed overnight at 42 °C with sense or anti-sense probes. After hybridization, unbound probe was removed by washing in 2 \times SSC, 0.5 \times SSC and then 0.2 \times SSC at 37 °C for 2 h. The tissue sections were incubated at 37 °C for 1 h with biotinylated mouse anti-digoxigenin, followed by addition of streptavidin-biotin-peroxidase complex for

20 min. The slides were then developed with 3-amino-9-ethylcarbazole (Boster Biotechnology). Ten random images (original magnification $\times 400$) of each slide underwent computer image analysis using Image-Pro Plus 6.0 software to assess the integrated optical density (A) of TGF- $\beta 1$ or CCN2-positive cells in liver tissues.

Immunohistochemistry

Formalin-fixed, paraffin-embedded sections (5 μm) were de-waxed and re-hydrated. Sections were incubated overnight at 4 $^{\circ}\text{C}$ with rabbit anti-human E-cadherin polyclonal antibody (Boster Biotechnology Co. Ltd., Wuhan, China), mouse anti-human cluster of differentiation 34 monoclonal antibody (Maixin Bio, Fuzhou, China), rabbit anti-human CCN2 polyclonal antibody (Santa Cruz, Heidelberg, Germany) or rabbit anti-human fibroblast-specific protein-1 (FSP-1) polyclonal antibody (Millipore Corporation, Billerica, MA, United States). Sections were washed in PBS and incubated at room temperature for 10 min with biotinylated goat anti-mouse and anti-rabbit IgG (Maixin Bio, Fuzhou, China). After washing with PBS, sections were incubated with streptavidin-peroxidase (Maixin Bio, Fuzhou, China) for 10 min and then developed with diaminobenzidine or 3-amino-9-ethylcarbazole.

Flow cytometry

Two milliliter of $1 \times 10^5/\text{mL}$ HepG2 cell suspension were placed to each well of 6-well tissue culture plates in 12% FBS-DMEM and incubated for 12 h. The cells were then cultured in 0.5% FBS-DMEM for 24 h. The cell culture medium was exchanged with 0.5% FBS-DMEM and the cells were incubated for another 24 h in the absence or presence of 100 ng/mL CCN2 (Biovendor, Modrice, Czech Republic) or 20 ng/mL TGF- $\beta 1$ (PeproTech, Rehovot, Israel). The cells were then trypsinized with 0.25% trypsin and washed in PBS. HepG2 cell-cycle progression was determined by resuspending the cells at 1×10^6 cells/mL in PBS, fixing the cells with 75% ethanol overnight, and then staining the cells with 0.1 mg/mL propidium iodide in a 0.1% sodium citrate/0.1% Triton X-100 solution in the presence of 0.2 mg/mL RNase for 30 min at room temperature in the dark. Analysis of cellular DNA content after cell staining with propidium iodide was performed by flow cytometry at an excitation wavelength of 488 nm. The distribution of cells in three major phases of the cycle (G0/G1, S, G2/M) was analyzed using CellQuest software (BD Biosciences, San Jose, CA, United States).

Migration assay

HepG2 migration studies were performed using a 12-well companion plate into which inserts were placed that had an uncoated membrane with 5- μm pores (Millipore, Billerica, MA). HepG2 cells, detached from stock dishes with 1 mmol/L EDTA, were suspended in DMEM and placed at 3×10^4 cells per insert for 6

h in the absence or presence of CCN2 (100 ng/mL) or TGF- $\beta 1$ (20 ng/mL) in the lower chamber of the well. Cells that adhered to the membrane were fixed with 100% methanol and stained with May-Grunwald's Giemsa. The numbers of HepG2 cells on the upper or lower surfaces were individually counted in 10 randomly selected microscopic fields at a magnification of $400 \times$. The rate of migration of HepG2 cells were expressed as a migration index (%) defined as follows: (number of cells on the undersurface of membrane/total number of cells on both surface of the membrane) $\times 100$.

Invasion assay

A HepG2 cell invasion assay was performed in a 24-well plate with ECMatrixTM cell culture inserts (Chemicon, United States). The inserts contained an ECMatrix-coated polycarbonate membrane with 8 μm pores which was rehydrated with 300 μL DMEM for 2-h at room temperature. 300 μL Hep G2 cells in DMEM (5×10^4 cells/mL) were added to each insert while 500 μL DMEM containing CCN2 (100 ng/mL) or TGF- $\beta 1$ (20 ng/mL) were added to the lower chamber. After 24 h, adherent cells were fixed with 100% methanol and stained with staining solution. The numbers of non-invaded cells on the upper surface and those of invaded cells on the under surface were counted in 10 randomly selected microscopic fields at a magnification of $400 \times$. The cell invasion index (%) was defined as follows: (number of cells on the undersurface of membrane/total number of cells on both surface of the membrane) $\times 100$.

Ethical approval

This work was approved by First Hospital of Jilin University and was carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. Informed consent was obtained from all patients prior to sample collection.

Statistical analysis

Statistical analysis of the data was performed using SPSS 13.0 for Windows (SPSS Inc, Chicago, IL, United States). The values reported represent the mean \pm SD of the measurements. Differences were analyzed statistically with paired sample Student's *t*-test and *P* < 0.05 was considered significant.

RESULTS

Localization of CCN2 mRNA in HCC

At the light microscopic level, all HCC samples tested in this study had multiple foci of carcinoma by HE or Masson's trichrome staining. The carcinoma foci were separated or wrapped by their surrounding stroma. Collagen bundles were present in the stroma (Figure 1A) while CD34, a specific marker of vascular endothelial cells, was detected in the vasculature surrounding the stroma and in a few small blood vessels within tumor foci (Fig-

Figure 1 Expression and distribution characteristics of transforming growth factor $\beta 1$ or connective tissue growth factor mRNA in human hepatocellular carcinoma. A: Masson's trichrome stain for collagen (blue) in hepatocellular carcinoma (HCC); B: Immunohistochemical detection of CD34 in vascular endothelial cells (brown) in HCC; C: Normal liver showing connective tissue growth factor (CCN2) mRNA expressed in connective tissue around the veins; D: Absence of staining of HCC when the *in situ* hybridization probes were omitted; E: HCC stained for transforming growth factor $\beta 1$ mRNA, showing reactivity in connective tissue and around the carcinoma foci; F: Over-expression of CCN2 mRNA in connective tissue and vascular endothelial cells (black arrow) in HCC. Original magnification, $\times 100$ in A and E, $\times 200$ in B, C, D and F. CF: Carcinoma foci; CT: Connective tissue.

ure 1B). *In situ* hybridization showed that CCN2 mRNA positive cells were mainly distributed in connective tissues surrounding the carcinoma foci and its associated vasculature. However, only mild CCN2 mRNA staining was detected in veinal vasculature in normal liver (Figure 1C) and there was no staining in HCC liver tissue when the *in situ* hybridization probe was omitted (Figure 1D). We next examined the expression and distribution of hepatic TGF- $\beta 1$ mRNA in HCC patients since TGF- β stimulates and interacts co-operatively with CCN2 to drive fibrosis and tumor progression^[7,13]. As expected, TGF- $\beta 1$ mRNA was detected in the connective tissues surrounding carcinoma foci where it was expressed concomitantly with CCN2 mRNA (Figure 1E and F).

Computer image analysis of CCN2 mRNA expression in comparison to normal controls revealed a 9.4-fold increase in stromal expression (60.27 ± 28.71 vs 6.42 ± 2.35 , $P < 0.01$) and a 1.9-fold increase in expression in carcinoma foci (12.36 ± 6.08 vs 6.42 ± 2.35 , $P < 0.01$, Table 1).

Relationship between CCN2 expression and EMT

Having shown the expression and localization of CCN2 mRNA, we next investigated the relationship between CCN2 and the occurrence of EMT, the latter of which was assessed by staining for either (1) E-cadherin which is expressed in normal epithelial cells but is absent or only weakly expressed in high-metastatic cancer cells^[8] or (2) FSP-1 which is a marker of fibroblasts and epithelial

Table 1 Expression levels of transforming growth factor β 1 or connective tissue growth factor mRNA in human hepatocellular carcinoma (mean \pm SD)

	<i>n</i>	TGF- β 1 mRNA (A)	CCN2 mRNA (A)
Normal control	6	6.24 \pm 2.35	6.42 \pm 2.35
Carcinoma foci	36	15.02 \pm 4.43 ^b	12.36 \pm 6.08 ^b
Stroma around carcinoma foci	36	47.56 \pm 7.31 ^d	60.27 \pm 28.71 ^d

^b*P* < 0.01 *vs* normal control; ^d*P* < 0.01 *vs* carcinoma foci. TGF- β 1: Transforming growth factor β 1; CCN2: Connective tissue growth factor.

cancer cells with EMT features. CCN2 mRNA (Figure 2A) or protein (Figure 2B) were detected in hepatoma cells at the edge of carcinoma foci by ISH or immunohistochemistry respectively. E-cadherin was present in areas that were adjacent to the carcinoma foci but it was only very weakly detectable in hepatoma cells within the carcinoma foci (Figure 2C). At the edges between carcinoma foci and the vasculature, hepatoma cells were FSP-1-positive in 33.3% (12/36) of HCC sections (Figure 2D). As CCN2 has been proposed as a key regulatory cytokine in tumor-stroma crosstalk in an animal model of HCC^[7], this aspect was investigated in our clinical specimens. As expected, CCN2 mRNA expression occurred in (1) fibroblast-like or myofibroblast-like HSC marked by expression of FSP-1 or α -smooth muscle actin (α -SMA) (Figure 2D-F); (2) hepatoma cells (Figure 2G) located along the border between tumor foci and vasculature; Since CCN2 mRNA was detected in hepatoma cells that were FSP-1-positive (Figure 2D and H), this finding supports a role for CCN2 in autocrine or paracrine regulation of EMT in human hepatoma cells.

Effect of CCN2 on hepatoma cell cycle distribution

Cell cycle analysis was assessed by flow cytometry of propidium iodide-stained HepG2 cells after treatment of the cells with 100 ng/mL CCN2 for 24 h. As shown in Table 2, approximately 53% of HepG cells were in G0/G1, 11% were in the S, and 34% were in G2/M after serum starvation of the cells in medium containing 0.5% FCS. After CCN2 stimulation, a relatively lower proportion of cells (41%) were in the G0/G1 phase (41.01 \pm 4.45 *vs* 53.56 \pm 2.51, *P* < 0.05), and a higher proportion (23.8%) were in S phase (23.85 \pm 2.35 *vs* 10.94 \pm 0.23, *P* < 0.05), as compared to control cells. However, TGF- β 1 stimulation did not significantly alter the distribution of phases of the cell cycle as compared to control cells.

CCN2 induces hepatoma cell migration and invasion

To determine effects of CCN2 on HepG2 cell migration, we used a chemotaxis assay in which the migration of HepG2 cells from the upper chamber of a culture insert was assessed following addition of CCN2 to the lower chamber. As shown in Figure 3A, CCN2 induced HepG2 cell migration across the polyethylene membrane in the culture insert. Cell migration was also promoted

Table 2 Effect of connective tissue growth factor on HepG2 cell cycle progression

Groups	G0-G1	S	G2-M
Normal control	53.56 \pm 2.51	10.94 \pm 0.23	34.17 \pm 1.29
CCN2	41.01 \pm 4.45 ^a	23.85 \pm 2.35 ^a	34.17 \pm 1.29
TGF- β 1	54.97 \pm 1.88	12.07 \pm 2.44	33.30 \pm 0.73

^a*P* < 0.05 *vs* normal control. TGF- β 1: Transforming growth factor β 1; CCN2: Connective tissue growth factor.

by TGF- β 1.

Since CCN2 expression was associated with EMT in hepatoma cells (see above), we further examined whether CCN2 played a role in HepG2 cell invasion through ECM using an ECMMatrix culture insert. As shown in Figure 3B, HepG2 invasion across the ECM layer was stimulated by either CCN2 or TGF- β 1, the latter of which was blocked by anti-CCN2 antibody but not normal IgG. These data indicate that HepG2 cell invasion is stimulated by CCN2 directly or by TGF- β 1-mediated CCN2 production.

DISCUSSION

In this study, we determined the expression and distribution of CCN2 in HCC, its relationship to HCC-associated EMT, and the role of CCN2 in stimulating hepatoma migration, invasion, or cell cycle progression *in vitro*. Our findings can be summarized as follows: (1) In comparison to normal controls, CCN2 mRNA expression was enhanced, respectively, 9.4- or 1.9-fold in tumor stroma or carcinoma foci; (2) A concomitant expression of CCN2 and TGF- β 1 mRNA was found in these areas; (3) CCN2 expression in the stroma, hepatoma cells or HSCs was correlated with expression of markers of EMT; (4) CCN2 promoted HepG2 cell migration, invasion or cell cycle progression; and (5) CCN2 neutralizing antibody blocked TGF- β 1-induced HepG2 cell invasion.

The initiation, growth and progression of HCC are dependent on an intricate crosstalk between tumor and stroma^[7]. Components of the microenvironment that surround hepatoma cells, including ECM protein and growth factors as well as its constituent non-tumor cells, are critical for HCC growth and metastasis^[6,19]. It has previously been demonstrated that TGF- β 1 plays an important role in HCC by stimulating fibrogenic remodeling of the liver and contributing to tumor progression^[20]. Produced downstream of TGF- β 1, CCN2 participates in a variety of pathophysiological processes, including formation of fibrous scar, angiogenesis, tumor growth^[21-24]. Expression of CCN2 is related to recurrence, metastasis and poor prognosis in human HCC and pancreatic cancer^[25,26]. Increasing evidence supports a role for CCN2 in mediating the matrigenic actions of TGF- β 1 in numerous cell types, especially those that have specialized role in ECM production such as HSC, pancreatic stellate cells and osteoblasts^[14-17]. In experimental HCC models,

Figure 2 Expression of connective tissue growth factor mRNA and its association with epithelial-mesenchymal transition in hepatocellular carcinoma. Connective tissue growth factor (CCN2) mRNA (A) or protein (B) were detected in hepatoma cells at the edge of carcinoma foci by *in situ* hybridization or immunohistochemistry respectively; C: E-cadherin was only weakly detectable in carcinoma foci but stained more intensely in normal hepatocytes; D, E: Fibroblast-specific protein-1 (FSP-1)-positive hepatoma cells (white arrow) were located at a position between the edge of carcinoma foci and vascular wall; FSP-1-positive (black arrows) (D) or (E) α -smooth muscle actin-positive (black arrows) fibroblast-like or myofibroblast-like hepatic stellate cell (HSC) were found within carcinoma foci; F-H: CCN2 mRNA was detected in either fibroblast-like or myofibroblast-like HSC (black arrows); CCN2 mRNA (G) or (H) FSP-1 were found in some hepatoma cells. Original magnification, $\times 400$ in A, B, C, D, F and G, $\times 200$ in E and H. Examples of positively stained cells or structures in each panel are arrowed.

LY2109761, an inhibitor of TGF- β 1, was shown to inhibit neo-angiogenesis, tumor growth and progression by down-regulation of CCN2 production^[6,7]. Our results show that human HCC is characterized by enhanced CCN2 expression in tumor stroma and tumor cells, as well as its co-expression with TGF- β 1. Collectively these data suggest that CCN2 is an important component of the tumor-stroma axis and likely plays an important role in the development and progression of HCC.

EMT is a cellular program characterized by loss of cell adhesion, repression of E-cadherin expression, rearrangement of the cellular cytoskeleton, upregulation of matrix remodeling factors and increased cell mobility^[27]. EMT is essential for numerous developmental processes

including embryo implantation, embryogenesis, organ development and fibrosis^[28-30]. Over past decade, the EMT process has been increasingly recognized to occur during the progression of various carcinomas such as HCC or pancreatic adenocarcinoma^[31,32]. Recent studies have shown that TGF- β 1 or hepatocyte growth factor induces EMT in HCC cell lines or in animal models^[27,32-34]. CCN2 has been demonstrated to promote human renal tubular epithelial cells to mesenchymal transition characterized by down-regulation of E-cadherin and up-regulation of α -SMA^[35]. In this study we showed that hepatoma cells with EMT characteristics (downregulation of E-cadherin and upregulation of FSP-1) were located at the tumor border and were positive for CCN2,

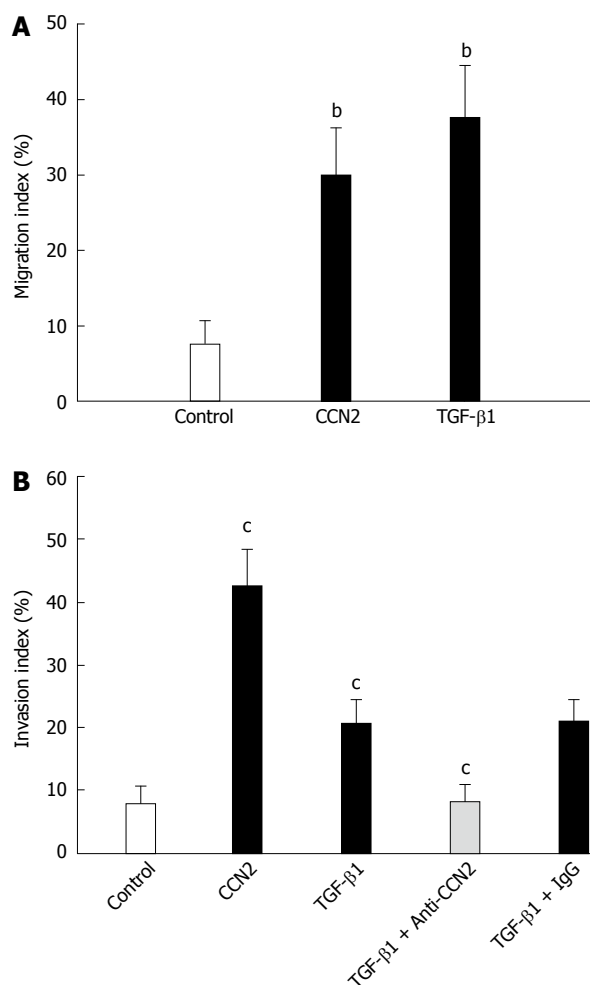

Figure 3 Connective tissue growth factor induces HepG2 cell migration or invasion *in vitro*. A: HepG2 cell migration assays were performed by placing the cells in culture inserts followed by incubation in a 12-well companion plate for 6 h in the absence (control) or presence of connective tissue growth factor (100 ng/mL) or transforming growth factor β 1 (TGF- β 1) (20 ng/mL) in the lower chamber; B: HepG2 cell invasion assays were performed by placing the cells in culture inserts followed by incubation in a 24-well companion plate for 24 h in the absence (control) or presence of connective tissue growth factor (100 ng/mL) or TGF- β 1 (20 ng/mL) in the lower chamber. For inhibitory studies, HepG2 cells were incubated with 25 μ g/mL anti-connective tissue growth factor (CCN2), or normal mouse immunoglobulin G during treatment with TGF- β 1. ^b P < 0.01 vs control or CCN2 group; ^c P < 0.05 vs TGF- β 1 group.

which was also detected in tumor- or stroma- associated HSCs. Taken together, these results support a role for HSC- or HCC-derived CCN2 in the process of EMT.

Tumor cell invasion and metastasis are complex and multistage processes that occur after cancer cells have undergone genotypic and phenotypic alterations resulting in the acquisition of a matrix-degrading and migratory phenotype^[36]. Tumor cell migration is necessary at the initiation of the metastatic cascade, at which time the tumor cells leave the primary site and migrate in response to, and toward, specific external chemotactic factors such as growth factors and ECM^[36,37]. In mouse models, proliferation and invasion of breast or pancreatic cancer cells are increased by CCN2, while the growth and metastasis of pancreatic adenocarcinoma

are attenuated by neutralizing anti-CCN2 antibody^[38,39]. Increasing evidence from *in vitro* studies demonstrates that CCN2 regulates cell motility, migration and invasion in glioma, melanoma or gastric cancer cells^[40-43]. Specifically, CCN2 induces gastric cancer cell migration through downregulation of E-cadherin *via* the nuclear factor κ B (NF- κ B) pathway while glioma tumor initiation or tumor stem cell invasion are promoted by CCN2 *via* its binding with integrin β 1 and tyrosine kinase receptor type A, and activation NF- κ B signal pathway^[40,43]. Downregulation of matrix metalloproteinase (MMP)-2 and MMP-9 contributed to the reduced invasion of gastric cancer cells in which CCN2 expression was knocked down^[41]. Moreover, down-regulation of CCN2 by either the TGF- β 1 inhibitor LY2109761 or CCN2 siRNA diminished hepatoma growth, intravasation and metastatic dissemination in an *in vivo* xenograft model or in cell culture systems^[7,18]. Thus, these findings are consistent with our observations that exogenous CCN2 induces hepatoma cell migration, invasion and cell cycle progression. These functional properties in hepatoma cells coupled with the pattern of CCN2 over-expression in HCC, support a role of CCN2 in the growth and metastasis of human HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the most common form of liver malignancy worldwide. HCC consists of a tumor parenchyma comprised of hepatoma cells and a surrounding microenvironment composed of various cell types such as hepatic stellate cells (HSCs), fibroblasts, and inflammatory cells that produce a variety of tumor stroma components including extracellular matrix (ECM) proteins, growth factors and cytokines. A growing body of literature has highlighted a fundamental role of the tumor microenvironment in modulating the process of hepatocarcinogenesis, epithelial-mesenchymal transition, tumor invasion and metastasis. Connective tissue growth factor (CTGF/CCN2) is downstream mediator of transforming growth factor β 1 (TGF- β 1)-induced ECM production in HSCs and hepatoma cells. CCN2 has been previously implicated in cancer metastasis and invasion in various tumors. However, the role of CCN2 in human HCC remains largely unknown.

Research frontiers

Recently, down-regulation of CCN2 by either the TGF- β 1 inhibitor LY2109761 or CCN2 siRNA appeared to inhibit the growth of HCC in culture or xenografted models. High intratumoral CCN2 expression was associated with vascular invasion and poor survival after curative resection of hepatocellular carcinoma. The preliminary results suggest that CCN2 might play a crucial roles in regulating the growth and metastasis of HCC.

Innovations and breakthroughs

To date, there have been a limited number of HCC studies using *in vitro* cell culture, animal models or human clinical specimens to address the roles of CCN2 in regulation of tumor growth and metastasis. In this study, the authors determined the expression characteristics of CCN2 in human HCC by histology and elucidated the roles of CCN2 on hepatoma cell migration, invasion and cell cycle progression. Furthermore, the authors described the relationship between the overexpression of CCN2 in human HCC and its association with epithelial-mesenchymal transition (EMT).

Applications

These studies suggest that CCN2 plays important roles in tumor growth and metastasis in human HCC and highlight CCN2 as potential novel therapeutic target.

Peer review

This paper provided some aspects on understanding EMT of HCC and mecha-

nisms on HCC migration and invasion. The result is interesting and suggest that a role for CCN2 in the growth and metastasis of HCC and highlight CCN2 as a potential novel therapeutic target.

Abstract

AIM: To investigate the adjunct anticancer effect of Astragalus polysaccharides in H22 tumor-bearing mice.

METHODS: To establish a solid tumor model, 5.0×10^6 /mL H22 hepatoma cells were inoculated subcutaneously into the right armpit region of Kunming mice (6-12 wk old, 18-22 g). When the tumors reached a size of 100 mm³, the animals were treated as indicated, and the mice were randomly assigned to seven groups ($n = 10$ each). After ten days of treatment, blood samples were collected from mouse eyes, and serum was harvested by centrifugation. Mice were sacrificed, and the whole body, tumor, spleen and thymus were weighed immediately. The rate of tumor inhibition and organ indexes were calculated. The expression levels of serum cytokines, P-glycoprotein (P-GP) and multidrug resis-

tance (*MDR*) 1 mRNA in tumor tissues were detected using enzyme-linked immunosorbent assay, Western blotting, and quantitative myeloid-derived suppressor cells reverse transcription-polymerase chain reaction, respectively.

RESULTS: The tumor inhibition rates in the treatment groups of Adriamycin (ADM) + Astragalus polysaccharides (APS) (50 mg/kg), ADM + APS (100 mg/kg), and ADM + APS (200 mg/kg) were significantly higher than in the ADM group (72.88% vs 60.36%, $P = 0.013$; 73.40% vs 60.36%, $P = 0.010$; 77.57% vs 60.36%, $P = 0.001$). The spleen indexes of the above groups were also significantly higher than in the ADM group (0.65 ± 0.22 vs 0.39 ± 0.17 , $P = 0.023$; 0.62 ± 0.34 vs 0.39 ± 0.17 , $P = 0.022$; 0.67 ± 0.20 vs 0.39 ± 0.17 , $P = 0.012$), and the thymus indexes of the ADM + APS (100 mg/kg) and ADM + APS (200 mg/kg) groups were significantly higher than in the ADM group (0.20 ± 0.06 vs 0.13 ± 0.04 , $P = 0.029$; 0.47 ± 0.12 vs 0.13 ± 0.04 , $P = 0.000$). APS was found to exert a synergistic anti-tumor effect with ADM and to alleviate the decrease in the sizes of the spleen and thymus induced by ADM. The expression of interleukin-1 α (IL-1 α), IL-2, IL-6, and tumor necrosis factor- α (TNF- α) was significantly higher in the ADM + APS (50 mg/kg), ADM + APS (100 mg/kg) and ADM + APS (200 mg/kg) groups than in the ADM group; and IL-10 was significantly lower in the above groups than in the ADM group. APS could increase IL-1 α , IL-2, IL-6, and TNF- α expression and decrease IL-10 levels. Compared with the ADM group, APS treatment at a dose of 50-200 mg/kg could down-regulate *MDR1* mRNA expression in a dose-dependent manner (0.48 ± 0.13 vs 4.26 ± 1.51 , $P = 0.000$; 0.36 ± 0.03 vs 4.26 ± 1.51 , $P = 0.000$; 0.21 ± 0.04 vs 4.26 ± 1.51 , $P = 0.000$). The expression level of P-GP was significantly lower in the ADM + APS (200 mg/kg) group than in the ADM group (137.35 ± 9.20 mg/kg vs 282.19 ± 20.54 mg/kg, $P = 0.023$).

CONCLUSION: APS exerts a synergistic anti-tumor

effect with ADM in H22 tumor-bearing mice. This may be related to its ability to enhance the expression of IL-1 α , IL-2, IL-6, and TNF- α , decrease IL-10, and down-regulate *MDR1* mRNA and P-GP expression levels.

INTRODUCTION

Cancer has become a major public health problem globally^[1]. The World Health Organization predicts that by 2030 an estimated number of 21.4 million new cases of cancer and 13.2 million cancer deaths will occur annually around the world^[2]. Surgery, radiotherapy, chemotherapy and endocrine therapy remains the classic cancer therapies^[3]. For advanced tumors, chemotherapy is still the treatment of choice, and although these drugs are effective, they are associated with severe adverse events and drug resistance, especially multidrug resistance (MDR)^[4].

Severe adverse events affect patients' compliance. Drug resistance, especially MDR, is the leading cause of treatment failure in cancer therapy. Once the MDR occurs, chemotherapy is no longer effective even with doses of drugs high enough to overcome the resistance; toxic effects are observed and resistance mechanisms can be further stimulated^[5]. One of the underlying mechanisms of MDR is cellular overproduction of P-glycoprotein (P-GP) which acts as an efflux pump for various anticancer drugs. P-GP is encoded by the *MDR1* gene and its over-expression in cancer cells has become a therapeutic target for circumventing MDR. A potential therapeutic strategy is to co-administer efflux pump inhibitors, although such reversal agents might actually increase the side effects of chemotherapy by blocking physiological anticancer drug efflux from normal cells. Although great efforts have been made to overcome MDR with the first- and second-generation reversal agents available in current clinical use for other indications (e.g., verapamil, cyclosporine A and quinidine) or analogues of the first-generation drugs (e.g., dexverapamil, valsopodar and cinchonine), few significant advances have been achieved. Clinical trials with the third-generation modulators (e.g., biricodar, zosuquidar and laniquidar) specifically for MDR reversal are being developed. The results however are not encour-

aging possibly because that the perfect reverser does not exist^[6].

Traditional Chinese medicine (TCM) and herbal medicines in particular have been used in the treatment of cancer for thousands of years in China, Japan, South Korea and other Asian countries. These medicines are widely accepted as current forms of adjuvant therapy in cancer treatment in the United States and Europe^[7,8]. TCM has been shown to play an adjunct anticancer role by inducing apoptosis and differentiation, enhancing the immune system, inhibiting angiogenesis and reversing MDR^[9]. As adjunct anticancer agents, TCM has great advantages in terms of increasing the sensitivity of chemotherapeutics, reducing the side effects and complications associated with chemotherapy, and improving patient quality of life and survival time^[10]. In the search for new cancer therapeutics with lower toxicity and fewer side effects, TCM has shown promise^[11].

The dried root of *Astragalus membranaceus* has a long history of medicinal use in TCM. *Astragalus* has demonstrated a wide range of potential therapeutic applications in immunodeficiency syndromes, as an adjunct cancer therapy, and for its adaptogenic effect on the heart and kidneys^[12]. *Astragalus* extract inhibits destruction of gastric cancer cells by mesothelial cells through its anti-apoptosis effects^[13]. The active pharmacological constituents of *Astragalus membranaceus* include various polysaccharides, saponins and flavonoids as well as L-arginine or L-canavanine^[14,15]. Among these, *Astragalus* polysaccharides (APS) have been most widely studied. APS plays its adjunct anticancer role by improving immune function^[16-19], counteracting the side effects of chemotherapeutic drugs^[12,15,20,21] and increasing the sensitivity of chemo-therapeutics^[13,17,18,22-25]. However, the mechanism underlying the adjunct anticancer property of APS, especially whether or not it involves the regulation of cytokines and reversal of MDR, is not completely clear.

Thus, the present study focuses on investigating the effect of APS on the expression of cytokines and P-GP in H22 tumor-bearing mice.

MATERIALS AND METHODS

Main reagents

APS (20 000-60 000 mol/L) was purchased from Shanxi Undersun Biomedtech Co. Ltd., China). Adriamycin (ADM), verapamil, and rifampicin (RFP) were purchased from the National Institutes for Food and Drug Control. Mouse interleukin-1 α (IL-1 α) enzyme-linked immunosorbent assay (ELISA) kit, mouse IL-2 ELISA kit, mouse IL-6 ELISA kit, mouse IL-10 ELISA kit and mouse tumor necrosis factor- α (TNF- α) ELISA kit, TaKaRa-RNA PCR Kit (AMV) Ver3.0, and TRIZOL reagent were purchased from Sigma Corporation, MO, United States. Goat anti-mouse IgG and fluorescein-affinity pure goat anti-rabbit IgG were purchased from Jackson ImmunoResearch Laboratories. Oligonucleotides and reagents for polymerase chain reaction (PCR) assay were

purchased from Sigma Corporation.

Cell lines and culture

H22 hepatoma cells lines (purchased from Beijing Cowin Biotech Co. Ltd., Beijing, China) were cultured in cell culture vessels *in vitro*. The H22 cells were harvested and inoculated intraperitoneally for 9 d to the eight Kunming mice (KM). To establish the tumor-bearing mouse model, cells with ascites were harvested and inoculated subcutaneously into the right armpit region of the mice.

Animals and trial groups

Male KM (age, 6–12 wk; weight, 18–22 g) were purchased from the Animal Center of the Third Xiangya Hospital. These animals were maintained at $25 \pm 1^\circ\text{C}$ and $60\% \pm 5\%$ humidity under a 12 h light-dark cycle. All experimental animals were housed under specific-pathogen-free conditions for 1 wk to get accustomed to the surroundings before initiation of the experiment. They were allowed free access to food and water throughout the study. All experimental protocols described in this study were approved by the Ethics Review Committee for Animal Experimentation of Central South University.

Mice were randomly assigned to one of the seven groups ($n = 10$ each): ADM group, ADM + RFP group, normal saline (NS) group, ADM + APS (50 mg/kg) group, ADM + APS (100 mg/kg) group, ADM + APS (200 mg/kg) group, ADM + VER group. All the agents were administered by intraperitoneal injection (*ip*): ADM 1.25 mg/kg, 0.2 mL, *qod* $\times 5$ d; RFP 40 mg/kg, 0.2 mL, *qd* $\times 10$ d; NS 0.4 mL, *qd* $\times 10$ d; APS 50 mg/kg, 100 mg/kg, 200 mg/kg 0.2 mL, *qd* $\times 10$ d; and VER 1 mg/kg, 0.2 mL, *qd* $\times 10$ d. After ten days of treatment, the organ indexes and tumor inhibition rate were calculated, and compared with those of control group.

Modeling of the tumor-bearing mice

This model was created by subcutaneous injection of H22 cells as previously described^[26–28]. Briefly, the H22 cells with ascites were harvested, diluted to a concentration of $5.0 \times 10^6/\text{mL}$ with sterilized NS, and inoculated subcutaneously into the right armpit region of the mice. Each mouse was weighed immediately after inoculation. During this period, growth rate and tumor size were measured every two days by determining two perpendicular dimensions. Then the volume of each tumor was calculated using the following formula: $\text{volume} = 1/2 \times \text{length} \times \text{width}^2$ ^[28,29]. When the tumors reached a size of 100 mm^3 (excluding maximum and minimum values) the animals were treated as indicated, and were randomly assigned to one of the groups mentioned above. Forty-eight hours after the final administration of tested drug on the 10th day of the experiment, blood samples were collected from the mice's eyes and serum was harvested by centrifugation. Mice were killed by pulling and breaking of the cervical vertebra, and the whole body, tumor, spleen, and thymus were weighed immediately. Sera were stored at -70°C and other specimens were stored in liq-

uid nitrogen for further analysis^[28,29].

Tumor inhibition rate and immune organ index

The inhibitory effect of experimental treatment on tumor growth was evaluated by tumor inhibition rate, and the influence of different drugs on the immune organs was evaluated by the immune organ index. The inhibitory rates of tumor growth were calculated as follows: $\text{inhibitory rate} = (1 - \text{average tumor weight in the experimental group} / \text{average tumor weight of control group}) \times 100\%$ ^[28,29]. The organ indexes of spleen and thymus were calculated as follows: $\text{organ index (\%)} = \text{average weight of organ} / (\text{average body weight}) \times 100\%$.

Measurement of cytokines

The serum levels of cytokines were determined by ELISA according to the manufacturer's instructions (eBioscience, United States). ELISA kits were employed for the measurement of the levels of IL-1 α , IL-2, IL-6, IL-10, and TNF- α .

Western blotting analysis

RFP (P-GP inducer) and VER (P-GP antagonist) were used as positive controls. Western blotting analysis was performed as previously described^[30–32]. Briefly, 200 mg of each tumor was frozen with liquid nitrogen and crushed in a mortar. The tumor samples were homogenized in a lysis buffer. Cells were washed twice with ice-cold PBS and total cell lysates were collected in sodium dodecyl sulfate (SDS) sample buffer (50 mmol Tris-HCl, pH 6.8, 100 mmol dithiothreitol (DTT), 2% SDS, 0.1% bromophenol blue, 10% glycerol). Cell lysates containing equal amounts of protein were separated by SDS-polyacrylamide gel electrophoresis and transferred to polyvinylidene difluoride membranes. After blocking in 5% non-fat milk in Tris-buffered saline with 0.1% Tween 20 (pH 7.6), membranes were incubated with the appropriate primary antibodies (goat anti-mouse IgG) at 4°C , overnight, and exposed to the appropriate secondary antibody (goat anti-rabbit IgG) for 3 h at 37°C . Immunoreactive proteins were visualized using the enhanced chemiluminescence system from Pierce (Rockford, IL, United States).

Quantitative real time reverse transcription-PCR

The *MDR1* mRNA expression level in the H22 tumor-bearing mice was measured using quantitative reverse transcription (QRT)-PCR. Briefly, total RNA was extracted using the TRIzol reagent following the manufacturer's instructions and reverse transcribed to cDNA using the Gene Amp RNA PCR kit in a DNA thermal cycler (Bio-Rad). QRT-PCR was performed with SYBR green PCR master mix in an ABI Prism 7700 real time PCR machine (Applied Biosystems, Foster City, CA, United States). The synthesized cDNA served as a template in a $25 \mu\text{L}$ reaction. A non-template control was included in all experiments. Primer sequences were as follows: P-GP GenBank, sense: 5'-TAATGCGACAGG AGATAGGCT-3',

Figure 1 Solid tumors from tumor-bearing mice. ADM: Adriamycin; RFP: Rifampicin; NS: Normal saline; APS: Astragalus polysaccharides; VER: Verapamil.

Table 1 Tumor inhibition rate and immune organ index ($n = 10$)

Group	Tumor weight (g)	Inhibition rate (%)	Spleen index	Thymus index
ADM + RFP	5.37 ± 1.31^a	60.00	0.51 ± 0.28^a	0.15 ± 0.04
ADM	5.32 ± 2.03^a	60.36	0.39 ± 0.17^a	0.13 ± 0.04
NS	13.42 ± 1.03	-	0.74 ± 0.21	0.15 ± 0.09

and antisense: 5'-CCGCCATTTGA CTGAAAGAA-CAT-3'; GAPDH GenBank: sense: 5'-GAGTCAACGGA TTTGGTTCG-3', and antisense: 5'-CGGAAGATG-GTGATGGGATT-3'. QRT-PCR was performed at 94 °C for 4 min, followed by 40 cycles at 94 °C for 15 s, at 60 °C for 25 s, and at 72 °C for 25 s. Data were analyzed with Sequence Detector software (v1.9, Applied Biosystems, Foster City, CA, United States). The mean Ct value for duplicate measurements was used to detect the expression of target genes, which were normalized to a housekeeping gene, which was used as an internal control [glyceraldehyde-3-phosphate dehydrogenase (GAPDH)] according to the $2^{-\Delta\Delta Ct}$ formula.

Statistical analysis

For statistical analysis of cytotoxicity, results from P-GP and *MDR1* mRNA expression assays were analyzed using SPSS 14.0 software (v14, SPSS Inc. Chicago, IL, United States). Differences among the experimental groups were analyzed by one-way analysis of variance. The real-time PCR data were analyzed using the SDS software on the ABI PRISM®7700 sequence detection system at a confidence limit of 95%. A $P < 0.05$ was considered statistically significant.

RESULTS

General health status of mice

There was no abnormality detected in the daily behavior,

autonomic activities, ingestion, hydroposia, pelage, feces, or urine of any of the mice in each experimental group after drug administration. In addition, there was no abnormal secretion from the eyes, ears, noses, or mouths of the mice.

Tumor inhibition rates and the immune organ index

After mice were killed, the solid tumors were removed from tumor-bearing mice and are shown in Figure 1. The tumor inhibition rate and immune organ index are shown in Table 1. The mean weight of tumors in the treatment groups was significantly lower than in the NS group ($P < 0.05$). The mean weight of tumors in ADM + APS (50 mg/kg), ADM + APS (100 mg/kg), and ADM + APS (200 mg/kg) groups were significantly lower than in the ADM group ($P < 0.05$). The tumor inhibition rates in these groups were significantly higher than in the ADM group ($P < 0.05$). The spleen indexes in the ADM + RFP, ADM, and ADM + VER groups were significantly lower than that of the NS group ($P < 0.05$) and the thymus index of the ADM + APS (200 mg/kg) group was significantly higher than that of the NS group ($P < 0.05$). The spleen indexes of the ADM + APS (50 mg/kg), ADM + APS (100mg/kg), and ADM + APS (200mg/kg) groups were significantly higher than that of the ADM group ($P < 0.05$), and the thymus indexes of the ADM + APS (100 mg/kg), ADM + APS (200 mg/kg) group were significantly higher than the ADM group ($P < 0.05$). Collectively, these results showed that APS can act syner-

gistically with AMD on tumor inhibition and can alleviate the decreased size of the spleen and thymus induced by AMD.

Expression levels of IL- α , IL-2, IL-6, TNF- α and IL-10

The expression levels of serum cytokines are shown in Table 2. The expression levels of IL-1 α , IL-2, IL-6, and TNF- α were significantly higher in the ADM + APS (50 mg/kg), ADM + APS (100 mg/kg), and ADM + APS (200 mg/kg) groups than in the NS group ($P < 0.05$), particularly in the medium- and high-dose groups. Cytokine levels were lower in the ADM group than in the NS group. The expression levels of IL-1 α , IL-2, IL-6, and TNF- α were also significantly higher ($P < 0.05$) in the ADM + APS (50 mg/kg), ADM + APS (100 mg/kg) and ADM + APS (200 mg/kg) groups than in the ADM group. The expression level of IL-10 was significantly lower ($P < 0.05$) in the ADM + APS (50 mg/kg), ADM + APS (100 mg/kg), and ADM + APS (200 mg/kg) groups than in either the NS or ADM groups. In summary, APS increased expression levels of IL-1 α , IL-2, IL-6, and TNF- α and decreased IL-10 levels.

Expression of P-GP in tumor tissue

The expression of P-GP in tumor tissue is shown in Figure 2. As assessed by computer-assisted gel analysis (Figure 3A), the ADM + RFP group exhibited a significantly higher P-GP expression than other groups. Different concentrations of APS and verapamil were found to down-regulate P-GP expression. APS down-regulated less P-GP expression than verapamil did. Also, APS (50-200 mg/kg) was found to down-regulate P-GP expression in a dose-dependent manner. The expression level of P-GP was significantly lower ($P < 0.05$) in the ADM + APS (200 mg/kg) and verapamil groups than in the ADM or ADM + RFP groups.

QRT-PCR detection of multidrug resistance 1 mRNA in tumor tissue

The expression of *MDR1* mRNA in tumor tissue is shown in Table 3 and Figure 3B. The ADM and ADM + RFP group showed significantly higher *MDR1* mRNA expression than the other groups ($P < 0.05$). Compared to the ADM group, the RFP group showed increased *MDR1* mRNA expression, and the VER group and APS groups showed decreased *MDR1* mRNA expression (P

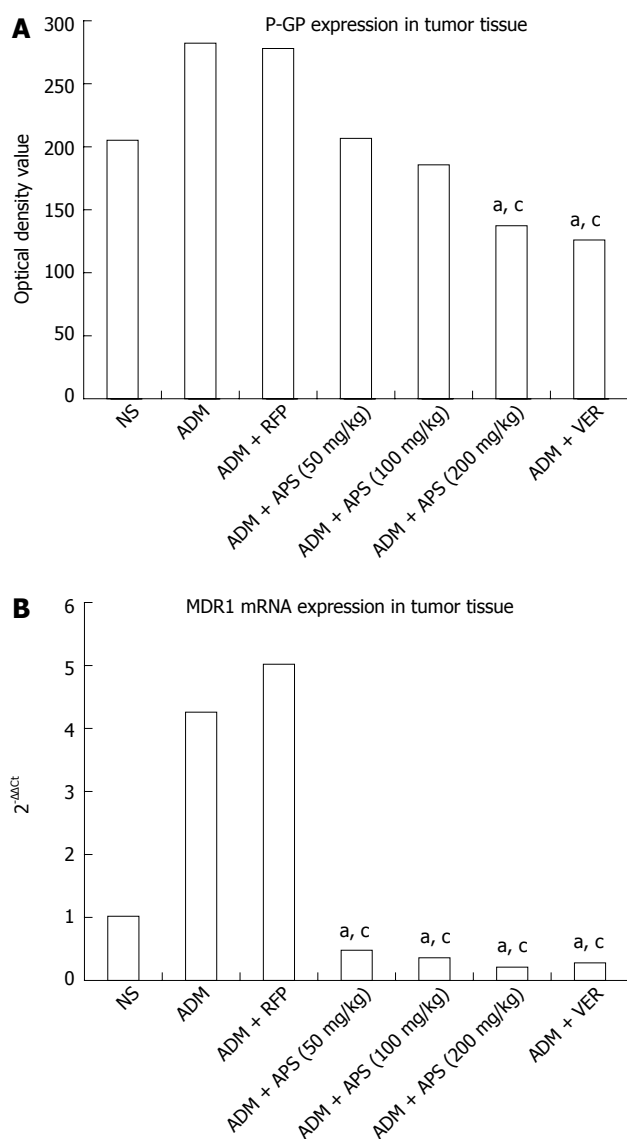

Figure 3 P-glycoprotein optical density values and *MDR1* mRNA expression in tumor tissues after different chemotherapeutic treatment. A: P-glycoprotein (P-GP) optical density values; B: *MDR1* mRNA expression. ^a $P < 0.05$ vs adriamycin (ADM) group; ^c $P < 0.05$ vs ADM + rifampicin (RFP) group. NS: Normal saline; APS: Astragalus polysaccharides; VER: Verapamil.

< 0.05). *MDR1* mRNA expression decreased with increasing concentrations of APS (50–200 mg/kg). *MDR1* mRNA expression was reduced in a dose-dependent manner.

DISCUSSION

Guo *et al.*^[24] reported that treatment with APS along with vinorelbine and cisplatin significantly improves quality of life in patients with advanced non-small-cell lung cancer over vinorelbine and cisplatin alone. Cui *et al.*^[22] reported that hepatocarcinogenesis could be prevented in rats fed with the aqueous extract of Astragalus, which is mainly composed of Astragalus polysaccharides. There are also reports that APS act as an adjunct anticancer agent^[13,18,23,25].

These results led the researchers to speculate that

Table 3 Multidrug resistance 1 mRNA expression in tumor tissue (2^{-ΔΔCt}) ($n = 10$)

Group	2 ^{-ΔΔCt} (mean ± SD)
ADM + RFP	5.02 ± 1.82
ADM	4.26 ± 1.51
NS	1.02 ± 0.05 ^{a,c}
ADM + APS (50 mg/kg)	0.48 ± 0.13 ^{a,c}
ADM + APS (100 mg/kg)	0.36 ± 0.03 ^{a,c}
ADM + APS (200 mg/kg)	0.21 ± 0.04 ^{a,c}
ADM + VER	0.28 ± 0.09 ^{a,c}

^a $P < 0.05$ vs adriamycin (ADM) group; ^c $P < 0.05$ vs ADM + rifampicin (RFP) group. NS: Normal saline; APS: Astragalus polysaccharides; VER: Verapamil.

the adjunct anticancer role of APS might be related to immune function enhancement. However, the mechanism underlying these effects remains to be determined. In particular, it is not completely clear whether APS is involved in the regulation of cytokines and reversal of MDR.

Our conclusions regarding the sensitivity to chemotherapy drugs were partially supported by the results of these studies. Compared with the ADM group, the mean weight of tumors was significantly decreased ($P < 0.05$) and the inhibition rates of tumors were significantly increased ($P < 0.05$) within the APS treatment range of 50 to 200 mg/kg. The spleen and thymus index were also significantly increased. Collectively, these results show that APS exerts a synergistic anti-tumor effect with ADM, and alleviates the decreased sizes of the spleen and thymus induced by ADM (Table 1). The cytokines IL-1 α , IL-2 and IL-6 are capable of inducing the proliferation of responsive T-cells. TNF- α has been proven to be an effective anticancer agent in *in vitro* and *in vivo* preclinical studies, by inducing apoptotic cell death and tumor necrosis. IL-10 inhibits the synthesis of IL-2 and TNF- α produced by activated macrophages and by helper T cells^[33]. In the present study, APS was found to induce increase in IL-1 α , IL-2, IL-6, and TNF- α expression and decrease in IL-10 expression (Table 2). APS effect on cytokine levels may be one of its adjunct anticancer mechanisms.

However, tumor immunology is a complex biological phenomenon, with the secretion, function and regulation of cytokines occurring through multiple mechanisms, and is mediated by a wide variety of cell populations. How APS induces expression of these cytokines merits further study.

It has been shown that drug resistance in tumor cells are related to *MDR1* upregulation and P-GP over expression^[34–36]. As a P-GP substrate, ADM can induce P-GP expression and consequently reduce its efficacy. In the present study, APS was found to enhance the chemosensitivity to ADM of H22 tumor-bearing mice. To determine whether APS is involved in P-GP expression, the P-GP inducer rifampin and P-GP inhibitor verapamil were used as positive controls. Western blotting analysis of P-GP expression and real-time PCR detection

of *MDR1* mRNA expression in tumor tissue revealed that APS (50 to 200 mg/kg) reduced P-GP protein and *MDR1* mRNA expression in a dose-dependent manner (Figures 2, 3 and Table 3). The expression levels of P-GP and *MDR1* were significantly decreased ($P < 0.05$) in the ADM + APS (200 mg/kg) treatment compared with the ADM or ADM + RFP treatment groups ($P < 0.05$). In the present study, APS was found to down-regulate *MDR1* mRNA and P-GP expression levels, thereby increasing the intracellular concentration of chemotherapeutic drugs. This may be the mechanism behind its secondary anti-cancer effects.

It has been reported that APS exhibits several therapeutic advantages in terms of increasing sensitivity to chemo-therapeutics, reducing the side effects and complications associated with chemotherapy^[12,15,20,21], and improving patient quality of life and survival time^[24]. In addition, our present study reveals that APS can regulate cytokine and P-GP expression levels. Thus, APS is a promising candidate for therapeutics that exhibit a low toxicity and few side effects.

In summary, APS was found to exert a synergistic anti-tumor effect with Adriamycin in H22 tumor-bearing mice *in vivo*. This may be related to its ability to enhance the expression of IL-1 α , IL-2, IL-6, and TNF- α , decrease IL-10, and down-regulate *MDR1* mRNA and P-GP expression levels.

COMMENTS

Background

Cancer has been a major public health problem globally. Traditional Chinese medicine has great advantages in terms of increasing sensitivity to chemotherapeutics, reducing side effects and complications associated with chemotherapy, and improving patient quality of life and survival. Astragalus membranaceus is widely accepted as a complementary and alternative medicine in cancer treatment. Astragalus polysaccharides (APS) are active constituents of Astragalus membranaceus.

Research frontiers

APS has been most widely studied mainly for its immunopotentiating properties, ability to counteract the side effects of chemotherapeutic drugs, and adjunct anticancer agent properties. However, the mechanism underlying the adjunct anticancer property of APS, specifically whether or not it involves the regulation of cytokines and reversal of multidrug resistance (MDR), is not completely clear. The present study focused on investigating the effect of APS on the expression of cytokines and P-glycoprotein (P-GP) in H22 tumor-bearing mice *in vivo*.

Innovations and breakthroughs

To date, there have been a limited number of studies regarding the adjunct anticancer property of APS. In the present study, APS was found to exert a synergistic anti-tumor effect with Adriamycin in H22 tumor-bearing mice. This may be related to its ability to enhance the expression of interleukin-1 α (IL-1 α), IL-2, IL-6, and tumor necrosis factor- α , decrease IL-10, and down-regulate *MDR1* mRNA and P-GP expression. This is the first study to report that the adjunct anticancer property of APS is partly through regulation of cytokines and P-GP expression in H22 tumor-bearing mice.

Applications

Traditional Chinese medicine has great advantages in terms of increasing sensitivity to chemo-therapeutics, reducing side effects and complications associated with chemotherapy, and improving patient quality of life and survival. APS could regulate cytokines and P-GP expression, and in the search for new cancer therapeutics with a lower toxicity and few side effects, APS is a promising candidate.

Terminology

APS, extracted and purified from Chinese medicinal herb Astragalus membranaceus roots, consist of several classes of neutral and acidic polysaccharides and glycoproteins. APS has also been observed to possess anti-tumor and anti-virus activities. Cytokine is a small protein released by cells and can exert a specific effect on the interactions between cells, on communications between cells or on the behavior of cells. P-GP is a plasma membrane protein which acts as a localized drug transport, actively exporting drugs out of the cell. Adjunct anticancer agents are a variety of medications that complement the chemotherapy regimen, help alleviate side effects of the treatment or symptoms of the cancer, or help potentiate the effect and activity of chemotherapy drugs.

Peer review

The manuscript reports on a possible adjunct anticancer effect of APS in tumor-bearing mice, using an *in vivo* animal model. Data on tumor inhibition were provided, and its possible effects on cytokines, *MDR1* mRNA and P-GP expression were elucidated. APS may be a promising candidate for cancer therapeutics that exhibits a low toxicity and few side effects.

cells stably expressing the luciferase gene were injected into the subcutaneous region of nude mice. One week later, the ectopic tumors were harvested and transplanted into the left liver lobe of nude mice. The AGS was used to establish the nude mouse orthotopic implantation tumor model. The tumor suppressor gene, paired box gene 5 (*PAX5*), which is a tumor suppressor in HCC, was transfected into HCC cells to validate the model. Tumor growth was measured by bioluminescence imaging technology. Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) and histopathology were used to confirm the tumorigenicity of the implanted tumor from the MHCC-97L cell line.

RESULTS: We successfully developed an orthotopic transplantation tumor model in nude mice with the use of an AGS. The success rate of tumor transplantation was improved from 60% in the control group to 100% in the experimental group using AGS. The detection of fluorescent signals showed that tumors grew in all live nude mice. The mice were divided into 3 groups: AGS-, AGS+/*PAX5*- and AGS+/*PAX5*+. Tumor size was significantly smaller in *PAX5* transfected nude mice compared to control mice ($P < 0.0001$). These fluorescent signal results were consistent with observations made during surgery. Pathologic examination further confirmed that the tissues from the ectopic tumor were HCC. Results from RT-PCR proved that the HCC originated from MHCC-97L cells.

CONCLUSION: Using an AGS is a convenient and efficient way of establishing an indirect orthotopic liver transplantation tumor model with a high success rate.

Abstract

AIM: To improve the outcome of orthotopic transplantation in a mouse model, we used an absorbable gelatin sponge (AGS) in nude mice to establish an orthotopic implantation tumor model.

METHODS: MHCC-97L hepatocellular carcinoma (HCC)

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common types of malignant tumors^[1-3]. Thus, establishing appropriate animal models is critical to promote our understanding of the molecular, cellular and pathophysiological mechanisms of HCC, and is essential for the development of new therapeutic strategies. Most HCC patients are diagnosed at an advanced stage when available treatments are ineffective. The ideal HCC animal model should display similarities to the human disease and accurately recapitulate the disease with a high success rate^[4]. Currently, the most commonly employed models of HCC are xenograft models, including subcutaneous and orthotopic transplantation in nude mice^[5-9]. Orthotopic transplantation of liver tumors allows the development of tumor metastases and provides relevant sites for host-tumor interaction and a microenvironment. Although this method is well accepted, its use is still quite limited. This is because construction of the model is complex, and a high level of technical skill is required. This model would be more popular if the surgical procedure could be simplified.

The goal of this study was to investigate the value of using an absorbable gelatin sponge (AGS) in HCC orthotopic transplantation, compared with the routine procedure. Previous research has shown that paired box gene 5 (*PAX5*) acts as a tumor suppressor in the development of HCC^[10]. Therefore, in this experiment, we also over-expressed *PAX5* in the xenograft tumor to validate the efficiency of the liver orthotopic transplantation tumor model in real time.

MATERIALS AND METHODS

Cell line

The human hepatocellular carcinoma cell line MHCC97L (a kind gift from the Liver Cancer Institute, Fudan University) was used in this study. Cells were maintained in Dulbecco's modified Eagle's medium (DMEM, Gibco BRL, Rockville, MD, United States) with 10% fetal bovine serum (Life Technologies, Carlsbad, CA, United States), 100 mg/mL penicillin G, and 50 µg/mL streptomycin (Life Technologies) at 37 °C in a humidified atmosphere containing 5% CO₂. MHCC97L cells stably

expressing the luciferase gene were constructed.

PAX5 expression plasmid construction and transfection

Complementary DNA corresponding to full-length *PAX5* was obtained by reverse transcription-polymerase chain reaction (RT-PCR) amplification of normal human stomach cDNA with primers specific to *PAX5*. The PCR aliquots were subcloned into the mammalian expression vector pcDNA3.1-TOPO TA (Life Technologies)^[11]. Either pcDNA3.1 or pcDNA3.1-*PAX5* was transfected into MHC-C97L cells using Lipofectamine 2000 (Life Technologies). Positive clones were selected in DMEM supplemented with G418 at a concentration of 500 µg/mL.

Animal model

MHCC97L cells (1×10^7 cells in 0.1 mL PBS) transfected with *PAX5* or pcDNA3.1 were subcutaneously injected into the dorsal left flank of 4-wk-old male Balb/c nude mice (1/group); the body weight of all mice was between 12 and 15 g. Six-week-old athymic male Balb/c nude mice weighing 16-18 g were used for xenograft tumor transplantation. The nude mice were obtained from the Chinese University of Hong Kong Laboratory Animal Service Center and maintained under specific pathogen free (SPF) conditions. All experimental procedures were approved by the Animal Ethics Committee of the Chinese University of Hong Kong.

Establishment of an orthotopic transplantation tumor model of HCC in nude mice

An orthotopic HCC mouse model was established to determine intrahepatic tumorigenicity. Subcutaneous tumors were harvested when they reached 1 cm in diameter and were cut into pieces under aseptic conditions. After washing with PBS, the tumors were rinsed in DMEM. Only intact pieces were chosen for further study. After removing thanatosis tissues, the tumors were cut into cubes 1 mm³ in size. One piece was then implanted into the left liver lobe of each mouse. The mice were divided into 3 groups. The ten mice in group I were operated without an AGS. The wounds were sutured using VICRYL Plus Suture 5-0 (Ethicon Inc, Somerville, NJ, United States) Absorbable gelatin sponges were used in groups II and III. The mice in groups II ($n = 6$) and III ($n = 6$) underwent tumor transplantation with or without *PAX5* expression. Intraperitoneal anesthesia was administered using 20 g/L pentobarbital sodium at 0.04 mL per gram body weight. Once anesthetized, the mice were fixed on an experiment board in the supine position. After sterilizing with 70% alcohol, a 2 mm transverse incision was made below the xiphoid, which was perpendicular to the median line and was 1-1.5 cm long. The left liver lobes were carefully pulled out of the abdominal cavity with a sterile cotton swab. A 0.2 cm incision was made in Glisson's capsule to serve as the transplantation site. The tumor tissue mentioned above was transplanted into recipient mouse livers using extra-fine forceps.

In group I, a routine procedure was carried out to

suture the incision in the liver and stop bleeding, and homeostasis was achieved by compression. In group II and group III, in addition to compression, the transplantation site was further covered by a 5 mm × 5 mm × 1.5 mm AGS (Nanjing Jinglin Biopharming Co. Ltd., Nanjing, Jiangsu, China). The liver was placed back into the enterocoelia using a sterile cotton swab, and shifting of the AGS was not allowed. If neither bleeding nor tumor tissue leakage occurred, then the skin was sterilized with 70% alcohol and the wound sutured with a Plus 5-0 suture line. The average operation time was 10 min. Following surgery, the mice were kept warm using a heat lamp and allowed to recover. The recovery period was reduced from 30 ± 5 min to 20 ± 5 min at room temperature. Following recovery, the mice were put back into their cages and raised under SPF conditions. All mice had free access to sterilized food and autoclaved water. We inspected the living conditions of the mice daily.

Mouse tumor bioluminescence imaging

For bioluminescence imaging, the animals were injected with the luciferase substrate D-luciferin at a dose of 150 mg/kg in 0.2 mL sterile isotonic saline.

Liver tumor growth rates were monitored using the Xenogen International Veterinary Information Service (IVIS) imaging system every week for 3 wk. All images were obtained after intraperitoneal injection of luciferin (100 mg/kg body weight; Synchem, Elk Grove Village, IL, United States). Ten minutes after injection of luciferin, nude mice were placed onto the Xenogen IVIS 200 imaging stage and were continuously sedated during image acquisition. Image analysis and bioluminescence quantification were performed using Living Image software (Caliper Life Sciences, Hopkinton, MA, United States). Once imaging was complete, each animal was removed from the Xenogen IVIS 200 imaging stage, placed on a heated platform in its original cage and allowed to recover. After the animals had fully recovered from the anesthesia, they were returned to the specific investigator.

After 3 wk, the mice were sacrificed. Following tumor excision from the euthanized mice, tumor weights were measured the same day. A portion of the tumor tissue was fixed in 10% formalin for subsequent histological examination, and the remaining tissue was snap-frozen in liquid nitrogen and stored at -70 °C for molecular studies.

Semi-quantitative RT-PCR

Total RNA was extracted from tissues using QIAzol reagent (Qiagen, Valencia, CA, United States). cDNA was synthesized from 2 µg total RNA using Transcriptase Reverse Transcriptase (Roche Applied Sciences, Indianapolis, IN, United States). Semi-quantitative RT-PCR analyses were performed using *PAX5* forward primer 5'-GTC-CATTCCATCAAGTCCTG-3' and *PAX5* reverse primer 5'-TTGCTGACACAACCATGGCT-3'. β -actin was used as an internal control for mRNA expression (5'-GTCTTCCCCTCCATCGTG-3' and 5'-AGGGT-GAGGATGCCTCTCTT-3').

Histologic evaluation

Formalin-fixed tumor was embedded in paraffin, and 4 µm sections were cut and stained with hematoxylin and eosin (HE) as previously described^[12].

Statistical analysis

Data were presented as mean ± SD. A repeated measures analysis of variance was used to compare the differences between groups. All analyses were performed using SPSS software (version 13.0, Chicago, IL, United States). Statistical significance was accepted at the level of $P < 0.05$.

RESULTS

One day after surgery, only six of ten mice in group I (without AGS) were alive after transplantation. The survival rate using the routine suture method was only 60%. In contrast, all mice in groups II and III were alive and recovered well. From the 7th day after surgery, the nude mice were scanned in the Xenogen IVIS 100 imaging system for a total of 3 wk. Fluorescence signals showed that transplanted tumors grew in all nude mice (Figure 1).

The fluorescence signal intensity was related to tumor size. The signal intensity steadily increased from the second week to the fourth week. Tumor size was significantly smaller in the *PAX5*-transfected nude mice from group III compared to the vector control mice from group II ($P < 0.0001$) (Figure 2). This indicated that *PAX5* gene expression inhibited tumor growth in nude mice (Figure 3). The area around the tumor and the surrounding tissues was euangiotic, and adjacent organs were strongly adhered.

HE staining further confirmed tumorigenesis of the liver tissue (Figure 4). Tumor tissue characteristics included atypia, big core, dark color, different cell size, irregular form, and nuclear division. Many of these characteristics were similar to those of the original cancer cells.

RT-PCR results showed that no *PAX5* expression was observed in the tissue from group II, and all the tissues from group III had a high *PAX5* mRNA level. This demonstrated that the HCC cells originated from MHCC-97L cells transfected with or without the *PAX5* expression plasmid (Figure 5), and the orthotopic liver tumor model was successfully established. We did not detect any intra-hepatic or abdominal metastases.

DISCUSSION

Currently, the most common way of producing liver orthotopic tumor models is either by implantation of an established subcutaneous tumor harvested from another nude mouse, or by injecting tumor cells directly into the liver^[6,7]. Both strategies require surgery following liver exposure. The tumor cell injection animal model is more relevant to clinical practice; thus, it can be a useful research model for lymph node metastasis^[13]. However, the technical difficulty associated with this model is that it is

Figure 1 Representative images of fluorescence signals in nude mice detected by the International Veterinary Information Service system. The fluorescence signal intensity shows xenograft tumor size.

hard to control tumor cell leakage during injection. Analyses are complicated by the fact that apparent metastasis may just be due to leakiness.

In the second method, the goal is to establish a subcutaneous model of human HCC in nude mice, and then to inoculate the liver in order to establish the orthotopic transplantation model. The principle is to make the HCC cells adapt to the environment and grow into tumor tissues, then implant the tumor into the host's liver. Thus, the survival rate of the transplanted tumor is supposed to increase.

Compared with subcutaneous and intraperitoneal xenografts in nude mice, the properties of invasion and metastasis in the orthotopic liver tumor model are better^[14-16]. Use of this model is limited due to the need for a highly complex surgical technique, especially in bleeding control. Routine surgery using incision suture takes

Figure 2 Harvesting orthotopic liver transplantation tumors. Tumors were harvested from the mice in groups II and III. Tumor size and weight in the paired box gene 5 (PAX5) group were smaller than those in the control group ($P < 0.0001$).

Figure 3 Tumor growth curve determined by the International Veterinary Information Service system. The P value was calculated using repeated measures analysis of variance. PAX5: Paired box gene 5.

a long time. This is one of the reasons why the mice in group I had a high mortality rate. If post-operative hemorrhage occurred, the mice would probably die, leading to failure of the long-term experiment. Thus the efforts to obtain the cell culture, establish a subcutaneous tumor and orthotopic tumor implantation would be in vain. An alternative method of achieving homeostasis is by suturing Glisson's capsule at the transplantation site. However, the mouse liver has an abundant blood supply, and the tissue is fragile and easily crushed. The method is further complicated by the possibility of bleeding at the suture site. Therefore, not many laboratory staff are capable of performing this procedure. To circumvent these difficulties, we used the AGS. The AGS is commonly used in surgery to stop minor bleeding at the surgical site. It is an aseptic solid material that has good deformability. In our experiment, covering the transplantation site with an AGS was an easy and effective way of maintaining homeostasis. The sponge was slowly absorbed and the cost was minimal. In addition, the sponge prevented the implanted tumor from moving out of the host's liver, increasing the success rate of the experiment. This procedure was safe, and none of the nude mice experienced post-operative complications or mortality, compared with the high post-operative mortality of 40% in group I. Importantly, adverse reactions to the sponge were not observed in normal tissues, as evaluated by HE staining. The gelatin was gradually absorbed and was absent when the mice were sacrificed.

Figure 4 Liver tissues from nude mice were detected by hematoxylin and eosin staining. A: Liver tumor, $\times 200$; B: Normal liver, $\times 200$.

Figure 5 Gene expression of paired box gene 5 in liver tumor tissues of mice *in situ* which was detected by reverse transcription-polymerase chain reaction. The expression of β -actin which acted as the internal control was determined. PAX5: Paired box gene 5.

The horizontal incision made during the operation should neither be too low nor too small. The optimal incision should be as small as possible to fully expose the left liver lobe. If it is too small, the liver could be crushed when pulled out, or there may not be enough space to place the AGS into the abdominal cavity. The size of the sponge should be appropriate-5 mm \times 5 mm \times 1.5 mm, enough to efficiently stop bleeding and be easily absorbed.

It should be noted that although we observed a high post-operative mortality in group I, all mice achieved homeostasis before closure of the abdominal cavity. One of the reasons for this high mortality may have been due to the fast post-operative recovery and frequent activities caused by pain. Administration of post-operative analgesics may reduce pain, thus might lead to a higher survival rate^[17-19]. However, analgesics were not administered in this study. We would also like to point out that in models established by the direct injection of cultured human HCC cells, an AGS may not prevent leakage. In such models, HCC cells are suspended in medium rather than forming a solid tumor. The sponge is hygroscopic, thus, if leakage occurs, the sponge would only aggravate the leak.

Post-operative evaluation of orthotopic tumors is also a challenge. Monitoring subcutaneous liver transplantation tumors may be performed either by touch or by visual inspection. Orthotopic tumors can be monitored by laparotomy, computed tomography (CT)/magnetic resonance imaging (MRI)/positron emission tomography (PET)-CT scanning, or using a high frequency ultrasound mini-probe. However, there are drawbacks associated

with each method. Frequent laparotomy may cause severe injury and death in mice. CT/MRI/PET-CT scanning is non-invasive, but the cost is high and is difficult to perform^[20-23]. Ultrasonic examination is less expensive, but analysis of the data requires a skilled operator^[24-26]. Finally, only some of the above-mentioned methods are quantitative.

Using the IVIS imaging system, bioluminescence was non-invasively measured in transplanted subcutaneous tumors using the IVIS imaging system (Xenogen Corp, Alameda, CA, United States) following injection of the luciferase substrate luciferin. Tumor growth was continuously monitored. According to the bioluminescence data, tumor growth conditions were analyzed in real time. The results showed successful tumor transplantation. Histopathology and PCR analyses showed that the transplanted tumor had the same phenotype as the liver tumor cell line MHCC-97L. Thus, the orthotopic transplantation tumor model was successfully established from the subcutaneous model of human HCC.

Based on our procedure, this operation has been simplified and can be completed in a very short period of time. The success rate is high, and reproducibility is good. Importantly, the model maintained the characteristics of the original cell line. Inspections were quantified in real time, and the model can be adapted for general use.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors and is the third leading cause of cancer-related death. The establishment of appropriate animal models of this disease could help people to understand the mechanisms driving HCC, leading to potential therapeutics and improvements in patient survival. An absorbable gelatin sponge was used as an efficient way of establishing an indirect orthotopic liver transplantation tumor model with a high success rate.

Research frontiers

It is reported that the conventional surgical method involves the liver capsule being sutured using microsurgery. Compared with the microsurgical method, the authors used an absorbable gelatin sponge which prevented bleeding and tissues being crushed during the experiment.

Innovations and breakthroughs

This is the first report on the use of an absorbable gelatin sponge to cover the transplantation site in the liver capsule. This experiment showed that the

absorbable gelatin sponge can be used to constrict the liver and stop bleeding, and to efficiently cover tumor tissue, thus, avoiding the tumor tissue moving out of the placement site.

Applications

Using the absorbable gelatin sponge to establish the HCC model is a convenient method for researchers to study HCC. The establishment of an animal model could provide a new way to perform more successful, convenient and efficient experiments.

Terminology

An absorbable gelatin sponge is a sterile, absorbable, water-insoluble, gelatin-base material which absorbs blood and provides an area for clot formation, and is used for hemostasis during surgery.

Peer review

Authors found a new technique to do HCC animal model experiment. It is easy to perform and has a high success rate. The study has been well conducted and provided further validation.

Abstract

AIM: To investigate the associations between interleukin (IL)-1B and IL-1RN polymorphisms and gastric cancers among the Tibet, Hui and Han ethnicities.

METHODS: Genomic DNA was extracted from peripheral blood of 210, 205, and 202 healthy volunteers and from 155, 158, and 197 gastric cancer patients from the Tibet, Hui, and Han populations, respectively. Polymorphisms in *IL-1B* and *IL-1RN* were analyzed by denaturing high-performance liquid chromatography.

RESULTS: Carriers of the *IL-1B*-31 CC genotype had an increased risk of intestinal type gastric cancer [odds ratio (OR) = 2.17, $P = 0.037$] in the Tibet ethnicity.

Carriers of the *IL-1B* 2/L genotype had an increased risk of both intestinal and diffuse types of gastric cancer (OR = 2.08, 2.31, $P = 0.007$, 0.016, respectively) in the Hui ethnicity. In the Han population, carriers of the *IL-1B*-31 CC, *IL-1B*-511CT, TT genotypes had increased risk of intestinal type gastric cancer (OR = 2.51, 2.74, 5.66, $P = 0.005$, 0.002, 0.000, respectively).

CONCLUSION: *IL-1B* and *IL-1RN* genotypes may differentially contribute to gastric cancer among the Tibet, Hui, and Han ethnicities in the Qinghai area of China.

INTRODUCTION

Gastric cancer (GC) is the second leading cause of cancer-related death worldwide, and approximately 42% of these deaths occur in China^[1,2]. Mortality of GC patients in China is the highest in the world, especially in the northwestern part of the country, which includes Qing-

hai province^[3]. There are 56 different ethnicities living in China. The Han ethnicity represents the major ethnicity within Qinghai province, while the Tibet and Hui are minority nationalities. The incidence of GC in the Tibet and Hui populations is higher than that in the Han ethnicity. However, the study of minority ethnicities is not advanced due to fewer individuals and poorer economic conditions^[4].

Interleukin (IL)-1B and IL-1RN belong to the *IL-1* gene cluster. The *IL-1* gene encodes both the glycoprotein IL-1 β , which is a pro-inflammatory cytokine, and the *IL-1* receptor antagonist (IL-1Ra), which is an anti-inflammatory cytokine. *IL-1B* is a potent inhibitor of gastric acid secretion and plays a major role in both initiating and amplifying the inflammatory response to *Helicobacter pylori* (*H. pylori*) infection^[5-7]. *IL-1RN* encodes the *IL-1Ra*, an anti-inflammatory cytokine that competitively binds to IL-1 receptors and modulates the potentially damaging effects of IL-1^[7,8]. Two biallelic polymorphisms in the *IL-1B* gene have been described, both C-T base transitions found at positions-511 (C>T) and -31 (T>C) bp from the translation initiation codon. IL-1RN has a variable number of identical tandem repeats polymorphism of 86 bp in intron 2. To date, over 50 studies have reported on the association between *IL-1B* and *IL-1RN* polymorphisms and GC risk^[5]. While some studies have reported that *IL-1B* and *IL-1RN* polymorphisms are associated with increased GC risk in both Caucasians and Asians^[5,6,9,10], other studies have shown inverse associations, especially in Asians^[11,12]. Two studies chose a single ethnicity population in two different regions with different prevalence rates of GC as their subjects^[10,13]. However, no study has examined several different ethnicities in a single geographical area at the same time. Thus, our study is the first to report such an examination.

Here, we investigated the associations between *IL-1B*-31, *IL-1B*-511 and *IL-1RN* polymorphisms and GC risk among the Tibet, Hui and Han ethnicities in the Qinghai area of China.

MATERIALS AND METHODS

Study subjects

Three ethnicities (Tibet, Hui and Han) from the Qinghai province of China were included in this study. Healthy controls included 210 Tibet, 205 Hui and 202 Han individuals who were enrolled from the Hainan Tibet Ethnicity Autonomous Prefecture, Minhe Hui Ethnicity Autonomous County, and Xining city in Qinghai province, respectively. Between December 2008 and October 2011, 155, 158 and 197 Tibet, Hui and Han individuals, respectively, with GC were enrolled from the Affiliated Hospital of Qinghai University. All recruited healthy controls were from families that had lived for a long time in that locality, did not marry other ethnicities for at least three generations, and were not related to each other. Both the age and sex of the healthy controls were matched to the patients and are shown in Table 1. None of these

subjects had a history of systemic lupus erythematosus, diabetes mellitus, rheumatoid arthritis, or inflammatory bowel disease. Subjects with a family history of any cancer were excluded. All patients were histologically confirmed as having noncardiac GC. Patients and controls were interviewed with regard to smoking status. Individuals who smoked once a day for over 1 year were defined as smokers. The presence of *H. pylori* infection in the sera of patients and controls was measured using an enzyme-linked immunosorbent assay (Anti-*H. pylori* enzyme immunoassay, Huamei Biotech Inc., China). This study was approved by the Clinical Research Ethics Committee of the Qinghai University of Medical Sciences, and all patients provided signed informed consent.

Analysis of the *IL-1B*-31, *IL-1B*-511 and *IL-1RN* polymorphisms

Genomic DNA was isolated from 5 mL of venous blood by the conventional proteinase K digestion and phenol/chloroform extraction method. Polymorphisms were analyzed by polymerase chain reaction (PCR)-based denaturing high-performance liquid chromatography (DHPLC). The corresponding primers have been described by Lu *et al.*^[14] and are shown together with the PCR conditions, PCR annealing temperatures and DHPLC detection methods in Table 2. PCR was performed with a 25 mL reaction mixture containing 100 ng of genomic DNA, 1.0 mmol/L of primer, 0.2 mmol/L of dNTP, 2.0 mmol/L of MgCl₂, and 1.0 U Taq DNA polymerase in 1 \times reaction buffer (Promega, Madison, WI, United States). DHPLC analysis was performed on a Transgenomic WAVE System. The detailed genotyping process has been previously described^[14]. The PCR products were applied to the DHPLC column at an optimal oven temperature and eluted with a linear acetonitrile gradient at a flow rate of 0.9 mL/min (Figure 1A). The genotypes identified by DHPLC analysis were further confirmed by DNA sequencing using the ABI Prism 377 DNA Sequencer. The sizes of *IL-1RN* PCR products were analyzed by DHPLC based on the relationship between elution time and base pair number of the fragment (Figure 1B).

H. pylori antibody assays

Enzyme-linked immunosorbent assay for detection of *H. pylori* was performed according to the manufacturer's instructions. After termination of the enzyme reaction, the absorbance at 630 nm was measured. Absorbance ratios (sample/negative control) equal to or greater than 2.1 were considered positive, and those below 2.1 were considered negative.

Statistical analysis

The data were analyzed using SPSS software (Version 13.0, SPSS, Chicago, IL, United States). The significance of the difference in the distribution of the polymorphisms among the different groups was calculated using the χ^2 test. All allelic distributions were examined for deviations from their corresponding Hardy-Weinberg

Figure 1 Typical denaturing high-performance liquid chromatography elution profiles for different genotypes. A: Representative denaturing high-performance liquid chromatography (DHPLC) profiles for different allelic polymerase chain reaction products containing the *interleukin-1B* (*IL-1B*)-311 C/T polymorphism site. In the first DHPLC, the CT genotype (lower panel) was discriminated from homozygous (upper panel). To determine the CC or TT genotype, the second DHPLC was run for the homozygous DNA mixed with a DNA sample known as the CC genotype. The profile of the CC genotype was unaltered, while that of the TT genotype changed into the same as the lower panel; B: DHPLC elution profiles of *IL-1RN* and *IL-1RN* variable number of identical tandem repeats were determined by elution time and base pair number of the fragment.

equilibrium. Multivariate logistic regression was used to obtain odds ratios (ORs) and 95%CI, adjusting for age, sex, smoking status and *H. pylori* infection. $P < 0.05$ (two-tailed) was considered statistically significant.

RESULTS

Clinical characteristics

The study population consisted of 210, 205 and 202 healthy controls and 155, 158 and 197 GC patients from the Tibet, Hui and Han ethnicities, respectively. Age, sex,

smoking status, and *H. pylori* infection in the GC patients and control subjects are shown in Table 1. There were no statistically significant differences between the cases and controls with regard to age, sex, and smoking status in each ethnicity group. However, *H. pylori* infection was significantly higher in the cases compared to the controls ($P = 0.023$, 0.001 and 0.027, respectively) in each ethnicity group. The genotype frequencies of *IL-1B*-31, *IL-1B*-511 and *IL-1RN* in the controls in each ethnicity group were in agreement with the Hardy-Weinberg equilibrium ($P > 0.05$ for all).

IL-1B-31, *IL-1B-511* and *IL-1RN* polymorphisms and GC risk

The frequencies of genotypes *IL-1B-31*, *IL-1B-511* and *IL-1RN* among the Tibet, Hui and Han ethnicities are summarized in Table 3. In the Tibet ethnicity group, the *IL-1B-31* CC genotype was significantly more frequent in GC patients (32.90%) compared with controls (24.29%) ($\chi^2 = 4.98$, $P = 0.026$). The risk of developing gastric cancer with this genotype was significantly increased (adjusted OR = 2.10, 95%CI: 1.09-4.04, $P = 0.027$).

In the Hui nationality group, the *IL-1RN* L/2 genotype was significantly more frequent in GC patients (40.50%) compared with controls (23.90%) ($\chi^2 = 11.47$, $P = 0.001$). The risk of developing GC with this genotype was significantly increased (adjusted OR = 2.11, 95%CI: 1.31-3.40).

Unlike the results obtained for individuals belonging to either the Tibet or Hui populations, two genotype sites were associated with GC in the Han ethnicity. For the *IL-1B-31* CT genotype, there was a significant difference between GC patients (51.77%) and controls (48.52%) ($\chi^2 = 4.61$, $P = 0.032$). There was also a significant difference in the CC genotype between GC patients (27.92%) and controls (19.31%) ($\chi^2 = 8.29$, $P = 0.004$). The risk of developing GC in patients with *IL-1B-31*CT or CC genotypes was significantly increased (adjusted OR = 1.69, 2.29; 95%CI: 1.03-2.76, 1.28-4.10; $P = 0.036$, 0.005, respectively). In addition, for the *IL-1B-511* genotypes, there was a statistically significant difference in the CT genotype distribution between GC patients (50.50%) and controls (49.09%) ($\chi^2 = 8.70$, $P = 0.003$). Additionally, there was also a statistically significant difference in TT genotype distribution between GC patients (32.67%) and controls (18.81%) ($\chi^2 = 18.90$, $P = 0.000$). The risk of developing GC in patients with the *IL-1B-511* CT or TT genotypes was significantly increased (adjusted OR = 2.16, 3.53; 95%CI: 1.28-3.65, 1.49-8.33; $P = 0.004$, 0.004, respectively).

IL-1B-31, *IL-1B-511* and *IL-1RN* polymorphisms and intestinal type GC risk

The identification of a genetic risk outline for GC could

help the populations most at risk. Therefore, the prevalence of *IL-1B-31*, *IL-1B-511* and *IL-1RN* polymorphisms in different GC subtypes were analyzed. In this study, there were 109, 106 and 139 cases (70.32%, 67.09% and 70.56%) of intestinal-type GC, and 46, 52 and 58 cases (29.68%, 32.91% and 29.44%) of diffuse or mixed-type GC in the Tibet, Hui and Han ethnicities, respectively. The frequencies of genotypes *IL-1B-31*, -511, and *IL-1RN* among intestinal-type GC and diffuse or mixed-type GC in all three populations are summarized in Table 4.

For individuals belonging to the Tibet ethnicity group, the *IL-1B-31* CC genotype was only associated with intestinal type GC ($P = 0.037$) with an adjusted OR of 2.17 (95%CI: 1.05-4.51).

In the Hui ethnicity group, the *IL-1RN* 2 genotype was associated with both intestinal and diffuse types of GC ($P = 0.007$, 0.016, respectively) with adjusted ORs of 2.08 and 2.31 (95%CI: 1.22-3.56, 1.17-4.56, respectively).

In the Han ethnicity group, the *IL-1B-31* CC genotype was only associated with intestinal type GC ($P = 0.005$) with an adjusted OR of 2.51 (95%CI: 1.32-4.76). However, compared to the TT genotype, the GC risk in *IL-1B-31* CT carriers did not achieve the threshold of statistical significance ($P = 0.067$) with an adjusted OR of 1.68 (95%CI: 0.97-2.90). Moreover, both the *IL-1B-511* CT and TT genotypes were only associated with intestinal type GC ($P = 0.002$, 0.000) with adjusted ORs of 2.74 and 5.66 (95%CI: 1.44-5.22, 2.82-11.33, respectively).

No other significant associations were found when GC patients were sorted according to age, sex, and presence of *H. pylori* infection (data not shown).

DISCUSSION

Like many other malignancies, GC develops as a result of complex interactions between environmental risk factors (e.g., unhealthy lifestyle, smoking, uncontrolled over-drinking, unhealthy diet, and *H. pylori* infection) and genetic alterations^[15]. This gene-environment interaction can alter gene expression and promote cell growth and carcinogenesis. The *IL-1B* and *IL-1RN* polymorphisms

are implicated in cancer risk through their influences on *IL-1B* transcription.

Since El-Omar *et al*^[5] reported that carriers of *IL-1B*-511 T or *IL-1B*-31 C were more susceptible to GC than other genotypes in 2000, other studies have reported on the associations between *IL-1B* and *IL-1RN* polymorphisms and GC risk in various populations but with mixed, or even conflicting results^[6,7,10-14]. To date, at least four meta-analyses on the associations between *IL-1B* and *IL-1RN* polymorphisms and GC have been reported, however, their outcomes were different and even opposite^[16-19]. In fact, the genetic/environmental interactions among different ethnic groups are quite complex. Thus, *IL-1B* and *IL-1RN* polymorphisms may play different roles in different populations or geographical areas.

Two studies have been performed to evaluate the differences in *IL-1B* and *IL-1RN* polymorphisms in patients of the same ethnicity - Chinese Han and Italian, respectively. Zeng *et al*^[10] found that the *IL-1B*-511 T/T genotype frequency was significantly higher in patients with GC than in control subjects (25.0% *vs* 12.5%, $\chi^2 = 6.7$, $P = 0.01$) in the low GC prevalence region (Guangdong), but was similar (23.0% *vs* 23.0%) in the high prevalence region (Shanxi). Perri *et al*^[13] did not find any association between GC occurrence and either *IL-1B*-511T or *IL-1RN* polymorphism when dividing the subjects between geographic areas displaying high prevalence rates (the North) or low prevalence rates (the South) in Italy.

To the best of our knowledge, this is the first study to examine the associations between *IL-1* polymorphisms and GC risk among several ethnicities in one area at the same time. We examined these polymorphisms and their potential association with GC risk among the Tibet, Hui and Han ethnicities in the Qinghai area of China. We found associations between *IL-1B*-511, *IL-1B*-31 and *IL-1RN* polymorphisms and GC risk among Tibet, Hui and Han ethnicities in the Qinghai area, which were not identical.

In the Tibet ethnicity group, the *IL-1B*-31 CC genotype was associated with GC. Additionally, our study showed that the *IL-1B*-31 CC genotype was only associated with intestinal type GC. Our results are consistent with those from several studies in Chinese and Caucasian populations, where *IL-1B*-31 CC polymorphisms were associated with an increased risk of GC^[10,20,21]. However, these results are inconsistent with those from other studies in Asian and Caucasian populations^[14,22,23].

In the Hui ethnicity group, the *IL-1RN*2 was associated with GC, and further study supported that the *IL-1RN*2 polymorphism was associated with both intestinal and diffuse types of GC. These findings were in agreement with those previously reported, including studies from Caucasian, Arab and Asian (including Chinese) populations^[13,20,22,24]. However, our findings also differ from those reported in several other studies^[14,25,26].

In the Han ethnicity group, the *IL-1B*-31 CT and CC genotypes and the *IL-1B*-511 CT and TT genotypes were associated with GC compared with the *IL-1B*-31 TT genotype

and the *IL-1B*-511 CC genotype, respectively. Moreover, the *IL-1B*-31 CC genotype was also only associated with intestinal type GC. Importantly, although *IL-1B*-31 CT carriers displayed a trend in risk, they did not achieve the threshold of statistical significance. The *IL-1B*-511 CT and TT genotypes were only associated with intestinal type GC, compared with the CC genotype. While this is the same in Caucasian and Chinese populations^[11,18,27,28], it differs from the findings observed in South Korean and Japanese populations in Asia^[10,20]. This study also revealed that *IL-1RN* polymorphisms were not associated with increased risk of GC in the Han ethnicity group, which is similar to that seen in Japanese and South Korean populations^[20].

It is interesting and important that the *IL-1B*-31, *IL-1B*-511 and *IL-1RN* polymorphisms and GC risk among the three ethnicities examined were not identical. Other studies have drawn similar conclusions. We believe that the differences among the ethnicities are related to different inherited gene backgrounds. This is supported by other studies which showed differential genetic/environmental interactions in different ethnic groups resulting in altered gene expression and altered effects on cell growth and tumorigenesis^[29]. The gene distributions of *IL-1B*-31, *IL-1B*-511 and *IL-1RN* among the Tibet, Hui and Han ethnicities in Qinghai were different. Despite this, they were at least somewhat related to other Asian populations. The *IL-1B*-31 TT genotype was less frequent in the Tibet population (22.38%) than in the Han population (32.18%). The *IL-1B*-511 TT genotype was more frequent in the Tibet population (29.52%) than in the Han population (18.81%). The *IL-1B*-511 TT genotype was significantly lower in the Hui population (20.98%) than in the Han population (32.17%). In addition, the *IL-1RN* L was significantly lower in the Hui (76.10%) population compared to both the Tibet population (88.10%) and the Han population (84.66%). Ethnic origin is a crucial determinant of the frequency of genetic markers in all populations. Our data may reflect the influence of past selective pressures on the genotypes of Tibet, Hui and Han ethnicities over a long period of time. Han, Tibet and Hui ethnicities have different origins. The Han population is the major ethnicity, while the Tibet and Hui ethnicities are considered to be minorities in the Qinghai province of China. The selected healthy controls of the Tibet ethnicity were living in the Hainan Tibet Ethnicity Autonomous prefecture in Qinghai province, which belongs to the Tibet Anduo area. Shi *et al.*^[30] studied more than 5000 male samples from 73 East Asian populations and reconstructed the phylogenetic geography of the D-M174 lineage. The suggested frequency of D-M174 in Tibet (41.31%) was close to Japan (35.08%) but different from the Han ethnicity (< 5%). Thus, the Tibet gene feature is more similar to the Han ethnicity, but also has its own characteristics. The Hui ethnicity migrated from Central Asia, Persia and the Arab world. Yao *et al.*^[31] analyzed M*, N* and R* mtDNAs and found that the western Eurasian specific haplogroup frequency in the Hui population was 6.7%, but no western Eurasian type was found in Han Chinese samples from the same place.

Since both the Tibet and Hui ethnicities practice endogamy, they tend to be ethnically homogeneous. Therefore, we believe that the Tibet, Hui, and Han ethnicities in the Qinghai area of China have different origins leading to different associations between *IL-1B*-31, *IL-1B*-511 and *IL-1RN* polymorphisms and GC risk.

Our study has some limitations. First, we did not consider education, consumption of alcohol, fresh fruits, and vegetables in the controls which could influence GC risk. Second, the altitude at which healthy controls lived was not considered. In this study, all of the Tibet controls and most of the Tibet patients lived in the plateau above 2800 meters of one another. For the Hui and Han populations, all controls and most patients lived within 2200 meters of each other. Finally, different eating habits among the groups were not investigated.

In conclusion, the present study shows different associations between the *IL-1B*-31, *IL-1B*-511 and *IL-1RN* polymorphisms and GC among the Tibet, Hui and Han ethnicities in the Qinghai area of China. No significant association was observed when GC patients were sorted by age, sex and the presence of *H. pylori* infection.

COMMENTS

Background

Studies suggest that polymorphisms in interleukin (IL)-1B and IL-1RN are associated with a differential risk of developing gastric cancer. However, there does not seem to be a consensus regarding these polymorphisms, since in some populations the polymorphisms are associated with increased disease occurrence, whereas in other populations, they are associated with a protective effect.

Research frontiers

There is no consensus regarding the associations between IL-1B, IL-1RN polymorphisms and gastric cancers in different areas or ethnicities. The authors investigated the associations between IL-1B and IL-1RN polymorphisms and gastric cancers among the Tibet, Hui and Han ethnicities in China.

Innovations and breakthroughs

The outcomes of previous studies on the associations between *IL-1B* and *IL-1RN* polymorphisms and gastric cancer were different and even opposite. The genetic/environmental interactions among different ethnic groups are quite complex. Thus, *IL-1B* and *IL-1RN* polymorphisms may play different roles in different populations or geographical areas. This study suggests that carriers of the *IL-1B*-31 CC genotype had an increased risk of intestinal type gastric cancer in the Tibet ethnicity, carriers of the *IL-1B* 2/L genotype had an increased risk of both intestinal and diffuse types of gastric cancer in the Hui ethnicity, while carriers of the *IL-1B*-31 CC, *IL-1B*-511 CT, TT genotypes have an increased risk of intestinal type gastric cancer in the Han population.

Applications

The study results suggest that *IL-1B* and *IL-1RN* genotypes may differentially contribute to gastric cancer among the Tibet, Hui and Han nationalities in the Qinghai area of China, and that *IL-1B* and *IL-1RN* polymorphisms may play different roles in different populations or geographical areas.

Terminology

Single nucleotide polymorphisms (SNPs) are short polymorphisms in the human DNA. SNPs occur once in every 300 nucleotides on average and can act as biological markers. When SNPs occur within a gene or in a regulatory region near a gene, they may play a more direct role in disease by affecting the gene's function. SNPs can also be used to track the inheritance of disease genes within families.

Peer review

This is a good descriptive study in which authors investigated *IL-1B* and *IL-1RN* polymorphisms in Han, Tibetan and Hui ethnic populations in Qinghai Province of China and their associations with gastric cancer risk in these populations. The topic is interesting and of potential clinical implications.

Abstract

Inflammatory myofibroblastic tumor (IMT) occurring at retroperitoneal sites has rarely been reported. We report the case of a previously well 14-year-old girl with no history of abdominal disease whose past medical history and family tumor history were unremarkable. She complained of intermittent abdominal pain for one month. An abdominal mass was found on physical examination and abdominal contrast-enhanced computed tomography (CT) showed a hypodense soft mass, the size and location of which suggested a well delineated retroperitoneal tumor surrounding the superior mesenteric vessels measuring 3.3 cm × 4.5 cm × 4.5 cm with enlarged lymph nodes. The patient underwent an exploratory laparotomy followed by biopsy and was subsequently diagnosed with retroperitoneal IMT. She was successfully treated with postoperative chemotherapy and oral diclofenac sodium. Following completion of therapy the mass was no longer palpable and no longer visible on CT scanning. The use of methotrexate and cisplatin for aggressive myofibroblastic tumors is also reviewed.

INTRODUCTION

Inflammatory myofibroblastic tumor (IMT) is a rare soft-tissue tumor with a clinical resemblance to malignant neoplasm^[1]. It is an unusual solid tumor commonly seen in children and young adults, and can occur at any site in the body, the lung being the most common site^[2]. Extrapulmonary IMTs account for 5% of all IMTs and retroperitoneal IMTs are relatively rare^[3]. The retroperitoneum is an unusual site of presentation in these rare tumors, which share the neoplastic characteristics of aggressive local tissue infiltration, recurrence after resection, and occasionally distant metastasis^[2,4]. Due to disease progression, lack of alternative therapeutic regimens, recurrence and poor prognosis, almost all patients with IMT have been treated with radical surgical resection or single non-steroidal anti-inflammatory drugs. Herein, we present a patient with a retroperitoneal IMT, who was successfully treated with chemotherapy and oral diclofenac sodium.

CASE REPORT

A 14-year-old girl was admitted to our hospital in June

Figure 1 Photograph of abdominal computer tomography. A: The complex soft tissue involved including the mesenteric vessels (arrow); B: Disappearance of the mass.

Figure 2 Photomicrograph of the tumor cells. A: A proliferation of spindle tumor cells (hematoxylin and eosin stain, $\times 200$); B: Positivity for smooth muscle actin ($\times 200$).

2009 with the chief complaint of intermittent abdominal pain for one month. She experienced intermittent abdominal pain without bloating every two days and all symptoms were in remission after she buckled both legs, however, the pain returned a few minutes later. The patient did not have symptoms of fever, nausea, vomiting, weight loss, bowel obstruction or other discomfort and she did not receive treatment to relieve these symptoms prior to admission. This 14-year-old girl was previously well with no history of abdominal disease, and her past medical history and family tumor history were unremarkable. Physical examinations showed a 7 cm abdominal mass in the right side of the umbilicus, which was hard, without tenderness and firm but mobile on palpation. Blood count analysis and tumor markers such as carcinoembryonic antigen and CA19-9 were negative. Abdominal contrast-enhanced computed tomography showed a hypodense soft mass, the size and location of which suggested a well delineated retroperitoneal tumor surrounding the superior mesenteric vessels which measured $3.3 \text{ cm} \times 4.5 \text{ cm} \times 4.5 \text{ cm}$ with enlargement of the surrounding lymph nodes (Figure 1A). Given that the preoperative diagnosis was unconfirmed and radical surgery was the most efficient therapeutic option, after a multidisciplinary discussion, an exploratory laparotomy

was performed. During the operation, a 10 cm round solid mass was found at the root of the mesentery. The tumor reached the uncinate process of the pancreas and the horizontal section of the duodenum. Complete excision of the mass was difficult, because the tumor surrounded most of the superior mesenteric artery branches. Therefore, biopsy of the mass was undertaken. Pathologic examination confirmed the diagnosis of IMT with a proliferation of spindle cells and dense polymorphic infiltration of mononuclear inflammatory cells (Figure 2A). On immunohistochemical staining, spindle cells were positive for vimentin, smooth muscle actin (Figure 2B) and CD68, but negative for Cluster of differentiation 34 (CD34), Cluster of differentiation 117 (CD117) and anaplastic lymphoma kinase-1 (ALK-1).

The postoperative course was uneventful and the patient was discharged from the hospital without complications. Three weeks after surgery, the patient received chemotherapy which consisted of 6 courses of middle dose methotrexate (20 mg/m^2) and cisplatin (30 mg/m^2) administered once a month, associated with oral administration of slow-release diclofenac sodium until cessation of chemotherapy. The patient was re-examined after completing chemotherapy; the mass was no longer palpable and was no longer visible on (computer tomog-

raphy) CT scanning (Figure 1B). Currently, the patient is alive without recurrence after 3 years of follow-up.

DISCUSSION

IMT was originally described in the lungs in 1937, and since then has been reported to occur throughout the body including the mesentery, stomach, abdomen, liver, mediastinum, retroperitoneum, omentum and bladder of children and adolescents^[5]. Retroperitoneal IMTs are extremely rare. This tumor was previously described as an inflammatory pseudotumor, inflammatory myofibroblastoma, lymphoplasmacytic, histiocytoma, and fibrous pseudotumor until 1994 when myofibroblastic tumor was established as a distinct low grade malignancy by the World Health Organization classification^[6-8]. The exact etiology of the disease is still not completely known. In a review of the medical literature, researchers have suggested that trauma, surgery, inflammation and infection by the Epstein-Barr virus or Human Herpes virus could result in the development of IMT^[9]. Others have insisted that a chromosomal rearrangement involving the *ALK* gene results in the activation of a tyrosine kinase receptor and could lead to abnormal expression^[10]. In the present case, the patient had no past medical history related to this disease, therefore, there is no evidence of a direct relationship between the development of the disease and susceptible factors.

The clinical presentation of the tumor often depends on its anatomical site. Retroperitoneal tumors usually grow slowly and always present as a solid abdominal palpable mass, accompanied by abdominal pain or weight loss. It is only when the retroperitoneal tumor increases in size resulting in obstructive symptoms, that intestinal obstruction may be diagnosed. As shown in our report, the patient presented with an atypical clinical manifestation of intermittent abdominal pain accompanied by a localized mass and no significant abnormal laboratory tests. The CT features in our patient showed varied degrees of enhancement on the complex soft tissue involving the mesenteric vessels with nonspecific findings, which was mostly indistinguishable from a malignant process. It is difficult to confirm this disease using these atypical clinical manifestations pre- or intra-operatively. A definite diagnosis therefore depends on histopathological evaluation after biopsy or resection.

When necessary, surgical resection could be considered the preferred treatment for IMT, which can also be used to confirm this disease. The recurrence rate has been reported to range from 18% to 40%, and only precise removal of the tumor will avoid recurrence^[11]. In our patient, the location of the tumor made it difficult to cure by means of a complete radical resection which may have led to intestinal ischemia and even postoperative short bowel syndrome. Steroids and radiotherapy as well as chemotherapy as adjuvant therapy are feasible alternatives to surgery. Chemotherapy, radiotherapy, and

even immunomodulation have not been reported to be consistently effective against this aggressive tumor^[12]. No other efficient treatment regimens have been reported for this tumor. Consequently, in patients with unresectable IMTs, treatment options are limited, and better recommendations have not been defined.

Nonsteroidal anti-inflammatory drugs (NSAIDs) have been successful in the treatment of IMTs when resectability is limited due to the tumor invading vital structures^[13]. Przkora *et al.*^[14] reported that two patients with nonresectable intra-abdominal IMTs had a satisfactory outcome after receiving treatment with nonsteroidal anti-inflammatory drugs. There is no evidence to prove that chemotherapy is effective when used singly, however, it may play a role following complete resection. As shown in our case, patients with unresectable retroperitoneal IMTs receiving conventional-dose methotrexate/cisplatin chemotherapy and oral NSAIDs can be symptom-free after 3 years of follow-up without relapse or metastasis and achieve a favorable prognosis. Therefore, chemotherapy combined with oral NSAIDs may be an effective therapeutic option for patients with unresectable IMT.

Our experience with the patient in this report might provide another treatment choice for patients with unresectable, residual or recurrent IMT.

In summary, our findings suggest that middle-dose chemotherapy and NSAIDs may be a feasible therapeutic choice in patients with unresectable retroperitoneal IMT.

Abstract

We present a case with hepatic myelopathy (HM) due to a surgical splenorenal shunt that was successfully treated by endovascular interventional techniques. A 39-year-old man presented with progressive spastic paraparesis of his lower limbs 14 mo after a splenorenal shunt. A portal venogram identified a widened patent splenorenal shunt. We used an occlusion balloon catheter initially to occlude the shunt. Further monitoring of the patient revealed a decrease in his serum ammonia level and an improvement in leg strength. We then used an Amplatzer vascular plug (AVP) to enable closure of the shunt. During the follow up period of 7 mo, the patient experienced significant clinical improvement and normalization of blood ammonia, without any complications. Occlusion of a surgically created splenorenal shunt with AVP represents an alternative therapy to surgery or coil embolization that can help to relieve shunt-induced HM symptoms.

Key words: Hepatic myelopathy; Shunts; Portosystemic; Hepatic encephalopathy; Embolization; Endovascular

INTRODUCTION

Hepatic myelopathy (HM) is a rarely reported disorder characterized by progressive spastic paraparesis of the lower extremities due to impaired corticospinal tract function in the setting of cirrhosis or portosystemic shunting^[1-3]. Over 85% of reported HM cases have been associated with surgical, angiographic, or spontaneous portosystemic shunting. Both HM and hepatic encephalopathy (HE) after a surgical portosystemic shunt are thought to be secondary to the increased shunting of portal venous toxins to the systemic circulation and from hypoperfusion and ischemia of the hepatocytes. However, unlike HE, conservative treatment of HM is usually considered inefficient.

Recently, outcomes for a small number of patients who have undergone liver transplantation (LT) for HM suggest a potential neurological benefit, especially with earlier transplantation^[4-6]. However, for patients with normal liver function or Child-Pugh A grade cirrhosis, the choice of LT vs other treatments (i.e., narrowing or occlusion of the shunt) is debatable^[3,4]. In addition, the limited donor organ supply remains a major issue. In the present study, we report a case with HM due to a surgical splenorenal shunt that was successfully occluded by

endovascular interventional techniques, which resulted in significant clinical improvement and normalization of blood ammonia.

CASE REPORT

Patient's history

A 39-year-old man presented in April 2010 with an 11 mo history of slowly progressive spastic paraparesis of his lower extremities. The patient in question had a history of hepatitis B disease. In March 2008, he underwent a surgical splenorenal shunt and splenectomy due to recurrent esophagogastric variceal bleeding and thrombocytopenia. In May 2009, fourteen months after his surgical splenorenal shunt, gait impairment was first noticed. An episode of HE was not seen during this period. The patient received conservative medical management, including protein restriction, non-absorbable antibiotics, lactulose and physical therapy, after the onset of gait impairment. However, these measures did not prevent the progressive decline in his mobility and this necessitated the use of a cane because of marked leg weakness, gait imbalance, and instability.

Physical examination

Physical examination revealed normal mental status and cranial nerve function, and the absence of asterixis. Kayser-Fleischer rings were absent, upper extremity strength and tendon reflexes were normal, and Hoffman's sign was absent. In the lower extremities, the legs were spastic, the tone was more noticeably increased with brisk tendon reflexes and there was clonus at the ankles. Plantar reflexes were extensor and the patient was unable to move his legs. There was no atrophy or any fasciculations, nor any evidence of ascites or peripheral edema.

Laboratory studies

Laboratory investigations showed normal serum levels of electrolytes, glucose, vitamin B12, and creatinine. He had mild anemia (hemoglobin level of 112 g/L; normal range, 120-160 g/L) and thrombocytopenia ($85 \times 10^3/\text{mm}^3$; normal range, 100×10^3 - $300 \times 10^3/\text{mm}^3$). Prothrombin time was 16 s (normal range, 11-14.5 s). Other values were as follows: 28 $\mu\text{mol/L}$ total bilirubin (normal range, 3-20 $\mu\text{mol/L}$); 15 $\mu\text{mol/L}$ conjugated bilirubin (normal range, 0-7 $\mu\text{mol/L}$); 156 $\mu\text{mol/L}$ ammonia (normal range, 18-45 $\mu\text{mol/L}$); 56 U/L alanine aminotransferase (normal range, 5-40 U/L); 65 U/L aspartate aminotransferase (normal range, 15-45 U/L); 126 U/L alkaline phosphatase (normal range, 30-115 U/L); 36 g/L albumin (normal range, 35-50 g/L); 45 g/L globulin (normal range, 21-40 g/L); international normalized ratio 1.3 (normal range, 0.9-1.2). His liver was graded as Child-Pugh class A.

Serum examinations for hepatitis B surface antigen and hepatitis B e-antigen were positive, but a test for hepatitis B core antigen was negative. Antibodies to hepatitis C virus and human immunodeficiency virus were nega-

tive, syphilis serology was negative, and an analysis of the cerebrospinal fluid was normal.

Magnetic resonance imaging of the brain and spine was normal, and an abdominal computed tomography (CT) revealed a cirrhotic liver. An abdominal ultrasound examination showed features of cirrhosis of liver and a Doppler study showed a widely-open splenorenal shunt. Electro-encephalography revealed no definite abnormality and an endoscopic examination revealed no esophagogastric varices.

Diagnosis and general management

Given the aforementioned extensive neurological evaluation, which did not identify any alternative explanation for the patient's spastic paraparesis of the lower extremities, the diagnosis of HM secondary to the surgical splenorenal shunting was made. After admission, with protein restriction and medication with lactulose, neomycin, B-vitamins, physical therapy, and antispastic agents for 3 wk, the patient showed no improvement in his spastic paraparesis, and his hyperammonemia remained within the range of 140-180 $\mu\text{mol/L}$.

After discussion with hepatologists, gastroenterologists, and vascular surgeons at the authors' hospital, we decided to occlude the surgical splenorenal shunt to prevent further neurologic deterioration. Informed consent was obtained from the patient.

Angiographic procedure

Under local anesthesia (2% lidocaine) and fluoroscopic guidance, venous access was obtained through the right internal jugular vein, and a 9 Fr with an angled-tip 80-cm long introducer sheath (Cook, Bloomington, Indiana) was advanced into the inferior vena cava. The splenorenal shunt was then catheterized with a 5 Fr Cobra catheter (Terumo Corporation, Tokyo, Japan) and an angled-tip 0.035-inch hydrophilic guidewire (Terumo). Initial portography and pressure measurements were performed with a 5 Fr multiple-side-hole catheter (Cook) positioned in the superior mesenteric vein. At the portal venogram, a widened patent shunt was seen (Figure 1), with a portacaval pressure gradient of 8.0 mmHg. The portal vein pressure was 12.5 mmHg.

Temporary balloon occlusion of the surgical splenorenal shunt

We initially placed an occlusion balloon catheter into the splenorenal shunt tract to test if the patient could be tolerable to the full embolization procedure. Following the angiographic procedure, over a 0.035-inch Amplatz wire (Cook), the 9 Fr introducer sheath advanced into the splenorenal shunt. A 7 Fr latex balloon catheter, with a maximum outer diameter of 16 mm (Boston Scientific, Watertown, Mass) was then inserted into the splenorenal shunt through the sheath. Under the inflated balloon, injection of contrast material through the sheath showed complete occlusion of the surgical splenorenal shunt. After the balloon occlusion, heparin infusion was given *via*

Figure 1 Digital subtraction portogram obtained via a catheter inserted through the distal splenorenal shunt into the superior mesenteric vein (arrows) using the right jugular vein approach. The wide patent splenorenal shunt (arrow heads) is shown. Note the inferior vena cava (curved arrow).

Figure 2 Coronal maximum intensity projection reconstruction of a contrast enhanced 64-slice helical computed tomography scan of the abdomen. A: Obtained 5 d after placement of an occlusion through the splenorenal shunt and shows the occlusion balloon placed within the shunt tract (arrows), note the inferior vena cava (curved arrow) and the left renal vein (arrow heads); B: Obtained 3 mo after the Amplatzer vascular plugs (AVP) occlusion procedure and shows the correct AVP position (arrow heads), opacification of the portal system (arrows), and no opacification of the surgical shunt, as well as the varices.

a peripheral vein, at a dosage of 120 mg/24 h, to avoid catheter-related thrombosis.

Following the balloon occlusion procedure, the patient's plasma ammonia level decreased to 110 $\mu\text{mol/L}$, 70 $\mu\text{mol/L}$, 60 $\mu\text{mol/L}$ and 50 $\mu\text{mol/L}$, on post-procedural days 2, 3, 5 and 6, respectively. He reported a

mild improvement in his leg strength and balance, while the other HE-related symptoms remained unchanged. Follow-up CT on post-procedural day 5 showed the balloon positioned appropriately (Figure 2A). Repeat liver function tests were normal, and repeat endoscopic examination confirmed no induction of esophagogastric varices. There was no evidence of ascites. Six days after the balloon occlusion procedure, we decide to occlusion the splenorenal shunt permanently with endovascular embolization.

Embolization of the surgical splenorenal shunt with an Amplatzer vascular plug

Given the relatively larger diameter of the splenorenal shunt, we decided to use an Amplatzer vascular plug (AVP) instead of conventional embolization materials (i.e., coils, glue, and particles).

The diameter of the surgical splenorenal shunt was approximately 13 mm in diameter, calculated on the angiography workstation. Given the diameter of the shunt, we used an 18-mm AVP (AGA Medical Corp., Golden Valley, MN, United States) with the 30%-50% oversizing recommended by the manufacturer, to prevent plug migration. For deploying the AVP, the 9 Fr introducer sheath advanced over a 0.035-inch Amplatz wire (Cook) into the most distal extreme of the splenorenal shunt. The AVP device was then advanced through the 9 Fr sheath and initially deployed by retracting the sheath, but without detaching the device. A control injection was performed, to ensure satisfactory positioning of the device and to enable repositioning. When in a satisfactory position, the AVP was detached by anticlockwise rotation of the AVP guide wire to unscrew it from the AVP device proper. Within minutes of deployment, the shunt had completely stopped. Injection of contrast material through the sheath showed complete occlusion of the surgical shunt.

Following AVP embolization, an indirect digital subtraction portography, carried out during the same procedure and obtained with a 4 Fr catheter (Terumo) inserted into the superior mesenteric artery (SMA) *via* the right femoral artery approach, was used to evaluate portal vein system. Digital subtraction SMA angiogram at the portal venous phase demonstrated a marked improvement in the opacification of the portal vein in comparison with that of the portography pre-deployment of the AVP (Figure 3), indicating an increase in antegrade intrahepatic portal vein perfusion. No contrast material passed through the surgical splenorenal shunt.

Follow-up

No complication was noted during and after the procedure. Five days after the AVP embolization, the patient's serum ammonia level had normalized to 40 $\mu\text{mol/L}$.

The patient was discharged 6 d post-AVP embolization. Doppler US confirmed complete occlusion of the splenorenal shunt. In June 2010, one month after the embolization, the patient reported a gradual improvement

Figure 3 After deploying the Amplatzer vascular plugs, indirect digital subtraction portography, obtained through the catheter inserted into the superior mesenteric artery using the right femoral artery approach, demonstrates opacification of the portal vein (arrows). Note the correct Amplatzer vascular plugs position (arrow heads) and no visualization of varices.

Figure 4 Axial image of contrast enhanced 64-slice helical computed tomography scan of the abdomen, showing the correct Amplatzer vascular plug position (curved arrow), opacification of the portal system (arrow heads), and a thrombosed shunt tract (arrows).

in strength; he was still moderately weak but was able to walk short distances (50-100 m) with crutches.

By 3 mo after the procedure, he was able to walk about 300-500 m with crutches. He still complained of stiffness and spasms in his legs, but improved compared to 3 mo ago. A follow-up contrast enhanced CT scan at the venous phase confirmed that the AVP position was correct, that there was opacification of the intrahepatic portal veins, that the splenorenal shunt tract was thrombosed, and that there was no opacification of the surgical shunt or varices (Figures 2B and 4).

The patient continued to show improvement in his HM symptoms over the next few months. In December 2010, 7 mo after the splenorenal shunt embolization, his strength improved significantly, he was able to walk 1 to 2 km aided by crutches, and had only mild stiffness in both legs. Esophagogastrosocopy showed no evidence of esophagogastric varices.

DISCUSSION

HM responds poorly to conservative medical therapy and it has a poor prognosis because of its progressive and irreversible nature^[2,3]. Currently, treatment options in HM include surgical ligation, liver transplantation, shunt reduction, or occlusion by interventional procedures. Surgical ligation has been reported to be effective, but is used only occasionally^[1]. LT remains a potentially definitive treatment for HM in patients with decompensated cirrhosis of Child-Pugh B and C grade^[4-6]. However, for patients with normal function liver or Child-Pugh A grade cirrhosis, the choice of LT vs other treatments (i.e., narrowing or occlusion of the shunt) is debatable^[1,2]. Our patient had no history of HE, and his laboratory studies showed no liver dysfunction, with the exception of an increase in his serum ammonia level. Thus, occlusion of the surgical splenorenal shunt may be an alternative therapeutic option.

Interventional endovascular shunt occlusion has been used previously to treat post-surgical shunt HE and post-

transjugular intrahepatic portosystemic shunt (TIPS) HE^[2,7]; however, the usefulness of the technique for post-surgical shunt HM has not yet been determined. In the present case, the patient's gait impairment was noticed 14 mo after his surgical splenorenal shunt, with a progressive decline in his mobility afterward. We successfully occluded the large surgical splenorenal shunt using an AVP. Following AVP embolization, the patient reported a gradual improvement in leg strength and balance. Seven months later the patient was able to walk 1 to 2 km aided by crutches, with only mild residual spasticity of his lower extremities. To our knowledge, reversal of HM by occlusion of a surgical splenorenal shunt with AVP has not been reported.

Possible embolizing materials for the embolization of the portosystemic shunt are coils, a detachable balloon, and an AVP. We chose AVP implantation for our patient due to the relatively large size of the surgical splenorenal shunt. In this situation, a number of coils would be needed to achieve adequate vessel closure. In addition, coil migration may occur when used in short shunt tracts^[7-10]. AVPs has recently been shown to be effective in the occlusion of internal iliac arteries^[9], the treatment of pulmonary arteriovenous malformations^[10], and as an occlusion system for a splenorenal shunt arising after TIPS^[8,11]. The advantage of the AVP, compared to coils, is that it can be more precisely placed within the vessel and that it can be repositioned or removed, if necessary.

There is some doubt as to whether portal pressure could rise after portosystemic shunt embolization. This would constitute a critical complication for the patient, resulting in the aggravation of esophageal varices or even the development of new varices^[2,12,13]. One study concluded that, to avoid the consequences of a sudden increase in portal pressure, embolization should be indicated only in patients with absent or mild esophageal varices and with no signs of hepatic failure, such as ascites or jaundice^[14]. In addition, routine periprocedural endoscopy is recommended in this setting to minimize the incidence of embolization-related complications. In this report, we used an occlusion balloon catheter initially to occlude the surgical shunt. Further monitoring of the

patient over the next few days revealed no evidence of induction varices or ascites; thus we decided to use an AVP to enable closure of the shunt.

Our case raises several unique points not previously noted in the literature. Firstly, to our knowledge, this is the first report of a surgical shunt relate-HM successfully embolized with AVP resulting in an immediate improvement in intrahepatic portal perfusion, normalization of blood ammonia, and a gradual improvement of HM-related symptoms. Secondly, since we were able to document a temporary balloon occlusion of the surgical shunt prior to permanent embolization, it may be possible to predict clinical and laboratory improvement. Finally, in patients with normal function liver or Child-Pugh A grade cirrhosis, shunt occlusion may represent a suitable alternative therapy to LT that can help to relieve shunt-induced HM symptoms.

In conclusion, for the present case, we successfully occluded a large surgical splenorenal shunt using an AVP, which resulted in significant clinical improvement of the shunt-induced HM symptoms. This technique represents a viable alternative to surgery or coil embolization, although further study is necessary. In addition, trial balloon occlusion of the shunt prior to complete permanent embolization can be used to predict the clinical and laboratory improvement.

Abstract

This case reports an application of conventional duodenoscope in a post pancreaticoduodenectomy patient with the help of retrieval balloon assisted enterography. The 56-year-old woman had pancreaticoduodenectomy with Child reconstruction 9 mo ago because of pancreatic adenocarcinoma and now there are recurrent enlarged lymph nodes in the anastomotic stoma of hepaticojejunostomy. Considering the patient's late-stage cancer, a plastic stent was then successfully placed there to drainage. The main challenge in this case was the extremely long afferent loop and blind cannulation through the anastomotic stoma of hepaticojejunostomy. Retrieval balloon assisted enterography is very helpful for duodenoscope going through the reconstructed intestinal tract and for the cannulation. After two weeks, the patient remained free of painful symptoms and free of fever. Liver function improved well. Four months after the placement of stent, the patient died of cachexia without jaundice, fever and abdominal pain according to her daughter's statement.

INTRODUCTION

Endoscopic interventions are usually very challenging in patients with anatomic changes caused by previous gastrointestinal surgery. Methods using front view endoscopy, single-balloon enteroscopy (SBE) and double-balloon enteroscopy (DBE) systems may aid in cholangiopancreatography in postsurgical conditions. In this case, an endoscopic retrograde cholangiopancreatography (ERCP) procedure was successfully performed using a conventional duodenoscope on a post-pancreaticoduodenectomy patient with the help of retrieval-balloon-assisted enterography. The patient was a 56-year-old woman who had undergone a pancreaticoduodenectomy 9 mo previously in another hospital because of pancreatic adenocarcinoma. Recurrent enlarged lymph nodes were found 9 mo after surgery in the anastomotic stoma of the hepaticojejunostomy. A plastic stent was placed in the stenosis and resulted in improved liver function.

CASE REPORT

A 56-year-old woman presented complaining of abdominal pain, fever and jaundice for two weeks. She had pancreaticoduodenectomy 9 mo previously in another hospital, and the pathological diagnosis was pancreatic adenocarcinoma. Two weeks before this admission, she began to feel abdominal distension and intermittent pain, accompanied by jaundice and fever. The highest fever was 38.6 °C.

Magnetic resonance imaging (MRI) showed that the lymph nodes of the hepatoduodenal ligament were enlarged and causing compression of the anastomotic stoma of hepaticojejunostomy (Figure 1). The intrahepatic bile duct was markedly expanded. The lymph nodes near the aorta were also enlarged.

Laboratory tests revealed: total white cells $5.9 \times 10^9/L$, neutrophilic granulocyte (%) 71.9%, total bilirubin 104 $\mu\text{mol/L}$, direct bilirubin 81.6 $\mu\text{mol/L}$, glutamate pyruvate transaminase 34 U/L, glutamic-oxal(o) acetic transaminase 25 U/L.

We performed ERCP using a conventional duodenoscope on this patient, which showed compressed stenosis of the anastomotic stoma of hepaticojejunostomy consistent with the MRI. We then successfully placed a plastic stent in the anastomotic stoma.

Within a few days after placement of the biliary stent, the fever resolved and there was no complaint of abdominal pain. Serum bilirubin levels also went down. Five days later, X-ray of the biliary system showed that no contrast remained in the bile duct and the patient was discharged. Two weeks after discharge, there was still no complaint of abdominal illness or fever. Laboratory tests showed: total white cells $5.9 \times 10^9/L$, neutrophilic granulocyte (%) 63.1%, total bilirubin 49.7 $\mu\text{mol/L}$, direct bilirubin 33.0 $\mu\text{mol/L}$, glutamate pyruvate transaminase 31 U/L, glutamic-oxal(o) acetic transaminase 55 U/L.

The procedure was performed with the patient under pharyngeal anesthesia and sedation (intramuscular 10 mg diazepam injection). The patient was placed in the left lateral decubitus position. ERCP was performed under fluoroscopic control using a therapeutic duodenoscope with a total length of 120 cm, and a working channel of 3.7-mm diameter (Olympus V260). The duodenoscope was advanced into the stomach and then the afferent jejunal loop through the gastrojejunal anastomosis. The afferent loop after pancreaticoduodenectomy is always longer compared to that after a Billroth II gastrectomy. In this case, after arriving at the afferent loop and pushing the whole duodenoscope into the patient's stomach and afferent loop by retrieval-balloon-assisted enterography, we realized we were a long way (approximately 30 cm) from the anastomotic stoma of the hepaticojejunostomy (Figure 2A).

The position of the anastomotic stoma of hepaticojejunostomy after pancreaticoduodenectomy was actually invariably near the porta hepatis opening downward to the afferent limb. After using contrast to see the whole picture of the afferent loop, we inserted the wire-guided

Figure 1 Magnetic resonance imaging showed compressed anastomotic stoma.

retrieval-balloon catheter to the extremity of the afferent limb, then inflated the balloon and drew back the catheter slowly. We focused on the possible position of the anastomotic stoma of the hepaticojejunostomy and tried to cannulate the intrahepatic bile duct using a guide wire and finally succeeded. It took only 9 min from when we saw the whole picture of afferent loop to successful cannulation (Figure 2B).

Consistent with the MRI, cholangiography showed the compressed anastomotic stoma of hepaticojejunostomy and expanded intrahepatic duct. We left the guide wire in the intrahepatic duct and removed the retrieval-balloon catheter. Because of the patient's late-stage cancer, we put a plastic stent through the stenosis of the anastomotic stoma. The stent went along the guide wire and was pushed by a long catheter to the proper site. Contrast came out of the intrahepatic duct into the afferent loop (Figure 2C). Five days later, X-ray showed that the stent remained in the correct position (Figure 3).

Four months later, the patient died of cachexia. According to a statement from her daughter, there was no jaundice, fever or abdominal pain during that time.

DISCUSSION

ERCP on patients with postsurgical anatomy changes, such as subtotal gastrectomy of Billroth II, Roux-en-Y hepaticojejunostomy and pancreaticoduodenectomy, is difficult to perform. Some case reports describe successful cannulation through front-viewing endoscopes^[1], SBE or DBE^[2-7]. However, rare cases of use of a conventional duodenoscope have been reported^[8-10].

One difficulty in ERCP with postsurgical anatomy changes is how to gain access to the right afferent loop. In our experience, for post-pancreaticoduodenectomy ERCP, the afferent loop was usually at the lesser curvature of stomach, so when we saw the gastrojejunal anastomosis after walking the duodenoscope along the greater curvature of stomach, the "upper tunnel" was the right afferent loop (Figure 4). Sometimes, it was difficult to get into the "upper tunnel" because of the relatively sharp angle. If it was hard to distinguish which was the

Figure 2 The process of blind cannulation through the anastomotic stoma of hepaticojejunostomy followed by placement of a plastic stent. A: The afferent loop was too long for the duodenoscope to reach the anastomotic stoma of hepaticojejunostomy; B: Successful cannulation into the intra hepatic bile duct with the help of the wire guided retrieval balloon catheter; C: A plastic stent was placed through the stenosis of the anastomotic stoma.

Figure 3 Five days after placement of biliary stent, X-ray of the biliary system showed the right position of the stent, and no contrast remained in the bile duct.

Figure 4 The "upper tunnel" was usually the exactly right afferent loop in post pancreaticoduodenectomy with cholecyst reconstruction.

upper, we would draw back the duodenoscope a little to "relax" the gastrojejunal anastomosis, making it easier to see distinguish the upper. Sometimes, we would also use a catheter (usually the wire-guided retrieval balloon that was used to remove the common bile duct stone) to explore into each limb, injecting contrast into the loop, followed by the scope advancing, and then found the afferent loop. It should be emphasized that in the ERCP with postsurgical anatomy changes, we could rely not only on what was visible through the endoscope, but also the X-ray images from enterology.

The main challenge in this case was the extremely long afferent loop. In an ordinary pancreaticoduodenectomy, the distance from the gastrojejunal anastomosis and the anastomotic stoma of hepaticojejunostomy is at least 60 cm. In theory, the duodenoscope could reach the anastomotic stoma, however, in this case the afferent loop was too long to reach. By using the retrieval balloon catheter and injecting contrast through it, we were able to see how much further we needed to go. The other key point to success in this case was that the surgeons knew the post-pancreaticoduodenectomy anatomy well and, as a result, knew where to cannulate. The retrieval-balloon catheter aided in approaching the anastomotic stoma of the hepaticojejunostomy and served as a sustainer to

achieve cannulation successfully.

The retrieval balloon could be used to explore the intestinal tract by injecting contrast through it under X-ray, especially in patients with postsurgical anatomy changes. We termed it retrieval-balloon-assisted enterography. It not only showed us the direction of the tract in order to guide the endoscope forward, but also facilitated forward movement of the endoscope with fewer injuries to the intestinal wall. In a subtotal gastrectomy of Billroth II with side-to-side jejunojejunostomy of afferent and efferent loops, the retrieval-balloon catheter could also be used, by lying in the right limb, as a guide to prevent the duodenoscope from sliding out of the right limb into another upon forward motion. Upon successful accessing of the right limb, the retrieval balloon is visible in the tract ahead, instead of jumping out of it.

Abstract

Aldo-keto reductase 1D1 (*AKR1D1*) deficiency, a rare but life-threatening form of bile acid deficiency, has not been previously described in China. Here, we describe the first two primary $\Delta 4$ -3-oxosteroid 5β -reductase deficiency patients in Mainland China diagnosed by fast atom bombardment-mass spectroscopy of urinary bile acids and confirmed by genetic analysis. A high proportion of atypical 3-oxo- $\Delta 4$ -bile acids in the urine indicated a deficiency in $\Delta 4$ -3-oxosteroid 5β -reductase. All of the coding exons and adjacent intronic sequence of the *AKR1D1* gene were sequenced using peripheral lymphocyte genomic DNA of two patients and one of the patient's parents. One patient exhibited compound heterozygous mutations: c.396C>A and c.722A>T,

INTRODUCTION

Primary $\Delta 4$ -3-oxosteroid 5β -reductase deficiency (OMIM 235555, also called congenital bile acid synthesis defect type 2, CBAS 2) is a rare but potentially life-threatening form of bile acid deficiency that presents with neonatal progressive intrahepatic cholestasis and normal or slightly elevated γ -glutamyltransferase (GGT)^[1]. In the patients described to date, it is noted that early diagnosis and primary bile acid treatment lead to progressive normalization of liver function and avoidance of liver transplantation^[2].

The aldo-keto reductase 1D1 (*AKR1D1*) gene encodes the only known human $\Delta 4$ -3-oxosteroid 5β -reductase, which catalyzes the reactions responsible for changes to the steroid nucleus of cholesterol in both major bile acid synthesis pathways^[3]. Mutations in *AKR1D1* lead to a

deficiency of the bile acids that normally facilitate the detachment of γ -glutamyl-transpeptidase from the canalicular membrane. So, unlike other causes of cholestasis that present with markedly elevated GGT, CBAS 2 presents with normal or slightly elevated GGT^[1].

To our knowledge, an accurate diagnosis of CBAS 2 requires *AKR1D1* gene analysis, but only 8 reported cases of CBAS 2 worldwide have been diagnosed both biochemically and genetically^[1,4]. To further the knowledge of the clinical features and therapeutic treatment of CBAS 2, here we describe two patients in Mainland China with progressive intrahepatic cholestasis in early infancy diagnosed by fast atom bombardment-mass spectrometry (FAB-MS) analysis of urinary bile acids and genetic analysis.

CASE REPORT

Patients

A male patient (patient 1) was delivered at term after an uneventful pregnancy by a caesarean delivery with a birth weight of 3100 g. The infant represented his mother's third pregnancy; the first two pregnancies were terminated by abortion for social reasons. The patient's parents were both healthy and non-consanguineous. He developed progressive jaundice from 10 d of life with dark urine. At the age of 4 mo, recurrent pruritus and white stool were noticed, and exploratory laparotomy was performed. Hepatic pathology showed marked giant transformation of hepatocytes, lobular disarray, hepatocellular bile stasis, mildly interlobular fibrosis, proliferation and inflammation. After treatment with traditional Chinese medicine for 2 mo, the pruritus was relieved, but the jaundice persisted. At the age of 11 mo, he was referred to the hospital. On physical examination, moderate jaundice was present. The abdomen was soft, and the liver was detected 2 cm below the xiphoid process and 4.5 cm below the right costal margin, while the spleen was detected 2 cm below the left costal margin. There were no dysmorphic features or cardiac murmur. Laboratory studies at 11 mo showed total bilirubin (TBil) 146 $\mu\text{mol/L}$ (normal range: 5.1–17.1 $\mu\text{mol/L}$), direct bilirubin (DBil) 113 $\mu\text{mol/L}$ (normal range: 0–6 $\mu\text{mol/L}$), alanine aminotransferase (ALT) 210 IU/L (normal range: 0–40 IU/L), aspartate aminotransferase (AST) 207 IU/L (normal range: 0–40 IU/L), alkaline phosphatase 162 IU/L (normal range: 42–383 IU/L), GGT 65 IU/L (normal range: 7–50 IU/L), total bile acids (TBA) 6.1 $\mu\text{mol/L}$ (normal range: 0–10 $\mu\text{mol/L}$). Abdominal ultrasound showed hepatomegaly 4.5 cm below the right costal margin and splenomegaly 5 cm below the left costal margin.

Another male patient (patient 2) born at term after an uneventful pregnancy by a caesarean delivery with a birth weight of 3950 g was the first child of a non-consanguineous couple. The mother had hepatitis B and the father was healthy. He developed mild jaundice from 3 d of life and did not receive any medicine. At the age of 11 wk, he was referred to our hospital. On physical examination,

Figure 1 Genomic DNA sequences in exon 7 of the *aldo-keto reductase 1D1* gene in patient 1. A: The arrow identified a heterozygote mutation for c.797G>A (p.R266Q) in this patient; B: The reverse strand sequence shows the same result.

mild jaundice was present. The abdomen was soft, and the liver was 4 cm below the right costal margin and 3 cm below the xiphoid process. The spleen was not felt. There were no dysmorphic features or cardiac murmur. Laboratory studies showed TBil 96.1 $\mu\text{mol/L}$ (normal range: 5.1–17.1 $\mu\text{mol/L}$), DBil 64.4 $\mu\text{mol/L}$ (normal range: 0–6 $\mu\text{mol/L}$), ALT 176 IU/L (normal range: 0–40 IU/L), AST 183 IU/L (normal range: 0–40 IU/L), GGT 33 IU/L (normal range: 7–50 IU/L), TBA 3 $\mu\text{mol/L}$ (normal range: 0–10 $\mu\text{mol/L}$). Abdominal ultrasound showed hepatomegaly 4.5 cm below the right costal margin and splenomegaly 2 cm below the left costal margin.

Urine bile acid analysis

For patient 1, the first urine sample was taken at 11 mo of age when ursodeoxycholic acid (UDCA) (150 mg/d) was discontinued for 7 d. The FAB-MS analysis showed that the largest bile acid peaks were consistent with the presence of residual amounts of ursodeoxycholic acid metabolite (m/z 528), and the atypical bile acids of dihydroxy-oxo-cholenoic acids present in the glycine conjugate (m/z 460) and taurine conjugate (m/z 510) forms and monohydroxy-oxo-cholenoic acids presents in the glycine conjugate (m/z 444) and the taurine conjugate (m/z 494) forms. Peaks attributable to the glycine and taurine conjugates of chenodeoxycholic acid and cholic acid (m/z 448, 464, 498, and 514) were present in traces or undetectable above background^[5]. A second urine sample was taken at 17 mo of age, when the patient was treated with UDCA (250 mg/d). Liver function test (LFT) was normal, with slightly elevated aminotransferase. The FAB-MS analysis showed that the largest bile acid peaks were consistent with ursodeoxycholic acid metabolite (m/z 528), a dihydroxy-oxo-cholenoic acid present as the glycine conjugate (m/z 460) and a monohydroxy-oxo-cholenoic acid present as the glycine conjugate (m/z 444).

For the second patient, a urine sample was taken at 3 mo of age, when he was treated with UDCA (100 mg/d). LFT had improved but was not completely normal. The FAB-MS analysis was similar to that for patient 1.

Genetic analysis

The study protocol conforms to the ethical guidelines of the Declaration of Helsinki of 1975. With the approval

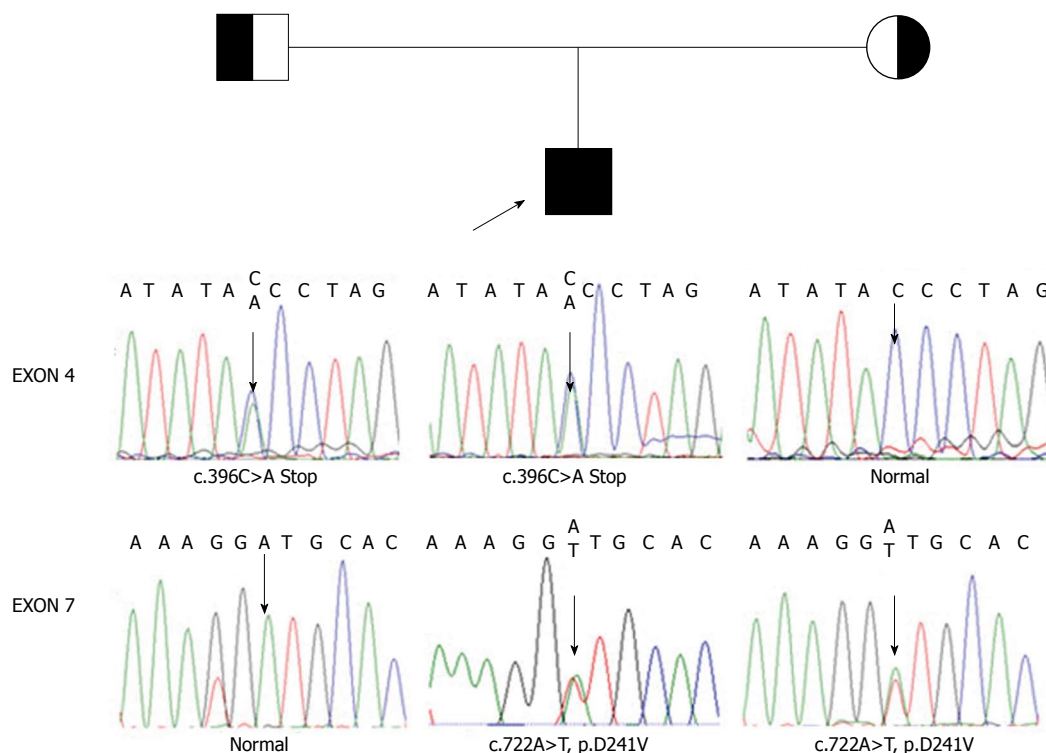

Figure 2 Pedigree for patient 2 shown with genomic DNA sequences in exons 4 and 7 of the *aldo-keto reductase 1D1* gene in patient 2 and his parents. The arrow in exon 4 identified C/A in patient 2s and his father, but C in his mother. The arrow in exon 7 identified A/T in patient 2 and his mother, but T in his father. These represent compound heterozygote with c.396C>A (nonsense mutation) from his father and c.722A>T (p.D241V) from his mother.

by the Ethics Committee on human research of the Children's Hospital of Fudan University and the informed consent of the parents, 1 mL of whole blood was drawn from the patient and his parents. To confirm the diagnosis and establish the molecular basis of the disorder, genomic DNA was isolated from the white blood cells. Then, we sequenced all of the coding exons and adjacent intronic sequence of the *AKR1D1* gene. Patient 1 was found to be heterozygous for c.797G>A in exon 7, which leads to an amino acid substitution of arginine by glutamine at amino acid position 266 (p.R266Q) (Figure 1). Patient 2 was revealed to be compound heterozygous for c.396C>A (nonsense mutation) and c.722A>T (p.D241V), the former from his father and the latter from his mother (Figure 2).

Management and treatment

Patient 1 was treated with UDCA (40 mg/kg per day) for 5 mo. Liver transaminase concentration was normalized (Figure 3A), and the degree of hepatomegaly was markedly reduced. Jaundice has improved and disappeared. Recently, liver function tests showed TBil 6.7 $\mu\text{mol/L}$, DBil 2.9 $\mu\text{mol/L}$, ALT 8 IU/L, AST 16 IU/L, and GGT 10 IU/L.

Patient 2 was treated with UDCA (40 mg/kg per day) for 4 mo. The liver transaminase concentration was normalized, and the degree of hepatomegaly was markedly reduced. Jaundice has improved and disappeared. After FAB-MS analysis of urine bile acid, the patient was given chenodeoxycholic acid (CDCA, 25 mg/kg per day)

instead of UDCA for 4 mo. After the CDCA was discontinued, the patient's total bilirubin and alanine aminotransferase was normal (Figure 3). However, the patient was not normally responsive to both visual stimuli and auditory stimuli. Magnetic resonance imaging at the age of 13 mo showed cerebral dysplasia with abnormally low levels of white matter.

DISCUSSION

Primary $\Delta 4$ -3-oxosteroid 5 β -reductase deficiency, first reported by Setchell *et al*^[6], is an extremely rare condition. We diagnosed two Chinese infants, both of whom presented with neonatal progressive intrahepatic cholestasis with markedly elevated serum conjugated bilirubin and aminotransferase but normal serum TBA and normal or slightly elevated GGT. Diagnosis of CBAS 2 was established by FAB-MS analysis of urinary bile acids and genetic analysis. According to clinical features and biochemical findings, bile acid synthesis deficiency was highly suspected^[1,7,8]. However, analyses of the bile acid profile and *AKR1D1* gene sequence were not available in our center at that time. Our patients were given a large dose of UDCA combined with a fat-soluble vitamin supplement, which was inadvertently found to produce a good response in our patients with CBAS 1.

The first urine sample of patient 1 was collected when UDCA (150 mg/d) was stopped 7 d, although there are several ions that may represent bile acid metabolites that are usually observed with UDCA therapy for metabolism

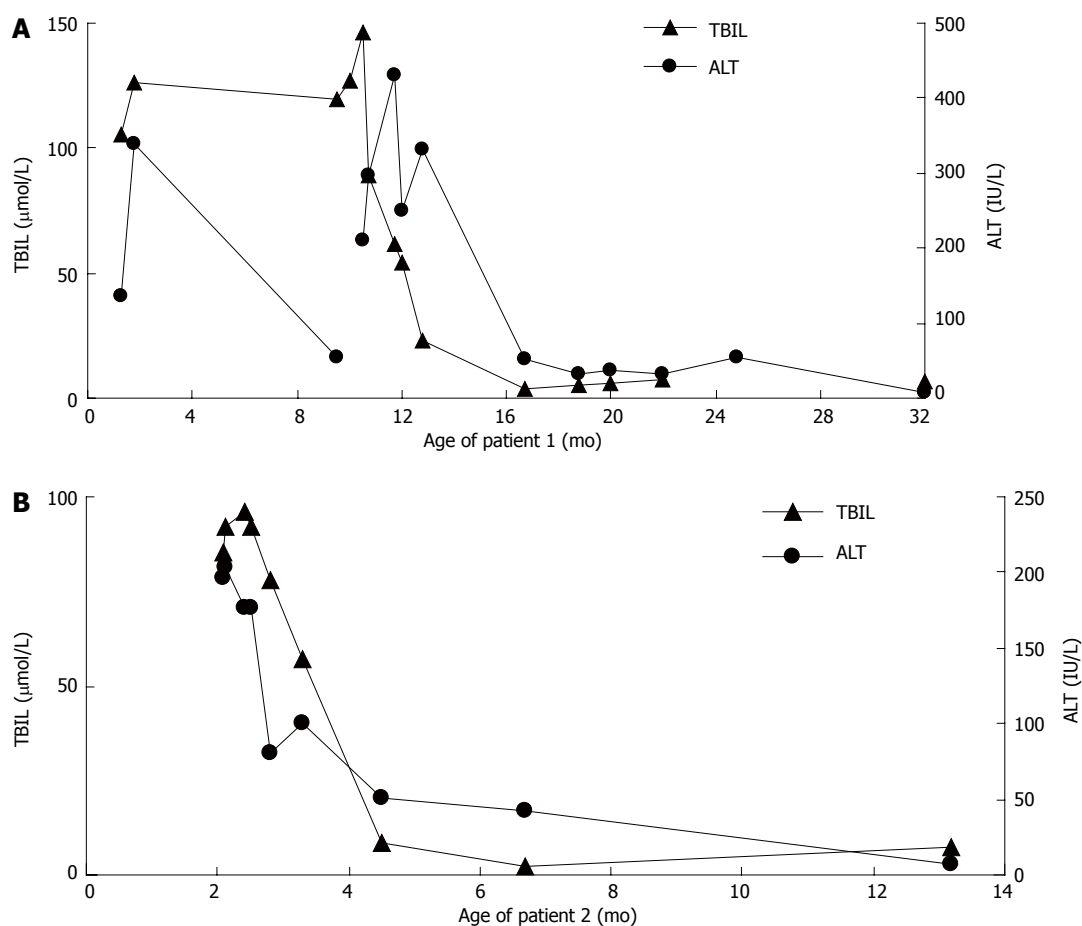

Figure 3 The responds of total bilirubin and alanine aminotransferase to treatment with ursodeoxycholic acid and/or chenodeoxycholic acid. A: Patient 1; B: Patient 2. TBIL: Total bilirubin; ALT: Alanine aminotransaminase.

of UDCA may be present, the profile was conspicuous by lack of normal primary bile acid conjugates that are characteristic of a bile acid synthetic defect involving a deficiency in the activity of the $\Delta 4$ -3-oxosteroid 5β -reductase deficiency. The second urine sample of patient 1 and the urine sample of patient 2 were collected when UDCA therapies were administered. The profiles were complicated by several ions that represent bile acid metabolites usually observed with UDCA therapy. Both were highly probable that these were primary defects in bile acid synthesis^[6]. To definitively confirm a primary defect^[4], we sequenced all the coding exons and adjacent intronic sequence of the *AKR1D1* gene.

Three new mutations in *AKR1D1* exons were detected in our patients, all of which altered the sequence and function of protein and were predicted to be disease causing by Mutation Taster (<http://www.mutationtaster.org/>). All of the altered amino acid loci are highly conserved among orthologous proteins in different species. There were two patients reported who were found with just one heterozygote mutation^[4]. We sequenced all the coding exons and adjacent intronic sequence of the *AKR1D1* gene, another heterozygous mutation might be outside the coding and splicing sequence or there might be a large DNA genomic aberration which couldn't be

found in Sanger sequencing^[4,8]. Based on biochemical changes in urine bile acids and mutations in *AKR1D1* gene, the diagnosis of CBAS 2 in both patients was confirmed.

UDCA is not recommended to be used in treatment of patients with the *AKR1D1* deficiency, because it has no ability to downregulate endogenous bile acid synthesis and prevent continued synthesis of atypical and potentially hepatotoxic bile acid intermediates and their metabolites^[9]. However, an analysis of the urinary bile acids of patient 1 showed that, even after liver function had normalized, large amounts of abnormal bile acids and UDCA remained. In addition, patient 2, who was treated by UDCA followed by CDCA, showed cerebral dysplasia with low levels of white matter. However, it would be difficult to determine whether this injury was due to the deficiency of delta 4-3-oxosteroid 5β -reductase and accumulation of abnormal bile acids in lipids in the cerebrum or intracranial space or to other metabolic complications.

In conclusion, we report the first two documented cases of CBAS 2 in Mainland China. Although rare, primary 3-oxo-delta 4-steroid 5β -reductase deficiency should be considered in patients with neonatal cholestatic jaundice with normal TBA and normal or slightly elevated GGT.

Abstract

Esophageal granular cell tumors (GCTs) are rare tumors of the esophagus. We evaluated the clinical and pathologic features of 9 esophageal GCT patients (5 men and 4 women) from our institute and reviewed the related disease literature. Patient age ranged from 25 to 53 years (mean: 41 years). All the patients were asymptomatic or presented with non-specific symptoms. Most GCTs occurred in the distal esophagus and were less than 6 mm in diameter. Computational analysis showed that the average gray-scale endoscopic ultrasound images of esophageal GCTs were greater than that of esophageal leiomyomas. Eight patients were treated by endoscopic resection, and 1 patient underwent surgical excision. No post-therapy recurrence or metastasis developed during follow-up (mean: 36.4 mo, range: 1-72 mo).

Key words: Esophageal granular cell tumor; Endoscopic

INTRODUCTION

Granular cell tumors (GCTs) are nerve sheath tumors composed of Schwann cells with granular cytoplasm^[1]. GCTs were first described in the 1920s by Abrikossoff in a series of 5 cases with benign tumors removed from the tongue. These tumors were once regarded as specific to skeletal muscle. However, subsequent studies identified GCTs in various other tissues, including skin, breast, respiratory tract, and biliary system^[1].

GCTs are relatively rare in the gastrointestinal tract, accounting for approximately 8% of all GCTs^[2,3]. Of these, only about 2% occur in the esophagus^[3]. Abrikossoff described the first case of an esophageal GCT in the early 1930s. To date, about 200 cases of esophageal GCTs have been described in the literature, mostly representing single case reports or small case series. Several aspects of esophageal GCTs remain to be elucidated, such as whether endoscopic ultrasound (EUS) can effectively diagnose the disease, what the appropriate management is, and whether GCTs undergo malignant degeneration. Therefore, we studied the clinical and pathologic features of esophageal GCTs by retrospectively analyzing all

esophageal GCT cases treated at our institution to address these unresolved issues.

CASE REPORT

Subjects

All the patients evaluated in this study were in- or outpatients treated at the First Affiliated Hospital, College of Medicine, Zhejiang University, between January 2001 and December 2011. All the patients were initially diagnosed with suspected esophageal submucosal protruding lesions (as revealed by conventional endoscopy), and were subsequently confirmed as GCT by histology. The study was approved by the hospital's ethics committee, and all the patients agreed to study participation.

EUS examinations

Patient preparation for EUS examinations was the same as those for conventional gastroscopy. The EUS equipment was composed of double cavity mirrors (Olympus GIF-2T 240), a mini-ultrasound probe with 12 MHz frequency, and the ultrasound device (Olympus EU M2000). Endoscopic specialists performed all operations, diagnoses, and therapeutic interventions.

Esophageal GCTs may be easily misdiagnosed as leiomyomas using EUS examination. To explore whether EUS can distinguish the two diseases by computer-aided image analysis, we compared the average gray-scale and gray-scale standard deviation of the EUS images for the two diseases. We selected the lesions with a range of interest for each of the cases, then determined the average gray-scale and gray standard deviation of the range of interest and compared the results for the two disease groups. The image analysis software was Photoshop CS2 9.0. The parameter indices of average gray-scale and gray standard deviation referred to the nature of echo and echogenicity, respectively.

Histological analysis

Eight cases underwent endoscopic resection, and the remaining case underwent surgical excision. The procedures for endoscopic resection of GCTs were the same as those used for other mucosal-based and submucosal esophageal lesions. In a case with esophageal GCT originating from the submucosa and having a diameter larger than 10 mm, the trans-thoracic operation was performed.

The tissue specimens obtained by endoscopic resection or surgical excision were fixed in 10% formalin and processed for paraffin embedding using standard methods. Sections of 4 mm thickness were stained with hematoxylin and eosin, and observed by light microscopy. Subsequently, specimens from all cases were stained for CD68, CD34, Ki-67, smooth muscle actin (SMA), S-100, GFAP, and p53 using standard immunohistochemistry techniques.

The criteria for histological diagnoses of GCT were: the tumor being mainly composed of larger tumor cells with cytoplasm rich in eosinophilic granules; the tumor cell morphology showing densely nested or stringy struc-

ture; the granules in the cytoplasm showing positive periodic acid-Schiff (PAS) staining; the tumor cells expressing S-100.

Follow-up examination and data analysis

To study the progression of GCTs, all the patients were followed-up with periodic endoscopic examination. Statistical analyses were performed using the SPSS 13.0 software for Windows. *P* values less than 0.05 (by a 2-tailed test) were considered statistically significant.

Results

The clinical characteristics of the patients are listed in Table 1. Our case series included 9 histologically confirmed esophageal GCT patients (5 men and 4 women). Patient age ranged from 25 to 53 years, with a mean age of 41 years. Of the 9 patients, 7 complained of nonspecific symptoms, including upper abdominal distension, poor appetite, belching, and acid reflux.

All 9 cases were initially diagnosed with suspected esophageal submucosal protruding lesions, as indicated by conventional endoscopy. The typical endoscopic appearance was isolated, tawny or grayish white submucosal nodules with the overlying mucosa being normal or slightly granular, without ulceration or mucosal depression (Figure 1). Seven cases involved the distal esophagus, and 2 cases involved the middle esophagus. Eight cases received computed tomography chest examination; all of which revealed a soft-tissue mass in the esophagus and partial narrowing of the esophageal lumen. The enhanced scan technique showed that all masses were moderately enhanced.

EUS was performed in 8 patients and showed that the tumors were slightly low echo and were circular or quasi-circular in shape. The surrounding esophageal structure appeared normal for all the lesions. Three cases originated from the mucosa, 2 from the submucosa, and 3 from the muscularis mucosa. The size of the tumors ranged from 4 to 11 mm in diameter. In comparison to esophageal leiomyomas, the esophageal GCTs showed slightly stronger echo. Quantitative gray-scale analysis confirmed this observation. Photoshop CS2 9.0 analysis of the EUS images of esophageal GCTs, compared to age-, sex-, size- and location-matched esophageal leiomyomas, indicated that the average gray-scale EUS images of esophageal GCTs were slightly and significantly greater than that of esophageal leiomyomas. Accordingly, we propose that the echo of GCTs may be stronger than that of esophageal leiomyomas.

Histological analysis showed that all tumors were composed of proliferating cells of slightly ovoid shape and with abundant eosinophilic granular cytoplasm. The tumors were PAS-positive. Diastase-resistant granules, representing lysosomes, were present within the cytoplasm of some cells. Immunohistological study showed that all the tumors were positive for S-100 and CD68, but negative for SMA, CD34, p53, GFAP, Ki-67, and CD117 (Figure 2).

No recurrence was observed after endoscopic or sur-

Table 1 Clinical characteristics of the patients with esophageal granular cell tumors

DISCUSSION

GCT is a rare type of esophageal submucosal tumor. Its character of dormant onset lends to the disease being overlooked or misdiagnosed. GCTs are female predominant^[4], and mainly occur in middle-age^[5,6]. In the current series of esophageal GCTs patients, the mean age was 41 years, but the sex distribution was more equal than in the collected literature. Since ethnicity may play a role in the development of GCTs^[7], the observed difference in sex distribution may reflect our patients' Chinese background. According to the collected literature, esophageal GCTs primarily occur in the distal esophagus. Orlowska *et al*^[6] reported that two-thirds of esophageal GCTs were found in the distal esophagus, with only 20% and 15% in the middle and proximal esophagus, respectively. Another case series reported by Goldblum *et al*^[5] showed that 12 of 13 patients had distal esophageal GCT. Similarly, our case series included 7 cases with GCTs in the distal esophagus, and only 2 cases of GCT in the middle esophagus.

In general, esophageal GCTs are initially observed by conventional gastroscopy and confirmed by histological analysis. The ability of EUS to show the size, origin, borders, and echo structure of the submucosal lesion, has dramatically improved the diagnostic accuracy for submucosal disorders^[8]. However, EUS may still misdiagnose some lesions with similar imaging features, such as esophageal GCTs and leiomyomas. In the current study, we applied computer-aided analysis techniques to comparatively analyze the ultrasound images of GCTs and leiomyomas. Our results showed that the gray value of esophageal GCTs was slightly, but significantly, greater than that of esophageal leiomyomas. This suggests that the EUS echo of esophageal GCTs is higher than that of leiomyomas, which possibly represents a discriminating feature of esophageal GCTs and leiomyomas. This feature may aid in the differential analysis of gray values on EUS images and help to improve the preoperative diagnostic accuracy of esophageal GCTs and possibly stimulate ideas for new strategies for earlier diagnosis and more effective treatment.

GCTs are potential malignant tumors. Fanburg-Smith *et al*^[9] proposed the first histological criteria for prospectively diagnosing malignancy in GCTs, which include tumor cell necrosis, tumor cell spindling, increased nuclear size, large nucleoli, mitotic activity, and nuclear pleomorphism. Due to the potential for malignancy, endoscopic resection or surgical excision is recommended for patients with esophageal GCTs. In the current study, 8 cases were treated by endoscopic resection and one

case was treated by surgical excision. All the patients were followed-up with periodic endoscopic examinations, during which no recurrence was detected. Our experience, as well as that of other treating physicians reported in the literature, defines endoscopic resection as a safe and effective therapeutic choice for esophageal GCTs^[10-12].

In conclusion, GCTs are uncommon esophageal tumors, which are mainly asymptomatic and located in the distal esophagus of middle-age subjects. Histology remains the gold standard for diagnosis of esophageal GCTs, while EUS may also provide important diagnostic information. Endoscopic resection or surgical excision should be performed due to the potential for malignancy.

Abstract

Hemobilia is a rare biliary complication of liver transplantation. The predominant cause of hemobilia is iatrogenic, and it is often associated with traumatic operations, such as percutaneous liver intervention, endoscopic retrograde cholangiopancreatography, cholecystectomy, biliary tract surgery, and liver transplantation. Percutaneous transhepatic cholangiography and liver biopsy are two major causes of hemobilia in liver transplant recipients. Hemobilia may also be caused by coagulation defects. It can form intracholedochal hematomas, causing obstructive jaundice. Herein we describe a patient with an intracholedochal hematoma resulting in significant obstructive jaundice after liver transplantation for fulminant hepatic failure. Previous studies have

INTRODUCTION

Fulminant hepatic failure is a syndrome characterized by impaired liver function in an acute setting. It is defined as the onset of hepatic encephalopathy and liver failure within 8 wk of jaundice^[1]. Liver transplantation remains the exclusive choice of treatment to improve the survival in the majority of patients with fulminant hepatic failure^[2]. Biliary complications following liver transplantation are a major cause of morbidity, but hemobilia is infrequent^[3]. Hemobilia may result in intracholedochal hematoma, causing obstructive jaundice. The current report describes a patient with intracholedochal hematoma leading to significant obstructive jaundice after liver transplantation for fulminant hepatic failure.

CASE REPORT

A 23-year-old female was admitted on July 15, 2010 with complaints of abdominal pain and distension, accompanied by fever, dark yellow urine, and xanthochromia for the past three days. The patient had been treated for psoriasis with traditional Chinese medicine for three months prior to admission. In addition, she had a 16-year history of hepatitis B virus infection. Despite being a carrier of the hepatitis B virus, the patient had no history of hepatitis and liver function tests had been normal during the follow-up.

On physical examination, the patient was conscious, and her orientation and calculations were normal. Jaundice was evident. The abdomen was slightly distended and soft, with tenderness and rebound tenderness, and a shifting dullness test was positive. The serum transaminase and total bilirubin levels were markedly elevated on admission. The laboratory test results were as follows: alanine transaminase (ALT), 5190 U/L; aspartate transaminase (AST), 7230 U/L; total bilirubin (TBIL), 142.8 $\mu\text{mol/L}$; and direct bilirubin (DBIL), 83.3 $\mu\text{mol/L}$ (Figure 1). The prothrombin time (PT) and activated partial thromboplastin time (APTT) were 26.5 s and 41.5 s, respectively. The international normalized ratio (INR) was 2.39. These results suggested significant impairment of coagulation function. In addition, serum hepatitis B virus DNA was present at 4.6×10^7 copies/mL.

The patient was treated with artificial liver support (ALS)-plasma exchange due to diminished liver function and impaired coagulation. Although the laboratory indicators improved (Figure 1), hepatic encephalopathy occurred and worsened progressively. Therefore, fulminant hepatic failure was diagnosed. On July 21, 2010 (post-admission day 7), the patient suffered a coma without pupillary light reflex, although the vital signs were stable. The patient underwent liver transplantation on July 23, 2010. A modified piggyback liver transplantation was carried out, and an end-to-end duct-to-duct anastomosis without a T-tube was performed to reconstruct the biliary tract. A continuous 6-0 polydioxanone suture was used for the posterior wall while interrupted sutures were applied for the anterior wall. She was maintained on a tacrolimus-based immunosuppressive regimen that included mycophenolate mofetil and glucocorticoid.

The patient regained consciousness on July 25, 2010 [post-transplantation day (PTD) 2]. The liver and coagulation functions were significantly improved. On PTD 4, the laboratory data were as follows: ALT, 553.8 U/L; AST, 187.4 U/L; TBIL, 58.7 $\mu\text{mol/L}$; DBIL, 28.5 $\mu\text{mol/L}$ (Figure 1); albumin, 37.2 g/L; PT, 9.2 s; APTT, 21.9 s; INR, 0.83; serum tacrolimus, 12.2 ng/mL; hemoglobin, 100 g/L; and platelet count, $61 \times 10^9/\text{L}$. Because red blood cells, plasma, and cryoprecipitate were transfused without platelets following a massive intra-operative hemorrhage (approximately 2500 mL), dilutional thrombocytopenia was diagnosed. Platelets were then transfused to treat the thrombocytopenia; however, the right leg became edema-

Figure 1 Laboratory test results of physical examination. A: Blood concentration of transaminases markedly decreased after artificial liver support (ALS)-plasma exchange, increased after liver transplantation due to ischemia reperfusion injury, and reached a peak on post-transplantation day 2, then decreased gradually to normal; B: Blood concentration of bilirubin. There are four marked peaks: bilirubin increased due to fulminant liver failure and decreased after two ALS-plasma exchanges, forming peaks 1 and 2; bilirubin increased after liver transplantation due to ischemia reperfusion injury and reached a peak, forming peak 3; bilirubin increased markedly because of the intrahepatic biliary ductal hematoma and decreased after percutaneous transhepatic intervention, forming peak 4.

tous on PTD 3. Doppler ultrasound revealed a thrombus in the femoral vein (Figure 2), which was punctured due to the ALS-plasma exchange. Subsequently, low molecular weight heparin (LMWH) was used to treat the deep venous thrombosis which relieved the edema, but the volume of bloody ascites gradually increased. On PTD 5, the hemoglobin decreased to 77 g/L. Anticoagulation was therefore discontinued and blood was transfused. However, the jaundice became severe again. On PTD 10, the TBIL was 281.2 $\mu\text{mol/L}$, and the DBIL was 154.7 $\mu\text{mol/L}$ (Figure 1). A computed tomography (CT) scan showed dilation of the intrahepatic biliary ducts and a huge hematoma below the right lobe of liver (Figure 3A). Therefore, obstructive jaundice was suspected.

To confirm the diagnosis of obstructive jaundice and relieve the biliary obstruction, endoscopic retrograde

Figure 2 Doppler ultrasound shows a thrombus in the right femoral vein. A: Axial plane; B: Sagittal plane. A.F.S.: Superficial femoral artery; V.FEM.S: Superficial femoral vein; V.P.F: Profound femoral vein.

cholangiopancreatography was performed, but failed and caused pancreatitis. So as an alternative, percutaneous transhepatic intervention was administered on PTD 10. Cholangiography showed a long intrabiliary filling defect crossing the strictured biliary anastomosis (Figure 3B). As fecal occult blood testing was positive, hemobilia leading to biliary hematoma was suspected. A 0.018-inch diameter micro-guidewire, a 6F sheath, a 0.038-inch diameter micro-guidewire, and an 8F catheter were manipulated through the hematoma sequentially, making the hematoma break into pieces, enlarging the contact surface with flowing bile and making it easy to dissolve. Then the 8F biliary drainage catheter was placed across the anastomosis with one end opening into the duodenum and the other end exiting the body (Figure 3C). The amount of biliary drainage was approximately 400 mL per day, and the jaundice was markedly relieved 2 d later (TBIL, 114.1 $\mu\text{mol/L}$; DBIL, 58.9 $\mu\text{mol/L}$) (Figure 1). The patient recovered well and the jaundice gradually diminished 10 d after percutaneous transhepatic biliary drainage (PTBD); when the TBIL was 55.5 $\mu\text{mol/L}$, the external end of the biliary drainage catheter was closed. The glucocorticoid was gradually tapered and discontinued on PTD 30. On September 14, 2010 (PTD 54), she experienced no more discomfort and the TBIL was 35.3 $\mu\text{mol/L}$ (Figure 1). The patient was discharged the next day with the biliary drainage catheter *in situ* and the external port closed.

At the first follow-up evaluation on January 29, 2011, magnetic resonance cholangiopancreatography showed the intrahepatic biliary ducts were slightly dilated (Figure 3D). A CT scan revealed that the hematoma below the liver was almost absorbed and the intrahepatic biliary ducts were slightly dilated (Figure 3E). The liver function tests were within normal ranges: TBIL, 11.3 $\mu\text{mol/L}$; DBIL, 3.5 $\mu\text{mol/L}$; ALT, 15.0 U/L; AST, 22.1 U/L (Figure 1). The serum tacrolimus was 8.4 ng/mL. Cholangiography was also performed through the biliary drainage catheter, showing that the intrahepatic biliary ducts were slightly dilated and that there was a stricture at the site of the anastomosis (Figure 4A). To prevent a more severe stricture and obstructive jaundice, a balloon dilatation

of the anastomotic stricture was performed (Figure 4B) to relieve the stricture (Figure 4C). To avoid the risk of infection and stenosis of the lumen, the biliary drainage catheter was replaced with a new catheter (Figure 4D). In addition, the mycophenolate mofetil was discontinued 6 mo after liver transplantation. The patient was then maintained on immunosuppressive therapy with tacrolimus (3 mg/d). Two weeks later at the second follow-up evaluation, the biliary drainage catheter was removed. During the one-year follow-up, the patient had no discomfort and her liver functions remained normal.

DISCUSSION

Biliary complications are a major cause of morbidity in liver transplant recipients, with an incidence of 10%-30% and a mortality rate of up to 10%. Biliary leaks and strictures are the most common biliary complications, followed by sphincter of Oddi dysfunction, hemobilia, and biliary obstruction from stones, sludge, casts, or cystic duct mucocoeles^[3]. Hemobilia is defined as bleeding into the biliary tree. Hemobilia arises when there is communication between a vascular structure and the biliary tree. The predominant cause of hemobilia is iatrogenic, such as percutaneous liver intervention, endoscopic retrograde cholangiopancreatography, cholecystectomy, biliary tract surgery, and liver transplantation^[4]. Percutaneous transhepatic cholangiography and liver biopsy are two major causes of hemobilia in liver transplant recipients^[3]. In addition, coagulation defects may cause hemobilia^[5]. Jolobe^[6] reported that hemobilia is a possible cause of jaundice in patients receiving anticoagulants, although hemobilia after liver transplantation is infrequent^[3,4]. The LMWH used to treat the thrombosis within the right femoral vein may be the cause of hemobilia in the current case.

The clinical manifestations of hemobilia are determined by the amount and speed of hemorrhage in the biliary tract. Profuse hemobilia often causes severe symptoms with colicky pain and gastrointestinal hemorrhage. In contrast, occult bleeding, which is more frequent, often lacks clinical significance as the blood inconspicuously flows into the intestine. Even if the blood does coagulate within the ducts, the clots are often promptly dissolved by the fibrinolytic activity of bile. Sometimes, the clots may escape dissolution, causing obstructive jaundice^[5]. Sandblom *et al*^[7] constructed a model of the biliary tract into which blood could be injected. When hemorrhage is severe and rapid, the blood mixes with the bile and forms mushy clots; when hemobilia is minor and slow, it does not mix with the bile, but flows into the bottom of the system where it forms a solid, pure clot that is a cast of the lumen. These pure clots remain stable, whereas the mixed clots dissolve rapidly. Sandblom *et al*^[5,7] also reported that the fate of clots is related to the bile flow, especially noting that when the clots are exposed to flowing bile, the dissolution is rapid. Our case is very interesting because hemobilia occurred with an

Figure 3 Diagnosis of obstructive jaundice. A: Before percutaneous transhepatic intervention, on computed tomography (CT) scan, intrahepatic biliary ducts are dilated and a huge hematoma is present below the right lobe of liver; B: Percutaneous transhepatic cholangiography shows a long intrabiliary filling defect (white arrow) crossing the strictured biliary anastomosis (black arrow); C: An 8F biliary drainage catheter was placed across the anastomosis with one end opening into the duodenum and the other end exiting the body; D: On magnetic resonance cholangiopancreatography, the intrahepatic biliary ducts were slightly dilated at the first follow-up; E: CT reveals that the hematoma below the liver was almost absorbed and the intrahepatic biliary ducts were slightly dilated at the first follow-up.

abdominal hemorrhage after administration of LMWH, and the biliary clot and the huge subhepatic hematoma formed simultaneously after discontinuation of LMWH. The abdominal hemorrhage was massive, causing the hemoglobin to decrease sharply. The hemobilia, however, was minor because there was no evidence of significant gastrointestinal bleeding.

The principles of managing hemobilia are to resuscitate the patient, control hemorrhage, and maintain biliary patency. Resuscitation with transfusion must be administered to obtain hemodynamic stability when the hemorrhage is severe and rapid. Additionally, coagulopathies should be corrected appropriately. When hemorrhage is active and prolonged, hemostatic interventions should be considered, including transcatheter arterial embolization (TAE), percutaneous thrombin injection, and surgery. TAE is the therapy of choice to achieve hemostasis, with a success rate of 75%-100%^[6]; however, TAE may not be appropriate in liver transplant patients because it can cause liver graft dysfunction and biliary ischemia. These complications are devastating, especially in the early post-transplantation period. Croutch *et al*^[8] reported that superselective arterial embolization is a safe treatment for hemobilia caused by PTBD in liver transplant recipients, and emphasized that it is important to use a microcatheter to achieve precise subselective localization and embolization, minimize spasm, and avoid occlusion of noninvolved arterial branches. In spite of this, the cases were all due to PTBD, which often causes small branches to bleed into bile ducts. For cases of hemobilia in anasto-

mosis or due to coagulopathy, TAE may not be appropriate.

If bleeding ceases and a biliary hematoma forms leading to biliary obstruction, it is important to maintain biliary patency. If a T-tube or PTBD is *in situ*, irrigation may be adequate to relieve obstruction; however, in recent years there has been a shift toward abandoning the use of T-tubes for biliary tract reconstruction because some studies have shown that biliary complications are positively related to T-tubes, such as biliary leakage after T-tube removal, anastomotic strictures, cholangitis, and biliary infections^[9]. Endoscopic nasobiliary drainage can also be used to decompress the biliary tract. It has been reported that endoscopic sphincterotomy with balloon extraction of clots could be an effective method to treat biliary clots^[4,10]. In addition, thrombolytic agents could be infused using a nasobiliary catheter to dissolve the biliary clots^[11]. Although the role of surgery is declining in the management of hemobilia and biliary clots, surgery is still indicated when non-surgical methods are not effective. The principles of surgery for hemobilia are to control the bleeding and clear the biliary tract. Methods involving ligation of the bleeding vessels, extraction of the biliary clots, lavage and biliary tract drainage are often used^[4,12].

In our case, percutaneous transhepatic intervention was used to break up the biliary hematoma and relieve bile stasis. During this intervention, a 0.018-inch diameter micro-guidewire, a 6F sheath, a 0.038-inch diameter micro-guidewire, and an 8F catheter were manipulated through the hematoma sequentially, breaking the hematoma up

Figure 4 Cholangiography was performed through the biliary drainage catheter. A: At the first follow-up, percutaneous transhepatic cholangiography shows the slightly dilated intrahepatic biliary ducts and a stricture at the site of anastomosis; B: Balloon dilatation of the anastomotic stricture; C: Anastomotic stricture was relieved after balloon dilatation; D: A new biliary drainage catheter was placed.

into pieces, enlarging the contact surface with flowing bile and making it easy to dissolve. Our case provides good proof of the principles underlying Sandblom's clinical and experimental study. Previous studies suggested that percutaneous transhepatic manipulations were major causes of hemobilia after liver transplantation^[3], but in our case, percutaneous transhepatic intervention was used to relieve the biliary obstruction and dissolve the biliary clot with a good outcome.

Abstract

Gastric intramural hematoma is a rare injury of the stomach, and is most often seen in patients with underlying disease. Such injury following endoscopic therapy is even rarer, and there are no universally accepted guidelines for its treatment. In this case report, we describe a gastric intramural hematoma which occurred within 6 h of endoscopic mucosal resection (EMR). Past medical history of this patient was negative, and laboratory examinations revealed normal coagulation profiles and platelet count. Following EMR, the patient experienced severe epigastric pain and vomited 150 mL of gastric contents which were bright red in color. Subsequent emergency endoscopy showed a 4 cm × 5 cm diverticulum-like defect in the anterior gastric antrum wall and a 4 cm × 8 cm intramural hematoma adjacent to the endoscopic submucosal dissection lesion. Following unsatisfactory temporary conservative management, the patient was treated surgically and made a complete recovery. Retrospectively, one possible reason for the patient's condition is that the arterioles in the submucosa or muscularis may have been damaged during deep and massive submucosal injection. Thus, endoscopists should be aware of this potential compli-

cation and improve the level of surgery, especially the skills required for submucosal injection.

INTRODUCTION

Gastric intramural hematoma is an uncommon disorder. Previously reported cases were caused by coagulopathy, trauma, aneurysm, peptic ulcer disease, pancreatitis, endoscopic therapy or spontaneous hematomas^[1-3]. However, gastric intramural hematoma after endoscopic intervention is even rarer. Here, we describe a gastric intramural hematoma accompanied by severe epigastric pain and hematemesis which occurred within 6 h of endoscopic mucosal resection (EMR).

CASE REPORT

A 33-year-old man had dull epigastric pain for 3 mo, and endoscopy showed a 0.4 cm × 0.5 cm polypoid protrusive lesion in the stomach antrum (Figure 1A). He was admitted for endoscopic treatment. He had no notewor-

Figure 1 Subepithelial tumor in the stomach antrum. A: Endoscopic examination showed a subepithelial tumor in the antrum; B: Endoscopic ultrasonography revealed that the tumor was localized in the mucosal layer.

Figure 2 Endoscopic mucosal resection. A: After injection of 15 mL saline, the whole nidus was lifted satisfactorily. However, an area of the uplifted mucosal layer was slightly blue; B: The lesion was successfully removed by high-frequency electrocoagulation, and a white wound was observed.

Figure 3 Pathologic examination revealed that the removed lesion from the gastric antrum was a tubular adenoma and *Helicobacter pylori* was not found.

thy medical history, and laboratory examinations showed the following: white blood cell count $8.14 \times 10^9/L$, hemoglobin 151 g/L, platelet count $206 \times 10^9/L$, prothrombin time 9.8 s, and activated partial thromboplastin time 26.7 s. Endoscopic ultrasonography showed that the lesion was localized in the mucosal layer (Figure 1B). Following discussion with the patient and his wife, EMR was carried out. He was given a submucosal 5-mL saline injection, and the nidus was not uplifted satisfactorily.

The operator then slowly injected another 10 mL saline into the distal lesion until the result was satisfactory (Figure 2A). The lesion was successfully removed by high-frequency electrocoagulation, and a white wound was observed (Figure 2B). The removed lesion was sent for pathologic examination which later revealed tubular adenoma and negative *Helicobacter pylori* infection (Figure 3). The patient's condition was stable after surgery. He received 40 mg omeprazole intravenously, and walked into the ward.

Half an hour after surgery, the patient experienced sudden persistent epigastric pain and paroxysmal colic without nausea or vomiting. He received an injection of anisodamine. Bedside ultrasonography of the abdomen did not reveal any apparent abnormalities, and the levels of serum lipase and amylase were normal. Although his pain was slightly reduced, he continued to have intermittent upper abdominal pain. Two hours later, he vomited 150 mL of gastric contents which were bright red in color. After vomiting, his epigastric pain was slightly reduced, and his vital signs were stable. Emergency plain film of the abdomen (KUB) did not reveal radiological evidence of a perforated viscus, and emergency endoscopy showed a 4 cm \times 5 cm diverticulum-like defect (Figure 4A) on the anterior gastric antrum wall, there was also a 4 cm \times 8 cm intramural hematoma on the greater curvature side of the lower gastric body adjacent to the EMR

Figure 4 Emergency endoscopy. A: A 4 cm × 5 cm diverticulum-like defect in anterior gastric antrum wall; B: A 4 cm × 8 cm intramural hematoma adjacent to the endoscopic submucosal dissection lesion and active bleeding.

wound, and active bleeding was observed (Figure 4B). Gastrointestinal decompression was performed. After 4 h observation, the patient still had intense paroxysmal pain, and 100 mL of blood was drained from the stomach. He underwent emergency laparotomy under endoscopic guidance, and approximately 300 mL intragastric blood was found. There was a 4 cm × 5 cm × 8 cm intramural hematoma on the distal anterior gastric wall, and the gastric wall was intact with no evidence of perforation. An incision was made in the gastric wall, and the hematoma in the stomach and gastric wall was evacuated manually. The area of suspicious bleeding in the gastric wall was sutured, and no source of active bleeding was identified. The operators sutured the EMR wound, and a subhepatic drain was inserted.

Recovery was uneventful and the patient was allowed oral intake three days after surgery. There was no evidence of gastric leak upon commencing diet, and the subhepatic drain was removed one week later. The patient was well at discharge. At the one-year follow-up, he was well and without complications.

DISCUSSION

Recently, EMR and endoscopic submucosal dissection (ESD) have been widely used. The most common complications of these endoscopic techniques are bleeding and perforation. Intraoperative and postoperative gastric intramural hematomas are clinically rare. EMR and ESD have been used in our hospital for 5 years, and this is the first case of postoperative gastric intramural hematoma. To date, there is only one reported case of intraoperative gastric intramural hematoma, which occurred during ESD^[4].

The pathological changes related to hematoma are damaged vessels and blood is confined to the space around the vessels. In previously reported cases, gastric intramural hematomas can result from coagulopathy, trauma, aneurysm, peptic ulcer disease, pancreatitis, repeated vomiting or spontaneous hematomas^[1,2]. However, the past medical history of our patient was entirely negative, and laboratory examinations showed normal

coagulation profiles and platelet count.

It is well known that there are few blood vessels in the gastric mucosal layer, while the submucosa and muscularis contain many blood vessels. Before lesion excision, ESD or EMR operators should inject hypertonic saline mixed with methylene blue around the lesion, to lift the lesion and completely separate the mucosal layer and muscularis. Thus, the wound would be confined to the submucosa, the muscularis would not be damaged, and complications would be very infrequent. In our case, the probable reasons for gastric intramural hematoma were that the very deep submucosal injection (retrospectively, lifting of the mucosal layer was slightly unsatisfactory, and the muscularis may have been injected), massive submucosal injection (15 mL), and arterioles in the submucosa or muscularis may have been damaged during submucosal injection. The blood from the damaged arterioles was confined between the submucosa and muscularis and formed a hematoma. As the hematoma grew, the mucosal layer was torn and the patient experienced epigastric pain. As the pressure increased, blood entered the gastric cavity from the EMR wound, and the patient vomited bright red gastric contents.

There is no established standard therapy for gastric intramural hematoma. In previous reports, most patients recovered following conservative management; however, surgery or arterial embolization may be necessary, depending on the patient's status^[1,3]. Although there was no radiographic evidence of perforation in our patient, he had severe epigastric pain and vomited blood. In order to avoid serious complications, a laparotomy was selected instead of conservative treatment in this patient.

Reported cases of gastrointestinal intramural hematoma following endoscopic procedures are very few and mostly confined to the esophagus^[5]. This type of gastric intramural hematoma is extremely rare, however, several authors have reported the incidence of gastric intramural hematoma following endoscopic therapy^[3,4,6]. Gastric intramural hematoma is dangerous, and can cause misery for the sufferer. When carrying out endoscopic procedures, endoscopists should be aware of this potential complication. In addition, endoscopists should improve

the level of surgery, especially the skills required for sub-mucosal injection.

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 ± 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

**EDITORIAL**

- 7131 Matrix metalloproteinase-9: A deleterious link between hepatic ischemia-reperfusion and colorectal cancer
Lenglet S, Mach F, Montecucco F

REVIEW

- 7134 Carcinoma of the gastroesophageal junction in Chinese patients
Huang Q
- 7141 Role of autoimmunity in primary biliary cirrhosis
Shi TY, Zhang FC
- 7149 Diagnostic and therapeutic progress of multi-drug resistance with anti-HBV nucleos(t)ide analogues
Song ZL, Cui YJ, Zheng WP, Teng DH, Zheng H

ORIGINAL ARTICLE

- 7158 *Gardenia jasminoides* attenuates hepatocellular injury and fibrosis in bile duct-ligated rats and human hepatic stellate cells
Chen YH, Lan T, Li J, Qiu CH, Wu T, Gou HJ, Lu MQ
- 7166 Oridonin induces apoptosis in gastric cancer through Apaf-1, cytochrome c and caspase-3 signaling pathway
Sun KW, Ma YY, Guan TP, Xia YJ, Shao CM, Chen LG, Ren YJ, Yao HB, Yang Q, He XJ
- 7175 Age-related symptom and life quality changes in women with irritable bowel syndrome
Tang YR, Yang WW, Liang ML, Xu XY, Wang MF, Lin L
- 7184 Mechanisms of cholecystokinin-induced calcium mobilization in gastric antral interstitial cells of Cajal
Gong YY, Si XM, Lin L, Lu J
- 7194 Establishment of a rat liver transplantation model with prolonged biliary warm ischemia time
Zhu XH, Pan JP, Wu YF, Ding YT
- 7201 Electroacupuncture alleviates stress-induced visceral hypersensitivity through an opioid system in rats
Zhou YY, Wanner NJ, Xiao Y, Shi XZ, Jiang XH, Gu JG, Xu GY

- 7212 Comparative genomic study of gastric epithelial cells co-cultured with *Helicobacter pylori*
Wang F, Luo LD, Pan JH, Huang LH, Lv HW, Guo Q, Xu CX, Shen SR
- 7225 Magnetic resonance-based total liver volume and magnetic resonance-diffusion weighted imaging for staging liver fibrosis in mini-pigs
Li H, Chen TW, Chen XL, Zhang XM, Li ZL, Zeng NL, Zhou L, Wang LY, Tang HJ, Li CP, Li L, Xie XY
- 7234 Adult-to-adult living donor liver transplantation for acute liver failure in China
Yuan D, Liu F, Wei YG, Li B, Yan LN, Wen TF, Zhao JC, Zeng Y, Chen KF
- 7242 Highlights for α -fetoprotein in determining prognosis and treatment monitoring for hepatocellular carcinoma
Xu XS, Qu K, Liu C, Zhang YL, Liu J, Song YZ, Zhang P, Liu SN, Chang HL
- 7251 Single nucleotide polymorphisms in the *CDH17* gene of colorectal carcinoma
Chen RY, Cao JJ, Chen J, Yang JP, Liu XB, Zhao GQ, Zhang YF
- 7262 Notch2 regulates matrix metalloproteinase 9 via PI3K/AKT signaling in human gastric carcinoma cell MKN-45
Guo LY, Li YM, Qiao L, Liu T, Du YY, Zhang JQ, He WT, Zhao YX, He DQ

BRIEF ARTICLE

- 7271 Impact of intestinal ischemia/reperfusion and lymph drainage on distant organs in rats
He GZ, Zhou KG, Zhang R, Wang YK, Chen XF
- 7279 Clinical features and risk factors of acute hepatitis E with severe jaundice
Xu B, Yu HB, Hui W, He JL, Wei LL, Wang Z, Guo XH
- 7285 Growth-inhibitory effects of MOB2 on human hepatic carcinoma cell line SMMC-7721
Leng JJ, Tan HM, Chen K, Shen WG, Tan JW
- 7290 *Ex-situ* liver surgery without veno-venous bypass
Zhang KM, Hu XW, Dong JH, Hong ZX, Wang ZH, Li GH, Qi RZ, Duan WD, Zhang SG
- 7296 Comparison between air and carbon dioxide insufflation in the endoscopic submucosal excavation of gastrointestinal stromal tumors
Shi WB, Wang ZH, Qu CY, Zhang Y, Jiang H, Zhou M, Chen Y, Xu LM

- 7302 Predictors and clinical outcomes for spontaneous rupture of hepatocellular carcinoma
Zhu Q, Li J, Yan JJ, Huang L, Wu MC, Yan YQ
- 7308 Short-term outcomes of laparoscopic total mesorectal excision compared to open surgery
Gong J, Shi DB, Li XX, Cai SJ, Guan ZQ, Xu Y
- 7314 Enteroenteroanastomosis near adjacent ileocecal valve in infants
Jiang WW, Xu XQ, Geng QM, Zhang J, Chen H, Lv XF, Lu CG, Tang WB
- 7319 High mobility group-box 3 overexpression is associated with poor prognosis of resected gastric adenocarcinoma
Tang HR, Luo XQ, Xu G, Wang Y, Feng ZJ, Xu H, Shi YW, Zhang Q, Wu LG, Xue CQ, Wang CW, Wu CY
- 7327 Donor safety and remnant liver volume in living donor liver transplantation
Shi ZR, Yan LN, Du CY
- 7333 Incidence of gastroesophageal reflux disease in Uyghur and Han Chinese adults in Urumqi
Niu CY, Zhou YL, Yan R, Mu NL, Gao BH, Wu FX, Luo JY
- 7341 Transjugular intrahepatic portosystemic shunt vs endoscopic therapy in preventing variceal rebleeding
Xue H, Zhang M, Pang JXQ, Yan F, Li YC, Lv LS, Yuan J, Palikhe M, Li WZ, Wang ZL
- 7348 c-Jun N-terminal kinase is required for thermotherapy-induced apoptosis in human gastric cancer cells
Xiao F, Liu B, Zhu QX
- 7357 Serum pepsinogen II is a better diagnostic marker in gastric cancer
Cao XY, Jia ZF, Jin MS, Cao DH, Kong F, Suo J, Jiang J

MATA-ANALYSIS

- 7362 A meta-analysis of the effects of energy intake on risk of digestive cancers
Yu XF, Wang YQ, Zou J, Dong J
- 7371 Itopride therapy for functional dyspepsia: A meta-analysis
Huang X, Lv B, Zhang S, Fan YH, Meng L

- 7378** Effect of dietary fiber on constipation: A meta analysis

Yang J, Wang HP, Zhou L, Xu CF

- 7384** Effectiveness of 5-fluorouracil-based neoadjuvant chemotherapy in locally-advanced gastric/gastroesophageal cancer: A meta-analysis

Ge L, Wang HJ, Yin D, Lei C, Zhu JF, Cai XH, Zhang GQ

CASE REPORT

- 7394** Entering the duodenal diverticulum: A method for cannulation of the intradiverticular papilla

Wang BC, Shi WB, Zhang WJ, Gu J, Tao YJ, Wang YQ, Wang XF

- 7397** Endoscopic ultrasound features of gastric schwannomas with radiological correlation: A case series report

Zhong DD, Wang CH, Xu JH, Chen MY, Cai JT

- 7402** Treatment of radiation-induced hemorrhagic gastritis with prednisolone: A case report

Zhang L, Xie XY, Wang Y, Wang YH, Chen Y, Ren ZG

- 7405** Delayed liver laceration following transjugular intrahepatic portosystemic shunt for portal hypertension

Liu K, Fan XX, Wang XL, Wu XJ

- 7409** ¹⁸F-fluorodeoxyglucose PET/CT findings of a solitary primary hepatic lymphoma: A case report

Pan B, Wang CS, Han JK, Zhan LF, Ni M, Xu SC

Contents

World Journal of Gastroenterology
Volume 18 Number 48 December 28, 2012

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings

I-VI Instructions to authors

ABOUT COVER Bo-Rong Pan (his wife in the left), PhD, MD, Professor, Outpatient Department of Oncology, Fourth Military Medical University, 175 Changle West Road, Xi'an 710032, Shaanxi Province, China.

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF

I-IX Editorial Board

EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Shuai Ma*
Responsible Electronic Editor: *Jun-Yao Li*
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Ling Jiang*
Proofing Editorial Office Director: *Jian-Xia Cheng*

Matrix metalloproteinase-9: A deleterious link between hepatic ischemia-reperfusion and colorectal cancer

Sébastien Lenglet, François Mach, Fabrizio Montecucco

Sébastien Lenglet, François Mach, Fabrizio Montecucco, Cardiology Division, Department of Medicine, Geneva University Hospital, Foundation for Medical Research, 1211 Geneva, Switzerland

Author contributions: Lenglet S wrote the paper; Mach F and Montecucco F approved the final version of the manuscript.

Lenglet S, Mach F, Montecucco F. Matrix metalloproteinase-9: A deleterious link between hepatic ischemia-reperfusion and colorectal cancer. *World J Gastroenterol* 2012; 18(48): 7131-7133 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7131.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7131>

Abstract

Despite the advent of improved surgical techniques and the development of cytotoxic chemotherapeutic agents useful for the treatment of colorectal cancer, the primary clinical challenge remains that of preventing and combating metastatic spread. Surgical resection is the best treatment for colorectal metastases isolated to the liver. However, in rodent models, the hepatic ischemia-reperfusion (I/R) applied during the surgery accelerates the outgrowth of implanted tumors. Among the adverse effects of I/R on cellular function, several studies have demonstrated an over expression of the matrix metalloproteinase-9 (MMP-9) in the ischemic liver. Since several studies showed high local levels of expression and activity of this proteolytic enzyme in the primary colorectal adenocarcinoma, the role of MMP-9 might be considered as a potential common mediator, favoring both growth of local tumor and the dissemination of colorectal carcinoma metastases.

INTRODUCTION

Colorectal cancer is one of the most commonly diagnosed cancers in developed countries and it is ranked as the second leading cause of death among cancer patients^[1]. The majority of these cases is sporadic and develops from a precursor lesion, the adenomatous polyp. At the diagnosis, colorectal cancer is localized to the colon (Dukes A and B stages) in 54% of cases, while it is metastatic to lymph nodes and distant organs (Dukes C and D stages) in the remaining 46%. The survival data demonstrate that the prognosis depends on the severity of the disease: around 80% of patients have long term survival with node negative disease (Dukes A and B stages), this percentage drop to 4% for 5-year survival in patients with metastases (Dukes D stage)^[2]. The liver is the most frequent metastatic site of colorectal cancer, and the complete surgical resection of isolated metastases in this organ has been shown to improve disease outcomes^[3]. Unfortunately, this therapeutic procedure does not avoid a high rate of metastasis recurrence within the

liver. Experimental evidence accumulated over the last two decades has suggested the association between the increase risk of metastatic relapse and their surgical resection in the liver. Indeed, besides the presence of residual or dormant malignant cells, the blood loss incurred during the operation disseminates colon cancer cells into the peripheral blood^[4]. In order to limit the blood loss during the parenchymal resection, surgeons occlude the inflow of blood to the liver.

HEPATIC ISCHEMIA-REPERFUSION INJURY

However, hepatic ischemia-reperfusion (I/R) is an additional and strong stimulus that promotes the outgrowth of micrometastases in the liver^[5]. Local response to I/R is quite complex, but it can be classified into two distinct phases. The acute hepatocellular injury is caused by reactive oxygen species, intracellular and mitochondrial Ca²⁺ overload, complement activation and release of cytotoxic cytokines, and is reflected by a rise in plasma liver enzymes. The late phase is characterized by neutrophil infiltration causing further damage to the parenchyma, mainly through a protease-dependent pathway^[6,7].

In a mouse model of colorectal liver metastases, van der Bilt and colleagues have demonstrated that intermittent clamping prevents both early and late hepatocellular damage and I/R-accelerated tumor growth^[8]. These results might be associated with the reduction of neutrophil infiltration in the parenchyma, which contributes to tumor growth by producing proliferation and angiogenesis-stimulating factors and cytokines^[8].

METALLOPROTEINASE 9 AND COLORECTAL CANCER

Numerous publications have demonstrated that the disease progression in animal models of tissue invasion and metastasis correlate with enhanced secretion of MMPs by tumor and/or stromal cells. Indeed, the metastatic cascade is characterized by the stromal invasion, "intravasation" of the circulatory system at the primary site, "extravasation" at the secondary site and outgrowth of new tumors. These progressive steps require degradation of the extracellular matrix components by proteolytic enzymes, such as matrix metalloproteinases (MMPs)^[9]. Increased expression of various isoforms (MMP-1, -2, -3, -7, -9, -12, -13) has been also related with the pathophysiology of the transformation of human neoplastic colorectal mucosa to adenomatous polyps, invasive colorectal cancers, and metastases^[10]. Among different MMPs, MMP-9 is of particular interest. Indeed, MMP-9 (also known as gelatinase B) is the main enzyme responsible for the degradation of type IV collagen (a major component of basement membranes) and the denatured collagens (gelatins). Importantly, this capacity of MMP-9 has been previously associated with colorectal cancer progression and dissemination of metastasis^[11].

Likewise, this gelatinase might also degrade different matrix substrates including collagen type I, V, VII, X and XI, elastin, fibronectin and laminin. In addition to these extracellular membrane components, MMP-9 cleaves different bioactive molecules, such as growth factors, cytokines, chemokines and also pro-MMPs (pro-MMP-2, pro-MMP-9 and pro-MMP13) and contributes to transform these molecules into their active forms^[12]. Various leukocyte subsets (including neutrophils, monocytes/macrophages and T lymphocytes) produce and release MMP-9.

Although MMP-9 is virtually absent in native livers, it is highly expressed in damaged livers after I/R injury^[13]. Its role has been investigated by Hamada and coworkers^[14], using MMP-9 deficient mice and mice treated with a specific neutralizing anti-MMP9 antibody. The authors demonstrated that, when MMP-9 is inhibited, mice were characterized by significant improvement in liver preservation outcomes. This beneficial effect (in both MMP-9 knockout and neutralizing antibody-treated mice) was also associated with a reduction of leukocyte recruitment and cytokine expression within this organ^[14]. Finally, in a next important step, Nicoud and coworkers demonstrated a direct relationship between the hepatic I/R-induced elevations in MMP-9 and the growth of metastatic colorectal carcinoma^[15]. To achieve this goal, they have subjected mice to hepatic ischemia after tumor cell injection and treated them with or without doxycycline (a broad-spectrum MMP inhibitor). Mice subjected to 30 min of 70% liver ischemia at the time of the tumor inoculation developed significantly larger tumor (expressed as number and volume), and, concomitantly, they were characterized by elevated MMP-9 levels in the systemic circulation and within liver. Accordingly, treatment with the MMP inhibitor strongly reduced the number and volume of the colorectal carcinoma metastasis in the liver. These results indicate that the inhibition of MMP-9 after the hepatic surgical resection of colorectal carcinoma metastases might be clinically relevant to prevent tumor relapse.

CONCLUSION

In summary, these studies have provided important and novel insights on the pivotal role of MMP-9 in the hepatic growth of colorectal carcinoma metastases. Furthermore, a therapeutic strategy targeting the early inhibition of MMP-9 might be a very promising approach to reduce the hepatic metastasis relapse following surgical manipulation of the liver. These preliminary results from basic research also represent a relevant input for developing more selective pharmacological inhibitors of MMP-9 to be tested *in vivo* in animal models of hepatic cancer dissemination. Although clinical studies investigating the role of MMP-9 in human beings are still lacking, these animal studies might suggest the scientific rationale for future applications targeting MMP-9 activity and expression in cancer care and prevention.

Abstract

Carcinoma of the gastroesophageal junction (GEJ) is defined as carcinoma that crosses the GEJ line, irrespective of where the tumor epicenter is located. This group of cancer is rare but controversial. Based on study results from the majority of epidemiologic and clinicopathologic investigations carried out in Western countries, this cancer is believed to arise from Barrett's esophagus (BE) and includes both distal esophageal and proximal gastric carcinomas because of similar characteristics in epidemiology, clinicopathology, and molecular pathobiology in relation to BE. As such, the most recent American Joint Committee on Cancer staging manual requires staging all GEJ carcinomas with the rule for esophageal adenocarcinoma (EA). This mandate has been challenged recently by the data from several studies carried out mainly in Chinese patients. The emerging evidence derived

from those studies suggests: (1) both BE and EA are uncommon in the Chinese population; (2) almost all GEJ cancers in Chinese arise in the proximal stomach and show the features of proximal gastric cancer, not those of EA; (3) application of the new cancer staging rule to GEJ cancer of Chinese patients cannot stratify patients' prognosis effectively; and (4) prognostic factors of GEJ cancer in Chinese are similar, but not identical, to those of EA. In conclusion, the recent evidence suggests that GEJ cancer in Chinese shows distinct clinicopathologic characteristics that are different from EA. Further investigations in molecular pathology may help illustrate the underlying pathogenesis mechanisms of this cancer in Chinese patients and better manage patients with this fatal disease.

INTRODUCTION

Carcinomas of the gastroesophageal junction (GEJ) is defined by the World Health Organization (WHO) as tu-

mors “that cross the oesophagogastric junction... regardless of where the bulk of the tumours lies”^[1]. Therefore, this cancer may arise from the distal esophagus, grow downward, cross the GEJ line, and invade the proximal stomach, or originate from the proximal stomach, grow upward, and invade the distal esophagus. For better surgical management of patients, Siewert and Stein classify this cancer into 3 types: Type I cancer shows epicenter in the distal esophagus 1-5 cm above the GEJ; Type III cancer centers within the proximal stomach 2-5 cm below the GEJ; and Type II tumor straddles the GEJ within a 3-cm longitudinal spread of 1 cm above and 2 cm below the GEJ^[2-4].

At present, the underlying mechanisms of tumorigenesis for this uncommon cancer are poorly understood^[5-7]. Several investigators from Western countries believe adenocarcinoma of the proximal stomach, i.e., gastric cardiac carcinoma, to be similar, or even identical, to Barrett’s esophagus (BE)-associated distal esophageal adenocarcinoma (EA) on the basis of comparable characteristics in epidemiology^[8-14], clinical presentations^[15-23], molecular pathobiology^[24], and histopathology^[17,25-27]. This notion has been adopted by the American Joint Committee on Cancer that published the 7th edition of the cancer staging manual (AJCC 7) in 2009, requiring staging all GEJ cancers with the rule for EA^[28].

Over the past decade, a growing body of evidence has been published on epidemiology^[29-31] and clinicopathology^[32-36] of GEJ carcinoma in Chinese patients with the standardized criteria. The emerging data suggest that GEJ carcinoma in Chinese is heterogeneous in histology and shows clinicopathologic features different from those of EA. This article critically reviews the most recent evidence on this fatal cancer in Chinese patients with the intention to promote clinical research and to better manage Chinese patients with this cancer.

BE AND DISTAL EA REMAIN SCARCE IN CHINESE

Several recent population-based studies using the BE diagnostic criteria of the American Gastroenterology Association show a very low frequency of BE in the Chinese population^[29,37-43]. In 2008, Tseng *et al*^[29] reported a frequency of 0.28% of patients with columnar-lined esophagus out of 19 810 consecutive subjects at annual health check-up with upper endoscopy. By histology, among those with columnar-lined esophagus only 12 subjects had intestinal metaplasia and were qualified as BE patients, rendering a prevalence rate of 0.06% in the general population^[29]. In referral patients for upper endoscopy, Kuo *et al*^[30] reported only 1.8% of BE cases from 735 consecutive subjects. Similar results were also described in another upper endoscopy study of 5179 patients with a prevalence rate of BE at 1% and 0.35% for referral and screening cases at annual health check-up. These results have been repeatedly confirmed by several other endoscopy studies^[40-42,44,45]. In addition to this very

low prevalence rate, BE in most Chinese subjects is in the short- or ultra-short segment, i.e., shorter than 3 cm in the longitudinal length^[40,46-49]. Chen *et al*^[49] studied 4120 qualified BE cases in a meta analysis of 308 original research articles published over the period from 1997 to 2007. They reported overwhelming BE cases (78%) in the short-segment and most in tongue- and island-like endoscopic mucosal lesion patterns (78%). The long segment BE is infrequent and has not been reported in Chinese women. In a histopathology study of distal esophageal mucosa in patients with proximal gastric carcinoma, Sun *et al*^[50] reported the finding of columnar-lined esophagus in up to 65% of the cases, 97% of which was confined within 1 cm above the GEJ line.

Similarly, EA remains rare in the Chinese population^[51-57], unlike that in patients from the West where the incidence of EA has been rapidly rising in the most recent years and EA has outnumbered esophageal squamous cell carcinoma^[58,59]. A population-based epidemiology study carried out in Taiwan over a 25-year period from 1979 to 2003 showed a steadily increasing trend for esophageal squamous cell carcinoma but not for EA^[60]. In another study in Hong Kong, investigators even reported a decreasing trend for EA over a 20-year period from 1984 to 2003^[31]. Among 10 751 new esophageal cancer cases reported to the Hong Kong Cancer Registry, the number of EA cases decreased from 224 in 1984 to 131 in 1998 to 2003, a dramatic drop of over 40% in incidence^[31].

By histopathology, investigators from a major tertiary medical center in Taiwan did not find a single case of EA over a 20-year period from 1987 to 2007^[35]. Most recently, armed with the WHO diagnostic criteria^[1] and the recently defined histological definition of the GEJ line^[61,62], pathologists in Nanjing studied histopathologic features of consecutive 206 radical resections of tumors in the distal esophagus in a homogenous Chinese population and identified only 2 (1%) cases of true EA^[34]. In that study, esophageal squamous cell carcinoma stays predominant^[34].

These clinical study data suggest that BE-related diseases including EA remain uncommon in the Chinese population in the most recent years and may not be the source of their GEJ cancer^[63].

CLINICOPATHOLOGIC FEATURES ARE NOT THOSE OF EA

To answer the question as to where GEJ cancer in Chinese patients arises and what clinicopathologic differences in this cancer between Chinese and Westerners could be, a recent comparison study on clinicopathologic features of GEJ cancer with the WHO diagnostic criteria was conducted between Chinese patients treated in Nanjing, China, and American patients treated in Boston, the United States^[33]. The researchers reported remarkable differences in almost all clinicopathologic characteristics of GEJ cancer between these two different ethnic

patient populations. In general, Chinese patients were 6-year younger, more in the female gender, and presented with tumors 1.5 cm larger in size. Their tumors were all centered in the proximal stomach and heterogeneous in histology with substantial proportions of the cases showing uncommon types such as adenosquamous cell carcinoma, neuroendocrine carcinoma, and pancreatic acinar-like adenocarcinoma^[32,33,64]. In contrast in American patients, almost all tumors were centered in the distal esophagus and homogeneous as EA in histology^[33]. As to the peri-tumor mucosal diseases in Chinese patients, although distal esophageal columnar metaplasia (14%) and dysplasia (0) were uncommon or absent, chronic gastritis (81%) and *Helicobacter pylori* (*H. pylori*) infection (35%) were widespread. Again, in a sharp contrast, distal esophageal columnar metaplasia (87%) and dysplasia (67%) in the Americans were overwhelming; but chronic gastritis (24%) and *H. pylori* infection (19%) were uncommon in the uninvolved proximal gastric mucosa^[33]. The results suggest that GEJ cancer in American patients is indeed associated with BE and shows the clinicopathologic features of EA^[25,65-68]. In contrast, GEJ cancer in Chinese is in fact primary proximal gastric cancer and different from EA.

Despite the fact that the results of this single comparison study confirm the rational on the AJCC 7 classification of this cancer as EA in American patients, the new AJCC 7 mandate for classification of all GEJ cancers as EA may be questionable and ineffective in Chinese patients.

APPLICATION OF STAGING RULES ON EA CANNOT EFFECTIVELY PREDICT SURVIVAL IN CHINESE PATIENTS

The updated AJCC 7 staging guideline classifies all GEJ cancers as EA and requires staging these tumors as esophageal cancer^[28]. The validity and effectiveness of this new mandate has been found problematic in Chinese patients. Researchers in Nanjing, China, investigated 142 cases of GEJ cancer and reported inferior stratification of survival prediction to survival stratification with the staging rule for gastric cancer, especially for pN and summary pIII C stages, when these cases were staged with the scheme for EA based on the AJCC 7 new guideline^[69]. They reported that the pN stage was more predictive in survival than the pT, which is consistent with the features of gastric cancer. In addition, they described a useful survival predictive value for celiac nodal disease and the lymph node ratio in patients with this cancer. In contrast, using the staging guideline for EA, they discovered illogical patient survival characteristics. For example, the Kaplan-Meier curves for patients staged at pIIIA predicted erroneously better survival than those staged at pIA and pIIB. Moreover, the survival curves also crossed in the cases staged at pIIB and pIIIB, indicating the existence of intra-group hetero-

geneity. Importantly, even with the staging scheme for gastric cancer, the survival curves for patients with this cancer were not distinctive and showed incorrectly better survival prediction for patients staged at p I B and p II B than those at p I A and p II A. Interestingly enough, patients staged at pN3b had the 5-year survival rate worse than those with pM1 and pIV diseases^[69]. These observations, taken along with the group clustering in p II A, p II B, p III A, and p III B, illustrate a poor discriminatory ability of the new AJCC 7 staging rule for this cancer in Chinese^[70,71].

One of intriguing facts in Chinese patients with this cancer is that despite the larger tumor size and higher overall pathologic stage with stage pIII-IV in 70% of cases, the 5-year survival rate for patients with stage pIII tumors is significantly better in Chinese than in American patients^[69]. A similar result for patients with proximal gastric cancer staged at pIII has been reported previously in an epidemiology study on the data derived from the Surveillance, Epidemiology, and End Results database^[11]. In that study, although the overall patient survival curves are almost identical between EA and proximal gastric cancer groups, a distinct separation in survival curves between these two groups is demonstrated for patients with pIII diseases; importantly, the patients with proximal gastric cancer and staged at pIII show a much better survival trend than those with EA^[11]. These results demonstrate a unique characteristic for proximal gastric cancer, which is distinctly different from that of EA^[69].

The aforementioned preliminary data suggest that GEJ cancer in Chinese cannot be staged predictively as EA with the new AJCC 7 guideline, as confirmed in a recent South Korean study^[72]. Even staged with the rules for gastric cancer, these cases cannot be monotonically stratified for prognosis prediction^[69], suggesting the existence of discrete pathobiological characteristics that set this cancer apart from EA and less characteristically from conventional gastric cancer^[73]. Regardless, the study of GEJ cancer in Chinese patients treated in Nanjing is limited by a relatively small sample size, advanced pT3 disease in the majority of the cases, and a lack of consistent surgical lymphadenectomy procedure carried out in all cases^[69]. Further investigation with defined criteria and a larger sample size is needed to validate those interesting results.

PROGNOSTIC FACTORS AND SIRT1 GENE EXPRESSION

In the most recent reports on prognostic factors of EA with a large sample size, well-defined clinicopathologic characteristics, and robust follow-up from Western countries, the worse 5-year disease-specific prognostic factors are found to be associated with higher pT, pN stages, advanced age over 76 years, signet-ring cell histology, poor tumor differentiation, and extra-nodal diseases^[74-77]. These prognostic factors for EA have been reported to

be similar, but not identical, to those in Chinese patients with GEJ cancer in recent publications^[78-80]. However, because of the limited number of reports on this issue, the results are a bit inconsistent. For instance, in one report with 514 surgical resection cases of GEJ cancer at a major medical center in China, tumor gross and histology type, stage, vascular invasion, and extent of surgical resection were found to be significant prognostic factors^[78]. In another detailed clinicopathology study report^[79], patient age over 70 years, tumor size larger than 8 cm, poor differentiation, the number of positive lymph nodes over 16, and advanced summary pathology stage were shown to be associated with worse outcomes. In contrast, lymphovascular invasion, which is associated with worse survival in EA^[80], is not shown to be a significant prognostic factor. Interestingly, celiac nodal metastasis and the lymph node ratio for the number of lymph node retrieved and nodal disease are reported to be significant prognostic factors^[81-83]. The investigators further reported that the ratio of the number of positive nodes identified *vs* the number of total lymph nodes evaluated was related to significantly worse overall survival^[79]. Furthermore, the patient survival rate becomes significantly worse for the lymph node ratio over 0.2, compared to the cases with negative nodal disease. The relative risk of worse prognosis for the ratio over 0.4 or 0.5 is 37-fold or 75-fold^[79]. This powerful prognostic prediction by the lymph node ratio is very practical in clinical settings where nodal dissection by individual surgeons and nodal retrieval by pathologists vary and a unified nodal dissection protocol is not universally executed. This simple, easy-to-use, and objective prognostic indicator in gastric cancer has been repeatedly confirmed by many other investigators around the world^[84-91].

Advanced age has been proven to be one of independent worse prognostic factors in GEJ cancer^[74,75,79]. This may result from genetic abnormalities in aging associated genes such as Sirt1, which is a recently discovered, aging-related histone deacetylase involved in regulation of multiple critical steps of stress responses, nutrient metabolism, and aging through deacetylation of a variety of subcellular molecules such as p53, forkhead transcription factors, PGC-1 α , NF- κ B, Ku70, and histones^[92-97]. An increasing body of evidence in molecular biology suggests a complex role for Sirt1 to play in tumorigenesis^[96-101]. Feng *et al*^[102] are the first to use tissue microarray and immunohistochemical methods to investigate the Sirt1 gene expression in proximal gastric cancer including GEJ cancer in Chinese patients. They reported that compared to normal controls, Sirt1 gene expression was significantly higher in a subgroup of GEJ cancer cases, which was significantly associated lymph node metastasis, higher pathologic stages, and worse survival prognosis with significantly lower 1- and 3-year survival rates (80% and 49%), compared to the Sirt1-negative cancer patient groups (89% and 71%), suggesting a prognostic predictive value for this molecule in patients with this cancer. It should be interesting to know how Sirt1 plays

in the initiation and progression of GEJ cancer in Chinese patients.

CONCLUSION

GEJ cancer is uncommon but poorly understood for its natural history, pathogenesis mechanisms, and prognosis. An increasing body of evidence accumulated in recent years suggests that GEJ cancer in Chinese patients arises mainly in the proximal stomach associated with chronic gastritis and shows a heterogeneous histology pattern. This cancer is distinctly different from EA and cannot be accurately stratified with the scheme for EA, as required by the updated AJCC 7 cancer staging guideline for patient survival prognosis prediction. Although the new AJCC 7 staging rule for gastric cancer may be used for this cancer, there exists considerable heterogeneity and indistinctive survival characteristics, suggesting the possibility of a distinct disease entity for this cancer.

Abstract

Primary biliary cirrhosis (PBC) is an autoimmune liver disease characterized by the presence of serum autoantibodies and chronic nonsuppurative destructive cholangitis. The pathogenesis of PBC involves environmental factors, genetic predisposition and loss of immune tolerance. In recent years, it has become univocally accepted that an inappropriately activated immune response is one of the most important factors in PBC. In this study, the role of autoimmunity in PBC is summarized and a feasible research orientation is recommended.

INTRODUCTION

Primary biliary cirrhosis (PBC) is an organ-specific autoimmune disease of the liver characterized by the presence of serum antimitochondrial antibodies (AMAs) and the destruction of small and medium-sized bile ducts. The histological manifestations are damaged biliary epithelial cells (BECs) and infiltration of T cells, B cells, macrophages, eosinophils and natural killer (NK) cells in the portal area, which eventually leads to cirrhosis and liver failure^[1]. PBC affects middle-aged women, and the natural disease history is 10 to 20 year. The annual incidence rates range between 0.7 and 49 cases per million persons, while the prevalence rates range between 6.7 and 402 cases per million persons^[2,3]. Advanced biochemical assays and improved acquisition of disease will lead to increased detection worldwide. Currently, the only recommended first-line therapy, early treatment with ursodeoxycholic acid (UDCA) at a dose of 13-15 mg/kg per day, can delay progression of histology and ameliorate long-term prognosis^[4]. However, approximately 25% of patients have no response to UDCA, and in these cases liver transplantation is needed^[5]. Exploration of pathogenesis is needed to discover novel target treatments. Deficiencies in autoimmune tolerance are critical factors of disease initiation and perpetuation. Therefore, the aim of this study was to demonstrate the function of autoimmunity in PBC.

HUMORAL IMMUNITY

Autoantibody-AMA

High titer of AMAs is the serological hallmark of PBC. It can be detected even before clinical symptoms or bio-

chemical anomalies. The proportion of AMA-negative patients has been minimized due to the development of sensitive detection technology^[6,7]. The highly disease-specific autoantibody, AMA-M2, recognizes components of the oxo-acid dehydrogenase complex (OADC) that are ubiquitously expressed on the inner mitochondrial membrane, including the E2 subset of the pyruvate dehydrogenase complex (PDC-E2). The antigens are released from apoptotic blebs of the BEC, or come from molecular mimicry of infectious agents, or from alteration of xenobiotics^[8]. However, transgenic mice aberrantly expressing PDC-E2 components on BECs do not show serological and histological features of PBC^[9], indicating that aberrant PDC-E2 expression is not sufficient for disease development.

Although AMA is found in most PBC patients, it may have no pathogenic role due to the following observations: (1) the titer of AMA is not associated with biochemical or histological manifestations, and there is no indication for a significant change in AMA levels after drug therapy^[10,11]; (2) approximately 5% of patients are AMA-negative with typical histological injury and exhibit the same treatment response as AMA-positive patients^[12,13]; and (3) although the antigens are ubiquitous, the disease is organ-specific.

However, some studies have identified novel features of AMAs in recent years. Lleo and colleagues^[14,15] demonstrated that PDC-E2 with antigenic reactivity was only detectable in apoptotic blebs of human intra-hepatic BECs; Moreover, in the presence of AMA, macrophages increased the expression of TNF-related apoptosis-inducing ligand (TRAIL) and produced intense inflammatory cytokines, such as tumor necrosis factor alpha (TNF- α) and interleukin (IL)-6. These results provide a mechanism for the biliary specificity and a physiopathologic role of AMA in PBC. Rigopoulou *et al*^[16] found that AMA-IgG₃ was associated with a more severe disease. The presence of IgA-anti-PDC-E2 in sera or saliva might be associated with the progression of PBC^[17]. The mechanism responsible is likely that a greater concentration of IgA in bile ducts can make cells more susceptible to apoptosis through constant transcytosis, resulting in subsequent bile duct damage^[18]. In addition, the production of AMA-IgM from peripheral blood mononuclear cells (PBMCs) from PBC patients was reduced after exposure to UDCA^[19].

Autoantibody-antinuclear antibodies

In addition to AMA, serum antinuclear antibodies (ANAs) are positive in approximately 1/3 patients with PBC. These antibodies provide important evidence for AMA-negative PBC. The typical staining pattern and clinical significance^[20-28] of ANAs are shown in Table 1.

B cells and plasma cells

Plasma cells that originate from B cells are sources of antibodies. As antigen presentation cells, B cells can secrete many kinds of cytokines and present costimulatory signals

to active antigen-specific T lymphocytes. Migita *et al*^[29] found that serum B-cell-activating factor (BAFF) levels were significantly higher in PBC patients than in healthy controls and HCV-infected patients, and were positively correlated with aspartate amino-transferase (AST) and total bilirubin levels. In liver, CD5⁺ and CD20⁺ cells were associated with BEC damage, suggesting that B cells have a role in regulating the portal destruction in PBC^[30]. Therefore, B cell depletion therapy might be an alternative to UDCA. In murine experiments, Ig μ (-/-)NOD.c3c4 mice demonstrated a decreased number of activated NK cells in the liver. The degree of granuloma formation, bile duct destruction, and salivary gland histology were also shown to be significantly attenuated^[31]. Moreover, anti-CD20 therapy every 2 wk in transforming growth factor-beta receptor II dominant negative (dnTGF- β RII) mice at age of 4-6 wk could reduce the number of B cells and CD8⁺ T cells in liver^[32]. In clinical therapy, two doses of 1000 mg rituximab separated by 2 wk were safe and effective in patients with an incomplete UDCA response. After treatment, not only did serum levels of total IgG, IgM, and IgA decrease significantly, but T regulatory (Treg) cells also increased, which was associated with increased mRNA levels of forkhead box 3 (Foxp3) and TGF- β in CD4⁺ T cells^[33].

In contrast, in 2-octynoic acid-bovine serum albumin (2OA-BSA)-induced mice, treatment with anti-CD20 and anti-CD79 antibodies increased the number of CD4⁺ and CD8⁺ T cells infiltrating around damaged bile ducts in portal areas, leading to more severe cholangitis^[34]. A similar phenomenon occurred in Ig μ (-/-)dnTGF- β RII mice. Adoptive transfer of CD19⁺ cells from dnTGF- β RII mice into recombination activating gene-1 (Rag-1)(-/-) mice resulted in decreased liver inflammation and bile duct damage^[35]. However, anti-CD20 therapy in dnTGF- β RII mice at age of 20-22 wk had little effect on liver lesions^[32]. The efficacies of different B cell depletion approaches in diverse murine models are shown in Table 2. Together, these findings suggest that there is a subclass of B cells that have a regulatory role by producing IL-10^[36]. However, further exploration of the function of B cells in PBC is needed before B cell depletion therapy can be applied to routine clinical work.

Elevated IgM

In addition to high titers of circulating AMAs, PBC patients have high levels of serum IgM that are not related to titers of AMAs. Compared with AMA-positive PBC, the level of serum IgM was lower in AMA-negative patients^[37,38]. Plasma cells in the portal tracts of PBC patients are found to be predominantly IgM-positive, while those cells predominantly express IgG in other forms of liver disease, such as autoimmune hepatitis and chronic hepatitis C^[39,40]. It has been shown that after treatment with UDCA, the level of IgM decreases at both short-term and long-term follow-up^[41], which is possibly due to a reduction in naïve B cell and IgM-memory B cell activation through down-regulation of the NF- κ B signal-

Table 1 The characteristics of antinuclear antibodies in primary biliary cirrhosis patients

Staining pattern	Autoantigen	Prevalence (%)	Clinical significance
Nuclear dot	SP100 ^[20,28]	25	Highly specific for PBC; Urinary tract infections
	PML ^[21,28]	19	Highly specific for PBC; Coexistence with anti-sp100
	SP140 ^[22]	15	Coexistence with anti-sp100 and anti-PML
Nuclear periphery	gp210 ^[23]	25	Association with disease severity and poor prognosis

PBC: Primary biliary cirrhosis; PML: Promyelocytic leukemia; LBR: Lamin B receptor.

Table 2 Differences in B cell depletion therapies in primary biliary cirrhosis murine models

Results	Model	Therapy (time)
Amelioration	NOD.c3c4 mice	Igμ knockout
	dnTGF-βR II mice	Anti-CD20 (4-6 wk)
Exacerbation	2OA-BSA-induced mice	Anti-CD20/Anti-CD79 (6 wk)
	dnTGF-βR II mice	Igμ knockout
No effect	dnTGF-βR II mice	Anti-CD20 (20-22 wk)

ing pathway^[19]. The mechanism of IgM elevation is still unclear in PBC, but abnormal Ig class switching may be involved. Lleo *et al.*^[42] showed that IgM was inversely associated with levels of CD40L promoter methylation in CD4⁺ T cells, suggesting that the CD40-CD40L interaction is involved in the production of high amounts of IgM. Moreover, CD40L is an essential molecule involved in Ig class switching.

CELLULAR IMMUNITY

It is thought that activated CD4⁺ T cells can recognize peptide PDC-E2163-176, while activated CD8⁺ T cells can recognize peptide PDC-E2159-167 and PDC-E2165-174 in PBC. Moreover, a large number of autoreactive T lymphocytes infiltrate the portal area.

CD4⁺ T cells

Effector CD4⁺ T cells: In patients with PBC, it is well accepted that an enhanced ratio of Th1 to Th2 cells is one of the most important factors^[43,44] in the onset of disease. After treatment with UDCA, serum interferon-gamma (IFN-γ)^[45] and liver IL-2^[45,46], which are Th1 cell-related cytokines, are decreased. However, the level of serum IFN-γ rebounded after 6 mo of therapy^[45]. Recently, besides Th1 cells, studies have shown that IL-17⁺ cells accumulate around the damaged bile ducts^[47,48], and BECs produce Th17-inducible cytokines (IL-6, IL-1β and IL-23) when stimulated with pathogen-associated molecular patterns (PAMPs)^[47]. In addition, the ratio of Th17 to Tregs is enhanced in PBMCs^[49].

Several experiments using murine models have indicated a central role of CD4⁺ T cells in the pathogenesis of PBC. NOD.c3c4-SCID mice can develop autoim-

mune cholangitis after adoptive transfer of splenocytes or CD4⁺ T cells^[50]. In IL-2Rα(-/-) mice, marked aggregation of IL-17⁺ cells within portal tracts compared to the periphery has been demonstrated. Interestingly, CD4⁺ T cells from the livers of normal C57BL/6J mice can secrete higher levels of IL-17 compared to those from spleens, indicating the role of the liver microenvironment in Th17 induction^[48].

It is currently unknown whether Th1 or Th17 cells are more important in the pathogenesis of the disease. IL-12p40(-/-)dnTGF-βR II mice have a dramatic reduction in histological autoimmune cholangitis and a significant decrease in the levels of intra-hepatic proinflammatory cytokines^[51], while worsening hepatic histology and elevated inflammatory cytokine production have been observed in IL-6(-/-)dnTGF-βR II mice^[52]. These findings might suggest that IL-12-inducible Th1 cells are more important than IL-6-inducible Th17 cells. However, the definitive conclusions on these mechanisms will require further investigation.

Treg cells: CD4⁺CD25^{high} regulatory T cells play a critical role in self-tolerance and the prevention of autoimmune disease. Patients with PBC display a relative reduction of circulating CD4⁺CD25^{high} Tregs compared to controls^[53,54]. The frequency of circulating Tregs can increase after 1 year of treatment with UDCA^[13]. However, the number of Foxp3⁺ cells is higher in the liver in PBC^[53], which is most likely due to the localization of CD8⁺ T cell blasts in the liver portal area^[55].

In addition to CD4⁺ Tregs, Bernuzzi *et al.*^[56] found that the CD8⁺ Treg (CD8⁺CD28⁺) population has striking phenotypic alterations, including decreased CD39 and increased CD127. Although CD8⁺ Tregs were not significantly different quantitatively between patients and healthy subjects, the *in vitro* induction of CD8⁺ Tregs by incubation with IL-10 was significantly reduced in PBC patients.

Murine models constructed by altering the signaling pathway of Treg cells can imitate PBC-like manifestations, which underscores the vital function of Tregs in disease. Zhang *et al.*^[57] demonstrated that Scurfy mice, which have complete ablation of Foxp3⁺ Tregs, exhibited a high titer of AMAs and elevated serum cytokines

Table 3 The characteristics of primary biliary cirrhosis murine models and primary biliary cirrhosis patients

(TNF-α, IFN-γ, IL-6, IL-12p40, and IL-23). In addition, these mice also had a substantial number of lymphocytes infiltrated around portal areas with bile duct damage. Both IL-2Rα(-/-)^[58] and dnTGF-βR II murine models^[59] show PBC-like characteristics.

CD8⁺ T cells

Compared to CD4⁺ T cells, CD8⁺ T cells play a more significant role in mediating the destruction of the bile duct. In PBC patients, CD45RO^{high}CD57⁺CD8^{high} T cells expressing elevated α4β7 and IL-5 accumulate around the portal area^[60]. Moreover, the ratio of CD8⁺ T cells to FoxP3⁺ cells is significantly higher in the liver at late stages of the disease^[53]. Biliary ductule damage by CD8⁺ T cells is also observed in non-obese diabetic autoimmune biliary disease (NOD.ABD) mice^[61]. CD8⁺ T cells from NOD.ABD mice can transfer liver inflammation into NOD.c3c4-SCID recipients. The liver of dnTGF-βR II mice has an increased number of CD8⁺ T cells and a higher ratio of CD8 to CD3 or CD4 cells^[59]. Furthermore, adoptive transfer of CD8⁺ T cells from dnTGF-βR II mice to Rag-1(-/-) recipients results in PBC-like liver lesions and AMA-positive sera, while CD4⁺ T cells predominantly cause bowel inflammation^[62]. Relative to IL-2Rα(-/-) mice, IL-2Rα(-/-) CD4(-/-) mice have increased biliary ductular damage. These findings also suggest that CD8⁺ T cells may mediate bile ductular injury under the background of Treg function loss^[63].

INNATE IMMUNITY

The innate immune system is the first line of defense against infection. Emerging evidence suggests that the liver is one component of the body's immune system^[64]. Traditional immunosuppressive drugs are not effective for PBC compared to other autoimmune diseases. Thus, the role of the innate immune system in PBC has garnered a lot of focus in recent years.

Toll-like receptor

The liver can encounter a number of pathogenic microorganisms and their by-products from the gut by acting

as a traffic hub. The expression of toll-like receptor (TLR) is normally regulated by a negative signaling pathway in the liver, which prevents inappropriate activation of inflammation.

After *in vitro* challenge with TLR ligands, circulating monocytes in PBC patients produce higher pro-inflammatory cytokines, including IL-1β, IL-6, IL-8, and TNF-α^[65]. The expressions of TLR3^[66] and TLR4^[67,68] are increased in BECs. Transfection of poly(I:C) into BECs induces a marked increase in mRNAs encoding a variety of chemokines/cytokines^[66]. In addition, the expressions of TLR4 in BECs^[67] and circulating monocytes^[69] both increase significantly after stimulation with lipopolysaccharide (LPS). Furthermore, the level of RP105, which is involved in the negative regulation of TLR4 signaling, is decreased in PBC monocytes^[69]. The interplay between LPS and TLR4 results in myeloid differentiation factor 88 (MyD88) recruitment, NF-κB activation and coding gene expression^[67,69]. After exposure to CpG, PBMCs from PBC patients produce higher levels of IgM and AMAs^[70,71]. Importantly, the effect can be inhibited by K⁺ channel blockers^[70] and UDCA^[19].

These results indicate that patients with PBC exhibit hypersensitivity of TLR signaling, which leads to a breakdown of self-tolerance. However, activation of the TLR signal pathway alone may not explain the entire course of the disease^[72]. Mice immunized with 2OA-BSA coupled with poly(I:C) showed alterations in the disease process and acceleration of fibrosis of liver.

NKT cells

NKT cells are a subset of lymphocytes possessing both T cell receptors (TCRs) and NK-specific receptors, and they play an important part in the modulation of the innate immune response and cytotoxicity.

Alpha-galactosylceramide (α-GalCer) is an activator of NKT cells, and the frequency of CD1d-α-GalCer-restricted NKT cells is similar between the peripheral blood and liver of healthy people. In contrast, the frequency of these cells in liver is significantly higher than in peripheral blood in PBC patients, and also higher than in healthy individuals^[73].

To define the function of CD1d-restricted NKT cells in the pathogenesis of PBC, Chuang *et al*^[74] generated CD1d(-/-)dnTGF- β R II mice and found that they developed decreased hepatic lymphoid cell infiltration and mild cholangitis. After immunization of 2-OA-BSA-induced PBC mice with α -GalCer, Wu *et al*^[75] found that the disease was exacerbated, including signs of portal inflammation, bile duct destruction and liver fibrosis. However, *in vivo* depletion of NK and NKT cells in the same murine model only suppressed AMAs and cytokine production, but did not change the portal cholangitis^[76]. Therefore, these data support the role of NK and NKT cells in the loss of autoimmune tolerance in PBC; however, the development of PBC also requires other pathological factors.

NK cells

NK cells are another component of the innate immune system, and function by secreting cytokines and lysing target cells. NK cells account for 30% of the total resident lymphocytes in the liver. Chuang *et al*^[77] reported an obvious higher frequency and absolute number of NK cells in both the blood and liver of PBC patients. Moreover, the cytotoxic activity and perforin expression of isolated NK cells were increased. Recently, Shimoda *et al*^[78] demonstrated that TLR4 ligand-stimulated NK cells destroyed autologous BECs in the presence of IFN- α synthesized by TLR 3 ligand-stimulated monocytes. In addition, there was an increased number of CD56⁺ cells scattered around the destroyed small bile ducts.

CHEMOKINES

Chemokines, which are 8-12 kDa heparin-binding cytokines, direct lymphocyte trafficking and positioning in tissues and play roles in modulating immune responses and shaping the severity of disease^[79]. In PBC, infiltrating memory T cells are culprits regarding the destruction of bile ducts.

Chemokines, interferon-gamma-inducible protein-10 (IP-10) and monokine-induced by gamma interferon (MIG), are increased in plasma and the portal area in PBC patients compared to controls. Moreover, the frequency of CXCR3⁺ cells is higher in both PBMCs and injured bile ducts. Intriguingly, daughters and sisters of PBC patients demonstrate increased plasma levels of IP-10 and MIG, but the frequency of circulating CXCR3⁺ cells is normal^[80]. Knockout of CXCR3 in Poly(I:C)-induced mice displayed a delayed and milder progression of cellular inflammation^[81].

Other chemokines may also be involved in recruiting inflammatory cells into the liver in PBC. BECs are a source of chemokine production that attracts monocytes into the liver^[82,83]. Stimulated by poly(I:C), BECs produce augmented CX3CL1 in the presence of monocytes pretreated with LPS through CD40-CD154 contact^[83]. In addition, BECs pretreated with LPS also secrete elevated CX3CL1^[83,84].

CONCLUSION

Substantial amounts of data to date have illustrated that autoimmunity plays a critical role in the pathogenesis of PBC. The adaptive immune response, the innate immune system and their interplay participate in the development of disease. However, there are clearly limitations and unanswered questions that still remain: (1) although some murine models have been established, they cannot imitate PBC in humans completely (Table 3); (2) *in vitro* experiments based on human samples may not completely reflect the endosomatic problems; and (3) the data to date are mainly based on PBMCs, which lack reliability without assessment in the local liver microenvironment. In order to address these problems, better murine models are needed. In the future, researchers must identify new mechanisms through the analysis of both *in vivo* and *in vitro* approaches for the development of effective treatment strategies for PBC.

Abstract

Nucleos(t)ide analogues (NA) are a breakthrough in the treatment and management of chronic hepatitis B. NA could suppress the replication of hepatitis B virus (HBV) and control the progression of the disease. However, drug resistance caused by their long-term use becomes a practical problem, which influences the long-term outcomes in patients. Liver transplantation is the only choice for patients with HBV-related end-stage liver disease. But, the recurrence of HBV after transplantation often caused by the development of drug resistance leads to unfavorable outcomes for the recipients. Recently, the multi-drug resistance (MDR) has become a common issue raised due to the development and clinical application of a variety of NA. This may complicate the antiviral therapy and bring poorly prognostic outcomes. Although clinical evidence has suggested that combination therapy with different NA could effectively reduce the viral load in patients with MDR, the advent of new antiviral agents with high potency and high genetic barrier to resistance brings hope to antiviral therapy. The future of HBV researches relies on how to

Song ZL, Cui YJ, Zheng WP, Teng DH, Zheng H. Diagnostic and therapeutic progress of multi-drug resistance with anti-HBV nucleos(t)ide analogues. *World J Gastroenterol* 2012; 18(48): 7149-7157 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7149.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7149>

INTRODUCTION

Globally, it is estimated that about 400 million are chronically infected with hepatitis B virus (HBV). The prevention and control of hepatitis B is an important public health issue. HBV infection may not only result in fulminant, subfulminant, and chronic hepatitis, but may also contribute to the development of liver cirrhosis and hepatocellular carcinoma in the long-term^[1]. Decades of clinical experiences have shown that the administration of nucleos(t)ide analogues (NA) could postpone the progression of the disease. NA mainly suppresses the

HBV replication and reduces the damage to hepatocytes by hindering the synthesis of reverse transcriptase (RT), which is the prerequisite for viral replication. The main disadvantage of NA is the recurrence of HBV after therapy interruption. Hence, the long-term treatment becomes a mandate. But, this paves the way for other challenges like HBV genome mutation and clinical drug resistance. The reports of multi-drug resistance (MDR) to NA in the recent years are increasing, and become an important issue for clinicians to modulate the treatment strategies during drug resistance.

MECHANISMS OF ANTIVIRAL RESISTANCE

HBV has a DNA genome. But, it replicates through an RNA intermediated reverse transcription. The lack of proofreading ability of the viral encoded, RNA-dependent DNA polymerase could result in potential mutations at each nucleotide position within the entire genome^[2]. This, together with the large number of virions produced (10^{12} - 10^{15} /d), indicates that every mutation of the 3.2 kb HBV genome can theoretically be produced daily^[3,4]. Under the selective pressure of antiviral agents, such diversity is likely to give rise to drug-resistant mutants^[5]. RT is the target of NA and also the chief place of gene mutations. Several factors are associated with the development of antiviral resistance, including viral fitness, potency, and genetic barrier to resistance of the antiviral agents^[6]. Studies have shown that there are five pathways leading to antiviral resistance^[7]. (1) The L-nucleoside pathway (rtM204V/I), leads to the resistance of lamivudine (LAM), emtricitabine, telbivudine (LdT), and clevudine. This pathway includes entecavir (ETV) resistance in LAM-experienced patients; (2) The acyclic phosphonate pathway (rtN236T), associates with the resistance to adefovir (ADV) and tenofovir disoproxil fumarate (TDF)^[8,9]; (3) A shared pathway (rtA181T/V), results in the selection of HBV quasiespecies when treated with L-nucleosides or acyclic phosphonates; (4) Naïve entecavir resistance pathway (rtL180M + rtM204V with either rtT184, S202, or M250 codon changes). In this pathway, three mutations are required to appear simultaneously accounting for the very low resistance profile of entecavir^[10]; and (5) Multidrug resistance pathway, complex patterns and clusters of specific mutations in HBV polymerase are associated with it.

TDF is recommended since 2008, as first line drug in patients chronically-infected with HBV and led to high rates of virologic success^[11,12]. Its effect on HBV DNA suppression appears similar to ETV and LdT and superior to LAM and ADV^[13,14]. It remains largely active even against ADV-resistant or ETV-resistant mutations^[15-17]. However, the rtA194T polymerase mutation has been found in HBV/HIV co-infected patients during TDF treatment and may be associated with TDF resistance^[18-20]. Whether the rtA194T mutation truly confers resistance against TDF has remained controversial, as the

in vitro phenotypic assays showed variable results across laboratories^[21,22]. Thus, the potential impact of this mutation on TDF susceptibility deserves further study^[20]. The primary antiviral drug resistance mutations in the polymerase gene are listed in Table 1^[23].

HBV strains, resistant to at least two anti-HBV agents from different subclasses of NA without a cross-resistance profile, are defined as MDR^[24]. The main reasons for MDR are the sequential monotherapy to treat primary resistance and use of agents with similar cross-resistance profiles. The development of MDR is a major challenge for antiviral therapy, and the improper administration of NA may lead to serious outcomes. Thus, more researches on the choice of antiviral agents in treating patients with MDR have been carried out and some significant solutions have been achieved.

THE CURRENT SITUATION AND STRATEGIES OF DIFFERENT TYPES OF MDR

LAM + ADV resistance

LAM, the first oral antiviral agent against HBV, is safe and well tolerated even in patients with decompensated liver cirrhosis^[25]. Globally, it has been mostly used with a low genetic barrier to resistance and cumulative incidence of resistance as high as 70% after 5 years of treatment^[26,27]. Early studies had suggested that, ADV monotherapy had shown similar antiviral effects to combination therapy with LAM+ADV for LAM-resistant patients in the short-term, and a strategy of switching to ADV monotherapy had widely been adopted^[28]. However, recent studies have showed that ADV resistant mutations emerge more frequently during sequential ADV monotherapy in LAM resistance than in treatment-naïve patients^[29,30]. The rate of ADV resistance in LAM-resistant patients was shown to be as high as 18% at 1 year, compared with 0% in LAM-naïve patients^[31]. Another long-term study reported that the cumulative genotypic resistance and virologic breakthrough at 5 years of sequential ADV monotherapy in LAM-resistant patients were 65.6% and 61.8%, respectively^[32]. Fung *et al.*^[33] reported that the cumulative rate of ADV resistance in LAM-resistant patients at 2 years was 18% for patients who were switched to ADV and 7% for patients who had ADV added to their treatment regimen. In another study of 42 LAM-resistant patients (HBeAg-negative), the ADV resistance rates at 15-18 mo of treatment were 21% (3/14) for patients who were switched to ADV and 0% for patients who had ADV added^[34]. It can be assumed that the ADV resistance rate in LAM-resistant patients can be greatly reduced by adding rather than switching to ADV. There are more researches exploring the mechanisms of LAM + ADV dual-resistance, as these two agents were launched early. When the mutations causing resistance to LAM and ADV are not on the same viral genome, a combination therapy of these two agents will likely be effective in suppressing the mutants

Table 1 Primary antiviral drug resistance mutations in the polymerase gene^[23]

	Domain A	Domain B	Domain C	Domain D	Domain E	Numbers of mutations
Lamivudine and Telbivudine	--	rtV173L rtL180M rtA181T/V	rtM204V/I	--	--	1
Adefovir	--	rtA181T/V		rtN236T	--	1
Tenofovir	--	rtA181T/V		rtN236T	--	?
Entecavir	--	rtL180M rtT184	rtM204I/V rtS202	--	rtM250I/V	3

resistant to each of the drugs. In contrast, when the antiviral resistance mutations are on the same viral genome, the combination treatment may not be adequate^[30]. *In vitro* analysis have shown that most of MDR mutations collocate on the same viral genome^[35], but the *in vivo* confirmation on the same is lacking. There is no unified clinical treatment strategy for LAM + ADV dual-resistance, but different methods of mono or combination therapy have been carried out.

Due to the limited alternative of NA in the early stage, interferon (IFN) had been tried as a choice for dual-resistance to LAM and ADV. Phenotypic analysis have indicated that IFN- α suppresses equally the mutant strains and wild-type strains *in vitro*^[36]. Furthermore, IFN- α also suppresses the replication of LAM-resistant and ADV-resistant mutants *in vivo*^[37]. Besides that, IFN- α administration predictably have reduced the resistance to NA when combined with LAM^[38,39], as IFN- α exhibits at least two HBV-specific antiviral activities independent of the viral polymerase sequence with one reducing the levels of core protein and replicative intermediates, and the other leading to posttranscriptional degradation of HBV RNA^[40]. However, there are certain potential limitations with IFN therapy such as low probability of sustained response, parenteral administration, relatively poor tolerability, and frequent and potential serious adverse effects in patients with advanced liver disease^[41]. These deficiencies limited the clinical application of IFN, and more researches focused on the application of oral NA in MDR.

In vitro studies show that the majority of MDR mutations to LAM and ADV collocate on the same viral genome^[31]. Therefore, the combination therapy with LAM and ADV may not effectively deal with the patients, who are resistant to these two agents. The advent of ETV enabled a new choice for antiviral therapy. Since TDF is not available in many Asian countries, the 2008 updated guidelines by Asian Pacific Association for the Study of the Liver recommended ETV in LAM and ADV resistant patients^[42]. But satisfactory clinical results were not acquired in these patients treated with ETV. Heo *et al*^[30] compared the clinical efficacy of LAM + ADV combined therapy and ETV monotherapy in patients with dual-resistance to LAM and ADV. The mean reduction in serum HBV DNA concentration was significantly lower in the LAM + ADV than in the ETV group. But, the difference in mean decline in serum alanine aminotransferase (ALT) levels over 12 mo of treatment and the rate

of HBeAg seroconversion at 12 mo did not differ significantly between two groups. Park *et al*^[43] reported that ETV monotherapy could not reach an optimal clinical efficacy in ADV-refractory chronic hepatitis B patients with prior LAM resistance. In this long-term study (up to 4 years), the authors have suggested that an early virologic response is essential for a successful ETV monotherapy in this group of patients. Clinically, initial virologic response at 3 mo (IVR-3) is an independent predictor for virologic response, and it may help determine whether to maintain ETV monotherapy or not. Choe *et al*^[44] evaluated the antiviral efficacy of ETV in patients, who had failed to achieve viral response during LAM and ADV rescue therapy. The virologic response was achieved in 1 of 18 patients with pre-existing rt204 mutations, whereas it was achieved in all 4 patients without pre-existing rt204 mutations regardless of the presence of rt181 or rt236 mutations. The poor treatment efficacy of ETV in patients with LAM and ADV dual-resistance might have resulted from the pre-existing rt204 mutations, which could further lead to ETV resistance.

As the ideal clinical efficacy was not achieved by ETV monotherapy, researches continued to seek other treatment strategies with ETV combination therapies. A study tried combination of ETV and ADV in LAM-resistant chronic hepatitis B patients with suboptimal response to LAM + ADV^[45]. This strategy provided superior virologic response and favorable resistance profiles, when compared with combination therapy of LAM and ADV. But similar to ETV monotherapy, an optimal virologic response still could not be reached. This may likely due to the relatively low antiviral potency of ADV, which suggested to replace ADV with another drug with a similar resistance profile and higher potency against LAM-resistant mutants.

TDF shares the similar molecular structure with ADV. It has higher antiviral potency and lower rate of developing drug resistance. Despite its structural similarity to ADV, TDF partially suppresses ADV-resistant HBV, and it is also highly effective against LAM-resistant virus, suggesting that this drug may be an effective treatment for patients who have previously failed treatment with LAM and ADV^[46]. Van Bommel *et al*^[47] introduced TDF for LAM-Resistant patients with high HBV DNA level during ADV therapy. The administration of TDF (300 mg daily for all the patients except one) led to an undetectable HBV DNA level in 19 of 20 patients within

a median of 3.5 mo. The only patient who did not become HBV DNA negative during the observation period received a reduced TDF dose (300 mg every second day) because of renal insufficiency. Patterson *et al.*^[48] reported similar efficacy with TDF in another group of similar patients. But, the virologic response to TDF in this study appeared to be inferior to that observed in treatment-naïve patients. The development of antiviral resistance to TDF in the long-term is uncertain, but the combination therapy with high potency NA without cross-resistance is still a superior strategy for MDR. Recently, Petersen *et al.*^[49] reported a multicenter study with ETV + TDF as rescue therapy in pretreated chronic hepatitis B patients. HBV DNA was undetectable in 51 out of 57 patients with different types of resistance, and the ALT levels improved in most of them, suggesting a reduction in liver inflammation. Besides, this strategy was efficient, safe, and well tolerated in patients with and without advanced liver disease. The updated 2009 American Association for the Study of the Liver Diseases (AASLD) practice guideline recommended TDF + ETV in patients with sequential LAM and ADV treatment failure^[27].

LAM + ETV resistance

ETV is an effective antiviral agent with high potency and high genetic barrier to resistance. In NA-naïve patients, the 5-year cumulative probability of genotypic ETV resistance and genotypic ETV resistance associated with virologic breakthrough was only 1.2% and 0.8%, respectively^[50]. However, the emergence of resistance to ETV occurs more frequently in LAM-refractory population. Based on the previous reports, the resistance to ETV in LMV-refractory patients was detected in 8% of patients after 12 mo, 43% after 48 mo, and 51% after 60 mo of treatment^[51,52]. In a clinical study, the cumulative rates of ETV genotypic resistance in patients with LAM resistance are 6%, 15%, 36%, 46%, and 51% from years 1 to 5, respectively^[53]. The resistance to ETV in the sequential monotherapy in LAM-refractory patients shares the same pathway (mutation of rtM204V/I) with LAM resistance. Yatsuji *et al.*^[54] reported a patient with dual-resistance to LAM and ETV, but was effectively treated with ADV. Interestingly, the typical mutation strains of ETV (rtL180M + M204V + S202G) were observed in this patient. An *in vitro* study indicated that the rtL180M + M204V + S202G mutant had no resistance against ADV, and this case report confirmed this view clinically. Another study included 12 patients with dual-resistance to LAM and ETV, and half of them reached complete virological response with the combination therapy of ADV and ETV after 18 mo. In addition, no enrolled patients developed virologic breakthrough and had mutations resistant to ADV at the end of follow-up. However, not all the patients realized virologic response, which may due to the low potency of ADV and high pretreatment levels of HBV DNA^[55]. This combination therapy strategy may be helpful as ETV is effective to rtA181T related mutant and ADV is effective to rtM204V related mutant. The

optimal strategy for such dual-resistance patients has not been determined due to less availability of literature data.

LAM + ADV + ETV resistance

Recently, MDR to three NA has been described in case reports. Liu *et al.*^[56] reported LAM + ADV could be helpful in a patient, who was resistant to LAM, ADV, and ETV. It could be speculated that the HBV DNA replication had been suppressed due to LAM and ADV. The immune response against the MDR strains might also have contributed to the clearance of these strains. The exact effect of this strategy remains to be observed due to the short follow-up period. Sayan *et al.*^[24] reported a case of another patient, who was effectively treated with ETV and TDF. Three primer drug resistance mutations in different domains of HBV viral polymerase, such as rtA181V/T, rtL180M + rtM204V mutations and the rtN236T, were characterized in the same genome, which might explain the MDR profile. In another study of MDR, amino acid changes consisting of L80V, L91I, M204I, S219A, N238D, and Y245H were found on the same dominant viral genome strain. These newly discovered mutation types may also relate to MDR^[57]. This type of resistance, usually caused by sequential monotherapy, may be effectively treated by combination therapy. However, the mechanisms and preventive methods for MDR to three NA need to be studied.

Treatment strategy of MDR in liver transplant recipients

Liver transplant is an effective method for patients with HBV-related end-stage liver disease. In a liver transplant setting, three different clinical phases have to be considered: (1) treatment of HBV infection during waiting list; (2) prophylaxis of hepatitis B recurrence after liver transplant; and (3) treatment of recurrent hepatitis B when prophylactic measures have failed^[58]. The main factors associated with HBV recurrence were HBeAg status at transplant listing and serum HBV-DNA level at transplant^[59]. The goals of antiviral therapy in the pretransplant patients include the reduction of viral load to low or nondetectable serum HBV DNA levels^[60]. The development of drug resistance for patients in the waiting list for liver transplant is a common problem. Osborn *et al.*^[61] found that the antiviral therapy failure in patients with HBV in the waiting list did not impair clinical outcomes when recognized early and also when the salvage therapy was promptly initiated and neither the survival rate with transplant nor without transplant was negatively impacted by antiviral therapy failure.

However, the recurrence of HBV after transplant is still a troublesome problem and may influence the long-term outcomes. The combination of both LAM and hepatitis B immunoglobulin (HBIG) has emerged as the most effective prophylactic strategy in HBV transplant recipients with a 3-year recurrence rate of 0-10%^[58,62,63]. But, the drug resistance to this combination therapy has also emerged. In addition to the typical resistance to LAM, it was detected in 45% of the immunosuppressed

patients within the first year following liver transplant^[64]. The escape mutation from anti-HBs occurs in the common α determinant region of the surface gene, which is a highly conservative region of the HBsAg protein^[65]. IFN is not currently used for the treatment of hepatitis B after transplantation, given the risk of graft rejection^[66,67]. The availability of ADV has changed the clinical course of LAM-resistant patients, and it is effective and safe among liver transplant recipients^[68-70]. Researches showed that ADV could be an effective rescue therapy for patients with LAM-resistant hepatitis B post-liver transplant^[71,72]. In a retrospective review, viral recurrence was noted in 5 out of 23 liver transplant recipients, who are on combination prophylaxis of LAM and HBIg with 1 patient receiving TDF and 4 receiving ADV. Only 1 death related to HBV recurrence was reported in this population, who had been switched to ADV^[73].

Apart from ADV, ETV appears to be a more attractive candidate than ADV for use in the transplant setting^[74]. A study of 30 patients receiving a combination of ETV and low-dose HBIg confirmed the efficacy and safety of ETV in preventing recurrence of HBV after liver transplant^[75]. Another small study of 8 patients showed that ETV was safe and effective as prophylaxis after liver transplant with no interactions observed with the immunosuppressive medications^[76]. Fung *et al.*^[77] reported that although only 26% of patients had complete viral suppression at the time of transplant and 91% of patients underwent loss of HBsAg after 2 years of follow-up. Also, 98.8% of patients achieved undetectable HBV DNA levels with ETV as the sole antiviral agent after liver transplant. It can be inferred that ETV may play an effective role in recipients resistant to both LAM and HBIg.

ETV could be a choice in liver transplant recipients, and TDF may also be effective when used alone or in combination therapy. Villet *et al.*^[78] reported a recipient who was resistant to LAM, ADV, and HBIg. The combination therapy of LAM and TDF effectively suppressed the HBV DNA replication. Karlas *et al.*^[79] reported that the combination therapy with ETV and TDF may prevent post-liver transplant hepatitis B recurrence even without HBIg maintenance therapy. He illustrated that the combination oral antiviral therapy might substitute for HBIg as indefinite prophylactic regimen due to profound antiviral efficacy and low risk of viral resistance. The optimal combination method for MDR in liver transplant recipients is still uncertain, and the therapeutic experiences in non-transplant patients could be learned.

NEW PERSPECTIVES ON THE RESEARCH OF MDR

There are still some limitations on the current research on drug resistance. For instance, the genetic analysis of resistance to NA inhibitors is usually focused on the RT domain, and only infrequently takes into consideration of the whole genome of intra-host HBV variants^[80-82].

Thai *et al.*^[83] reported that the rtM204I/V substitution is insufficient for establishing resistance against LAM. The analysis of 639 HBV whole-genome sequences obtained from 11 patients showed that rtM204I/V was independently acquired by more than one intra-host HBV variant, indicating the convergent nature of LAM resistance. Currently, the most commonly used methods for detecting HBV drug-resistance mutations are direct sequencing and reverse hybridization^[84]. However, these methods do not enable haplotype analysis, and hence, they cannot be used to determine the collocation of mutations on the same viral genome. This limits the accurate identification of viral mutants that are resistant to drugs with high genetic barrier^[85]. Recently, several next-generation sequencing technologies, such as ultra-deep pyrosequencing, are available to generate more data^[85-88]. These methods may offer significant advantages in explaining and predicting the responses of HBV patients to antiviral therapy and enable quantification of HBV quasispecies variants.

Recently, some studies analyzed the mutation pattern in relation to the HBV genotypes and found that the rtL180M mutation is significantly connected to the rtM204V mutation in genotypes A, B, and C. Also, the HBV genotypes differ in their mutation pattern of LAM resistance^[89]. Another study indicated the association of genotype C with higher rates of hepatitis B recurrence after transplant due to LAM resistance^[90]. It can be inferred that HBV genotypes may play an important role in the progression of HBV-related liver disease and response to antiviral therapy. The assessment of HBV genotype prior to the treatment may help to individualize the antiviral therapy and reduce the incidence of treatment failures and complications^[91,92]. However, the relationship between HBV genotypes and antiviral resistance is unclear. Extensive researches may provide new perspectives for the prevention and optimal rescue therapy to patients with drug resistance.

PREVENTION OF MDR

Treatment failure in anti-HBV therapy could be regarded as an iatrogenic factor, and a judicious use of NA in chronic hepatitis B patients is the most effective prophylaxis against the development of MDR. Thus, proper strategy should be applied by clinicians at the beginning of therapy. An antiviral agent with the highest potency and a high genetic barrier to resistance should be selected^[93,94]. The pros and cons of initiating the treatment with combination therapy in minimizing the development of antiviral resistance are currently being investigated^[95,96]. Avoiding the sequential use of NA monotherapy is an effective preventive method for MDR^[24]. A roadmap suggested that HBV DNA concentration at week 12 after initial treatment should be checked to identify patients with primary treatment failure, which is defined by < 1 log copies/mL reduction of HBV DNA concentration. For patients with primary treatment failure with good drug compliance, addition of another NA is indicated. The second assessment of HBV DNA should then be

Table 2 Patterns and pathways of antiviral drug resistance in chronic hepatitis B in the context of cross-resistance^[99]

Pathway	Amino acid substitution in the rt domain	LAM	LdT	ETV	ADV	TDF
	WT	S	S	S	S	S
L-nucleoside (LAM/LdT)	M204I/V	R	R	I	S	S

LAM: Lamivudine; LdT: Telbivudine; ETV: Entecavir; TDF: Tenofovir; ADV: Adefovir; NA: Nucleos(t)ide analogues.

done at week 24^[97,98]. Treatment strategies in patients with partial virologic response are based on the potency and genetic barrier of the antiviral agent. Patients receiving NA with a high genetic barrier can remain the treatment beyond 48 wk. Patients receiving a less potent NA should continue treatment and be re-assessed at week 48, and those, who receive NA with a low genetic barrier, should add a more potent drug due to the high risk of resistance when the treatment is not adapted^[26]. To avoid MDR, the combination therapy of NA with cross-resistance should be avoided. The patterns and pathways of antiviral drug resistance in chronic hepatitis B in the context of cross-resistance are listed in Table 2^[99]. Patient's adherence to antiviral therapy is another important factor in avoiding resistance. Adherence may be monitored using patient reports, dispensed medication counts, or HBV DNA detection^[93]. If low response or virologic breakthrough is observed with the primary treatment, gene sequencing should be done to find out the type and location of mutations, in order to guide the optimal rescue therapy. Recently, An *et al*^[100] reported that the family history, negative conversion time of HBV DNA, and different NA were independent risk factors of gene resistant mutation, which provided a theoretical basis for predicting drug resistance and salvage treatment.

There is still no consensus statement on the management of MDR in current HBV treatment guidelines. However, the guidelines for primary treatment failure could be used in order to prevent MDR. The management of antiviral-resistant HBV in guidelines is listed in Table 3^[27,101]. In these updated guidelines, the combination therapy was not recommended in all circumstances. The antiviral agents with high potency and high genetic

barrier to resistance, such as ETV and TDF, could also be used alone.

CONCLUSION

In summary, MDR to NA is a thorny issue in the anti-HBV therapy. The clinical efficacy in patients has been improved to some extent by the combination therapy. ETV and TDF can be regarded as the optimal choice for patients with MDR. Further investigations on the mechanisms and optimal treatment modalities are still lacking. The progress and emergence of new genetic testing technology will probably improve the anti-HBV therapy. The newly discovered forms of gene mutations to resistance may provide useful clues to solve the problem of MDR. The efficacy of IFN in patients with MDR needs further exploration. The development of new anti-HBV agents, which act not only on RT, but also on other targets of HBV, may be a new approach to prevent MDR in NA.

fects of *Gardenia jasminoides* on liver fibrosis and the detailed molecular mechanisms were also assessed in human hepatic stellate cells (LX-2) *in vitro*.

RESULTS: Treatment with *Gardenia jasminoides* decreased serum alanine aminotransferase (BDL vs BDL + 100 mg/kg *Gardenia jasminoides*, 146.6 ± 15 U/L vs 77 ± 6.5 U/L, $P = 0.0007$) and aspartate aminotransferase (BDL vs BDL + 100 mg/kg *Gardenia jasminoides*, 188 ± 35.2 U/L vs 128 ± 19 U/L, $P = 0.005$) as well as hydroxyproline (BDL vs BDL + 100 mg/kg *Gardenia jasminoides*, 438 ± 40.2 μ g/g vs 228 ± 10.3 μ g/g liver tissue, $P = 0.004$) after BDL. Furthermore, *Gardenia jasminoides* significantly reduced liver mRNA and/or protein expression of transforming growth factor β 1 (TGF- β 1), collagen type I (Col I) and α -smooth muscle actin (α -SMA). *Gardenia jasminoides* significantly suppressed the upregulation of TGF- β 1, Col I and α -SMA in LX-2 exposed to recombinant TGF- β 1. Moreover, *Gardenia jasminoides* inhibited TGF- β 1-induced Smad2 phosphorylation in LX-2 cells.

CONCLUSION: *Gardenia jasminoides* exerts antifibrotic effects in the liver fibrosis and may represent a novel antifibrotic agent.

Abstract

AIM: To investigate the anti-hepatofibrotic effects of *Gardenia jasminoides* in liver fibrosis.

METHODS: Male Sprague-Dawley rats underwent common bile duct ligation (BDL) for 14 d and were treated with *Gardenia jasminoides* by gavage. The ef-

bile duct-ligated rats and human hepatic stellate cells. *World J Gastroenterol* 2012; 18(48): 7158-7165 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7158.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7158>

INTRODUCTION

Chronic liver injury causes the accumulation of extracellular matrix (ECM) such as α -smooth muscle actin (α -SMA) in the liver and subsequently contributes to liver fibrosis and later cirrhosis^[1-6]. This eventually leads to hepatic dysfunction, portal hypertension, and hepatocellular carcinoma (HCC)^[7-9]. Hepatic stellate cells (HSC) are the principal liver cells that promote liver fibrosis^[3,9-12]. Upon activation by various stimuli such as transforming growth factor (TGF)- β 1, HSC transdifferentiate into myofibroblasts and then produce excessive ECM proteins, resulting in liver fibrosis^[13-15]. Strategies aimed at disrupting TGF- β 1 synthesis and/or signaling pathways markedly ameliorates liver fibrosis in an experimental model^[16].

Herbal medicines have been frequently investigated for their hepatoprotective and antifibrotic effects in both humans^[17] and animal models^[18]. A number of studies have shown that administration of Chinese herbs lead to a decrease in hepatic TGF- β 1 expression and severity of fibrosis in rats^[19,20]. Yin-Chen-Hao-Tang (YCHT) decoctions have long been used as antiinflammatory, antipyretic, choleric and diuretic agents for liver disorders and jaundice. Several studies provide clinical evidence of its effectiveness in the treatment of various liver disease. YCHT is an aqueous extract derived from three herbs: *Artemisia capillaries* Thunb (Herba *Artemisiae Capillaris*, Yin-Cen-Hao), *Gardenia jasminoides* Ellis (*Fructus Gardeniae*, Zhi-zi) and *Rheum officinale* Baill (Emodin, Da-huang) with a ratio of 4:3:1 in weight. YCHT was reported to suppress liver fibrosis in rats induced by a choline-deficient diet^[21]. Long-term administration of YCHT in rats ameliorated hydrophilic bile acids-induced hepatic injury presumably by reducing oxidative stress and the degree of hepatic fibrosis^[22]. These studies have indicated that YCHT as a promising therapeutic agent in chronic liver disease. Recent studies showed that *Artemisia capillaries* and Emodin (the main compound of *Rheum officinale*) are well-known herbal hepatotherapeutic drugs for the treatment of liver fibrosis^[23-25]. However, whether *Gardenia jasminoides* has an anti-fibrotic effect on liver fibrosis and the involved detailed mechanism has not been fully understood yet.

The aim of the current study is to investigate the beneficial effects of *Gardenia jasminoides* on liver fibrosis using the bile duct ligation (BDL) rat model *in vivo* and TGF- β 1-stimulated HSCs *in vitro*.

MATERIALS AND METHODS

Materials

Recombinant human TGF- β 1 was obtained from R

and D (Minneapolis, MN, United States). α -SMA and TGF- β 1 antibodies were purchased from Abcam (Cambridge, MA, United States). Phospho-Smad2 and Smad2 antibodies were obtained from Cell Signaling Technology (Boston, MA, United States). α -tubulin antibody was purchased from Sigma-Aldrich (St. Louis, MO, United States). DMEM and fetal bovine serum (FBS), penicillin/streptomycin and trypsin were obtained from Invitrogen (Carlsbad, CA, United States). *Gardenia jasminoides* standard (purity > 99%) was purchased from the Institute of Chinese Pharmaceutical and Biological Products.

Preparation of *Gardenia jasminoides*

Gardenia jasminoides was prepared as described previously^[22] by boiling the dried *Gardenia jasminoides* fruits with distilled water for 5 h. The extract was filtered, freeze-dried, and kept at 4 °C. The yield of water extract of *Gardenia jasminoides* was 8.33% (w/w). The dried extract was dissolved in distilled water before use.

Animal experiments

All animal experimental protocols were approved by the local animal care and use committee according to criteria outlined in Guide for the Care and Use of Laboratory Animals from the National Academy of Sciences (National Institutes of Health publication 86-23, 1985 revision). For experiments with BDL, rats were randomly divided into five groups ($n = 8$). Each day, four animals underwent BDL, and a sham-operated animal was used as a healthy control. Twenty-four hours after surgery, the four BDL animals were randomly assigned to receive 14 d of daily gavage consisting of ddH₂O (the treatment control and vehicle), while treatment groups received 25, 50 and 100 mg/kg *Gardenia jasminoides* (suspended in ddH₂O) by gavage. The sham controls also received ddH₂O by gavage. At the end of experiment, rats were anesthetized, serum was collected and livers were removed. Some portions of liver tissue were fixed in 10% formalin or embedded in paraffin specimen medium. Others were snap frozen in liquid nitrogen and stored at -80 °C until use.

Serum biochemistry and liver histology

Serum alanine aminotransferase (ALT), and aspartate aminotransferase (AST) were analyzed with kits from Thermo Fisher Scientific (United States). Formalin-fixed tissue was embedded in paraffin, and sections of liver (4 μ m) were stained with hematoxylin and eosin (HE) to evaluate the morphological changes and stage of liver fibrosis according to the Ishak Stage Score. The liver hydroxyproline content was measured as described^[26].

Quantitative real-time polymerase chain reaction

Total RNA was extracted using TRIzolTM Reagent (Invitrogen, United States) according to the manufacturer's instructions. Total RNA (1 μ g) was reverse transcribed, followed by quantitative real-time reverse transcription polymerase chain reaction (qRT-PCR) using the Bio-Rad

Table 1 Primer sequences for real-time reverse transcription polymerase chain reaction

Gene	Primer sequences	Size (bp)	Accession number
Rat	TGF- β 1 Forward: 5'-TACAACAGCACCCGCGACCG-3' Reverse: 5'-TGCGTTGTGTCGGTCCACCA-3'	117	NM_021578.2

TGF- β 1: Transforming growth factor- β 1; Col I: Collagen type I; GAPDH: Glyceraldehydes-3-phosphate dehydrogenase.

iCycler Iq system. The qRT-PCR reactions were carried out in a total volume of 25 μ L containing 12.5 μ L of SYBR Premix Ex TaqTM (2 \times) (TaKaRa Biotechnology Co., Ltd, Dalian, China), 2 μ L of cDNA, 5 pmol of forward and reverse primers, and 9.5 μ L of distilled H₂O. The sequences of the rat and human primers used are listed in Table 1, respectively. PCR was performed at 95 $^{\circ}$ C for 30 s, and then run for 45 cycles at 95 $^{\circ}$ C for 5 s and 60 $^{\circ}$ C for 20 s. The relative amount of mRNA was calculated using the comparative C_t ($\Delta\Delta C_t$)^[27]. The glyceraldehyde 3-phosphate dehydrogenase (GAPDH) gene was used as a reference for normalizing data. The derived normalized values were the mean of three runs.

Western blotting

Total proteins were extracted and subjected to SDS-PAGE and analyzed by immunoblotting as described previously^[28]. Primary antibodies against α -SMA, p-Smad2, Smad2 and α -tubulin were used. Horseradish peroxidase-coupled secondary antibodies were bought from Promega (Promega). The protein bands were detected employing ECL chemiluminescence (Thermo Scientific).

Cell culture

LX-2, a well-characterized cell line derived from human HSCs, was used in the *in vitro* studies. Recombinant TGF- β 1 and *Gardenia jasminoides* (Standard) were used at doses shown in individual figure legends. Cells were cultured in DMEM supplemented with 10% fetal bovine serum, 1 mmol/L L-glutamine, and 100 IU/mL streptomycin/penicillin.

Statistical analysis

SPSS version 16.0 for Windows was used for all analysis. All values are expressed as mean \pm SD. The statistical significance between experimental groups was determined by *t* test or analysis of variance. *P* values < 0.05 were considered statistically significant.

RESULTS

Treatment with *Gardenia jasminoides* attenuated liver fibrosis in BDL rats

Both BDL and sham-operated rats were orally administered continuously either with the vehicle or *Gardenia*

jasminoides (25, 50, 100 mg/kg body weight) for 2 wk. BDL in rats is associated with significant increases in liver fibrosis; this was confirmed by HE staining of liver tissues. In contrast, *Gardenia jasminoides* treatment groups had significantly less liver fibrosis (Figure 1), with the lowest scores in the 100 mg/kg *Gardenia jasminoides* treatment group.

Gardenia jasminoides treatment also reduced the elevated levels of serum ALT and AST, which are indicators of hepatocellular damage induced by BDL (Figure 2A and B). Hydroxyproline analysis revealed significantly lower levels of this fibrosis marker in the livers of the *Gardenia jasminoides* treatment groups (Figure 2C). This was also confirmed by hepatic histology. In particular, the hydroxyproline content in the 100 mg/kg group was reduced to levels similar to those in the control group.

To uncover the mechanisms underlying this beneficial phenomenon, we investigated the effects of *Gardenia jasminoides* on the expression of fibrotic gene. mRNA expression of TGF- β 1 and collagen I (Col I) was significantly reduced in the livers of *Gardenia jasminoides* treatment groups (Figure 2D and E). Western blot analysis also revealed a significant reduction in α -SMA protein expression in the livers of groups treated by 50 and 100 mg/kg *Gardenia jasminoides*, respectively (Figure 2F). Taken together, these data suggest that the *Gardenia jasminoides* therapy greatly reduces fibrosis formation in BDL rats.

Treatment with *Gardenia jasminoides* attenuates TGF- β 1-induced HSC activation

Because *Gardenia jasminoides* reduced markers of hepatic fibrosis in BDL rats, we next examined whether this therapy has similar antifibrotic effects in a human HSC line (LX-2 cells). The mRNA levels of TGF- β 1 and Col I were significantly increased in response to recombinant TGF- β 1 for 24 h. However, *Gardenia jasminoides* downregulated the mRNA levels of TGF- β 1 and Col I in LX-2 exposed to TGF- β 1 in a dose-dependent manner (Figure 3A and B). The protein expression of α -SMA as detected by Western blotting was also reduced in LX-2 cells after *Gardenia jasminoides* treatment (Figure 3C). Together, these results indicate that *Gardenia jasminoides* exerts its antifibrotic effects in the liver by repressing TGF- β 1, Col I and α -SMA expression.

Figure 1 *Gardenia jasminoides* markedly improved the histology in bile duct ligation rats. Representative pictures of hematoxylin and eosin staining (magnification $\times 200$) from rats subjected to bile duct ligation (BDL) or sham-operated rats treated with vehicle or *Gardenia jasminoides*. A: Sham; B: BDL + vehicle; C: BDL + *Gardenia jasminoides* (25 mg/kg per day); D: BDL + *Gardenia jasminoides* (50 mg/kg per day); E: BDL + *Gardenia jasminoides* (100 mg/kg per day); F: Scores of double-blinded assessments of liver histology with respect to fibrosis. ^b $P < 0.01$ vs sham; ^c $P < 0.05$, ^d $P < 0.01$ vs BDL + vehicle ($n = 8$).

***Gardenia jasminoides* reduces Smad2 phosphorylation in TGF- β 1-stimulated LX-2 cells**

Phosphorylated Smad2 plays an important role in the activation of TGF- β 1-induced Col I and α -SMA expression^[29-31]. To determine whether *Gardenia jasminoides* attenuation of Col I and α -SMA expression is mediated through this pathway, we measured Smad2 expression and phosphorylation levels. As shown in Figure 4, *Gardenia jasminoides* significantly reduced Smad2 phosphorylation induced by TGF- β 1 in LX-2 cells without affecting the total amount of Smad2, thereby suggesting that the inhibitory effects of *Gardenia jasminoides* on the expression of Col I and α -SMA is mediated by the blocking of TGF- β 1-stimulated Smad2 phosphorylation.

DISCUSSION

Liver fibrosis is a key risk factor for the development of cirrhosis and chronic liver failure. Activation of HSCs is a crucial component of this process^[11,12]. In the current study, we evaluated the therapeutic effects of *Gardenia jasminoides* *in vivo* in a BDL cholestatic rat model and *in vitro* in human hepatic cells.

Chronic cholestasis leads to liver necrosis, fibrosis, and cirrhosis, partly due to an accumulation of toxic bile acids in the liver^[32]. Therapy with *Gardenia jasminoides* is based on the hepatoprotective properties of YCHT decoctions containing *Gardenia jasminoides*^[22]. Because previous studies have demonstrated that the other two ingredients, *Artemisia capillaris* Thunb and *Rheum officinale* Baill, have hepatoprotective properties, we hypothesized that *Gardenia jasminoides* might also improve hepatic function in patients

with cholestatic liver diseases. As seen in this report, this hypothesis is supported by our experimental results. Biochemical and gene expression analyses demonstrated that elevated markers of liver dysfunction such as ALT and AST were reduced by *Gardenia jasminoides*.

Continuous accumulation of the ECM causes hepatofibrosis. Collagen is the main component of the extracellular matrix in fibrotic tissue^[3]. Hydroxyproline, a major component of collagen, was used as an indicator for evaluation of the degree of liver fibrosis^[33]. *Gardenia jasminoides* treatment (50 and 100 mg/kg) significantly attenuated collagen accumulation as evidenced by the inhibition of BDL-elevated hydroxyproline concentrations and the proportion of fibrotic tissue.

It is well-known that HSCs activation plays a pivotal role in the process of liver fibrosis, and α -SMA is a marker of activated HSCs^[12,34,35]. In the current study, Western blotting indicated that *Gardenia jasminoides* (50 and 100 mg/kg) markedly suppressed the activation of HSCs. To determine whether human cells would show react similarly to *Gardenia jasminoides*, we treated human HSCs cell line, LX-2 cells, with different concentrations of *Gardenia jasminoides*. In contrast to vehicle, *Gardenia jasminoides* decreased the expression of TGF- β 1, Col I and α -SMA. These data are consistent with the results of our *in vivo* study. Together, these results provide compelling evidence supporting the beneficial effects of *Gardenia jasminoides* on the rat model of cholestasis and human liver cells.

Further analysis of this antifibrotic effect suggests that *Gardenia jasminoides* suppressed the expression of Col I and α -SMA *via* the TGF- β 1/Smad2 signaling

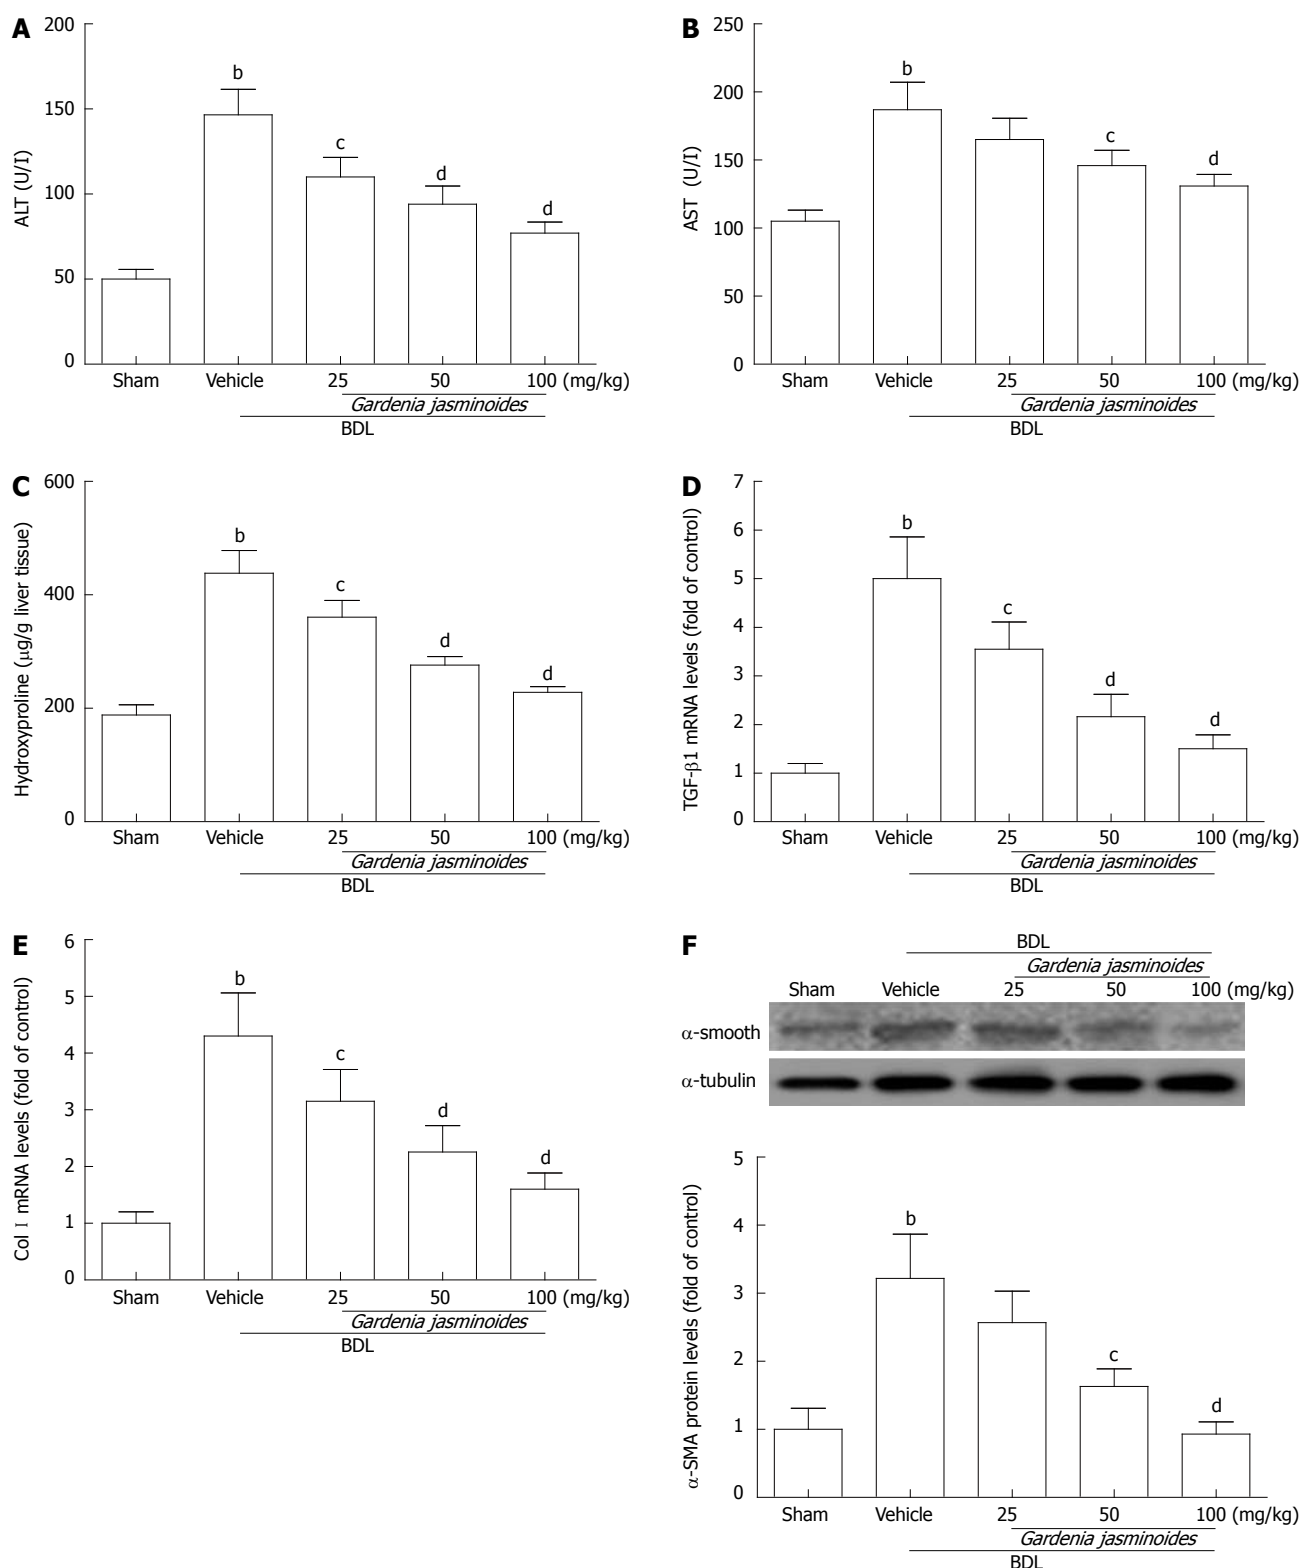

Figure 2 Biochemical and fibrotic gene expression in bile duct ligation rats. *Gardenia jasminoides* significantly improved liver function and reduced the expression of liver fibrosis marker genes from rats submitted to bile duct ligation (BDL) or sham-operated rats treated with vehicle or *Gardenia jasminoides*. A: Serum levels of alanine aminotransferase (ALT); B: Serum levels of aspartate aminotransferase (AST); C: Liver hydroxyproline content; D, E: Liver mRNA expression of transforming growth factor-β1 (TGF-β1) (D) and collagen type I (Col I) (E); F: Liver protein expression of α-smooth muscle actin (α-SMA) detected by Western blotting. ^b*P* < 0.01 vs sham; ^c*P* < 0.05, ^d*P* < 0.01 vs BDL + vehicle (*n* = 8).

pathway. HSCs are the major target of TGF-β1, which helps to stimulate the transdifferentiation of HSCs into fibrogenic myofibroblasts^[36]. The production of TGF-β1 is upregulated in myofibroblasts and proliferating bile

duct epithelia after BDL, which further contribute to the fibrogenic process in an autocrine/paracrine manner^[37]. Downstream signaling in HSCs involves signaling transcription factors such as Smad2. In addition, TGF-β1 is

Figure 3 *Gardenia jasminoides* significantly reduced the expression of fibrotic marker genes in a human hepatic stellate cells line. Cells were exposed to transforming growth factor- β 1 (TGF- β 1) (5 ng/mL) in combination with the indicated concentrations of *Gardenia jasminoides* or vehicle for 24 h. A: mRNA expression of TGF- β 1 in LX-2 cells; B: mRNA expression of collagen type I (Col 1) in LX-2 cells; C: Western blotting analysis of α -smooth muscle actin (α -SMA) expression in LX-2 cells. ^b P < 0.01 vs sham; ^c P < 0.05; ^d P < 0.01 vs TGF- β 1 + vehicle (n = 3).

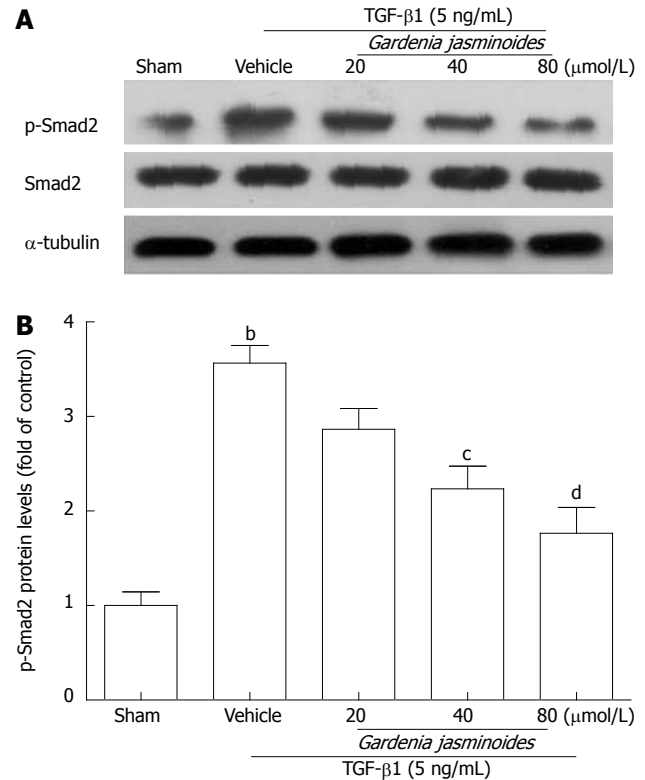

Figure 4 *Gardenia jasminoides* significantly reduced transforming growth factor- β 1-induced Smad2 phosphorylation and Smad2 protein expression in LX-2 cells. Cells were exposed to transforming growth factor- β 1 (TGF- β 1) (5 ng/mL) in combination with the indicated concentrations of *Gardenia jasminoides* or vehicle for 24 h. The expression of p-Smad2 and Smad2 in LX-2 cells was evaluated by Western blotting. ^b P < 0.01 vs sham; ^c P < 0.05; ^d P < 0.01 vs TGF- β 1 + vehicle (n = 3).

thought to mediate the activation of Smad2 through its phosphorylation^[38]. Here, we found that *Gardenia jasminoides* reduced Smad2 phosphorylation in a dose-dependent manner using LX-2 cells. These findings are consistent with a significant antifibrotic effect of *Gardenia jasminoides* mediated through the inhibition of the TGF- β 1/Smad2 pathway. How *Gardenia jasminoides* represses Smad2 phosphorylation remains to be determined.

In summary, we demonstrate that *Gardenia jasminoides* improves the therapeutic response in a rat model of cholestasis and *in vitro* in human hepatic cells. These findings suggest that *Gardenia jasminoides* might be beneficial in patients with chronic cholestatic disorders. To further elucidate the detailed mechanisms, additional comparative studies will be needed to investigate the hepatoprotective of *Gardenia jasminoides* on other liver disease models as well as patients with liver fibrosis.

COMMENTS

Background

Liver fibrosis is a major cause of morbidity and mortality worldwide. However, there are only a few effective antifibrotic therapies for patients with liver fibrosis. Yin-Chen-Hao-Tang (YCHT) decoctions has long been used as antiinflammatory, antipyretic, choleric and diuretic agent for liver disorders and jaundice and several studies provide clinical evidence for its effectiveness in the treatment of various liver disease. However, whether *Gardenia jasminoides*, one of the

components of YCHT decoctions, has anti-fibrotic effect on liver fibrosis and the involved detailed mechanism has not been fully understood yet. In the present study, the anti-hepatofibrotic effects of *Gardenia jasminoides* were evaluated.

Research frontiers

Strategies aimed at disrupting transforming growth factor $\beta 1$ (TGF- $\beta 1$) synthesis and/or signaling pathways markedly ameliorates liver fibrosis in experimental model. Inhibition of TGF- $\beta 1$ signaling pathway may be related to the protective effects of *Gardenia jasminoides* on the bile duct ligation (BDL) rat model *in vivo* and TGF- $\beta 1$ -stimulated HSCs *in vitro*.

Innovations and breakthroughs

Treatment with *Gardenia jasminoides* decreased serum alanine aminotransferase and aspartate aminotransferase as well as hydroxyproline after BDL. Protective mechanisms of *Gardenia jasminoides* are associated with reduced hepatic mRNA and/or protein expression of TGF- $\beta 1$, collagen type I (Col I) and α -smooth muscle actin (α -SMA). *Gardenia jasminoides* significantly suppressed the expression of TGF- $\beta 1$, Col I and α -SMA in hepatic stellate cells exposed to recombinant TGF- $\beta 1$. Moreover, *Gardenia jasminoides* inhibited TGF- $\beta 1$ -induced Smad2 phosphorylation in hepatic stellate cells.

Applications

By understanding the effects and mechanism of *Gardenia jasminoides* on liver fibrosis, the present study may present a promising strategy in the treatment of patients with liver fibrosis.

Peer review

The present manuscript describes the effect of *Gardenia jasminoides* extract (YCHT) on the process of fibrosis that develops in rat liver after ligation of the common bile duct. This Chinese herbal medicine reduced the levels of serum transaminases, hydroxyproline, TGF- $\beta 1$ (and its mRNA), collagen type 1 and α -smooth muscle actin. The treatment also decreases the TGF- $\beta 1$ -induced Smad2 phosphorylation in a human stellate cell line LX-2. This study clearly demonstrates that treatment of fibrosis, even by classical medical treatment has an effect.

Abstract

AIM: To investigate the effect and mechanism of oridonin on the gastric cancer cell line HGC-27 *in vitro*.

METHODS: The inhibitory effect of oridonin on HGC-27 cells was detected using the 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay. After treatment with 10 $\mu\text{g/mL}$ oridonin for 24 h and 48 h, the cells were stained with acridine orange/ethidium bromide. The morphologic changes were observed under an inverted fluorescence microscope. DNA fragmen-

tation (a hallmark of apoptosis) and lactate dehydrogenase activity were examined using DNA ladder assay and lactate dehydrogenase-release assay. After treated with oridonin (0, 1.25, 2.5, 5 and 10 $\mu\text{g/mL}$), HGC-27 cells were collected for annexin V-phycoerythrin and 7-amino-actinomycin D double staining and tested by flow cytometric analysis, and oridonin-induced apoptosis in HGC-27 cells was detected. After treatment with oridonin for 24 h, the effects of oridonin on expression of Apaf-1, Bcl-2, Bax, caspase-3 and cytochrome c were also analyzed using reverse-transcript polymerase chain reaction (RT-PCR) and Western blotting.

RESULTS: Oridonin significantly inhibited the proliferation of HGC-27 cells in a dose- and time-dependent manner. The inhibition rates of HGC-27 treated with four different concentrations of oridonin for 24 h (1.25, 2.5, 5 and 10 $\mu\text{g/mL}$) were $1.78\% \pm 0.36\%$, $4.96\% \pm 1.59\%$, $10.35\% \pm 2.76\%$ and $41.6\% \pm 4.29\%$, respectively, which showed a significant difference ($P < 0.05$). The inhibition rates of HGC-27 treated with oridonin at the four concentrations for 48 h were $14.77\% \pm 4.21\%$, $21.57\% \pm 3.75\%$, $30.31\% \pm 4.91\%$ and $61.19\% \pm 5.81\%$, with a significant difference ($P < 0.05$). The inhibition rates of HGC-27 treated with oridonin for 72 h at the four concentrations were $25.77\% \pm 4.85\%$, $31.86\% \pm 3.86\%$, $48.30\% \pm 4.16\%$ and $81.80\% \pm 6.72\%$, with a significant difference ($P < 0.05$). Cells treated with oridonin showed typical apoptotic features with acridine orange/ethidium bromide staining. After treatment with oridonin, the cells became round, shrank, and developed small buds around the nuclear membrane while forming apoptotic bodies. Lactate dehydrogenase (LDH) release assay showed that after treated with 1.25 $\mu\text{g/mL}$ and 20 $\mu\text{g/mL}$ oridonin for 24 h, LDH release of HGC-27 caused by apoptosis increased from $22.94\% \pm 3.8\%$ to $52.68\% \pm 2.4\%$ ($P < 0.001$). However, the change in the release of LDH caused by necrosis was insignificant, suggesting that

the major cause of oridonin-induced HGC-27 cell death was apoptosis. Flow cytometric analysis also revealed that oridonin induced significant apoptosis compared with the controls ($P < 0.05$). And the apoptosis rates of HGC-27 induced by the four different concentrations of oridonin were $5.3\% \pm 1.02\%$, $12.8\% \pm 2.53\%$, $28.5\% \pm 4.23\%$ and $49.6\% \pm 3.76\%$, which were in a dose-dependent manner ($P < 0.05$). After treatment for 24 h, DNA ladder showed that oridonin induced a significant increase in DNA fragmentation in a dose-dependent manner. RT-PCR revealed that mRNA expression levels were up-regulated compared with the controls in caspase-3 (0.917 ± 0.103 vs 0.357 ± 0.019 , $P < 0.05$), cytochrome c (1.429 ± 0.111 vs 1.002 ± 0.014 , $P < 0.05$), Apaf-1 (0.688 ± 0.101 vs 0.242 ± 0.037 , $P < 0.05$) and Bax (0.856 ± 0.101 vs 0.278 ± 0.027 , $P < 0.05$), whereas down-regulated in Bcl-2 (0.085 ± 0.012 vs 0.175 ± 0.030 , $P < 0.05$). Western blotting analysis also confirmed this result.

CONCLUSION: Apoptosis of HGC-27 induced by oridonin may be associated with differential expression of Apaf-1, caspase-3 and cytochrome c, which are highly dependent upon the mitochondrial pathway.

INTRODUCTION

Gastric cancer is a common cancer of the digestive system and the second most common type of cancer worldwide. Its incidence varies among different regions and countries. There are approximately 934 000 new cases of gastric cancer worldwide each year, of which 56% occur in East Asia. Among these new cases in East Asia, 41% come from China and 11% from Japan^[1,2]. Most patients

present with advanced stage. Surgery plus chemotherapy remains the first-line therapy. Despite rapid advances in surgical procedures and radiotherapy/chemotherapy, few chemotherapeutic drugs for gastric cancer have shown promising results. Treatment efficacies vary from person to person, with a prevalence of cure of $< 30\%$ ^[3]. Therefore, it is important to search and develop new and more effective anti-gastric cancer drugs. In recent years, traditional Chinese medicine (TCM) has played an increasingly important role in the prevention and treatment of tumors. In particular, the integration of TCM with Western medicine has appreciably improved the efficacy of drug combinations and prolonged patient survival.

Rabdosia rubescens, a medicinal herb in TCM, has therapeutic actions (e.g., heat-clearing, detoxifying, anti-inflammation, antinociceptive, anti-tumor). Oridonin (molecular formula: $C_{20}H_{20}O_6$; relative molecular weight: 364.42) is a tetracyclic diterpenoid compound. It is a monomer component extracted from *Rabdosia rubescens*. In China, structural and pharmacological studies on *Rabdosia rubescens* started in the mid 1980s. Results indicated that oridonin is one of the most important anti-tumor components of *Rabdosia rubescens*^[4,5]. Studies have suggested that oridonin has certain anti-tumor effects on cervical cancer, human epidermal squamous cell carcinoma, leukemia, liver cancer, malignant melanoma, colon cancer, breast cancer, and other tumors^[6-12]. A study on colon cancer found that the mechanism of oridonin-induced apoptosis and aging of colon cancer cells might lie in increased histone acetylation and changes in the expressions of p16, p21, p27 and c-myc^[13]. A study on laryngeal cancer indicated that oridonin can induce apoptosis through inhibiting the epidermal growth factor receptor signaling pathway and by increasing oxidative stress^[14]. Oridonin can induce the apoptosis of hepatoma cells through the reactive oxygen species-mitogen-activated protein kinase-p53 pathway^[15]. In another study on cervical cancer, oridonin induced the apoptosis of cervical cancer cells through the phosphatidylinositol 30-kinase-Akt pathway^[16]. In addition, some recent studies suggested that oridonin can also inhibit the proliferation of tumor cells by increasing the autophagy of tumor cells^[17-19]. All of these findings suggest that oridonin has good anti-tumor effects.

Our previous studies on gastric cancer also suggested that oridonin has a notable inhibitory effect on the proliferation of gastric cancer cells^[20]. However, the exact mechanism by which oridonin induces the apoptosis of gastric cancer cells remains undefined. In this study, the effect of oridonin on gastric cancer cells and its possible mechanism of action were explored.

MATERIALS AND METHODS

Experimental reagents

The human gastric cancer cell line HGC-27 as well as the instruments and equipments needed for this study were provided by the Zhejiang Provincial Key Laboratory of Gastroenterology (Zhejiang, China). Roswell Park Memo-

rial Institute (RPMI) 1640 medium was purchased from the Shanghai Pufei Biotech (Shanghai, China). Fetal bovine serum (FBS), 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide, acridine orange/ethidium bromide (AO/EB) fluorescent dye and lactate dehydrogenase (LDH) test reagents were purchased from YK Biotech (Hangzhou, China). Bcl-2, Bax, Apaf-1, caspase-3 and β -actin primers were synthesized by Invitrogen (Shanghai, China). Trizol RNA extraction reagent was purchased from Invitrogen (Carlsbad, CA, United States). Taq DNA polymerase and PrimeScript™ reverse-transcript polymerase chain reaction (RT-PCR) Kit and other PCR reagents were purchased from TaKaRa Corporation (Osaka, Japan).

Cell culture

HGC-27 cells were routinely cultivated in RPMI 1640 medium containing 10% FBS, 100 U/mL penicillin, and 100 U/mL streptomycin at 37 °C with 5% CO₂. Cells were passaged at 80% confluency using 1 mmol/L ethylene diamine tetraacetic acid (EDTA)-0.025% trypsin for 3-5 min, and subcultured at a ratio of 1:3-1:5. Cells at the logarithmic growth phase were collected for experiments.

Determination of inhibition of cell growth

HGC-27 cells at the logarithmic growth phase were obtained. The cell concentration was adjusted to 4×10^4 /mL. Then, 200 μ L of the above-mentioned cell suspension was added into each well of several 96-well plates. When cells adhered to the wall, the stock solution of oridonin (50 mg/mL) was added into each well to obtain final concentrations of oridonin of 0, 1.25, 2.5, 5 and 10 μ g/mL. Five parallel wells were established for each drug concentration. After each well was removed from the incubator after different time periods of cultivation (based on experimental design), 20 μ L MTT [prepared using 5 mg/mL phosphate-buffered saline (PBS) at pH 7.4] was added. The well was removed again after 4 h of cultivation. The supernatant was aspirated carefully; 150 μ L dimethyl sulfoxide was added to each well and homogenized. A Multi-Mode Microplate Reader (Infinite M200; Tecan, Geneva, Switzerland) was used to determine the absorbance (A), with a detection wavelength of 570 nm and a reference wavelength of 630 nm. The inhibition of cell growth was calculated using the following formula:

$$\text{Inhibition (\%)} = [1 - (A_{\text{treated}} - A_{\text{blank}}) / (A_{\text{control}} - A_{\text{blank}})] \times 100\%$$

Determination of LDH activity

HGC-27 cell culture media treated with oridonin (0, 1.25, 2.5, 5, 10 and 20 μ g/mL) for 24 h were collected. After centrifugation of the cell culture medium at 1000 g for 5 min at 4 °C, supernatants were carefully aspirated: these were marked "LDH_{necrosis}". Precipitated cells were rinsed three times in PBS (pH 7.4), and then lysed with 0.4% Triton X-100 for 30 min on ice. Cell lysate supernatants were centrifuged at 3000 g for 5 min at 4 °C: these were marked "LDH_{apoptosis}". Residual adherent HGC-27 cells were collected after treatment with different concentra-

tions of oridonin using 0.4% Triton X-100 for 30 min on ice. Cell lysate supernatants were centrifuged at 3000 g for 5 min at 4 °C: these were marked "LDH_{live}". LDH levels were measured in the three supernatants mentioned above (LDH_{necrosis}, LDH_{apoptosis} and LDH_{live}) on a fully automatic biochemical analyzer (LX20; Beckman Coulter, Brea, CA, United States). LDH levels in supernatants (LDH_{necrosis} and LDH_{apoptosis}) were applied for the analysis of oridonin-induced necrosis and apoptosis of HGC-27 cells. The percentages of apoptosis and necrosis were calculated using the following formulae:

$$\text{Necrosis (\%)} = [\text{LDH}_{\text{necrosis}} / (\text{LDH}_{\text{necrosis}} + \text{LDH}_{\text{apoptosis}} + \text{LDH}_{\text{live}})] \times 100\%$$

$$\text{Apoptosis (\%)} = [\text{LDH}_{\text{apoptosis}} / (\text{LDH}_{\text{necrosis}} + \text{LDH}_{\text{apoptosis}} + \text{LDH}_{\text{live}})] \times 100\%$$

DNA fragmentation (DNA ladder) assay

HGC-27 cells (including suspended cells and adherent cells) were collected after treatment with oridonin (0, 1.25, 2.5, 5, 10 μ g/mL) for 24 h. They were rinsed three times in PBS at 4 °C. This was followed by degradation using 100 μ g cell lysates (1% NP-40, 20 mmol/L EDTA, 50 mmol/L Tris-HCl, pH 7.5) at 4 °C for 10 min, followed by centrifugation at 15 000 g for 20 min. RNase A (20 μ g/mL) was added to the supernatant at 37 °C for 1 h. Then 20 μ L 0.5 mol/L NaCl and 120 μ L 50% isopropanol were added and the mixture left overnight at -20 °C. The supernatant was removed after centrifugation at 15 000 g for 15 min at 4 °C. The supernatant was allowed to dry naturally and was dissolved in TE buffer (10 mmol/L Tris-HCl pH 7.4, 10 mmol/L EDTA pH 8.0), followed by electrophoresis at 100 V for 40 min using 0.1 mg/L, 2% agarose gels. A gel imaging system (FluorChem FC2; Alpha Innotech, Palo Alto, CA, United States) was used for observation and taking photographs.

Flow cytometric analysis

HGC-27 cells were treated by oridonin (0, 1.25, 2.5, 5, 10 μ g/mL) as describe above and the cells were collected for annexin V-phycoerythrin and 7-amino-actinomycin D double staining. Briefly, the cells were washed with PBS for three times, and stained according to the manufacturer's instructions (Guava Nexin® Reagent kit, 4700-1140, Millipore, United States). Samples were then analyzed using Guava EasyCyte Plus (Millipore, United States) within 30 min after the staining.

Cell morphology

AO/EB apoptotic staining was used to detect the morphology of apoptotic cells. After treatment with 10 μ g/mL oridonin for 24 h and 48 h, the cells were washed three times in PBS at room temperature. The 80 μ L AO/EB cocktail (Solomon Bio-Sci and Tech Co, China) was added to the culture plates for 30 min prior to observation under an inverted fluorescence microscope (IX71; Olympus, Tokyo, Japan). Viable cells stained only by AO appeared bright green with intact structure, whereas cells in early apoptosis showed bright green nuclear staining. Late apop-

otic cells stained by AO low and EB were red-orange with condensation of chromatin as dense orange areas. The experiment was repeated three times in each group.

Semi-quantitative RT-PCR analysis

HGC-27 cells were collected after treatment with 10 μ g/mL oridonin for 24 h. Total cellular RNA was extracted using the Trizol Reagent Kit according to manufacturer's instructions. The concentration and quality of total RNA extracted were confirmed using a Protein-Nucleic Acid Analyzer (GeneQuant Pro DNA/RNA; GE Healthcare, Piscataway, NJ, United States) and RNA electrophoresis. cDNA synthesis and PCR detection were conducted using a PCR instrument (PTC-200; Bio-Rad, Hercules, CA, United States) according to the instructions given for the PrimeScript™ RT-PCR Kit. Primers were designed using the freely available primer design software Primer Premier 5.0. The primers of β -actin, Apaf-1, Bcl-2, Bax, caspase-3 and cytochrome c are shown in Table 1.

The reaction conditions were as follows: 94 °C for 4 min; 94 °C for 45 s, 50 °C for 45 s, and 72 °C for 45 s, for 30 cycles; and followed by extension at 72 °C for 10 min before ending. Electrophoresis (1% agarose gel, 120 V for 30 min) was carried out. The gel imaging system (FluorChem FC2; Alpha Innotech) was used for observation and taking photographs.

Western blotting verification

Gastric cancer cell samples were homogenized in lysis buffer (50 mmol/L Tris-HCl, pH 8.0, 150 mmol/L, 1% Triton X-100, and 100 μ g/mL Phenylmethanesulfonyl fluoride). The concentration of total protein was quantitated by bicinchoninic acid method. Sixty μ g total proteins from each sample were loaded on a 15% sodium dodecylsulfonate-polyacrylate gel electrophoresis gel and the proteins were transferred to a polyvinylidene fluoride membrane (Bio-Rad, United States). Blotted membranes were blocked in 5% bovine serum albumin and subsequently exposed to primary antibodies specific for Apaf-1 (1:500, sc65891, Santa Cruz, United States), Bcl-2 (1:300, sc7382, Santa Cruz, United States), Bax (1:300, sc70406, Santa Cruz, United States), caspase-3 (1:300, sc7272, Santa Cruz, United States) and cytochrome c (1:800, sc13156, Santa Cruz, United States), respectively. After incubation with the appropriate secondary antibody, the membranes were treated with electrochemiluminescence reagent (Generay, China) and exposed to autoradiographic films. Beta-actin was also detected as an internal control.

Statistical analysis

The experiments were repeated three times independently. Data were presented as the mean \pm SD. Data were analyzed using SPSS software ver13.0 (SPSS, Chicago, IL, United States). If the results were distributed normally, the two independent samples *t* test was used for comparison. For comparisons between groups of more than two unpaired values, one-way analysis of variance (ANOVA) was used. If an ANOVA *F* value was significant, post-hoc comparisons were performed between groups. If results were not normally distributed, the Mann-Whitney *U* test was used to compare two groups of unpaired values, whereas for comparisons between groups of more than two unpaired values, the Kruskal-Wallis *H* test was used. *P* < 0.05 was considered significant.

RESULTS

Inhibitory effect of oridonin on growth of HGC-27 cells

The HGC-27 cell-growth inhibition rate after treatment with different concentrations of oridonin (0, 1.25, 2.5, 5, 10 μ g/mL) is shown in Figure 1A. The inhibition rates of HGC-27 treated with the four different concentrations of oridonin for 24 h (1.25, 2.5, 5, 10 μ g/mL) were 1.78% \pm 0.36%, 4.96% \pm 1.59%, 10.35% \pm 2.76% and 41.6% \pm 4.29%, with a significant difference (*P* < 0.05). The inhibition rates of HGC-27 treated with oridonin for 48 h at the four concentrations were 14.77% \pm 4.21%, 21.57% \pm 3.75%, 30.31% \pm 4.91% and 61.19% \pm 5.81%, with a significant difference (*P* < 0.05). The inhibition rates of HGC-27 treated with oridonin for 72 h at the four concentrations were 25.77% \pm 4.85%, 31.86% \pm 3.86%, 48.30% \pm 4.16% and 81.80% \pm 6.72%, respectively, with a significant difference (*P* < 0.05). As the drug concentration increased, HGC-27 cell-growth inhibition was gradually enhanced.

Oridonin induced apoptosis of HGC-27 cells

HGC-27 cells were tested by LDH release assay after treated with oridonin for 24 h, and we found that apoptosis-induced LDH release increased from 22.94% \pm 3.8% at 1.25 μ g/mL to 52.68% \pm 2.4% at 20 μ g/mL (*P* < 0.001). However, the change in the release of LDH caused by necrosis was insignificant (*P* > 0.05, Figure 1B), suggesting that the major cause of oridonin-induced HGC-27 cell death was apoptosis.

DNA of HGC-27 cells was also extracted and tested by DNA ladder analysis after treatment with oridonin for 24

Figure 1 Inhibition of growth and lactate dehydrogenase release assay of HGC-27 cells after treatment with different concentrations of oridonin. A: Inhibition of growth HGC-27 cells; B: Lactate dehydrogenase (LDH) release assay of HGC-27 cells. The change in the release of LDH caused by apoptosis was significant.

Figure 2 DNA ladder diagram after treatment with different concentrations of oridonin for 24 h. 1: Control; 2: 1.25 μg/mL oridonin; 3: 2.5 μg/mL oridonin; 4: 5 μg/mL oridonin; 5: 10 μg/mL oridonin.

h. As shown in Figure 2, oridonin induced a significant increase in DNA fragmentation in a dose-dependent manner.

Flow cytometric analysis also revealed that oridonin could induce significant apoptosis compared with the controls ($P < 0.05$, Figure 3). And the apoptosis rates of HGC-27 induced by oridonin at the four concentrations were $5.3\% \pm 1.02\%$, $12.8\% \pm 2.53\%$, $28.5\% \pm 4.23\%$ and $49.6\% \pm 3.76\%$, respectively, which were in a dose-dependent manner ($P < 0.05$).

Apoptotic morphology of HGC-27 cells after treated with oridonin

Apoptotic morphology was further observed under light microscopy and we found that, in the negative control group, HGC-27 cells were closely connected and uniform in size (Figure 4A). After treatment with oridonin, the cells became round (Figure 4B, black arrow), shrank, and developed small buds around the nuclear membrane while forming apoptotic bodies (Figure 4C, black arrow). AO/EB staining showed that, in the negative control group, cells were closely connected, uniform in size, and green in color (Figure 4D). After treatment with oridonin,

the typical features of cells at different phases of apoptosis could be seen. Live cytoplasm and nuclei appeared all green. Early apoptotic nuclei were yellowish-green and pyknotic, and the cytoplasm was stained green. In the mid-phase and late apoptosis, nuclei were pyknotic, and nuclei and cytoplasm were yellowish-green. Dying cells were pyknotic and red-orange (Figure 4E and F).

Effect of oridonin on HGC-27-induced gene expression

After treatment with oridonin for 24 h, gray ratio analyses of RT-PCR revealed that mRNA expression was up-regulated compared with control in caspase-3 (0.917 ± 0.103 vs 0.357 ± 0.019 , $P < 0.05$), cytochrome c (1.429 ± 0.111 vs 1.002 ± 0.014 , $P < 0.05$), Apaf-1 (0.688 ± 0.101 vs 0.242 ± 0.037 , $P < 0.05$) and Bax (0.856 ± 0.101 vs 0.278 ± 0.027 , $P < 0.05$), whereas down-regulated in Bcl-2 (0.085 ± 0.012 vs 0.175 ± 0.030 , $P < 0.05$). These findings suggested that oridonin-induced apoptosis of HGC-27 cells was correlated with changes in the expression of caspase-3, cytochrome c, Apaf-1, Bcl-2 and Bax. Agarose gel electrophoresis of the RT-PCR products is shown in Figure 5A, and the ratios between the indicators for the three PCR analyses and optical density of β -actin are shown in Figure 5B. Protein levels analyzed by Western blotting also confirmed this result (Figure 5C).

DISCUSSION

Apoptosis plays a key part in the evolution of organisms, homeostasis, and development of multiple systems, including cancer. Tumorigenesis occurs when a series of oncogenes and proto-oncogenes are activated and overexpressed within tumor cells. The genes and their products are important regulators of apoptosis. Their abnormal expression blocks the apoptotic process of tumor cells, increasing the number of tumor cells, thereby promoting tumor growth. The typical morphological features of apoptotic cells are: cell shrinkage; in some organelles, ribosomes and nuclear debris are “wrapped” by the cell membrane into apoptotic bodies, which bud off from the

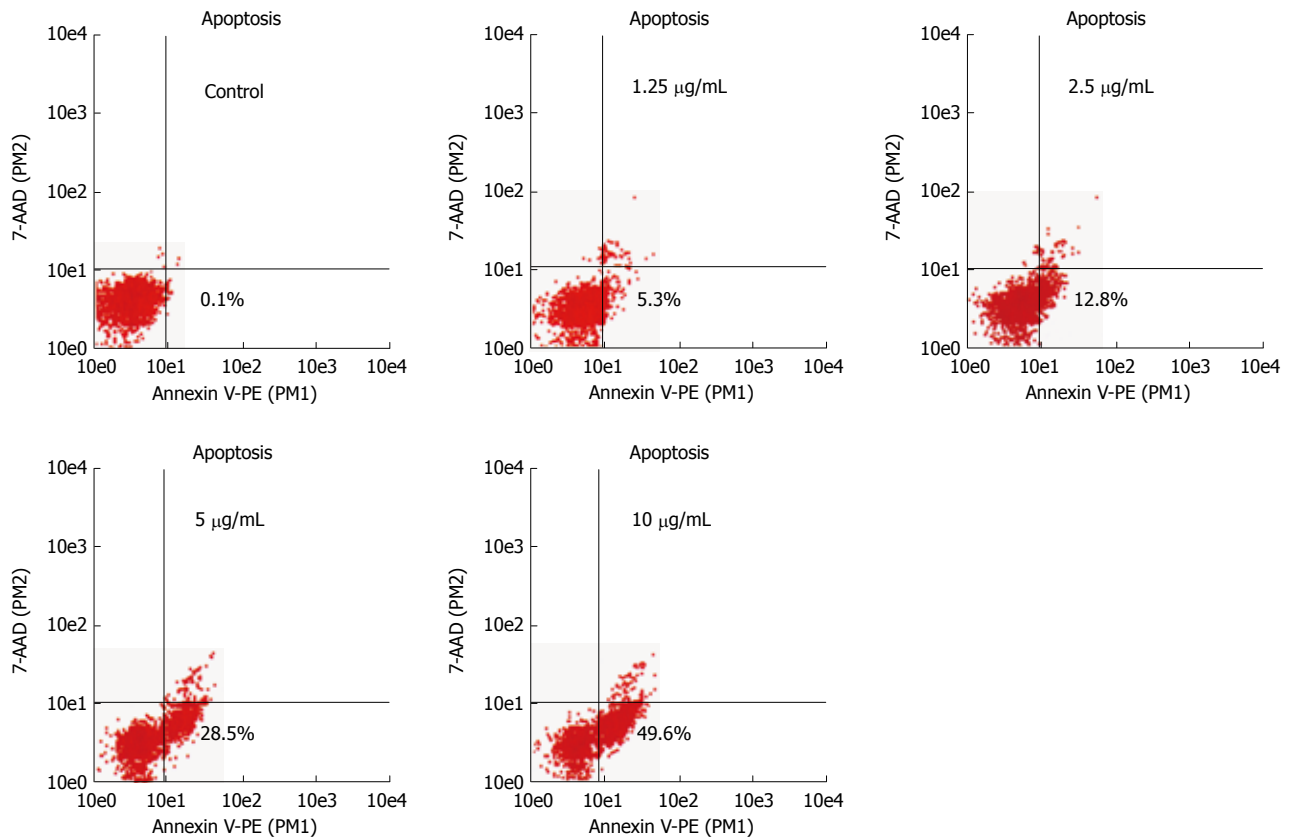

Figure 3 Analysis of apoptosis in HGC-27 cells. Flow cytometric analysis showed that oridonin induced the apoptosis of HGC-27 cells in a dose dependent manner. The x-axis indicates the Annexin V-positive populations and the y-axis indicates the 7-AAD-positive populations. The lower right was the early apoptotic cells.

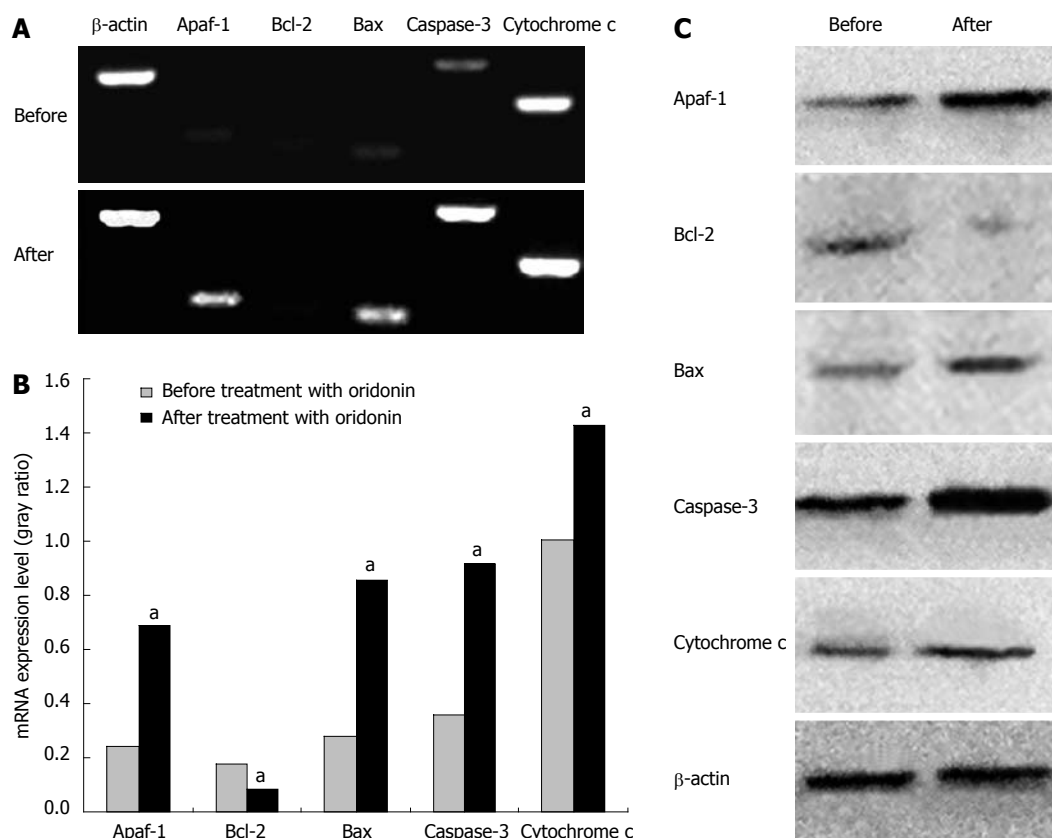

Figure 5 Changes in gene expression after treatment with 10 µg/mL oridonin for 24 h. After treatment with oridonin for 24 h, the expression of caspase-3, cytochrome c, Apaf-1 and Bax was up-regulated, whereas that of Bcl-2 was down-regulated. A: Agarose gel electrophoresis of the reverse-transcript polymerase chain reaction products; B: Results of optical density analyses of Apaf-1/β-actin, Bcl-2/β-actin, Bax/β-actin, caspase-3/β-actin, and cytochrome c/β-actin before and after treatment with oridonin (paired *t* test, ^a*P* < 0.05 vs before treatment with oridonin); C: Western blotting analysis.

cell surface and are finally “swallowed” by macrophages, epithelial cells and other phagocytic cells; phosphatidylserine eversion; condensation and marginalization of nuclear chromatin; and DNA fragmentation. Important molecules involved in apoptosis are: apoptosis-promoting molecules such as cysteine containing the aspartate-specific protease (caspase) family, and cytochrome c; and apoptosis-inhibitory molecules such as the Bcl-2 family. Apoptotic signaling pathways mainly involve the cell membrane receptor pathway [e.g., Fas/Fas ligand and tumor necrosis factors (TNF)/TNF receptor] or mitochondrial pathway conduction, which activates the caspases (caspase-8 or caspase-9) and key molecules of the downstream signal transduction pathway in succession to initiate caspase (caspase-3) and start apoptosis. In addition, apoptosis can also start in a caspase-independent manner^[21,22].

The Bcl-2 family contains molecules that can regulate apoptosis^[23]. These can be divided into two main categories: anti-apoptotic genes (particularly Bcl-2) and pro-apoptotic genes (particularly Bax). Bcl-2 can form protein dimers with the pro-apoptotic protein Bax and plays a decisive role in the apoptosis signaling pathway. If the Bcl-2/Bax ratio is decreased, apoptosis occurs^[24]. Changes in the expression of the Bcl-2 protein family lead to increased permeability of the outer membrane of mitochondria, thus triggering mitochondrial release of cy-

tochrome c. Apaf-1 can activate caspase-3. If cytochrome c is released into the cytoplasm, it forms the Apaf-1/cytochrome c complex with Apaf-1. After the Apaf-1/cytochrome c complex binds with ATP/dATP, Apaf-1 can “call” caspase-9 through its CARD domain to form apoptotic bodies, activate caspase-3, and start the caspase cascade reaction, thereby leading to apoptosis^[25].

Recent studies have shown that the anti-tumor activity of oridonin is related to its induction of apoptosis^[16,26-28]. In the present study, the MTT assay initially confirmed that oridonin can have a notable inhibitory effect on the proliferation of HGC-27 cells in a dose- and time-dependent manner. Our previous studies also suggested that oridonin has a notable inhibitory effect on the proliferation of gastric cancer^[20]. Previous studies also found the growth-inhibitory activity of oridonin on cancer cells^[29,30]. Light microscopy and AO/EB staining revealed that, after treatment with oridonin, HGC-27 cells became round, shrank, developed pyknosis, and formed small buds around the nuclear membrane as well as apoptotic bodies. The LDH release assay showed that oridonin could induce the death of gastric cancer cells mainly through its induction of apoptosis, and that the apoptotic effect was enhanced significantly as the concentration increased. These results were consistent with previous reports^[31-34]. DNA ladder analyses demonstrated that, after treatment

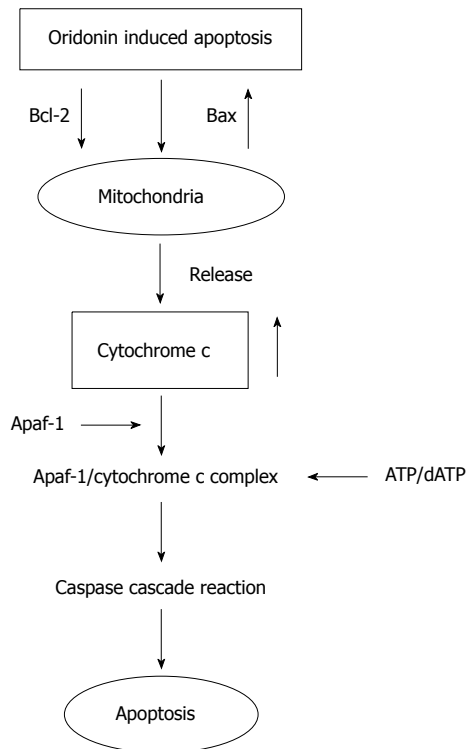

Figure 6 Possible mechanism by which oridonin induces the apoptosis of HGC-27 cells.

with different concentrations of oridonin, obvious DNA fragmentation could be seen. This finding indicated that oridonin could inhibit the proliferation of HGC-27 cells and induce their apoptosis. To further study the molecular mechanism of oridonin-induced apoptosis, semi-quantitative RT-PCR and Western blotting analysis were conducted to observe changes in expression of caspase-3, cytochrome c, Apaf-1, Bax and Bcl-2 mRNA after treatment with oridonin. Expression of caspase-3, cytochrome c, Apaf-1 and Bax was up-regulated, whereas that of Bcl-2 was down-regulated. The results showed that oridonin could inhibit the proliferation of HGC-27 cells, and that this effect was related to its induction of tumor-cell apoptosis. Liu *et al.*^[35] also found that oridonin induced a decrease in Bcl-2/Bax ratio and activation of caspase-3. Zhang *et al.*^[36] reported that regulation of the Bcl-2 and MAPK families may be the effector mechanisms of oridonin-induced L929 cell death, independent of the caspase pathway. So we speculated that oridonin may change expression of Bcl-2 and Bax, and then trigger the release of cytochrome c through the mitochondrial pathway to further activate the caspase cascade reaction and induce HGC-27 apoptosis (Figure 6).

In conclusion, oridonin significantly inhibited the proliferation and promoted apoptosis of gastric cancer cell line HGC-27. And the apoptosis of HGC-27 induced by oridonin may be associated with differential expression of Apaf-1, caspase-3 and cytochrome c, which are highly dependent upon the mitochondrial pathway.

COMMENTS

Background

Gastric cancer is a common cancer of the digestive system and the second most common type of cancer worldwide. It is important to seek and develop new and more effective anti-gastric cancer drugs. *Rabdosia rubescens*, a medicinal herb, has therapeutic actions. Studies have suggested that oridonin has certain anti-tumor effects in many kinds of tumors. However, the exact mechanism by which oridonin induces the apoptosis of gastric cancer cells remains undefined. In this study, the effect of oridonin on gastric cancer cells and its possible mechanism of action were explored.

Research frontiers

Studies have suggested that oridonin has certain anti-tumor effects on cervical cancer, human epidermal squamous cell carcinoma, leukemia, liver cancer, malignant melanoma, colon cancer, breast cancer, and other tumors. It has been found that the mechanism of oridonin-induced apoptosis and aging of colon cancer cells might lie in increased histone acetylation and changes in the expressions of p16, p21, p27 and c-myc. Oridonin can induce the apoptosis of hepatoma cells through the reactive oxygen species-mitogen-activated protein kinase-p53 pathway. In addition, some recent studies suggested that oridonin can also inhibit the proliferation of tumor cells by increasing the autophagy of tumor cells. All of these findings suggest that oridonin has good anti-tumor effects.

Innovations and breakthroughs

In the present study, the authors found that oridonin significantly inhibited the proliferation and promoted apoptosis of gastric cancer cell line HGC-27. And the apoptosis of HGC-27 induced by oridonin may be associated with differential expression of Apaf-1, caspase-3 and cytochrome c. The authors speculated that oridonin may change expression of Bcl-2 and Bax, and then trigger the release of cytochrome c through the mitochondrial pathway to further activate the caspase cascade reaction and induce HGC-27 apoptosis.

Applications

Oridonin possesses potent anti-gastric cancer activities associated with inhibition of proliferation and regulation of pathways critical for maintaining apoptosis induction. These results may lay the groundwork for further studies to establish the causal relationship between oridonin anti-tumor activity and specific genetic pathways and to identify molecular markers that will guide the development of future clinical therapies. Therefore, oridonin may represent a novel therapeutic option for gastric cancer.

Terminology

Gastric cancer is still the second leading cause of cancer-related death worldwide, particularly in Asian countries. Traditional Chinese medicine (TCM) has played an increasingly important part in the prevention and treatment of tumors. In particular, integration of TCM with Western medicine has appreciably improved the efficacy of drug combinations and prolonged patient survival. Oridonin (molecular formula: $C_{20}H_{20}O_6$; relative molecular weight: 364.42) is a tetracyclic diterpenoid compound, which was extracted from *Rabdosia rubescens*.

Peer review

The authors demonstrated the effect and mechanism of oridonin on HGC-27 gastric cancer cell line and suggested that oridonin may represent a novel therapeutic option for gastric cancer.

Abstract

AIM: To explore age-related changes in symptoms and quality of life (QoL) of women with irritable bowel syndrome (IBS).

METHODS: Two-hundred and fifty-four female adult outpatients with IBS attending the Department of Gastroenterology at the First Affiliated Hospital of Nanjing Medical University between January, 2008 and October, 2008 were approached. Patients with a history of abdominal surgery, mental illness or those who had recently taken psychotropic drugs were excluded. A physician obtained demographic and abdominal symptom data. All patients were asked to complete the Zung Self-Rated Anxiety and Depression Scale

(SDS/SAS) and the IBS-specific QoL questionnaire. The patients were divided into six groups according to age, in 10-year increments: 18-27 years, 28-37 years, 38-47 years, 48-57 years, 58-67 years and 68-75 years (maximum 75 years). Age-related differences of abdominal pain or discomfort were analyzed using rank-sum tests. Differences in SDS/SAS and IBS-QoL scores between age groups were analyzed using one-way analysis of variance. Pearson's correlations evaluated potential associations between IBS symptoms, psychological factors and QoL in each age group.

RESULTS: There were no differences in the distribution of IBS subtypes between age groups ($\chi^2 = 20.516$, $P = 0.153$). Differences in the severity of abdominal pain/discomfort with age were statistically significant ($\chi^2 = 25.638$, $P < 0.001$); patients aged 48-57 years, 58-67 years or 68-75 years had milder abdominal pain/discomfort than those in the younger age groups. The severity of anxiety or depressive symptoms did not differ between age groups (SDS, $\chi^2 = 390.845$, $P = 0.110$; SAS, $\chi^2 = 360.071$, $P = 0.220$). Differences of IBS-QoL scores were statistically significant between age groups ($\chi^2 = 1098.458$, $P = 0.011$). The scores of patients in the 48-57-year group were lower than those in the 18-27-year and 28-37-year groups (48-57-year group vs 18-27-year group, 74.88 ± 8.76 vs 79.76 ± 8.63 , $P = 0.021$; 48-57-year group vs 28-37-year group, 74.88 ± 8.76 vs 79.04 ± 8.32 , $P = 0.014$). The scores in the 68-75-year group were lower than those in the 18-27-year, 28-37-year and 38-47-year groups (68-75-year group vs 18-27-year group, 71.98 ± 9.83 vs 79.76 ± 8.63 , $P = 0.003$; 68-75-year group vs 28-37-year group, 71.98 ± 9.83 vs 79.04 ± 8.32 , $P = 0.002$; 68-75-year group vs 38-47-year group, 71.98 ± 9.83 vs 76.44 ± 8.15 , $P = 0.039$). Anxiety and depression were negatively correlated with QoL in all age groups (SDS and QoL: 18-27-year group, $r = -0.562$, $P = 0.005$; 28-37-year group, $r = -0.540$, $P < 0.001$; 38-47-year group, $r = -0.775$, $P < 0.001$; 48-57-year group, $r = -0.445$, $P = 0.001$; 58-67-year group, $r =$

-0.692, $P < 0.001$; 68-75-year group, $r = -0.732$, $P < 0.001$. SAS and QoL: 18-27-year group, $r = -0.600$, $P = 0.002$; 28-37-year group, $r = -0.511$, $P < 0.001$; 38-47-year group, $r = -0.675$, $P < 0.001$; 48-57-year group, $r = -0.558$, 58-67-year group, $P = 0.001$; $r = -0.588$, $P < 0.001$; 68-75-year group, $r = -0.811$, $P < 0.001$). A negative correlation between abdominal pain severity and QoL was found in patients aged more than 58 years (58-67-year group, $r = -0.366$, $P = 0.017$; 68-75-year group, $r = -0.448$, $P = 0.048$), but not in younger patients (18-27-year group, $r = 0.080$, $P = 0.716$; 28-37-year group, $r = -0.063$, $P = 0.679$; 38-47-year group, $r = -0.029$, $P = 0.812$; 48-57-year group, $r = -0.022$, $P = 0.876$).

CONCLUSION: Factors affecting QoL should always be treated in IBS, especially emotional problems in young adults. Even mild abdominal pain should be controlled in elderly patients.

INTRODUCTION

Irritable bowel syndrome (IBS) is the most common functional gastrointestinal disorders. It is common in Chinese people, representing approximately 11% of outpatient cases in gastroenterology departments^[1]. Patients with IBS have long-term symptoms including abdominal pain or discomfort related to defecation, accompanied by emotional disorders such as anxiety or depression, and often have a poor quality of life (QoL)^[2,3]. The abdominal symptoms of IBS may be related to changes of gastrointestinal motility, visceral sensitivity and other factors^[4,5], and affected by estrogen and progesterone levels and psychological factors^[6-8]. Anxiety or depression in IBS patients may be associated with physical discomfort and mental stress, and related to the patient's response to the disease and the degree of social support^[9,10].

It is widely recognized that gastrointestinal motility, visceral sensitivity, and estrogen and progesterone levels differ between people of different ages^[11,12], as do cognitive abilities and the response to disease^[13]. Do abdominal pain or discomfort, anxiety and depression vary with

age in IBS patients? Are there age-related differences in the impact of these symptoms on QoL? In this study, we explored these two questions.

IBS is more common in women than in men, and female IBS patients report more severe symptoms and generally have lower QoL^[1]. Therefore, we investigated age-related changes of symptoms and QoL in female patients with IBS in a Chinese population, with the aim of improving individual treatment.

MATERIALS AND METHODS

Subjects

First-time outpatients who attended the Department of Gastroenterology at the First Affiliated Hospital of Nanjing Medical University between January, 2008 and October, 2008 and met the Rome III criteria for IBS were recruited^[14].

All patients were initially asked to undergo routine blood, urine and stool hemocult tests, stool form examination, and endoscopy or radiographic examination of the gastrointestinal tract. Patients younger than 18 years, with a structural bowel disease or a history of abdominal surgery, diagnosed with mental illness by a psychiatrist or who had recently taken psychotropic drugs were excluded^[1]. Pregnant patients were not included.

Measurements

The age of each subject was recorded. A physician obtained demographic and abdominal symptom data. All patients were asked to completed the Zung Self-Rated Anxiety and Depression Scale (SAS/SDS) and the IBS-specific QoL (IBS-QoL) questionnaire^[15-19].

IBS subtypes: Based on the Rome III diagnostic criteria and Bristol Stool Form Scale^[14], the patients were divided into the following groups: IBS with constipation (IBS-C), IBS with diarrhea (IBS-D), mixed IBS (IBS-M) and unsubtyped IBS (IBS-U).

IBS abdominal symptoms: The patients were asked about the severity of their abdominal pain/discomfort, which was rated on a three-point response scale as follows: mild ("can be ignored if I don't think about it"), moderate ("cannot be ignored, but does not affect my lifestyle") or severe ("affects my lifestyle")^[20].

SAS/SDS: Anxiety and depression were measured using the SAS and SDS assessment tools, respectively^[15-17]. Each of the SAS and SDS comprises 20 questions with four possible responses to each: never, rarely/sometimes, frequently and always. Higher SAS/SDS scores indicate a greater degree of anxiety/depression.

IBS-QoL: The IBS-QoL^[18,19] comprises 34 self-reported items; a higher total score indicates a better QoL. There are also eight subscale scores for dysphoria, interference with activities, body image, health concerns,

Table 1 Severity of abdominal pain/discomfort and Zung Self-Rated Anxiety and Depression Scale scores in each age group

Age group (yr)	Total (n)	Severity of abdominal pain/discomfort (n)			Mean rank	SDS score	SAS score
		Mild	Moderate	Severe			
18-27	23	12	5	6	150.74	52.17 ± 8.03	39.09 ± 8.18
28-37	46	29	10	7	133.84	51.83 ± 5.09	39.65 ± 6.16
38-47	68	34	22	12	149.66	54.03 ± 6.66	41.25 ± 7.17
48-57	52	45	9	1	106.90	54.24 ± 7.60	42.31 ± 7.37
58-67	42	33	8	1	110.82	54.60 ± 6.09	39.83 ± 6.82
68-75	20	17	3	0	102.53	56.15 ± 4.98	42.45 ± 7.81

The severity of abdominal pain/discomfort differed between age groups ($\chi^2 = 25.638$, $P < 0.001$). There were no differences in Zung Self-Rated Anxiety Scale (SAS) or Zung Self-Rated Depression Scale (SDS) scores between any age groups (SDS, $\chi^2 = 390.845$, $P = 0.110$; SAS, $\chi^2 = 360.071$, $P = 0.220$).

Figure 1 Distribution of irritable bowel syndrome subtypes in each age group. IBS: Irritable bowel syndrome; IBS-C: IBS with constipation; IBS-D: IBS with diarrhea; IBS-M: Mixed IBS; IBS-U: Unsubtyped IBS.

Figure 2 Severity of abdominal pain/discomfort by age. 1 = Mild; 2 = Moderate; 3 = Severe.

food avoidance, social reaction, sexual issues and relationship problems.

Age groups: The patients were divided into six groups according to age, in 10-year increments: 18-27 years, 28-37 years, 38-47 years, 48-57 years, 58-67 years and 68-75 years (maximum 75 years)^[21-23].

Statistical analysis

All data were analyzed using SPSS Version 19.0. Statistical significance was set at $P < 0.05$. Categorical data and ratios were analyzed using the χ^2 test. Rank-sum tests were used to analyze ranked data. All measurement data are reported as the mean \pm SD. Differences in SDS/SAS and IBS-QoL scores between age groups were analyzed using one-way analysis of variance. Pearson's correlations were used to evaluate the potential associations between IBS symptoms, psychological factors and QoL in each age group.

RESULTS

Patient background and clinical data

Two hundred and fifty-four women with IBS were approached for recruitment to this study. These patients were aged between 18 and 75 years (46.67 ± 14.26

years). The median duration of IBS was 3 years, and 8.4% of the patients had a history of IBS of more than 10 years. There were no differences in the duration of IBS between age groups (average duration of each group: 2.79 ± 2.48 years, 2.22 ± 2.27 years; 2.94 ± 3.29 years, 2.97 ± 3.32 years, 4.27 ± 4.79 years, 4.35 ± 6.55 years, respectively; $\chi^2 = 129.4$, $P = 0.101$). One hundred and twenty-three patients (48.4%) were diagnosed with IBS-D, 105 (41.3%) with IBS-C, 22 (8.7%) with IBS-M and 4 (1.6%) with IBS-U. There were no differences in the distribution of IBS subtypes between age groups ($\chi^2 = 20.516$, $P = 0.153$), as shown in Figure 1.

Symptoms by age

Abdominal pain/discomfort: Differences in the severity of abdominal pain/discomfort with age are shown in Figure 2. These differences were statistically significant ($\chi^2 = 25.638$, $P < 0.001$; Table 1); patients aged 48-57 years, 58-67 years or 68-75 years had milder abdominal pain/discomfort than those in the younger age groups.

Anxiety and depression: SAS and SDS scores with age are shown in Figure 3. There were no statistically significant differences between any age groups (SDS, $\chi^2 = 390.845$, $P = 0.110$; SAS, $\chi^2 = 360.071$, $P = 0.220$; Table 1), indicating that the severity of anxiety and depression does not vary with age.

Figure 3 Zung self-rated anxiety and depression scale scores according to age. SAS/SDS: Zung self-rated anxiety and depression scale.

QoL: IBS-QoL scores with age are shown in Figure 4A. These differences were statistically significant between age groups ($\chi^2 = 1098.458$, $P = 0.011$; Figure 4B). The scores of patients in the 48-57-year group were lower than those in the 18-27-year and 28-37-year groups ($P = 0.021$, $P = 0.014$). The scores in the 68-75-year group were lower than those in the 18-27-year, 28-37-year and 38-47-year groups ($P = 0.003$, $P = 0.002$ and $P = 0.039$, respectively).

Association of abdominal pain, anxiety and depression with QoL

As shown in Figure 5, the severity of abdominal pain/discomfort was negatively correlated with IBS-QoL score in the 58-67-year and 68-75-year groups ($P < 0.05$), but there was no correlation in the 18-27-, 28-37-, 38-47- or 48-57-year groups. SAS and SDS scores were negatively correlated with IBS-QoL score in all age groups ($P < 0.01$).

DISCUSSION

In this study, most of the 254 women with IBS were middle-aged. IBS-D was the most common subtype, followed by IBS-C, IBS-M and IBS-U. The distribution of IBS subtypes showed no difference between any age groups, consistent with previous epidemiological studies^[1,23,24].

Our study suggests that the severity of abdominal pain/discomfort differs in patients of different ages, but anxiety and depressive symptoms do not. Patients aged 48-57 years or 68-75 years had the worst QoL. Anxiety and depression were negatively correlated with QoL in all age groups, and a negative correlation between abdominal pain severity and QoL was found in patients aged more than 58 years, but not in younger patients.

Defecation-related abdominal pain/discomfort is the principal symptom of IBS^[14]. In the present study, patients older than 48 years had milder abdominal pain/discomfort. Visceral hypersensitivity, psychological factors, motility, immunity and infection are the major

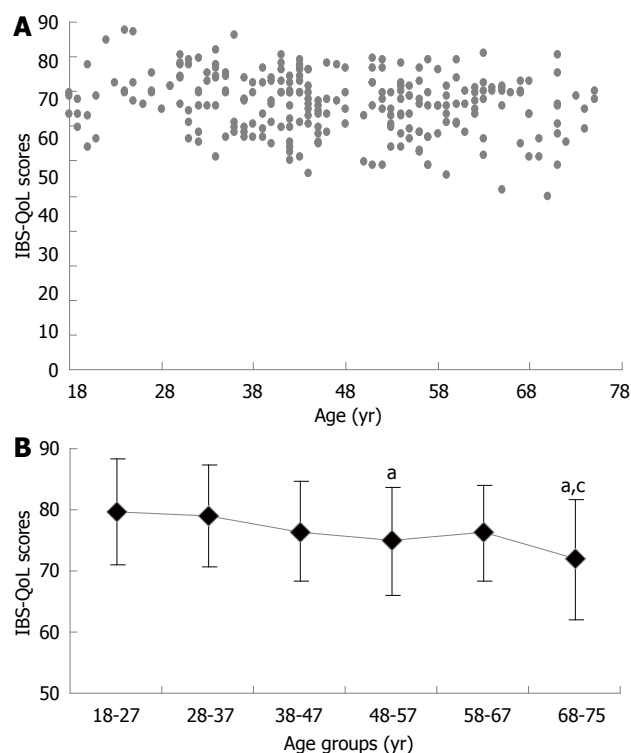

Figure 4 Specific quality of life questionnaire scores for patients with irritable bowel syndrome. A: Specific quality of life questionnaire scores for patients with irritable bowel syndrome (IBS) according to age; B: Specific quality of life questionnaire scores for patients with IBS in each age group. ^a $P < 0.05$ vs 18-27-year and 28-37-year groups; ^c $P < 0.05$ vs 48-57-year group. QoL: Quality of life; SAS/SDS: Zung self-rated anxiety and depression scale.

pathophysiologic factors in abdominal pain/discomfort in IBS^[4,5,25-27], and the role of visceral hypersensitivity in the pathogenesis of IBS has become commonly accepted in recent years. IBS patients have been reported to have a decreased intestinal pain perception threshold and are more likely to report feeling pain^[28,29]. Some studies have shown visceral sensitivity to decrease with age^[12]. Sanoja *et al*^[7] found that estrogen and progesterone can regulate sensitivity to pain and temperature sensation, and Heitkemper *et al*^[30], summarizing the results of recent research, found that estrogen and progesterone can affect the symptoms of IBS. Most women over the age of 48 years are in the menopause or perimenopausal period, and the decline of estrogen and progesterone levels may be accompanied by decreased visceral sensitivity.

In the modern bio/psychosocial medical model, IBS is recognized as a psychosomatic disorder accompanied by various emotional disorders, among which anxiety and depression are the most common. The present study found no differences in SAS/SDS scores between age groups, suggesting that the severity of anxiety and depression is similar in patients of differing ages.

Although it has been confirmed that coping capacity increases with age^[13], ageing is accompanied by reduced sleep quality and blood hemoglobin concentration, and both of these are closely related to depression^[31-33]. Negative life events, social support and other factors are also involved in the occurrence of anxiety and depres-

Figure 5 Association of abdominal pain/discomfort severity, and Zung self-rated anxiety and depression scale scores for patients with irritable bowel syndrome in each age group. A: Age 18-27 years; B: Age 28-37 years; C: Age 38-47 years; D: Age 48-57 years; E: Age 58-67 years; F: Age 68-75 years. A1 to F1, association of abdominal pain/discomfort with quality of life in each age group. Severity of abdominal pain/discomfort was negatively correlated with irritable bowel syndrome-specific quality of life questionnaire (IBS-QoL) scores in the 58-67-year and 68-75-year groups ($P < 0.05$), but there was no correlation in the 18-27-year, 28-37-year, 38-47-year or 48-57-year groups ($P > 0.05$); A2 to F2, association of Zung Self-Rated Depression Scale (SDS) scores with quality of life in each age group. SDS scores were negatively correlated with IBS-QoL scores in all age groups ($P < 0.01$); A3 to F3, association of Zung Self-Rated Anxiety Scale (SAS) scores with quality of life in each age group. SAS scores were negatively correlated with IBS-QoL scores in all age groups ($P < 0.01$).

sion^[10,34,35]. None of these factors showed any significant age-related differences in IBS patients.

QoL relates to the functional capabilities of individuals in social life and reflects subjective feelings. It is an important concept in biomedical and social psychology, but is of greatest concern in disease states and when evaluating treatments for disease-related symptoms. In patients with IBS, it is regarded as a major measure of clinical outcome and is widely used in clinical studies^[18,19]. Previous studies have shown that bowel symptoms, anxiety and depression are important factors in the QoL of IBS patients^[36-38]. The present study demonstrated age-related differences in the QoL of women with IBS; the QoL of patients aged 48-57 years or over 68 years was poorer than that of younger patients. However, the patients in the older age groups had milder abdominal pain, and their degree of anxiety and depression was similar to that of the other age groups. Thus, what caused the decline of their QoL? Pines *et al.*^[39] found that the reduction of hormone levels in menopausal women resulted in various physical symptoms that affected QoL, and hormone replacement therapy partially improved these symptoms. Menopause-related factors may have responsible for the poor QoL of the patients aged 48-57 years in our study. In addition, we speculate that multiple other factors such as decreased activity or social support, or impaired psychological status may lead to a poor QoL in older patients. It is necessary to identify other factors that affect QoL in these patients, in addition to bowel symptoms, anxiety and depression.

We also investigated changes with age in the correlation of abdominal pain, anxiety and depressive symptoms with QoL, and found that anxiety and depression were negatively correlated with QoL in all age groups.

Psychologists believe that IBS is a psychosomatic disorder; most IBS patients have core symptoms of anxiety or depression, while gastrointestinal symptoms such as abdominal pain and changes in bowel habit represent

somatization^[40]. In our previous study, we found that most IBS patients complained of nonspecific somatic symptoms such as dizziness, insomnia and fatigue^[1]. We should therefore pay attention to the treatment of anxiety, depression and other negative emotions in IBS patients. In the present study, found that, in young and middle-aged patients (18-57 years), QoL was negatively correlated with anxiety and depression, but not associated with the severity of abdominal pain/discomfort. Therefore, improving gastrointestinal symptoms only may not improve QoL in these age groups, and antidepressant treatment may be more important. In IBS patients aged over 58 years, abdominal pain/discomfort was mild but closely associated with QoL. Thus, even slight abdominal pain should be controlled in the treatment of older patients. Although age-related physiological and psychological changes may be directly or indirectly related to ovarian function and female hormone levels, this was a retrospective study and thus we lack information on the patients' hormone levels and menstrual history. Furthermore, the use of self-reported measures and individual differences in literacy and understanding may have affected the results. None of these limitations could be avoided.

In conclusion, the following points should be borne in mind when treating women with IBS. Firstly, in patients aged 48-57 years or over 68 years, factors other than IBS-related symptoms that affect QoL should be treated. Secondly, negative emotions should be treated in all patients; anti-anxiety and antidepressant treatment are especially important in young adults. Thirdly, to improve QoL, even mild abdominal pain should be controlled in elderly patients.

COMMENTS

Background

Irritable bowel syndrome (IBS) is the most common functional gastrointestinal

disorder. IBS is more common in women than in men, and female IBS patients report more severe symptoms and generally have a lower quality of life (QoL). Age-related changes, such as gastrointestinal motility, visceral sensitivity, estrogen and progesterone levels, cognitive abilities and the response to disease may cause differences in abdominal pain or discomfort, anxiety and depression and reduced QoL levels. Therefore, the authors investigated age-related changes of symptoms and QoL levels in female patients with IBS in a Chinese population, with the aim of improving individual treatment profiles.

Research frontiers

The symptoms of IBS may be related to changes in gastrointestinal motility and visceral sensitivity and are affected by estrogen and progesterone levels, psychological factors, patient response to pain and the degree of social support. All of the above factors differ between people of different ages. In this study, authors demonstrate that differences in abdominal pain or discomfort levels, but not anxiety or depression, and their association with QoL exist in patients in different age groups.

Innovations and breakthroughs

Recent reports have highlighted the differences in IBS abdominal and psychological symptoms in different genders and IBS subtypes, which can guide individual treatment regimens. Other reports have referred to the different age distributions of IBS patients. However, no study has investigated age-related changes in symptoms and their association with QoL in IBS patients, particularly in an exclusively female patient cohort or in a Chinese population.

Applications

In this study, the authors have demonstrated the difference of IBS symptoms and their association with QoL in each patient age group. With this knowledge, the authors may improve individual treatment regimens for IBS according to the patient age.

Terminology

Zung self-rated anxiety and depression scale (SAS/SDS) are assessment tools that are used to measure anxiety and depression, respectively. Higher SAS/SDS scores indicate a greater degree of anxiety/depression. IBS-specific QoL questionnaire (IBS-QoL) is a QoL assessment tool, which was specifically set up for patients with IBS. A higher IBS-QoL score indicates a better QoL.

Peer review

The authors explored the age-related changes of symptoms, QoL and the correlations between these two parameters in a population of Chinese women. The results demonstrated that factors that affect QoL should always be treated in IBS, especially emotional problems in young adults, and even mild abdominal pain should be controlled in elderly patients. These findings will help to improve the treatment of individuals with IBS.

Abstract

AIM: To investigate the effect of sulfated cholecystokinin-8 (CCK-8S) on calcium mobilization in cultured murine gastric antral interstitial cells of Cajal (ICC) and its possible mechanisms.

METHODS: ICC were isolated from the gastric antrum of mice and cultured. Immunofluorescence staining with a monoclonal antibody for c-Kit was used to identify ICC. The responsiveness of ICC to CCK-8S was measured using Fluo-3/AM based digital microfluorimetric measurement of intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$). A confocal laser scanning microscope was used to monitor $[\text{Ca}^{2+}]_i$ changes. The selective CCK₁ receptor antagonist lorglumide, the intracellular Ca^{2+} -ATPase inhibitor thapsigargin, the type III inositol 1,4,5-triphosphate (InsP_3) receptor blocker xestospongin C and the L-type voltage-operated Ca^{2+} channel inhibitor nifedipine were used to examine the mecha-

nisms of $[\text{Ca}^{2+}]_i$ elevation caused by CCK-8S. Immunoprecipitation and Western blotting were used to determine the regulatory effect of PKC on phosphorylation of type III InsP_3 receptor (InsP_3R) in ICC. Protein kinase C (PKC) activator phorbol 12-myristate 13-acetate (PMA) and inhibitor chelerythrine were used to assess the role of PKC in the CCK-8S-evoked $[\text{Ca}^{2+}]_i$ increment of ICC.

RESULTS: ICC were successfully isolated from the gastric antrum of mice and cultured. Cultured ICC were identified by immunofluorescence staining. When given 80 nmol/L or more than 80 nmol/L CCK-8S, the $[\text{Ca}^{2+}]_i$ in ICC increased and 100 nmol/L CCK-8S significantly increased the mean $[\text{Ca}^{2+}]_i$ by $59.30\% \pm 4.85\%$ ($P < 0.01$). Pretreatment of ICC with 5 $\mu\text{mol/L}$ lorglumide inhibited 100 nmol/L CCK-8S-induced $[\text{Ca}^{2+}]_i$ increment from $59.30\% \pm 4.85\%$ to $14.97\% \pm 9.05\%$ ($P < 0.01$), suggesting a CCK₁R-mediated event. Emptying of intracellular calcium stores by thapsigargin (5 $\mu\text{mol/L}$) prevented CCK-8S (100 nmol/L) from inducing a $[\text{Ca}^{2+}]_i$ increase. Moreover, pretreatment with xestospongin C (1 $\mu\text{mol/L}$) could also abolish the CCK-8S-induced effect, indicating that Ca^{2+} release from InsP_3R -operated stores appeared to be a major mechanism responsible for CCK-8S-induced calcium mobilization in ICC. On the other hand, by removing extracellular calcium or blocking the L-type voltage-operated calcium channel with nifedipine, a smaller but significant rise in the $[\text{Ca}^{2+}]_i$ could be still elicited by CCK-8S. These data suggest that the $[\text{Ca}^{2+}]_i$ release is not stimulated or activated by the influx of extracellular Ca^{2+} in ICC, but the influx of extracellular Ca^{2+} can facilitate the $[\text{Ca}^{2+}]_i$ increase evoked by CCK-8S. CCK-8S increased the phosphorylation of InsP_3R , which could be prevented by chelerythrine. Pretreatment with lorglumide (5 $\mu\text{mol/L}$) could significantly reduce the CCK-8S intensified phosphorylation of InsP_3R . In the positive control group, treatment of cells with PMA also resulted in an enhanced phosphorylation of InsP_3R . Pretreatment with various concentrations of PMA (10 nmol/L-10 $\mu\text{mol/L}$) apparently inhibited the effect of CCK-8S and the effect of

100 nmol/L PMA was most obvious. Likewise, the effect of CCK-8S was augmented by the pretreatment with chelerythrine (10 nmol/L-10 μ mol/L) and 100 nmol/L chelerythrine exhibited the maximum effect.

CONCLUSION: CCK-8S increases $[Ca^{2+}]_i$ in ICC *via* the CCK₁ receptor. This effect depends on the release of InsP₃R-operated Ca^{2+} stores, which is negatively regulated by PKC-mediated phosphorylation of InsP₃R3.

INTRODUCTION

In the gastrointestinal (GI) tract, phasic contractions are caused by electrical activity termed slow waves, which are generated and propagated by the interstitial cells of Cajal (ICC)^[1,2]. The initiation of pacemaker activity in the ICC is caused by rhythmic cytoplasmic Ca^{2+} oscillation^[3,4]. The ICC can regulate slow-wave-driven peristaltic activity as well as mediate motor inputs from the GI nervous system^[5,6]. ICC abnormalities are associated with many GI motility disorders, such as achalasia of cardia, slow transit constipation and irritable bowel syndrome^[7,8]. Therefore, understanding the mechanisms underlying pacemaker activity and excitability of ICC is of crucial importance^[9]. Although neurohumoral regulation of GI function has been studied in some detail, less is known about the mechanisms of how neurohumoral factors regulate pacemaker activities in the ICC.

Cholecystokinin (CCK) is a bioactive peptide that regulates a variety of physiological functions, acting as both hormone and neurotransmitter in the GI tract^[10,11]. Sulfated CCK-8 (CCK-8S), which has frequently been used in research studies, is one of the main biologically active forms of CCK^[12]. The regulatory actions of CCK are mediated by two receptor subtypes, CCK₁ and CCK₂ receptors. CCK receptors are distributed in enteric nerves and smooth muscles^[13]. In addition, CCK₁ receptors are also found in the ICC, suggesting a role for the ICC in the mediation of CCK effects^[14].

CCK inhibits gastric emptying by relaxing the proxi-

mal part of the stomach and increasing pyloric pressure^[10,12]. However, the mechanisms of the regulatory effects of CCK on gastrointestinal motility are not clear. Previous studies have shown that CCK can activate phospholipase C (PLC) through binding to its distinct receptors^[15]. This activation leads to the production of diacylglycerol (DAG) and inositol 1,4,5- triphosphate (InsP₃), which in turn activates protein kinase C (PKC) and mobilizes intracellular calcium ($[Ca^{2+}]_i$)^[16]. Through this signaling pathway, CCK may participate in various physiological responses, such as secretion, neurotransmission and muscle contraction^[17]. However, the cross-talk of the CCK-8S triggered PKC and Ca^{2+} signaling pathways is not been well understood. The aims of this study were to investigate the effect of CCK-8S on $[Ca^{2+}]_i$ in the ICC and the respective contributions of InsP₃R-sensitive intracellular Ca^{2+} stores and extracellular Ca^{2+} sources in those responses. Additionally, the role of PKC in regulation of CCK-8S-triggered calcium signaling pathway was also studied.

MATERIALS AND METHODS

Preparation of cells and cell culture

All experiments were performed according to the guiding principles for the care and use of animals approved by Institutional Animal Use and Care Committee of the First Affiliated Hospital of Nanjing Medical University. Every effort was made to minimize both the number of animals used and their suffering.

Balb/c mice (5-6 wk) of either sex were purchased from the laboratory of the First Affiliated Hospital of Nanjing Medical University. The animals were anesthetized by chloroform inhalation and killed by cervical dislocation. The stomach was excised and the contents were washed away with ice-cold Krebs-Ringer bicarbonate (KRB). The mucosa was removed by peeling. In Sylgard dishes filled with Krebs solution, the tissues were washed three times and then cut into about 0.5 cm segments. The segments were transferred into a centrifuge tube and dispersed with an enzyme solution containing collagenase 1.3 mg/mL, trypsin inhibitor 2 mg/mL and ATP 0.27 mg/mL. The centrifuge tube was incubated at 37 °C for 30 min and the tissue segments were blown for 30 s with pipette every 5 min during incubation. An equal volume Medium 199 containing 10% fetal bovine serum was added to stop digestion. The tube was centrifuged at 1000 rpm for 3 min and then the supernatant was removed. The sediment was suspended with Medium 199 and cells were collected by pouring the suspension through a 200-mesh sieve. After centrifugation at 1000 rpm for 3 min, the cells were dispersed with Medium 199 and then plated onto 35 mm glass-bottom culture dishes (NEST Biotechnology Co., Ltd, China) coated with rat-tail tendon collagen (5 mg/mL). The cells were then cultured at 37 °C in a 95% O₂-5% CO₂ incubator in Medium 199 supplemented with 2% Penicillin-Streptomycin liquid and murine stem cell factor (5 ng/mL).

Labeling of cultured ICC by c-Kit immunofluorescence

Cultured ICC were fixed in acetone (4 °C, 8 min). Following fixation, preparations were washed for 40 min in phosphate buffered saline (PBS; 0.01 mol/L, pH 7.4) and then incubated in 10% goat serum for 1 h to reduce nonspecific antibody binding. To examine the ICC, we incubated cultured ICC overnight at 4 °C with a rabbit anti-mouse monoclonal c-Kit antibody (1:300 in PBS). Immunoreactivity was detected using Alexa Fluor 488 (1:1000 in PBS, 60 min, room temperature), and nuclei were stained with Hoechst 33 258. Cells were examined under a confocal laser scanning microscope (LSM710, Zeiss, Germany) at an excitation wavelength appropriate for Alexa Fluor 488 (488 nm).

Measurement of intracellular Ca^{2+} concentration

Changes in $[Ca^{2+}]_i$ were monitored using Fluo-3/AM, which was initially dissolved in dimethyl sulfoxide (DMSO) and stored at -20 °C. The cultured ICC grown on glass-bottom dishes were rinsed twice with PBS and then incubated in Medium 199 containing 5 μ mol/L Fluo-3/AM in the 95% O₂-5% CO₂ incubator for 40 min. Following rinsing for two more times, the dishes were scanned every 2 s with a confocal laser scanning microscope. Fluorescence was excited at a wavelength of 488 nm and emitted light was observed at 515 nm. The variations of $[Ca^{2+}]_i$ fluorescence emission intensity were expressed as F/F₀, where F₀ is the intensity of the first imaging.

Immunoprecipitation, electrophoresis and immunoblotting

Prepared from gastric ICC using equal volumes of a cell suspension, isolated cells were assayed for protein concentration. Following appropriate treatments, cells were pelleted and resuspended in 0.5 mL of ice-cold lysis buffer. Cell samples were sonicated and left on ice for 30 min to solubilize. Immunoprecipitation of InsP₃R was performed using a 1:100 dilution of an InsP₃R3-specific monoclonal antibody. Following 2 h of incubation with the InsP₃R3 antibody at 4 °C, immobilized protein A beads were added to each sample for 1 h at 4 °C. As a control, samples were also prepared without immunoprecipitating antibody. Following immunoprecipitation of InsP₃R3, proteins were separated by SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose. Membranes were probed with a 1:1000 dilution of phospho-(Ser/Thr) substrate antibody that specifically detected phosphorylated Ser/Thr residues with Arg at the -2 or -3 position within the PKC substrate sequence. Immunoreactivity was visualized using a 1:1000 dilution of peroxidase-conjugated secondary antibody. Where indicated, the nitrocellulose membrane was stripped of primary and secondary antibodies at 50 °C for 30 min.

Drugs and solutions

CCK-8S, collagenase, trypsin inhibitor, ATP, thapsigargin, chelerythrine, phorbol 12-myristate 13-acetate (PMA), nifedipine, Hoechst 33258, DMSO, HEPES were pur-

chased from Sigma (United States). SCF was purchased from Peprotech (United States). Rat-tail tendon collagen was purchased from Shengyou Biotechnology Co., Ltd (Hangzhou, China). C-Kit monoclonal antibody and phospho-(Ser/Thr) substrate antibody were from Cell Signaling Technology (United States). Type III InsP₃R-specific monoclonal antibody, protein A beads were from BD Biosciences Transduction Laboratories (United States). Alexa Fluor 488 (goat anti-rabbit secondary antibody) and Fluo-3/AM were from Invitrogen (United States). L-glutamide was purchased from Santa Cruz (United States). Xestospongin C was from Calbiochem (Germany). Medium 199, fetal bovine serum and Penicillin-Streptomycin liquid were purchased from Gibco (United States).

The KRB solution contains (mmol/L): NaCl 117, KCl 4.7, MgSO₄ 1.2, NaHCO₃ 25, KH₂PO₄ 1.2, Glucose 11 and CaCl₂ 2.6; pH was 7.4. Lysis buffer contains (mmol/L): NaCl 150, NaF 100, Tris 50, EDTA 10, Triton X-100 1%, and 1 complete EDTA-free protease inhibitor mixture tablet; pH was 7.4.

Statistical analysis

Data were expressed as mean \pm SE. Differences in the data were evaluated by ANOVA or by Student's *t* test. Zeiss Zen 9.0 was used to analyze the calcium intensity data and GraphPad Prism 5.0 for charting. Differences between control and test values were considered significant when *P* < 0.05.

RESULTS**Identification of cultured ICC**

After the cells were isolated and plated onto culture dishes, it was initially difficult to identify the ICC. After prolonged culture (4-7 d), the cultured ICC, were identified by c-Kit immunofluorescence and showed distinctive shapes, such as spindle, triangular or stellar-like with two to five long processes (Figure 1).

Effects of CCK-8S on intracellular Ca^{2+} intensity in cultured ICC

Addition of CCK-8S produced substantial, dose-dependent elevations of Fluo-3/AM fluorescence in cytoplasm and nucleus of the ICC, indicating that free calcium level had increased compared with the control (Figure 2A). When given \leq 50 nmol/L CCK-8S, the $[Ca^{2+}]_i$ did not increase (Figure 2B). As shown in Figure 2D, CCK-8S (100 nmol/L) significantly increased the mean $[Ca^{2+}]_i$ by $59.30\% \pm 4.85\%$ (*P* < 0.01, *n* = 6) and CCK-8S (80 nmol/L and 500 nmol/L) also evoked $[Ca^{2+}]_i$ increases in the percentage of cells responding ($20.22\% \pm 5.48\%$ and $39.32\% \pm 2.51\%$, respectively, Figure 2C, E and F). Group data for the $[Ca^{2+}]_i$ changes in response to CCK-8S at different concentrations are shown in Figure 2F.

CCK-8S increases $[Ca^{2+}]_i$ in cultured ICC via CCK₁ receptor

The CCK₁ receptor (CCK₁R) has been reported to be

Figure 1 Identification of cultured interstitial cells of Cajal. A-C: Prolonging the culture to 4-7 d, the cultured interstitial cells of Cajal (ICC), which are identified by c-Kit immunofluorescence, had distinctive shapes such as spindle, triangular or stellate-like with two to five long processes. ICC were fixed with acetone and identified immunologically using a monoclonal c-Kit antibody and Alexa Fluor 488-conjugated secondary fluorescent antibody. Nuclei were stained with Hoechst 33258 dye (B, blue); C: A merged image of A and B; D: A light microscopical image of ICC.

expressed in GI ICC^[14]. To identify the subtype of CCK receptor involved in the CCK-8S-induced increase in $[Ca^{2+}]_i$, the CCK₁R selective antagonist lorglumide was employed. Pretreatment of ICC with 5 μ mol/L lorglumide for 2 min inhibited 100 nmol/L CCK-8S-induced $[Ca^{2+}]_i$ increment from $59.30\% \pm 4.85\%$ to $14.97\% \pm 9.05\%$ ($P < 0.01$, $n = 6$) (Figure 3), suggesting a CCK₁R-mediated event.

CCK-8S-induced calcium mobilization in cultured ICC

To determine the source of CCK-8S-induced calcium mobilization, intracellular calcium release and extracellular calcium influx were investigated. Firstly, the ICC were exposed to CCK-8S in a medium without extracellular calcium and subsequently to specific intracellular Ca^{2+} -ATPase inhibitor thapsigargin. Compared with control, emptying of intracellular calcium stores by thapsigargin (5 μ mol/L) prevented CCK-8S (100 nmol/L) to induce a $[Ca^{2+}]_i$ increase (Figure 4A), indicating that Ca^{2+} release from intracellular stores appeared to be a major mechanism responsible for CCK-8S-induced calcium mobilization in the ICC. This result was similar to the effect of CCK-8S in murine gastric smooth muscle cells^[18], but unlike that in murine myenteric neurons^[19]. To further understand the mechanisms of CCK-8S-induced intracellular calcium release, the specific $InsP_3$ R inhibitor xestospongine C was used. Xestospongine C (1 μ mol/L) completely abolished $[Ca^{2+}]_i$ increases triggered by CCK-8S (Figure 4B).

Removing extracellular Ca^{2+} or blocking L-type voltage-operated calcium channel by nifedipine partly decreased the effect of CCK-8S (Figure 4C-E). These data indicate that the $[Ca^{2+}]_i$ release is not stimulated or activated by the influx of extracellular Ca^{2+} in gastric antrum ICC, while the influx of extracellular Ca^{2+} can facilitate the $[Ca^{2+}]_i$ increase evoked by CCK-8S.

CCK-8S stimulation results in PKC-dependent phosphorylation of $InsP_3$ R3

Experiments were undertaken to determine whether CCK-8S could evoke PKC to increase phosphorylation of $InsP_3$ R3. Samples containing equal amounts of protein were stimulated with CCK-8S (100 nmol/L) before or following administration of chelerythrine. PMA was used as a positive control. All drug/agonist treatments were 5 min in duration. CCK-8S resulted in a markedly increased phosphorylation of $InsP_3$ R3 in the ICC as compared with unstimulated ICC. When pretreated with chelerythrine for 5 min, CCK-8S-induced $InsP_3$ R3 phosphorylation was completely inhibited. Pretreatment with CCK₁R lorglumide (5 μ mol/L) significantly reduced the CCK-8S intensified phosphorylation of $InsP_3$ R3. As a positive control, PMA also enhanced phosphorylation of $InsP_3$ R3 in ICC (Figure 5).

Effect of PKC on CCK-8S-evoked response in cultured ICC

To investigate functional consequence of $InsP_3$ R3 phosphorylation by PKC on $[Ca^{2+}]_i$ changes of the ICC, the following experiments were performed. Followed by CCK-8S (100 nmol/L), PMA at various concentrations could significantly reduce the CCK-8S-evoked $[Ca^{2+}]_i$ response ($P < 0.01$, $n = 6$, Figure 6), and the effect of 100 nmol/L PMA was most obvious. Under the same conditions, chelerythrine showed the opposite effect to PMA ($P < 0.01$, $n = 6$, Figure 7), and 100 nmol/L chelerythrine exhibited the maximum effect.

DISCUSSION

In recent years, many studies have focused on the effects of CCK receptor ligands on GI motor functions, as the pharmacological characterization of these agents in humans is of potential therapeutic value^[20,21]. CCK and its related peptides have been implicated in the pathophysiology of functional digestive diseases, such as functional dyspepsia, achalasia of cardia and irritable bowel syndrome^[22,23]. Previous studies suggested that either an altered release of CCK or abnormal responses to this peptide could contribute to symptoms of GI dysmotility^[24,25]. However, the mechanisms of the effects of CCK on GI motility are unclear. Previous studies revealed that CCK could evoke calcium signaling in cultured myenteric neurons and activate them^[19,26]. The GI ICC also express CCK₁R and play an important role in regulating the GI motility; therefore, it is meaningful and necessary to understand the effect of CCK on the ICC in

Figure 2 The regulation of sulfated cholecystokinin-8 on $[Ca^{2+}]_i$ in cultured interstitial cells of Cajal from the murine gastric antrum. A1: Fluorescent intensity image of Fluo-3/AM loaded cultured interstitial cells of Cajal (ICC) under normal conditions; A2-6: Fluorescent intensity gradually increased in the presence of cholecystokinin-8 (CCK-8S) (100 nmol/L); B-E: Effects of different concentrations of sulfated CCK-8S on mean $[Ca^{2+}]_i$. In each case, cells from at least five different cell cultures; F: Effects of CCK-8S were estimated as percentage of $\Delta F/F_0$, where F_0 was derived from the averaged intensity of the first 10-30 frames minus the background in the cell-free region and ΔF is fluorescent intensity of the response minus F_0 . ^a $P < 0.05$, ^b $P < 0.01$ vs control.

Figure 3 Sulfated cholecystokinin-8 activates interstitial cells of Cajal through the cholecystokinin1 receptor. A: Compared with the control; B: Lorglumide significantly inhibited cholecystokinin-8 (CCK-8S)-induced increase in $[Ca^{2+}]_i$ of interstitial cells of Cajal; C: Quantification of $[Ca^{2+}]_i$ changes shown in A and B. Each experiment was repeated at least three times. $^bP < 0.01$ vs control.

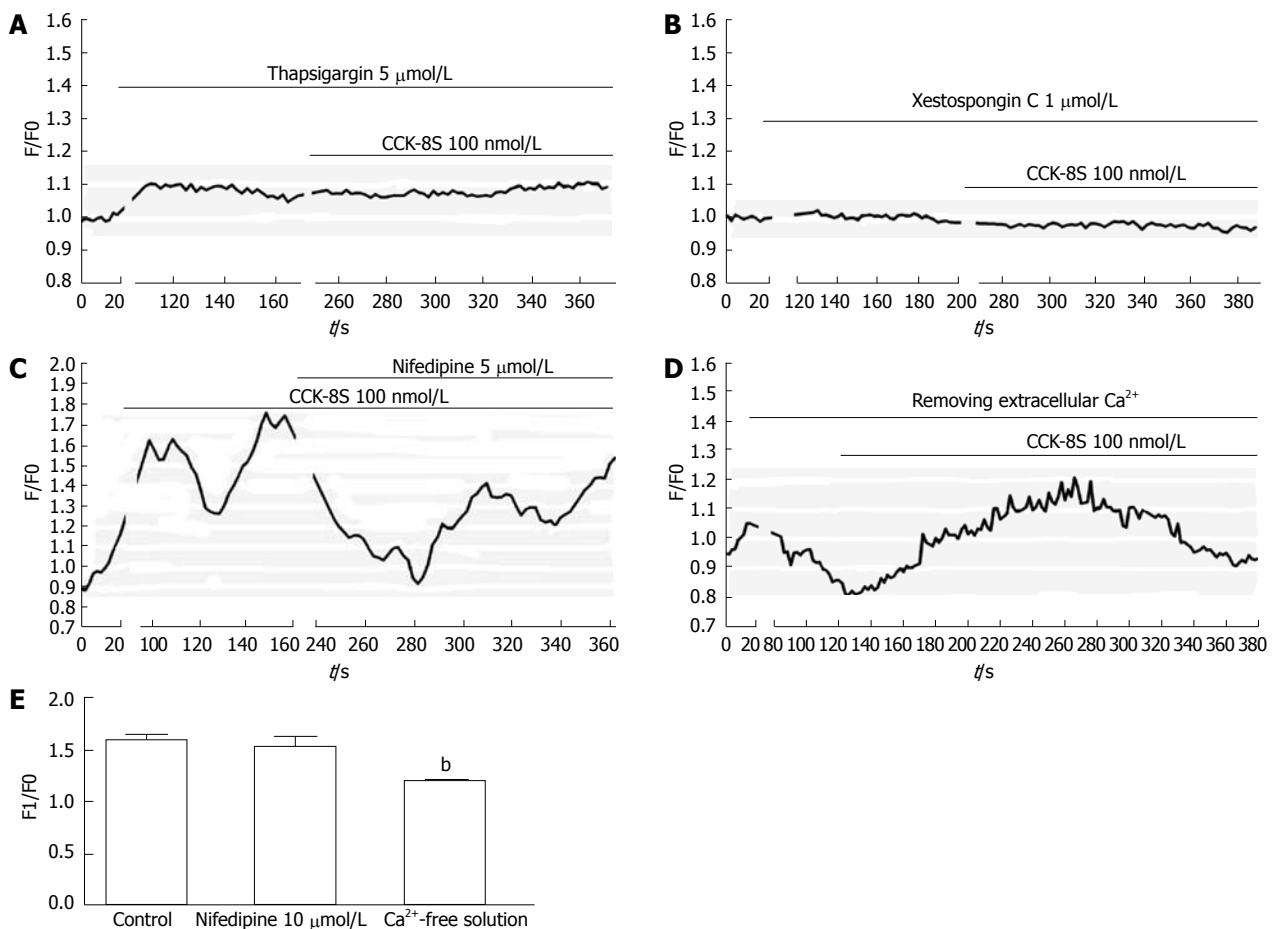

Figure 4 Sulfated cholecystokinin-8 induced calcium mobilization in cultured interstitial cells of Cajal. A, B: Pretreatment with 5 μ mol/L thapsigargin (A) or 1 μ mol/L xestospongine C (B) completely abolished sulfated cholecystokinin-8 (CCK-8S)-induced $[Ca^{2+}]_i$ increases; C: Addition of nifedipine resulted in a smaller peak of $[Ca^{2+}]_i$ in comparison with normal conditions; D: The CCK-8S-elicited $[Ca^{2+}]_i$ increase in the calcium-free medium was lower than that in the calcium-containing buffer; E: Quantification of $[Ca^{2+}]_i$ changes following addition of nifedipine or removal of extracellular Ca^{2+} . The fluorescence was normalized as F_1/F_0 (F_1 : Maximal fluorescence after drug addition; F_0 : Basal fluorescence before drug addition). $^bP < 0.01$ vs control.

Figure 5 Sulfated cholecystokinin-8 stimulation of interstitial cells of Cajal resulted in the protein kinase C-dependent phosphorylation of type III inositol 1,4,5-triphosphate receptor. **A:** Western blots of proteins were immunoprecipitated with type III inositol 1,4,5-triphosphate receptor (InsP₃R3)-specific antibody. The immunoprecipitated proteins were probed with antibody specific for phosphorylated Ser/Thr protein kinase C (PKC) substrate sequences. The sulfated cholecystokinin-8 (CCK-8S)-induced phosphorylation of InsP₃R3 was apparently inhibited by pretreatment with chelerythrine. Pretreatment with lorglumide (5 μ mol/L) could significantly reduce the CCK-8S intensified phosphorylation of InsP₃R3. In the positive control group, treatment of cells with phorbol-12-myristate-13-acetate (PMA) also resulted in an enhanced phosphorylation of InsP₃R3; **B:** The nitrocellulose membrane in **A** was stripped and reprobed with InsP₃R3 (1:1000) to determine the levels of InsP₃R3 immunoprecipitated. Each cell sample contained nearly equal amounts of InsP₃R3.

controlling GI motility. Our study indicated that CCK-evoked gastric contraction is probably mediated through direct action on CCK₁R located on the ICC. However, with respect to GI motility, both the ICC network and the gastrointestinal nervous system play essential roles in producing highly coordinated peristalsis^[27,28]. Additional studies are needed to investigate the role of interactions between the enteric neurons and the ICC in CCK-evoked effect.

In the GI ICC, the cytoplasmic Ca²⁺ oscillation is responsible for the pacemaker activity. The pacemaker activity is generated in the ICC and then transferred to smooth muscle cells through the gap junctions^[1,29]. In this study, we proved that CCK-8S markedly increased [Ca²⁺]_i in cultured gastric antrum ICC, and the biological effects of CCK-8S were mainly mediated *via* CCK₁R located on the ICC. Two major mechanisms are involved in [Ca²⁺]_i increment during the contraction: calcium release of endoplasmic reticulum Ca²⁺ store, and/or calcium influx from the extracellular space through activation of calcium channels^[29]. We have shown that emptying of the intracellular calcium stores by thapsigargin completely blocked the enhancement effect of CCK-8S on the [Ca²⁺]_i level of ICC. Removing extracellular calcium could also inhibit the effect of CCK-8S, but not abolish it. Therefore, both mechanisms mediate the CCK-8S action and Ca²⁺ release from intracellular stores appears to be the major mechanism. The CCK-8S-induced [Ca²⁺]_i increment could be abolished by blockage of InsP₃R, suggesting a predominant role of InsP₃R-operated stores in CCK-8S-induced intracellular Ca²⁺ release. However, the CCK-8S-evoked [Ca²⁺]_i increment was persistent in the presence of L-type calcium channel blocker nifedipine, indicating that the [Ca²⁺]_i release is not activated by the influx of extracel-

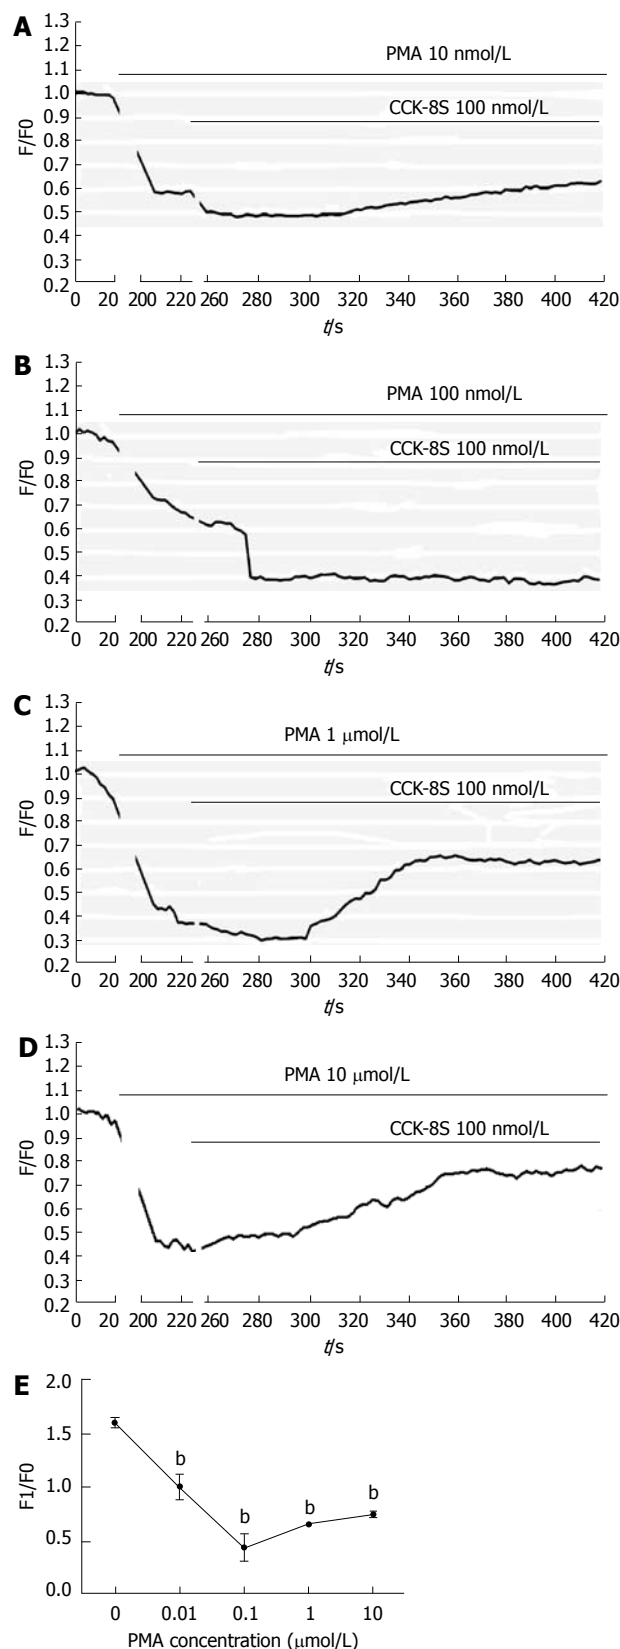

Figure 6 Effects of phorbol-12-myristate-13-acetate on sulfated cholecystokinin-8-evoked Ca²⁺ signaling in interstitial cells of Cajal. Fluo-3-loaded interstitial cells of Cajal were pretreated with various concentrations of Phorbol-12-myristate-13-acetate (PMA) (**A**: 10 nmol/L; **B**: 100 nmol/L; **C**: 1 μ mol/L; **D**: 10 μ mol/L) for 4 min before addition of sulfated cholecystokinin-8 (CCK-8S) (100 nmol/L). All could significantly reduce the CCK-8S-evoked [Ca²⁺]_i response; **E**: Quantification of [Ca²⁺]_i changes shown in A-D. Each experiment was repeated at least three times. ^bP < 0.01 vs control.

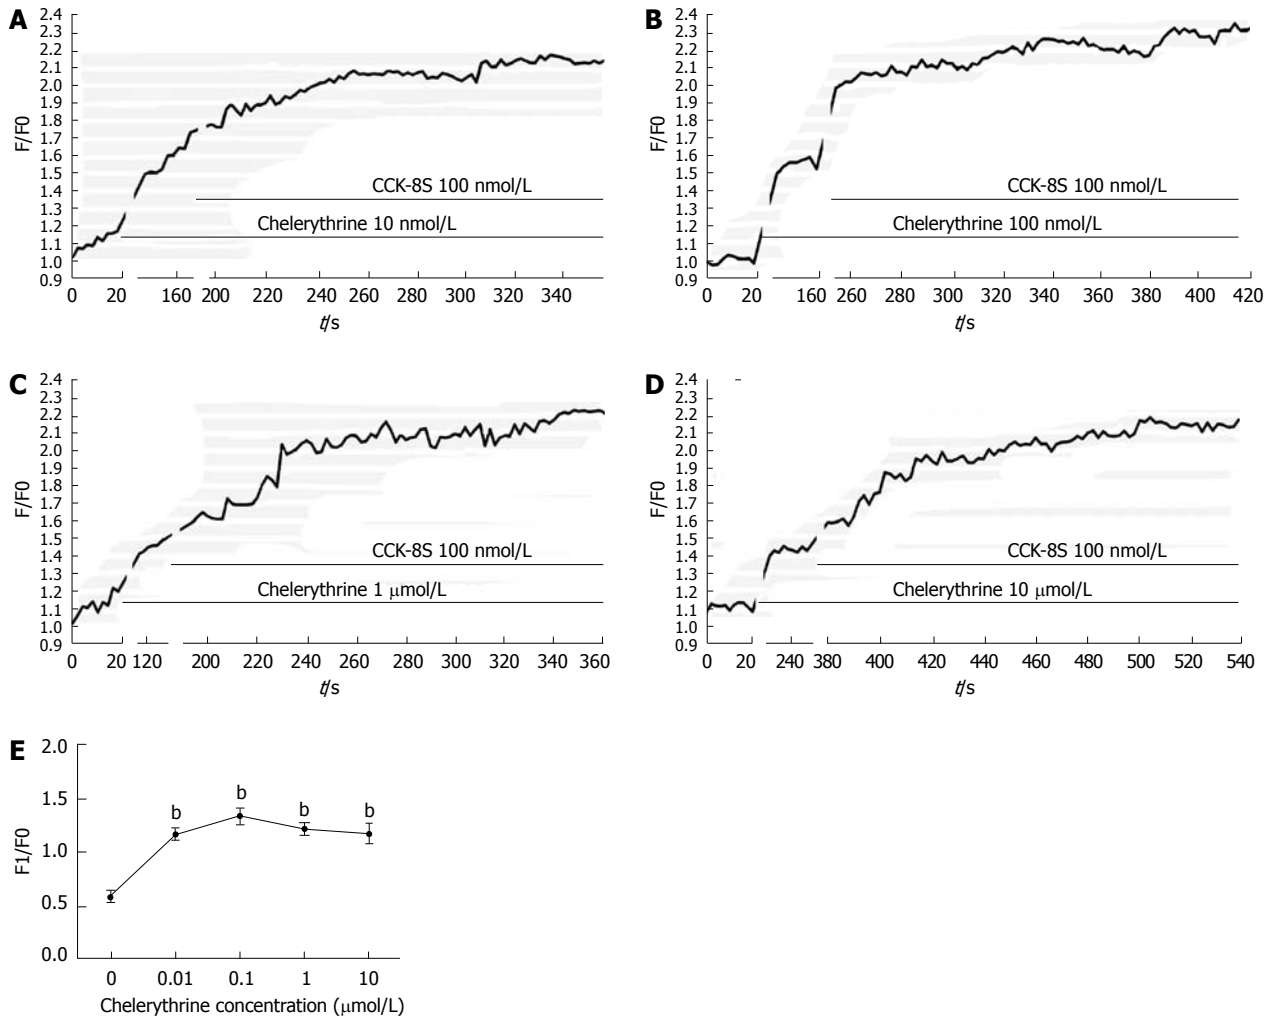

Figure 7 Effects of chelerythrine on Sulfated cholecystokinin-8-evoked Ca^{2+} signaling in interstitial cells of Cajal. Fluo-3-loaded interstitial cells of Cajal were pretreated with various concentrations of chelerythrine (A: 10 nmol/L; B: 100 nmol/L; C: 1 μ mol/L; and D: 10 μ mol/L) for 2 min before administration of cholecystokinin-8 (CCK-8S) (100 nmol/L). All could significantly increase the CCK-8S-evoked $[Ca^{2+}]_i$ response; E: Quantification of $[Ca^{2+}]_i$ changes shown in A-D. lular calcium, while the influx of extracellular calcium can facilitate the $[Ca^{2+}]_i$ increase evoked by CCK-8S.

InsP₃Rs are a family of Ca^{2+} channels of the endoplasmic reticulum (ER) that are widely distributed in different tissues^[30,31]. InsP₃ triggers opening of the InsP₃R, which can rapidly release Ca^{2+} stored in the ER into the cytosol, generating a transient increase of $[Ca^{2+}]_i$ ^[32]. The kinetics of $[Ca^{2+}]_i$ response depends on the amount of InsP₃, but many other signaling pathways participate in modulating the response. Among them, phosphorylation of InsP₃R by a series of kinases has been reported^[16,33,34]. In the present study, increased phosphorylation of InsP₃R3 in gastric ICC induced by CCK-8S was significantly prevented by pretreatment with the PKC specific inhibitor chelerythrine, while treatment of cells with the PKC activator PMA alone resulted in an enhanced phosphorylation of InsP₃R3, indicating an important regulatory role of PKC activation in this event. In addition, PMA potently reduced the peak of CCK-8S-induced calcium oscillation, while chelerythrine exhibited an opposite

effect. Thus, we might conclude that the activation of PKC negatively regulates CCK-8S-evoked calcium mobilization by phosphorylation of InsP₃R3. It is consistent with our previous study in other cells^[18]. The inhibition of Ca^{2+} release by PKC may be very useful to avoid full ER- Ca^{2+} emptying after agonist stimulation, which could have deleterious effects for the cell, first because of the waste of energy that would result from having a full ER- Ca^{2+} emptying after each agonist stimulation and second because of the effects of ER- Ca^{2+} depletion in terms of triggering the activation of stress signaling pathways^[35,36].

In summary, data obtained in our study suggest that: (1) CCK-8S could evoke calcium mobilization in cultured ICC; (2) the biological effects of CCK-8S are probably *via* CCK₁R located on the ICC; (3) this process is mainly mediated by the release of InsP₃-dependent intracellular Ca^{2+} from ER; and (4) CCK-8S could activate PKC simultaneously, which increases the phosphorylation of InsP₃R3 to negatively regulate the intracellular Ca^{2+} release in the ICC.

COMMENTS

Background

The interstitial cells of Cajal (ICC) are pacemaker cells in the gastrointestinal (GI) tract; their pacemaker activity is mediated by rhythmic intracellular Ca^{2+} oscillation. Cholecystokinin (CCK) contributes to the regulation of GI motility. To date, the mechanisms of the regulatory effects of CCK remain unclear. The finding that ICC express CCK₁ receptor (also known as CCK-AR) suggests a role for ICC in the mediation of CCK effects. It is worth investigating the direct effect of CCK on intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) in the ICC.

Research frontiers

Many neurotransmitters, including circulating hormones, modulate the ICC pacemaker activity. However, the effect of CCK on GI ICC remains unclear.

Innovations and breakthroughs

In the present study, the authors found that CCK evoked the calcium signaling in the ICC mainly via the Ca^{2+} release of InsP_3R -operated stores and CCK activated protein kinase C simultaneously to negatively regulate the release of Ca^{2+} stores. The findings provide a novel insight into the mechanisms of the regulatory effects of CCK on GI motility.

Applications

The findings may provide clues to the mechanisms of the effects of CCK and its analogs in the treatment of GI motility disorders to some extent.

Peer review

The authors investigated the effect of sulfated cholecystokinin octapeptide on calcium mobilization in cultured murine gastric antral interstitial cells of Cajal and its possible mechanisms. They found that cholecystokinin octapeptide could evoke the $[\text{Ca}^{2+}]_i$ signaling in interstitial cells of Cajal through the Ca^{2+} release of InsP_3R -operated stores. Additionally, CCK-8S activated PKC simultaneously to negatively regulate the release of $[\text{Ca}^{2+}]$ stores. The manuscript is highly interesting.

Abstract

AIM: To investigate the impact of different time points of secondary warm ischemia on bile duct in a rat autologous liver transplantation model with external bile drainage.

METHODS: One hundred and thirty-six male inbred SD rats were randomly assigned to one of four groups (I-IV) according to the secondary warm ischemia time of 0, 10, 20 and 40 min. A rat model of autologous liver transplantation with continuous external biliary drainage under ether anesthesia was established. Ten rats in each group were used to evaluate the one-week survival rate. At 6 h, 24 h, 3 d and 7 d after reperfusion of the hepatic artery, 6 rats were killed in each group to collect the blood sample via the infrahepatic vena cava and the median lobe of liver for assay. Warm ischemia time of liver, cold perfusion time, anhepatic

phase, operative duration for biliary external drainage and survival rates in the four groups were analyzed for the establishment of models.

RESULTS: No significant difference was shown in warm ischemia time, anhepatic phase and operative duration for biliary external drainage among the four groups. Five of the 40 rats in this study evaluated for the one-week survival rate died, including three deaths of severe pulmonary infection in group IV. A significant decrease of one-week survival rate in group IV was noted compared with the other three groups. With the prolongation of the biliary warm ischemia time, the indexes of the liver function assessment were significantly elevated, and biliary epithelial cell apoptosis index also increased. Pathological examinations showed significantly aggravated inflammation in the portal area and bile duct epithelial cell injury with the prolonged secondary warm ischemia time. Microthrombi were found in the micrangium around the biliary tract in some sections from groups III and IV.

CONCLUSION: The relationship between secondary warm ischemia time and the bile duct injury degree is time-dependent, and 20 min of secondary warm ischemia time is feasible for the study of bile duct injury.

INTRODUCTION

Liver transplantation has dramatically improved the prognosis, morbidity and mortality of the patients with end-stage liver diseases. Of all liver transplant recipients, 10%-40% develop biliary complications associated with a mortality rate of 8%-15%^[1,2]. With the improvement of surgical techniques, the incidence of anastomotic biliary strictures decreased remarkably, whereas the nonanastomotic biliary strictures (NAS) have become the major type of biliary complications of liver allograft. NAS, which is also called ischemic cholangiopathy, appears early during the immediate postoperative period, and it is characterized by biliary strictures and dilatations at any location in the biliary system of the transplanted liver^[3].

Knowledge about the pathogenesis of NAS is slowly emerging from clinical and experimental studies performed during the last decade. The cause of NAS is multifactorial, and ischemia/reperfusion injury of the biliary epithelium is considered as one of the major causes^[4]. The most commonly used procedure for revascularization of the liver graft in clinical practice is initial portal reperfusion and subsequent reconstruction of the hepatic artery. Compared with liver cells, the bile duct epithelial cells experience an extra ischemia process [the time from portal vein (PV) recanalization to hepatic artery (HA) recanalization], which is "secondary warm ischemia time in the biliary tract (SWIT)" or "relative warm ischemia time in the biliary tract". This is the special phase of biliary tract warm ischemia in the graft.

During the transplantation process, the warm ischemia of biliary tract includes temporal warm ischemia of liver graft during procurement and secondary warm ischemia in the biliary tract. Because warm ischemic time in the harvesting of donor liver after cardiac death (DCD) is inevitable, more and more studies focus on the effect of secondary warm ischemia time on bile duct injury^[5]. In this study, we investigated the impact of different time points of secondary warm ischemia in a rat autologous liver transplantation model with external bile drainage.

MATERIALS AND METHODS

Animals and experimental groups

One hundred and thirty-six male inbred SD rats weighing 220-250 g were purchased from the Animal Center of Yangzhou University (Yangzhou, China). The rats were housed and fed at the Animal Center of Drum Tower Hospital for least 7 d before transplantation to acclimate them to the environment. All rats were provided with standard laboratory chow and water and housed in accordance with institutional animal care policies. Prior to the study, the rats were fasted for 8 h and were allowed free access to water.

The following experimental protocol was approved by the Animal Care and Use Committee of the Drum Tower Hospital and conformed to the Guide for the Care and Use of Laboratory Animals published by the National Institutes of Health.

All rats were randomly assigned to four experimental groups according to the secondary warm ischemia time. Group I had no SWIT, in which simultaneous reperfusion was performed through the PV and HA after cold perfusion. The SWIT in groups II-IV was 10, 20 and 40 min, in which blood reperfusion of HA was performed 10, 20 or 40 min after PV reperfusion, respectively. Ten rats in each group were used to evaluate the one-week survival rate.

Surgical procedures

A rat model of autologous liver transplantation with continuous external biliary drainage under ether anesthesia was established in this study. It was described as follows:

A midline incision was made on the abdomen. The ligaments around the liver were dissociated and severed. The left diaphragm vein, hepatoesophageal ligament vein and right adrenal vein were separated, ligated and severed. The liver was turned left, and the suprahepatic vena cava (SHVC) was anatomized. And the common bile duct, HA, and PV were anatomized over the margin of the duodenal bulb. The infrahepatic vena cava (IHVC) was dissociated downwards about 6-8 mm. The liver was dissociated completely except for the hepatic blood vessels in and out, and the common bile duct.

A clamp was placed on the crossing of the cranial mesenteric vein and splenic vein, and the PV was pricked with a transfixion pin and fixed by another clamp. Then heparin saline (35 U/mL, 3 mL) was injected to make the rat heparinized and allow liver blood to enter the general circulation.

The abdominal aorta was pricked between the common iliac artery and left renal artery with pinhead and fixed by a clamp, and it was blocked from the area above the celiac trunk to the area below the puncture point by a clamp. The clamps were placed on the SHVC and IHVC with IHVC outflow tract left before cold perfusion. Lactated Ringer's solution of 20 mL (4 °C, containing heparin 12.5 U/mL) was perfused at 2.5 mL/min through the PV by an infusion pump and the abdominal aorta, respectively. The liver surface was covered with 4 °C lactated Ringer's solution to lower the temperature. The normal anatomical position of liver was maintained to avoid uneven perfusion. Subsequently, the color of the liver faded (Figure 1A).

The transfixion pin was removed after the perfusion, the PV and abdominal aorta were repaired using 9-0 prolene suture, and the IHVC outflow tract was restored with 8-0 prolene suture. The clamp was loosened to check whether the restoration was successful. The HA was clamped for the removal of the pre-remained line in groups II-V, then the PV, abdominal aorta, SHVC and IHVC were unclamped to end the anhepatic phase. The

Figure 1 Surgical procedure for a rat model of autologous liver transplantation with continuous external biliary drainage. A: Lactated Ringer's solution was perfused by an infusion pump through the portal vein and the abdominal aorta; B: A polyethylene catheter was inserted into the common bile duct for external biliary drainage; C: The free ends of external biliary drainage tube and jejunal fistula tube were connected.

liver surface was covered with 38 °C normal saline (20 mL) for rapid rewarming. Thus the liver was filled with blood and turned red. The intestinal tract was placed back to the abdominal cavity during the secondary warm ischemia-reperfusion. The abdominal cavity was covered with wet gauze and heated by a lamp to maintain normal temperature.

The distal end of the bile duct was ligated and a polyethylene catheter (inner diameter 0.8 mm, outer diameter 1.2 mm) was inserted into the common bile duct for external biliary drainage. A jejunal fistula was established to return the remaining bile into the enterohepatic circulation. A 15-cm portion of polyethylene catheter (inner diameter 1.2 mm, outer diameter 1.5 mm) was inserted approximately 2 cm into jejunum through a stab in the je-

junum wall and fixed to the peritoneum (Figure 1B). The free ends of external biliary drainage tube and jejunal fistula tube were brought out of the body through a stab on the back of the rat's neck and connected with a short hypodermic needle (Figure 1C).

Sample collection

At 6 h, 24 h, 3 d and 7 d after reperfusion of the hepatic artery, six rats were killed in each group to collect blood sample *via* the infrahepatic vena cava and the median lobe of liver for assay. The serum was separated and stored at -70 °C until analysis. Washed with cold saline solution, the liver samples were stored immediately in liquid nitrogen until analysis.

Analysis of establishment of models

Analysis of establishment of models included warm ischemia time of liver (the time from abdominal aorta clamping to cold perfusion of liver), cold perfusion time, anhepatic phase (the time from PV clamping to PV reperfusion), operative duration for biliary external drainage and survival rates in the four groups.

Liver function assessment

The liver function assessment included measurements of serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (AKP), total bilirubin (TB) and direct bilirubin (DB). The serum samples were collected at 6 h, 24 h, 3 d and 7 d after reperfusion of HA and liver function test was conducted by automatic biochemistry analyzer (HITACHI 7600).

Apoptosis assay of bile duct epithelia

Apoptosis of biliary tract epithelia was identified by detecting DNA fragmentation *in situ* in serial sections at 6 and 24 h after HA reperfusion. DNA fragmentation was detected by TUNEL staining, which was performed on deparaffinized and dehydrated sections using the In Situ Cell Death Detection kit (Zhongshan Biomedical Technology Co., Beijing, China) according to the manufacturer's instructions. TUNEL-positive cholangiocytes displayed a characteristic morphology of apoptosis, such as chromatin condensation, cell fragmentation and apoptotic bodies. Apoptotic cells were examined at original magnification $\times 400$ in 10 randomly chosen fields per section. The apoptotic index was calculated as percentage of apoptotic cells related to the total number of cholangiocytes.

Histological evaluation of bile duct injury

Six hepatic specimens were collected at 24 h after reperfusion of HA in each group. The liver specimens for light microscopy were fixed with 10% formalin and then embedded in paraffin. The sections were stained with hematoxylin and eosin for histological examination. Bile duct injury in specimens was semi-quantified by calculating a bile duct injury severity score (BDISS)^[6] based on the following three components: bile duct damage (graded

Figure 2 Pathological examination of the lung after the death of three rats in group IV (hematoxylin-eosin; original magnification $\times 400$).

as 0, absent; 1, mild; 2, moderate; and 3, severe; modified from the Banff criteria for defining acute rejection); ductular proliferation (graded 0-3, using a similar scale as stated earlier); and cholestasis (graded 0-3, using a similar scale as stated earlier). This resulted in a minimal BDISS of zero and a maximum score of nine points. All examinations were conducted by an experienced pathologist who was unaware of the other study data.

Statistical analysis

Results were expressed as mean \pm SD. Numerical data was analyzed with Statistical Analysis System. One-way repeated measures analysis of variance with the Student-Newman-Keuls test was performed for multiple comparisons to test the effect of time, groups, and the interaction between the time and groups. A P value of < 0.05 was considered significant.

RESULTS

Analysis of establishment of models

The cold perfusion time in each group was eight minutes with the use of an infusion pump. No significant difference was shown in warm ischemia time, anhepatic phase and operative duration for biliary external drainage among the four groups ($P > 0.05$). Five of the 40 rats in this study evaluating the one-week survival rate died, including one death of bleeding caused by unsuccessful abdominal aorta repair (group III), one of sudden respiratory arrest after HA reperfusion (group IV) and three of severe pulmonary infection (group IV). The result of autopsy after the death of three rats in group IV showed serious pulmonary vascular exudation and edema accompanied with pulmonary consolidation. Pathological examination revealed obvious leucocyte infiltration in alveolar cavity and pulmonary interstitium, numerous inflammatory exudates around bronchi, and alveolar wall damage with microvascular endothelial cell injury and bleeding (Figure 2). A significant decrease of one-week survival rate in group IV was noted compared with the other three groups ($P < 0.05$, Table 1).

Table 1 Analysis of establishment of models

Group	Warm ischemia time (min)	Anhepatic phase (min)	Operative duration for biliary external drainage (min)	1-wk survival rate (%)
I	3.1 ± 0.5	18.1 ± 1.2	6.2 ± 1.2	100
II	3.0 ± 0.4	17.6 ± 1.5	7.1 ± 1.4	100
III	3.3 ± 0.3	18.5 ± 1.1	6.7 ± 1.6	90
IV	3.2 ± 0.5	17.9 ± 1.7	6.5 ± 2.0	60

Liver function assessment

A significant increase of ALT, AST, AKP, TB and DB was observed at 6 h, 24 h, day 3 and day 7 ($P < 0.05$) after operation in the three groups compared with the results in group I. The increased indexes of liver function test in group IV were higher than in groups II and III, and there were significant differences among these three groups at 6 h, 24 h, day 3 and day 7 after operation ($P < 0.05$).

ALT and AST reached the peak at 6 h after autologous liver transplantation, and very significant decrease was observed on post-operative days 3 and 7 ($P < 0.01$). Other liver function indexes, including AKP, TB and DB, reached the peak at post-operative 24 h, and there was significant decrease on post-operative days 3 and 7 ($P < 0.05$, Table 2).

Apoptosis assay of bile duct epithelia

The apoptosis index of bile duct epithelia in groups I at 6 and 24 h after hepatic artery reperfusion was 5.87 ± 0.50 and 7.13 ± 0.60 . Compared with group I, there was a significant increase of apoptosis index at 6 and 24 h in groups II and III ($P < 0.05$), and a very significant increase in group IV ($P < 0.01$). The increased apoptosis index in group IV was higher than in groups II and III, and there were significant differences among these three groups at post-operative 6 and 24 h ($P < 0.05$). In all groups, the apoptosis index at 24 h after hepatic artery reperfusion was higher than at 6 h, but no significant differences were noted ($P > 0.05$) (Table 3; Figure 3A and B).

Histological evaluation of bile duct injury

The predominant injuries of bile duct in group I included cholangiocytes lined in disorder, diversified morphous and edema, inflammatory cell infiltration, migrated chromatin, and the necrotic and caducous cell debris in the lumen under light microscope. The bile duct showed more histological changes in groups II and III, and the most significant injury occurred in group IV (Figure 4A and B). Microthrombi were found in the micrangium around the biliary tract in some sections from groups III and IV.

Compared with group I, there was a significant increase of BDISS at 6 and 24 h in groups II and III ($P < 0.05$), and a very significant increase of apoptosis in group IV ($P < 0.01$). The BDISS in group IV was higher than in groups II and III, and there were significant differences among the three groups at post-operative 6 and

24 h ($P < 0.05$). In all groups, BDISS at 24 h after hepatic artery reperfusion was higher than at 6 h, but no significant differences were noted ($P > 0.05$, Table 3).

DISCUSSION

Grafts from DCD are used to increase the number of organs available for liver transplantation, and warm ischemic time in the donor in addition to subsequent cold ischemia-reperfusion injury is believed to result in increased damage to biliary epithelial cells^[7,8]. It is associated with a higher risk of biliary strictures, and the incidence of NAS after DCD ranged from 10% to 30% compared with an incidence of 1%-10% after brain death^[9-11]. The present experiment used a rat model of autologous orthotopic liver transplantation to simulate I/R injury of the biliary tract, which simulated the whole process of clinical liver transplantation. This model decreased the possibility of blood vessel or vascular anastomosis damage compared with allogeneic orthotopic liver transplantation, and it avoided the effects of immuno-

logic rejection. This model is simple and has a high successful rate, better reflects the pathophysiologic process of bile ducts, and provides an approach for investigating the intrahepatic bile duct injury in liver transplantation caused directly by I/R injury^[12].

More and more studies have focused on the role of bile salt toxicity in the development of bile duct injury after transplantation, and bile composition analysis may be important in evaluating the liver function^[13-15]. Establishing a stable model of orthotopic liver transplantation with external biliary drainage in rats is needed to provide the possibility for dynamic detection of bile characteristics after transplantation. But the lack of bile in the gut lumen is one of the factors associated with an increase in translocation of bacteria through the intestinal mucosa. It has been proposed that the intestinal bile flow is important to the immunity because bile salt has a dispersion effect on lipopolysaccharide and endotoxin, which had been proved to correlate with suppression of cellular immunity^[16]. In experimental models, internal biliary drainage resulted in better systemic immune status, and improved intestinal barrier and mucosal immune functions^[17]. The operative duration for biliary external drainage in this study was 6.7 ± 1.7 min, and no rat died of biliary complication. The biliary extra-drainage model in rat autologous liver transplantation in this study provides a simple and reliable method for dynamic collection of bile, and it could be applied in various experimental studies.

Hepatocytes are supplied by both the hepatic artery and the portal vein, but bile ducts entirely depend on arterial blood supply for oxygenation. The terminal arteriole of hepatic artery branches off into the peribiliary plexus (PBP), which supplies the intrahepatic bile ducts. Therefore, the changes of PBP usually altered the intra-

Figure 3 With the prolongation of secondary biliary warm ischemia time, more biliary epithelial cells became apoptotic. A: Biliary epithelial cell apoptosis in group I at 24 h after hepatic arterial (HA) reperfusion; B: Biliary epithelial cell apoptosis in group IV at 24 h after HA reperfusion (hematoxylin-eosin; original magnification $\times 400$).

hepatic bile duct structure. Post-transplantational hepatic artery ischemia induces ischemia and occlusion of PBP, which is the vital reason leading to aggravation of ischemia of intrahepatic bile ducts^[18-20]. The pathomorphologic changes of biliary tract showed that the relationship between secondary ischemia time and pathological structural injury was time-dependent, and the biliary tract injury in group IV was most serious among the four groups in this study. Microthrombi were found in the microcrangium around the biliary tract in some sections from groups III and IV. Accordingly, the serum levels of liver function increased with the prolonged second warm ischemia time. The levels of AKP, TB and DB, in particular, revealed the injury of the bile duct, which became worse with the longer second warm ischemia time.

Bile duct epithelia are highly susceptible to reoxygenation after anoxia^[21]. The increased susceptibility to reoxygenation injury by cholangiocytes is associated with increased production of toxic reactive oxygen species by cholangiocytes during reoxygenation with concomitant low basal levels of the antioxidant glutathione in these epithelial cells^[22]. Apoptosis is one of the two mechanisms by which cell death occurs (the other is the pathological process of necrosis). Accumulating evidence suggests that apoptosis plays an important role in ischemia-reperfusion injury in organ transplantation^[23,24] and it is widely taken as a reference index to evaluate bile duct epithelial injury. With the prolongation of the biliary warm ischemia time,

Figure 4 Histological examination of the liver at 24 h after hepatic arterial reperfusion. A: Cholangiocyte injury can be found in group I; B: More marked injury occurs in group IV (hematoxylin-eosin; original magnification $\times 400$).

the biliary epithelial cell apoptosis index was significantly elevated, and the apoptosis index at 24 h after hepatic artery reperfusion was higher than at 6h, but with no significant differences.

In conclusion, the relationship between secondary warm ischemia time and the bile duct injury degree is time-dependent. Because of a lower one-week survival rate in the 40 min group, 20 min of secondary biliary warm ischemia time is feasible for the study of bile duct injury in a rat autologous liver transplantation model with external bile drainage.

ACKNOWLEDGMENTS

We want to thank Dr. Chen Jun for his work in pathological analysis.

COMMENTS

Background

With the improvement of surgical techniques, the incidence of anastomotic biliary strictures after liver transplantation decreased remarkably, whereas the nonanastomotic biliary strictures became the major type of biliary complications of liver allograft. Diffuse non-anastomotic biliary strictures remain the most challenging type of biliary complication as they are frequently therapy-resistant and often associated with long-term consequences.

Research frontiers

Warm ischemic time in donation after cardiac death in addition to subsequent cold ischemia-reperfusion injury is believed to result in increased damage to biliary epithelial cells. Compared with liver cells, the bile duct epithelial cells experience an extra ischemia process, which includes the time from portal vein

recanalization to hepatic artery recanalization, and this is "secondary warm ischemia time in the biliary tract" or "relative warm ischemia time in the biliary tract". This is the special phase of biliary tract warm ischemia in the grafts, and more and more studies have focused on the effect of secondary warm ischemia time on bile duct injury.

Innovations and breakthroughs

Because warm ischemic time in the harvesting of donor liver after cardiac death is inevitable, more and more studies have investigated the effect of secondary warm ischemia time on bile duct injury. In this study, the authors investigated the impact of different time points of secondary warm ischemia in a rat autologous liver transplantation model with external bile drainage. This model provides a simple and reliable method for dynamic collection of bile, and can be applied in various experimental studies.

Applications

This study demonstrated that the relationship between secondary warm ischemia time and the bile duct injury degree is time-dependent. Because of the lower one-week survival rate in the 40 min group, the authors proposed that 20 min of secondary biliary warm ischemia time should be feasible for the study of bile duct injury in a rat autologous liver transplantation model with external bile drainage.

Terminology

This is a well designed and conducted experimental study with very interesting results. The literature review was adequate. The materials and methods were adequate and coincident to the objective of the study. Newer studies with your rat model with prolonged secondary biliary will help us to elucidate unanswered questions in hepatobiliary surgery.

Abstract

AIM: To investigate whether stress-induced visceral hypersensitivity could be alleviated by electroacupuncture (EA) and whether EA effect was mediated by endogenous opiates.

METHODS: Six to nine week-old male Sprague-Dawley rats were used in this study. Visceral hypersensitivity was induced by a 9-d heterotypic intermittent stress (HIS) protocol composed of 3 randomly stressors, which included cold restraint stress at 4 °C for 45 min, water avoidance stress for 60 min, and forced swimming stress for 20 min, in adult male rats.

The extent of visceral hypersensitivity was quantified by electromyography or by abdominal withdrawal reflex (AWR) scores of colorectal distention at different distention pressures (20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg). AWR scores either 0, 1, 2, 3 or 4 were obtained by a blinded observer. EA or sham EA was performed at classical acupoint ST-36 (Zu-San-Li) or BL-43 (Gao-Huang) in both hindlimbs of rats for 30 min. Naloxone (NLX) or NLX methiodide (m-NLX) was administered intraperitoneally to HIS rats in some experiments.

RESULTS: HIS rats displayed an increased sensitivity to colorectal distention, which started from 6 h (the first measurement), maintained for 24 h, and AWR scores returned to basal levels at 48 h and 7 d after HIS compared to pre-HIS baseline at different distention pressures. The AWR scores before HIS were 0.6 ± 0.2 , 1.3 ± 0.2 , 1.9 ± 0.2 and 2.3 ± 0.2 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. Six hours after termination of the last stressor, the AWR scores were 2.0 ± 0.1 , 2.5 ± 0.1 , 2.8 ± 0.2 and 3.5 ± 0.2 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. EA given at classical acupoint ST-36 in both hindlimbs for 30 min significantly attenuated the hypersensitive responses to colorectal distention in HIS rats compared with sham EA treatment [AWRs at 20 mmHg: 2.0 ± 0.2 vs 0.7 ± 0.1 , $P = 4.23 \times 10^{-4}$; AWRs at 40 mmHg: 2.6 ± 0.2 vs 1.5 ± 0.2 , $P = 0.00163$; AWRs at 60 mmHg: 3.1 ± 0.2 vs 1.9 ± 0.1 , $P = 0.003$; AWRs at 80 mmHg: 3.6 ± 0.1 vs 2.4 ± 0.2 , $P = 0.0023$; electromyographic (EMG) at 20 mmHg: 24 ± 4.7 vs 13.8 ± 3.5 ; EMG at 40 mmHg: 60.2 ± 6.6 vs 30 ± 4.9 , $P = 0.00523$; EMG at 60 mmHg: 83 ± 10 vs 39.8 ± 5.9 , $P = 0.00029$; EMG at 80 mmHg: 94.3 ± 10.8 vs 49.6 ± 5.9 , $P = 0.00021$]. In addition, EA at the acupuncture point BL-43 with same parameters did not alleviate visceral hypersensitivity in HIS rats. EA in healthy rats also did not have any effect on AWR scores to colorectal distention at distention pressures

of 20 and 40 mmHg. The EA-mediated analgesic effect was blocked by pretreatment with NLX in HIS rats [AWR scores pretreated with NLX *vs* normal saline (NS) were $2.0 \pm 0.70 \pm 0.20$, $2.80 \pm 0.12 \pm 1.50 \pm 0.27$, $3 \pm 2.00 \pm 0.15$ and $3.60 \pm 0.18 \pm 2.60 \pm 0.18$ for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg; $P = 0.0087$, 0.0104 , 0.0117 and 0.0188 for 20, 40, 60 and 80 mmHg, respectively]. Furthermore, EA-mediated analgesic effect was completely reversed by administration of m-NLX, a peripherally restricted opioid antagonist (EMG pretreated with m-NLX *vs* NS were $30.84 \pm 4.39 \pm 13.33 \pm 3.88$, $74.16 \pm 9.04 \pm 36.28 \pm 8.01$, $96.45 \pm 11.80 \pm 50.19 \pm 8.28$, and $111.59 \pm 13.79 \pm 56.42 \pm 8.43$ for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg; $P = 0.05026$, 0.00034 , 0.00005 , 0.000007 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg, respectively).

CONCLUSION: EA given at classical acupoint ST-36 alleviates stress-induced visceral pain, which is most likely mediated by opioid pathways in the periphery.

INTRODUCTION

Irritable bowel syndrome (IBS) is a common gastrointestinal disorder characterized by chronic visceral pain and bloating in association with altered bowel movements^[1-3]. Chronic visceral pain, the cardinal feature of IBS, has been difficult to treat^[4-6]. Acupuncture is an ancient form of traditional Chinese medicine that can be traced back for more than 3000 years. The acupuncture procedure involves the insertion of thin needles into the skin and underlying muscle layer, which are termed acupuncture loci, or "acupoints". In traditional acupuncture, the needles are twisted right and left at 0.5- to 1-s intervals. More recently, acupuncture needles are stimulated by electricity at various frequencies (1-100 Hz), which is termed electroacupuncture (EA). EA has been used extensively for treatment of various painful

conditions and gastrointestinal diseases, including IBS, functional dyspepsia, constipation, and diarrhea^[7-9]. It has been shown that EA treatment results in a significant improvement both in general conditions and in symptoms of bloating^[10,11]. Combined EA at the acupuncture points ST-36 and PC-6 significantly increases the threshold of rectal sensations induced by rectal distension in IBS patients^[8,12,13], suggesting that EA might be a promising method to treat visceral pain in patients with IBS. However, research into EA for chronic visceral pain is still in its infancy, and much of the limited scientific evidence surrounding it is fragmentary and often contradictory^[14-16]. Thus, further investigations of EA efficacy and its mechanisms are definitely merited. Recently, we have developed a rat model of visceral hypersensitivity induced by heterotypic intermittent stress (HIS)^[17]. These rats displayed no robust inflammation or injury in the colon, but a significantly higher visceromotor response (VMR) to colorectal distention (CRD) compared with age-matched controls. Thus, the animal model resembles some characteristics of IBS seen in human patients. The aim of this study was to investigate whether EA has therapeutic benefits on visceral hypersensitivity induced by HIS, and if so, what is the underlying mechanism. We found that EA treatment at acupoint ST-36 significantly attenuated abdominal withdrawal reflexes (AWRs) in HIS rats at distention pressures of 20 and 40 mmHg, and in both stressed and non-stressed rats at distention pressures of 60 and 80 mmHg. Pretreatment with naloxone (NLX), an opioid receptor antagonist, or NLX methiodide (m-NLX), a selectively peripherally acting opioid receptor antagonist, completely reversed the EA effect in HIS rats.

MATERIALS AND METHODS

Animals

Six to nine week-old male Sprague-Dawley rats ($n = 94$) housed at approximately 22 °C with a 12-h light/dark cycle were used in this study. Care and handling of these animals were approved by the Institutional Animal Care and Use Committee at the University of Texas Medical Branch and at Soochow University. The animals were euthanized by decapitation at various times indicated in the Result section after the end of *in vivo* behavioral studies. Compared with our previous report that HIS-induced visceral hypersensitivity returned to normal level 24 h after termination of the last stressor in Wistar rats^[17], HIS-induced visceral hyperalgesia lasted longer in SD rats than in Wistar rats. Therefore, SD rats were used in this experiment. Rats were grouped before experiment and were single-housed during experiments.

Heterotypic intermittent stress protocol

Rats were subjected to 9 consecutive days of a HIS protocol comprised of 3 randomly selected stressors, which included cold restraint stress (CRS) at 4 °C for 45 min, water avoidance stress (WAS) for 60 min, and forced

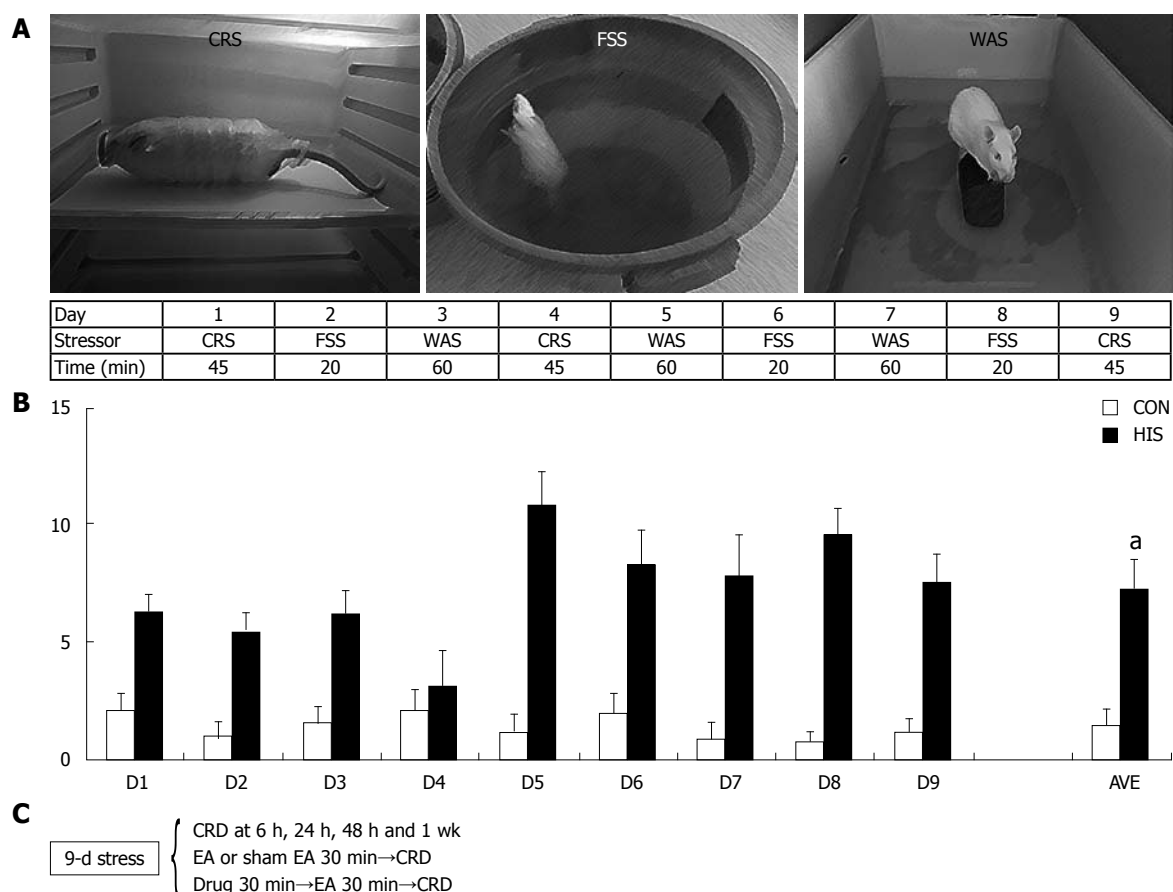

Figure 1 Heterotypic intermittent stress protocol and pellets count. **A:** Nine-day heterotypic intermittent stress (HIS) protocol comprising three different randomly arranged stressors; **B:** Stress accelerated colonic transit ($n = 10$ for control, $n = 8$ for HIS), which was accompanied by an increase in visceral hypersensitivity ($^{\circ}P < 0.05$). **C:** A schematic representation of the various treatments: stressors, colorectal distention (CRD) and drug treatment with time sequence. CON: Control; AVE: The mean number of pellets for all 9-d stress protocol or from respective control rats; CRS: Cold restrained stressor; FSS: Forced swimming stressor; WAS: Water avoidance stressor.

swimming stress (FSS) for 20 min, as described previously^[17] and in Figure 1A. In brief, each stressor was applied between 8 am and 11 am. For CRS, the rats were restrained in a clear plastic container (6 cm in diameter \times 18 cm in length). The container had 2-cm diameter openings at each end for the rat to breathe normally. The restraining container was placed in cold room at 4 °C for 45 min. The CRS was given to rats on days 1, 4 and 9. For WAS, the rat was placed for 60 min on a brick (12 cm high \times 6 cm wide \times 8.5 cm long) in the middle of a plastic container (14 cm high \times 36 cm wide and \times 54 cm long) filled with water at room temperature (approximately 22 °C) within 1 cm from the top. The rats were subjected to WAS on days 3, 5 and 7. For FSS, the rat was forced to swim for 20 min in a plastic container (38 cm high \times 24 cm wide \times 32 cm long) filled to a depth of 12 cm below the top with water at room temperature (approximately 22 °C). The FSS was given to rats on days 2, 6 and 8. Age-matched control rats were brought to the laboratory and handled identically without the stress protocol.

Heterotypic intermittent stress was chosen because clinical findings suggest that long-term stress, rather than short-term stress, exacerbates symptoms of IBS. In

addition, variable stressors are less likely to produce adaptation when compared to repeated applications of the same stressor. The number of pellets during each stress protocol was counted for each rat in order to measure colonic transit during stress protocol (Figure 1B). It is remarkable that stress accelerated defecation rate when compared with controls (two sample t test, $P < 0.001$). The number of pellets in the stress situations is not time dependent as it is in the control situation. This is most likely due to the different stressors used. The increase in number of pellets and visceral hypersensitivity in the stress situations indicates that this model can mimic the major characteristics of patients with IBS and thus it is a suitable rat model for study of the effect and mechanisms of EA treatment.

Measurement of visceral hypersensitivity to graded colorectal distention

Electromyographic recordings. Visceral hypersensitivity was measured by electromyographic (EMG) measurements of VMR to CRD as described previously^[18]. Briefly, under anesthesia with isoflurane, 2 electrodes were implanted in the external oblique muscle and externalized behind the head. Rats were allowed 1 wk to

Figure 2 Schematic representation of electroacupuncture points. ST-36 (Zu-San-Li) is thought to be relevant to gastrointestinal tract while Gao-Huang is not.

recover from the surgery. After recovery, baseline EMG measurement was recorded, and then 9-d stress protocol was applied. After termination of last stressor, the EMGs were recorded again from these rats. In some cases, EA or sham EA was applied during the stress protocol. Under anesthesia with isoflurane, a flexible balloon (5 cm) constructed from a surgical glove finger attached to a tygon tubing was inserted 8 cm into the descending colon and rectum *via* the anus and held in place by taping the tubing to the tail. Rats were placed in small Lucite cubicles (20 cm × 8 cm × 8 cm) (Bioengineering Department, University of Texas Medical Branch, Galveston, TX) and allowed to adapt for 30 min. CRD was performed by rapidly inflating the balloon to constant pressure. Pressure was measured using a sphygmomanometer connected to a pressure transducer. The balloon was inflated to various pressures (20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg) for a 20 s stimulation period followed by a 2 min rest. EMG was recorded continuously during the experiment on a Biopac System EMG 100 °C. The EMG signal was amplified, filtered at 300 Hz and digitized using Acknowledge software (Biopac Systems, Inc., CA, United States). The area under the curve (AUC) for EMG activities during each 20 s of distention was calculated using an in-house written computer program^[18]. The net value for each distention was calculated by subtracting the baseline value derived from the AUC for the 20 s pre-distention period. EMG was measured before HIS and 6 h, 1 d, 2 d and 7 d after termination of last stressor. Each rat was tested for EMG twice for each distention pressure and the mean AUC of EMG calculated from the two repeated measurements was used for each rat for each pressure in the following statistical analysis.

Abdominal withdrawal reflex scores: Visceral hypersensitivity was also measured by grading behavioral response of rats to CRD as described previously^[3,19]. In brief, under anesthesia with isoflurane, a flexible latex balloon (5 cm) attached to a tygon tube was inserted 8 cm into the descending colon and rectum *via* anus and held in place by taping the tube to tail. Rats were placed in small lucite cubicles and allowed to adapt for 30 min. CRD

was performed by rapidly inflating the balloon to constant pressure using a sphygmomanometer. The balloon was inflated to 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg for 20 s followed by 2 min rest. Behavioral response to CRD was measured by visual observation of AWR by a blinded observer and AWR was scored either 0 (normal behavior), 1 (slight head movement), 2 (contraction of abdominal muscles), 3 (lifting of abdominal wall) or 4 (body arching and lifting of pelvic structures). AWR scores were measured before HIS and 6 h, 1 d, 2 d and 7 d after termination of last stressor. The experimenter, who assigned the AWR scores and performed the EMG analysis, was masked to the control or stressed group assignment, to the sham or EA treatment, and to the drug applied (saline or NLX/m-NLX). Each rat was tested twice for AWR score for each distention pressure and the mean AWR score from the two repeated measurements was used for each rat for each pressure in the following statistical analysis.

Electroacupuncture treatment

EA was applied by a pair of stainless steel suture needles. Hook-shaped needles were used to avoid spontaneous removal of inserted acupuncture needles from rat body^[20,21]. Two acupoints were used in this study: ST-36 (Zu-San-Li) or BL-43 (Gao-Huang). ST-36, equivalent to the human acupoint ST-36 (Figure 2), is located at 5 mm lateral to the anterior tubercle of the tibia and 10 mm below the knee joint^[21-23]. BL-43, equivalent to the human acupoint BL-43 (Figure 2), was used as an irrelevant acupuncture point to the colon. The needles were inserted bilaterally at a depth of 5 mm into the skin and underlying muscles at acupuncture point. To compare the effect of EA at an irrelevant acupoint, the same stimulation parameters were used to stimulate the BL-43. The needles inserted into acupoints were stimulated by an EA apparatus (Model G-6805-2, Shanghai Medical Electronic Apparatus Company, China) with a constant rectangular current of alternating trains of dense-sparse frequencies (100 Hz for 1.05 s and 2 Hz for 2.85 s alternately, pulse width, 0.1 ms). This combination of dense-sparse frequency would maximally induce opioid release of met-enkephalin and dynorphin A^[24]. Electrical stimulus intensity was set at the threshold for a detectable muscle twitch (approximately 1 mA). The stimulation was delivered for 30 min. For sham EA group, the needle set was inserted into the ST-36, but no electrical stimulation was applied. Behavioral tests were performed immediately after termination of EA.

Drug administration

After finishing the first distension series, NLX (0.1 mg/kg, Sigma) or m-NLX (1 mg/kg, Sigma) was administered intraperitoneally to HIS rats on the second day. Thirty min after the administration of NLX or m-NLX, EA at ST-36 was given for 30 min. The second distension series was performed immediately after termination of EA. The AUCs for the EMG signals or AWR scores

Figure 3 Heterotypic intermittent stress increased abdominal withdrawal reflex scores to colorectal distention. A: Abdominal withdrawal reflex (AWR) scores were used as a function of distention pressure (20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg). Heterotypic intermittent stress (HIS) significantly enhanced AWR scores measured at 6 h and 24 h after termination of last stressor when compared with baseline (Pre) under 20 mmHg, 60 mmHg and 80 mmHg distention pressure, while HIS significantly enhanced AWR scores measured at 6 h after termination of last stressor when compared with Pre group under 40 mmHg distention pressure [Tukey *post hoc* test following Friedman analysis of variance (ANOVA)]. Therefore, HIS can enhance visceral hypersensitivity in rats at 6 h and 24 h after termination of last stressor generally when compared with baseline (Pre). AWR scores returned to normal level 48 h after termination of last stressor ($n = 8$ rats for each group; $^aP < 0.05$ vs Pre); B: HIS remarkably reduced distention threshold. Distention threshold was the minimal distention pressure to evoke abdominal movement. In agreement with AWR scores, distention threshold started to reduce at 6 h and maintained at a low level at 24 h and returned to normal level 48 h after termination of last stressor (Friedman ANOVA followed by Tukey *post hoc* test, $n = 8$ rats for each group; $^aP < 0.05$ vs Pre).

from two distention series were calculated. m-NLX is a selectively peripherally acting opioid receptor antagonist. The time schedule of experimental protocol is shown in Figure 1C.

Statistical analysis

All data were expressed as mean \pm SE. Statistical analysis were conducted using commercial software OriginPro 8 (OriginLab, United States) and Matlab (Mathworks, United States). Normality was checked for all analyses. Significance between groups was determined using two sample *t* test, Friedman analysis of variance (ANOVA) or two-way repeated-measures ANOVA followed by Tukey *post hoc* test or Mann-Whitney test where appropriate. The level of significance was set at $P < 0.05$.

RESULTS

HIS produced visceral hypersensitivity

To determine whether HIS induces visceral hypersensitivity, AWR scores to CRD were measured in rats before and after the 9-d HIS protocol. The AWR scores before HIS were 0.6 ± 0.2 , 1.3 ± 0.2 , 1.9 ± 0.2 and 2.3 ± 0.2 for 20, 40, 60 and 80 mmHg distention pressures, respectively. Six hours after termination of the last stressor, the AWR scores were 2.0 ± 0.1 , 2.5 ± 0.1 , 2.8 ± 0.2 and 3.5 ± 0.2 for 20, 40, 60 and 80 mmHg distention pressures, respectively (Figure 3A). Since the first measurement was at 6 h, the time when it started was unknown. To determine the time course of stress-induced visceral hypersensitivity, AWR scores were recorded 6, 24, 48 h, and 7 d after the HIS protocol. There was clear time effect for HIS on AWR scores for all distention pressures (Friedman ANOVA; $n = 8$ rats for each group). The increase in AWR scores started at 6 h, maintained for 24 h, and AWR scores returned to

basal levels at 48 h and 7 d after HIS compared with pre-HIS baseline at different distention pressures ($P < 0.05$, Tukey *post hoc* test following Friedman ANOVA, Figure 3A). In addition, the distention threshold was measured in these rats before and after HIS protocol. Distention threshold was the minimal distention pressure to evoke abdominal movement. The distention threshold was 38.3 ± 1.5 mmHg before HIS and was 23.9 ± 1.3 , 25.3 ± 0.8 , 29.0 ± 1.8 , 34.7 ± 0.9 mmHg at 6, 24, 48 h and 1 wk after termination of the last stressor, respectively. There was significant time effect on the distention threshold (Friedman ANOVA, $P < 0.001$, $n = 8$ rats for each group). In agreement with the AWR scores, the distention threshold was significantly lower at 6 h and 24 h, and returned to the baseline level at 48 h and 7 d after HIS protocol compared with pre-HIS baseline ($P < 0.05$, Tukey *post hoc* test following Friedman ANOVA, Figure 3B).

To further confirm the visceral hypersensitivity induced by HIS, EMG measurements were performed on rats before and after HIS. The AUC of EMG recordings before HIS was 10.6 ± 1.6 , 29.2 ± 3.3 , 41.3 ± 4.3 and 52.4 ± 5.1 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. Six h after termination of the HIS protocol, the AUCs were 24.0 ± 4.7 , 60.2 ± 6.6 , 83.0 ± 10.0 and 94.3 ± 10.9 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. There was significant time effect of HIS on EMG for all pressures [$P < 0.001$, two-way repeated measures ANOVA, with significant time \times pressure interaction ($P < 0.001$); $n = 6$ rats for each group]. The AUCs were higher at 6, 24 and 48 h, and returned to baseline values one week after termination of HIS compared with pre-HIS baseline for 40, 60 and 80 mmHg, with no significant difference between AUC of EMG of different time points at 20 mmHg ($P < 0.05$,

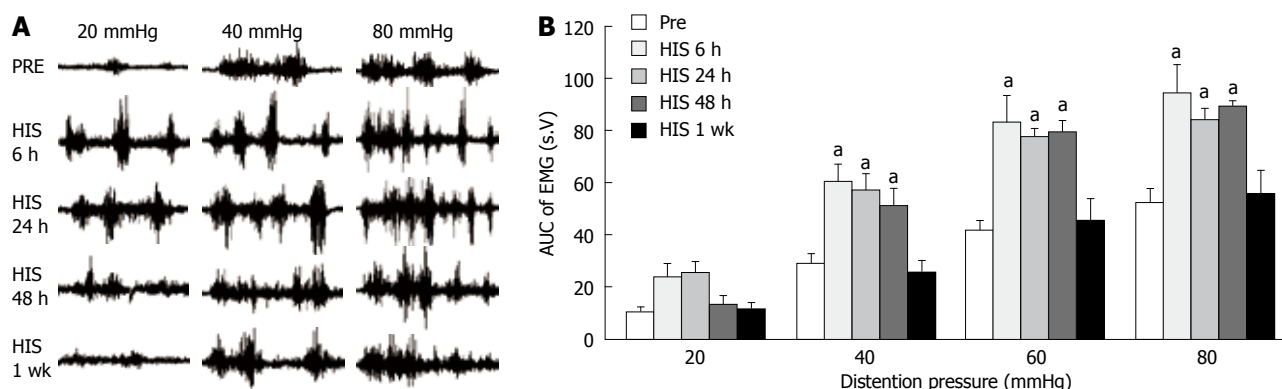

Figure 4 Heterotypic intermittent stress enhanced electromyographic activities in response to colorectal distention. Electromyographic (EMG) activities in the external oblique muscle in response to graded colorectal distention (CRD) were measured before stress and 6 h, 24 h, 48 h and 7 d after termination of heterotypic intermittent stress (HIS). The magnitude of EMG activity was expressed as area under curve (AUC). A: Examples of EMG activities recorded from baseline (Pre), 6 h, 24 h, 48 h and 7 d after termination of HIS in rats responding to distention pressures of 20 mmHg, 40 mmHg and 80 mmHg; B: Bar graph shows the changes in average of AUC before and after HIS protocol. There was no significant difference between EMGs of different time points at 20 mmHg. The magnitude of EMG activity of 6 h, 24 h and 48 h was significantly larger than that of Pre at distention pressures of 40 mmHg, 60 mmHg and 80 mmHg (Tukey *post hoc* test following two-way repeated measures analysis of variance, $n = 6$ rats for each group; $^aP < 0.05$ vs Pre).

Tukey *post hoc* test following two-way repeated measures ANOVA, Figure 4A and B).

EA treatment suppressed visceral hypersensitivity in HIS rats

To determine whether EA suppressed visceral hypersensitivity induced by HIS, AWR scores and AUCs of EMG recordings after EA treatment were compared with those after sham EA treatment. To define the specificity of EA-mediated analgesic effect in rats, we also examined EA effect on age-matched healthy rats (controls). Since AWR scores returned to the baseline level 48 h and EMG data returned to baseline level one week after termination of last stressor (Figures 3A and 4B), EA at acupoints ST-36 (Figure 2) was applied to control and HIS rats for 30 min within 48 h after termination of last stressor. For sham EA group, the needle set was inserted into the ST-36, but no electrical stimulation was applied. AWR scores and EMG activities were recorded immediately after termination of EA. Both distention stress and EA treatment affected AWRs ($n = 8$ rats for each group, two-way repeated measures ANOVA: under 20 mmHg, stress effect, $P < 0.001$; EA treatment effect, $P < 0.01$; under 40 mmHg, stress effect, $P < 0.001$; EA treatment effect, $P < 0.05$), with significant stress \times EA treatment interaction for 20 mmHg and 40 mmHg pressures ($P < 0.05$ for 20 mmHg and 40 mmHg). HIS sham group showed a significant increase in AWR scores compared with control sham group under 20 mmHg and 40 mmHg distention pressures (HIS sham *vs* control sham, for 20 mmHg: 2 ± 0.2 *vs* 0.6 ± 0.1 ; for 40 mmHg: 2.6 ± 0.2 *vs* 1.4 ± 0.2 ; $P < 0.05$, Tukey *post hoc* test following two-way repeated measures ANOVA), while there was no significant difference in AWR scores between control and HIS groups after EA treatment. EA treatment at ST-36 point significantly decreased AWR scores in HIS rats (sham EA *vs* EA, AWRs at 20 mmHg: 2.0 ± 0.2 *vs* 0.7 ± 0.1 ; at 40 mmHg: 2.6 ± 0.2 *vs* 1.5 ± 0.2 ; at 60 mmHg: 3.1 ± 0.2

vs 1.9 ± 0.1 ; at 80 mmHg: 3.6 ± 0.1 *vs* 2.4 ± 0.2 ; $P < 0.05$, Tukey *post hoc* test following two-way repeated measures ANOVA, Figure 5A), but had no effect on control rats under 20 mmHg and 40 mmHg pressures. Under 60 mmHg and 80 mmHg pressures, stress \times EA treatment interaction was not significant ($n = 8$ rats for each group, two-way repeated measures ANOVA); EA treatment significantly decreased AWR scores in both control and HIS rats under 60 mmHg and 80 mmHg pressures ($P < 0.05$, EA effect, two-way repeated measures ANOVA, Figure 5A).

To further confirm the EA effect on stressed rats, EMGs were performed before and after EA or sham EA treatment (Figure 5B and C). Both distention pressure and EA treatment affected AUCs of HIS rats significantly ($n = 6$ rats for each group, two-way repeated measures ANOVA: pressure effect, $P < 0.001$; EA treatment effect, $P < 0.05$), with significant pressure \times EA treatment interaction ($P < 0.001$). Rats that received EA treatment showed a significant decrease in their AUCs compared to rats that received sham EA under 40 mmHg, 60 mmHg and 80 mmHg distention pressures 6 h after HIS (EMG for sham EA *vs* EA, at 20 mmHg: 24 ± 4.7 *vs* 13.8 ± 3.5 ; EMG at 40 mmHg: 60.2 ± 6.6 *vs* 30 ± 4.9 , $P = 0.00523$; EMG at 60 mmHg: 83 ± 10 *vs* 39.8 ± 5.9 , $P = 0.00029$; EMG at 80 mmHg: 94.3 ± 10.8 *vs* 49.6 ± 5.9 , $P = 0.00021$; $P < 0.05$, Tukey *post hoc* test following two-way repeated measures ANOVA, Figure 5B and C), without significant effect under 20 mmHg pressure. This demonstrates that EA suppressed visceral hypersensitivity, and is in agreement with previous studies that EA treatment attenuated chronic visceral hyperalgesia induced by neonatal colonic injection of acetic acid^[23]. It is of note that results from EMG recordings at 20 mmHg were different from those of AWR scores after EA treatment.

To exclude the non-specific effect of EA treatment, EA was applied at Gao-Huang. Gao-Huang, an equivalent to the human acupoint BL-43 (Figure 2), was

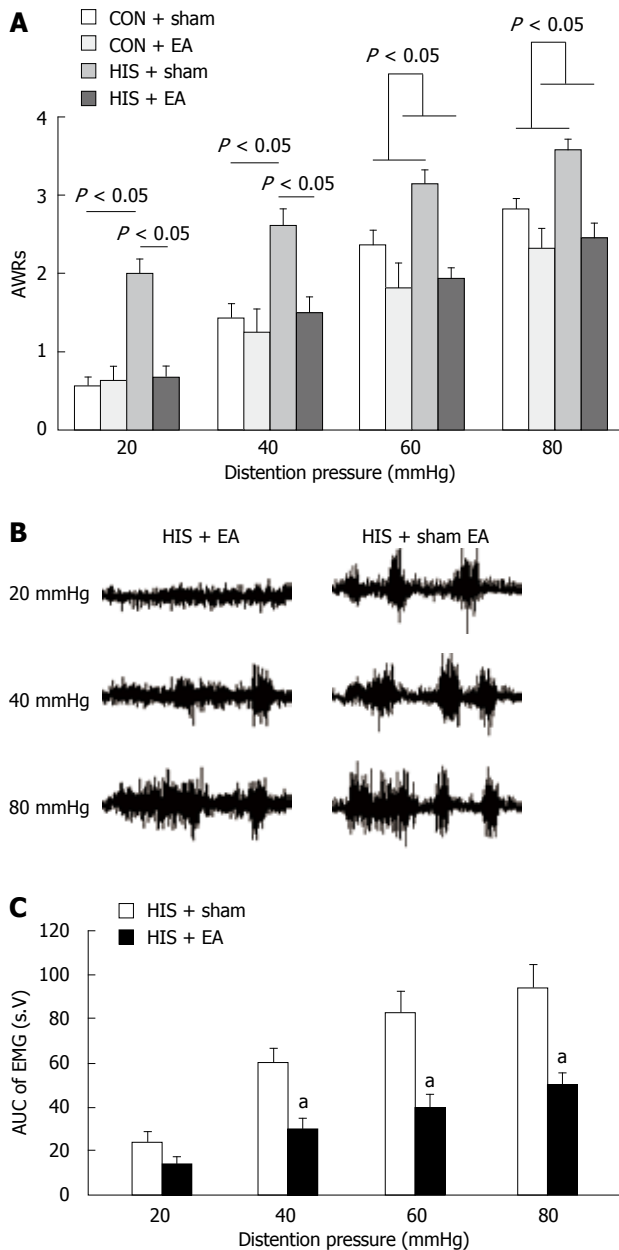

Figure 5 Electroacupuncture treatment attenuated the abdominal withdrawal reflex scores and electromyographic activities. Electroacupuncture (EA) treatments were delivered for 30 min within 24 h after termination of last stressor. For sham EA group, the needle set was inserted into the ST-36 but no electrical stimulation was applied. **A:** The effects of stress exposure and EA treatment on abdominal withdrawal reflex (AWR) scores. Heterotypic intermittent stress (HIS) sham group showed a significant increase in AWR scores compared to control sham group under 20 mmHg and 40 mmHg distention pressures, while there was no significant difference in AWR scores between control and HIS groups after EA treatment. EA treatment at ST-36 point significantly decreased AWR scores in HIS rats, but had no effect on control rats under 20 mmHg and 40 mmHg pressures [Tukey *post hoc* test following two-way repeated measures analysis of variance (ANOVA)]. EA treatment significantly decreased AWR scores in both control and HIS rats under 60 mmHg and 80 mmHg pressures (two-way repeated measures ANOVA, $n = 8$ rats for each group; $P < 0.05$); **B:** Representative electromyographic (EMG) traces recorded immediately after termination of EA (left) or sham EA (right); **C:** Bar graph showing effects of EA treatment and sham EA on EMG recordings. The EMG was significantly decreased by EA treatment at pressure of 40 mmHg, 60 mmHg and 80 mmHg in stressed rats compared to sham EA groups (Tukey *post hoc* test following two-way repeated measures ANOVA, $n = 6$ rats for each group; ^a $P < 0.05$ vs HIS + sham group). CON: Control.

Figure 6 Effect of electroacupuncture at Gao-Huang. Same electroacupuncture (EA) parameters as EA at ST-36 (Zu-San-Li) were used for BL-43 (Gao-Huang) treatment in heterotypic intermittent stress (HIS) rats. Although the abdominal withdrawal reflexes (AWRs) to colorectal distention heavily depend on the pressure level (two-way repeated measures analysis of variance, pressure effect, $P < 0.001$), EA treatment at BL-43 point on HIS rats showed no significant effect on pain perception; $n = 7$ rats for each group.

chosen as an irrelevant acupuncture point to the colon. EA at BL-43 for 30 min did not produce any effect on AWR scores in HIS rats [$n = 7$ rats for each group. Two-way repeated measures ANOVA (EA treatment effect, $P > 0.05$; pressure \times EA interaction effect, $P > 0.05$), Figure 6].

NLX reversed EA-induced analgesic effects

To explore the possible involvement of endogenous opioid system in EA-induced antihyperalgesia, we then examined the effect of systemically injected NLX on EA-induced analgesia. After the 9-d HIS protocol, rats received intraperitoneal injection of 0.1 mg/kg of NLX in 1 mL 30 min before the beginning of EA at ST-36 points. Equal volume of normal saline (NS) was used as control. Immediately after EA termination, the AWR scores to CRD were determined (Figure 7A). The AWR scores from HIS rats pretreated with NS were 0.70 ± 0.20 , 1.50 ± 0.27 , 2.00 ± 0.15 and 2.60 ± 0.18 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. The AWR scores in HIS rats pretreated with NLX were 2.0 , 2.80 ± 0.12 , 3 and 3.60 ± 0.18 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. Pretreatment of NLX significantly reduced the EA-induced suppression of AWR scores of HIS rats under all distention pressures when compared with NS group [$n = 5$ rats for each group, Friedman ANOVA, NLX effect, $P < 0.001$; $P < 0.05$, Mann-Whitney test following Friedman ANOVA, Figure 7A]. This indicates the involvement of endogenous opioid system in mediating EA analgesic effects on HIS-induced visceral hyperalgesia. To exclude the non-specific effect of NLX, we further determined whether NLX itself produced any effect on AWR scores in control rats without EA treatment (Figure 7B). The AWR scores before 0.1 mg/kg of NLX in 1 mL treatment in control rats were 1.00 ± 0.16 , 1.90 ± 0.10 , 2.50 ± 0.22 and 2.70 ± 0.20 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. The

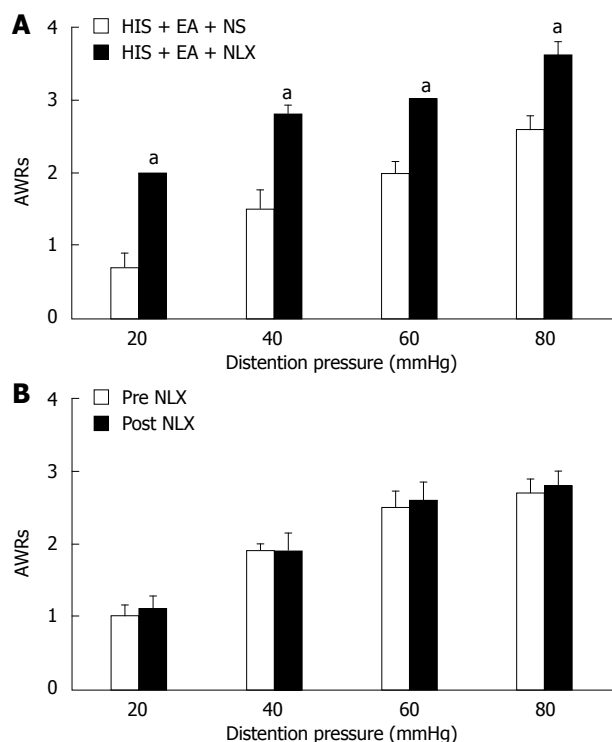

Figure 7 Reversal of electroacupuncture-mediated analgesic effect by naloxone. A: The opioid receptor antagonist, naloxone (NLX) (0.1 mg/kg body weight, $n = 5$), or normal saline (NS) was administrated intraperitoneally 30 min before electroacupuncture (EA) application. Abdominal withdrawal reflex (AWR) scores were recorded immediately after EA termination in rats pretreated with NLX or NS. Both pressure and NLX injection significantly affected the AWRs to colorectal distention in rats [Friedman analysis of variance (ANOVA), $P < 0.001$ for pressure effect and for NLX injection effect]. Bar graph showed that NLX (0.1 mg/kg body weight) completely blocked the EA-induced analgesic effect when compared with NS treatment at all pressures (Mann-Whitney test following Friedman ANOVA). $n = 5$ rats for each group. ^a $P < 0.05$ vs NS-EA group; B: Same dose of NLX treatment did not produce any effect on AWR scores in control rats without EA treatment (Friedman ANOVA). AWRs were only significantly affected by different pressure levels ($P < 0.001$). $n = 5$ rats for each group. Control rats were not exposed to heterotypic intermittent stress (HIS).

AWR scores after 0.1 mg/kg of NLX in 1 mL treatment were 1.10 ± 0.19 , 1.90 ± 0.24 , 2.60 ± 0.24 and 2.80 ± 0.20 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. This suggests that NLX itself did not produce any effect on AWR scores in control rats ($n = 5$ rats for each group, Friedman ANOVA, NLX effect, $P > 0.05$). Similarly, we did not observe any effect of NLX on AWR scores in HIS rats without EA treatment (data not shown). These data suggest that the inhibitory effect of NLX on visceral analgesia is associated with EA treatment.

m-NLX inhibited EA-induced analgesic effects

To further determine whether peripheral opioid system is involved in the EA-induced analgesic effect, m-NLX was administrated prior to EA treatment. m-NLX is an opioid receptor antagonist that can not cross the blood-brain barrier, thereby only acting at peripheral nervous system. After the 9-d HIS protocol, rats received intraperitoneal injections of 1 mg/kg of m-NLX in 1 mL 30 min before

Figure 8 Reversal of electroacupuncture-mediated analgesic effect by naloxone methiodide. The opioid receptor antagonist, naloxone methiodide (m-NLX), or normal saline (NS) was administrated intraperitoneally (5 mg/kg body weight) 30 min before electroacupuncture (EA) application. Electromyographic (EMG) activities were recorded immediately after EA from rats pretreated with m-NLX and NS. A: Examples of EA effects on EMG activities pretreated with NS (top) or m-NLX (bottom); B: Bar graph showing that m-NLX completely blocked the EA-induced analgesic effect. The magnitude of EMG activity was significantly increased by m-NLX treatment at pressure of 40 mmHg, 60 mmHg and 80 mmHg (Tukey *post hoc* test following two-way repeated measures analysis of variance, $n = 6$ rats for each group; ^a $P < 0.05$ vs EA + NS group).

the beginning of EA at ST-36 points. Equal volume of NS was used as control. EMG recordings were measured immediately after EA termination. The AUCs of EMG activities from HIS rats pretreated with NS were 13.33 ± 3.88 , 36.28 ± 8.01 , 50.19 ± 8.28 and 56.42 ± 8.43 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. The AUCs of EMG activities in HIS rats pretreated with m-NLX were 30.84 ± 4.39 , 74.16 ± 9.04 , 96.45 ± 11.80 and 111.59 ± 13.79 for 20 mmHg, 40 mmHg, 60 mmHg and 80 mmHg distention pressures, respectively. Pretreatment of m-NLX (1 mg/kg, *i.p.*) significantly reduced the analgesic effects induced by EA in a pressure-dependent manner ($n = 6$ rats for each group, two-way repeated measures ANOVA, NLX effect, $P < 0.01$; pressure \times NLX interaction, $P < 0.01$). The effect of pretreatment of m-NLX was significant under 40 mmHg, 60 mmHg and 80 mmHg, but not under 20 mmHg ($P < 0.001$, Tukey *post hoc* test following two-way repeated measures ANOVA, Figure 8). To further determine the specificity of m-NLX, a low dose of m-NLX (0.1 mg/kg) was injected intraperitoneally. Pretreatment with a low dose of m-NLX did not affect the EA-induced suppression of EMG activities in HIS rats (data not shown). In addition, systemic injection of m-NLX (1 mg/kg, *i.p.*) did not produce any effect on the AUCs of EMG activities in normal or HIS rats without EA treatment (data not shown). These data suggest that EA may affect the peripheral opioid system to induce analgesia in HIS rats.

DISCUSSION

The present study examined the mechanisms involved in EA-induced analgesia in a rat model of visceral hypersensitivity induced by HIS. EA treatment significantly reduced AWR scores (Figure 5A) and suppressed EMG responses (Figure 5C) to colorectal distention in the stressed rats, but not in non-stressed rats, at the pressures of 20 mmHg and 40 mmHg, indicating that EA had an analgesic effect in this model. Although EA has been used clinically for alleviation of various types of pain^[25,26], there is not enough scientific validation for the use of EA in visceral pain. Together with our previous report that EA attenuated visceral pain induced by neonatal acetic acid infusion^[23], we have provided additional evidence for EA treatment for visceral pain in different models.

Acupuncture is being increasingly accepted by practitioners and patients, especially during the last three decades. EA is a modification of this technique that stimulates acupoints (or called acupuncture points) with electrical current instead of manual manipulations. The EA procedures may stimulate the somatic afferent nerves innervating the skin and muscles of the body, which was different from transcutaneous electrical nerve stimulation (TENS). EA typically involves penetration of the skin by fine, solid metallic needles, which are manipulated by electrical stimulation. TENS is a treatment that has been shown to be effective for pain relief in a variety of conditions. Electrodes for TENS are placed on the skin. Electric current applied at different pulse rates (frequencies) and intensities is used to stimulate these areas so as to provide pain relief. In this study, we focused on the EA-mediated effect in stressed animal models. We showed that EA at ST-36, but not at BL-43, significantly suppressed the visceral motor responses to CRD (Figure 6). Koo *et al.*^[27] reported that ankle sprain pain was relieved by EA at SI-6, but not at nearby LI-4. More recently, they reported that EA-induced analgesic effects in capsaicin-induced hyperalgesia are produced only by stimulation at SI-3/TE-8 of the forelimb, but not at nearby points (LI-3/LI-6) or several other points (GB-30/GB34, BL-40/BL-60, GV-2/GV-6)^[28]. Kim *et al.*^[29] demonstrated that acupuncture at HT-7, but not at nearby point TE-8, inhibited dopamine release in the nucleus accumbens and suppressed behavioral hyperactivity in the morphine addiction model, thus suggesting the acupoint-specificity. However, the acupoint specificity of EA effect in visceral pain remains unknown. In the present study, two acupoints, ST-36 and BL-43, were selected. The acupoint ST-36 has been used empirically for the treatment of gastrointestinal diseases for many years, while acupoint BL-43 is not thought to be related to the GI tract (Figure 2). EA at ST-36, but not at BL-43, significantly suppressed the visceral motor responses to CRD (Figure 6), suggesting that the EA effect is not a non-specific effect and it may be associated with acupoint and its related afferent fibers. This finding is consistent with a previous study which found that EA at ST-36, but not at BL-21, significantly reduced the increase in mean arterial blood pressure in response to

rectal distension in dogs^[30]. Since the parameter used for EA treatment at BL-43 is the same as at ST-36, further experiments are needed to investigate whether different stimulation parameters used to stimulate BL-43 produce the analgesic effect in this model. In addition, it is worth noting that our results showed that EA produced a significant analgesic effect only on the HIS-induced visceral hyperalgesia, but not on the age-matched healthy rats, at the distention pressures of 20 mmHg and 40 mmHg (Figure 5A). This further indicates that EA-produced analgesic effect is not a non-specific effect and that it may be disease-related under low stimulation intensity. The reason why EA did not produce inhibitory effect under low distention pressure remains unknown. It is most likely that low distention pressure produced the low responses that are not sensitive to EA treatment. However, there has been a certain degree of skepticism about acupoint and disease specificity. There was no statistical difference between acupoint and nonacupoint acupuncture in an experimental human pain model, thus suggesting no acupoint specificity. Rong *et al.*^[31] reported that manual acupuncture at ST-36 produced anti-nociceptive effect on CRD in healthy rats. This discrepancy may be due to the application of different methods of acupuncture and distention pressure as well. Therefore, the acupoint and disease specificity of EA treatment is still a controversial issue and is a subject of further study of pain.

EA analgesic effect in various conditions may be mediated by different mechanisms. These include opioid and non-opioid mechanisms^[32-35]. The involvement of the endogenous opioid system is a well-established hypothesis for explanation of EA effects. The involvement of non-opioid mechanisms in EA analgesia was confirmed by experiments in which administration of 5-HT or catecholamine or adrenoceptor antagonists or depletion of cellular monoamine content blocked the EA-induced analgesic effect^[36,37]. It appears that the underlying mechanisms of EA analgesic effect in various conditions may depend on the specific conditions^[28]. In this study, the systemic application of opioid receptor antagonist NLX completely blocked the EA-mediated analgesic effects, indicating that endogenous opioid pathways were involved in EA-mediated analgesia in the rat model of visceral pain. This was consistent with the reports of different animal models of visceral pain^[22,38]. In the present study, we focused on the role of opioid system because previous studies indicate that opioid system was sensitive to environmental factors, and changes in its expression attenuated the pain sensitivity in different models^[23,39-43]. However, we cannot rule out that other systems may also be affected by EA treatment. The net result of regulatory changes in cell signaling proteins induced by EA, however, is to attenuate visceral hypersensitivity.

The processing of pain information occurs at central (spinal and supraspinal) and peripheral sites, and thus modification of pain levels can be achieved through interventions at multiple sites. Although the exact locations where EA modifies pain are not clearly identified, EA is thought to activate the ascending sensory pathways such

as spinal dorsal horn and thalamus, or the descending pain inhibitory mechanisms, such as opioid, adrenergic and serotonergic pathways. Most of previous studies have resolved only the central mechanism of EA analgesia, and only a few reports have investigated the peripheral mechanism of EA effect. Somatic inputs (i.e., EA-activated input) and noxious visceral signals (i.e., CRD) might converge and interact in the neurons at spinal dorsal horn level. Their interactions were manifested as that when the cutaneous stimuli were applied, the neuronal response to CRD was reduced in most cases^[31]. Kim *et al.*^[28] showed that EA suppresses capsaicin-induced secondary hyperalgesia through an endogenous spinal opioid mechanism, thus indicating EA modulation of pain through a central, but not peripheral, mechanism. The anti-nociceptive effect of EA at ST-36 was abolished by pretreatment with NLX but not by m-NLX by observation of mean arterial blood pressure in response to rectal distension in dogs^[30]. These results suggest that EA at ST-36 may reduce visceral pain via central opioid pathway. In this study, we demonstrated that EA-mediated analgesia was completely blocked by m-NLX. m-NLX is unable to cross the blood-brain barrier and blocks only peripheral opioid receptors^[30,44], thus indicating that EA analgesia is likely mediated by peripheral opioid receptors. Recent studies showed that peripheral opioid receptors were activated by EA at the inflammatory site on the CFA model^[45]. NMDA receptor expression in primary sensory neurons is inhibited by EA^[46], suggesting the peripheral effect of EA analgesia. Again, this discrepancy points out the fact that EA-mediated analgesic effect may be disease and/or organ-specific. Since previous studies have shown that stimulation frequencies of EA determine the types of opioid peptides released in the nervous system^[24], further experiments are needed to explore which subtypes of opioid receptors are involved in mediating EA antihyperalgesic effects and to identify the location from which the opioids are released, e.g., the peripheral nerve terminals *vs* immunocytes, the mucosa/submucosa *vs* muscle layer of the colon.

In conclusion, together with our previous report^[23], the present study demonstrated that EA treatment given at classical acupoint ST-36 produces an analgesic effect on visceral hyperalgesia in a rat model of IBS. The EA effect is mediated by endogenous opioid pathways, possibly at peripheral sites, thus providing scientific evidence for the treatment of visceral pain in functional gastrointestinal disorders using EA.

COMMENTS

Background

Irritable bowel syndrome (IBS) is a common gastrointestinal disorder characterized by chronic visceral pain and bloating in association with altered bowel movements. Acupuncture is an ancient form of traditional Chinese medicine that has been used to treat diseases. Recently, acupuncture needles are stimulated by electricity at various frequencies, which is termed electroacupuncture (EA). However, the mechanism underlying EA-induced analgesia in visceral pain remains unknown.

Research frontiers

The present study used EA to treat visceral hypersensitivity of rats which was

induced by a heterotypic intermittent stress (HIS) protocol. EA at acupoint Zu-San-Li significantly decreased visceral hypersensitivity of rats. EA-mediated analgesic effect was completely reversed by administration of naloxone (NLX) methiodide, a peripherally restricted opioid antagonist. The mechanism underlying the effect of EA on visceral hypersensitivity of rats induced by HIS which is a rat model of IBS appears to involve the mediation of peripheral opioid system.

Innovations and breakthroughs

This is the first study to indicate that EA treatment produces an analgesic effect on visceral hyperalgesia in a rat model of IBS induced by heterotypic intermittent stress. The EA effect is mediated by endogenous opioid pathways, possibly at peripheral sites.

Applications

The present study demonstrated that EA treatment produces an analgesic effect on visceral hyperalgesia in a rat model of IBS. The EA effect is mediated by endogenous opioid pathways, possibly at peripheral sites, thus providing scientific evidence for the treatment of visceral pain in functional gastrointestinal disorders using EA.

Terminology

IBS is a common gastrointestinal disorder characterized by chronic visceral pain and bloating in association with altered bowel movements. EA, acupuncture needles are stimulated by electricity at various frequencies (1-100 Hz); this method is developed from acupuncture, an ancient form of traditional Chinese medicine. NLX methiodide, a selectively peripherally acting opioid receptor antagonist.

Peer review

This paper describes positive effects of EA on responses to bowel extension in stressed rats. It is reported that EA diminished the number of pellets produced, the subjectively scored abdominal reflexes and the power of the electromyography of the abdominal muscles in response to colon extension, in stressed rats compared to control rats. Moreover, the effect of EA was antagonized by both a central and peripheral acting opiate antagonist. The effects presented are significant, and the antagonizing effect with NLX was convincing. The results presented are important for clinicians and for the fundamental scientific community as well.

Abstract

AIM: To identify genes potentially involved in *Helicobacter pylori* (*H. pylori*)-induced gastric carcinogenesis.

METHODS: GES-1 cells were co-cultured with *H. pylori* strains isolated from patients with gastric carcinoma (GC, $n = 10$) or chronic gastritis (CG, $n = 10$) for *in vitro* proliferation and apoptosis assays to identify the most and least virulent strains. These two strains were *cagA*-genotyped and used for further *in vivo* carcinogenic virulence assays by infecting Mongolian gerbils for 52 wk, respectively; a broth free of *H. pylori* was lavaged as control. Genomic profiles of GES-1 cells co-cultured with the most and least virulent strains were determined by microarray analysis. The most differentially expressed genes were further verified using quantitative real-time polymerase chain reaction in GES-1

cells infected with the most and least virulent strains, and by immunohistochemistry in *H. pylori* positive CG, precancerous diseases, and GC biopsy specimens in an independent experiment.

RESULTS: GC-derived *H. pylori* strains induced a potent proliferative effect in GES-1 cells in co-culture, whereas CG-derived strains did not. The most (from a GC patient) and least (from a CG patient) virulent strains were *cagA*-positive and negative, respectively. At week 52, CG, atrophy, metaplasia, dysplasia, and GC were observed in 90.0%, 80.0%, 80.0%, 90%, and 60.0%, respectively, of the animals lavaged with the most virulent strain. However, only mild CG was observed in 90% of the animals lavaged with the least virulent strain. On microarray analysis, 800 differentially expressed genes (49 up- and 751 down-regulated), involving those associated with cell cycle regulation, cell apoptosis, cytoskeleton, immune response, and substance and energy metabolisms, were identified in cells co-cultured with the most virulent strain as compared with those co-cultured with the least virulent strain. The six most differentially expressed genes (with a betweenness centrality of 0.1-0.2) were identified among the significant differential gene profile network, including *JUN*, *KRAS*, *BRCA1*, *SMAD2*, *TRAF1*, and *HDAC6*. Quantitative real-time polymerase chain reaction analyses verified that *HDAC6* and *TRAF1* mRNA expressions were significantly more up-regulated in GES-1 cells co-cultured with the most virulent strain than in those co-cultured with the least virulent strain. Immunohistochemistry of gastric mucosal specimens from *H. pylori*-positive patients with CG, intestinal metaplasia (IM), dysplasia, and GC showed that moderately positive and strongly positive *HDAC6* expression was detected in 21.7% of CG patients, 30.0% of IM patients, 54.5% of dysplasia patients, and 77.8% of GC patients ($P < 0.001$). The up-regulation of *TRAF1* expressions was detected in 34.8%, 53.3%, 72.7%, and 88.9% specimens of CG, IM, dysplasia, and GC, respectively ($P < 0.001$).

CONCLUSION: The overexpression of *HDAC6* and *TRAF1* in GES-1 cells co-cultured with the GC-derived strain and in *H. pylori*-positive dysplasia and GC suggests that HDAC6 and TRAF1 may be involved in *H. pylori*-induced gastric carcinogenesis.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a pathogenic bacterium colonizing gastric mucosae, especially in the antrum. It has been accepted to be the primary cause of upper gastrointestinal disorders, such as acute and chronic gastritis, peptic ulcer disease, and gastric cancer^[1]. *H. pylori* infection is common worldwide with a prevalence of approximately 50%, especially in Eastern Asian populations, and the infection is usually a life-long event^[2]. However, over 80% of *H. pylori*-infected individuals remain asymptomatic for their whole lifetime despite the presence of chronic gastric inflammation or chronic gastritis (CG), caused by *H. pylori* infection^[3]. The subsequent outcomes of persistent *H. pylori* infection are highly variable. Approximately, 10%-20% of *H. pylori*-infected individuals are subject to peptic ulcer disease, including gastric and duodenal ulcers^[4]. Of note, individuals infected by *H. pylori* are at a higher risk of gastric carcinoma (GC) (1%-2%) and mucosa-associated lymphoid tissue (MALT) lymphoma (< 1%)^[5]. Therefore, gastric cancer may well be an infectious disease^[6]. Additionally, it has been reported that *H. pylori* infection is associated with esophageal diseases, such as gastroesophageal reflux disease, Barrett's esophagus, and esophageal carcinoma, as well as extra-gastrointestinal diseases, such as cardiovascular diseases, although controversies exist^[7,8]. Such variation in clinicopathological outcomes of *H. pylori* infection is believed to result from the variations in the virulence of different strains, genetic background of the host, and more importantly, the host-pathogen interactions.

It has been widely accepted that *H. pylori* is the major cause of GC in most (65%-80%) patients^[9]. Dietary risks, such as nitrate- and nitrite-enriched smoked or salted foods, are attributed to the *in vivo* biochemical activities of *H. pylori*^[10]. Genetic susceptibility has also been identi-

fied in 10% of GC patients^[11]. The canonical paradigm of gastric carcinogenesis has been established for more than two decades as a consecutive but dynamic progression of *H. pylori* infection, namely, CG, gastric atrophy (GA), intestinal metaplasia (IM), dysplasia, and finally GC^[12]. Thus, *H. pylori* infection plays a leading role in the pathogenesis of GC^[13].

It is likely that *H. pylori* strains themselves are highly variable in virulence to gastric mucosal epithelia, especially in terms of the carcinogenic effect. Genomic profiling analyses have identified a wide range of genetic variations among *H. pylori* strains isolated from patients with different gastric pathologies. Global gene expression profiles also vary greatly in human gastric epithelial immortalized cells infected with spiral *vs* coccoid *H. pylori*^[14]. These findings suggest that gastric epithelial cells tune in the expression of their genes, especially those associated with tumorigenesis, in response to specific *H. pylori* strains or a specific virulent factor of the strain. In addition to the core genes, strain-specific genes are thought to play an essential role in *H. pylori* propagation and pathogenesis.

How gastric epithelial cells respond to *H. pylori* clinical isolates derived from patients with different pathologies, such as GC and CG specimens, at the genome-wide level remains unknown. Therefore, this study was carried out to identify genes potentially involved in *H. pylori*-induced gastric carcinogenesis, by comparing the genomic profiles between gastric epithelial cells co-cultured with *H. pylori* strains isolated from patients with GC and those co-cultured with strains from patients with CG.

MATERIALS AND METHODS

Patients and specimens

The study protocol was approved by the Institutional Review Boards at the Third Xiangya Hospital of Central South University and Hunan Provincial Hospital, respectively. All patients gave written informed consent prior to the enrollment. A total of 350 outpatients who underwent upper gastrointestinal endoscopy at the Department of Gastroenterology, the Third Xiangya Hospital of Central South University, and the Department of Gastroenterology of Hunan Provincial Hospital were consecutively enrolled. Gastric mucosal biopsy specimens were obtained from 182 patients. Three gastric biopsy specimens, 3-5 cm to the pylorus, were collected for the rapid urease test and the histological examination. The rapid urease test was performed using a rapid urease test kit (Sanqiang Biotechnology, Sanming, China). Of the 182 patients, 113 patients were found positive for *H. pylori* infection as detected by the rapid urease test. The histological classification followed the updated Sydney system^[15]; the most serious pathology was documented as the histological diagnosis of each patient with concomitant mucosal pathologies. Thus, 23 patients were histologically diagnosed with CG, 30 with intestinal metaplasia (IM), 33 with dysplasia, and 27 with GC. In the present study, gastric specimens from CG and GC patients were used

for *H. pylori* isolation and subculture.

***H. pylori* isolation and subculture**

Gastric mucosal specimens from patients with CG and GC were ground into homogenates and inoculated onto a Columbia agar plate (Sangong Biotech, Shanghai, China) supplemented with 6% sheep blood. Plates were incubated at a mixed atmosphere of 10% CO₂, 5% O₂, and 85% N₂, at 37 °C for 72 h. *H. pylori* colonies were validated by using colony identification, Gram staining, light microscopy, and urease test (Fujian Sanqiang Biochemical Co. Ltd., Sanming, China) prior to further use. Subculture of *H. pylori* was performed as described above. Twenty *H. pylori* strains were isolated from 10 CG and 10 GC patients, and used for further experiments.

Identification of the most and least virulent strains isolated from CG and GC specimens

GES-1 cell culture and co-culture with *H. pylori*: GES-1 cell line, a human gastric epithelium immortalized cell line, was purchased from Ai-yan Biotechnology Co., Ltd., Shanghai, China. GES-1 cells were cultured in high-glucose Dulbecco's modified Eagle's medium (Invitrogen, Carlsbad, CA) containing 10% fetal bovine serum (Invitrogen, Carlsbad, CA), at 37 °C and in a humidified atmosphere of 5% CO₂. GES-1 cells at the exponential growth phase were harvested and seeded onto 96-well plates, at a density of 5×10^3 cells per well. *H. pylori* strains were resuspended in phosphate buffer solution (PBS) at a density of 3.0×10^8 cfu/mL using a spectrophotometer (Eppendorf, Hamburg, Germany). Following the cell cycle synchronization with 2% serum starvation, GES-1 cells were co-cultured with *H. pylori* strains in GES-1 cell culture media at a cell/bacterium ratio of 5:1, 1:1, 1:50, and 1:200, respectively. The number of bacteria was examined using a spectrometer, whilst that of cells was determined using TC10 automated cell counter (Bio-Rad Laboratories, Philadelphia, PA). A mono-culture of GES-1 cells in the absence of *H. pylori* was used as a control. The number of GES-1 cells was fixed among co-cultures as well as mono-culture. The experiments were performed in duplicate and repeated in triplicate independently.

3-(4,5-dimethylthiazol-2)-2,5-diphenyltetrazolium bromide cell proliferation assay: Following 12 h, 24 h, and 48 h of co-culture, 20 µL 3-(4,5-dimethylthiazol-2)-2,5-diphenyltetrazolium bromide (MTT) solution (Sangong Biotech, Shanghai, China) was added into the culture medium for a further 4-h incubation at 37 °C prior to the supplementation of 150 µL dimethyl sulfoxide (Invitrogen, Carlsbad, CA). The optical density at the wavelength of 490 nm ($A_{490\text{ nm}}$) was determined using an ELISA microplate reader (Bio-Tek, Winooski, VT). The experiments were performed in duplicate and repeated in triplicate independently.

Identification of *cagA* gene in *H. pylori* strains with

real-time polymerase chain reaction: The DNA samples were isolated using a bacterial DNA extraction kit (Boehringer Ingelheim GmbH, Ingelheim, Germany). Briefly, the most and least virulent *H. pylori* strains were resuspended in GTEL buffer and pre-incubated in TESK buffer at 55 °C for 2 h. The RNA contained in the *H. pylori* strains was eliminated using 20-µg/mL RNase at 55 °C for 10 min. The DNA samples were isolated using the phenol-chloroform-isopentanol (25:24:1) extraction technique. Genotyping for *cagA* was performed using the primers of the following sequences (Sangon Biotech Co., Ltd., Shanghai, China): sense, 5'-ATGGAAAATATCATACAACCCC-3', and antisense, 5'-CATCTTCTAAATGGGAAACGCC-3'; length, 268 bp. The thermal cycling condition was as follows: pre-denatured at 96 °C for 1 min; denatured at 94 °C for 1 min and annealed at 60 °C for 1 min, 35 cycles; and extended at 94 °C for 1 min. Polymerase chain reaction (PCR) products were separated on 1% agarose gels containing 0.5 g/mL ethidium bromide and visualized by ultraviolet transillumination. *H. pylori* strain NCTC 11639 (Institute of Digestive Disease, Shanghai, China) was used as a positive control and *H. pylori* strain NCTC 12908 (Institute of Digestive Disease, Shanghai, China) as a negative control.

Cell apoptosis analysis with flow cytometry: Following 12, 24, and 48 h of co-culture, GES-1 cells were collected, washed in chilled PBS, and fixed in 70% pre-chilled (-20 °C) ethanol at 4 °C for 18 h, and resuspended at a density of 1×10^6 /mL. Fixed GES-1 cells were washed in PBS three times and stained with propidium iodide (Sigma, St Louis, MO) for 30 min prior to the analysis using an EPICS® ALTRA™ flow cytometer (Beckman Coulter, Inc., Brea, CA). The experiments were performed in duplicate and repeated in triplicate independently.

The *H. pylori* strain that exhibited the most significant cell proliferative effect on MTT assay over 24 h of co-culture (36.8% increase) was harvested from a GC specimen and deemed as the most virulent strain, while a strain from a CG specimen that exhibited the least significant cell proliferative effect on MTT assay over 24 h of co-culture (15.0% increase) was deemed the least virulent.

***In vivo* carcinogenicity assay in Mongolian gerbils**

The two representative strains, the most and the least virulent, were subsequently used to establish a *H. pylori* infection animal model^[16]. The animal care and use complied with the regulations established and approved by the Animal Research Committee at Central South University. Seven-week-old specific-pathogen-free male Mongolian gerbils ($n = 30$) were purchased from the Laboratory Animal Center, Zhejiang Provincial Institute of Medical Sciences, Hangzhou, China. Gerbils were housed in an environment constantly maintained at a temperature of 25 °C, a relative humidity of 55%, and a 12 h/12 h light/dark cycle. Animals had no access to rodent chow for 12 h and

PCR: Polymerase chain reaction.

drinking water for 4 h prior to the pretreatment with 0.3 mL 50% ethanol lavage per animal. *H. pylori* strains were cultured for three days using the aforementioned protocol, and resuspended in 7.5% (w/v) heat-inactivated brain heart infusion broth (Sangong Biotech, Shanghai, China) at a density of 1.0×10^9 cfu/mL using a spectrophotometer (Eppendorf). Fasted animals were lavaged with 0.5-mL suspension of the most or least virulent *H. pylori* strain ($n = 10$ for each strain) per animal three times, at a 12 h interval. Ten animals that were lavaged with the broth alone using the same protocol served as the control. Animals were allowed to resume oral intake two hours following the last lavage. Animals were sacrificed by cervical dislocation 4, 16, 28, 40 and 52 wk ($n = 2$ at each time point) following the lavage with *H. pylori* suspensions or broth. Fresh gastric mucosal specimens were collected from the gastric antrum and body for the rapid urease test, and the duplicate specimens were fixed in 4% paraformaldehyde for histological examination using hematoxylin and eosin staining.

Determination of the differentially expressed genes between GES-1 cells co-cultured with the most and least virulent strains

Total RNA extraction: The two representative *H. pylori* strains were co-cultured with GES-1 cells for 24 h, respectively, at a cell/bacterium ratio of 1:50, the optimal ratio for *H. pylori*-induced cell proliferation as determined in MTT assay. Mono-cultured GES-1 cells were used as a control. Total cellular RNA was extracted from infected and non-infected cells using Qiagen RNeasy Mini kit (Invitrogen, Carlsbad, CA) for further microarray analysis and quantitative real-time (qRT)-PCR verification. RNA concentration and purity were determined using an ultraviolet spectrometer (Eppendorf). Denaturing agarose gel electrophoresis was performed to validate the integrity of RNA samples. The experiments were performed in duplicate and repeated in triplicate independently.

Oligonucleotide microarray: The GeneChip Human Genome U133 Plus 2.0 Array (Affymetrix, Santa Clara, CA, United States), containing 48 000 transcript probes, was used to assess the global gene expression of GES cells in response to *H. pylori* infection. Microarray analysis was performed as instructed by the manufacturer. Chip scanning and data analysis were processed using Affymetrix Microarray Suit Software 5.0 to identify significant differential gene expression profiles. A gene with a signal ratio of more than 2.0 (up-regulated) or less than

0.5 (down-regulated) was defined to be a differentially expressed gene when co-cultured GES-1 cells were compared with control cells, or when cells co-cultured with the most virulent strain were compared with those co-cultured with the least virulent strain.

Validation of potential carcinogenesis-associated genes among the most differentially expressed genes

Quantitative real-time polymerase chain reaction in GES cells: Two carcinogenesis-associated genes that encode histone deacetylase 6 (HDAC6) and tumor necrosis factor receptor-associated factor 1 (TRAF1)^[17,18] were among the most differentially expressed genes. Due to their unknown roles in the pathogenesis of GC, the transcriptions of HDAC6 and TRAF1 were evaluated using quantitative real-time polymerase chain reaction (qRT-PCR). Primer pairs for qRT-PCR were listed in Table 1. GAPDH, as an internal control, was co-amplified with the specific genes. Briefly, total cellular RNA was extracted from GES cells infected with the most and least virulent strains as well as uninfected GES cells, and reversely transcribed into cDNA by M-MLV reverse transcriptase and random hexamer primer (Invitrogen, Carlsbad, CA). The cDNAs were amplified by 30 PCR cycles of denaturation at 94 °C for 30 s, annealing at 53 °C for 45 s, and extension at 72 °C for 30 s. As a final step, the extension was at 72 °C for 1 min. PCR products were separated on 1% agarose gels containing 0.5 g/mL ethidium bromide and visualized by ultraviolet transillumination. SYBR qPCR Mix (Invitrogen, Carlsbad, CA) was used to monitor DNA synthesis. The experiments were performed in duplicate and repeated in triplicate independently.

Immunohistochemistry in gastric biopsy specimens:

In an independent experiment, *H. pylori*-positive gastric mucosal specimens from the 113 patients were used for immunohistochemistry (IHC) to verify the expression of HDAC6 and TRAF1 in different gastric pathologies. Briefly, goat-anti-HDAC6 (1:100; Santa Cruz Biotechnology, Inc., Heidelberg, Germany) and rabbit-anti-TRAF1 (1:100; BIOS, Beijing, China) were used as primary antibodies. Conjugated biotin was identified by using horseradish peroxidase-labeled streptavidin (1:200; Santa Cruz Biotechnology, Inc.) and visualized by using 3,3'-diaminobenzidine (1:200; Santa Cruz Biotechnology, Inc.). Overall, at least 200 cells in ten randomly selected fields were counted, and the percentages of positive cells against the total counted cells were calculated for each specimen. The IHC staining intensity was semiquantitatively

Figure 1 GES-1 cell proliferation as determined by 3-(4,5-dimethylthiazol-2)-2,5-diphenyltetrazolium bromide assay (A) and cell apoptosis as determined by flow cytometry (B) after co-culture with *helicobacter pylori* isolated from patients with gastric carcinoma (GC, $n = 10$) or chronic gastritis (CG, $n = 10$) for 48 h in relation to control cells. The ratio denotes the ratio of GES-1 cells vs *Helicobacter pylori* cells. ^a $P < 0.05$ vs control group; ^c $P < 0.05$ vs CG group. OD: Optical density.

determined as negative (positive cells $< 10\%$), moderately positive ($10\%-50\%$), and strongly positive ($> 50\%$). The experiments were performed in duplicate and repeated in triplicate independently.

Statistical analysis

SPSS ver. 13.0 (SPSS Inc., Chicago, IL) was used for the statistical analysis. All numerical data were expressed as mean \pm SD, and compared by using the Student's *t*-test or analysis of variance, when appropriate. All categorical data were expressed as percentage and compared by using the χ^2 -test or Fisher's exact probability test, when appropriate. A *P* value of less than 0.05 was considered statistically significant.

RESULTS

GC-derived *H. pylori* strains induced potent proliferation in GES-1 cells

As shown in Figure 1A, GES-1 cells exhibited an overall cell proliferative response over time to the co-culture with *H. pylori* isolated from GC. A low-concentration (5:1) GC-derived *H. pylori* infection *in vitro* had minimal effect on GES-1 cell proliferation. At a cell/*H. pylori* ratio of 1:1 or 1:50, GES-1 cells co-cultured with GC-derived *H. pylori*

strains had a significantly higher proliferation rate relative to those with CG-derived *H. pylori* strains and control cells. In contrast, CG-derived *H. pylori* co-culture at a ratio of 5:1, 1:1, and 1:50 had no significant impact on cell proliferation over time. Of note, the co-culture at a higher concentration (1:200) *H. pylori* isolated from either GC or CG compromised the proliferation capability of GES-1 cells.

GC- and CG-derived *H. pylori* strains induced comparable apoptosis in GES-1 cells

Flow cytometry analysis showed that the apoptosis rate increased over time in cells co-cultured with *H. pylori* and non-infected cells (Figure 1B). In comparison with the control cells, GES-1 cells co-cultured with GC- or CG-derived *H. pylori* strains had a significantly increased apoptotic rate at 24 and 48 h at the ratios of 1:50, and at all time points at the ratio of 1:200. However, there was no significant difference in the increase of apoptotic rate between GES-1 cells co-cultured with GC-derived *H. pylori* strains and those co-cultured with CG-derived *H. pylori* strains.

The most virulent GC-derived *H. pylori* strain induced gastric mucosal carcinogenesis in the animal model

The most virulent strain, which was derived from a GC patient, and the least virulent strain, which was derived

Figure 2 Identification of status of *cagA* gene in *Helicobacter pylori* strains using real-time polymerase chain reaction. A: DNA ladder; B: *Helicobacter pylori* (*H. pylori*) stain NCTC 11639 (positive control); C: The most virulent gastric carcinoma-derived strain; D: The least virulent chronic gastritis-derived strain; E: *H. pylori* stain NCTC 12908 (negative control).

from a CG patient, were genotyped to be *cagA* positive and *cagA* negative, respectively (Figure 2). *H. pylori* rapid urease testing was found positive in 60.0% (6/10), 70.0% (7/10), and 0.0% (0/10) of the animals lavaged with the most virulent strain, least virulent strain, and control lixivium, respectively. No animals, except one in the group infected with most virulent strain that died at week 3, accidentally died during the experiment. *H. pylori* infection was present in all animals lavaged with *H. pylori*, but in none of the control animals, as shown by histological examination. The animals lavaged with the most virulent strain were more prone to precancerous diseases and gastric carcinoma than those lavaged with the least virulent strain and control lixivium. At week 52, CG, atrophy, metaplasia, dysplasia, and GC were observed in 90.0% (9/10), 80.0% (8/10), 80.0% (8/10), 90% (9/10), and 60.0% (6/10), respectively, of the animals lavaged with the most virulent strain (Table 2). Precancerous lesions including gastric atrophy, intestinal metaplasia, and dysplasia were observed from the 4th week, and gastric cancer occurred as early as at week 28 (Figure 3A, Table 2). However, only mild CG was observed in 90% (9/10) of the animals lavaged with the least virulent strain (Figure 3B, Table 2). In addition, gastric ulceration was observed in 50.0% (5/10) and 40.0% (4/10), respectively, in the two groups. The gastric mucosa was within normal limits in all control animals at any time points (Figure 3C, Table 2).

Microarray analysis identified significant differential gene expression profiles in GES-1 cells co-cultured with the most versus least virulent *H. pylori* strains

Microarray analysis identified 2834 and 314 differentially expressed genes in GES-1 cells co-cultured with most or least virulent *H. pylori* strain, respectively, compared with non-infected cells (Figure 4). Furthermore, 800 differentially expressed genes (49 up- and 751 down-regulated), involving those associated with cell cycle regulation, cell apoptosis, cytoskeleton, immune response, and sub-

stance and energy metabolisms, were identified in cells co-cultured with the most virulent strain compared with those co-cultured with the least virulent strain (Table 3). Six most differentially expressed genes (with a betweenness centrality of 0.1-0.2) were identified among the significant differential gene profile network, including JUN, KRAS, BRCA1, SMAD2, TRAF1, and HDAC6 (Table 4).

Up-regulated expressions of HDAC6 and TRAF1 in GES-1 cells co-cultured with the most vs least virulent *H. pylori* strains

qRT-PCR analyses verified significant up-regulations of HDAC6 and TRAF1 mRNA expression in GES-1 cells co-cultured with the most virulent strain or least virulent *H. pylori* strain, compared with the control cells (Figure 5A). Furthermore, HDAC6 and TRAF1 mRNA expressions were more significantly up-regulated in GES-1 cells co-cultured with the most virulent strain than in those co-cultured with the least virulent strain (Figure 5B).

Progressive over-expression of HDAC6 and TRAF1 in CG, precancerous disease, and GC specimens on immunohistochemistry

The histology and immunohistochemistry of gastric mucosal specimens from *H. pylori*-positive patients with CG (Figure 6A, E and I), IM (Figure 6B, F and J), dysplasia (Figure 6C, G and K), and GC (Figure 6D, H and L) showed that moderately positive and strongly positive HDAC6 expression were detected in 5 (21.7%) of 23 CG patients, 10 (30.0%) of 33 IM patients, 18 (54.5%) of 33 dysplasia patients, and 21 (77.8%) of 27 GC patients ($P < 0.001$). Furthermore, the positive rate of HDAC6 expression was significantly higher in dysplasia and GC, compared to that in CG ($P = 0.014$; $P < 0.001$) and in IM ($P = 0.049$; $P < 0.001$). However, there was no difference in the positive rate between CG and IM, and between dysplasia and GC. Similarly, the up-regulation of TRAF1 expressions was detected in 8/23 (34.8%), 16/33 (53.3%), 24/33 (72.7%), and 24/27 (88.9%) specimens of CG, IM, dysplasia, and GC, respectively ($P < 0.001$). The positive rate of TRAF1 expression was significantly greater in dysplasia and GC vs CG ($P = 0.005$; $P < 0.001$) and in GC vs IM ($P = 0.003$), whereas there was no difference between CG and IM and between dysplasia and GC.

DISCUSSION

Gastric carcinogenesis is a pathological process of cell cycle disorder and uncontrolled growth resulting from multiple aberrant gene alterations in response to extrinsic stimulus like *H. pylori* infection. The dysregulation of the balance between cell proliferation and apoptosis plays a pivotal role in this pathogenesis^[19]. The proliferation rate of epithelial cells that are co-cultured with *H. pylori* isolated from gastric mucosal biopsy specimens is shown to be two-fold higher than that of the normal control. *H. pylori* eradication can reverse the proliferative effect on gastric mucosal epithelia though^[20]. Moreover, both *H. pylori*

Table 2 Pathological outcomes of gastric mucosae from Mongolian gerbils lavaged with the most virulent gastric carcinoma-derived strain, the least virulent chronic gastritis-derived strain, and the control broth over 52 wk

	Pathological outcomes				
	Chronic gastritis	Gastric atrophy	Intestinal metaplasia	Gastric dysplasia	Gastric carcinoma
GC (<i>n</i> = 10)	9 (90.0%) ^b	8 (80.0%) ^{b,d}	8 (80.0%) ^{b,d}	9 (90.0%) ^{b,d}	6 (60.0%) ^{b,d}

Control (<i>n</i> = 10)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)

^b*P* < 0.01 *vs* control group; ^d*P* < 0.01 *vs* CG group. GC: Gastric carcinoma; CG: Chronic gastritis.

Figure 3 Representative histological microphotographs (hematoxylin and eosin staining, 200 ×, scale bar = 100 μm) of gastric mucosal specimens collected from Mongolian gerbils lavaged with the GC-derived *Helicobacter pylori* strain (A: gastric carcinoma), the CG-derived strain (B: chronic gastritis), and the control fixative (C) at the 28th week.

Figure 4 Cluster analysis of gene expression profiles in GES-1 cells in response to the most and least virulent *Helicobacter pylori* strains. The red, green, and black colors indicate up-regulated, down-regulated, and equivalent expression. 1-1: Uninfected GES-1 cells (control); 2-2: GES-1 cells co-cultured with the GC-derived strain; 3-2: GES-1 cells co-cultured with the CG-derived strain. GC: Gastric carcinoma; CG: Chronic gastritis.

intracellular extracts and secretions are found to directly stimulate epithelial growth. Our results indicate that the effects of *H. pylori* co-culture on GES-1 cell proliferation are *H. pylori* concentration dependent, preferably at a cell/*H. pylori* ratio of 1:50; however, the presence of high-concentration *H. pylori* suppresses GES-1 growth instead. The antiproliferative effect of high-concentration *H. pylori* has been reported in multiple cell lines. This inhibitive effect is associated with the production of massive cytotoxic factors, which cause DNA damage, induce cell apoptosis, increase the synthesis of induced nitric oxide synthase, and upregulate p53 expression^[21-23]. Of

note, GC-derived *H. pylori* strains produced a more potent proliferative effect on GES-1 cells than CG-derived *H. pylori* strains, which is consistent with the findings of Yu *et al*^[24]. Moreover, both GC- and CG- *H. pylori* strains had a mild and comparable effect on apoptosis of GES-1 cells in a concentration-dependent but not strain-specific manner as shown by flow cytometry. These findings suggest that *H. pylori* strain-specific virulence may not be associated with gastric epithelial apoptosis, at least *in vitro*.

H. pylori strains isolated from humans are capable of colonizing the gastric mucosa of Mongolian gerbils^[16,25]. Additionally, Hirayama *et al*^[26] reported that *H. pylori*-infected Mongolian gerbils exhibited a gastric mucosal pathology similar to human *H. pylori* infection. In the present study, infection with the most virulent GC-derived *H. pylori* strain in Mongolian gerbils resulted in a series of mucosal pathologies that manifest as chronic inflammation, atrophy, intestinal metaplasia, or dysplasia more frequently than did the infection with the CG-derived strain over 52 wk. Moreover, GC developed as early as 28 wk following the infection with the GC-derived strain. This observation may be of significant clinical implications. First, previous studies have reported that the time to develop GC is approximately 62 wk^[24] or even 72 wk after infection^[27]. We assume that less virulent or less carcinogenic strains may have been used in the previous studies, and we propose that more carcinogenic strains should be used in animal experiments related to *H. pylori*-induced carcinogenesis and prevention of *H. pylori*-induced GC. Second and more importantly, it is suggested that the *H. pylori* strains that exhibit a potent epithelial prolifera-

tive effect are highly virulent and carcinogenic, and that individuals infected with these strains are at high risk for the development of GC and should receive appropriate *H. pylori* eradication therapy.

Human whole-genome microarray analysis identifies a large number of significant differentially expressed genes in GES-1 cells co-cultured with *H. pylori* strains *vs* non-infected control cells, which clearly indicates that *H. pylori* activates and inactivates a series of gene transcription of GES-1 cells *in vitro*. Our transcriptional profiling results were generally consistent with the previous reports. Liu *et al*^[14] reported that *H. pylori* infection induced the up-regulated expression of multiple chemokines and chemokine receptors, such as IL-8 and CCL5, as well as of apoptosis-related genes, such as GADD45A. Eftang *et al*^[28] reported that *interleukin-8* was the single most up-regulated gene in whole genome profiling of *H. pylori* exposed gastric epithelial cells. MAPK and NF- κ B cellular pathways were also powerfully activated; the marked up-regulation of TP53BP2 corresponding to ASPP2 protein may interact

Table 4 Most differentially expressed genes in GES-1 cells co-cultured with the most virulent gastric carcinoma-derived strain *vs* the least virulent chronic gastritis-derived strain

HDAC6	0.092239	Histone deacetylase 6	Cell proliferation and tumor angiogenesis

with *H. pylori* CagA, and cause marked p53 suppression of apoptosis. Sohn *et al*^[29] suggested that the intracellularly translocated CagA may be involved in epithelial mesenchymal transition. However, the present study, for the first time, reports that the expression of HDAC6 and TRAF1 is up-regulated in gastric mucosal cells upon co-culture with GC-derived, *cagA*-positive *H. pylori* strain, and the expressions of these two proteins are progressively up-regulated in CG, intestinal metaplasia, dysplasia, and GC. Furthermore, such response seems to be strain-specific for many genes as the number of differentially expressed genes in cells co-cultivated with the GC-derived strain is 9-fold that in those co-cultured with the CG-derived strain. These significant differentially expressed genes involve genes that are known to be associated with tumorigenesis, among which HDAC6 and TRAF1 are the most prominent ones. The upregulation of HDAC6 and TRAF1 expressions in response to the GC-derived *H. pylori*-strain and in relation to *H. pylori* infection in patients with GC was verified by qRT-PCR in GES-1 cells *in vitro* and by immunohistochemistry in gastric specimens taken from patients with different gastric pathologies. To our best knowledge, this is the first study to identify the overexpression of HDAC6 and TRAF1 in *H. pylori*-associated GC, and to suggest a potential role of these genes in *H. pylori*-induced gastric carcinogenesis.

Histone is an important component of eukaryotic chromatin. Acetylation and deacetylation of histone are essential for the regulation and modification of gene expression^[30]. A newly-discovered mechanism of carcinogenesis is that HDAC family proteins aberrantly binding to a specific promoter region may cause cryptic transcription and inhibit normal gene transcription, initiating the malignant transformation^[31]. HDAC6 functions to modulate gene expression by removing the acetyl group from histones, which contributes to oncogenic cell trans-

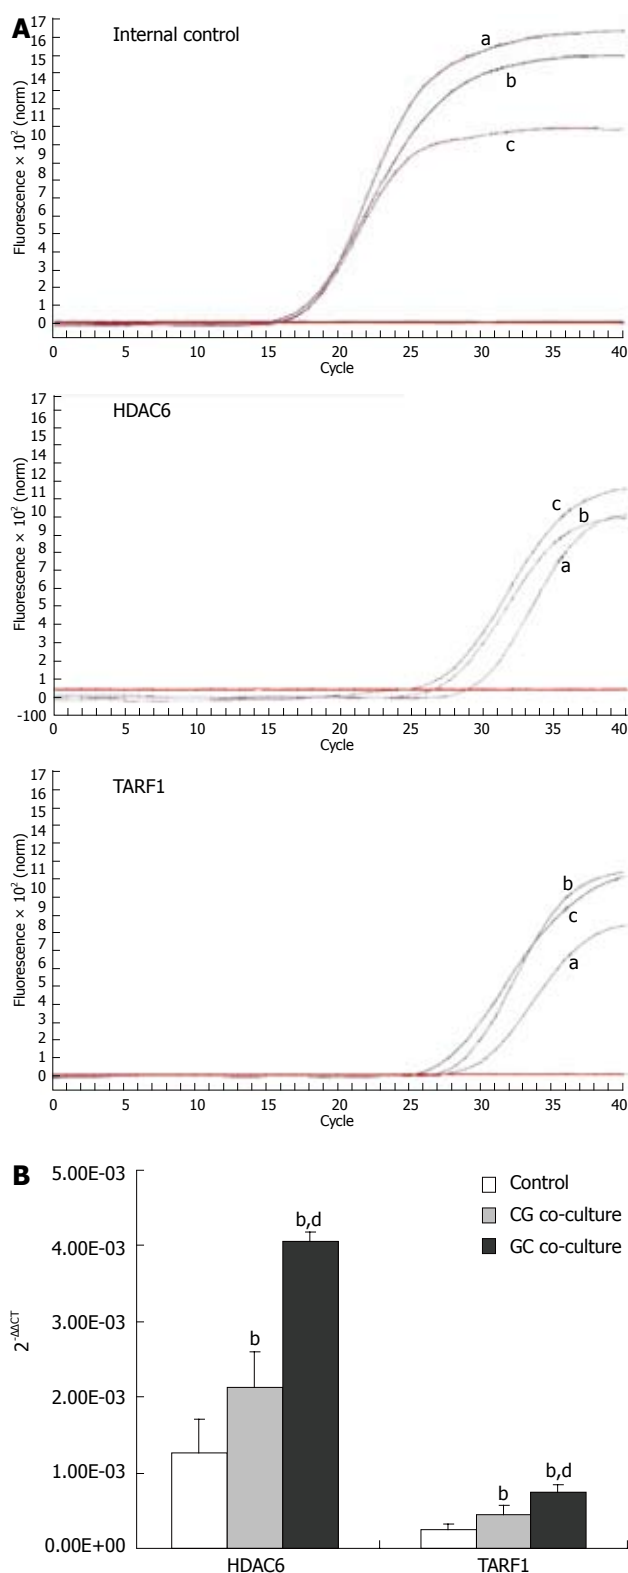

Figure 5 Verification of HDAC6 and TRAF1 up-regulation in GES-1 cells in response to the most and least virulent *Helicobacter pylori* strains as determined by quantitative real-time polymerase chain reaction analysis. A: Representative quantitation of mRNA expression of GAPDH, HDAC6 and TRAF1 in GES-1 cells (a), GES-1 cells co-cultured with the CG-derived *Helicobacter pylori* (*H. pylori*) strain (b) and GES-1 cells co-cultured with the GC-derived *H. pylori* strain (c); B: Graphic analysis showing mRNA expression of HDAC6 and TRAF1 expressions in GES-1 cells in GES-1 cells, GES-1 cells co-cultured with the CG-derived *H. pylori* strain and GES-1 cells co-cultured with the GC-derived *H. pylori* strain. ^b*P* < 0.01 vs the control; ^d*P* < 0.01 vs cells co-cultured with the CG-derived *H. pylori* strain.

formation^[32]. Aoyagi *et al*^[33] reported that HDAC6 could directly regulate HSP90 expression via deacetylation. The targeted inhibition of HDAC6 reduces the deacetylation of HSP90 but increases the acetylation simultaneously, destroying HSP90 chaperones and resulting in molecular function failure. HDAC6 synergizes with HDAC10 to regulate vascular endothelial growth factor receptors through heat shock protein mediation as well^[34]. HDAC6 has been found to be implicated in multiple malignancies, such as esophageal cancer, lung cancer, breast cancer, and oral squamous cell carcinoma^[35,36]. Zhang *et al*^[35] reported that high-HDAC6-expressing premenopausal breast cancer patients exhibited a favorable tumor-free survival and a sensitive response to endocrine therapy. HDAC is also thought to be associated with breast cancer metastasis as it de-acylates microtubules, whereas the combined use of estrogen antagonist and paclitaxel significantly suppresses the de-acylation of microtubules^[37,38]. In the present study, the expression of HDAC6 mRNA was highly up-regulated in GES-1 cells co-cultured with the GC-derived *H. pylori* strain compared with those co-cultured with the CG-derived strain and uninfected control cells. It is likely that *H. pylori* infection activates HDAC6 to dysregulate the synthesis of histones in gastric epithelial cells^[39]. However, further investigation is required to elucidate the exact mechanisms of *H. pylori* infection and the functional roles of *H. pylori*-activated HDAC6 overexpression in gastric carcinoma.

TRAF is a new member of the tumor necrosis factor (TNF) family^[40]. Seven TRAF isoforms have been reported to interact directly with cell-surface receptors and regulate cell survival/death balance^[41]. TRAF1 activates NF- κ B to gradually initiate immortalization and tumorigenesis in GC^[42]. Sughra *et al*^[43] reported that TRAF1 functions primarily to up-regulate the transcription of IKK β , an inhibitor of NF- κ B and to enhance the activity of IKK β as well. Therefore, TRAF1 activates and interacts with NF- κ B simultaneously. The overexpression of TRAF1 has been identified in nasopharyngeal carcinoma and lymphoma^[44,45]. The variation in TRAF1 expression is associated with the occurrence, metastasis, and induction of chemotherapy resistance of malignant tumors^[46]. Similar to HDAC6, TRAF1 is verified by qRT-PCR to be up-regulated in GES-1 cells co-cultured with *H. pylori* strains, especially the GC-derived strain in the present study. Again, how *H. pylori* infection up-regulates TRAF1 expression and what downstream genes are activated and/or deactivated by *H. pylori*-induced TRAF1 overexpression require further investigation.

The roles of HDAC6 and TRAF1 in *H. pylori*-associated GC remain to be elucidated although their expression is significantly up-regulated in epithelial cells stimulated with GC-derived *cagA* positive *H. pylori* strain. Our GC animal model experiment showed that the proliferative effect *in vitro* of GC-derived *cagA* positive *H. pylori* strain can contribute to the carcinogenesis of gastric mucosa *in vivo*. However, the up-regulated expression of HDAC6 and TRAF1 may not be causative of proliferative or carcinogenic effect of the GC-derived *H. pylori* strain as no

Figure 6 Histology and immunohistochemistry (400 ×, scale bar = 50 μm) of HDAC6 and TRAF1 in gastric specimens of patients with chronic gastritis (CG, *n* = 23), intestinal metaplasia (IM, *n* = 30), dysplasia (*n* = 33), and gastric carcinoma (GC, *n* = 27).

“loss-of-function” or “gain-of-function” experiment has been performed to elaborate the pathogenetic effect of HDAC6 and TRAF1 in GC. Moreover, we were unable to follow up GC patients in subsequent treatment period as they were referred to various general surgeons among multiple institutions at the patients’ own will. Therefore, the clinicopathological values of HDAC6 and TRAF1 are yet to be investigated, which are expected to be clinically useful for the prediction of prognosis and treatment resistance.

In conclusion, GC-derived *H. pylori* strains induce a more potent proliferative but comparable apoptotic effect in GES-1 cells as compared to CG-derived strains. HDAC6 and TRAF1 are identified to be up-regulated in GES-1 cells co-cultured with the GC-derived strain, which are further verified *in vivo*. These findings indicate that these two genes may be involved in *H. pylori* induced gastric carcinogenesis, although their exact roles require further investigation.

COMMENTS

Background

Helicobacter pylori (*H. pylori*) is a pathogenic bacterium colonizing gastric mucosae. It has been accepted to be the primary cause of upper gastrointestinal

disorders, such as acute and chronic gastritis, peptic ulcer disease, and gastric cancer. However, the subsequent outcomes of persistent *H. pylori* infection are highly variable. Such variation in clinicopathological outcomes of *H. pylori* infection is believed to result from the variations in the virulence of different strains, genetic background of the host, and more importantly, the host-to-pathogen interactions. How gastric epithelial cells respond to *H. pylori* clinical isolates derived from patients with different pathologies, such as chronic gastritis (CG) and gastric cancer (GC) specimens, at the genome-wide level remains unknown. Therefore, this study was carried out to identify genes potentially involved in *H. pylori*-induced gastric carcinogenesis, by comparing the genomic profiles between gastric epithelial cells co-cultured with *H. pylori* strains isolated from patients with GC and those co-cultured with strains from patients with CG.

Research frontiers

It is likely that *H. pylori* strains themselves are highly variable in virulence to gastric mucosal epithelia, especially in terms of the carcinogenic effect. Genomic profiling analyses have identified a wide range of genetic variations among *H. pylori* strains isolated from patients with different gastric pathologies. Global gene expression profiles also vary greatly in human gastric epithelial immortalized cells infected with spiral *versus* coccoid *H. pylori*. These findings suggest that gastric epithelial cells tune in the expression of their genes, especially those associated with tumorigenesis, in response to specific *H. pylori* strains or a specific virulent factor of the strain. In addition to the core genes, strain-specific genes are thought to play an essential role in *H. pylori* propagation and pathogenesis.

Innovations and breakthroughs

This observation may be of significant clinical implications. First, previous studies have reported that the time to develop GC is approximately 62 wk or even 72 wk after infection. The authors assume that less virulent or less carcinogenic strains may have been used in the previous studies, and the authors propose that more carcinogenic strains should be used in animal experiments related to *H. pylori*-induced carcinogenesis and prevention of *H. pylori*-induced GC. Second and more importantly, it is suggested that the *H. pylori* strains that exhibit a potent epithelial proliferative effect are highly virulent and carcinogenic, and that individuals infected with these strains are at high risk for the development of GC and should receive appropriate *H. pylori* eradication therapy.

Applications

The roles of HDAC6 and TRAF1 in *H. pylori*-associated GC remain to be elucidated although their expression is significantly up-regulated in epithelial cells stimulated with GC-derived *cagA* positive *H. pylori* strain. These findings indicate that these two genes may be involved in *H. pylori* induced gastric carcinogenesis, although their exact roles require further investigation.

Peer review

The authors performed DNA microarray analysis comparing gene expression profiles between GES-1 cell lines co-cultured with highly virulent (*cagA*+) and low virulent (*cagA*-) *H. pylori* strains isolated from human gastric mucosa tissue with CG and GC tissue, respectively. These two strains showed different effect on the GES-1 cell line in cell proliferation activity but similar effect on the cell lines in apoptotic property. They identified 800 differentially expressed genes, and from six most differentially expressed genes, they selected TRAF1 and HDAC6. The authors examined HDAC1 and TRAF1 expression at the mRNA level in GES-1 cells co-cultured with the *H. pylori* strains above, and confirmed that these expressions were up-regulated in these cell lines. They also examined the expressions of these molecules immunohistochemically in surgically resected or biopsied specimens. These works are laborious and are considered to be scientifically of significant value.

Abstract

AIM: To determine whether and how magnetic resonance imaging (MRI)-based total liver volume (TLV) and diffusion weighted imaging (DWI) could predict liver fibrosis.

METHODS: Sixteen experimental mature mini-pigs (6 males, 10 females), weighing between 20.0 and 24.0 kg were prospectively used to model liver fibrosis induced by intraperitoneal injection of 40% CCl₄ dissolved in fat emulsion twice a week for 16 wk, and by feeding 40% CCl₄ mixed with maize flour twice daily for the subsequent 5 wk. All the survival animals underwent percutaneous liver biopsy and DWI using $b = 300, 500$ and 800 s/mm^2 followed by abdominal gadolinium-enhanced MRI at the 0, 5th, 9th, 16th and 21st weekend after beginning of the modeling. TLV was obtained on enhanced MRI, and apparent diffusion coefficient (ADC) was obtained on DWI. Hepatic tissue specimens were stained with hematoxylin and Masson's trichrome staining for staging liver fibrosis. Pathological specimens were scored using the human METAVIR classification system. Statistical analyses were performed to determine whether and how the TLV and ADC could be used to predict the stage of liver fibrosis.

RESULTS: TLV increased from stage 0 to 2 and decreased from stage 3 ($r = 0.211$; $P < 0.001$). There was a difference in TLV between stage 0-1 and 2-4 ($P = 0.03$) whereas no difference between stage 0-2 and 3-4 ($P = 0.71$). TLV could predict stage ≥ 2 [area under receiver operating characteristic curve (AUC) = 0.682]. There was a decrease in ADC values with increasing stage of fibrosis for $b = 300, 500$ and 800 s/mm^2 ($r = -0.418, -0.535$ and -0.622 , respectively; all $P < 0.001$). Differences were found between stage 0-1 and 2-4 in ADC values for $b = 300, 500$ and 800 s/mm^2 , and between stage 0-2 and 3-4 for $b = 500$ or 800 s/mm^2 (all $P < 0.05$). For predicting stage ≥ 2 and ≥ 3 , AUC was 0.803 and 0.847 for $b = 500 \text{ s/mm}^2$, and 0.848 and 0.887 for $b = 800 \text{ s/mm}^2$, respectively.

CONCLUSION: ADC for $b = 500$ or 800 s/mm^2 could be better than TLV and ADC for $b = 300 \text{ s/mm}^2$ to pre-

dict fibrosis stage ≥ 2 or ≥ 3 .

INTRODUCTION

Liver fibrosis can be prevented or reversed at early stage by antifibrotic treatment or by eliminating the cause^[1,2]. If liver fibrosis could not be prevented at early stage, it would lead to end-stage liver diseases^[3]. Therefore, accurately staging liver fibrosis is important in choosing appropriate therapy to improve the prognosis of this disease. Percutaneous liver biopsy is currently considered a gold standard for assessing stage of fibrosis, but this invasive method is limited by inter- and intra-observer variability and sampling error^[4,5]. To overcome the limitations of liver biopsy, noninvasive, reproducible and reliable methods are greatly needed. Transient elastography or FibroTest (Bio-Predictive) have been proposed for the diagnosis of liver fibrosis, but their use in clinical practice is being investigated^[6].

Diffusion-weighted imaging (DWI), a type of functional magnetic resonance (MR) technique, has been developed to characterize diseased tissues. This technique allows measurement of the combined effects of micro-circulation of blood (perfusion) and molecular brownian motion of water within liver parenchyma, expressed as a whole by apparent diffusion coefficient (ADC)^[7]. Previous studies have shown that ADC values of the liver are lower in patients with cirrhosis compared with control subjects, which is thought to reflect a restriction of the motion of water molecules in fibrotic tissues^[8,9]. Nevertheless, ADC values obtained in the previous experiences for studying liver fibrosis widely varied because of the employed settings of so-called *b*-values^[8,10]. In addition, a previous study also reported that total liver volume (TLV) would change with the progress of liver fibrosis^[11]. To our knowledge, there have been no data focusing on the correlation of liver ADC value obtained by different *b* values with the stage of liver fibrosis, and the correlation between magnetic resonance imaging (MRI)-based TLV and stage of liver fibrosis^[11-14]. Thus, the purpose of this study was to prospectively investigate these correlations

and determine whether and how TLV and DWI could predict the stage of liver fibrosis.

MATERIALS AND METHODS

Animal model

Animals were used in full compliance with the National Council of Animal Care guidelines. The protocol was approved by the Committee of the Ethics of Animal Experiments of our institute.

Sixteen experimental mature mini-pigs (6 males, 10 females), weighing between 20.0 and 24.0 kg, were used in our study. Previous studies have established a standardized experimental model of liver cirrhosis in swine using CCl₄ and ethanol^[15]. According to the above-mentioned modeling method, liver fibrosis was induced by intraperitoneal injection of 40% CCl₄ dissolved in fat emulsion (0.25 mL/kg body weight) twice a week for 16 wk, and by feeding 40% CCl₄ mixed with maize flour (0.75 mL/kg body weight) twice daily for the subsequent 5 wk because of the peritoneal adhesions resulting from the intraperitoneal injection. To minimize the chemical peritonitis involving liver, we chose the left hypogastrium as the intraperitoneal injection position and the injections were stopped two days before each MR examination. In addition, because the administration of alcohol in conjunction with CCl₄ results in more stable and accelerated liver fibrogenesis in a large animal model, we used 5% alcohol-water mixture as the sole drinking water, and maize flour was taken as the staple food in the 21 wk^[16].

MRI technique

On the 0, 5th, 9th, 16th and 21st weekend after the beginning of modeling fibrosis, all mini-pigs were given general anesthesia with an injection of ketamine (15 mL/kg weight) and diazepam (0.8 mg/kg per hour) through the ear vein before the MR examination. The anterior surface of the thorax and abdomen of the animals were shaved to obtain good contact between the skin and the cardiac electrodes or respiratory triggering. We also used a belt around the abdomen to reduce the effect of respiratory motion.

The mini-pigs were examined on a 1.5 T whole body MR scanner (Signa Excite; GE Medical Systems, Milwaukee, WI). When the cardiac and respiratory signals were satisfied, each animal was positioned supinely in an 8-channel phased array body coil. After the pilot scan with axial, coronal, and sagittal images for localization, the MR protocols including SPGR T1-weighted imaging (T1WI), fast recovery fast spin echo (FRFSE) T2-weighted imaging (T2WI), and single-shot echo-planar imaging (EPI) DWI were performed. The parameters for DWI were as follows: TR = 4000 ms, TE = 49.2 ms, field of view (FOV) = 34 × 34 cm, slice thickness = 5.0 mm, slice space = 2.0 mm, matrix of 192 × 256 mm, number of excitation = 2, *b* values of 0-300, 0-500 and 0-800 s/mm², and tridirectional diffusion gradients. After DWI acquisition, 20 mL gadodiamide (Magnevist,

Figure 1 Magnetic resonance images. A-C: In a mini-pig with liver fibrosis stage 2, diffusion weighted images of the liver are obtained with b values of 300, 500 and 800 s/mm^2 , respectively; D-F: Corresponding apparent diffusion coefficient maps. Three regions of interest are carefully drawn on the right lobes of the liver for each b values; G: A manual tracing of the liver is shown on an axial contrast-enhanced magnetic resonance imaging, and the outline shows the liver areas (S).

Bayer Healthcare, Germany) was intravenously injected (0.2 mmol/L per kg body weight) with a pressure injector (Spectris MR Injection System; Medrad, Inc, Warrendale, PA) at a dose of 3 mL/s followed by a 20-mL saline solution flush for contrast-enhanced three-dimensional liver acquisition with volume acceleration (3D LAVA). The parameters for 3D LAVA were: TR = 3.9 ms, TE = 1.8 ms, FOV = 34×34 cm, slice thickness = 5.0 mm, and matrix 256×224 mm.

MR image analysis

The original MRI data were directly interfaced and forwarded to the workstation (GE, AW4.1, Sun Microsystems, Palo Alto, CA, United States) to obtain ADC maps at each b values. An experienced radiologist (the first author with 3 years of experience in thoracoabdominal radiology) who was blinded to the pathologic results

placed three circular regions of interest (ROIs) each with approximately 1-2 cm in diameter in the consecutive three maximal slices of the right lobe of the liver (3 ROIs per slice, 9 ROIs per mini-pig) for each b value (Figure 1A-C), avoiding areas of artifact, diaphragm and intrahepatic vasculature. The ADC value of each ROI as well as the ADC map (Figure 1D-F) was automatically generated. The ADC values of the three ROIs in each slice were then averaged to give an estimate of ADC value for this slice. Representative ADC values of the three slices were then averaged to obtain a final estimate of the liver ADC value to be used for data analysis.

In addition, TLV measurements were performed employing planimetry in all animals by the above-mentioned radiologist. Initially, liver profile was manually traced on each transverse image using a trackball. The software automatically calculated the number of pixels enclosed by

Figure 2 Photomicrograph (original magnification, $\times 400$; Masson's trichrome stains) of histologic sections from liver biopsy specimens in a mini-pig with stage 2 liver fibrosis shows liver periportal fibrosis.

the traced liver contours on each image, and provided the cross-sectional area of the liver on a slice-by-slice basis. The sum of the above areas multiplied by the section thickness provided the TLV (Figure 1G)^[17].

Reproducibility studies

To test the interobserver variability of TLV and ADC values measurement, we randomly chose the MR data of all animals on the 9th weekend for the repeated MR measurements, which were performed two weeks after the first measurement by an experienced radiological professor (the corresponding author with 14 years of experience in abdominal radiology). The precision of the two measurements on the 9th weekend was determined as the coefficient of variance (CV) on the basis of the formula: $CV (\%) = (s/X) \times 100$, where s is the SD, and X is the mean of TLV or ADC values. The resultant precision was expressed as an average %CV. When %CV was less than 10%, interobserver variability of TLV and ADC values measurements were regarded as small, and the results were reliable.

Histopathology

After the MR examination in each mini-pig, an 18-gauge ultrasound-guided core percutaneous biopsy was performed in the right liver lobe because the biopsy in the right lobe of the liver was used as the standard for staging liver fibrosis^[18]. When the mini-pigs died during the follow-up period before the 21st weekend, the dead mini-pigs underwent immediate laparotomy, and the entire liver was resected. When the mini-pigs were living on the 21st weekend, 1/3 animals were randomly sacrificed by air injection into the auricular vein shortly after the last percutaneous biopsy and underwent the laparotomy, and the entire liver was also resected. Subsequently, three thin slices were randomly cut from any lobe of the liver and diced into the usual tissue block of about 2 mm thickness for further staging liver fibrosis to confirm the stage of the fibrosis determined by percutaneous biopsy immediately prior to death. Furthermore, the final fibrosis stage of resected liver was determined by the average

of the stages across the three thin slices.

Hepatic tissue specimens obtained by biopsy and laparotomy were stained with hematoxylin and eosin (H and E) and Masson's trichrome staining for pathologic examination. Because the morphology and histology of experimental mini-pig liver are similar to that of human liver^[15], two experienced hepatopathologists (the 11th and 12th authors with 10 and 36 years of experience in hepatopathology, respectively) scored pathological specimens using the human METAVIR classification system^[19]. Any discrepancies between the two observers were settled by consensus. This scoring system has a five-point scale: stage 0, no fibrosis; stage 1, portal fibrosis; stage 2, periportal fibrosis (Figure 2); stage 3, septal fibrosis; and stage 4, cirrhosis. Additionally, we considered the weekend on which liver fibrosis was initially confirmed by pathologic examination as that the fibrosis occurred during the follow-up.

Statistical analysis

All statistical analyses were carried out with SPSS (version 17.0, SPSS, Chicago IL, United States). A $P < 0.05$ was considered to represent a significant difference. The interobserver agreement for the two pathologists with regard to the fibrosis stage, or for the percutaneous biopsy and the laparotomy was expressed by means of κ statistics. When κ values were 0-0.40, 0.41-0.60, 0.61-0.80, and 0.81-1.00, the concordance was considered as poor, moderate, good, and excellent agreement, respectively. The TLV and ADC values were of skewness. Spearman's rank correlation analyses were used to assess the correlation between TLV and fibrosis stage, or between the ADC values and fibrosis stage. TLV or ADC values were compared between patients stratified by fibrosis stages using Mann-Whitney tests together with Bonferroni correction for multiple comparisons. The cutoff value of TLV or ADC values were then determined with receiver-operating characteristic (ROC) analysis for predicting moderate liver fibrosis (stage ≥ 2) and advanced liver fibrosis (stage ≥ 3).

RESULTS

Animal model and histopathologic findings

During the follow-up period, one, two and four animals died between week 5 and 9, between week 9 and 16, and between week 16 and 21, respectively. On the 0, 5th, 9th, 16th and 21st weekend, mean body weight of the survived animals was 22 ± 1.31 kg, 24.1 ± 2.41 kg, 24 ± 2.45 kg, 25.3 ± 2.81 kg, and 23.5 ± 1.78 kg, respectively. There was no significant difference in body weight between any two weekends during the follow-up period (all $P > 0.05$), mini-pigs treated with CCl₄ did not put on weight during the whole progress of experiment. In addition, there was good agreement between fibrosis stages determined by the percutaneous biopsy and by the laparotomy (κ , 0.80; 95%CI, 0.75-0.84). Therefore, according to the human METAVIR classification system, survived mini-pigs with liver fibrosis at different stages confirmed on the follow-

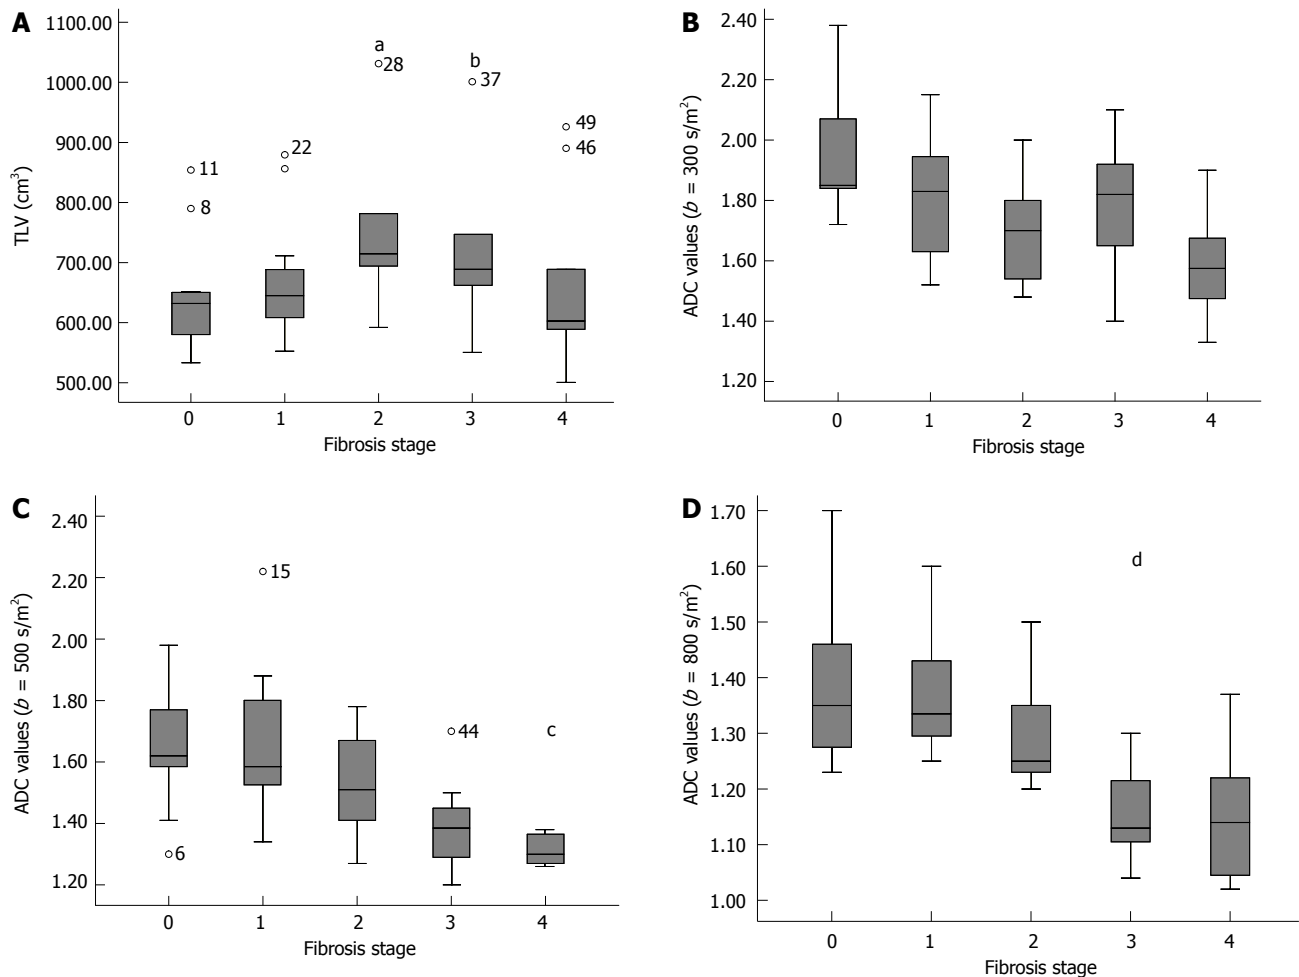

Figure 3 Box plots. A-D: Total liver volume (TLV), and apparent diffusion coefficient (ADC) values of the liver for $b = 300 \text{ s/mm}^2$, 500 s/mm^2 and 800 s/mm^2 corresponding to fibrosis stages, respectively. In A, symbols a and b indicate extreme outliers of TLV in stage 2 and 3, respectively; and symbol c in C and symbol d in D indicate extreme outliers of ADC for $b = 500 \text{ s/mm}^2$ in stage 4 and for $b = 800 \text{ s/mm}^2$ in stage 3, respectively. Horizontal bars represent medians of TLV or ADC.

Table 1 Mini-pigs with liver fibrosis at different stages confirmed on the follow-up weekends (*n*)

Weekend	S0	S1	S2	S3	S4
0 (16)	16	0	0	0	0
5 (16)	3 ¹	8	5	0	0
9 (15)	0	3	7	5	0
16 (13)	0	1 ¹	1	7	4
21 (9)	0	1 ¹	1 ¹	1	6

¹The liver fibrosis at this stage in the mini-pigs is similar to this disease at the immediately preceding stage during the follow-up. S0, S1, S2, S3 and S4 represent stage 0, stage 1, stage 2, stage 3 and stage 4, respectively.

up weekends are illustrated in Table 1.

Interobserver variability of TLV and ADC measurements

In all animals on the 9th weekend, CV was 8.2% (range, 2.7%-15.6%) for TLV. CV was 9.2% (range, 5.2%-17.3%), 8.4% (range, 5.3%-15.5%) and 7.6% (range, 4.5%-13.2%) for ADC values with $b = 300$, 500 and 800 s/mm^2 , respectively. Therefore, interobserver variability of TLV and ADC values were small, and the first measurement

was used as the final results.

TLV corresponding to stages of liver fibrosis

TLV corresponding to stage of liver fibrosis is shown in Table 2. TLV tended to increase from stage 0 to 2, but decrease from stage 3 (Figure 3A) ($r = 0.211$, $P < 0.001$). Furthermore, significant difference could be found between stage 0 and 2 ($P < 0.001$) while TLV could not differentiate other individual stages of fibrosis (all $P > 0.05$). Additionally, there was significant difference between stage 0-1 and 2-4 ($P = 0.03$), whereas there was no difference between stage 0-2 and 3-4 ($P = 0.71$).

ADC values corresponding to stage of liver fibrosis

ADC values corresponding to stage of liver fibrosis are illustrated in Table 2. There was a decrease in liver ADC values with the increasing degree of fibrosis for $b = 300$, 500 and 800 s/mm^2 (Figure 3B-D, respectively) ($r = -0.418$, -0.535 and -0.622 , respectively; $P < 0.001$). ADC values could differentiate fibrosis stage between stage 0 and 2 for $b = 300 \text{ s/mm}^2$; between stage 0 and 4 for $b = 300$, 500 and 800 s/mm^2 ; between stage 1 and 4, stage

ADC (b = 800 s/mm ²)				
1.29 $\times 10^{-3}$ mm ² /s	Prediction of stage ≥ 2	0.848	78.3	80.0
1.23 $\times 10^{-3}$ mm ² /s	Prediction of stage ≥ 3	0.887	84.8	81.2

TLV: Total liver volume; AUC: Area under the receiver operating curve; ADC: Apparent diffusion coefficient.

0 and 3, or stage 1 and 3 for $b = 500$ or 800 s/mm²; and between stage 2 and 4 for $b = 800$ s/mm² (all $P < 0.05$). There were no differences between stage 0 and 1, between stage 2 and 3, and between stage 3 and 4 for $b = 300, 500$ and 800 s/mm² (all $P > 0.05$). Additionally, there were significant differences between stage 0-1 and 2-4 for $b = 300, 500$ and 800 s/mm², and between stage 0-2 and 3-4 for $b = 500$ or 800 s/mm² (all $P < 0.05$).

ROC analyses of TLV and liver ADC for predicting stage ≥ 2 and ≥ 3

According to the generally accepted guidelines in Turkey and elsewhere^[20], the patients who had liver fibrosis stage ≥ 2 should receive treatment whereas those with liver fibrosis stage ≤ 1 should not. Therefore, we did not perform ROC analyses of TLV and liver ADC values for predicting fibrosis stage ≥ 1 . There was relatively more overlap for the TLV predicting fibrosis stage ≥ 2 and stage ≥ 3 . ROC analyses showed that TLV could predict fibrosis stage ≥ 2 with a cut-off value of 656.25 cm³, representing a small AUC. However, liver ADC values had a better sensitivity and a specificity for predicting fibrosis stage ≥ 2 and ≥ 3 (Table 3). We also found that

there was a higher diagnostic performance for $b = 500$ or 800 s/mm² compared with $b = 300$ s/mm² for prediction of fibrosis stage ≥ 2 and ≥ 3 .

DISCUSSION

Activation of hepatic stellate cells (the main collagen-producing cells) by fibrogenic cytokines is a central event in fibrosis^[21]. Other cells including portal fibroblasts and bone marrow - derived cells may also be involved in the fibrogenic process^[22-26]. In the past, liver fibrosis was considered to be irreversible, however, hepatic fibrosis is now regarded as a dynamic process with potential for regression^[27]. The accumulation of proteins in the extracellular matrix promotes the formation of scars that bridge together adjacent portal triads and central veins. Ultimately, hepatic fibrosis leads to cirrhosis, associated with nodule formation and organ contraction^[27].

To prevent progression of this disease resulting in cirrhosis, accurately staging fibrosis is of clinical importance. Some studies indicated that DWI could be a useful technique for staging liver fibrosis^[12,28], and that TLV would change with the progress of liver fibrosis^[11,14]. We initially performed a follow-up study focusing on the correlation between stage of liver fibrosis and TLV or liver ADC values by comparing the performance of different b values, and determining how TLV and DWI could predict the stage of liver fibrosis. This study was performed with a large animal model (experimental mini-pigs) because the morphology and histology of its liver were similar to that of human liver, and the liver fibrosis was induced mainly by a matured method of inferior intraperitoneal injection of 40% CCl₄ according to a previous study^[15].

In this study, we found that TLV tended to increase from stage 0 to 2, but decrease from stage 3 of liver fibrosis. Our results were almost consistent with a published study^[29]. According to Liu *et al.*^[29], liver volume (LV) in patients with liver fibrosis tended to increase with the severity of fibrosis from stage 0 to 3, but decrease in stage 4, indicating that TLV tended to increase gradu-

ally with the severity of fibrosis. The presumed pathologic mechanism for LV increase in early stage would be the ballooning of hepatocytes along with increased fibrotic component^[14]. In advanced fibrosis, LV gradually decreased because of the segmental or global liver atrophy^[30]. However, our findings were inconsistent with other published reports^[11,14]. According to Tarao *et al.*^[14], LV in patients with alcoholic liver fibrosis increased gradually with the severity of fibrosis but did not decrease in the stage of alcoholic cirrhosis. The inconsistency of our findings with this published article could be explained by the reason that liver fibrosis was induced by alcoholics. As demonstrated by Li *et al.*^[11], TLV tended to decrease gradually with the increasing degree of virus-induced liver fibrosis staged with the pathologic scoring system (Ishak scale). It is the difference in pathologic scoring system that could be used to explain the inconsistency of our findings with this published article.

In addition to TLV, liver ADC value would be another indicator to quantitatively evaluate liver fibrosis. We found negative correlations between ADC and stage of fibrosis for $b = 300, 500$ and 800 s/mm^2 , which were consistent with these previous studies^[12,31]. According to these articles^[12,31], there was a decrease in liver ADC with increasing degree of fibrosis, and moderate negative correlations could be found between ADC values and fibrosis stages. However, Boulanger *et al.*^[32] found that there was no correlation between the histological grade of fibrosis and ADC using small b values of $50\text{--}250 \text{ s/mm}^2$, and we could presume that the difference in ADC value between normal and fibrotic liver could not be found by using the small b values because the ADC value obtained by the small b values could be prone to be influenced by liver perfusion^[33].

For prediction of fibrosis stage ≥ 2 , ROC analyses in our study showed that TLV could be a predictor with an AUC of 0.682 and the sensitivity and specificity of more than 70% by using a cut-off value of 656.25 cm^3 . TLV could not be a predictor of stage ≥ 3 because there was no difference between stage 0-2 and 3-4.

In comparison with TLV, we found that ADC values obtained with $b = 500 \text{ s/mm}^2$ and 800 s/mm^2 could be better predictors to predict liver fibrosis stage ≥ 2 because of higher AUC of 0.803 and 0.848 using cut-off ADC of $1.51 \times 10^{-3} \text{ mm}^2/\text{s}$ and $1.29 \times 10^{-3} \text{ mm}^2/\text{s}$, respectively. Moreover, ADC values obtained with $b = 500 \text{ s/mm}^2$ and 800 s/mm^2 could also predict liver fibrosis stage ≥ 3 with AUC of 0.847 and 0.887 using cut-off ADC of $1.44 \times 10^{-3} \text{ mm}^2/\text{s}$ and $1.23 \times 10^{-3} \text{ mm}^2/\text{s}$, respectively. Comparing with $b = 500 \text{ s/mm}^2$ and 800 s/mm^2 , we found a relatively lower AUC of 0.743 for a liver ADC value of $1.82 \times 10^{-3} \text{ mm}^2/\text{s}$ obtained using $b = 300 \text{ s/mm}^2$ for prediction of fibrosis stage ≥ 2 . Because there was no difference in ADC value for $b = 300 \text{ s/mm}^2$ between liver fibrosis stage 0-2 and 3-4, ADC value obtained in the current setting could not be used to predict liver fibrosis stage ≥ 3 . Generally, we found that ADC

values with $b = 500$ or 800 s/mm^2 could be better than $b = 300 \text{ s/mm}^2$ for predicting stage of liver fibrosis, which were consistent with the study by Taouli *et al.*^[12]. They suggested that ADC measured on DWI could be used to best quantify liver fibrosis when the b value is 500 s/mm^2 or greater in the comparisons among b values of 0, 50, 300, 500, 700 and 1000 s/mm^2 . This may be because ADC maps acquired with longer b values are less contaminated by perfusion effects. That is, they are more truly diffusion weighted^[33]. Taken together, we concluded that liver ADC measured on DWI with $b = 500$ or 800 s/mm^2 could be recommended for predicting stage of liver fibrosis.

Compared with previous studies, the advantages of our study might be more persuasive to confirm that DWI obtained with several b values could be used to predict stage of liver fibrosis because the normal animals used in this study had been confirmed to have no fibrosis, hepatic steatosis and inflammation by biopsy. A previous clinical study suggested that healthy patients without any symptoms of liver disease could be defined as nonfibrotic, free of steatosis and inflammation, which might influence the ADC value^[34]. According to Angulo *et al.*^[35], most patients with acute liver disease and even with chronic liver cirrhosis remained asymptomatic until decompensation occurred. We could presume that the authors of the previous study might consider the patients with asymptomatic acute or chronic liver disease as healthy patients, which resulted in selection bias. Furthermore, there might be a long interval between patients undergoing liver biopsy and undergoing MRI, and the stage of liver fibrosis might change during the interval, which would potentially affect the results^[36]. Another advantage of this study was that we determined how to use TLV and ADC values to predict stage of liver fibrosis.

There were some limitations in our study. Firstly, our sample size was relatively small. Therefore, further studies involving a larger number of samples are needed to evaluate TLV and ADC values for predicting liver fibrosis stage. Secondly, our study was based on an animal experiment, but our findings could provide some useful information that TLV and ADC values could predict the stage of fibrosis, and we will conduct further studies to confirm the results.

In conclusion, TLV and ADC values might be used to predict stage of liver fibrosis. TLV could predict stage ≥ 2 with a lower diagnostic accuracy, but ADC values with $b = 500$ or 800 s/mm^2 might be good predictors for stage ≥ 2 and ≥ 3 with a higher diagnostic accuracy. This study might provide a noninvasive method for predicting stage of liver fibrosis.

COMMENTS

Background

As a noninvasive method, magnetic resonance imaging has been developed to characterize liver fibrosis. Apparent diffusion coefficient (ADC) obtained by diffusion-weighted imaging (DWI) for studying liver fibrosis widely varied because of the employed settings of so-called b -values. In addition, total liver vol-

ume (TLV) obtained by computed tomography would change with the progress of liver fibrosis. However, correlations of liver ADC value obtained by different *b* values or magnetic resonance imaging (MRI)-based TLV with the stage of liver fibrosis, and whether and how TLV and DWI could predict the stage of liver fibrosis remained unclear.

Research frontiers

ADC obtained by magnetic resonance (MR) DWI for multiple *b* values and TLV obtained by enhanced MR imaging are the hotspots for the research on assessing the stages of liver fibrosis. How the ADC and TLV would change with the increasing stage of liver fibrosis, and whether TLV and DWI could predict the stage of liver fibrosis have not been determined.

Innovations and breakthroughs

The authors utilized magnetic resonance imaging to assess the changes of apparent diffusion coefficient obtained by DWI and TLV obtained by enhanced scans with the stage of liver fibrosis, and utilized receiver-operating characteristic (ROC) curve analysis to determine whether TLV and DWI could predict the stage of liver fibrosis.

Applications

The authors found that TLV and ADC values might predict stage of liver fibrosis. ADC values with *b* = 500 or 800 s/mm² might be good predictors for stage ≥ 2 and ≥ 3 with higher diagnostic accuracy, but TLV could predict stage ≥ 2 with a lower diagnostic accuracy. Although this is an experimental study, the findings could be helpful for the relevant clinical studies.

Terminology

DWI, a method that assesses the diffusion of protons within tissue by applying motion sensitizing gradients that causes diffusing protons to lose signal. The amount of signal loss is influenced by the strength of the diffusion weighting (the diffusion sensitivity parameter or *b* value of the sequence) and the ability of protons to diffuse through tissues (the ADC).

Peer review

This interesting study determined whether MRI based liver volume and DWI are useful to stage liver fibrosis in mini-pigs. Results presented in this paper showed that TLV increased during stage 0-2, whereas it decreased from stage 3 liver fibrosis. The ADC values were decreased with increasing stage of fibrosis. Authors conducted histopathological studies in liver biopsy specimens to analyze the damage during fibrosis. Overall, these findings show that both TLV and ADC values provide an important tool to predict stage of liver fibrosis.

Abstract

AIM: To investigate the long-term outcome of recipients and donors of adult-to-adult living-donor liver transplantation (AALDLT) for acute liver failure (ALF).

METHODS: Between January 2005 and March 2010, 170 living donor liver transplantations were performed at West China Hospital of Sichuan University. All living liver donor was voluntary and provided informed consent. Twenty ALF patients underwent AALDLT for rapid deterioration of liver function. ALF was defined based on the criteria of the American Association for the Study of Liver Diseases, including evidence of coagulation abnormality [international normalized ratio (INR) ≥ 1.5] and degree of mental alteration without pre-ex-

isting cirrhosis and with an illness of < 26 wk duration. We reviewed the clinical indications, operative procedure and prognosis of AALDLT performed on patients with ALF and corresponding living donors. The potential factors of recipient with ALF and corresponding donor outcome were respectively investigated using multivariate analysis. Survival rates after operation were analyzed using the Kaplan-Meier method. Receiver operator characteristic (ROC) curve analysis was undertaken to identify the threshold of potential risk factors.

RESULTS: The causes of ALF were hepatitis B ($n = 18$), drug-induced ($n = 1$) and indeterminate ($n = 1$). The score of the model for end-stage liver disease was 37.1 ± 8.6 , and the waiting duration of recipients was 5 ± 4 d. The graft types included right lobe ($n = 17$) and dual graft ($n = 3$). The mean graft weight was 623.3 ± 111.3 g, which corresponded to graft-to-recipient weight ratio of $0.95\% \pm 0.14\%$. The segment V or VIII hepatic vein was reconstructed in 11 right-lobe grafts. The 1-year and 3-year recipient's survival and graft survival rates were 65% (13 of 20). Postoperative results of total bilirubin, INR and creatinine showed obvious improvements in the survived patients. However, the creatinine level of the deaths was increased post-operatively and became more aggravated compared with the level of the survived recipients. Multivariate analysis showed that waiting duration was independently correlated with increased mortality ($P = 0.014$). Furthermore, ROC curve revealed the cut-off value of waiting time was 5 d ($P = 0.011$, area under the curve = 0.791) for determining the mortality. The short-term creatinine level with different recipient's waiting duration was described. The recipients with waiting duration ≥ 5 d showed the worse renal function and higher mortality than those with waiting duration < 5 d (66.7% vs 9.1%, $P = 0.017$). In addition, all donors had no residual morbidity. Furthermore, univariate analysis did not show that short assessment time induced the high morbidity ($P = 0.573$).

CONCLUSION: Timely AALDLT for patients with ALF greatly improves the recipient survival. However, further systemic review is needed to investigate the optimal treatment strategy for ALF.

Adult-to-adult living donor liver transplantation for acute liver failure in China. *World J Gastroenterol* 2012; 18(48): 7234-7241 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7234.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7234>

INTRODUCTION

Acute liver failure (ALF) is a condition in which rapid deterioration of liver function results in hepatic encephalopathy and coagulopathy in individuals without pre-existing cirrhosis^[1]. Because ALF progresses rapidly and recovers poorly, the emergency liver transplantation is recommended to treat ALF which has a high likelihood of death^[1]. However, because the shortage of donor organ and the long waiting time for a suitable graft, the patients might deteriorate further and eventually die while waiting. Living donor liver transplantation (LDLT) is an effective option for this dilemma, which may reduce waiting time and provide more optimal timing for surgery and shorter cold ischemia time.

Adult-to-adult LDLT (AALDLT) for ALF has recently been reported, mostly in Asians^[2-4], although it possibly increases the donor's risk because of large-sized graft removed and an evaluation of donor in an urgent scenario. In addition, an optimal graft might not be obtained because of a short assessment time for donors. The recent reports have described the optimal survival rate of recipients and the minimum rate of morbidity of the donors^[2-6]. However, a small sample could not support AALDLT as a better solution for patients with ALF. Thus, the continued development of AALDLT treatment is necessary to determine treatment option for patients with ALF.

ALF caused by hepatitis B virus (HBV) infection has a lower spontaneous recovery rate than that induced by drugs^[7]. In China, the most frequent cause of ALF is HBV, thus emergency AALDLT will be particularly significant for these patients with a high mortality and limited deceased organs. In this study, we reported the long-term outcome of recipients and donors of emergency

AALDLT for ALF performed in our center.

MATERIALS AND METHODS

Patients

Between January 2005 and March 2010, 170 LDLTs were performed at West China Hospital of Sichuan University. Twenty ALF patients underwent AALDLT for rapid deterioration of liver function. ALF was defined based on the criteria of the American Association for the Study of Liver Diseases (AASLD)^[1], including evidence of coagulation abnormality [international normalized ratio (INR) ≥ 1.5] and any degree of mental alteration without pre-existing cirrhosis and with an illness of < 26 wk duration. Patients with underlying chronic diseases such as chronic hepatitis B and autoimmune hepatitis were included if their disease has only been recognized for < 26 wk. Patients with cirrhosis identified by histologic examination of the liver explants were excluded. Informed consent was obtained from the patients and their families.

Donor evaluation

The primary selection criteria for a living liver donor were: being voluntary and providing informed consent which clearly stated that living liver donation can lead to donor risk. Each donation was approved by the Ethics Committee of West China Hospital of Sichuan University. The first essentiality of donor medical evaluation included ABO blood type identity or compatibility and age < 65 or > 18 years. Donors with known medical disorder that significantly increased a perioperative risk or contraindicated donation were excluded. Liver biochemistry, hepatitis serological tests, and complete blood cell count, coagulation test, cardio-pulmonary function tests to exclude chronic liver disease or potential contraindication were routinely performed in donors. Computed tomography (CT) scan for volumetric size measurement was performed to evaluate graft size and the size of the future remnant donor liver. The donors' remnant liver volume should be greater than 30% of the total liver volume (TLV) by CT volumetry. Dual graft liver transplantation with two left hemiliver or a combination of a right hemiliver and left hemiliver was adopted when the suitability of single graft transplant was in doubt in view of donor safety [remnant liver volume (RLV) $< 30\%$ of TLV] or small-for-size graft for recipients [graft volume to recipient standard liver volume (GV/SLV) ratio $< 40\%$]. The donor assessment was usually completed within 24-48 h to shorten the waiting time of recipients.

For minimizing the risks and complications of definitive donors, the typical preoperative invasive diagnostic procedures, including hepatic angiography, liver biopsy, and cholangiography, were abolished and the following managements were adopted: (1) hepatic angiography was substituted with CT arteriography to study the tracks and variations of the hepatic artery, but hepatic angiography will further be performed if hepatic artery was not visualized; (2) preoperative endoscopic retrograde

choledochopancreatography was routinely substituted by magnetic resonance cholangiopancreatography and intraoperative cholangiography^[8].

Donor and recipient operations

The donor and recipient operation was performed according to the previously published technique^[8]. Intraoperative liver biopsy was routinely performed to exclude donors with severe hepatic steatosis. We emphasized the following practices, including identifying hepatic incision line with intraoperative ultrasonography, hepatectomy using an ultrasonic dissector without inflow occlusion, identifying biliary duct anatomy by intraoperative cholangiography and leaving middle hepatic vein (MHV) in the donor side. Recipients' great saphenous vein or cryopreserved vessels were anastomosed between the crassitude tributaries of the graft MHV (> 5 mm in diameter) and inferior vena cava to avoid graft (segment V and VIII) congestion and to provide sufficient functioning liver mass. Weight and volume of the grafts were respectively measured using the balance and water replacement method in the back table, and graft-to-recipient weight ratio (GRWR) and GV/SLV ratio were calculated. In addition, the rate of donor RLV was calculated as follows: $[(TLV - GV)/TLV] \times 100\%$.

Postoperative treatment and follow-up

Each donor and recipient were routinely cared in the intensive care unit of liver transplantation after operation, and transferred to the regular ward when their conditions became stable. Liver biochemical tests, blood routine examination, hepatic vascular status and remnant liver volume regeneration were monitored during hospital stay and follow-up. The Clavien classification system for liver transplantation was used to respectively define postoperative recipient^[9] and donor complications^[10]. Standard immunosuppression regimen is triads of ciclosporin or tacrolimus, mycophenolate mofetil and prednisone. Lamivudine was given orally to recipients with hepatitis B once the decision to perform liver transplantation was made, and was continued throughout and after the operation. Hepatitis B immunoglobulin was used for the prevention of hepatitis B relapse. Discharge donors and recipients were regularly followed up with an endpoint of September 30, 2010.

Statistical analysis

Data were expressed as mean and standard deviations or as median and range depending on the distribution. Continuous variables of two groups were compared by the Student *t* test or the Mann-Whitney test as appropriate. Survival rates after operation were analyzed using the Kaplan-Meier method. Multivariate Cox regression further analyzed the independently related factors of mortality. Receiver operator characteristic (ROC) curve analysis was undertaken to identify the threshold of potential risk factors. Statistical significance was defined as $P < 0.05$. All statistical analysis were performed using

RESULTS

Recipient characteristics

Patients included 17 men and 3 women, with mean age of 39.5 ± 7.3 years (range, 29-63 years). The causes of ALF were hepatitis B (*n* = 18, including 10 patients with acute hepatitis B and 8 patients with acute-on-chronic hepatitis B), drug-induced (*n* = 1) and indeterminate (*n* = 1). The parameters of the recipients are summarized in Table 1. The average score of the model for end-stage liver disease (MELD) was 37.1 ± 8.6, ranging from 24 to 55. Hepatorenal syndrome was present in four patients, but none required preoperative hemodialysis. Three patients received dual grafts transplantation with right hemiliver and left hemiliver, and their accumulated grafts weight was 800 g, 754 g and 680 g, respectively. The overall graft weight was 623.3 ± 111.3 g (range, 400-850 g) and the graft volume was 618.3 ± 111.0 cm³ (range, 400-870 cm³), which corresponded to the GRWR of 0.95% ± 0.14% (range, 0.75%-1.31%) and GV/SLV of 46.2% ± 7.2% (range, 37%-68%). The segment V or VIII hepatic vein, which was 8.5 ± 2.5 mm (range, 5-13 mm), were reconstructed in 11 right-lobe grafts. The methods

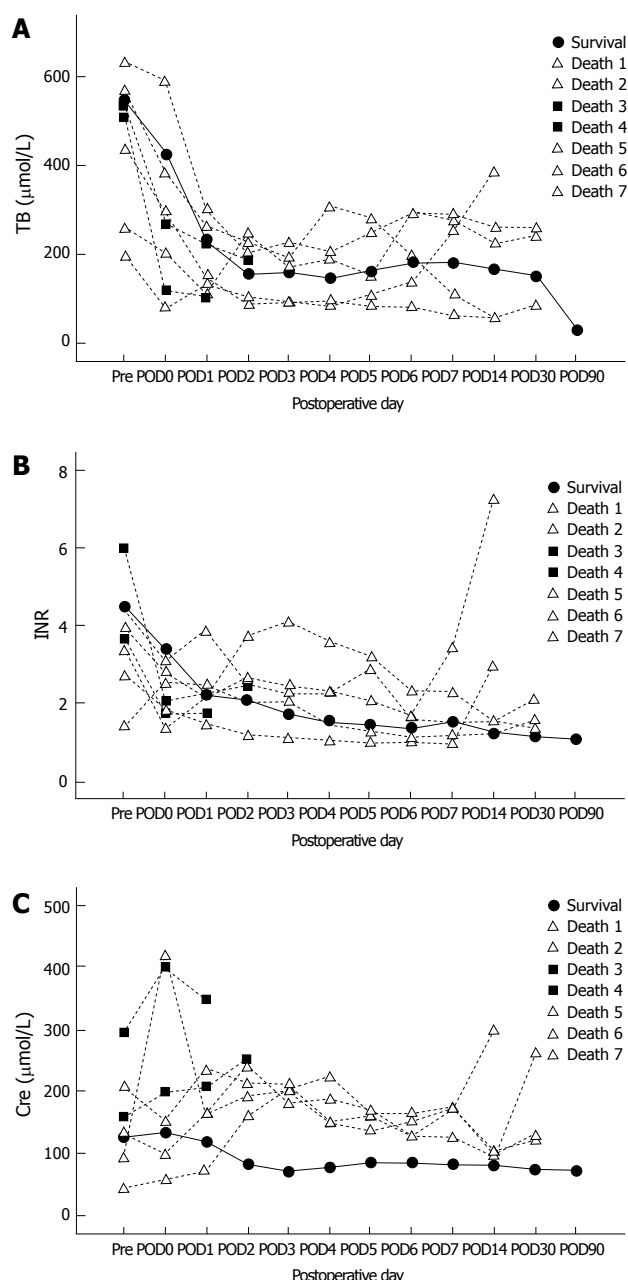

Figure 1 Hepatic and renal function change of all recipients with acute liver failure. The solid line displays the mean of values level in survived recipients ($n = 17$). The dashed line displays the values level of seven dead recipients. The triangles show the dead recipients with survival time > 7 d, and the black boxes show the dead recipients with survival time < 2 d. A: Total bilirubin (TB) tendency; B: INR: International normalized ratio tendency; C: Creatinine (Cre) tendency.

of biliary reconstruction included duct-to-duct manner without T-tube ($n = 17$) and with T-tube ($n = 1$), Roux-en-Y anastomosis ($n = 1$) and combined duct-to-duct and Roux-en-Y anastomosis ($n = 1$).

Recipient outcomes

The respiratory tube was extubated at median postoperative 10 h (range, 5-95 h) in all patients. Hospital stay was 33.7 ± 18.5 d (range, 1-84 d) and seven recipients died in hospital. Postoperative liver and renal function

Table 2 Classification of common complications of the recipients

Clavien grade	Complications	<i>n</i>	
Grade I (<i>n</i> = 2)	Pleural effusion (mild)	1	
	Anastomotic stoma stenosis of right hepatic vein without treatment	1	
Grade II (<i>n</i> = 10)	II a	Pleural effusion (server) using pleurocentesis	1
		Transfusion 4 foreign blood units and pleural effusion (mild)	2
		A persistent elevated prothrombin time > 20 over 3 d	1
		Transient increase in creatinine levels (> twice the pretransplantation level) for one month	1
	II b	Bile duct stricture corrected by endoscopic therapy, and pulmonary infection	1
		Hepatic artery thrombus requiring surgery, and bile leakage requiring endoscopic procedure	1
		Postoperative bleeding requiring laparotomy	1
Grade III (<i>n</i> = 0)	None	0	
Grade IV (<i>n</i> = 7)	Renal failure and/or hepatic function failure	5	
	Pulmonary infection	1	
	Abdominal infection from bile leakage	1	
Total		17	

are shown in Figure 1. Postoperative results of total bilirubin, INR and creatinine showed obvious improvement in survived patients. However, the creatinine level of dead cases was increased postoperatively and was more aggravated than the level of survived recipients.

A total of 17 (85%) recipients suffered from different grades of complications (Table 2). One biliary anastomotic stricture occurred, which was successfully treated by an endoscopic procedure. One patient required surgical revision for hepatic artery thrombosis and endoscopic procedure for bile leakage. One case required laparotomy for intraperitoneal hemorrhage. Seven recipients (35%) died in hospital, and the others were still alive. The 1-year and 3-year recipient survival and graft survival rates were 65%. One patient died from the acute rejection after one month. One case developed severe pulmonary mixed infection (*Burkholderia cepacia*, and *Acinetobacter baumannii*/*Acinetobacter baumannii*) and died three weeks later. Two patients died from severe pulmonary infection (*Pseudomonas aeruginosa* and *Klebsiella pneumonia*) after one month. One case required surgical procedure for bile leakage on POD14, but died of abdominal infection on the second postoperative day 5. Two patients died from the continuing severe hepatic function failure on POD1 and POD2.

The patient 1-year and 3-year survival rates were 65%, and 13 patients were still alive (Figure 2). No significant related factors for a recipient mortality were observed using univariate analysis, including MELD scores, preoperative total bilirubin, pre-creatinine, pre-INR, GV/SLV and reconstruction of segment hepatic vein outflow as shown in Table 3 (all $P > 0.05$). And the similar operative liver and renal functions were observed in group with and without segment hepatic vein outflow (all $P > 0.05$). However, gender ($P = 0.037$), the longer duration of waiting ($P = 0.014$) and higher creatinine level on POD1 ($P = 0.021$) were associated with the mortality. Furthermore,

Figure 2 Survival curve of patients with acute liver failure. The patient 1-year and 3-year survival rates in the present study were 65%.

Figure 3 Short-term creatinine level change with different recipient waiting time. The recipients with waiting time ≥ 5 d (the solid line) showed a higher creatinine level than those with waiting time < 5 d (the dashed line).

multivariate analysis showed that waiting time was only independently correlated with the increased mortality ($P = 0.016$), but the clinical significance was likely not accepted because of a low odds ratio (OR = 1.19, 95%CI = 1.033-1.385). Furthermore, ROC curve revealed the cut-off value of waiting time was 5 d ($P = 0.011$, area under the curve = 0.791) for determining the mortality. The short-term creatinine levels and recipient's waiting duration are shown in Figure 3. We found that recipients with waiting duration ≥ 5 d showed the worse renal function and higher mortality than with waiting duration < 5 d (66.7% *vs* 9.1%, $P = 0.017$).

Donor results

The mean age of the 23 living donors was 37.7 ± 10.2 years (range, 19-58 years). The preoperative parameters of donors are shown in Table 3. The mean donor assessment was 2.1 ± 1.3 d (range, 1-5 d). The assessment

Table 3 Univariate analysis of the mortality in the acute liver failure cases

Variables	P value	Variables	P value
Gender	0.037	Outflow reconstruction	0.924

BMI	0.914	Blood loss	0.608
Child-Pugh scoring	0.963	Operation duration	0.536
MELD scoring	0.727	Re-warm ischemia	0.394
MELD scoring grade (> 30)	0.306	Pre_TB	0.878
Waiting duration	0.014	Pre_Cre	0.563
GV/SLV	0.396	Pre_INR	0.670
GW/BW	0.385	POD1_TB	0.622
Anhepatic phase	0.620	POD1_Cre	0.021
Cold ischemia	0.767	POD1_INR	0.930

GV/SLV: Graft volume to recipient standard liver volume; GW/BW: Graft weight to recipient body weight; MELD: Model for end-stage liver disease; BMI: Body mass index; Pre: Preoperative; POD1: One of postoperative day one; TB: Total bilirubin; INR: International normalized ratio.

time was more than 3 d in five donors, including 3 d ($n = 2$), 4 d ($n = 1$) and 5 d ($n = 2$). The assessment time was prolonged because some excluded potential donors resulted in re-evaluating another donor, whose causes included viral hepatitis, blood type incompatibility, obesity or graft size mismatch. Five donors with mild steatosis were observed by biopsy and their macrosteatosis was less than 30% (maximum 25%), and three of the five cases developed mild hepatic function impairment and recovered within one week. The RLV/TLV was $56.6\% \pm 12.1\%$ (range, 26%-79%). It was less than 30% in only one case, but the total bilirubin (60-90.8 $\mu\text{mol/L}$) was high within postoperative three days.

The complications of donors are shown in Table 4. There was no death and grade IV morbidity. Surgical morbidity was found in 11 patients (47.8%) in this series. However, the major complication only occurred in one donor, which was severe pleural effusion with pleurocentesis and classified as grade IIIa. Pleural effusion was the most frequent morbidity for living donor, and occurred in 8 cases (34.8%). Four donors developed mild hepatic function impairment, but spontaneously recovered within one week. One case with pulmonary infection had hyperbilirubinemia more than 3 wk, and the hepatic function was recovered with Transmetil treatment. The mean hospital stay was 13.4 ± 3.5 d (range, 6-22 d). The similar morbidity and postoperative hepatic function were found between donors with short (< 3 d) and with long (≥ 3 d) assessment time (all $P > 0.1$). With a median follow-up of 29 mo, all donors had no residual morbidity and resumed normal preoperative activities with normal liver function. Furthermore, univariate analysis did not show that short assessment time induced the high morbidity ($P = 0.573$) and the correlation between RLV/TLV and the morbidity ($P = 0.268$).

DISCUSSION

Initially LDLT for ALF was only performed in children.

Table 4 The characteristics of living donors

Parameters	Donors (n = 23)
Preoperative

Grade IIIa (n = 1)	
Pleural effusion (server) using pleurocentesis	1

Hepatic function impairment: Mild, hyperbilirubinemia (TB being 51–85 μmol/L for more than 3 d or 34–51 μmol/L on POD7) and/or PT prolongation (6–8 s for more than 3 d or 4–6 s on POD7); Moderate, hyperbilirubinemia (TB > 85 μmol/L for more than 3 d or exceeding 51 μmol/L on POD7) and/or PT prolongation (> 8 s for more than 3 d or exceeding 6 s on POD7). BMI: Body mass index; RLV: Remanet live volume; TLV: Total liver volume; TB: Total bilirubin; INR: International normalized ratio; PT: Prothrombin time.

Since the first report of successful AALDLT using right-lobe graft for adult ALF patients by Lo *et al*^[11], AALDLT has been gradually accepted as an alternative treatment for adult ALF patients. Most cases came from Asian countries^[2–4,6], whereas a few cases were reported from Western countries^[5]. Experiences of AALDLT in ALF are summarized in Table 5^[2–6,12–17]. The mean waiting time was mostly less than five days and 1-year survival rate (> 70%) was satisfactory in the recipients. Zero mortality and low morbidity (< 40%) were achieved in all donors. Thus, it is rational to conclude that AALDLT is a safe treatment for patients with ALF.

This study demonstrated that AALDLT was an efficient treatment for patients with ALF. Patients who survived postoperatively (n = 13, 65%) were still alive at the postoperative 1-year and 3-year. This result was worse

than those reported in literature (> 70%), the possible explanations include worse preoperative patient condition, increased waiting time, inadequate venous draining resulting from right-lobe graft without MHV.

The MELD score was used to allocate cadaveric liver grafts among patients with end-stage liver disease^[18], and was also considered to be a useful indicator of LDLT in ALF patients^[19–21]. Several authors suggested that MELD scores greater than 25 should be considered as a relative contraindication for transplantation because of the poor outcomes^[22]. Yantorno *et al*^[20] advocated the MELD score cut-off value for determining whether a transplantation was indicated should be 30. In our series, the mean MELD was 37.1 ± 8.6, which was higher than that reported from all other centers (Table 5). The mortality of recipients with MELD > 30 (7 of 15, 46.7%) was higher than those with MELD ≤ 30 (0 of 5), but not statistically significant (P = 0.306). The increased MELD score may account for an increased mortality (65%) in our reports. However, Matsui *et al*^[13] considered that MELD score has little clinical significance for ALF patients who received plasma exchange.

In the present study, multivariate analysis identified waiting duration as the sole independent prognostic factor for 1-year mortality. The duration of waiting time for liver transplantation can significantly affect patient survival, especially for patients with ALF^[2,6,23]. Prolonged waiting time means increased risk of severe complications, including deterioration of hepatic or/and renal function, intracranial bleedings or sepsis^[6,24], which contributed to increased mortality in our series. The mean waiting time in this study was slightly longer than that in other centers (5 d *vs* 3.7 d). Recipients with waiting duration ≥ 5 d correlated with worse outcome. This was possibly due to the following causes, such as delayed donor evaluation or/and the hesitancy for LDLT from the patient's family. This result was possibly of defective clinical significance because of the low odds ratio of waiting duration (OR = 1.19) for a recipient mortality and the small sample size of our study. However, this data showed that timely LDLT for ALF patients greatly improved the recipient survival.

On one hand, the graft volume is positively correlated with the recipient outcome in LDLT^[16,25,26]. To meet the demand of patients with ALF, a safety margin of a smaller graft was GV/SLV > 30%–35%^[4,12,27]. Despite acceptable survival with GV/SLV < 30%^[28] was reported, small graft should be avoided if possible^[4,11]. Based on recent reports (Table 4), satisfactory survival resulted from right-lobe graft with a GV/SLV more than 30%. In this study, the mortality of recipients was not associated with GV/SLV because of the GV/SLV > 37%. On the other hand, right liver graft without middle hepatic vein may lead to venous congestion of right anterior segments^[16,29–31]. The functional graft volume relies on a perfect outflow^[32,33], thus it is necessary to reconstruct the crassitude hepatic vein outflow to avoid graft congestion. Our data can not provide evidence to answer whether a graft with or without MHV correlates to recipient mor-

¹Four pediatric recipients were not clarified from 36 cases in this report. Major complications of donors were defined as the Clavine grade III-IV. MELD: Model for end-stage liver disease; GV/SLV: Graft volume to recipient standard liver volume; ND: Not described. The latest report was as the summarized standard if multiple reports were from the same center and author.

tality because all grafts were without middle hepatic vein. However, comparable patient outcome was achieved in our series which warrants that the reconstruction of a crassitude hepatic vein outflow is necessary.

Some scholars concerned that the expedited donor assessment may incur poor donor outcome. However, there was no mortality or reoperation among donors in our series. Although 34.8% of donors suffered from complications, all improved spontaneously or with conservative management except one pleural effusion with pleurocentesis. This morbidity was slightly higher than that reported by other centers because of the variation of defining and reporting complications^[34,35]. Postoperative complications of donors is usually underestimated even using the Clavien classification (1992 version)^[13,36]. Thus, this morbidity in our center was acceptable using the new Clavien classification. In addition, our results also indicated that transitory assessment for donors had no negative effect on the donor outcome. Similarly, the small sample size in our study is still insufficient to determine a potential correlation between expedited donor assessment and donor outcome. In our experience, a rapid evaluation process did not bring any negative effect to donors.

In summary, this study demonstrated that AALDL should be performed as early as possible in patients with ALF for a satisfactory survival rate. There are few studies with a large sample size to support AALDLT as a better treatment for patients with ALF. Thus, a systemic review and continued development of AALDLT are important to determine treatment option for patients with ALF.

COMMENTS

Background

Acute liver failure (ALF) is a condition with rapid deterioration of liver function. Because ALF progresses rapidly and recovers poorly, the emergency liver transplantation is recommended as the effective treatment for ALF which has a high likelihood of death. Adult-to-adult living-donor liver transplantation (AALDLT) would help address the shortage of available organs for patients with ALF.

Research frontiers

AALDLT for ALF has recently been mostly reported in Asia and there were

also cases reported in Western countries. The recent reports have described the optimal survival rate of recipients and the minimum rate of morbidity of the donor. However, a small sample could not support AALDLT as a better solution for patients with ALF. Thus, the continued development of AALDLT treatment is necessary to determine the treatment option for patients with ALF.

Innovations and breakthroughs

This study evaluated the outcome of recipients with ALF and living donor in detail. Based on the Clavien classification, the outcome of recipients and donors were first objectively evaluated. The authors indicated that the duration of waiting was an independent risk factor for a recipient's mortality. In addition, sample size is still small among studies of AALDLT for ALF in the world. Thus, this study presented some experience for further system reviews.

Applications

This study indicated that patients with ALF should receive AALDL as early as possible for satisfactory survival rate. And the model for end-stage liver disease score may not be related to the outcome of recipient's outcome.

Terminology

ALF is a condition in which rapid deterioration of liver function results in altered mentality and coagulopathy in individuals without preexisting cirrhosis.

Peer review

The manuscript provided information about LTx for ALF in China. This is a very interesting analysis of a series of 20 patients who underwent LDLT for ALF. From the "west-countries" point of view, these series are important as we may consider increasing our rate of LDLT for several etiologies, including ALF.

Abstract

AIM: To explore the prognostic value in the monitoring of treatment efficacy of serial α -fetoprotein (AFP) in hepatocellular carcinoma (HCC) patients.

METHODS: We searched MEDLINE, EMBASE and COCHRANE LIBRARY through April 21, 2012, to find qualifying articles. Our overall search strategy included terms for HCC, AFP, treatment response, and prognosis. Literature was limited to English-language, human studies. Studies reporting cumulative survival rates were summa-

rized qualitatively. For the prognostic meta-analysis, we undertook a series of meta-analyses that summarised the Cox proportional hazard ratios (HRs) by assuming a random effects model. With regards to the correlation of AFP change with radiologic response, the categorical dichotomous variables were assessed using Poisson relative risks (RRs), which were incorporated into the random effects model meta-analysis of accuracy prediction. Between-study heterogeneity was estimated by use of the I^2 statistic. Publication bias was evaluated using the Begg funnel plot and Egger plot. Sensitivity analyses were conducted first by separating systemic treatment estimates from locoregional therapy estimates, evaluating different AFP response cut-off point effects, and exploring the impact of different study sizes.

RESULTS: Of 142 titles identified in our original search, 11 articles (12 clinical studies) met our criteria. Six studies investigated outcome in a total of 464 cases who underwent systemic treatment, and six studies investigated outcome in a total of 510 patients who received locoregional therapy. A random-effects model meta-analysis showed that AFP response was associated with an mortality HR of 0.55 (95%CI, 0.47-0.65) across HCC in overall survival (OS) and 0.50 (95%CI, 0.38-0.65) in progression-free survival. Restricting analysis to the six eligible analyses of systemic treatment, the pooled HRs were 0.64 (95%CI, 0.53-0.77) for OS. Limiting analysis to the six analyses of locoregional therapy, the pooled HRs for OS was 0.39 (95%CI, 0.29-0.53). We showed a larger pooled HR in the 50% definition studies (HR, 0.67, 95%CI, 0.55-0.83) compared with that from the 20% definition studies (HR, 0.41, 95%CI, 0.32-0.53). Restricting analysis to the four studies including over 100 patients individually, the pooled HR was 0.65 (95%CI, 0.54-0.79), with a pooled HR for OS of 0.35 (95%CI, 0.23-0.46) in the studies of less than 100 patients. As to radiological imaging, 43.1% (155/360) of the patients in the AFP response group presented with a radiological overall response, while the response rate decreased to 11.5% (36/313) in the patients from the

AFP nonresponse group. The RR of having no overall response was significantly lower in the AFP response group than the AFP nonresponse group (RR, 0.67; 95%CI, 0.61-0.75). In terms of disease control rate, 86.9% (287/330) in the AFP response group and 51.0% (153/300) in the AFP nonresponse group showed successful disease control, respectively. The RR of disease control failure, similarly, was significantly lower in the AFP response group (RR, 0.37; 95%CI, 0.23-0.58). But these findings could be overestimates because of publication and reporting bias.

CONCLUSION: HCC patients presenting with an AFP response are at decreased risk of mortality. In addition, patients with an AFP response also present with a higher overall response rate and disease control rate.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide, and as a result of the spread of hepatitis C virus and hepatitis B virus infection during the past century, its incidence will further increase in the future in both Asia and in western countries^[1,2]. Transarterial therapy, systemic agents, and radiofrequency ablation remain as mainstays of treatment in advanced HCC^[3]. Conventionally, the treatment response of HCC to systemic therapy or other nonsurgical treatment modalities is assessed by radiologic imaging using conventional criteria, such as World Health Organization (WHO) criteria or Response Evaluation Criteria in Solid Tumors^[4-6]. However, despite successful clinical correlations for other solid tumors, these radiological response-based criteria have been criticized for not adequately reflecting treatment response and tumor viability for HCC. It has constantly been observed that a small subset of HCC patients could derive benefits from treatment despite the absence of radiologic response^[7-9]. Thus, the sole use of radiologic criteria has underestimated the efficacy of novel treatment in early clinical trials and the search for better, alternative ways of assessing treatment response continues to be important.

While imaging is being explored, widespread efforts have been made to identify serological markers that predict survival and response to treatment^[10], and among which, serum α -fetoprotein (AFP) (a glycoprotein that is expressed by HCC and secreted into the serum of approximately 70% of patients with HCC) have been widely studied^[11,12]. In the half century after AFP was first described, it was extensively studied as a screening and diagnostic tool for HCC^[13-15]. Although there have been some early observational studies that have suggested that AFP trend might be useful in assessing treatment response, until recently, there has been no clinical study to validate the significance of serial AFP monitoring in association with the treatment response of HCC^[16,17]. In the past few years, several studies have investigated the role of AFP response to treatment in HCC, which mainly focused on the overall survival (OS) and progression-free survival (PFS), and validated its correlation with radiological response. However, estimates of the prognostic value of the AFP response between studies differed wildly. The aim of this analysis is to review published studies that investigated the correlation between AFP response and prognosis in HCC, and to use standard meta-analysis techniques to summarise the accuracy of AFP response in prediction of survival in HCC patients.

MATERIALS AND METHODS

Study identification

We searched MEDLINE, EMBASE, and COCHRANE LIBRARY from inception to April 21, 2012, for articles evaluating the AFP level and response to treatment on the prognostic outcome in HCC patients. Our overall search strategy included terms for HCC (e.g., hepatocellular carcinoma, liver carcinoma, liver cancer, liver malignant neoplasm), AFP (e.g., α -fetoprotein, alpha-fetoprotein, AFP), treatment response (e.g., change, decline, response), and prognosis (e.g., mortality, survival, recurrence). Literature was limited to English-language, human studies. We also searched references of included articles. Only published studies in peer-review journals were included. Data from review articles, case reports, abstracts, and letters were not included.

Study eligibility and selection

Studies were eligible if survival was analyzed in HCC cases stratified by AFP response or not. To be included in our meta-analysis, articles had to meet both of the following criteria: they reported a risk estimate [e.g., hazard ratio (HR) or relative risk (RR) relating AFP response to subsequent death using survival analysis regression models], and they reported an estimate of precision, such as a standard error or 95%CI. We also included articles that failed to report precision directly but from which we could reconstruct an estimate of precision using *P* values and other study data^[18]. Correlation of AFP change with radiologic response was desirable, but it was not a must (Table 1).

Data synthesis and statistical analysis

To avoid duplicate data, we identified articles that included the same cohort of patients by reviewing inter-study similarity in the country in which the study was done, investigators in the study, source of patients, recruitment period, and inclusion criteria. Early studies published as a series of articles from the same author or institution that contained significant overlap of patient data were excluded and only the most recently published study containing the most up-to-date data was included. If several estimates were reported in the same article, we chose the most fully adjusted estimate (i.e., multivariate regression was selected over univariate regression, which was selected over unadjusted Kaplan-Meier analysis).

For the prognostic meta-analysis, we undertook a series of meta-analysis that summarised the HRs by assuming a random effects model. With regards to the correlation of AFP change with radiologic response, the categorical dichotomous variables were assessed using the RRs, which were incorporated into the random effects model meta-analysis of accuracy prediction. Between-study heterogeneity was estimated by use of the I^2 statistic; typically, values above 50% are deemed to suggest large between-study heterogeneity, values below 50% are deemed to represent low heterogeneity. Publication bias was evaluated using the Begg funnel plot and Egger plot. However, these estimates can have large uncertainty, especially in the presence of few trials, and should be interpreted with caution^[19].

Sensitivity analysis were conducted first by separating systemic treatment estimates from locoregional therapy estimates. Second, to evaluate AFP response cut-off point effects, we calculated estimates for studies whose AFP response was defined as 20% decline of the initial level *vs* those with the AFP response definition of 50% decline. Third, to explore the impact of study size, we conducted sensitivity analyses by components which included over 100 patients. Finally, we evaluated the influence of each study on the overall estimate by calculat-

ing a pooled HR, omitting each estimate 1 at a time. All analysis were conducted using Stata 12 (StataCorp, College Station, Texas).

RESULTS

Eligible studies

Thirteen studies were identified that provided survival data stratified by AFP response or not^[20-32]. Two studies were excluded from further analysis: one was excluded because it did not provide a definite AFP response cut-off point, and extraction of survival data for the AFP response cases and AFP nonresponse cases was not possible, and another article, which was a letter to editor, was also excluded^[31,32]. Hence a total of 11 articles remained eligible for pooling risk estimates, reporting on 974 patients, of whom 463 had a positive AFP response. The main characteristics and results of eligible studies evaluating AFP response in HCC patients were summarised in Table 1.

Description of studies

Of the 11 eligible articles, all were based on retrospective analysis of survival data with quite heterogeneity. Sample sizes ranged from 42 to 149 patients with a median of 62 patients. Six eligible articles assessed survival in the systemic treatment setting, with data from a total of 464 patients available for pooling (sample size range, 42 to 107 patients)^[20,21,26,28-30]. In the locoregional therapy setting, five articles were eligible, including 6 individual clinical studies, resulting in a total of 510 patients available for pooling (sample size range, 51 to 149 patients)^[22-25,27]. In one of these studies, patients were treated in the locoregional setting either by hepatic artery infusion chemotherapy, or concurrent chemoradiation therapy^[24]. In this study, it was possible to assess estimators of survival in the two patient cohorts separately, and each cohort was therefore considered separately for pooling purposes. In the systemic treatment studies, all patients received systemic regimens

(sorafenib, thalidomide, doxorubicin, *etc.*). In the locoregional therapy studies, chemotherapy and radiotherapy were used. Of all the included analysis, five defined AFP response as a 50% decline from the initial level^[21,23,25,27,29], and another seven proposed a definition of 20% decline^[20,22,24,26,28,30]. Across the included studies that reported the number of participants with AFP response, the overall prevalence of AFP response was 47% (range, 17%-79%), with a median sample size of 38 (range, 9 to 101). Follow-up time varied widely across studies, with a median of 35.3 mo (range, 4 to 100 mo) (Table 2).

With regards to radiologic response, the evaluation criteria were based on the WHO criteria. Complete response (CR) was defined as the complete disappearance of all known lesions on radiologic grounds. Partial response (PR) was defined as a decrease of 50% or more in the product of two perpendicular diameters of the largest tumor nodule for at least 4 wk without the appearance of new lesions or progression of lesions. Sta-

ble disease (SD) was defined as a less than 50% decrease or not more than a 25% increase in the product of two perpendicular diameters of the largest tumor nodule. Progressive disease was defined as more than a 25% increase in the product of two perpendicular diameters for the largest tumor nodule or one of the measurable lesions or as the appearance of new lesions. In view of these indices, the overall response rate referred to the total rate of CR and PR, whereas the disease control rate was defined as the total rate of CR, PR and SD.

Relationship between AFP response and OS in HCC

Of the 12 clinical studies eligible for pooling of OS data, 9 provided estimates of the HR associated with AFP response and its 95%CI^[20,21,23-26,28,30]. In the remaining studies, these data points were calculated from data presented in the articles^[22,27,29]. Table 3 details the results of survival analyses performed in eligible studies^[18], and Figure 1 displays a plot of HRs and associated 95%CI for OS from each study. AFP response was associated with a decrease in all-cause mortality following HCC, with a pooled HR for OS across all studies of 0.55 (95%CI, 0.47-0.65), and with significant evidence of heterogeneity between the contributing studies ($I^2 = 65\%$, $P = 0.001$). Evidence of significant publication bias was observed according to the funnel plot of lnHRs, with smaller studies showing significant effects^[18].

Because the investigators' approaches to adjustment for confounding factors varied widely by study and type of treatment, we conducted a sensitivity analysis to confirm robustness. Restricting analysis to the six eligible analysis in which patients received systemic treatment, the pooled HR was 0.64 (95%CI, 0.53-0.77) ($I^2 = 77\%$, $P = 0.001$) for OS^[20,21,26,28-30]. Limiting analysis to the six analysis in which patients under went locoregional therapy, the pooled HR for OS was 0.39 (95%CI, 0.29-0.53) ($I^2 = 0\%$, $P = 0.83$)^[22-25,27] (Figure 1A).

To assess the effect of cut-off point of AFP response, HRs were pooled from particular studies that defined AFP response as either 50% decline of initial level^[21,23,25,27,29] or

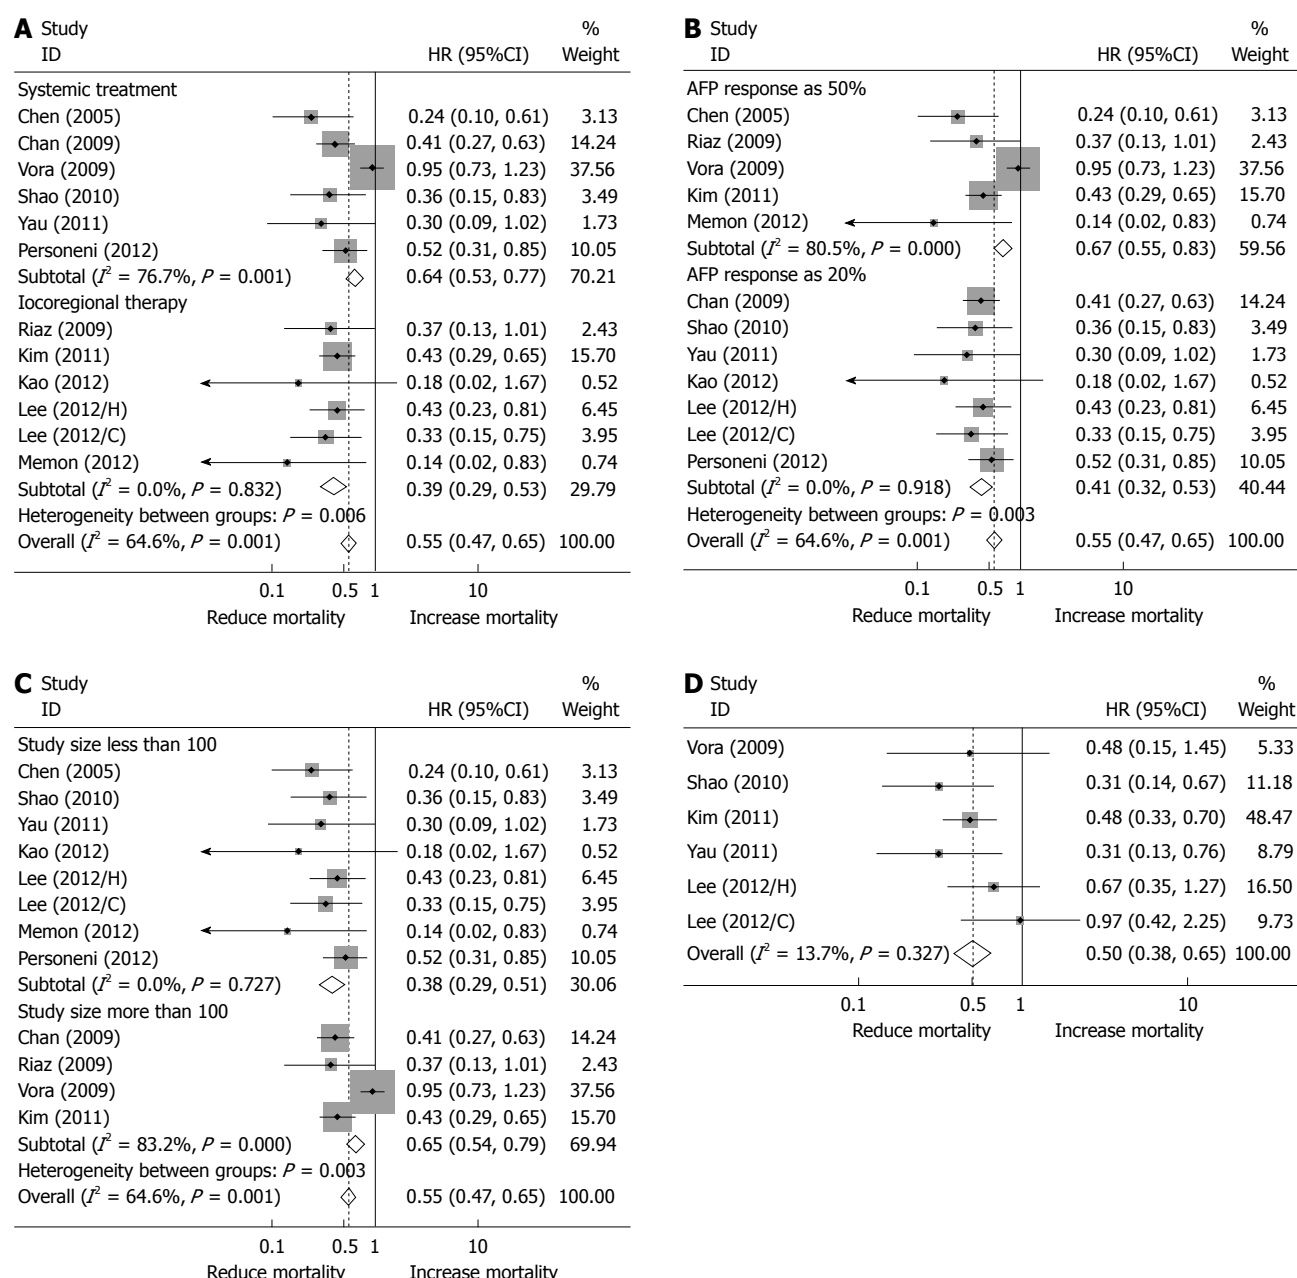

Figure 1 Forest plots representing hazard ratios of overall survival and progression free survival in hepatocellular carcinoma patients associated with α -fetoprotein response. A: Subgroup analysis according to systemic treatment and locoregional therapy; B: Subgroup analysis according to α -fetoprotein (AFP) response definition of 20% decline of its initial level and 50% decline; C: Subgroup analysis according to study size larger than 100 patients and less than 100 patients; D: Hazard ratios (HRs) of progression free survival in hepatocellular carcinoma patients associated with AFP response.

20% decline, respectively^[20,22,24,26,28,30]. This demonstrated a larger pooled HR in the 50% definition studies (HR, 0.67, 95%CI, 0.55-0.83) compared with that from the 20% definition studies (HR, 0.41, 95%CI, 0.32-0.53). In the 50% group, there was significant evidence of study heterogeneity ($I^2 = 81\%$, $P < 0.001$) (Figure 1B). This observed increased HR of mortality in the 50% definition studies contradicts our supposition that greater AFP response in the patient would predict better overall survival.

Restricting analysis to the four studies including over 100 patients individually, the pooled HR was 0.65 (95%CI, 0.54-0.79), again with evidence of study heterogeneity ($I^2 = 83\%$, $P = 0.003$)^[21,22,24-26,28,30]. The remaining eight studies

included less than 100 patients individually, and the pooled HR for OS was 0.35 (95%CI, 0.23-0.46), with no evidence of heterogeneity ($I^2 = 0$, $P < 0.001$)^[20,23,27,29] (Figure 1C).

Finally, we excluded individual study estimates 1 at a time to examine the influence of each study on the overall HR. It turned out that heterogeneity was mainly from the study by the Vora *et al*^[29] study, that only the omission of this study appreciably changed the pooled HR, with the HR decreasing to 0.40 (95%CI, 0.33-0.49) and eliminating the heterogeneity across all studies ($I^2 = 0$, $P = 0.91$).

able for assessment of PFS, and the pooled HR was 0.50 (95%CI, 0.38-0.65), with no obvious heterogeneity ($I^2 = 13\%$, $P = 0.33$)^[23,24,28-30]. This result should, however, be interpreted with caution because of the small number of contributing studies (Figure 1D).

AFP response in association with radiological response

Of the 12 eligible clinical studies, 8 provided data evaluable for assessment of radiological overall response rate^[20,23-25,27-29] and 7 reported on disease control rate^[20,23,24,27-29]. A radiological response summary is presented in Table 4. Overall, 43.1% (155/360) of the patients in the AFP response group presented the radiological overall response, while the response rate declined to 11.5% (36/313) in the patients from the AFP nonresponse group. The RR of having no overall response rate (Figure 2A) was significantly lower in the AFP response group than the AFP nonresponse group (RR, 0.67; 95%CI, 0.61-0.75) with no heterogeneity ($P = 0.65$, $I^2 = 0\%$). In terms of disease control rate, 86.9% (287/330) in the AFP response group and 51.0% (153/300) in the AFP nonresponse group

showed successful disease control, respectively. The RR of disease control failure, similarly, was significantly lower in the AFP response group (RR, 0.37; 95%CI, 0.23-0.58) (Figure 2B). No significant heterogeneity of studies was found on these parameters ($P = 0.09$, $I^2 = 45\%$).

DISCUSSION

Treatment response in HCC patients has been heterogeneous, with some patients showing impressive treatment effects, but others showing limited or no evidence of response^[33,34]. The hypothesis that AFP response to treatment is a determinant of prognosis in HCC is an attractive mechanism for explaining any inter-individual variation in clinical outcome^[55]. For patients with elevated AFP at baseline, the AFP trend was shown to be static or rising during the course of the disease, and a number of patients with undetectable AFP at baseline were found to have detectable and rising trends of AFP value upon disease progression^[17,36]. For patients who underwent partial hepatectomy, the AFP level fell rapidly and remark-

ably after removal of tumors, but this rose at the time of recurrence^[37,38]. These findings suggested that AFP response could be potentially useful in predicting survival and the efficacy of treatment.

The present systematic review of the literature and meta-analysis was done to assess the impact of AFP response on HCC prognosis. Twelve eligible studies were identified that investigated the relationship between AFP response and prognosis in HCC. Strengths of the study included a comprehensive, systematic review of the literature by a multidisciplinary team including specialists in cancer, hepatology, and epidemiologic methods, thereby avoiding selection bias on the basis of study quality.

Using these studies, pooled estimates of outcome of HCCs expressing AFP were derived. Although our results showed that estimates of the significance of AFP response varied substantially between studies, these results support the notion that in the HCC patients who underwent systemic treatment and locoregional therapy, AFP response is predictive for better overall survival, with a pooled HR of 0.55 (95%CI, 0.47-0.65). In the HCC patients, AFP response had prognostic significance, whether it was defined by 50% decline of its initial level or 20% decline. This latter result, however, contradicted our supposition that greater AFP response should be associated with better survival, which was probably due to the individual differences from different clinical trials, and the small number of contributing studies. AFP response also seems to predict better PFS, with a pooled HR of 0.50 (95%CI, 0.38-0.65). However, this result should be interpreted with caution considering the small number of contributing studies. Our findings suggest that AFP response has a strong correlation with radiological response. When compared with the AFP nonresponse group, there were significant trends toward higher overall response rates (RR, 0.67; 95%CI, 0.61-0.75) and disease control rates (RR, 0.37; 95%CI, 0.23-0.58) in the AFP response group.

Although our results showed that HCCs expressing AFP response to treatment seem to be associated with a better prognosis, one caveat to this conclusion is publication bias, which is a major concern in all forms of meta-analysis, as smaller studies showing no statistically significant effects are more likely to remain unpublished^[39,40]. Indeed, it is not unusual for small, early studies to report a positive relationship or large effect that subsequent much larger studies fail to replicate. In the present study, there was some evidence for publication bias in the AFP response, and the risks calculated in our meta-analysis could be overestimates as a result of publication and reporting bias^[41]. Furthermore, advanced tumors were over-represented in the studies, given that they constituted approximately 64% of all HCC.

Heterogeneity between studies may represent a further potential source of bias in our analysis. The importance of heterogeneity between studies on summary estimates of HRs was carefully assessed. Although no attempt was made in our meta-analysis to quality-score reports^[42,43], it is clear that the design of some studies is not optimal.

The larger study by Vora *et al.*^[29] showed less of an effect of AFP response on prognosis, probably due to the great heterogeneity produced by the HCC patients selected from the different clinical trials. Through sensitivity analysis, we found that this study was the main source of the heterogeneity in this meta-analysis, and after the exclusion of this study, the HR estimate decreased to 0.40 (95%CI, 0.33-0.49), as did heterogeneity ($I^2 = 0$, $P = 0.91$).

Here we describe substantial inconsistency of results on the effectiveness of AFP response to predict survival of HCC. The main factors we identified as responsible for these findings are: long periods of patient recruitment, which leads to heterogeneity within a study because treatment of HCC has evolved over the course of the study; selection bias of patients because of different treatment clinical trials included, suggesting that AFP might be sensitive to some kinds of therapies but not to others; and the absence of a uniform definition of positive AFP response, leading to different results when using different cut-off points. Moreover, variability in the length of follow-up used to detect the events of interest also hampers comparability between studies since risk of survival is time-dependent. Inconsistency in the inclusion of clinical and pathological factors predicting survival mortality as covariables in multivariate analysis could be an additional contributing factor^[41].

Notwithstanding this, the studies pooled in this meta-analysis provide data on 974 HCC cases and support the opinion that AFP response to treatment is a determinant of prognosis in HCC. However, multicenter prospective studies that are better designed, with assessors blinded to the clinical data, and homogeneous HCC cohorts analyzed prospectively, are required to unequivocally assess the precise prognostic effect of AFP response in the HCC. In addition, most studies have empirically defined a 50% drop or 20% drop as an AFP response, while it has to be validated critically in future prospective series.

COMMENTS

Background

Conventionally, the treatment response of hepatocellular carcinoma (HCC) to systemic therapy or other nonsurgical treatment modalities is assessed by radiologic imaging using conventional criteria, such as World Health Organization criteria or Response Evaluation Criteria in Solid Tumors. However, despite successful clinical correlations for other solid tumors, these radiological response-based criteria have been criticized for not adequately reflecting treatment response and tumor viability for HCC.

Research frontiers

In the half century after α -fetoprotein (AFP) was first described, it was extensively studied as a screening and diagnostic tool for HCC. Although there have been some early observational studies that suggested that AFP trend might be

useful in assessing treatment response, until recently, there has been no clinical study to validate the significance of serial AFP monitoring in association with treatment response of HCC.

Innovations and breakthroughs

This is the first attempt to systemically review the prognostic value of AFP response world wide. A total of 11 articles and 974 cases of HCC patients were collected from the international literature and evaluated for clinical and biochemical features such as AFP response. This study results revealed that AFP response was associated with a decreased mortality across HCC in overall survival and progression-free survival, respectively. As to radiological imaging, when compared with the AFP nonresponse patients, there were significant trends toward higher overall response rates and disease control rates in the AFP response patients.

Applications

The study results suggest that the AFP is a potentially monitoring serum index and the AFP response to treatment could be used for monitoring treatment efficacy and determining the prognosis of HCC patients. In addition, the results demonstrate that AFP could also make up for the drawbacks of imaging and is able to aid radiological tools in the monitoring of prognosis and treatment.

Terminology

AFP, which is a glycoprotein that is secreted into the serum of approximately 70% of patients with HCC, has potential values in monitoring of prognosis and treatment for HCC. AFP response, that AFP level would reduce during treatment of HCC patients, was defined as 20% or 50% decline of the initial level by most studies.

Peer review

The authors provide results of a meta-analysis, with this manuscript, on level changes of circulating AFP in HCC patients receiving local and systemic therapies, and gave some reasonable comments and proposals for further validation of the results from literature. The analysis is of importance for prognosis assessment and evaluation of different therapies. A multi-center study is needed for further confirmation.

Abstract

AIM: To investigate the relationship between c.343A>G and c.2216A>C polymorphism sites in the *CDH17* gene and colorectal carcinoma.

METHODS: Ninety-three non-consanguineous colorectal carcinoma patients admitted to the Department of Oncology at the First Affiliated Hospital of Zhengzhou University were included in this study. Ninety-three peripheral venous blood samples, of approximately one milliliter from each patient, were collected between

December 2009 and August 2010. The genomic DNA of these peripheral venous blood samples were extracted and purified using a Fermentas Genomic DNA Purification Kit (Fermentas, CA) according to the manufacturer's protocol. The single nucleotide polymorphisms (SNPs) of the liver-intestine cadherin (*CDH17*) gene c.343A>G and c.2216A>C were determined by the polymerase chain reaction-single strand conformation polymorphism method (PCR-SSCP) in 93 peripheral venous blood samples from patients suffering with colorectal carcinoma. Typical samples that showed different migration bands in SSCP were confirmed by sequencing. Directed DNA sequencing was used to check the correctness of the genotype results from the PCR-SSCP method.

RESULTS: There was a significant association between the c.2216 A>C SNPs of the *CDH17* gene and the tumor-node-metastasis (TNM) grade, as well as with lymph node status, in 93 peripheral venous blood samples from colorectal carcinoma patients. The genotype frequencies of A/C, A/A, and C/C were 12.90%, 33.33% and 53.76%, respectively. There was a significant correlation between lymph node metastasis, TNM grade, and the genotype distribution ($P < 0.05$). The C/C genotype raised the risk of lymph node metastasis and the TNM grade. There was a significant difference in the TNM grade and lymph node metastasis between the A/A and C/C genotypes ($P = 0.003$ and $P = 0.013$, respectively). Patients with colorectal carcinoma carrying the C allele tended to have a higher risk of lymph node metastasis and have a higher TNM grade. The difference between the TNM grades, as well as the lymph node metastasis of the two alleles, was statistically significant ($P < 0.01$).

CONCLUSION: The SNPs of the *CDH17* gene c.2216 A>C might be clinically important in the prognosis of colorectal carcinoma.

INTRODUCTION

Colorectal carcinoma (CRC) has traditionally been one of the four cancers with the highest mortality worldwide, but the incidence was relatively low historically in Asian populations. However, the prevalence of colorectal neoplasms has increased by 2- to 4-fold in some developed Asian countries, including China, Japan, South Korea and Singapore in the past few decades, due to changes in dietary habits and lifestyle, as well as certain genetic factors of Asian populations^[1]. The etiology of CRC is multifactor, involving hereditary causes, environmental factors, and somatogenic changes occurring during tumor progression. At present, the assured mechanism of the occurrence and development of colorectal carcinoma is still unknown. While several aspects of colorectal carcinoma have been investigated, CRCs can be parsimoniously subdivided into two major groups defined by the genetic pathways involved^[2]. Its correlation with single nucleotide polymorphisms (SNPs) remains largely unknown.

SNPs are the most common type of genomic sequence variation^[3], and are thought to be associated with population diversity, susceptibility to disease, and individual response to drug treatments. Many SNPs are silent, with no direct effect on the gene products but, by virtue of the linkage disequilibrium existing across the human genome, they can still be used as genetic markers to locate adjacent functional variants that contribute to diseases. Foreseeable common SNP discoveries may not permit the identification of the small subset of patients that contain most cancers^[4]. SNPs may also have functional consequences if they directly affect the coding or regulatory (usually promoter) regions of a gene. There have been cumulative studies on the associations between cancer risk and SNPs in selected candidate genes; to date, numerous SNPs associated with susceptibility to both cancer types have been identified, but their effect on disease risk may differ among populations^[5], and such information may shed light on the molecular and genetic basis of the polygenic nature of cancer. These SNPs may be used as surrogate biomarkers of the genetic background of CRC patients, to predict therapeutic response and prognosis^[6].

The *CDH17* gene is a member of the cadherin superfamily; genes encoding calcium-dependent, membrane-associated glycoproteins. The human *CDH17* gene located on chromosome 8q22.1 has eighteen exons and encodes liver-intestine cadherin (LI-cadherin) protein (also known as cadherin-17). LI-cadherin is a structurally unique member of the cadherin superfamily^[7]. In contrast to classic cadherins, such as E- and N-cadherin, the extracellular domain of LI-cadherin consists of seven, instead of the usual five, structurally defined cadherin repeats. Its cytoplasmic domain is also small, comprising only 20 amino acids without a β -catenin binding region, and exhibits no homology with the corresponding region of classic cadherins, which consists of 150-160 amino acids. LI-cadherin is also known to possess biological functions distinct from classic cadherins. The adhesive function of LI-cadherin is independent of any interaction with cytoplasmic components, such as catenins or the actin cytoskeleton, although in E-cadherin this function crucially depends on the formation of a cadherin-catenin complex and anchorage to the actin cytoskeleton^[8,9]. The mechanism responsible for the regulation and function of this cadherin has been elucidated. Expression of LI-cadherin has been reported in gastric adenocarcinoma of the intestinal type and colorectal carcinoma^[10,11]. In colorectal carcinoma, LI-cadherin expression has been reported in well-differentiated carcinoma, but not in poorly-differentiated carcinoma. It has been found that reduced expression of LI-cadherin is closely associated with tumor progression and lymph node metastasis of human colorectal carcinoma^[12]. However, the detailed clinicopathologic significance of LI-cadherin has not been elucidated.

In this study, through a PubMed, Embase, Google Scholar, CBMdisc and CNKI SNPs search, we found that for the *CDH17* gene c.343A>G and c.2216A>C, the SNPs gene phenotype is A/G and the gene frequency phenotype is about 50%. We detected the SNPs of the *CDH17* gene c.343A>G and c.2216A>C by polymerase chain reaction-single strand conformation polymorphism method (PCR-SSCP), and directed sequencing in colorectal carcinoma patients. We then analyzed the distribution frequencies of the genotypes and alleles of the two polymorphism sites. To evaluate the role of *CDH17* gene polymorphisms in colorectal tumor aggressiveness, the associations between genotype and clinicopathologic parameters were also analyzed.

MATERIALS AND METHODS

Patients, blood sample source and storage

Ninety-three patients undergoing curative surgery for colorectal cancer at the First Affiliated Hospital of Zhengzhou University were included in this study after giving their informed consent. Peripheral blood samples were collected in ethylenediaminetetraacetic acid-containing tubes between December 2009 and August 2010 from these patients. All samples were immediately placed in refrigeratory conditions and stored at 4 °C until they could

be further processed.

DNA isolation

Genomic DNA was extracted using a Fermentas Genomic DNA Purification Kit (Fermentas, CA) according to the manufacturer's protocol. The amount of isolated DNA was determined spectrophotometrically.

Primer synthesis

Primer sequences for the *CDH17* gene c.343A>G and c.2216A>C were synthesized by Shanghai Sangon Biological Engineering Technology and Services Co. Ltd (Table 1).

PCR-SSCP analysis and sequencing of the *CDH17* gene c.343A>G and c.2216A>C

The fragments encompassing the *CDH17* gene c.343A>G and c.2216A>C were amplified by PCR. The twenty microlitre PCR amplification reaction system contained < 1 µg template DNA, 10 µL of 2 × Taq PCR Master Mix [Tiangen Biotech (Beijing) Co., Ltd.], 0.4 µL of forward and reverse primers (10 µmol/L), and 3.2 µL of double distilled water. PCR reaction conditions were as follows: initial denaturation at 94 °C for 5 min, followed by 35 cycles of denaturation at 94 °C for 30 s, annealing for 30 s and extension at 72 °C for 1 min, and a final extension at 72 °C for 10 min, with preservation being carried out at 4 °C. After 2.0% agarose gel electrophoresis (containing Evans blue dye), PCR products were observed by a gel imaging instrument. Fragment sizes of PCR products were 159 bp and 198 bp, respectively, and indicated with DL100 DNA Marker.

The amplified products were denatured in 95% formamide at 95 °C for 10 min, and analyzed on 12% polyacrylamide gels at 160 V for 15 min and 30 V for 6-8 h in 1 × Tris-Borate-EDTA buffer at normal body temperature. A modified silver staining method was applied for visualization. Briefly, the gels were soaked in 10% ethanol and 0.5% acetic acid for 10 min, then transferred to 0.2% AgNO₃ solution for 10 min and washed with distilled water three times. The staining reaction was developed with the use of 3% NaOH and 0.25% formaldehyde, and the gels were fixed in 10% ethanol and 0.5% acetic acid. Staining reactions were promoted by gentle shaking.

The detection of SSCP analysis was performed. Samples showing an altered mobility pattern were then subjected to sequencing analysis by Shanghai Sangon Biological Engineering Technology and Services Co. Ltd.

Statistical analysis

Statistical analysis was performed using SPSS for Windows version 17.0. Differences in allele and genotype frequencies were evaluated by the χ^2 or Fisher exact test. We used logistic regression models to calculate χ^2 tests for genotypic and allelic association and odds ratios (OR) with their 95%CI. Association between each of the SNPs and clinicopathological parameters was assessed using the χ^2 test. To study correlation between clinical parameters and genotypes of the *CDH17* gene c.343A>G and c.2216A>C polymorphisms in multivariate mode we used binary logistic regression, with each parameter as a dependent variable, and genotypes of the two studied SNPs together with other clinical parameters as independent variables. Differences in ordered categorical data were evaluated for significance with the rank sum test; the mean ranks were used to express risk degree. The Holm-Bonferroni method was used for multiple comparisons. A *P* value of ≤ 0.05 was considered statistically significant.

RESULTS

Clinicopathologic parameters in colorectal carcinomas

The characteristics of 93 patients with colorectal carcinoma are given in Tables 2 and 3. Of the 93 patients, 49% (46/93) were female and 51% (47/93) were male. The mean age of the female patients (the mean \pm SD deviation was 56.41 \pm 14.91 years) did not differ significantly from that of the males (the mean \pm SD deviation was 58.19 \pm 11.60 years).

PCR products of *CDH17*

The PCR-SSCP analysis generated two fragments as expected; 159bp for c.343A>G, and 198bp for c.2216A>C (Figure 1).

The correlation between the genotype of the *CDH17* gene c.343A>G and clinicopathologic parameters in colorectal carcinomas

The genotype of the *CDH17* gene c.343A>G: The genotype frequencies of the *CDH17* gene c.343A>G A/A, A/G, and G/G were 27.96% (26/93), 47.31% (44/93), and 24.73% (23/93), respectively. The frequencies of the A allele and G allele were 51.61% and 48.39%, respectively.

The correlation between the genotype of the *CDH17* gene c.343A>G and clinicopathologic parameters: There were no significant differences in gender, age, tu-

Services Co. Ltd (Figure 2).

The correlation between the genotype of the *CDH17* gene c.343A>G and lymph node metastasis: The results of logistic regression analysis are shown in Table 4, and indicate that the G/G genotype of the *CDH17* gene c.343A>G raised the risk of lymph node metastasis (OR of genotype G/G, genotype A/A to genotype A/G were 7.292 and 2.431, respectively). The results of multiple comparisons by the Holm-Bonferroni method ($\alpha' = 0.017$) were as follows: *P* value was 0.102 when genotype A/A was compared with genotype A/G; *P* value was 0.062 when genotype A/A was compared with genotype G/G; *P* value was 0.000 when genotype A/G was compared with genotype G/G. This indicates that there was a significant difference in lymph node metastasis between the A/G and G/G genotypes.

The *CDH17* gene c.343A>G site allele G raised the risk of lymph node metastasis (OR of allele G to allele

TNM: Tumor-node-metastasis.

The correlation between the genotype of the *CDH17* gene c.343A>G and TNM grade: The results of the Kruskal-Wallis test are shown in Table 5. It revealed that the *CDH17* gene c.343A>G genotype G/G raised the risk of TNM grade (the mean ranks of A/G, A/A and G/G genotype were 39.32, 48.15 and 60.39, respectively). The results of multiple comparisons by the Holm-Bonferroni method ($\alpha' = 0.017$) were as follows: *P* value was 0.197 when genotype A/A was compared with genotype A/G; *P* value was 0.127 when genotype A/A was compared with genotype G/G; *P* value was 0.001 when genotype A/G was compared with genotype G/G. This suggests that there was a significant difference in TNM grade between the A/G and G/G genotypes.

The correlation between the genotype of *CDH17* gene c.2216A>C and clinicopathologic parameters in colorectal carcinomas

The genotype of the *CDH17* gene c.2216A>C: The genotype frequencies of the *CDH17* gene c.2216A>C A/C, A/A, and C/C were 12.90% (12/93), 33.33% (31/93), and 53.76% (50/93), respectively. The frequencies of the A allele and C allele were 39.78% and 60.22%, respectively.

The allele G raised the risk of TNM grade (the mean ranks of allele A and allele G were 87.71 and 99.68, respectively) (Table 5). However, the Kruskal-Wallis test showed that the difference between the TNM grade of the two alleles was not statistically significant ($H = 2.561$; $df = 1$; $P = 0.110$).

The correlation between the genotype of the *CDH17* gene c.2216A>C and clinicopathologic parameters: There was no significant difference in gender, age, tumor location, macroscopic appearance, histologic type, invasion depth, differentiation, hematogenous metastasis, or recurrence among the three genotypes of the *CDH17* gene c.2216A>C ($P > 0.05$). However, there was a significant correlation between tumor size, lymph node metastasis, and TNM grade, and its genotype frequencies ($P < 0.05$) (Table 3).

The correlation between the genotype of the *CDH17* gene c.2216A>C and tumor size: The results of the χ^2

Table 6 The correlation between the genotype and allele frequency of *CDH17* gene c.2216A>C and lymph node metastasis *n* (%)

	Lymph node metastasis		OR (95%CI)
	No	Yes	
Genotype			
A/C	10 (16.9)	2 (5.9)	1.000 (reference)
A/A	25 (42.4)	6 (17.6)	1.200 (0.206-6.977)
C/C	24 (40.7)	26 (76.5)	5.417 (1.076-27.272)
Allele frequency			
A	60 (50.8)	14 (20.6)	1.000 (reference)

test indicate that there was a significant correlation between tumor size and the genotype of the *CDH17* gene c.2216A>C. However, the results of multiple comparisons by the Holm-Bonferroni method ($\alpha' = 0.017$) suggest that there was no significant difference in tumor size between any of its genotypes (*P* value was 0.018 when genotype A/A was compared with genotype A/C; *P* value was 0.625 when genotype A/A was compared with genotype C/C; *P* value was 0.027 when genotype A/C was compared with genotype C/C).

The correlation between the genotype of the *CDH17* gene c.2216A>C and lymph node metastasis: The results of logistic regression analysis are shown in Table 6, and indicate that the C/C genotype of the *CDH17* gene c.2216A>C raised the risk of lymph node metastasis (OR of genotype C/C, genotype A/A to genotype A/C were 5.417 and 1.200, respectively). The results of multiple comparisons by the Holm-Bonferroni method ($\alpha' = 0.017$) were as follows: *P* value was 0.067 when genotype A/A was compared with genotype A/C; *P* value was 0.003 when genotype A/A was compared with genotype C/C; *P* value was 0.027 when genotype A/C was compared with genotype C/C. This indicates that there was a significant difference in lymph node metastasis between the A/A and C/C genotypes.

CDH17 gene c.2216A>C site allele C raised the risk of lymph node metastasis (OR of allele C to allele A was 3.990) (Table 6). The χ^2 test showed that the difference between the lymph node metastasis of the two alleles was statistically significant ($\chi^2 = 16.488$; $df = 1$; $P = 0.000$).

The correlation between the genotype of the *CDH17* gene c.2216A>C and TNM grade: The results of the Kruskal-Wallis test are shown in Table 7, and reveal that the *CDH17* gene c.2216A>C genotype C/C raised the risk of TNM grade (the mean ranks of the A/A, A/C, and C/C genotype were 38.77, 42.00 and 53.30, respectively). The results of multiple comparisons by the Holm-Bonferroni method ($\alpha' = 0.017$) were as follows: *P* value was 0.718 when genotype A/A was compared with genotype A/C; *P* value was 0.013 when genotype A/A was compared with genotype C/C; *P* value was 0.168 when genotype A/C was compared with genotype C/C. This

TNM: Tumor-node-metastasis.

suggests that there was a significant difference in TNM grade between the A/A and C/C genotypes.

The Kruskal-Wallis test showed that allele C raised the risk of TNM grade (the mean ranks of allele A and allele C were 78.09 and 103.68, respectively) (Table 7). The difference between the TNM grade of the two alleles was statistically significant ($H = 11.225$; $df = 1$; $P = 0.001$).

DISCUSSION

CDH17 is a marker for the diagnosis of adenocarcinomas of the digestive system

Cancer is a complex disease where genetic mutations, rearrangement, deletions, or gene polymorphisms may affect not only cancer development, but also cancer progression and, as a result, could influence cancer phenotypes^[13,14]. The *CDH17* gene is located on chromosome 8q22.1 and encodes LI-cadherin. LI-cadherin, belonging to a subclass of the 7D-cadherin superfamily, is present in the fetal liver and gastrointestinal tract during embryogenesis, but the gene becomes silenced in healthy adult liver and stomach tissues. It functions as a peptide transporter and cell adhesion molecule to maintain tissue integrity in epithelia. However, recent findings have reported aberrant expression of LI-cadherin in major gastrointestinal malignancies, including hepatocellular carcinoma (HCC), stomach and colorectal cancers, and its clinical association with tumor metastasis and advanced tumor stages^[15,16]. LI-cadherin manifests distinct and unique roles in tumorigenesis originating from different organs. In the epithelium of the healthy human stomach, the level of LI-cadherin expression is negligible, whereas an overexpression of this molecule is observed frequently in gastric carcinoma^[17-19]. When the transcriptome of gastric cancer was studied by serial analysis of gene expression, LI-cadherin was found associating with an intestinal type of gastric cancer^[20]. In addition, high tumoral LI-cadherin levels tend to correlate with advanced stages of gastric cancer, and are associated with a poor prognosis and lymph node metastasis^[21,22]. That silencing LI-cadherin has positive actions in the processes of LoVo cell invasion and metastasis, and the interactions among matrix metalloproteinase (MMP)-2, MMP-9, and

LI-cadherin, participates in the multiple steps of invasion and metastasis in LoVo colorectal cancer cells^[23].

This observation was further supported by a study using high density DNA microarrays to identify differentially-expressed genes in advanced stages of gastric cancer, in which an upregulation of *CDH17* was found among genes associated with cell adhesion, cell cycle, cellular motility, and DNA synthesis^[24]. Unlike normal gastric tissues, LI-cadherin is found scattered throughout the healthy human pancreas. Less LI-cadherin is expressed in poorly-differentiated tumor tissues of ductal adenocarcinoma of the pancreas, and this low level of LI-cadherin is correlated with advanced stages of the cancer. When LI-cadherin is used as a prognostic biomarker, the survival time is longer for those patients with LI-cadherin-positive tumors when compared with those having LI-cadherin-negative tumors^[25]. In the midst of identifying new target for HCC detection and treatment, LI-cadherin is likely an attractive candidate^[26]. The elevated level of LI-cadherin in tumors is correlated to high serum alpha-fetoprotein level, tumor invasion, and advanced stage tumor, associating with poor prognosis, of HCC patients. For primary colorectal carcinoma, the expression of LI-cadherin is diminished in tumor tissues. Clinically, this low level of LI-cadherin is correlated to dedifferentiation of tumors, tumor invasion, and late tumor stages. However, significant differences in the survival of cancer patients have not been found, irrespective of whether the expressions of LI-cadherin are low or high. In addition, a negligible level of LI-cadherin has been documented in several colorectal cancer cell lines when compared with those in normal colonic mucosal cells^[27]. This observation is further supported by a separate study showing a reduced expression of LI-cadherin in cancer tissues and such expression was correlated with dedifferentiation of tumors and poor survival of patients^[28]. But Gröne *et al.*^[29] study showed *CDH17* protein and gene expression analyses do not support application of molecular classifiers for prediction of clinical outcome in current routine diagnostic as a basis for patient-orientated therapy in stage Union for International Cancer Control II colon cancer. Further studies are needed to develop prognosis signatures applicable in patient care. Despite these findings, LI-cadherin was found present in colorectal adenocarcinoma in a separate study^[30].

The SNPs in c.343A>C and c.2216A>C polymorphism sites of *CDH17* gene

In this study we investigated the SNPs in c.343A>C and c.2216A>C polymorphism sites of *CDH17* gene and the associations between genotype of them and clinicopathologic parameters were also analyzed to evaluate the role of SNPs in colorectal tumor aggressiveness. The possibility that different genetic polymorphisms in the *CDH17* gene may regulate, at least in part, LI-cadherin expression and/or activity, is an attractive hypothesis that may help to identify patients who are susceptible to

colorectal carcinoma.

There have been many studies on the associations between cancer risk and SNPs. But the associations between *CDH17* gene SNPs in c.343A>C and c.2216A>C polymorphism sites and colorectal carcinoma risk have not been reported.

The missense substitution (c.343A>G) mapped

In our study, the first missense substitution (c.343A>G) mapped to the amino acid position 115 and was responsible for the amino acid change of 115 Glu with Lys. The genotype frequencies of A/A, A/G and G/G were 27.96%, 47.31% and 24.73%, respectively. The frequencies of the A allele and G allele were 51.61% and 48.39%, respectively. According to the SNP database (rs2243518), the frequency of the G allele in our population is lower than that in Europeans (84.2%). In comparison, its reported frequency in Sub-Saharan African and Asians is 95.8% and 56.7%, respectively. There were no significant difference in gender, age, tumor location, tumor size, macroscopic appearance, histologic type, invasion depth, differentiation, hematogenous metastasis, and recurrence among the genotype distribution ($P > 0.05$). But we found a significant correlation between the genotype distribution and lymph node metastasis and TNM grade ($P < 0.05$). The results of logistic regression analysis indicate that the G/G genotype raised risk of lymph node metastasis (OR of genotype G/G, genotype A/A to genotype A/G were 7.292 and 2.431, respectively). The results of multiple comparison by Holm-Bonferroni ($\alpha' = 0.017$) indicate that there was a significant difference in lymph node metastasis between the A/G and G/G genotypes ($P = 0.000$). And patients with colorectal carcinoma carrying the G allele tended to have a higher risk of lymph node metastasis (OR of allele G to allele A was 1.767). But χ^2 test showed that the difference between the lymph node metastasis of two alleles was not statistically significant ($\chi^2 = 3.450$; $df = 1$; $P = 0.063$). In addition, the results of Kruskal-Wallis revealed that the genotype G/G raised risk of TNM grade (the mean ranks of A/G, A/A and G/G genotype were 39.32, 48.15 and 60.39, respectively). And the results of multiple comparison by Bonferroni ($\alpha' = 0.017$) suggest that there was a significant difference in TNM grade between the A/G and G/G genotypes ($P = 0.001$). Patients with colorectal carcinoma carrying the G allele tended to have a higher TNM grade (the mean ranks of allele A and allele G were 87.71 and 99.68, respectively). But the Kruskal-Wallis test showed that the difference between the TNM grade of two alleles was not statistically significant ($H = 2.561$; $df = 1$; $P = 0.110$).

SNP (c.2216A>C) mapped to the amino acid

The second SNP we investigate here (c.2216A>C) mapped to the amino acid position 739 and was responsible for the amino acid change of 739 Ala with Glu. The genotype frequencies of A/C, A/A and C/C were

12.90%, 33.33% and 53.76%, respectively. The frequencies of the A allele and C allele were 39.78% and 60.22%, respectively. According to the SNP database (rs1051624), the frequency of the C allele in our population is higher than that in Europeans (58.3%). In comparison, its reported frequency in African-American and Asians is 23.9% and 58.3%, respectively. There were no significant difference in gender, age, tumor location, macroscopic appearance, histologic type, invasion depth, differentiation, hematogenous metastasis, and recurrence among the genotype distribution ($P > 0.05$). But there were a significant correlation between tumor size, lymph node metastasis and TNM grade and the genotype distribution ($P < 0.05$). Firstly, the results of χ^2 test indicate that there was a significant correlation between tumor size and the genotype distribution. But the results of multiple comparison by Holm-Bonferroni ($\alpha' = 0.017$) suggest that there were no significant difference in tumor size between any two genotypes ($P > 0.017$). But Kwak *et al.*^[31] study showed that reduced expression of liver intestine-cadherin had a significant correlation with tumoral dedifferentiation and short overall survival in this series. In addition, early and frequent loss of liver intestine-cadherin expression might be a more sensitive indicator than E-cadherin to predict more aggressive tumoral behavior. Secondly, the results of logistic regression analysis indicate that the C/C genotype raised risk of lymph node metastasis (OR of genotype C/C, genotype A/A to genotype A/C were 5.417 and 1.200, respectively). And the results of multiple comparison by Holm-Bonferroni ($\alpha' = 0.017$) indicate that there was a significant difference in lymph node metastasis between the A/A and C/C genotype ($P = 0.003$). And patients with colorectal carcinoma carrying the C allele tended to have a higher risk of lymph node metastasis (OR of allele C to allele A was 3.990). The χ^2 test showed that the difference between the lymph node metastasis of two alleles was statistically significant ($\chi^2 = 16.488$; $df = 1$; $P = 0.000$). Lastly, the results of Kruskal-Wallis test revealed that genotype C/C raised risk of TNM grade (the mean ranks of A/A, A/C and C/C genotype were 38.77, 42.00 and 53.30, respectively). And the results of multiple comparison by Holm-Bonferroni ($\alpha' = 0.017$) suggest that there was a significant difference in TNM grade between the A/A and C/C genotypes ($P = 0.013$). Patients with colorectal carcinoma carrying the C allele tended to have a higher TNM grade (the mean ranks of allele A and allele C were 78.09 and 103.68, respectively). And the difference between the TNM grade of two alleles was statistically significant ($H = 11.225$; $df = 1$; $P = 0.001$). SNPs of the *CDH17* gene c.2216A>C and lymph node metastasis deserve further consideration in future studies as a clinical indicator during presurgical evaluation. And we found here patients with colorectal carcinoma carrying the C allele tended to have a higher TNM grade. This suggests that this SNPs would be a good predictor of lymph node status and TNM grade prior to surgical intervention and thereby provides an indicator for deciding

whether chemotherapy should be given or not.

***CDH17* mRNA is alternatively spliced to produce two variant transcripts**

It has been reported^[32] that *CDH17* mRNA is alternatively spliced to produce at least two variant transcripts, one of which was with exon 7 skipping and another with both exon 6 and exon 7 skipped. The consequences of both splicing patterns would introduce premature translational stop codon in the reading frame, thereby producing either nonfunctional protein or potentially dominant negative protein. And *CDH17* aberrant splicing was highly associated with tumor dissemination and shorter survival of HCC patients. It has been showed that aberrant mRNA splicing of the *CDH17* gene in liver tissues was triggered by the specific constellation of two *CDH17* single nucleotide polymorphisms (651T and IVS6 + 35G). And the functional T-G haplotype of *CDH17* (651C>T and IVS6 + 35A>G) is a genetic susceptibility factor for the development of HCC in a Chinese population^[33]. *CDH17* becomes an attractive target for HCC therapy^[16]. And it has been proposed that LI-cadherin is a useful immunohistochemical marker for diagnosis of adenocarcinomas of the digestive system^[25] and *CDH17* may be an oncogene up-regulating invasive feature of gastric cancer cells and could be a hopeful target for the control of gastric cancer progression^[34]. Moreover, it has been revealed that LI-cadherin participates in the multiple steps of invasion and metastasis in LoVo colorectal cancer cells^[35,36]. In our study we investigated the SNPs in c.343A>C and c.2216A>C polymorphism sites of *CDH17* gene. The c.343A>G polymorphism site mapped to the amino acid position 115 and was responsible for the amino acid change of 115 Glu with Lys. The c.2216A>C polymorphism site mapped to the amino acid position 739 and was responsible for the amino acid change of 739 Ala with Glu. We found that patients with colorectal carcinoma carrying the C allele of c.2216A>C tended to have a higher risk of lymph node metastasis and a higher TNM grade. The reason is possible that the SNPs of the c.2216A>C cause the amino acid change and result in the LI-cadherin expression and/or activity changes. The polymorphism of c.343A>G also causes the amino acid change. But there is no significant difference between c.343A>G SNPs and TNM grade as well as lymph node metastasis between the A and G alleles. It is possibly because that the *CDH17* mRNA is spliced with the polymorphism site skipped (exon 6).

A significant association was found between c.2216A>C SNPs of *CDH17* gene (rs1051624) and TNM grade as well as with lymph node status

In summary, in a Chinese Han colorectal carcinoma patient population of Henan province, a significant association was found between c.2216A>C SNPs of *CDH17* gene (rs1051624) and TNM grade as well as with lymph node status. With logistic regression analysis a correlation

between TNM grades as well as with lymph node metastasis and C/C genotype of *CDH17* gene c.2216A>C was found. And patients with colorectal carcinoma carrying the C allele tended to have a higher risk of lymph node metastasis and a higher TNM grade, suggesting that this polymorphism might be clinically important in prognosis. Validation and functional studies are needed to assess the significance of these associations in clinical practice.

ACKNOWLEDGMENTS

We thank Yuan-Ting Gu for their wisdom and guidance in the retrieval and evaluation of these samples, and Shui-Jun Zhang, Shao-Min Zhang for assistance with acquisition of historical reference. This paper is written in tribute to professor Sugimura and with respect to other former faculty members and staff in the department of pathology at the First Affiliated Hospital of Zhengzhou University for the care and preservation of records and tissue samples from the pre-intensivist era. We particularly thank Dond-Ling Gao who worked on the technical aspects of tissue retrieval and preparation.

COMMENTS

Background

Colorectal carcinoma (CRC) has been the fourth place of common cancer incidence rate in the China. The etiology of CRC is multifactorial, involving hereditary causes, environmental factors, and somatogenic changes occurring during tumor progression. The single nucleotide polymorphisms (SNPs), as the third generation of heredity markers, are the most common type of genomic sequence variations, which are thought to be associated with population diversity, susceptibility to diseases, and individual response to drug treatments. It has become one of the hot spots in research. There have been cumulative studies on the associations between disease risk and SNPs in selected candidate genes. *CDH17* gene, also known as cadherin-17 and liver-intestine cadherin (LI-cadherin), is a member of the cadherin superfamily, genes encoding calcium-dependent, membrane-associated glycoproteins. The human *CDH17* gene located on chromosome 8q22.1 has eighteen exons and encodes LI-cadherin protein. There has been found that reduced expression of LI-cadherin protein is closely associated with tumor progression and lymph node metastasis of human colorectal carcinoma.

Research frontiers

At present, the research of relation between *CDH17* gene SNPs and diseases are relatively less at home and abroad. In this study, authors detected the genotype of the *CDH17* gene c.343A>G and c.2216A>C SNPs sites by the polymerase chain reaction-single strand conformation polymorphism and directed DNA sequencing in ninety-three colorectal carcinoma patients. The objective of this study is to analyze the phenotype and distribution frequencies of genotype and allele of the *CDH17* gene c.343A>G and c.2216A>C polymorphism sites and to evaluate the correlation between the two polymorphism sites of *CDH17* gene and tumor occurrence and development as well as clinicopathologic parameters of colorectal carcinoma.

Innovations and breakthroughs

There were no significant difference in gender, age, tumor location, tumor size, macroscopic appearance, histologic type, invasion depth, differentiation, hematogenous metastasis, and recurrence among the genotypes of *CDH17* gene c.343A>G. But there were a significant correlation between lymph node metastasis and Tumor-node-metastasis (TNM) grade and the genotype frequencies of it. Colorectal carcinoma patients carrying the G/G genotype have a higher risk of lymph node metastasis and a higher TNM grade compared with those carrying A/G genotype. There were no significant difference in gender, age, tumor location, tumor size, macroscopic appearance, histologic type, invasion

depth, differentiation, hematogenous metastasis, and recurrence among the genotypes of *CDH17* gene c.2216A>C. But there were a significant correlation between lymph node metastasis and TNM grade and the genotype frequencies of it. The C/C genotype and C allele of this SNPs site might be a risk factor for a higher risk of lymph node metastasis and a higher TNM grade of colorectal carcinoma patient.

Applications

The SNPs of *CDH17* gene c.2216 A>C might be clinically important in prognosis of colorectal carcinoma.

Peer review

The study analyzed polymorphisms of *CDH17* gene in blood samples collected from 93 colorectal carcinoma patients and found a strong association between c.2216A>C and TNM grade of the cancer, suggesting a potential value of using this gene as a prognostic marker of colorectal carcinoma. This is an interesting study.

Abstract

AIM: To clarify the role of activated Notch2 in the invasiveness of gastric cancer.

METHODS: To investigate the invasiveness of silencing *Notch2* gene expression, we established a Notch2

small interfering RNA (siRNA) transfected cell line using the MKN-45 gastric cancer cell line. After the successful transfection confirmed by real-time reverse transcription-polymerase chain reaction (RT-PCR) and Western blotting, migration and invasion assays were employed to evaluate the aggressiveness of the gastric cancer. RT-PCR and Western blottings were employed to confirm the down-regulation of Notch2 and to evaluate the expression of epithelial mesenchymal transition-related gene matrix metalloproteinase 9 (MMP9), Akt, p-Akt. To confirm the relationship between PI3K-Akt and MMP9, the PI3K inhibitor LY294002 was used to treat MKN-45 cells.

RESULTS: Notch2 expression was dramatically decreased after Notch2 siRNA transfection ($100.00\% \pm 9.74\%$ vs $11.61\% \pm 3.85\%$, $P < 0.01$ by qRT-PCR). There was also a marked reduction of Notch target gene *Hes1* ($100.00\% \pm 4.74\%$ vs $61.61\% \pm 3.58\%$, $P < 0.05$) at the mRNA, indicating an inhibition of Notch signaling. Inhibition of Notch signaling was also confirmed by the marked reduction of Notch2 intracellular domain at the protein levels ($100.00\% \pm 9.74\%$ vs $65.61\% \pm 7.58\%$, $P < 0.05$). Down-regulation of Notch2 by siRNA enhanced tumor cell invasion ($100.00\% \pm 21.64\%$ vs $162.22\% \pm 16.84\%$, $P < 0.05$) and expression of MMP9 (1.56 fold, $P < 0.05$), and activated the pro-MMP9 protein to its active form (1.48 fold, $P < 0.05$). There was no significant difference in the protein levels of Akt between the two groups ($100.00\% \pm 10.87\%$ vs $96.61\% \pm 7.33\%$, $P > 0.05$), while down-regulation of Notch2 elevated p-Akt expression ($100.00\% \pm 9.87\%$ vs $154.61\% \pm 13.10\%$, $P < 0.05$). Furthermore, p-Akt and MMP9 was down-regulated in response to the inhibitor LY294002 (p-Akt $100.00\% \pm 8.87\%$ vs $58.27\% \pm 5.01\%$, $P < 0.05$; MMP9 $100.00\% \pm 9.17\%$ vs $50.03\% \pm 4.88\%$, $P < 0.05$).

CONCLUSION: Notch2 may negatively regulate cell invasion by inhibiting the PI3K-Akt signaling pathway

in gastric cancer.

INTRODUCTION

Gastric carcinoma is one of the most common malignancies and one of the most important causes of the cancer-related death worldwide^[1]. Most of the current available therapeutic methods for advanced gastric cancer, such as chemotherapy and chemoembolization, are less optimal, thus the prognosis of gastric cancer is rather poor. This is largely attributed to a lack of complete understanding of the exact cause and mechanisms for this malignancy. Hence, identification of critical molecular pathways of gastric cancer development would greatly facilitate the development of more effective therapies.

Notch signaling pathway is involved in several cellular processes, such as proliferation, differentiation, apoptosis, cell fate decision, and maintenance of stem cells^[2-5]. It also plays an important role in the control of tumorigenesis. Activated Notch receptor can be oncogenic or tumor suppressive depending on the tumor type and cellular context^[6]. However, the mechanisms by which Notch signaling activates or suppresses tumorigenesis remain unclear. Recently, activation of Notch signaling pathway has been found to stimulate tumorigenesis *via* regulating epithelial mesenchymal transition (EMT)^[7].

EMT is a unique process by which epithelial cells undergo remarkable morphologic changes characterized by a transition from epithelial cobblestone phenotype to mesenchymal phenotype leading to increased motility and invasion^[4]. During the acquisition of EMT characteristics, epithelial cells lose cell-cell junction, which is associated with actin cytoskeleton reorganization, expression of proteins that promote cell-cell contact, and appearance of the expression of mesenchymal markers.

Recently, Notch signaling pathway was found to be involved in the acquisition of EMT in both physiological and pathological processes^[8]. However, how Notch signaling regulates EMT is largely unknown.

The Notch pathway includes a conserved family of transmembrane receptors (Notch1-4) that interact with a number of specific ligands (DLL1, DLL3, DLL4, Jagged1 and Jagged2) to regulate cell fate. Notch signaling initiates following the binding of the Notch ligands to the Notch receptors, causing an enzymatic cleavage of Notch receptors by γ -secretase to release the intracellular domain of the Notch receptor (NICD). NICD is the active form of Notch receptors which can translocate into the nucleus, where it assembles a large transcriptional activation complex that interacts with the conserved transcription factor CSL [CBF-1, Su (H) and Lag-2], and then activates the transcription of CSL-dependent downstream targets^[9]. Many target genes of Notch signaling have been identified in various cell contexts, but the Hairy/Enhancer of Split (Hes) family of basic helix-loop-helix (bHLH) proteins are believed to be the direct Notch targets, including Hes1 and Hey1. Among the Notch signaling genes, Notch2 appears to function as a biological antagonist for Notch1 in many cancers, such as breast cancer^[10], colorectal cancer^[11], malignant mesothelioma^[12], multiple myeloma^[13], and embryonal brain tumors^[14]. Although major advances have been made in the understanding of the opposite effects of Notch2 and Notch1 in cancer development, the exact molecular mechanisms underlying a biological interaction between Notch1 and Notch2 remain unclear, and few studies have been done on the possible relationship between Notch1 and Notch2 in gastric cancer.

Notch2 signal pathway plays a potential oncogenic role in several malignancies, such as hematologic malignancies including multiple myeloma^[15], B cell chronic lymphocytic leukemia, and B cell and T cell acute lymphoblastic leukemia^[16,17], and solid tumors including glioblastoma^[18], and colon cancer^[19]. It also plays a tumor suppressive role in some solid tumors, such as breast cancer^[20], and small cell lung cancer^[21,22]. In gastric cancer, Notch2 has been proved to be overexpressed by Sun *et al*^[23] and He^[24].

In this study, we aimed to address whether Notch2 is also involved in control of gastric cancer progression and investigate the effects of Notch2 signaling on gastric cancer aggressiveness.

MATERIALS AND METHODS

Cell culture and transfections

Human gastric cancer cell line MKN-45 (Cell Collection of the Chinese Academy of Sciences, Shanghai, China) was cultured in RPMI 1640 (HyClone Laboratories Inc., Logan, United States) supplemented with 10% fetal bovine serum (HyClone Laboratories Inc., Logan, United States), 100 U/mL penicillin and streptomycin, in a 5% CO₂ atmosphere at 37 °C.

Small interfering RNA knockdown of Notch2

MKN-45 cells were transfected with small interfering RNA (siRNA) against Notch2 and scrambled siRNA (Santa Cruz Biotechnology, CA, United States) constructs using the commercial transfection reagent (Santa Cruz Biotechnology, CA, United States) according to the manufacturer's instructions. Following transfection, cells were incubated at 37 °C in a CO₂ incubator for 48 h before being harvested for the assays described below.

Real-time quantitative reverse transcription-polymerase chain reaction analysis for gene expression

Total RNA was isolated by the RNAiso plus reagent (TaKaRa Biotechnology Co., Dalian, China) and then reverse transcribed into complementary DNA (cDNA) using the Primescript™ reverse transcription Master Mix (TaKaRa Biotechnology Co., Dalian, China) according to manufacturer's instructions. Reverse transcription reaction was performed at 37 °C for 15 min followed by 85 °C for 5 s. The primers used in the polymerase chain reaction (PCR) reactions are described in Table 1. One mL of reverse transcription reaction product was used for quantitative reverse transcription-PCR (qPCR) reaction in a total volume of 20 µL. The qPCR cycles were as follows: 95 °C for 30 s, followed by 40 cycles of 95 °C for 5 s and 60 °C for 34 s. PCR amplifications were undertaken with the Applied Biosystems 7500/7500 Fast Real-Time PCR Software (Applied Biosystems, CA, United States) using the SYBR® Premix Ex Taq™ II (TaKaRa Biotechnology Co., Dalian, China). Data were analyzed according to the comparative Ct method and were normalized to glyceraldehyde-3-phosphate dehydrogenase expression in each sample. All qPCR assays were performed in triplicate.

Protein extraction and Western blotting analysis

Total protein was extracted from the treated cells using RIPA lysis buffer (Beyotime Biotechnology, Haimen, China) supplemented with 1 mmol/L phenylmethanesulfonyl fluoride. The protein concentration was measured by BCA protein assay system (Beyotime Biotechnology, Haimen, China). Total proteins (40-50 µg) were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred onto polyvinylidene difluoride (PVDF) membranes. The blots were blocked with 5% skim milk in Tris buffered saline containing 0.1% Tween-20 (TBST) for 2 h at room temperature, incubated with primary antibodies against N2ICD (Abcam Inc., Cambridge, United Kingdom) (1:1000), Hes1 (Abcam Inc., Cambridge, United Kingdom) (1:500), matrix metalloproteinase 9 (MMP9) (Abcam Inc., Cambridge, United Kingdom) (1:1000), Akt (Cell Signaling Technology, Inc., Danvers, MA, United States) (1:1000), and p-Akt (Cell Signaling Technology, Inc., Danvers, MA, United States) (1:1000). β-actin (Zhongshan Golden Bridge Biotech, Beijing, China) (1:10 000) was used as a loading control. The membranes were reacted with respective primary antibodies overnight at 4 °C. After being washed in TBST

Table 1 Primer sequences used for the real-time polymerase chain reaction analysis

MMP9: Matrix metalloproteinase 9; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

for three times, the membranes were incubated with horse-radish peroxidase-conjugated anti-rabbit or anti-mouse IgG (Zhongshan Golden Bridge Biotech, Beijing, China) (1:10 000) for 1 h at room temperature. The protein bands were detected using the Super Signal West Pico Chemiluminescent Substrate (Thermo Fisher Scientific Inc., Rockford, IL, United States) and imaged using a VersaDoc Imaging System (Bio-Rad Laboratories Co., Ltd. Hercules, CA, United States). Densitometric analysis was performed using Quantity One Software v4.62 (Bio-Rad Laboratories Co., Ltd. Hercules, CA, United States) and the results were presented as the mean of three independent experiments.

Migration and invasion assays in vitro

The effects of Notch2 siRNA on the migratory and invasive abilities of MKN-45 cells were assayed in 24-well plates using relevant kits (BD Biosciences, United States). Approximately 3×10^4 cells were seeded for the 12 h migration assay, and 3×10^5 cells for the 24 h invasion assay and the invasive activity of the Notch-2 siRNA-transfected MKN-45 cells was tested using BD Falcon™ Cell culture inserts coated with BD Matrigel™ Basement Membrane Matrix (BD Biosciences, United States). Briefly, transfected MKN-45 cells were resuspended in serum-free medium and seeded into the upper chamber of the assay system. The bottom wells of the system were filled with complete growth medium. After 12 and 24 h incubation, the migrated and invaded cells were washed twice with ice-cold PBS and then fixed with 4% paraformaldehyde for 15 min and stained with methyl violet (0.01% v/v) for 30 min. The numbers of migrated or invaded cells were then counted from 5 random fields under 200 and 400 magnification.

MMP9 activity assay

The culture media from Notch2 siRNA- and scrambled siRNA-transfected MKN-45 cells grown in 6-well plates were collected, spun at $12\,000 \times g$ for 10 min at 4 °C to remove cell debris, and the supernatant collected for MMP9 assay using a commercial enzyme-linked immunosorbent assay kits (RD Systems, Inc., Minneapolis, MN) according to the manufacturer's instructions.

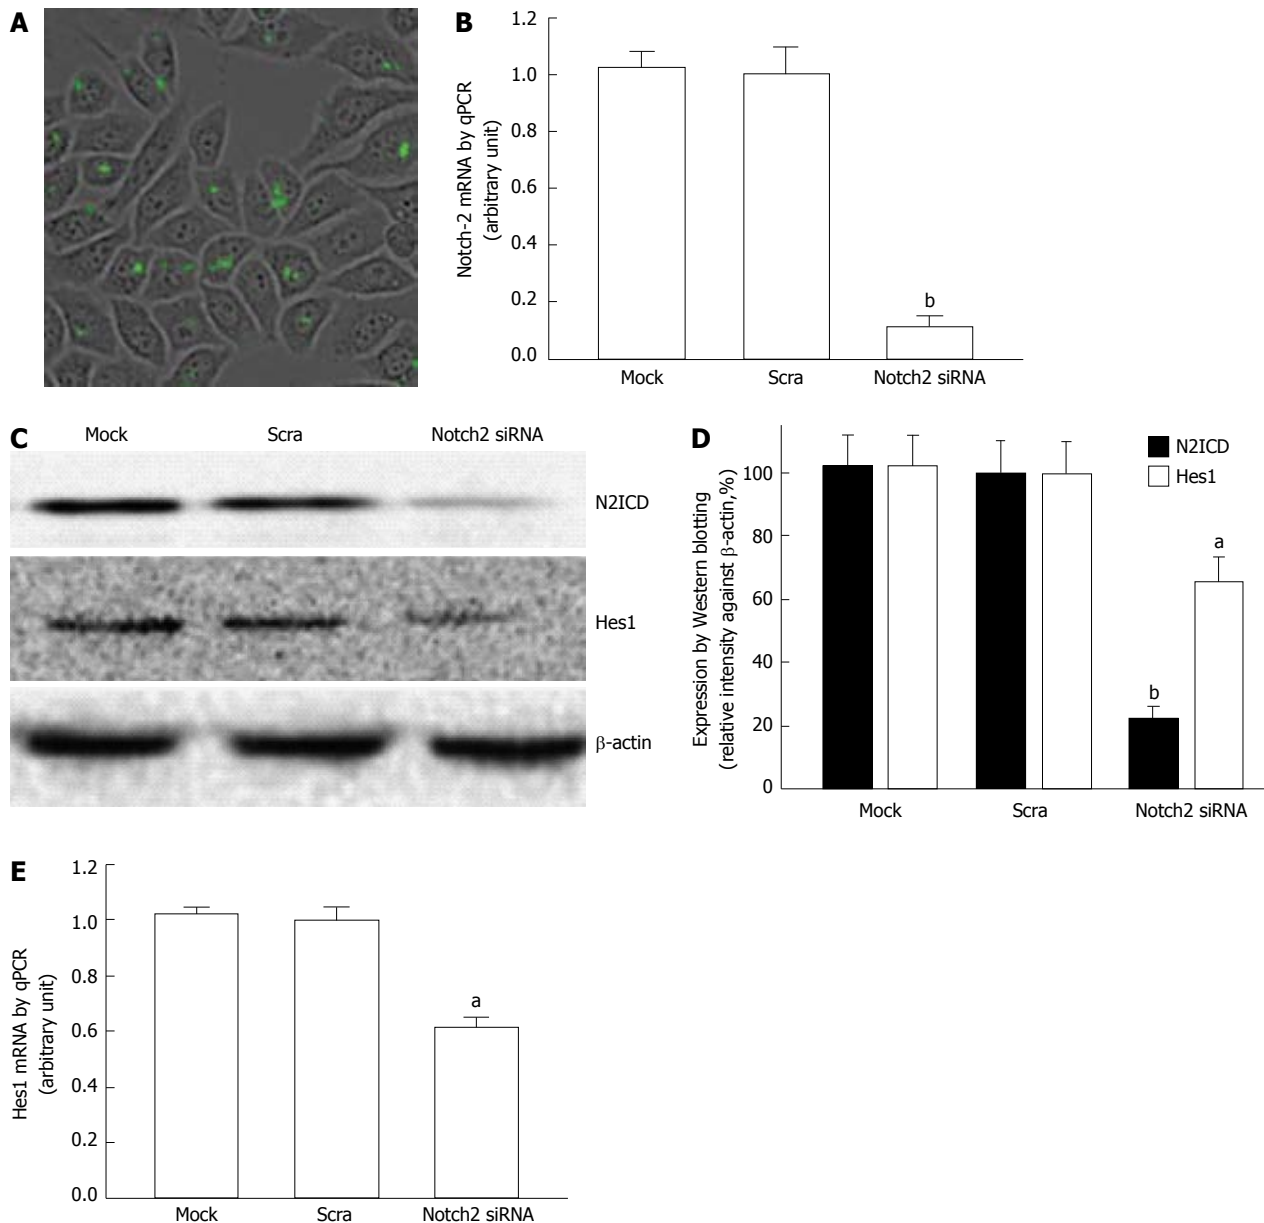

Figure 1 Verification of successful transfection and knockdown of Notch2. ^a $P < 0.05$, ^b $P < 0.01$ vs the Mock or Scra groups. Scra: Scrambled small interfering RNA (siRNA); qPCR: Quantitative reverse transcription polymerase chain reaction.

Statistical analysis

Data analysis was performed using SPSS19.0 (IBM, Armonk, New York, United States) and displayed using Sigma Plot10.0 (Systat Software Inc, San Jose, CA, United States). Comparison of the differences between the groups was performed using a one-way analysis of variance followed by the Bonferroni correction. All data were expressed as the mean \pm SD. A P value of < 0.05 was considered statistically significant.

RESULTS

Knockdown of Notch2 enhanced the migration and invasion of MKN-45 cells

After successful transfection of Notch2 siRNA into MKN-45 cells (Figure 1A) and a marked knockdown of Notch2

($> 90\%$) at mRNA (Figure 1B) and protein (Figure 1C and D) levels, there was a marked reduction of Notch target gene Hes1 at the mRNA (Figure 1E), indicating an inhibition of Notch signaling. Inhibition of Notch signaling was also confirmed by the marked reduction of Notch2 intracellular domain (N2ICD) at the mRNA (Figure 1D) and protein (Figure 1C) levels.

In the cells with confirmed knockdown of Notch2, the ability of cells to migrate and invade was evaluated as described in the "Materials and Methods". MKN-45 cells with Notch2 knockdown showed an increased cell migration (Figure 2B and E) compared with the cells transfected with scrambled siRNA (Scra, Figure 2A and E). Similarly, MKN-45 cells with Notch2 knockdown showed an increased cell invasion (Figure 2D and F) compared with the cells transfected with scrambled siRNA (Scra,

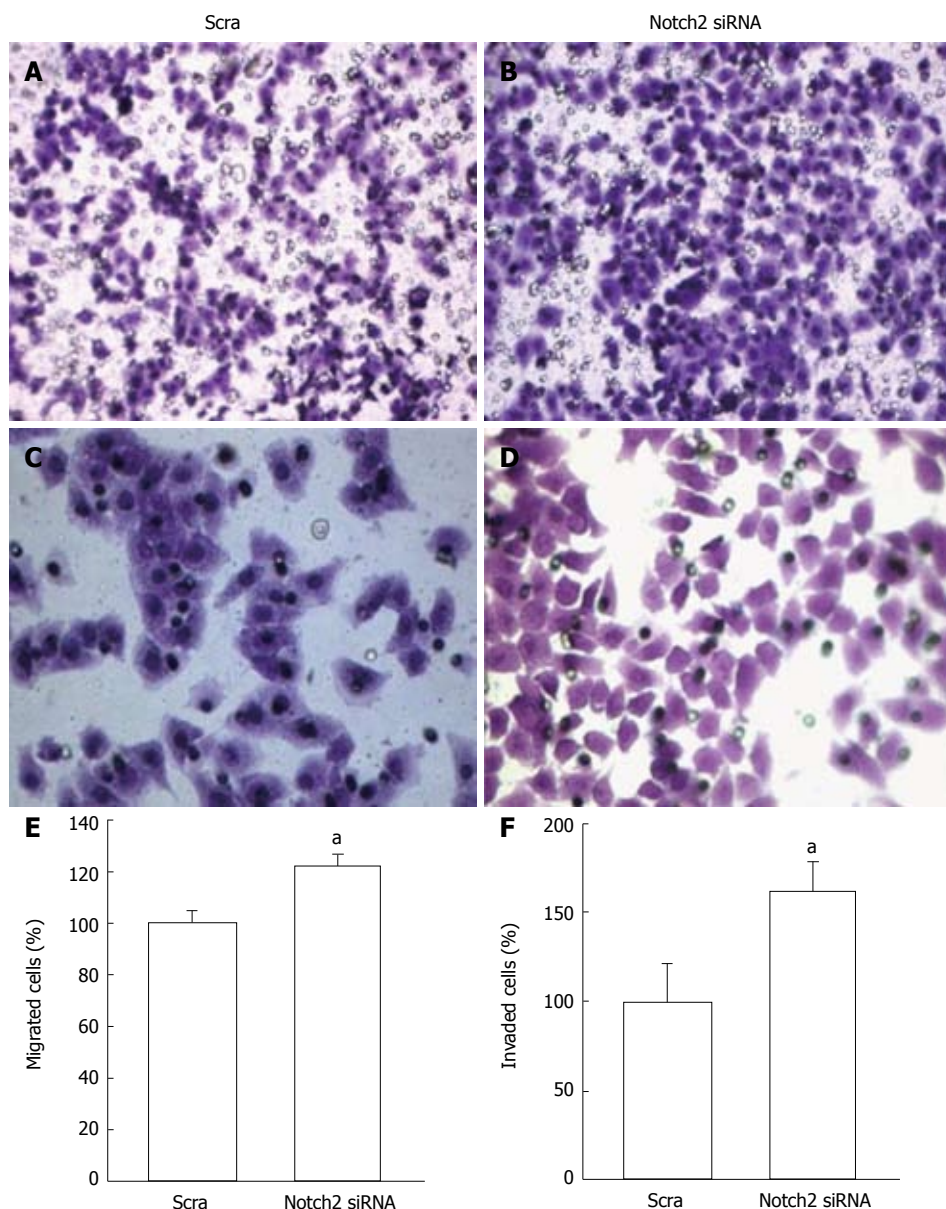

Figure 2 Knockdown of Notch2 led to an increased migration and invasion of MKN-45 cells. Cells were transfected with scrambled small interfering RNA (siRNA) (Scra, A, C) or Notch2 siRNA (B, D) for 48 h, and the effect of the migration (A, B, E) and invasion (C, D, F) were assayed as described in "Materials and Methods". The number of migrated cells or invaded cells were quantitated (E, F). ^a $P < 0.05$ vs the Scra groups. A, B, $\times 200$; C, D, $\times 400$.

Figure 2C and F).

Knockdown of Notch2 enhanced the expression and activity of MMP9 in MKN-45 cells

Tumor metastasis occurs by a series of steps, including cell invasion, degradation of basement membranes, and the stromal extracellular matrix, ultimately leading to tumor cell invasion and metastasis. The MMPs are a family of related enzymes that degrade extracellular matrix, which are considered to be important factors in facilitating tumor invasion and metastasis. Among these MMPs, MMP9 is considered an important factor involved in the degradation of basement membrane collagen in facilitating invasion and metastases in gastric cancer. Knockdown of Notch2 in MKN-45 cells markedly enhanced the expression of MMP9 at mRNA (Figure 3A) and protein (Figure 3B and C) levels. Additionally, knockdown of Notch2 led to a 1.48-fold increase in MMP9 activity (Figure 3D).

Effect of Notch2 knockdown on the expression of PI3K/Akt pathway in MKN-45 cells

In order to elucidate the mechanisms of Notch2 mediated alteration in MMP9, we measured the expression of PI3K downstream target Akt in the MKN-45 cells transfected with or without Notch2 siRNA. Knockdown of Notch2 by siRNA increased the Akt phosphorylation (Figure 4A and B). Blocking the PI3K/Akt pathway by PI3K inhibitor LY294002 resulted in a reduced expression of MMP9 (Figure 4C and D).

DISCUSSION

Aberrant expression of Notch pathway has been found in a variety of human cancers, including cancers of breast, brain, cervix, lung, colon, head and neck, kidney, bone marrow, lymph nodes and stomach^[25-27]. Abnormal Notch signaling is also linked to EMT. Notch signaling is known to suppress apoptosis and promote cell

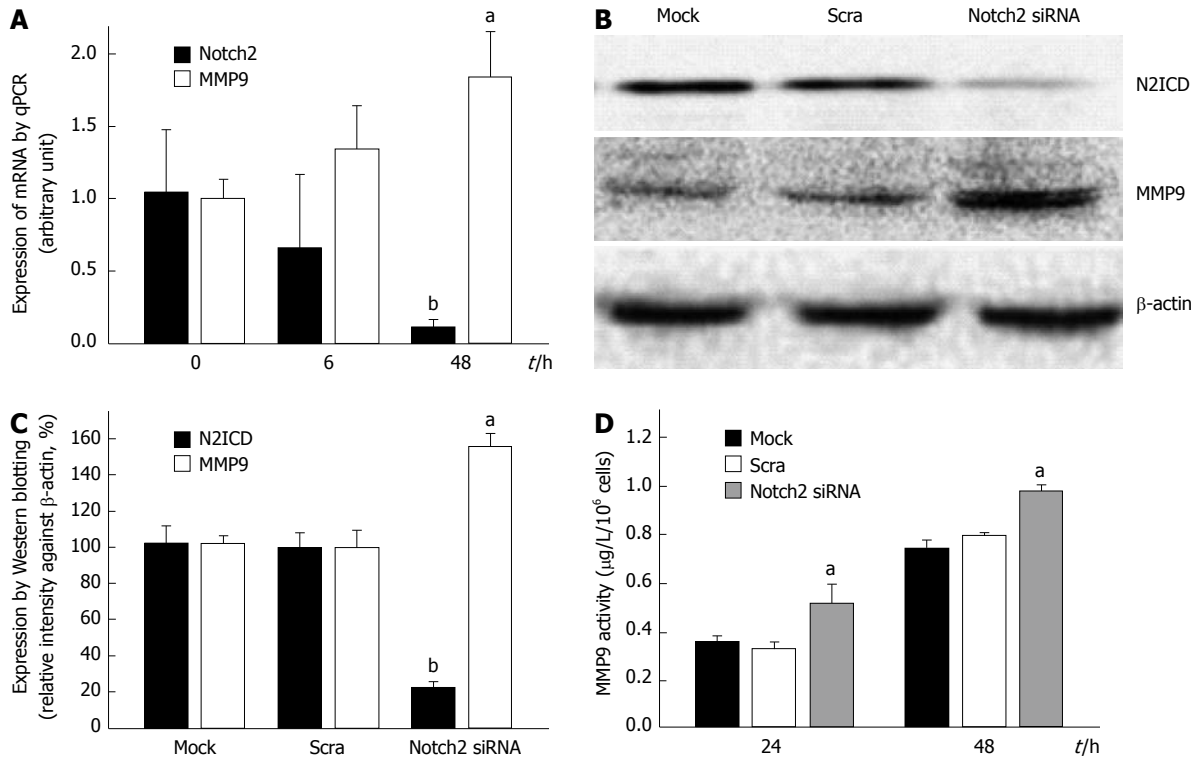

Figure 3 Knockdown of Notch2 enhanced the expression and activity of matrix metalloproteinase 9. The small interfering RNA (siRNA) mediated knockdown of Notch2 (A) and Notch2 intracellular domain (N2ICD) (B, C) was associated with a marked increase in the expression (A, B, C) and activity (D) of matrix metalloproteinase 9 (MMP9). ^a*P* < 0.05, ^b*P* < 0.01 vs the blank control groups. qPCR: Quantitative reverse transcription polymerase chain reaction.

proliferation through a growth factor-mediated survival pathway^[28-30]. However, the precise role and mechanism of Notch for tumor invasion remains unclear. In this study, we found that siRNA mediated down-regulation of Notch2 in gastric cancer cells could (1) increase tumor cell invasion; (2) enhance MMP9 expression and its activities; and (3) promote the phosphorylation of PI3K pathway as demonstrated by increased p-Akt level.

Tumor metastasis occurs *via* a series of steps, including cell invasion, degradation of basement membranes and the stromal extracellular matrix, ultimately leading to tumor cell invasion and metastasis. The MMPs are a family of related enzymes that degrade extracellular matrix, which are considered to be important factors in facilitating tumor invasion and metastasis^[31-33]. Among these MMPs, MMP9 has been considered an important factor involved in the degradation of basement membrane collagen in facilitating invasion and metastases in gastric cancer^[34,35]. MMP9 is a downstream target for PI3K/Akt pathway, which is an important signaling pathway in controlling cell proliferation^[36,37]. In physiological circumstances, MMP9 plays an important role in tissue remodeling associated with various physiological and pathological processes such as morphogenesis, angiogenesis, tissue repair, cirrhosis, arthritis, and metastasis^[38]. MMP9 is required for maintaining normal tissue structure and epithelial integrity. Under pathological conditions, particularly in various cancers, abnormal expression and activity of MMP9 have been reported^[34,39-42]. Abnormal function of MMP9 is linked to tumor cell migration, invasion and metastasis^[35,39]. The

role of MMP9 in the development of gastric cancer has been reported and the expression of metalloproteinase-9 or its inhibitor is related to a more aggressive phenotype of gastric cancer or correlated with lymph node metastasis in advanced gastric carcinoma^[35,43], but how MMP9 is regulated in gastric cancer is unclear.

Based on our study, we propose that physiological cellular level of Notch2 may be required for the maintenance of normal MMP9 function. Reduced Notch2 may enhance the proliferative and invasive potential of cancer cells, likely through activation of PI3K/Akt pathway and ensuing increase in MMP9 activities. In this perspective, Notch2 appears to function as a tumor suppressor gene in gastric cancer.

Here, we showed that the facilitation of MMP9 expression by down-regulation of Notch2 may be mediated by the up-regulation of p-Akt. Thus, these results suggest that up-regulation of Notch2 could potentiate the anti-tumor and anti-metastasis activities partly through the up-regulation of MMP expression. Because we observed that down-regulation of Notch2 promoted MMP9 expression, we tested the effects of Notch2 on the invasion of MKN-45 cells. We found that down-regulation of Notch2 promoted the invasion of MKN-45 cells. These results were consistent with MMP9 data, showing that down-regulation of Notch2 could promote cancer cell invasion partly through up-regulation of MMP9. On the basis of our results, we propose a hypothetical pathway by which Notch2 may inhibit invasion of MKN-45 cells, partly through PI3K-Akt signaling pathway.

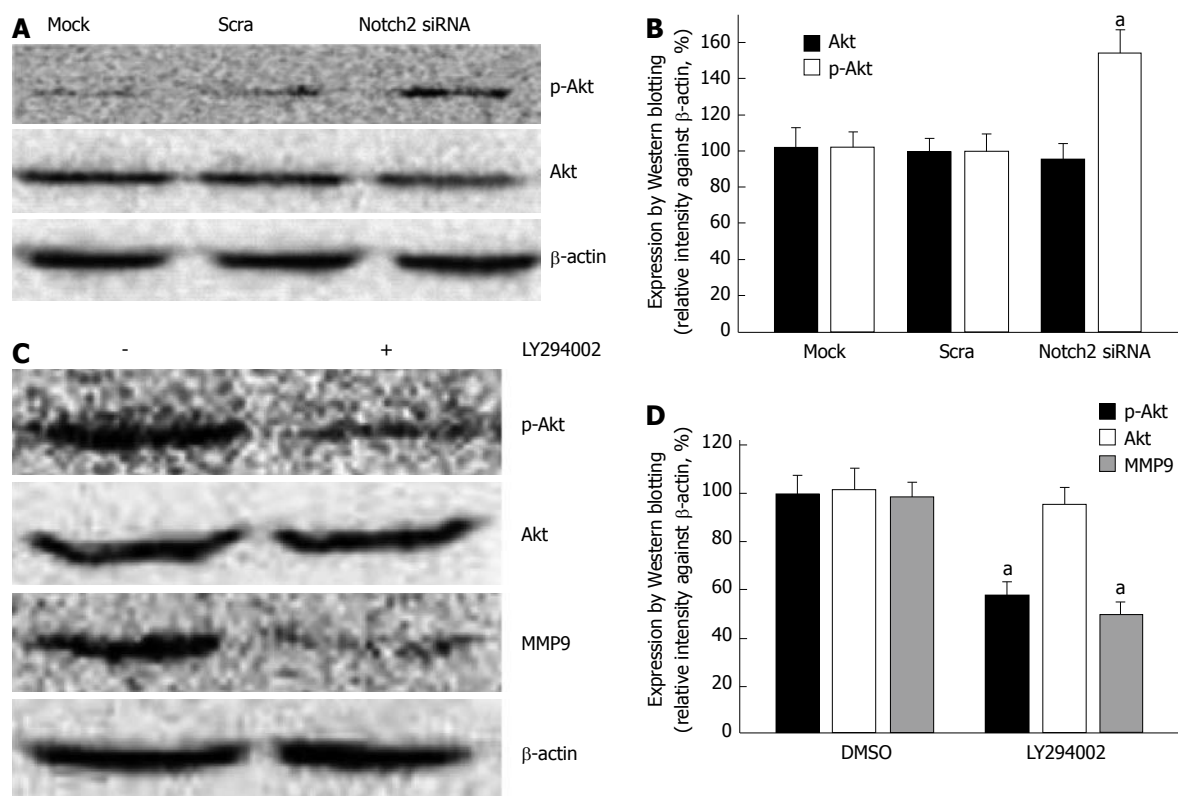

Figure 4 Knockdown of Notch2 enhanced the expression of matrix metalloproteinase 9 via increased phosphorylation of p-Akt in MKN-45 cells. A, B: Knockdown of Notch2 led to an increased phosphorylation of Akt (p-Akt); C, D: Blockade of PI3K/Akt pathway by LY294002 (20 μ mol/L) abolished the effect of Notch small interfering RNA (siRNA) in Akt phosphorylation and matrix metalloproteinase 9 (MMP9). ^a $P < 0.05$ vs the all control groups. DMSO: Dimethyl sulfoxide.

Notch has been reported to cross-talk with other major cell growth and apoptotic regulatory pathways, including the PI3K-Akt pathway^[44]. Hyperactivation of PI3K/Akt pathway has previously been observed in human gastric cancer^[45]. It has recently been shown that activation of Notch1 enhanced the survival of melanoma cells^[29] and leukemia cells *via* activation of the PI3/Akt pathway^[46]. In our study, down-regulation of Notch2 by siRNA led to the activation of PI3K/Akt pathway, which is associated with an increased expression and function of MMP9, suggesting that Notch2 can regulate MMP9 *via* PI3K/Akt pathway and increased Akt phosphorylation. Interestingly, we also observed that inactivation of Akt by LY294002 eliminated Akt phosphorylation and MMP9 expression. These results suggest that Notch2 can induce Akt signaling.

In summary, the role of Notch2 in malignancies is uncertain. Although the overexpression of Notch2 has been confirmed, Notch2 appeared to function as a tumor suppressor gene in gastric cancer in this study. Further studies are warranted before Notch inhibitor based therapeutic approaches are employed in the treatment of advanced gastric cancer.

sic Medical Sciences, Lanzhou University, Lanzhou, China) for their technical assistance.

COMMENTS

Background

Notch is one of the most important signaling pathways involved in cell fate determination. Activation of the Notch pathway requires the binding of a membrane-bound ligand to the Notch receptor in the adjacent cell which induces proteolytic cleavages and the activation of the receptor. A unique feature of the Notch signaling is that the processes such as modification, endocytosis or recycling of the ligand, have been reported to play critical roles in Notch signaling, however, the underlying molecular mechanism appears context-dependent and often controversial.

Research frontiers

There are four Notch receptors (Notch 1-4) and five ligands [Jagged 1, Jagged 2, delta-like ligand-1, -3 and -4 (DLL1, DLL3 and DLL4)] in mammals. Recently, it is reported to be involved in tumorigenesis as oncogenes or tumor suppressors, and proposed as prognostic factors or anti-cancer targets in aggressive or advanced cancers. This study was undertaken to investigate whether Notch2 is also involved in the control of gastric cancer progression, and the effects of Notch2 signaling in gastric cancer aggressiveness.

Innovations and breakthroughs

Abnormal Notch signaling has been reported in many human solid tumors. This is the first study to characterize the role of Notch signaling in gastric cancer aggressiveness. The findings indicated that Notch2 may negatively regulate the cell invasion of human gastric carcinoma.

Terminology

Four Notch receptors (Notch 1-4) and five ligands (Jagged 1, Jagged 2, DLL1, DLL3, and DLL4) are found in mammals. Ligand-receptor interaction between two neighboring cells is involved in developmental, physiologic and pathologic processes.

Peer review

The Notch signaling pathway plays a crucial role in the maintenance and the development of several tissues. Ectopic expression of Notch has been found in a variety of human cancers. In this work, the authors indicate that Notch2 could negatively regulate the cell invasion of human gastric carcinoma. By this way, the authors described Notch2 as a tumor suppressor gene in gastric cancers. At the same time, the authors detected an increased expression and activity of matrix metalloproteinase 9, arguing that such increase could be related to the enhanced migration and invasiveness. The results are clear and support the authors' hypothesis.

Abstract

AIM: To investigate the impact of intestinal ischemia/reperfusion (I/R) injury and lymph drainage on distant organs in rats.

METHODS: Thirty-two Sprague-Dawley male rats, weighing 280-320 g, were randomly divided into blank, sham, I/R, and ischemia/reperfusion and drainage (I/R + D) groups ($n = 8$). All rats were subjected to 60 min ischemia by clamping the superior mesenteric artery, followed by 120 min reperfusion. The rats in the I/R + D group received intestinal lymph drainage for 180 min. In the sham group, the abdominal cavity was opened for 180 min, but the rats received no treatment. The blank group served as a normal and untreated control. A chromogenic limulus assay kit was used for quantita-

tive detection of serum endotoxin. The serum concentrations of tumor necrosis factor- α (TNF- α), interleukin (IL)-6, IL-1 β , soluble cell adhesion molecules (sICAM-1), and high mobility group protein box 1 (HMGB1) were determined with an enzyme-linked immunosorbent assay kit. Histological evaluations of the intestine, liver, kidney, and lung were performed by hematoxylin and eosin staining and immunohistochemistry. HMGB1 protein expression was assayed by western blot analysis.

RESULTS: The serum levels of endotoxin and HMGB1 in the I/R and I/R + D groups were significantly higher than those in the sham group (endotoxin, I/R and I/R + D *vs* sham: 0.033 ± 0.004 EU/mL, 0.024 ± 0.003 EU/mL *vs* 0.017 ± 0.009 EU/mL, respectively, $P < 0.05$; HMGB1, I/R and I/R + D *vs* sham: 5.473 ± 0.963 EU/mL, 4.906 ± 0.552 EU/mL *vs* 0.476 ± 0.406 EU/mL, respectively, $P < 0.05$). In addition, endotoxin and HMGB1 were significantly lower in the I/R + D group compared to the I/R group ($P < 0.05$). The serum inflammatory factors IL-6, IL-1 β , and sICAM-1 in the I/R and I/R + D groups were significantly higher than those in the sham group (IL-6, I/R and I/R + D *vs* sham: 41.773 ± 9.753 pg/mL, 19.204 ± 4.136 pg/mL *vs* 11.566 ± 2.973 pg/mL, respectively, $P < 0.05$; IL-1 β , I/R and I/R + D *vs* sham: 144.646 ± 29.378 pg/mL, 65.829 ± 10.888 pg/mL *vs* 38.178 ± 7.157 pg/mL, respectively, $P < 0.05$; sICAM-1, I/R and I/R + D *vs* sham: 97.360 ± 12.714 ng/mL, 48.401 ± 6.547 ng/mL *vs* 33.073 ± 5.957 ng/mL, respectively; $P < 0.05$). The serum TNF- α in the I/R group were significantly higher than in the sham group (45.863 ± 11.553 pg/mL *vs* 18.863 ± 6.679 pg/mL, respectively, $P < 0.05$). These factors were significantly lower in the I/R + D group compared to the I/R group ($P < 0.05$). The HMGB1 immunohistochemical staining results showed no staining or apparent injury in the blank group, and slight staining at the top of the microvillus was detected in the sham group. In the I/R group, both the top of villi and the basement membrane were stained for HMGB1 in most areas, and injury in the I/R + D group was less than that in the I/R group. HMGB1 expression in the liver, kidney,

and lung of rats in the I/R + D group was significantly lower than the rats in the I/R group ($P < 0.05$).

CONCLUSION: Lymph drainage could block the “gut-lymph” pathway, improve intestinal barrier function, and attenuate distant organ injury incurred by intestinal I/R.

INTRODUCTION

The gut is an important functional organ for the immune and endocrine systems, as well as its role as a protective barrier. Intestinal ischemia/reperfusion (I/R) injury is the “motor” of systemic inflammatory response syndrome (SIRS), acute respiratory distress syndrome (ARDS), and multiple organ dysfunction syndrome (MODS)^[1-3]. Severe trauma, acute necrotizing pancreatitis, major surgery, extensive burns, and other stresses are all associated with intestinal barrier dysfunction. Although extensive investigative efforts have focused on clarifying the pathogenesis of SIRS, ARDS and MODS induced by intestinal I/R, the specific mechanism still remains controversial^[4].

Recently, numerous studies have shown that the transport of inflammatory mediators occurs through the intestinal lymphatics in trauma-hemorrhage shock (T/HS). Deitch *et al.*^[5] demonstrated that toxic gut-derived substances enter the mesenteric lymph to cause lung injury. In addition, ligating the lymph duct in a variety of species after hemorrhagic shock can prevent distant organ injury^[6]. Damle *et al.*^[7], Watkins *et al.*^[8] and Jordan *et al.*^[9] have shown that lymph is the key link between T/HS and MODS. The production and release of inflammatory factors through the “gut-lymph” pathway to the circulatory system can cause acute lung injury (ALI) and a systemic inflammation state^[10-13]. Our recent work, together with findings by other investigators, suggests that thoracic/mesenteric lymphatic duct ligation prior to intestinal I/R injury protects the lung from injury and modulates the serum levels of endotoxin, D-lactate, diamine oxidase, and cytokines^[14,15]. However, the composition of lymph that is responsible for distant organ injury remains unknown.

Some experiments have demonstrated that T/HS lymph

is sterile and does not contain measurable levels of endotoxin^[16], but does contain some biologically active non-microbial protein and lipid species^[17,18]. Recent studies proposed that mesenteric lymph-induced distant organ injury in intestinal I/R was directly mediated by gut-derived endogenous ligands, one of which is the high mobility group protein box 1 (HMGB1). In intestinal I/R injury, intestinal epithelium cells and macrophages synthesize and release toll-like receptor 4 (TLR4) endogenous ligands, which can be recognized by and combine with TLR4^[19]. HMGB1 is also the key factor of inflammation of aseptic injury (including T/HS and liver I/R injury)^[20,21]. In liver I/R injury, HMGB1 can directly combine with TLR2 or TLR4 and cause inflammation^[22]. The binding of HMGB1 and TLR4 may also be the most important trigger of the inflammatory response to I/R injury in the heart, kidney, brain, lung, and other organs^[23-26]. Recent studies suggest that HMGB1 acts as a late mediator of lethal sepsis and an early mediator of inflammation and necrosis following I/R injury^[19,27,28].

This study is a continuation of our previous study. We hypothesized that the HMGB1-TLR4 combination plays an important role in the distant organ injury caused by intestinal I/R injury. The purpose of this study was to determine the impact of intestinal I/R injury and lymph drainage on the intestine and distant organs in rats, and to clarify whether HMGB1 in the intestinal mesenteric lymph after I/R mediates distant organ injury.

MATERIALS AND METHODS

Animals

Thirty-two male Sprague-Dawley rats that were specific pathogen-free grade and weighed 280-320 g were purchased from Beijing Vital River Laboratory Animal Technology Co. Ltd. The rats were housed under barrier-sustained conditions at a temperature of 25 °C with 12 h light/dark cycles, and had free access to water and food for five days prior to the operation. The rats were randomly divided into four groups: blank, sham, ischemia/reperfusion and drainage (I/R + D), and I/R ($n = 8$ for each group). All rats were maintained in accordance with the recommendations of the Guide for the Care and Use of Laboratory Animals. The research protocols were approved by the Academic Committee of Peking Union Medical College and Chinese Academy of Medical Sciences.

Intestinal I/R and lymph drainage

Prior to the operation, all rats were fasted overnight, but were allowed access to water *ad libitum*. The rats were anesthetized with an intraperitoneal injection of 1% sodium pentobarbital (50 mg/kg). A midline incision was performed to bluntly separate the superior mesenteric artery (SMA) and intestinal lymphatic trunk. In the I/R and I/R + D groups, the SMA was occluded for 60 min with an artery clamp, followed by reperfusion for 120 min. In the I/R + D group, a small incision was made on the proximal end of the intestinal lymphatic trunk. A catheter (Jinan Medical Silicone Tube Plant, China)

Table 1 Serum levels of endotoxin and high mobility group protein box 1 in the ischemia/reperfusion and ischemia/reperfusion + drainage groups compared to respective controls (mean \pm SD, $n = 8$)

Groups	Endotoxin (EU/mL)	HMGB1 (ng/mL)
Blank	0.014 \pm 0.005	0.277 \pm 0.292
Sham	0.017 \pm 0.009 ^a	0.476 \pm 0.406
I/R + D	0.024 \pm 0.003 ^{a,c,e}	4.906 \pm 0.552 ^{a,c}
I/R	0.033 \pm 0.004 ^{a,c}	5.473 \pm 0.963 ^{a,c}

^a $P < 0.05$ vs the blank group; ^c $P < 0.05$ vs the sham group; ^e $P < 0.05$ vs the I/R group. I/R: Ischemia/reperfusion; I/R + D: Ischemia/reperfusion + drainage; HMGB1: High mobility group protein box 1.

was inserted into the incision obliquely 3-5 mm toward the distal end. A small amount of medical adhesive (Beijing Fuaile Science and Technology Development Co. Ltd, China) was used on the serosa adjacent to the right kidney to fix the catheter. Outflow of lymph from the catheter was collected with a sterile test-tube (Nunc, Denmark) for 180 min. In the sham group, the abdominal cavity was opened for 180 min but the rats received no treatment. The blank group served as a normal and untreated control. The lymph (0.6-1.2 mL per rat) was collected for 180 min.

Specimen collection

After the operation, the catheter was removed. Blood was then extracted from the inferior vena cava and centrifuged at 3000 g for 15 min at 4 °C; the serum was separated and stored at -80 °C for further analysis. After the rats were fully exsanguinated, a 3 cm proximal section of the jejunum and 3 cm distal section of the ileum were excised, rinsed in ice-cold normal saline, and dried on filter paper. The liver, kidney, and lung were stored at -80 °C.

Sample analysis

Measurement of endotoxin: A chromogenic limulus assay kit (Yi Hua Medical Technology Co. Ltd, Shanghai, China) was used for the quantitative detection of serum endotoxin, and the assay was performed according to the manufacturer's directions.

Cytokines and HMGB1 assay: The serum concentrations of tumor necrosis factor- α (TNF- α), interleukin (IL)-6, IL-1 β , soluble cell adhesion molecules (sICAM-1), and HMGB1 were determined using enzyme-linked immunosorbent assay kits (Sun Biomedical Technology Co., Ltd., Beijing, China) according to the kit protocols.

Hematoxylin and eosin staining of rats tissue slices: Samples of the intestine, liver, kidney, and lung were fixed in 10% formalin solution and sectioned (4 mm) after dehydration, cleaning, and paraffin embedding. The sections were flattened, mounted, and heated on blank glass slides. Histological evaluations were performed by hematoxylin and eosin staining and pathological examination.

HMGB1 immunohistochemistry: The slices of intes-

tine, liver, kidney, and lung embedded in paraffin were used for histological examination. A mouse anti-HMGB1 primary antibody (Beijing Biosynthesis Biotechnology Co., Ltd., China) and biotinylated secondary antibody (Beijing Biosynthesis Biotechnology Co., Ltd., China) were used for immunohistochemical staining. Brownish-yellow stained areas were recognized as regions with positive antigen expression.

HMGB1 protein expression-Western blotting analysis:

Total protein extract was prepared, and samples were separated using sodium dodecyl sulfate polyacrylamide gels. Proteins were then transferred to nitrocellulose membranes overnight at room temperature and blocked for 8 h with 5% bovine serum albumin. The membranes were then incubated overnight in anti-HMGB1 primary antibody (1 μ g/mL, ABCAM Ltd, Cambridge, United Kingdom) diluted in blocking solution (1:500, Beijing Biosynthesis Biotechnology Co., Ltd., China). Membranes were washed in Tris-buffered saline with Tween and incubated in horseradish peroxidase-conjugated mouse secondary antibodies in 5% milk (1:3000, Santa Cruz Inc., United States) for 1 h at room temperature. Protein bands were visualized by chemiluminescence.

Statistical analysis

Quantitative data were presented as mean \pm SD. Statistical software SPSS 17.0 (SPSS, Inc., Chicago, IL, United States) was used to test the homogeneity of variance. Multiple comparisons were performed with one-way analysis of variance followed by a least-significant difference test. Statistical significance was set at $P < 0.05$.

RESULTS

Serum levels of HMGB1, endotoxin and inflammatory factors

The serum levels of HMGB1 and endotoxin in the I/R and I/R + D groups were significantly higher than those in the blank and sham groups ($P < 0.05$). In addition, the level of endotoxin in the I/R group was higher than that in the I/R + D group ($P < 0.05$). The level of HMGB1 in the I/R group was slightly higher than that in the I/R + D group, but the difference was not significant ($P > 0.05$) (Table 1).

The levels of inflammatory cytokines IL-6, IL-1 β and sICAM-1 in the I/R and I/R + D groups and TNF- α in the I/R group were remarkably higher than those in the blank and sham groups ($P < 0.05$). The levels of inflammatory factors in the I/R + D group were markedly lower compared to those in the I/R group ($P < 0.05$). There was no significant difference in cytokine levels between the blank and sham groups ($P > 0.05$) (Table 2).

Intestinal, liver, kidney and lung HMGB1 immunohistochemistry

Intestinal morphology showed little change in the sham group compared to the blank group. In contrast, the jeju-

Figure 1 Immunohistochemistry staining of high mobility group protein box 1 in the jejunum (A), ileum (B), liver (C), kidney (D) and lung (E) (*n* = 8). I/R + D: Ischemia/reperfusion and drainage; I/R: Ischemia/reperfusion. Images shown at 100× magnification (A and B) and 200× magnification (C, D and E).

^a*P* < 0.05 *vs* the blank group; ^c*P* < 0.05 *vs* the sham group; ^e*P* < 0.05 *vs* the I/R group. I/R: Ischemia/reperfusion; I/R + D: Ischemia/reperfusion + drainage; TNF: Tumor necrosis factor; IL: Interleukin; sICAM: Soluble cell adhesion molecule.

num and ileum mucosa in the I/R group showed swelling and atrophy, and appeared fragile and black in color in some segments of the intestine. In the I/R + D group, the intestinal mucosa showed slight swelling, no breakage, and less apparent damage than the I/R group.

Analysis of the jejunum and ileum in the blank group confirmed that there was no HMGB1 staining or apparent injury. A small amount of staining at the top of the microvilli was detected in the sham group, indicating slight injury. In the I/R group, both the top of villi and the basement membrane were stained for HMGB1 in most areas. Injury in the I/R + D group was less than that in the I/R group, although we did find some areas showing positive staining (Figure 1A and B).

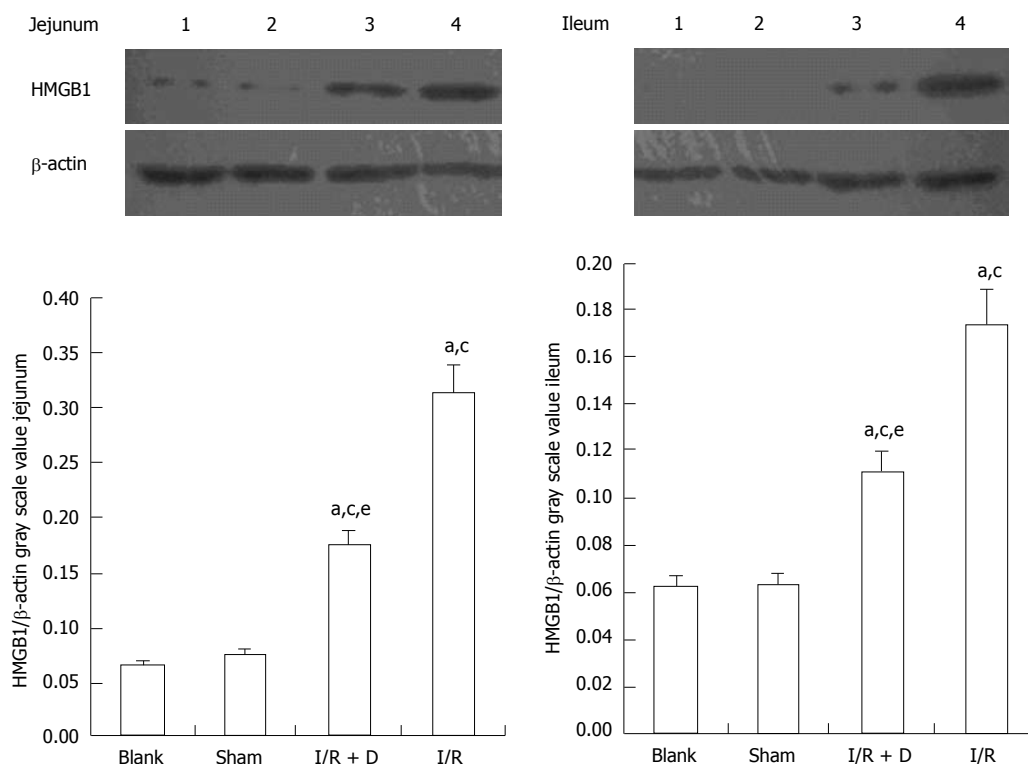

Figure 2 Expression levels of high mobility group protein box 1 protein in the jejunum and ileum ($n = 8$). Top: Western blotting analysis of high mobility group protein box 1 (HMGB1) in the jejunum (left) and ileum (right). Lane 1: Blank; Lane 2: Sham; Lane 3: I/R + D; Lane 4: I/R; Bottom: Quantification of HMGB1 protein levels in the jejunum (left) and ileum (right). HMGB1 levels were normalized to the levels of the β -actin internal control. ^a $P < 0.05$ vs the blank group; ^c $P < 0.05$ vs the sham group; ^e $P < 0.05$ vs the I/R group. I/R + D: Ischemia/reperfusion and drainage; I/R: Ischemia/reperfusion.

There was a significant level of HMGB1 staining in the liver of I/R group, while only a few liver cells were stained in the I/R + D group. HMGB1 staining in the medullary region and the outer medulla of the kidney were obviously increased in the I/R group compared to controls. Analysis of HMGB1 expression in the lung showed that a large number of cells, including endothelial cells and macrophages, were positively stained. Immunohistochemistry in the blank and sham groups showed almost no yellow staining in the liver, kidney, or lung (Figure 1C-E).

Intestinal, liver, kidney and lung HMGB1 expression by western blot

The expression of HMGB1 levels in the jejunum and ileum was significantly higher ($P < 0.05$) in the I/R and I/R + D groups than in the blank and sham groups (which corresponded to the immunohistochemistry data) and HMGB1 expression was significantly lower in the I/R + D group than in the I/R group ($P < 0.05$) (Figure 2). Furthermore, the expression of HMGB1 protein levels in the liver, kidney, and lung was significantly higher in the I/R and I/R + D groups than in the blank and sham groups ($P < 0.05$), and levels in all three organs in the I/R + D group were significantly lower than those in the I/R group ($P < 0.05$) (Figure 3). Together, these data showed that rats in the I/R + D group had significantly less injury than those of the I/R group, suggesting that blocking the “gut-lymph” pathway may attenuate the increase in HMGB1 levels incurred by I/R, and consequently decrease distant

tissue injury.

DISCUSSION

Intestinal I/R injury can lead to severe intestinal damage and increased intestinal permeability. This study showed that intestinal I/R causes intestinal morphological changes, such as intestinal mucosal injury, visible erosion, necrosis, interstitial congestion in the lamina propria of villi top, edema, inflammation, and mucosa and submucosa hemorrhage. In the jejunum and ileum, slight staining was observed at the top of microvilli in the sham group, and both the top villi and the basement membrane were stained in most areas in the I/R group. Moreover, we found that injury in the I/R + D group was less than that of the I/R group. Our previous study in rats showed that the intestinal permeability increased and bacteria translocated after I/R injury, and that the mucosal thickness and villus height were significantly lower than in the control group^[29].

Recent studies have shown that the key mechanism of intestinal I/R injury that leads to a systemic inflammatory response and injury of distant tissues and organs may be mediated by several gut-derived cytokines released in the circulatory system through the “gut-lymph” pathway, which causes downstream injurious effects. The “gut-lymph” pathway theory is based on several observations. Firstly, lymph drainage before hemorrhagic shock can prevent organ dysfunction caused by the shock^[8,30];

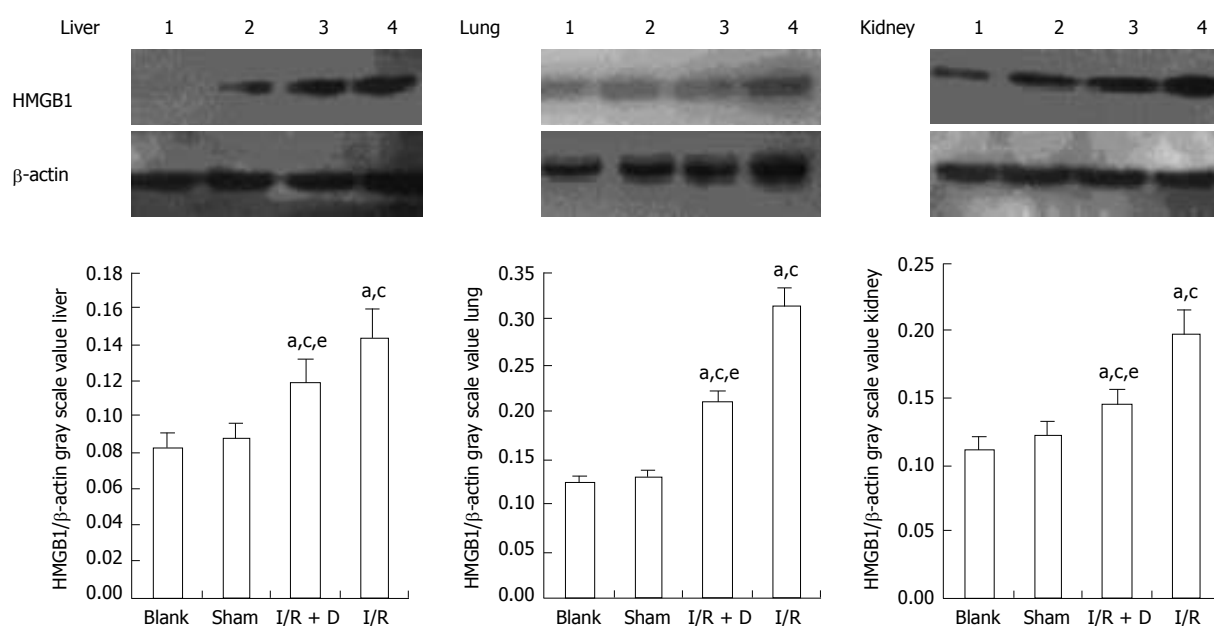

Figure 3 Expression levels of high mobility group protein box 1 in the liver, lung, and kidney ($n = 8$). Top: Western blotting analysis of high mobility group protein box 1 (HMGB1) in the liver (left), lung (middle), and kidney (right). Lane 1: Blank; Lane 2: Sham; Lane 3: I/R + D; Lane 4: I/R; Bottom: Quantification of HMGB1 protein levels in the liver (left), lung (middle), and kidney (right). HMGB1 levels were normalized to the levels of the β -actin internal control. ^a $P < 0.05$ vs the blank group; ^c $P < 0.05$ vs the sham group; ^e $P < 0.05$ vs the I/R group. I/R + D: Ischemia/reperfusion and drainage; I/R: Ischemia/reperfusion.

and secondly, injecting normal animals with the lymph from animals undergoing hemorrhagic shock can lead to a variety of pathological injuries^[12], such as increased permeability, alveolar cell apoptosis, and accumulated neutrophils in the lung.

In this study, our results demonstrated a change in intestinal morphology and an increase in endotoxin, HMGB1, and cytokine serum levels in rats with intestinal I/R injury. Importantly, we found that intestinal lymph drainage could significantly reduce the symptoms of I/R injury. The endotoxin, HMGB1, and cytokine serum levels in the I/R + D group were significantly reduced compared to the I/R group. Cavriani *et al.*^[15] observed that lymphatic ligation changed the serum levels of IL-1 β and IL-10, and alleviated the inflammatory response and lung injury in rats. Our previous study also indicated that intestinal lymph duct ligation could effectively reduce intestinal permeability and inflammatory cytokine and endotoxin levels in the circulation in rats after I/R injury^[14,29]. Another study^[31] showed that D-lactate could be detected in the circulation during ischemia for 5 min in I/R rats, and as time progressed, the degree of intestinal mucosa damage increased. Therefore, the D-lactate level could be an early indicator of mucosa damage and permeability changes. The results reported in this study are consistent with previous findings. These studies suggest that both lymph ligation and drainage can block the "gut-lymph" pathway and exert a protective effect on intestinal barrier function.

HMGB1 is the endogenous ligand of TLR4, and the HMGB1-TLR4 combination is an important step in I/R injury^[32]. HMGB1, which was initially found to be a late lethal inflammatory factor in sepsis, was recently considered to be an inflammatory cytokine in ALI and hepatic

injury. In the early stages, HMGB1 levels increases immediately and continue to slowly increase as reperfusion time is extended. Moreover, an anti-HMGB1 antibody was able to alleviate the inflammation response, as well as significantly reduce myeloperoxidase, IL-1 β , and IL-6 expression levels, and especially decrease the accumulation of neutrophils and pulmonary edema^[23,33]. A recent study^[4] found no bacteria or endotoxin in the circulation in rats with some trauma, surgery-induced SIRS, distant organ injury, and the administration of a TLR4 blocker significantly reduced inflammation and tissue damage. Therefore, it may not be endotoxin, but rather the endogenous ligand that activates TLR4.

During I/R injury, the intestinal epithelial cells and macrophages synthesize and release TLR4 endogenous ligands, which bind to TLR4. TLR4 then activates signaling pathways, such as nuclear factor- κ B, and regulates the synthesis of proteins and enzymes that promote the synthesis and release of a variety of cytokines. This results in the subsequent injury of the distant organs^[19,23,27]. This study showed that serum levels of HMGB1 were significantly higher in the I/R and I/R + D groups than in the blank and sham groups, and that HMGB1 in the I/R + D group was significantly lower than in the I/R group. These results were consistent with HMGB1 protein expression in the intestine, liver, kidney, and lung as determined by western blot. The immunohistochemistry analysis of HMGB1 in the liver, kidney, and lung also showed that the distant organs were damaged during intestinal I/R injury. Yang *et al.*^[34] and Liu *et al.*^[35] found that treatment of transient ischemic rats with a neutralizing anti-HMGB1 antibody could reduce IL-6 mRNA and TNF- α mRNA on the surface of intestinal mucosa, attenuate injury, and improve the

survival rate. This indicates that HMGB1 released during the early stage may be the factor that promotes intestinal injury and a systemic inflammatory response. In this study, we observed an improvement in morphology, and the serum levels of endotoxin, inflammatory cytokines, and HMGB1 in the I/R + D group were significantly lower than in the I/R group. This could be due to the low blood flow caused by ischemia and hypoxia when organs were subjected to perfusion. It could also be due to the fact that factors such as inflammatory cytokines diffuse throughout the entire body through reperfused blood^[7,36]. The degree of the injury in the liver, kidney, and lung, as well as the expression of HMGB1 in the I/R group, were significantly greater than in the I/R + D group ($P < 0.05$). This demonstrates that HMGB1 participates in the occurrence and development of the injury during intestinal I/R, and that blocking the “gut-lymph” pathway can effectively reduce the injury of the intestinal barrier function and the levels of systemic inflammatory cytokines, as well as attenuate the stimulation of HMGB1 on intestine and distant organs.

In conclusion, intestinal injury after I/R can stimulate the release of HMGB1, endotoxin, and inflammatory cytokines, which may be related to intestinal barrier dysfunction and distant organ injury. Intestinal lymph drainage may improve the morphology and function of the intestine, reduce the levels of cytokines and endotoxin in circulation, and attenuate the injury of distant organs by blocking the “gut-lymph” pathway; providing a reference for clinical treatment.

COMMENTS

Background

Intestinal ischemia/reperfusion (I/R) injury is the “motor” of systemic inflammatory response syndrome (SIRS), acute respiratory distress syndrome (ARDS), and multiple organ dysfunction syndrome (MODS). The ligating lymph duct in a variety of species after hemorrhagic shock can prevent distant organ injury. However, the composition of lymph that is responsible for distant organ injury remains unknown.

Research frontiers

Recent studies proposed that mesenteric lymph-induced distant organ injury in intestinal I/R was directly mediated by gut-derived endogenous ligands, one of which is the high mobility group protein box 1 (HMGB1). HMGB1 acts as a late mediator of lethal sepsis and an early mediator of inflammation and necrosis following I/R injury. The research hot spot is whether HMGB1 in the intestinal mesenteric lymph after I/R mediates distant organ injury.

Innovations and breakthroughs

This study is a continuation of previous study. The authors hypothesized that the HMGB1 and toll-like receptor 4 (TLR4) combination plays an important role in the distant organ injury caused by intestinal I/R injury. The purpose of this study was to determine the impact of intestinal I/R injury and lymph drainage on the intestine and distant organs in rats, and to clarify whether HMGB1 in the intestinal mesenteric lymph after I/R mediates distant organ injury.

Applications

The study results suggest that intestinal injury after I/R stimulate the release of HMGB1, endotoxin, and inflammatory cytokines, and that lymph drainage could block the “gut-lymph” pathway, improve intestinal barrier function, reduce cytokine and endotoxin, and attenuate the injury of distant organs incurred by intestinal I/R; providing a reference for future clinical practice.

Terminology

Intestinal I/R injury: Intestinal I/R injury is the “motor” of SIRS, ARDS and MODS, and can be associated with severe trauma, acute necrotizing pancreatitis, major surgery, extensive burns, and other stresses; HMGB1: HMGB1 is one of the endogenous ligands which can be recognized by and combine with TLR4, and is also the key factor of inflammation of aseptic injury.

Peer review

This is a good descriptive study in which the authors have analyzed the impact of intestinal I/R injury and lymph drainage on distant organs in rats. The authors conclude that lymph drainage could block the “gut-lymph” pathway, improve intestinal barrier function, reduce cytokine and endotoxin, and attenuate the injury of distant organs in intestinal I/R lesions. The experiments were well designed, and the results were clearly demonstrated and analyzed. The techniques are appropriate and the conclusions are supported by the data presented.

Abstract

AIM: To compares the clinical features of patients infected with hepatitis E virus (HEV) with or without severe jaundice. In addition, the risk factors for HEV infection with severe jaundice were investigated.

METHODS: We enrolled 235 patients with HEV into a cross-sectional study using multi-stage sampling to select the study group. Patients with possible acute hepatitis E showing elevated liver enzyme levels were screened for HEV infection using serologic and molecular tools. HEV infection was documented by HEV antibodies and by the detection of HEV-RNA in serum. We used χ^2 analysis, Fisher's exact test, and Student's *t* test where appropriate in this study. Significant predictors in the univariate analysis were then included in a forward, stepwise multiple logistic regression model.

RESULTS: No significant differences in symptoms, alanine aminotransferase, aspartate aminotransferase, al-

kaline phosphatase, or hepatitis B virus surface antigen between the two groups were observed. HEV infected patients with severe jaundice had significantly lower peak serum levels of γ -glutamyl-transpeptidase (GGT) (median: 170.31 U/L vs 237.96 U/L, $P = 0.007$), significantly lower ALB levels (33.84 g/L vs 36.89 g/L, $P = 0.000$), significantly lower acetylcholine esterase (CHE) levels (4500.93 U/L vs 5815.28 U/L, $P = 0.000$) and significantly higher total bile acid (TBA) levels (275.56 μ mol/L vs 147.03 μ mol/L, $P = 0.000$) than those without severe jaundice. The median of the lowest point time tended to be lower in patients with severe jaundice (81.64% vs 96.12%, $P = 0.000$). HEV infected patients with severe jaundice had a significantly higher viral load (median: 134 vs 112, $P = 0.025$) than those without severe jaundice. HEV infected patients with severe jaundice showed a trend toward longer median hospital stay (38.17 d vs 18.36 d, $P = 0.073$). Multivariate logistic regression indicated that there were significant differences in age, sex, viral load, GGT, albumin, TBA, CHE, prothrombin index, alcohol overconsumption, and duration of admission between patients infected with acute hepatitis E with and without severe jaundice.

CONCLUSION: Acute hepatitis E patients may naturally present with severe jaundice.

INTRODUCTION

Although hepatitis E was recognized as a new disease in 1980, the virus was first visualized in 1983 and its genome was cloned and characterized in 1991, however, the disease is probably ancient but was not recognized until modern times^[1-6]. Hepatitis E is the most important or the second most important cause of acute clinical hepatitis in adults throughout Asia, the Middle East and Africa^[1]. Hepatitis E virus (HEV) is a small round RNA-containing virus that is the only member of the genus *Hepevirus* in the family *Hepeviridae*^[7]. The clinical course of hepatitis E is usually more severe than hepatitis A, and is frequently complicated by protracted coagulopathy and cholestasis. HEV accounts for more than 50% of acute viral hepatitis in young adults in developing countries^[8]. The disease course is benign, and severe jaundice is rarely reported. Severe icteric forms are unusual in patients without cirrhosis and have been documented in immunocompromised patients^[9]. These cases did not progress to fulminant hepatitis or severe acute hepatitis. However, the differences in the demography, mode of transmission, and clinical features of patients infected with HEV with and without severe jaundice have not been sufficiently studied. Thus, the present study was designed to determine the clinical features and risk factors of acute hepatitis E with severe jaundice in patients without cirrhosis. Jaundice was very marked in all patients. HEV infection was documented by HEV antibodies and by the detection of HEV-RNA in serum. Here, we studied a well-characterized population of HEV-infected individuals enrolled in a large Chinese cohort study. Acute HEV in our patients was characterized by severe jaundice with serum bilirubin levels above 171 $\mu\text{mol/L}$.

MATERIALS AND METHODS

Patients

Between December 2005 and December 2010, we diagnosed 235 cases of acute hepatitis E at Beijing YouAn Hospital affiliated to Capital Medical University in Beijing. Patients with possible acute hepatitis E showing elevated liver enzyme levels were screened for HEV infection using serologic and molecular tools. Biliary tract complications were ruled out by abdominal ultrasonography. Toxin- and drug-related causes of abnormal liver function tests were ruled out by patient history. 235 patients tested positive for serum HEV RNA. Serum samples which had been stored frozen (or below -20°C) were thawed prior to analysis. The samples were screened for immunoglobulin M (IgM) antibody to hepatitis A virus (AxSYM System, Abbott), hepatitis B virus surface antigen (HBsAg), IgM antibody to hepatitis B core antigen (AxSYM System, Abbott), polymerase chain reaction for HBV DNA and antibody to hepatitis C virus (AxSYM System, Abbott). Subsequently, the serum was also tested for IgM anti-Epstein-Barr virus antibody [anti-HEV IgM, enzyme-linked immunosorbent assay (ELISA), Biotest], and IgM anti-cytomegalovirus antibody (AxSYM System,

Abbott). Diagnosis of drug-induced hepatitis was based on patient history and clinical course; the lymphocyte stimulation index for drugs was used as an adjunct. Acute hepatitis of unknown etiology was a diagnosis of exclusion. Acute hepatitis E was defined by the presence of HEV RNA in acute-phase sera. Drugs and alcohol were excluded as likely etiological agents by patient history and a review of patient medications. Other causes of liver disease were excluded by testing for serum ceruloplasmin, 24-h urinary copper, antinuclear antibody, antismooth muscle antibody, serum iron and iron-binding capacity and alpha-1 antitrypsin levels.

We enrolled 235 patients with HEV. The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the Institutional Review Board at each institution. Informed consent was obtained from each patient.

Epidemiological survey and laboratory examinations

All patients enrolled in the study provided detailed medical history, including general data such as age, sex, onset of illness, travel history before onset of illness, history of blood transfusion, alcohol intake, medicine use, and disease complications. Acute hepatitis E with severe jaundice was defined as total bilirubin $> 171 \mu\text{mol/L}$. In this study, an underlying disease was defined as an active illness where the patient had received medical care before the onset of hepatitis. Overconsumption of alcohol was defined as daily ethanol ingestion over 50 g for 5 years or longer. To minimize recall bias and/or interview bias, we performed the following: we visited each patient at home twice in 3 mo and using an open-ended questionnaire assisted them to recall their daily ingestion and/or alcohol intake during the 2 mo preceding the onset of illness, and compared that with their current eating and drinking habits. In the laboratory examinations, total bilirubin, bilirubin direct, alanine aminotransferase (ALT), aspartate aminotransferase (AST), γ -glutamyltranspeptidase (GGT), alkaline phosphatase (ALP), albumin (ALB), acetylcholine esterase (CHE), total bile acid (TBA) and prothrombin index (PTA) were measured, using a sequential multi-autoanalyzer at each hospital.

Detection of anti-HEV IgM

Serum samples were tested for HEV IgG and IgM using a commercial ELISA kit (Wan Tai Pharmaceutical Co., Beijing, China) produced with two recombinant peptides corresponding to amino acid residues 396-603 of the major structural protein specified by open reading frame 2 of the HEV genome. The sensitivity and specificity of the ELISA kit was demonstrated by Zhang *et al.*^[10]. Serum samples were tested according to the manufacturer's instructions with three negative and positive control wells included on each plate. The samples with an optical density less than the cutoff value (cutoff value for IgG was equal to the mean optical density for the three negative controls on each plate plus 0.12, and the cutoff value for IgM was equal to the mean optical density for the three

negative controls on each plate plus 0.26) were considered negative. Samples with an optical density greater than or equal to the cutoff value were tentatively considered reactive and were retested in duplicate to confirm the result.

Detection of HEV RNA

Using the QIAamp RNA Blood Mini Kit (QIAGEN, Germany), RNA was reverse transcribed into cDNA with 10 units of AMV Reverse Transcriptase (Promega, Madison, WI, United States) at 42 °C for 60 min. The primers used in this study were synthesized as previously described^[10]. The primer positions indicated below are relative to the HEV strain JYI-Chisai01C (GenBank accession number AB 197674): P1: 5'AAC(T)TATGC ACAGCCGGGTTG3' (forward position 5725-5746) P2: 5'CCCTTATCCTGCTGAGCATTTCTC3' (reverse position 6433-6455); P3: 5'GTC(T)ATGC(T)TC(T)TGC ATACATGGCT-3' (forward position 6010-6031) P4: 5' AGCCGACGAAATC(T)AATTCTGTC-3' (reverse po-

sition 6336-6357). The first round of polymerase chain reaction (PCR) was carried out in a 50 μL reaction volume with 8 μL cDNA, 25 pmol of each primer (P1, P2), 1 μL of 10 mmol/L dNTPs, and 0.5 μL TaKaRa Ex Taq polymerase. PCR was conducted for 35 cycles at 94 °C for 1 min, 55 °C for 45s and 72 °C for 1 min with a final extension time of 72 °C for 7 min. The second round reaction were carried out in a 50 μL volume with 8 μL of the first-round product, 25 pmol of each primer (P3/P4), and 0.5 μL TaKaRa Ex Taq polymerase. The parameters were the same as the first round. The second-round PCR products were separated by 2% agarose gel.

Statistical analysis

We used χ^2 analysis, Fisher's exact test, and Student's *t* test where appropriate in this study. Significant predictors in the univariate analysis were then included in a forward, stepwise multiple logistic regression model. A *P* value of < 0.05 was considered statistically significant; all tests were two-tailed. Data were analyzed using the statistical software StatView for Macintosh (Version 5.0 StatView, SAS Institute Inc., NC, United States).

RESULTS

Patients infected with HEV: Characteristics, laboratory data and outcome

Of the 235 patients with acute hepatitis E, 70 were diagnosed with acute hepatitis E and severe jaundice and 165 were diagnosed with acute hepatitis E without severe jaundice. Of the patients with acute hepatitis E and severe jaundice, 64 were male and 6 were female (all non-pregnant) with a median age of 56 years (range: 20-85years). Twenty-seven (39%) of these patients demonstrated alcohol overconsumption. Of the patients with acute hepatitis E without severe jaundice, 125 were male and 40 were female (all non-pregnant) with a median age of 51 years. Sixteen (10%) of these patients demonstrated alcohol overconsumption.

Comparison between patients infected with HEV

Comparison of baseline characteristics between the two groups. A comparison of characteristics between acute hepatitis E patients with severe jaundice and acute hepatitis E patients without severe jaundice is shown in Table 1.

There were significant differences in age and the male-female ratio between the two groups. There were no significant differences in occupation, history of traveling to endemic areas, blood transfusion, or the presence of underlying disease(s) between the two groups. Overconsumption of alcohol was observed in a higher proportion of patients infected with severe jaundice compared with those without severe jaundice (27/70 vs 16/165, *P* = 0.003). None of the patients had a history of ingesting raw wild deer, boar, bear or rabbits, or a history of blood transfusion, ingestion of raw pig liver, and/or undercooked pig intestines before the onset of illness. There were no significant differences in the intake of raw fish or shellfish between the two groups.

Table 2 Relation between acute hepatitis E with severe jaundice and risk factors

Risk factors	SE	P value	OR	95%CI

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; GGT: γ -glutamyl-transpeptidase; ALP: Alkaline phosphatase; ALB: Albumin; CHE: Acetylcholine esterase; TBA: Total bile acid; PTA: Prothrombin index; HBsAg: Hepatitis B virus surface antigen; OR: Odds ratio.

Comparison of clinical features between the two groups

The clinical features of the study population are shown in Table 1. There were no significant differences in symptoms, ALT, AST, ALP, or HBsAg between the two groups. HEV infected patients with severe jaundice had significantly lower peak serum levels of GGT (median: 170.31 U/L *vs* 237.96 U/L, $P = 0.007$), significantly lower ALB levels (33.84 g/L *vs* 36.89 g/L, $P = 0.000$), significantly lower CHE levels (4500.93 U/L *vs* 5815.28 U/L, $P = 0.000$) and significantly higher TBA levels (275.56 μ mol/L *vs* 147.03 μ mol/L, $P = 0.000$) than those without severe jaundice. The lowest median PT tended to be lower in the severe jaundice group (81.64% *vs* 96.12%, $P = 0.000$). The proportion of patients with PT $\leq 60\%$ was not significantly different in the severe jaundice group (7/60 *vs* 11/146, $P = 0.424$). HEV infected patients with severe jaundice had a significantly higher viral load (median: 134 *vs* 112, $P = 0.025$) than those without severe jaundice. HEV infected patients with severe jaundice showed a trend toward longer median hospital stay (38.17 d *vs* 18.36 d, $P = 0.073$).

Relation between acute hepatitis E with severe jaundice and risk factors

The multivariate logistic regression analysis indicated that there were significant differences in age, sex, viral load, GGT, ALB, TBA, CHE, PTA, alcohol overconsumption, and duration of admission between acute hepatitis E patients with and without severe jaundice. The relations between acute hepatitis E patients with severe jaundice and risk factors are shown in Table 2.

DISCUSSION

Clinically, HEV usually causes a self-limiting illness, with an average incubation period of 40 d, moderate jaundice,

and complete resolution of hyperbilirubinemia and normalization of aminotransferases within 1-6 wk. Laboratory findings in patients with HEV are also similar to other forms of viral hepatitis and include elevated serum bilirubin, alanine aminotransferase, aspartate transaminase, alkaline phosphatase, and gamma-glutamyl-transferase levels^[11]. The cases presented here are exceptional in that some patients had severe jaundice. We report 70 cases of acute hepatitis E with severe jaundice, no pruritus, normal serum creatinine levels, and normal PTA. Most cases of acute hepatitis E do not have severe jaundice. In this study, 70 of 235 cases with acute hepatitis E had severe jaundice. Our report is rather unique in that detailed personal interviews were performed to explore patients' exposures which may not have been recalled when the patient was originally investigated for hepatitis E. We maintained an attitude of strict neutrality during the interview to minimize recall bias and/or interview bias. The characteristics of the patients with hepatitis E and severe jaundice included in our study are summarized as follows: many patients were 4060 years of age, similar to endemic cases reported in Asia^[12,13], 64 patients (90%) were male; none of the patients had a history of ingesting wild animal meat or undercooked intestines. Raw or partially cooked shellfish are a common cause of HEV infection as shellfish filter large volumes of water. Five patients (7%) had a history of ingesting raw fish or shellfish. Four patients seemed to have underlying diseases. Recently, Mizuo *et al*^[14] reported that the presence of underlying disease(s) influence the severity of hepatitis E. The presence of underlying diseases was also significantly different between patients with severe jaundice and patients without severe jaundice. Sixteen patients (10%) demonstrated alcohol overconsumption. In our series, patients with severe jaundice consumed alcohol on a regular basis compared to those without severe jaundice, there were also significant differences in other background characteristics between the two groups. Alcohol overconsumption, however, was not associated with illness severity. Whether overconsumption of alcohol is associated with susceptibility to acute hepatitis E requires further research.

Physical examination revealed 235 icteric subjects, in otherwise good health, with no signs of hepatic failure. Specifically, there was no history of medication or drug use, and the patients denied taking any herbal supplements. Cholelithiasis is an unlikely explanation for jaundice, as there was no evidence of cholecystitis found on repeat imaging studies or during surgery, and there was no evidence of choledocholithiasis. There were no significant differences in symptoms, ALT, AST, ALP, or HBsAg between the two groups. Patients with severe jaundice showed more severe clinical manifestations (including laboratory data such as ALB, CHE and TBA levels, PTA and duration of hospital stay) than those without severe jaundice. Patients with severe jaundice had significantly lower peak serum GGT levels ($P = 0.007$) which requires further research. The proportion of patients with PT $\leq 60\%$, however, was not significantly different between the two groups. Bernardin *et al*^[15] reported that the severity of

hepatitis E was related to dose of the virus. We found that patients with severe jaundice had a significantly higher viral load than those without severe jaundice. The mechanisms underlying the development of severe jaundice during acute hepatitis E are likely to be multifactorial. It is well known that inflammatory liver cell necrosis is a factor in jaundice in the setting of acute viral hepatitis. Other cofactors of hyperbilirubinemia may include concomitant etiologies such as autoimmune cholangitis and accentuation of preoperative jaundice after laparotomy^[16,17]. Such cofactors can be ruled out in our patients as none of the patients underwent abdominal surgery, and autoimmune cholangitis is unlikely since serum autoantibodies were absent. It is therefore possible to hypothesize that HEV itself had a direct effect on the development of high-grade hyperbilirubinemia in these patients. Some data indicate that HEV has not only hepatocytic but also biliary tropism, and replicates within bile epithelial cells^[18-20]. However, the mechanisms underlying high-grade hyperbilirubinemia in HEV infection remain unclear.

According to our results, age, sex, GGT, ALB, CHE, TBA, viral load, and alcohol overconsumption seem to be risk factors affecting patients with acute HEV and severe jaundice (odds ratio = 1.026, 0.291, 0.997, 0.857, 1.000, 1.006, 1.005 and 2.476, respectively). In multivariate analysis, fever symptoms, ALT, AST, ALP, and HBsAg were not significant risk factors for acute HEV infection with severe jaundice. Taking into account that the majority of HEV infections in endemic areas are caused by genotype 1, a definitive picture of the differences in acute HEV infected patients with severe jaundice according to the genotype need to be obtained from more in-depth studies.

In conclusion, patients with acute hepatitis E may naturally present with severe jaundice. However, further clinical, epidemiological and virological studies are needed to elucidate HEV infection with severe jaundice and the association between HEV genotype and severe jaundice as well as its underlying mechanism.

COMMENTS

Background

Clinically, hepatitis E virus (HEV) usually causes a self-limiting illness, with an average incubation period of 40 d, moderate jaundice, and complete resolution of hyperbilirubinemia and normalization of aminotransferases within 1-6 wk. Laboratory findings in patients with HEV are also similar to other forms of viral hepatitis and include elevated serum bilirubin, alanine aminotransferase, aspartate transaminase, alkaline phosphatase, and gamma-glutamyl-transferase levels. The clinical course of hepatitis E is usually more severe than hepatitis A, and is frequently complicated by protracted coagulopathy and cholestasis.

Research frontiers

HEV accounts for more than 50% of acute viral hepatitis in young adults in developing countries. Severe icteric forms are unusual in patients without cirrhosis and have been documented in immunocompromised patients. These cases did not progress to fulminant hepatitis or severe acute hepatitis. However, the differences in the demography, mode of transmission, and clinical features of

patients infected with HEV with and without severe jaundice have not been sufficiently studied.

Innovations and breakthroughs

In this study, 70 of 235 cases with acute hepatitis E had severe jaundice, no pruritus, normal serum creatinine levels, and normal prothrombin index. Most cases of acute hepatitis E do not have severe jaundice. The report is rather unique in that detailed personal interviews were performed to explore patients' exposures which may not have been recalled when the patient was originally investigated for hepatitis E. The authors maintained an attitude of strict neutrality during the interview to minimize recall bias and/or interview bias.

Applications

The study was designed to determine the clinical features and risk factors of acute hepatitis E with severe jaundice in patients without cirrhosis. Jaundice was very marked in all patients. Acute HEV in the patients was characterized by severe jaundice with serum bilirubin levels above 171 $\mu\text{mol/L}$. These patients with severe jaundice might represent true cases of acute hepatitis E.

Terminology

The HEV is a small, non-enveloped, icosahedral, positive-sense, single-strand RNA virus. HEV is responsible for the majority of cases of what was previously called enterically transmitted non-A, non-B hepatitis. Hepatitis E is endemic in many subtropical and tropical areas. In these areas, hepatitis E occurs both epidemically and sporadically. Hepatitis E is a self-limiting disease of varying severity, presenting as acute, icteric hepatitis, with clinical and morphological findings similar to those of hepatitis A. Recent studies have found immunoglobulin G to HEV in several wild and domestic animal species native to developing and industrialized countries. Molecular evidence for natural HEV infection in swine has been reported for HEV-endemic and -nonendemic countries worldwide.

Peer review

The paper describes the characteristics of patients with a more severe jaundice than the remainder of the group.

Abstract

AIM: To investigate the growth-inhibiting and apoptosis-inducing effects of the gene MOB2 on human hepatic carcinoma cell line SMMC-7721.

METHODS: The full-length cDNA of the MOB2 gene was amplified from human umbilical vein endothelial cells. The correct full-length MOB2 cDNA was subcloned into the eukaryotic expression vector pEGFP-C1. After lipofection of the MOB2 gene into cancer cells, the levels of MOB2 protein in the cancer cells were detected by immunoblotting. To transfect the recombinant plasmid vector pEGFP-CI-MOB2 into SMMC-7721 cells, the cells were cultured in Dulbecco's Modified Eagle's

Medium with 10% fetal calf serum and glutamine, and then mixed with liposomes, Lipofectamine 2000 and the plasmid vector pEGFP-CI-MOB2.

RESULTS: We observed the growth and proliferation of SMMC-7721 cells containing pEGFP-CI-MOB2 and analyzed their apoptosis and growth cycle phases by flow cytometry. We successfully transfected the recombinant plasmid vector pEGFP-CI-MOB2 into SMMC-7721 cells and screened for a single clone cell containing MOB2. After transfection, MOB2 enhanced growth suppression, induced apoptosis, increased the ratio of G0/G1, significantly inhibited the advance of cell cycle phase, and arrested cells in G0/G1 phase.

CONCLUSION: MOB2 overexpression induces apoptosis and inhibits the growth of human hepatic cancer cells, which may be useful in gene therapy for hepatic carcinoma.

INTRODUCTION

Mps-one-binder (Mob) family proteins belong to a conserved gene family found in yeast^[1-3], *Drosophila*^[4,5] and mammals^[6]. Mob1 protein was originally identified as a regulator of mitotic exit and cytokinesis in yeast^[1]. In *Drosophila*, Mob1 is a key component of the Hippo

signaling pathway^[5,7] and thus plays a role in tumor suppression. Mob2 binds to Cbk1, a conserved protein kinase that is similar to human myotonic dystrophy kinase. Mob2 promotes polarized cell growth and induces asymmetric cell fate in fission yeast^[3,8-10]. In *Drosophila*, the Mob2 protein binds directly to the Tricornered protein, an ortholog of nuclear Dbf2-related (Ndr) kinase^[11]. Previous work has also shown that Dmob2 is involved in photoreceptor morphogenesis by regulating the subcellular localization of Crumbs, a cell polarity gene, and phosphorylated moesin^[12]. Knockdown of Dmob2 expression causes abnormal actin rearrangement and results in abnormal rhabdomere formation, which suggests that Dmob2 may regulate actin dynamics during rhabdomere formation^[12].

Ndr kinase belongs to a subfamily of serine/threonine protein kinases that control cell division and morphogenesis in various cell types^[13]. Ndr2 is induced in the mouse amygdala during fear memory consolidation. Other studies have demonstrated that this kinase plays an important role in neurite formation^[14]. Tricornered, the Ndr kinase ortholog in *Drosophila*, interacts with actin filaments and regulates dendritic tiling and branching^[11]. SAX-1, the ortholog of Ndr kinase in nematodes, activates the RhoA-GTPase signaling pathway during neurite formation^[14]. These results strongly indicate the importance of Ndr kinases in neurite formation. Mob proteins have been shown to bind Ndr kinases, making them important in kinase activation^[6]. In this study, we investigated what role Mob proteins play in the human hepatic carcinoma cell line SMMC-7721.

MATERIALS AND METHODS

Materials

The eukaryotic expression vector pEGFP-C1 and competent cells of *Escherichia coli* DH5 α were routinely preserved by the central laboratory of our hospital. We used the following materials in our studies: RNeasy Protect mini kit (Qiagen, Germany); SMARTTM PCR cDNA synthesis kit (Clontech, United States); DNA gel extraction kit (Dalian TaKaRa, China); plasmid mini preparation kit (Shanghai Huasun Biotechnology, China); KOD-Plus DNA polymerase (TOYOBO, United States); T4 DNA ligase and restriction enzymes (*Hind*III and *Kpn*I) (New England Biolabs, United States); Lipofectamine 2000 (Invitrogen, United States); rabbit anti-MOB2 monoclonal antibody (Santa Cruz Biotechnology, United States); and horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG (Zhongshan, China). Nucleic acid sequencing was performed by Shanghai Yingjun Bioengineering (China). MOB2 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) primers were synthesized by Shanghai Yingjun Bioengineering.

Construction of recombinant MOB2 vector

Total RNA was isolated from human umbilical vein endothelial cells. Full-length MOB2 cDNA was amplified

by reverse-transcriptase polymerase chain reaction. The primer pairs for MOB2 fragment amplification were designed based on the MOB2 mRNA sequence provided by GenBank using the Premier Primer 5.0 software package. The primer sequences used were as follows:

5'-CCCAAGCTTCCATGGACTGGCTCATGGGGAAGTC-3' (forward primer) and 5'-CGGGGTACCTCATCTCCTTCACGTGGTTCTG-3' (reverse primer). The reaction conditions were as follows: 94 °C for 1 min, 94 °C for 30 s, 60 °C for 30 s, and 68 °C for 75 s. After 35 amplification cycles, the product was extended at 68 °C for 2 min. After removal of the pEGFP cDNA with *Hind*III and *Kpn*I, the amplified fragment was inserted into pEGFP-C1 to make the expression vector pEGFP-C1-MOB2.

Cell culture and gene transfection

SMMC-7721 cells were maintained in Dulbecco's Modified Eagle's Medium containing 10% calf serum, 100 U/mL penicillin and 100 μ g/mL streptomycin in a humidified chamber at 37 °C with 5% CO₂. Transient transfections were performed. Gene transfer was conducted using the liposome-mediated method (Lipofectamine 2000; Invitrogen, United States) according to the manufacturer's instructions. Blank control, empty vector (pEGFP-C1) and pEGFP-C1-MOB2 transfection groups were constructed in this experiment.

Western blotting

To harvest cells under non-denaturing conditions, we removed the medium and rinsed the cells with ice-cold PBS. Ice-cold lysis buffer (500 μ L) was added to each well. The cells were scraped from the surface and transferred to an Eppendorf tube on ice. Each sample was then sonicated four times for 5 s while being kept cold. The mixture was centrifuged for 10 min at 4 °C, and the supernatant was saved as lysate for later use. The proteins (150 μ g) in the lysate were separated by sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis (10% polyacrylamide gel containing 0.1% SDS) and then transferred to a polyvinylidene difluoride membrane by electrophoretic blotting. The membranes were probed with specific antibodies and then treated with anti-rabbit IgG-HRP (1:2000). Protein bands were visualized by enhanced chemiluminescence using the procedure recommended by the manufacturer (Thermo Scientific, United States). The expression of GAPDH was measured as a control.

Flow cytometry analysis

Cell cycle parameters were determined by propidium iodide labeling of nuclear DNA. Cells (10⁶) were trypsinized and resuspended in 70% ethanol before being stored for later use. The cells were treated with RNase and Triton X-100 as well as with propidium iodide to label the nuclear DNA. The labeled cells were analyzed by flow cytometry at 630 nm for propidium iodide. The cell cycle parameters were determined using the DNA cell cycle analysis in the software provided by the manufacturer (Invitrogen).

Figure 1 MOB2 protein level in SMMC-7721 cells. 1: Control group; 2: Empty vector transfection group; 3: pEGFP-C1-MOB2 transfection group.

Determination of growth of cancer cells using trypan blue staining

SMMC-7721 cells were trypsinized and seeded into 24-well plates at a density of $10^5/\text{mL}$. After transfection, cells were digested and counted using trypan blue staining under an inverted light microscope for five consecutive days.

Plate colony formation assay

Approximately 100 cells were added to each well of a six-well culture plate. After incubation at 37°C for 15 d, cells were washed twice with PBS and stained with Giemsa solution. The number of colonies containing ≥ 50 cells was counted under a microscope [plate clone formation efficiency = (number of colonies/number of cells inoculated) $\times 100\%$]. Each experiment was performed in triplicate.

Statistical analysis

Student's *t* test and analysis of variance were performed for statistical analysis with SPSS version 10.0.

RESULTS

Verification of MOB2 expression vector

After the recombinant plasmid pEGFP-C1-MOB2 was digested by both *Hind*III and *Kpn*I, two bands appeared in the gels, with the larger band at about 3945 bp and the smaller one at 734 bp, showing that the eukaryotic expression vector had been successfully constructed. The results of nucleic acid sequencing indicated that the full-length Chinese MOB2 cDNA had been cloned successfully. BLAST analysis demonstrated that the cloned sequence was 100% homologous to the previously reported MOB2 sequence.

Detection of MOB2 expression

Western blotting indicated that uninfected SMMC-7721 cells and empty-vector-infected SMMC-7721 cells showed only faint traces of MOB2 gene product. In contrast, a bright MOB2 band was obtained from pEGFP-C1-MOB2-infected SMMC-7721 cells. Western blotting indicated that 72 h after transfection with pEGFP-C1-MOB2, MOB2 protein expression increased by 3.8 times compared with that of the control group ($P < 0.01$). These results suggested that the transduction of the MOB2 gene was successful and that expression of the protein was significantly higher after transfection (Figure 1).

Figure 2 Effects of pEGFP-C1-MOB2 transfection on proliferation of SMMC-7721 cells.

Figure 3 The growth of SMMC-7721 cells was examined by plate colony formation assay. ^a $P < 0.05$ when compared with pEGFP-C1-MOB2 cells and control vector cells.

MOB2 inhibits cell proliferation in vitro

To analyze the function of MOB2, we studied the rate of cell proliferation of MOB2-expressing SMMC-7721 cells. The growth curves, as determined by a trypan blue staining assay, showed that MOB2 significantly inhibited proliferation of SMMC-7721 cell lines when compared with parental SMMC-7721 cells and control clone cells (Figure 2). A colony formation assay showed that MOB2-overexpressing SMMC-7721 cells formed significantly fewer colonies than control clone cells ($P < 0.001$) (Figure 3), suggesting an inhibitory effect of MOB2 on human hepatic carcinoma SMMC-7721 cells.

Inhibition of cell cycle by MOB2

To determine the effect of MOB2 on the cell cycle, we measured cell cycle distribution in MOB2-expressing SMMC-7721 cells. In these cell lines, the S-phase population was markedly decreased while the G1 population was significantly increased compared with the control-vector cells and the SMMC-7721 cells ($P < 0.01$). Neither

Figure 4 The cell cycle in parental SMMC-7721 cells, control vector cells and pEGFP-C1-MOB2 cells was determined by FACS Caliber cytometry. ^a*P* < 0.05 when compared with pEGFP-C1-MOB2 cells and control vector cells.

cell line had significant changes in the G2 population (Figure 4, Table 1).

DISCUSSION

Ndr kinase belongs to a subfamily of serine/threonine protein kinases that control cell division and morphogenesis in various cell types^[13]. Ndr2 is induced in the mouse amygdala during fear memory consolidation. Further studies have demonstrated that this kinase plays an important role in neurite formation^[14]. Tricornered, the Ndr kinase ortholog in *Drosophila*, interacts with actin filaments and regulates dendritic tiling and branching^[11]. SAX-1, the ortholog of Ndr kinase in nematodes, activates the RhoA-GTPase signaling pathway during neurite formation^[14]. These results strongly indicate the importance of Ndr kinases in neurite formation. Mob proteins have been shown to bind Ndr kinases, making them important in kinase activation^[6]. These results suggest that MOB2 might play a suppressive role in tumor pathogenesis.

To examine whether MOB2 plays a suppressive role in cancer cells, we applied a gain-of-function approach by introducing MOB2 into cells to investigate its biological function. SMMC-7721 cells were transfected with a MOB2-pEGFP-expressing eukaryotic vector and selected using G418. We successfully established cell lines that stably expressed MOB2 protein at dramatically elevated levels compared with control cells. Subsequent functional studies demonstrated that overexpression of MOB2 led to G1/S transition blockage and significantly reduced *in vitro* cell growth.

A tumor suppressor gene is a gene that slows down cell growth and thus reduces the probability that a cell in a multicellular organism will turn into a tumor cell. A mutation or deletion of such a gene increases the probability of the formation of a tumor and fails to keep cancer from growing. The results of the present study indicate that the MOB2 gene plays a role in carcinogenesis and may be a candidate tumor suppressor gene. Furthermore,

Table 1 Overexpression of MOB2 retarded cell cycle progression from G1 to S phase

Group	Cell cycle		
	G1	S	G2
SMMC-7721	42.41 ± 2.32	32.52 ± 4.53	23.54 ± 3.42
pEGFP-C1/SMMC-7721	45.45 ± 1.32	31.3 ± 3.11	24.24 ± 1.32
pEGFP-C1-MOB2/SMMC-7721	65.33 ± 4.34	17.33 ± 2.65	16.82 ± 3.14

our results clearly suggest that overexpression of MOB2 can inhibit proliferation and result in apoptosis of ovarian cancer cells. Therefore, reactivation of the MOB2 signaling pathway might provide an effective gene therapy strategy for human hepatic carcinoma.

COMMENTS

Background

Some reports suggest that knockdown of MOB2 expression causes abnormal actin rearrangement and results in abnormal rhabdomyere formation in *Drosophila*. However, few reports exist regarding the effects in MOB2 on cancer cells. In this study, the authors investigated what role the MOB2 proteins play in the human hepatic carcinoma cell line, SMMC-7721.

Innovations and breakthroughs

In this study, by cloning the MOB2 gene and transferring it into hepatocellular carcinoma cell line SMMC-7721, the authors investigated the growth-inhibiting and apoptosis-inducing effects of MOB2 gene on carcinoma cells and concluded that the over-expression of MOB2 gene could induce apoptosis and inhibit the growth of hepatic carcinoma cell line SMMC-7721.

Applications

These results suggest that MOB2 functions as an inhibitor of hepatic carcinoma and might serve as a new novel biological target to cure hepatic carcinoma.

Terminology

Mps-one-binder (Mob) family proteins belong to a conserved gene family found in yeast, *Drosophila*, and mammals. In *Drosophila*, MOB2 acts as a tumor suppressor through its function as a key component of the Hippo signaling pathway.

Peer review

In this study, the authors applied a gain-of-function approach to examine the biological processes regulated by MOB2 in SMMC-7721 cells. They demonstrated the functional importance of MOB2 in the suppression of SMMC-7721 cell growth. This is an important result, and it can bring out a new field in clinical tumor treatment.

Abstract

AIM: To evaluate the results of hepatic resection with *ex-situ* hypothermic perfusion and without veno-venous bypass.

METHODS: In 3 patients with liver tumor, the degree of the inferior vena cava and/or main hepatic vein involvement was verified when the liver was dissociated in the operation. It was impossible to resect the tumors by the routine hepatectomy, so the patients underwent *ex-situ* liver surgery, vein cava replacement and hepatic autotransplantation without veno-venous bypass. All surgical procedures were carried out or supervised by a senior surgeon. A retrospective analysis was performed for the prospectively collected data from patients with liver tumor undergoing *ex-situ* liver surgery, vein cava replacement and hepatic autotransplantation without veno-venous bypass. We also compared our data with the 9 cases of Pichlmayr's group.

RESULTS: Three patients with liver tumor were analysed. The first case was a 60-year-old female with a huge haemangioma located in S1, S4, S5, S6, S7 and S8 of liver; the second was a 64-year-old man with cholangiocarcinoma in S1, S2, S3 and S4 and the third one was a 55-year-old man with a huge cholangiocarcinoma in S1, S5, S7 and S8. The operation time for the three patients were 6.6, 6.4 and 7.3 h, respectively. The anhepatic phases were 3.8, 2.8 and 4.0 h. The volume of blood loss during operation were 1200, 3100, 2000 mL in the three patients, respectively. The survival periods without recurrence were 22 and 17 mo in the first two cases. As for the third case complicated with postoperative hepatic vein outflow obstruction, emergency hepatic vein outflow extending operation and assistant living donor liver transplantation were performed the next day, and finally died of liver and renal failure on the third day. Operation time (6.7 ± 0.47 h vs 13.7 ± 2.6 h) and anhepatic phase (3.5 ± 0.64 h vs 5.7 ± 1.7 h) were compared between Pichlmayr's group and our series ($P = 0.78$).

CONCLUSION: *Ex-situ* liver resection and liver autotransplantation has shown a potential for treatment of complicated hepatic neoplasms that are unresectable by traditional procedures.

INTRODUCTION

In 1988, *ex vivo* liver resection and liver autotransplantation were pioneered by Pichlmayr *et al*^[1], who tried to open a new platform for unresectable hepatobiliary malignancies and explore new modalities for liver surgery. In 1990, the whole liver was explanted and then perfused with cold preservation solution. The hepatic resection was performed on the back table and the remnant liver was reimplanted orthotopically. The aim of the extracorporeal hypothermic parenchymal resection was to extend oncological radicality by achieving an R0 margin with a better tumor-free cutting edge. But *ex-situ* liver surgery with veno-venous bypass aggravated ischemia-reperfusion injury of liver and resulted in the liver failure, which is the most common reason for the operation abortion. Subsequently, Hannoun *et al*^[2] and Sauvanet *et al*^[3] endeavored to improve the *ex-situ* technique. However, it is still difficult to avoid the ischemia-reperfusion injury and liver failure. To resolve this problem, we performed *ex-situ* liver surgery without veno-venous bypass in three patients with tumors involving inferior vena cava (IVC) based on the animal experiments. We introduce our experience in this operation as follows.

MATERIALS AND METHODS

Patients

From December 1999 to December 2008, a total of 1700 patients with hepatic tumors underwent routine hepatectomy at our hepatobiliary department. The extent of IVC and/or main hepatic vein (MHV) involved by the tumors was assessed by preoperative radiographic inspection. However, the degree of the tumor-involved IVC and/or main hepatic vein could not be confirmed by the preoperative inspection in three patients. Finally, it was verified when the liver was dissociated during the operation. The tumors were unresectable by the routine hepatectomy, so we performed *ex-situ* liver surgery, vein cava replacement and hepatic autotransplantation without veno-venous bypass. All surgical procedures were carried out or supervised by a senior surgeon (Dong JH). Patients' conditions are summarized in Table 1. There were two males and one female, with a mean age of 60 years (range, 55-65 years). Two patients suffered from cholangiocarcinoma and the other one from hemangioma.

Preoperative assessment

All patients were examined with computed tomography (CT) as indicated to exclude extrahepatic malignant disease of the abdomen, pelvis or chest. The location of the tumor and extent of involvement of intrahepatic vessel and IVC (Table 1) were assessed before surgery with CT (Figure 1A) and magnetic resonance imaging (Figure 1B). Cardiovascular, renal and pulmonary fitness for surgery was evaluated with an exercise electrocardiogram, chest radiography, and pulmonary function testing in all patients.

Table 1 General conditions of the three patients with liver tumor

No.	Sex	Age (yr)	Disease	Segments involved	Tumor diameter (cm)	Vessels involved or infiltrated
1	Female	60	Hemangioma	1, 4, 5, 6, 7, 8	20	IVC (circum 190°, length 5 cm)
2	Male	64	Cholangiocarcinoma	1, 2, 3, 4	6	IVC (circum 80°, length 3 cm)
3	Male	55	Cholangiocarcinoma	1, 5, 7, 8	5	IVC (circum 60°, length 2 cm) RHV, MHV, RPV

IVC: Inferior vena cava; RHV: Right hepatic vein; MHV: Main hepatic vein; RPV: Right portal vein; Circum: Circumference.

Anesthetic management

This type of surgery should be performed always with the presence of anesthesiologists who have experience with liver resection and are able to manage prolonged IVC occlusion and the changes that occur with liver reperfusion. During surgery, all patients were monitored by standard non-invasive techniques. In addition, a Swann-Ganz catheter and an arterial line should be placed before surgery in the patients who planned to undergo total vascular exclusion (TVE) with hypothermic perfusion. Body warmers were routinely employed to prevent hypothermia intraoperatively.

Method and techniques

We routinely used a bilateral subcostal incision which provided adequate exposure for almost all types of liver resection. After mobilization of liver, a double examination of the liver by palpation and ultrasonography was performed to confirm the number and size of the lesions, to define their relationship to intrahepatic vascular structures, exclude undiagnosed liver metastases and lastly to determine the resection line.

The approach of vascular control was chosen depending on the tumor location and extent of tumor involvement. The retrohepatic cava was partially occluded by a side clamp^[4] if the extent of involved IVC was small ($\leq 60^\circ$ circumferentially and ≤ 2 cm longitudinally). However, the TVE was needed to guarantee clear surgical field^[4-8] if the IVC was involved in a larger extent. The technique of TVE we used involves mobilization of the liver, exposure and control of the suprahepatic and infrahepatic vena cava as well as the portal structures (portal vein and hepatic artery)^[9,10]. *En bloc* liver and a segment of the vena cava were removed finally (Figure 2A).

IVC was quickly replaced with a 20-mm ringed polytetrafluoroethylene (PTFE) graft if it was infiltrated by the tumor. After that, IVC was unclamped (Figure 2B).

Hypothermic hepatic perfusion and bench hepatectomy: After parenchymal transection was completed, the liver was perfused and harvested as described for whole organ procurement. The hilar structures were divided on the bench. After cannulation of the portal and arterial

Figure 1 Computed tomography and magnetic resonance imaging of tumor. A: Preoperative computed tomography scan (case 1) demonstrated a large hemangioma located in S1, S4, S5, S6, S7 and S8 of liver, and inferior vena cava (IVC) was involved and compressed severely (IVC circumference 190°, longitude 5 cm); B: Magnetic resonance imaging (case 3) showed the tumor located in S1, S5, S7 and S8, with a diameter of 5 cm; IVC (circumference 60°, longitude 2 cm), right hepatic vein thrombus, main hepatic vein as well as right portal vein were infiltrated by the tumor.

Figure 2 Main technical aspects of *ex-situ* liver surgery without veno-venous bypass. A: Bench hepatectomy-cutting line of removed liver (case 3); B: Infiltrated inferior vena cava was replaced with a 20-mm ringed polytetrafluoroethylene graft; C: Reconstruction of inferior vena cava when polytetrafluoroethylene graft was removed (case 1); D: Anastomosis was performed in excised portal vein, hepatic artery and hepatic duct of residual right hepatic lobe (case 2).

systems, the liver was flushed with preservation solution [histidine-tryptophan-ketoglutarate (HTK)-Bretschneider] at 4 °C and packed with ice immediately. The volume of HTK used was 1 L. Proper hepatic artery and common bile duct were flushed respectively as well. The tumor was excised with cavipulse ultrasonic surgical aspirator and dipolar electrocautery unit under intraoperative ultrasonographic guide, and the involved blood vessels were partially excised, repaired, formed and reconstructed. Figure 2C shows that the involved IVC was peeled off, trimmed and replaced anastomosed PTFE graft in right

trisegmentectomy in the case of hemangioma.

The hepatic resection was performed on the back table and the remnant liver was reimplanted orthotopically (Figure 2D). After meticulous hemostasis, a fibrin glue sealant was sprayed on the cut surface. After irrigation, a closed suction drain was inserted, and the wound was closed in layers.

Statistical analysis

Fisher's exact tests were used to compare variables between Pichlmayr *et al*^[1] and the present series. All statisti-

cal analyses were performed using Stat View 5.0J (Abacus Concepts, Berkeley, CA). $P < 0.05$ was defined as significant difference.

RESULTS

Neither major perioperative surgical nor anesthesiological complications were observed and no respiratory complications were noticed during surgery or the immediate postoperative period. Patient general features and tumor characteristics are summarized in Table 1. The intraoperative clinical outcomes and postoperative clinical course are summarized in Table 2. The first case was a 60-year-old female with a huge hemangioma located in S1, S4, S5, S6, S7 and S8 of the liver; the second was a 64-year-old man with cholangiocarcinoma in S1, S2, S3 and S4 and the third one was a 55-year-old man with a huge cholangiocarcinoma in S1, S5, S7 and S8 (Table 1). The operation time for the three patients were 6.6, 6.4 and 7.3 h, respectively. The anhepatic phases were 3.8, 2.8 and 4.0 h. The volume of blood loss during operation were 1200, 3100 and 2000 mL, respectively. The survival period without recurrence was 22 and 17 mo in the first two cases, respectively. As for the third case, which was complicated with hepatic vein outflow obstruction after operation, emergency hepatic vein outflow extending operation and assistant living donor liver transplantation (LDLT) were performed the next day, and finally he died of liver and renal failure on the third day. Operation time (6.7 ± 0.47 h *vs* 13.7 ± 2.6 h) and anhepatic phase (3.5 ± 0.64 h *vs* 5.7 ± 1.7 h) were compared between Pichlmayr *et al*^[1] and our series (Table 3) ($P = 0.78$).

DISCUSSION

Ex-vivo liver resection and liver autotransplantation represents a new approach for liver surgery. We simplified the operation by omitting the veno-venous bypass, which shortened the operative time and anhepatic period.

Most liver tumors can be removed with conventional resection techniques using partial or total vascular occlusion when needed. But it is difficult to resect the central liver or posterior segments where hepatic veins are involved. The procedure would result in massive hemorrhage or air embolism if it was performed in such patients.

The accessory left hepatic artery should be occluded carefully, or it will lead to hepatic congestion or excessive bleeding. Huguet *et al*^[9] and Choi *et al*^[10] reported that TVE resulted in blood congestion of IVC and portal vein definitely and caused a series of physiopathologic problems. The congested blood re-enters the circulation and aggravates the injury of ischemia-reperfusion when the influx was recovered, especially in patients with liver cirrhosis. The mortality can reach up to 75% after the hepatectomy using the TVE method.

With the development of surgical techniques, the veno-venous bypass has been applied to complicated hilum hepatectomy^[11]. The blood in portal vein and IVC was by-passed by the bio-pump to ensure the stability of general circulation and lessen the ischemia-reperfusion injury when the TVE was performed. The total veno-venous bypass technique enhances the tolerance of liver to warm ischemia. In this condition, the safe time limit of liver tolerance to total vascular occlusion seems to be 30-120 min^[7,12,13], which is short for extensive and complex tumors in a direct contact with major vascular structures.

To overcome this limitation and to reduce liver damage, the concept of hypothermic perfusion has come into consideration. This technique enables liver resection to proceed *in situ*, *ante situm* or *ex vivo*. The liver was filled by Belzer's University of Wisconsin solution. The tolerance to the ischemia phase is extended to 4 h with hypothermic liver perfusion. Azoulay *et al*^[14] completed complicated liver resections using combined veno-venous bypass and *in situ* hypothermic perfusion, and they testified that the duration of liver tolerance to ischemia could last 90

min at least in 85% cases. The IVC must be replaced and reconstructed if it is infiltrated by tumors extensively.

Ante situm liver resection (*in vivo* hypothermic perfusion and veno-venous bypass) has been applied widely to resect the tumors located in hepatic hilum, confluence of hepatic vein and IVC, but veno-venous bypass was used during the operation which led to severe water, electrolyte and acid-base imbalance during the first post-operative week. Azoulay *et al*^[14] reported that the mortality from *ex-situ* liver resection with hypothermic perfusion (28%) was higher than that from *in vivo* hepatectomy (8%). We reviewed the pertinent literature published from 1992 to 2007 and found that 41 cases underwent *ex-situ* liver surgery with hypothermic perfusion. But only one patient underwent *ex-situ* liver surgery with hypothermic perfusion without veno-venous bypass, and the patient is still alive^[15]. However, 10 patients died after the resection with veno-venous bypass with a mortality of 24%^[15-22]. Cabezuolo *et al*^[23] suggested that, in the resection with veno-venous bypass, the hemodynamic stability of the body and regional organs (kidney, gastrointestinal tract) was improved during the anhepatic phase, but the rate of kidney failure was not decreased. The procedure without veno-venous bypass has been verified to be feasible and safe during the past few years. The cost was reduced because this technique shortens the total operation time, reduces hemorrhage during operation and decreases the rates of reperfusion injury.

Taking into account these controversial facts and the deficiency of liver graft, we performed *ex-situ* liver surgery, vein cava replacement and hepatic autotransplantation without veno-venous bypass in three cases. The general conditions of the three cases are described in Table 1.

The first case is a patient with a huge hemangioma located in S1, S4, S5, S6, S7 and S8 (Figure 1A) where IVC was involved and compressed severely. It is likely to lead to grave hemorrhage if IVC is dissected in the operation because of involvement of IVC (circumference 190°, longitude 5 cm). The other two cases were patients with cholangiocarcinoma located at S1, S2, S3 and S4 and S1, S5, S7 and S8, respectively. The extension of infiltrated IVC was large (circumference $\geq 60^\circ$, longitude ≥ 2 cm)^[6,24].

Although the tumor diameter was about 5 cm, the IVC, right hepatic vein, MHV and right portal vein were involved in the third patient. And the aim of cholangiocarcinoma resection was to achieve an R0 margin with a better tumor-free cutting edge. So it is difficult to complete the resection in a short time if the *in situ* or *ante situm* procedure was performed. But the *ex-situ* liver resection with hypothermic perfusion could decrease the chance of blood disseminated, and provide more chances to achieve an R0 margin^[25].

We have accumulated much experience in performing complicated hepatectomy and liver transplantation. Before we performed the *ex-situ* liver surgery under hypothermic perfusion and without veno-venous bypass, we had done the operation in the animal experiments with the protocol approved by the ethics committee of

the hospital. In order to shorten the operation time, we repaired the IVC, and performed the *ex-vivo* hepatectomy when the IVC was resected at back table in the first case. The segment S2 and S3 was autotransplanted when the PTFE graft was removed. The operation time and the anhepatic phase were 6.6 and 3.8 h, respectively.

For the other two patients with cholangiocarcinoma, we performed *ex-vivo* hepatectomy with liver reimplantation. The segment 4b, 5, 6, 7 and 8 and segment 2, 3 and 4 were autotransplanted, respectively. Their operation time was 6.4 and 7.3 h and anhepatic phase was 2.8 and 4.0 h, respectively.

We compared our data with the Pichlmayr *et al*^[1] of 9 cases undergoing *ex-vivo* hepatectomy with veno-veno bypass. Our procedure shortened the time of surgery and anhepatic phase because we avoided the veno-venous bypass, although there was no significant difference between the different techniques ($P = 0.78$), possibly due to the small number of cases. Furthermore, no hepatic dysfunction resulting from the delayed liver hemoperfusion occurred in our group after operation. But in the 9 cases of Pichlmayr *et al*^[1], four cases suffered from hepatic dysfunction because of the delayed liver hemoperfusion. Although 3 cases received liver transplantation, they were all died of liver failure finally. In our study, the patients 1 and 2 are still alive without recurrence. The third case was complicated with acute liver failure because of outflow obstruction of hepatic vein after operation. Although emergency hepatic vein outflow extending operation and assistant LDLT were performed the next day, he died of liver and kidney failure at last. Therefore, it is important to reconstruct the outflow tract of hepatic vein for *ex-vivo* hepatectomy.

In conclusion, the *ex-situ* liver surgery under hypothermic perfusion and without veno-venous bypass extends the group of surgical patients, and offers a chance for the patients with unresectable liver tumor by traditional procedures. But further clinical studies are needed to verify the feasibility of this technique in clinical practice.

COMMENTS

Background

Primary liver malignancies together with metastatic liver tumors are the most common tumor types in human. Experimental studies are being conducted in hepatic resection with *ex-situ* hypothermic perfusion if huge lesions are located in hepatic hilum or hepatic vein confluence, which involved and/or infiltrated main hepatic vein and inferior vena cava (IVC).

Research frontiers

In some patients, the degree of the IVC and/or main hepatic vein involved by tumors is so extensive that it is impossible to resect the tumors by the routine hepatectomy. The *ex-situ* liver surgery, vein cava replacement and hepatic autotransplantation without veno-venous bypass have been performed.

Innovations and breakthroughs

The extracorporeal hypothermic parenchymal resection was to extend the oncological radicality by achieving an R0 margin with a better tumor-free cutting edge. But *ex-situ* liver surgery with veno-venous bypass aggravates ischemia-reperfusion injury of liver and results in liver failure. To resolve this problem, the authors performed *ex-situ* liver surgery without veno-venous bypass in three cases with tumors involving IVC based on animal experiments.

Applications

Ex-vivo liver resection and liver autotransplantation has shown a potential for treatment of complicated hepatic neoplasms that are unresectable by traditional procedures.

Peer review

The authors described their experience in hepatic resection with total vascular exclusion, *ex-situ* liver surgery, without the need of veno-venous bypass because of immediate replacement of inferior vena cava. The topic is of interest in the specific surgical field.

Abstract

AIM: To evaluate the safety and efficacy of CO₂ insufflation compared with air insufflation in the endoscopic submucosal excavation (ESE) of gastrointestinal stromal tumors.

METHODS: Sixty patients were randomized to undergo endoscopic submucosal excavation, with the CO₂ group ($n = 30$) and the air group ($n = 30$) undergoing

CO₂ insufflation and air insufflation in the ESE, respectively. The end-tidal CO₂ level (pETCO₂) was observed at 4 time points: at the beginning of ESE, at total removal of the tumors, at completed wound management, and 10 min after ESE. Additionally, the patients' experience of pain at 1, 3, 6 and 24 h after the examination was registered using a visual analog scale (VAS).

RESULTS: Both the CO₂ group and air group were similar in mean age, sex, body mass index (all $P > 0.05$). There were no significant differences in PetCO₂ values before and after the procedure ($P > 0.05$). However, the pain scores after the ESE at different time points in the CO₂ group decreased significantly compared with the air group (1 h: 21.2 ± 3.4 vs 61.5 ± 1.7 ; 3 h: 8.5 ± 0.7 vs 42.9 ± 1.3 ; 6 h: 4.4 ± 1.6 vs 27.6 ± 1.2 ; 24 h: 2.3 ± 0.4 vs 21.4 ± 0.7 , $P < 0.05$). Meanwhile, the percentage of VAS scores of 0 in the CO₂ group after 1, 3, 6 and 24 h was significantly higher than that in the air group (60.7 ± 1.4 vs 18.9 ± 1.5 , 81.5 ± 2.3 vs 20.6 ± 1.2 , 89.2 ± 0.7 vs 36.8 ± 0.9 , 91.3 ± 0.8 vs 63.8 ± 1.3 , respectively, $P < 0.05$). Moreover, the condition of the CO₂ group was better than that of the air group with respect to anal exsufflation.

CONCLUSION: Insufflation of CO₂ in the ESE of gastrointestinal stromal tumors will not cause CO₂ retention and it may significantly reduce the level of pain, thus it is safe and effective.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common tumors of mesenchymal tissue in the digestive system, with a property of non-directional differentiation. They are formed as a result of the overproliferation of immature spindle cells or epithelioid cells^[1], and characterized by overexpression of CD117 and CD34 based on the pathology. Thus, they can be distinguished from other mesenchymal tissue tumors such as leiomyoma, leiomyosarcomas, Schwann tumors and neurofibroma, *etc.*

GISTs appear unexpectedly, and the significance of EUS in the diagnosis and differentiation of GISTs has now been defined^[2]. However, GISTs should be considered as tumors inclined to recur and metastasize because their potential malignancy is difficult to predict. GISTs which are derived from the mucous layer and submucosa in the digestive tract are usually referred to endoscopic treatment, but lesions originating from the muscularis propria are difficult to completely resection; furthermore, multiple complications such as acute perforation can occur.

In recent years, with rapid advances in endoscopic submucosal excavation (ESE) to treat GISTs, ESE has been the preferred choice instead of surgical excision and follow-up observation as in the past. However, abdominal pain and abdominal discomfort after operation are apparent in patients undergoing ESE with the insufflation of air. Using CO₂ as a replacement for air could mean a remarkable improvement, because CO₂ can be absorbed by the gastrointestinal mucosa rapidly and be discharged from the body by respiration.

Foreign experts and scholars have begun investigating the application of CO₂ in endoscopic submucosal dissection^[3], endoscopic retrograde cholangiopancreatography^[4], as well as in double-balloon enteroscopy^[5], *etc.* So far, however, there has no report about the effect of endoscopic submucosal excavation with the insufflation of CO₂. In this study, we evaluate the safety and efficacy of CO₂ insufflation in ESE compared with the insufflation of air as control. We conducted this work as a prospective, comparative pilot study.

MATERIALS AND METHODS

Patients

From March 2011 to February 2012, 61 patients diagnosed as having submucosal lesions of the digestive tract derived

from muscularis propria distinguishable by endoscopic ultrasound (EUS) and computed tomography (CT) (26 were transferred from other hospitals) were enrolled in this study. One patient diagnosed with rectal malignant mesenchymoma with liver metastasis was not in conformity with the inclusion criteria. Sixty patients signed the medical informed consent form before the ESE. All 60 patients gave their consent to be randomized to undergo endoscopic submucosal excavation with insufflation of air ($n = 30$) or CO₂ ($n = 30$) by means of random numbers generated from the computer. The 60 patients were clinically manifested by abdominal discomfort, abdominal mass and hematochezia without intestinal obstruction; 13 of the 60 patients did not experience any noticeable symptoms.

The exclusion criteria were as follows: malignant GISTs with metastasis; intestinal obstruction; vascular invasion; large lesion (> 10 cm) that failed complete resection; young age (< 14 years) and incapable of finishing the relevant questionnaire; chronic obstructive pulmonary disease patients with the retention of CO₂; acute digestive tract hemorrhage or variation from normal; shock with various causes; severe cardiopulmonary cerebral diseases; inability to tolerate the preoperative preparation; allergic to propofol; pregnancy, breast-feeding, *etc.*

Experimental equipment

The main instruments used included a gastroscope (GIF-Q260J, Olympus, Japan), enteroscope (CF-Q260AI, Olympus, Japan), ultrasound gastroscope (UE-260, Olympus, Japan), CO₂ air-insufflation equipment (UCR, Olympus, Japan), needle (INJ1-A1-07.160, Medwork, Germany), hot biopsy forceps (FD-1U-1, Olympus, Japan), hemoclips (HX-610-135 and HX-610-090, Olympus, Japan), needle knife (3281, Boston, America), TT knife (KD-640L, Olympus, Japan), snare (99052012225MW, MTW/Edoscopic, Germany), high-frequency electric knife (ICC-200, ERBE, Germany) and argon plasma coagulation (APC300, ERBE, Germany). A transparent cap (D-201-11802/D-201-13404/D-201-10704, Olympus, Japan) was added to the tip of the endoscope during the endoscopic submucosal excavation.

Experimental methods

Intravenous anesthesia was executed by an anesthetist, who used propofol (AstraZeneca) to maintain general anesthesia. Routine oxygen treatment was performed (2-3 mL/min); meanwhile, heart rate, respiration, blood pressure, blood oxygen saturation and PetCO₂ were continuously monitored under anesthesia. Propofol was started as normal with 1.5-2.5 mg/kg, observing the change of life signs. Routine endoscopy was performed as soon as the absence of consciousness was seen, while respiration, heart rate, blood oxygen saturation, *etc.*, were essentially normal. Additional propofol at 0.3-0.5 mg/kg was given to sustain proper sedation in the event that the patient had a reaction.

No eating or drinking for 8 h prior to surgery was allowed. EUS was performed to ensure the stage and identification of the main lesions. CT examination was also used to observe the composition of the tumor and the

Table 1 Patient characteristics

Group	CO ₂ insufflation (n = 30)	Air insufflation (n = 30)	P value ¹

relationship with the surrounding organs and vessels, in order for it to be distinguished from other lesions. Like GISTs, advanced gastric cancer or gastric lymphoma can also grow outward, while GIST always showed the uneven thickening of stomach wall, obvious local invasion as well as the swelling of perigastric, hilar and abdominal lymph nodes, with an evenly enhanced mass. Patients with GISTs originating from the muscularis propria without metastasis to other regions were treated by endoscopic submucosal excavation under anesthesia.

The standard operating procedures were as follows: (1) Marking: it is recommended to carry out electrical coagulation at the edge of the distinguished lesion marked by use of an argon knife; (2) Submucosal insufflation: multiple parts of the submucosa outside the marker points were irrigated with normal saline (including methylene blue and epinephrine); (3) Incising mucosa at the edge of lesion: a needle knife was employed to spot-incise up till the submucosa, and a TT knife was used to incise the mucosa along the lateral margin of the marking point; (4) Excision: a snare was used to enclose the mucosa and submucosa of the lesions and expose the muscularis propria, then the lesion was excised along the edge with a TT knife. If lesions which were clinging to the serosa layer could not be excised completely, it was recommended to perform full-thickness isolation and carry out a perforation initiative. The wound was then observed carefully to see if there were tumors remaining. No remaining tumors existed under endoscopy. Subsequently all the removed tissues were sent for pathological examination to rule out positive margins, which proved that the tumor was excavated completely; and (5) Wound management: for the small blood vessels which were visible in the wound, electrocoagulation hemostasis was recommended by use of argon knife, and if need be, the wound was closed by suture with a metallic hemostatic clamp, as well as by spraying tissue glue on the wound to prevent hemorrhaging.

In order to ensure the double-blind nature of the trial, both the endoscope and the valve of the CO₂ insufflation equipment were covered by black cloth. Someone was put in charge of the valve of the insufflation equipment and

the switch of the gas pump; both the operator and the patient did not know what type of gas had been used.

Measuring of PetCO₂

Studies have shown that the partial pressure of end-tidal carbon dioxide (PetCO₂) and the arterial partial pressure of carbon dioxide [p(CO₂)] of a normal adult are very similar and close to each other, so that [p(CO₂)] is usually replaced by PetCO₂ because of its noninvasive characteristic^[6]. In this trial, we use the portable CO₂ analyzer (ULT-1, Datex-Ohmeda, Finland) to measure PetCO₂. The PetCO₂ was measured by nurses randomly at the following four time-points: at beginning of ESE, at total removal of the tumors, after completed wound management, and 10 min after ESE.

Grading of abdominal pain

The 100 mm visual analog scale (VAS) was applied to grade pain according to the varying degrees of severity^[7]. The spectrum of VAS is 0-100; the minimal point is 0 which means no pain, the maximal one is 100 which means unbearable agony. Patients' abdominal pain was assessed at 1, 3, 6 and 24 h after ESE. Consequently, questionnaires were collected at the endoscopy center in our hospital.

Statistical analysis

Statistical analysis was performed by using the software SPSS13.0 (SPSS Inc, Chicago, IL, United States). The results were expressed as mean ± SD, variables in the two groups were analyzed with a Student's *t* test. The comparison of mean VAS at all time points was analyzed with the nonparametric, rank-sum test for two independent samples (Wilcoxon, 1945). Percentage of pain scores of 0 at each time point between the two groups were preceded with chi-square test. The value of PetCO₂ at each time point was analyzed through the repeated measures of analysis of variance. *P* value < 0.05 was considered statistically significant.

RESULTS

Comparison of baseline characteristics between the two groups

All 60 patients completed the study protocol. Thirty patients were enrolled in the CO₂ group (17 males, 13 females, mean age 52.1 years) and 30 patients in the air group (16 males, 14 females, mean age 50.9 years). The body type was indicated by body mass index; in the CO₂ group the value was 21.63 kg/m², while in the air group this was 21.79 kg/m², there was no statistical difference between the two groups (*P* > 0.05). The actual clinical data are shown in Table 1.

Endoscopic submucosal excavation treatment in the two groups

The patients' diseased regions in the CO₂ group consisted of esophagus (4/30), stomach (22/30), rectum (2/30) and sigmoid colon (2/30), while in the air group, the diseased regions included esophagus (6/30), stomach (21/30),

Table 2 Endoscopic submucosal excavation treatment characteristics

Group	Location (n)	Diameter (cm)	Operating time (min)	Success rate (%)	Full-thickness isolation (n)
CO ₂	Esophagus (4)	1.7	41	100	3
	Stomach (22)	1.3	23		
	Rectum (2)	1.5	40		
	Sigmoid colon (2)	1.9	47		
Air	Esophagus (6)	1.1	43	100	2
	Stomach (21)	0.7	31		
	Rectum (2)	0.9	38		
	Sigmoid colon (1)	1.7	51		

Table 3 Comparison of PetCO₂ between the two groups

Time point	CO ₂ group (mmHg)	Air group (mmHg)	P value
Beginning of ESE	34.01 ± 2.03	33.32 ± 2.21	0.78
Removal of the tumors	31.21 ± 2.35	30.59 ± 2.73	0.73
Wound management	32.75 ± 2.69	32.01 ± 2.22	0.92
10 min after ESE	33.23 ± 2.56	32.61 ± 2.78	0.79

ESE: Endoscopic submucosal excavation.

rectum (2/30) and sigmoid colon (1/30). The mean diameters of tumors of the CO₂ group and the air group were 1.6 ± 0.3 cm (range 0.5–5.0 cm) and 1.2 ± 0.5 cm (range 0.5–4.0 cm), respectively. The mean operating time was 35 ± 12 min in the CO₂ group, and this was 41 ± 10 min in the air group. The success rate for complete resection of tumor was 100%. Both the CO₂ group and the air group had light intraoperative bleeding; the mean bleeding volume was approximately 10 mL, without postoperative bleeding. Five cases were diagnosed with extraluminal type under endoscopic ultrasonography; it was recommended to perform full-thickness isolation and a perforation initiative for 3 cases of 5 belonging to the CO₂ group, and for 2 cases of 5 belonging to the air group. There was no statistical difference in the ESE between the two groups ($P > 0.05$). The actual clinical data are shown in Table 2.

Comparison of PetCO₂ between the two groups

The value of PetCO₂ was compared at the following four time points: beginning of ESE, at removal of the tumors, at completed wound management, and 10 min after ESE. The value was expressed as mean ± SD; the clinical data are shown in Table 3. From the mean value at each time point above, we could conclude that the value of PetCO₂ at each time point between the two groups had no statistical difference ($P > 0.05$, Figure 1A).

Comparison of abdominal pain between the two groups after revival from anesthesia

The VAS was applied to evaluate the level of abdominal pain of the patients at the following four time points^[8]: 1, 3, 6 and 24 h after anesthesia revival, respectively. The results showed that there was a significant difference of the value of VAS at 1, 3 and 6 h after revival from anesthesia between the two groups ($P < 0.05$, Figure 1B).

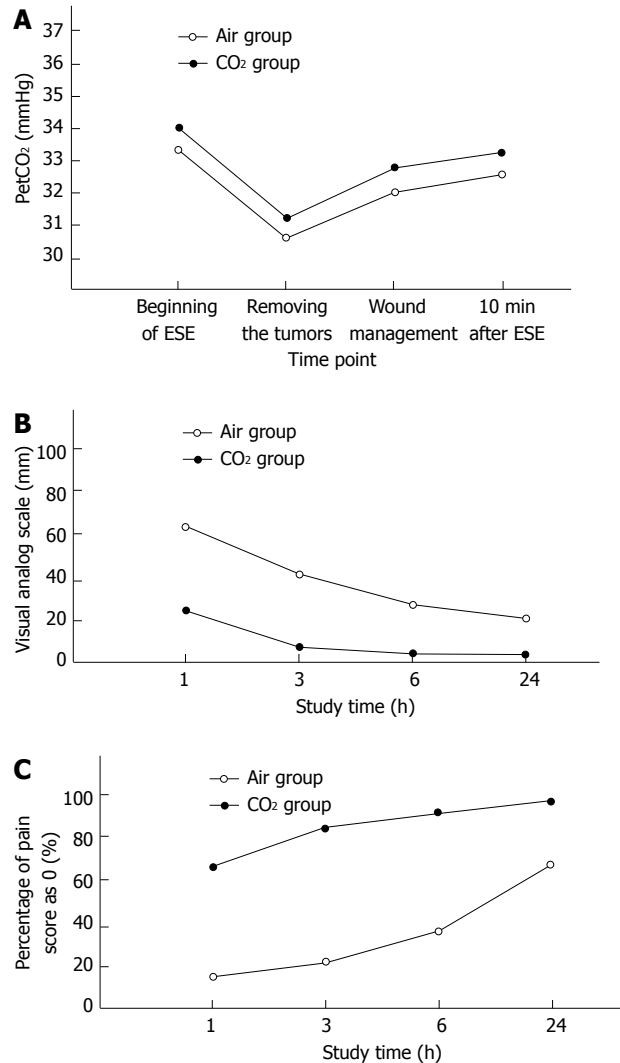

Figure 1 The comparison of PetCO₂ (A), visual analog scale (B) and percentage of pain score of 0 (C) at each time point between the CO₂ group and the air group. ESE: Endoscopic submucosal excavation.

Moreover, a comparison of the value of VAS at 24 h after revival from anesthesia between the two groups still had statistical difference. From Figure 1B, we can see that there was a slow decline in the air group, while the curved line declined more obviously in the CO₂ group (1 h: 21.2 ± 3.4 vs 61.5 ± 1.7 ; 3 h: 8.5 ± 0.7 vs 42.9 ± 1.3 ; 6 h: 4.4 ± 1.6 vs 27.6 ± 1.2 ; 24 h: 2.3 ± 0.4 vs 21.4 ± 0.7 , $P < 0.05$). Furthermore, the curved line returned to the baseline at 6 h after anesthesia revival in the CO₂ group; however, in the air group the curved line never returned to baseline. The percentage of VAS scores of 0 at each time point was subjected to chi-square test, and the result demonstrated that the percentage of VAS scores of 0 in the CO₂ group was significantly higher than that in the air group (1 h: 60.7 ± 1.4 vs 18.9 ± 1.5 ; 3 h: 81.5 ± 2.3 vs 20.6 ± 1.2 ; 6 h: 89.2 ± 0.7 vs 36.8 ± 0.9 ; 24 h: 91.3 ± 0.8 vs 63.8 ± 1.3 , respectively, $P < 0.05$, Figure 1C). Consequently, in the ESE of gastrointestinal stromal tumors, the condition of abdominal pain at each time point after revival from anesthesia could be clearly aggravated by the application of CO₂.

Comparison of anal exsufflation between the two groups

In checking the anal exsufflation of patients in the two groups at 1, 2 and 4 h after treatment, only 21% of the patients in the CO₂ group had anal exsufflation at 1 h after anesthesia revival, while 7% lasted for 2 h or more. However, 73.8% of the patients in the air group had anal exsufflation, and nearly 14.3% had a moderate or great amount of flatus, 28.6% lasted for 4 h or more. A comparison of the two groups at 1, 2 and 4 h after revival from anesthesia was carried out with a chi-square test, and a *P* value < 0.01 was found which was considered statistically significantly different. The amount of anal exsufflation had a negative correlation with the degree of abdominal pain and distension; furthermore, it also had a negative correlation with recovery time of abdominal distension in the air group.

DISCUSSION

GISTs should be considered as potentially malignant tumors owing to their unpredictable recurrence and metastasis; however, there are no definite clinical criteria for the diagnosis and treatment of GISTs^[9]. EUS, especially an EUS-fine needle aspiration, plays an important part in the diagnosis of GISTs, can determine the nature of submucosal lesions of the digestive tract and is instructive in the choice of treatment methods. GISTs with a diameter of 3–5 cm shown in the endoscopic examination and by pathology are more likely to be malignant; therefore, such GISTs are supposed to be thoroughly surgically excised^[10–14]. Although large GISTs are more inclined to be malignant, the small ones also have the possibility, so it is irrational to regard tumor size as the only standard for the malignancy of GISTs^[11,15]. In this study, we defined the risk classification of GISTs according to the National Institutes of Health^[16]. Consequently, the GISTs with definite diagnosis should be treated as much as possible.

Nowadays, a variety of surgical methods (as well as chemotherapy) for the treatment of GISTs are recognized in foreign and domestic studies. Surgical operation is still the traditional treatment; many patients with GISTs have been reported as being excised by undergoing laparoscopy^[17,18], and it is significantly important to excise larger lesions by surgical treatment. Imatinib, a tyrosine kinase inhibitor, is currently being used to treat GISTs which have unique kinase mutations that serve as targets for medical therapy, but some disadvantages exist such as high cost of therapy, long-term treatment and indeterminate side-effects; meanwhile few studies are reported about the treatment for GISTs with unclear symptoms^[19,20]. However, endoscopic therapy for these is much rarer. Choosing the treatment for GISTs that has lesser invasive injury and lower cost under endoscopy is rather clinically valuable.

Endoscopic mucosal resection (EMR) can be applied to the treatment of patients with distinguishable lesions of the digestive tract, such as early carcinoma and submucosal tumor. Moreover, EMR has not only the same therapeutic effect as surgical operation, but a short oper-

ating time, short hospitalization time, rapid recovery and low medical costs. However, it is hard to accomplish *en bloc* resection by the use of EMR for those lesions whose size is 2 cm or more. As a result, the remains are likely to recur and lead to many complications such as bleeding and perforation. Compared with EMR, ESE is able to excise a large majority of GISTs and provide intact data for pathological diagnosis. For preoperative evaluation of benign stromal tumors whose size is 5 cm or less, ESE is able to accomplish *en bloc* resection. ESE fully demonstrates the superiority of minimally invasive surgery as it has the advantage of rapid recovery, short hospitalization time and low medical costs. In our study, ESE was preferable for the GISTs originating from the muscularis propria, but not from the muscularis mucosae.

ESE is appropriate for GISTs originating from the muscularis propria; however, too much air insufflation because of a long operating time leads to pain for the patients in various degrees after revival from anesthesia. Pain caused by abdominal distension is the most common type, resulting from gastrointestinal gaseous tension. Therefore, it is recommended to select inhaling CO₂ instead of air, as the CO₂ is easily soluble in blood and other body liquids. It is not only rapidly absorbed by the gastrointestinal tract, but easily eliminated from the body by respiration. Patients never appear to have a metabolic disorder such as CO₂ retention. Yamano *et al.*^[21] has reported that the usage of CO₂ in enteroscopy could effectively alleviate the subjective pain of patients. In summary, our study investigated the comparison between the application of CO₂ and air insufflation for the ESE operation; the postoperative subjective pain of patients was measured by VAS and results suggested that the absolute VAS was lower in the CO₂ group than in the air group, and the number of patients with severe postoperative pain was also fewer in the CO₂ group.

We compared the value of PetCO₂ at the following four time points: beginning of ESE, at total removal of the tumors, at completed wound management, and 10 min after ESE. From the above data, we could draw conclusions that there were no significant differences of PetCO₂ at each time point between the two groups, suggesting that CO₂ is not able to cause postoperative retention as well not influencing the safety during the operation.

Comparing postoperative anal exsufflation between the two groups, the results revealed that the time of anal exsufflation in the CO₂ group is shorter than that in the air group, and that the flatus of patients in the CO₂ group is also less, which demonstrates that CO₂ is much easier to be absorbed. Both the difficulty of operation and the ratio of various related complications will increase in the case of the existence of a large amount of remaining gas.

The GISTs partly derived from muscularis propria are diagnosed as extraluminal type or clinging to the serosa by EUS. Those tumors clinging to the serosa layer cannot be excised completely by ESE; it is suggested to perform full-thickness excision and bring out a perforation initiative. In our study, there were five patients with full-thickness excision of GISTs who had little gas entry

into the abdominal cavity so that there was less obvious abdominal pain, and no postoperative abnormal conditions happened compared with other patients by ESE. However, the patients with full-thickness excision among the air group had severe abdominal pain as well as long-term gastrointestinal decompression.

In summary, CO₂ insufflation could effectively alleviate the pain of patients when the GISTs were excised by ESE, without the risk of CO₂ retention. The safety of CO₂ insufflation is comparable to that of air insufflation, and less pain exists after operation. Therefore, it is hopeful that CO₂ insufflation will become the standard method for ESE with full-thickness excision and it is apparent that this method will be widely applied in the future.

COMMENTS

Background

Gastrointestinal stromal tumors are the most common tumors of mesenchymal tissue in the digestive system. In recent years, endoscopic submucosal excavation has been used to treat gastrointestinal stromal tumors (GISTs) instead of surgical excision. The application of CO₂ in endoscopic submucosal excavation (ESE) could reduce the complications of the procedure effectively.

Research frontiers

Foreign experts and scholars have begun investigating the application of CO₂ in endoscopic submucosal dissection, endoscopic retrograde cholangiopancreatography, as well as in double-balloon enteroscopy, *etc.* So far, there has not been a report about the effect of endoscopic submucosal excavation with the insufflation of CO₂. In this study, the authors evaluate the safety and efficacy of CO₂ insufflation in ESE compared with the insufflation of air as control.

Innovations and breakthroughs

In this study, the authors have detailed the superiority of CO₂ insufflation in ESE. Compared with air insufflation, the pain scores after ESE at different time points in the CO₂ group decreased significantly. Meanwhile, the percentage of visual analog scale (VAS) scores of 0 in the CO₂ group after 1, 3, 6 and 24 h was significantly higher than that in the air group. Moreover, the condition of the CO₂ group was better than that of the air group in respect of anal exsufflation.

Applications

CO₂ insufflation could effectively alleviate the pain of patients when GISTs are excised by ESE without the risk of CO₂ retention. Therefore, it is hopeful that CO₂ insufflation will become the standard method for ESE with full-thickness excision and it will certainly be widely applied in the future.

Peer review

The authors examined the application of CO₂ insufflation in endoscopic submucosal excavation. The results suggested that the postoperative pain of patients measured by VAS seems to be lower in the CO₂ group than that in the air group, and the time of anal exsufflation in the CO₂ group is also shorter than that in the air group. So, CO₂ insufflation may be the standard method for the ESE with full-thickness excision in the future.

Abstract

AIM: To determine the risk factors for hepatocellular carcinoma (HCC) rupture, and report the management and long-term survival results of patients with spontaneous rupture of HCC.

METHODS: Among 4209 patients with HCC who were diagnosed at Eastern Hepatobiliary Surgery Hospital from April 2002 to November 2006, 200 (4.8%) patients with ruptured HCC (case group) were studied retrospectively in term of their clinical characteristics and prognostic factors. The one-stage therapeutic approach to manage ruptured HCC consisted of initial management by conservative treatment, transarterial embolization (TACE) or hepatic resection. Results of various treatments in the case group were evaluated and compared with the control group (202 patients) without ruptured HCC during the same study period. Continuous data were expressed as mean \pm SD or me-

dian (range) where appropriate and compared using the unpaired *t* test. Categorical variables were compared using the Chi-square test with Yates correction or the Fisher exact test where appropriate. The overall survival rate in each group was determined using the Kaplan-Meier method and a log-rank test.

RESULTS: Compared with the control group, more patients in the case group had underlying diseases of hypertension (7.5% *vs* 3.0%, $P=0.041$) and liver cirrhosis (87.5% *vs* 56.4%, $P<0.001$), tumor size >5 cm (83.0% *vs* 57.4%, $P<0.001$), tumor protrusion from the liver surface (66.0% *vs* 44.6%, $P<0.001$), vascular thrombus (30.5% *vs* 8.9%, $P<0.001$) and extrahepatic invasion (36.5% *vs* 12.4%, $P<0.001$). On multivariate logistic regression analysis, underlying diseases of hypertension ($P=0.002$) and liver cirrhosis ($P<0.001$), tumor size >5 cm ($P<0.001$), vascular thrombus ($P=0.002$) and extrahepatic invasion ($P<0.001$) were predictive for spontaneous rupture of HCC. Among the 200 patients with spontaneous rupture of HCC, 105 patients underwent hepatic resection, 33 received TACE, and 62 were managed with conservative treatment. The median survival time (MST) of all patients with spontaneous rupture of HCC was 6 mo (range, 1-72 mo), and the overall survival at 1, 3 and 5 years were 32.5%, 10% and 4%, respectively. The MST was 12 mo (range, 1-72 mo) in the surgical group, 4 mo (range, 1-30 mo) in the TACE group and 1 mo (range, 1-19 mo) in the conservative group. Ninety-eight patients in the control group underwent hepatic resection, and the MST and median disease-free survival time were 46 mo (range, 6-93 mo) and 23 mo (range, 3-39 mo) respectively, which were much longer than that of patients with spontaneous rupture of HCC undergoing hepatic resection ($P<0.001$). The 1-, 3-, and 5-year overall survival rates and the 1-, 3- and 5-year disease-free survival rates in patients with ruptured HCC undergoing hepatectomy were 57.1%, 19.0% and 7.6%, 27.6%, 14.3% and 3.8%, respectively, compared with those of 77.1%, 59.8% and 41.2%, 57.1%, 40.6% and 32.9% in 98 patients with-

out ruptured HCC undergoing hepatectomy ($P < 0.001$).

CONCLUSION: Prolonged survival can be achieved in selected patients undergoing one-stage hepatectomy, although the survival results were inferior to those of the patients without ruptured HCC.

Predictors and clinical outcomes for spontaneous rupture of hepatocellular carcinoma. *World J Gastroenterol* 2012; 18(48): 7302-7307 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7302.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7302>

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common neoplasms, and its incidence is increasing worldwide because of the increasing prevalence of hepatitis B and C virus infection^[1,2]. One of the life-threatening complications of HCC is the spontaneous rupture of the tumor, with intra-peritoneal hemorrhage. Spontaneous rupture of HCC occurs in 3%-26% of all patients with HCC, and the mortality rates are high in a range of 32%-66.7%^[3-7].

There are few reports of predictors for spontaneous rupture of HCC^[8-10]. In addition, clinicians often feel helpless when facing these complicated situations, and little information is available in the literature to guide clinicians as to the most appropriate management of this complication. The prognosis of ruptured HCC was poor, a median survival of 1.2-4 mo if left untreated^[11], but some studies have reported better survival with staged hepatectomy^[3]. There is still a debate concerning the best approach in cases of HCC rupture^[12]. The following treatments have been employed for the ruptured HCC: hepatic resection, conservative treatment and transcatheter arterial embolization (TACE)^[8,11-14]. It is also unclear whether the clinical outcome of definitive treatment including hepatic resection was affected by the complication of tumor rupture.

We, therefore, conducted this retrospective study to determine the risk factors for HCC rupture, and to report the management of patients with spontaneous rupture of HCC and long-term survival results during a 5-year period at a single center in China.

MATERIALS AND METHODS

Patients

From April 2002 to November 2006, 4209 patients with

HCC visited Eastern Hepatobiliary Surgery Hospital. Among them, 200 patients (4.8%) had hemoperitoneum due to spontaneous rupture of the tumor. The clinical records of these 200 patients (case group) were retrospectively reviewed and compared with 202 patients without ruptured HCC (control group) who were randomly chosen by matching age, sex and time of admission from the patients who visited our hospital in the same period.

All patients had a chest X-ray, ultrasonography (USG) of abdomen, and contrast computed tomography (CT) or magnetic resonance imaging (MRI) of abdomen. Laboratory blood tests were performed, including antigen to hepatitis B surface, antibodies to hepatitis C, alpha-fetoprotein (AFP), carcinoembryonic antigen, carbohydrate antigen 19-9, serum albumin, total bilirubin, aspartate aminotransferase, alanine aminotransferase, prothrombin time and so on. Progression profile of HCC (number of tumors, maximum tumor size, macroscopic tumor thrombus and extrahepatic invasion), treatments employed, and survival time were recorded. The liver function status was evaluated using the Child-Pugh classification system. HCC was staged according to the tumor node metastasis (TNM) staging system proposed by the American Joint Committee on Cancer (AJCC)^[15].

HCC was diagnosed by at least two radiologic imaging examinations showing characteristic features of HCC, or one radiologic imaging examination showing characteristic features of HCC associated with AFP ≥ 400 ng/mL. Ruptured HCC was diagnosed by the identification of a space-occupying lesion(s) in the liver using USG, CT or MRI. The following CT findings are useful for diagnosing a ruptured HCC: hemoperitoneum, HCC with surrounding perihepatic hematoma, active extravasation of contrast materials, tumor protrusion from the hepatic surface, focal discontinuity of the hepatic surface and an enucleation sign^[5].

Therapeutic options were determined for each patient according to the tumor feature and liver function. Selected patients with resectable tumor(s) and well preserved liver function were considered for surgery, and these patients with Child-Pugh class A liver function underwent major hepatic resection, while those patients with Child-Pugh class B liver function received minor hepatic resection. Patients with unresectable tumor(s) and well preserved liver function were considered for TACE, while those with poor liver function (Child-Pugh class C) were suggested to receive conservative treatment.

Statistical analysis

Information of patient details, intraoperative parameters, postoperative course, and disease progress was collected and analyzed retrospectively. Continuous data were presented as mean \pm SD or median (range) where appropriate and compared using the unpaired t test. Categorical variables were compared using the χ^2 test with Yates correction or the Fisher exact test where appropriate. Factors associated with a P value < 0.05 in the univariate analysis were sequentially entered into the multivariate

logistic regression analysis to indicate the relatively independent risk factors.

Group comparisons were performed using the Chi-square test for independence or the Fisher exact test for comparisons of the two groups. The overall survival rate in each group was determined using the Kaplan-Meier method and a log-rank test. The survival period defined as the length of time from the onset of the spontaneous rupture of the HCC to the death of the patient or the closing date of the study. The closing date for the study was November 31, 2011.

Table 2 Multivariate analysis for factors related with spontaneous rupture of hepatocellular carcinoma

Variables	HR	95%CI for HR	<i>P</i> value
Hypertension (presence <i>vs</i> absence)	7.75	2.10-28.57	0.002
Liver cirrhosis (presence <i>vs</i> absence)	7.16	3.96-12.97	< 0.001
Tumor size (≤ 5 cm <i>vs</i> > 5 cm)	3.97	2.28-6.93	< 0.001
Protrusion from the liver surface (yes <i>vs</i> no)	6.51	2.31-10.84	0.008
Vascular thrombus (presence <i>vs</i> absence)	2.90	1.48-5.70	0.002
Extrahepatic invasion (yes <i>vs</i> no)	3.78	2.04-7.00	< 0.001

HCC: Hepatocellular carcinoma; HR: Hazard ratio; CI: Confidence interval.

RESULTS

Clinical data between the case group and the control group are presented in Table 1. The initial symptoms of spontaneous rupture of HCC were the sudden onset of abdominal pain (134 patients, 67%), shock at admission (102 patients, 51%), and abdominal distension (66 patients, 33%).

Risk factors related to spontaneous rupture of HCC

Compared with the control group, more patients in the case group had underlying diseases of hypertension (7.5% *vs* 3.0%, *P* = 0.041) and liver cirrhosis (87.5% *vs* 56.4%, *P* < 0.001), tumor size > 5 cm (83.0% *vs* 57.4%, *P* < 0.001), tumor protrusion from the liver surface (66.0% *vs* 44.6%, *P* < 0.001), vascular thrombus (30.5% *vs* 8.9%, *P* < 0.001) and extrahepatic invasion (36.5% *vs* 12.4%, *P* < 0.001) (Table 1). On multivariate logistic regression analysis, underlying diseases of hypertension and liver cirrhosis, tumor size > 5 cm, tumor protrusion from the liver surface, vascular thrombus and extrahepatic invasion remained predictive for spontaneous rupture of HCC (Table 2).

Management of patients with spontaneous rupture of HCC

Among the 200 patients with spontaneous ruptured HCC, 126 (63%) had stage I or II HCCs according to the TNM staging system proposed by the AJCC^[15]. After recovery from the initial insult with blood replacement, correction of coagulopathy and cardiovascular monitoring and complete clinical evaluation, 105 patients were considered suitable for curative hepatic resection which was performed on a median of 15 d (range, 7-35 d) after rupture, 33 received TACE, and 62 were given conservative treatment. Of the 105 patients considered for hepatic resection, 72 (58.1%) underwent major hepatic resection while the remaining ones received minor hepatic resection. Operative details of these 105 patients undergoing hepatectomy are shown in Table 3.

Acute hemorrhage was successfully controlled in all patients (100%) undergoing hepatic resection during the first hospital admission, compared with 31.0% patients receiving TACE and 16.5% patients receiving conservative treatment. One patient (0.9%) died of liver failure

Table 3 Operative detail of 105 patients undergoing hepatectomy

Detail	n
Type of hepatectomy	105
Minor hepatectomy	43
Major hepatectomy	62
Operating time (min)	166.8 ± 70.2
Duration of blood inflow occlusion (min)	16.9 ± 9.0
Blood loss (mL)	811.4 (50-5000)
Surgical margins	
R0 resection	92
R1 resection	12
R2 resection	1
Hospital mortality	1
Major complications	
Post-operative bleeding	0
Liver failure	1
Bile leak	1
Pleural effusion	51
Postoperative hospital stay (d)	17.3 ± 6.7

on day 20 after hepatic resection, 10 (30.3%) patients died of liver failure after TACE and 36 (58.1%) patients died of bleeding after conservative treatment within 30 days of hospitalization, respectively.

Survival analysis of patients with spontaneous rupture of HCC

At the closing date of the study, 187 patients with spontaneous rupture of HCC died, including 92 (87.6%) in the surgical group, 33 (100%) in the TACE group and 62 (100%) in the conservative group. The median survival time (MST) of all patients with spontaneous rupture of HCC was 6 mo (range, 1-72 mo), and the overall survival rates at 1, 3 and 5 years were 32.5%, 10% and 4%, respectively. The MST was 12 mo (range, 1-72 mo) in the surgical group, 4 mo (range, 1-30 mo) in the TACE group and 1 mo (range, 1-19 mo) in the conservative group. The 1-, 3-, and 5-year overall survival rates in the surgical group were 57.1%, 19.0% and 7.6%, respectively, while they were 12.1%, 0% and 0% in the TACE group and 1.6%, 0% and 0% in the conservative group. In addition, the 1-, 3-, and 5-year disease-free survival rates of surgical group were 27.6%, 14.3% and 3.81%, respectively, while they were 9.1%, 0% and 0% in the TACE group and none in the conservative group.

In the 98 patients in the control group who underwent hepatic resection, the MST and median disease-free survival time were 46 mo (range, 6-93 mo) and 23 mo (range, 3-39 mo), respectively, which were much longer than in the patients with spontaneous rupture of HCC undergoing hepatic resection ($P < 0.001$). Accordingly, the 1-, 3- and 5-year overall survival rates of these 98 patients were 77.1%, 59.8% and 41.2%, and the 1-, 3- and 5-year disease-free survival rates were 57.1%, 40.6% and 32.9%, both of which were significantly longer than that of patients with spontaneous rupture of HCC undergoing hepatic resection ($P < 0.001$) (Figure 1).

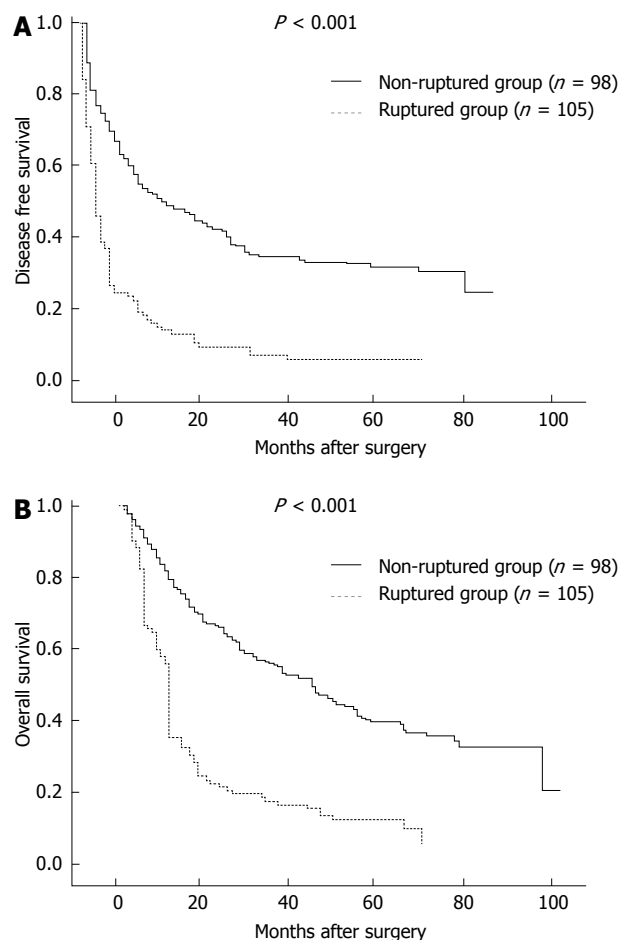

Figure 1 Overall survival and disease-free survival in patients with and without ruptured hepatocellular carcinoma undergoing hepatic resection.

DISCUSSION

As a life-threatening complication of HCC, spontaneous rupture of HCC is one of the most common emergencies in liver surgery. Seeking for the risk factors failed to conclude a widely accepted result^[5,16].

A widely accepted hypothesis for the mechanism of rupture of HCC suggests that rupture is usually preceded by rapid expansion of the tumor secondary to bleeding from within its substance, and a high intratumoral pressure due to occlusion of the hepatic venous outflow by tumor invasion results in rupture^[9]. In our study, we found that tumor protrusion from the liver surface, vascular thrombus and extrahepatic invasion were predictive for spontaneous rupture of HCC, which were consistent with previous studies^[5,9,16]. The protruded tumor without surrounding normal parenchyma may easily rupture due to compression or friction to the adjacent diaphragmatic muscle, abdominal wall and gastrointestinal tracts. Therefore, the presence of extrahepatic invasion more likely leads to rupture. Moreover, the maximum tumor size > 5 cm was one of the risk factors predicting rupture of HCC. However, in our study, rupture of tumors as small as 2 cm was found, which was consistent with a report by Tanaka *et al.*^[17]. It is difficult to explain how a small HCC

located in the periphery of the liver would rupture by above mechanism. More recent studies suggested that underlying vascular dysfunction may play a role^[8]. The vessels in the ruptured HCC tend to be more friable due to increased collagenase expression and increased collagen IV degradation^[10]. This proposed mechanism may help to explain why some of the small tumors also rupture.

Interestingly, in our study, the presence of hypertension and liver cirrhosis remained predictive for spontaneous rupture of HCC. The reasons may be as follows. HCC is a vascular tumor and bleeding secondary to rupture can cause tearing of vessels with uncontrollable blood loss, hypertension can directly result in an increase of pressure within the tumor. In addition, patients with cirrhosis have underlying coagulopathy. Both of the two factors may promote the process of rupture described above.

Previous studies have shown a very poor prognosis, with a 30-d mortality rate in the range of 30%-70%^[13,19,21], and recent reports have indicated a significant decrease in the mortality rate. In our study, we observed an overall 30-d mortality rate of 23.5%, while the mortality rate was only 0.95% (one patient) among the patients in whom hepatectomy was successfully conducted.

In another series, the 1-year and 3-year survival rates for patients who underwent emergency resection were only 60% and 42%, respectively^[22]. Miyamoto *et al.*^[23] reported that half of the hospital mortality of emergency hepatectomy for ruptured HCC was due to liver failure. One group reported that only 12.5% of the patients with ruptured HCC could be managed with hepatic resection, while another group reported a percentage of 59.3%^[4,24,25]. In our study, which yielded similar results, 52.5% (105/200) of patients with ruptured HCC could be managed with hepatic resection. In two case series of delayed resection for ruptured HCCs from Japan, no in-hospital mortality was observed, and 1- and 3-year survival rates of 71%-77% and 48%-54%, respectively, were achieved^[26,27]. In our series, the 1-year, 3-year and 5-year survival rates were 57.1%, 19.0% and 7.6%, respectively, for the patients with one-stage resection, and the MST in the surgical group was 12 mo.

For patients with unresectable HCC, TACE was the best option for the treatment of patients with ruptured tumor, and the MST in the TACE group was significantly longer than that in the conservative group. Most of the patients in the conservative group died within 1 mo as a result of re-rupture, re-bleeding or hepatic failure.

Historically, the prognosis for ruptured HCC is thought to be worse than for non-ruptured HCC, due to multiple factors. The patients with ruptured HCC harbor advanced disease at presentation, the incidence of coexisting cirrhosis is high, and peritoneal seeding may occur at the time of rupture. However, recent studies have challenged this concept, stating that the long-term survival for ruptured HCC may be equivalent to non-ruptured HCC^[20], especially when the comparison was adjusted for tumor stage^[28]. However, in our study, patients with ruptured HCC had a much worse long-term prognosis

than those without.

In conclusion, spontaneous ruptured HCC is a life threatening condition and a commonly encountered surgical emergency. For HCC patients who had underlying diseases of hypertension and liver cirrhosis, extrahepatic invasion and tumor size > 5 cm, high propensity to rupture should be considered. As long as preoperative clinical evaluation meets surgery requirements, elective one-stage hepatectomy in patients with ruptured HCC should be suggested. Prolonged survival can be achieved in selected patients undergoing one-stage hepatectomy, although the survival results were inferior to those of the patients who did not have the complication of rupture.

COMMENTS

Background

Spontaneous ruptured hepatocellular carcinoma (HCC) is a life threatening condition and a commonly encountered surgical emergency. There are few reports of predictors for spontaneous rupture of HCC. It was also not clear whether the clinical outcome of definitive treatment including hepatic resection is affected by the complication of tumor rupture.

Research frontiers

Seeking for the risk factors failed to conclude a widely accepted result. Several recent studies reported better survival with staged hepatectomy, and challenged traditional concept, stating that the long-term survival for ruptured HCC may be equivalent to non-ruptured HCC. There is still a debate concerning the best approach in cases of HCC rupture.

Innovations and breakthroughs

In this study, the presence of hypertension and liver cirrhosis remained predictive for spontaneous rupture of HCC. Patients with ruptured HCC had a much worse long-term prognosis than those without.

Applications

The study results suggest that for HCC patients who had underlying diseases of hypertension and liver cirrhosis, extrahepatic invasion and tumor size > 5 cm, high propensity to rupture should be considered. Prolonged survival can be achieved in selected patients undergoing one-stage hepatectomy, although the survival results were inferior to those of the patients who did not have the complication of rupture.

Terminology

HCC is the most common primary malignant tumor of the liver which originates from liver parenchymal cells. Spontaneous rupture of HCC refers to the HCC ruptured without any sign.

Peer review

The authors analyzed the clinical data of patients with spontaneous ruptured HCC and non-ruptured HCC for detecting the risk factors for HCC rupture, and reporting the management and long-term survival results of patients with spontaneous ruptured of HCC. They determined the risk factors and evaluated the prognosis for spontaneous rupture of HCC. This conclusion well guided clinicians as to the most appropriate management of this complication. The study was carefully designed and the evaluation of the results was also appropriate. The manuscript was well organized and well written.

Abstract

AIM: To investigate the short-term outcome of laparoscopic total mesorectal excision (TME) in patients with mid and low rectal cancers.

METHODS: A consecutive series of 138 patients with middle and low rectal cancer were randomly assigned to either the laparoscopic TME (LTME) group or the open TME (OTME) group between September 2008 and July 2011 at the Department of Colorectal Cancer of Shanghai Cancer Center, Fudan University and pathological data, as well as surgical technique were reviewed retrospectively. Short-term clinical and oncological outcome were compared in these two groups. Patients were followed in the outpatient clinic 2 wk after the surgery and then every 3 mo in the first year if no adjuvant chemoradiation was indicated. Statistical analysis was performed using SPSS 13.0 software.

RESULTS: Sixty-seven patients were treated with LTME and 71 patients were treated with OTME (sex ratio 1.3:1

vs 1.29:1, age 58.4 ± 13.6 years vs 59.6 ± 9.4 years, respectively). The resection was considered curative in all cases. The sphincter-preserving rate was 65.7% (44/67) vs 60.6% (43/71), $P = 0.046$; mean blood loss was 86.9 ± 37.6 mL vs 119.1 ± 32.7 mL, $P = 0.018$; postoperative analgesia was 2.1 ± 0.6 d vs 3.9 ± 1.8 d, $P = 0.008$; duration of urinary drainage was 4.7 ± 1.8 d vs 6.9 ± 3.4 d, $P = 0.016$, respectively. The conversion rate was 2.99%. The complication rate, circumferential margin involvement, distal margins and lymph node yield were similar for both procedures. No port site recurrence, anastomotic recurrence or mortality was observed during a median follow-up period of 21 mo (range: 9-56 mo).

CONCLUSION: Laparoscopic TME is safe and feasible, with an oncological adequacy comparable to the open approach. Further studies with more patients and longer follow-up are needed to confirm the present results.

Gong J, Shi DB, Li XX, Cai SJ, Guan ZQ, Xu Y. Short-term outcomes of laparoscopic total mesorectal excision compared to open surgery. *World J Gastroenterol* 2012; 18(48): 7308-7313 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7308.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7308>

INTRODUCTION

Rectal cancer accounts for approximately half of all colorectal cancer cases in China. Significant advances have been achieved in the treatment of rectal cancer in the past

few decades. With the introduction of total mesorectal excision (TME), laparoscopic technique, as well as pre- and postoperative chemo-radiotherapy, the local control rate and survival of rectal cancer patients have dramatically improved. The TME principles, which were first described by Heald *et al.*^[1], are currently considered the standard practice for mid and low rectal cancer as local recurrence is reduced to less than 5%^[2]. A complete TME consists not only of the routine excision of intact mesorectum, but also preservation of the autonomic nervous system and the sphincters.

Laparoscopic surgery has been used in the treatment of colorectal cancer since the end of the 1990s with the purpose of ameliorating postoperative recovery without compromising oncological adequacy. Although laparoscopy in colon cancer has gained acceptance due to its proven benefits^[3,4], which include fewer perioperative complications, faster postoperative recovery and comparable survival rates, laparoscopy in rectal cancer is still not recommended as the treatment of choice by National Comprehensive Cancer Network guidelines. Laparoscopic rectal surgery is more complex and technically demanding, especially for mid and low rectal cancer. As surgical techniques and equipment have developed, the feasibility and safety of laparoscopic TME (LTME) have been reported by many institutes^[5,6]. Moreover, long-term survival following LTME seems to be comparable to open TME (OTME)^[7,8]. However, there are few well-designed studies which have addressed this particular issue. Most of the randomized clinical trials on rectal cancer were performed in the early 2000s when the laparoscopic rectal surgical technique was still being developed, and the majority of these studies included both colon and sigmoid cancer^[9,10]. Thus it is inclusive whether laparoscopic surgery for rectal cancer is comparable to open surgery.

The aim of this study was to compare the short-term outcomes of LTME and OTME in mid and low rectal cancers in a series of unselected patients. The primary endpoints were operative details (operating time, blood loss, sphincter preservative rates and conversions), perioperative complications (anastomotic leak, obstruction, and wound infections) and postoperative recovery (urinary function, use of analgesics, and return of bowel movement). The secondary endpoints were pathological evaluations (positive margin involvement, number of lymph nodes harvested and length of inferior margin).

MATERIALS AND METHODS

Patients

Between September 2008 and July 2011, a consecutive series of 138 patients diagnosed with middle and low rectal cancer underwent surgical treatment at the Department of Colorectal surgery of Shanghai Cancer Center, Fudan University. The diagnosis in these patients was confirmed by a full colonoscopy plus a biopsy. The inclusion criteria were: patients diagnosed with rectal cancer with the tumor located ≤ 10 cm from the anal verge.

All patients received a systematic preoperative assessment including physical examination, biochemical analysis and a five-marker panel (carcinoembryonic antigen, carbohydrate antigen 19-9, cancer antigen 724, cancer antigen 242 and cancer antigen 125 for female patients) assay. Chest, abdominal and pelvic computed tomography scans were performed to rule out any pulmonary or liver metastasis. In addition, magnetic resonance imaging or endorectal ultrasound was performed to evaluate the preoperative staging. Patients staged at cT3/4 cTxN+ were assigned to neoadjuvant treatment in the absence of contraindications, and therefore were excluded from this series. The exclusion criteria also comprised patients with a former history of radiotherapy or chemotherapy, patients with distant metastases and patients with contraindication to laparoscopic surgery. An American Society of Anesthesiologists (ASA) grade was assigned to each patient by an anesthetist before surgery. Low molecular weight heparin was administered subcutaneously as prophylactic anticoagulant treatment and D-dimer was monitored regularly at day 1, 4 and 7 postoperatively.

Follow-up

Patients were routinely followed in the outpatient clinic 2 wk after surgery and every 3 mo for the first year, then every 6 mo for the second year, and every year thereafter. If there was an indication for adjuvant chemoradiation, follow-up data was complemented by phone contact with the patients as well as contact with the patients' current treating physicians. Data were collected and reviewed retrospectively, including patients' demographics, preoperative staging, surgical technique, pathological evaluations and postoperative recovery.

Surgical technique

All patients underwent low anterior resection (LAR) or abdominoperineal resection (APR) according to accepted TME principles. All surgeries were performed by the same team of surgeons with proven expertise in colorectal cancer surgeries who perform more than 100 laparoscopic and open colorectal surgeries annually. All patients were operated on under general anesthesia.

Four trocars were introduced after CO₂ pneumoperitoneum was established at 12 to 15 mmHg. A 10-mm port was positioned 0.5 cm above the umbilicus for observation. Another 10-mm port was introduced one-third of the distance from the right anterior superior iliac spine to the navel as the major operative site. Two additional 5-mm ports were placed for assistance. One port was set one-third of the distance from the left anterior superior iliac spine to the navel. The other was positioned at a digit inferior to the umbilicus crossing the left parasternal line reserved for possible colostomy.

Firstly, the peritoneal cavity was inspected carefully for any metastasis or tumor implantation. Adopting a median-to-lateral approach, the sigmoid was held by the assistant to the left and the right mesorectum was dissected starting from the sacral promontory. Sharp dis-

Figure 1 Surgical technique. A: Care must be taken not to injure the left ureter (arrow) while dissecting the inferior mesenteric artery; B: Careful preservation of the left colic artery (arrow); C: Preservation of bilateral sympathetic hypogastric nerves (arrows).

section continued along the “yellow-white boundary”, that is, between the adipose tissue in the sigmoid colon mesorectum and left peritoneum to the junction of the mesorectum. Dissection then proceeded as far as the origin of the inferior mesenteric artery (IMA). Care was taken not to injure the left ureter while dissecting the IMA (Figure 1A). The IMA and its concomitant vein were skeletonized and ligated using endoscopic clips close to the origin of the IMA. The left colic artery and vein were preserved (Figure 1B). It should be noted that the superior hypogastric plexus and sympathetic hypogastric nerves were at risk at this level (Figure 1C).

The next phase of surgery was pelvic dissection. The peritoneum was incised from the level of the sacral promontory posterior to the rectum down to the apex of the coccyx. It was important to recognize the loose

avascular plane between the parietal and visceral pelvic fascia before initiating sharp dissection of the presacral area. Anterior dissection occurred in the retrovesical septum in males and in the retrovaginal space in females. The rectosacral ligament and anococcygeal ligament were divided and incised at the level of the fourth sacral vertebra. The mesorectum was circumferentially mobilized while kept intact. A linear endoscopic cutting stapler was introduced to transect the rectum 2-5 cm below the tumor. Depending on the size of the lesion, a transverse incision of 3-4 cm was made to extract the specimen through a wound protector. The distal colon was transected 10 cm above the lesion. Before re-establishing the pneumoperitoneum, an anvil of the circular stapler was placed in the proximal colon and was fixed by a purse-string suture. The bowel was then returned to the peritoneal cavity, and the incision was sutured. The pneumoperitoneum was re-established. The last step of the procedure was to perform a low or ultra low rectal anastomosis with a circular stapler inserted transanally. The two tissue donuts created by the circular stapler were verified for integrity. The distal donut was sent for pathological examination as the circumferential margin.

For patients who have a deep, narrow pelvis, laparoscopic rectal transection is difficult. To guarantee a microscopically clear distal margin, the rectum was transected under direct vision with an assistant pulling the rectum outwards *via* the anus. Preservation of the sphincters was pursued based on the ability to achieve radical tumor removal. In patients with a very low tumor, the sphincters were unable to be preserved. The specimen was removed from the perineal incision and a permanent colostomy was performed at the anterolateral port.

Conversion was defined as performing any procedure using an open technique, other than extracting the specimen or transection of rectal cancer *via* the anus. The decision to convert was made when major complications occurred or when radical removal was impossible.

Patients in the OTME group underwent routine operation according to the TME principles. All patients were stratified based on tumor-node-metastasis classification. The duration of postoperative analgesia was as needed and was monitored. According to the National Comprehensive Cancer Network guidelines, patients who could possibly benefit received adjuvant chemotherapy or radiotherapy.

This study was approved by the Ethical Committee of Shanghai Cancer Center, Fudan University and all patients gave informed consent.

Statistical analysis

The statistical analysis was carried out using the SPSS software package version 13.0 (Chicago, IL, United States) and Windows 7. Parametric variables were expressed as mean \pm SD. The Student's *t* test was used to assess differences between the LTME and OTME groups. The χ^2 test (or Fisher's exact test where appropriate) and exact tests were performed to compare vari-

ables between the two groups. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Patients' characteristics

Between September 2008 and July 2011, a total of 138 patients were randomly assigned to either the LTME group or the OTME group. Sixty-seven patients underwent LTME and 71 patients underwent OTME. The sex ratio (male: female) was 1.3:1 and 1.29:1 for LTME and OTME, respectively. The mean age was 58.4 ± 13.6 years in the LTME group, and 59.6 ± 9.4 years in the OTME group. The two groups were well matched for age, sex ratio, body mass index, ASA, pathological tumor staging and differentiation grades as shown in Table 1.

Surgery and postoperative recovery

As shown in Table 1, there was no statistical difference in the types of surgical procedures chosen, including LAR and APR. The resection was considered curative in all cases. The sphincter-preserving rate was 65.7% (44/67) for LTME and 60.6% (43/71) for OTME and the difference was statistically significant. No protective diverting stoma was fashioned in either groups. Conver-

Table 2 Comparison of complications

Complications	LTME	OTME
Ureter damage	1	0
Anastomotic leak	1	1
Obstruction	1	3
Wound infection	1	2

LTME: Laparoscopic total mesorectal excision; OTME: Open total mesorectal excision.

sion to an open procedure was required in 2 cases (2.99%) due to ureter damage and severe adhesion, respectively.

Despite the fact that the operating time was significantly longer for LTME than OTME, there was significantly less hemorrhage in the LTME group than in the OTME group. Patients in the LTME group also enjoyed a significantly faster postoperative recovery, including lower requirement for analgesia and urinary drainage, faster return of bowel movement and earlier hospital discharge.

Complications

One patient (1.5%) suffered an anastomotic leakage in both the LTME group and in the OTME group (1.4%). A total of 4 patients suffered an obstruction, 1 (1.5%) in the LTME group and 3 (4.2%) in the OTME group. In addition, 1 patient and 2 patients in the LTME group and OTME group, respectively, suffered a wound infection. These differences were not statistically significant. There was no perioperative mortality (Table 2).

Oncological outcome and follow-up

With regard to oncological adequacy, the length of the specimen, distal margin of the tumor, number of harvested lymph nodes and positive circumferential margin were all comparable between the two groups. Short-term follow-up was available for all patients, with a median follow-up period of 21 mo (range: 9-56 mo). No port site recurrence, anastomotic recurrence or mortality was observed during the follow-up period.

DISCUSSION

Although laparoscopic surgery for colon cancer has been widely accepted due to its proven benefits, this technique for rectal cancer is controversial. In this report, we compared laparoscopic surgery to open surgery following TME principles in a consecutive series of patients who were operated on by a team of surgeons extensively experienced in laparoscopic colorectal surgery.

There is a growing body of literature reporting similar outcomes following LTME and OTME. Our results did not differ from the conclusion drawn from other publications that LTME was safe and feasible. Patients who underwent LTME benefited from a faster recovery, including less bleeding, less pain, faster return of urinary function and bowel movement, similar to that found in previous studies^[11].

However, there is still debate on whether LTME can

deliver an equally satisfying oncological radicality, allowing tumor-free margin and sufficient lymph node yield, while being minimally invasive^[12]. There is a lack of multicenter randomized trials addressing this particular issue. While we are still waiting for the results of the COLOR II trials, CLASICC remains the only randomized controlled trial available^[13,14]. The early results of CLASICC reported higher, but non-significant, rates of positive circumferential resection margin involvement, which did not translate into a difference in 3-year local recurrence rates. The 5-year follow-up results of the CLASICC trial were unable to show a difference in local recurrence, suggesting that this was probably the result of a learning curve effect. Not surprisingly, most investigations have reported different results. According to a meta-analysis conducted by Anderson *et al.*^[15], the positive radical margin involvement rate of rectal cancer was not significantly different between laparoscopic surgery and open surgery. Similar results were obtained for distal margin involvement.

With regard to lymph node yield, our study reported a mean number of 20.3 lymph nodes for LTME and 21.1 for OTME with no statistical difference. This was slightly less than that found by Dulucq *et al.*^[16]. They retrieved an average of 24.5 lymph nodes. However, our results were superior to most other studies where the mean number of lymph nodes harvested varied from 8 to 14^[17].

Due to the complicated nature of the TME procedure for middle and low rectal cancer, there are only a few publications which compare sphincter-preserving rates between laparoscopic and open approaches. It is worth noting that in our series, the sphincter-preserving rate was significantly higher in the LTME group. This may have been due to the fact that LTME provides the surgeon with a much more flexible operating space and allows them to dissect more easily down to the pelvic floor especially in patients with a deep, narrow pelvis. This clear, magnified and direct view is not available during OTME^[18,19]. Nonetheless, this study showed that having a deep, narrow pelvis with a large tumor complicated the LTME procedure and prolonged the operating time, but did not affect postoperative outcomes^[20]. The introduction of a linear endoscopic cutting stapler also guarantees a more satisfactory distal transection. Even when sphincter resection was inevitable, these advantages still facilitated pelvic surgery. Similar results were reported by Gezen *et al.*^[21] who had a higher rate of neo-adjuvant chemoradiation-treated patients in the LTME group. However, these advantages were not found in the largest series of rectal laparoscopic surgery, involving 612 patients, led by Zheng *et al.*^[22]. It is noteworthy that an increased rate of APR was observed in the LTME group in a relatively small series of Greek patients with mid and rectal cancer. This might be explained by the significantly lower location of the tumors in the LTME patients^[23].

Another advantage of laparoscopic surgery is greater magnification and better illumination of the surgical field, thus allowing better exposure of the autonomic nerves and their protection. Our study showed that pa-

tients in the LTME group required a significantly shorter period of urinary drainage. Considering the mean age in this series, patients were predisposed to possible sexual dysfunction before surgery. However, the incidence of postoperative sexual dysfunction was not taken into account in this study.

Conversion has always been a major concern of laparoscopic rectal surgery. Studies in the early 2000s reported a conversion rate as high as 20%. The CLASICC study also associated conversion with a clear survival disadvantage. However, researchers in the CLASICC trial were unable to attribute this disadvantage to advanced tumor stage or to surgeon-related factors. Conversion was found to be associated with poor prognosis^[24]. The latest studies report a conversion rate of 3%-22%, suggesting the involvement of patient selection and surgeons. In the present study, our conversion rate was 2.99%, and was closer to that found by Leroy *et al.*^[25] and Milsom *et al.*^[26]. This may be explained by the exclusion of patients staged at cT3/4 cTxN+ or with a former history of pelvic radiotherapy. With regard to postoperative complications, the distribution and incidence was similar between the 2 groups. Furthermore, a recent meta-analysis led by Lin *et al.*^[27] concluded that robotic surgery was superior to laparoscopic surgery in terms of conversion, and could be an alternative in patients who are more likely to undergo conversion.

Admittedly, a clear limitation of our study was that selection bias cannot be completely, even though the two groups were well balanced in terms of demographics and tumor statistics. However, by prospectively enrolling a consecutive series of patients operated on by the same team of surgeons, we hoped to avoid the learning curve effect. The follow-up period was too short to draw any conclusions as to the long-term outcome of LTME versus OTME, however, by continuing to enroll and follow-up patients, we hope to deliver more valuable information in the future.

Our study demonstrated that laparoscopic TME is safe and feasible, with an oncological adequacy comparable to the open approach. From our perspective, laparoscopic TME is performed through laparoscopic apparatus which are thin and long. In this way, tumors can be completely removed almost without being touched. Further studies with more patients and longer follow-up are needed to confirm the present results.

COMMENTS

Background

Rectal cancer accounts for approximately half of all colorectal cancer cases in China. With the introduction of total mesorectal excision (TME), laparoscopic technique, as well as pre- and postoperative chemo-radiotherapy, the local control rate and survival in rectal cancer patients have been dramatically improved.

Research frontiers

Although laparoscopy in colon cancer has gained acceptance due to its proven benefits, laparoscopy in rectal cancer is still not recommended as the treatment of choice by National Comprehensive Cancer Network guidelines. In this study, the authors demonstrated that laparoscopic TME (LTME) was advantageous in terms of clinical outcomes and comparable in oncological outcomes to open TME (OTME) in patients with mid and low rectal cancers.

Innovations and breakthroughs

Recent reports have highlighted similar outcomes following LTME and OTME in rectal cancer patients. This is the first study to prospectively compare LTME and OTME in a consecutive series of patients with middle and low rectal cancer regardless of the preservation of sphincters.

Applications

The present analysis confirmed the short-term benefits and comparable oncological adequacy of laparoscopic TME compared with the open procedure. This will be comforting to those surgeons performing the technique and should help to promote the laparoscopic TME approach so that a large multicenter randomized trial of LTME can be conducted to demonstrate its long-term benefits.

Peer review

The manuscript is generally well written, has an academic highlight that of the first study to prospectively compare LTME and OTME in a consecutive series of patients with middle and low rectal cancer. It is important that the shape and location of the intersigmoid recess for providing surgery of anus and rectum in laparoscopic total mesorectal excision and open mesorectal excision.

Abstract

AIM: To investigate the feasibility and the effectiveness of ileoileostomy in the region adjacent to the ileocecal valve, which can retain the ileocecal valve in infants.

METHODS: This is a retrospective review of 48 patients who underwent ileoileostomy in the region adjacent to the ileocecal valve (group 1) and 34 patients who underwent ileocecal resections and ileotransversanastomosis (group 2). Patients were monitored for the time to flatus, resumption of eating, length of hospital stay after surgery, serum total bile acid, vitamin B12 and postoperative complications.

RESULTS: The time to flatus, time until resumption of eating and post-operative length of hospital stay showed no statistically significant differences between the two groups. Serum total bile acid and vitamin B12

were not significantly different between the two groups at post-operative day 1 and day 3, but were significantly decreased at 1 wk after operation in group 2. None of the patients died or suffered from stomal leak in these two groups. However, the incidence of diarrhea, intestinal infection, disturbance of acid-base balance and water-electrolytes in group 1 was lower than in group 2.

CONCLUSION: Ileoileostomy in the region adjacent to the ileocecal valve is safe and results in fewer complications than ileotransversanastomosis in infants.

Enteroenteroanastomosis near adjacent ileocecal valve in infants. *World J Gastroenterol* 2012; 18(48): 7314-7318 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7314.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7314>

INTRODUCTION

Ileocecal valve plays a very important role in the regulation of intestinal transit. It acts as a barrier to delay passage for small bowel contents and hence increases absorption. It also prevents reflux from the caecum into the ileum^[1,2].

Anatomically, the terminal ileum has poor vascularization. The arterial supply of the terminal ileum in the region adjacent to the ileocecal valve comes from a single arch from the ileocolic artery. Therefore, conventional wisdom is, for a lesion involving the region of the ileum that is about 10-15 cm away from the ileoce-

cal valve, a right hemicolectomy should be selected^[3]. However, it was established in adults that the danger of incompetence of the anastomosis sutures near the blind gut was not greater than that in ileotransversanastomosis^[4]. Moreover, long-term results in adult patients after resection of the small intestine with the enteroenteroanastomosis near the blind gut were better than in patients with resection of the ileocecal valve, regarding passage of the intestinal contents^[4].

A previous study reported that an intact ileocecal valve was essential for better nutritive conditions in the newborn undergoing extensive small intestinal resection^[5]. In non-tumoral lesions, preservation of the ileocaecal valve to retain its important function should be considered. The terminal ileum has a high incidence of intussusception, transmesenteric hernia, intestinal atresia and necrotizing enterocolitis. Our aim was to determine the feasibility of ileoileostomy in the region adjacent to the ileocecal valve and compare the rate of complications of ileoileostomy in the region adjacent to the ileocecal valve and ileocolostomy after ileocecal resections in infants.

MATERIALS AND METHODS

Subjects

This is a retrospective review of 48 patients who underwent ileoileostomy in the region adjacent to the ileocecal valve (group 1) and 34 patients who underwent ileocecal resections and ileocolostomy (group 2) in the Department of Pediatric Surgery, Nanjing Children's Hospital, affiliated to Nanjing Medical University, between January 1, 2003 and May 3, 2011. In this study, all patients were without extensive ileal resection. We and our patients have established a long-term friendly relationship. The study was approved by the Ethics Committee of Nanjing Children's Hospital, affiliated to Nanjing Medical University. Informed consent was obtained from all the guardians of the subjects.

The patients were categorized into two groups. Group 1 included 48 patients (26 males and 22 females aged 1 d to 10.6 mo; median age 4.8 mo) who underwent ileoileostomy in the region adjacent to the ileocecal valve. Causes of surgery included intussusception (7), transmesenteric hernia (11), intestinal atresia (5), necrotizing enterocolitis (17), mesenteric cyst (5) and duplication of intestine (3). Group 2 included 34 patients (20 males and 14 females aged 1 d to 9.1 mo; median age 4.2 mo) who underwent ileocecal resections and ileocolostomy. Causes of surgery included intussusception (7), transmesenteric hernia (10), intestinal atresia (4), necrotizing enterocolitis (9), mesenteric cyst (2) and duplication of intestine (2) (Table 1).

No patient died during this study. The patients with underlying pathology associated with chronic diarrhea such as short bowel syndrome were excluded. Patients were monitored in the time to flatus, resumption of eating and length of hospital stay after surgery, serum total bile acid, vitamin B12 and post-operative complications.

Table 1 Subjects and their primary diseases

	Group 1	Group 2
Patients	48 (26 males and 22 females)	34 (20 males and 14 females)
Age	1 d to 10.6 mo (median age 4.8 mo)	1 d to 9.1 mo (median age 4.2 mo)
Primary diseases	Intussusception (7) Transmesenteric hernia (11) Intestinal atresia (5) Necrotizing enterocolitis (17) Mesenteric cyst (5) Duplication of intestine (3)	Intussusception (7) Transmesenteric hernia (10) Intestinal atresia (4) Necrotizing enterocolitis (9) Mesenteric cyst (2) Duplication of intestine (2)

Table 2 Time to flatus, resumption of eating, and length of hospital stay after surgery

	Time to flatus after surgery (d)	Time of resumption of eating after surgery (d)	Length of hospital stay after surgery (d)
Group 1	2 ± 0.9	6 ± 0.4	8 ± 3.1
Group 2	2 ± 0.7	5 ± 0.8	8 ± 2.5

Surgical process at ileocecal junction

In brief, for group 1, the mesentery close to the bowel wall was dissociated and the ileocolic artery trunk was reserved. After resection of the lesions of the terminal ileum, pulsatile bleeding was visible in the two ends of the bowel. An ileoileostomy was then performed with 5-0 PDS (2-5 cm away from the ileocecal valve at a median distance of 3.5 cm) with no embed. The arteria ileocolica was reserved. No intestinal decompression was added (Figure 1).

In group 2, after resection of the terminal ileum, ileocecal junction and the ascending colon and part of the colon transversum, an ileocolostomy was performed with 5-0 PDS.

The lesion resulting in the bowel resection was purple or gray, the mesenteric vascular pulse and bowel peristalsis disappeared, and the intestinal wall was inelastic. The resected bowel was approximately 10-30 cm.

Statistical analysis

Statistical analysis was carried out using SPSS software, version 14.0 (SPSS Inc., Chicago, IL, United States). A Pearson Chi-square test was used to compare the complications found in the two groups. The time of flatus, resumption of eating and length of hospital stay after operation were expressed as mean ± SD. Parameters were analyzed by Student's *t* test. For the above parameters, *P* < 0.05 was considered statistically significant.

RESULTS

Time to flatus, resumption of eating, and length of hospital stay after surgery

The time to flatus, resumption of eating, and length of hospital stay after surgery showed no statistically significant differences between the two groups (Table 2).

Figure 1 Enteroenteroanastomosis near the adjacent ileocecal valve.

Figure 2 Incidence of diarrhea, intestinal infection, and disturbance of acid-base balance and water-electrolytes in group 1 was lower than in group 2, but the incidence of incisional wound, ankylerteron, and septicaemia showed no differences. ^b*P* < 0.01 vs group 1.

Table 3 Serum total bile acid ($\mu\text{mol/L}$) and serum vitamin B12 (pg/mL)

	1 d after surgery	3 d after surgery	1 wk after surgery
Bile acid ¹			
Group 1	12.2 \pm 2.8	11.7 \pm 1.8	11.8 \pm 2.2 ²
Group 2	10.8 \pm 2.4	10.5 \pm 3.2	7.4 \pm 2.1
Vitamin B12 ²			
Group 1	712.5 \pm 143.4	696.2 \pm 108.5	683.2 \pm 104.2 ²
Group 2	685.3 \pm 131.5	623.8 \pm 132.1	560.8 \pm 99.2

¹Normal levels: 0-10 $\mu\text{mol/L}$; ²Normal levels (200-900 pg/mL). ^a*P* < 0.05 vs group 2.

After surgery, we advised nurses and parents to pay attention to the first flatus (anal exhaust) or defecation

of the children, and recorded the time as well.

Resumption of eating was guided and determined by little liquid in gastrointestinal decompression, no yellow or green liquid in gastrointestinal decompression, no flatulence, and successful defecation.

Serum total bile acid and vitamin B12

Serum total bile acid and vitamin B12 (Table 3) showed no significant differences between the two groups at post-operative day 1 and day 3, but were significantly decreased at 1 wk after operation in group 2.

Post-operative complications

None of the patients died or suffered from stomal leak in these two groups. However, the incidence of diarrhea,

bacterium in stool cultivante, and disturbance of water-electrolytes in group 1 was lower than in group 2 (Figure 2).

DISCUSSION

The present study showed that ileoileostomy in the region adjacent to the ileocecal valve was safe and was associated with fewer complications.

Previous studies have demonstrated that resection of the ileocaecal valve has several adverse effects. The ileocecal segment has been considered to possess a weak sphincteric action and functions in the flow of chyme and gut motility^[1]. The ileocaecal valve prevents the reflux of chyme, and thus prevents bacterial overgrowth from colonic bacterial flora in the small intestine. In the absence of an ileocecal valve, the colonic bacteria can reflux into the small intestine, resulting in infections of the small intestine and inflammation of the ileal mucosa^[6-11]. Moreover, in the absence of the ileocecal valve, transit time was decreased and there was reduced exposure to the absorptive surface. Without adequate detention time in the small intestine, accelerated chyme transport may lead to diarrhea, steatorrhea, malnutrition, dehydration, hypoalbuminemia and loss of minerals^[12]. Dorney *et al*^[3] found that the small bowel length required for survival was more than twofold when the ileocaecal valve was resected.

In animals and humans, bile salts and vitamin B12 have been shown to be major reclamation products from the ileum^[13-16]. Further studies showed that the ileal absorption of bile salts is mediated by an apical sodium-dependent bile acid transporter located in the terminal ileum^[17]. Previous studies have shown that patients with an ileal resection or disease of the distal ileum excreted bile salts in the feces significantly faster than healthy control subjects^[18]. Moreover, patients who underwent massive ileal resections, especially ileocecal resections, showed malabsorption of bile acids^[19,20]. Moreover, the anemia that occurred after ileocecal resection may have been due to deficiency in vitamin B12. As a result, preserving the ileal valve and terminal ileum might produce improved results.

Fernando *et al*^[21] found that in most of the specimens from human cadavers analyzed in their study, the arterial supply of the ileocecal junction was from the ileocolic artery, superior mesenteric artery, and terminal ileal branches of the superior mesenteric artery. In their study, anastomosis in the ileocecal junction with small windows was observed in 38 (70%) cases, more than the cases for large windows. Moreover, Serova^[4] demonstrated that the danger of incompetence of the anastomosis sutures in the region adjacent to the ileocecal valve was not higher than that in ileotransversanastomosis, and the immediate and long-term results in the enteroenteroanastomosis group were much better than in the group that had exclusion of the ileocecal segment. In our study, we demonstrated that after dissociating the mesentery close to the bowel wall and removing the part of the vascular network adjacent to the ileocecal junction, en-

teroenteroanastomosis near the blind gut was safe and no anastomotic leakage occurred.

Though there is a possibility of increasing the enteric cavity pressure of the ileocecal junction, we found that ileoileostomy only 2-5 cm away from the ileocecal valve is safe and effective in infants. This allowed a fluid diet to go through the ileal valve more easily than a solid diet. We also found that ileoileostomy in the region adjacent to the ileocecal valve was accompanied by fewer complications. As a result, the surgical method can be used clinically. Moreover, regarding the importance of the ileocecal valve, ileoileostomy in the region adjacent to the ileocecal valve might be helpful when a massive small bowel resection is necessary.

COMMENTS

Background

Ileocecal valve plays a very important role in the regulation of intestinal transit. It acts as a barrier to delay passage for small bowel contents and hence increases absorption. It also prevents reflux from the caecum into the ileum. In non-tumoral lesions, preservation of the ileocaecal valve to retain its important function should be considered.

Research frontiers

The terminal ileum has poor vascularization. The arterial supply of the terminal ileum in the region adjacent to the ileocecal valve comes from a single arch from the ileocolic artery. This study focuses on the feasibility of ileoileostomy in the region adjacent to the ileocecal valve and the complications of ileoileostomy in the region adjacent to the ileocecal valve.

Innovations and breakthroughs

Though there is a possibility of increasing the enteric cavity pressure of the ileocecal junction, the authors found that ileoileostomy only 2-5 cm away from the ileocecal valve is safe and effective in infants. This allowed a fluid diet to go through the ileal valve more easily than a solid diet. The authors also found that ileoileostomy in the region adjacent to the ileocecal valve was accompanied by fewer complications.

Applications

Enteroenteroanastomosis near the adjacent ileocecal valve can be used clinically. Moreover, regarding the importance of the ileocecal valve, ileoileostomy in the region adjacent to the ileocecal valve might be helpful when a massive small bowel resection is necessary.

Abstract

AIM: To elucidate high mobility group-box 3 (HMGB3) protein expression in gastric adenocarcinoma, its potential prognostic relevance, and possible mechanism of action.

METHODS: Ninety-two patients with gastric adenocarcinomas surgically removed entered the study. HMGB3 expression was determined by immunohistochemistry through a tissue microarray procedure. The clinicopathologic characteristics of all patients were recorded, and regular follow-up was made for all patients. The inter-relationship of HMGB3 expression with histological and clinical factors was analyzed using non-parametric tests. Survival analysis was carried out by Kaplan-Meier (log-rank) and multivariate Cox (Forward LR) analyses between the group with overexpression of HMGB3 and the group with low or no HMGB3 ex-

pression to determine the prognosis value of HMGB3 expression on overall survival. Further, HMGB3 expression was knocked down by small hairpin RNAs (shRNAs) in the human gastric cancer cell line BGC823 to observe its influence on cell biological characteristics. The MTT method was utilized to detect gastric cancer cell proliferation changes, and cell cycle distribution was analyzed by flow cytometry.

RESULTS: Among 92 patients with gastric adenocarcinomas surgically removed in this study, high HMGB3 protein expression was detected in the gastric adenocarcinoma tissues *vs* peritumoral tissues ($P < 0.001$). Further correlation analysis with patients' clinical and histology variables revealed that HMGB3 overexpression was obviously associated with extensive wall penetration ($P = 0.005$), a positive nodal status ($P = 0.004$), and advanced tumor-node-metastasis (TNM) stage ($P = 0.001$). But there was no correlation between HMGB3 overexpression and the age and gender of the patient, tumor localization or histologic grade. Statistical Kaplan-Meier survival analysis disclosed significant differences in overall survival between the HMGB3 overexpression group and the HMGB3 no or low expression group ($P = 0.006$). The expected overall survival time was 31.00 ± 3.773 mo (95%CI = 23.605-38.395) for patients with HMGB3 overexpression and 49.074 ± 3.648 mo (95%CI = 41.925-57.311) for patients with HMGB3 no and low-level expression. Additionally, older age ($P = 0.040$), extensive wall penetration ($P = 0.008$), positive lymph node metastasis ($P = 0.005$), and advanced TNM tumor stage ($P = 0.007$) showed negative correlation with overall survival. Multivariate Cox regression analysis indicated that HMGB3 overexpression was an independent variable with respect to age, gender, histologic grade, extent of wall penetration, lymph nodal metastasis, and TNM stage for patients with resectable gastric adenocarcinomas with poor prognosis (hazard ratio = 2.791, 95%CI = 1.233-6.319, $P = 0.019$). In the gene function study,

after HMGB3 was knocked down in the gastric cell line BGC823 by shRNA, the cell proliferation rate was reduced at 24 h, 48 h and 72 h. Compared to BGC823 shRNA-negative control (NC) cells, the cell proliferation rate in cells that had HMGB3 shRNA transfected was significantly decreased ($P < 0.01$). Finally, cell cycle analysis by FACS showed that BGC823 cells that had HMGB3 knocked down were blocked in G1/G0 phase. The percentage of cells in G1/G0 phase in BGC823 cells with shRNA-NC and with shRNA-HMGB3 was $46.84\% \pm 1.7\%$, and $73.03\% \pm 3.51\%$ respectively ($P = 0.001$), whereas G2/M cells percentage decreased from $26.51\% \pm 0.83\%$ to $17.8\% \pm 2.26\%$.

CONCLUSION: HMGB3 is likely to be a useful prognostic marker involved in gastric cancer disease onset and progression by regulating the cell cycle.

INTRODUCTION

Gastric cancer is reported to be one of the common devastating types of cancer. It has a high occurrence rate, short survival period and high mortality rate. The mortality rate can be up to 25.2/100 000 in China, which accounts for 25% of deaths in malignant cancer. The occurrence ratio and mortality are ranked as No. 1 and No. 2 in malignant cancer^[1]. Usually gastric cancer is already at a late stage when it is diagnosed; the 5-year survival rate in clinical stage III and IV patients is only about 28.4% and 7.6%, respectively. There are many factors including lymph node metastasis, extent of wall penetration, pathological tumor-node-metastasis (pTNM) stage, and surgical mode *etc.*, associated with prognosis of the disease. Those factors are more clinipathologically related, however, investigating molecular biomarkers can not only provide indications for clinic prognosis, but also can identify potential targets for clinical therapy.

High mobility group-box 3 (HMGB3) belongs to the high mobility group box (HMG-box) subfamily. It has 99% homology with HMGB1 and HMGB2^[2]. This subfamily has a HMG-box, so it can regulate gene transcription by participating with formation of enhancosomes.

The HMG-box subfamily also plays an important role in DNA replication, transcription, recombination and repair, *etc.*^[3,4]. HMGB3 was reported to have high expression in embryos and weak expression in adult tissues. HMGB3 is important in keeping the balance between self-renewal and differentiation status in mouse hematopoietic stem cells^[5]. Also it was known that HMGB3 is indispensable in maintaining mouse leukemia stem cell self-renewal capability. Simultaneously overexpression of HMGB3, c-MyB and CBX5 can make hematopoietic stem/progenitor cells immortalized^[6]. Recent studies showed that HMGB3 and NPU98 fusion protein forms a new oncogenic gene in leukemia^[7]. HMGB3 also participates in recurrence of acute lymphoid leukemia and it shows high expression in the progression phase of breast cancer^[8]. HMGB3 was identified as one of the bio-markers detected in peripheral blood in lung cancer^[9]. Though HMGB3 is found in some types of cancers, its role in gastric cancer is still unclear.

In this study, we observed the expression of HMGB3 in gastric adenocarcinoma tissues by immunohistochemistry, and analyzed its correlation between expression level and clinicopathologic variables and prognosis. We found that HMGB3 showed a high expression level in gastric cancer *vs* peritumoral tissues. And HMGB3 overexpression was obviously associated with extensive wall penetration, a positive nodal status, advanced TNM stage and poor prognosis. Moreover, we silenced HMGB3 expression in BGC823 gastric cancer cell line by small interfering RNA (siRNA), and observed the changes in cell proliferation and cell cycle. BGC823 cells with HMGB3 knocked down showed a decreased proliferation rate and the ratio of G0/G1 phase cells in the cell cycle significantly increased. Results above indicate that the overexpression of HMGB3 is a marker for poor prognosis of gastric adenocarcinomas and that it may function by affecting gastric cell proliferation and cell cycle.

MATERIALS AND METHODS

Patients and specimens

Tissue microarrays (TMAs) from a total of 92 consecutive cases of gastric adenocarcinomas operated on in our hospital from December 2006 to October 2007 were prepared for immunohistochemical testing. All the patients were given radical resection and D1+ or D2 lymphadenectomy followed by adjuvant chemotherapy with the regimen epirubicin, cisplatin and fluorouracil. No preoperative therapy was given to any patient. The pathologic staging was made according to American Joint Committee on Cancer TNM staging system. The follow up end point was defined as the death of patients. The use of the tissue samples in TMA analysis and clinical data was approved by Medical Ethics Committee of Jiangsu University and the patients. Patients' clinical and histopathologic data were summarized in Table 1.

Tissue microarrays

For each case, we selected the tumor foci for the TMA

construction during routine diagnosis by marking them on the more representative hematoxylin-eosin-stained slide with a waterproof pencil. At the same time we chose corresponding peritumoral tissue as a control. The advanced tissue arrayer (ATA-100, Chemicon International, Temecula, CA, United States) was used to create holes in a recipient paraffin block to acquire cylindrical core tissue biopsies with a diameter of 1 mm from the specific areas of the “donor” block. The tissue core biopsies were transferred to the recipient paraffin block at defined array positions. The TMAs contained tissue samples from 92 formalin-fixed, paraffin-embedded cancer specimens with known diagnosis, and correlated noncancerous tissues from the same patients. The block was incubated in an oven at 45 °C for 20 min to allow complete embedding of the grafted tissue cylinders in the paraffin of the recipient block, and then stored at 4 °C until microtome sectioning.

Immunohistochemical staining

Rabbit-derived anti-human HMGB3 antibody (Epitomics, Cat. #2416-1) were used for immunohistochemical (IHC) detection of HMGB3 protein in TMAs. TMA sections were processed for IHC demonstration of HMGB3 protein by the Biotin-Avidin-Peroxidase detection system (Sigma). The anti-HMGB3 antibodies were used at 1:50 dilutions. Endogenous peroxidase was inhibited by incubation with freshly prepared 3% hydrogen peroxide with 0.1% sodium azide. Nonspecific staining was blocked with 0.5% casein and 5% normal goat se-

rum. TMAs were incubated with biotinylated goat anti-rabbit antibodies and ExtrAvidin-conjugated horseradish peroxidase. Staining was developed with diaminobenzidine substrate and sections were counterstained with hematoxylin. Normal mouse serum or phosphate-buffered saline (PBS) replaced anti-HMGB3 antibodies used as negative controls.

The quantification of HMGB3 protein expression

HMGB3 expression was semiquantitatively estimated as the total HMGB3 immunostaining score, which was calculated as the sum of a proportion score and an intensity score. The proportion score reflects the fraction of positive staining cells (score 0, < 5%; score 1, 5%-10%; score 2, 10%-50%; score 3, 50%-75%; score 4, > 75%). The intensity score represents the staining intensity (score 0, no staining signal; score 1, weak positive signal; score 2, moderate positive signal; score 3, strong positive signal). Finally, a total expression score was given ranging from 0 to 12. Based on the analysis in advance, the overexpression of HMGB3 was defined as a total expression score $\geq 9^{[10]}$.

Cell line and culture conditions

The human gastric cancer cell line BGC823 was obtained from the American Type Culture Collection (Rockville, MD). The cells were cultured in Dulbecco's modified Eagle's minimal essential medium media supplemented with 10% fetal bovine serum (Gibco), penicillin (100 IU/mL) and streptomycin (100 mg/mL) and grown in a humidified incubator with a 5% CO₂ atmosphere at 37 °C.

RNA interference

Human HMGB3 small hairpin RNA (shRNA) and control shRNA were obtained from Shanghai R and S Biotechnology Co., Ltd, and were transfected into cells using Lipofectamine 2000 reagent (Life Technologies, Carlsbad, CA, United States) according to the manufacturer's instructions.

Cell proliferation assay

Cells were plated at a density of 5×10^3 cells/well in 96-well plates in 200 μ L medium. After siRNA was transfected for 24 h, 48 h and 72 h, 20 μ L MTT was added to each well. The mixture was incubated at 37 °C for 4 h in the dark, washed to remove media and MTT, and 200 μ L dimethyl sulfoxide added to each well. The absorption value at 490 nm was recorded.

Cell cycle analysis

The BGC823/blank, BGC823/small hairpin RNAs-negative control (shRNAs-NC) shRNA-NC and BGC823/shRNA-HMGB3 cells were seeded in six-well plates at a concentration of 5×10^5 cells/mL. Cells were harvested following trypsinization, washed once with cold PBS and fixed in 70% ethanol for 24 h. DNA staining was carried out by resuspending the cells in a solution of PBS containing 20 mg/mL of RNase A, 50 mg/mL of propidium iodide, with subsequent incubation at 37 °C for 30

Figure 1 Expression of high mobility group-box 3 in gastric adenocarcinoma tissue and peritumoral tissue. A: Peritumoral tissue, no staining; B: Peritumoral tissue, weak staining; C: Gastric adenocarcinoma tissue, weak staining; D: Gastric adenocarcinoma tissue, highly positive staining.

min. The stained cells were analysed for the FL-2 area using a flow cytometer (Beckman Coulter, Brea, CA), and DNA histograms were analyzed using Modifit software. Experiments were performed in triplicate. Results are presented as percentage of cells in a particular phase.

Statistical analysis

Data was analyzed using the statistical package for the Social Sciences Version 16.0 (SPSS 16.0). For clinical data statistical analysis, the inter-relationship of HMGB3 expression with histology or clinical factors was analyzed using nonparametric tests. The screen of significant factors associated with survival rate in patients with gastric adenocarcinoma used Kaplan-Meier and log-rank test; Cox regression analysis (Forward LR) was used for multivariate analysis and to determine the 95% confidence interval. Cell experiment data were expressed as mean \pm SD of three independent experiments. Significance of differences between groups was determined by one-way analysis of variance. The significance was set at $P < 0.05$.

RESULTS

Expression of HMGB3 protein in the gastric adenocarcinomas

Expression of HMGB3 protein was evaluated by immunohistochemical staining. In gastric adenocarcinoma cells, the expression of HMGB3 protein was mainly found in the nucleus, and weakly detected in cytoplasm (Figure 1). Positive staining was detected at a level of 94.57% (87/92) in gastric adenocarcinoma tissue, and 52.17% (48/92) in peritumoral tissue with significant difference ($P < 0.001$). The rate of HMGB3 overexpression (total expression

score ≥ 9) was elevated in gastric adenocarcinoma tissue compared with corresponding peritumoral tissue (54.35% vs 0.00%, $P < 0.001$). The difference in HMGB3 expression between peritumoral and normal (distant) tissues was not assessed. We also detected the HMGB3 mRNA level in gastric adenocarcinoma tissue and the corresponding peritumoral tissues by using quantitative reverse transcriptase-polymerase chain reaction, and it was found that HMGB3 mRNA expression level was significantly higher in gastric cancer than in peritumoral samples (detailed data not shown).

Relevance between HMGB3 expression and patients' clinical and histopathologic characteristics

We analyzed the correlation between HMGB3 expression and age, gender, tumor localization, histologic grade, extent of wall penetration, lymph node metastasis and tumor stage. The results showed that HMGB3 expression level was much higher in the pT3-4 group compared to the pT1-2 group ($P = 0.005$); it was also much higher in the N1-3 group compared to the N0 group ($P = 0.004$) and in the stage III + IV group compared to the stage I + II group ($P = 0.001$); all the results were statistically significant. But the correlation between HMGB3 expression and the age and gender of the patient and tumor localization, histologic grade had no statistical significance (Table 1).

We used Kaplan-Meier survival analysis to analyze the gender, age, tumor localization, histologic grade, extent of wall penetration, lymph node metastasis, tumor stage and HMGB3 expression correlation with patient's prognosis. It was observed that there was no correlation between gender, tumor localization and histologic grade with prognosis. But age ($P = 0.040$), extent of wall pen-

Stomach fundus	11	31.455 \pm 7.193	17.356-45.553	0.226 ¹
Gastric body	33	41.395 \pm 3.640	34.226-48.493	0.297 ²
Gastric antrum	48	41.410 \pm 3.211	35.116-47.703	0.922 ³

¹P = 0.226 vs gastric antrum; ²P = 0.297 vs stomach fundus; ³P = 0.922 vs gastric body. HMGB3: High mobility group box 3.

etration ($P = 0.008$), lymph node metastasis ($P = 0.005$), TNM tumor stage ($P = 0.007$) and HMGB3 overexpression ($P = 0.006$) showed a correlation with overall survival (Table 2). This survival analysis revealed that HMGB3 overexpression affected overall survival. There was a significant difference in overall survival between groups with HMGB3 overexpression and with no or low level expression (Table 2 and Figure 2). The expected overall survival time was 31.00 ± 3.773 mo for tumors with HMGB3 overexpression (95%CI = 23.605-38.395) and 49.074 ± 3.648 mo for tumors with HMGB3 no or low level expression (95%CI = 41.925-57.311). Multivariate Cox regression analysis indicate that HMGB3 overexpression was predictive of mortality (hazard ratio = 2.791, 95%CI = 1.233-6.319, $P = 0.019$), and as an independent variable with respect to age, gender, histologic grade, extent of wall penetration, lymph node metastasis, and TNM stage for patients with resectable gastric adenocarcinomas.

Silencing of HMGB3 expression inhibits BGC823 cell proliferation

To determine whether HMGB3 RNAi had an inhibitory effect on gastric cancer cell line BGC823 cell proliferation, we measured cell growth with an MTT assay. Data demonstrated that after HMGB3 was silenced, the cell proliferation rate significantly reduced in 24 h, 48 h, 72 h. Compared to BGC823 cells with shRNA-NC, cell prolifer-

Figure 3 Effects of small hairpin RNAs-high mobility group-box 3 on BGC823 cell proliferation by MTT assay. Data shown as mean \pm SD. Experiment was performed in triplicate, $P < 0.01$ small hairpin RNAs-negative control (shRNAs-NC) vs shRNA-high mobility group-box 3 (HMGB3).

eration rate in cells that have HMGB3 siRNA transfected was decreased significantly ($P < 0.01$; Figure 3). These results indicate that knockdown of HMGB3 inhibits cell proliferation.

Silencing of HMGB3 impacts cell cycle progression

To identify a potential mechanism for HMGB3-specific silencing-mediated reduction of cell proliferation, cell cycle distribution was assessed using flow cytometry. The analysis showed that the percentage of cells in G0/G1 phase increased significantly ($P = 0.001$), whereas cells in the G2/M phases decreased in BGC823/HMGB3 RNAi cells compared with their parental controls. The percentage of cells in G1/G0 phase in BGC823 cells with shRNA-NC and with shRNA-HMGB3 was $46.84\% \pm 1.7\%$ and $73.03\% \pm 3.51\%$ respectively, whereas the percentage of cells in G2/M was $26.51\% \pm 0.83\%$ and $17.8\% \pm 2.26\%$. These data suggest that HMGB3 silencing may induce G0/G1 cell arrest (Figures 4 and 5).

Results above showed that high expression of HMGB3

Figure 4 Flow cytometry analysis of cell cycle distribution in BGC823 cells after transfection of high mobility group-box 3 small hairpin RNA for 48 h. A: Small hairpin RNAs (shRNA)-negative control; B: shRNA-high mobility group-box 3 group.

Figure 5 Cell cycle distribution in BGC823 cells after transfection of high mobility group-box 3 small hairpin RNA for 48 h. Data shown as mean \pm SD. in gastric cancer positively correlated with extensive wall penetration, positive lymph node metastasis, advanced tumor stage, and poor prognosis. Multivariable Cox regression indicated that this protein overexpression can be used as an independent biomarker in prognosis of gastric cancer. It implies that HMGB3 might participate in gastric cancer onset and development. Further silencing of HMGB3 expression in the gastric cancer cell line by shRNA showed that cell proliferation decreased and the cell cycle was blocked in G0/G1 phase. These results indicate that HMGB3 had a role in the proliferation and cell cycle of gastric cancer cells.

DISCUSSION

The onset and progression of gastric cancer correlated with various molecular and genetic incidents. To investigate the significance of the molecular expression in gastric cancer may help us to identify potential treatment targets and (or) predictive markers of prognosis.

The HMG Box subfamily is a family of non-histone chromosomal proteins; these members including HMGB1,

HMGB2 and HMGB3^[2]. HMGB family is thought to play a fundamental role in DNA replication, nucleosome assembly and transcription. There are studies overwhelmingly focusing on HMGB1, since it is widely expressed in all kinds of cell types in adult vertebrates. HMGB1 has been shown to interact with recombination activating gene 1 (RAG1) and RAG2 to play a role in immunology and inflammation, and is associated with proliferation and metastasis of many tumor types^[11,12]. However, little is known about the function of HMGB3.

In this study, we analyzed the role of HMGB3 in gastric cancer. Firstly, we observed HMGB3 expression in gastric adenocarcinoma and found it has a high expression level. The positive expression rate in gastric adenocarcinoma is 94.57% (87/92); the overexpression rate reached 54.35% (50/92). While the positive expression rate in gastric peritumoral tissue is 52.17% (48/92), no overexpression was found in it. Pourhoseingholi *et al.*^[13] reported that HMGB3 also has high expression in progressive breast cancer. A combination of proofs that there is high expression of HMGB3 in recursive leukemia^[8] and the pivotal role of HMGB3 in maintaining the self-renewal capability of leukemia stem cells^[6] imply that HMGB3 is a critical gene participating in cancer progression. Secondly, we further analyzed the correlation of HMGB3 expression with gastric cancer clinicopathologic variables and prognosis. We found high HMGB3 expression correlates with extensive wall penetration, positive lymph node metastasis and advanced tumor stage, which are the important prognostic factors in gastric cancer. Kaplan-Meier survival analysis showed HMGB3 high expression is negatively correlated with the overall survival of patients with resected gastric adenocarcinoma. The expected overall survival time in high HMGB3 expression patients is 31.000 ± 3.773 mo, while in no or low HMGB3 expression patients it is 49.074 ± 3.648 mo. Multivariate analysis shows HMGB3 overexpression can work as an independent variable for poor survival in resectable gastric adenocarcinoma. In analyzing factors affecting gastric cancer prognosis, different research groups reached more or less different conclusions since the methods used and the samples they ana-

lyzed were different. However, there are common factors including age, tumor late stage, small surgical area, large cancer volume, adjuvant chemotherapy *etc.* correlated with poor prognosis in gastric cancer^[14-17]. Many researchers reported that pathological classification is also an important factor affecting prognosis^[14,15,17], though in this study it showed a negative result. This could be due to the number of level II and III patients being large, thus affecting the conclusion. Now the diagnosis and therapy of tumors is entering the “molecular moment”. Molecular biomarkers not only could be prognostic factors, but could also be potential therapeutic targets for clinical therapy. Mitogen-activated protein kinase, Janus kinase/signal transducers and activators of transcription and nuclear factor-kappaB were reported to have high expression levels in gastric cancer^[18-20]; however, none of them can be used as a prognostic biomarker alone. Ki67 and PNCa have been widely used to indicate a high cancer cell proliferation rate, and both of them are highly expressed in gastric cancer^[21]; however, neither has been used to determine prognosis^[22,23]. Her2, a therapy target in breast cancer^[24,25], is also found in gastric cancer as a new prognostic factor and a novel therapeutic target^[26,27]. Lastly, we used the gastric cancer cell line BGC823 to investigate cell proliferation and cell cycle changes after silencing of HMGB3. It was observed that the cell proliferation rate was greatly reduced, and the cell cycle was blocked in G1/G0 phase. This indicates that HMGB3 may promote cell proliferation through cell cycle progression. Researchers found that the number of G2/M cells was significantly reduced in HMGB3^{-/-} mouse hematopoietic progenitor cells and this could be attributed to blockage of the cell cycle in G0/G1 phase^[5]. In *Xenopus*, Terada *et al.*^[28] observed that the cell proliferation rate of retinal progenitor cells can be promoted with overexpression of HMGB3. They further discovered that this is accompanied by P27 downregulation^[29]. P27 is a member of the cyclin dependent kinase inhibitor family, CIP/KIP, and can prevent activation of cyclin E-CDK6 and cyclin D-CDK4, which consequently blocks cells in G1 phase^[30]. Thus, we propose that the mechanism under which HMGB3 promotes cancer onset and development is mainly by enhancing cell proliferation.

In summary, high-level expression of HMGB3 protein was detected in gastric adenocarcinoma cells. The overexpression of HMGB3 was correlated with a poor prognosis of gastric cancer patients. HMGB3 may promote gastric cancer cell proliferation by regulating the cell cycle. Therefore, our data encourages further investigations to elucidate the role of HMGB3 and its molecular mechanism.

COMMENTS

Background

Gastric cancer is reported to be one of the common devastating types of cancer that has a high occurrence rate, short survival period and high mortality rate. The mortality rate can be up to 25.2/100 000 in China, which accounts for 25% of deaths in malignant cancer. The occurrence ratio and mortality are ranked as No. 1 and No. 2 in malignant cancer.

Research frontiers

Recent studies showed that high mobility group-box3 (HMGB3) and NPU98 fusion protein form a new oncogenic gene in leukemia. HMGB3 also participates in recurrence of acute lymphoid leukemia and it shows a high expression level in the progression phase of breast cancer. HMGB3 was identified as one of the biomarkers detected in peripheral blood in lung cancer. Though HMGB3 is found in some types of cancers, its role in gastric cancer is still unclear.

Innovations and breakthroughs

The authors observed the expression of HMGB3 in gastric adenocarcinoma tissues by immunohistochemistry, and analyzed its correlation between expression level and clinicopathologic variables and prognosis. Results indicated that the overexpression of HMGB3 is a marker for poor prognosis of gastric adenocarcinomas. HMGB3 may function through affecting gastric cell proliferation and cell cycle.

Peer review

The results are interesting and suggest that HMGB3 is likely to be a useful prognostic marker involved in gastric cancer disease onset and progression by regulating the cell cycle.

Abstract

AIM: To evaluate the relationship between donor safety and remnant liver volume in right lobe living donor liver transplantation (LDLT).

METHODS: From July 2001 to January 2009, our liver transplant centers carried out 197 LDLTs. The clinical data from 151 cases of adult right lobe living donors (not including the middle hepatic vein) were analyzed. The conditions of the three groups of donors were well matched in terms of the studied parameters. The donors' preoperative data, intraoperative and postoperative data were calculated for the three groups: Group 1 remnant liver volume (RLV) < 35%, group 2 RLV 36%-40%, and group 3 RLV > 40%. Comparisons included the different remnant liver volumes on postoperative liver function recovery and the impact of systemic conditions. Correlations between remnant liver volume and post-operative complications were also analyzed.

RESULTS: The donors' anthroposomatology data, op-

eration time, and preoperative donor blood test indicators were calculated for the three groups. No significant differences were observed between the donors' gender, age, height, weight, and operation time. According to the Chengdu standard liver volume formula, the total liver volume of group 1 was 1072.88 ± 131.06 mL, group 2 was 1043.84 ± 97.11 mL, and group 3 was 1065.33 ± 136.02 mL. The three groups showed no statistically significant differences. When the volume of the remnant liver was less than 35% of the total liver volume, the volume of the remnant had a significant effect on the recovery of liver function and intensive care unit time. In addition, the occurrence of complications was closely related to the remnant liver volume. When the volume of the remnant liver was more than 35% of the total liver volume, the remnant volume change had no significant effect on donor recovery.

CONCLUSION: To ensure donor safety, the remnant liver volume should be greater than the standard liver volume (35%) in right lobe living donor liver transplantation.

INTRODUCTION

To solve the shortage of liver grafts in adult liver trans-

plantation, an increasing number of transplant centers have used right graft living donor liver transplantation. This surgical method can provide a greater proportion of liver grafts to meet the metabolic demands of recipients. However, right lobe graft donors take more risks and have more complications than left graft donors. This has created considerable controversy with respect to donor safety. At the present time, there have been 17 donor deaths reported, and the morbidity was reported to be in the range of 20% to 30%^[1-3].

It has been reported in the literature that donor complications are closely related to remnant liver volume (RLV)^[4,5]. Initial experiences from previous studies have suggested leaving a remnant of not less than 30%^[6]. Other articles have reported that remnant liver volumes less than 35% do not appear to be a contraindication for right liver procurement in living donors^[7].

Considering the controversy regarding safety and remnant liver volume in right-lobe living donor liver transplantation (LDLT), we analyzed our own data. We retrospectively examined the remnant liver volume in our right graft donors and compared those donors with different remnant liver volumes. Thus, the aim of the present study was to assess the relationship between donor recovery, complications and the volume of remnant liver^[7,8].

MATERIALS AND METHODS

Patient population

From July 2001 to January 2009, our transplant centers carried out 197 LDLTs. Inclusion criteria were: (1) a healthy adult donor, age > 18 and < 60 years; (2) a right liver graft without the middle hepatic vein (MHV); (3) adult-to-adult LDLT; (4) single donors; and (5) without a history of long-term drinking. Exclusion criteria: (1) age < 18 or > 60 years; (2) a left hepatic graft or left lateral lobe graft; (3) double donor grafts; (4) adult-to-child transplants; and (5) donors that were hepatitis B virus or hepatitis C virus carriers.

After the above selection criteria eliminated some patients, eligible subjects were identified. In total, we identified 151 cases of right liver adult-to-adult living donors (not including the MHV). Ninety cases were male and 61 were female. The total liver volume was calculated using the Chengdu standard liver volume formula^[9,10]. The volume of actual grafts (excluding the MHV of the right liver) was measured intraoperatively. Remnant liver volume = the total liver volume - the volume of the actual graft. According to the ratio of the remnant liver volume to the total liver volume, the cases within the study group were further subdivided into three groups: Group 1: RLV < 35% ($n = 14$), group 2: RLV 36%-40% ($n = 20$), and group 3: RLV > 40% ($n = 117$).

Written informed consent was obtained from all patients to include their data in this study, which was approved by the HuaXi Ethics Committee and conformed to the ethical guidelines of the 1975 Declaration of Helsinki.

Preparation of preoperative clinical data

Indicator variables included: age, gender, body height

(error < 1 cm), and body weight (error < 0.5 kg). Preoperative donor blood test indicators were also obtained. These indicators included: hemoglobin (HGB), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and total bilirubin (TBIL). Donor selection was based on a designated radiologist row computerised tomography examination and determination of liver volume. All donors used the same surgery/medical team.

Surgical procedures

An LDLT was completed through a right subcostal incision with an upward midline extension. Intraoperative cholangiography *via* cystic duct cannulation was required to evaluate the anatomy of the bile duct. A right hilar dissection was then performed to isolate the right hepatic artery, right portal vein, and right hepatic duct^[11]. The right lobe of the liver was then rotated towards the left side for division of the ligaments on the right side of the liver, the minute venous branches between the anterior surface of the inferior vena cava and the posterior surface of the paracaval portion of the caudate lobe. To prevent impeding the circulation, the right hepatic vein and the right inferior hepatic veins that were larger than 5 mm were preserved until the time of harvesting.

The transection plane was determined by intraoperative ultrasonography and the temporary occlusion of the right portal vein and right hepatic artery. After identification of the confluence of the left and right hepatic ducts, the right hepatic duct was divided near the confluence of the hepatic ducts using scissors. The divided end was closed transversely using a continuous 5-0 prolene suture. The transection was carried down to the junction of the right hepatic vein and the inferior vena cava. The right hepatic artery was then divided. To accomplish this, the right hepatic vein was clamped at the junction with the inferior vena cava and divided. The stumps of the right portal vein and right hepatic vein were closed with continuous nonabsorbable sutures. The falciform ligament was then sutured to the anterior abdominal wall. A drain was inserted into the right subphrenic cavity prior to wound closure^[12].

Measurement of volume

The weight of the grafted liver was measured using a pan scale, the error was found to be less than 10 g. The volume was measured using the drainage method in a 3 L beaker full of saline; the error was found to be less than 10 mL.

Postoperative procedures

Postoperatively, donors stayed in the intensive care unit (ICU) for monitoring and oxygen, and received parenteral nutrition which was rich in branched-chain amino acids. Donors began parenteral nutrition following intestinal function recovery. When necessary, donors received blood transfusions or plasma and human serum albumin. Postoperative monitoring of HGB, ALT, AST, TBIL, and the international standardization ratio (INR) was performed. ICU time, hospital stay, timely diagnosis, and

treatment of surgical complications were recorded. Donor follow up was 6 to 48 mo, and all follow up information was recorded.

Statistical analysis

The mean ± SD of the data are presented. The SPSS program (version 15.0, SPSS Inc., United States) was used for the statistical analysis. After testing for normal distribution using Kurtosis and Skewness tests, descriptive variables including pre-operative, intra-operative, post-operative and prognostic parameters, were calculated. Fisher's exact test was used to detect the differences among the groups for categorical variables, including gender. Independent-sample *t* tests were calculated to detect differences among the groups for continuous random variables including HGB, ALT, AST, TBIL, volumetric data, postoperative INR, ICU time, hospital stay, and reasonable and customary (R and C). A correlation analysis using the χ^2 test was conducted to determine the incidence of complications. The difference was considered significant if $P < 0.05$.

RESULTS

Baseline data of donors

The donors' anthroposomatology data, operation time, and preoperative blood test indicators were calculated for the three groups: Group 1 RLV < 35%, group 2 RLV 36%-40%, and group 3 RLV > 40%. These data are shown in Table 1. No significant differences were observed between the donors' gender, age, height, weight, and operation time. Preoperative data on ALT, AST, TBIL and HGB were also collected among the three groups of donors. These results suggested that

the conditions of the three groups of donors were well matched in terms of the studied parameters.

Volume-related parameters

Compared to Heinemann, Urata, Vauthey^[13-16], and the Lee formulae^[17], the Chengdu standard liver volume formula was demonstrated to be more reliable in LDLT. In LDLT, this formula can more accurately forecast total liver volume^[10]. Standard liver volumes in the 151 cases were calculated using the Chengdu formula: SLV (mL) = $11.5 \times \text{body weight (kg)} \pm 334$. The volumes of the actual grafts (excluding the MHV of the right liver) were measured intraoperatively. Remnant liver volume = the total liver volume - the volume of the actual graft. We determined the ratio of the remnant liver by remnant liver volume/standard liver volume. The liver volume-related parameters are shown in Table 1.

According to the Chengdu standard liver volume formula, the total liver volume in group 1 was 1072.88 ± 131.06 mL, group 2 was 1043.84 ± 97.11 mL, and group 3 was 1065.33 ± 136.02 mL. The three groups showed no statistically significant differences. However, the graft volume in group 1 was 745.00 ± 100.22 mL, group 2 was 653.80 ± 56.55 mL, and group 3 was 534.83 ± 89.26 mL, revealing a statistically significant difference between the groups. Remnant liver volume also showed significant differences.

Postoperative characteristics

Postoperative monitoring of donor ALT peak, AST peak, TBIL peak, INR peak, and HGB value was conducted during their ICU stay and hospital stay. Postoperative characteristics are illustrated in Figure 1. The ALT peak in the smallest remnant liver volume in group 1 was

Table 2 Complications of the 50 donors classified according the modified Clavien system

Grades, <i>n</i> (%)	Complications	<i>n</i>
Grade 1, 28 (18.5)	Transient bile leak treated conservatively	7
	Superficial wound infection treated without antibiotics	2
	Postoperative voice change	3
	Mild pleural effusion treated conservatively	2
	Mild subphrenic effusion treated conservatively	5
	Hyperbilirubinemia > 1.3 mg/dL 7 d after operation	9
Grade 2, 9 (6.0)	Intra-abdominal bleeding requiring blood transfusion	1
	Bile leak not requiring ERCP or surgical intervention	3
	Dyspepsia	1
	Chyle leak	1
	Wound infection requiring antibiotics	1
	Pneumonia requiring antibiotics	2
Grade 3a, 8 (5.3)	Bile leak needing ERCP	3
	Pleural effusion requiring thoracic cavity puncture	2
	Pleural effusion requiring thoracic drainage	1
	Subphrenic infection requiring abdominal cavity puncture	1
	Chylothorax requiring thoracic cavity puncture	1
	Portal vein thrombosis requiring re-laparotomy	1
Grade 3b, 5 (3.3)	Biliary stricture requiring ERCP with stent placement	2
	Abdominal hematoma requiring intervention	1
	Intra-abdominal bleeding requiring re-laparotomy	1
Grade 4a		0
Grade 4b		0
Grade 5		0

ERCP: Endoscopic retrograde cholangiopancreatography.

325.64 ± 202.33 U/L, this value was significantly higher than that in the other two groups (196.85 ± 130.62 U/L and 200.70 ± 150.94 U/L, respectively). The AST peak of 339.79 ± 172.91 U/L was also significantly higher than that in group 2 and group 3 (P value = 0.010 and 0.003, respectively). The ALT peak and AST peak in groups 2 and 3 showed no significant difference (P = 0.915 and 0.893, respectively). However, differences in the TBIL peak, INR peak, and HGB value among the three groups of donors were observed, but no statistical differences were found.

The ICU time for group 1 was 6.93 ± 2.13 d, significantly longer than that for group 2 and group 3 (5.10 ± 1.62 d vs 5.33 ± 1.63 d, respectively). There was no statistical difference in ICU stay between groups 2 and 3. The three groups of patients exhibited no significant difference in hospitalization time.

Clavien classification system of complications

The Clavien classification system has been increasingly used in the analysis of post-surgical complications^[18,19]. Researchers have also begun to use this classification in the LDLT donor complication category^[20,21]. The donor complications were calculated according to the Clavien classification system of grading.

Donor complication grade

Fifty donors that exhibited a total of 151 complications. According to the Clavien grading system, 28 cases had grade 1 complications, 9 cases had grade 2 complications,

Figure 1 Postoperative characteristics of the donors. RLV: Remnant liver volume; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; INR: International standardization ratio; ICU: Intensive care unit.

8 cases had grade 3a complications, and 5 cases had grade 3b complications. No serious grade 4 or 5 complications were observed. There were no donor deaths (Table 2).

Analysis of donor complications

A correlation analysis of the χ^2 test was used to compare different grades of complications among the three groups of donors (Table 3). R and C correlation analysis revealed that the complication grade had a significant relationship with remnant liver volume.

DISCUSSION

The evaluation of suitable donors is related to both donor and recipient safety. The volume of the graft liver should ensure the absolute safety of the donor, but also meet the needs of the recipient. For example, if the remnant liver volume is too small for the body, it can lead to acute liver failure in the donor. If the graft is too small, it can result in small-for-size graft syndrome^[22,23]. In general, the younger the donor, the better is the liver's regenerative capacity^[24], thus donors aged between 18 and 60 years are required.

In this study, donors age ranged from 18 to 60 years. During the preoperative examination, there were no obvious abnormal liver functions, obvious blood vessels, biliary anatomical abnormalities, or intraoperative liver biopsies with serious fatty degeneration. According to the remnant liver volume, the study group was divided into three groups. Data for each group of donors was recorded, and included preoperative parameters, operative time, and intraoperative blood loss. No statistical differences between the groups were found. The three groups also had homogeneity of the body, excluding other factors of donor recovery.

Postoperative data revealed that the ALT and AST peaks in group 1 donors were significantly higher than those in the other two groups. There were no significant differences (P = 0.915 and 0.893, respectively) for the ALT peak or AST peak between groups 2 and 3. The

Table 3 Postoperative complications of donors

Complications	Grades					P value
	No complications (n = 101)	Grade 1 (n = 28)	Grade 2 (n = 9)	Grade 3a (n = 8)	Grade 3b (n = 5)	
Group 1 (RLV < 35%), n = 14	3	5	3	2	1	0.000
Group 2 (40% > RLV > 35%), n = 20	10	4	3	1	2	
Group 3 (RLV > 40%), n = 117	88	19	3	5	2	

RLV: Remnant liver volume.

ICU time in group 1 donors was significantly longer than that in group 2 and 3 donors. No statistical differences in ICU time between groups 2 and 3 were observed.

Postoperative indicators showed that when the remnant liver volume was greater than 35% of standard liver volume, the volume of the remnant liver had no significant effect on the recovery of liver function or the ICU time, however, when the remnant liver volume was less than 35%, this led to a much slower recovery of liver function.

In LDLT, there are three possible types of short-term complications. One type of complication includes bleeding, biliary leakage, embolization, liver failure, metabolic abnormalities caused by cholinesterase, and hypophosphatemia. The second are open surgery-related complications and include intra-abdominal infections, incisional hernias, adhesions, and intestinal obstruction. There are also complications associated with anesthesia.

An international statistical analysis showed that the incidence of complications in donors was 10%-30%, while the case fatality rate was 0.1%-0.3%^[4,25-27]. In this study, 33% of the 151 complications occurred in 50 patients. According to the Clavien grading system, the patients in this study experienced 28 grade 1 complications, 9 grade 2 complications, 8 grade 3a complications, and 5 grade 3b complications. There were no serious grade 4 or grade complications and no donor deaths. R and C correlation analysis showed that complication grades had a significant relationship with remnant liver volume.

In summary, when the volume of a remnant liver was less than 35% of the standard liver volume, the volume of the remnant had a significant effect on the recovery of liver function and ICU time. In addition, the occurrence of complications was closely related to remnant liver volume. Recipients were only available if good results were expected. Therefore, the interests of the donor should be accounted for to minimize their risks during surgery.

ACKNOWLEDGMENTS

COMMENTS

Background

An increasing number of transplant centers have used right graft living donor liver transplantations. This surgical method could provide a greater number of

liver grafts to meet the metabolic demands of recipients. However, right lobe graft donors take more risks and have more complications than left graft donors. This has created considerable controversy with respect to donor safety. At the present time, 26 donor deaths have been reported, and morbidity was reported to be in the range of 20% to 30%.

Research frontiers

The literature has reported that donor complications are closely related to remnant liver volume (RLV). The authors retrospectively examined the RLV in right graft donors and compared those donors with other different RLVs.

Innovations and breakthroughs

This has created considerable controversy with respect to RLV and donor safety. The aim of the present study was to assess the relationship between donor recovery, complications and the volume of remnant liver.

Applications

The SPSS program (version 15.0, SPSS Inc., United States) was used for the statistical analysis. After testing for normal distributions using Kurtosis and Skewness tests, descriptive variables including pre-operative, intra-operative, post-operative and prognostic parameters were calculated. Fisher's exact test was used to detect the differences among the groups for categorical variables, including gender. Independent-sample *t* tests were used to detect differences among the groups for continuous random variables including hemoglobin, alanine aminotransferase, aspartate aminotransferase, total bilirubin, volumetric data, postoperative International Normalized ratio, intensive care unit time, hospital stay, and reasonable and customary. A correlation analysis using the chi-squared test was conducted to determine the incidence of complications.

Peer review

This study is an analysis of 151 cases of adult right lobe living related donor to determine the effect of volume of the remnant liver on post operative complications. The conclusions reached was that volumes less than 35% of total liver volumes were associated with increased complications and length of recovery. This is a significant study adding further to the knowledge in this area of liver transplantation.

Abstract

AIM: To investigate the incidence of gastroesophageal reflux disease (GERD) and its related risk factors in Uygur and Han Chinese adult in Urumqi, China.

METHODS: A population-based cross-sectional survey was undertaken in a total of 972 Uygur (684 male and 288 female) aged from 24 to 61 and 1023 Han Chinese (752 male and 271 female) aged from 23 to 63 years. All participants were recruited from the residents who visited hospital for health examination from November 2011 to May 2012. Each participant signed an informed consent and completed a GERD questionnaire (Gerd

Q) and a lifestyle-food frequency questionnaire survey. Participants whose Gerd Q score was ≥ 8 and met one of the following requirements would be enrolled into this research: (1) being diagnosed with erosive esophagitis (EE) or Barrett's esophagus (BE) by endoscopy; (2) negative manifestation under endoscopy (non-erosive reflux disease, NERD) with abnormal acid reflux revealed by 24-h esophageal pH monitoring; and (3) suffering from typical heartburn and regurgitation with positive result of proton pump inhibitor test.

RESULTS: According to Gerd Q scoring criteria, 340 cases of Uygur and 286 cases of Han Chinese were defined as GERD. GERD incidence in Uygur was significantly higher than in Han Chinese (35% vs 28%, $\chi^2 = 11.09$, $P < 0.005$), Gerd Q score in Uygur was higher than in Han Chinese (7.85 ± 3.1 vs 7.15 ± 2.9 , $P < 0.005$), and Gerd Q total score in Uygur male was higher than in female (8.15 ± 2.8 vs 6.85 ± 2.5 , $P < 0.005$). According to normalized methods, 304 (31%) cases of Uygur were diagnosed with GERD, including 89 cases of EE, 185 cases of NERD and 30 cases of BE; 256 (25%) cases of Han Chinese were diagnosed with GERD, including 90 cases of EE, 140 cases of NERD and 26 cases of BE. GERD incidence in Uygur was significantly higher than in Han Chinese (31% vs 25%, $\chi^2 = 9.34$, $P < 0.005$) while the incidences were higher in males of both groups than in females (26% vs 5% in Uygur, $\chi^2 = 35.95$, $P < 0.005$, and 19.8% vs 5.2% in Han, $\chi^2 = 5.48$, $P < 0.025$). GERD incidence in Uygur male was higher than in Han Chinese male (26% vs 19.8%, $\chi^2 = 16.51$, $P < 0.005$), and incidence of NERD in Uygur was higher than in Han Chinese ($\chi^2 = 10.06$, $P < 0.005$). Occupation ($r = 0.623$), gender ($r = 0.839$), smoking ($r = 0.322$), strong tea ($r = 0.658$), alcohol drinking ($r = 0.696$), meat-based diet (mainly meat) ($r = 0.676$) and body mass index (BMI) ($r = 0.567$) were linearly correlated with GERD in Uygur ($r = 0.833$, $P = 0.000$); while gender ($r = 0.957$), age ($r = 0.016$), occupation ($r = 0.482$), strong tea ($r = 1.124$), alcohol drinking ($r = 0.558$), meat diet ($r = 0.591$) and BMI

($r = 0.246$) were linearly correlated with GERD in Han Chinese ($r = 0.786$, $P = 0.01$). There was no significant difference between Gerd Q scoring and three normalized methods for the diagnosis of GERD.

CONCLUSION: GERD is highly prevalent in adult in Urumqi, especially in Uyghur. Male, civil servant, smoking, strong tea, alcohol drinking, meat diet and BMI are risk factors correlated to GERD.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a common acid-related disease worldwide, and severely affects the quality of life of patients. The incidence of GERD is high in Western and developed countries, however, due to changes in lifestyle and dietary habits the incidence of GERD has increased in the Asian-Pacific region in recent years^[1,2], particularly in China. This is due to the introduction of Western fast food into the Chinese dietary structure which has had a significant influence since its introduction ten years ago. The incidence of GERD in China is rising year by year^[3], and is showing a “low in south and high in north” trend^[4]. Xinjiang is located in the Northwest region of China, and Uyghur is the main minority group in this autonomous region of China. An important dietary custom in local residents is to prioritize meat (mainly beef and lamb), cooked wheat food, and alcohol drinking. In addition, strong tasting foods are favored. Together with the development of social and cultural diversity, there appears to have been culture blendings and interactions between Uyghur and Han Chinese as time goes by. In addition to these factors, the particular geographic and climatic characteristics of Xinjiang exert an influence on the lifestyle and dietary customs of local inhabitants. Therefore, there are currently both similarities and differences between Uyghur and Han Chinese with regard to lifestyle and dietary customs. Furthermore, genetics studies have revealed that the Han Chinese gene contains Oriental Mongoloid characteristics, while the Uyghur gene contains both Caucasian and Oriental Mongoloid characteristics. To our knowledge, there has been little research focusing on the incidence of GERD with regard to minority groups^[5],

and large-scale studies focusing on GERD in the Uyghur population alone have not been carried out. Based on the above research background, we aimed to elucidate the following: (1) Does lifestyle and dietary customs or dietary structure in Xinjiang inhabitants impact on GERD occurrence; (2) differences in the incidence of GERD in Uyghur and Han Chinese; and (3) potential risk factors related to GERD, and provide guidance in clinical practice.

MATERIALS AND METHODS

Participants

This study was a population-based cross-sectional, randomized, single center, open-label trial. A total of 972 Uyghur (684 males and 288 females) aged 24 to 61 years and 1023 Han (752 males and 271 females) aged 23 to 63 years living in Urumqi were enrolled into this study. All participants, who were residents of Xinjiang, China (college students, workers and civil servants) were recruited from those who attended the First Affiliated Hospital of Xinjiang Medical University for a health examination from November 2011 to May 2012. All participants signed an informed consent before participating in this research. Each subject completed a GERD questionnaire (Gerd Q) scale and a lifestyle-food frequency questionnaire (FFQ).

Inclusion criteria

Participants whose Gerd Q score was ≥ 8 and who met one of the following requirements were enrolled in this study: (1) diagnosed with erosive esophagitis (EE) or Barrett's esophagus (BE) on upper gastrointestinal endoscopy; (2) negative manifestations on endoscopy (non-erosive reflux disease, NERD) with abnormal acid reflux revealed by 24-h esophageal pH monitoring; and (3) suffering from typical heartburn and regurgitation with a positive proton pump inhibitor (PPI) test.

Exclusion criteria

Any participant who met one of the following requirements was excluded from this study: (1) receiving a PPI or H₂ receptor blocker; (2) suffered from serious gastrointestinal diseases (esophageal stricture, peptic ulcer, esophagus or stomach tumor) or a history of abdominal surgery; (3) suffered from major organ insufficiency; and (4) pregnant and lactating women.

Assessment of lifestyle and dietary customs

Alcohol consumption in individuals was estimated by multiplying the mean weekly alcohol intake by the concentration of alcohol (12% alcohol for wine or 4% alcohol for beer). Alcohol intake per week of ≥ 140 g for males and ≥ 70 g for females was assessed as alcohol consumption. If a participant smoked more than 10 cigarettes per day then he/she was assessed as a smoker. Tea consumption over the past month was determined using a FFQ^[6]. Nutritional intake was assessed using a validated 110-item FFQ (the Block 98)^[7]. Body mass index (BMI) ≥ 25 kg/m² was defined as overweight.

Table 1 Gastroesophageal reflux disease questionnaire scale

Symptom	Symptoms in the past 7 d	0 d	1 d	2-3 d	4-7 d
Positive symptom	Heart burn	0	1	2	3
	Regurgitation	0	1	2	3
Negative symptom	Upper abdominal pain	3	2	1	0
	Nausea	3	2	1	0
Positive affect	Sleeping disorder	0	1	2	3
	Extra medication	0	1	2	3

Gerd Q and scoring

Total cumulative Gerd Q score was calculated by a gastroenterologist according to Gerd Q after questioning each participant about his or her symptoms during the previous 7 d. Subjects whose Gerd Q score was ≥ 8 were estimated to have pathological acid reflux^[8] (Table 1).

Assessment by upper gastrointestinal endoscopy

Subjects who were willing to undergo endoscopy were instructed to stop all medications that affected alimentary motility and endocrine function, and then fasted for at least 8 h. The presence or absence of reflux esophagitis, endoscopically suspected esophageal metaplasia and hiatal hernia were determined by specialized endoscopists. If EE was present, it was graded according to the Los Angeles classification^[9]. The diagnosis of BE was based on endoscopy and pathology^[10].

Ambulatory 24-h esophageal pH monitoring

Subject who were willing to undergo 24-h esophageal pH monitoring were instructed to stop all medications that affected alimentary motility and endocrine function for at least 2 wk. Ambulatory 24-h esophageal pH monitoring was performed after fasting for at least 8 h. Single-use pH electrodes were placed 5 cm above the proximal margin of the lower esophageal sphincter. The subjects were encouraged to eat regular meals, however, the intake of food and drink with a pH below 4 was restricted. All subjects recorded their meal times (start and end), body position (supine and upright), and any symptoms in a diary. The data were collected using a portable data logger (Digitrapper Mark III, Synetics Medical Co., Stockholm, Sweden) with a sampling rate of 4 s, and were transferred to a computer for analysis. The variables assessed for gastroesophageal reflux in the distal probe were the total percentage of time the pH was < 4 , the percentage of time the pH was < 4 in the supine and upright positions, the number of episodes where the pH was < 4 , the number of episodes the pH was < 4 for ≥ 5 min, the duration of the longest episode where the pH was < 4 and the DeMeester composite score^[11]. A DeMeester score ≥ 14.72 was considered abnormal.

Statistical analysis

All measured data were expressed as mean \pm SD. The χ^2 test, *U* test and analysis of variance were used for comparisons between the groups, linear regression and multi-

variate logistic regression (backward) analyses were used for related factors analysis. Values of $P < 0.05$ (two-tailed) were considered statistically significant. All calculations were performed using SPSS version 20.0 software (IBM SPSS Statistics 20).

RESULTS**Baseline characteristics of the participants**

There were no statistically significant differences between the Uygur and Han participants in terms of occupation, gender, age, smoking (long-term and excessive smoking) and alcohol consumption (chronic overdrinking), however, there was a significant difference between the two groups in terms of dietary customs (mainly meat compared with mainly vegetarian) (Table 2).

GERD incidence in Uygur and Han participants

According to Gerd Q scoring criteria, a total score of ≥ 8 was regarded as the assessment point. GERD was detected in 340 Uygur participants (incidence 35%) and in 286 Han participants (incidence 28%). The incidence of GERD in Uygur was significantly higher than that in Han Chinese ($\chi^2 = 11.09$, $P < 0.005$). The Gerd Q score in Uygur (7.85 ± 3.1) was higher than that in Han (7.15 ± 2.9) ($P < 0.005$), and the Gerd Q total score in Uygur males (8.15 ± 2.8) was higher than that in females (6.85 ± 2.5) ($P < 0.005$) (not listed in Table 2).

All participants who had been diagnosed with GERD using the Gerd Q scale underwent further endoscopy. Mucosal lesions were diagnosed as EE or BE, respectively, according to pertinent criteria, while those participants who did not have positive endoscopy findings underwent one of the following examinations: 24-h esophageal pH monitoring or the PPI test, and if any one of these two examinations was positive, the participant was diagnosed with NERD. According to the above three normalized methods (upper gastrointestinal endoscopy, 24-h esophageal pH monitoring and the PPI test), 304 Uygur participants were diagnosed with GERD (incidence 31%), including 89 cases of EE, 185 cases of NERD and 30 cases of BE; 256 Han participants were diagnosed with GERD (incidence 25%), including 90 cases of EE, 140 cases of NERD and 26 cases of BE. The incidence of GERD in Uygur was significantly higher than that in Han, and the incidence of GERD in male Uygur and Han was higher than that in female Uygur and Han, respectively (Table 3).

There was no significant difference between Gerd Q scoring criteria and the three normalized methods regarding the diagnosis of GERD (Uygur: $\chi^2 = 1.48$, $P > 0.5$; Han: $\chi^2 = 0.83$, $P > 0.5$) (not listed in Table 3).

Differences in lifestyle and dietary customs between Uygur and Han participants

We compared the GERD groups and normal groups, and analyzed the relationship between the following factors and GERD using the *U* and χ^2 tests in order to illus-

Table 2 Baseline characteristics of the participants

Ethnic group	<i>n</i>	Occupation (college students, workers/civil servants)	Gender (male/female)	Age (yr)	Smoking (yes/no)	Alcohol drinking (yes/no)	Diet custom (mainly meat/mainly vegetable)

BMI: Body mass index.

trate their potential impact on the occurrence of GERD (Figure 1). We found that, occupation (civil servant) and BMI were the collective factors related to GERD shared by the two ethnic groups and both genders; in Uygur participants with GERD, both males and females were correlated with strong tea and alcohol drinking (Figure 1A and B); while for Han participants with GERD, both males and females were correlated with strong tea, alcohol drinking and dietary custom (mainly meat) (Figure 1C and D).

Multivariate logistic regression analysis of risk factors for GERD in Uygur and Han participants

We analyzed the correlation between GERD and these factors further using a multivariate linear statistical method. The relationships between the risk factors for GERD in the two ethnic groups are listed below (Table 4 and Figure 2). Seven factors were found to correlate with GERD in Uygur and Han Chinese, respectively.

After removing age as a risk factor, the backward elimination method revealed that seven factors showed a significant linear correlation with GERD in Uygur participants (Table 4): occupation ($r = 0.623$), gender

($r = 0.839$), smoking ($r = 0.322$), strong tea ($r = 0.658$), alcohol drinking ($r = 0.696$), mainly meat ($r = 0.676$) and BMI ($r = 0.567$). Accordingly, the regression equation was: y (GERD) = $-6.464 + 0.623 \times \text{occupation} + 0.839 \times \text{gender} + 0.322 \times \text{smoking} - 0.658 \times \text{strong tea} - 0.696 \times \text{drinking} - 0.676 \times \text{mainly meat} + 0.567 \times \text{BMI}$ ($r = 0.833$, $P = 0.000$) (Figure 2A).

For Han Chinese, seven factors showed a significant linear correlation with GERD: gender ($r = 0.957$), age ($r = 0.016$), occupation ($r = 0.482$), strong tea ($r = 1.124$), alcohol drinking ($r = 0.558$), mainly meat ($r = 0.591$) and BMI ($r = 0.246$), particularly strong tea and BMI (Table 4). Accordingly, the regression equation was: y (GERD) = $-4.882 + 0.957 \times \text{gender} - 0.016 \times \text{age} + 0.482 \times \text{occupation} - 1.124 \times \text{tea} - 0.558 \times \text{drinking} - 0.591 \times \text{meat} + 0.246 \times \text{BMI}$ ($r = 0.793$, $P = 0.008$) (Figure 2B).

DISCUSSION

GERD is a chronic disorder which has a significant impact on quality of life, and consumes a large number of medical resources worldwide. The incidence of GERD is higher than ever, particularly in Asian countries and

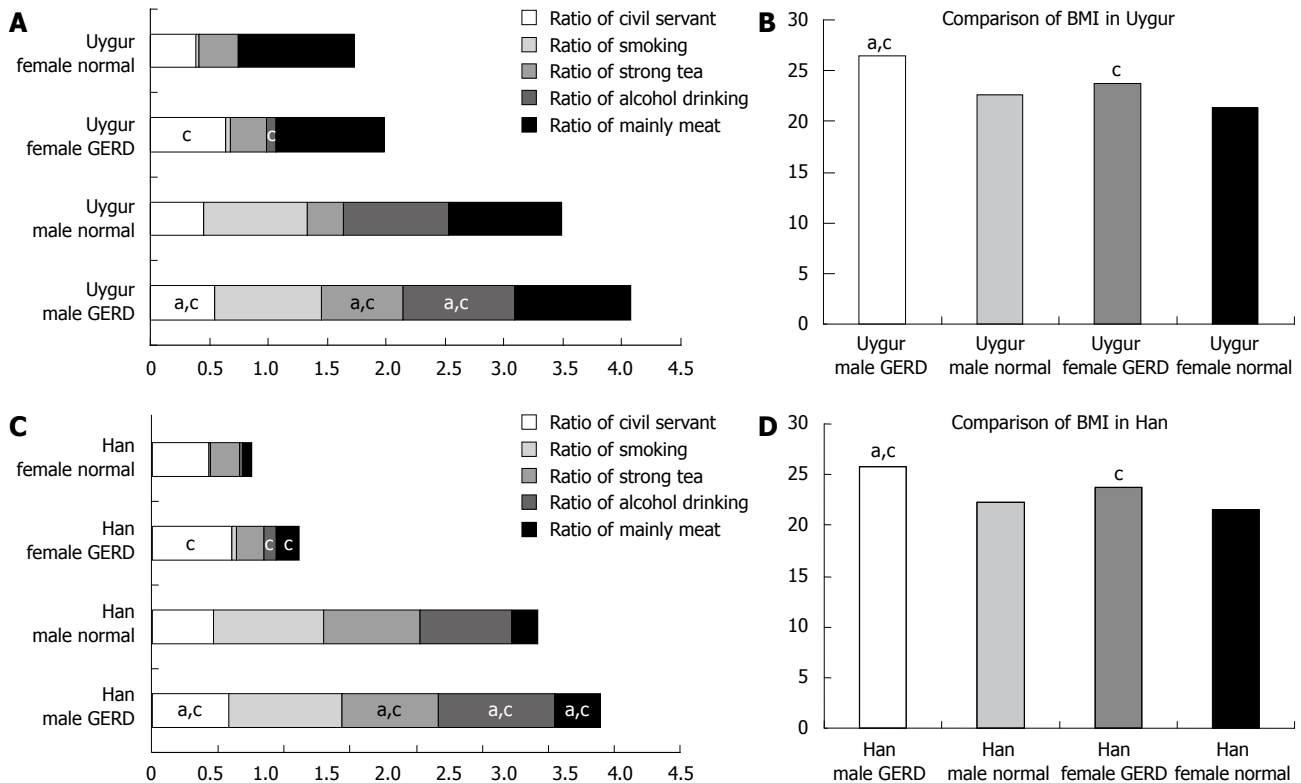

Figure 1 Relationship between occupation (civil servant), smoking, strong tea, alcohol drinking as well as body mass index and gastroesophageal reflux disease in Uyghur and Han Chinese adults. **A:** For gastroesophageal reflux disease (GERD) males, civil servant ratio (OR = 1.49, 95% CI 1.44-1.54), strong tea ratio (OR = 5.36, 95% CI 5.29-5.41), alcohol drinking ratio (OR = 2.33, 95% CI 2.13-2.53); **B:** Body mass index (BMI) value (26.5 ± 3.1 vs 22.7 ± 3.0 for GERD males vs normal males, $P < 0.005$ and 26.5 ± 3.1 vs 23.8 ± 3.8 for GERD males vs GERD females, $P < 0.01$) were higher than those in normal males and in GERD females, respectively; while for GERD females, civil servant ratio (OR = 2.77, 95% CI 2.56-2.98), alcohol drinking ratio (OR = 6.81, 95% CI 5.62-8) and BMI value (23.8 ± 3.8 vs 21.4 ± 2.9 , $P < 0.05$) were higher than those in normal females; **C:** For GERD males, civil servant ratio (OR = 1.64, 95% CI 1.59-1.7), strong tea ratio (OR = 2.3, 95% CI 2.23-2.36), alcohol drinking ratio (OR = 3.3, 95% CI 3.19-3.41), mainly meat ratio (OR = 2.35, 95% CI 2.28-2.42); **D:** BMI value (25.8 ± 3.5 vs 22.3 ± 2.7 for GERD males vs normal males, $P < 0.005$ and 25.8 ± 3.5 vs 23.8 ± 3.0 for GERD males vs GERD females, $P < 0.01$) were higher than those in normal males and in GERD females, respectively; while for GERD females, civil servant ratio (OR = 2.05, 95% CI 1.86-2.24), alcohol drinking ratio (OR = 4.44, 95% CI 3.61-5.27), mainly meat ratio (OR = 2.58, 95% CI 2.19-2.97) and BMI value (22.9 ± 3.8 vs 20.4 ± 2.9 , $P < 0.01$) were higher than those in normal females. ^a $P < 0.05$ vs male of the same ethnic group; ^c $P < 0.05$ vs female of the same ethnic group.

Figure 2 The risk factors linearly correlated with gastroesophageal reflux disease in both Uyghur (A) and Han Chinese (B).

China. Many publications on GERD have focused on southern China, however, there are few reports which have focused on northern China or minority groups. Therefore, the purpose of our large-scale, population-based investigation was to determine whether lifestyle

and dietary customs of the local residents in Xinjiang play a role in GERD, whether the incidence of GERD is different between Uyghur and Han Chinese, and which risk factors can lead to GERD.

By applying normalized methods (upper gastroin-

testinal endoscopy, 24-h esophageal pH monitoring and the PPI test), a total of 304 Uyghur (31%) and 256 Han (25%) participants were classified as having GERD, 61% had NERD, 29% had EE and 10% had BE in the Uyghur GERD group (254 male and 50 female), and in the Han group (203 male and 53 female), 55% had NERD, 35% had EE and 10% had BE. The incidence of GERD in Uyghur was significantly higher than that in Han Chinese adults. The results of the present investigation also showed that the incidence of GERD in both Uyghur and Han male adults was higher than that in Uyghur and Han female adults, respectively. In addition, the incidence of NERD in Uyghur was higher than that in Han. Using stratification analysis, we found that in Uyghur with GERD, civil servant ratio, strong tea ratio, alcohol drinking ratio and BMI value in males were higher than those in normal males and females, respectively. The civil servant ratio, alcohol drinking ratio and BMI value in Uyghur females with GERD were higher than those in normal females. In Han with GERD, the same results as those described in Uyghur were observed, however, the mainly meat ratio in both males and females with GERD was higher than that in normal males and females. Regression analysis further revealed a correlation between seven factors and GERD in Uyghur and Han participants, respectively. The above results indicated the presence of ethnic and gender differences between Uyghur and Han Chinese with regard to GERD in China. The correlation between occupation, alcohol drinking as well as BMI and GERD was similar to previous studies^[12-14]. A recent study found that the incidence of GERD in Caucasians was higher than that in other ethnic groups, which suggested that Caucasian was a related factor^[15]. Anthropology research has demonstrated that the gene structure in Uyghur subjects contains Caucasian and Mongolian bloodlines^[16,17], thus the gene fusion characteristics in Uyghur may reasonably explain their different phenotype with regard to GERD, which is not only different from but also similar to that of Han Chinese. The mainly meat ratio in both male and female Han participants with GERD was higher than that in normal males and females, respectively, and may be an independent risk factor associated with GERD. Although we cannot explain this result in Han at present, further research is needed in order to determine whether this result is objective, and whether ethnic groups or gene polymorphisms are related to GERD occurrence^[18,19].

It has been shown that there are geographic and population (gender, age, ethnic group) differences in the incidence of GERD^[20]. Related GERD etiological factors include BMI, smoking, alcohol consumption, esophageal hiatus, and inheritance. GERD may also be associated with chronic cough, asthma, pharyngitis, stomatitis and sleep disorder^[12]. In the present study, the incidence of GERD in Han was higher than that found in several previous reports^[3,4], and was possibly due to environmental differences. To date, there have been no published reports on GERD in Uyghur, our findings

showed that the incidence of GERD in Uyghur (including NERD) was significantly higher than that in Han. In addition, the incidence of GERD in Uyghur was higher than that in Israeli subjects, while the GERD ratio in females was lower than those in Israeli and Japanese females^[21,22]. However, our findings were in agreement with those in previous studies carried out in Western populations, which indicated a ethnic group difference^[23], further highlighting ethnic group and geographical differences.

The Gerd Q was designed by Jones *et al*^[8] in 2007, and was used to assess and diagnose GERD, and to assess symptom changes and quality of life in GERD patients. Several studies have demonstrated its effectiveness and reliability^[24]. Receiver operating characteristic curve analysis revealed that when taking a score of 8 as the diagnostic threshold for GERD, the accuracy rating was up to 70%, which was close to the diagnostic level of a gastroenterologist. After comparing the diagnostic rate for GERD, we found that there was no significant difference between the normalized methods and the Gerd Q scale, thus a Gerd Q score of ≥ 8 can be used as a standard to diagnose GERD. Since more than 50% of GERD patients have NERD, it is impracticable to diagnose GERD routinely using endoscopy or 24-h esophageal pH monitoring in China. Therefore, in the case of a young or middle-aged patient intolerant of invasive examination who has typical reflux symptoms, but no warning symptoms, a diagnostic method based on symptoms may be desirable. We suggest that the Gerd Q scale may be used as a primary clinical diagnostic approach^[25,26].

The backward method of logistic regression analysis revealed that gender, occupation, strong tea, alcohol drinking, mainly meat and BMI were the six common related risk factors in Uyghur and Han adults with GERD; for Uyghur adults with GERD, smoking was a related risk factor which was different from that in Han, and for Han, age was a related risk factor which was different from that in Uyghur. Furthermore, all factors correlated with GERD in a linear manner. Because the age of 75% of the participants in this investigation ranged from 35 to 45 years, we did not analyze the relationship between age stratification and GERD, however, the results revealed a gender difference (Table 4). Gender, smoking and alcohol drinking have been demonstrated to be risk factors for GERD^[12]. Smoking was not shown to correlate with GERD in Han participants. The smoking ratio which was lower in Han than in Uyghur and racial difference were the main risk factors, in addition to occupation related to GERD in Han. This may have been due to the nature of work, lifestyle, and less exercise in Han. The above results confirmed the correlation between these risk factors and GERD. We suggest that males and civil servants are susceptible to GERD. A recent study demonstrated that gender was a related factor for GERD in Japan^[27], and our results are consistent with these findings.

Xinjiang is located in Northwest China, and is a multi-

ethnic area, where the day is longer than the night, and cold and dry conditions are the main climatic features which are different from those inland, and dinner-to-bed time is shorter than that inland. A recent report indicated that shorter dinner-to-bed time was significantly associated with an increased OR for GERD^[28]. Uyghur is the main minority group in Urumqi, and the ethnic culture, religion, lifestyle and dietary customs are different from those in Han, as mainly meat (beef and lamb) and dairy products are important dietary components. Han Chinese who live in the same region have many similarities to Uyghur subjects with the exception of differences such as meat and milky tea (milky tea is a conventional drink in Uyghur). The dietary structure of residents in Xinjiang is characterized by high caloric, high fat, spicy, strong flavors, strong tea, smoking and alcohol drinking which are more prevalent in males; in addition, changing lifestyle, obesity prevalence, as well as changing population structure have increasingly led to transition of the disease spectrum, which has become and is becoming common and an important etiology of GERD in Uyghur and Han Chinese. Drinking strong tea is a common traditional custom in Uyghur and Han subjects in Xinjiang, Fu-Brick tea which the Uyghur drink and the various teas which the Han drink are fermentative green teas. Green tea consumption has also been shown to be negatively associated with the risk of chronic atrophic gastritis, as green tea can suppress the proliferation of *Helicobacter pylori* in the stomach and inhibit the progression of chronic atrophic gastritis^[29]. Therefore, green tea, especially strong green tea, can increase gastric acid secretion leading to the development of GERD symptoms. Thus, we consider green tea to be a significant risk factor for GERD^[10].

In conclusion, the present investigation and logistic regression analysis with regard to GERD in a large population clearly demonstrated that GERD is highly prevalent in adults living in Urumqi. The incidence of GERD in Uyghur and Han adults, especially Uyghur, was similar to that in Western populations. There are ethnic group and gender differences between Uyghur and Han, and regional differences between China's Xinjiang residents and other countries. Being male, smoking, alcohol drinking, strong tea, mainly meat and BMI are the main risk factors for GERD in Uyghur, while being male, civil servant, alcohol drinking, strong tea, mainly meat and BMI are the main risk factors for GERD in Han. These factors have a significant impact on GERD symptoms and quality of life. Our results also demonstrated that the Gerd Q can be used to diagnose GERD and possibly allow the evaluation of clinical efficacy in GERD patients.

Based on the above results, it would be very advantageous to prevent the development of GERD and cure it by optimizing lifestyle (such as controlling weight^[30], aerobic exercise, avoid overeating, appropriate sleep^[31], modifying dietary structure (low caloric intake, low fat intake, avoid strong and spicy foods, more vegetables, high cellulose, less stimulating beverages, less smoking, less alcohol drinking), and reducing foods and drugs

that probably lead to a fall in lower esophageal sphincter pressure. When suffering from GERD symptoms, one should consult a doctor and undergo appropriate treatment under the guidance of the doctor.

COMMENTS

Background

The incidence of gastroesophageal reflux disease (GERD) is high in Western and developed countries, however, along with changing lifestyle and dietary habits, the incidence of GERD has also increased in the Asian-Pacific region in recent years, particularly in China, and the incidence in China is rising year by year. Xinjiang is located in the northwest region of China, and Uyghur is the main minority group in this autonomous region. The gene for GERD in Uyghur is a fusion gene of Caucasian and Mongoloid characteristics. The dietary characteristics of local residents prioritizes meat (mainly beef and lamb), cooked wheaten food, and alcohol drinking. In addition, strong food tastes are favored. To date, there have been few studies on the incidence of GERD with regard to minority groups, and based on this research background, authors designed and performed this study.

Research frontiers

Studies show that there are geographical, and population (gender, age, ethnic group) differences in the incidence of GERD, and etiological factors include body mass index, smoking, alcohol consumption, esophageal hiatus hernia, and inheritance. Authors analyzed the prevalence of GERD in Urumqi, and compared the similarities and differences between Uyghur and Han Chinese adults, and then identified risk factors for GERD. This investigation is fundamental for similar studies in the future.

Innovations and breakthroughs

This is a large-scale, epidemiological and cross-sectional, novel investigation focusing on gastroesophageal reflux disease in Uyghur and Han subjects residing in Xinjiang, China. To date, there have only been a few reports on GERD in minority groups, and to our knowledge large-scale studies focusing on GERD in Uyghur alone have not been carried out. SPSS analysis revealed the risk factors related to GERD, and the results provide further insight into the lifestyle, dietary customs and racial differences relating to GERD between Uyghur and Han.

Applications

The particular lifestyle and dietary customs of Uyghur prompted us to investigate the similarities and differences between Uyghur and Han Chinese living in Xinjiang, China. Their results will go a long way towards research into GERD characteristics in minority groups in China. Several studies have demonstrated that, when taking a score of 8 (using GERD questionnaire, Gerd Q) as the diagnostic threshold for GERD, the accuracy rating was up to 70% which was close to the diagnostic level of a gastroenterologist. They suggest that Gerd Q may be used as a primary clinical diagnostic approach and a standard for estimating GERD.

Peer review

GERD is a world-wide disease that affects the quality of life (reflux may depend only on the sphincter defect and may be caused by bile reflux). GERD reached a high level in Western countries (not only in the so-called developed). The Western life style and diet habits, including fast-food, has been introduced in China, more in the north than in south.

Abstract

AIM: To compare early use of transjugular intrahepatic portosystemic shunt (TIPS) with endoscopic treatment (ET) for the prophylaxis of recurrent variceal bleeding.

METHODS: In-patient data were collected from 190 patients between January 2007 and June 2010 who suffered from variceal bleeding. Patients who were older than 75 years; previously received surgical treatment or endoscopic therapy for variceal bleeding; and complicated with hepatic encephalopathy or hepatic cancer, were excluded from this research. Thirty-five cases lost to follow-up were also excluded. Retrospective analysis was done in 126 eligible cases. Among them, 64 patients received TIPS (TIPS group) while 62 patients received endoscopic therapy (ET group). The relevant data were collected by patient review or telephone calls. The occurrence of rebleeding, hepatic encephalopathy or other complications, survival rate

and cost of treatment were compared between the two groups.

RESULTS: During the follow-up period (median, 20.7 and 18.7 mo in TIPS and ET groups, respectively), rebleeding from any source occurred in 11 patients in the TIPS group as compared with 31 patients in the ET group (Kaplan-Meier analysis and log-rank test, $P = 0.000$). Rebleeding rates at any time point (6 wk, 1 year and 2 year) in the TIPS group were lower than in the ET group (Bonferroni correction $\alpha' = \alpha/3$). Eight patients in the TIPS group and 16 in the ET group died with the cumulative survival rates of 80.6% and 64.9% (Kaplan-Meier analysis and log-rank test $\chi^2 = 4.864$, $P = 0.02$), respectively. There was no significant difference between the two groups with respect to 6-wk survival rates (Bonferroni correction $\alpha' = \alpha/3$). However, significant differences were observed between the two groups in the 1-year survival rates (92% and 79%) and the 2-year survival rates (89% and 64.9%) (Bonferroni correction $\alpha' = \alpha/3$). No significant differences were observed between the two treatment groups in the occurrence of hepatic encephalopathy (12 patients in TIPS group and 5 in ET group, Kaplan-Meier analysis and log-rank test, $\chi^2 = 3.103$, $P = 0.08$). The average total cost for the TIPS group was higher than for ET group (Wilcoxon-Mann Whitney test, 52 678 RMB *vs* 38 844 RMB, $P < 0.05$), but hospitalization frequency and hospital stay during follow-up period were lower (Wilcoxon-Mann Whitney test, 0.4 d *vs* 1.3 d, $P = 0.01$; 5 d *vs* 19 d, $P < 0.05$).

CONCLUSION: Early use of TIPS is more effective than endoscopic treatment in preventing variceal rebleeding and improving survival rate, and does not increase occurrence of hepatic encephalopathy.

INTRODUCTION

Esophagogastric varices bleeding (EGVB) is prone to be fatal, and often induces deterioration of liver function and may lead to bacterial infection, hepatorenal syndrome, or other complications.

Currently, the first-line treatments in prevention of variceal rebleeding include medication^[1-3] and endoscopic therapy (ET)^[4-6]. Transjugular intrahepatic portosystemic shunt (TIPS) is effective in preventing rebleeding, but due to post-operative stent stenosis and a high incidence of hepatic encephalopathy^[7-11], this procedure is considered not superior to the conventional treatment in survival rate. Consequently, TIPS has been used only as a rescue approach after first-line treatment fails^[12-14]. A large number of studies have shown that although TIPS can effectively control acute bleeding, it has a high mortality rate. Bare stents were used previously, but recently coated stents have been more commonly used, thus the clinical efficacy of TIPS must be re-evaluated^[15-19]. Hence, in this study, through out-patient and telephone communication based follow-up, data of patients with upper gastrointestinal bleeding due to varices over the past three years who were managed in the Department of Gastroenterology, First Affiliated Hospital of Xi'an Jiaotong University, were collected. We compared TIPS with endoscopic surgery in the prevention of gastrointestinal rebleeding, improvement of survival rates and other aspects, in order to assess the feasibility, necessity and long-term efficacy of early implementation of the TIPS treatment.

MATERIALS AND METHODS

Patient data

Patients admitted to our hospital between January 2007 and June 2010 due to upper gastrointestinal bleeding resulting from varices who received TIPS or ET for the first time were included.

Inclusion criteria: (1) Age between 18 and 75 years; (2) liver cirrhosis confirmed by medical history, clinical

manifestations and diagnostic imaging examinations; (3) liver function < 13 points according to Child score; (4) endoscopy confirmed bleeding due to esophageal varices before treatment; and (5) no endoscopic and interventional therapy or surgical treatment prior to admission.

Exclusion criteria: (1) A history of hepatocellular carcinoma (HCC) or malignant tumors of other organs; (2) severe organ dysfunction [heart failure, respiratory failure, moderate to severe jaundice (serum bilirubin > 3-5 mg/dL), hepatorenal syndrome or chronic renal insufficiency]; (3) hepatic encephalopathy stage \geq second stage; and (4) ectopic variceal bleeding. The general information of the patients who were eligible for endoscopic therapy was obtained from the database at our endoscopy room. At the same time, the information of patients eligible for TIPS were obtained from the inpatient database.

Treatment

All patients chose their treatment plans after they were informed of their conditions, and they were required to sign an informed consent for the special treatment they selected. Patients treated with TIPS (TIPS group) received either elective or immediate (in case of acute bleeding phase) interventional treatment. Patients with endoscopic treatment (ET group) were administered with endoscopic band ligation or tissue adhesive agent injection when their acute bleeding was controlled by medication or combined therapy with three-balloon catheters.

TIPS procedure: Catheters commonly used in TIPS included: RUPS-100, balloon dilatation catheter and guide wire, and the metal stent. Stents used in the procedures included bare metal stents (Luminexx, Codis or Zilver stents) of 8 mm and 10 mm in diameter, and coated stent (Fluency coated stent) with an average diameter of 8 mm. The right internal jugular vein was punctured under local anesthesia. Under X-ray monitoring, the guide wire was manipulated to the hepatic vein. A puncture needle was used to establish a pathway to the portal vein, which was then dilated with the balloon catheter. The stent was then put in place to complete the portal systemic shunting. Angiography was performed and if esophageal varice was still present, Corbra 2 catheter was delivered to the varicose vein. Ethanol or stainless steel ring was used to embolize the vein. Postoperative strategies included prevention of hepatic encephalopathy and infection, and heparin treatment for 1 wk, followed by oral intake of aspirin for 1-3 mo after discharge.

Endoscopic treatment: (1) Six-ligation devices (United States Wilson-Cook Company, Model: MBL-6-F) were used in endoscopic variceal ligation. Ligation started at the dentate line near the cardia (varicose vein bulging site) with a high density and a large number of ligating points. All varicose veins should be ligated. For some varicose veins, 2-3 ligations were done at differ-

ent locations with bands. The procedure was repeated every two weeks until the varices disappeared or almost disappeared; (2) Endoscopic tissue adhesive injection was administered with the endoscopic sclerosis needle (Germany Ahmed Walker Medical Products Service Co., Ltd; Model: INJ1-A1-10.220), tissue adhesive [α -butyl cyanoacrylate ester; Kang Pat medical glue (embolic)], using sandwich technique.

Postoperative follow-up. All the patients were followed up by the outpatient department through telephone calls. Patients in the TIPS group were scheduled for check-ups at the outpatient department with portal vein Doppler ultrasound at 1 wk, 1 mo and 3 mo, and then every 6-12 mo after the surgery. Patients in the ET group received gastroscopy one mo after treatment, and then once every 3 mo until the 4th one was done. Follow-up continued for 3 years until February 2011. The goal of the follow-up was to check for rebleeding, and check for death, hepatic encephalopathy, and treatment-related complications. Data of repeated treatment, causes and frequency of re-hospitalization, and hospital costs were also evaluated at follow-up.

Statistical analysis

SPSS 13.0 software was used for statistical analysis. Continuous normally distributed variables were analyzed using two independent samples *t* test. Continuous non-normally distributed variables were analyzed using Wilcoxon-Mann Whitney test. χ^2 test or Fisher exact test was used for data measurement. Kaplan-Meier curve analysis was used to analyze the occurrence of rebleeding, hepatic encephalopathy as well as incidence of death. Log-rank test was used to compare the two methods of treatment regarding the differences in prognosis and outcome. Other prognostic variables, after being assigned by grading or quantification, were analyzed by Cox regression to evaluate the impact of covariates on the prognosis. *P* values were two-sided, and *P* < 0.05 was considered as statistically significant.

RESULTS

Comparable study sample

There was no significant difference in gender, age, cause of disease, clinical manifestations, liver function, endoscopic examination and laboratory indicators between the two groups, thus making the sample statistically comparable (Table 1).

Technique comparison

In the TIPS group, 15 patients used 10-mm internal diameter stents, and the rest used 8 mm. Twenty-four patients used the Fluency coated stents, and the rest with bare stents. Thirty-three patients also underwent interventional embolization of esophageal varices during TIPS procedure. In the ET group, 44 patients were subjected to simple routine endoscopic variceal ligation, 13 were treated with endoscopic tissue adhesive injection, and the rest 5 patients were treated with the combined therapy. Ligations were made about 1-3 times per person (on average, 1.2 times per person); and one tissue adhesive injection was used on average.

Rebleeding

The average follow-up was 20.7 ± 1.3 mo for the TIPS group, and 18.7 ± 1.3 mo for the ET group. Eleven cases in the TIPS group and 31 cases in ET group had gastrointestinal rebleeding. Kaplan-Meier analysis showed that there were significant differences in the overall rebleeding rates between the two groups (*P* = 0.000) (Figure 1A). Bonferroni correction showed that at week 6, month 12 and month 24 after operation, the occurrence of rebleeding was significantly lower in TIPS group than in ET group. Cox multivariate regression analysis showed that among the covariates (grouping variables, combined portal hypertensive gastropathy, gastroesophageal varice 2/isolated gastric varice 1, liver function with B/C grade, prothrombin time > 16 s and cirrhosis due to viral hepatitis), only grouping variable with TIPS therapy was a factor affecting the rate of rebleeding [TIPS treatment: B = -1.41; Exp (B) = 0.24, 95% confidence

Figure 1 Kaplan-Meier analysis. A: The non-occurrence of rebleeding in the two groups; B: Survival rate; C: The non-occurrence of hepatic encephalopathy. TIPS: Transjugular intrahepatic portosystemic shunt; ET: Endoscopic therapy.

Table 2 Comparison of cause of death and post-operative severe complications between two groups

	TIPS group	ET group
Cause of death		
Gastrointestinal bleeding	3	9
Liver failure	4	6
Hepatic encephalopathy	0	1
Infection	1	0
Post-operative severe complications		
Fever	2	2
Spontaneous peritonitis	0	2
Hepatorenal syndrome	0	1
Acute peritonitis	0	1

TIPS: Transjugular intrahepatic portosystemic shunt; ET: Endoscopic therapy.

interval (CI) (0.12, 0.50); $P = 0.001$]. Of the 31 patients in ET group, 8 rebleeding patients received rescue TIPS treatment. Of those 8 patients, one patient, who used a bare stent, had rebleeding 10 mo later. Examination showed stent stenosis, and the patient received conservative treatment. One patient had massive gastrointestinal bleeding, resulting in death 14 mo after operation. No rebleeding occurred in the remaining 6 patients.

Postoperative survival

There were 8 deaths in TIPS group and 16 deaths in ET group. Kaplan-Meier survival analysis showed that the cumulative survival rate was significantly higher in the TIPS group than in the ET group (80.6% *vs* 64.9%, Kaplan-Meier analysis and log-rank test $\chi^2 = 4.864$, $P = 0.02$) (Figure 1B). Individual time point comparison showed that there was no significant difference 6 wk after operation between the two groups in survival rate; after 12 mo and 24 mo, the survival rate was significantly higher in the TIPS group than in the ET group (92% *vs* 79%; 89% *vs* 64.9%). Cox regression curves showed that the covariates [age > 53 years, with ascites, cirrhosis due to hepatitis, liver function with total bilirubin > 34 $\mu\text{mol/L}$, creatinine (CRE) > 77 $\mu\text{mol/L}$] age > 53 years, viral hepatitis (hepatitis B virus and hepatitis C virus) resulting in cirrhosis, as well as CRE > 77 $\mu\text{mol/L}$ were predictable factors affecting survival. Wald test revealed

that after adjusting these risk factors, TIPS therapy was more beneficial for improving survival [$B = -0.89$; Exp (B) = 0.41, 95%CI (0.16, 1.00); $P = 0.04$]. Comparison in the cause of death between the two groups is shown in Table 2.

Hepatic encephalopathy and other complications

Twelve of the postoperative TIPS patients had newly onset of hepatic encephalopathy (Child A grade 4, Child B grade 8), and 5 in ET (Child A grade 2, Child B grade 3). Kaplan-Meier curve analysis showed that there was no statistically significant difference between the two groups in the non-occurrence of hepatic encephalopathy (TIPS group 81.2% *vs* ET group 91.8%, $P = 0.08$) (Figure 1C). Individual time point comparison showed that the non-occurrence of hepatic encephalopathy 6 wk after operation in the ET group was higher than in the TIPS group, the difference being statistically significant (TIPS group 82.8% *vs* ET group 95.1%), and after 12 mo and 24 mo, the difference was no longer statistically significant (TIPS group 82.8% *vs* ET group 91.8%, TIPS group 81.2% *vs* ET group 91.8%). Cox regression analysis showed that all selected covariates (age > 53 years, ascites, cirrhosis due to hepatitis, liver function grade with Tbil > 34 $\mu\text{mol/L}$, CRE > 77 $\mu\text{mol/L}$) had no significant effect on the occurrence of hepatic encephalopathy [grouping variable for TIPS treatment: $B = 0.94$; Exp (B) = 2.56, 95%CI (0.86, 7.62); $P = 0.09$]. Other complications are shown in Table 2.

Hospitalization costs

Hospitalization cost was compared between the two groups (Table 3). The cumulative total cost of hospitalization was 52 678 RMB/person in TIPS group and 38 844 RMB/person in ET group; the cost in the TIPS group was significantly higher than in the ET group ($P < 0.05$). In the follow-up period, the average hospitalization frequency for the TIPS group was 0.4 times/person and 1.3 times/person for the ET group; ET group had a significantly higher frequency of hospitalization than the TIPS group ($P = 0.01$). The average length of hospital stay during the follow-up for TIPS group was 5 d/person and 19 d/person for ET group; the ET group had

Table 3 Comparison of length of hospital stay and expenses between two groups

	Initial TIPS (64 cases)	Rescue TIPS (8 cases)	Rest of ET (54 cases)
Average total expense (RMB)	52 678	63 003	35 298
Average length of hospital stay during follow-up (d)	5	20	18
Average number of hospitalization during follow-up	0.4	2.1	1.2

TIPS: Transjugular intrahepatic portosystemic shunt; ET: Endoscopic therapy.

significantly longer hospital stay than the TIPS group ($P < 0.05$). The patients in the ET group who received TIPS treatment after the failure of endoscopic treatment were included into rescue TIPS group, and comparative results are shown in Table 3.

DISCUSSION

Currently, the endoscopic variceal treatment remains a predominant method for prevention and treatment of recurrent gastrointestinal bleeding^[19]. However, endoscopic therapy cannot fundamentally solve the problem of portal hypertension, and patients often cannot tolerate repeated therapies, therefore leading to a high rate of rebleeding. The TIPS procedure, through reducing portal pressure, serves to prevent and control esophageal and gastric variceal bleeding, and alleviate ascites as well. Therefore, with respect to preventing recurrent gastroesophageal bleeding, TIPS is better than endoscopic therapy.

For the TIPS procedure, stenosis of the stent is an important cause of postoperative recurrent bleeding. Previous studies have shown that the rate of stent stenosis is about 30%-70%^[20] with the use of bare stent in TIPS whereas the postoperative patency rate is up to 100% with the use of coated stents and Viatorr stent grafts^[21-23], and compared with bare stents, they did not increase the incidence of hepatic encephalopathy. This study showed that in the TIPS group, five cases had postoperative stenosis. Of the five cases, only one used the coated stent, and this patient did not follow doctor's orders to take aspirin for anticoagulation after being discharged from hospital. This further confirms that the use of coated stent can significantly lower the incidence of postoperative stent stenosis, and anticoagulation therapy can further reduce postoperative stent stenosis.

It has been confirmed that with respect to prevention of recurrent bleeding, TIPS is better than medication therapy^[13] and endoscopic therapy^[14]. The postoperative rebleeding rate was 12%-22% in TIPS, and it is even lower with the use of coated stent. For endoscopic therapy, however, the rebleeding rate is much higher (20%-43%)^[15]. Recently, a study by García-Pagán *et al.*^[24], comparing the use of Viatorr stent graft TIPS with drug combined endoscopic variceal ligation treatment, showed that in the 16 mo follow-up, only one case of re-

current bleeding occurred in the TIPS group as opposed to 14 cases in the other groups (3.1% *vs* 45.2%, $P = 0.001$). In this study, 17.2% of patients in the TIPS group had recurrent bleeding. Cases of rebleeding caused by stenosis of the stent were mostly seen in patients with bare stents. In the ET group, 50% of the patients had recurrent bleeding. This further confirmed that TIPS is superior to endoscopic therapy in prevention of recurrent bleeding and coated stents can further reduce the incidence of recurrent bleeding by lowering the rate of stent stenosis.

It has been shown that TIPS can effectively reduce refractory ascites (RA). It can also lower the incidences of hepatorenal syndrome (HRS), hepatic hydrothorax and other portal hypertension syndromes that are closely related to refractory ascites^[24]. In this study, serious postoperative complications associated with portal hypertension, such as RA, HRS and spontaneous bacterial peritonitis, mainly occurred in the ET group, possibly due to increased portal pressure acting as a common mechanism resulting in the above syndromes, whereas TIPS can effectively reduce portal pressure^[25].

A large number of clinical studies^[13,14] and meta-analyses^[15,25,26] indicate that TIPS procedure is not superior to endoscopic therapy with respect to improvement of survival time. This is the main reason why TIPS is used as a rescue option after the failure of the traditional therapeutic method. However, although rescue TIPS procedure can effectively control acute bleeding, the postoperative one-year survival rate is only 27%-55%^[27]. Most of the previous studies on TIPS procedure were based on the use of bare stents, and most patients chose TIPS 2-3 years after traditional treatment, thus making TIPS appear to be not superior to ET in survival rates.

In the study by García-Pagán *et al.*^[24], the patients in the TIPS group received TIPS with coated stent at the first incidence of bleeding during the early stages. Results showed that early and middle stage survival rates were much higher in TIPS group than in drug combined endoscopic group (post-operative 6 wk rate for TIPS group was 97% and combined therapy group 67%; post-operative 1 year rate for TIPS group was 86% and combined therapy group 61%), and the middle to long-term efficacy was similar to this study. As for the combined endoscopic group, of the 7 patients who received rescue TIPS due to recurrent bleeding, 4 died within 36 d. Another five patients died due to recurrent bleeding that led to liver failure and incapability to undergo remedy TIPS. Therefore, early implementation of TIPS after the first bleeding may raise the long-term survival rate better than endoscopic therapy. To use TIPS only after the failure of the traditional method may cause the patient to lose the opportunity for the TIPS procedure, thus delaying the illness and lowering survival rate.

Previous studies indicate that the incidence rate of hepatic encephalopathy, 1 year after TIPS was 30%-55%^[8,9]. Most cases occur in the early post-operative stage, and are transient in nature. As the brain adapts and adjusts to the

increase in ammonia toxins brought by the redistribution of intestinal blood flow, the symptoms disappear^[8]. The incidence rate of persistent hepatic encephalopathy that respond poorly to medication was low, 3%-7%^[10] for bare stent and 8%^[9] for coated stent. García-Pagán *et al.*^[24] showed that early TIPS treatment did not increase the incidence rate of hepatic encephalopathy (TIPS 28% and combined endoscopic therapy 40%, $P = 0.13$). This study demonstrated similar findings. Although in the early post-operative stage, more cases of hepatic encephalopathy occurred in TIPS group than in the ET group, these were mostly transient, and can quickly be controlled through timely administration of anti-hepatic encephalopathy medication.

In this study, although in the early stage, the average overall time spent in the TIPS group is longer than in the ET group, it significantly reduced re-hospitalization and the length of hospital stay. It also decreased incidences of RA, HRS and other portal hypertension related complications. In the ET group in this study, patients who underwent EBL had an average of 1.2 ligations per person. If following the regular course of treatment, the average total cost in the ET group may not be lower than that in the TIPS group. Also, after the failure of the endoscopic therapy, rescue TIPS increases the total cost. This does not comply with the principles of health economics and may cause the patient to lose the opportunity for the TIPS procedure, thus delaying their treatment of illness and lowering the survival rate.

COMMENTS

Background

Variceal bleeding is a severe complication of portal hypertension and a major cause of death in patients with cirrhosis. Combined treatment with vasoactive drugs and endoscopic techniques is the recommended standard of care for patients with acute variceal bleeding. However, treatment failure occurs in about 10% - 20% of patients requiring treatment with a transjugular intrahepatic portosystemic shunt (TIPS) as rescue therapy. TIPS is highly effective in controlling bleeding in such patients, but mortality is still very high. The authors conducted a study to determine whether early treatment with TIPS can improve outcomes in patients with cirrhosis and variceal bleeding compared with endoscopic therapy.

Research frontiers

TIPS has been used for more than 20 years to treat the complications of portal hypertension. Previous studies evaluating the role of TIPS in the prevention of recurrent variceal bleeding showed that TIPS reduces the rebleeding rate but increases hepatic encephalopathy without improving survival. TIPS is currently recommended only as a rescue therapy. Current practice guidelines for treating patients with acute variceal bleeding recommend fluid resuscitation, antibiotic prophylaxis, and vasoactive drugs such as glypressin or somatostatin analogues, followed by early endoscopy and either ligation or sclerosis of the varices.

Innovations and breakthroughs

In this study, early treatment with TIPS, as compared with medical treatment, was associated with an improved prognosis among patients at high risk for uncontrolled bleeding or rebleeding on the basis of a hepatic venous pressure gradient of 20 mmHg or higher. The results of a randomized, multi-center study that compared early TIPS with optimal medical therapy (endoscopic therapy plus vasoactive drugs) in patients at high risk for rebleeding who were either in Child-Pugh class B with active bleeding at endoscopy or in Child-Pugh class C. This study shows the benefit of early TIPS in patients with Child-Pugh class B or C disease who are at high risk for uncontrolled bleeding with standard therapy.

Applications

The study re-evaluated how the authors approach variceal bleeding in patients with Child-Pugh class B or C disease. Physicians should consider the early

use of TIPS with an e-PFTE-covered stent as first-line therapy rather than as rescue treatment if rebleeding occurs in high-risk patients with Child-Pugh B or C disease.

Terminology

TIPS is a technique in which a stent is placed between the portal vein and hepatic vein in the liver to provide a portosystemic shunt to reduce portal hypertension. The procedure is carried out under radiological control through the internal jugular vein. Successful shunt placement will stop/prevent bleeding. Endoscopic variceal ligation is a technique with less trauma and fewer side effects, in which varices were sucked into an endoscope allowing them to be occluded with a tight rubber band.

Peer review

The main drawbacks of the present study are that it is a retrospective analysis, and the study groups were not randomized. However, this study provides another evidence that early TIPS is associated with significant advantages over endoscopic therapy in terms of rebleeding rates, survival and length of hospital stay.

Abstract

AIM: To investigate the role of c-Jun N-terminal kinase (JNK) in thermotherapy-induced apoptosis in human gastric cancer SGC-7901 cells.

METHODS: Human gastric cancer SGC-7901 cells were cultured *in vitro*. Following thermotherapy at 43 °C for 0, 0.5, 1, 2 or 3 h, the cells were cultured for a further 24 h with or without the JNK specific inhibitor, SP600125 for 2 h. Apoptosis was evaluated by immunohistochemistry [terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL)] and flow cytometry (Annexin vs propidium iodide). Cell proliferation was determined by 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide. The production of p-JNK, Bcl-2, Bax and caspase-3 proteins was evaluated by Western blotting. The expression of JNK at mRNA level was determined by reverse transcription polymerase chain reaction.

RESULTS: The proliferation of gastric carcinoma SGC-7901 cells was significantly inhibited following thermotherapy,

and was 32.7%, 30.6%, 43.8% and 52.9% at 0.5, 1, 2 and 3 h post-thermotherapy, respectively. Flow cytometry analysis revealed an increased population of SGC-7901 cells in G0/G1 phase, but a reduced population in S phase following thermotherapy for 1 or 2 h, compared to untreated cells ($P < 0.05$). The increased number of SGC-7901 cells in G0/G1 phase was consistent with induced apoptosis (flow cytometry) following thermotherapy for 0.5, 1, 2 or 3 h, compared to the untreated group ($46.5\% \pm 0.23\%$, $39.9\% \pm 0.53\%$, $56.6\% \pm 0.35\%$ and $50.4\% \pm 0.29\%$ vs $7.3\% \pm 0.10\%$, $P < 0.01$), respectively. This was supported by the TUNEL assay ($48.2\% \pm 0.4\%$, $40.1\% \pm 0.2\%$, $61.2\% \pm 0.29\%$ and $52.0\% \pm 0.42\%$ vs $12.2\% \pm 0.22\%$, $P < 0.01$) respectively. More importantly, the expression of p-JNK protein and JNK mRNA levels were significantly higher at 0.5 h than at 0 h post-treatment ($P < 0.01$), and peaked at 2 h. A similar pattern was detected for Bax and caspase-3 proteins. Bcl-2 increased at 0.5 h, peaked at 1 h, and then decreased. Furthermore, the JNK specific inhibitor, SP600125, suppressed p-JNK, Bax and caspase-3 at the protein level in SGC7901 cells following thermotherapy, compared to mock-inhibitor treatment, which was in line with the decreased rate of apoptosis. The expression of Bcl-2 was consistent with thermotherapy alone.

CONCLUSION: Thermotherapy induced apoptosis in gastric cancer cells by promoting p-JNK at the mRNA and protein levels, and up-regulated the expression of Bax and caspase-3 proteins. Bcl-2 may play a protective role during thermotherapy. Activation of JNK *via* the Bax-caspase-3 pathway may be important in thermotherapy-induced apoptosis in gastric cancer cells.

INTRODUCTION

Gastric cancer is the second leading cause of cancer death worldwide and may remain one of the leading causes of all deaths in the near future^[1-3]. At present, the majority (about 80%) of patients diagnosed with gastric cancer are in an advanced stage with limited surgical options^[4]. Chemotherapy is an alternative treatment for advanced gastric cancer, however, patient outcome following chemotherapy is still very poor, with a median overall survival time of less than 1 year^[5]. Chemotherapy with cytotoxic drugs usually leads to severe toxicity which lowers the quality of life of patients. Thermotherapy is a new cancer treatment which is used following surgical, radiotherapy, chemotherapy and biological treatments. Thermotherapy induces malignant cell apoptosis and has a synergistic effect with chemotherapy resulting in improved outcomes and reduced side effects of chemotherapy, particularly in the later stages of malignancy or in tumors resistant to other treatments^[6,7]. A few studies have reported that induction of cellular apoptosis is important in thermotherapy, but the underlying mechanism remains to be explored.

c-Jun N-terminal kinase (JNK) is a member of the mitogen-activated protein kinase family. Activation of JNK by phosphorylation has been implicated in a variety of processes, including embryonic development, cellular transformation and initiation of apoptosis following various stresses^[8-11]. It has been reported that overexpression of JNK may cause cellular apoptosis in transfected cells^[12-14]. However, the function of JNK is complicated during cell stress, because JNK also has anti-apoptotic action^[15]. Thus, it is believed that JNK has either anti- or pro-apoptotic activity depending on cell type, apoptotic stimuli and other signalling pathways^[16]. JNK can be activated by thermotherapy, and ultimately leads to cellular apoptosis^[17]. It is unclear whether JNK involves or regulates apoptosis of gastric cancer cells in response to thermotherapy. In the current study, the human gastric cancer cell line, SGC-7901, was chosen as a model for thermotherapy-induced apoptosis *in vitro*. The role of JNK was determined to further investigate the underlying mechanism of thermotherapy-induced apoptosis in human gastric cancer. This may provide useful information for both clinical therapy and basic scientific research in gastric cancer.

MATERIALS AND METHODS

Reagents and equipment

Annexin V-fluoresceine isothiocyanate (V-FITC), propidium iodide (PI), 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphen-

yltetrazolium bromide (MTT) were obtained from Sigma (St. Louis, MO, United States). Mouse monoclonal antibodies against human p-SAPK/JNK (Thr183/Tyr185), Caspase-3, Bcl-2, Bax and the JNK-specific inhibitor, SP600125, were also purchased from Sigma (St. Louis, MO, United States). The M-MLV reverse transcription polymerase chain reaction (RT-PCR) kit was purchased from Promega (Beijing, China). Taq DNA polymerase was purchased from Takara (Dalian, China). Fetal bovine serum was purchased from Sijichun Bioengineering Materials, Inc. (Hangzhou, Zhejiang, China). Dulbecco's Modified Eagle Media (DMEM) culture media and 0.25% trypsin were purchased from Invitrogen-GIBCO (Carlsbad, CA, United States). dNTP and TRIzol were purchased from Invitrogen (Invitrogen, United States). Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining kits was purchased from KGI (Nanjing, China). The gastric cancer cell line, SGC-7901^[18], was obtained from the Jiangxi Province Digestive Institute (Jiangxi, Nanchang, China).

Gastric cancer cell thermotherapy and JNK blockage

Gastric cancer SGC-7901 cells were cultured in DMEM media (high glucose) supplemented with 10% fetal bovine serum, 100 U/mL penicillin, and 100 µg/mL streptomycin. The cells were maintained at 37 °C and 5% CO₂ in an incubator, and the culture medium was changed every 2-3 d. After thermotherapy (43 °C) treatment for 0, 0.5, 1, 2 or 3 h, SGC-7901 cells were cultured for a further 24 h. In addition, the JNK-specific inhibitor, SP600125, was added to SGC-7901 cells 2 h before thermotherapy treatment to determine whether the JNK pathway was involved in thermotherapy-induced apoptosis.

Proliferation of SGC-7901 cells determined by MTT assay

The cells (2×10^5 cell/mL) were seeded onto 96-well plates with 200 µL in six wells for each thermotherapy treatment for 0, 0.5, 1, 2 and 3 h. Twenty µL of MTT solution (5 mg/mL) was added to each well and incubated at 37 °C for 4 h, and the reaction was terminated with a detergent solution to lyse the cells and solubilize the colored formazan crystals. The supernatant was centrifuged at 3000 g for 10 min to obtain a formazan pellet. The supernatant was removed, and the pellet was dissolved completely with 150 µL dimethyl sulfoxide and observed at a wavelength of 570 nm using an enzyme-linked immunosorbent assay plate reader.

The relative inhibition rate was calculated as a percentage, as follows: $(1 - A_{\text{experiment}}/A_{\text{control}}) \times 100\%$. Three independent experiments were performed.

Cell cycle analysis and apoptosis assays

The effect of thermotherapy on the cell cycle and apoptosis in SGC-7901 cells was analyzed by flow cytometry. Cells floating in medium combined with the adherent layer were collected by trypsinization and fixation with 2 mL citrate buffer for 1 h. For detection of the cell cycle,

Table 1 Primers for reverse transcription polymerase chain reaction

Gene	Primer sequence	Size (bp)	Annealing temperature
<i>β-actin</i>	F: TCAGGTCATCACTATCGGCAAT	432	57 °C
	R: AAAGAAAGGGTGTAAAAGGCA		
<i>JNK</i>	F: CACAGTCCTAAAACGATACC	354	57 °C
	R: CCACACAGCATTGATAGAG		

JNK: c-Jun N-terminal kinase; F: Forward primer; R: Reverse primer.

the cells were stained with propidium iodide (1500 μ L) after RNase A (1500 μ L) treatment. The labeled cells were immediately analyzed by flow cytometry to evaluate the cell cycle and apoptosis. TUNEL assay, in which the residue of digoxigenin-labeled dUTP was catalytically incorporated into the DNA by terminal deoxynucleotidyl transferase II, was performed according to the manufacturer's instructions. The positive particles of diaminobenzidine staining were viewed under an optical microscope. The number of apoptotic cells was counted under a microscope (400 \times) and expressed as the apoptotic index (the number of apoptotic bodies/1000 cells).

Western blotting

Protein concentrations from isolated SGC-7901 cells were determined. The proteins were separated using sodium dodecyl sulfate polyacrylamide gel electrophoresis gels (polyacrylamide concentration 100 g/L) and electrophoretically transferred to polyvinylidene difluoride (PVDF) membranes. The PVDF membranes were blocked with 5% skimmed milk at 37 °C for 1 h and probed with the primary antibody: mouse anti-human JNK (1:2000), caspase-3, Bcl-2, Bax (1:1000), or β -actin (1:1000) monoclonal antibody overnight at 4 °C. The labeled antibody was visualized by horseradish peroxidase-conjugated goat anti-mouse immunoglobulin G (1:5000) and enhanced chemiluminescence. The blots were washed with 1 \times Tris-buffered saline and Tween buffer for 10 min, 3 times between each step. The density of the targeted bands was quantified using the Quantity One 4.6.2 Imaging Analysis System.

RT-PCR analysis

Total RNA was extracted from the SGC-7901 cells with TRIzol following the manufacturer's instructions. cDNA was synthesized from 2 μ g total RNA using the M-MLV RT-PCR kit in a 20 μ L volume, according to the manufacturer's instructions. Two μ L of cDNA, 2 μ L each primer (50 pmol/L), 1 μ L dNTP mix (10 mmol/L) and 1 μ L Taq DNA polymerase were used for the PCR analysis. The PCR amplification cycles consisted of denaturation at 94 °C for 5 min, 35 cycles of denaturation at 94 °C for 60 s, annealing for 60 s, extension at 72 °C for 60 s, and final elongation at 72 °C for 10 min. The PCR products were separated on a 1.5% agarose gel, stained with 0.5 mg/mL ethidium bromide, and visualized by ultraviolet

Table 2 Cell cycle of SGC-7901 cells following thermotherapy for various time periods (%)

Group	SGC-7901 cells		
	G0-G1	S	G2-M
0 h	27.22	62.47	10.31
1 h	71.15 ^a	22.52 ^a	6.33
2 h	70.89 ^a	17.11 ^a	12

^a $P < 0.05$ vs without thermotherapy treatment.

light. Gene expression was normalized to glyceraldehyde-3-phosphate dehydrogenase and shown as the ratio of absorbance values. The primer sequences and annealing temperature are listed in Table 1.

Statistical analysis

Statistical analysis was performed using statistical software (SPSS version 13.0). Data are expressed as the mean \pm SD. The means of 2 groups were compared using the *t* test. The means of more than 2 groups were compared using one-way analysis of variance, and $P < 0.05$ was regarded as statistically significant.

RESULTS

Inhibitory effect of thermotherapy on gastric cancer cells

To evaluate the effects of thermotherapy on cell viability, cultured gastric cancer SGC-7901 cells underwent thermotherapy for different time periods. Viability inhibitory rates of gastric carcinoma SGC-7901 cells were about 30%, 30%, 43% and 53% after 0.5, 1, 2 and 3 h of thermotherapy, respectively. These data suggest that proliferation of gastric carcinoma SGC-7901 cells was significantly inhibited in a time-dependent manner.

Effect of thermotherapy on cell cycle distribution in gastric cancer cells

The effects of thermotherapy on the cell cycle of SGC-7901 cells were determined using flow cytometry. Our results showed that thermotherapy increased the number of SGC-7901 cells in G0/G1 phase, but reduced the number in S phase ($P < 0.05$) at 1 h and 2 h, compared with that at 0 h. These results suggest that thermotherapy arrested gastric cancer cells in G0/G1 phase, inhibiting mitosis, and subsequent proliferation (Figure 1 and Table 2).

Induction of apoptosis by thermotherapy in gastric cancer cells

As arrest of cell cycle progression in tumor cells is usually associated with concomitant activation of cell apoptosis pathways, we investigated the effect of thermotherapy on induction of apoptosis in SGC-7901 cells by flow cytometry and TUNEL assay. Flow cytometry showed that the proportion of apoptotic cells was significantly increased after thermotherapy for 0.5, 1, 2 and 3 h, compared to untreated SGC-7901 cells, which was further confirmed

Figure 1 Cell cycle change in SGC-7901 cells following thermotherapy for various time periods. A-C: Cell cycle distribution in SGC-7901 cells following thermotherapy for 0 h, 1 h, 2 h respectively. Thermotherapy increased the number of SGC-7901 cells in G0/G1 phase, but reduced the number in S phase ($P < 0.05$) at 1 h and 2 h, compared with that at 0 h.

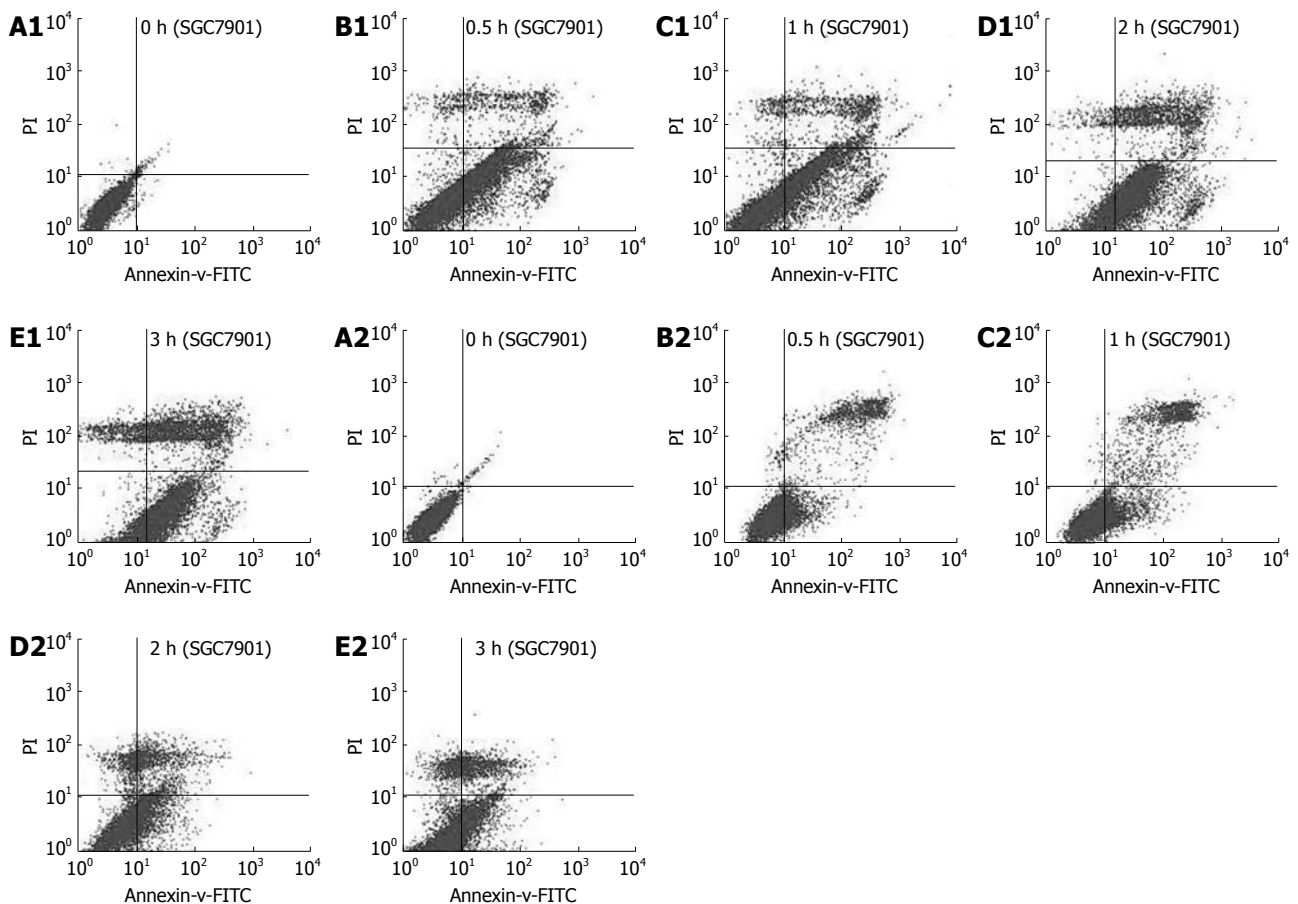

Figure 2 Apoptotic rate of SGC7901 cells with or without SP600125 treatment following thermotherapy for various time periods. A1, B1, C1, D1, E1: Apoptotic rate of SGC-7901 cells without SP600125 treatment, significantly increased after thermotherapy for 0.5, 1, 2 and 3 h, compared to that at 0 h ($P < 0.01$); A2, B2, C2, D2, E2: Apoptotic rate of SGC-7901 cells with SP600125 treatment, significantly inhibited cellular apoptosis induced by thermotherapy at 0.5, 1, 2 and 3 h ($P < 0.01$), compared to that at the same time points in the control groups. PI: Propidium iodide; FITC: Fluorescein isothiocyanate.

by TUNEL assay (Table 3). To further address the role of JNK in thermotherapy-induced apoptosis, pretreatment of cells with the JNK-specific inhibitor, SP600125, significantly inhibited cellular apoptosis induced by thermo-

therapy at 0.5, 1, 2 and 3 h ($P < 0.01$), compared to that at the same time points in the control groups. The apoptotic rates at 0 h ($P > 0.05$) in the experimental group and the control group were similar (Figures 2 and 3, Table 3).

Figure 3 Apoptosis of SGC-7901 cells with or without SP600125 treatment following thermotherapy for various time periods (×400). Apoptotic cells showing yellow fluorescence. A1, B1, C1, D1, E1: Apoptosis of SGC-7901 cells without SP600125 treatment, significantly increased after thermotherapy for 0.5, 1, 2 and 3 h, compared to that at 0 h ($P < 0.01$); A2, B2, C2, D2, E2: Apoptosis with SP600125 treatment, significantly inhibited cellular apoptosis induced by thermotherapy at 0.5, 1, 2 and 3 h ($P < 0.01$), compared to that at the same time points in the control groups.

These results suggested that the JNK-specific inhibitor, SP600125, significantly inhibited thermotherapy-induced apoptosis in gastric cancer cells.

Stimulation of p-JNK protein expression by thermotherapy

To determine whether thermotherapy activates p-JNK expression in gastric cancer cells, the expression level of p-JNK protein was determined in SGC-7901 cells following thermotherapy for 0.5, 1, 2 and 3 h using Western blotting analysis. The protein production of p-JNK was significantly higher at 0.5 h than that at 0 h post-treatment (Figure 4) ($P < 0.01$), peaked at 2 h, and then decreased. Interestingly, p-JNK protein was slightly lower at 1 h than that at 0.5 h post-treatment. Thus, these results clearly indicate that JNK in gastric cancer cells was activated by thermotherapy.

Effect of thermotherapy on JNK mRNA expression

Since activation of JNK is known to induce JNK mRNA expression in several cell systems, we examined whether the expression of JNK mRNA was also induced by thermotherapy in gastric cancer cells. The expression of JNK mRNA in SGC-7901 cells was determined by RT-PCR analysis, which showed that the induction patterns of the expression of p-JNK protein and JNK mRNA were very similar in thermotherapy-induced apoptosis. Namely, the

the effect of thermotherapy on gastric cancer cells.

Effect of JNK on Bax, Bcl-2 and caspase-3 proteins expression in thermotherapy-induced apoptosis

Apoptosis-related proteins, such as Bax, Bcl-2 and caspase-3 are known to cause cell apoptosis. Thus, the activation of JNK may affect the expression of Bax, Bcl-2 and caspase-3 proteins in thermotherapy-induced apoptosis. To determine whether the expression of Bax, Bcl-2 and caspase-3 proteins was regulated by activation of JNK protein, we measured the expression of Bax, Bcl-2 and

caspase-3 proteins in SGC-7901 cells treated with thermotherapy at various time points using Western blot analysis. As shown in Figure 4, the expression of Bax and caspase-3 proteins was significantly higher at 0.5 h than at 0 h post-treatment ($P < 0.01$), reached a maximum at 2 h, followed by a decrease, and was slightly lower at 1 h than at 0.5 h post-treatment. Bcl-2 was increased at 0.5 h, peaked at 1 h, and decreased thereafter.

To further understand how the activation of JNK regulates the expression of Bax, Bcl-2 and Caspase-3 proteins in thermotherapy-induced apoptosis in SGC-7901 cells we

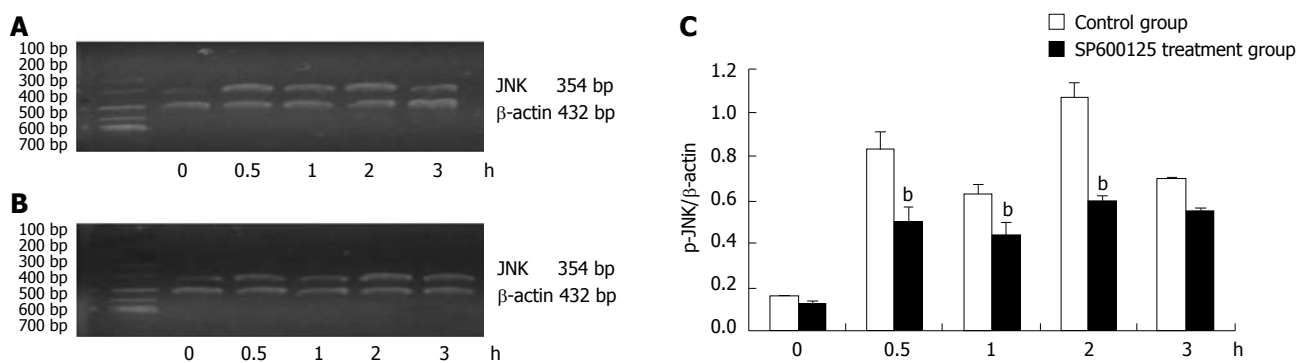

Figure 5 Expression of c-Jun N-terminal kinase at the mRNA level in SGC-7901 cells with or without SP600125 treatment following thermotherapy for various time periods. A: Expression of c-Jun N-terminal kinase (JNK) at the mRNA level in SGC-7901 cells without SP600125 treatment; B: Expression of JNK at the mRNA level in SGC-7901 cells with SP600125 treatment; C: Comparison of JNK at the mRNA level in SGC-7901 cells with or without SP600125 treatment; Expression of JNK at the mRNA level in SGC-7901 cells with SP600125 treatment was significantly inhibited compared with that in SGC-7901 cells without SP600125 treatment ($^bP < 0.01$).

used the JNK-specific inhibitor, SP600125, which exhibits significant selectivity for JNKs leading to inhibition of phosphorylation of both c-Jun and JNKs^[19]. Therefore, we treated SGC-7901 cells with thermotherapy in the absence or presence of SP600125 and analyzed the expression of p-JNK, Bax, Bcl-2 and caspase-3 proteins (Figure 4). We found that the presence of SP600125 significantly reduced the p-JNK level at various time points ($P < 0.01$), while the p-JNK level did not change markedly at 0 h ($P > 0.05$), compared to cells in the absence of SP600125. Concurrently, the expression of Bax and caspase-3 protein was also inhibited in the presence of SP600125, as well as that of p-JNK. However, there was no significant difference in the expression of Bcl-2 in SGC-7901 cells at any of the time points ($P > 0.05$) between the SP600125 treatment and mock treatment (Figure 4). These results collectively indicate that thermotherapy induced-apoptosis may be mediated by activation of JNK and the up-regulated expression of Bax and caspase-3 proteins, causing cellular apoptosis in gastric carcinoma cells. Bcl-2 protein did not seem to be involved and played a protective role in this process. These data suggest that JNK plays an important role in thermotherapy-induced apoptosis in gastric carcinoma cells.

DISCUSSION

Thermotherapy is a new cancer therapy which has re-emerged in the last 20 years, and plays an important role in comprehensive tumor treatment. Combined thermo- and chemo-therapy (green therapy) has become one of the important auxiliary therapies, as it improves the efficacy of cancer treatment^[20,21]. Heat-induced cell apoptosis was reported in the 1990s. More recently, JNK was activated in apoptotic U937 cells by radiotherapy^[22], and similar results were obtained using thermotherapy in human colon cancer^[16]. Thus, the expression of phospho-JNK at the protein level and JNK at the mRNA level were determined in SGC-7901 cells treated with thermotherapy. Thermotherapy increased the expression of p-JNK at different time points, and the protein produc-

tion of p-JNK was significantly higher at 0.5 h than that at 0 h post-treatment ($P < 0.01$), peaked at 2 h, and then decreased. The reason for this decline may be that some SGC-7901 cells were killed directly, not by induced apoptosis at 3 h, and a few SGC-7901 cells restarted proliferation after a long period of thermotherapy. It is interesting that p-JNK protein was slightly lower at 1 h than that at 0.5 h post-treatment, this indicates that SGC-7901 cells may have the ability to respond to thermotherapy. Similarly, the RT-PCR data showed that the induction patterns of the expression of p-JNK protein and JNK mRNA level were very similar in thermotherapy-induced apoptosis (Figures 4 and 5). Namely, the expression of JNK mRNA was significantly higher at 0.5 h than that at 0 h post-treatment ($P < 0.01$), reached a maximum at 2 h, followed by a decrease, and was slightly lower at 1 h than at 0.5 h post-treatment. Taken together, these results demonstrate that JNK plays a role in the effects of thermotherapy in gastric cancer cells. However, the mechanism of JNK activation in thermotherapy-induced apoptosis is still largely unknown in gastric cancer cells.

JNK is thought to induce mitochondria-dependent apoptosis mainly through direct or indirect activation of Bax and down-regulation of Bcl-2^[23-27], a pro-apoptotic Bcl-2 family member, which plays an essential role in inducing apoptosis^[28]. It is well known that most cell apoptosis-inducing factors eventually cause cell apoptosis through the caspase-mediated signal transduction pathway^[29,30], and caspase3 is a main effector in cell apoptosis. Therefore, to investigate the roles of Bax, Bcl-2 and caspase3 proteins during thermotherapy-induced apoptosis in human gastric cancer cells, we determined the expression of Bax, Bcl-2 and caspase3 proteins in thermotherapy-stimulated SGC-7901 cells. The data showed that thermotherapy increased the expression of Bax protein at different time points, which peaked at 2 h, and then decreased. These findings were similar to those obtained for the expression of p-JNK and caspase-3 proteins after thermotherapy in SGC-7901 cells. Bcl-2 was increased at 0.5 h and peaked at 1 h. These results suggest that thermotherapy-induced apoptosis was associated with activation

of JNK and increased expression of Bax and caspase-3 proteins. The JNK-specific inhibitor, SP600125, substantially inhibited thermotherapy-induced activation of JNK expression and the expression of Bax and caspase-3 proteins. No significant change in the expression of Bcl-2 was observed. Apoptosis was significantly decreased compared to that in thermotherapy-treated cells alone at different time points (Figure 4). These findings proved that thermotherapy-induced apoptosis is associated with JNK activation through up-regulation of the expression of Bax and caspase-3 proteins. These results suggest that the JNK cascade is required for apoptosis induction following thermotherapy in human gastric cancer SGC-7901 cells, which will be investigated in the future.

In summary, our study demonstrates that thermotherapy promoted phospho-JNK production, induced cell apoptosis and inhibited SGC-7901 cell viability. JNK was phosphorylated and activated, and the expression of Bax and caspase-3 was upregulated which subsequently caused cellular apoptosis in gastric cancer cells during thermotherapy. Bcl-2 protein, an anti-apoptotic protein, was not involved and played a protective role in this process. Therefore, JNK plays a critical role in thermotherapy-induced apoptosis in human gastric cancer.

COMMENTS

Background

Gastric carcinoma is one of the most common human cancers worldwide and is likely to remain a leading cause of death in the near future. New approaches in the treatment of gastric cancer are required. Recent studies have shown that c-Jun N-terminal kinase (JNK) is involved in thermotherapy-induced apoptosis in colon cancer cells, and is involved in vitamin E succinate-induced apoptosis in gastric carcinoma cells. However, it is unknown whether JNK is involved in thermotherapy-induced gastric carcinoma cell apoptosis, and which pathway is affected. These problems need to be explored in further studies. Thermotherapy is a novel approach in the treatment of gastric cancer.

Research frontiers

JNK, a member of the mitogen-activated protein kinase (MAPK) family, is activated through phosphorylation of JNK and has been implicated in a variety of processes in response to various stresses. It is believed that JNK has anti- or pro-apoptotic activity depending on cell type, apoptotic stimuli and other signalling pathways. However, the role of p-JNK during thermotherapy-induced apoptosis has not yet been elucidated. In this study, the authors demonstrate that activation of JNK via the Bax-caspase-3 pathway may represent an important mechanism in thermotherapy-induced apoptosis in gastric cancer cells.

Innovations and breakthroughs

Recent reports have highlighted that JNK is involved in thermotherapy-induced apoptosis in colon cancer cells. This is the first study to report that JNK is also involved in thermotherapy-induced apoptosis in gastric carcinoma cells. Furthermore, the studies show that activation of JNK via the Bax-caspase-3 pathway may represent an important mechanism in thermotherapy-induced apoptosis in gastric cancer cells.

Applications

The results of this study indicate the role of JNK in thermotherapy-induced apoptosis in gastric carcinoma cells, and are the basis for further investigations on the mechanism of thermotherapy-induced apoptosis which may be used in clinical applications.

Terminology

JNK is a member of the MAPK family. Many studies have shown that JNK activation has anti- or pro-apoptotic activity depending on cell type, apoptotic stimuli and other signalling pathways. Unsurprisingly, activation of JNK via the Bax-caspase-3 pathway may cause cell apoptosis following thermotherapy in gastric cancer cells.

Peer review

The paper describes the effects of thermotherapy on apoptosis and cell cycle progression in human gastric cancer. Further, the role of JNK was determined to investigate the underlying mechanism of thermotherapy-induced apoptosis in human gastric cancer. It would be interesting to have some pieces of information in the field of gastric cancer therapy.

RESULTS: Rates of *H. pylori* infection remained high in Northeastern China. Rates of *H. pylori* IgG positivity were greater in the gastric cancer and gastric atrophy groups compared to the control group (69.1% and 75.7% vs 49.7%, $P < 0.001$). Higher levels of PG II (15.9 $\mu\text{g/L}$ and 13.9 $\mu\text{g/L}$ vs 11.5 $\mu\text{g/L}$, $P < 0.001$) and lower PG I / PG II ratio (5.4 and 4.6 vs 8.4, $P < 0.001$) were found in patients with gastric cancer or gastric atrophy compared to healthy controls, whereas no correlation was found between the plasma PG I concentration and risk of gastric cancer ($P = 0.537$). In addition, multivariate logistic analysis indicated that *H. pylori* infection and atrophic gastritis were independent risk factors for gastric cancer. Lower plasma PG I / PG II ratio was associated with higher risks of atrophy and gastric cancer. Furthermore, plasma PG II level significantly correlated with *H. pylori*-infected gastric cancer.

CONCLUSION: Serum PG II concentration and PG I / PG II ratio are potential biomarkers for *H. pylori*-infected gastric disease. PG II is independently associated with risk of gastric cancer.

Abstract

AIM: To investigate screening makers for gastric cancer, we assessed the association between gastric cancer and serum pepsinogens (PGs).

METHODS: The subjects comprised 450 patients with gastric cancer, 111 individuals with gastric atrophy, and 961 healthy controls. Serum anti-*Helicobacter pylori* (*H. pylori*) immunoglobulin G (IgG), PG I and PG II were detected by enzyme-linked immunosorbent assay. Gastric atrophy and gastric cancer were diagnosed by endoscopy and histopathological examinations. Odds ratios and 95% CIs were calculated using multivariate logistic regression.

INTRODUCTION

Gastric cancer remains the third leading cause of cancer death in China^[1]. *Helicobacter pylori* (*H. pylori*) and gastric atrophy have both been identified as etiological factors for gastric cancer. However, screening and eradication of *H. pylori* in the general population is not advised because the cost of programs outweighs the modest effect on reduced incidences of gastric cancer. Therefore, identification of patients with the early stage gastric cancer could improve treatment and survival. Gastric atrophy, the precancerous lesion of gastric cancer, can be diagnosed by histological examination, and measurement of serum concentration of pepsinogens (PGs). Levels of two biochemically and immunologically distinct types, PG I and PG II, indicate different status of gastric mucosa. Serum PG level screening can be carried out at low cost in countries with high and moderate incidences of gastric cancer, such as Japan and China^[2].

Most studies have demonstrated that low concentrations of PG I and low PG I /PG II ratios in the serum or plasma are indicators of atrophic gastritis, which are linked with elevated gastric cancer risk^[3-5]. However, few studies have assessed correlations between PG II and gastric cancer risk^[6,7]. It is well known that *H. pylori* infection leads to development of both atrophic gastritis and gastric cancer. Detection of serum anti-*H. pylori* immunoglobulin G (IgG) antibodies and screening for gastric atrophy and gastric cancer at an early stage are important for clinical assessments and interventions^[8,9]. Absence of data on *H. pylori* infection and serum PG levels are available in large epidemiological surveys. To identify relationships between gastric mucosal lesions and serum PG levels, we carried out an assessment of PG I and PG II levels, PG I /PG II ratio and risk of gastric cancer in a cross-sectional study.

MATERIALS AND METHODS

Study participants

Four hundred and fifty patients with gastric cancer were selected from the Department of Gastric and Colorectal Surgery, and Department of Gastroenterology, First Hospital of Jilin University, from 2008 to 2010. All gastric cancer patients underwent tumor resection with histologically confirmed diagnosis of gastric adenocarcinoma. From 2009 to 2010, gastric atrophy cases and healthy controls were recruited from the check-up center of the same hospital. The subjects were of Han descent from the Changchun region. A total 1109 subjects (644 male and 465 female, aged 35-80 years) participated in the study. Gastric atrophy was diagnosed by endoscopy and histopathological examinations. Written informed consent was obtained from all subjects and the study protocol was approved by the Ethics Committee of the First Hospital, Jilin University.

Sampling and determination of serum

Fasting blood was taken for all participants and serum

was collected and stored at -80 °C. In the gastric cancer group, the samples were collected before surgery. Serum PG I and PG II levels were measured by enzyme-linked immunosorbent assay (ELISA) (Biohit ELISA kit, Biohit, Helsinki, Finland). Serum IgG antibodies to *H. pylori* were detected by ELISA using an *H. pylori*-IgG ELISA kit (Biohit). The antibody titers were defined by optical density values according to the manufacturer's protocol and titers higher than the cutoff value of 30 EIU were considered as positive for *H. pylori* infection. The quality control sample showed a coefficient of variation (CV) of 6.4%. For the pooled plasma samples the CV was 4.5%. According to the Chinese guidelines for diagnosis, patients are considered to have atrophic gastritis if PG I is $\leq 82.3 \mu\text{g/L}$ and PG I /PG II ratio is ≤ 6.05 ^[10]. The quality control samples showed CVs of 4.5%, 4.3% and 4.7% for *H. pylori*, PG I and PG II, respectively. All suspected cases with gastric atrophy by serum screening were re-determined by endoscopic biopsy and histological examinations.

Statistical analysis

The data did not fit a normal distribution, therefore, we used the Wilcoxon rank sum test to compare medians (quartiles) between the two groups. The χ^2 test was used to compare multiple sample rates. Non-conditional logistic regression analysis was used to calculate the odds ratio of risk-related factors for gastric cancer and its 95%CI. Two tailed *P* values < 0.05 were considered as statistically significant. All statistical analysis were carried out by SPSS version 18 software.

RESULTS

There were 450 patients with gastric cancer (324 male and 126 female, aged 35-80 years). Sixty-four cases were categorized as tumor-node-metastasis stage I (14.2%), 182 as stage II (40.4%), 145 as stage III (32.2%), and 59 as stage IV (13.1%). Among the 1109 participants, 148 individuals were screened for gastric atrophy using serum PG examination and 111 patients were confirmed with gastric atrophy by biopsy and histopathological examinations. Seventeen subjects were diagnosed with pseudopositive gastric atrophy and excluded from the study; 20 participants who rejected endoscopic examinations were also excluded. The remaining 961 individuals were included in the control group. The mean age was older in the gastric cancer group than in the gastric atrophy and control groups. The subject characteristics are summarized in Table 1.

H. pylori infection

H. pylori-positive rates in the gastric cancer and gastric atrophy groups were significantly higher compared to those in the control group (69.1% and 75.7% *vs* 49.7%, *P* < 0.001). The *H. pylori* infection rates were higher in the 45-65 years group compared to those aged < 45 years or > 65 years. Among the 450 gastric cancer patients, *H. pylori* infection rate was higher in those with stage I and

Table 1 Comparison of *Helicobacter pylori* infection between gastric cancer and control groups

	Gastric cancer group (%)	Gastric atrophy group (%)	Control group (%)	P value
No.	450	111	961	
<i>H. pylori</i> infection				
Negative	139 (30.9)	27 (24.3)	483 (50.3)	< 0.001
Positive	311 (69.1)	84 (75.7)	478 (49.7)	
Sex				
Male	324 (72.0)	66 (59.5)	564 (58.7)	< 0.001
Female	126 (28.0)	45 (40.5)	397 (41.3)	
Age				
< 45 yr	38 (8.4)	20 (18.0)	285 (29.7)	< 0.001
45-65 yr	240 (53.3)	81 (73.0)	607 (63.2)	
> 65 yr	172 (38.2)	10 (9.0)	69 (7.2)	

H. pylori: *Helicobacter pylori*.

stage II disease, compared to those with stage III and IV disease (73.6% *vs* 63.7%, $P = 0.02$). There were no correlations found between *H. pylori* infection and pathological type, tumor site, and differentiation of tumors (well-differentiated 50%, mild differentiation 69.8%, and poor differentiation 72.9%, $P = 0.47$).

PG levels

The median (interquartile range; IQR) PG I and PG II levels, and the ratio of PG I /PG II in the controls were 92.6 $\mu\text{g/L}$ (75.0-116.1), 11.5 $\mu\text{g/L}$ (7.1-18.4), and 8.4 $\mu\text{g/L}$ (6.1-11.1), respectively. PG II level in the gastric cancer group was significantly higher than that in the control group ($P < 0.001$), whereas the PG I /PG II ratio showed a marked decline ($P < 0.001$) (Table 2). However, no statistically significant difference was found in PG I level between the two groups ($P = 0.532$). In the control group, a higher PG I level was detected in patients with *H. pylori* infection compared to *H. pylori*-negative patients (median: 99 *vs* 78.9 $\mu\text{g/L}$, $P < 0.001$).

Median (IQR) levels of PG I and PG II, and PG I /PG II ratio were 94.4 $\mu\text{g/L}$ (38.9-148.8), 13.3 $\mu\text{g/L}$ (7.7-22.5) and 6.2 (3.5-10.0) $\mu\text{g/L}$ for 139 *H. pylori*-negative gastric cancer patients, respectively. Median (IQR) levels of PG I and PG II, and PG I /PG II ratio were 92.2 $\mu\text{g/L}$ (53.0-145.3), 18.4 $\mu\text{g/L}$ (10.4-30.0) and 5.1 $\mu\text{g/L}$ (3.5-7.2), respectively, for 311 *H. pylori*-positive gastric cancer patients. The difference in PG II level and PG I /PG II ratio was significant ($P = 0.01$) between *H. pylori* (-) and *H. pylori* (+) subjects. However, no significant difference in PG I concentrations was found between *H. pylori* (-) and *H. pylori* (+) cases in the gastric cancer group (92.2 $\mu\text{g/L}$ *vs* 94.4 $\mu\text{g/L}$, $P = 0.96$) (Table 3). In addition, serum PG I concentration was significantly lower in patients with stage III and IV tumors compared to stage I and II (Table 4).

DISCUSSION

Serum PG I is produced by chief cells and mucous neck cells of gastric fundic glands, while PG II is produced

by those cells and also by pyloric glands and Brunner's glands^[11]. Atrophic gastritis, characterized by loss of the specialized cells and glands in the stomach, is considered as a gastric cancer precursor lesion^[12]. Serum PG levels, pepsin precursors, reflect the functional and morphological status of the gastric mucosa. It is widely accepted in gastric *H. pylori* infection that the fundic gland mucosa and PG I levels gradually decrease, whereas PG II levels remain constant^[13,14]. Consequently, a stepwise reduction of the PG I /PG II ratio is closely linked to progression of atrophic gastritis. However, PG II is considered to be a subordinate marker in clinical diagnosis. In fact, PG II, a mature marker of gastric epithelia, reflects the physiological or pathophysiological functions of the gastric system^[15,16].

Gastritis is more prevalent and severe in Japan, with more corpus predominant atrophy and intestinal metaplasia^[17-19]. PG I ≤ 70 ng/mL and PG I /PG II ratio ≤ 3.0 have been used for the diagnosis of extensive atrophic gastritis with sensitivity of 80% and specificity of 70%^[20]. In contrast, our study showed a low incidence of gastric mucosal atrophy in the Chinese population. Inconsistency between studies may be due to different ethnic groups with different genetic backgrounds, different ELISA kits, and different cutoff values used for assessment of gastric mucosal atrophy^[21]. We used PG I ≤ 82.3 $\mu\text{g/L}$ and PG I /PG II ratio ≤ 6.05 according to the study for diagnosis of atrophic gastritis in the Chinese population^[10]. For reference, the cut-off points of PG I and PG I /PG II ratio were calculated using receiver operator characteristic (ROC) curves. For patients with atrophic gastritis, the area under the ROC for PG I was 0.878 (95%CI: 0.837-0.919) and the best cutoff value was 82.30 $\mu\text{g/L}$ (sensitivity 85.9%, specificity 75.1%). The area under the ROC for PG I /PG II ratio was 0.819 (95%CI: 0.767-0.871) and the best cutoff value was 6.05 (sensitivity 78.3%, specificity 71.6%)^[10]. The limitation of our study was that it could not determine the area under the curve *via* numerical integration of ROC curves, because we did not administer a further validity study. In our study, we found that serum PG I levels were significantly decreased in the gastric atrophy group, but no difference was found between the gastric cancer and control groups. Thus, it is considered that serum PG I levels represent gastric atrophy but not gastric cancer. The reason was that the prevalence of gastric atrophy was relatively low in our gastric cancer group compared with that in Japan. In Japan, the incidence of gastritis was higher than in other countries, and it was characterized by heavy predominant atrophy and intestinal metaplasia in the corpus of the stomach. Compared to the findings in Japan, our study showed a lower incidence of gastric mucosal atrophy. This may be due to differences in the research populations and their genetic backgrounds, even though the same *H. pylori* infection can lead to differences in severity of gastric atrophy^[22-24]. Other factors such as the use of proton pump inhibitors (PPIs) may also influence the incidence of gastric atrophy. However, a history of using PPIs and lifestyle

Table 2 Comparison of pepsinogen levels between gastric cancer, gastric atrophy and control groups

	Gastric cancer group	Gastric atrophy group	Control group	P value (cancer vs control)	P value (atrophy vs control)
PG I (μg/L)	93.2 (49.8-147.3)	64.0 (52.3-75.3)	92.6 (75.0-116.1)	0.537	< 0.001
PG II (μg/L)	15.9 (9.0-28.0)	13.9 (11.9-16.9)	11.5 (7.1-18.4)	< 0.001	< 0.001
PG I /PG II	5.4 (3.5-8.1)	4.6 (3.6-5.3)	8.4 (6.1-11.1)	< 0.001	< 0.001

Data are expressed as median (interquartile range). PG: Pepsinogen.

Table 3 *Helicobacter pylori* infection and pepsinogen levels of serum in gastric cancer patients

	<i>H. pylori</i> (+) (n = 311)	<i>H. pylori</i> (-) (n = 139)	P value
PG I (μg/L)	92.2 (53.0-145.3)	94.4 (38.9-148.8)	0.96
PG II (μg/L)	18.4 (10.4-30.0)	13.3 (7.7-22.5)	0.01
PG I /PG II	5.1 (3.5-7.2)	6.2 (3.5-10.0)	0.01

Data are expressed as median (interquartile range). PG: Pepsinogen; *H. pylori*: *Helicobacter pylori*.

were not investigated in this study. A further prospective control study is needed. PG II levels were significantly increased in patients with gastric atrophy and gastric cancer, especially in *H. pylori* (+) gastric cancer, resulting in a reduction in PG I /PG II ratio, which was consistent with a previous study^[6].

A few studies have investigated PG II serum level as an independent biomarker with potential clinical applications^[23]. Higher PG II expression has been demonstrated in patients with gastric ulcers, suggesting that PG II level reflects chronic inflammation in *H. pylori*-related chronic gastritis^[26-28]. Another study has shown that insertion/deletion polymorphisms of the PG II gene are highly associated with genetic predisposition to gastric cancer in the carriers^[16]. Our study demonstrated that chronic *H. pylori* infection is at a high level in the Chinese population. The overall *H. pylori* (+) rate in patients with gastric carcinoma was 78.6% in young patients (< 45 years), which was significantly higher than that in the control group (51%). Active gastritis caused by *H. pylori* infection and chronic inflammation resulted in elevated PG II levels in the gastric cancer group.

We also found that serum PG I level was significantly lower in patients with stage III and IV tumors, compared to those with stage I and II tumors. The mechanism is unclear but it may be associated with gastric mucosal atrophy gradually increasing with advancing gastric cancer.

We demonstrated that serum PG II level significantly increased in Chinese patients with *H. pylori*-infected gastric cancer, indicating that PG II can be used as an independent diagnostic marker for gastric cancer. It is cost-effective to screen PG II in countries with a high incidence of gastric cancer, compared with the high cost of endoscopy. Further studies on normal ranges of PG II and its changes in gastric diseases may elucidate its physiological and pathological functions.

In conclusion, PG II can be used as an independent diagnostic marker for gastrointestinal cancer^[29-31].

Table 4 Gastric cancer stages and serum pepsinogen levels

TNM stage (n)	PG I (μg/L)	PG II (μg/L)	PG I /PG II
I (64)	101.4 (76.3-147.3)	18.4 (12.1-27.2)	6.3 (4.5-8.4)
II (182)	96.3 (44.7-167.2)	16.3 (9.3-27.1)	5.5 (4.0-8.2)
III (145)	85.8 (43.4-133.3)	15.4 (8.8-28.7)	4.9 (2.8-7.5)
IV (59)	71.5 (35.7-137.0)	13.1 (6.7-13.1)	5.1 (3.1-8.1)
P value	0.02	0.44	0.09

PG: Pepsinogen; TNM: Tumor-node-metastasis.

ACKNOWLEDGMENTS

The authors would like to thank everybody who participated in this study; particularly Mr. Chang-Song Guo and Ms. Ying Song for their technical support.

COMMENTS

Background

Early detection is an important way to reduce mortality of gastric cancer. Measurement of serum pepsinogen (PG) is a popular non-invasive serological screening test for gastric cancer.

Research frontiers

Research has shown that serum-PG testing, based on the combination of the measurement of serum PG I concentration and the PG I /PG II ratio, is a good predictor of atrophic gastritis and gastric cancer development.

Innovations and breakthroughs

PG II has been as considered a subordinate marker in clinical diagnosis. In this study, we demonstrated that the serum PG II level significantly increased in *Helicobacter pylori*-infected gastric cancer in the Chinese population, indicating that PG II can be used as an independent diagnostic marker for gastric cancer.

Applications

Serum PG II level measure is a good method for screening patients with gastric cancer. It is very cost-effective to screen PG II in countries with high incidences of gastric cancer, compared with the high cost of endoscopy.

Terminology

PGs are inactive proenzymes for the specific digestive enzyme, pepsin, originating from the gastric mucosa, and can be classified into PG I and PG II.

Peer review

The authors performed a clinical epidemiological study and evaluated the possibility and significance of PG II in serum and PG I /PG II ratio as the diagnostic markers for Chinese patients with gastric cancer and gastric atrophy. They concluded that serum level of PG II could be a useful diagnostic marker for patients with gastric cancer.

Abstract

AIM: To quantitatively assess the relationship between energy intake and the incidence of digestive cancers in a meta-analysis of cohort studies.

METHODS: We searched MEDLINE, EMBASE, Science Citation Index Expanded, and the bibliographies of retrieved articles. Studies were included if they reported relative risks (RRs) and corresponding 95% CIs of digestive cancers with respect to total energy intake. When RRs were not available in the published article, they were computed from the exposure distributions. Data were extracted independently by two investigators and discrepancies were resolved by discussion with a third investigator. We performed fixed-effects meta-analyses and meta-regressions to compute the summary RR for highest versus lowest category of energy intake and for per unit energy intake and digestive cancer incidence by giving each study-specific RR a weight that was proportional to its precision.

RESULTS: Nineteen studies consisting of 13 independent cohorts met the inclusion criteria. The studies

included 995 577 participants and 5620 incident cases of digestive cancer with an average follow-up of 11.1 years. A significant inverse association was observed between energy intake and the incidence of digestive cancers. The RR of digestive cancers for the highest compared to the lowest caloric intake category was 0.90 (95% CI 0.81-0.98, $P < 0.05$). The RR for an increment of 239 kcal/d energy intake was 0.97 (95% CI 0.95-0.99, $P < 0.05$) in the fixed model. In subgroup analyses, we noted that energy intake was associated with a reduced risk of colorectal cancer (RR 0.90, 95% CI 0.81-0.99, $P < 0.05$) and an increased risk of gastric cancer (RR 1.19, 95% CI 1.08-1.31, $P < 0.01$). There appeared to be no association with esophageal (RR 0.96, 95% CI 0.86-1.07, $P > 0.05$) or pancreatic (RR 0.79, 95% CI 0.49-1.09, $P > 0.05$) cancer. Associations were also similar in studies from North America and Europe. The RR was 1.02 (95% CI 0.79-1.25, $P > 0.05$) when considering the six studies conducted in North America and 0.87 (95% CI 0.77-0.98, $P < 0.05$) for the five studies from Europe.

CONCLUSION: Our findings suggest that high energy intake may reduce the total digestive cancer incidence and has a preventive effect on colorectal cancer.

INTRODUCTION

An important discovery in recent years is that lifestyle and environmental factors affect cancer initiation, promotion, and progression. Epidemiological studies strongly suggest that the majority of cancer deaths can be attributed to factors such as unhealthy diets, tobacco, alcoholism, infections, and occupational exposure. In particular, data from several observational studies support the theory that diet plays an important role in the initiation of many common cancers^[1]. Calorie restriction (CR) is an experimental mode in which test animals receive a lower-calorie diet than ad libitum-fed controls. It has emerged as the most potent, broadly acting dietary intervention for preventing carcinogenesis in rodent models of cancer^[2]. Recent reports of extended life span and delayed cancer development in response to CR in rhesus monkeys^[3] and observations that CR during the premenopausal years decreases postmenopausal breast cancer risk in women^[4] suggest that the anticancer effects of CR reported in rodent models extend to primates, including humans.

Although animal models have clearly demonstrated a protective effect of CR on cancer risk, it is less clear and there is little direct evidence that such a protective effect exists in humans. A study of normal-weight humans found that a 20% energy restriction for 10 wk did not reduce oxidative DNA damage^[5]. In free-living populations, it is difficult to answer the important question of whether such an effect exists within the range of energy intake by humans. In human populations, energy intake is determined by physical activity, body size, and metabolic efficiency, and all these factors may be related to cancer risk, which makes the relationship between energy intake and cancer in humans complex.

Very few studies have assessed the relationship between CR and the risk of various cancer sites because of ethical issues. One study of the 1944-1945 Dutch famine and subsequent overall cancer incidence^[6] found no evidence that the short famine affected overall cancer risk. However, higher energy intake in childhood may increase the risk of developing cancer in adulthood^[7]. Data from case-control studies may be subject to recall bias with respect to energy intake and to selection bias with respect to the control group. Additional prospective cohort studies excluding those biases would be more useful for observing energy-cancer associations. We therefore systematically reviewed and performed a meta-analysis of prospective cohort studies to quantitatively assess the association between energy intake and digestive cancer risk in free-living human populations.

MATERIALS AND METHODS

Literature search

We searched the electronic databases MEDLINE (1966 to May, 2012), EMBASE (1985 to May, 2012), and Science Citation Index Expanded (1945 to May, 2012),

using the Medical Subject Heading term energy intake combined with digestive system neoplasms. Furthermore, we reviewed reference lists of retrieved articles to search for additional studies. Only studies published as full-length articles in English were considered.

Inclusion and exclusion criteria

For inclusion, studies had to fulfill the following criteria: have a prospective cohort design, report relative risks (RR) or hazard ratios and their corresponding 95% CIs (or data to calculate them) of digestive cancers relating to every category of energy intake, and provide the categories or total intake of calories. Studies were excluded if a case-control design was used, the experimental participants were children or adolescents, energy intake from special food was reported in which the total intake of calories could not be calculated, or adequate classification of intake could not be determined because categories of energy intake were not reported. If multiple published reports from the same study cohort were available, we included only the one with the most detailed information for both outcome and energy intake. If there were multiple articles on different types of digestive cancers in the same cohort, we combined the outcomes to calculate the summary RR and its corresponding 95% CIs.

Data extraction

Data were extracted independently by two investigators (Yu XF and Dong J) according to the meta-analysis of observation studies in epidemiology guidelines^[8], and discrepancies were resolved by discussion with a third investigator (Zou J). For each study, the following information was extracted: first author's last name, year of publication, country of origin, follow-up period, number of patients and cases, digestive cancer sites, category amounts of energy intake, outcome assessment, RR or hazard ratios of cancer and the corresponding 95% CIs for every category of energy intake, and covariates adjusted for in the statistical analysis.

Statistical analysis

The measures of interest were the RR and the corresponding 95% CIs for included cohort studies. When RRs were not available in the published article, they were computed from the exposure distributions. We computed the summary RR for highest versus lowest category of energy intake and for per unit energy intake and digestive cancer incidence by giving each study-specific RR a weight that was proportional to its precision (i.e., the inverse of the variance was derived, when necessary, from the reported 95% CIs).

Statistical heterogeneity among studies was estimated using Q and I^2 statistics. For the Q statistic, heterogeneity was considered present for $P < 0.1$. We pooled the study-specific estimates using both the fixed-effect model and the random-effect model proposed by DerSimonian and Laird; when a significant heterogeneity was

Figure 1 Flow diagram of the search strategy and study selection.

found, the random-effect model results were presented. A sensitivity analysis was also conducted, in which one study at a time was removed and the rest were analyzed to estimate whether the results could have been markedly affected by a single study.

Finally, publication bias was evaluated with funnel plot visual analysis and with the Begg's and Egger's tests. $P < 0.05$ was considered statistically significant. All statistical analyses were performed with STATA (Version 9.0; Stata Corp., College Station, TX).

RESULTS

Using the predefined search strategy, we identified 19 publications and 13 prospective cohort studies (Figure 1), including 995 577 participants and 5620 incident cases of digestive cancer with an average follow-up of 11.1 years, which were eligible for inclusion in the meta-analysis^[9-27]. The characteristics of the included cohorts are summarized in Table 1. Initial agreement between the two reviewers on whether a study was eligible for inclusion occurred for 108/113 manuscripts (95.6%; $\kappa = 0.912$). Of the 13 cohorts included in the meta-analysis, 6 were conducted in Europe, 6 in North America (United States), and 1 in Asia (Singapore).

From the 13 cohorts reporting energy intake, 11 cohorts could be used for the qualitative meta-analyses for the highest versus the lowest category of exposure and digestive cancer incidence. Figure 2A shows the estimated RRs for the highest versus lowest category of energy intake from cohort studies. The summary RR of digestive cancers from all combined studies was 0.90 (95%CI 0.81-0.98). There was no significant heterogeneity across the studies ($Q = 14.6$, $P = 0.148$, $I^2 = 31.4\%$).

From the included cohorts, nine studies could be used in the per unit energy intake meta-analysis. The

summary RR of digestive cancers for an increment of 239 kcal/d energy intake was 0.97 (95%CI 0.95-0.99), and no significant heterogeneity between studies was present ($Q = 11.7$, $P = 0.167$, $I^2 = 31.4\%$) (Figure 2B).

When stratified by the site of digestive cancer, we noted that energy intake was associated with a reduced risk of colorectal cancer (RR 0.90, 95%CI 0.81-0.99) and an increased risk of gastric cancer (RR 1.19, 95%CI 1.08-1.31). There appeared to be no association with esophageal (RR 0.96, 95%CI 0.86-1.07) or pancreatic (RR 0.79, 95%CI 0.49-1.09) cancer. Associations were also similar in studies from North America and Europe. The RR was 1.02 (95%CI 0.79-1.25) when considering the six studies conducted in North America and 0.87 (95%CI 0.77-0.98) for the five studies from Europe.

There was no indication of publication bias from either visualization of the funnel plot or Egger's ($P = 0.661$) and Begg's ($P = 0.533$) (Figure 3) tests. A sensitivity analysis, in which one study was removed at a time, was performed to evaluate the stability of the results. This analysis confirmed the stability of our results.

DISCUSSION

Over the past 30 years, CR has emerged as the most potent, broadly acting dietary intervention for preventing carcinogenesis in rodent models of cancer. Some observational studies further support the hypothesis that CR has beneficial effects on longevity and cancer risk in humans^[28]. However, physical activity and body size are highly related to total energy intake, and it is difficult to assess the independent effect of energy intake on cancer risk. In addition, energy intake is also difficult to assess in large-scale epidemiologic studies. Animal experimental studies have suggested the importance of energy balance as a determinant for cancer risk^[28,29]. Although very few studies have assessed the relationship between CR and the risk of various cancer sites in humans because of ethical issues, we quantitatively assessed the relationship between energy intake and the incidence of digestive cancers in a meta-analysis of cohort studies. Our meta-analysis yielded an inconsistent result in former studies and showed that energy intake was inversely associated with the risk of digestive cancers. The summary RR of digestive cancers was 0.97 (95%CI 0.95-0.99) for an increment of 239 kcal calorie intake per day.

Data from countries that experienced varying degrees of energy restriction during World War II may support our results. For example, a cohort of Norwegians showed reduced breast cancer risk when exposed to acute (< 1 year) energy restriction (50% reduction in caloric intake without significant changes in diet quality)^[30]. In contrast, survivors of the Dutch famine of 1944, during which energy restriction (70% reduction in rations for adults; 50% reduction in rations for children) was more severe than in the Norwegian study, experienced higher breast cancer rates but no apparent change in risk of any other cancer^[6]. Cohorts exposed to even

longer and more severe (> 80% reduction in normal energy intake) energy restriction, such as European Jewish survivors exposed to the Holocaust^[31] or Russian survivors of the Siege of Leningrad^[32], show increased

risk of some cancers. The confounding effects of severe physical and psychosocial stress, malnutrition, infection, and other factors associated with war conditions make these studies challenging to interpret. However, based

Figure 2 Summary relative risks of digestive cancers. A: The highest vs lowest category of energy intake from included cohorts; B: An increment of 1 MJ/day energy intake from included cohorts. Squares represent study-specific relative risk (RR) estimates (size of the square reflects the study-specific statistical weight, that is, the inverse of the variance); horizontal lines represent 95% CIs; diamonds represent summary RR estimates with corresponding 95% CIs.

Figure 3 Publication bias in the studies. Begg's funnel plot indicating no publication bias in the studies included in this meta-analysis. No indication of publication bias was noted from both visualization of the funnel plot and Egger's test.

on data from animal and human studies, it seems clear that although CR typically decreases cancer risk, the anti-cancer effects associated with reduced energy intake can be neutralized or overcome in the presence of extreme stressors, such as what occurred during World War II.

The mechanisms responsible for CR-mediated beneficial effects on cancer are thought to involve metabolic

adaptations to CR itself, including (1) decreased production of growth factors and anabolic hormones^[33,34]; (2) decreased production of reactive oxygen species and modulation of the endogenous antioxidant systems that decrease oxidative stress and free radical-induced DNA damage^[35,36]; (3) decreased plasma concentrations of inflammatory cytokines and an increase in circulating corticosteroids, ghrelin, and adiponectin that results in reduced inflammation^[37-40]; and (4) protection against aging-associated deterioration in immunosurveillance^[41]. In addition, CR simultaneously affects multiple processes that are involved in cancer pathogenesis, including DNA repair processes, removal of damaged cells through apoptosis, autophagy, and protection from the effects of damaging agents (e.g., toxic and genotoxic compounds)^[42,43]. Many of the effects of CR are probably mediated by regulation of gene expression, including upregulation of tumor suppressor genes and genes promoting DNA and cellular repair, protein turnover, stress resistance and antioxidant genes, downregulation of proinflammatory genes, and modulation of energy metabolism pathways^[44,45]. Whether CR with adequate nutrition reduces the cancer incidence in humans is unknown, but data from studies of long-term CR suggest that the metabolic and physiological responses to CR in

humans are similar to those in rodents and monkeys^[46-49].

To further elucidate the relationship between energy intake and risk of digestive cancer at various sites, we performed subgroup analysis and noted that energy intake was associated with a reduced risk of colorectal cancer and an increased risk of gastric cancer. There appeared to be no association with esophageal or pancreatic cancer. Colorectal cancer is one of the most common cancers worldwide. Only one study assessed the association between energy restriction and colorectal cancer risk^[50]. This study observed no significant relationship between energy restriction early in life and subsequent colon carcinoma risk in men and women who had lived in a western city in 1944-1945 (hunger winter) in the Netherlands. Interestingly, of studies that have examined the relationship between energy intake and colon cancer, many prospective investigations have similarly found inverse associations with greater energy intake, whereas case-control studies have observed positive associations^[51-55].

A combined analysis of 13 case-control studies demonstrated a positive association with total energy intake in 11 of the 13 studies. The association was similar between men and women, between younger (< 50 years old) and older (> 50 years old) people, between colon and rectal cancer, and between right and left colon cancer sites^[54]. On the other hand, cohort studies have usually reported a weak or null association^[15,18]. In the study by Bostick *et al.*^[10], a decreasing risk of colon cancer with increasing total energy intake was seen following age-adjusted analysis. The RR comparing the highest quintile (> 2.238 kcal/d) with the lowest quintile (< 1.301 kcal/d) was 0.60 (95%CI 0.39-0.92). Martínez *et al.*^[16] reported a weak positive association between energy intake and colorectal cancer. The age-adjusted RR for the highest compared with the lowest quintile of energy intake was 1.18 (95%CI 0.89-1.57). Among 63 257 Asian participants followed for an average of 7 year in which 310 incident cases of colorectal cancer were identified, no significant difference was found between the median total caloric intake of patients with colorectal cancer (1494.0 kcal/d) and controls (1483.5 kcal/d)^[56].

In our meta-analysis, 10 cohorts were identified from Finland, the Netherlands, Norway, and the United States. The summary RR of colorectal cancer was 0.90 (95%CI 0.81-0.99) for the highest versus lowest category of energy intake. We observed an inverse association between energy intake and the risk of colorectal cancer. The inverse association observed in some of these prospective studies may be explained by the greater energy intake associated with energy expenditure from greater physical activity, which is protective against colon cancer^[57].

There were over 20 case-control studies concerning the relationship between total energy intake and the risk of gastric cancer. In all studies, total energy consumed during adulthood was assessed. Some studies reported a positive association between total energy intake and the risk of gastric cancer^[58-62]. Regarding cohort studies, Ahn *et al.*^[63] reported a approximately 60% decreased

risk of gastric cancer with increased total energy intake in Korea. Kasum *et al.*^[22] studied the association between energy intake and the risk of gastric cancer in postmenopausal women in the United States. Among 34 651 participants followed for an average of 14 years in which 56 incident cases of gastric cancer were identified, the summary RR of stomach cancer was 1.10 for an increment of 250 kcal/d energy intake. Our meta-analysis including two cohort studies suggested a significant positive relationship between energy intake and gastric cancer (RR = 1.19; 95%CI 1.08-1.31).

Over the past three decades, many studies have been conducted to examine the relationship between energy intake and pancreatic cancer. Harnack *et al.*^[17] found that in 33 976 postmenopausal women in the United States, the summary RR of pancreatic cancer for individuals with an energy intake of > 1900 kcal/d was 1.20 (95%CI 0.67-2.15) compared with those having an intake of < 1450 kcal/d. In 27, 111 male smokers in Finland, Stolzenberg-Solomon *et al.*^[23] studied the association between energy intake and the risk of pancreatic cancer. After following participants for an average of 10.2 years, 163 incident cases of exocrine cancer of the pancreas were identified. The RR comparing the highest quintile (> 3410 kcal/d) with the lowest quintile (< 2155 kcal/d) was 0.62 (95%CI 0.36-1.07). After a pooled analysis of three cohort studies, we found that the summary RR of pancreatic cancer was 0.79 (95%CI 0.49-1.09) for the highest versus lowest category of energy intake. Thus, there appears to be no obvious association between energy intake and pancreatic cancer risk.

Some limitations of this meta-analysis should be acknowledged. First, as in all observational studies of diet and disease, the possibility of bias and confounding factors cannot be excluded. However, cohort studies, which are less susceptible to bias because of the prospective design, also showed an inverse association between energy intake and risk of digestive cancers, suggesting that the finding is not likely attributable to recall and selection bias. Individual studies may have failed to adjust for potential known or unknown confounders. Second, energy intake in our study may be a marker for greater nutrient intake and better nutritional status, because energy is correlated with many nutrients, and their combined effect may also explain the protective association that we observed. Dietary data do not necessarily reflect absorbed or biologically active doses and may contain measurement error from nutritional assessment techniques and nutrient databases, and participants may have changed their diets since baseline. All these parameters may have attenuated risk estimates. Third, we extracted the risk estimates that reflected the greatest degree of the control potential confounders because it was difficult to obtain raw data from each study to conduct standardized adjustments. Therefore, the results based on adjustment for different confounders were likely different from those based on standardized adjustments. Finally, only published studies were included in our meta-analysis. Therefore, publication bias may have occurred,

although no publication bias was indicated from both visualization of the funnel plot and Egger's test.

This meta-analysis presents epidemiologic evidence about the relationship between energy intake and risk of digestive cancers. In summary, we observed an inverse association between energy intake and the risk of digestive cancers. High energy intake may increase the risk of gastric cancer and decrease that of colorectal cancer. However, because physical activity, body size, and metabolic efficiency are highly related to total energy intake and expenditure, it is difficult to assess a possible independent effect of energy intake on digestive cancer risk. More investigations are needed to determine the biological mechanism of the inverse relationship between energy intake and the incidence of digestive cancers.

COMMENTS

Background

An important discovery in recent years is that lifestyle and environmental factors affect cancer initiation, promotion and progression. Epidemiological studies strongly suggest that the majority of cancer deaths can be attributed to factors such as unhealthy diets, tobacco, alcoholism, infections, and occupational exposure. Recent reports of extended life span and delayed cancer development in response to calorie restriction (CR) in rhesus monkeys and observations that CR during the premenopausal years decreases postmenopausal breast cancer risk in women suggest that the anticancer effects of CR reported in rodent models extend to primates, including humans.

Research frontiers

Very few studies have assessed the relationship between CR and the risk of various cancer sites because of ethical issues. One Dutch famine study and subsequent overall cancer incidence found no evidence that the short famine affected overall cancer risk. However, higher energy intake in childhood may increase the risk of developing cancer in adulthood. Data from case-control studies may be subject to recall bias with respect to energy intake and to selection bias with respect to the control group. Prospective cohort studies excluding those biases would be more useful for observing energy-cancer associations.

Innovations and breakthroughs

This meta-analysis presents epidemiologic evidence about the relationship between energy intake and risk of digestive cancers. They observed an inverse association between energy intake and the risk of digestive cancers. High energy intake may increase the risk of gastric cancer and decrease that of colorectal cancer. However, because physical activity, body size, and metabolic efficiency are highly related to total energy intake and expenditure, it is difficult to assess a possible independent effect of energy intake on digestive cancer risk. More investigations are needed to determine the biological mechanism of the inverse relationship between energy intake and the incidence of digestive cancers.

Applications

The study results suggest that an inverse association between energy intake and the risk of digestive cancers. High energy intake may increase the risk of gastric cancer and decrease that of colorectal cancer. They could prevent digestive cancers by controlling energy intake.

Terminology

CR is an experimental mode in which test animals receive a lower-calorie diet than ad libitum-fed controls. It has emerged as the most potent, broadly acting dietary intervention for preventing carcinogenesis in rodent models of cancer.

Peer review

This manuscript presents a meta-analysis of selected studies about the effects of energy intake on risk of digestive cancer. It is well designed with the use of only prospective studies. Appropriate statistical methods are used for each reported meta-analysis for the assessment of effects on outcome.

Abstract

AIM: To evaluate the therapeutic effects of itopride vs other drugs (placebo, domperidone, mosapride) for functional dyspepsia (FD).

METHODS: Randomized controlled trials (RCTs) of itopride for FD were retrieved from databases. Relevant information was extracted and analyzed, using the relative risk (RR) and weighted mean deviation, as appropriate. A random or fixed effect model was used, based on the heterogeneity of the included articles, and visual inspection of funnel plots was used to evaluate publication bias.

RESULTS: Nine RCTs enrolling 2620 FD cases were included; 1372 cases received itopride treatment and 1248 cases received placebo or other drugs (control groups). Compared with control groups, itopride had superior RR values of 1.11 [95%CI: (1.03, 1.19), $P = 0.006$], 1.21 [95%CI: (1.03, 1.44), $P = 0.02$], and

1.24 [95%CI: (1.01, 1.53), $P = 0.04$] for global patient assessment, postprandial fullness, and early satiety, respectively. For the Leeds Dyspepsia Questionnaire score, the weighted mean deviation was -1.38 [95%CI: (-1.75, -1.01), $P < 0.01$]. The incidence of adverse effects was similar in the itopride and control groups. The funnel plots for all indicators showed no evidence of publication bias.

CONCLUSION: Itopride has good efficacy in terms of global patients assessment, postprandial fullness, and early satiety in the treatment of patients with FD and shows a low rate of adverse reactions. Itopride can greatly improve FD syndromes-score.

INTRODUCTION

Functional dyspepsia (FD) is a common, functional gastrointestinal disorder^[1]. In a multi-centre Asian study of 1115 patients with uninvestigated dyspepsia (UD) (Rome II criteria) from nine countries, 43% turned out to have FD after investigation^[2]. FD places a heavy financial burden on society^[3,4]. Globally the majority of patients suffering from dyspepsia, which account for approximately

5% of primary care, fall into the category of FD^[5]. FD is a complex problem resulting from the interaction of gastric dysmotility^[6,7], visceral hypersensitivity, and psychological factors, and causes delayed gastric emptying, abnormal gastric regulation, and aberrant myoelectricity. As many as 60% of FD patients have gastric dysmotility. Outcomes of drug therapy [including Chinese herbal medicines, antidepressant drugs, proton pump inhibitors (PPI), and *Helicobacter pylori* (*H. pylori*) eradication] for FD patients have not been satisfactory^[8-10] compared with placebos. Although prokinetic agents have been proven to improve symptoms in FD patients by reducing gastroesophageal reflux, promoting gastric emptying, and improving gastric regulation, metoclopramide is associated with a high incidence of central nervous system (CNS)-related adverse drug reactions (ADRs), domperidone can elevate serum prolactin levels and cause gynecomastia and galactorrhea, and cisapride has been withdrawn because of safety concerns including high risk of prolonging the QT interval and severe arrhythmias^[11].

Itopride, a novel prokinetic agent, works by antagonizing dopamine D₂-receptors and inhibiting acetylcholinesterase^[12]. It does not cause any CNS-related ADRs because its high polarity does not allow it to cross the blood-brain barrier, it barely elevates prolactin levels and does not prolong the Q-T interval^[5]. In a multicentre, randomised, double-blind, placebo-controlled trial, itopride significantly improved symptoms in patients with FD, and showed a greater response rate than placebo^[13]. However, it was recently reported that itopride was no more effective in showing a difference in symptom response from placebo in FD^[5]. Therefore, given the conflicting results for efficacy in some study reports and the possible serious adverse reactions (SARs) of itopride, a meta-analysis of randomised controlled trial (RCT) data published prior to December 2011 was conducted, with a view to evaluating more objectively the efficacy and safety of itopride in the treatment of FD.

MATERIALS AND METHODS

Inclusion and exclusion criteria

Inclusion criteria for the studies used in the analysis required that they: (1) contained inclusion and exclusion criteria, and the study design was an RCT with a quality level above B; (2) were designed to study FD as the target population; (3) had a study group that was given itopride and a control group that was given placebo, domperidone, or mosapride, *etc.*; and (4) included one or more of the following indicators for comparison of efficacy between itopride and other therapy: Global patient assessment (GPA), postprandial fullness, early satiation, epigastric discomfort, adverse reaction, and the Leeds Dyspepsia Questionnaire (LDQ) score. Studies were excluded that had: (1) incomplete data; (2) been re-published (only those with credible data were chosen); (3) a control group that used itopride together with other drugs; (4) patients with obvious organic diseases such as

gastritis, peptic ulcer, and cholecystitis, *etc.*; and (5) baseline data that were not similar.

Literature search and data collection

Databases searched included the Cochrane Library, PubMed, Elsevier, EMBASE, ISI, CNKI, VIP Chinese Scientific and Technological Periodical Database and Wanfang Data, prior to December 2011. Search terms and search strategy included: “itopride”, “functional dyspepsia”, “randomized or random or randomly or randomised”, “controlled trial”, “Yi Tuo Bi Li” (the Chinese character for “itopride”), “Gong Nen Xing Xiao Hua Bu Liang” (the Chinese character for “functional dyspepsia”), “sui ji dui zhao” (the Chinese character for “randomized control”), excluding studies involving children or pregnant women, as well as review papers. Meanwhile, articles published in core journals in China and abroad this year, such as *Chinese Journal of Digestion*, *Chinese Journal of Internal Medicine*, *Chinese Journal of Gastroenterology*, *Gastroenterology*, and *Gut* were searched manually. Conference papers published this year were also consulted, along with the references of the included articles, so as to include studies that may have been omitted. Extracted data included outcome measures, risk of bias and characteristics of trials, patients, and interventions. Authors of included trials were approached for additional information when necessary. The articles were screened by two reviewers independently, according to the steps for preliminary screening and full-text screening, and any differences were settled through discussions by the reviewers themselves or with assistance from a third party.

Quality evaluation

Study quality was evaluated according to the quality evaluation criteria recommended in the Cochrane Reviewers' Handbook 4.2.2. Briefly, the quality of a study was rated A, B, or C based on its randomization method, allocation concealment, double-blind method, missing follow-up, and withdrawal from observation. Grade A completely conforms to the four quality standards and has the lowest possibility of bias. Grade B partially conforms to one or more quality standards and shows moderate possibility of bias. Grade C does not conform to any of the four quality standards and has a high possibility of bias.

Data analysis

Revman 5.0 (the Cochrane collaboration; <http://www.cochrane.org/>) was used for statistical analysis of the data. Relative risk (RR) was used to test the heterogeneity of such numerical data as GPA, epigastric fullness, early satiation, epigastric discomfort, and adverse reactions between the two groups of each study. Weighted mean deviation (WMD) was used for statistical analysis of the LDQ scores, and the effect variables were expressed by 95% confidence intervals. Statistical assessment was then performed using a χ^2 test of homogeneity and evaluation of the inconsistency index (I^2) statistic. The I^2 statistic is defined as the percentage of variability caused by hetero-

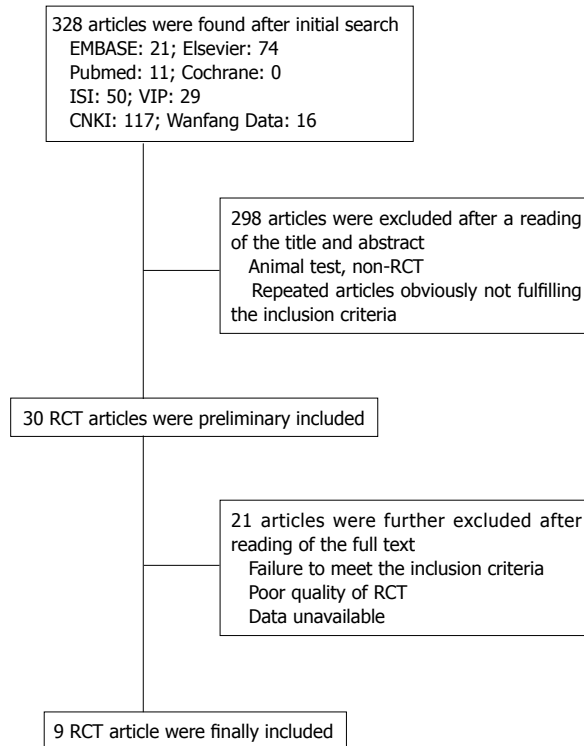

Figure 1 Flow chart of article inclusion and screening. RCT: Randomized controlled trial.

geneity rather than chance with values $> 50\%$ representing the possibility for substantial heterogeneity. A fixed effect model was used to estimate the overall effect if RR was homogenous; if RR was non-homogenous, a random effect model was used.

Publication bias

Funnel plots were drawn using the RR values of each of GPA, epigastric fullness, early satiation, epigastric discomfort, and adverse reactions of the two groups included in the meta-analysis as the X coordinate and the standard error (SE) (log RR) as the Y coordinate, as well as using the mean deviation (MD) of LDQ scores as the X coordinate and the SE (MD) as the Y coordinate, after which the symmetry of the plots was observed to evaluate the impacts of publication bias. Subgroup analyses were performed to evaluate intervention effects in trials comparing itopride *vs* placebo or other prokinetic agents, trials with adequate bias control (assessed through randomization methods) and publication status.

RESULTS

Results of the literature search and information on included studies

328 articles were collected; 319 were excluded for not meeting the inclusion criteria, nine RCT articles^[5,13-20] were finally included, as shown in Figure 1. Of the included RCT articles, seven were graded as grade B and two as grade A. Included studies contained a total of 2620 patients, 1372 of whom received itopride, and 1248

received placebo or other control drugs. Table 1 shows the basic characteristics of the studies included.

Analysis results of efficacy indicators

GPA: Six RCT articles^[5,13,14,18-20] reported the GPA of itopride in FD patients, of which three were domperidone-controlled, one was mosapride-controlled, and the other two were placebo-controlled. The chi-square value of the test for heterogeneity was 13.69, with an I^2 value of 49%, indicating that there was homogeneity of effects among the trials. Therefore, a fixed effect model was used, and the calculated RR value was 1.11 [95%CI: (1.03, 1.19), $P = 0.006$], as shown in Figure 2A. Itopride improved the GPA of FD patients more significantly than control groups.

Postprandial fullness: Four RCT articles^[15-17,20] reported the efficacy of itopride with respect to postprandial fullness of FD patients, all of which were domperidone-controlled. The chi-square value of the test for heterogeneity was 6.09, with an $I^2 = 51\%$, indicating that there was heterogeneity of effects among the trials. Therefore, a random effect model was used, and the calculated RR value was 1.21 [95%CI: (1.03, 1.44), $P = 0.02$], as shown in Figure 2B. Itopride improved the postprandial fullness of FD patients more significantly than domperidone.

Early satiation: Four RCT articles^[15-17,20] reported the efficacy of itopride with respect to early satiation of FD patients, all of which were domperidone-controlled; the chi-square value of the test for heterogeneity was 9.18, with a $I^2 = 67\%$, indicating that there was heterogeneity of effects among the trials. Therefore, a random effect model was used, and the calculated RR value was 1.24 [95%CI: (1.01, 1.53), $P = 0.04$]. Compared with domperidone, itopride improved the early satiation of FD patients more significantly.

Epigastric discomfort: Three RCT articles^[15,16,20] reported the efficacy of itopride with respect to epigastric discomfort of FD patients, all of which were domperidone-controlled; the chi-square value of the test for heterogeneity was 2.67, with a $I^2 = 25\%$, indicating that there was homogeneity of effects among the trials. Therefore, a fixed effect model was used, and the calculated RR value was 1.00 [95%CI: (0.88, 1.14), $P = 0.98$]. Itopride and domperidone had similar efficacy on epigastric discomfort of FD patients.

LDQ: Two RCT articles^[5,13] reported that itopride improved the LDQ scores of FD patients, both of which were placebo-controlled; the chi-square value of the test for heterogeneity was 18.53, and $I^2 = 84\%$, indicating that there was heterogeneity of effects between the trials. Therefore, a random effect model was used, and the calculated WMD value was -1.38 [95%CI: (-1.75, -1.01), $P < 0.01$]. Thus, itopride improved the LDQ scores of FD patients more significantly than placebo.

Table 1 Clinical data of included articles

Ref.	Year	Quality grade	Total cases	Duration of therapy (wk)	Treatment group			Control group

Talley <i>et al</i> ^[5] , NOR	2008	A	626	8	308 (109/199)	43	100 mg <i>tid</i>	318 (96/222)	43	Placebo

Incidence of ADRs: Eight RCT articles^[13-20] reported the ADRs of itopride in the treatment of FD patients, of which six were domperidone-controlled, one was mosapride-controlled, and the other one was placebo-controlled; the chi-square value of the test for heterogeneity was 4.51, with a $I^2 = 0\%$, indicating that there was homogeneity of effects among the trials. Therefore, a fixed effect model was used, and the calculated RR value was 0.96 [95%CI: (0.78, 1.17), $P = 0.67$], as shown in Figure 2C. Analysis of the sub-groups showed that itopride did not have a higher incidence of ADRs than domperidone, mosapride, or placebo.

Analysis of publication bias

As compared with the control groups, itopride's funnel plots of GPA, postprandial fullness, early satiation, epigastric discomfort, and ADR all showed a symmetrical shape that was narrow at the top and wide at the bottom, indicating that there was no publication bias.

DISCUSSION

The pathogenesis of FD is far from fully understood, but gastrointestinal motility and visceral sensitivity are proven to play very important roles^[21,22] in the occurrence of FD symptoms. Clinically, prokinetic agents, such as domperidone, cisapride, and mosapride, are often used to treat these patients. Recently a meta-analysis by Hiyama^[23] showed a significant treatment benefit in favour of prokinetic agents in patients with FD. However, in that study, itopride is rarely involved. Given the concern for safety and efficacy of the existing prokinetic agents, a novel agent that is safer and more effective is urgently needed. Itopride is a prokinetic agent that has a completely different mechanism of action from existing ones; it works by both antagonizing dopamine receptors and inhibiting the activity of acetylcholinesterase. It not only stimulates release of acetylcholine, but also inhibits its degradation, thus promoting gastrointestinal motility. There are a few well-designed RCTs on the efficacy of itopride in

the treatment of FD, and the reported efficacy was controversial. Therefore, a meta-analysis of previously published high quality RCTs was conducted.

In the present study, when compared with the control groups, the RRs of itopride for GPA, postprandial fullness, and early satiation of FD patients indicate that this drug could significantly improve the GPA scores, postprandial fullness, and early satiation in FD patients. However, it did not improve epigastric discomfort more significantly than the comparator, which could be a result of itopride's action of increasing postprandial gastric receptive relaxation^[24] and gastrointestinal motility^[20]. To further evaluate the efficacy of itopride in improving the symptoms of FD patients, the LDQ was used to evaluate FD patients' symptoms at baseline and after treatment, and the calculated WMD was -1.38 [95%CI: (-1.75, -1.01), $P < 0.01$], suggesting that the drug could significantly reduce the LDQ scores of FD patients, which made the results more convincing. As for safety, it showed that the incidence of ADRs was no higher for itopride than for domperidone, mosapride, or placebo. The ADRs attributed to itopride were mainly abdominal pain and diarrhoea, which were all mild to moderate, without clinically related changes in the electrocardiogram, particularly prolongation of QT intervals. This appears to be different from other prokinetic agents, possibly because the polarity of itopride largely prevents it from entering the brain or the CNS^[25]. In addition, as compared with other dopamine receptor antagonists, itopride caused a much lower incidence of CNS-related ADRs and hyperprolactinaemia while keeping dopamine active. Meanwhile, there were fewer drug interactions of itopride compared with other prokinetic agents^[26], probably because itopride is metabolized by a monooxygenase, while mosapride and other prokinetics are metabolized by cytochrome P450, as reported by Mushiroda^[26].

Considering the discrepancy in contradictory trial results^[12,20], study design issues are important. There were several probable reasons, including heterogeneity of the conditions and differences in patient selection.

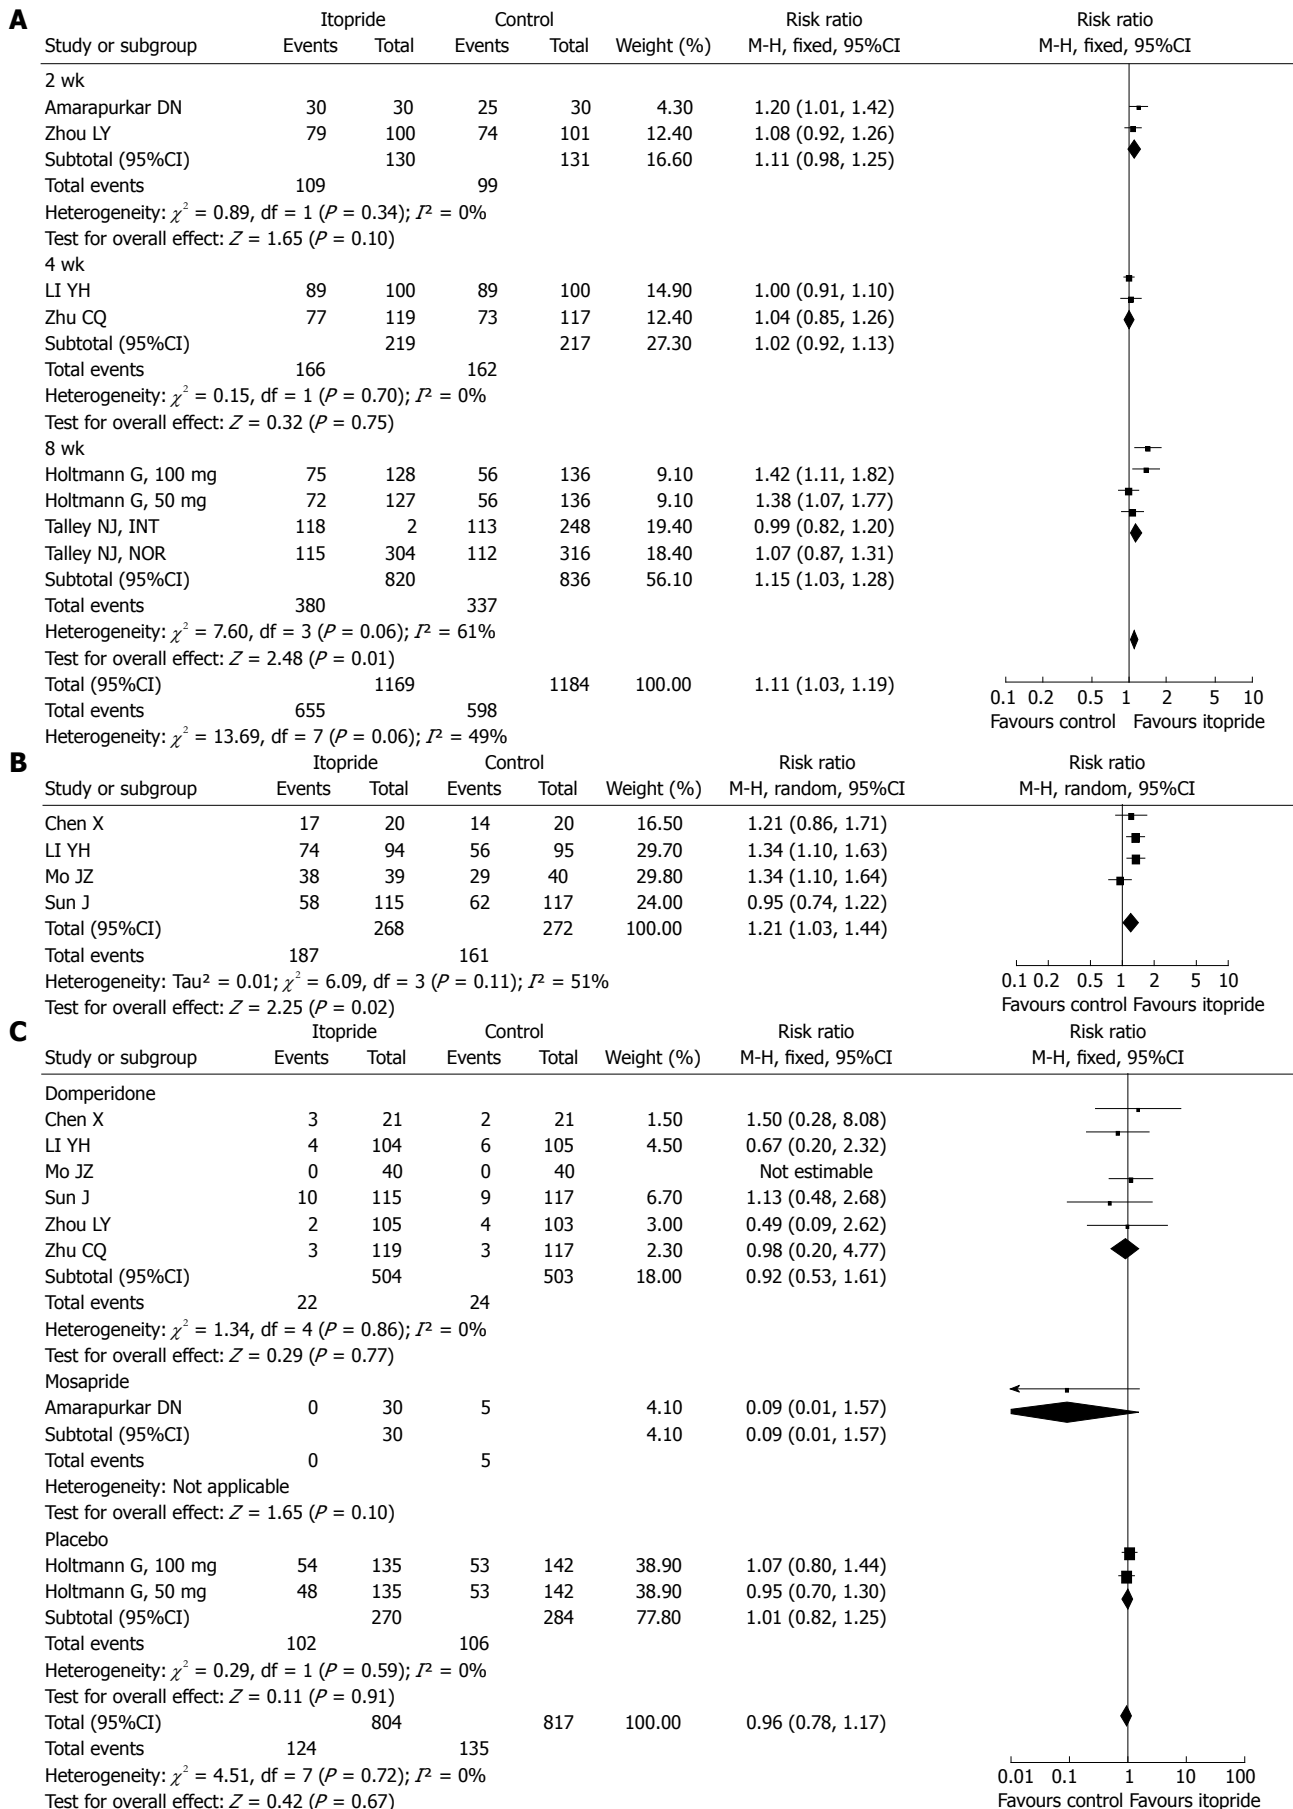

Figure 2 Forest plot for global patient assessment (A), postprandial fullness (B) and adverse reactions (C) with itopride treatment for functional dyspepsia.

In the Tally's trial, the requirement that all patients had to be *H. pylori* negative, exclusion of heartburn and that the LDQ score needed to be > 9 at baseline meant high intensity scores for the typical symptoms of pain and fullness were needed for LDQ, all of which might contribute to the high placebo response rate^[12]. On the other hand, the majority of dyspeptic subjects overlap with heartburn symptoms as well as *H. pylori* infection, and heartburn also is a predictor of response, so the exclusion criteria were much stricter in the Tally's study, as Veldhuyzen mentioned^[27].

This meta-analysis covered a wide range of high-quality articles, and all studies included were randomized controlled trials RCTs. In addition, the diagnostic criteria for inclusion of articles were uniform. Considering publication bias, that is, the disproportionate publication of research articles with a positive result than of those with a negative result, an effort was made to collect as full a range of related literature as possible through many different approaches (including computer search, manual search, and literature tracing), and repeated publications were excluded. All nine studies included in this analysis had definitive inclusion criteria and baseline descriptions of sex, age, disease severity, and concomitant medications of the population included, and the ratios of the population in the study groups and the control groups were reasonable.

However, the present study did have some limitations. Firstly, the ethnic groups of the populations in the articles were varied. Race and/or western lifestyle are important risk factors^[28,29]. Secondly, because of differences in trial design, comparators used for the control group, and follow-up, there was a large degree of heterogeneity among the studies included, as well as in the GPA, early satiation, and LDQ scores. For this reason, a random effect model was used for the meta-analysis, which probably affected the results of the evaluation. Thirdly, *Helicobacter pylori* may play a role in pathogenesis of functional dyspepsia^[1]. However, seven of the FD trials included in this meta-analysis were from Asia, which has a higher prevalence of Hp, and this probably affected the results.

In summary, the results of this meta-analysis suggest that itopride has therapeutic benefits with respect to GPA, postprandial fullness, early satiation, and the LDQ of FD patients, with a lower incidence of ADRs. However, because of the existence of heterogeneity, further studies of more high-quality RCTs with consistent indicators are probably warranted to validate the safety and efficacy of itopride.

ACKNOWLEDGMENTS

We would like to acknowledge and thank Min Zhao and Bing-Bing Chen for their help with searching for trials and their comments.

COMMENTS

Background

Functional dyspepsia (FD) is a complex problem resulting from the interac-

tion of gastric dysmotility, visceral hypersensitivity, and psychological factors, which causes delayed gastric emptying, abnormal gastric regulation, and aberrant myoelectricity. As many as 60% of FD patients have gastric dysmotility. Itopride works by antagonizing dopamine D2-receptors and inhibiting acetylcholinesterase. In a multicentre, randomised, double-blind, placebo-controlled trial, itopride significantly improved symptoms in patients with FD, and showed a greater rate of response than placebo. However, it was recently reported that itopride was not more effective in showing a difference in symptom response from placebo in FD. Therefore, it is necessary to perform a comprehensive meta-analysis to evaluate more objectively the efficacy and safety of itopride in the treatment of FD.

Research frontiers

Although prokinetic agents are proven to improve symptoms in FD patients, metoclopramide is associated with a high incidence of central nervous system-related adverse drug reactions, domperidone can elevate serum prolactin levels and cause gynecomastia and galactorrhea, and cisapride has been withdrawn due to safety concerns including high risk of prolonging the QT interval and severe arrhythmias. It is essential to search for more effective and safe drugs.

Innovations and breakthroughs

The study comprehensively searched for all randomised controlled trials involving itopride in the treatment of FD, and used meta-analysis to analyze the effects and safety of itopride.

Applications

The results indicate that itopride has therapeutic benefits with respect to Global Patient Assessment, postprandial fullness, early satiation, and the Leeds Dyspepsia Questionnaire of FD patients, with a lower incidence of adverse drug reactions.

Peer review

The author investigated the efficacy of itopride for functional dyspepsia in a meta-analysis. The article is overall easy to understand, and the method of meta-analysis is correct. The results are interesting and suggest that itopride shows good efficacy for the treatment of global patients assessment, postprandial fullness, and early satiety in patients with FD.

Abstract

AIM: To investigate the effect of dietary fiber intake on constipation by a meta-analysis of randomized controlled trials (RCTs).

METHODS: We searched Ovid MEDLINE (from 1946 to October 2011), Cochrane Library (2011), PubMed for articles on dietary fiber intake and constipation using the terms: constipation, fiber, cellulose, plant extracts, cereals, bran, psyllium, or plantago. References of important articles were searched manually for relevant studies. Articles were eligible for the meta-analysis if they were high-quality RCTs and reported data on stool frequency, stool consistency, treatment success, laxative use and gastrointestinal symptoms. The data were extracted independently by two researchers (Yang J and Wang HP) according to the described selection criteria. Review manager version 5 software was used for analysis and test. Weighted mean difference with 95%CI was used for quantitative data, odds ratio (OR)

with 95%CI was used for dichotomous data. Both I^2 statistic with a cut-off of $\geq 50\%$ and the χ^2 test with a P value < 0.10 were used to define a significant degree of heterogeneity.

RESULTS: We searched 1322 potential relevant articles, 19 of which were retrieved for further assessment, 14 studies were excluded for various reasons, five studies were included in the analysis. Dietary fiber showed significant advantage over placebo in stool frequency (OR = 1.19; 95%CI: 0.58-1.80, $P < 0.05$). There was no significant difference in stool consistency, treatment success, laxative use and painful defecation between the two groups. Stool frequency were reported by five RCTs, all results showed either a trend or a significant difference in favor of the treatment group, number of stools per week increased in treatment group than in placebo group (OR = 1.19; 95%CI: 0.58-1.80, $P < 0.05$), with no significant heterogeneity among studies ($I^2 = 0$, $P = 0.77$). Four studies evaluated stool consistency, one of them presented outcome in terms of percentage of hard stool, which was different from others, so we included the other three studies for analysis. Two studies reported treatment success. There was significant heterogeneity between the studies ($P < 0.1$, $I^2 > 50\%$). Three studies reported laxative use, quantitative data was shown in one study, and the pooled analysis of the other two studies showed no significant difference between treatment and placebo groups in laxative use (OR = 1.07; 95%CI 0.51-2.25), and no heterogeneity was found ($P = 0.84$, $I^2 = 0$). Three studies evaluated painful defecation: one study presented both quantitative and dichotomous data, the other two studies reported quantitative and dichotomous data separately. We used dichotomous data for analysis.

CONCLUSION: Dietary fiber intake can obviously increase stool frequency in patients with constipation. It does not obviously improve stool consistency, treatment success, laxative use and painful defecation.

INTRODUCTION

Constipation is a health problem that influences almost 20% of the world's population^[1]. It is a bothersome disorder which negatively affect the quality of life and increase the risk of colon cancer^[2]. There are a wide-range of treatment methods. Life-style modification, such as increased fluid intake or exercise, are usually recommended as first-line treatment, but data on the effectiveness of these measures are limited^[3]. Laxatives are most commonly used for treatment of constipation, but frequent use of these drugs may lead to some adverse effects^[4,5], alternative treatment measure is, therefore, needed. Soluble fiber absorbs water to become a gelatinous, viscous substance and is fermented by bacteria in the digestive tract. Insoluble fiber has a bulking action^[6]. Dietary fiber is the product of healthful compounds and has demonstrated some beneficial effect. Increase of dietary fiber intake has been recommended to treat constipation in children and adults^[7-9]. In a large-population case-control study, Rome found that dietary fiber intake was independently negatively correlated with chronic constipation, despite the age range and the age at onset of constipation^[10]. Although there have been several randomized controlled trials (RCTs) studying the relationship between dietary fiber and constipation, no definitive quantitative summary is available, therefore we conducted a meta-analysis of RCTs, and report it below.

MATERIALS AND METHODS

Data selection

We searched Ovid MEDLINE (from 1946 to October 2011), Cochrane Library (2011) and PubMed to identify RCTs studying dietary fiber and constipation. We used the following terms: constipation as medical subject headings and free text terms, which were combined with fiber, cellulose, plant extracts, cereals, bran, psyllium or plantago. References of important articles were searched manually for relevant studies.

Study selection

Studies were included if they met the following criteria: (1) studies investigating the association between the intake

of dietary fiber and constipation; (2) RCTs with a trial quality greater than or equal to 3 points judged by Jadad score; (3) constipation was defined by symptoms according to the Roma criteria or clinical diagnosis; (4) studies reporting at least one of the following data: stool frequency, stool consistency, treatment success, laxative use, gastrointestinal symptom; and (5) dietary fiber was used as the only active intervention in treatment group.

Data extraction

The data were extracted independently by two researchers (Yang J and Wang HP) according to the described selection criteria. Disagreement was resolved by discussion with the third person. The following data were extracted: the first author's name, year of publication, study design, interventional method, study period, sample size, outcomes, method used to generate the randomization, level of blinding, withdrawn or drop-outs explanations.

Statistical analysis

Review manager version 5 software was used for all meta-analyses and tests for heterogeneity. Weighted mean difference with 95%CI was used for quantitative data, odds ratio with 95%CI was used for dichotomous data. Both I^2 statistic with a cut-off of $\geq 50\%$ and the χ^2 test with a P value < 0.10 were used to define a significant degree of heterogeneity. Random-effects model was applied. A two-tailed $P < 0.05$ was considered statistically significant.

RESULTS

We searched 1322 potential relevant articles, 19 of which were retrieved for further assessment, and 14 studies were excluded for the reasons as shown in Figure 1. As a result, five studies were included, and the characteristics of the included studies are listed in Table 1.

Stool frequency was reported by five RCTs^[11-15]. Results showed either a trend or a significant difference in favor of the treatment group, and an increased number of stools per week in treatment group compared with the placebo group [odds ratio (OR) = 1.19; 95%CI: 0.58-1.80, $P < 0.05$], with no significant heterogeneity among the studies ($I^2 = 0$, $P = 0.77$). Of note, stool frequency was expressed as median (interquartile range) in Chmielewska's study^[14], and we used the formula to transform it into mean \pm SD (Figure 2A)^[16].

Four studies evaluated stool consistency^[12-15], one of them presented outcome in terms of percentage of hard stool^[13], which was different from others, so we included the other three studies for analysis. Results showed no statistical difference between two groups (OR = 0.43; 95%CI: -0.24-1.11, $P > 0.05$), however substantial heterogeneity existed ($P < 0.1$, $I^2 > 75\%$) (Figure 2B).

Two studies reported treatment success^[12,14]. The pooled analysis (Figure 2C) for overall results found significant difference between groups (OR = 2.21; 95%CI: 0.35-12.69, $P > 0.05$). There was significant heterogeneity between stud-

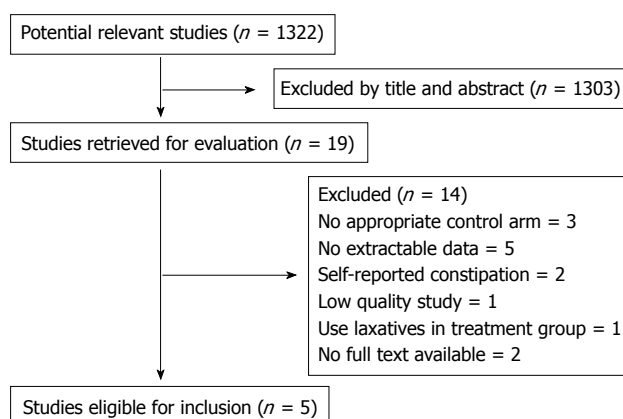

Figure 1 Study selection step.

ies ($P < 0.1$, $I^2 > 50\%$).

Three studies reported laxative use^[12,14,15], quantitative data was shown in one study^[15], and the pooled analysis (Figure 2D) of the other two studies showed no significant difference between treatment and placebo groups in laxative use (OR = 1.07; 95%CI: 0.51-2.25, $P = 0.85$), and no heterogeneity was present ($P = 0.84$, $I^2 = 0\%$).

Three studies evaluated painful defecation^[11,14,15]: one study presented both quantitative and dichotomous data^[14], the other two studies separately reported quantitative and dichotomous data^[11,15]. Evaluation method for quantitative data was different, one used actual frequency, the other two used frequency of occurrence (often/occasional/none). We used dichotomous data for analysis. The pooled estimate (Figure 2E) showed a nonsignificant trend in favor of treatment group (OR = 0.54; 95%CI: 0.15-1.91, $P = 0.34$). No statistically significant heterogeneity was present, but I^2 was moderate ($P > 0.1$, $I^2 = 43\%$).

DISCUSSION

This meta-analysis shows that the number of stools was increased significantly in dietary fiber group. Results demonstrated either a trend or a significant difference in favor of dietary fiber group. As for stool consistency, the overall results showed a trend in favor of fiber group, but no statistical difference was found. The substantial heterogeneity may influence the results, and the heterogeneity may be caused by different rating scale, ranging

from 0 to 4, from 0 to 5 and from 0 to 7 in three included studies, respectively. Although the rating sequence is unanimous, with a higher score indicating looser stools, different scale range may still influence the final results. Stool consistency was present as hard stool percentage in another included study^[13], 41.7% and 75% of the patients who received dietary fiber or placebo, respectively, reported hard stools, the percentage being obviously lower in the dietary fiber group.

Two high-quality RCTs compared dietary fiber with lactulose for treatment of constipation^[17,18], and found that dietary fiber and lactulose achieved comparable results in the treatment of childhood constipation. Dietary fiber is as effective as lactulose in improving stool frequency, stool consistency and treatment success, however, no difference was observed in treatment success between dietary fiber and placebo group in our meta-analysis. The possible reason was discussed. Constipation condition was more severe in the patients in Chmielewska's study, who had a lower baseline stool frequency per week and a higher percentage of hard stool than the studies mentioned above^[17,18] and the other study^[12] used for analysis. It suggests that dietary fiber may not be so effective in severe constipation and can only be used in mild to moderate constipation, or perhaps the dosage of glucomannan (2.52 g/d) used in Chmielewska's study is not high enough to exert effect. Nurko *et al*^[19] suggested that behavior modification, such as parental positive reinforcement and good patient-doctor relationship, may have impact on the treatment outcome. So the effect of dietary fiber on different grades of constipation should be explored in further studies and it is also important to balance the behavior factors in comparison.

Dichotomous data was used to analyze the laxative use in our study, which can only reflect how many patients used the laxatives, but not indicate how often it was used. Quantitative data about laxative use can better reflect the degree of dependence. If the time when laxative was used is described, the outcome will be more useful for overall analysis.

Gastrointestinal symptoms were reported by several studies. Because data was presented by different methods, only painful defecation was analyzed, and results showed that there was no significant difference between dietary fiber and placebo groups.

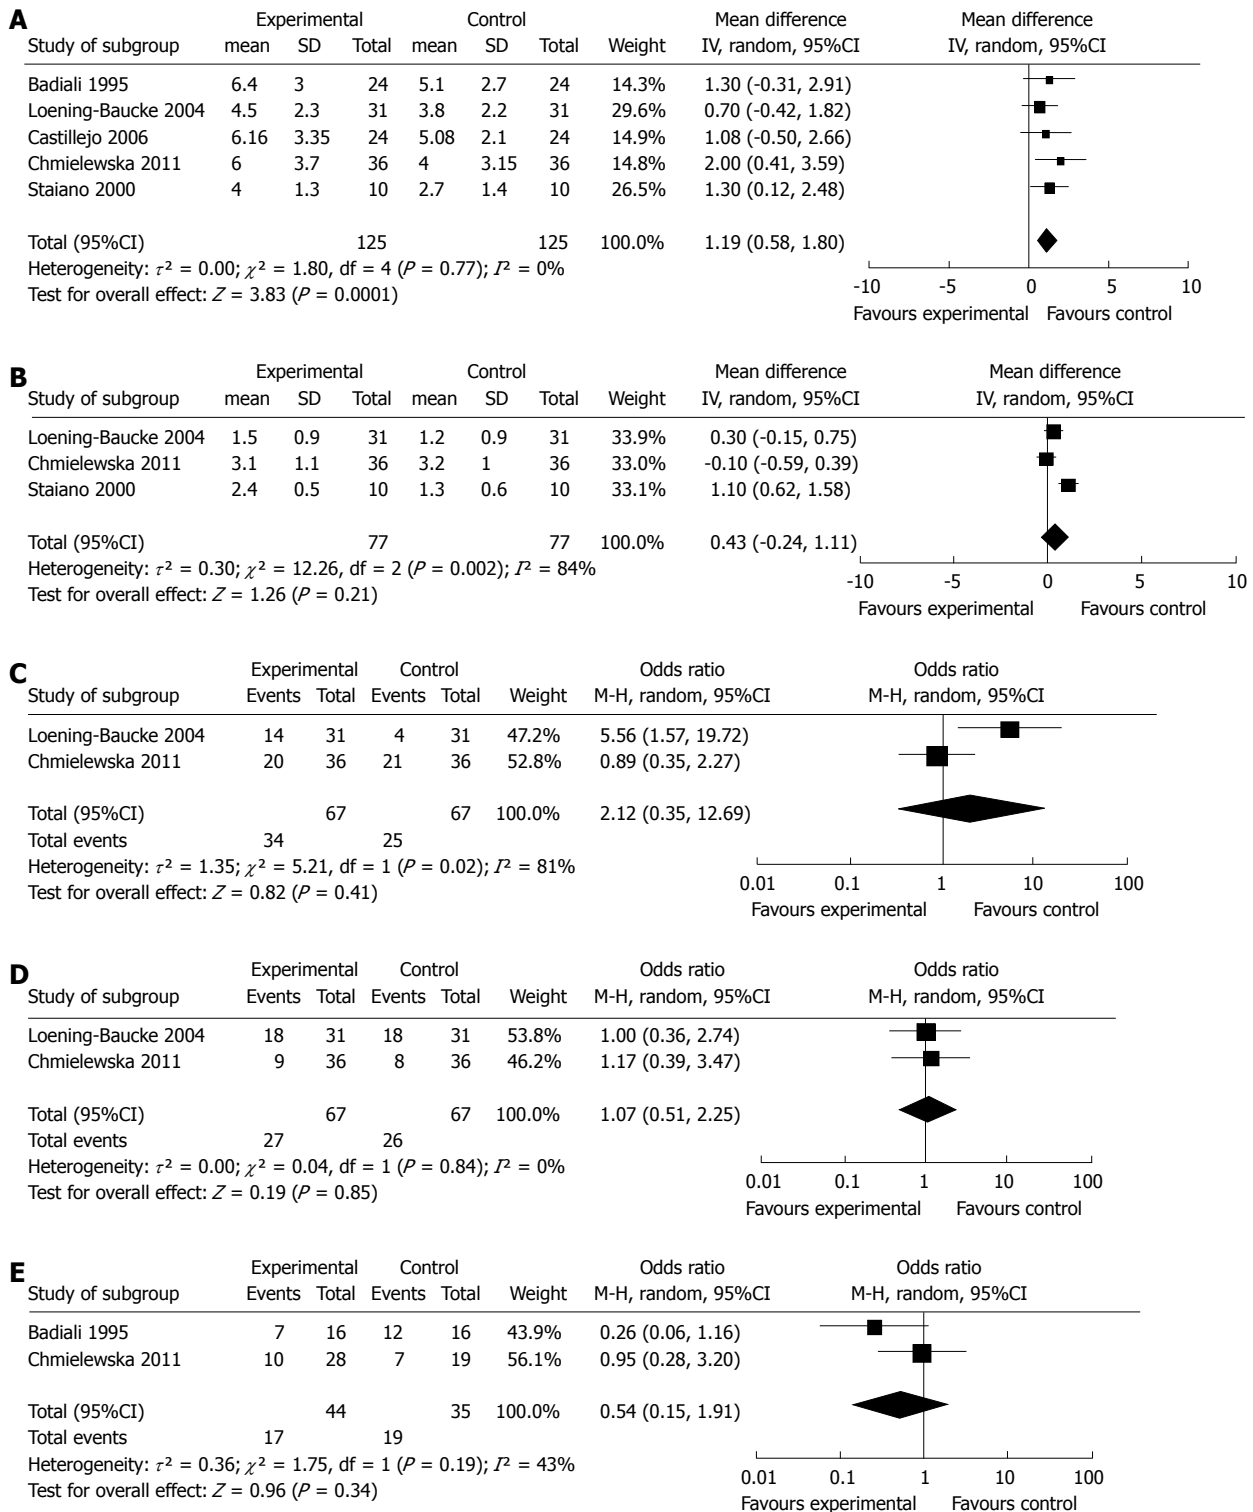

Figure 2 Pooled estimate of odds ratio and 95%CI. A: Stool frequency; B: Stool consistency; C: Treatment success; D: Laxative use; E: Painful defecation. IV: Iverse variance; M-H: Mantel-Haenszel.

We used rigid research methods and described search strategy, eligibility criteria and data extraction method in detail. We included high-quality studies (Jadad score ≥ 3) into the analysis. Because of the strict selection criteria, only five small sample-sized studies were included. Definite heterogeneity existed in the analysis. Neurologically impaired children were included, although no difference

was present between dietary fiber and placebo groups during baseline period, disease itself can interfere with the outcome. Some of the studies are limited to pediatric patients, stool withholding and stool toileting refusal often occurred^[20], which is uncommon among constipated adults, although no heterogeneity was found in the analysis of stool frequency, potential limitation still existed. As

scarce data of gastrointestinal syndromes was reported, and different evaluation and presentation methods were used, less data can be used for the analysis.

There were meta-analyses examining the efficacy of fiber in constipation previously, in which data of fiber and laxative were pooled for analysis^[21,22]. Recently, a systematic review of the efficacy of fiber in the management of chronic idiopathic constipation was published^[23], six RCTs were included, four RCTs compared the effect of soluble fiber with placebo^[24-27], and one study^[27] used the combined intervention with celandine, aloe vera and psyllium. Celandine and aloe vera contain several alkaloids with known aperient effect, which may influence the outcome of the patients. Of the two trials examining the effect of insoluble fiber^[11,28], one trial^[28] recruited patients with self-reported constipation, subjective error may be more obvious when the outcome was assessed by non-medical staff.

In summary, our meta-analysis demonstrated that dietary fiber can obviously increase stool frequency in patients with constipation. The result also showed that dietary fiber did not obviously improve stool consistency, treatment success, laxative use and painful defecation. However, there were some possible influential factors such as small sample-sized studies, severity of constipation, assessment method for outcomes, *etc.* So further large trials examining the effect of dietary fiber in the treatment of constipation are needed, the possible influential factors should be taken into consideration, and more gastrointestinal symptoms and adverse events should be reported before dietary fiber was formally recommended.

COMMENTS

Background

Constipation is one of the widespread health problems. There is a wide-range of treatment methods. Life-style modification is usually recommended as first-line treatment, but data on the effectiveness of these measures are limited. Laxatives are most commonly used for treatment of constipation, but frequent use of these drugs may lead to some adverse effects, and alternative treatment measure is therefore needed. Increase of dietary fiber intake has been recommended to treat constipation of children and adults. There have been several randomized controlled trials (RCTs) studying the relationship between dietary fiber and constipation, however no definitive quantitative summary is available.

Research frontiers

Some studies reported that dietary fiber can increase stool frequency, improve stool consistency and have no obviously adverse effects. Two studies concluded that dietary fiber is as effective as lactulose treatment and seems to have less side effects. However, in another study, dietary fiber was not found more effective than placebo in therapeutic success and it might increase the frequency of abdominal pain.

Innovations and breakthroughs

This meta-analysis demonstrated that dietary fiber can obviously increase stool frequency in patients with constipation. The result also showed that dietary fiber did not obviously improve stool consistency, treatment success, laxative use and painful defecation, however, there were some possible influential factors such as small sample-sized studies, severity of constipation, and assessment method for outcomes. Further large trials examining the effect of dietary fiber in the treatment of constipation are needed, the possible influential factors should be taken into consideration and more gastrointestinal symptoms and adverse events should be reported before dietary fiber was formally recommended.

Applications

The study results suggest that dietary fiber intake is a potential therapeutic method that could be used in the treatment of constipation.

Terminology

Constipation: Present with any two of the six symptoms of less than 3 defecations per week, straining, lumpy or hard stools, sensation of incomplete evacuation, sensation of anorectal obstruction or blockage, digital maneuvers; Dietary fiber: Dietary fiber is a broad category of non-digestible food ingredients that includes non-starch polysaccharides, oligosaccharides, lignin, and analogous polysaccharides with an associated healthful benefit.

Peer review

The effectiveness of dietary fiber on constipation is inconsistent. So far no definitive quantitative summary is available. This is a well performed meta-analysis, in which the authors analyzed the effect of dietary fiber in constipation. The results are interesting and suggest that dietary fiber intake is a potential therapeutic method that could be used in preventing and treating constipation. This analysis provides valuable information for further trials and clinical application.

Abstract

AIM: To investigate the effectiveness of 5-fluorouracil-based neoadjuvant chemotherapy (NAC) for gastroesophageal and gastric cancer by meta-analysis.

METHODS: MEDLINE and manual searches were performed to identify all published randomized controlled trials (RCTs) investigating the efficacy of the fluorouracil-based NAC for gastroesophageal and gastric cancer, and RCTs of NAC for advanced gastroesophageal and gastric cancer *vs* no therapy before surgery. Studies that included patients with metastases at enrollment were excluded. Primary endpoint was the odds ratio (OR) for improving overall survival rate of patients with gastroesophageal and gastric cancer. Secondary endpoints were the OR of efficiency for down-staging tumor and increasing R0 resection in patients with gas-

troesophageal and gastric cancer. Safety analyses were also performed. The OR was the principal measurement of effect, which was calculated as the treatment group (NAC plus surgery) *vs* control group (surgery alone) and was presented as a point estimate with 95% confidence intervals (CI). All calculations and statistical tests were performed using RevMan 5.1 software.

RESULTS: Seven RCTs were included for the analysis. A total of 1249 patients with advanced gastroesophageal and gastric cancer enrolled in the seven trials were divided into treatment group ($n = 620$) and control group ($n = 629$). The quality scores of the RCTs were assessed according to the method of Jadad. The RCT quality scores ranged from 2 to 7 (5-point scale), with a mean of 3.75. The median follow-up time in these studies was over 3 years. The meta-analysis showed that NAC improved the overall survival rate (OR 1.40, 95%CI 1.11-1.76; $P = 0.005$), which was statistically significant. The 3-year progression-free survival rate was significantly higher in treatment group than in control group (37.7% *vs* 27.3%) (OR 1.62, 95%CI 1.21-2.15; $P = 0.001$). The tumor down-stage rate was higher in treatment group than in control group (55.76% *vs* 41.38%) (OR 1.77, 95%CI 1.27-2.49; $P = 0.0009$) and the R0 resection rate of the gastroesophageal and gastric cancer was higher in treatment group than in control group (75.11% *vs* 68.56%) (OR 1.38, 95%CI 1.03-1.85; $P = 0.03$), with significant differences. No obvious safety concerns about mortality and complications were raised in these trials. There were no statistically significant differences in perioperative mortality (5.08% *vs* 4.86%) (OR 1.05, 95%CI 0.57-1.94; $P = 0.87$ fixed-effect model) and in the complication rate between the two groups (13.25% *vs* 9.66%) (OR 1.40, 95%CI 0.91-2.14; $P = 0.12$ fixed-effect model). Trials showed that patients from Western countries favored NAC compared with those from Asian countries (OR 1.40, 95%CI 1.07-1.83). Monotherapy was inferior to

multiple chemotherapy (OR 1.40, 95%CI 1.07-1.83). Intravenous administration of NAC was more advantageous than oral route (OR 1.41, 95%CI 1.09-1.81).

CONCLUSION: Fluorouracil-based NAC can safely improve overall survival rate of patients with gastroesophageal/gastric cancer. Additionally, NAC can down the tumor stage and improve R0 resection.

INTRODUCTION

Gastric and esophageal cancers are among the leading causes of cancer-related death worldwide^[1,2]. In spite of a declining incidence of the distal stomach cancer in the Western countries over the past decades, the incidence of adenocarcinoma of the lower esophagus and the gastroesophageal junction has dramatically increased in the world^[3]. Early-stage gastric and gastroesophageal cancers are curable with surgical treatment alone, with a 5-year overall survival rate of 90%. However, the majority of gastric and gastroesophageal cancer patients are diagnosed with advanced diseases (stages III or IV)^[4]. The advanced gastric and gastroesophageal cancer without distant metastasis is still a potentially curable disease, but the prognosis is poorer than the early-stage diseases. Treatment of advanced gastroesophageal cancer is still a challenge for gastrointestinal surgeons. Localized tumors, limited to the submucosa, can be best treated surgically, with a long-term survival of 70%-95%, but the prognosis of locally advanced tumors is poor due to a high unresectability rate at presentation, and a much higher relapse rate after radical surgery^[5,6], thus demanding further studies regarding neoadjuvant treatment.

Theoretically, the administration of the neoadjuvant chemotherapy (NAC) appears to have several potential benefits for gastroesophageal and gastric cancers: to reduce the tumor volume, to improve the R0 resection rate, to act on micrometastases and to evaluate tumor chemosensitivity to cytotoxic medications. Randomized trials and meta-analyses have demonstrated a benefit with neoadjuvant or perioperative chemotherapy in gastric and gas-

troesophageal cancers. However, the optimal approach in individual patients is not clear and remains controversial^[7,8]. The aim of the current meta-analysis under such circumstances was to evaluate the effectiveness of NAC in treatment of gastric and gastroesophageal cancers and explore the optimal strategy for chemotherapy delivery.

MATERIALS AND METHODS

Data collection and selection

MEDLINE and manual searches were carried out to identify all published RCTs that compared the fluorouracil-based NAC plus surgery with surgery alone for advanced gastric and gastroesophageal cancers. The search was done on PubMed using three sets of terms: "esophagogastric junction/gastroesophageal/gastric"; "carcinoma/cancer"; and "neoadjuvant chemotherapy/preoperative chemotherapy". A limit was set on the randomized controlled trials (RCTs) and the terms were set to title/abstract.

Inclusion criteria

The following inclusion criteria were used: (1) RCTs that compared the fluorouracil-based NAC plus surgery with no treatment before surgery for gastric and gastroesophageal cancers; (2) blindness of the trial was not required; (3) patients with pathologically diagnosed esophagogastric junction or gastric adenocarcinoma, without prior treatment before entering the trial, but with a history of potentially curative surgery; and (4) studies which were considered updated.

Exclusion criteria

(1) Studies on preoperative radiotherapy or immunotherapy; and (2) studies with the control group receiving chemotherapy were excluded.

The data of each RCT were collected by two reviewers (Zhang GQ and Wang HJ) independently. The results were consistent.

Data checking and assessment

Methodological quality of trials was evaluated using the modified Jadad quality scores^[9], which include secure method of randomization, allocation concealment, double-blinding, and information on withdrawals, and losses to follow-up. Based on these criteria, the studies were divided into high-quality group (score ≥ 3) and low-quality group (score ≤ 2). Two reviewers independently assessed the eligibility of each trial.

Data extraction

The following data were extracted from each study and recorded using a predesigned form: authors, year of publication, patient population, country of investigators, sample size (total, eligible, and per arm), chemotherapy regimen, cycles of chemotherapy, follow-up period, curative effect (survival rate, rate of macroscopic radical resection and cancer stage at pathological examination), and adverse events. Two reviewers did the extraction independently.

Meta-analysis protocol

Data were obtained directly from included articles or calculated by percentage in each article. The meta-analysis was performed using Review Manager 5.1 software (provided by Cochrane Collaboration). Outcomes assessed by this meta-analysis included the overall survival, three-year progression-free survival rate, tumor down-staging rate, R0 resection rate, safety analysis and subgroup analysis. Overall survival was defined as the time between the treatment randomization and the date of the last follow-up or of the patient's death. Patients who were lost to follow-up were considered as dead. Locoregional recurrence was measured either from the date of treatment randomization to the occurrence of the event or to the date of last follow-up. Heterogeneity between the trials was assessed to determine which model would be used in the meta-analysis. A sensitivity analysis was performed by changing the meta-analysis model. An odds ratio (OR) was the principal measurement of effect. It was calculated as the treatment group *vs* the control group.

Statistical analysis

All statistical analysis were performed spontaneously using Review Manager 5.1 software^[10]. Heterogeneity between the trials was assessed using Chi-square test. The OR was presented with a 95%CI. I^2 statistics was used for the degree of heterogeneity evaluation, and $P < 0.05$ was considered statistically significant.

RESULTS

Eligible trials

Seven RCTs were identified, and the quality scores of the RCTs were assessed according to the method of Jadad. The details are shown in Table 1. The RCT quality scores ranged from 2 to 7 (5-point scale), with a mean of 3.75 (Tables 2 and 3).

Overall survival rates

There was no significant heterogeneity between the trials ($P = 0.52$), and the fixed effects model was used. The data in the seven studies^[11-17] were available for the analysis of overall survival. There were 620 patients in the treatment group and 629 patients in the control group in this meta-analysis. The median follow-up time was over three years. The OR, expressed as treatment group *vs* control group, was 1.40 (95%CI 1.11-1.76; $P = 0.005$). The difference of the overall survival between the treatment group and the control group was statistically significant. The overall survival was increased by 7.96% in the treatment group compared with the control group (Figure 1A). The number needed to treat (NNT) was 12. A sensitivity analysis was performed by changing the effect model into the random effect model. The results showed that the confidence interval of the odds ratio did not lie across the non-effect line, and the difference of the overall survival was statistically significant between the treatment group

and the control group when the random effect model was used. The fixed effect model and the random effect model were used respectively to evaluate the sensitivity of the results of the analysis (Figures 1B and 2).

Three-year progression-free survival rate

Three studies^[11,12,15] compared the 3-year progression-free survival (PFS) rates between the two groups. The 3-year PFS rate was higher in treatment group than in control group (37.7% *vs* 27.3%), (OR 1.62, 95%CI 1.21, 2.15; $P = 0.001$, fixed-effect model) and NNT was 10 (Figure 3A and B).

Tumor down-staging rate

Three studies^[12,13,15] describing the pathological staging of gastroesophageal and gastric cancers after resection (269 in treatment group and 290 in control group) were included in the analysis. The rate of pT1-2 was higher in treatment group than in control group (55.76% *vs* 41.37%) (OR 1.77, 95%CI 1.27, 2.49; $P = 0.0009$, fixed-effect model) and the NNT was 7 (Figure 4A and B).

R-0 resection rate

The resection rate of gastroesophageal and gastric cancers was reported in four trials^[11,12,13,15]. Since no obvious heterogeneity was observed in these studies ($P = 0.31$, I^2

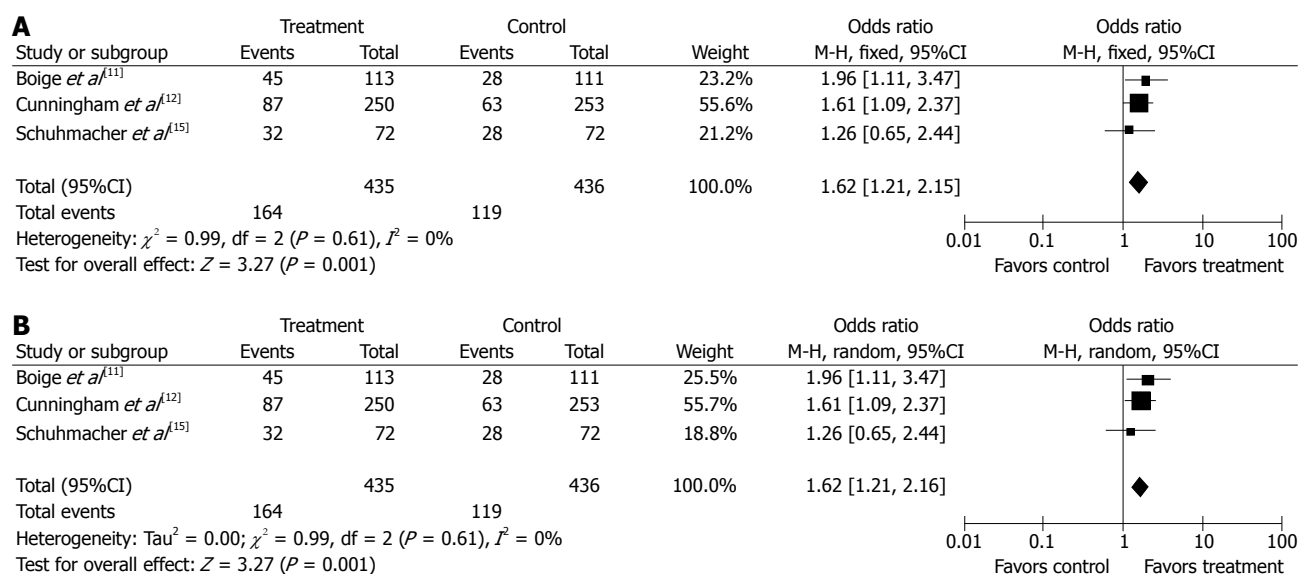

Figure 3 Effect of neoadjuvant chemotherapy in progression free survival rate. A: Progression free survival rate (fixed effects model); B Progression free survival rate (random effects model).

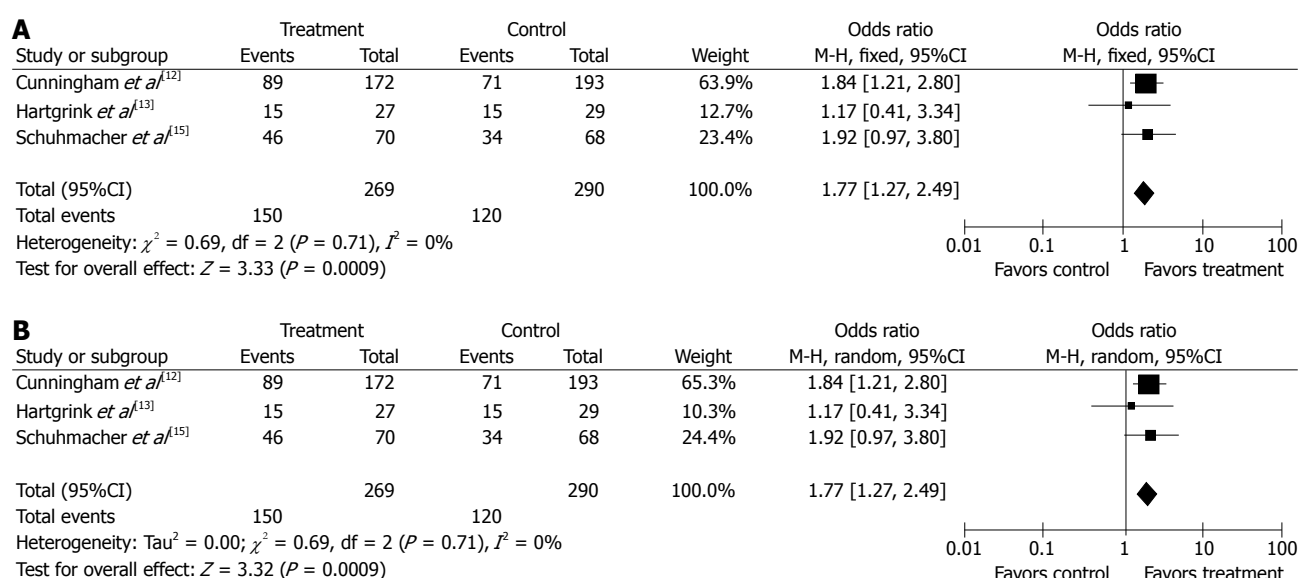

Figure 4 Effect of neoadjuvant chemotherapy in tumor down-staging. A: Tumor down-staging rate (fixed effects model); B Tumor down-staging rate (random effects model).

= 17%), the fixed-effect model was used. The R0 resection rate of the gastroesophageal and gastric cancers was higher in treatment group than in control group (OR 1.38, 95%CI 1.03-1.85, $P = 0.03$, fixed-effect model) and the NNT was 15 (Figure 5A and B).

Safety analysis

Safety analysis included both chemotherapy-induced adverse effects (grade 3/4, defined according to the Common Toxicity Criteria of the National Cancer Institute, version 2.0) and postoperative complication and mortality. Two studies reported^[11,12] grade 3/4 adverse effects of NAC, including gastrointestinal side effect in 18.1 % (60/332) and leukopenia in 9.9% (33/332). Three stud-

ies^[11,12,15] reported perioperative mortality with no statistically significant difference ($P = 0.87$) between the two groups (5.08% *vs* 4.86%), (OR 1.05, 95%CI 0.57-1.94, fixed-effect model) (Figures 6 and 7).

Subgroup analysis

Factors that might influence the results in the two groups were studied (Figure 8). When the overall survival rate was set as the end point, gastroesophageal and gastric cancer patients were benefited more from perioperative chemotherapy than from NAC alone (OR 1.40, 95%CI 1.11-1.76, NNT = 12). Trials showed that patients from Western countries favored NAC compared with those from Asian countries (OR 1.40, 95%CI 1.07-1.83).

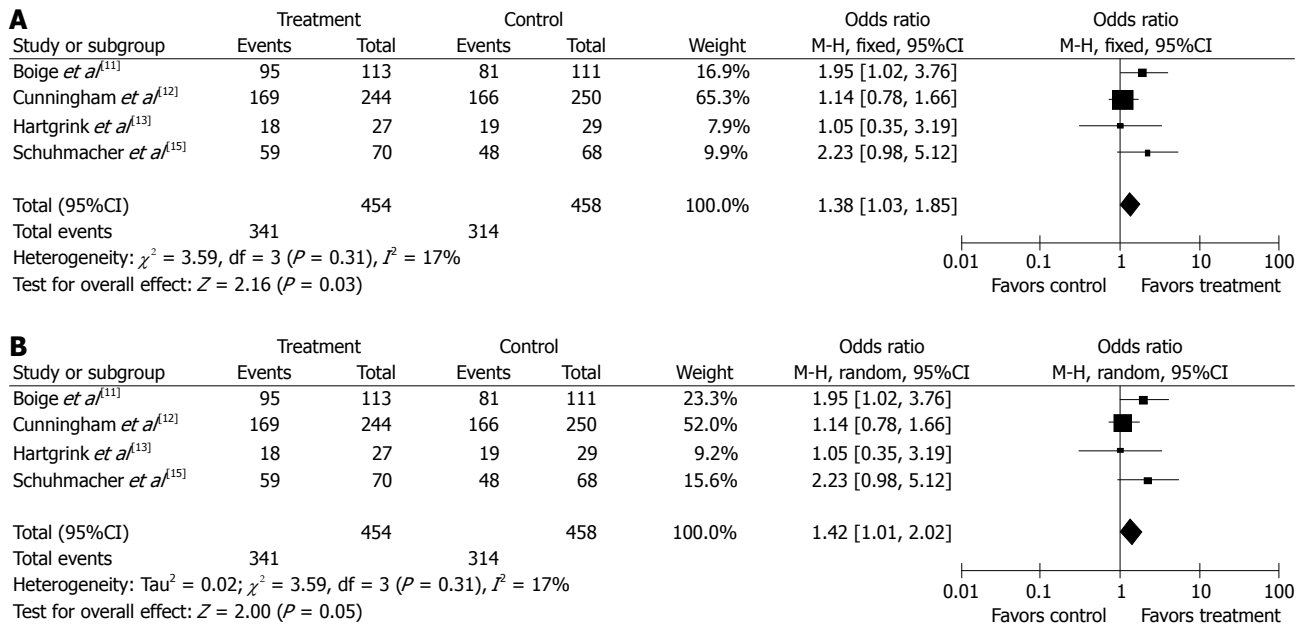

Figure 5 Effect of neoadjuvant chemotherapy in tumor R-0 resection. A: R-0 resection rate (fixed effects model); B: R-0 resection rate (random effects model).

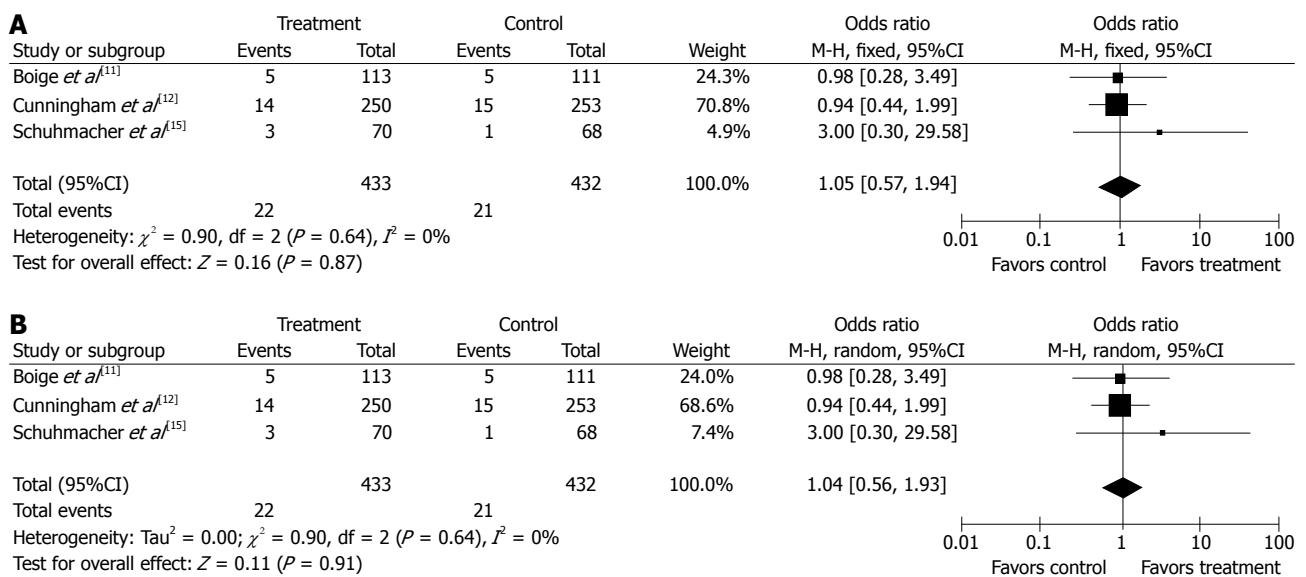

Figure 6 Effect of neoadjuvant chemotherapy in perioperative mortality. A: Perioperative mortality rate (fixed effects model); B: Perioperative mortality rate (random effects model).

Monotherapy was inferior to multiple chemotherapy (OR 1.40, 95%CI 1.07-1.83). Intravenous administration of NAC was more advantageous than oral route (OR 1.41, 95%CI 1.09-1.81) (Figure 7).

DISCUSSION

Gastric cancer remains to be an important health issue worldwide. Over the past two decades, the incidence of distal gastric cancer has been decreased, but the incidence of proximal and esophagogastric junction cancers has been increased significantly^[18]. The treatment of the gastroesophageal and gastric cancer is dependent on the TMN staging of the tumor. The advanced gastroesopha-

geal and gastric cancers (stage III-IVB) without evidence of distant metastasis are potentially curable, but these tumors usually present with a more advanced stage and are associated with a worse prognosis^[19], and a combination therapy, including surgery, chemotherapy and radiotherapy, is often needed. Chemotherapy is an adjuvant treatment modality in the form of adjuvant chemotherapy, NAC and concomitant chemoradiotherapy^[20]. NAC has several advantages: (1) it is well tolerated; (2) it can better control the micrometastasis^[21]; and (3) it might downstage the tumor to the greatest extent and increase the probability of R0 resection so as to facilitate the surgery^[22,23], thus improving the survival rate of the patients with gastroesophageal and gastric cancer. However, it might delay

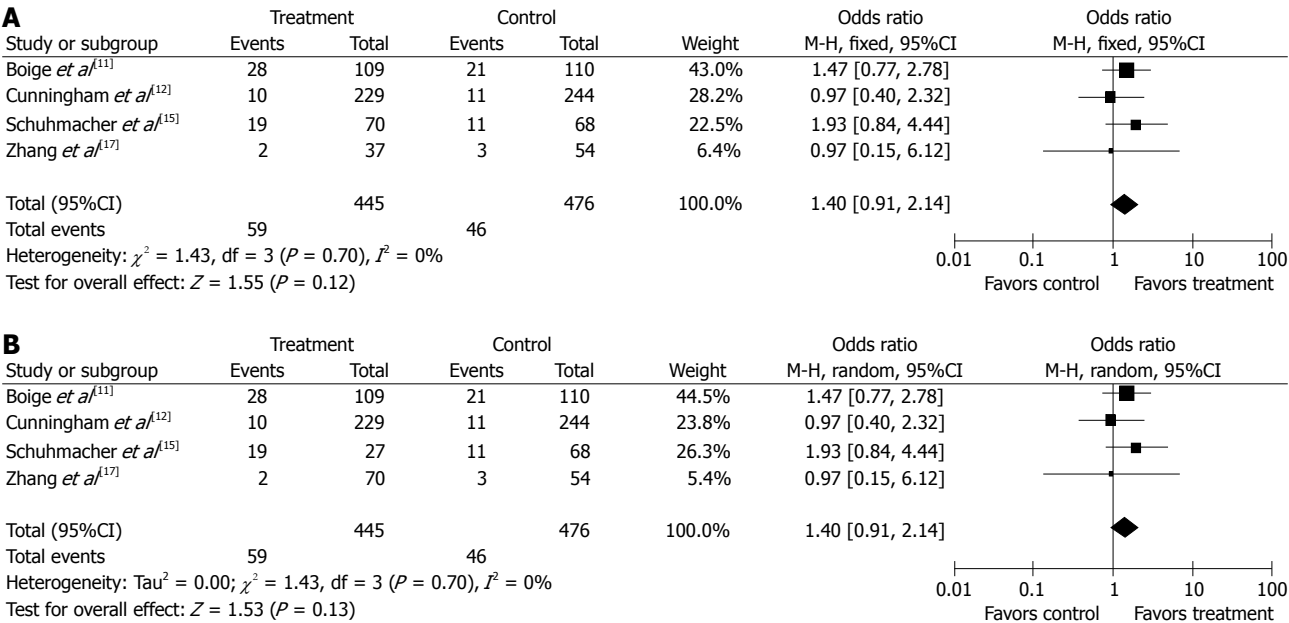

Figure 7 Effect of neoadjuvant chemotherapy in postoperative complications. A: Postoperative complications rate (fixed effects model); B: Postoperative complications rate (random effects model).

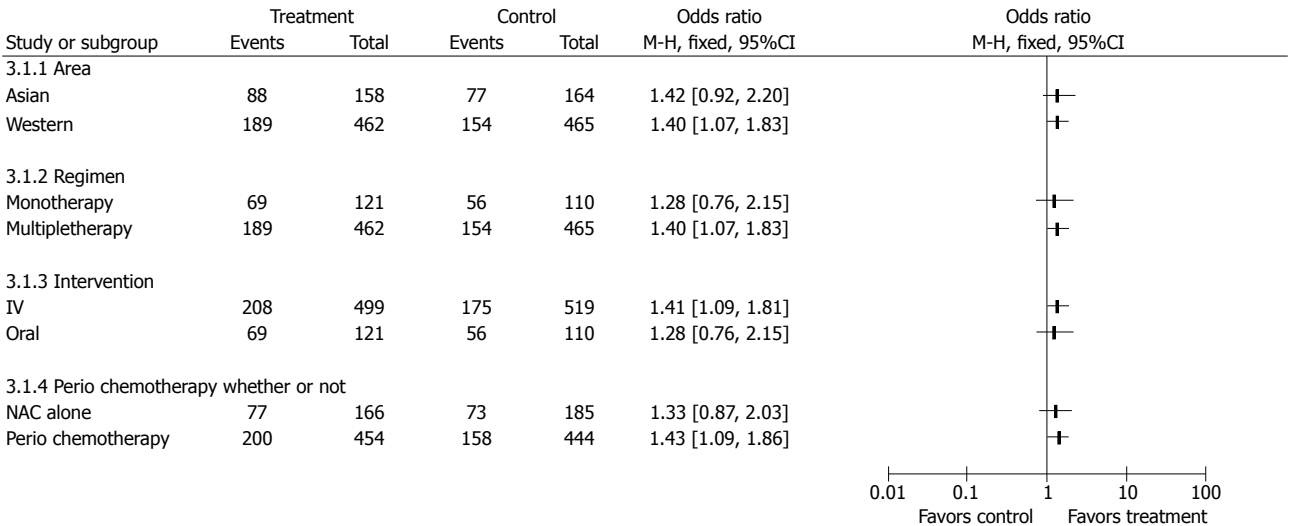

Figure 8 Subgroup analysis showing different overall survival rates in patients with advanced gastric cancer.

the curative treatment if the tumor does not respond to the NAC, which is also costly and may be detrimental to the patients. Theoretically, NAC can increase the survival rate and improve the quality of life of the patients. However, the meta-analysis by Him^[8] failed to show the benefit of NAC in patient survival. Li's study^[7] demonstrated a minor but significant benefit in patient survival. The result coincided with our studies, which shows that 5-fluorouracil-based NAC has a benefit on the overall survival of gastroesophageal and gastric cancer patients. Our meta-analysis demonstrated the feasibility of NAC for locally gastroesophageal and gastric cancer patients. NAC could downstage the tumor (NNT = 7) and increase the R0 rate of gastric cancer (NNT = 15). To examine the role of NAC alone in improving the overall survival rate

of gastroesophageal and gastric cancer patients who did not receive postadjuvant chemotherapy, data from four trials^[13,15-17] were further analyzed, showing that NAC had no effect on the overall survival rate of gastroesophageal and gastric cancer patients (OR 1.34, 95%CI 0.87-2.06). These may contribute to the factors that the included studies had a very small sample size with different follow-up time, different cycles of treatment as well as different tumor locations, which could be too underpowered to demonstrate any positive results. Alternatively, this might be attributed to the fact that currently used preoperative chemotherapeutic agents may not be effective enough to eradicate micrometastases. No clear conclusion could be reached as yet about the effect of NAC alone on the overall survival rate of gastroesophageal and gastric

cancer patients. Fortunately, the perioperative chemotherapy shows some effect in the overall survival rate of gastroesophageal and gastric cancer patients (OR 1.43, 95%CI 1.09-1.86). It has been found that 5-fluorouracil-based NAC benefits the overall survival of gastroesophageal and gastric cancer patients.

The regimen of the NAC might affect the outcome of the treatment. Therefore, the regimen factors concerning NAC for gastroesophageal and gastric cancer should be taken into account. Several regimens have been used in the NAC of gastroesophageal and gastric cancer. Our current meta-analysis showed that fluorouracil-based combination regimen and intravenous route of NAC had a high efficiency for gastroesophageal and gastric cancer patients. The effective response rate will help down-stage tumors to the greatest extent and increase the probability of R0 resection, thus improving the survival rate of the patients.

Subgroup analysis also showed that the outcome of NAC for gastroesophageal and gastric cancer was better in trials from Western countries than in those from Asian countries and in multi-agent regimens as well. The increasingly higher incidence of the gastroesophageal cancer in Western countries compared with Asian countries^[12] and the different constituent of tumor stage may influence the final results.

Another major concern in our meta-analysis is the efficiency and safety of NAC in the studies included. Mortality directly links with treatment failure, which mainly comprises locoregional recurrence, secondary primary malignancy, and distant metastasis. In this meta-analysis, the outcomes of 3-year PFS were analyzed. The difference of 3-year PFS was statistically significant between the treatment group and the control group, which suggests that NAC with a 5-fluorouracil-based regimen is effective in the locoregional control of gastroesophageal and gastric cancer when a locoregional treatment is administered. Our meta-analysis showed that gastric cancer patients could well tolerate NAC. Grade 3/4 gastrointestinal and leukopenia adverse events of NAC occurred in 32% (112/343) of gastroesophageal and gastric cancer patients. The rate of complications in the treatment group was not obviously higher than in the control group, indicating that NAC is a safe modality for gastric cancer (OR 1.05, 95%CI 0.75-1.48). The efficiency and the safety were assessed in treatment group, but disease progression during NAC is another potential concern in patients with a loss of opportunity for surgery. In this meta-analysis, three trials^[11,12,15] showed a disease progression rate of 10.6% (46/435). The R-0 resection rate was higher in treatment group than in control group (OR 1.57, 95%CI 1.21-2.02, NNT = 11), indicating that disease progression after NAC is not a major concern for its resection. The results were consistent with the study showing that lack of response to NAC may delay curative surgery, and chemotherapy-induced toxicity may lead to increased surgical complications^[24,25].

In addition, funnel plot observation did not indicate obvious publication bias in the two subgroups (Figure 2).

The sensitivity analysis showed similar results by excluding the trials with Jadad score less than 2. In this meta-analysis, the primary endpoint about the overall survival rate with a fixed model OR of 1.40 (95%CI 1.11-1.76) *vs* a random model OR of 1.40 (95%CI 1.11-1.76) (Figure 1A, B), indicated that the trial quality was good, which was not influenced by the factors, such as selection bias and other trials.

NAC has been proven effective against some cancers, such as breast cancer^[26], head and neck squamous cell carcinoma^[27]. However, it is not recommended as a standard regimen for gastroesophageal and gastric cancer, primarily because of the significantly different strategies used around the world. However, adjuvant chemoradiotherapy is a standard treatment in the USA, perioperative chemotherapy is the first choice in Europe, and surgery and adjuvant chemotherapy are recommended in Japan, where D2 surgery is effective and safe^[28-30]. Some studies have demonstrated that NAC and D2 surgery can effectively improve the overall survival^[31], whereas a recent study showed no benefits^[32]. Whether NAC benefits D2 dissection lacks strong evidence. Fortunately, our meta-analysis provided the up-to-date evidence for the positive effect of NAC in gastroesophageal and gastric cancers, but further studies are required to determine its best regimen and response-based neoadjuvant concept.

In conclusion, our study provides information on the efficacy of NAC with 5-fluorouracil-based regimen in gastroesophageal and gastric cancer patients. This regimen was regarded as the most effective one before the emergence of Taxanes. The incorporation of Taxanes into the 5-FU/cisplatin (FP) regimen makes up the Taxol/5-FU/cisplatin (TPF) regimen, which is a promising treatment strategy for gastroesophageal and gastric cancers^[33]. A number of trials have been registered to examine the role of NAC in treatment of advanced gastric cancer, such as S-1 plus cisplatin or S-1 and cisplatin plus Taxanes^[34,35]. However, its effectiveness is yet to be confirmed by the meta-analysis. With all these clinical and scientific efforts, these treatment strategies will definitely continue to further improve the outcome of gastroesophageal and gastric cancer patients.

COMMENTS

Background

Although the prevalence of distal gastric cancer has declined, the world-wide incidence of gastroesophageal junctional adenocarcinoma is increasing. For patients who present with gastric and gastroesophageal cancer, surgery remains the cornerstone of treatment, which can potentially improve the long-term survival. However, the prognosis of the patients remains poor. Chemotherapy has been proven to be effective for advanced gastric cancer. Neoadjuvant chemotherapy (NAC) plays a role in improving the prognosis of the patients with advanced gastric cancer and gastroesophageal junctional adenocarcinoma, but its value remains controversial because of lack of well-powered trials.

Research frontiers

Meta-analysis was used to evaluate the effectiveness of NAC for advanced gastric/gastroesophageal cancer in this study.

Innovations and breakthroughs

The meta-analysis provided the up-to-date evidence for the positive effect of NAC in locally advanced gastric and gastroesophageal cancer. NAC im-

proved the R0 resection rate (95%CI: 1.03-1.85), tumor down-staging (95%CI: 1.27-2.49) and survival rate (95%CI: 1.11-1.76) for the 1249 patients enrolled in seven trials. Surgery was safe after preoperative 5-fluorouracil-based chemotherapy while no obvious morality and complication concerns were raised in these trials. These findings suggest that NAC can improve the survival rate of patients with advanced gastric and gastroesophageal cancer.

Applications

Based on the studies on the efficacy and feasibility of the preoperative chemotherapy with 5-fluorouracil-based regimen and with the increasing acceptance of the concept of NAC, additional studies on new regimens and well-designed powerful trials are highly encouraged in patients with locally advanced gastric and gastroesophageal cancer. More experiments are expected to focus on individualized treatment under the guidance of molecular marker for the NAC.

Terminology

D₂ surgery: the extent of lymphadenectomy (D₁₋₃), in which complete dissection of up to the second group nodes was defined as D₂ according to the rules of the Japanese Research Society for Gastric Cancer; TNM classification of malignant tumors: "pT" indicates the pathological stage after surgery and "cTNM" indicates the clinical pretreatment tumor stage; Taxanes: they represent one of the more effective targets in current cancer therapy, which block cell cycle progression through centrosomal impairment, induction of abnormal spindles and suppression of spindle microtubule dynamics. Paclitaxel (Taxol) is the prototype of the taxane family of anti-tumor drugs, which has been approved for treatment of metastatic gastric cancer; Number needed to treat: It is often used to describe how many patients would need to be treated to prevent one event. It is determined from the absolute difference between one treatment and another.

Peer review

This is an excellent analysis. The authors submit a meta-analysis of the available randomized controlled trials investigating the utility of neoadjuvant therapy for gastric and gastroesophageal cancer. Overall, the paper is very strong, the data appropriately analyzed and the conclusions reasonable. The supposition the neoadjuvant therapy for gastroesophageal cancers remaining controversial is not entirely the case. Most centers across the world have embraced this approach based on the strong data supporting efficacy.

Abstract

Successful cannulation of the common bile duct may be difficult in patients in whom the papilla is located entirely within a diverticulum. In this study, we report successful biliary cannulation in three patients following intubation of the distal tip of the duodenoscope into the duodenal diverticulum and locating the major papilla. No complications occurred during the operation or during the postoperative period. This method didn't need second incubation an endoscope and might lower the burden of patients. So this skill is useful to deal with the papilla hidden inside the large diverticulum because of its safety and convenience.

INTRODUCTION

Periampullary diverticula (PAD) are found in 9% to 32.8% of patients who undergo endoscopic retrograde cholangiopancreatography (ERCP)^[1]. The papilla often exists at the superior or inferior border of the PAD. Occasionally, identification of the papillary orifice and successful cannulation of the common bile duct (CBD) may be more difficult in patients in whom the papilla is located entirely within the diverticulum, even for endoscopic experts. In this report, we present three cases where the papilla was hidden in a large duodenal diverticulum. Successful biliary cannulation was achieved following intubation of the distal tip of the duodenoscope into the duodenal diverticulum.

CASE REPORT

Three male patients (aged 70, 78 and 82 years) were admitted to our hospital as a result of right upper quadrant pain and fever and jaundice. Magnetic resonance cholangiopancreatography revealed intra- and extra-hepatic bile duct dilation (CBD stones were presented in patient one and patient two). On ERCP, the papilla could not be found at the rim of large duodenal diverticula (one with septa). We therefore suspected that the papilla was hidden inside the diverticula. With careful searching, the papil-

Figure 1 The duodenal diverticulum to be located intradiverticular papilla for biliary cannulation. A: The papillary orifices can be indistinctly seen at the left side of the inner diverticular borders in patient 1 and patient 2 (arrow), but not seen at all in patient 3; B: Successful biliary cannulation was achieved after facing the intradiverticular papilla; C: Endoscopic retrograde cholangiography showing stones in the common bile duct in patient 1 and patient 2 and dilation of the common bile duct in patient 3; D: Extracted bile stones in the duodenal diverticulum in patient 1 and patient 2.

lary orifices were indistinctly seen at the left side of the inner diverticular borders in patient one and patient two, but were not visualized in patient three (Figure 1). Several attempts were made to evert the papilla out of the diver-

ticulum, including dilating the diverticular rim, using two devices in one channel (a catheter and a sphincterotome), but without success. As the diverticulum was judged to be large enough to accommodate the distal tip of a duo-

denoscope, we decided to intubate the duodenoscope (JF-260V, Olympus Medical System, Tokyo, Japan) into the duodenal diverticulum by gently adjusting the knob, and by push-pull the duodenoscope. Eventually, we discovered that the orifices in all three patients were on the left side of the inner diverticular borders, opening towards the medial and posterior wall of the diverticulum. Subsequently, the orifices were faced by finely adjusting the direction of the endoscope, and by carefully exploring the papillary alignment (Figure 1). Biliary cannulation and stone extraction was then conducted using a small biliary sphincterotomy and balloon dilatation (Figure 1). No complications occurred during the procedure or during the postoperative period. All patients were well on discharge shortly after surgery.

DISCUSSION

PAD is outpunching from the duodenum that represents herniation of the mucosal or submucosal layers through a defect in the muscular wall within a radius of 2 to 3 cm of the ampulla of Vater. The prevalence of PAD increases with age and has been reported in 65% of elderly patients^[2]. There is now clear evidence of an association between duodenal diverticula and bile duct stones, particularly in the absence of gallbladder stones^[3]. The location of the papilla with respect to the diverticulum is divided into two categories. In type I the papilla is at the rim or within 2 cm of the edge of the diverticulum, and this is called a peri-diverticular papilla (PDP). In type II cases, the papilla lies inside or at the middle of the bottom edge of the diverticulum or between two adjacent diverticula, and this is termed an intradiverticular papilla (IDP)^[4]. According to a report by Tham *et al*^[5], type I and type II cases accounted for 74.7% and 25.3%, respectively, in a cohort of 83 patients with diverticular papilla. Previously, successful cannulation in patients with PAD has varied from 61% to 95.4%, which is significantly lower than that observed in those without PAD^[1,5]. Two recent studies reported that PAD did not cause any technical difficulties at ERCP or increase the risk of complications, however, this was true only when patients with the undetectable papilla were excluded^[3,6]. It is reasonable to speculate an even lower successful cannulation rate in IDP patients in whom papilla are often more difficult to locate than in PDP patients. Therefore great efforts are needed to find new methods to achieve successful cannulation in patients with IDP.

In recent years, new devices and new manipulations for successful biliary cannulation in patients with IDP have been reported. These include using a two-devices-in-one-channel method^[7], balloon dilation of a narrow-necked diverticulum^[8], using an ultrathin gastroscope to locate the papilla^[9], an endoscopic ultrasound-guided rendezvous technique^[10], endoclip-assisted biliary cannulation^[11], and the double-endoscope method^[12].

Our study suggests an alternative skill for biliary cannulation in patients with IDP, which didn't need second incubation an endoscope. In contrast to colon diverticu-

la, the PAD is relatively fixed as they are located behind the retroperitoneum. Also the adjacent kidney and pancreas could provide further support to diverticula wall. Thus, we can relatively easily control the position of the duodenoscope in the duodenal diverticulum. To avoid sudden movements in the PAD, the duodenoscope can also be pulled back to the duodenal lumen for stone extraction. There were no complications, such as bleeding or perforation, during ERCP treatment of these three patients. So this skill is a safe and convenient method which may lower the burden of patients.

We conclude that intubating the distal tip of the duodenoscope into the large duodenal diverticulum, thereby locating the hidden papilla, is a safe and convenient skill that facilitates both biliary cannulation and endoscopic treatment in the hands of experienced practitioners, which didn't need second incubation an endoscope and may lower the burden of patients.

Endoscopic ultrasound features of gastric schwannomas with radiological correlation: A case series report. *World J Gastroenterol* 2012; 18(48): 7397-7401 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7397.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7397>

Abstract

Gastric schwannomas are rare mesenchymal tumors of the gastrointestinal tract. They are usually misdiagnosed as other submucosal tumors preoperatively. Experience of the imaging features of gastric schwannomas is extremely limited. In this report, we summarize the features of a series of endoscopic ultrasound (EUS) images of gastric schwannomas in an effort to improve the diagnosis and differential diagnosis rate. We retrospectively reviewed the endosonographic features of four patients with gastric schwannomas and their computed tomography imaging results. Gastric schwannomas had heterogeneous hypoechogenicity or isoechoogenicity, and a well-demarcated margin. The tumors originated from the fourth layer. Cystic changes and calcification were uncommon. Marginal hypoechoic haloes were observed in two patients. The results described here were different from those of previous studies. In the EUS evaluation, the internal echogenicity of gastric schwannomas was heterogeneous and low, but slightly higher than that of muscularis pro-

INTRODUCTION

Schwannomas of the gastrointestinal (GI) tract are relatively rare, representing about 3% of all mesenchymal tumors of the GI tract^[1]. They are usually encapsulated benign tumors of the peripheral nerve sheath composed of differentiated schwann cells, with an excellent prognosis after surgical resection. Malignant transformation of gastric schwannomas is extremely rare^[2,3]. It is difficult to differentiate a gastric schwannoma from gastrointestinal stromal tumors (GISTs). Schwannomas are often misdiagnosed as GISTs on radiological examination^[4]. However, GISTs have greater malignant potential and require surgical resection and imatinib-based adjuvant therapy. Therefore, it is important to differentiate be-

Figure 1 Computed tomography images showed rounded masses in the stomachs, with homogeneous ($n = 3$) or heterogeneous ($n = 1$) internal contrast enhancement. A: Contrast-enhanced computed tomography (CT) showed a solitary, exophytic, soft, internal homogeneous tissue mass (arrow) in the greater curvature of the stomach, the mass exhibited central ulceration (Case 3); B: CT during the portal venous phase of contrast enhancement showed a heterogeneous contrast enhanced mass (arrow) in the body of the stomach (Case 1).

tween gastric schwannomas and other potentially malignant gastrointestinal tumors, especially GISTs. To date, there is only one report describing the endoscopic ultrasonography (EUS) features of gastric schwannomas^[5]. In this study, we analyzed 4 gastric schwannomas using EUS imaging. The results we observed were unlike those of previous studies.

CASE REPORT

From October 21, 2008 to December 27, 2011, four tumors were histologically identified as gastric schwannomas after surgery at the Second Affiliated Hospital of Zhejiang University School of Medicine. Clinical data and tumor size were recorded. This retrospective review was approved by the Ethics Committee of the Second Affiliated Hospital of Zhejiang University School of Medicine. All patients provided written informed consent before performing EUS and surgery.

Endosonography was applied using ultrasound endoscopes [the Olympus GF-UM200, GF-UCT240-AL5 and GF-UE260-AL5 (7.5 MHz; Olympus Optical Co. Japan)]. EUS scanning showed many features that were evaluated, including the following: presence or absence of mucosal ulceration; the regularity of the marginal

border (regular or irregular); the presence of lobulation of the surface; the shape of the tumor (oval to round or non-oval distorted); the presence of a marginal halo, echogenicity (hypoechoic or hyperechoic); homogeneity (homogeneous or heterogeneous); presence of internal echogenic or cystic foci; and presence of exophytic development (tumor development outside the gastric wall). Computed tomography (CT) images and radiological reports were retrospectively reviewed. The CT features were analyzed with the pattern of contrast enhancement.

Two patients underwent laparotomy and resection of tumor and two other patients underwent subtotal gastrectomy. Three of 4 patients underwent regional lymphadenectomy. Immunohistochemical studies were performed on the resected tissue to evaluate the expression of S100 protein, α -smooth muscle actin (α -SMA), desmin, CD117, CD34 and Ki67. All four patients underwent EUS and CT examinations before surgery.

Follow-up data were obtained from clinical records and from the treating doctors.

The clinicopathological characteristics of the patients and the surgical data and outcomes are summarized in Table 1. All 4 cases were female (age ranged from 32 to 50 years). One patient was asymptomatic, and the schwannoma was accidentally discovered in this patient by ultrasonic examination in the follow-up of a hystero-myoma. Three patients had symptoms including ructus, bloating and epigastric pain, weight loss, melena and hematemesis.

The patients underwent multiple examinations before surgery, but none had a correct preoperative diagnosis of schwannoma. They were misdiagnosed as having GISTs. Upper endoscopy revealed that one patient had a submucosal tumor with a central ulcer and that the other patients did not have ulceration. All the tumors were located in the gastric body (2 in the greater curvature and 2 in the lesser curvature).

The CT images showed rounded masses in the stomachs, with homogeneous ($n = 3$) (Figure 1A) or heterogeneous ($n = 1$) (Figure 1B) internal contrast enhancement. One of the masses was accompanied by enlargement of the lymph nodes.

The EUS evaluation revealed that all the tumors were hypoechoic, with a connection between the tumor and the muscularis propria. The echogenicities of the tumors were heterogeneous with an internal high-echo region (Figure 2A). Two of the patients had tumors with marginal hypoechoic regions (Figure 2B). The shapes of all tumors were oval, with well-demarcated margins, and the growth patterns of the tumors were exogastric. The tumors had smooth surfaces, except one which had an ulcer. None had internal cystic lesions, lobulations, or calcification (Table 2). Endoscopic ultrasound-guided fine needle aspiration was performed in one patient, but failed to confirm the diagnosis because of insufficient tissue biopsy for immunohistochemistry.

Histological examination showed that the tumors were composed of spindle cells. There were lymphoid cuffs

Table 1 Clinicopathological features of the patients

Case	Age (yr)	Sex	Size (cm)	Clinical Presentation	Site (gastric body)	Management	Outcome (mo)
1	32	Female	3.3 × 4.0	Ructus, bloating, epigastric pain	Greater curvature	Laparoscopic wedge resection	14
2	39	Female	4.9 × 4.0	Weight loss	Lesser curvature	Laparoscopic wedge resection	4
3	50	Female	8.1 × 5.3	Melena, hematemesis (GI bleeding)	Great curvature	Subtotal gastrectomy	5
4	49	Female	5.0 × 3.5	Incidental on ultrasonic examination for hysteromyoma follow-up	Lesser curvature	Subtotal gastrectomy	39

Lob: Lobulation; Halo: Marginal halo; Cyst: Internal cystic lesion; Spots: High spots; Cal: Calcified lesion.

Figure 2 Endoscopic ultrasonography of tumors. A: Endoscopic ultrasonography (EUS) showed a well-circumscribed heterogeneous hypoechoic mass with internal flake high-echo arising from the proper muscle layer of the stomach (case 3); B: EUS showed a round heterogeneous hypoechoic mass with marginal halo (arrow) (case 1).

Figure 3 Histological examinations showed that the lymphoid cuff (arrow) (A) and immunohistochemical evaluation revealed the spindle tumor cells stained positive for S-100 protein (B).

surrounding the tumors (Figure 3A). Immunohistochemical evaluation revealed strong expression of S-100 protein in all tumors (Figure 3B). None of the tumors showed expression of CD117, CD34 or desmin. All tumors revealed low proliferation, as estimated from the low proportion of Ki67-positive cells (Ki67 < 5%).

DISCUSSION

GI schwannomas are benign, slow growing tumors regarded as tumors distinct from conventional schwannomas. These tumors arise from the nerve sheath of the gut wall, rather than from the central nervous system and

GIST: Gastrointestinal stromal tumors.

from soft tissues^[6]. The stomach is the most common site of origin of GI schwannomas^[2]. The tumors are most commonly located in the body of the stomach^[3]. The tumors predominantly occur in older adults (mean age is 58 years) with a marked female predominance^[6,7]. Gastric schwannomas are usually asymptomatic or associated with non-specific abdominal discomfort. They are accidentally discovered or when complications, such as GI bleeding, arise. Endoscopically, gastric schwannomas appear as elevated submucosal masses, with or without central ulcers. Endoscopic biopsies always yield false-negative results. The definitive diagnosis of gastric schwannomas is determined by pathological and immunohistochemical examination of surgical specimens. The tumors are typically negative for CD117, desmin, α -SMA and positive for S100. They stain variably with CD34^[2].

It may be helpful to gain limited information through EUS, CT, magnetic resonance imaging (MRI), and positron emission tomography (PET) to differentiate gastric schwannomas from other gastric submucosal tumors. In previous studies, gastric schwannomas displayed well-circumscribed masses with heterogeneous or homogeneous contrast enhancement on CT^[7,8]. On MRI examination, gastric schwannomas are sharply demarcated, strongly enhanced tumors, having low to medium signal intensity on T1 weighted images, and high signal intensity on T2 weighted images^[9]. However, the radiological imaging features of gastric schwannomas are not specific. They are quite similar to those of gastric stromal tumors. Recent reports described several cases of gastric schwannoma with increased fluorodeoxyglucose (FDG) uptake on PET. It is therefore necessary to distinguish schwannomas from low risk GISTs when assessing submucosal tumors of the stomach that show a high FDG accumulation^[4,10].

Presently, reports on the EUS features of gastric schwannomas are extremely limited, due to the rarity of these tumors. The EUS features of gastric schwannomas have been described as round submucosal masses with marginal haloes, and homogeneous internal echogenicity

without internal echogenic foci^[5,11]. One study indicated that the echogenicities of gastric schwannomas were much lower than the normal surrounding muscle layers. Therefore, the authors considered that these findings may be useful for differentiating schwannomas from GISTs^[5]. Nevertheless, EUS findings of gastric schwannomas revealed a hypoechoic mass, with some hyperechoic foci, in some other case reports^[12,13]. According to our results, the internal echogenicity of gastric schwannomas was heterogeneous and low, but slightly higher than that of muscularis propria, with internal patch high echo. They were not homogeneous and extremely low. CT imaging showed that the tumors showed homogeneous or heterogeneous contrast enhancement. This meant that these tumors were hypervascular. The blood within the schwannomas was very slow-flowing. It is usually not possible to demonstrate flow with color or power Doppler sonography. The slow flow of blood, in spite of the hypervascular nature, can be explained by the observation that the internal echoes of the four tumors appeared similar to or slightly higher than those of muscularis propria, with some patchy hyperechoic areas. Although a lymphoid cuff was observed in each patient, it was not always continuous, which may explain why the marginal hypoechoic halo was only found in two cases. All 4 gastric schwannomas in our study lacked a cystic change, indicating that cystic changes are uncommon in this type of tumor. Only 2 cases with cystic changes on CT examinations have been reported in the literature^[8]. Another clinicopathological study found no cases of cystic change or gross necrosis in 51 cases^[3]. No calcification within gastric schwannomas was reported in previous reports. However, cysts, hemorrhagia, and necrosis were common in GISTs, and calcification was seen in 6% of GISTs^[14]. The differential diagnosis of gastric schwannomas and GISTs in EUS images are summarized in Table 3.

In conclusion, gastric schwannomas are rare benign mesenchymal tumors of the stomach. However, it is necessary to differentiate these tumors from other submucosal tumors of the stomach, particularly GISTs. The EUS features of gastric schwannomas are varied. On EUS evaluation, heterogeneous hypoechogenicity or isoechogenicity, a well-demarcated margin, fourth-layer origination, and lack of cystic change and calcification may be considered to be helpful findings for the diagnosis of gastric schwannoma. A marginal halo was perhaps the characteristic feature, but not an essential one. Ulceration may be seen in large tumors. More EUS studies should be conducted to delineate the characteristic features that can help differentiate these mesenchymal tumors.

Abstract

Radiation-induced gastritis is an infrequent cause of gastrointestinal bleeding. It is a serious complication arising from radiation therapy, and the standard treatment method has not been established. The initial injury is characteristically acute inflammation of gastric mucosa. We presented a 46-year-old male patient with hemorrhagic gastritis induced by external radiotherapy for metastatic retroperitoneal lymph node of hepatocellular carcinoma. The endoscopic examination showed diffuse edematous hyperemic mucosa with telangiectasias in the whole mucosa of the stomach and duodenal bulb. Multiple hemorrhagic patches with active oozing were found over the antrum. Anti-secretory therapy was initiated for hemostasis, but melena still occurred off and on. Finally, he was successfully treated by prednisolone therapy. We therefore strongly argue in favor of prednisolone therapy to effectively treat patients with radiation-induced hemorrhagic gastritis.

INTRODUCTION

Radiation-induced gastritis is a serious complication of radiation therapy and can cause upper gastrointestinal bleeding. There have been no effective options to manage this complication. We encountered a 46-year-old male patient with hemorrhagic gastritis induced by external radiotherapy for the treatment of metastatic retroperitoneal lymph node of hepatocellular carcinoma (HCC). Successful hemostasis was achieved with treatment of prednisolone.

CASE REPORT

A 46-year-old man diagnosed with HCC received left lobectomy in December 2010. Two courses of transcatheter arterial chemoembolization with 5-fluorouracil, oxaliplatin, mitomycin and lipiodol (5-10 mL) were administered from January 2011 to July 2011 for intrahepatic recurrence. He received liver transplantation in September 2011. He was treated with sorafenib 400 mg *bid* from January 2011. In November 2011, he received

Figure 1 Endoscopic appearance of antral mucosa. A: Multiple telangiectasias spontaneously bleeding at diffuse antral mucosa after radiation therapy; B: After prednisone was discontinued, multiple hemorrhagic spots were still visible at antral mucosa; C: After 1 mo of prednisone maintenance therapy, there were residual telangiectasias with no bleeding tendency.

helical radiotherapy using tomotherapy (total 63.7 Gy) for the treatment of metastatic retroperitoneal lymph node. The dosages delivered to the stomach, intestine and liver were 18.70 Gy, 18.10 Gy and 10.78 Gy, respectively. During the course of radiotherapy, sirolimus was continued against transplantation rejection and sorafenib was discontinued. Three months after radiotherapy, the patient had hematemesis and melena. He was admitted to the emergency room. His vital signs were quite unstable: blood pressure was 84/56 mmHg; heart rate was 92 beats/min and respiratory rate was 20 breaths/min. Laboratory evaluation revealed severe anemia with a hemoglobin level of 37 g/L, prothrombin time was 11.4 s, activated partial thromboplastin time was 27.5 s, international normalization ratio was 0.98 and platelets was 68×10^9 /L. Blood transfusion was administered.

The endoscopic examination showed diffuse edematous hyperemic mucosa with telangiectasia in the whole mucosa of the entire examined stomach and duodenal bulb. Multiple hemorrhagic patches with active oozing were visible over the antrum (Figure 1A). He was diagnosed as having radiation-induced gastritis. Omeprazole (40 mg *bid* *iv*) and sucralfate (1 g *tid* oral) were given for a week. However, upper gastrointestinal bleeding still occurred off and on. Due to the inaccessibility of argon plasma coagulation, he was treated with prednisolone. The starting dose of prednisolone was 40 mg daily. Hematemesis and melena stopped 3 d later, and fecal occult blood test was negative. Then, he received oral prednisone, 25 mg daily. The dosage was gradually reduced by 5 mg every 3 d and down to zero within 15 d after hospital discharge. His hemoglobin levels improved to 60 g/L. Unfortunately, 2 wk after prednisone was discontinued, his melena recurred. The endoscopic examination still showed multiple hemorrhagic spot at antral mucosa (Figure 1B). The hemoglobin levels decreased to 34 g/L. We treated him with prednisolone again. Within 3 d, his hematocrit stabilized and the melena resolved. He then received maintenance prednisone (10 mg daily). One month later, he underwent follow-up endoscopy, which revealed some residual telangiectasias with no bleeding friability (Figure 1C). No gastrointestinal bleeding recurred. His hemoglobin levels improved to 88 g/L without blood transfusions or iron supplements.

DISCUSSION

Radiation-induced gastritis is a serious complication of radiation therapy and difficult to manage. It usually happens 2-9 mo after initial radiotherapy^[1-3]. A high total dose and, above all, high daily fraction appear to be the main risk factors in gastric injuries. Radiologic durability dosage of the stomach and intestine is defined as 45 Gy, and that of rectum is defined as 55 Gy. The initial injury is characteristically acute inflammation of gastric mucosa. If injury progresses, vasculopathy may evolve to progressive obliterative endarteritis and endothelial proliferation, leading to mucosal ischemia, ulceration, and telangiectasias^[4]. The characteristic endoscopic finding is the presence of telangiectasia. Other endoscopic findings include diffuse erythema of mucosa, shallow or deep ulcers and scar formation.

Radiation-induced hemorrhagic gastritis is a diffuse process with multiple bleeding sites^[4]. The standard method has not been established. Repeated endoscopies and the anti-secretory agents all yielded unsatisfactory control of bleeding. Argon plasma coagulation had been reported for successful hemostasis of radiation-induced hemorrhagic gastritis, colitis and proctitis^[1,2,5-7]. Surgery may be necessary if other treatment fails, but it is associated with a high morbidity.

Rectal steroids have often been recommended for the treatment of radiation-induced proctitis. Kochhar *et al*^[8] reported that steroids successfully treated radiation-induced proctosigmoiditis. But only few instances of

steroids therapy for radiation induced gastritis have been reported. In our case, we chose to use prednisolone because prednisolone can reduce inflammation. Although the pathogenesis of radiation-induced gastritis is not entirely clear, it was presumed to be an inflammatory process. A large number of cell types, interacting molecular signals including cytokines and growth factors, and various molecules on the endothelial cell surface are involved. It was reported that the mucosal levels of interleukin (IL)-2, IL-6, and IL-8 were significantly higher in patients with radiation proctitis^[9]. Prednisolone can inhibit inflammation by a diverse array of mechanisms, including decreasing chemotaxis of monocytes and neutrophils, inhibiting adhesive molecule synthesis and decreasing eicosanoid production. Prednisolone's anti-inflammatory functions may reduce gastric mucosa damage and degeneration as well.

In this case, the upper gastrointestinal bleeding recurred when prednisone was discontinued. It indicated that sufficient time of prednisone administration is needed for the effective treatment. In fact, when the patient received prednisone for a prolonged duration, no gastrointestinal bleeding recurred. Therefore, the patients with radiation-induced hemorrhagic gastritis should continue with maintenance prednisone because the radiation-induced injury is a chronic course and may last a long time.

During radiotherapy, the patient continued taking sirolimus against transplantation rejection, which also has an anti-angiogenic effect. Many studies have shown that anti-angiogenetic agent in combination with radiotherapy produces a synergistic anti-tumor efficacy without increasing toxicity^[10,11].

This report described a further potential treatment modality for radiation-induced hemorrhagic gastritis. More patients and longer follow-up are necessary to confirm the effectiveness of prednisolone in this form of gastritis.

Abstract

The transjugular intrahepatic portosystemic shunt (TIPS) is an acceptable procedure that has proven benefits in the treatment of patients who have complications from portal hypertension due to liver cirrhosis. Delayed liver laceration is a rare complication of the TIPS procedure. We describe a patient with portal hypertension due to liver cirrhosis, who suddenly presented with abdominal hemorrhage and liver laceration 8 d after TIPS. Few reports have described complications after TIPS placement. To the best of our knowledge, this is the first report describing delayed liver laceration. This potential and serious complication appears to be specific and fatal for TIPS in portal hypertension. We advocate careful attention to the technique to avoid this complication, and timely treatment is extremely important.

Delayed liver laceration following transjugular intrahepatic portosystemic shunt for portal hypertension. *World J Gastroenterol* 2012; 18(48): 7405-7408 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i48/7405.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i48.7405>

INTRODUCTION

Since its first introduction in the 1990s, transjugular intrahepatic portosystemic shunt (TIPS) has played an increasingly important role in the management and treatment of the complications of portal hypertension (PH). Now, established indications for TIPS include active variceal hemorrhage not controlled by endoscopic and pharmacologic treatment (mainly from gastric and ectopic varices), secondary prevention of bleeding, refractory hydrothorax and ascites, Budd-Chiari and veno-occlusive syndrome, hepatopulmonary syndrome, hepatorenal syndrome, and prophylaxis of complications in patients with cirrhosis who need major abdominal surgery^[1-3].

TIPS as a treatment for PH has been performed for > 20 years in our hospital. Five hundred cases of PH have been treated^[4,5]. With improvement in the technical skills of interventional radiologists over time, technical complications such as abdominal bleeding, stent migration, hemobilia, and hepatic artery injury have become extremely rare^[6,7]. This paper reports a case of delayed liver laceration 8 d after TIPS in a patient with PH.

CASE REPORT

A 45-year-old female patient was admitted to our institution

Figure 1 Gastroscopy showing severe esophageal and gastric varices.

because of hematemesis. She had a few years history of PH due to liver cirrhosis of unclear etiology, and had been hospitalized twice for gastrointestinal bleeding. On examination, she was emaciated and had moderate ascites requiring diuretic treatment. Endoscopy showed severe hypertensive gastropathy with severe esophageal and gastric varices (Figure 1). Abdominal computed tomography demonstrated a classical PH appearance with liver cirrhosis and splenomegaly (Figure 2A). Plain chest film showed left hydrothorax. Abnormal laboratory findings on admission were as follows: hemoglobin concentration, 71 g/L; platelet count, $3 \times 10^{10}/L$. Child-Pugh class A and normal renal function are not laboratory findings and were not abnormal.

The TIPS procedure was performed according to the standard method under local anesthesia (1% lidocaine hydrochloride). After the right internal jugular vein was percutaneously punctured, a 10-Fr, 41-cm long sheath (Rösch-Uchida TIPS Puncture Set; Cook, Bloomington, IN, United States) was placed in the suprahepatic portion of the inferior vena. After catheterization of the right hepatic vein, measurement of hepatic venous pressure and portal puncture were performed. At no stage during attempted puncture of the portal vein was contrast agent seen to enter the hepatic arterial system, bile ducts, or peritoneal cavity. Portal venography was performed to evaluate the anatomy and determine the direction of portal flow (Figure 2B). With the use of a hydrophilic guide wire (Radiofocus guide wire; Terumo Europe, Leuven, Belgium), the portal vein was catheterized. The dilation of the intrahepatic parenchymal tract was performed using a low-profile balloon with 8 mm diameter. In this particular case with large varices of the gastric coronary vein, embolization using coils and gelatin sponge was performed to reduce the risk of rebleeding. Polytetrafluoroethylene (PTFE)-covered Fluency stent grafts (8 mm \times 6 cm, manufactured by Angiomed GmbH Co., subsidiary of C.R. Bard, Murray Hill, NJ, United States) were used. After placement of the stents, portography was performed to ensure no contrast extravasation within the shunt, and the portal pressure was measured (Figure 3). The portosystemic gradient reduced from 50 to 34 cm H₂O. The 5-Fr catheter should be routinely retained inside the portal vein through the right internal jugular vein after the procedure

for the purpose of postoperative regional anticoagulation (heparin 4000 U/d) and re-examination.

Doppler ultrasound of the liver on d 1 and 7 following TIPS confirmed shunt patency and showed no evidence of liver parenchymal hemorrhage. The patient was transferred onto low molecular weight heparin (4100 U/d) and hepatoprotective drugs (such as magnesium isoglycyrrhizinate injection 200 mg/d, polyene phosphatidylcholine injection 930 mg/d, and ornithine aspartate injection 20 g/d), and made good clinical progress.

On d 8 following TIPS she developed sudden severe right upper abdominal pain, which did not significantly improve after analgesic treatment. Laboratory findings showed a drop in hemoglobin to 49 g/L, with deterioration of liver and coagulation function: serum alanine aminotransferase (ALT), 202 U/L; serum aspartate aminotransferase (AST), 300 U/L; total bilirubin, 38 μ mol/L; prothrombin time, 22 s; and international normalized ratio, 1.8. At the same time, she developed clinical evidence of hypovolemic shock, with confusion, cool periphery, and systemic hypotension. Emergency ultrasound showed massive hemoperitoneum. The patient's anticoagulation therapy was stopped, and vasoactive drugs were given to maintain blood pressure. The same day the patient was transferred to the intensive care unit due to hemorrhagic shock with an Acute Physiology and Chronic Health Evaluation II score of 17. A large volume of blood (about 1 L) was drained from the abdominal cavity by paracente-

Figure 3 Completion venography of transjugular intrahepatic portosystemic shunt showing good flow and no contrast extravasation.

sis. Exploratory laparotomy revealed massive hemoperitoneum (3 L). The active bleeding source was located in the liver parenchyma behind the gallbladder bed of the right hepatic lobe and was controlled with direct suturing and perihepatic packing. Erythrocyte suspension, 25 U, fresh frozen plasma, 2 L, platelet concentrate, 10 U, and cryoprecipitate, 20 U, were infused during and after surgery. The bleeding had ceased and the packs were removed after 6 d. However, postoperative liver dysfunction gradually appeared. Total bilirubin continued to increase, up to 505 $\mu\text{mol/L}$, but ALT and AST were normal (cholenzyme separation). Finally, she died of liver failure 23 d after TIPS.

DISCUSSION

Since the first clinical application was presented by Rössle *et al*^[8] in 1989, TIPS has gained widespread popularity and has become the treatment of choice in many clinical scenarios for complications related to PH^[9]. TIPS is an interventional radiology procedure that results in decompression of the splanchnic venous system in patients with PH by creating a low-resistance channel between an intrahepatic branch of the portal vein and a main hepatic vein^[9]. When compared with endoscopic ligation and sclerotherapy, TIPS shows a significant advantage with respect to hemostasis (87% *vs* 45%, $P = 0.03$), rebleeding (31% *vs* 54%, $P = 0.0005$) and mortality (29% *vs* 48%, $P = 0.05$)^[10]. TIPS is as effective as surgical shunting in preventing variceal bleeding and is also more cost-effective^[11,12]. Evidence has now been provided that the use of TIPS at an early stage may represent a new perspective and improve the outcome and survival of high-risk bleeding patients selected by simple clinical prognostic indicators^[13]. It has been reported that, in patients with Child-Pugh class C disease or class B disease with active bleeding who were admitted for acute variceal bleeding, the early use of TIPS with an e-PTFE covered stent was associated with significant reductions in failure to control bleeding, rebleeding, and mortality, with no increase in the risk of hepatic encephalopathy^[14].

TIPS can markedly reduce portal pressure, but associated complications are also common. Direct procedure-

related complication rates during TIPS have been reported in up to 20% of procedures^[6]. Gaba *et al*^[15] have conducted an in-depth discussion of complications and how to avoid TIPS-related operations in 2010. Freedman *et al*^[6] have described a large series of TIPS complications, after analyzing TIPS procedures and complications at four American centers and reviewing the literature. They have reported that the most dangerous complications were related to transhepatic needle puncture, such as biliary duct injury, hemobilia, transcapsular tearing, arterial puncture, or portal venous rupture. In the event of such complications, direct surgical suture as well as local and perihepatic gauze packing can often effectively stop bleeding. However, if there has been uncontrollable bleeding despite repeated surgical interventions, postoperative evolution toward hepatic insufficiency (acute or progressive), and portal vein injuries that cannot be reconstructed, liver transplantation may be the only option to salvage the patient^[16].

The current patient with decompensated liver cirrhosis was admitted to hospital with upper gastrointestinal bleeding. After adjustment of the liver and blood coagulation function, TIPS was performed to prevent variceal rebleeding. Routine anticoagulation with low molecular weight heparin was given in order to prevent early stent thrombosis and improve the stent patency rate. However, delayed liver laceration suddenly occurred 8 d after surgery. We consider that it may have been related to the following factors: (1) patients with liver cirrhosis suffer from coagulation disorders; (2) small blood vessels of liver parenchyma were damaged during the TIPS procedure; and (3) stent anticoagulation was given with low molecular weight heparin when thrombosis had not formed in a timely manner.

To the best of our knowledge, delayed liver laceration after TIPS has not been reported previously. There have been only three previous reports about late intrahepatic hematoma following TIPS, occurring in patients with Budd-Chiari syndrome (BCS). In each case the hematoma resolved with conservative management. It was considered that the cause of hematoma may have been related to the use of postoperative heparin^[17].

With the introduction of the e-PTFE covered stent, the long-term patency of shunts has significantly improved^[2,4,11,18]. Regular anticoagulation is given to prevent early shunt thrombosis through systemic or local application. A randomized study of anticoagulation following TIPS has reported reduced incidence of early thrombosis but no instances of intrahepatic hemorrhage, although this study comprised only 49 patients, 25 of whom stopped anticoagulation 3 d after TIPS^[19].

Advanced cirrhosis is often accompanied by severe liver atrophy, rigidity of the liver, and enlargement of liver fissure. Anatomical variations of intrahepatic branches of the portal and hepatic veins affect the success rate of the puncture. This often requires repeated puncture or appropriate adjustments of the angle^[20]. Many candidates for TIPS have cirrhosis and are more prone to arterial

injuries because of enlargement and increased flow in the hepatic arteries. Therefore, multiple puncture and early postoperative anticoagulation may be an important risk factor for bleeding. So, early and timely examination has become an effective means of diagnosis and treatment of such complications. Some studies have reported that dynamic gadolinium-enhanced serial magnetic resonance examination may be useful to demonstrate and localize active bleeding, and if performed serially, may have the potential to quantify the rate of bleeding, which may potentially decrease the time needed to identify a site of hemorrhage during surgery^[21].

In conclusion, delayed liver laceration is a rare but fatal complication of TIPS, which to date has not been reported in patients with PH. TIPS is increasingly accepted as an important management option for PH and other diseases such as BCS, therefore, this complication must be borne in mind. We advocate that careful attention to technique is vital to avoid complications. However, when complications do arise, the first step to stop bleeding is immediate imaging and secure local hemostasis with direct suturing and perihepatic gauze packing. If the bleeding does not stop, based on the clinical status and concomitant liver failure, liver transplantation may be necessary.

Abstract

Primary hepatic lymphoma is extremely rare, and only a few cases have been described on positron emission tomography (PET) or PET/computed tomography (PET/CT) imaging in the English literature. We report a case of a 55-year-old woman who presented with low-grade fever and weight loss of three months. On CT scanning, a mass was identified which appeared to be a hypoattenuating lesion, on ultrasonographic imaging, the mass was hypoechoic, therefore, liver abscess or hepatic metastasis from a gastrointestinal primary was initially suspected. Tumor markers such as alpha-fetoprotein, carcinoembryonic antigen and carbohydrate antigen 19-9 were within normal limits. PET/CT demonstrated a large abnormal ring-like hypermetabolic focus in the right liver lobe. The lesion was resected and the histo-

INTRODUCTION

Primary hepatic lymphoma (PHL) is an uncommon malignancy of the liver, and has been described in only a few reports in the English literature. The prevalence of PHL is 0.4% in extranodal non-Hodgkin's lymphomas, and 0.016% in all non-Hodgkin's lymphomas^[1]. The incidence of PHL has increased in recent years, and may be related to the human immunodeficiency virus (HIV) epidemic. Due to its rarity, clinical manifestations and laboratory tests are non-specific, the disease is usually misdiagnosed preoperatively, and the final diagnosis depends on histological examination from liver biopsy. In

the present report, we present a patient with pathologically confirmed primary hepatic diffuse large B cell lymphoma originating from the germinal center.

CASE REPORT

A 55-year-old woman presented with intermittent low-grade fever and weight loss of 10 kg in the previous 3 mo. She had no remarkable past medical history except for an operation for a benign gastric stromal tumor. She was admitted to our hospital due to right upper quadrant abdominal pain in June 2009. Gastroscopy of the esophagus suggested stromal tumor, and the patient underwent endoscopic resection of the esophageal stromal tumor. Immunohistochemical examination showed that the markers CD34, alpha-smooth muscle actin and Des were positive, and CD117 as well as S-100 were negative. On examination, the patient was in good spirits, the skin and mucosa were anicteric, there was no splenomegaly or enlarged superficial lymph nodes, and the liver was not palpable. Laboratory findings on admission were as follows: total white cell count $7.9 \times 10^9/L$, hematocrit 0.29 L/L, hemoglobin 8.7 g/dL; total bilirubin 11.6 $\mu\text{mol/L}$ (normal range 3.4–20.5 $\mu\text{mol/L}$), aspartate aminotransferase 17 IU/L (normal range 0–60 IU/L), alanine aminotransferase 7 IU/L (normal range 0–60 IU/L), alkaline phosphatase 123 IU/L (normal range 40–150 IU/L); lactate dehydrogenase 209.0 IU/L (normal range 135.0–215.0 IU/L), C-reactive protein 52.50 mg/L (normal range 0.00–80.00 mg/L), calcium 2.09 mmol/L (normal range 2.00–2.60 mmol/L); and positive antibody for hepatitis B virus, and negative antibody for hepatitis C virus. Serology for HIV was negative. The levels of tumor markers, such as alpha-fetoprotein, carcinoembryonic antigen, and carbohydrate antigen 19-9 were within normal limits. Chest X-ray did not reveal any abnormalities. On ultrasound, the lesion showed heterogeneous hypo-echoicity relative to normal hepatic parenchyma in the right liver and its border was clear, dotted blood flow could be seen around the edge of the lesion on Color Doppler imaging. Computed tomography showed a solid, cystic hypodense lesion in the right hepatic lobe measuring 10.0 cm \times 6.1 cm on plain image. The enhancement image after injection of iodinated contrast revealed mild rim enhancement in the arterial phase. Obvious enhancement in the portal venous phase was observed (Figure 1). Primary hepatocarcinoma, liver abscess, and metastasis from the gastrointestinal tract were initially suspected. In order to make an accurate diagnosis and stage the lesion, the patient was referred for a whole body positron emission tomography/computed tomography (PET/CT) scan to identify other sites of involvement. The patient was injected with 6.1 millicuries of ^{18}F -fluorodeoxyglucose (FDG) and after 60 min of uptake time, she underwent a whole body scan in a dedicated PET/CT scanner. An abnormal ring-like metabolic focus in the right liver lobe was observed, with a maximum FDG uptake of 17.7 (Figure 2), the center exhibited less FDG uptake, and other body sites

were negative. Hepatocarcinoma and liver abscess were suspected. In order to establish a diagnosis, ultrasound-guided percutaneous liver biopsy was performed, and five strips of liver tissue were extracted from the lesion. However, examination of the tissue was inconclusive as it showed fibroplasia and hyaline degeneration interspersed with lymphocytes. The patient underwent open laparotomy and partial hepatectomy for diagnosis and treatment.

There was no significant mesenteric or retroperitoneal lymphadenopathy, no ascites were observed in the abdominal cavity, and the gastrointestinal tract was normal. The tumor was located in segments IV and I of the right liver lobe adhered to the hepatic flexure of the colon and renal capsule.

The intraoperative frozen section revealed a small round cell tumor. Microscopic histopathological examination showed a multinucleated giant cell tumor and hepatic sinusoidal infiltration, interstitial lymphocyte reactive hyperplasia with spotting hemorrhagic areas and necrosis. The surrounding liver tissues revealed intrahepatic cholestasis and lymphocytic infiltration around the bile ducts. Immunohistochemical staining was positive for CD20, Bcl-6, Mum-1 and Ki-67 ($> 80\%$), and negative for CD30, Bcl-2, and cytokeratin (Figure 3). The diagnosis of diffuse B-cell lymphoma originating from the germinal center was made.

The patient was discharged 2 wk after surgery, and did not receive chemotherapy or radiotherapy. After 25 mo follow-up, she was in good health.

DISCUSSION

PHL, which is defined as a lesion or lesions confined to the liver only without the involvement of any other organ or lymph nodes, is extremely rare, accounting for less than 0.01% of all non-Hodgkin's lymphomas, and can occur in any age group but is usually found in middle-aged men. The pathogenesis of PHL is unclear, and it is usually seen in organ transplant recipients, in patients receiving immunosuppressive therapy and in individuals with AIDS. In recent years, studies have indicated that hepatitis C infection is strongly related to PHL, a possible cause is hepatitis C virus stimulating B lymphocytes and chronic polyclonal proliferation, leading to liver lymphoma^[2,3].

The clinical manifestations are atypical including fever, weight loss, night sweat and right upper abdominal pain. Lactate dehydrogenase and blood calcium are sometimes elevated^[4,5]. Primary hepatic lymphoma presenting as fulminant hepatic failure with hyperferritinemia was described by Haider *et al*^[6]. The most frequent pathology in PHL is diffuse large B cell followed by small lymphocytic, T cell, follicular and marginal B cell lymphoma. PHL responds to therapy and may have a better prognosis than hepatocellular carcinoma, as it is chemosensitive, and early aggressive combination chemotherapy may result in sustained remission^[7].

Primary hepatic lymphoma has its own characteristic imaging features. It can be classified into 3 morphologic

Figure 1 Obvious enhancement in the portal venous phase was observed. A: A hypodense area in the right liver lobe was seen on plain computed tomography; B: The hypodense lesion showed mild rim enhancement in the arterial phase; C: Obvious enhancement was seen in the portal phase.

Figure 2 An abnormal ring-like metabolic focus in the right liver lobe was observed, with a maximum fluorodeoxyglucose uptake of 17.7. A: Positron emission tomography/ computed tomography imaging showed a high metabolic focus in the right liver lobe; B: Fusion imaging revealed a ring-like high uptake focus with lower uptake in the center of the lesion (as shown by the white arrow).

Figure 3 Immunohistochemical staining was positive for CD20, Bcl-6, Mum-1, Ki-67 and negative for CD30, Bcl-2, cytokeratin. A: The normal structure of liver tissue was damaged, and showed dysplastic, almost naked nuclear lymphocytes, diffuse infiltration of liver tissue, tumor cells were mainly composed of round and oval cells, and spindle, polygonal, and multinucleated giant tumor cells were also seen (hematoxylin and eosin, $\times 400$); B: Bcl-6 was positive, and CD10 as well as Mum-1 were negative (immunohistochemistry, $\times 400$).

patterns: solitary liver mass, multiple focal nodules and diffuse infiltrative disease, the first 2 patterns are the most common^[8], and an imaging study showed a solitary space-occupying lesion or multiple heterogeneous lesions which were well-defined suggesting hepatocarcinoma or metastasis from the gastrointestinal tract^[9]. Elsayes *et al*^[10] described 12 cases of PHL, three of which presented with a single focal lesion (25%), eight (67%) patients presented with multiple well-defined lesions, and one patient (8%) presented with diffuse hepatic involvement on CT imaging. The lesions in three patients demonstrated rim enhancement following intravenous iodinated contrast administration. The features of rim enhancement were

similar to those in our case. PHLs are usually hypoechoic relative to normal liver on ultrasound imaging, and in a minority of cases, the lesions can be anechoic, hypoechoic areas with high perinodular and low intranodular vascularization on Doppler sonography, which are easily misdiagnosed as angiomas^[11,12]. On contrast-enhanced ultrasonography, the lesion has mild inhomogeneous hyperenhancement in the arterial phase and wash-out in the portal and late phases^[13]. On magnetic resonance imaging (MRI), PHLs usually have moderate to high signal intensity on T2-weighted images and are mild to moderate hypointense relative to liver on T1-weighted images^[14,15]. The enhanced image is variable, mainly manifestations

of early intense ring or predominantly ring enhancement. The imaging features of PHL on ultrasound, MRI and CT have been reported, while the imaging features of PHL on PET and single photon emission computed tomography are relatively rare (the number of PET or PET/CT studies is small compared to the large number of ultrasound CT and MRI studies on PHL). PET/CT scanning which can produce whole body imaging data and distinguish primary liver lesions from metastatic disease is superior to CT, MRI and ultrasound which only visualize a limited portion of the body. Thus, PET/CT is advantageous in the diagnosis and treatment of liver lymphoma. To the best of our knowledge, three cases of multiple PHL and one case of diffuse infiltrative disease have been described using PET/CT imaging. While diffuse infiltrative disease is extremely rare, Kang *et al*^[16] reported one case using PET imaging in the English literature, this type of PHL is easily misdiagnosed as hepatitis or diffuse cholangiocellular carcinoma. However, a solitary PHL on PET/CT imaging has not been reported. Whether primary or secondary lymphoma of the liver is present, imaging with FDG or Ga67 PET showed high uptake. In our case report, the lesion demonstrated a ring-like hypermetabolic area, which suggested tumor viability. The level of isotope uptake may correlate with disease activity and tumor proliferation^[17,18].

In conclusion, PHL is a rare disease, its clinical symptoms, laboratory results, and imaging results are non-specific, therefore, it is difficult to establish a diagnosis immediately. Thus, when a solitary hypermetabolic lesion on PET/CT scanning is found in the liver and no other organ or tissue is involved, PHL should be considered, hepatoma and liver abscess should be excluded and a liver biopsy performed for further management.

ACKNOWLEDGMENTS

Acknowledgments to reviewers of World Journal of Gastroenterology

We acknowledge our sincere thanks to our reviewers. Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of our World Series Journals. Both the editors of the journals and authors of the manuscripts submitted to the journals are grateful to the following reviewers for reviewing the articles (either published or rejected) over the past period of time.

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homoge-

neous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval

of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A....; B....; C....; D....; E....; F....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals ac-

cording to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 ± 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
