### Abstract

There have been some breakthroughs in the diagnosis and treatment of esophageal achalasia in the past few years. First, the introduction of high-resolution manometry with pressure topography plotting as a new diagnostic tool has made it possible to classify achalasia into three subtypes. The most favorable outcome is predicted for patients receiving treatment for type II achalasia (achalasia with compression). Patients with type I (classic achalasia) and type III achalasia (spastic achalasia) experience a less favorable outcome. Second, the first multicenter randomized controlled trial published by the European Achalasia Trial group reported 2-year follow-up results indicating that laparoscopic Heller myotomy was not superior to endoscopic pneumatic dilation (PD). Although the follow-up period was not long enough to reach a convincing conclusion, it merits the continued use of PD as a generally available technique in gastroenterology. Third, the novel

endoscopic technique peroral endoscopic myotomy is a promising option for treating achalasia, but it requires increased experience and cautious evaluation. Despite all this good news, the bottom line is a real breakthrough from the basic studies to identify the actual cause of achalasia that may impede treatment success is still anticipated.

### INTRODUCTION

Achalasia is the only primary motor disorder of the esophagus with a well-understood pathophysiology. It affects both sexes and all races equally<sup>[1-3]</sup>. Achalasia involves the selective loss of inhibitory neurons in the myenteric plexus, leading to the production of vasoactive intestinal polypeptide (VIP), nitric oxide (NO), and inflammatory infiltrate responsible for abnormal lower esophageal sphincter (LES) dysfunction. An unopposed excitation of the LES causes its dysfunction or failure to relax in response to swallowing<sup>[3,4]</sup>.

Clinical presentations include dysphagia for both liquid and solid food, and food regurgitation may be severe enough to produce pulmonary complications such as cough or aspiration pneumonia. Weight loss usually

occurs as a result. The diagnosis of achalasia is made on the basis of the results of barium esophagography, esophageal manometry, and endoscopy. Typical radiological signs are classic “bird-beak” of the gastroesophageal junction, with atonia and a dilated esophageal body observed by barium ingestion and fluoroscopy. Manometry is still the standard diagnostic test for achalasia. The basic criteria required for diagnosis of achalasia include the absence of relaxation of the LES or abnormal swallowing relaxation of the LES and the absence of peristalsis in the esophageal body. However, an endoscopic examination, preferably endoscopic ultrasonography or computed tomography, is always necessary to distinguish primary achalasia from the secondary form<sup>[5]</sup>, in cases of possible malignancy<sup>[6]</sup>. A greater risk of esophageal squamous cell carcinoma among achalasia patients is well established. Male achalasia patients have substantially greater risks for both squamous cell carcinoma and adenocarcinoma of the esophagus<sup>[7]</sup>. Recent advances in the diagnosis of esophageal achalasia by using updated high-resolution manometry (HRM) with pressure topography plotting have made it possible to classify achalasia into three subtypes. Furthermore, it is now possible to predict the outcome of each type of achalasia<sup>[8-10]</sup>. In this paper, the implications of the recent findings in the diagnosis and treatment of esophageal achalasia are reviewed and discussed.

## **PATHOGENESIS**

The mechanisms responsible for the selective loss of inhibitory neurons in the myenteric plexus that produces VIP, NO and inflammatory infiltrate responsible for abnormal LES dysfunction is still not well understood<sup>[11]</sup>. However, specimens taken from autopsy or myotomy have shown the histological damage of the esophageal myenteric plexus and an inflammatory response consisting of CD3/CD8-positive cytotoxic T lymphocytes, variable numbers of eosinophils and mast cells, loss of ganglion cells, and neurofibrosis<sup>[12,13]</sup>. These events occur even at the early inflammatory stages of achalasia, and the underlying cause has not yet been identified. Previous studies have implicated hereditary, neurodegenerative, genetic, infectious, and autoimmune mechanisms. The most acceptable hypothesis suggests that achalasia may be caused by viral and autoimmune factors, leading to the inflammatory changes and damage to the myenteric plexus.

Achalasia patients with certain genetic backgrounds are reported to develop an autoimmune reaction and hence the production of autoantibodies that cause chronic inflammation and destruction of inhibitory neurons<sup>[12,13]</sup>. In addition, infiltration of the myenteric ganglia with CD3/CD8-positive lymphocytes that express activation markers, IgM antibodies, and evidence of complement activation have been observed within the myenteric ganglia<sup>[14-16]</sup>. Moreover, antibodies against myenteric neurons have been detected in the serum of patients with esophageal achalasia; especially in those with a specific

human leukocyte antigen genotype (DQA1 × 0103 and DQB1 × 0603 alleles)<sup>[17-19]</sup>. The above evidence indicates that an autoimmune mechanism likely plays an important role in achalasia. However, the trigger for the destructive autoimmune events is unknown. So far, viral infection is believed to be the main cause. Some possible causative infections are varicella zoster and measles viruses<sup>[16,20-22]</sup>. However, some may argue that antineuronal antibodies have also been reported in the serum of gastroesophageal reflux disease patients and even in healthy individuals, suggesting that these antibodies may simply result from tissue damage secondary to inflammation<sup>[19]</sup>. The other unanswered question is why only neurons in the esophagus and LES are destroyed. The results of some studies have led to the hypothesis that neurotropic viruses, especially those with a predilection for squamous epithelium, could be involved; however, these findings have been inconsistent<sup>[16,20-23]</sup>.

Although there have been many excellent basic studies, the presence of viral antibodies in the serum of patients has been an inconsistent finding. The method to verify the actual cause of achalasia that may impede treatment success is yet to be determined.

## **DIAGNOSIS**

The diagnosis of achalasia is on the basis of the results of gastroscopy, manometry, and timed barium esophagography. Pseudoachalasia is always excluded by either computed tomography or endoscopic ultrasonography. Since the emergence of HRM with pressure topography plotting, esophageal achalasia can be classified into three subtypes<sup>[8-10]</sup>. In type I achalasia (classic achalasia), impaired LES relaxation but no significant pressurization within the esophageal body is observed. In type II achalasia (with compression), swallowing of water causes rapid panesophageal pressurization. This may exceed LES pressure, causing the esophagus to empty. Type III achalasia (spastic achalasia) is also associated with rapidly propagated pressurization; however, the pressurization is attributable to an abnormal lumen, obliterating contraction. HRM can be used to predict the outcome of each type of achalasia. Patients in whom HRM shows type II achalasia (esophageal pressurization) are more likely to respond to therapies such as pneumatic dilation (PD), heller myotomy (HM), and botulinum toxin (BT) (overall, 70%-100%), compared to those with type I (overall, ≥ 50%-63.3%) and type III (overall, about 30%) achalasia<sup>[8,10]</sup>. HRM may play an increasingly important role in the diagnosis of esophageal achalasia in the future, especially when the technique becomes more affordable.

## **CURRENT TREATMENT OPTIONS**

Currently, there is no cure for esophageal achalasia. The only available therapeutic options are to loosen the LES and treat the symptoms<sup>[24]</sup>. However, the advantages of each option must be considered in the patients.

Pharmacological management such as smooth muscle relaxation usually plays a minor role in the treatment of esophageal achalasia<sup>[2,24]</sup>. Nitrates increase NO concentration in smooth muscle cells, and calcium antagonists block calcium and hence esophageal muscle contractions. By so doing, LES pressure can be reduced, but the efficacy is usually unsatisfactory and incomplete, with intolerable side effects such as headache, dizziness, and pedal edema. This is the same for other drugs such as sildenafil<sup>[25]</sup>.

## ENDOSCOPIC TREATMENT

Endoscopic treatment with BT injection at the terminal nerve endings of myoneural junctions prevents the release of acetylcholine from vesicles. This causes chemical denervation, which may last for several months<sup>[26]</sup>. As a result of its wider safety range and fewer complications, local injection of BT into the LES muscle of patients with achalasia lowers LES tone, and the patient becomes asymptomatic. This treatment yields excellent immediate responses with success rates of > 90%. However, the results last only 6-9 mo on average in most patients, and only half of all the patients benefit for > 1 year<sup>[27]</sup>. Complications of BT therapy for achalasia are minor because the dosage used is too small to induce serious adverse effects such as generalized paralysis. It is therefore used to treat elderly patients or patients with high surgical risks<sup>[28]</sup>.

The most commonly used endoscopic balloon dilator is the rigiflex dilator. The dilation procedure can be performed under fluoroscopic<sup>[29]</sup> or endoscopic guidance<sup>[30,31]</sup>. The number of dilation sessions and the inflation time needed for a successful dilation vary and are operator dependent. Immediate and short-term results have reportedly been good in most series<sup>[30-33]</sup>. However, large-scale long-term follow-up investigations<sup>[28,34,35]</sup> have reported unfavorable recurrence in patients who have undergone fluoroscopically guided PD. During a prolonged observation period (median, 13.8 years) in a prospective follow-up investigation study conducted by Eckardt *et al.*<sup>[29]</sup>, only 40% of the patients treated using a single PD procedure remained in remission at 5 years. Generally, the response to PD is still determined on the basis of subjective improvement in symptoms, such as dysphagia, regurgitation, and chest pain, by performing structured interviews with validated symptom score methods<sup>[29,36]</sup>. However, additional radiographic findings could reliably predict clinical remission and strongly suggest the need for further treatment in patients with poor esophageal clearance after each dilation. This could prevent sigmoid-type achalasia<sup>[37-39]</sup>. It is generally accepted that the predictors of risk factors for relapse after PD include young age (< 40-45 years), male sex, single dilation with a 3.0 cm balloon, post-treatment LES pressure > 10-15 mmHg, poor esophageal emptying after timed barium swallow, and type I and type III achalasia pattern on HRM<sup>[2,40]</sup>. Complications attributable to PD are uncommon. The most severe complication is perfora-

tion<sup>[41]</sup>, which was reported to be approximately 2% in a recent analysis by Katzka *et al.*<sup>[42]</sup>.

Peroral endoscopic myotomy (POEM) is a novel endoscopic esophagomyotomy for achalasia that was first reported by Pasricha *et al.*<sup>[43]</sup> in porcine models and subsequently by Inoue *et al.*<sup>[44]</sup> in humans. POEM is performed by dissection and division of the inner circular muscle layer of the esophagus through a submucosal tunnel created endoscopically by a small proximal opening in the esophageal mucosa. POEM can be used to perform deeper myotomy incisions in the thoracic esophagus than that performed in surgical myotomy, which is difficult for the surgeon, and is indicated especially for patients with advanced disease and for those with severe fibrosis. Theoretically, injury to the vagus nerve should be less than that with the surgical approach. So far, several centers are using the POEM technique and have achieved good short-term results without serious complications, but long-term follow-up results are required<sup>[45]</sup>. There is concern that POEM is a sophisticated and demanding technique, even for experienced endoscopists, and serious complications such as purulent mediastinitis may develop. Revisional surgery might be difficult and involve extensive procedures such as esophagectomy because the plane between the submucosal and muscular layers will be inflamed and scarred after the endoluminal approach<sup>[46]</sup>.

A few Chinese studies have reported the utility of self-expanding, 30-mm metallic stents for achalasia at a single center over a 10- to 13-year period, with a long-term clinical success rate > 80%<sup>[47-50]</sup>. There were no perforations or mortality associated with the treatment, but stent migration occurred in 5% of the patients, reflux in 20%, and chest pain in 38.7%. Overall, the self-expanding, 30-mm metallic stents were associated with better long-term clinical efficacy in the treatment of patients with achalasia than treatment with PD.

## SURGICAL TREATMENT

From a surgical point of view, minimally invasive HM has become the gold standard procedure for achalasia in the spectrum of current treatment options<sup>[51,52]</sup>. Myotomy of the LES is the most direct method used and by far the best treatment modality for satisfactory long-term results with very low mortality. Overall success rates of laparoscopic HM (LHM) were 47%-82% at 10 years<sup>[53,54]</sup>. Systematic reviews and meta-analysis that have compared existing treatment methods for achalasia have found that surgery is superior to PD<sup>[55,56]</sup>. However, the major adverse event after surgery is severe reflux. There is much debate on the role of fundoplication with myotomy in the reported literature<sup>[57-59]</sup>. Intraoperative endoscopy during videoscopic HM is used to guide the extent and adequacy of myotomy by utilizing a focused dissection with preservation of the natural antireflux mechanisms around the gastroesophageal junction and by limiting the extent of myotomy along the cardia. By

so doing, postoperative reflux symptoms are minimized. A concomitant endoscope examination during HM to guide myotomy and routine fundoplication is clinically necessary, despite disagreement about the fundoplication procedure<sup>[60,61]</sup>. In addition, there is a lot of debate on the choice of laparoscopic cardiomyotomy as the primary treatment for achalasia or as a second-line treatment following the failure of nonsurgical intervention<sup>[62]</sup>. Some doctors believe that laparoscopic cardiomyotomy can be more technically difficult following PD<sup>[63]</sup>. However, it has been shown that laparoscopic cardiomyotomy can be as safe and effective as first- or second-line treatment, even after the failure of PD<sup>[64]</sup>. In general, esophagectomy should be reserved only for those cases in which simpler operations have failed. In summary, as stated in the recent Kagoshima consensus, despite the variations as to the length of the myotomy and the addition of an antireflux procedure, good overall long-term results suggest that these operative variations are not critical<sup>[65]</sup>.

## WHICH IS THE BETTER CHOICE: LHM OR PD? THE ONGOING DEBATE

In general, LHM is considered to be superior to PD for treating achalasia. Many experts have regarded LHM as the first choice of treatment for achalasia, at the cost of reflux complications. However, it should be noted that the first randomized controlled multicenter trial published by the European Achalasia Trial group that compared LHM and PD reported that, after 2 years of follow-up, LHM was not associated with superior rates of therapeutic success<sup>[66]</sup>. The large sample size gathered from 15 European centers and the excellent design of the study gave adequate statistical power for obtaining convincing results for the two treatment groups. Perforation of the esophagus occurred in 4% of the patients during PD, whereas mucosal tears occurred in 12% during LHM. Abnormal exposure to esophageal acid was observed in 15% and 23% of the patients in the PD and LHM groups, respectively. In addition, when considering the cost-effectiveness of treatment strategies for achalasia, laparoscopic myotomy has a higher initial cost, and PD is the most cost-effective treatment option for adults with achalasia. It is unclear how the results of the European Achalasia Trial actually affect the ongoing debate between gastroenterologists and surgeons on the treatment of choice for esophageal achalasia. This study had the following limitations. First, this was only a 2-year cohort study, and the intermediate and long-term remission rates have yet to be proven. Second, the good results for PD may be questioned by the definition of treatment failure in redilation sessions. In fact, all patients in the PD group routinely received at least two sessions of dilation. A maximum of three redilation sessions was allowed. However, this is an ongoing study, and more information will be collected in the future. The debate on which is the better choice between LHM and PD for

esophageal achalasia is ongoing; however, it is generally accepted that myotomy is usually suggested for younger patients (age, < 40-45 years), male patients, and those with pulmonary symptoms who failed to respond to one or two initial dilations<sup>[2,67]</sup>.

In summary, despite the ongoing debate and the report of the first randomized control trial, the minimally invasive surgical treatment seems to yield better results than PD with the currently available evidence, despite being less cost-effective and resulting in more reflux symptoms. POEM is a promising technique and is associated with good short-term results without serious complications, but long-term results are not yet available. Despite these advancements, the actual cause of achalasia has not yet been identified, and this knowledge may improve treatment success in the future.

Enzyme-linked immunosorbent assay was used to measure blood circulating ghrelin, somatostatin (SST) and glucose-dependent insulinotropic peptide (GIP) levels.

**RESULTS:** Results show an unexpected dual regulatory role for epithelial *Pten* signalling in the specification/differentiation of enteroendocrine cell subpopulations in the small intestine. Our data indicate that *Pten* positively regulates chromogranin A (CgA) expressing subpopulations, including cells expressing secretin, ghrelin, gastrin and cholecystokinin (CCK). In contrast, *Pten* negatively regulates the enteroendocrine subtype specification of non-expressing CgA cells such as GIP and SST expressing cells.

**CONCLUSION:** The present results demonstrate that *Pten* signalling favours the enteroendocrine progenitor to specify into cells expressing CgA including those producing CCK, gastrin and ghrelin.

Roy SAB, Langlois MJ, Carrier JC, Boudreau F, Rivard N, Perreault N. Dual regulatory role for phosphatase and tensin homolog in specification of intestinal endocrine cell subtypes. *World J Gastroenterol* 2012; 18(14): 1579-1589 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i14/1579.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i14.1579>

### Abstract

**AIM:** To investigate the impact of phosphatase and tensin homolog (*Pten*) in the specification of intestinal enteroendocrine subpopulations.

**METHODS:** Using the Cre/loxP system, a mouse with conditional intestinal epithelial *Pten* deficiency was generated. *Pten* mutant mice and controls were sacrificed and small intestines collected for immunofluorescence and quantitative real-time polymerase chain reaction. Blood was collected on 16 h fasted mice by cardiac puncture.

### INTRODUCTION

The phosphatase and tensin homolog (*PTEN*) tumour

suppressor gene is one of the most frequently mutated/deleted genes in various human cancers<sup>[1,2]</sup>. PTEN is a lipid and protein phosphatase. Its best-known substrate, the phosphatidylinositol 3,4,5-trisphosphate (PIP3), is a lipid second messenger mainly produced by class IA phosphatidylinositol 3-kinases (PI3Ks)<sup>[3]</sup>. PTEN dephosphorylates PIP3 to produce phosphatidylinositol 4,5-bisphosphate, which inhibits PI3K-dependent effectors such as the downstream kinases Akt and pyruvate dehydrogenase kinase 1. PI3Ks have been implicated in many signalling pathways that regulate cell survival, growth, proliferation, migration, phagocytosis, and metabolism<sup>[4]</sup>. PTEN has also been shown to regulate genomic stability<sup>[5,6]</sup>, stem cell renewal<sup>[7,8]</sup>, senescence<sup>[9]</sup> and cell differentiation<sup>[10-12]</sup>.

The multiple cellular functions of PTEN suggest that this protein plays major roles in overall system homeostasis. Indeed, homozygous deletion of *Pten* in the mouse causes early embryonic lethality by embryonic day (E) 9.5, whereas *Pten* heterozygous mice (*Pten*<sup>+/-</sup>) develop, over a period of time, various dysplasia and hyperplasia in organs such as the breast, thyroid, prostate and intestine<sup>[1,2,13]</sup>. As reviewed by Knobbe *et al*<sup>[14]</sup>, *Pten* has also been conditionally deleted in many specific tissues. These models have established the tumour suppressive function of *Pten* but have also unravelled its important role in the maintenance of normal physiological functions in various tissues such as the immune system, skin, lung, liver, pancreas and hypothalamus<sup>[14]</sup>.

In a previous study, we reported that *Pten* is important for intestinal homeostasis<sup>[10]</sup>. The villin-Cre system was used to specifically inactivate *Pten* in the mouse intestinal epithelium. *Pten* mutant mice developed an intestinalomegaly associated with an increase in epithelial cell proliferation. Histological analysis also demonstrated significant perturbation of the crypt-villus architecture, a marked increase in goblet cells and a decrease in enteroendocrine cells, suggesting a role for *Pten* in the commitment of the multipotential-secretory precursor cell<sup>[10]</sup>.

Enteroendocrine cells are hormone-secreting epithelial cells that are scattered throughout the gastrointestinal epithelium and although they represent only 1% of the intestinal epithelium, taken together, they constitute the major endocrine organ of the body<sup>[15,16]</sup>. At least 10 different enteroendocrine cell types have been identified in the small intestine and are classified based on their main hormonal products<sup>[16,17]</sup>. The various hormones produced by these endocrine cells [ghrelin (GHR), gastrin-releasing peptide (GRP), glucose-dependent insulinotropic peptide (GIP), secretin (SCT), peptide YY (PYY), glucagon-like peptide-1 (GLP-1), glucagon-like peptide-2 (GLP-2), cholecystokinin (CCK), neurotensin, serotonin, substance P, somatostatin (SST) and motilin] control important physiological functions, such as gastrointestinal motility, glycaemia, exocrine pancreatic secretion, biliary secretion, digestion, gut epithelial renewal and appetite<sup>[16,18,19]</sup>. Most enteroendocrine cell types secrete chromogranin A (CgA), a soluble glycoprotein stored with hormones and neuropeptides in secretory granules of endocrine cells.

The important role of enteroendocrine cells in whole body homeostasis prompted us to further analyze the effect of intestinal epithelial deletion of *Pten* on the specification of the various enteroendocrine subpopulations. Using our Cre/loxP *Pten* conditional knock out mouse model<sup>[10]</sup>, we report herein an unexpected dual regulatory role for epithelial *Pten* signalling in the specification of enteroendocrine cells. Our data indicate that *Pten* positively influences the determination and specification of CgA-expressing cell subpopulations in the small intestine including those expressing secretin, ghrelin, gastrin and CCK. Conversely, *Pten* limits determination and specification of non-expressing CgA endocrine cell subpopulations, including GIP and SST.

## MATERIALS AND METHODS

### Animals

BALB/*c-Pten*<sup>fx/fx</sup> mice were purchased from The Jackson Laboratory (Bar Harbor, ME, United states). The C57BL/6 12.4KbVilCre transgenic line was provided by Dr. Deborah Gumucio (University of Michigan, Ann Arbor, MI, United states)<sup>[20]</sup>. Genomic DNA was isolated using the Spin Doctor genomic DNA kit from Gerard Biotech according to the manufacturer's protocol. Both mutations were genotyped following protocols already published<sup>[20]</sup> or as directed by The Jackson Laboratory. For this study, the BALB/*c-Pten*<sup>fx/fx</sup> mice were first crossed with the C57BL/6 12.4KbVilCre to generate F1-generation heterozygous animals. F1-generation heterozygous animals were then backcrossed with BALB/*c-Pten*<sup>fx/fx</sup> mice to produce F2-generation experimental animals. All experiments were conducted in F2-generation experimental animals. All mice were maintained on regular diet in the transgenic mouse facility at the Faculty of Medicine and Health Sciences of the Université de Sherbrooke. All experiments were approved by the animal research committee of the Faculty of Medicine and Health Sciences of the Université de Sherbrooke.

### Tissue collection, tissue preparation, RNA extraction and gene expression analysis

Digestive tracts from 120-d-old *Pten*<sup>ΔIEC</sup> mice and control littermates were fixed in 4% paraformaldehyde (PFA) overnight at 4 °C, then dehydrated and embedded in paraffin. Sections of 5 μm were applied to Probe-On Plus slides (Fisher Scientific, Ottawa, ON, Canada) and kept at room temperature until used<sup>[10,21]</sup>. Total RNA was isolated and processed using the Totally RNA extraction kit (Ambion, Grand Island, NY, United states). Reverse-transcription polymerase chain reaction (RT-PCR) and quantitative real-time PCR were performed as described previously<sup>[21]</sup>. Quantitative real-time PCR conditions were as follows: one cycle of 15 min at 95 °C; 50 cycles at 95 °C for 15 s; 59 °C for 30 s and 72 °C for 30 s. The following forward and reverse primers were used: Hairy and enhancer of split 1 (NM\_008235), 5'-TTCCAAGC-TAGAGAAGGCAGA-3', 5'-GTTGATCTGGGT-

CATGCAGTT-3'; Atonal homolog 1 (NM\_007500), 5'-GCTTCCTCTGGGGGTTACTC-3', 5'-ACAACGAT-CACCACAGACCA-3'; Neurogenin 3 (NM\_009719), 5'-CGGATGACGCCAAACTTACAAAG-3' 5'-CA-CAAGAAGTCTGAGAACAACAG-3'; Growth factor independent 1 (NM\_010278), 5'-TCCGAGTTCGAG-GACTTTTG-3', 5'-CATGCATAGGGCTTGAAAGG-3'; Neurogenic differentiation 1 (NM\_010894), 5'-AGC-CACGGATCAATCTTCTCT-3', 5'-GACGTGCCCTCTA-ATCGTGAAA-3'; Pancreatic and duodenal homeobox 1 (NM\_008814), 5'-AACCCGAGGAAAACAAGAGG-3', 5'-TTCAACATCACTGCCAGCTC-3'; Forkhead box O1 (NM\_019739), 5'-CCGGAGTTTAACCAGTCCAA-3', 5'-TGCTCATAAAGTCCGGTGCTG-3'; Forkhead box a1 (NM\_008259), 5'-CAAGGATGCCTCTCCACACTT-3', 5'-TGACCATGATGGCTCTCTGAA-3'; Forkhead box a2 (NM\_010446), 5'-GAGCACCATTACGCCTTCAAC-3', 5'-GGCCTTGAGGTCCATTTTGT-3'; PDGB (NM\_013551), 5'-TGCACGATCCTGAAACTCTG-3', 5'-TGCATGCTATCTGAGCCATC-3'.

### Immunofluorescence

Immunofluorescence staining was performed as previously described<sup>[21]</sup>. The following antibodies were used at the indicated dilutions: FITC-conjugated anti-mouse IgG (1:200, Vector, Burlingame, CA, United states), FITC-conjugated anti-rabbit IgG (1:200, Vector), AlexaFluor 568 donkey anti-goat (1:400, Invitrogen, Grand Island, NY, United states), AlexaFluor 488 donkey anti-goat (1:400, Invitrogen), AlexaFluor 488 donkey anti-rabbit (1:400, Invitrogen), rabbit anti-SP-1 CgA (1:1000, ImmunoStar, Hudson, WI, United states), goat anti-CgA (1:50, SantaCruz, Santa Cruz, CA, United states), rabbit anti-gastrin (1:200, Chemicon, Billerica, MA, United states), goat anti-GIP (1:100, SantaCruz), mouse anti-serotonin (1:200, LabVision, Kalamazoo, MI, United states), rabbit anti-secretin (1:1000, Phoenix pharmaceuticals, Burlingame, CA, United states), goat anti-SST (1:100, SantaCruz), goat anti-ghrelin (1:100, SantaCruz), rabbit anti-CCK (1:100, ab92128 gift from Rehfeld JF)<sup>[22]</sup>.

### Measurement of circulating hormone levels

Blood was collected on 16 h fasted mice by cardiac puncture. Serum levels of total ghrelin and GIP were measured using Millipore ELISA kits (EZRGRT-91K, EZRMGIP-55K) (Millipore, Billerica, MA, United states) according to manufacturer's instructions. Serum levels of SST were measured using the Phoenix Pharmaceuticals ELISA kit EK-060-03, according to the manufacturer's instructions.

### Statistical analysis

All cell count analyses were performed using continuous serial sections from low-powered fields of well-oriented intestinal cross-sections in a blind manner on an average of 10 independent fields per animal. Three different intestinal sections were evaluated: duodenum, jejunum and ileum. The total number of enteroendocrine cells

was counted per crypt-villus axis. Image magnification was calibrated by comparison with a stage micrometer (graticules™ Ltd., Tonbridge, Kent, England). Statistical analyses were performed using two-way ANOVA. For qRT-PCR, data were analyzed using the Mann Whitney-test for abnormal distribution. Differences were considered significant with a *P* value of < 0.05. All statistical analyses were carried out using Graph Pad Prism 5 (Graph Pad Inc., San Diego, CA).

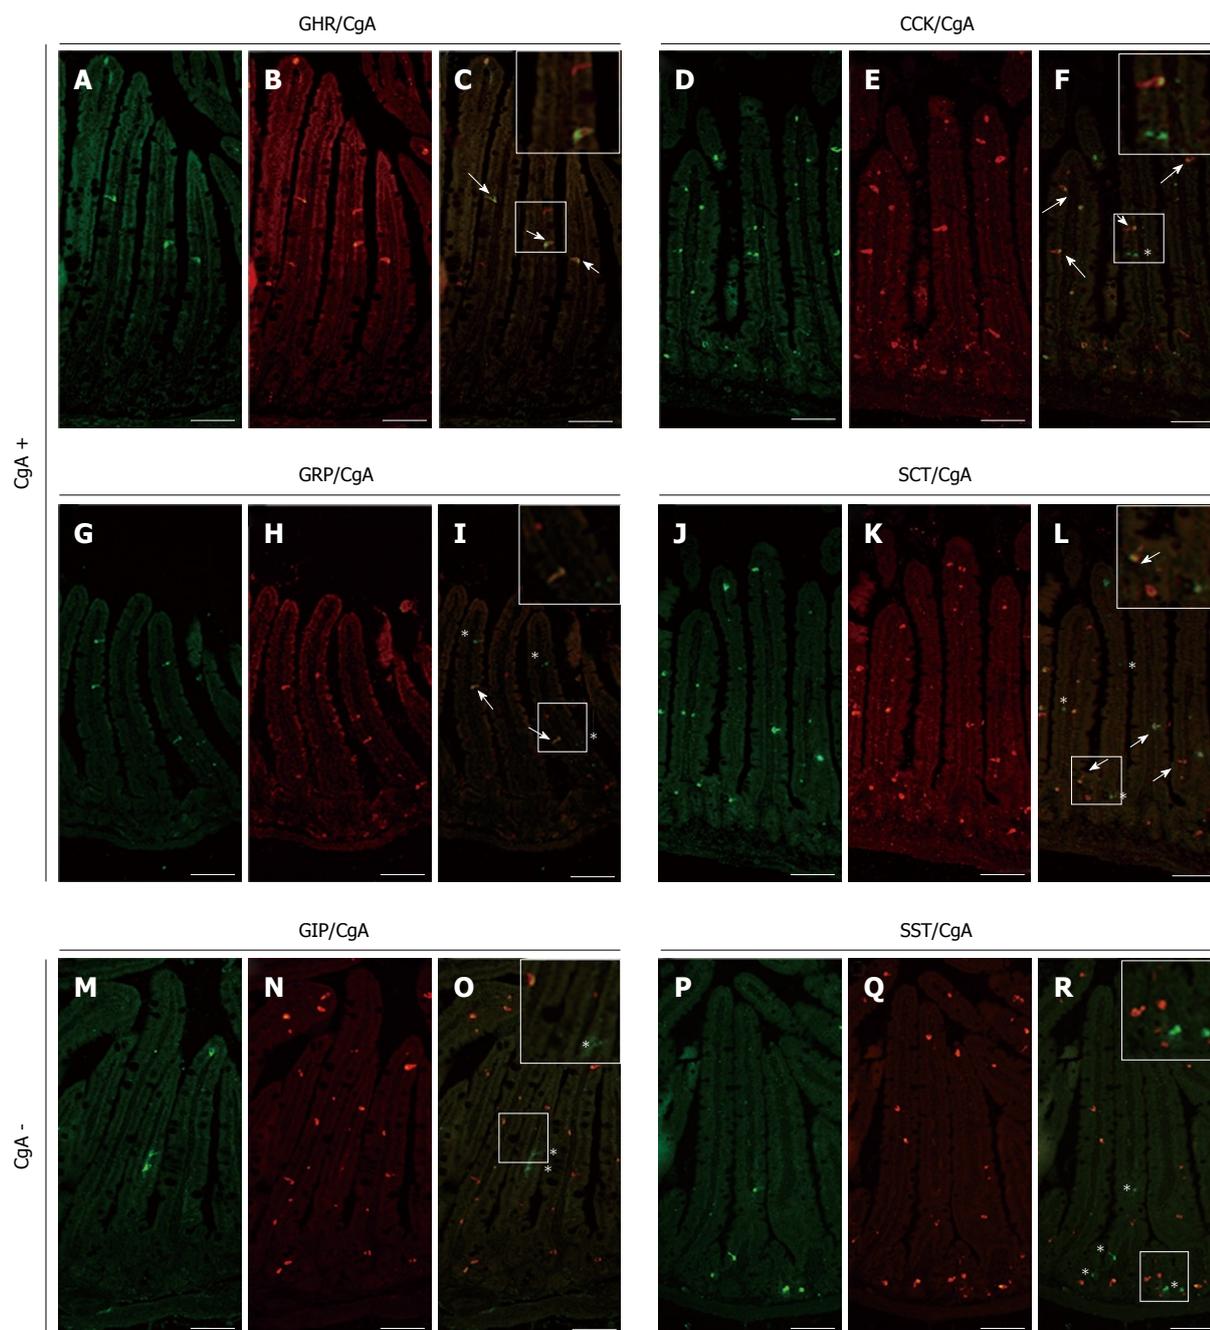

## RESULTS

### **CgA is not expressed in all enteroendocrine cell subtypes of the mouse small intestinal epithelium**

Mice homozygous for the floxed exon 5 of the *Pten* gene<sup>[23]</sup> were bred to the *villin*-Cre transgenic line, which directs expression of the transgene in all epithelial cells of the small intestine and colon, including stem cells, but not in the mesenchymal compartment<sup>[20]</sup>. Conditional knock-out mice for *Pten* (*Pten*<sup>Δ<sup>Ex5</sup></sup>) were born at the expected Mendelian ratios, survived for more than 1 year, and grew normally without obvious gross physical abnormalities<sup>[10]</sup>. In a previous study with these mice, we reported an overall decrease in the number of enteroendocrine cells using a CgA antibody<sup>[10]</sup>. Over the years, there has been a lingering controversy where a number of studies showed that all endocrine cell subpopulations express CgA<sup>[18,24,25]</sup> while others reported that some cell subpopulations do not express CgA<sup>[17,26]</sup>. Therefore, individual analysis of various intestinal endocrine subpopulations was first performed for their co-expression with CgA in the mouse small intestine. Double-labelling with CgA (Figure 1B, E, H and K) and specific antibodies directed against ghrelin (Figure 1A), CCK (Figure 1D), gastrin (Figure 1G) and secretin (Figure 1J) confirmed co-expression of CgA with ghrelin (Figure 1C) as well as with CCK- (Figure 1F), gastrin- (Figure 1I) and secretin- (Figure 1L) producing enteroendocrine cells in the mouse small intestine. On the other hand, double-labelling with CgA antibody (Figure 1N and Q) and specific antibodies directed against GIP (Figure 1M) and SST (Figure 1P) supported the exclusion of co-expression between GIP (Figure 1O), SST (Figure 1R) and CgA in the mouse small intestine. The specificity of our CgA antibodies was confirmed with the use of two different CgA antibodies from two different commercial sources, in which the exact same cells were labeled in consecutive sections from a same specimen with both antibodies.

### **Loss of intestinal epithelial *Pten* impairs the specification of CgA expressing enteroendocrine cells**

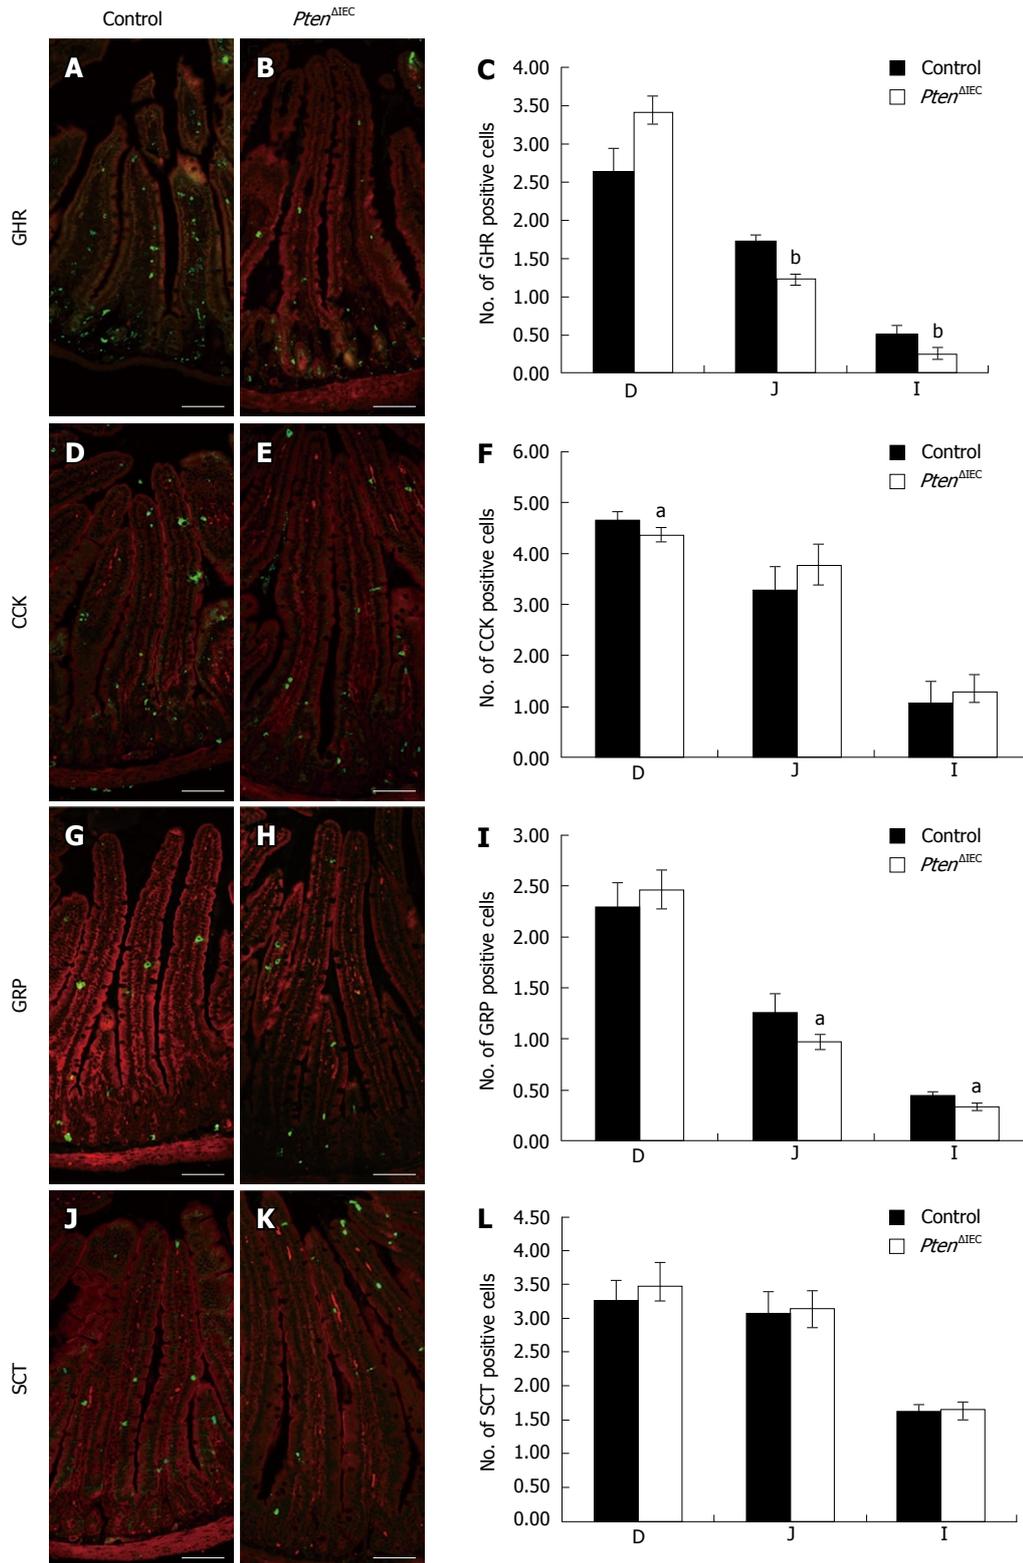

Enteroendocrine subtype specification appears to be regulated by distinct mechanisms<sup>[17,26]</sup>. Since our previous study only investigated CgA-expressing cells, the impact of *Pten* loss of expression on the specification of the various enteroendocrine cell subpopulations in the small intestine was further analyzed. We first analyzed how the loss of epithelial *Pten* alters specification of CgA-expressing en-

**Figure 1 Analysis of chromogranin A co-expression in mouse small intestinal endocrine subpopulations.** Small intestine sections of adult control mice were co-immunostained with antibodies directed against ghrelin (GHR) (A), cholecystokinin (CCK) (D), gastrin-releasing peptide (GRP) (G), secretin (SCT) (J) glucose-dependent insulinotropic peptide (GIP) (M) or somatostatin (SST) (P) and against chromogranin A (CgA) (respectively B, E, H, K, N and Q). The arrows in images C, F, I and L show co-expression of CgA respectively with GHR, CCK, GRP and SCT while asterisks in images F, I, L, O and R point to CgA-negative enteroendocrine cells. The number of arrows and asterisks within the crypt-villus axis represents the average proportion of labelled cells per units. Scale bar: 50  $\mu$ m.

teroendocrine cells along the various sections of the small intestine (duodenum, jejunum and ileum). Although some enteroendocrine cells are restricted to specific regions of the small intestine, each region was analyzed in order to verify the possible delocalization of subpopulations along the rostro-caudal axis of the gut. The intestinal mucosa of *Pten*<sup>AIEC</sup> and control mice was stained with specific markers for each enteroendocrine cell subtype and positive cells were counted (Figure 2). A significant decrease of 29% in the jejunum (1.2 positive cells per crypt-villus axis

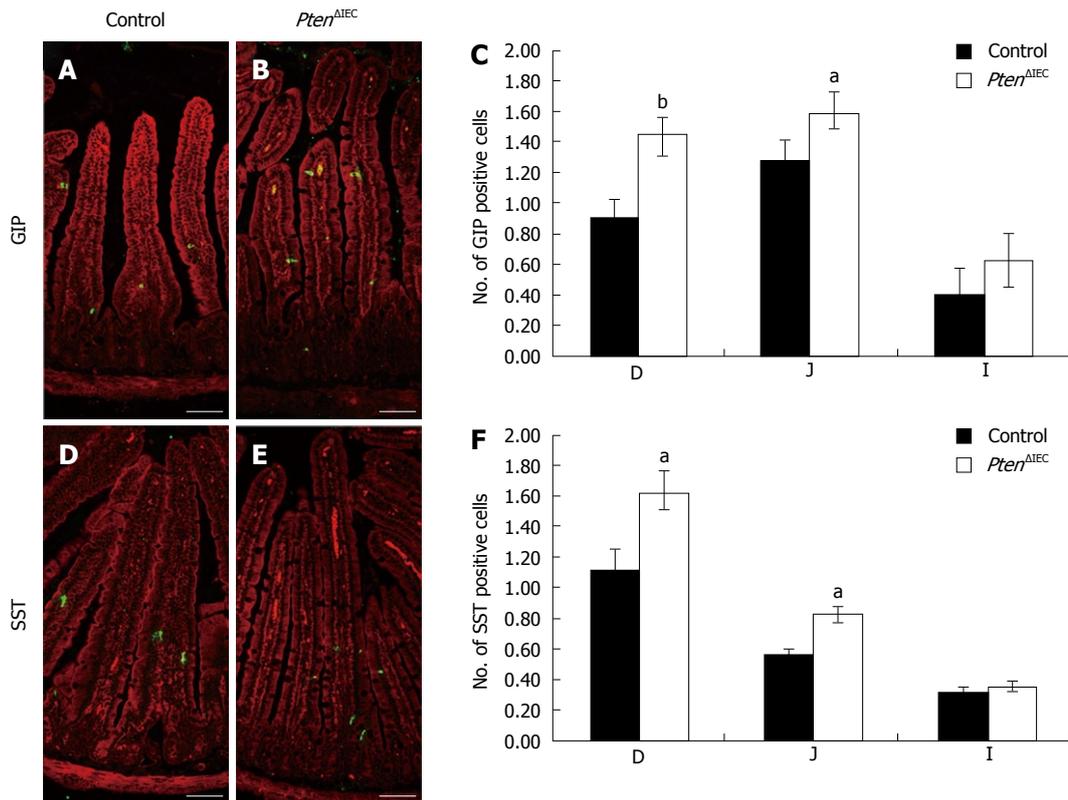

*vs* 1.7) and 51% in the ileum (0.25 cell *vs* 0.52 cell) was observed (Figure 2C) in the ratio of positive ghrelin cells in *Pten* mutant mice (Figure 2B) compared to control littermates (Figure 2A). A modest but significant decrease of 10% (Figure 2F) was also observed in the ratio of positive CCK cells in the duodenum of the mutant mice (4.4 cell *vs* 4.7 cell) (Figure 2E). There was also a significant 23% decrease in gastrin-positive cells in the jejunum (1 cell *vs* 1.3 cell) and a decrease of 29% in the ileum (0.34 cell *vs* 0.44 cell) in *Pten*<sup>AIEC</sup> (Figure 2H and I) when compared to

**Figure 2** Epithelial *Pten* positively regulates commitment of chromogranin A-positive enteroendocrine subpopulations in the small intestine. Duodenum, jejunum and ileum of adult control and *Pten*<sup>AIEC</sup> mice were immunostained with antibodies against ghrelin (GHR) (A and B), cholecystokinin (CCK) (D and E), gastrin-releasing peptide (GRP) (G and H) and secretin (SCT) (J and K). Positive cells were counted from intestinal sections of controls (*n* = 6) and mutants (*n* = 5). Statistical analysis (C, F, I, L) represents the average number of positive cells per crypt-villus axis in each section of the intestine. Error bars represent SE. Scale bar: 50  $\mu$ m. D: Duodenum; J: Jejunum; I: Ileum. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.001.

control mice (Figure 2G and I). Finally, secretin immunostaining showed no modulation in the number of secretin-positive cells in *Pten*<sup>AIEC</sup> (Figure 2K and L) *vs* control mice

(Figure 2J and L). Taken together, these results suggest that *Pten* positively influences production of CgA-expressing enteroendocrine cell subpopulations.

**Figure 3** Epithelial *Pten* negatively regulates commitment of chromogranin A-negative enteroendocrine subpopulations in the small intestine. Duodenum, jejunum and ileum of adult control and *Pten*<sup>ΔIEC</sup> mice were immunostained with antibodies against glucose-dependent insulinotropic peptide (GIP) (A and B) and somatostatin (SST) (D and E). Positive cells were counted from intestinal sections of controls (*n* = 6) and mutants (*n* = 5). Statistical analysis (C and F) represents the average number of positive cells per crypt-villus axis in each section of the intestine. Error bars represent SE. Scale bar: 50 μm. D: Duodenum; J: Jejunum; I: Ileum. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

### Loss of epithelial intestinal *Pten* positively influences the specification of CgA negative enteroendocrine cells

We next examined if the specification of CgA-negative cells was affected following the loss of epithelial *Pten*. As illustrated in Figure 3, there was a marked 61% (duodenum) and 25% (jejunum) increase in GIP-positive cells in *Pten*<sup>ΔIEC</sup> (Figure 3B and C) when compared to control mice (Figure 3A and C) (respectively 1.45 positive cells *vs* 0.9 in the duodenum and 1.6 cells *vs* 1.28 in the jejunum). SST immunostaining in both duodenum and jejunum revealed an increase of 45% in the number of SST-positive cells in *Pten*<sup>ΔIEC</sup> (Figure 3E and F) *vs* control mice (Figure 3D and F) (respectively 1.65 cells *vs* 1.15 cell and 0.85 cell *vs* 0.6 cell). Hence, these data suggest that *Pten* signalling negatively controls specification of CgA-negative cells in the intestinal epithelium.

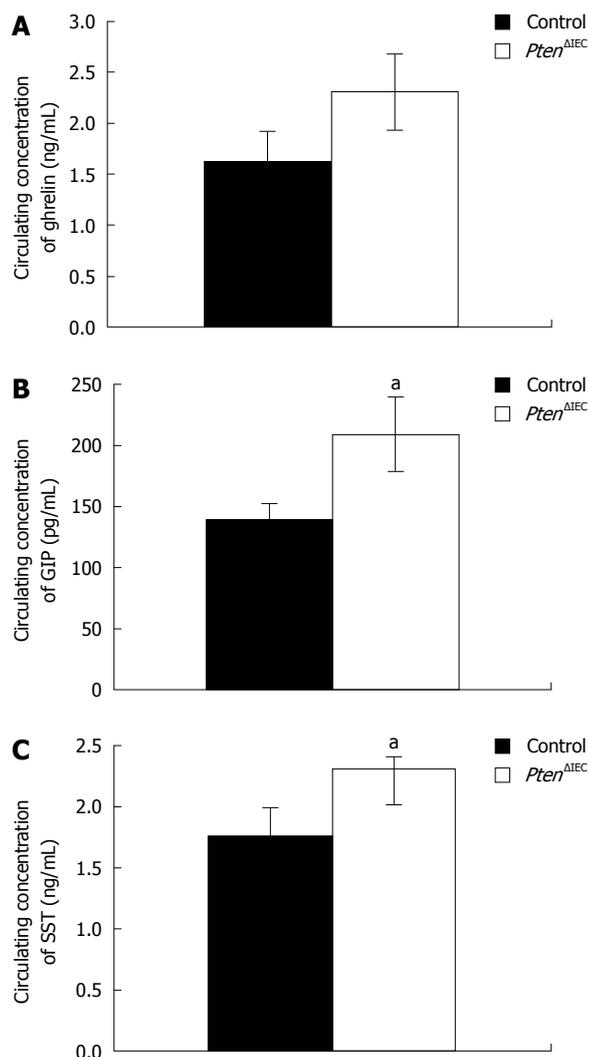

### Loss of epithelial *Pten* signalling leads to deregulation of circulating GIP and SST levels

In light of these observations, we next investigated whether deregulation in the number of enteroendocrine cells in the intestinal epithelium of the *Pten*<sup>ΔIEC</sup> mice has an impact on their circulating levels. We chose to focus on the enteroendocrine subpopulations where the deregulation was more considerable. Circulating ghrelin, GIP and SST levels were analysed by ELISA assay. A 1.5-fold and 1.3-fold increase in GIP (Figure 4B) and SST (Figure 4C)

levels, respectively, were observed in *Pten*<sup>ΔIEC</sup> mice when compared to control littermates. No significant difference in ghrelin levels was observed between *Pten*<sup>ΔIEC</sup> mice and control mice (Figure 4A).

### *Pten* expression impacts differently on various pro-enteroendocrine specification factors

Comparative analysis of secretory lineage and specific pro-enteroendocrine determination factors was next investigated by quantitative PCR to clarify the role of *Pten* during enteroendocrine subtype specification. The Notch pathway, and more specifically the transcription factors Hairy enhancer of Split (Hes-1) and Math1, is crucial in the determination of the intestinal progenitor cell to absorptive or secretory cell fate (Figure 5)<sup>[27,28]</sup>. We also investigated if loss of epithelial *Pten* could deregulate the production of secretory precursors. Quantitative PCR analysis of mutant *vs* wild-type littermates revealed no modulation of Math1 or Hes-1 mRNA levels in the mutant animals (Table 1). Modifications downstream of the Notch pathway during enteroendocrine cell determination were also subsequently assessed. The proendocrine bHLH transcription factor Ngn3 has been shown to contribute to the maintenance and specification of enteroendocrine precursors (Figure 5)<sup>[29]</sup>. Our analysis revealed that the Ngn3 mRNA expression was significantly reduced by 2.07-fold in the mutant animals (Table 1). BETA2/

**Figure 4** Loss of epithelial *Pten* signalling modulates circulating levels of glucose-dependent insulinotropic peptide and somatostatin. A: Analysis of circulating ghrelin level revealed no significant modulation between adult *Pten*<sup>AIEC</sup> mice ( $n = 10$ ) and control littermates ( $n = 10$ ); B: Analysis of circulating glucose-dependent insulinotropic peptide (GIP) level revealed a 1.5-fold increase in adult *Pten*<sup>AIEC</sup> mice ( $n = 10$ ) when compared to control littermates ( $n = 10$ ); C: Analysis of circulating somatostatin (SST) level revealed a 1.3-fold increase in adult *Pten*<sup>AIEC</sup> mice ( $n = 10$ ) when compared to control littermates ( $n = 10$ ). Error bars represent SE. <sup>a</sup> $P < 0.05$ .

NeuroD1, Pancreatic and duodenal homeobox 1 gene (*Pdx1*), the winged helix *Foxa1* and the forkhead box-containing (*FoxO1*) transcription factors have also been shown to control the determination of specific enteroendocrine subpopulations<sup>[16,30-33]</sup>. The gene transcript level of BETA2/NeuroD1, linked to specification of secretin and CCK producing cells<sup>[34]</sup>, was reduced by 1.40-fold in mutant animals (Table 1). *Pdx1*, which regulates serotonin and GIP producing cells (Figure 5)<sup>[31,32]</sup>, was found to be significantly increased by 2.15-fold at the gene transcript level in mutant mice (Table 1). *FoxO1* factors are downstream targets of the PI3K/AKT pathway<sup>[35]</sup> and affect the subcellular localization of *Pdx1* in the pancreas and, hence, its transcriptional activity<sup>[36]</sup>. *FoxO1* gene transcript level was found to be reduced by 1.95-fold in the *Pten*<sup>AIEC</sup>

**Table 1** Gene expression changes in the small intestine of *Pten*<sup>AIEC</sup> mice

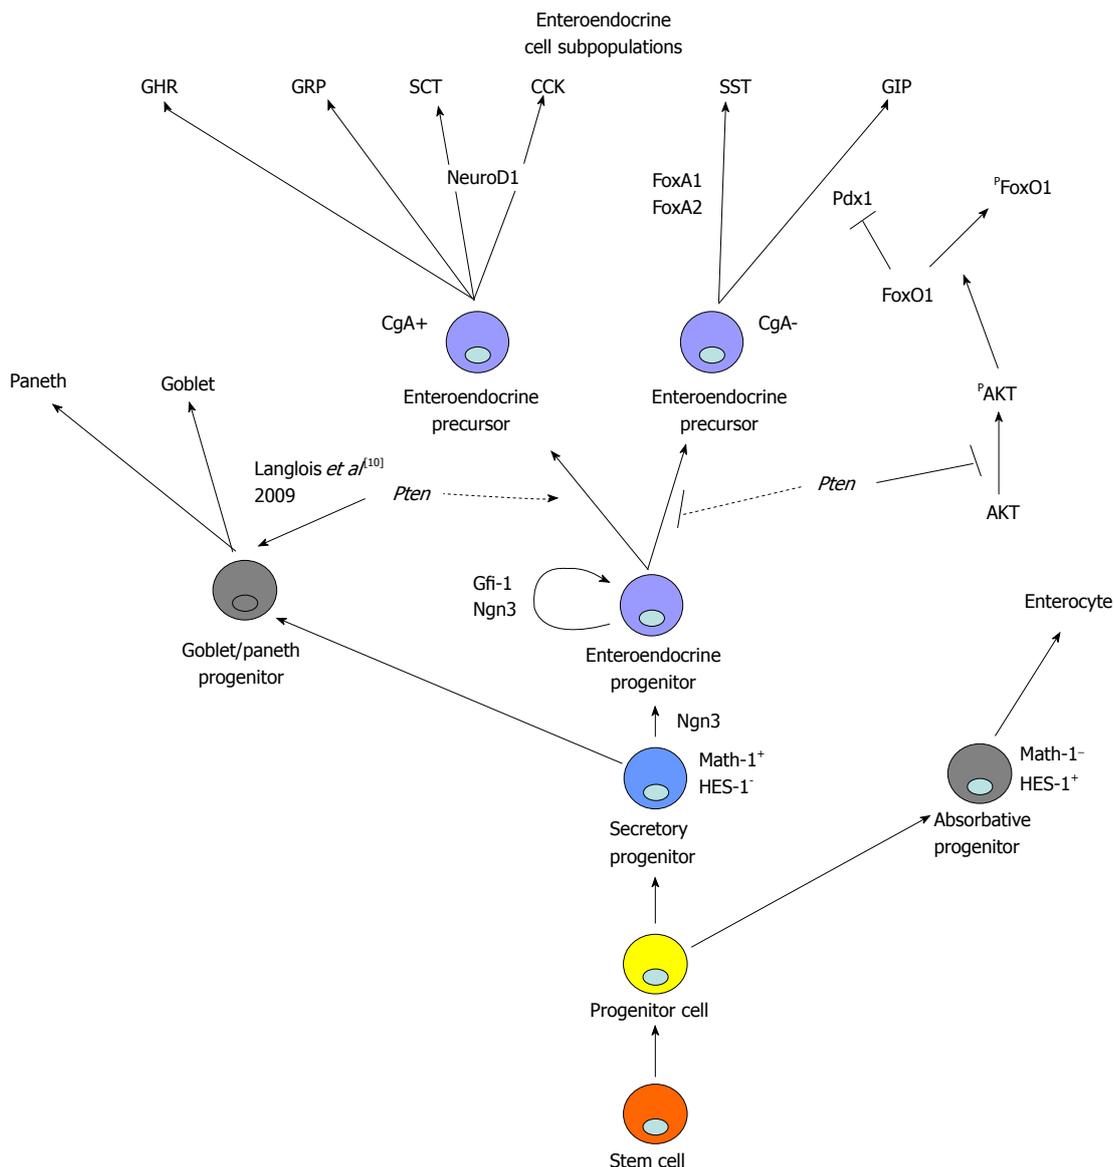

Gene description	Gene symbol	Fold	P value
Hairy and enhancer of split 1	<i>Hes1</i>	-1.08	NS
Atonal homolog 1	<i>Math 1</i>	-2.05	NS
Neurogenin 3	<i>Ngn3</i>	-2.07	0.033
Growth factor independent 1	<i>Gfi1</i>	1.07	NS
Neurogenic differentiation 1	<i>NeuroD1</i>	-1.40	0.002
Pancreatic and duodenal homeobox 1	<i>Pdx1</i>	2.15	0.048
Forkhead box O1	<i>FoxO1</i>	-1.95	0.017
Forkhead box a1	<i>Foxa1</i>	2.64	0.017
Forkhead box a2	<i>Foxa2</i>	-1.25	NS

Target expression was quantified relatively to PDGF expression. Fold changes represent the ratio of mean expression values (control/mutant). Negative values indicate reduction in *Pten*<sup>AIEC</sup> intestines. NS: Non significant fold change (Mann-Whitney test).

mice (Table 1). Finally, the winged helix transcription factors *Foxa1* is essential for the differentiation of SST-, GLP-1- and PYY-expressing endocrine cells (Figure 5)<sup>[33]</sup>. Accordingly, we found an increase of 2.64-fold in *Foxa1* gene transcript expression in *Pten*<sup>AIEC</sup> mice (Table 1).

## DISCUSSION

Endocrine cells found scattered in the gastrointestinal epithelium represent the major endocrine organ of the body<sup>[15,16]</sup>. The various hormones produced by these endocrine cells control numerous physiological functions<sup>[16,18,19]</sup>. Recently, by using conditional tissue-specific disruption of *Pten* in the epithelium of the gut, we revealed a key role for epithelial *Pten* in intestinal morphogenesis, in the maintenance of crypt-villus axis architecture, in cell proliferation and in secretory cell commitment<sup>[10]</sup>. We had also reported an overall decrease in the number of enteroendocrine cells using a CgA antibody. However, the choice of CgA as a pan marker for all enteroendocrine cells has been challenged. Commonly used as a biomarker for endocrine granules, CgA plays a role in the biogenesis of mobile secretory granules and the release of hormones through the regulated secretory pathway<sup>[37]</sup>. Over the years, there has been a lingering controversy in which some studies showed that all endocrine cell subpopulations express CgA<sup>[18,24,25]</sup> while others reported that enteroendocrine cell subpopulations producing GIP, GLP-1 or SST do not express CgA<sup>[17,26]</sup>. Fixation artefacts and different CgA antibodies may account for this controversy. Also, it has been demonstrated that CgA expression in enteroendocrine subpopulations varies from one species to another as well as in pathologies such as colorectal cancer and inflammatory bowel diseases<sup>[38-42]</sup>. Herein, our analysis of the various intestinal endocrine subpopulations with CgA antibodies confirmed the absence of co-expression between GIP and SST with CgA. Therefore, the important role of enteroendocrine cells in whole body homeostasis prompted us to further analyze the effect of intestinal epithelial deletion of *Pten* on the specification of the various en-

**Figure 5 Proposed model for mode of action of epithelial *Pten* signalling in intestinal epithelial determination and specification of enteroendocrine progenitor cell fate.** Epithelial *Pten* signalling is not essential for maintenance or determination of the secretory precursor. *Pten* represses specification of glucose-dependent insulinotropic peptide (GIP)-expressing cells by maintaining FoxO1 in the nucleus. GHR: Ghrelin; GRP: Gastrin-releasing peptide; SCT: Secretin; CCK: Cholecystokinin; SST: Somatostatin; GIP: Glucose-dependent insulinotropic peptide; CgA: Chromogranin A.

teroendocrine subpopulations. Since all enteroendocrine subtype cells are still detectable in the mutant mice, our results suggest that *Pten* is not a direct and indispensable regulator of enteroendocrine cell determination. Nevertheless, our data revealed a dual role for *Pten* signalling in enteroendocrine cell specification. Indeed, our results indicate that *Pten* signalling facilitates the specification of CgA-expressing enteroendocrine cell subpopulations while it negatively controls specification of CgA-negative cells in the intestinal epithelium. Furthermore, our results showed that the number of GIP and SST cells as well as their associated circulating hormone levels was increased in mutant mice. Although the number of ghrelin cells was decreased, no significant modulation in ghrelin serum level was observed in the *Pten*<sup>ΔIEC</sup> mice. This may be explained by the fact that ghrelin endocrine cells found in

the stomach epithelium are strong contributors for total circulating ghrelin levels<sup>[43,44]</sup>, and are not likely affected by the loss of epithelial *Pten* in the intestine. Nevertheless, the lack of modulation in circulating levels of ghrelin does not imply that the reduction observed in the cell number in the intestine has no local consequences in this tissue. Indeed, such a reduction could influence specific physiological intestinal functions, such as motility, digestion and epithelial renewal<sup>[16,18,19]</sup>. Finally, analyses of each enteroendocrine cell subtypes along the rostro-caudal axis of the small intestine confirmed that the loss of *Pten* does not influence normal distribution of these endocrine cell subpopulations.

Our data also indicate that *Pten* affects the expression of key regulators for cell lineages and/or proenteroendocrine determination. Since the Notch/Hes-1

path is required for the specification of progenitor cells into the absorptive lineage and since *Math1* is required for specification into the secretory lineage<sup>[27,28]</sup>, we therefore analyzed whether the loss of epithelial *Pten* could alter their expression. Lack of modulation in *Math1* and *Hes-1* gene transcripts suggest that *Pten* is not involved in the initial decision steps for lineage determination. Once the initial decision is made between secretory and absorptive cell lineages, the fate of enteroendocrine progenitor cells is defined by proendocrine bHLH transcription factors such as *Ngn3* and *BETA2/NeuroD1*. *Ngn3* acts downstream of *Math1*<sup>[27,29]</sup> and has been shown to contribute to the maintenance of the enteroendocrine precursors and to the differentiation of all enteroendocrine subpopulations in mice<sup>[29,45,46]</sup>. Unlike *Ngn3*, expression of *BETA2/NeuroD1* is restricted to a subset of enteroendocrine cells<sup>[34]</sup>. *BETA2/NeuroD1* controls terminal differentiation of secretin and CCK producing cells in the intestine as revealed by the absence of these subpopulations in *BETA2/NeuroD1* null mice<sup>[34]</sup>. In addition, *BETA2/NeuroD1* acts downstream of *Ngn3*<sup>[45]</sup>. Our analysis revealed that the expression of both bHLH transcription factors was reduced in absence of epithelial *Pten*, thereby impacting on the production of specific enteroendocrine subpopulations (Figure 5). Over the years, other factors have been shown to be important in the differentiation/specification of several enteroendocrine cell subpopulations<sup>[16,30-33]</sup>. Such is the case for the winged helix transcription factor *Foxa1*, previously shown to be essential for the differentiation of SST, GLP-1 and PYY expressing cells<sup>[33]</sup>. *Foxa1* expression was found to be increased in *Pten*<sup>ΔIEC</sup> mice, hence correlating with the increased production of SST-expressing cells in these mice (Figure 5). The same logic can be applied to *Pdx-1*. Indeed, studies from *Pdx1*-null mice revealed an increase in the number of serotonin cells and a decrease in the GIP-expressing cell population<sup>[31,32]</sup>. Herein, *Pdx-1* gene transcript was found to be significantly increased in absence of epithelial *Pten*, thereby matching the deregulation seen in GIP cell specification (Figure 5). In addition, *FoxO1* gene transcript was found to be significantly reduced in the absence of epithelial *Pten*. *FoxO1* competes with *FoxA2* for binding to the *Pdx1* promoter, resulting in inhibition of *Pdx1* transcription<sup>[36]</sup> (Figure 5). Aside from these observations, one could speculate that phosphorylation of *FoxO1* affects its subcellular localisation leading to its exclusion from the nucleus. This nuclear/cytoplasm shuttling phosphorylation of *FoxO1* ultimately decreases its transactivation potential<sup>[36,47]</sup>. Furthermore, PI3K/Akt is a major upstream signalling pathway leading to the phosphorylation of *FoxO1* and its exclusion from the nucleus<sup>[35]</sup>. In a previous study with *Pten*<sup>ΔIEC</sup> mice, we reported that loss of *Pten* resulted in increased phosphorylation levels of *Akt*<sup>[10]</sup>. Thus, it is tempting to extrapolate that following the loss of intestinal epithelial *Pten* and activation of *Akt*, targeted *FoxO1* protein would become more phosphorylated and exported to the cytoplasm allowing expression of *Pdx1* and specification of GIP-expressing cells.

In summary, our results reveal a distinctive role for *Pten* in specification/differentiation of enteroendocrine cell subpopulations. *Pten* signalling negatively regulates the enteroendocrine subtype specification of non-expressing CgA cells such as GIP and SST expressing cells. In contrast, *Pten* signalling positively affects CgA-expressing cells such as ghrelin, gastrin and CCK cells. Many of these enteroendocrine cell subtypes are known to play critical roles in whole body physiological functions. Incretin hormones such as GLP-1 and GIP have been shown to potentiate glucose-stimulated insulin secretion<sup>[48]</sup>, while double-mutant mice for GIP and GLP-1 exhibit glucose intolerance<sup>[49]</sup>. Likewise, the importance of enteroendocrine cells in lipid absorption has recently been shown with the generation of intestinal-conditional *Ngn3* null mice<sup>[46]</sup>. A study with *Gip*-receptor null mice revealed a crucial role for GIP in promoting the efficient storage of ingested fat suggesting that inhibition of the GIP signal could represent a therapeutic approach against obesity<sup>[50]</sup>. Further analysis will be needed to better evaluate the impact and possible networking of small intestinal endocrine cell deregulation following the loss of *Pten* signalling on overall metabolism in the mouse.

## ACKNOWLEDGMENTS

The authors thank Garand MP and Lamarre S for help with statistical analysis, Morisset JA for the use of reagents and Dr. Gumucio DL for providing the 12.4kbVil-Cre transgenic line used in the study.

## COMMENTS

### Background

The phosphatase and tensin homolog (*PTEN*) tumour suppressor gene is a lipid and protein phosphatase frequently mutated/deleted in various human cancers. Its best-known substrate, the phosphatidylinositol 3,4,5-trisphosphate, is a lipid second messenger mainly produced by class IA phosphatidylinositol 3-kinases (PI3Ks). PI3Ks have been implicated in many signalling pathways that regulate cell survival, growth, proliferation, migration, phagocytosis, and metabolism. In previous study, authors reported that *Pten* is important for intestinal homeostasis as well as in the commitment of enteroendocrine cells. The important role of enteroendocrine cells in whole body homeostasis prompted people to further analyze the effect of intestinal epithelial deletion of *Pten* on the specification of the various enteroendocrine subpopulations.

### Research frontiers

Enteroendocrine cells located in the gut epithelium are the largest and least understood population of hormone-producing cells in the body. The various hormones and peptides produced by these endocrine cells control important physiological functions, such as gastrointestinal motility, glycaemia, exocrine pancreatic secretion, biliary secretion, digestion, gut epithelial renewal and appetite. In recent years, studies have placed the regulation of these gut hormones as potential targets for novel treatments of metabolic diseases such as type 2 diabetes and obesity.

### Innovations and breakthroughs

In the current study, the authors report a distinctive role for *Pten* in specification/differentiation of enteroendocrine cell subpopulations. *Pten* signalling negatively regulates the enteroendocrine subtype specification of non-expressing chromogranin A (CgA) cells such as glucose-dependent insulinotropic peptide and somatostatin expressing cells. In contrast, *Pten* signalling affects positively CgA-expressing cells such as ghrelin, gastrin and cholecystokinin cells.

## Applications

Many of these enteroendocrine cell subtypes are known to play critical roles in whole body homeostasis. These experimental data can be used in further studies to better evaluate the impact on general metabolism and possible networking of small intestinal endocrine cell deregulation following the loss of Pten signalling.

## Peer review

This is a high quality descriptive study in which authors analyze the impact of the *PTEN* intestinal knockdown in the specification of intestinal enteroendocrine subpopulations.

### Abstract

**AIM:** To investigate the mechanisms of the biological roles of Dickkopf-3 (Dkk-3) in cell invasion, survival and apoptosis in colon cancer cells.

**METHODS:** Three human colon cancer cell lines, i.e., HT-29, LoVo and SW480, were used. Overexpression of Dkk-3 induced by pEGFP-N1-Dkk-3-GFP plasmid in LoVo cells was performed using Lipofectamine 2000 reagent. Reverse transcription polymerase chain reaction and Western blotting were performed to determine the mRNA and protein expression levels of Dkk-3, respectively. Cell proliferation assay, cell cycle analysis, hoechst 33258 assay and Matrigel invasion assay were performed on Dkk-3 overexpressing transfectants.

**RESULTS:** The mRNA and protein expressions of Dkk-3 in HT-29 (mRNA:  $0.06 \pm 0.02$ , protein:  $0.06 \pm 0.01$ ) and LoVo (mRNA:  $0.07 \pm 0.02$ , protein:  $0.07 \pm 0.02$ ) cells were significantly lower than that in SW480 cells (mRNA:  $0.92 \pm 0.04$ , protein:  $0.69 \pm 0.13$ ; all  $P < 0.05$ ), and the greatest levels of invasiveness was

in LoVo cells. Dkk-3 overexpression inhibited the proliferation and invasion of LoVo cells and induced cell cycle arrest at G<sub>0</sub>/G<sub>1</sub> phase and subsequent apoptosis, as indicated by increased chromatin condensation and fragments, upregulated Bax and cytochrome c protein, downregulated survivin and Bcl-2 protein, and the activation of caspase-3 and caspase-9. Furthermore, Dkk-3 overexpression reduced the accumulation of cytosolic fraction of  $\beta$ -catenin.

**CONCLUSION:** Dkk-3 overexpression induced apoptosis in human colon cancer possibly through the mitochondrial pathway. Dkk-3 may be involved in the Wnt/ $\beta$ -catenin signaling pathways in colon cancer.

### INTRODUCTION

The prevalence of colorectal cancer is increasing in Asia. Many Asian countries, including China, Japan, South Korea, and Singapore, have experienced a 2-4 folds increase in the incidence of colorectal cancer (CRC) during the past few decades<sup>[1]</sup>. Even in the United States, colorectal cancer is the third most commonly diagnosed cancer and the second leading cause of cancer deaths among cancers

that affect both men and women<sup>[2,3]</sup>. However, the cellular mechanisms involved in CRC are not fully described. Recent studies have shown that the Wnt signaling pathway, which is composed of canonical Wnt signaling *via* Wnt/ $\beta$ -catenin and noncanonical Wnt signaling *via* the Wnt/ $\text{Ca}^{2+}$  pathway and Wnt/c-Jun N-terminal kinase (JNK) (planar cell polarity), regulates proliferation, fate specification, polarity and migration of cells<sup>[4,5]</sup>. The Wnt signaling pathway can be blocked by two functional classes of Wnt antagonists: the secreted frizzled-related proteins (sFRP) and the Dickkopf (Dkk)<sup>[6]</sup>.

Dkk-3, also known as reduced expression in immortalized cells, is a member of a recently identified gene family encoding secreted proteins that control cell fate during embryonic development<sup>[7-9]</sup>. Deletion at Dkk-3 locus has been found in many cancers, such as lung cancer<sup>[10]</sup>, gastric cancer<sup>[11]</sup> and ovarian cancer<sup>[12]</sup>. In acute lymphoblastic leukaemia<sup>[13]</sup>, prostate cancer<sup>[14]</sup>, bladder cancer<sup>[15,16]</sup> and renal cell carcinoma<sup>[16]</sup>, Dkk-3 expression is reduced or silenced. Interestingly, Dkk-3 is strongly expressed at the base of the crypts in human colon, which is known to contain proliferating epithelial precursor cells<sup>[17]</sup>. Therefore, Dkk-3 may be an important component of the gastrointestinal proliferative regulatory network<sup>[17]</sup>.

However, the relationship between Dkk-3 and colon cancer remains unclear. We hypothesized that: (1) Dkk-3 expression may be inhibited epigenetically in colon cancer cells; (2) Dkk-3 may be a tumor suppressor and plays an important role in mitochondria-mediated apoptosis; and (3) Dkk-3 may be involved in the Wnt/ $\beta$ -catenin signaling pathways in colon cancer cells. In the present study, we investigated the mechanisms of the biological roles of Dkk-3 in cell invasion, survival and apoptosis of human colon cancer cells.

## MATERIALS AND METHODS

### Construction of expressing plasmids

The pEGFP-N1-Dkk-3-GFP plasmid constructed to target Dkk-3 (RefSeq ID: BC007660) was obtained from Genechem Co., Ltd. (Shanghai, China). pEGFP-N1 plasmid (Genechem Co., Ltd.) was cut with *Xho*I/*Kpn*I and ligated by T4 DNA ligase with gene encoding Dkk-3, making Dkk-3-pEGFP construct. The plasmid construct was confirmed by DNA sequencing.

### Cell culture and transfection conditions

The human colon cancer cell lines HT-29, LoVo and SW480 were obtained from the Cell Collection Center of Chinese Academy of Sciences (Shanghai, China). The cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) (GibcoBRL, Grand Island, NY, United States) supplemented with 10% fetal bovine serum and were maintained in a humidified incubator at 37 °C with a supply of 5% CO<sub>2</sub>/95% air atmosphere. Transfections were performed using Lipofectamine 2000 reagent (Invitrogen, Carlsbad, CA) according to the manufacturer's instructions. After 48 h of transfection, cells were used

for cell cycle analysis, hoechst 33258 assay, Matrigel invasion assay, reverse transcription polymerase chain reaction (RT-PCR) analysis and Western blotting analysis. The transient expression of green fluorescent protein (GFP) was detected under a fluorescence microscope (Olympus; Shinjuku-ku, Tokyo, Japan) at an excitation wavelength of 460-490 nm.

### RT-PCR

After 48 h of transfection, total cellular RNA was isolated by Trizol (Invitrogen, Carlsbad, CA) and 2  $\mu$ g of RNA was treated with DNase and used as a template for the reverse transcription reaction following the manufacturer's instructions (Fermentas, United States). The resultant cDNA was then used in PCRs and analyzed by gel electrophoresis. The following primers were used: Dkk-3 sense 5'-GGGAGACGAAGAAGGCAGAAGG-3' and Dkk-3 antisense 5'-CCAGGTGATGAGGTCCAGAAGC-3'; glyceraldehyde-3-phosphate dehydrogenase (GAPDH) sense, 5'-AGGTGAAGGTCGGAGTCAAC-3', and GAPDH anti-sense, 5'-CGCTCCTGGAAGATGGT-GAT-3'. The PCR conditions were as follows: 94 °C for 5 min, followed by 35 cycles of 94 °C for 30 s, 60 °C for 30 s, and 72 °C for 1 min. The final extension was at 72 °C for 5 min. PCR products were analyzed on 1.2% agarose gels containing 0.5 g/mL ethidium bromide and were visualized under ultraviolet light. Band density was analyzed and quantified using Genetools software (Syngene, Cambridge, United Kingdom).

### Western blotting analysis

Equal amounts of proteins were resolved by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred onto nitrocellulose membranes (Millipore, Bedford, MA, United States) by wet transfer system (Bio-Rad, Hercules, CA, United States). Membranes were blocked with 10% non-fat dry milk in Tris-buffered saline Tween-20 and incubated first with primary antibodies at 4 °C overnight and then with horseradish peroxidase-conjugated anti-mouse, anti-rabbit or anti-goat secondary antibody for 2 h at room temperature. The following antibodies were used: Dkk-3 (R and D Systems Inc., Minneapolis, MN, United States) 1.5  $\mu$ g/mL,  $\beta$ -catenin (Abcam, Cambridge, United Kingdom) 1:5000, survivin, Bax, Bcl-2 and Cyt-c (Santa Cruz Biotechnology, Santa Cruz, CA, United States) 1:1000, Caspase-9 (Abcam, United States) 1:1000, Caspase-3 (Abcam, United States) 1:250 and Actin (Santa Cruz Biotechnology, Santa Cruz, CA, United States) 1:2000. Specific proteins were visualized using an enhanced chemiluminescence system (Millipore, Bedford, MA, United States) and then exposed with Kodak X-ray film. Protein band intensities were determined densitometrically using the video-imaging CMIASWIN system (Bio-Rad, Hercules, CA, United States).

### Cell proliferation assay

Cell proliferation was determined by the WST-8 tetrazolium salt assay (Cell Counting Kit-8, Beyotime Inst Bio-

tech, China), which quantifies the amount of formazan dye formed when tetrazolium salt is cleaved by cellular mitochondrial dehydrogenase present in viable cells. Cells were seeded in 96-well plates at a density of  $2 \times 10^3$ /well in 0.1 mL of culture medium. Viability of cells 0, 12, 24, 36, 48, 60 and 72 h after transfection was evaluated. Two hours before the end of the specified incubation period, 10  $\mu$ L WST-8 reagent was added to the cells. At the end of the incubation, cell density was estimated by measuring the absorbance of the colored formazan reaction product at 450 nm using an iMark Microplate Absorbance Reader (Bio-Rad, United States).

### Cell cycle analysis

Cell cycle status was determined by measuring cellular DNA content after staining with propidium iodide by flow cytometry. After 48 h transfection, cells were centrifuged, washed twice with ice-cold phosphate buffer saline (PBS), and fixed in 70% ethanol at 4 °C for 24 h. Cells were then centrifuged at 1000 r/min for 5 min, and the supernatant was discarded. The pellets were then washed twice with 4 mL PBS and then stained with 0.5 mL RNase A (2 mg/mL) and 0.5 mL propidium iodide (0.1% in 0.6% Triton-X in PBS) for 30 min in the dark. Samples were then analyzed on a FACSCalibur flow cytometer (Beckman Coulter, Inc. Fullerton, CA).

### Hoechst 33258 assay for apoptosis

Apoptotic cells were detected by Hoechst 33258 staining following the manufacturer's protocol (Apoptosis Hoechst staining kit, Beyotime Biotechnology, Jiangsu, China) after 48 h transfection. Briefly, cells were first fixed in 0.5 mL methanol for 30 min and then rinsed with PBS twice; 1 mg/mL Hoechst 33258 reagent was used to stain the apoptotic cells in dark at room temperature for 5 min, after which the cells were again washed with PBS twice. The stained cells were examined and immediately photographed under a fluorescence microscope (Olympus; Shinjuku-ku, Tokyo, Japan) at an excitation wavelength of 330-380 nm. Apoptotic cells were identified on the basis of morphologic changes in their nuclear assembly by observing chromatin condensation and fragment staining by Hoechst 33258. In each group, ten microscopic fields were selected randomly and counted.

### Invasion assay

Transwell chambers (Corning, New York, NY, United States) were used to examine the ability of cells to invade through a Matrigel-coated filter following the manufacturer's instructions. DMEM was added to the upper chambers and allowed to hydrate for 2 h at 37 °C with 5% CO<sub>2</sub>. Next,  $1 \times 10^5$  LoVo cells transfected with various plasmids were added to the upper chamber and grown in serum-free medium on 8.0  $\mu$ m porous polycarbonate membranes, which were coated with diluted Matrigel basement membrane matrix. The lower chambers were filled with DMEM medium containing 10% fe-

tal bovine serum. After 24 h incubation, the cells remaining on the upper surface of the filter were removed using cotton tips, and the cells that migrated to the underside of the membrane were fixed with 4% paraformaldehyde and stained with Giemsa (Sigma). Cells in 10 random fields of view at  $\times 400$  magnifications were counted and expressed as the average number of cells/field of view.

### Colony formation assay

Cells from the colon cancer cell line LoVo ( $2 \times 10^5$  cells per well) were transfected with 0.5  $\mu$ g Dkk-3-expressing or empty vector (pEGFP-N1) using Lipofectamine 2000 reagent (Invitrogen, Carlsbad, CA). Transfected cells were selected with antibiotic G-418 Sulfate (0.4 mg/mL) (Merck, Darmstadt, Germany) for 2 wk. Colonies were fixed with methanol/acetone (1:1), stained with Giemsa, and counted. All experiments were performed in triplicate.

### Statistical analysis

All continuous values were expressed as mean  $\pm$  SD. One-way analysis of variance was used for comparisons among groups. Student's *t* test was used for comparison of the values between two groups. SPSS 16.0 for Windows (SPSS Inc., Chicago, IL, United States) was used for statistical analysis. Statistical significance was defined as  $P < 0.05$ .

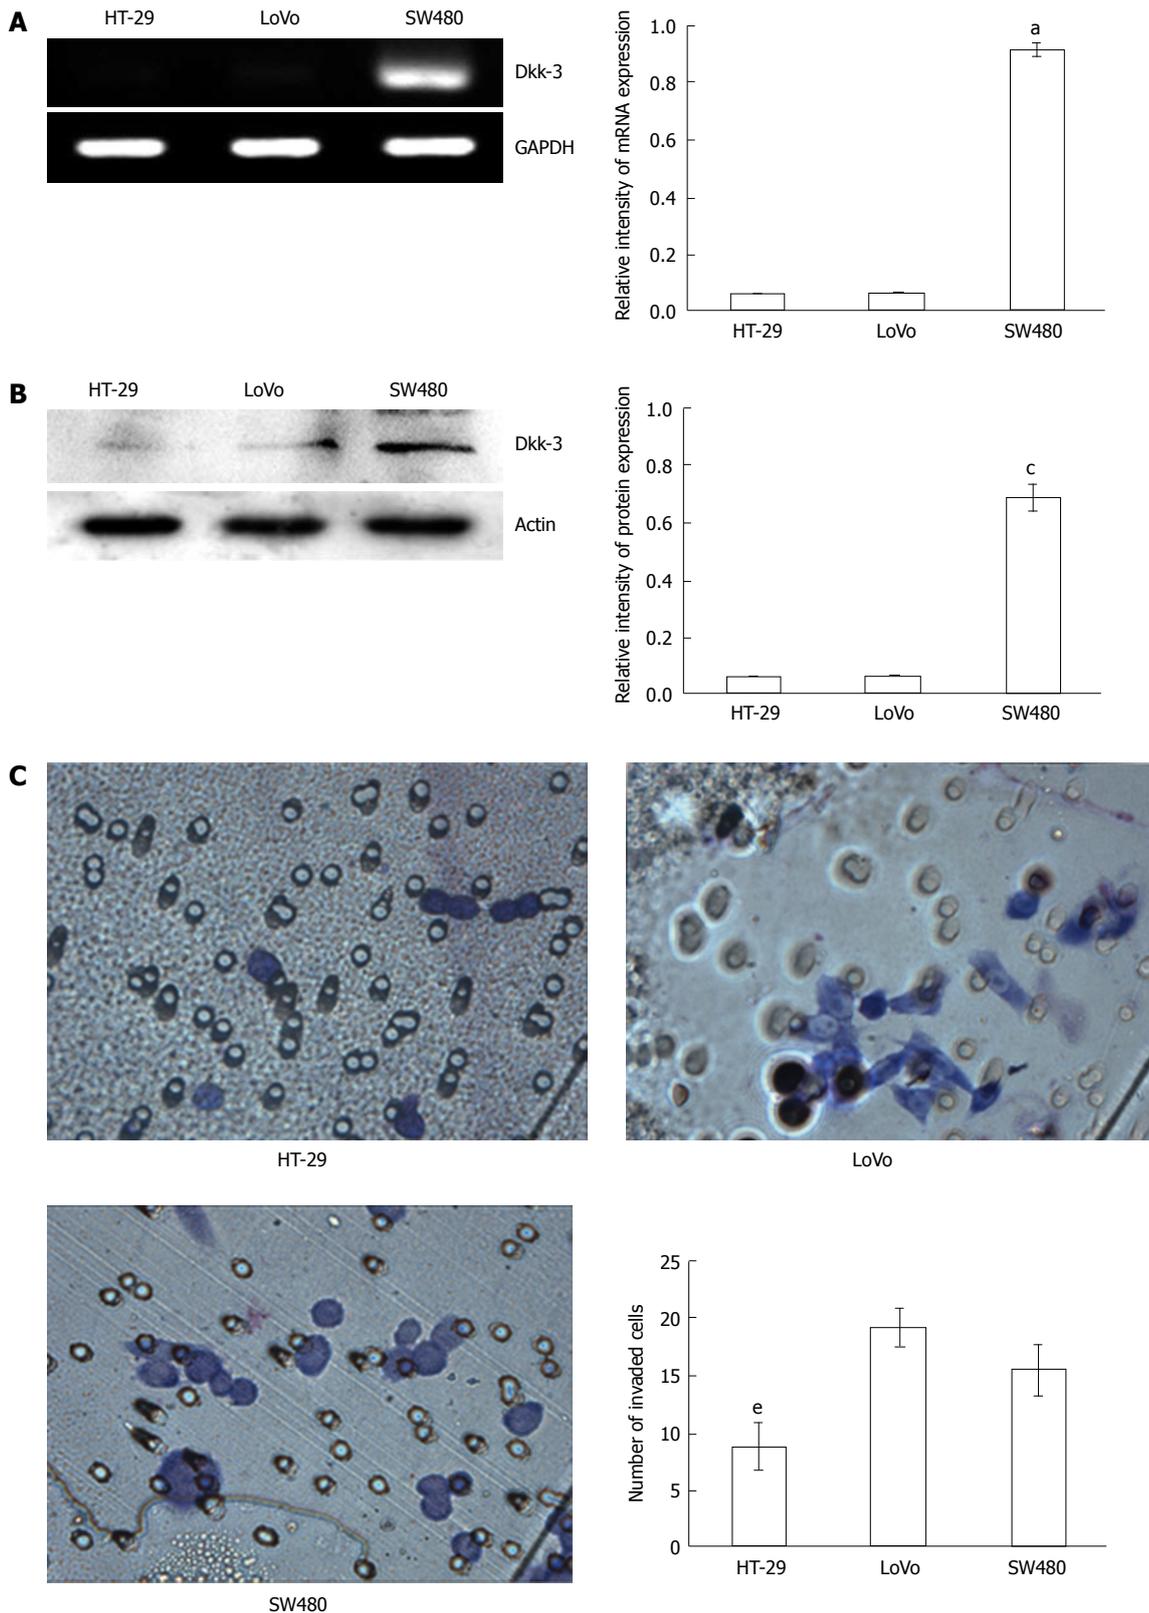

## RESULTS

### Correlation between Dickkopf-3 expression levels and invasion ability in human colon cancer cell lines

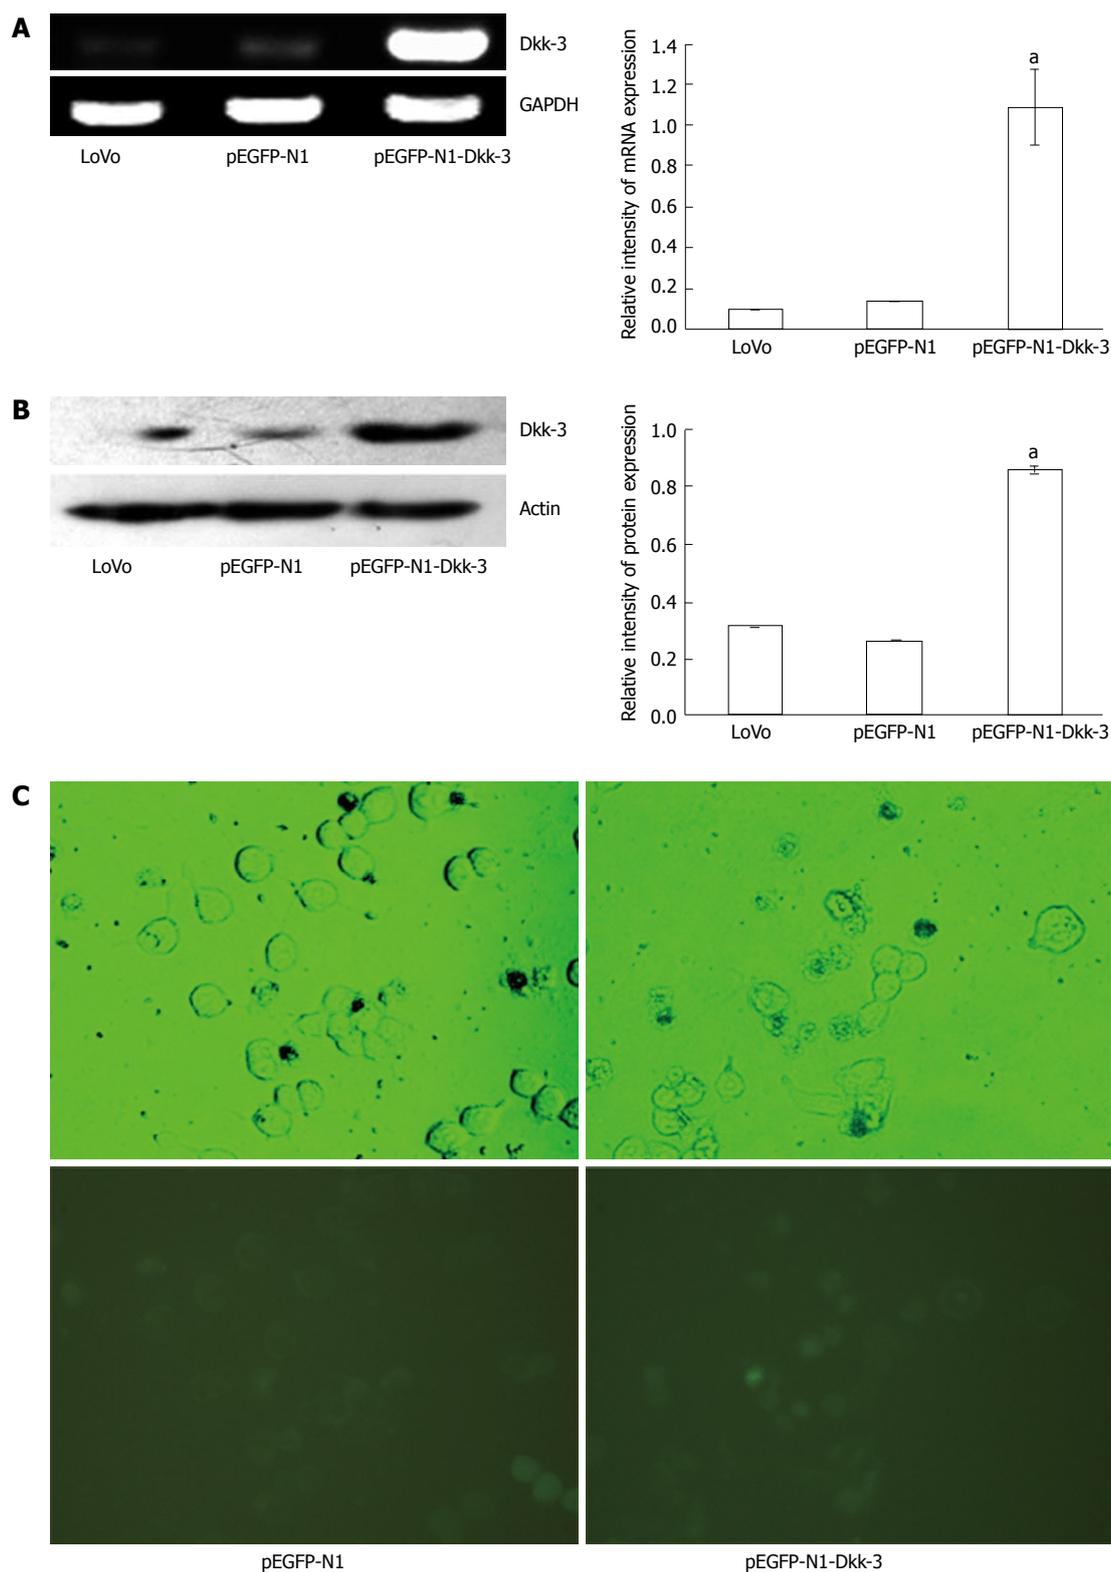

To determine the endogenous expression of Dkk-3, we compared the Dkk-3 level in three human colon cancer cell lines (HT-29, LoVo and SW480). As shown in Figure 1A and B, Dkk-3 expression was significantly higher in SW480 cells (mRNA:  $0.92 \pm 0.04$ , protein:  $0.69 \pm 0.13$ ; all  $P < 0.05$ ) as compared with HT-29 (mRNA:  $0.06 \pm 0.02$ , protein:  $0.06 \pm 0.01$ ) and LoVo cells (mRNA:  $0.07 \pm 0.02$ , protein:  $0.07 \pm 0.02$ ). We also examined the ability of these cells to invade Matrigel, which is a well-established *in vitro* model for assessing tumor invasiveness. The result showed that the greatest levels of invasiveness was in LoVo cells ( $19.25 \pm 1.65$ ), which was followed by the SW480 ( $15.50 \pm 2.12$ ) and HT-29 ( $8.75 \pm 2.10$ ,  $P < 0.05$  vs LoVo or SW480), an order consistent with their known metastatic potentials (Figure 1C). These preliminary findings provoked us to track the question of whether modulation of Dkk-3 could affect colon cancer progression.

### Overexpression of Dickkopf-3 by pEGFP-N1-Dkk-3-GFP plasmid in human colon cancer LoVo cells

To study the biological role of Dkk-3 in colon cancer progression, we used pEGFP-N1-Dkk-3-GFP plasmid coding for full-length human Dkk-3 to enhance the Dkk-3 gene expression in the human colon cancer LoVo cells. The expression of the recombinant human Dkk-3 was analyzed by RT-PCR and Western blotting

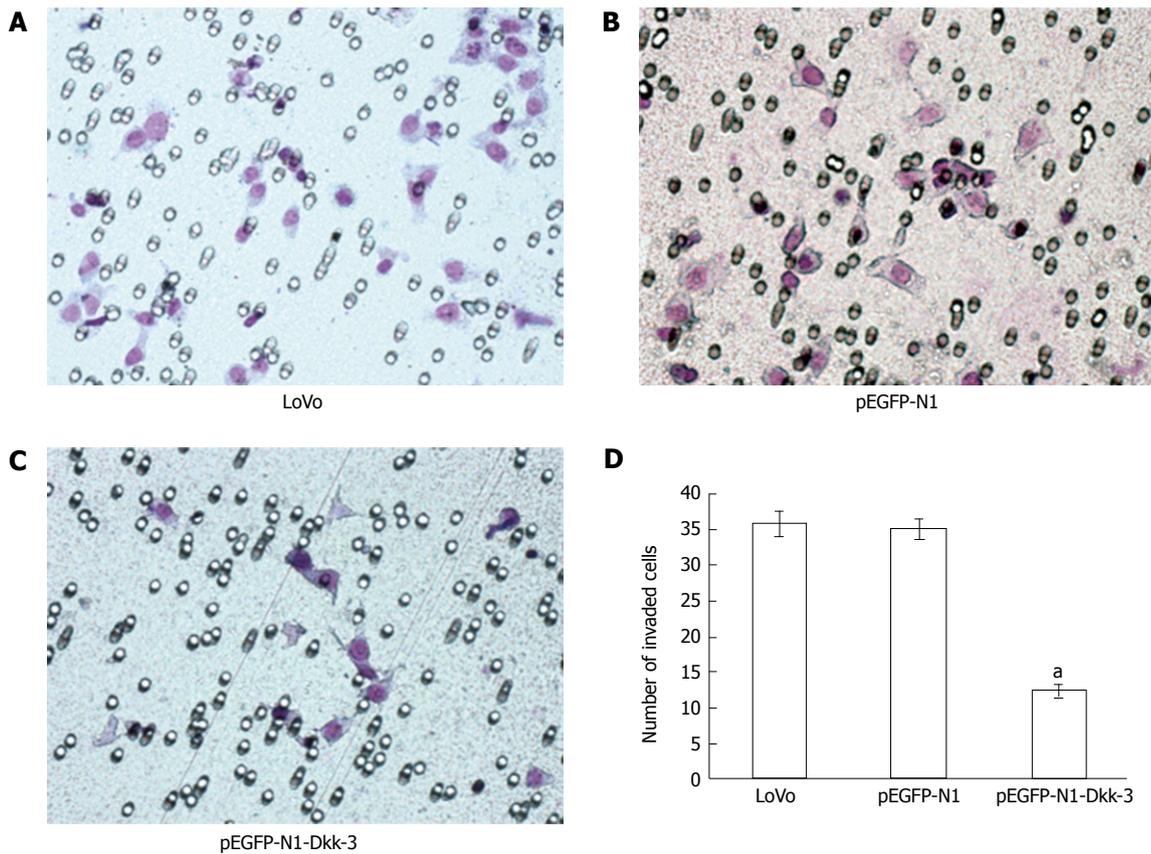

**Figure 1** Levels of Dickkopf-3 mRNA and protein expression correlate with invasive potential of human colon cancer cell lines. A: Semi-quantitative reverse transcription polymerase chain reaction of RNA extracted from colon cancer cell lines, HT-29, LoVo and SW480, respectively, and the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA was amplified as a control. <sup>a</sup> $P < 0.05$  vs HT-29 or LoVo using Student's *t* test; B: Endogenous Dickkopf-3 (Dkk-3) protein expression was examined by immunoblot analysis of total cellular protein isolated from three colon cancer cell lines: HT-29, LoVo and SW480, and actin was utilized as a loading control. <sup>c</sup> $P < 0.05$  vs HT-29 or LoVo using Student's *t* test; C: Human colon cancer cells, HT-29, LoVo and SW480 invading through the Matrigel were counted under a microscope in ten random fields at  $\times 400$  magnification. <sup>e</sup> $P < 0.05$  vs LoVo or SW480 using Student's *t* test.

**Figure 2** pEGFP-N1-Dkk-3-GFP plasmid induces overexpression of Dickkopf-3 in human colon cancer LoVo cells. A: Semi-quantitative reverse transcription polymerase chain reaction of RNA extracted from pEGFP-N1-Dkk-3-GFP plasmid transfected LoVo cells and the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA was amplified as a control; B: Immunoblotting of total protein lysates extracted from pEGFP-N1-Dkk-3-GFP plasmid transfected LoVo cells, and actin was included as a loading control; C: Green fluorescent protein (GFP) was also detected under a fluorescence microscope in pEGFP-N1-Dkk-3-GFP plasmid transfected LoVo cells (× 400). <sup>a</sup>*P* < 0.05 vs LoVo or pEGFP-N1 using Student's *t* test.

analysis. As shown in Figure 2A, analysis of the transfected cells ( $1.09 \pm 0.11$ , *P* < 0.05) for Dkk-3 expression *via* semi-quantitative RT-PCR demonstrated a specific

increase in mRNA levels for each gene relative to the pEGFP-N1 plasmid-transfected cells ( $0.14 \pm 0.02$ ) or untreated LoVo cells ( $0.10 \pm 0.02$ ). Immunoblot analysis

**Figure 3** Overexpression of Dickkopf-3 inhibits invasion in human colon cancer LoVo cells. Representative number of invading cells through the Matrigel was counted under microscope in ten random fields at × 400 magnification. Each bar represented the mean ± SD. <sup>a</sup>*P* < 0.05 vs LoVo or pEGFP-N1 using Student's *t* test. The results are representative of three separate experiments.

of cell extracts was carried out to determine whether increased mRNA expression, as observed, correlated with increased translation of the gene product. Figure 2B shows that the protein expression level of Dkk-3 was significantly increased in pEGFP-N1-Dkk-3 group ( $0.86 \pm 0.12$ , *P* < 0.05) compared with the pEGFP-N1 group ( $0.26 \pm 0.04$ ) or untreated LoVo cells ( $0.31 \pm 0.04$ ). A similar trend was observed by immunoblot analysis with the result of RT-PCR. The transient expression of GFP was observed under a fluorescence microscope after 48 h transfection (Figure 2C). Figure 2C indicates that the efficient transduction of pEGFP-N1-Dkk-3-GFP plasmid was approximately 70% after 48 h transfection.

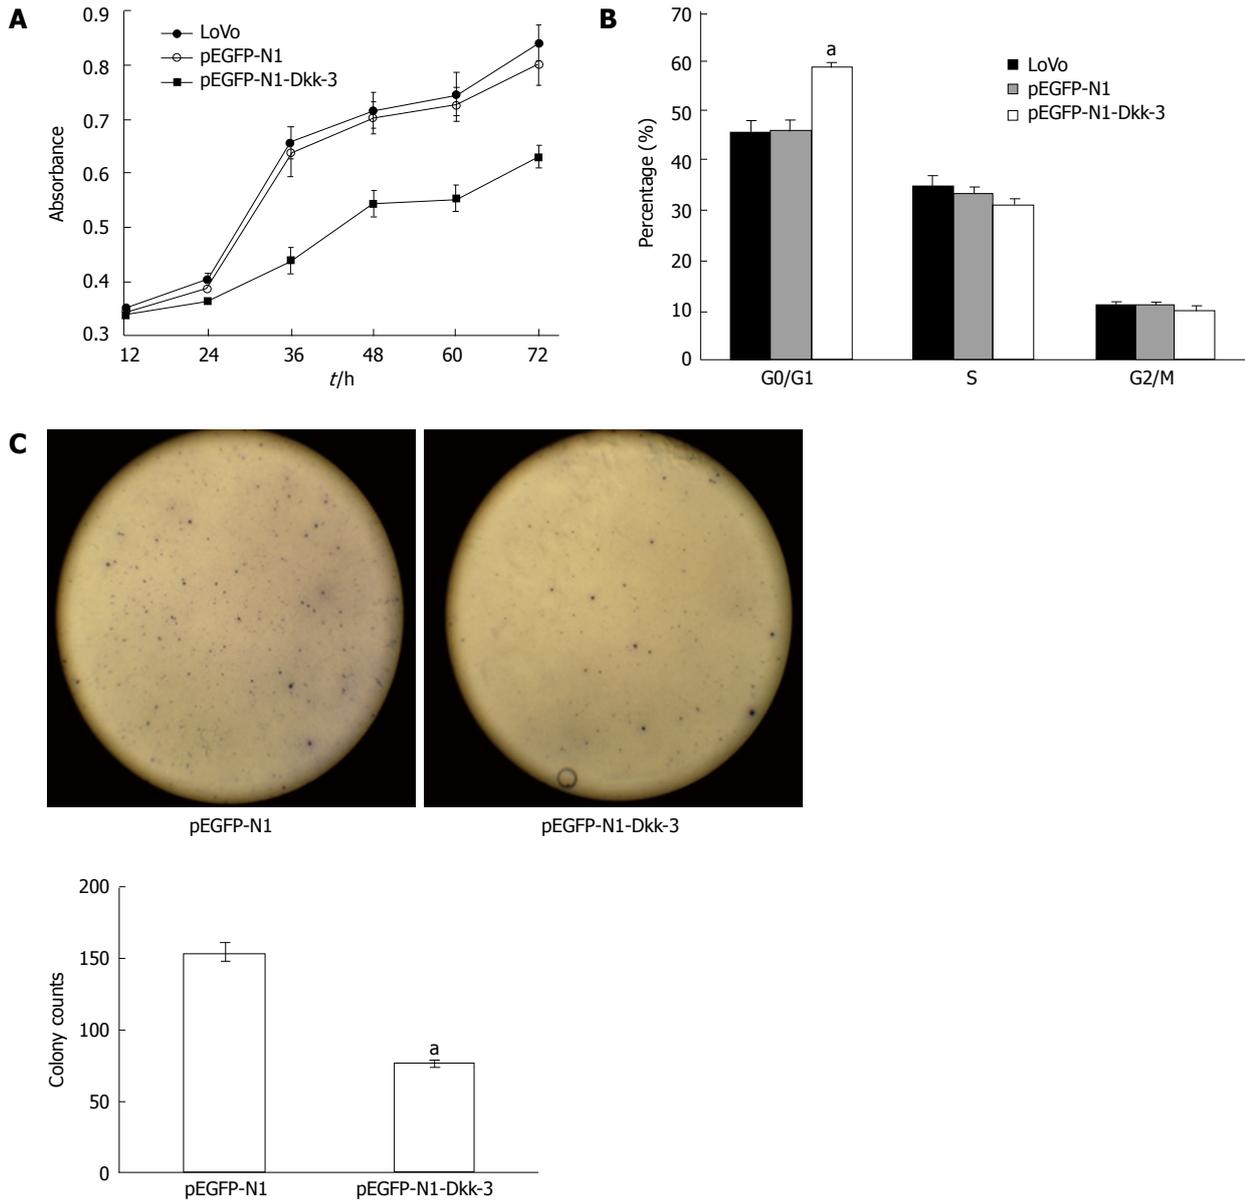

**Effect of Dickkopf-3 overexpression on invasion in human colon cancer LoVo cells**

To evaluate the impact of Dkk-3 overexpression on invasion of human colon cancer LoVo cells, a Matrigel invasion assay was performed. When compared with normal LoVo cells ( $36.00 \pm 1.85$ ) or cells transfected with pEGFP-N1 plasmid ( $36.25 \pm 1.49$ ), pEGFP-N1-Dkk-3-GFP plasmid-transfected cells ( $12.50 \pm 0.96$ , *P* < 0.05) showed a substantial reduction in invasive ability. Invasion of LoVo cells was reduced to about 70% of the controls by pEGFP-N1-Dkk-3-GFP plasmid (Figure 3). Thus, LoVo cell invasion into Matrigel was substantially regulated by

Dkk-3 function. Dkk-3 expression was required for colon cancer cell invasion leading to tumor metastasis.

**Effect of Dickkopf-3 overexpression on proliferation in human colon cancer LoVo cells**

To assess the potential effects of Dkk-3 overexpression on proliferation in human colon cancer LoVo cells, we investigated cell growth *in vitro*. Using the tetrazolium salt (WST-8) cell viability assay (see “Materials and Methods”), we generated a time-response curve by incubating cultures of transfected LoVo cells for 12, 24, 36, 48, 60 and 72 h, which showed a time-dependent inhibition of cell viability (Figure 4A). pEGFP-N1 transfection had no effect on the proliferative ability of LoVo cells, whereas pEGFP-N1-Dkk-3-GFP plasmid transfection caused a dramatic reduction in the proliferation of LoVo cells (*P* < 0.05). On the other hand, we performed colony formation assays using LoVo cells transfected with a *Dkk-3* gene construct (pEGFP-N1-Dkk-3-GFP) or with an empty vector (pEGFP-N1). The number of colonies formed was counted after 2 wk culture. When compared with the pEGFP-N1 plasmid-transfected cells ( $154.67 \pm 5.86$ ), we observed that *Dkk-3* overexpression ( $77.00 \pm 2.65$ , *P* < 0.05) decreased markedly the number of colonies (Figure 4C).

**Figure 4** Overexpression of Dickkopf-3 inhibits proliferation and induces G0/G1 arrest in human colon cancer LoVo cells. A: Dickkopf-3 (Dkk-3) inhibits proliferation in human colon cancer LoVo cells; B: Forty-eight hours after transfection, LoVo was used for cell cycle analysis using a FACSCalibur flow cytometer; C: The dickkopf homolog 3 gene Dkk-3 inhibited tumor cell colony formation. LoVo cells were transfected with pEGFP-N1-Dkk-3-GFP plasmid or with pEGFP-N1 and were maintained in the presence of G418 sulfate for 2 wk. Quantitative analysis of colony numbers are shown as the mean  $\pm$  SD. <sup>a</sup> $P < 0.05$  vs pEGFP-N1 using Student's *t* test.

**Effect of Dickkopf-3 overexpression on cell cycle in human colon cancer LoVo cells**

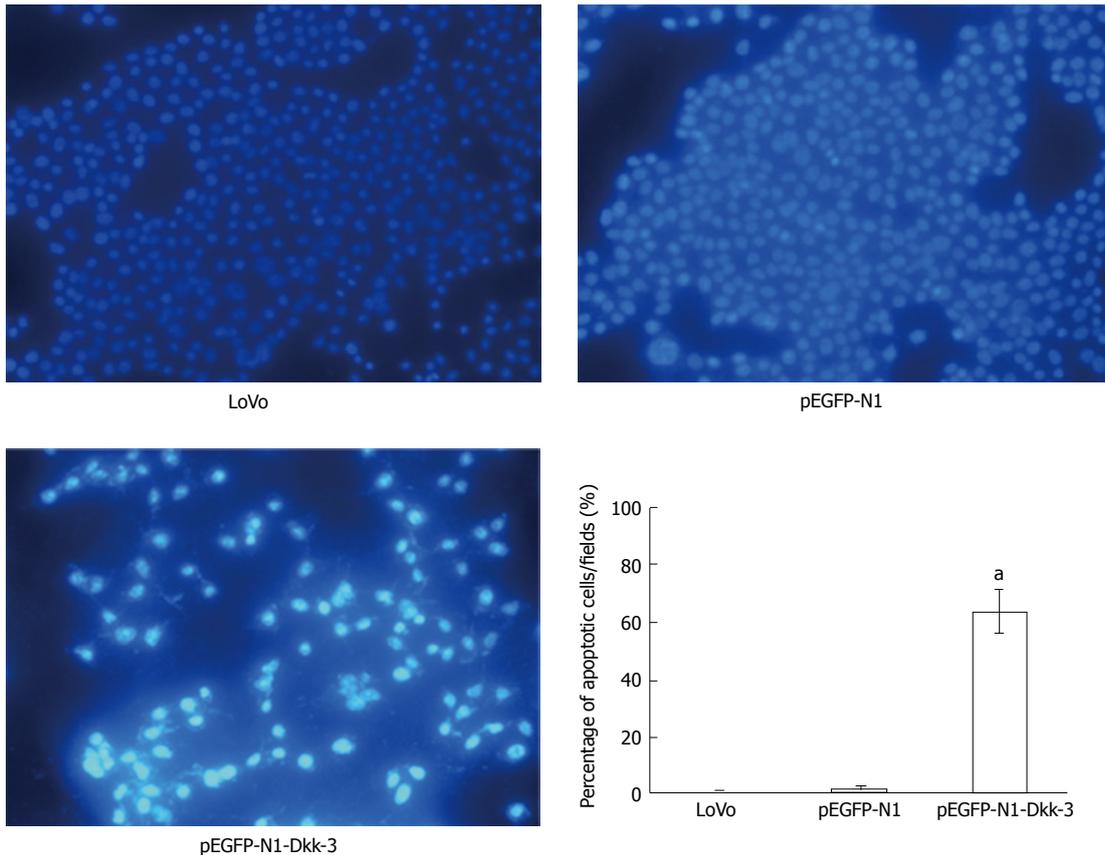

To investigate the precise mechanisms of the decreased cell viability observed in LoVo transient *Dkk-3* transfectants, we analyzed the cell cycle distribution profile by flow cytometry with propidium iodide. After 48 h transfection, the cells were fixed and stained with the DNA intercalating fluorescent dye propidium iodide. As shown in Figure 4B, untreated LoVo cells had normal cell cycle profiles with approximately 45% of cells in G<sub>0</sub>/G<sub>1</sub> phase containing 2N DNA content and 12% of cells in G<sub>2</sub>/M phase containing 4N DNA content. The percentage of cells in the G<sub>0</sub>/G<sub>1</sub> phase of the cell cycle was significantly higher in Dkk-3 transfected LoVo cells ( $0.59 \pm 0.01$ ,  $P < 0.05$ ).

**Effect of Dickkopf-3 overexpression on apoptosis in human colon cancer LoVo cells**

The morphological changes of the apoptotic cells were detected by Hoechst 33258 staining (Figure 5). After 48 h transfection, cells were fixed and stained with Hoechst 33258 at room temperature. In the untreated LoVo cells ( $0.67 \pm 0.52$ ) and pEGFP-N1 group ( $1.33 \pm 1.21$ ), the nuclei were stained weak homogeneous blue, while in the group transfected with pEGFP-N1-Dkk-3-GFP plasmid ( $63.67 \pm 7.71$ ,  $P < 0.05$ ), bright chromatin condensation and nuclear fragmentation were found.

**Effect of Dickkopf-3 overexpression on cytoplasmic  $\beta$ -catenin accumulation in human colon cancer LoVo cells**

Dkk-3 has been reported to induce changes in  $\beta$ -catenin

**Figure 5** Detection of apoptosis by Hoechst 33285. The apoptotic feature was assessed by observing chromatin condensation and fragment staining. <sup>a</sup> $P < 0.05$  vs control cells (untreated LoVo cells or pEGFP-N1-transfected LoVo cells).

localization consistent with an increase in cell-cell adhesion<sup>[9]</sup>. To address this question in colon cancer, we examined the  $\beta$ -catenin expression level in mock and *Dkk-3* transfectants. As shown in Figure 6A, transient transfection of *Dkk-3* affected Wnt signaling by reducing the accumulation of cytosolic fraction of  $\beta$ -catenin.  $\beta$ -catenin often yields doublets on Western blot analysis, perhaps as a result of being phosphorylated (most often tyrosine or serine phosphorylation)<sup>[9]</sup>.

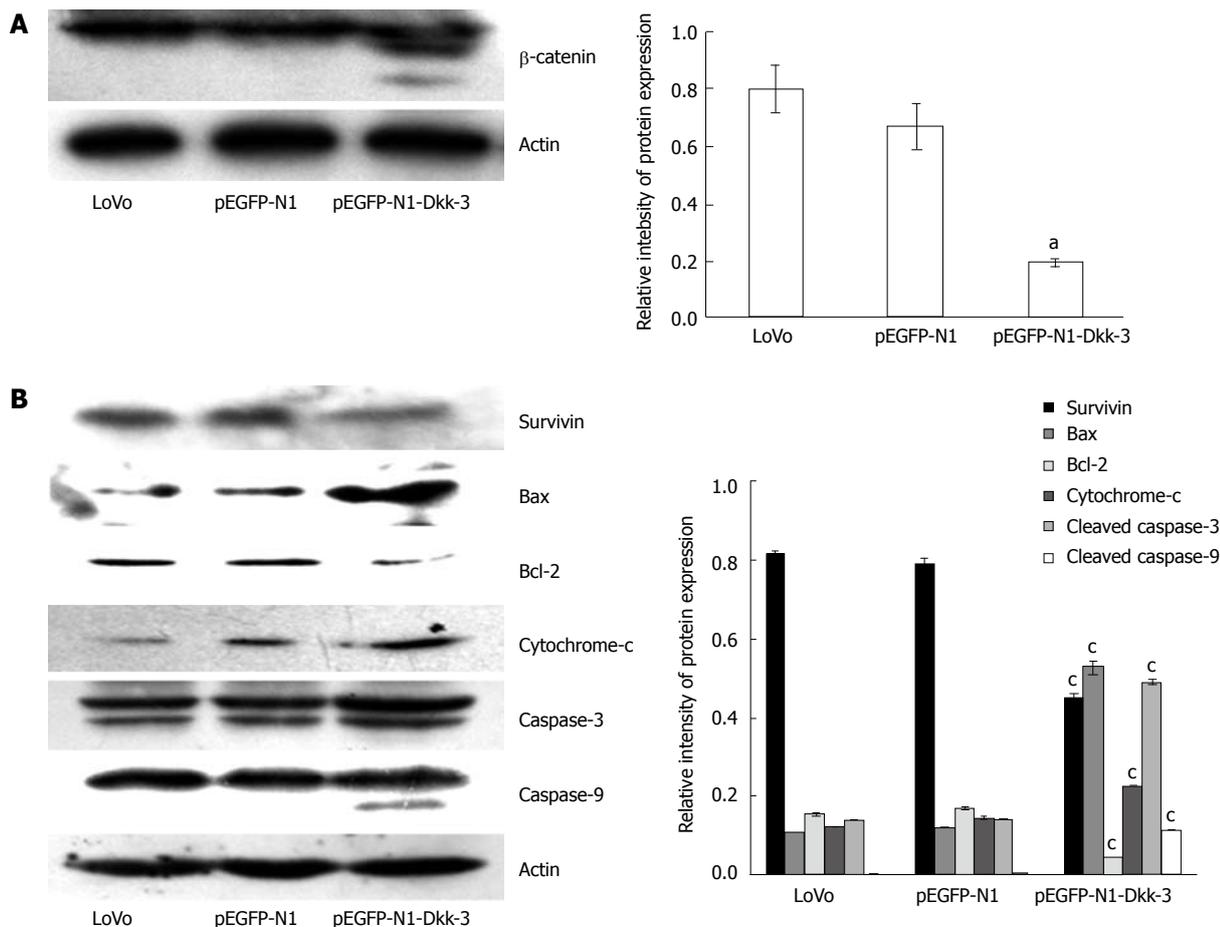

#### **Overexpression of Dickkopf-3 induces apoptosis through activation of mitochondrial pathway in LoVo cells**

To further investigate the detailed apoptotic mechanism, we examined the effect of *Dkk-3* overexpression on mitochondrial pathway. As shown in Figure 6B, *Dkk-3* overexpression caused a decline in survivin levels, a member of the inhibitors of apoptosis proteins family, which is known to block apoptosis by inhibiting caspases and mitochondria-mediated apoptosis<sup>[18]</sup>. It has been proposed that one of the main regulatory steps of programmed cell death is controlled by the ratio of anti-apoptotic and proapoptotic members of the Bcl-2 family of proteins<sup>[19,20]</sup>. The role of mitochondrial damage in apoptosis was suggested to be mediated by the release of cytochrome c<sup>[21]</sup>. Upon cleavage by upstream proteases in an intracellular cascade, the activation of caspase-3 is considered as a hallmark of the apoptotic process<sup>[22]</sup>.

*Dkk-3* overexpression also induced an increase in Bax protein levels and a decrease in Bcl-2 levels in LoVo cells, which led to a decrease in the antiapoptotic/proapoptotic (Bcl-2/Bax) ratio (Figure 6B). In addition, the expression levels of the cytosolic cytochrome c which was suggested to be involved in mitochondrial damage, the activated caspase-3 and the activated caspase-9 were significantly increased with *Dkk-3* overexpression.

## **DISCUSSION**

The Wnt signalling pathway has long been known to direct growth and patterning during embryonic development<sup>[23,24]</sup>. Recent evidence also implicates that Wnt signalling pathway is involved in the postembryonic regulation of stem-cell number in epithelia, such as those of the skin and intestine, which undergo constant renewal<sup>[24]</sup>. The pathway is composed of canonical Wnt signaling *via* Wnt/ $\beta$ -catenin and noncanonical Wnt signaling *via* the Wnt/ $\text{Ca}^{2+}$  pathway and Wnt/c-JNK (planar cell polarity)<sup>[4,5]</sup>. Wnt signaling pathway is often activated in many cancers and the expression of Wnt antagonists is often downregulated epigenetically<sup>[4,7,24-29]</sup>. The extracellular antagonists of the Wnt signalling pathway can be divided into two broad classes. Both classes of molecule prevent ligand-receptor interactions, but by different mechanisms: members of the first class, including

**Figure 6** Overexpression of Dickkopf-3 inhibits downstream signaling and induces apoptosis in LoVo cells through mitochondrial pathway. A: Dickkopf-3 (Dkk-3) reduces cytoplasmic accumulation of  $\beta$ -catenin; B: Western blotting analysis of survivin, Bcl-2, Bax, cytochrome c, caspase-3 and caspase-9 protein after 48 h transfection with pEGFP-N1-Dkk-3-GFP plasmid in LoVo cells. Actin was used as a loading control. <sup>a</sup>*P* < 0.05 vs LoVo or pEGFP-N1 using Student's *t* test.

the sFRP family, Wnt inhibitory factor-1 and Cerberus, primarily binds to Wnt proteins; the second class comprising certain members of the Dkk family, binds to one subunit of the Wnt receptor complex<sup>[6]</sup>.

Human Dkk-related genes are composed of Dkk-1, Dkk-2, Dkk-3, and Dkk-4, together with a unique Dkk-3 related protein termed Soggy (Sgy)<sup>[7]</sup>. Dkk-3, the most divergent family member, is proposed to function as a secreted tumor suppressor since it is downregulated in a number of cancer cells<sup>[28]</sup>. Dkk-3 has been reported to be silenced or down-regulated in 12 (70.6%) of 17 gastric cancer cell lines and in 3 (33.3%) of 9 colon cancer cell lines, and the loss of gene expression was associated with promoter methylation, which could be restored by demethylating agents<sup>[30]</sup>. Tissue microarrays have shown that the number of microvessels in Dkk-3-positive CRC samples was significantly higher than that in Dkk-3-negative samples (*P* = 0.001), and Dkk-3 expression was also increased with rising numbers of microvessels (*P* < 0.0001)<sup>[29]</sup>. In addition, Dkk-3 has been revealed to inhibit cancer proliferation and induce apoptosis in several cancers<sup>[25,26,31-36]</sup>. Overexpression of Dkk-3 in normal fibroblasts suppresses tumor growth *via* induction of interleukin-7<sup>[32]</sup>. In malignant glioma<sup>[37]</sup>, Dkk-3 transfection

led to apoptosis due to the activation of phosphorylated jun proto-oncogene, caspase-9, and caspase-3 and the reduction of  $\beta$ -catenin. In renal cell carcinoma<sup>[25]</sup>, prostate cancer<sup>[26,31,35]</sup>, testicular cancer<sup>[38]</sup>, bladder cancer<sup>[34]</sup> and breast cancer<sup>[33]</sup>, overexpression of Dkk-3 was found to lead to apoptotic cell death in a c-JNK phosphorylation-dependent manner and/or endoplasmic reticulum stress. In osteosarcoma<sup>[9]</sup>, transfection of Dkk-3 and dominant-negative LRP5 significantly lowers the cell invasion capacity and cell motility, and also induces changes in  $\beta$ -catenin localization consistent with an increase in cell-cell adhesion. However, Dkk-3 functional analysis and the regulation mechanism have not been reported in colorectal cancer.

In the present study, we focused on proliferation and apoptosis of colon cancer cells. We examined the anti-proliferation ability of Dkk-3 overexpression by pEGFP-N1-Dkk-3-GFP plasmid in human colon cancer LoVo cells, and measured the extent of cell proliferation by the WST-8 assay (Figure 4A). Interestingly, overexpression of Dkk-3 effectively suppressed cellular proliferation of colon cancer cells in a time-dependent fashion (Figure 4A). On the other hand, overexpression of Dkk-3 inhibited tumor cell colony formation in LoVo

cells (Figure 4C).

To investigate the precise mechanisms responsible for the Dkk-3 overexpression-mediated abortive cell divisions, we sought to examine the cell cycle distribution profile of Dkk-3 transfectants. The percentage of cells arrested in G<sub>0</sub>/G<sub>1</sub> phase of the cell cycle was also increased in Dkk-3 transfectants. It was also revealed that Dkk-3 overexpression resulted in apoptosis (Hoechst 33258) in Dkk-3 transfectants (Figure 5). The morphological features in LoVo cells of apoptotic *vs* necrotic cell death can be distinguished under microscopy<sup>[39]</sup>. Apoptotic LoVo cells were identified by observing chromatin condensation and fragment staining by Hoechst 33258. It suggests that if early apoptotic cells are not ingested by phagocytes in time, secondary necrosis would proceed<sup>[40]</sup>.

One of the main regulatory steps of programmed cell death is controlled by the ratio of antiapoptotic and proapoptotic members of the Bcl-2 family of proteins<sup>[19,20]</sup>. Overexpression of antiapoptotic Bcl-2 family members can tip the delicate balance in favor of survival, thereby conferring drug resistance, at least in some cellular tumor model systems<sup>[41-43]</sup>. On the other hand, overexpression of proapoptotic Bax or Bak is sufficient to increase the sensitivity of malignant cancer cells to apoptosis and to overcome drug resistance<sup>[43-45]</sup>. Bcl-2 in the unphosphorylated form complexes with Bax, and thus its phosphorylation releases Bax from the Bcl-2-Bax complex<sup>[22,46-48]</sup>. Unbound Bax translocates from cytosol to the mitochondrial membrane to signal triggering of the downstream apoptotic cascade, such as release of cytochrome c and activation of executionary caspases<sup>[22,44-46]</sup>. The activation of caspase-3, upon its cleavage by upstream proteases, is considered as a hallmark of the apoptotic process<sup>[41]</sup>. In agreement with the hypothesis, activated caspase-3 and -9 were detected in Dkk-3 transfectants. Our results showed that overexpression of Dkk-3 decreased Bcl-2/Bax ratio, caused the release of cytochrome c, and the activation of caspase-3 and caspase-9 in LoVo cells (Figure 6B). Further studies are required to determine the exact mechanism whether Dkk-3 enhances apoptosis-inducing effects on human colon cancer cells, which is cross-talking activation of death receptors pathway of apoptosis.

In conclusion, Dkk-3 is anti-proliferative and proapoptotic in colon cancer LoVo cells. Overexpression of Dkk-3 caused 2N DNA accumulation in LoVo cells, suggesting that the Dkk-3 transfectants arrest in G<sub>0</sub>/G<sub>1</sub> phase preceding cell death. These abnormal cells probably trigger activation of programmed cell death that is mitochondrially-driven and executed through the activated caspase by the cleavage of downstream targets. The LoVo cell death program is also mediated through downregulation of survivin. Therefore, Dkk-3 functions as a tumor suppressor in colon cancer cells and its downregulation may be involved in colon cancer progression. Moreover, Dkk-3 may be involved in the Wnt/ $\beta$ -catenin signaling pathways in colon cancer cells.

## COMMENTS

### Background

The Wnt signal transduction pathway is activated in many cancers and the expression of Wnt antagonists are often downregulated epigenetically. Wnt antagonists can be divided into two functional classes, the secreted frizzled related proteins and the Dickkopf (Dkk). The *Dkk* gene family of secretory modulators of canonical Wnt/ $\beta$ -catenin signaling is involved in the control of proliferation, polarity and migration, cell fate specification and differentiation. Dkk-3, also known as reduced expression in immortalized cells, is the most divergent family member and proposed to function as a secreted tumor suppressor since it is downregulated in a number of cancer cells.

### Research frontiers

Recently, Wnt antagonists have received increasing and specific attention due to their potential role in carcinogenesis. Dkk-3 has been revealed to inhibit cancer proliferation and induce apoptosis in malignant glioma, breast cancer, osteosarcoma, renal cell carcinoma, prostate cancer, testicular cancer and bladder cancer.

### Innovations and breakthroughs

Few studies have described the correlation between Wnt antagonists and the development of colon cancer. The results of this study suggest that Dkk-3 may act as negative regulators of Wnts and may be involved in the Wnt/ $\beta$ -catenin signaling pathways in colon cancer cells. Dkk-3 may be a crucial Wnt signaling regulator in colon cancer and an important component of the gastrointestinal proliferative regulatory network.

### Applications

In this study, the mRNA and protein expressions of Dkk-3 were investigated in colon cancer cells and that the aberrant expression of Wnt antagonists may play an important role in carcinogenesis of colon cancer. This finding may help improve early diagnosis and new therapies by blocking this pathway in the treatment of colon cancer.

### Terminology

The Wnt signaling pathway is one of evolutionarily-conserved signal transduction pathways to direct growth and patterning during embryonic development, from Hydra to humans. Wnt signals regulate many aspects of development which include the proliferation, fate specification, polarity, and migration of cells. Moreover, overactivation of Wnt signaling by mutation is an important factor in oncogenesis in the human colon and other tissues. The pathway is composed of canonical Wnt signaling via Wnt/ $\beta$ -catenin and noncanonical Wnt signaling or pathways that are  $\beta$ -catenin independent.

### Peer review

The authors investigated the mechanisms of the biological roles of Dkk-3 in colon cancer. It revealed that Dkk-3 played an important role in mitochondria-mediated apoptosis and Dkk-3 may be involved in the Wnt/ $\beta$ -catenin signaling pathways in colon cancer cells. The article is a good attempt to work on the hypothesis and the results may represent a molecular mechanism of colon carcinogenesis.

**METHODS:** After SGC-7901 cells were treated with toxicarioside A at various concentrations (0.5, 1.5, 4.5, 9.0  $\mu$ g/mL) for 24 h or 48 h, cell viability was determined by 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide assay, and the motility and invasion of tumor cells were assessed by the Transwell chamber assay. Immunofluorescence staining, reverse transcription polymerase chain reaction and Western blotting were performed to detect the expression of basic fibroblast growth factor (bFGF) and fibroblast growth factor receptor-1 (FGFR1), and nuclear factor-kappa B (NF- $\kappa$ B) activation was examined by electrophoretic mobility shift assay.

**RESULTS:** The results showed that toxicarioside A was capable of reducing cell viability, inhibiting cell growth, and suppressing cell migration and invasion activities in a time- and dose-dependent manner in SGC-7901 cells. Further analysis revealed that not only the expression of bFGF and its high-affinity receptor FGFR1 but also the NF- $\kappa$ B-DNA binding activity were effectively blocked by toxicarioside A in a dose-dependent manner compared with the control group ( $P < 0.05$  or  $P < 0.01$ ). Interestingly, application of the NF- $\kappa$ B specific inhibitor, pyrrolidinedithiocarbamate (PDTC), to SGC-7901 cells significantly potentized the toxicarioside A-induced down-regulation of bFGF compared with the control group ( $P < 0.05$ ).

**CONCLUSION:** These findings suggest that toxicarioside A has an anti-gastric cancer activity and this effect may be achieved partly through down-regulation of NF- $\kappa$ B and bFGF/FGFR1 signaling.

Toxicarioside A inhibits SGC-7901 proliferation, migration and invasion *via* NF- $\kappa$ B/bFGF signaling. *World J Gastroenterol* 2012; 18(14): 1602-1609 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i14/1602.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i14.1602>

## INTRODUCTION

*Antiaristoxicaria* (Pers.) Lesch (Moraceae) is a well known precious species widespread in the tropical rain forest of Southeast Asia. Its latex and seeds contain a complex mixture of cardenolide glycosides and is therefore toxic<sup>[1]</sup>. Representative toxicariosides A-L have recently been identified from the latex and seeds of *Antiaristoxicaria* in our laboratory and by others<sup>[2-5]</sup>. Classically, cardenolides are used to treat congestive heart failure and arrhythmia<sup>[6-8]</sup>. Additionally, certain cardenolides extracted from some plants or animals have been demonstrated to be capable of blocking tumor cell proliferation through regulation of cell signal transduction<sup>[9-15]</sup>.

Currently, gastric cancer is one of the leading malignancies in China. However, the treatment outcome is not satisfactory because early diagnosis of gastric cancer remains difficult and most patients have already developed metastatic lesions when diagnosed<sup>[16]</sup>.

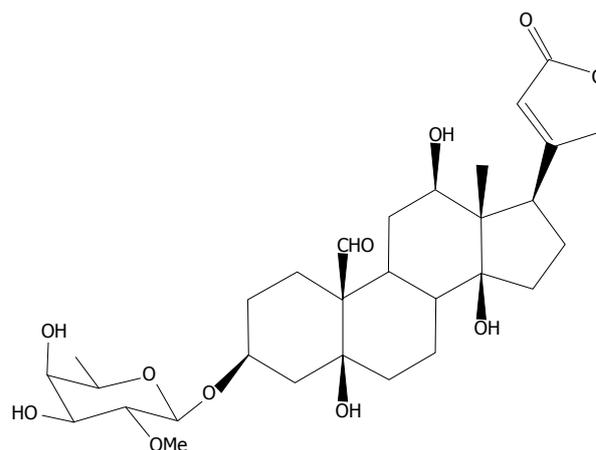

Basic fibroblast growth factor (bFGF) has been shown to be a multifunctional growth factor for tumor development<sup>[17-20]</sup>, and it exerts its biological effects mainly through interaction with its high-affinity receptor, fibroblast growth factor receptor-1 (FGFR1)<sup>[21-24]</sup>. Compiling evidence has demonstrated that bFGF signaling is involved in the development of gastric cancer<sup>[25,26]</sup>.

Nuclear factor-kappa B (NF- $\kappa$ B) is a ubiquitous dimeric transcription factor that plays pivotal roles in regulating the expression of genes encoding cytokines and chemokines that are involved in tumor proliferation, angiogenesis, and synthesis of anti-apoptotic proteins<sup>[27,28]</sup>. It has been documented that NF- $\kappa$ B can mediate bFGF signaling<sup>[29]</sup> and some types of cardiac glycosides can block the activation of NF- $\kappa$ B<sup>[30,31]</sup>. As a result, we hypothesize that cardiac glycosides may suppress gastric tumor growth *via* a decrease in NF- $\kappa$ B activity and blocking of the bFGF signaling pathway. In the present study, we attempted to test this hypothesis in an *in vitro* cell culture model.

## MATERIALS AND METHODS

### Plant material

Latex of *Antiaristoxicaria* (Pers.) Lesch collected in Lingshui county of Hainan Province, China in November 2005 was identified with the assistance of Professor Zhunian

**Figure 1** The structure of toxicarioside A.

Wang at the Institute of Crops Genetic Resources, Chinese Academy of Tropical Agricultural Sciences. The specimen was numbered as No. AN200511.

### Chemicals and reagents

Rabbit-anti human bFGF and FGFR1 were purchased from Santa Cruz (Santa Cruz, CA, United States). Rhodamine (TRITC)-conjugated mouse anti-rabbit immunoglobulin G (IgG), fluorescein isothiocyanate (FITC)-conjugated mouse anti-rabbit IgG, 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT), trypan blue and pyrrolidinedithiocarbamate (PDTC) were obtained from Sigma (Sigma Aldrich, St Louis, MO, United States). Fetal bovine serum (FBS), RPMI 1640 medium and trypsin were procured from Gibco (Gibco, Carlsbad, CA, United States).

### Extraction and isolation of toxicarioside A

With 95% EtOH, 4.0 L of the latex of *Antiaristoxicaria* were extracted thrice at room temperature and filtered. The combined extract was evaporated *in vacuo* to yield a syrup (263.8 g), which was fractionated sequentially with petroleum ether, EtOAc, and n-BuOH. The EtOAc fraction (8.68 g) that showed potent cytotoxic activity in the bioassay was passed through pressure-reduced column chromatography using step-wise elution with CHCl<sub>3</sub>-MeOH (50:1, 20:1, 10:1, 5:1, 2:1, 1:1 and 0:1, v/v), generating seven corresponding fractions, A1-A7. Fraction A7 (2.55 g) was further separated on silica gel column chromatography, from which compound 1 (788.1 mg) was eluted with CHCl<sub>3</sub>-MeOH (14:1, v/v). On the basis of spectral data and chemical analyses, compound 1 was defined as toxicarioside A (Figure 1).

### Cell culture

Human gastric cancer cell line (SGC-7901) was obtained from the Cell Bank of Type Culture Collection of Chinese Academy of Sciences, Shanghai Institute of Cell Biology. Cells were cultured in RPMI 1640 medium supplemented with 10% FBS, 100 IU/mL penicillin and 100 mg/mL streptomycin at 37 °C in a humidified atmosphere with 5% CO<sub>2</sub>. Cells at the logarithmic phase were

used for experiments.

### **Proliferation assay**

MTT assay and trypanblue staining were used to determine the growth and viability of SGC-7901 cells. For the MTT assay, SGC-7901 cells in logarithmic growth were trypsinized and harvested and then the cells were seeded onto a 96-well plate. After 24 h, fresh RPMI 1640 medium containing different concentrations of toxicarioside A (0.5, 1.5, 4.5, 9.0  $\mu\text{g}/\text{mL}$ ) was added at 100  $\mu\text{L}$  per well, respectively, and 6 replicate wells were used for each of the concentrations. After incubation for different time intervals, 10  $\mu\text{L}$  of MTT (5  $\text{mg}/\text{mL}$ ) was added to each well and the cells were further incubated at 37  $^{\circ}\text{C}$  for 4 h. The supernatant was then removed and 100  $\mu\text{L}$  DMSO was added into each well. Absorbance (A value) at a wavelength of 490 nm was measured with a Bio-TekEXL808 microplate reader (Bio-Rad, Hercules, CA, United States). For trypanblue staining, SGC-7901 cells were trypsinized and seeded into 24-well plates at a density of  $0.5 \times 10^4/\text{mL}$ . After 4.5  $\mu\text{g}/\text{mL}$  toxicarioside A was added, the cells were collected and counted using trypan blue staining under an inverse light microscope for 3 consecutive days.

### **Invasion and migration assay**

Invasion assays were performed in a 24-well Transwell chamber (Corning, Lowell, MA, United States) as previously described<sup>[32]</sup>. Briefly, each Transwell chamber was coated with 15  $\mu\text{g}$  Matrigel,  $5 \times 10^4$  cells were seeded to pre-coated filters in 200  $\mu\text{L}$  of serum-free medium containing different concentrations of toxicarioside A (0.5, 1.5, 4.5, 9.0  $\mu\text{g}/\text{mL}$ ) in triplicate. The lower parts of the chambers were filled with 500  $\mu\text{L}$  of RPMI 1640 medium containing 10% FBS. After incubation in a 5%  $\text{CO}_2$  humidified incubator at 37  $^{\circ}\text{C}$  for 24 h, the cells on the upper surface were gently removed with a cotton swab, and the filters were fixed with 95% alcohol for 15-20 min and stained with hematoxylin-eosin for 15 min. The number of cells on the lower surface of the filters was quantified under a microscope. The same procedures were followed for the migration assay except the Transwell chambers were not coated with Matrigel.

### **Immunofluorescence staining**

To detect the expression of bFGF as well as its receptor FGFR1 in SGC-7901 cells, the rabbit antibody (1:100) against bFGF and FGFR1 were used. The antigenic sites were localized by TRITC-conjugated mouse anti-rabbit IgG and FITC-conjugated mouse anti-rabbit IgG, and images of antigenic sites were captured under a laser scanning confocal microscope (FV500, Olympus, Tokyo, Japan).

### **RNA extraction and reverse transcription polymerase chain reaction**

Total RNA was extracted with Trizol reagent (Invitrogen, Carlsbad, CA, United States) following the manufacturer's protocols. Reverse transcription polymerase chain

reaction was carried out using pairs of primers (Invitrogen) as follows for semiquantitative assessment: bFGF (NM\_002006.4) sense, 5'-AAG AGC GAC CCT CAC ATC AA-3'; anti-sense, 5'-TCG TTT CAG TGC CAC ATC CGT CAA TA CC-3', yielding a 225 bp product; FGFR1 (M34641) sense, 5'-CTT CTGT TTC AG-3'; anti-sense, 5'-TCC ACA ATG CAG GTG TAG TT-3', yielding a 354 bp product.  $\beta$ -actin (NM\_001101) sense, 5'-GTT GCG TTA CAC CCT TTC TT-3', anti-sense, 5'-CGA AGG CTC ATC ATT CAA AA-3', yielding a 443 bp product. The products were separated by electrophoresis on a 1.5% agarose gel and visualized under UV using the gel documentation system (Bio-Rad Gel Doc1000, Bio-Rad). The mRNA levels of bFGF, FGFR1 were calculated based on the densitometric values of the specific bFGF, FGFR1 bands after adjustment with that of the  $\beta$ -actin band.

### **Western blotting analysis**

This was performed as previously described with minor modifications<sup>[33]</sup>. Cells were homogenized and separated by sodium dodecyl sulfate-polyacrylamide gel (12.5%) electrophoresis followed by electrophoretic transfer of proteins from the gel to a nitrocellulose membrane blot (Bio-Rad). The blot was incubated with a rabbit anti-bFGF antibody (1:500) or a rabbit anti-FGFR1 antibody (1:500) at 4  $^{\circ}\text{C}$  overnight, followed by incubation with the corresponding horseradish peroxidase-conjugated anti-biotin antibody (1:2000) at room temperature for 1 h. The immunoreactive signals were visualized with enhanced chemiluminescence reagents (Pierce, Rockford, IL, United States).

### **Electrophoretic mobility shift assay**

To determine NF- $\kappa\text{B}$  activation, electrophoretic mobility shift assay (EMSA) was conducted essentially as described previously<sup>[34]</sup>. In brief, nuclear proteins (10  $\mu\text{g}$ ) were incubated with the reaction buffer for 20 min at room temperature, followed by incubation with oligonucleotide containing the consensus sequence for the NF- $\kappa\text{B}$ -DNA binding site (5'-AGAGTGGGAATT TC-CACTCA-3')<sup>[35]</sup> (synthesized by Invitrogen, Shanghai, China). The reaction mixture was separated in a non-denaturing polyacrylamide gel (6%) that was later stained by SYBR Green EMSA staining solution from Molecular Probes (Invitrogen) with continuous, gentle agitation for about 20 min, protected from light. The gel was then washed in 150 mL of  $\text{dH}_2\text{O}$  and the stained nucleic acids were visualized and the image documented under UV using the gel documentation system (Bio-Rad Gel Doc1000).

### **Statistical analysis**

All data are expressed as mean  $\pm$  SE. For a comparison between two groups, the Student's *t* test was performed. For comparisons among multiple groups, an ANOVA was carried out, followed by a Student-Newman-Keuls test. Differences were considered significant when  $P < 0.05$ .

## RESULTS

### Effect of toxicarioside A on SGC-7901 cell proliferation

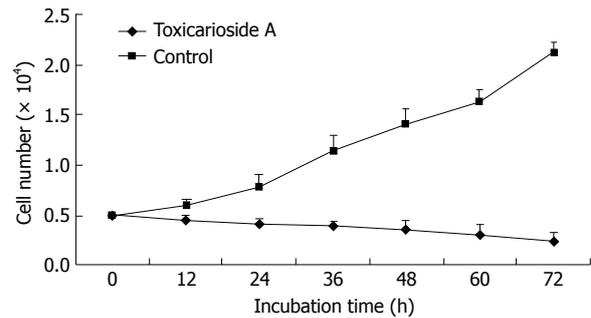

To assess the effect of toxicarioside A on the growth of gastric cancer, SGC-7901 cells were treated at various concentrations (0.5, 1.5, 4.5, 9.0 µg/mL) for 24–48 h and cell viability following these treatments was determined by MTT assays. As shown in Table 1, toxicarioside A reduced SGC-7901 cell viability in a time- and dose-dependent manner. Cell growth curves also showed that toxicarioside A significantly inhibited SGC-7901 cell growth as compared with the control (Figure 2).

### Effect of toxicarioside A on SGC-7901 cell migration and invasion

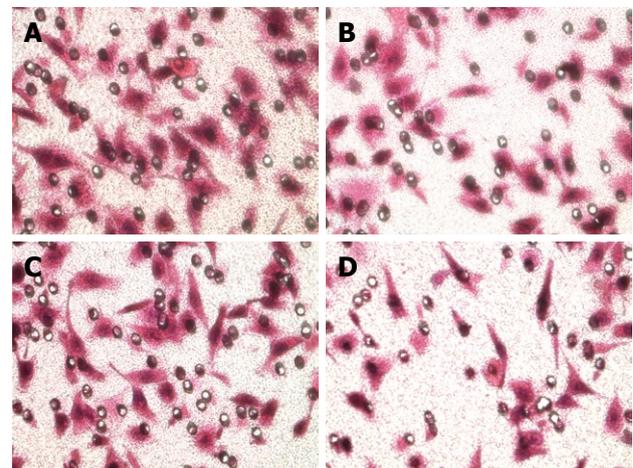

The results of Transwell cell migration and invasion are presented in Table 2 and Figure 3. Clearly, the addition of toxicarioside A to the medium in the upper chamber resulted in significant suppression of SGC-7901 migration and invasion in a dose-dependent manner at 1.5, 4.5 and 9.0 µg/mL, toxicarioside A inhibited SGC-7901 migration by 22.38% ± 10.64%, 39.58% ± 11.62% and 48.13% ± 10.12%, respectively (*P* < 0.05), and inhibited SGC 7901 invasion by 24.03% ± 9.06%, 44.68% ± 9.19% and 54.38% ± 8.17%, respectively (*P* < 0.01), as compared with the control group.

### Effect of toxicarioside A on bFGF and FGFR1 in SGC-7901 cells

At the protein level, the expression of bFGF and FGFR1 was predominantly detected in the cytoplasm of SGC-7901 cells and toxicarioside A significantly decreased this ex-

**Figure 2** Effect of toxicarioside A on the growth curve of human gastric cancer cell line cells. Cells were plated in 24-well plates at a density of  $1 \times 10^4$ /mL and treated with 4.5 µg/mL toxicarioside A for 72 h. The results shown are representative of three independent experiments.

**Figure 3** Representative figures of cell migration and invasion in non-treated and toxicarioside A-treated human gastric cancer cell line cells. A: Migration in the control group; B: Migration in the toxicarioside A-treated (4.5 µg/mL) group; C: Invasion in the control group; D: Invasion in the toxicarioside A-treated group.

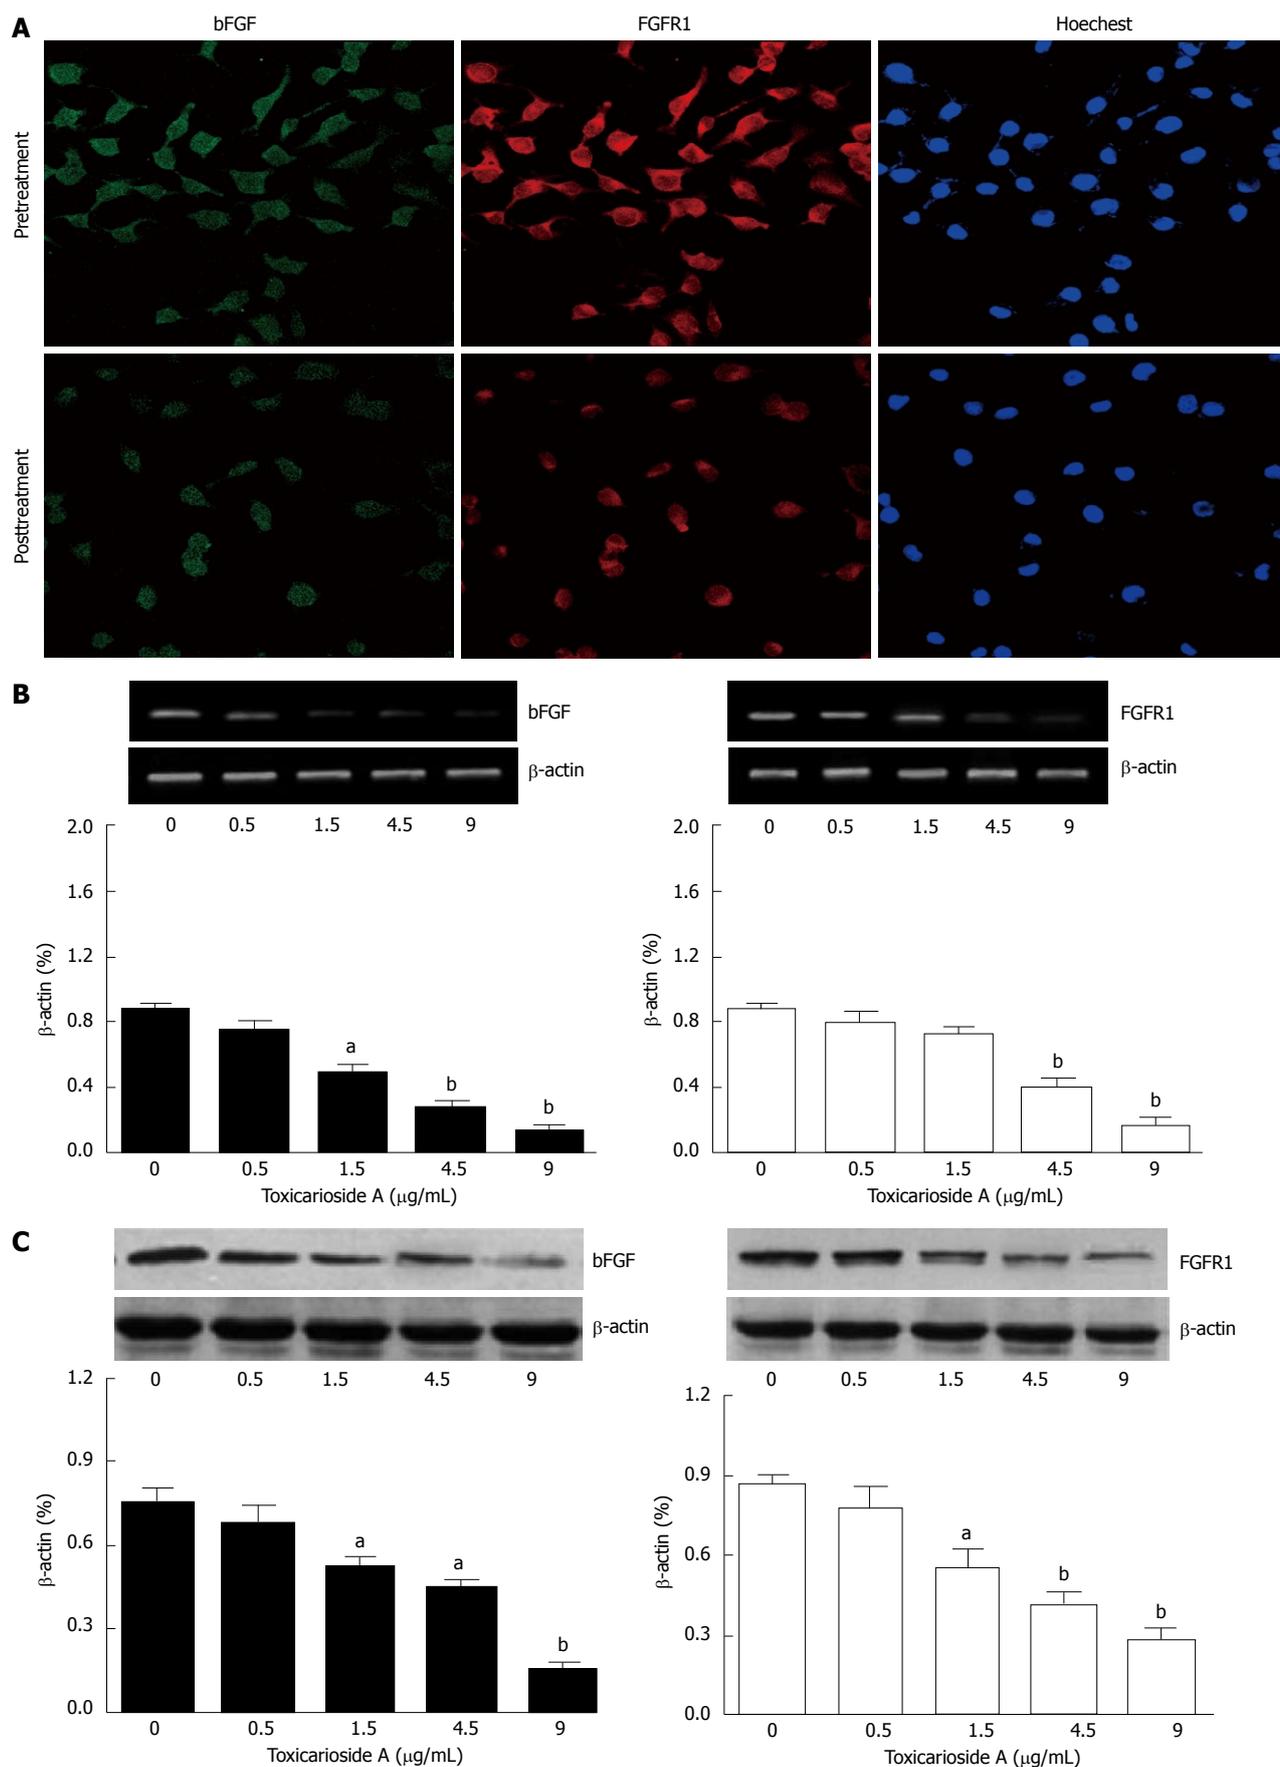

pression, as assessed by immunofluorescence staining (Figure 4A) and Western blotting analysis (Figure 4C). At the mRNA level, the expression of bFGF and FGFR1 was decreased by toxicarioside A in a dose-dependent manner in SGC-7901 cells (Figure 4B).

### Effect of toxicarioside A on NF-κB-DNA binding activity in SGC-7901 cells

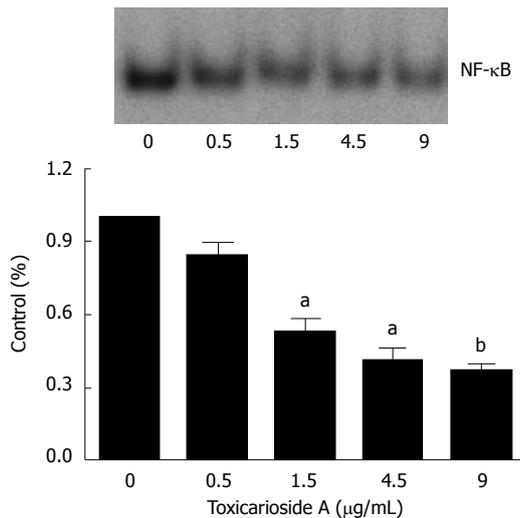

To determine the effect of toxicarioside A on NF-κB activation, the NF-κB-DNA binding activity was determined in both toxicarioside A-treated and control SGC-7901 cells by EMSA. As shown in Figure 5, after treatment with toxicarioside A at various concentrations for 48 h, the NF-κB-DNA binding activity was decreased in a dose-dependent manner as compared with the control group (*P* < 0.05 or *P* < 0.01, Figure 5).

### Effect of PDTC on toxicarioside A-induced downregulation of bFGF

To further determine whether NF-κB activation was necessary for bFGF expression, and was involved in toxicarioside A-induced downregulation of bFGF, a specific in-

**Figure 4 Basic fibroblast growth factor and fibroblast growth factor receptor-1 expression in human gastric cancer cell line cells.** A: The expression of basic fibroblast growth factor (bFGF) and fibroblast growth factor receptor-1 (FGFR1) were detected using rhodamine and fluorescein isothiocyanate-conjugated mouse anti-rabbit immunoglobulin G in non-treated and toxicarioside A (4.5 μg/mL)-treated cells; B: bFGF and FGFR1 mRNA expression by reverse transcription polymerase chain reaction; C: bFGF and FGFR1 protein levels by Western blotting analysis. Results are depicted as mean ± SE of three independent experiments. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.

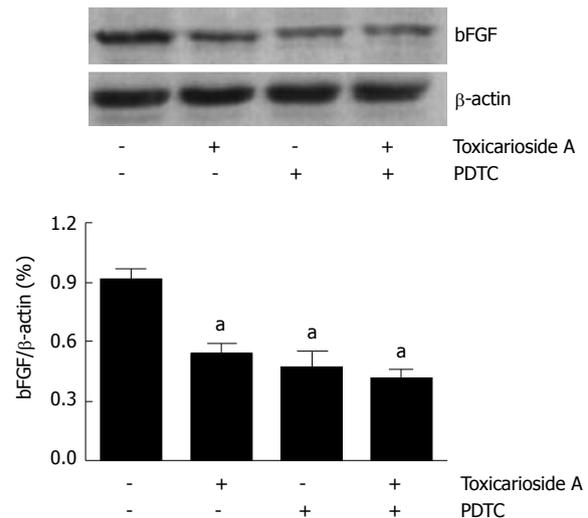

**Figure 5** Effect of toxicarioside A on nuclear factor-kappa B-DNA binding activity in human gastric cancer cell line cells. After cells were incubated with various concentrations of toxicarioside A for 48 h, nuclear proteins were isolated and electrophoretic mobility shift assay was performed to determine nuclear factor-kappa B (NF-κB)-DNA binding activity. Results are depicted as mean ± SE of three independent experiments. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

hibitor of NF-κB activation, PDTC, was used. As shown in Figure 6, PDTC treatment significantly blocked bFGF expression, which was potentized when both PDTC and toxicarioside A were added to SGC-7901 cells.

## DISCUSSION

*Antiaristoxicaria* (Pers.) Lesch (Moraceae) is widespread in the tropical rain forest of southeastern Asia, and is best known for its remedial properties against injuries due to poisoned arrows, darts and blowdarts<sup>[36]</sup>. The latex-sap and seeds of *Antiaristoxicaria* consists of a complex mixture of active cardenolide glycosides, from which several cardenolides have been isolated in our laboratory and other research groups<sup>[2-5]</sup>. Besides the classical effect of the cardenolides on inhibition of the ubiquitous cell surface  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase, the effect of cardiac glycosides on the growth of human malignant tumor cells has been reported in the recent past<sup>[11-15]</sup>. In the present work, we investigated the anti-cancer activity of toxicarioside A isolated from the latex of *Antiaristoxicaria*. Both the MTT assay and the growth curve analysis revealed that toxicarioside A resulted in inhibition of gastric cancer cell proliferation in a dose- and time-dependent manner. Malignant tumors are characterized by invasion and metastasis, an extremely complex process involving multi-steps. In this study, we assessed the migrating and invasive capabilities of SGC-7901 cells using the Transwell chamber assay. The results demonstrated that toxicarioside A not only suppressed cell motility, but also significantly reduced its ability to degrade the recombinant basement membrane in SGC-7901 cells.

To further investigate the molecular mechanism underlying the anti-tumor properties of cardenolides, we assessed the effect of toxicarioside A on bFGF expres-

**Figure 6** Effect of inhibitor, pyrrolidinedithiocarbamate, on basic fibroblast growth factor protein expression. Administration of pyrrolidinedithiocarbamate (PDTC) (50 μmol/L) reinforced the toxicarioside A (4.5 μg/mL)-induced downregulation of basic fibroblast growth factor (bFGF). Results are depicted as mean ± SE of three independent experiments. <sup>a</sup> $P < 0.05$  vs control group.

sion in SGC-7901 cells. It is well known that bFGF, a regulatory factor secreted from cells, is involved in a variety of biological processes including cell differentiation, cell growth, migration, angiogenesis, and tumor formation<sup>[19,20]</sup>. The biological effect of bFGF is achieved mainly through interaction with its high-affinity receptor, FGFR1<sup>[21-24]</sup>. To elucidate whether the bFGF/FGFR1 signaling pathway was a target of toxicarioside A in gastric cancer cells, we evaluated changes in the expression of bFGF and FGFR1 in SGC-7901 cells after treatment with toxicarioside A at various concentrations. The results demonstrated that toxicarioside A down-regulated the expression of bFGF and FGFR1 at both mRNA and protein levels in SGC-7901 cells in a dose-dependent manner.

Next, we sought to investigate the molecules involved in the toxicarioside A-induced down-regulation of bFGF in SGC-7901 cells. The NF-κB signaling pathway is a central common regulator for the process of inflammation, viral replication, tumorigenesis, and apoptosis<sup>[37,38]</sup>, and as a result has emerged as a potential target of numerous pharmaceutical agents<sup>[39,40]</sup>. Our results showed that toxicarioside A had an obvious suppressive effect on NF-κB-DNA binding activity in a dose-dependent manner, and treatment with an NF-κB specific inhibitor augmented the toxicarioside A-induced bFGF down-regulation in SGC-7901 cells, suggesting that the activated NF-κB may be partly necessary for bFGF expression in gastric cancer.

In summary, toxicarioside A weakened the abnormal activation of NF-κB to down-regulate the expression of bFGF, which in turn, interfered with bFGF/FGFR1 signal transduction subsequently leading to suppression of proliferation, migration and invasion in SGC-7901 cells. Future research will focus on identification of new targets to provide the theoretical basis for the potential

application of toxicarioside A in the clinical treatment of gastric cancer.

## COMMENTS

### Background

The latex and seeds of *Antiaristoxicaria* contain a complex mixture of cardenolide glycosides, and representative toxicariosides A-L have recently been identified in our laboratory and by others. Some cardenolides have been demonstrated to be capable of blocking tumor cell proliferation through regulation of cell signal transduction.

### Research frontiers

Gastric cancer is one of the leading malignancies in China. However, the treatment outcome is not satisfactory because early diagnosis of gastric cancer remains difficult and most patients have already developed metastatic lesions when diagnosed. It is important to investigate the strategies that could inhibit gastric cancer effectively.

### Innovations and breakthroughs

To date, little is known about the underlying mechanism regarding the anti-cancer effects of toxicarioside A. Therefore, this study was conducted to investigate the anti-cancer activity of toxicarioside A on gastric cancer growth and migration and the underlying molecular mechanisms *in vitro*.

### Applications

This study indicates the first evidence of the underlying molecular mechanisms of the anti-cancer activity of toxicarioside A in gastric cancer. These results provide the theoretical basis for the potential application of toxicarioside A in the clinical treatment of gastric cancer.

### Terminology

*Antiaristoxicaria* (Pers.) Lesch (Moraceae) is a well known precious species widespread in the tropical rain forest of Southeast Asia, and the latex and seeds of *Antiaristoxicaria* consist of a complex mixture of active cardenolide glycosides.

### Peer review

This manuscript showed toxicarioside A inhibits the proliferation, invasion and migration in a gastric cancer cell line, and these phenomena were correlated with down-regulation of nuclear factor- $\kappa$ B/basic fibroblast growth factor signaling. The design of study is solid and experiments were elegantly performed.

### Abstract

**AIM:** To report the results of a medical management of sphincter of oddi dysfunction (SOD) after an intermediate follow-up period.

**METHODS:** A total of 59 patients with SOD (2 men and 57 women, mean age 51 years old) were included in this prospective study. After medical treatment for one year, the patients were clinically re-evaluated after an average period of 30 mo.

**RESULTS:** The distribution of the patients according to the Milwaukee's classification was the following: 11 patients were type 1, 34 were type 2 and 14 were type 3. Fourteen patients underwent an endoscopic sphincterotomy (ES) after one year of medical treatment. The median intermediate follow-up period was  $29.8 \pm 3$  mo (3-72 mo). The initial effectiveness of the medical treatment was complete, partial and poor among 50.8%, 13.5% and 35%, respectively, of the patients.

At the end of the follow-up period, 37 patients (62.7%) showed more than 50% improvement. The rate of improvement in patients who required ES was not significantly different compared with the patients treated conservatively (64.2% vs 62.2%, respectively).

**CONCLUSION:** Our study confirms that conservative medical treatment could be an alternative to endoscopic sphincterotomy because, after an intermediate follow-up period, the two treatments show the same success rates.

### INTRODUCTION

Sphincter of oddi dysfunction (SOD) is a functional gastrointestinal abnormality characterized by pancreatobiliary pain that can be debilitating and may impair the quality of life. The cause of SOD remains speculative, but it could be due to hormonal or neurological disturbances of the sphincter of oddi (SO), leading to its intermittent obstruction despite the absence of organic

abnormalities<sup>[1-4]</sup>. The best way to establish diagnosis and manage SOD remains controversial, mainly in SOD type 2 and 3 of the Milwaukee classification<sup>[5,6]</sup>. The diagnosis of SOD is usually based on a high index of clinical suspicion. Direct endoscopic manometry of the SO is an invasive procedure that remains the gold standard for the diagnosis of SOD<sup>[7-9]</sup>. However, dynamic biliary scintigraphy has been used as a non-invasive tool for evaluation of the SO by providing indirect evidence of increased sphincter resistance. The contribution of the biliary scintigraphy appears to predict, with good effectiveness, the clinical success of biliary endoscopic sphincterotomy in SOD types 1 and 2 of the Milwaukee classification<sup>[10,11]</sup>. The management of SOD is also controversial, and it is based on the relaxation of the SO, which should improve the symptoms of SOD. The treatment can be accomplished pharmacologically either by an endoscopic procedure or surgically<sup>[12,13]</sup>. The surgical procedure is often replaced by an endoscopic procedure<sup>[14-16]</sup>. Several studies have suggested that there is a benefit from endoscopic sphincterotomy (ES) in SOD patients having high SO basal pressures at the time of manometry. However, procedural pancreatitis cannot be completely avoided, and surgical treatment will be necessary in some cases. Morbidity and mortality after ES have been reported to be as high as 9.8% and 2.3%, respectively. Moreover, long-term data regarding the rate of restenosis and complications resulting from repeated therapy are limited. If SO manometry findings are abnormal, the relief of pain after sphincterotomy occurs in 90%-95% of patients with type 1 SOD, 85% of patients with type 2 SOD, and 55%-60% of patients with type 3 SOD. However, almost uniformly and despite ES, some patients continue to have pain that is consistent with nonspecific chronic pain disorders, suggesting a multifactorial cause for SOD<sup>[17-19]</sup>. Endoscopic stenting is no longer recommended as a routine method of treatment of SOD because endoscopic stenting is associated with poor symptomatic relief and a high risk of stent-induced pancreatitis<sup>[20]</sup>. Many pharmacologic agents that are known to relax the SO have already been used in the management of SOD. However, although medical therapy may be an attractive initial approach in patients with sphincter of Oddi dysfunction, data on intermediate clinical outcomes associated with pharmacological treatment is scant<sup>[21-31]</sup>. In a recent study<sup>[32]</sup>, we showed that a one-year treatment period with trimebutine could significantly reduce pain in patients suffering from SOD, reducing the need for ES. Our aim in the current study was to determine the efficacy of medical therapy in relieving symptoms of SOD compared to ES after a prolonged follow-up period.

## MATERIALS AND METHODS

As described in our previous study<sup>[32]</sup>, fifty-nine patients complaining of SOD were included in this prospective monocentric study between 1999 and 2005. The patients

included 57 women and 2 men, with a mean age of 50.5 ± 12.3 years old (range 20-75 years old), which were followed for a mean duration of 29 mo after the end of the endoscopic or medical treatment. The main inclusion criterion was biliary or pancreatic pain after cholecystectomy after ruling out the diagnosis of residual lithiasis or the presence of a tumor. The following data were collected: age, sex, cholecystectomy, the time elapsing since the onset of the symptoms, pain and rate of SOD occurrence. All of the patients underwent biliopancreatic endoscopic ultrasonography in order to rule out the diagnosis of a residual lithiasis or the presence of a tumor (none of the patients underwent secretin-magnetic resonance cholangiopancreatography). The diameters of the main biliary pathway and the canal de Wirsung were systematically measured during these procedures. An initial biological check-up was carried out when the first painful episode occurred after the medical consultation. The biological check-up included the measurement of the following proteins: transaminases (alanine aminotransférase and aspartate aminotransférase), gamma-glutamyltransferase, alkaline phosphatases, total and conjugate bilirubin, amylase and lipase. PD-SOD was defined as the association between recurrent pancreatic pain with an increased level of serum lipase (> 3N). An initial biliary scintigraphy was carried out systematically on all of the patients. An initial hepatic and pancreatic biological assessment was done at the first event of abdominal pain. In addition, a biliary scintigraphy was performed for all patients in order to determine the isotopic hile to duodenum transit time (HDTT). According to the Milwaukee classification of SOD, the patients were subdivided into three groups. All of the patients were clearly informed about the various therapeutic modalities to manage their disease, the chances of success and the rates of complications of the medical therapy or endoscopic treatment. For each patients, we proposed an initial management of SOD by medical treatment, planned for a one-year duration; it consisted of a combined treatment, an association of trimebutine (200 mg three times per day) and nitrates taken sublingually when needed, mainly at the onset of abdominal pain. In the case of intolerance or counter-indication to the nitrates, a treatment with trimebutine alone was proposed. If previous treatment with trimebutine had been unsuccessful, only the nitrate derivatives were prescribed. If the painful attacks occurred too frequently (> 1 per week), a transdermal nitrate treatment (5 mg/d) was prescribed. The patients attended clinical follow-up consultations every four mo for a period of one year. After one year of medical therapy, an evaluation of painful symptoms was performed for each patient. The efficacy of the treatment was considered complete if there was a complete disappearance of the painful symptoms; the efficacy was considered partial if there was a greater than 50% reduction in the frequency and intensity of the pain and considered poor when the frequency and intensity of the pain decreased by less than 50%. In the cases where the medical treat-

Age, mean $\pm$ SD, yr	50.5 $\pm$ 12

ment was only partially successful or poor, endoscopic sphincterotomy was proposed to the patients, but not to the remaining patients. If medical treatment was successful, endoscopic treatment was not proposed. When the indications for endoscopic treatment had been chosen, the patients received clear information concerning the procedure. The endoscopic treatment was performed under general anaesthesia and consisted of an endoscopic retrograde cholangiopancreatography, with realization of a biliary sphincterotomy on patients with isolated biliary symptoms or dual sphincterotomy (biliary and pancreatic) on patients with both biliary and pancreatic symptoms. All of the patients were called by telephone to propose a follow-up examination with a hepatic biological assessment and an abdominal ultrasound in order to measure the diameter of the main biliary and pancreatic ducts; among the patients who refused this assessment, a simple evaluation of the clinical symptoms was proposed. The management was considered successful if there was an improvement greater than 50% compared to the initial symptoms; it was considered a failure if there was an absence of significant improvement by the patient. This study was approved by our local ethics committee.

### Statistical analysis

Statistical analysis was carried out on the data with the Statview software program (Abacus concept, Inc., Berkeley, CA, 1992). Quantitative data were expressed as the mean  $\pm$  SD. The significance of the differences was tested using the Student's *t* test or paired *t* tests to make comparisons between groups. Nonparametric tests (Mann Whitney tests) were performed when the Student's *t* test was not appropriate. The qualitative variables were compared using the chi-square test with Yate's correction when appropriate and with Fisher's exact test for 2  $\times$  2 contingency tables. The significance threshold was set at  $P < 0.05$ .

Global effect

Without prolongation of HDTT	17 (44.7)	

HDTT: Hile to duodenum transit time.

## RESULTS

### Characteristics of the SOD and treatment

The patients developed the symptoms of SOD after a mean period of  $9.3 \pm 1.2$  years (range, 1-38 years) after the cholecystectomy. The patient's main characteristics are presented in Table 1. According to the three Milwaukee groups, there were no significant differences in age (type 1,  $56.2 \pm 2.1$  years old; type 2,  $48.1 \pm 2.1$  years old; and type 3,  $52.1 \pm 3.5$  years old,  $P = 0.22$ ) or the time elapsing from diagnosis to the cholecystectomy (type 1,  $11 \pm 3.6$  years; type 2,  $8.6 \pm 1.6$  years; and type 3,  $10 \pm 2.4$  years;  $P = 0.93$ ). Five patients were treated with nitrates only (8.4%), 12 were treated with trimebutine only (20.3%), and 42 patients had a combined treatment of nitrates and trimebutine (71.1%). The mean duration of the treatment period was  $11.5 \pm 0.8$  mo. The efficacy of the medical therapy was considered to be complete or partial in 38 patients (64.3%) and poor in 21 patients (35%). Details concerning the success of the medical treatment are presented in Table 2. Among the 21 patients with poor results from the medical management, 14 (23.7%) agreed to undergo ES, including 12 with an isolated biliary sphincterotomy and 2 with an associated pancreatic sphincterotomy (dual sphincterotomy). In patients with a dual sphincterotomy, a pancreatic duct stenting was performed. A lengthening of the isotopic time of transit was present before the ES in 11 patients of the 14 who underwent this intervention (78.5%) and in 21 patients of the 45 without ES (46.6%) ( $P = 0.02$ ). Other characteristics concerning ES are presented in Table 3. The complications of the ES were severe acute pancreatitis in two cases, which had resolved favourably with medical treatment. Among the patients requiring an ES, three patients had mixed biliary and pancreatic symptoms, and 9 patients had an isolated pancreatic pattern; among these patients, only 3 had a lengthening of the HDTT on the biliary scintigraphy corresponding to the 3 patients with isolated pancreatic symptoms as defined in the Materials and Methods section.

### Intermediate follow-up period

Five patients refused to participate in the follow-up period. The intermediate follow-up period was  $29.8 \pm 3$  mo (3-72 mo). Thirty-seven patients either did not pres-

ent any additional painful events or improved by more than 50% (62.7%). Twenty-two patients still presented painful episodes (38.6%). The characteristics of the patients following endoscopic treatment are presented in Table 3. An abdominal ultrasound was performed in 45 patients and highlighted a dilation of the main biliary duct in 10 patients (22%). A biological laboratory assessment was also performed in these 45 patients. Among these patients, 6 still presented abnormal liver and pancreatic enzyme serum levels. At the end of the follow-up period, there was no significant difference in the size of the main biliary duct (at the beginning of the study, 49% of patients had dilation, and at the end of the study, 22% still had dilation of the main biliary duct) ( $P = 0.49$ ); these characteristics are presented in Table 4.

## DISCUSSION

The present study demonstrates that medical management with trimebutine may improve pain in patients suffering from SOD. Moreover, our study shows that after an intermediate follow-up period, the success of medical treatment (62%) does not differ from that of ES (64%). The medical treatment of SOD is usually disappointing, although nitrates or calcium-channel blockers can decrease basal pressure of the SO<sup>[32-36]</sup>. A positive effect of erythromycin on the motility of the SO has been suggested, but its clinical efficacy has not been demonstrated<sup>[29]</sup>. Somatostatin also modifies the SO activity but in the direction of an increase in the frequency of the phasic contractions of basal pressure. Therefore, somatostatin would be of little benefit for the indication of SOD and would not be suitable as a preventive measure after endoscopic retrograde cholangiopancreatography. The injection of botulinum toxin within the sphincter was tested in humans and pigs and promoted a significant reduction in the basal pressure in 50% of the cases<sup>[37-41]</sup>. On the clinical level, the injection of botulinum toxin was beneficial in 55% of the patients who suffered from biliary pain post-cholecystectomy without disturbance of the hepatic enzymes or dilation of the bile duct. However, 90% of the patients who experienced improvement presented a recurrence of symptoms after 6 mo, making the effect of botulinum toxin inconstant

and transitory<sup>[37-41]</sup>. Endoscopic management is mainly based on the ES, requiring SOD diagnosis to be formally established, i.e., based on the description of a basal high pressure of the SO. However, despite its high rate of success (86%-91%), ES is associated with high morbidity (19%-30%). Moreover, the natural course of SOD has not been well documented so far, so that the use of this endoscopic strategy remains highly controversial<sup>[42-49]</sup>.

Our research group previously described the effects of trimebutine on Oddi motility in a prospective study on patients with post-cholecystectomy pain<sup>[29]</sup>. We also reported in another study<sup>[32]</sup> that a one-year medical management could avoid the need for ES and had a success rate of 64%. Kovács *et al.*<sup>[21]</sup> previously suggested that, depending on the Milwaukee classification, medical treatment should be first attempted and its efficacy subsequently reassessed; if this treatment fails or is poorly tolerated, ES can then be proposed, especially for type 1 or 2 SOD patients, based on the presence of a lengthening of the HDTT. The lengthening of the HDTT as a factor for predicting a favourable response to ES decreases with the Milwaukee types, as mentioned by Cicala *et al.*<sup>[17]</sup>. In our study, 100% of the type 1 patients, 78% of the type 2 patients and none of the type 3 patients showed a lengthening of the HDTT and underwent ES successfully, whereas the immediate efficacy of ES was only 86%. This ES success rate is quite similar to the success rate reported in the literature, which ranged between 86% and 91%<sup>[18,50-52]</sup>. Few studies have addressed the intermediate natural history of SOD. The available data suggest that the clinical course is variable depending, in part, on the initial biliary classification. In a one-year follow-up study, seven SOD type 2 patients with abnormal SO pressure treated by a sham procedure continued to have symptoms, which ended only after subsequent ES. All patients continued to do well four years later. Five other SOD type 2 patients with abnormal SO pressure refused ES; after four years, three were unimproved while two had “fair” improvement. The clinical course was unpredictable after a sham or ES treatment in patients with SOD type 3 biliary pain. In another report, 11 such patients were followed for two years after ES. Four improved symptomatically, while

seven had no change in their symptoms. Eleven other patients had a sham procedure, five of which improved, while six had no change in their symptoms during a two-year follow-up period<sup>[53]</sup>. In our study, the monitoring of the response rate to ES after an average period of 29 mo showed a loss of efficacy of the ES in 3 patients. Therefore, the rate of patient improvement did not differ significantly in the presence or absence of a previous ES according to the performance or not of an ES.

In conclusion, our study confirms that a conservative medical treatment could be an alternative to ES because, after an intermediate follow-up period, the two treatments show the same success rates.

## COMMENTS

### Background

Sphincter of oddi dysfunction (SOD) is a symptom characterized by recurrent abdominal pain. It has been showed that endoscopic treatment called endoscopic sphincterotomy (ES) can improve symptoms but with a high level of complications. Pharmacologic agents have been tested in this pathology but are still disappointing.

### Research frontiers

Many ways of treatment (medical, endoscopic) are still studied because none of them offer a satisfying and safe rate of prolonged improvement.

### Innovations and breakthroughs

The authors here demonstrate that, after a long follow-up (29 mo), a medical treatment with trimebutine can have the same success rate than ES.

### Applications

The demonstration of a long-term efficacy of a medical conservative treatment is important because it can avoid the need for ES which is associated with morbidity and mortality after ES of 9.8% and 2.3% respectively. This study demonstrates that a medical conservative treatment with trimebutine may be an effective alternative to the endoscopic sphincterotomy since, after an intermediate follow-up, the two treatments show the same success rate.

### Terminology

The sphincter of oddi is a muscular valve that controls the flow of digestive juices (bile and pancreatic juice) through the ampulla of Vater into the second part of the duodenum. ES is an endoscopic technique developed to examine and treat abnormalities of the bile ducts, pancreas and gallbladder. The procedure was developed as an extension to the diagnostic examination, endoscopic retrograde cholangio pancreatography; with the addition of "sphincterotomy", abnormalities found during the study could be treated at the same time without the need for invasive surgery.

### Peer review

This study is about the results of a medical management of SOD after an intermediate follow-up. It is well-written.

virus (HIV) (group HBV/HIV), 138 (10.2%) alcohol abuse (group HBV/alcohol); 109 (8.0%) subjects had at least two cofactors and 924 were in the cofactor-free (CF) group.

**RESULTS:** Compared with patients in group CF those in group HBV/alcohol were older and more frequently had cirrhosis ( $P < 0.001$ ), those in group HBV/HDV were younger ( $P < 0.001$ ), more frequently resided in the south of the country and had cirrhosis ( $P < 0.001$ ), those in group HBV/HCV were older ( $P < 0.001$ ) and more frequently had cirrhosis ( $P < 0.001$ ). These cofactors were all independent predictors of liver cirrhosis in HBsAg positive patients. Multivariate analysis showed that an older age [odds ratio (OR) 1.06, 95% CI: 1.05-1.08], alcohol abuse with more than 8 drinks daily (OR 2.89, 95% CI: 1.81-4.62) and anti-HDV positivity (OR 3.48, 95% CI: 2.16-5.58) are all independently associated with liver cirrhosis. This association was found also for anti-HCV positivity in univariate analysis, but it was no longer associated (OR 1.23, 95% CI: 0.84-1.80) at multivariate analysis.

**CONCLUSION:** Older age, HDV infection and alcohol abuse are the major determinants of severe liver disease in chronic HBV infection, while HCV replication plays a lesser role in the severity of hepatic damage.

### Abstract

**AIM:** To evaluate the clinical relevance of each cofactor on clinical presentation of chronic hepatitis B.

**METHODS:** Out of 1366 hepatitis B surface antigen (HBsAg) positive subjects consecutively observed in 79 Italian hospitals, 53 (4.3%) showed as the only cofactor hepatitis D virus (HDV) infection [hepatitis B virus (HBV)/HDV group], 130 (9.5%) hepatitis C virus (HCV) (group HBV/HCV), 6 (0.4%) human immunodeficiency

**Key words:** Chronic hepatitis B; Hepatitis B virus/hepatitis D virus dual infection; Hepatitis B virus/hepatitis C virus dual infection; Alcohol abuse

**Peer reviewers:** Can Gonen, MD, Department of Gastroenterology, Kutahya State Hospital, 43100 Kutahya, Turkey; Khaled Jadallah, MD, Assistant Professor of Medicine, Consultant, Gastroenterologist and Hepatologist, Department of Internal Medicine, King Abdullah University Hospital, Jordan University of Science and Technology, Irbid 22110, Jordan

## INTRODUCTION

Seroepidemiological studies on the aetiology of chronic hepatitis in Italy performed in the 1980s, 1990s<sup>[1-3]</sup> and in 2001<sup>[4]</sup> showed a progressive reduction in the prevalence of hepatitis B surface antigen (HBsAg) positive cases from 60.7% observed in cases collected from 1976 to 1981<sup>[1]</sup> to 13% found in 2001<sup>[4]</sup>. Despite this, infection by the hepatitis B virus (HBV) is still responsible for a sizeable number of cases of chronic hepatitis and/or hepatocellular carcinoma (HCC), and the burden of HBV infection on the healthcare system in Italy is still heavy.

In a multicentre study carried out on 1829 patients with cirrhosis in 1992, the prevalence of HBV-related cases was 13.8%; in particular, HBV was the only aetiological factor in 4.2% of cases, most cases being associated with cofactors (9.6%): hepatitis D virus (HDV) in 3.4%, hepatitis C virus (HCV) in 3.2% and alcohol abuse in the remaining 3%<sup>[5]</sup>. In human immunodeficiency virus (HIV)/HBV dual infection, found in 3.7%-4.6% of HIV positive subjects in Italy but estimated around 10% in people with HIV infection worldwide<sup>[6]</sup>, the prevalence of patients with cirrhosis is reported as higher than in HIV-negative/HBV-positive cases<sup>[7]</sup>. Cofactors may therefore play a substantial role in the progression of HBsAg positive chronic hepatitis to the more severe clinical forms<sup>[8-10]</sup>.

The gradual reduction in the percentage of HBsAg positive cases was associated with a dramatic decrease in the prevalence of cases with HBV/HDV dual infection<sup>[11-13]</sup>. About a quarter of HBsAg positive patients with chronic hepatitis were anti-HDV positive in 1978-1981<sup>[14]</sup> and in 1987<sup>[15]</sup>; this prevalence was lower in 1992 (14.4%)<sup>[16]</sup>, in 1997 (8.3%)<sup>[17]</sup> and in 2001 (9.9%)<sup>[4]</sup>. No data to this effect are available on HBV/HCV dual infection and on the association of HBV infection/alcohol intake<sup>[18]</sup>.

Our survey on the largest series of patients with chronic hepatitis ever studied in Italy showed an overall low HDV prevalence in HBsAg chronic carriers (9%), a high prevalence of patients with HBV/HCV dual infection (16.9%) and alcohol abuse (10.4%)<sup>[4]</sup>. The data from this study allow us to evaluate the current main characteristics of patients with HBV/HDV or HBV/HCV chronic infection or HBV infection/alcohol abuse compared with a large control group of HBsAg chronic carriers with no evident cofactor.

## MATERIALS AND METHODS

The study design was more extensively described in a previous paper<sup>[4]</sup>. Seventy-nine centres participated in

the study, 25 in the North, 24 in the Centre and 30 in the South of Italy and the two main islands (Sicily and Sardinia).

All subjects consecutively referred from February 1 to July 31, 2001 as in-patients or out-patients to one of the 79 Italian centres were recruited; 9997 patients with chronic hepatitis were enrolled. Both tertiary and peripheral centres were randomly selected by a systematic cluster sampling procedure. For each of these three geographical areas, all of the hospitals were identified and listed numerically according to an assigned number. In each list, a single hospital was considered as a cluster. The first cluster was randomly chosen, whereas the others were selected with a probability proportional to the required number of hospitals at systematic intervals. Both prevalent and incident cases were recruited. We defined as "incident cases" all new diagnoses of chronic liver disease made during the enrolment period, and as "prevalent cases" all subjects with a previous diagnosis of chronic liver disease observed during the study period.

For each subject, the demographic, clinical and aetiological data were recorded using a pre-coded questionnaire. The amount of alcohol intake was determined using a standard questionnaire containing information on the daily intake of various alcoholic beverages and lifetime duration of alcohol consumption. An alcohol intake of more than 40 g daily for males and 30 g daily for females for at least 10 years was considered as an aetiological cofactor<sup>[19,20]</sup>.

HBV serum markers, HBsAg, anti-HBc, hepatitis B e antigen (HBeAg), anti-HBeAg and anti-HDV were determined by commercial immunoenzymatic assays. Antibodies to HCV were detected by 3rd generation commercial immunoenzymatic assays. Antibodies to HIV 1 and 2 were determined by commercial enzyme-linked immunosorbent assay (Diasorin Biomedica, Saluggia, Vercelli, Italy; Abbott Labs, North Chicago, Illinois, United States) and the positive results were confirmed by a Western Blot analysis (Genelabs Diagnostics, Science Park Drive, Singapore). Patients were enrolled in 2001 when various methods of different sensitivity were used to detect HBV viral load in different centres in Italy. For this reason, we preferred not to evaluate the predicting value of HBV viral load; data on HBV-DNA were given as positive or negative.

Data on HDV-RNA and HDV-Ag were not available. We classified patients as asymptomatic carriers when alanine aminotransferase (ALT) values were persistently normal in the absence of clinical, biochemical and ultrasound signs of chronic liver disease. Chronic hepatitis was diagnosed only on the basis of liver histology. Liver cirrhosis was diagnosed from a liver biopsy or the presence of unequivocal clinical, biochemical and ultrasound signs<sup>[20]</sup>. HCC diagnosis was based on histology, imaging techniques or biochemical parameters ( $\alpha$ -feto protein greater than 400 ng/mL)<sup>[21,22]</sup>. Patients with serum markers suggesting autoimmune liver disease and those with liver disease associated with genetic disorders were excluded from the study.

### Statistical analysis

Continuous variables were summarised as mean  $\pm$  SD or median and interquartile range, and categorical variables as absolute and relative frequencies. Differences in the means were evaluated by an unpaired Student *t* test or Kruskal-Wallis one-way analysis of variance, and the  $\chi^2$  test was applied to categorical variables. Crude odds ratios (OR) and their 95% CI for the association of liver cirrhosis with potential risk factors were calculated by univariate analysis. Adjusted OR were calculated by stepwise logistic regression analysis to identify factors independently associated with liver cirrhosis. Only factors associated with liver cirrhosis by univariate analysis were included in the logistic regression analysis. In the logistic model liver cirrhosis was the outcome variable, while age, sex, anti-HDV, anti-HCV, alcohol intake, and body mass index were the independent variables.

## RESULTS

Of the 1366 HBsAg positive patients, 924 (67.6%) lacked all the cofactors investigated (HDV, HCV, HIV and alcohol abuse); this group of patients was named the cofactor-free (CF) group. Fifty-nine (4.3%) patients showed HDV infection (anti-HDV positive) as the only cofactor (group HBV/HDV), 130 (9.5%) HCV infection (group HBV/HCV), 6 (0.4%) HIV infection (group HBV/HIV), 138 (10.2%) alcohol abuse (group HBV/alcohol) and 109 (8.0%) had more than one cofactor (group with two or more cofactors). Overall, 333 (24.4%) patients had no liver biopsy at presentation; of the remaining 1033 cases, 278 subjects (26.9%) were classified as asymptomatic carriers, 453 (43.9%) as having chronic hepatitis, 249 (24.9%) as having liver cirrhosis and 53 (5.1%) patients had a diagnosis of HCC. Interferon treatment was given in 365 (26.7%) patients and 244 (17.9%) patients received Lamivudine. Excluding cases under immunosuppressive therapy, approximately all HBeAg positive and half of HBeAg negative cases showed active HBV replication. Fifty-seven (4.2%) patients were born outside Italy, and only 4 of them were born in China.

### Characteristics of the CF group

The 924 HBsAg positive subjects with none of the cofactors investigated were more frequently males (66.5%) and observed as out-patients (81.1%) and as prevalent cases (83.2%); they aged  $48.1 \pm 14.3$  years, were infrequently HBeAg positive (12.6%) and frequently showed a mild clinical presentation: 26.9% of cases were asymptomatic carriers, 56.9% of patients showed chronic hepatitis, 12.4% liver cirrhosis and 3.8% had HCC.

### Comparison according to anti-HDV status

The 59 anti-HDV positive patients were younger than those in group CF ( $46.7 \pm 11.8$  years *vs*  $48.1 \pm 14.3$  years;  $P < 0.001$ ) and showed higher ALT levels ( $128 \pm 116$  IU/L *vs*  $98 \pm 290$  IU/L,  $P = 0.008$ ); they were more frequently observed as in-patients (25.4% *vs* 18.9%,  $P = 0.3$ ), were

more frequently born in southern Italy or on one of the two main islands (67.8% *vs* 52.9%,  $P = 0.029$ ) and more frequently had liver cirrhosis (37.3% *vs* 12.4%,  $P \leq 0.001$ ); none of the 59 anti-Delta positive patients had HCC (Table 1).

### Comparison according to anti-HCV status

The 130 subjects co-infected with HCV were older than those in group CF ( $55.2 \pm 14.7$  years *vs*  $48.1 \pm 14.3$  years,  $P < 0.0001$ ), and more frequently showed liver cirrhosis (23.1% *vs* 12.4%,  $P < 0.001$ ); this group contained the highest prevalence of patients with HCC observed in the study (6.2%) (Table 1). Active HCV replication as evaluated by positive HCV-RNA by RT-PCR was found in 115 subjects (88.5%).

### Comparison according to anti-HIV status

Only 6 patients showed HBV/HIV dual infection; all of these patients were males and younger than those in group CF. Four of them were HBeAg positive and none had liver cirrhosis (Table 1).

### Comparison according to alcohol abuse

Compared with patients in group CF, the 138 HBsAg positive patients with alcohol abuse as the only cofactor were older ( $52.6 \pm 11.8$  years *vs*  $48.1 \pm 14.3$  years,  $P < 0.0001$ ), were more frequently males (92.6% *vs* 66.5%,  $P < 0.0001$ ), had had fewer years of schooling (85.9% *vs* 67.0%,  $P < 0.001$ ) and more frequently showed liver cirrhosis (31.1% *vs* 12.4%,  $P < 0.0001$ ) and HCC (5.1%).

### Comparison according to the presence of two or more cofactors

Of the 109 patients in this group, 21 had HBV/HDV/HCV concurrent infection, 12 HBV/HDV dual infection plus alcohol abuse, 64 had HBV/HCV dual infection plus alcohol abuse, and 12 had HBV/HDV/HCV concurrent infection plus alcohol abuse. Compared with group CF, patients with two or more cofactors were more frequently males (86.8% *vs* 66.5%,  $P < 0.001$ ), in-patients (28.0% *vs* 18.9%,  $P = 0.003$ ) and had liver cirrhosis (35.8% *vs* 12.4%,  $P < 0.001$ ). They more frequently belonged to larger families (24.5% *vs* 14.6%,  $P < 0.01$ ) and had had fewer years of schooling (84.3% *vs* 67.0%,  $P < 0.001$ ). Only 4 patients showed HCC (Table 1).

### Variables associated with the presence of cirrhosis

At the univariate analysis older age, anti-HCV, HCV-RNA positivity, alcohol abuse, anti-HDV and anti-HIV positivity were all associated with liver cirrhosis. Multivariate analysis showed that age (OR 1.10, 95% CI: 1.08-1.11), alcohol abuse (between 4 and 8 drinks daily: OR 2.30, 95% CI: 1.29-4.10; more than 8 drinks daily: OR 2.42, 95% CI: 1.31-4.46), HDV positivity (OR 2.68, 95% CI: 1.56-4.61) and anti-HIV (OR 5.78, 95% CI: 1.50-22.27) were independent predictors of the development of cirrhosis, whereas anti-HCV and HCV-RNA positivity were no longer associated (Table 2).

### Comparison according to the severity of liver cirrhosis

The Child-Pugh Score was calculated for 229 (92.0%) of the 249 patients with cirrhosis: 104 cases in group CF, 43 cases in group HBV/Alcohol, 19 cases in group HBV/HDV, 30 cases in group HBV/HCV and 33 cases in the HBV/two or more cofactors group. The prevalence of patients in the Child-Pugh Classes B or C was lower in group CF (31.7%), than in group HBV/Alcohol (44.2%), in group HBV/HCV (43.3%) and in the HBV/two or more cofactors group (75.8%,  $P < 0.001$ ) (Table 3).

## DISCUSSION

This study is based on three strong points: the first, a large sample size, the second, the validity of the random selection including both tertiary and peripheral hospitals all over the country, which may have avoided the selection of “difficult-to-treat” patients, and lastly, the homogeneity of each single cofactor group and of the comparative CF group, making this study the first to investigate the clinical presentation of CF HBsAg positive chronic hepatitis and the influence of each single cofactor (HDV, HCV and alcohol intake).

Excluding the 442 patients with one or more cofactors enabled us to examine a group of almost a thousand patients with HBsAg positive chronic hepatitis and no cofactor. Most of these patients showed a mild clinical presentation and only a minority of them had liver cirrhosis (12.4%), prevalently in the Child A stage. The low

prevalence of HCC (3.9%) refers to HCC at the time of diagnosis. No information is available on the risk of occurrence of HCC, death or orthotopic liver transplantation over time, since the present study is cross-sectional and no evaluation of the clinical outcomes was made.

Despite the decreasing endemicity levels, HDV infection maintains its geographical distribution in our country, i.e., more frequent in southern Italy and on the two main islands, as previously described<sup>[15-17]</sup>. Compared with those in group CF, patients in group HBV/HDV showed a more severe clinical presentation: they were younger, more frequently hospitalised and with evidence of cirrhosis. In accordance with the low prevalence of patients with HCC in previous studies<sup>[5]</sup>, no patient in our HBV/HDV group showed HCC, most probably reflecting a more severe course of the illness with a rapid transition to death or to the need for liver transplantation before HCC becomes evident<sup>[23]</sup>. On the other hand, patients in group HBV/HCV were older than those in group CF, more frequently had liver cirrhosis and showed an almost double prevalence of HCC. These differences, although not statistically significant, may suggest that subjects with long-lasting HBV/HCV dual infection are at a higher risk of developing liver cirrhosis with or without liver cancer<sup>[24-26]</sup>.

Most patients in group HBV/Alcohol were males with a low educational level, a combination more frequently associated with a high risk of alcohol abuse. The prevalence of patients with cirrhosis was 2.5 times higher in group HBV/alcohol than in group CF, a dif-

<sup>b</sup>*P* < 0.001 *vs* hepatitis B virus (HBV)/two or more cofactors. Patients with hepatocellular carcinoma are not included. CF: Cofactor-free; HCV: Hepatitis C virus; HDV: Hepatitis D virus.

ference most probably due to alcohol intake rather than to the association of the two aetiological factors, since, as described in a previous paper<sup>[4]</sup>, 41.8% of 761 patients showing alcohol abuse as the only aetiological factor had liver cirrhosis. The group of patients with two or more cofactors is a miscellany of 4 subgroups that are too small to be analysed or compared with group CF or with the other cofactor groups. This miscellaneous group with more than one cofactor may be more frequently exposed to the aetiological agents of liver disease and to a higher risk of developing liver cirrhosis and/or HCC.

As observed in previous Italian studies<sup>[4,17,18]</sup>, the majority of HBsAg positive patients in this study were found to be HBeAg negative. Patients with HBV/HCV dual infection and those with HBV plus alcohol abuse showed a lower prevalence of HBeAg positive cases than those in the other aetiological groups, probably because they were

older and HBeAg loss is, at least in part, a time-dependent phenomenon.

In conclusion, HBV chronic infection was frequently associated with a mild or moderate clinical condition. Liver cirrhosis and HCC were detected in less than one sixth of cases, and viral and metabolic cofactors unfavourably influenced the clinical course in patients with chronic HBV infection since their presence was associated with an increased risk of cirrhosis, an association proven by multivariate logistic regression analysis for HDV infection and alcohol abuse.

## COMMENTS

### Background

Many cofactors play a substantial role in the progression of hepatitis B surface antigen positive chronic hepatitis to more severe clinical forms.

**Research frontiers**

The study aimed to evaluate the clinical relevance of each cofactor on the severity of the clinical presentation of chronic hepatitis B.

**Innovations and breakthroughs**

Older age, hepatitis D virus co-infection and alcohol abuse are the major determinants of severe liver disease in chronic hepatitis B virus (HBV) infection. Conversely, hepatitis C virus replication plays a lesser role in the severity of hepatic damage.

**Applications**

Removal of some risk factors may hamper the progression of chronic HBV-related liver disease in many patients.

**Peer review**

This is a large-size, multicentre study showing the importance of comorbidities in exacerbating hepatocellular necroinflammation and playing a substantial role in the progression to a more advanced stage of liver disease.

### Abstract

**AIM:** To investigate risk factors for low bone mineral density (BMD) in celiac disease (CD) patients, focusing on circulating autoantibodies against osteoprotegerin (OPG).

**METHODS:** Seventy asymptomatic CD adult patients on gluten-free diet (GFD) and harbouring persistent negative CD-related serology were recruited. Conventional risk factors for osteoporosis (e.g., age, sex, menopausal status, history of fractures, smoke, and body mass index) were checked and BMD was assessed by dual energy X ray absorptiometry. Serum calcium and parathyroid hormone (PTH) levels were evaluated. Thirty-eight patients underwent repeat duodenal biopsy. Serum samples from a selected sub-group of 30 patients, who were also typed for human leukocyte antigen (HLA) DQ2 and DQ8 haplotype, were incubated

with homodimeric recombinant human OPG and tested by western blotting with an anti-OPG antibody after immunoprecipitation.

**RESULTS:** Despite persistent negative CD-related serology and strict adherence to GFD, 49 out of the 70 (74%) patients displayed low BMD. Among these patients, 13 (24%) showed osteoporosis and 36 (76%) osteopenia. With the exception of age, conventional risk factors for osteoporosis did not differ between patients with normal and low BMD. Circulating serum calcium and PTH levels were normal in all patients. Duodenal mucosa healing was found in 31 (82%) out of 38 patients who underwent repeat duodenal biopsy with 20 (64%) still displaying low BMD. The remaining 7 patients had an incomplete normalization of duodenal mucosa with 6 (84%) showing low BMD. No evidence of circulating antibodies against OPG was found in the serum of 30 celiac patients who were tested for, independent of BMD, duodenal histology, and HLA status.

**CONCLUSION:** If any, the role of circulating autoantibodies against OPG in the pathogenesis of bone derangement in patients with CD is not a major one.

## INTRODUCTION

Celiac disease (CD) is a permanent gluten intolerance in genetically predisposed individuals who display an inflammatory process in the small intestinal mucosa with villous atrophy, crypt hyperplasia, and increased number of lymphocytes<sup>[1]</sup>.

Evidences indicate that a low bone mineral density (BMD) is found in 20%-50% newly diagnosed patients with CD<sup>[2]</sup>. By means of dual energy X ray absorptiometry (DEXA) it can be now rapidly and easily obtained semi-quantitative values of BMD<sup>[3]</sup>.

Osteoporosis is a quantitative and qualitative alteration in the components of bone tissue, in which the process of demineralization becomes intense and prolonged and minerals are used up more quickly than they can be replaced resulting in bones fragility and increased risk of fractures<sup>[4,5]</sup>. Individual's gender, constitution and age as well as variations in endocrine systems associated with factors such as the menopause, and the presence of other pathologies, can all interact with lifestyle factors, including smoking, lack of exercise and low dietary calcium intake, to determine the onset of osteoporosis<sup>[6]</sup>.

Impaired absorption of calcium during CD is thought to result principally from loss of villous in the proximal intestine, where calcium is most actively absorbed, and also from the unabsorbed fatty acids, which bind calcium in the intestinal lumen and may reduce dietary vitamin D absorption<sup>[7]</sup>. Adherence to a strict gluten-free diet (GFD) will reverse the histological changes in the intestine and also the biochemical evidence of calcium malabsorption<sup>[8]</sup>, resulting in normal BMD in these treated patients<sup>[9]</sup>. Nevertheless, there may be long-term impairment of bone mineralization in some otherwise healthy CD patients adhering to GFD<sup>[10]</sup>. Furthermore, osteopenia has been found in treated CD patients who showed improvement or even complete healing of intestinal mucosa<sup>[11]</sup>. These findings suggest that other mechanisms of bone injury than calcium malabsorption are probably involved in patients with CD<sup>[12]</sup>.

Mediators of inflammatory immune-mediated responses (e.g., cytokines), parathyroid hormone (PTH), estrogens, androgens, corticosteroids and vitamin D are all acknowledged to affect BMD by modulating the receptor activator of nuclear factor B/receptor activator of nuclear factor B-ligand/osteoprotegerin [RANK/RANK-L/osteoprotegerin (OPG)] system<sup>[13]</sup>. Furthermore, neutralizing auto-antibodies against OPG have been recently shown in the sera of a few patients with CD, leading to the hypothesis that blocking the inhibitory effect of OPG on RANKL may have a role in the development of bone derangement in these patients<sup>[14]</sup>. Nevertheless, this finding has not yet been confirmed by others, so the role of auto-antibodies against OPG, if any, in the pathogenesis of reduced BMD in patients with CD remains to be established.

This study aimed at investigating risk factors associated with low BMD in patients with CD, focusing on circulating auto-antibodies against OPG.

## MATERIALS AND METHODS

### Patients recruitment

Seventy consecutive outpatients with CD (13M, 57F; median age 40.5 years, range 20-68 years) who reported no current symptoms, claimed to be adherent to a GFD for at least 2 years and harboured persistent (at least 18 mo) negative CD-related serology (anti-endomysium and anti-transglutaminase IgA antibodies) were recruited. Diagnosis of CD was performed on the basis of clinical presentation, positive CD-related serology and suggestive histological findings on duodenal biopsy<sup>[15]</sup>. Dietary compliance was assessed by periodic interview during follow-up visits and classified as good according to Leffler *et al.*<sup>[16]</sup>. Data on height, weight, time since diagnosis, symptoms beginning, age at menarche, cycle regularity, menopausal status, drug use, calcium intake, life style, smoking, and history of fracture were collected. Blood samples were collected in the morning after a 12 h fast in order to measure serum calcium and parathormone levels. Thirty-eight patients (8M, 30F; median age 41 years, range 20-60 years) underwent repeat duodenal biopsy after a period of at least 12 mo since GFD beginning.

A subgroup of 30 patients (8M, 22F; median age 44 years, range 21-60 years), who were typed for HLA-DQ2 and DQ8 haplotype, were selected in order to measure antibodies against OPG.

### Histology

At least four duodenal biopsies were collected during upper gastrointestinal endoscopy. Intraepithelial lymphocytes have been identified using CD3 immunostaining and a value  $\leq 25$  lymphocytes/100 epithelial cells was considered normal. Histological changes were classified according to Marsh criteria (stage 0: Normal mucosa; stage 1: Increased number of intra-epithelial lymphocytes; stage 2: Crypts proliferation; stage 3a-3b-3c: Respectively mild, moderate and severe villous atrophy)<sup>[17]</sup>.

### Measurement of BMD

All patients underwent lumbar spine and femoral neck BMD evaluation by means of DEXA. A T-score 1 to 2.5 and  $> 2.5$  distinguished osteopenia and osteoporosis, respectively.

### Measurement of antibodies against osteoprotegerin

Non-fasting serum samples were obtained from the selected subgroup of 30 CD patients. Measurement was performed according to Riches *et al.*<sup>[14]</sup>. Briefly, serum samples were incubated at a 1:100, 1:50, and 1:25 dilution with 12.5 ng of homodimeric recombinant human OPG (R and D Systems, Minneapolis, United States) and also with protein G-coated agarose beads (Calbiochem, Darmstadt, Germany) that had been pre-incubated with 5% albumin to reduce non-specific binding. After incubation for 1 h at 37 °C, the beads were washed five times with phosphate-buffered saline, suspended in 30  $\mu$ L of reducing sample buffer, and incubated at 90 °C for 5 min. After brief centrifugation,

**Table 1** Characteristics of the 70 treated celiac disease patients with negative serology according to bone mineral density as assessed by dual energy X ray absorptiometry

Variables	Overall (n = 70)	Normal BMD (n = 21)	Low BMD (n = 49)	P
Sex (M/F)	13/57	2/19	11/38	0.31
Age (yr)	40.5 ± 10.5	31.0 ± 9.7	43.0 ± 9.7	0.00
Time since diagnosis	2.8 ± 0.6	2.5 ± 0.5	2.4 ± 0.4	0.37
BMI	22.2 ± 1.4	22.5 ± 1.3	22.0 ± 1.4	0.40

the supernatant was loaded onto a 12% polyacrylamide gel, subjected to electrophoresis at 200 V for 60 min, transferred to membrane, and therefore probed with a mouse monoclonal antibody against human OPG (Abcam, Cambridge, United Kingdom). A peroxidase-conjugated donkey anti-mouse antibody (Jackson, Suffolk, United Kingdom) at a 1:5000 dilution was used for detection. Equal loading was assessed by probing the blot with peroxidase-conjugated goat anti-human antibody (Jackson) at a 1:5000 dilution. Immunolabeled bands were detected with the use of a chemiluminescent substrate and a chemiluminescence imager. A homodimeric recombinant human OPG (R and D Systems) was used as positive control. A 55-kDa band indicated the presence of antibodies against OPG.

The study was approved by the local research Ethical Committee, and informed consent was obtained from all participants.

### Statistical analysis

Comparison of proportions was performed using  $\chi^2$  test. A multivariate analysis was performed using Multivariate Analysis of Variance (MANOVA) to identify variables associated with low BMD. Difference was considered significant if the *P* value was < 0.05. Data were analyzed using the Statistical Package for Social Services, Version 16.0 (SPSS Inc., IL, United States).

## RESULTS

Forty-nine out of the 70 (74%) CD patients displayed low BMD, with 13 (24%) accounting for osteoporosis and 36 (76%) for osteopenia (Table 1). Multiple logistic regression analysis showed that age was the only one variable which positively correlated with low BMD (Table 1). Serum calcium and PTH levels were normal in all patients. A complete healing of duodenal mucosa was found in 31 out of 38 (82%) patients who underwent repeat intestinal biopsies. In this specific subgroup, 20 (64%) patients showed a low BMD compared to 6 out of 7 (86%) patients who were found to carry an incomplete duodenal mucosa healing (*n* = 1 Marsh 1, *n* = 2 Marsh 2, *n* = 4 Marsh 3) (Table 2, *P* = 0.4).

No evidence of the 55-kDa band was found in serum samples of the subgroup of 30 patients who were tested

for, indicating no presence of auto-antibodies against OPG (Figure 1). The characteristics of this subgroup of CD patients, including HLA DQ2 and DQ8 status, are shown in Table 3.

## DISCUSSION

Currently, serology is employed to select individuals needing to undergo intestinal biopsy for diagnosing CD as well as to monitor adherence and response to GFD<sup>[18,19]</sup>. However, confirming a previous observation<sup>[20]</sup>, this study shows that, despite a persistent negative serology, 18% of CD patients with good adherence to GFD have an incomplete normalization of intestinal mucosa (e.g., 82% negative predictive value in detecting intestinal mucosal recovery).

A GFD normally gains mucosal damage in CD patients restoring calcium absorption, and this can support an improvement in bone mineralization in one year<sup>[21]</sup>. Nevertheless, a GFD rarely normalizes BMD in adult patients, so nutritional supplementation may be necessary<sup>[22,23]</sup>. Findings of this study show a higher prevalence (74%) of bone demineralization in adulthood diagnosed CD patients notwithstanding long-term strict adherence to GFD and persistent negative CD-related serology.

No differences in acknowledged risk factors for osteoporosis have been found between patients with low

**Figure 1** No evidence of the 55-kDa band was found in serum samples of the subgroup of 30 patients who were tested for, indicating no presence of auto-antibodies against osteoprotegerin. A: Western blotting (representative serum samples from a series of 30 celiac disease patients) showing the absence of antibodies against osteoprotegerin (OPG) after immunoprecipitation. Positive control indicates a 55 kDa band (arrow, lane 2) as the presence of antibodies against OPG. Negative control is shown in the lane 1; B: Western blotting confirms the equal loading of the gel by means of the addition of staining for immunoglobulins. Molecular-weight markers are shown in lane M.

and normal BMD except for age, suggesting that CD is a major one. Even though serum calcium levels may not adequately reflect calcium absorption, no patient showed low levels of serum calcium, and this was in accordance with the finding that calcium absorption returns to normal setting after one year GFD<sup>[24]</sup>. Furthermore, a significant proportion of patients (64%) on GFD showed low BMD, even if they displayed complete recovery of duodenal lesions as assessed by Marsh classification<sup>[25]</sup>. Nevertheless, recent observations suggested that normal Marsh grade does not exclude villous atrophy when assessed morphometrically<sup>[26]</sup>.

Despite the high frequency of low BMD, there is still not a consensus about the timing for BMD evaluation in CD patients<sup>[27]</sup>. A novel finding of this study is that DEXA performed 92% negative predictive value in detecting intestinal mucosa recovery. So, based on this finding, the use of DEXA could be proposed for its additive value in this specific issue (e.g., a non-pathological DEXA has 92% probability to predict intestinal mucosa recovery in CD patients on GFD).

Insight of the molecular mechanism regulating osteoclast formation and activation progressed a lot in the past 10 years, with the identification of the RANKL/RANK signaling system as well as the discovering of OPG, a protein that appeared to protect from excessive bone reabsorption<sup>[28,29]</sup>. Fiore *et al.*<sup>[30]</sup> demonstrated that OPG/RANKL ratio was significantly lower in CD patients with normalization of duodenal histology than in healthy controls and it positively correlated with low BMD. It has been hypothesized that in some patients OPG is bound to a plasma protein(s) and this could inactivate it<sup>[31]</sup>.

In this study, circulating antibodies against OPG were not found in 30 CD patients. This contrasts with findings of Riches *et al.*<sup>[14]</sup> who showed auto-antibodies against OPG in a man with CD on GFD presenting with severe osteoporosis and high bone turnover. As authors demonstrated, these auto-antibodies had the potential to block

the inhibitory effect of OPG on RANKL and this lead to the hypothesis that they may play a role in the development of bone derangement. In the same report, authors detected these circulating auto-antibodies in three among 15 additional patients with CD and low BMD, while there was no evidence of them in serum specimens from 10 healthy controls and 14 patients with autoimmune hypothyroidism. If these CD patients were or were not on GFD was not indicated by the authors and data on duodenal mucosa histology were not provided.

It is unlikely that discrepancy between Riches *et al.*<sup>[14]</sup> and findings of this study relies on the selection of patients neither on the used methodology. Indeed, it seems that the subgroup of 30 CD patients who were tested for antibodies against OPG is representative enough with respect to the variables that may affect the possible appearance of auto-antibodies (e.g., BMD, duodenal histology, HLA). Furthermore, Riches *et al.*<sup>[14]</sup> anti-OPG antibodies measurement methodology has been strictly followed. A positive control has been checked in order to validate the procedure and several serum sample dilutions have been tested in order to increase sensitivity. Nevertheless, that a long-term GFD, as is the case of this study, may reduce the production of circulating auto-antibodies against OPG towards undetectable levels may be a possibility. At this regard, the occurrence of a limited amount of mucosal antibodies could be taken into account. Furthermore, genetic background affecting the immune system (e.g., auto-antibody development) may be another issue. Indeed, HLA DQ2 heterodimer has been shown to be more involved than HLA DQ8 heterodimer in complicated CD<sup>[32]</sup>. While for HLA-DQ2 a single deamidation in a gluten peptide is enough to produce a CD4+ T cell response, for HLA-DQ8 it is necessary a deamidation at two positions in the gluten peptide, resulting in a more limited generation of strong antigenic gluten peptides than HLA DQ2 haplotype<sup>[33]</sup>. Furthermore, the HLA-DQ8 peptidic domain is more easily degraded limiting the availability for antigen presentation<sup>[34]</sup>. With this in mind, in this study all 30 CD patients who were screened for antibodies against OPG were also tested for HLA DQ2/DQ8 alleles. As expected<sup>[35]</sup>, a proportion of 77% and 23% for DQ2 and DQ8 haplotype, respectively, was found, indicating an unselected sample at this regard. Anyway, although the role of HLA molecules and the association to particular genotypes has been well established in CD pathogenesis, HLA is estimated to contribute only for the 35% of the genetic risk, suggesting that more genetic risk factors had to be involved in CD susceptibility<sup>[36]</sup>.

In conclusion, the negative results of this study indicate that auto-antibodies against OPG, if any, do not play a major role in the pathogenesis of bone demineralization in patients with CD, suggesting that other mechanisms should be investigated.

## COMMENTS

**Background**

Evidences indicate that a low bone mineral density (BMD) is found in 20%-50% newly diagnosed patients with celiac disease (CD). Adherence to a strict gluten-free diet (GFD) will reverse the histological changes in the intestine and also the biochemical evidence of calcium malabsorption, resulting in normal BMD in these treated patients. Nevertheless, there may be long-term impairment of bone mineralization in some otherwise healthy CD patients adhering to GFD. Furthermore, osteopenia has been found in treated CD patients who showed improvement or even complete healing of intestinal mucosa.

**Research frontiers**

Other mechanisms of bone injury than calcium malabsorption are probably involved in patients with CD. Mediators of inflammatory immune-mediated responses (e.g., cytokines), parathyroid hormone (PTH), estrogens, androgens, corticosteroids and vitamin D are all acknowledged to affect BMD by modulating the receptor activator of nuclear factor B/receptor activator of nuclear factor B-ligand/osteoprotegerin [RANK/RANK-L/osteoprotegerin (OPG)] system. Recently, circulating neutralizing autoantibodies against OPG have been shown in CD patients with low BMD leading to the hypothesis that blocking the inhibitory effect of OPG on RANKL may have a role in the development of bone derangement in these patients.

**Innovations and breakthroughs**

This study aimed at investigating risk factors associated with low BMD in patients with CD, focusing on circulating auto-antibodies against OPG. Findings confirm a high prevalence of low BMD in CD patients despite strict adherence to GFD, persistent negative serology, and healing of duodenal lesions. Since auto-antibodies against OPG have not been found in serum samples from a subgroup of patients who were tested for, it can be argued that, if any, the role of antibodies against OPG in the pathogenesis of reduced BMD in patients with CD remains to be established.

**Applications**

The study further supports the importance of early diagnosis in order to avoid bone complications in CD patients. Furthermore, it remarks that autoantibodies against OPG do not play a major role in the pathogenesis of bone demineralization in patients with CD, suggesting that other mechanisms of bone derangement should be investigated.

**Peer review**

This is an interesting study showing antibodies to OPG are not present at least systemically to explain persistent low bone density in coeliac subjects. Authors guess there is a small possibility that mucosal antibodies could still be present which should still be alluded to.

### Abstract

**AIM:** To characterize the colon microbiota in two women histologically diagnosed with collagenous colitis using a culture-independent method.

**METHODS:** Biopsies were taken from the ascending colon and the total DNA was extracted. Universal bacterial primers were used to amplify the bacterial 16S rRNA genes. The amplicons were then cloned into competent *Escherichia coli* cells. The clones were sequenced and identified by comparison to known sequences.

**RESULTS:** The clones could be divided into 44 different phylotypes. The microbiota was dominated by Firmicutes and Bacteroidetes. Seven phylotypes were

found in both patients and constituted 47.5% of the total number of clones. Of these, the most dominating were clones similar to *Bacteroides cellulosilyticus*, *Bacteroides caccae*, *Bacteroides thetaiotaomicron*, *Bacteroides uniformis* and *Bacteroides dorei* within Bacteroidetes. Sequences similar to *Faecalibacterium prausnitzii* and *Clostridium citroniae* were also found in both patients.

**CONCLUSION:** A predominance of potentially pathogenic *Bacteroides spp.*, and the presence of clones showing similarity to *Clostridium clostridioforme* were found but the overall colon microbiota showed similarities to a healthy one. Etiologies for collagenous colitis other than an adverse bacterial flora must also be considered.

### INTRODUCTION

Collagenous colitis (CC), an idiopathic inflammatory bowel disease, is a subtype of microscopic colitis (MC) together with lymphocytic colitis (LC)<sup>[1]</sup>. It is considered as a common cause of chronic diarrhea. In Sweden the incidence is approx four to five cases per 100 000<sup>[2]</sup>. The incidence for

both CC and LC in Europe and North America is almost as high as for Crohn's disease and ulcerative colitis<sup>[2]</sup>.

CC is clinically characterized by chronic non-bloody diarrhea, often combined with abdominal pain and weight loss<sup>[2]</sup>. The colonic mucosa appears macroscopically normal or near-normal and the diagnosis is made by microscopic examination of mucosal biopsies that reveals diagnostic histopathological changes. CC was first described in 1976 by Lindström<sup>[3]</sup> in a woman with chronic watery diarrhea in whom histological examination revealed a thick subepithelial collagenous deposition in the rectum. In 1989, Lazenby *et al.*<sup>[4]</sup> proposed the term lymphocytic colitis in a group of patients with chronic diarrhea and normal colonoscopy with only minor histological changes, where the microscopic evaluation of colonic biopsy specimens revealed modestly increased inflammation in the lamina propria without subepithelial collagen deposition or other mucosal changes.

The peak incidence of MC is in individuals between 55 years and 70 years of age. The female:male ratio is about 7:1 for CC. For LC the female predominance is less pronounced, with a female:male ratio of 2-3:1<sup>[5]</sup>. However, the disease can occur at all ages, and a few children with CC have been reported<sup>[6,7]</sup>. Bile acid malabsorption is found in about 27%-44% of patients with CC and 9%-60% in patients with LC<sup>[5,8-9]</sup>. Treatment with bile acid binding medications is effective in patients with bile-acid malabsorption but can also be effective in patients without bile-acid malabsorption<sup>[10]</sup>.

Both etiology and pathogenesis of MC are uncertain. The most widely held hypothesis is that a noxious agent in the lumen, probably originating from the bacterial microflora, may have a major pathogenic role in the chronic intestinal inflammation. This is supported by regression of symptoms and histopathological changes after diversion of the fecal stream, and recurrence after restoration of intestinal continuity<sup>[11,12]</sup>. Other observations supporting this hypothesis are the sudden onset of diarrhea and that treatment with antibiotics may have positive effects<sup>[2,13]</sup>. The increased infiltration of lymphocytes in the mucosa also indicates a proinflammatory component in the lumen. There are case reports of linking pathogenic bacteria such as *Clostridium difficile*, *Yersinia enterocolitica*, *Campylobacter jejuni* and *Aeromonas hydrophila* to MC<sup>[2,7,14-16]</sup>.

The human microbiota in healthy persons as well as in patients with inflammatory bowel disease has been analyzed in several studies using culture-independent methods<sup>[17-19]</sup>. However, to our knowledge no such studies have been performed on patients diagnosed with CC. The aim of the present study was to characterize the mucosa-associated microbiota in the ascending colon in two women histologically diagnosed with CC, by cloning and sequencing of the bacterial 16S rRNA genes.

## MATERIALS AND METHODS

### Subjects and samples

Two female patients, 51 years and 60 years old (A and B)

with a known diagnosis of MC, took part in the study. Patient A, otherwise healthy, started to experience watery, non-bloody diarrhea after an antibiotic treatment for gastroenteritis 10 years earlier. Colonoscopy was performed and she was diagnosed with LC. She was treated with Loperamid<sup>®</sup> (Merck NM AB, Stockholm, Sweden). Two years later she had a relapse of watery, non-bloody diarrhea and a second colonoscopy was performed, still indicating LC. This time she improved spontaneously. At the time of the present study, after a period of stress and a viral gastroenteritis, she started to lose weight and had frequent, watery, non-bloody diarrhea. The present colonoscopy showed a slightly swollen mucosa and increased vascular pattern. The histological examination revealed a thickened subepithelial collagen layer as well as inflammation in the lamina propria and a damaged surface epithelial layer. Patient B had a history of chronic thyroiditis but was otherwise healthy. She was diagnosed with CC as well as with bile acid malabsorption 4 years before the study. At that time she improved spontaneously but had a recurrence after a period of major stress. Previously, she was treated with non-steroidal anti-inflammatory drugs due to muscular stiffness and actually experienced an improvement of her bowel function by this treatment. At the time of the present colonoscopy her symptoms had improved due to dietary fat reduction. Colonoscopy showed an increased vascular pattern in the right colon but was otherwise normal. Histological examination could verify a collagenous colitis.

Neither patient had any medication at the time of the colonoscopy. Celiac disease had been excluded in both women. They were both non-smokers.

The patients were asked to avoid fiber-rich foods such as fruits, vegetables, grains and seeds some days before the colonoscopy. The day before the examination they ate a plain breakfast, and no solid food was allowed after noon. Intestinal cleansing was carried out with Phosphoral<sup>®</sup> (Clean Chemical Sweden AB), a salt preparation with osmotic effects. Colonoscopy was performed and serial biopsies throughout the colon as well as two extra biopsies from the right colon were collected. The histological examination followed routine procedures. The latter were placed in tubes with TE-buffer [10 mmol Tris-HCl, 1 mmol ethylenediaminetetraacetic acid (EDTA), pH 8.0], frozen immediately in liquid nitrogen and stored at -80 °C. The study was approved by the Ethics Committee at Lund University. The women gave written, informed consent before entering the study.

### DNA extraction and amplification

Frozen tissue samples were thawed on ice and a single biopsy was transferred to a 1.5 mL tube with 190 µL Buffer G2 (DNA Tissue Kit; Qiagen, GmbH, Hilden, Germany) and 10 µL of Proteinase K (Qiagen). Eight to ten sterile glass (2 mm) beads were added and the cells were lysed at 56 °C for 3-4 h in a shaking water bath. Tubes were cooled on ice and shaken for 30 min on an Eppendorf Mixer 5432 (Eppendorf, Hamburg, Germany) at 4 °C

to disintegrate all bacteria. After centrifugation at  $300 \times g$  for one minute, the solution was transferred to a Qia-gen sample tube, and total DNA was extracted by using Biorobot EZ1 (Qiagen) according to the manufacturer's instructions. DNA was eluted in 200  $\mu$ L.

### Polymerase chain reaction amplification and cloning

The bacterial 16S rRNA genes were amplified by the universal primers ENV1 and ENV2 annealing to positions 8-27 and 1492-1511, respectively, according to *Escherichia coli* (*E. coli*) numbering<sup>[20]</sup>. The reaction mixture contained 5  $\mu$ L of  $10\times$  polymerase chain reaction (PCR) buffer (100 mmol Tris-HCl, 15 mmol MgCl<sub>2</sub>, 500 mmol KCl, pH 8.3), each deoxynucleotide phosphate at a concentration of 200  $\mu$ mol, 2.5 U of Tag DNA Polymerase (Roche Diagnostics, GmbH, Mannheim, Germany) and 10 pmol of each primer. To each tube, 5  $\mu$ L of extracted sample DNA was added and sterile water was added to 50  $\mu$ L. As negative controls, water was added to the reaction mixture instead of DNA. Amplification was performed on an Eppendorf Mastercycler (Eppendorf AG, Hamburg, Germany). Initially, the reaction was heated to 94 °C for 3 min, followed by 25 cycles of denaturing at 94 °C for 1 min, annealing at 50 °C for 45 s and elongation at 72 °C for 2 min. Finally, the reaction was held at 72 °C for 7 min before cooling down to 4 °C. Six PCR tubes were prepared from each sample and then pooled. Forty-two  $\mu$ L of the pooled reaction mixture from one sample was separated on a 1.5% (w/v) agarose gel (Agarose Type III; Sigma Aldrich, St Louis, Mo., United States) in TBE-buffer (89 mmol Tris, 89 mmol boric acid and 2.5 mmol EDTA, pH 8.3). The agarose gel was stained with ethidium bromide (0.5 mg/L) and the band was cut out from the gel. DNA was purified by using Wizard<sup>®</sup> SV Gel and PCR Clean-Up System (Promega Corp., Madison, WI, United States). For cloning Promega pGEM<sup>®</sup>-T Vector System and *E. coli* JM 109 (Promega Corp.) competent cells were used as described previously<sup>[20]</sup>. Colonies were selected randomly and recultivated on LB-agar containing ampicillin, and then harvested and stored in freezing buffer at -80 °C.

### Sequencing

Selected clones were single-strand sequenced by MWG Biotech (Ebersberg, Germany). ENV1 primer was used as sequencing primer. Sequences were edited using Bioedit Sequence Alignment editor 7.0.5.3<sup>[21]</sup>. Sequences were identified by comparing them to sequences using the option "seqmatch" available at the Ribosomal Database Project<sup>[22]</sup>. Sequences were checked for chimeric artifacts by using the Bellerophon server<sup>[23]</sup> and by creating phylogenetic trees of both 5'- and 3'- ends of the sequences. DNAdist calculations were performed using the Phylip DNAdist program using the "similarity table" option (available at: <http://mobyli.pasteur.fr/cgi-bin/portal.py?form=dnadist>)<sup>[24]</sup>. Sequences representing the different phylotypes have been submitted to Genbank

and the accession numbers are HQ992999- HQ993042.

### Diversity calculations

Shannon and Simpson's indices were used for diversity calculations. The Shannon index is based on the proportional abundance of species and accounts for both evenness and species richness. Simpson's index is the dominance measure where the abundance of commonest species is considered more than species richness<sup>[25]</sup>. The Simpson's index was expressed as 1/D.

## RESULTS

Two clone libraries were constructed, one for patient A with 87 clones and one for patient B with 90 clones. Five clones were suspected chimeras and were removed from the dataset before analysis. The lengths of the sequenced fragments were approximately 750 bp. Sequences showing > 98% similarity to each other were assigned to a single phylotype and a total of 44 phylotypes were identified (Table 1).

Sequences could be grouped into 22 phylotypes in patient A and 29 phylotypes in patient B. Shannon's and Simpson's diversity indices were calculated and both the patients showed similar values. The Shannon index was 2.61 for patient A and 2.78 for patient B, and the Simpson index was 8.13 for A and 9.29 for patient B. Firmicutes and Bacteroidetes were the dominating phyla with 50.6% and 47.2% in patient A and 57.8% and 42.2% in patient B, respectively (Figure 1).

In patient A Porphyromonadaceae constituted 1.2% of the clones and in patient B, Porphyromonadaceae and Rikenellaceae constituted 11.1% of the clones. Only two clones (2.3%) similar to Enterobacteriaceae were found in patient A.

The most common phylotypes were sequences similar to *Blautia wexlerae* (23 clones), *Faecalibacterium prausnitzii* (13 clones) and *Clostridium citroniae* (9 clones) within Firmicutes, and *Bacteroides dorei* (29 clones), *Bacteroides caccae* (16 clones) and *Bacteroides cellulosilyticus* (9 clones) within Bacteroidetes (Table 1). These phylotypes showed > 97% similarity to the closest type strain except for *C. citroniae*. Out of the 44 phylotypes identified, the two patients had 7 in common and 5 of these were assigned to Bacteroidetes and two to the Firmicutes. The phylotypes in common constituted 84 clones (47.5%) of the total number of clones. Sequences similar to *F. prausnitzii* and *C. citroniae* were found in both patients (Table 1). Within Bacteroidetes the shared phylotypes were most similar to, *Bacteroides thetaiotaomicron*, *Bacteroides uniformis*, *B. cellulosilyticus*, *B. caccae* and *B. dorei*.

## DISCUSSION

In the present study the microbiota of the ascending colon in the two female patients with CC showed similarities to a normal colon microbiota with Firmicutes and

Table 1 Sequences grouped into phylotypes at 98% similarity

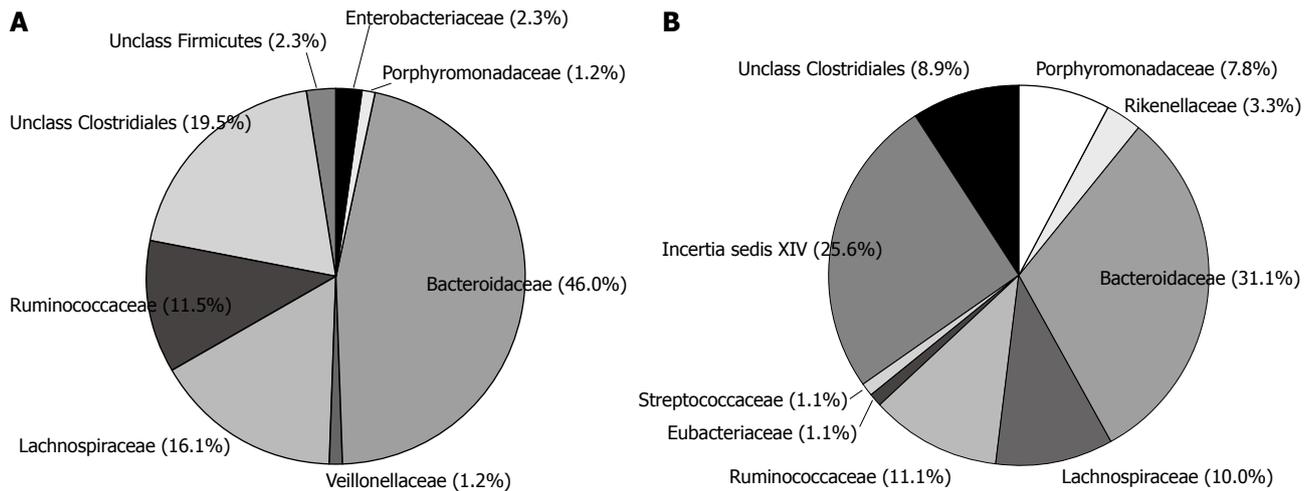

Phylotype No.	Closest type strain	Acc. No <sup>1</sup>	Similarity (%) <sup>2</sup>	No. of clones <sup>3</sup>	Distribution of clones <sup>4</sup>	Assignment of clones

The type strain showing the highest similarity to the sequence is shown. Assignment of the clones to bacterial family level was done using the "sequence match" option in the Ribosomal data base<sup>[22]</sup>. <sup>1</sup>Accession number for the type strain; <sup>2</sup>Similarity to the closest type strain; <sup>3</sup>The total number of clones assigned to the phylotype; <sup>4</sup>Number of clones found in patient A and B, respectively.

Bacteroidetes as dominating phyla, making up 97.7% and 100.0% of the clones in patient A and B, respectively. Only two clones close to Enterobacteriaceae were found in patient A. In several studies, the microbiota of healthy persons have been analyzed by sequencing of the 16S rRNA genes using either fecal samples or tissue samples from the intestinal mucosa<sup>[17,18,26-28]</sup>. All these studies showed a predominance of Firmicutes and Bacteroidetes while Verrucomicrobia, Actinobacteria and gamma proteobacteria were detected at lower frequency.

The proportion of clones belonging to *Bacteroides*

was 47.0% in patient A and 31.1% in patient B. These were higher figures than Wang *et al.*<sup>[18]</sup>, using a similar methodology, found in biopsies taken from the ascending colon from a healthy, 54-year old woman where *Bacteroides* constituted 24.4% of the clones. Hayashi *et al.*<sup>[17]</sup> analyzed fecal samples of 3 healthy men aged 27, 34 and 54 years, and the proportion of *Bacteroides* was 4.2%, 3.4% and 14.9%, respectively. In another study of fecal samples from a healthy 40-year old man, *Bacteroides* constituted 14.4% of the total number of clones<sup>[26]</sup>. Delgado *et al.*<sup>[27]</sup> analyzed clones from the descending colon from

**Figure 1** Distribution of clones at family level. Assignment of the clones were done using the Ribosomal Data Base Project Release 10 and the option "seqmatch"<sup>[22]</sup>. A: Patient A; B: Patient B.

a healthy 45-year old man and found one clone out of 20 (5%) belonging to *Bacteroides*. Of the 44 phylotypes found here, the two patients had only 7 in common. However, these shared phylotypes constituted 47.5% of the total number of clones. Within *Bacteroides* five phylotypes were common to both patients. Of these the most dominating were clones similar to *B. caccae* and *B. dorei* making up 25.4% of the total number of clones (Table 1). Both species belong to the *Bacteroides fragilis* group that are opportunistic pathogens isolated from a variety of anaerobic infections and cause about 50% of all anaerobic bacteremias<sup>[29,30]</sup>.

A subgroup of *B. fragilis*, enterotoxigenic *B. fragilis* (ETBF), that can secrete a proinflammatory enterotoxin, has been found to be implicated in traveller's diarrhea<sup>[31]</sup>. In a study by Zhang *et al.*<sup>[32]</sup>, significantly more ETBF were found in patients with watery diarrhea (26.8%) than in the control group (12.4%). ETBF was also found at a higher frequency in patients over 30 years of age compared to the control group. Additionally, it was shown that 27.0% of patients over the age of 60 carried ETBF compared to 3.7% for the control group. It has been suggested that *Bacteroides fragilis* toxin can bind to receptors on the epithelial cells, leading to a signal cascade and cleavage of cadherine promoting an increased intestinal permeability<sup>[33]</sup>. An increased intestinal permeability was shown in one patient with CC, using an Ussing chamber<sup>[12]</sup>. Permeability was measured on biopsies taken from the sigmoid colon and it was shown that the intestinal integrity was improved after a fecal diversion by an ileostomy, but after restoration of the bowel continuity the permeability increased again<sup>[12]</sup>. Some improvement has been reported when CC patients were treated with metronidazole, penicillin or erythromycin<sup>[34]</sup>. *Bacteroides* are sensitive to metronidazole and that might point to *Bacteroides* as a possible disease-provoking agent<sup>[30]</sup>. On the other hand, the positive effect shown with penicillin and erythromycin speaks against *Bacteroides*<sup>[34]</sup>.

It has been shown that *Akkermansia muciniphila* and

strains of *Clostridium*, *Prevotella* and *Bacteroides* are able to degrade mucin<sup>[35,36]</sup>. The type strain *B. thetaiotaomicron* NCTC 10582 was shown to express glycosidases and glycosulphatase and could degrade pig gastric mucin<sup>[37]</sup>. In the present study 4 clones from patient A and 3 clones from patient B showed high similarity (99.3%-99.9%) to the type strain *B. thetaiotaomicron* NCTC 10582 (Table 1). Clones belonging to *Akkermansia muciniphila* were not found. However, it has been shown that this species represents only about one percent of the microbiota in healthy children and adults<sup>[38]</sup>. One might speculate that specific components present within the microbiota of the CC patients, i.e., *Bacteroides spp.*, that has an impact both on the colonic mucin layer and the intestinal permeability, leading to an immune response.

The clones resembling *Clostridium clostridioforme*, *Clostridium citroniae*, *Clostridium aspargifforme* and *Clostridium aldenense* were distributed into 7 phylotypes showing 95%-99.7% similarity to the different type strains. Four clones from patient A showed high similarity to *C. clostridioforme* and *C. aldenense*. Also in patient B, 5 clones resembling *C. clostridioforme* were found, but they showed lower similarity to the type strain. They are all related and belong to cluster XIVa as defined by Collins *et al.*<sup>[39]</sup>, Warren *et al.*<sup>[40]</sup> and Mohan *et al.*<sup>[41]</sup>. Strains of *C. clostridioforme* and closely related species have been involved in a variety of infections<sup>[42]</sup>. In a study of autistic children, all of whom had gastrointestinal symptoms, high counts of fecal isolates showing 95% similarity to *C. clostridioforme* were found in the diseased children but not in the controls. It cannot be excluded that the presence of sequences resembling *C. clostridioforme* might play a role in the disease in the patients analyzed here.

Clones identified as *F. prausnitzii* of the Ruminococcaceae family were found in both patients and constituted about 7% of the total number of clones. These bacteria together with *Eubacterium rectale* and *Roseburia spp.* are known as butyrate producers and usually make up about 5%-10% of the human microbiota and can be re-

garded as commensals<sup>[43]</sup>. No clones resembling *Lactobacillus* nor Actinobacteria or Verrucomicrobia were found. This can probably be explained by the fact that too few clones were sequenced and that they usually constitute a minor part of the microbiota. Previously published case reports have suggested *Clostridium difficile*, *Yersinia enterocolitica*, *Campylobacter jejuni* and *Aeromonas hydrophila* to CC as possible pathogens<sup>[2,7,14-16]</sup>. This could not be confirmed in the present study. As different pathogens are described, and the fact that the colonic microbiota was similar to a healthy one, the etiology to CC may not primarily depend on abnormal microbiota, and antibiotics may not be the treatment of choice in this entity, as it is sometimes considered<sup>[34]</sup>.

This study has some limitations. Only two patients were examined and the method applied here only detects the dominant bacteria. Future research needs to examine the presence of common pathogens in the bowel, but also etiologies of CC other than bacteria must be considered.

To the best of our knowledge, this is the first study of the intestinal microbiota in patients with a histologically diagnosed CC, by a culture-independent method. The overall composition of the colonic microbiota was similar to a healthy one with dominance of Firmicutes and Bacteroidetes. Due to the fact that only two patients were analyzed it is difficult to draw any conclusions, but in both patients a high proportion of potentially pathogenic species of *Bacteroides* and clones related to *C. clostridioforme* were found.

## ACKNOWLEDGMENTS

We thank Martin Olesen, MD, PhD for characterizing the patients histologically and Ingrid Palmquist, RN for excellent technical assistance.

## COMMENTS

### Background

Collagenous colitis (CC) is an idiopathic inflammatory bowel disease characterized by chronic non-bloody diarrhea. CC is regarded as a subtype of microscopic colitis. The etiology is unknown but a noxious agent, probably originating from the microbiota, in the intestinal lumen has been proposed to have a pathogenic role. However, no attempt to analyze the microbiota in diseased patients has been done.

### Research frontiers

The intestinal mucosa is colonized by a huge number of bacteria that are important for health and disease. In several studies the gut microbiota has been analyzed by culture-independent methods in patients with intestinal inflammatory diseases such as ulcerative colitis and Crohn's disease.

### Innovations and breakthroughs

Having the opportunity to obtain histologically well-defined collagenous colitis samples, the authors have characterized the dominant microbiota in two diseased patients.

### Applications

Culture-independent methods can be used for analyzing the dominant mucosa-associated microbiota in collagenous colitis.

### Terminology

The meaning of the word microbiota here is synonymous to the bacterial flora in the intestine.

### Peer review

It is well organized. Several papers have been presented in support of micro-

biota from controls, but no speculation have been made about findings in this paper and clinical applications, limitations of the study and future of research in this field.

### Abstract

**AIM:** To determine the effectiveness of pancreatic duct (PD) stent placement for the prevention of pancreatitis after endoscopic retrograde cholangiopancreatography (ERCP) in high risk patients.

**METHODS:** Authors conducted a single-blind, randomized controlled trial to evaluate the effectiveness of a pancreatic spontaneous dislodgement stent against post-ERCP pancreatitis, including rates of spontaneous dislodgement and complications. Authors defined high risk patients as having any of the following: sphincter of Oddi dysfunction, difficult cannulation, prior history of post-ERCP pancreatitis, pre-cut sphincterotomy, pancreatic ductal biopsy, pancreatic sphincterotomy, intraductal ultrasonography, or a procedure time of more than 30 min. Patients were randomized to a stent group ( $n = 60$ ) or to a non-stent group ( $n = 60$ ). An abdominal radiograph was obtained daily to assess

spontaneous stent dislodgement. Post-ERCP pancreatitis was diagnosed according to consensus criteria.

**RESULTS:** The mean age ( $\pm$  standard deviation) was  $67.4 \pm 13.8$  years and the male: female ratio was 68:52. In the stent group, the mean age was  $66 \pm 13$  years and the male: female ratio was 33:27, and in the non-stent group, the mean age was  $68 \pm 14$  years and the male: female ratio was 35:25. There were no significant differences between groups with respect to age, gender, final diagnosis, or type of endoscopic intervention. The frequency of post-ERCP pancreatitis in PD stent and non-stent groups was 1.7% (1/60) and 13.3% (8/60), respectively. The severity of pancreatitis was mild in all cases. The frequency of post-ERCP pancreatitis in the stent group was significantly lower than in the non-stent group ( $P = 0.032$ , Fisher's exact test). The rate of hyperamylasemia were 30% (18/60) and 38.3% (23 of 60) in the stent and non-stent groups, respectively ( $P = 0.05$ ,  $\chi^2$  test). The placement of a PD stent was successful in all 60 patients. The rate of spontaneous dislodgement by the third day was 96.7% (58/60), and the median (range) time to dislodgement was 2.1 (2-3) d. The rates of stent migration, hemorrhage, perforation, infection (cholangitis or cholecystitis) or other complications were 0% (0/60), 0% (0/60), 0% (0/60), 0% (0/60), respectively, in the stent group. Univariate analysis revealed no significant differences in high risk factors between the two groups. The pancreatic spontaneous dislodgement stent safely prevented post-ERCP pancreatitis in high risk patients.

**CONCLUSION:** Pancreatic stent placement is a safe and effective technique to prevent post-ERCP pancreatitis. Therefore authors recommend pancreatic stent placement after ERCP in high risk patients.

## INTRODUCTION

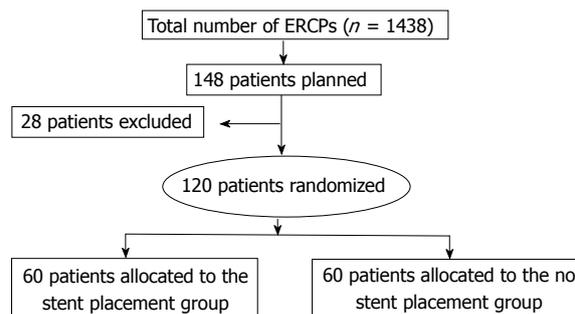

Acute pancreatitis is a serious complication of endoscopic retrograde cholangiopancreatography (ERCP). The frequency of post-ERCP pancreatitis varies between 1% and 9%<sup>[1-6]</sup> in average risk patients, and its prevention remains a critical issue. Impaired drainage of the pancreatic duct (PD), leading to acinar injury, is a commonly accepted mechanism of injury<sup>[7,8]</sup>. Possible causes of impaired drainage include mechanical, chemical and thermal injury, as well as subsequent edema and spasm of the duodenal papilla.

Several prospective studies have confirmed that PD stent placement prevents post-ERCP pancreatitis, especially in high risk patients<sup>[9-13]</sup>. However, no consensus has yet been reached on the indications for prophylactic PD stent placement or on the type of stent which should be used. Therefore, we conducted a single-blind, randomized controlled trial (RCT) to evaluate the effectiveness of spontaneous dislodgement stents in preventing post-ERCP pancreatitis in high risk patients.

## MATERIALS AND METHODS

### Study design

This RCT was conducted in Tokai University Hospital, Japan between April 2006 and June 2010. During this period, we performed 1438 ERCPs on patients with pancreatobiliary diseases. All procedures for this study were performed by one physician (Kawaguchi Y), an experienced surgeon with more than 2000 prior ERCP cases. Independent patient-related and procedure-related risk factors for post-ERCP pancreatitis have been previously published<sup>[3-5,14-16]</sup>. Patients at high risk of post-ERCP pancreatitis who met any of the following criteria were enrolled in this RCT: (1) A previous history of post-ERCP pancreatitis; (2) Sphincter of Oddi dysfunction; (3) Difficult cannulation; (4) Pre-cutting; (5) PD biopsy; (6) Intraductal PD ultrasonography; or (7) ERCP procedure time > 30 min prior to PD stent placement. Difficult cannulation was defined as > 10 min of attempted cannulation. We performed PD guidewire placement or pan-

**Figure 1** Trial profile.

creatic sphincterotomy in some cases of difficult cannulation. Exclusion criteria were as follows: (1) Inability to provide written informed consent; (2) Performance status of 4; (3) Age 19 years or younger; (4) Pregnancy or breastfeeding; (5) Inability to access duodenal papilla endoscopically; (6) Previous endoscopic sphincterotomy or endoscopic papillary balloon dilation; (7) Inability to insert a guidewire into the PD; (8) Patients requiring PD drainage; (9) Patients requiring endoscopic papillectomy; (10) Pancreatic head cancer; or (11) Pancreas divisum.

Of 148 patients screened, 120 patients who satisfied the inclusion criteria participated in this study. Patients were randomly assigned into a stent placement group (60 patients) and a non-stent placement group (60 patients) after the completion of diagnostic or therapeutic ERCP (Figure 1). Randomization was conducted by a simple randomization method without any stratification factor. After diagnostic or therapeutic ERCP was achieved and eligibility was confirmed, a research assistant assigned patients to either the stent or non-stent group, allocating patients using a uniform random number algorithm. All patients provided written informed consent before study entry. This study was approved by Institutional Review Board of Tokai University Hospital (Clinical Trials; University Hospital Medical Information Network Identification Number in Japan, 3995).

### Endoscopic procedures and patient cares

Each patient's past medical history was obtained and physical examination was performed prior to ERCP. Lidocaine gel (4%) was used for pharyngeal anesthesia. Intravenous administration of midazolam with pethidine hydrochloride was used for conscious sedation. All patients received an intravenous drip infusion of 20 mg nafamostat mesilate during the examination, starting before ERCP, with the same dose of nafamostat mesilate as well as antibiotics administered afterwards.

ERCP was performed in standard fashion with JF-240, JF-260V or TJF240 video endoscopes (Olympus, Tokyo, Japan); PR-V216Q, PR-V234Q or PR-V220Q catheters (Olympus) and Jagwire guidewires (Boston Scientific Japan, Tokyo, Japan) were used. We used 5 Fr straight polyethylene stents, 3 cm in length, unflanged on the PD side, and with two flanges on the duodenal side (GPDS-5-3; Cook Endoscopy Inc., Winston-Salem, NC,

ERCP: Endoscopic retrograde cholangiopancreatography; IDUS: Intraductal ultrasonography.

United States). Stent dislodgment was confirmed by daily serial abdominal radiography. If the stent remained on the third day, it was removed endoscopically. In the stent group, we performed PD cannulation followed by contrast injection, guidewire insertion, and stent placement under fluoroscopy. All 120 patients were hospitalized for at least 3 d after the procedure for observation of potential pancreatitis or other complication, regardless of stent placement. On the assumption that the frequency of post-ERCP pancreatitis was 2.3% and 20% in the stent and non-stent group, respectively, 60 patients were needed in each group for 80% power and 5% type I error.

### Definitions

The definition of post-ERCP pancreatitis was based on Cotton's criteria<sup>[17]</sup>, with a modified definition of severity. Instead of the number of hospital days, we evaluated the degree of severity of pancreatitis by number of days before resuming feeding. Post-ERCP pancreatitis was defined as pancreatic pain and hyperamylasemia within 24 h post-procedure. Pancreatic pain was defined as persistent pain in the epigastric or periumbilical region. Hyperamylasemia was defined as an amylase level greater than three times the upper limit of normal in our institution.

### Outcomes

The primary outcome was frequency and severity of post-ERCP pancreatitis. As secondary outcomes, we evaluated the frequency of serum hyperamylasemia, the success rate of stent placement, time to stent dislodgement, and other complications.

### Statistical analysis

This trial was designed as a superiority study to detect differences in clinical effectiveness to prevent post-ERCP pancreatitis with the addition of PD stent placement. The effectiveness of pancreatic stenting was analyzed on an intention-to-treat basis.

The  $\chi^2$  test or Fisher's exact test were used to evaluate proportional differences. The Student *t* test was used

for comparing continuous variables. Univariate evaluation was made for each potential risk factor. All statistical analyses were performed with StatView Ver. 5.0 (SAS Institute, Cary, NC, United States) and StatMate 4 (ATMS, Tokyo, Japan).

## RESULTS

### Patient characteristics

Tables 1 and 2 show basic patient characteristics including risk factors for post-ERCP pancreatitis and final diagnosis in both groups. The mean age ( $\pm$  standard deviation) of all patients was  $67.4 \pm 3.8$  years and the male:female ratio was 68:52. In the stent group, the mean age was  $66 \pm 13$  years and the male:female ratio was 33:27, whereas the mean age was  $68 \pm 14$  years and the male:female ratio was 35:25 in the non-stent group. There were no significant differences between groups with respect to age, gender, final diagnosis, or type of endoscopic intervention (Table 1).

### Pancreatic stenting

The placement of the PD stent was successful in all 60 patients and no complications were observed (Table 3).

### Post-ERCP pancreatitis

The overall rate of post-ERCP pancreatitis was 7.5% (9/120). The rate of post-ERCP pancreatitis in the stent and non-stent groups was 1.7% (1/60) and 13.3% (8/60), respectively ( $P = 0.032$ , Fisher's exact test). The severity of pancreatitis was mild in all nine patients (Table 4). The rate of hyperamylasemia was 30% (18/60) and 38.3% (23/60) in the stent and non-stent groups, respectively ( $P = 0.05$ ,  $\chi^2$  test).

**Table 3 Placement of the pancreatic duct stent**

No. of patients	60
Success rate in stent placement	100%
Rate of spontaneous stent dislodgement	96.7%
Duration time to dislodgement, d, (range)	2.1 (23)
Complications

Post-ERCP pancreatitis	8 (13.3%)	1 (1.7%)	0.0322
Mild	8	1	0.0322
Moderate	0	0	-
Severe	0	0	-
Average serum amylase level in pancreatitis cases (IU/L) (range)	1720 (820-2040)	1240 (746-1964)	0.04

ERCP: Endoscopic retrograde cholangiopancreatography. The Chi-square test or Fisher's exact test was used to determine the significance of associations, and  $P < 0.05$  was regarded as significant.

### Stent dislodgement

The rate of spontaneous dislodgement by the third day was 96.7% (58/60), and the median (range) time to dislodgement was 2.1 (range, 2-3) d (Table 3).

### Other complications

The rates of stent migration, hemorrhage, perforation, infection (cholangitis or cholecystitis) or other complications were 0% (0/120) in both groups (Table 3).

### Risk factors of post-ERCP pancreatitis

Table 5 shows the final diagnoses of those patients with post-ERCP pancreatitis patients in both groups. Regarding univariate analysis of risk factors for post-ERCP pancreatitis, there were no significant differences between groups with respect to various high risk factors studied (Table 6).

## DISCUSSION

We conducted a single-blind, randomized controlled clinical study to evaluate the effectiveness of spontaneous dislodgement PD stents for preventing post-ERCP pancreatitis in high risk patients. The overall rate of post-ERCP pancreatitis was 7.5%. This was consistent

with reported rates of post-ERCP pancreatitis, ranging from 1% to as high as 40% in patients with risk factors<sup>[1-5,7-13,18-22]</sup>. The rate of post-ERCP pancreatitis in the stent and non-stent groups was significantly different at 1.7% and 13.3%, respectively. Thus, prophylactic PD stenting may reduce the rate of post-ERCP pancreatitis from 13.3% to 1.7% in high risk patients. Our study suggested that PD stent placement prevented post-ERCP pancreatitis in high risk patients. However the severity of pancreatitis in this study was mild in all cases and we were therefore unable to assess the efficacy of pancreatic stents for severe post-ERCP pancreatitis. Considering the sample size of this study and no cases of severe post-ERCP pancreatitis, this study had a limitation to determine any significant difference in severity between the two groups.

Several prospective studies have suggested that prophylactic PD stent placement decreases the risk of pancreatitis in high risk patients<sup>[9-14]</sup>. In contrast, Smithline *et al*<sup>[2]</sup> reported that PD stent insertion after ERCP did not have a significant beneficial effect in individuals undergoing biliary sphincterotomy for various indications. These differences may be attributed to variable levels of risk for pancreatitis in the individual study populations. However, two independent meta-analysis on the use of pancreatic stent placement for post-ERCP pancreatitis prophylaxis in patients at high risk of post-ERCP pancreatitis have demonstrated that stent placement significantly reduced the incidence of post-ERCP pancreatitis<sup>[10,23]</sup>. Based on these meta-analyses, European Society of Gastrointestinal Endoscopy guidelines recommend prophylactic pancreatic stent placement to prevent post-ERCP pancreatitis in high risk patients<sup>[24]</sup>. An updated meta-analysis of RCTs involving pancreatic stent place-

ERCP: Endoscopic retrograde cholangiopancreatography; IDUS: Intraductal ultrasonography.

ment also showed that pancreatic stent placement after ERCP reduced the risk of post-ERCP pancreatitis and was beneficial for patients at high risk compared to those who did not have stenting<sup>[25]</sup>. However, several areas requiring further clarification were noted, including the efficacy of pancreatic stents for severe post-ERCP pancreatitis, identification of risk factors and management of adverse events, optimal stent design and material, timing of both placement and removal, and comparison of stenting with wire-guided cannulation or pharmacoprophylaxis<sup>[25]</sup>. Several of these points warrant further investigation.

Regarding indications for stenting, prophylactic pancreatic stent placement has been shown to be cost-effective in patients at high risk of post-ERCP pancreatitis, but not in those at average risk<sup>[26]</sup>. Caution should be used when attempting prophylactic pancreatic stent placement due to the incidence of post-ERCP pancreatitis after failed attempts, which may be as high as 65%<sup>[27]</sup>. As such, prophylactic pancreatic stent placement in high risk patients is cost-effective only if the success rate of stent placement exceeds 75%. Careful selection of patients with risk factors for post-ERCP pancreatitis is therefore critical.

The type of stent used may also play an important role in prophylactic care. As for diameter of stents, most recent studies have used 3 Fr and 5 Fr diameter pancreatic stents. In two recent RCTs, 5 Fr stents proved equivalent to 3 Fr stents for most outcomes studied, though successful insertion of 5 Fr stents was achieved significantly more often<sup>[28,29]</sup>. Placement of 3-4 Fr stents require a small-caliber guidewire (0.018-0.025 inch), a procedure that is difficult and which requires a high level of experience<sup>[17,18,30,31]</sup>. In contrast, the 0.035-inch guidewire used for 5 Fr stents is relatively easy to use for stent placement. Regarding stent length, we used very short (3 cm) stents in this study. Long stents may be more difficult to place and may have higher rates of spontaneous dislodgement, causing damage to the intestines. We therefore recommend the use of shorter stents.

Regarding placement of PD stents, previous studies reported a 5%-10% failure rate and a low rate of complications (2%)<sup>[29,13]</sup>. It is difficult to cannulate the PD after

all the procedures, and PD cannulation itself may cause pancreatitis. Unsuccessful cases were reported to be at a higher risk of pancreatitis<sup>[7,27]</sup>. In our study, we could place PD stents successfully in all patients. PD stent-related complications, such as migration or occlusion, did not occur in any patients. Based on the previous literature and our outcomes, we recommend 5 Fr diameter and very short (3 cm) stents.

As for optimal stent design, Sofuni *et al*<sup>[12]</sup> reported that the unflanged duodenal pigtail-type stent dislodged spontaneously at a higher rate, and that handling of the short duodenal pigtail stent may be complicated, such as the sudden forward movement of the stent on release, requiring close attention and experience. In addition, an internal flange may make spontaneous PD stent dislodgement difficult. In contrast, stents without an internal flange may dislodge spontaneously into the duodenum by pancreatic juice flow or friction with passing food. Since we used 5 Fr straight type stents without an internal flange, stents dislodged spontaneously in 1 d or 2 d in most cases. In our study, the spontaneous dislodgement rate was 96% at 3 d, with a median of 2.1 d. In the absence of spontaneous migration out of the PD at 5-10 d post-ERCP, prompt endoscopic stent removal is recommended due to the increased risk of post-ERCP pancreatitis (relative risk 5.2 in patients without *vs* with spontaneous stent elimination at 2 wk) and potential for stent-induced damage to the PD<sup>[28,29]</sup>. It is our recommendation to avoid the use of stents with an internal flange and to confirm stent dislodgement, or to remove stents in a timely interval, preferably within 1-2 wk after ERCP.

Finally, prophylactic pancreatic stent placement by operator and location warrants discussion. According to survey data, only a small percentage of endoscopists utilize prophylactic pancreatic stenting. The incidence of post-ERCP pancreatitis and a high ERCP volume were independently associated with the use of prophylactic pancreatic stenting<sup>[32-35]</sup>. From these surveys, endoscopists who did not place prophylactic pancreatic stents cited lack of experience in this technique as a primary reason<sup>[32]</sup>. We anticipate that a stent insertion success rate and low rate of complications can also be achieved in other institutions by ERCP specialists. Placement of

pancreatic stents is quickly becoming standard practice. However, many endoscopists remain unfamiliar with the specific techniques required to achieve safe and effective PD guidewire access and stent placement. It is critically important that all endoscopists performing ERCP become proficient in techniques for safe and effective stent placement.

Our study has several limitations. First, this study is single-blind and observation bias is inevitable. Second, we could not evaluate the risk of post-ERCP pancreatitis in patients who failed PD stent placement. Third, we could not evaluate the efficacy of PD stenting alone because nafamostat mesilate was administered in both groups.

In conclusion, pancreatic spontaneous dislodgement stent placement decreases the risk of post-ERCP pancreatitis in patients who are likely to develop post-ERCP pancreatitis.

## COMMENTS

### Background

Acute pancreatitis is a serious complication of endoscopic retrograde cholangiopancreatography (ERCP) and its prevention remains a critical issue. Though several studies have confirmed that pancreatic duct (PD) stent placement prevents post-ERCP pancreatitis, no consensus has yet been reached on the indications for prophylactic PD stent placement or on the type of stent.

### Research frontiers

In this study, the authors demonstrated that pancreatic stent placement was a safe and effective technique to prevent post-ERCP pancreatitis. Authors recommend pancreatic stent placement after ERCP procedures in high risk patients.

### Innovations and breakthroughs

All procedures in this study were performed by one endoscopist (Kawaguchi Y), an experienced operator with more than 2000 prior ERCP cases. Independent patient-related and procedure-related risk factors for post-ERCP pancreatitis have been previously published. This study suggests that PD stenting can significantly reduce post-ERCP pancreatitis in high risk patients.

### Applications

By the general use of the pancreatic stent placement after ERCP procedures in high risk patients, post-ERCP pancreatitis may decrease in the future.

### Terminology

The authors used 5 Fr straight polyethylene stents, 3 cm in length, unflanged on the pancreatic duct side, and with two flanges on the duodenal side. As this stent dislodges spontaneously into the duodenum as a result of pancreatic juice flow or friction with passing food, it is termed a spontaneous dislodgement stent.

### Peer review

The pancreatic spontaneous dislodgement stent placement safely prevented post-ERCP pancreatitis in high risk patients. This result is very impressive.

### Abstract

**AIM:** To investigate the association between hepatitis C infection and type 2 diabetes mellitus.

**METHODS:** Observational studies assessing the relationship between hepatitis C infection and type 2 diabetes mellitus were identified *via* electronic and hand searches. Studies published between 1988 to March 2011 were screened, according to the inclusion criteria set for the present analysis. Authors performed separate analyses for the comparisons between hepatitis C virus (HCV) infected and not infected, and HCV infected and hepatitis B virus infected. The included studies were further subgrouped according to the study design. Heterogeneity was assessed using  $I^2$  statistics. The summary odds ratios with their corresponding 95% CIs were calculated based on a random-effects model. The included studies were subgrouped according to the study design. To assess any factor that could potentially affect the outcome, results were further stratified by age group (proportion of  $\geq 40$  years), gender (proportion of male gender), body mass index (BMI) (pro-

portion of BMI  $\geq 27$ ), and family history of diabetes (i.e., self reported). For stability of results, a sensitivity analysis was conducted including only prospective studies.

**RESULTS:** Combining the electronic database and hand searches, a total of 35 observational studies (in 31 articles) were identified for the final analysis. Based on random-effects model, 17 studies ( $n = 286\ 084$ ) compared hepatitis C-infected patients with those who were uninfected [summary odds ratio (OR): 1.68, 95% CI: 1.15-2.45]. Of these 17 studies, 7 were both a cross-sectional design (41.2%) and cohort design (41.2%), while 3 were case-control studies (17.6%). Nineteen studies ( $n = 51\ 156$ ) compared hepatitis C-infected participants with hepatitis B-infected (summary OR: 1.92, 95% CI: 1.41-2.62). Of these 19 studies, 4 (21.1%), 6 (31.6%) and 9 (47.4%) were cross-sectional, cohort and case-control studies, respectively. A sensitivity analysis with 3 prospective studies indicated that hepatitis C-infected patients had a higher risk of developing type 2 diabetes compared with uninfected controls (summary odds ratio: 1.41, 95% CI: 1.17-1.7;  $I^2 = 0\%$ ). Among hepatitis C-infected patients, male patients (OR: 1.26, 95% CI: 1.03-1.54) with age over 40 years (summary OR: 7.39, 95% CI: 3.82-9.38) had an increased frequency of type 2 diabetes. Some caution must be taken in the interpretation of these results because there may be unmeasured confounding factors which may introduce bias.

**CONCLUSION:** The findings support the association between hepatitis C infection and type 2 diabetes mellitus. The direction of association remains to be determined, however. Prospective studies with adequate sample sizes are recommended.

## INTRODUCTION

Hepatitis C virus (HCV) infections has been identified as one of the leading causes of chronic liver disease with serious sequelae such as end-stage cirrhosis and liver cancer<sup>[1]</sup>. Moreover, chronic HCV infection has been associated with several extrahepatic complications<sup>[2-4]</sup>. The suggestion that HCV may be associated with type 2 diabetes mellitus (type 2 DM) was first made by Allison in 1994. Since then, scores of observational studies assessing the association between HCV and type 2 DM have been published. However, these studies have provided inconclusive results, with some studies supporting the excess type 2 DM risk with HCV infection compared to non-HCV infected controls<sup>[3,5]</sup>, and some studies showed differently<sup>[6-8]</sup>. There are narrative reviews which have assessed the association between HCV infections and type 2 DM<sup>[9-13]</sup>. In 2008, a meta-analysis of observational studies reported an excess type 2 DM risk with HCV infection<sup>[14]</sup>. After these reviews were published, new observational studies in which prevalence of type 2 DM in patients with HCV infection was assessed have been carried out in endemic countries. As the epidemiology of HCV is complex and heterogeneous, information from studies across geographic regions is important. Moreover, the current review also assesses the traditional risk factors.

The objectives were (1) to investigate the available evidence on the association between HCV infections and type 2 DM; and (2) to assess the effect of study design and traditional risk factors on the association.

## MATERIALS AND METHODS

### Data sources and search strategy

Published studies that assess the association between HCV and type 2 DM were searched in MEDLINE, EMBASE and PubMed databases covering the period from 1980 to March 2011. Literature search was carried out using the combination of terms “diabetes”, “diabetes mellitus”, “type II diabetes mellitus”, “type 2 diabetes mellitus”, “type II diabetes”, “T2D”, “T2DM”, “type 2 DM”, “non-insulin dependent diabetes”, or “NIDDM” and “hepatitis”, “hepatitis C”, “hepatitis C virus”, “HCV”, “HVC”, or “chronic hepatitis” and “risk”, “risk factor”, “case-control”, “cohort”, “clinical trial”, “cross-sectional”, “epidemiology”, “observational”, “meta-analysis”, “systematic review”, or “review”. In addition,

we searched Cochrane Database of Systematic Reviews, Cochrane Central Database of Controlled Trials, Database of Abstracts of Reviews of Effects, Google Scholar, European Association for the Study of the Liver, Eurosurveillance (<http://www.eurosurveillance.org/ViewArticle.aspx?ArticleId=695>), and GlaxoSmithKline (<http://www.gsk.com/reportsandpublications.htm>). We also searched the reference lists of the retrieved articles and reviews of this field<sup>[9,10,13,14]</sup>. Our search was limited to human studies and English publications. We also contacted the corresponding authors for any missing data or clarification.

### Study selection

Inclusion criteria for studies were: (1) An epidemiologic study design to conduct a primary or secondary data analysis; (2) At least 1 comparison group without HCV; (3) Provision of sufficient data to calculate odds ratio (OR) or relative risk (RR) comparing type 2 DM in HCV infected patients to non-HCV infected patients; (4) Controlled for at least age and gender in the study design or analysis; and (5) Conducted with not less than 20 HCV-infected patients. HCV was confirmed with the detection of anti-HCV (tested with ELIZA) or HCV RNA (detected by reverse transcriptase polymerase chain reaction). Type 2 DM was confirmed with one of the following criteria; (1) Self-reported type 2 DM (i.e., physician diagnosed); (2) Self-reported diabetes with no history of insulin medication; (3) If fasting plasma glucose exceeding 7.0 mmol/L (126 mg/dL) on two separate occasions; or (4) Impaired fasting glycaemia was between 6.1 mmol/L and 7.0 mmol/L with no insulin medication. Where available, hepatitis B virus (HBV) is confirmed with positive hepatitis B surface antigen and/or detectable serum HBV DNA. Definition of covariates such as family history of diabetes was taken directly from included studies. Studies with patients having other causes of chronic liver disease such as cirrhosis, autoimmune hepatitis, steatohepatitis, primary biliary cirrhosis, primary cholangitis, and hepatocellular carcinoma were excluded. One author (Mak JW) first screened titles and abstracts of publications using eligibility criteria.

Two authors (Naing C, Ahmed SI) independently recorded the detailed information from each primary study using piloted forms that include relevant items: author, year of publication, country, confirmation of type 2 DM, confirmation of HCV, confirmation of HBV (if presented), study design, number of controls and of cases, genotype of HCV (if provided), distribution of age and gender, family history of diabetes. Any discrepancy between these two investigators was resolved by discussion, and by consultation with another author (Maung M).

### Statistical analysis

The degree of heterogeneity between studies was assessed using chi-square and  $I^2$  test. An  $I^2$  value greater than > 50% is considered substantial heterogeneity<sup>[15]</sup>. We used the assumptions that OR from a case control

Table 1 Preferred reporting items for systematic reviews and meta-analysis reporting

Section/topic	No.	Checklist item	Reported on page
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both	Title: Meta-analysis
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number	Abstract
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known	Introduction
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes and study design	Introduction
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number	NA
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale	Methods: Search strategy and eligibility of relevant studies
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched	Methods: Search strategy and eligibility of relevant studies
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated	Search strategy
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis)	Methods: Eligibility of relevant studies; PRISMA flowchart provided
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators	Methods: Data extraction and outcome measures
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made	
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis	
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means)	Methods: Statistical analysis
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., $I^2$ ) for each meta-analysis	

PICOS: Participants, interventions, comparisons, outcomes and study design; PRISMA: Preferred reporting items for systematic reviews and meta-analysis; NA: Not available.

study approximates the RR in a cohort study. The summary OR with their corresponding 95% CI was calculated based on a random-effects model. We performed separate analysis for the comparisons between (1) HCV infected and not infected and (2) HCV infected and HBV infected. The included studies were subgrouped by the study design. In order to assess any factor that could potentially affect the outcome, results were stratified by age group (proportion of  $\geq 40$  years), gender (proportion of male gender), body mass index (BMI) (proportion of BMI  $\geq 27$ ), and family history of diabetes (i.e. self reported), where there was enough data. We also examined the funnel plots for potential publication bias among the included studies. A sensitivity analysis was conducted including only prospective studies. Data entry and analysis was performed using RevMan 5.1<sup>[16]</sup>. The methods and findings of the present review have been reported based on the preferred reporting items for systematic reviews and meta-analysis checklist (PRISMA) (Table 1)<sup>[17]</sup>.

## RESULTS

### Study selection

Figure 1 provides a flowchart of the present review. We retrieved 57 full articles. Of these, 26 publications were excluded because: (1) They were reviews<sup>[10-12]</sup>; (2) They did not adequately distinguish type 2 DM from diabetes<sup>[18,19]</sup>; (3) They were conducted in a special population such as transplant patients<sup>[20,21]</sup>, patients with Human immunodeficiency virus<sup>[22]</sup>, with cryoglobulinemia<sup>[23]</sup>, or with thalassemia<sup>[24]</sup>; (4) They did not include or provide data on patients without HCV infection<sup>[25-31]</sup>; (5) They were conducted in patients with known chronic liver disease<sup>[32-35]</sup>; (6) It had less than 20 HCV infected patients<sup>[36-38]</sup>; and (7) It had duplicate data<sup>[39]</sup>. The remaining 31 publications of 35 independent studies<sup>[5,7,8,40-67]</sup> were eligible for inclusion in the present meta-analysis. Four publications<sup>[8,55,56,66]</sup> assessed both HCV positive *vs* negative and HCV positive *vs* HBV positive.

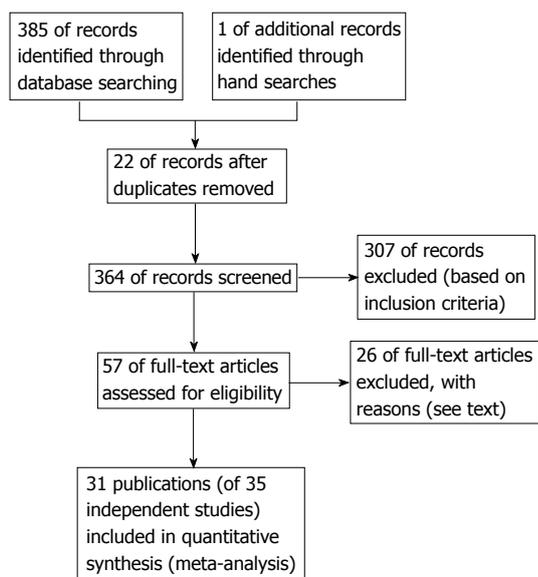

### Study characteristics

A summary of study characteristics in the present analy-

**Table 2** Characteristics of the included studies

Study	Country	Type of study	Age, yr (mean ± SD)	Confirmation of HCV	Confirmation of T2D
Akbar <i>et al</i> <sup>[40]</sup>	Saudi Arabia	CC	94% had > 40 <sup>2</sup>	Anti-HCV	FBS
Antonelli <i>et al</i> <sup>[41]</sup>	Italy	CC	65 ± 10	Anti-HCV, HCV RNA	FPG

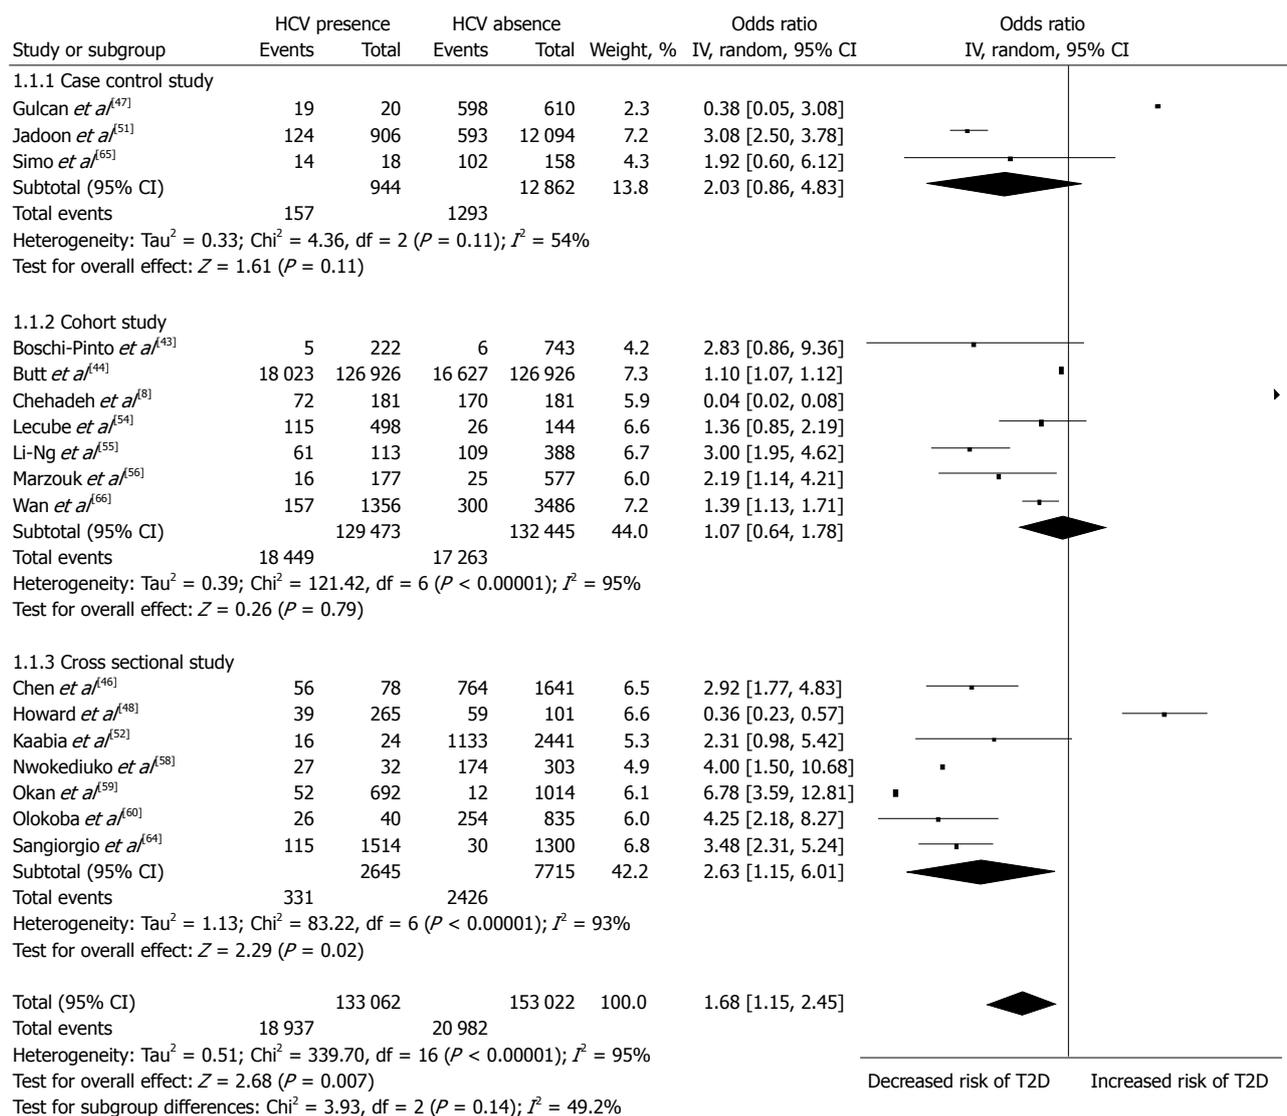

**Figure 1** Flowchart of studies identified for the present review.

sis is presented in Table 2. Five studies were carried out in United States<sup>[5,44,48,55,57]</sup>, and three each in Italy<sup>[41,45,64]</sup>, Japan<sup>[42,43,50]</sup> and Taiwan<sup>[46,49,66]</sup>, among others. Notably,

4 studies<sup>[51,60,62,67]</sup> identified for the present analysis were published between 2010 and March 2011. Of the included studies, 17 studies ( $n = 286\ 084$ ) compared HCV-infected participants with those uninfected; 7 were both a cross-sectional design (41.2%) and cohort design (41.2%), while 3 (17.6%) were case-control studies (Figure 2). Nineteen studies ( $n = 51\ 156$ ) compared HCV-infected participants with HBV-infected; 4 (21.1%), 6 (31.58%) and 9 (47.4%) were cross-sectional, cohort and case-control, respectively (Figure 3). The sample size of the included studies widely varied from 135<sup>[52]</sup> to 126 926 participants<sup>[43]</sup>.

**Main results**

Of the included studies, 17 studies ( $n = 286\ 084$ ) compared HCV-infected participants with those uninfected and the pooled OR was 1.68 (95% CI: 1.15-2.45). There was, however, substantial heterogeneity among studies ( $I^2 = 95\%$ , heterogeneity  $P < 0.001$ ). Nineteen studies ( $n = 51\ 156$ ) compared HCV- infected participants with HBV-infected and the pooled OR was 1.92 (95% CI: 1.41-2.62). There was evidence of considerable heterogeneity among studies ( $I^2 = 91\%$ , heterogeneity  $P < 0.001$ ). Among HCV-infected patients, based on available data, male patients

**Figure 2 Forest plot of comparison: Hepatitis C virus-infected patients vs hepatitis C virus-noninfected patients, outcome is type 2 diabetes mellitus.** HCV: Hepatitis C virus; IV: Inverse variance; T2D: Type 2 diabetes mellitus.

(summary OR: 1.26, 95% CI: 1.03-1.54) with age over 40

years (summary OR: 7.39, 95% CI: 5.82-9.38) had significantly increased type 2 DM prevalence (Table 3). Funnel plots of the associations between HCV and type 2 DM were investigated, providing little evidence of publication bias (Figure not shown).

For better stability of the results, sensitivity analysis with three prospective studies (n = 6449)<sup>[43,54,66]</sup> provided the pooled OR: 1.41 (95% CI: 1.17-1.7, I<sup>2</sup> = 0%), supporting the increased frequency of type 2 DM in HCV (Figure 4).

## DISCUSSION

This review indicates that patients with HCV infections were at higher risk of developing type 2 DM compared with patients with HBV infection. Findings of this review are comparable with a previous review<sup>[14]</sup>, and a large sample-individual study<sup>[56]</sup>. In the 2008 review<sup>[14]</sup> an excess risk of type 2 DM in HCV-infected cases was observed in

**Figure 3 Forest plot of comparison: Hepatitis C virus-infected patients vs hepatitis B virus-infected patients, outcome is type 2 diabetes mellitus.** HCV: Hepatitis C virus; HBV: Hepatitis B virus; IV: Inverse variance; T2D: Type 2 diabetes mellitus.

comparison to HBV-infected controls (summary OR: 1.63, 95% CI: 1.11-2.39). In the present analysis, this is also encountered (summary OR: 1.92, 95% CI: 1.41-2.62) and the association becomes stronger over time.

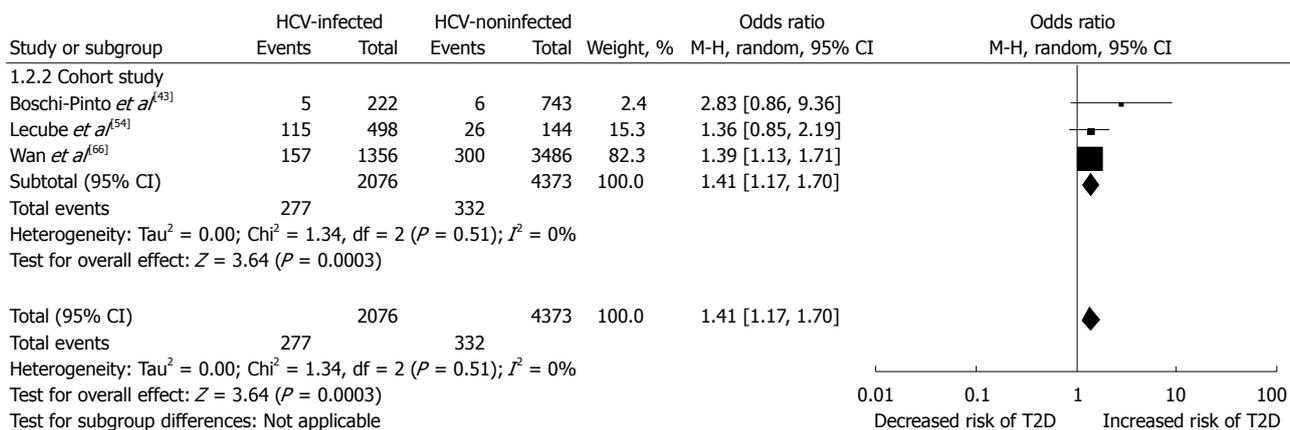

As both these viruses can replicate in extra-hepatic sites they can produce  $\beta$ -cell damage resulting in diabetes<sup>[10,61]</sup>. The lower risk in HBV infection could be explained by two factors: (1) Hepatitis B has been controlled in most developed countries, with active HBV vaccination programme; the occurrence of chronic HBV and its complications in these countries is very low; and (2) The disease progression is rather fast in HBV infection and therefore very few patients reach the level of cirrhosis and thus diabetes frequency is lower in this population<sup>[61]</sup>.

An excess risk of type 2 DM in HCV infected cases was also observed in comparison to non-HCV infected controls in the present analysis (summary OR: 1.63, 95%

CI: 1.11-2.39). The evidence of heterogeneity in these studies could be explained by variation in definition of case and control subjects and in the sample size of the primary studies.

Available studies had suggested that an expression of the HCV core protein induces hepatic insulin resistance through alterations in signaling in the insulin receptor substrate-1 pathway. This, along with other factors such as diet and obesity, can result in expression of the diabetic phenotype<sup>[38,61,68-70]</sup>. When insulin resistance reaches extents no longer compensated by the  $\beta$ -cell, insulin secretion declines and hyperglycemia emerges<sup>[10,68,70]</sup>. The complex interaction of chronic HCV infection with the host hepatic glucose and lipid metabolism has not been fully understood<sup>[10,65,67,70]</sup> and it remains to be determined.

In the studies identified, anti-HCV antibody was assessed only at the entry point of the study. Anti-HCV is considered as time-varying<sup>[43]</sup>. As such, there may be

**Figure 4 Sensitivity analysis with prospective studies: Hepatitis C virus-infected patients vs hepatitis C virus-non-infected patients, outcome is type 2 diabetes mellitus.** HCV: Hepatitis C virus; M-H: Mantel-Haenszel; T2D: Type 2 diabetes mellitus.

a likelihood of changes in serological status of anti-HCV over the study period. Liver disease and endocrine disorders, both common in the general population, have a bidirectional and complex relationship<sup>[69]</sup>. In addition, it is conceivable that patients with an earlier stage of chronic HCV infection have  $\beta$ -cell dysfunction but that diabetes does not become established until cirrhosis has supervened. Thus, a combination of  $\beta$ -cell dysfunction and insulin resistance is required for overt expression of diabetes mellitus<sup>[2,10,45]</sup>. Patients in some of the primary studies were not confirmed for the absence of cirrhosis by liver biopsy which is the best predictor of disease progression<sup>[2]</sup>. As such, we were unable to rigorously exclude cirrhosis individuals from the present analysis, and including these patients in the analysis may have exaggerated the association estimated. Of interest, it has been postulated that HCV has a permissive rather than a direct effect on the development of diabetes and acts in concert with other determinants to lead to diabetes<sup>[70]</sup>. Recent animal model evidence suggests a more direct effect of HCV infection on insulin resistance in the liver<sup>[38]</sup> indicating the role of hepatic tumor necrosis factor- $\alpha$  in affecting insulin signaling in this animal model of HCV infection<sup>[71]</sup>. In the present review, as cross-sectional and longitudinal prospective studies both show the same evidence, an excess type 2 DM risk in HCV-infected persons suggests a direct role of HCV in inducing derangement of glucose metabolism<sup>[9,10,45]</sup>. Further, there may be other factors influencing the development of type 2 DM in HCV infected patients which is not possible to address in the present analysis.

There are limitations to the present study. Most, if not all, observational studies have the potential for ascertainment bias<sup>[10,70]</sup> particularly for the studies in which diabetes status was defined by self report. Thus, there may be biased estimates of association. Moreover, recall bias is a factor in case-control studies. Although confounding factors were addressed in many of these observational studies, it is likely that there may be unmeasured confounding factors which may introduce bias into our findings. Further, as patient level data were not available

for each study, we could not make further adjustments for important factors such as genotype that were not included in most of the primary studies.

**Biological plausibility**

Findings of those prospective studies<sup>[42,53,66]</sup> which have measured HCV prior to diagnosis of type 2 DM support evidence for a temporal relationship between exposure and outcome. In a study<sup>[43]</sup>, a significant link between viral load and diabetes was found and it supported the diabetogenic role of HCV infection. The influence of viral load on the progression rate of type 2 DM was not examined in most of the studies. More research is needed to assess a dose-response association. It is also recommended that surveillance of HCV could indicate whether trends in its incidence continue to reflect changes in the prevalence of type 2 DM in the defined group.

**Public health implications**

If the associations do support temporality, the early detection and provision of aggressive antiviral treatment for HCV could prevent the development of type 2 DM, particularly in patients at high risk of HCV.

Nevertheless, the findings of the current analysis, to a certain extent, represent the HCV endemic countries. The present study has significant strengths in two ways: (1) It is comprehensive, including most recent studies; and (2) It addresses traditional risk factors (age, gender, BMI, family history of diabetes) which could potentially affect the outcome. As the prevalence of obese patients obtained in the group of HCV-positive patients with type 2 DM was significantly lower than that in diabetic HCV-negative patients found in an independent study<sup>[8]</sup> and also in the present meta-analysis, it is suggesting the pathogenesis of diabetes in HCV infection could be different from that in the general population.

**ACKNOWLEDGMENTS**

We are grateful to the participants and the researchers of the primary studies identified for this analysis. We wish

to thank the International Medical University (IMU), Malaysia for giving an opportunity to conduct this study. We extend our thanks to Cik Zuhariah Mohd Nordin and Farhana Abdul Ghafar (IMU library) for their help in literature collection.

## COMMENTS

### Background

Several observational studies assessing the association between hepatitis C virus (HCV) infection and type 2 diabetes mellitus (type 2 DM) have been published. However, these studies have provided inconclusive results, with some studies supporting the excess type 2 DM with HCV infection compared to non-infected controls, and some studies showing differently. The authors, thus, performed a meta-analysis to synthesise the available evidence on the association between HCV infections and type 2 DM.

### Research frontiers

Based on the available evidence, the present study aimed to investigate the association between HCV infection and type 2 DM, and also the effect of study design and traditional risk factors on the association

### Innovations and breakthroughs

Combining the electronic database and hand searches, a total of 35 observational studies (in 31 articles) were identified for the final analysis, based on the inclusion criteria set for the present analysis. The findings support the association between HCV infection and type 2 DM. However, the direction of association remained to be determined.

### Applications

The results support an association between HCV infection and type 2 DM. Findings of this review are comparable with previous reviews, and a large sample-individual study. An early detection and provision of aggressive antiviral treatment for HCV could prevent the development of type 2 DM.

### Peer review

The authors show the review of the association between HCV infection and diabetes by meta-analysis. This paper is an interesting and instructive manuscript.

ease (GSD) and to evaluate the risk of symptomatic GSD among diabetic patients.

**METHODS:** The study was conducted by analyzing the National Health Research Institutes (NHRI) dataset of ambulatory care patients, inpatient claims, and the updated registry of beneficiaries from 2000 to 2008. A total of 615 532 diabetic patients without a prior history of hospital treatment or ambulatory care visits for symptomatic GSD were identified in the year 2000. Age- and gender-matched control individuals free from both GSD and diabetes from 1997 to 1999 were randomly selected from the NHIR database ( $n = 614\ 871$ ). The incidence densities of symptomatic GSD were estimated according to the subjects' diabetic status. The distributions of age, gender, occupation, income, and residential area urbanization were compared between diabetic patients and control subjects using Cox proportion hazards models. Differences between the rates of selected comorbidities were also assessed in the two groups.

**RESULTS:** Overall, 60 734 diabetic patients and 48 116 control patients developed symptomatic GSD and underwent operations, resulting in cumulative operation rates of 9.87% and 7.83%, respectively. The age and gender distributions of both groups were similar, with a mean age of 60 years and a predominance of females. The diabetic group had a significantly higher prevalence of all comorbidities of interest. A higher incidence of symptomatic GSD was observed in females than in males in both groups. In the control group, females under the age of 64 had a significantly higher incidence of GSD than the corresponding males, but this difference was reduced with increasing age. The cumulative incidences of operations for symptomatic GSD in the diabetic and control groups were 13.06 and 9.52 cases per 1000 person-years, respectively. Diabetic men exhibited a higher incidence of operations for symptomatic GSD than did their counterparts in the control group (12.35 vs 8.75 cases per 1000 person-years).

### Abstract

**AIM:** To investigate the prevalence of gallstone dis-

**CONCLUSION:** The association of diabetes with increased symptomatic GSD may provide insight to the treatment or management of diabetes in clinical settings.

## INTRODUCTION

Gallstone disease (GSD) is one of the most common and costly digestive diseases worldwide, and it is more prevalent in Europe and America than in Asia and Africa. Symptomatic GSD and its related complications inflict heavy economic costs and social burdens<sup>[1-3]</sup> because surgical gallbladder removal, usually by laparoscopic cholecystectomy, is often required. GSD affects 10%-15% of the United States population (over 25 million people). Approximately 25% of the patients require treatment, at a cost of several billion dollars annually<sup>[4]</sup>. The prevalence of GSD in Taiwan is 4.3%-10.7% and increases significantly with age, which is consistent with reports from other countries<sup>[5]</sup>. In addition, an increasing trend in the incidence of severe GSD among patients aged 20-39 years has been reported in Taiwan<sup>[6]</sup>. Published epidemiological studies of GSD have revealed a steady upward trend in the admission rates for treatment of gallstones since the 1990s<sup>[7]</sup>. However, the reported prevalence of GSD varies considerably depending on study design, patient ethnicity, and geographic region<sup>[8-11]</sup>. A number of factors, including old age, female gender, genetics, diet, obesity, diabetes, and the use of oral contraceptives or hormone therapy, have been associated with increased risk of GSD<sup>[12,13]</sup>.

Diabetic patients appear to have an increased risk of developing gallstones<sup>[14,15]</sup>. Although previous studies reported mixed results regarding the temporal relationship between GSD and diabetes, the reciprocal relationship between GSD and diabetes suggests a common etiological or biological mechanism<sup>[16]</sup> that may be reflected in gallstone composition. Gallstones are generally classified

as either cholesterol stones or pigment stones according to their morphology and composition. The composition of cholesterol stones varies widely across different populations. For example, gallstones consist of more than 50% cholesterol in Western patients and an overwhelming 95% in Germany<sup>[17-20]</sup>. A mechanistic link between diabetes and GSD was recently defined using an animal model with increased cholesterol secretion and insulin resistance<sup>[21]</sup>.

The inconsistent reports of the prevalence of GSD in diabetic patients have been attributed primarily to variations in study design<sup>[22-26]</sup>. One case-control study reported an estimated GSD rate of 32.7% in patients with diabetes and 20.8% in corresponding non-diabetic controls<sup>[14]</sup>. In contrast, Persson *et al*<sup>[22]</sup> reported no differences in the prevalence of GSD between diabetic patients and controls. Another case-control study reported that diabetes increased the prevalence of gallstones in females but not in males (47% *vs* 26%)<sup>[23]</sup>. To our knowledge, few studies have investigated the incidence of GSD in diabetic and non-diabetic patients using a cohort design. Furthermore, the majority of studies have been hospital-based or community-based, which might compromise the representativeness of the study sample, thus reducing the statistical power for comparisons of GSD risk in patients with and without diabetes. A population-based follow-up study conducted in Kinmen, Taiwan, reported that the incidence of GSD was 3.56% per year among type 2 diabetics<sup>[24-27]</sup>. However, it seems to be inappropriate to generalize the results from this small sample ( $n = 281$ ) to the entire Taiwanese population.

Examining the co-occurrence of medical conditions related to diabetes and GSD may shed light on a common etiology and enable the identification of common biological mechanisms or pathways, which may greatly contribute to clinical interventions for GSD. Furthermore, diabetic patients with a number of complications must be aware of the symptoms and treatment for all of these diseases<sup>[28]</sup>. Given that most patients with GSD are asymptomatic and are not aware that they have gallstones, although the assessment of GSD risk among diabetic patients may add disease burden to policy makers responsible for planning health care resources, this may draw attention to the importance of managing diabetes *per se* and its related complications in clinical settings<sup>[1,29,30]</sup>.

This study aimed to examine the risks of developing GSD among diabetic patients. The presence of comorbidities associated with diabetes was also evaluated in the representative diabetic cohorts retrieved from the Taiwanese National Health Research Insurance (NHRI) database.

## MATERIALS AND METHODS

### Data source

The Department of Health in Taiwan created the universal National Health Insurance (NHI) system in 1995, and approximately 96% of the Taiwanese population

had been covered in the NHI program by the end of 1996<sup>[28]</sup>. The Bureau of NHI (BNHI) has contracts with 97% of hospitals and 90% of clinics across the island<sup>[31,32]</sup>. To ensure the accuracy of the claim data, the BNHI conducts expert reviews of a random sample of 50-100 ambulatory and inpatient claims from each hospital and clinic quarterly. The computerized administrative claims and datasets compiled by the NHRI are made available to investigators for research purposes after the individual health information is encrypted to ensure privacy<sup>[33]</sup>. This study was conducted using the NHRI dataset of ambulatory care claims, inpatient claims, and the updated registry of beneficiaries from 2000 to 2008.

### Study cohorts and comorbidities

Diabetic ambulatory care claims record the patients with diabetes-related diagnoses (ICD-9: 250 or A-code: A181). An individual was classified as a diabetic patient if she or he had an initial diabetes-related diagnosis at any time in 2000 and then experienced one or more additional diagnoses within the subsequent 12 mo. The first and last outpatient visits within a given year must be at least 30 d to avoid the accidental inclusion of miscoded patients<sup>[34]</sup>. To detect newly diagnosed gallstone cases, we excluded patients who sought hospital or ambulatory care treatment for gallstones (ICD-9: 574) from 1997 to 1999. A total of 615 532 diabetic patients were identified in the year 2000.

Subjects in the control group were selected from all beneficiaries insured in 2000 who were free from both diabetes and GSD from 1997 to 2000. A total of 614 871 control individuals were randomly selected to generate an age- and gender-matched control population for the diabetic group.

Once the study subjects were identified, we examined the ambulatory care visits and hospitalization claims for selected comorbidities including hypertension (ICD-9: 401, 405), gout (ICD-9:274), hyperlipidemia (ICD-9: 272.0-272.9, A182), cystic fibrosis (ICD-9: 277.0), sickle cell anemia (ICD-9: 282.6), cirrhosis (ICD-9: 571.2, 571.5, 571.6), cholangitis (ICD-9: 576.1), Caroli's disease (ICD-9: 576.2), Crohn's disease (ICD-9: 555.9), and hemolytic anemia (ICD-9: 282-283). The comorbidities mentioned above were counted only when the initial diagnosis had been made during the study period (2000-2008).

### Study endpoints

The study subjects from the diabetic and control groups were linked to ambulatory care visits and hospitalization claims from 2000 to 2008 for possible gallstone episodes (ICD-9-CM 574). Person-years (PYs) of follow-up were calculated for each diabetic patient from the time of his/her first diagnosis of diabetes in 2000 to the date of the first ambulatory care visit or hospitalization due to gallstones prior to the end of 2008. The PYs for control subjects were defined as the period between the first day of insurance coverage by NHI in 2000 and the date that the first gallstone symptoms developed and

were diagnosed.

### Statistical analysis

The age, sex, occupation, income, and residential urbanization level were compared between diabetic patients and control subjects. The differences in the rates of selected comorbidities were assessed in the two groups. We also estimated the incidence densities of symptomatic GSD according to the subjects' diabetic status.

Cox proportion hazards models were generated to assess the gender- and age-specific effects of diabetes on the risk of developing gallstones. Hazard ratios (HR) and 95% CI were calculated to estimate the relative risk of developing symptomatic GSD. All analyses were performed using SAS statistical software (version 9.1 for Windows; SAS Institute, Inc., Cary, NC), and the results were considered to be statistically significant when two-tailed *P* values were less than 0.05.

## RESULTS

A total of 615 532 diabetic patients and 614 817 control participants who were initially free of symptomatic GSD were included in this study (Table 1). The two groups had similar baseline age and gender distributions, with a mean age of 60 years and a greater proportion of females. Although the average insurance premium was lower for patients in the diabetic group, the Charlson score was extraordinarily higher. The geographical distributions and urbanization scores of diabetic patients were also similar to those of the control group.

The diabetic group exhibited significantly higher baseline rates for all comorbidities of interest (Table 2). The largest discrepancy in prevalence was noted for hyperlipidemia (73.4% *vs* 37.8%), followed by hypertension (86.7% *vs* 61.8%) and gout (32.4% *vs* 23.3%).

Over the 8-year follow-up period, 60 734 diabetic patients and 48 116 controls developed symptomatic GSD and underwent operations. The cumulative operation rates for the diabetic and control groups were 9.87% and 7.83%, respectively (Table 3). A higher incidence of symptomatic GSD was also found in females than in males in both groups. Particularly, females under the age of 64 in the control group had a significantly higher incidence of GSD (20% and 22% more) than the corresponding males, but this difference decreased with increasing age. A similar but less significant pattern was also observed in the diabetic group (Table 3). Figure 1 shows that the cumulative incidence rates of operations for symptomatic GSD in the diabetic and control groups were 13.06 and 9.52 cases per 1000 PYs between 2000 and 2008. Diabetic men had a higher incidence of operations for symptomatic GSD than did their control counterparts (12.35 *vs* 8.75 cases per 1000 PYs), representing a significantly increased adjusted hazard ratio of 1.12 (95% CI: 1.07-1.16) for diabetic men. Furthermore, diabetic women also had a modest but significant additional risk of developing GSD during the 8-year follow-up period (HR = 1.05; 95% CI: 1.01-1.08).

## DISCUSSION

This study aimed to explore the risk of developing symptomatic GSD in diabetic patients compared with the general population and to examine the risk of comorbidities related to diabetes. The study revealed a higher incidence of symptomatic GSD in patients with diabetes in all age groups. Furthermore, the cumulative incidence trends were more marked in women than in men. The prevalence of selected comorbidities was higher in the diabetic group with symptomatic gallstones than in those without gallstones.

A previous study in an Italian population reported that the cumulative incidence of GSD was 0.67% per year, and GSD was more common in females than in males<sup>[13]</sup>. Another study reported that the 5-year incidence of gallstone disease was approximately 2%-3% among Danish individuals over the age of 40<sup>[12]</sup>. Our analysis of the Taiwanese NHRI datasets revealed that the incidence and the incidence density of symptomatic GSD in non-diabetic patients were approximately 7% and 9% per year, respectively. These incidence estimates are slightly higher than those measured in Western countries. Previous evidence has shown that both incidence and prevalence increase with age<sup>[1,9-12]</sup>. Therefore, one

<sup>1</sup>Hypertension (ICD-9: 401-405, A260, A269), gout (ICD-9: 274), hyperlipidemia (ICD-9: 272.0-272.4, A182), cystic fibrosis (ICD-9: 277.0), cirrhosis (ICD-9: 571.2, 571.5, 571.6), cholangitis (ICD-9: 575.8, 576.1), Caroli's disease (ICD-9: 576.2), Crohn's disease (ICD-9: 555.0, 555.1, 555.9), hemolytic anemia (ICD-9: 282-283); <sup>2</sup>Based on  $\chi^2$  test.

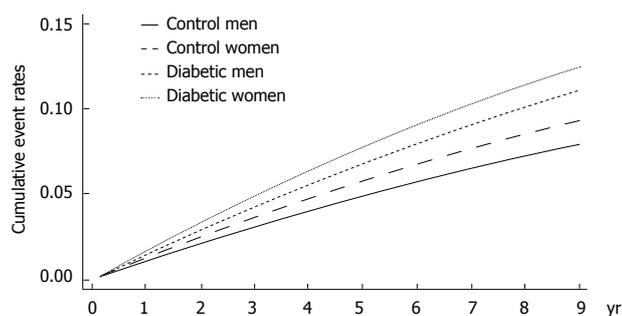

potential explanation for this discrepancy might be that the control group in this study, which was age- and gender-matched to the diabetic group, was older than the study cohorts in previous reports.

Despite the controversies about the prevalence of GSD in diabetic *vs* non-diabetic groups, GSD is not uncommon in patients with diabetes. Previous studies have reported that roughly 14%-30% of diabetic patients develop GSD<sup>[14,22-25]</sup>. One population-based follow-up study indicated that 3.56% of type 2 diabetic patients developed GSD per year. However, no conclusions about relative risk can be made based on these estimated incidence rates because no control groups were included in these studies<sup>[27]</sup>. Our study, based on a population-based dataset in Taiwan, illustrated that approximately 9.52% of the Taiwanese population developed symptomatic GSD annually, and the incidence density was higher in diabetic group than in the general population (13.06% *vs* 9.52%). In addition, females and older individuals were more likely to develop symptomatic GSD, regardless of their diabetes status. The results were consistent with the previously described epidemiology of GSD. It is noteworthy that gender differences in symptomatic GSD in-

**Figure 1** Cumulative incidence of gallstone disease in patients with or without diabetes over the study period.

incidence were not significant in patients over 64 years of age in either the diabetic or the control group, suggesting that age is a more important variable than gender.

Our findings indicate that subjects in the diabetic group suffer from more comorbidities than those in the control group, which was not surprising, but the significantly higher incidence rates of hypertension and hyperlipidemia were particularly noteworthy. Gallbladder function and bile acid metabolism are the two major factors associated with gallstone formation<sup>[35]</sup>. Diabetes or insulin resistance may affect gallbladder motility or contractility, further promoting the formation of gallstones<sup>[36-40]</sup>. This may be explained by the fact that diabetes tends to lower the levels of high-density-lipoprotein cholesterol and raise the triglyceride and low-density-lipoprotein levels, that may subsequently affect gallbladder dysmotility<sup>[35,37,39]</sup>. Previous evidence has shown that hypersecretion of hepatic cholesterol and altered lipid profiles derived from diabetic dyslipidemia may also be linked to the super-saturation of bile with cholesterol, thereby altering bile acid metabolism and cholesterol crystallization<sup>[40,41]</sup>. The higher incidence of symptomatic

GSD in diabetes may be attributable to the higher prevalence of hypertension and hyperlipidemia among diabetic patients.

Considerable clinical evidence has indicated that an array of abdominal manifestations is likely to be associated with GSD and diabetes, including cystic fibrosis, cirrhosis, cholangitis, Caroli's disease, and Crohn's disease<sup>[5,11,42-48]</sup>. Calcium salts of unconjugated bilirubin in the enterohepatic circulation have been suggested to underlie these co-occurring manifestations. For instance, bilirubin excretion may be related to an increased risk of calcium bilirubinate precipitation, especially in chronic hemolytic disorders. Chronic bacterial infections of the bile ducts may also contribute to gallstone formation by increasing the combination of unconjugated bilirubin with calcium<sup>[41,46]</sup>. Based on the results of this study (Table 2), we strongly suggest that gallstones developed in diabetic patients were primarily cholesterol stones; this hypothesis will be examined directly in future studies.

Gallstone formation may be caused by many etiological factors, each of which may produce different clinical consequences. Most patients remain asymptomatic for a long period, frequently for life. Gallstones may traverse the cystic duct with or without symptoms of obstruction. Transient cystic duct obstruction causes periodic painful episodes, whereas persistent obstruction usually produces inflammation and acute cholecystitis, leading to the onset of symptomatic GSD. However, there is little information regarding the direct mechanisms that underlie the increased onset of GSD in diabetes. Because elderly patients are more likely to develop symptomatic GSD, it is important to diagnose GSD early in patients with diabetes. Patients may benefit from the early detection of GSD and the underlying comorbidities that may promote both GSD and diabetes, which could subsequently enhance the effectiveness of diabetes management.

Urban-rural differences were also detected in this study. Diabetic patients in metropolitan areas had a higher incidence of symptomatic GSD than patients from rural areas. The observed urbanization-level differences likely reflect the differences in the distribution of medical resources and/or treatment-seeking behaviors<sup>[49]</sup>. Future research is needed to explain the urban-rural variations and enable policy-makers to promote policies that will reduce or eliminate these differences.

There were several limitations that should be noted in this study. First, potential misclassification might arise due to our exclusive reliance on claims datasets. A previous report showed that the accuracy of diabetes diagnoses in the NHI claims data was only 74.6%<sup>[50]</sup>. In order to avoid this bias, we included and analyzed only the patients that had been diagnosed with diabetes at least twice, with the first and the last outpatient visits at least 30 d but less than one year apart. It is also possible that newly diagnosed or undiagnosed diabetic cases without records of ambulatory care visits were included in the control group. Therefore, the overall difference in incidence of GSD could have been underestimated<sup>[51]</sup>. Second, type 1 and type 2 diabetes were not differentiated in this dataset, which limited our interpretation of the study findings. However, other studies have shown that type 2 diabetes accounted for the majority of diabetic patients in Taiwan; as a result, the interpretations of our results are likely to be most relevant for type 2 diabetes<sup>[52,53]</sup>. Third, other factors that might confound our results were not available, such as body mass index, socioeconomic status, duration and treatment of diabetes, smoking, alcohol use, family history of GSD, *etc.* Fourth, the incidence of symptomatic GSD among diabetic patients with/without comorbidities was not reported; therefore, these differences in prevalence could not be analyzed.

Despite the above-mentioned limitations, this is one of very few studies to examine the risk of symptomatic GSD in patients with diabetes using a Taiwanese population-based cohort study design. Given the high coverage rate of National Health Insurance in Taiwan, the likelihood of non-response and loss to follow-up was relatively limited, ensuring the representativeness of the sample. In addition, we took advantage of the longitudinal nature of the NHI dataset to follow up the incidence rate of symptomatic GSD and related comorbidities in diabetic and control groups.

In conclusion, an increased risk of symptomatic GSD in diabetic patients over an 8-year study period was observed in this study. Diabetes and GSD may share a number of common risk factors or etiologies. A crucial link between insulin resistance and increased cholesterol predisposed the diabetic patients to gallstone formation<sup>[21]</sup>. These results may provide insight into the treatment or management of diabetes in clinical settings. Future research is needed to facilitate public health prevention or intervention programs to reduce the incidence of symptomatic GSD<sup>[54]</sup>.

## COMMENTS

### Background

Gallstone disease (GSD) is one of the most common of all digestive diseases worldwide. Symptomatic GSD and related complications necessitate surgical removal of gallbladder, inflicting a heavy economic costs and social burdens. Most patients with GSD are asymptomatic and unaware of having gallstones. Diabetic patients with complications particularly require an adequate awareness for care management of GSD. The apparent incongruity for GSD prevalence in diabetic patients should be attributable to varied study designs.

### Research frontiers

This study aimed to investigate the incidence of GSD and examined the risks of developing symptomatic GSD among the diabetes using a cohort design and retrieving data from the National Health Insurance Research database of Taiwan.

### Innovations and breakthroughs

The results showed that the cumulative operation rates for diabetes and controls were 9.87% and 7.83% among 615 532 diabetic patients and 614 817 control participants over the 8-year follow-up period. Diabetic patients also tended to have significantly higher prevalence in developing comorbidities, most notably hyperlipidemia and hypertension. Higher incidence of symptomatic GSD was found in females than in males in both groups. Females aged < 64 years in control group had a significantly higher incidence than corresponding males, but the difference reduced with increasing age. A similar but less significant pattern was also observed in diabetic group. Both diabetic men and women were characterized with higher incidence of symptomatic GSD operation than their corresponding counterparts after 8-year follow-up. The authors concluded that higher incidence of symptomatic GSD was found in patients with diabetes in all age groups and the trends of cumulative incidence were more marked for women than men. In addition, the prevalence of selected comorbidities in diabetic group with gallstone was also higher than those without symptomatic GSD.

### Terminology

GSD is caused by gallstones that block the normal flow of bile if they lodge in any of the ducts that carry bile from the liver to the small intestine. Severe damage or infections affecting the gallbladder, liver, or pancreas can occur if any of these ducts remain blocked for a significant period of time, which necessitate surgical removal of gallbladder, usually by laparoscopic cholecystectomy.

### Peer review

This is a good study in which authors analyzed incidence of symptomatic GSD in patients with diabetes by using a representative database over a long period of time. The results are interesting and suggest that diabetes is associated with increased risk of developing symptomatic GSD. The investigators also drew a conclusion that patients with diabetes developed more symptomatic GSD in all age groups and were more notable for women than men. This study was based on a nationwide population-based datasets, which illustrated that about 9.52% population in Taiwan developed symptomatic GSD per year and the incidence density was higher in diabetic patients (13.06%). Diabetes associated with increased risk of developing symptomatic GSD was observed over an 8-year study period. Being female and with older ages were associated with increased incidence of symptomatic GSD, however, the potential importance of gender was overridden by aging.

### Abstract

**AIM:** To conduct a bacterial culture study for monitoring decontamination of automated endoscope reprocessors (AERs) after high-level disinfection (HLD).

**METHODS:** From February 2006 to January 2011, authors conducted randomized consecutive sampling each month for 7 AERs. Authors collected a total of 420 swab cultures, including 300 cultures from 5 gastro-scope AERs, and 120 cultures from 2 colonoscope AERs. Swab cultures were obtained from the residual water from the AERs after a full reprocessing cycle. Samples were cultured to test for aerobic bacteria, anaerobic bacteria, and mycobacterium tuberculosis.

**RESULTS:** The positive culture rate of the AERs was 2.0% (6/300) for gastro-scope AERs and 0.8% (1/120) for colonoscope AERs. All the positive cultures, including 6 from gastro-scope and 1 from colonoscope AERs, showed monofloral colonization. Of the gastro-scope

AER samples, 50% (3/6) were colonized by aerobic bacterial and 50% (3/6) by fungal contaminations.

**CONCLUSION:** A full reprocessing cycle of an AER with HLD is adequate for disinfection of the machine. Swab culture is a useful method for monitoring AER decontamination after each reprocessing cycle. Fungal contamination of AERs after reprocessing should also be kept in mind.

### INTRODUCTION

Gastrointestinal (GI) scopes are complex reusable instruments that require unique consideration with respect to decontamination. Most of the guidelines with updated guidance emphasize decontamination of these scopes<sup>[1-3]</sup>. While decontamination has been reviewed by several working groups in Britain, problems related to preventing contamination of rinse water, and procedures to monitor contamination have not been addressed thus far. In a recent study, we reported that GI scope contamination might be the result of a contaminated automated

endoscope reprocessor (AER)<sup>[4]</sup>. There is currently no literature on the quality of disinfection of AERs after reprocessing with high-level disinfection (HLD). Therefore, we conducted this bacterial culture study on AERs after HLD in order to monitor the quality of disinfection.

## MATERIALS AND METHODS

From February 2006 to January 2011, a 5-year prospective bacterial study was conducted with randomized consecutive sampling every month in GI scope unit, Chang Gung Memorial Hospital, Kaohsiung Medical Center. We took a total of 420 swab cultures, including 300 cultures from gastroscopy AERs and 120 cultures from a colonoscopy AER. The swab cultures were obtained from the dependent part of the inner surface of the AER after a full reprocessing cycle. Collected samples were cultured to test for aerobic and anaerobic bacteria and mycobacterium tuberculosis. The samples were incubated at 37 °C and examined for bacterial growth at 24 h and 48 h and for mycobacterium growth at 6 wk, and then the results were analyzed.

Culture results were reported as positive or negative. If a culture was positive, the specific AER was reprocessed and could only be used again for clinical use after repeated cultures were found negative according to our previous method<sup>[2]</sup>. GI scope decontamination was performed in accordance with the guidelines of the European Society of GI Endoscopy (ESGE)<sup>[3]</sup>. Manual cleaning was performed by trained GI nurses, with tap water, enzymatic soap, brushing, and irrigation, followed by AER, performed by a trained health technician. The liquid disinfectant used was 2.4% alkaline glutaraldehyde, and disinfectant-soaking duration was 20 min. If the cultures were positive, the soaking duration was prolonged to 25 min. The disinfectant was forced into the working channels and the GI scope was completely submerged. Then, the GI scopes were flushed with sterile filtered water prior to forced air-drying. The disinfectant solution, 2.4% alkaline glutaraldehyde, was stored at a temperature of 15 °C-30 °C and changed every 2 wk despite overstorage<sup>[4]</sup>.

### Reprocessing cycle of AER

After each scope procedure, thorough manual cleaning with Endozime Premium (Ruthof Corporation, NY, United States), including brushing and flushing of all accessible endoscope channels, was performed before automatic endoscope disinfection. We used the EW-30 AER (Aizu Olympus Co., Ltd, Tokyo, Japan) for reprocessing. Manual cleaning and reprocessing was performed by a fully trained scope nurse using accredited standards of practice as defined by the Digestive Endoscopy Society of Taiwan. HLD involved total immersion of the scope in 2.4% alkaline glutaraldehyde solution (Cidex 14, Ethicon, Inc., NJ, United States) for 20 min at a preset temperature of 25 °C and an additional washing cycle of 30 min

**Table 1** Rate of positive swab culture from the automated endoscope reprocessor after gastroscopy and colonoscopy reprocessing *n* (%)

Category	AER	P value
Gastroscopy ( <i>n</i> = 300)	6 (2.0)	NS
Colonoscopy ( <i>n</i> = 120)	1 (0.8)	NS
Total ( <i>n</i> = 420)	7 (1.7)	NS

AER: Automated endoscope reprocessor; NS: Not significant.

**Table 2** Organisms from swab culture of automated endoscope reprocessor after a full cycle of reprocessing with high-level disinfection

Category	Gastroscopy	Colonoscopy	Total
GNGN Bacteria <sup>1</sup>	2	1	3
<i>Moraxella osloensis</i>	1	-	1
Yeast-like organisms	2	-	2
<i>Candida glabrata</i>	1	-	1
Total positive culture	6	1	7

<sup>1</sup>All of the positive cultures had aerobic bacteria and mono-floral colonization. GNGN: Glucose-nonfermenting gram-negative bacteria.

in each reprocessing. The disinfectant was forced into the suction channels and the scope was completely submerged. The normal relief valve pressure of the AER was  $1.85 \pm 0.05$  kgf/cm<sup>2</sup>, and the water supply requirements were 17 L/min. Subsequent flushing with 200 cc of 90% alcohol for 10 min, rinsing, and drying were essential steps to remove the chemical solution and prevent bacterial colonization during storage. The rinse cycle used reverse osmosis-treated water for decontamination.

### Statistical analysis

The  $\chi^2$  test was used to analyze independent and paired samples. Statistical analyses were performed using the SPSS statistical software for Windows, version 19.0 (Chicago, IL, United States). *P* values less than 0.05 were considered statistically significant.

## RESULTS

The overall positive culture rate was 1.7% (7/420) in swab cultures from AERs after a full reprocessing cycle with HLD. For gastroscopy and colonoscopy AERs, the positive swab culture rates were 2.0% (6/300) and 0.8% (1/120) respectively, without a statistically significant difference in the culture rate between the upper and lower GI scope AERs (Table 1). All 7 positive swab cultures, including 6 gastroscopy reprocessing culture and 1 colonoscopy reprocessing culture, showed monofloral colonization. None of the cultures was positive for mycobacterium tuberculosis, and no anaerobic bacteria were found in any swab cultures. Among the cultures from gastroscopy reprocessing, 50% (3/6) were positive for aerobic bacteria, while the remaining 50% (3/6) showed fungal contamination (Table 2).

## DISCUSSION

The British Society of Gastroenterology Endoscopy Committee first published recommendations on endoscope decontamination practices in 1988, and recommendations from the fourth working group were published in the journal *Gut* in 1998<sup>[1]</sup>. Some of these decontamination recommendations are based on microbiological studies<sup>[5-8]</sup>. Most of the decontaminating guidelines are directed towards GI scopes and associated devices, but no literature is available on AER decontamination. According to our previous report, leakage of the inflow water valve of an AER could be one of the reasons for failure of decontamination of GI scopes and associated devices, even after subjecting them to a full reprocessing cycle<sup>[4]</sup>. Therefore, in this study, we aimed to monitor proper disinfection of AERs after HLD; to the best of our knowledge, this is the first study to do so. The overall positive culture rate of swab cultures from AERs after a full reprocessing cycle with a HLD process was 1.7% (7/420). Surprisingly, the rate was lower than the previously reported 18.4%-24% contamination rate for GI scope culture<sup>[5-8]</sup>. This suggests the contamination of GI scopes is not fully caused by AER contamination. We would like to clarify that since drying has been shown to be an important component of GI scope decontamination, the same is true of AERs as well?

The importance of drying in decontamination to make this point clearer is performing in our ongoing study. On the other hand, controlled trials in the field of GI scope decontamination are lacking because of a reluctance to expose “placebo control” patients to the risk of an infection. A controlled study to clarify the relationship between AER and GI scope contamination is necessary and is ongoing in our lab. An AER should be used for all GI scope decontamination following manual cleaning. Effective disinfection is difficult to achieve due to the complex nature of the internal structures of these long and narrow diagnostic instruments<sup>[4,9,10]</sup>. Manual disinfection is unacceptable. Inflow water used in an AER should be free of particulate contamination and microorganisms. This can be achieved either by using bacteria-retaining filters or by reverse osmosis. In our GI scope units, we used water treated by reverse osmosis in AER reprocessing<sup>[10]</sup>. The final rinse water should be sampled from the AER and regularly tested for microbiological quality in accordance with the current Health Technical Memorandum (HTM)<sup>[11]</sup>. A glutaraldehyde-based disinfectant (Cidex<sup>®</sup>) that was widely used in the past has been withdrawn from the United Kingdom market by its manufacturer. This is not only because there have been advances in the development of disinfectants with superior bactericidal activity but also because glutaraldehyde is chemically related to formaldehyde and has similar toxic effects on the skin and mucous membranes as formaldehyde does. The resulting adverse effects include severe dermatitis, conjunctivitis, sinusitis, asthma, and even chemical colitis. A further problem with glutaraldehyde-based disinfectants is their potential to cross-link residual protein material. The resulting amalgam is very difficult to remove from the working channels

of endoscopes that have been repeatedly flushed with aldehydes<sup>[3]</sup>. This again underscores the importance of manual pre-cleaning and brushing of all accessible internal channels and valve chambers before disinfection. Glutaraldehyde and its derivatives kill most bacteria and viruses (including human immunodeficiency virus and hepatitis B) in less than 5 min. Mycobacteria are more resistant to 2% glutaraldehyde, and earlier guidelines recommended that endoscopes be immersed in 2% glutaraldehyde for 20 min at room temperature<sup>[1]</sup>. Although we did not detect mycobacterial contamination in our study, we found that of the 1.7% positive cultures from AERs, 50% (3/6) were positive for fungal contamination. The high rate of fungal contamination is most likely due to failure to properly dry the AER after completion of reprocessing. Other than manual pre-cleaning and reprocessing disinfection, the last of the major processes of decontamination of a scope is drying before storage<sup>[3]</sup>. This step can prevent contamination by fungus or bacterial colonization on the surface of the GI scope after disinfection. It has been recommended that, before the start of each list, each scope to be used should undergo a full reprocessing cycle unless last used and decontaminated within the preceding 3 h. Many GI units are now using drying and storage chambers built purposefully for these scopes, some of which have been shown to prevent colonization of endoscope channels for up to 72 h. Therefore, all AERs should be validated and tested in accordance with guidance provided in the DoH Estates and Facilities HTM publications and relevant standards<sup>[12]</sup>. AERs should also include flow monitoring for each individual channel to detect blockages.

Furthermore, variant Creutzfeldt-Jacob disease (vCJD) is a rare and fatal condition caused by the consumption of beef contaminated by the bovine spongiform encephalopathy agent<sup>[13]</sup>. In contrast to the traditional forms of CJD, vCJD contaminated in GI tract, conventional HLD with AER was reported hard to full decontamination. ESGE guideline suggested that endoscope study is not recommended in possible patients<sup>[14]</sup>. Fortunately, there is no patient with suspicion of vCJD infection before endoscope examination, and there was no positive culture for vCJD in our series. The further study is necessary.

In conclusion, a full reprocessing cycle of an AER with HLD is adequate for disinfection of the machine. Swab culture is a useful method for monitoring AER decontamination after each reprocessing cycle. Fungal contamination of AER after reprocessing should be considered.

## ACKNOWLEDGMENTS

The authors would like to thank Miss Ching-Yin Huang for culture processing, and endoscopic reprocessing.

## COMMENTS

### Background

Swab culture is a simple method for the detection of bacterial contamination. In the real world, it is always used to monitor the clearing effectiveness such

as the button of the elevator. But up to now, there are still now ideal methods to monitor the decontaminated effect of automated endoscopy reprocessor itself in clinical practices.

### Research frontiers

Automated endoscopy reprocessor is a very important washing machine for the endoscopy decontamination in daily clinical practice. Authors apply the swab culture method to monitor the examined endoscopy, which is the source of the reprocessor contamination.

### Innovations and breakthroughs

In fact, decontamination of the automated endoscopy reprocessor is limited description before. Swab culture is a common method for the identification of the pathological organisms from the wound infection. For the quality of the infection control and the hospital identification with high standard monitoring, the results of the swab culture from the automated endoscopy reprocessor should be a standard score of a hospital identification and guideline in the clinical practice in the future.

### Applications

The study results suggest that the method of swab culture from the inner surface of automated endoscopy reprocessor is a useful method that could be used in monitoring decontamination after a complete endoscopy reprocessing cycle.

### Terminology

Automated endoscopy reprocessor: Automated endoscopy reprocessor is a automatic washing machine for the decontamination of the practically used endoscopy. Accompanist with high-level disinfection, it is effective prevention the hospital acquired microbiological infection.

### Peer review

This is an interesting prospective study. Which has dealt with an important topic not properly covered before. The authors analyze the monitoring effect of swab culture from the inner surface of automated endoscopy reprocessor after the end of daily decontamination. The results are interesting and suggest that swab culture is a potential monitoring method that could be used in preventing not complete disinfection or contamination induced by hospital acquired infectious outbreak.

### Abstract

**AIM:** To develop a prognostic approach for gastrointestinal stromal tumors (GISTs) using a cluster of indicators and follow-up information.

**METHODS:** One hundred and four GISTs that had not been subjected to targeted therapies were collected and classified by NIH risk assessment and anatomic location. By immunohistochemistry, the expressions of PTEN, Ki-67, CD44s matrix metalloproteinase (MMP)-9 and TIMP-1 were detected on tissue microarray. Univariate and multimarker survival analyses were performed and then a COX hazard proportion model was constructed to evaluate a cluster of predictors of GIST.

**RESULTS:** Our data showed small intestinal GIST are more aggressive than gastric GIST. The NIH risk assessment correlated with disease-free survival for

either gastric GIST or small intestinal GIST. Immunohistochemical analysis revealed that Ki-67 labeling indexes (LIs) < 5% predicted higher disease-specific survival (DSS) in gastric and small intestinal GIST. CD44s positivity and PTEN LIs  $\geq$  50% correlated with higher DSS in gastric GIST. MMP-9 and TIMP-1 had no correlation with survival. Multimarker analysis revealed that the expression pattern of PTEN LIs  $\geq$  50% combined with Ki-67 LIs < 5% and CD44s positivity reliably predicted favorable outcomes for gastric GIST ( $P = 0.009$ ), as did the combination of PTEN LIs  $\geq$  50% and Ki-67 LIs < 5% for small intestinal GIST ( $P = 0.011$ ). Authors also found that high NIH risk grade was correlated with DSS in patients with gastric GIST and disease-free survival in patients with small intestinal GIST.

**CONCLUSION:** PTEN LIs  $\geq$  50%, Ki-67 LIs < 5% and CD44s positivity provides an accurate, favorable prognosis for gastric GIST. PTEN LIs  $\geq$  50% and Ki-67 LIs < 5% does the same for small intestinal GIST. Ki-67 LIs enhances the NIH assessment.

### INTRODUCTION

Gastrointestinal stromal tumor (GIST) is the most com-

mon mesenchymal tumor in the alimentary tract. The principle pathogenesis of GIST has been identified as the continuous activation of KIT, caused by gain-of-function mutation in c-kit<sup>[1]</sup> or platelet derived growth factor  $\alpha$  (PDGFRA)<sup>[2]</sup>. Based on this finding, the molecular targeted therapy of imatinib<sup>[3]</sup> or sunitinib<sup>[4,5]</sup> has achieved great success.

Clinicians are trying to improve the survival rate of GIST patients by prophylactic interference of imatinib or sunitinib, based on the prognosis. Because of the expense of the targeted therapy, an accurate prognosis is very important, but prognoses of GIST are highly variable. Although the NIH risk assessment is currently used as a standard guideline for localized tumors<sup>[6]</sup>, many researchers consider that evaluation of large cohorts is necessary for reliable data. Some modifications have been made to the NIH assessment, to enhance prediction accuracy<sup>[7,8]</sup>. Current researchers have also found some molecular indicators, such as p16<sup>INK4a</sup><sup>[9]</sup>, PTEN<sup>[10]</sup>, p53<sup>[11,12]</sup>, p27<sup>[13,14]</sup>, CD44s<sup>[15,16]</sup> and some other cell-cycle regulators<sup>[17]</sup>, but their utility is debated. Despite the mixed opinion, there are limitations in using one marker for a prognosis. A tumor is resulted from the accumulation of numerous molecular incidents, and one prognostic marker may only be applicable to a minority of patients. Our objective was to find a multi-marker indicator to improve prognoses for all patients. PI3K/Akt has been found to be a major signal transduction pathway in GIST<sup>[18]</sup>. Accordingly, we selected PTEN, the inhibitor of PI3K/Akt, for analysis. The markers related to adhesion and metastasis, such as CD44s, matrix metalloproteinase (MMP)-9 and TIMP-1, were also selected. Ki-67 was chosen to analyze the prognostic value of cell proliferation. All five markers were detected on tissue microarray of 104 GISTs. Follow-up survival data was collected. The prognostic values of these five markers were analyzed and compared to the NIH risk assessment.

## MATERIALS AND METHODS

### Case collecting

A total of 155 gastric and small intestinal GISTs were collected from the archive of the Pathology Department of Chinese PLA General Hospital. All the tumors were reassessed by the immunohistochemical panel of CD117, CD34, SMA and S-100 protein. The cases with CD117 positivity were diagnosed as GIST. One hundred and four cases were completely followed-up. One hundred and twenty one samples were obtained from these 104 cases. These tumor samples included primary, recurrent and metastatic GIST. All the tumor paraffin blocks were used to construct the tissue microarray.

### Risk assessment

Formalin fixed, paraffin embedded, HE stained slides were reviewed by two experienced pathologists. The mitotic index was determined by counting 50 adjacent high-power fields in the most active areas. Using the NIH

risk assessment<sup>[6]</sup>, all the tumors were classified into four grades of risk: very low, low, intermediate and high.

### Tissue microarray and immunohistochemistry

Three tissue cores, 1 mm in diameter, were sampled from each tumor specimen to construct the tissue microarray (TMA). The TMA blocks were sectioned at 4  $\mu$ m and stained with hematoxylin-eosin sequentially. Antigen retrieval was carried out with EDTA (pH 8.0; Santa Cruz Biochemistry, Calif) for 15 min by microwave. The primary antibody was incubated for 1 h at room temperature and subsequently detected using a Two-step PicTure™ kit (PV6000, Invitrogen Co. Carlsbad California United States). The primary antibodies, sources, and dilutions were as follows: CD117, A4502, polyclonal, Dako A/S Co. Ltd., Denmark, 1:200; SMA, clone 1A4, Invitrogen Co. Carlsbad California, United States, 1:100; S-100, clone 4C4.9, Invitrogen Co. Carlsbad California, United States, 1:50; Ki-67, clone K-2, Invitrogen Co. Carlsbad California, United States, 1:50; PTEN, clone 28H6, Invitrogen Co. Carlsbad California, United States 1:100; CD44s, clone 156-3c11, Novocastra Laboratories Ltd. Newcastle, United Kingdom, 1:50; MMP-9, clone 15W2, Novocastra Laboratories Ltd. Newcastle, United Kingdom, 1:25; TIMP-1, clone 6F6a, Novocastra Laboratories Ltd. Newcastle, United Kingdom, 1:50.

The labeling indexes (LIs, %) of PTEN and Ki-67 were determined by counting 1000 cells in the most active area. For CD117, SMA, S-100, CD44s, MMP-9 and TIMP-1, staining of more than 10% of the tumor cells was considered positive.

### Statistical analysis

All the patients were followed up after the resection of the tumor. The death of patients with GIST, untreated with imatinib, was selected as the end point. We analyzed follow-up data using Stata Statistical Software (Intercooled Stata 7.0, Stata Co., College Station, TX). The  $\chi^2$  test was used to analyze the expression status of the selected markers. Survival analysis was performed using Kaplan-Meier plots and the log-rank test to reveal the prognostic usefulness of the selected markers. Univariate and multivariate COX proportional hazard models with both backward and forward elimination of variables were also constructed to find the most significant factor for prognosis. Statistical significance was set at  $P < 0.05$ .

## RESULTS

### Clinicopathologic features and the follow-up data

In a total of 155 patients, having a male-to-female ratio of 2.5:1 (111 *vs* 44), there were 83 gastric and 72 small intestinal GISTs. A total of 104 cases had complete follow-up data. The median follow-up time was 33 mo, within the range of 3 to 230 mo. Fifty one cases without follow-up data were excluded from the subsequent survival analysis.

In 83 gastric patients, the male to female ratio was 2.1:1 (55 *vs* 26). The age ranged from 13 to 82 years (mean: 55.4

years; median: 57 years). The 62 followed-up cases included 42 males and 20 females. Thirteen patients died of GIST, four were alive with GIST and 45 were disease-free. The survival time of the 13 died patients ranged from 6 to 132 mo. The 3-year disease-specific survival rate (DSS) was 80.77%  $\pm$  11.5% and the 5-year DSS was 66.51%  $\pm$  17.06%.

In 72 small intestinal patients, the male to female ratio was 3.3:1 (55 *vs* 17). The age ranged from 20 to 77 years (mean: 50.6 years; median: 51.5 years). Forty-two followed-up cases included 31 males and 11 females. Fifteen patients died of GIST, four were alive with GIST and 23 were event-free. The survival time of the died patients ranged from 3 to 230 mo. The 3-year DSS was 73.65%  $\pm$  14.24% and the 5-year DSS was 61.76%  $\pm$  18.30%. There was no significant difference between the DSS of patients with gastric and small intestinal GIST ( $P = 0.274$ ).

There were 23 patients that suffered recurrence, nine with gastric GIST and 14 with small intestinal GIST. Most of them were noted to have intra-abdominal spreading. A total of 16 patients developed metastasis, eight with gastric GIST and eight with small intestinal GIST. Small intestinal GIST presented a higher liability to recurrence and metastasis than gastric GIST (22/42 *vs* 17/60,  $P = 0.013$ ). GIST metastasized to the liver in 15 cases, indicating that the liver was another common metastatic site. One of these 15 patients suffered multi-organic metastases to the bone, brain and lung at the same time. Beside liver metastasis and abdominal spread, one patient also suffered metastasis to subcutaneous tissue. Detailed information on the 155 GISTs is provided in Table 1.

Five patients suffered a secondary malignant tumor. Two patients with gastric GIST had early and advanced gastric adenocarcinoma, respectively. Three small intestinal GIST patients were found to have early gastric carcinoma, sigmoid colonic adenocarcinoma and bile duct adenocarcinoma, respectively.

### Comparison of selected immunohistochemical markers in gastric and small intestinal GISTs

Sixty-one gastric and 42 small intestinal GIST patients were included in the analysis of survival data based on the expressions of selected immunohistochemical markers. These results are summarized in Table 2 and displayed in Figure 1. All 103 GISTs were CD117 positive. Among these 103 cases, 83 were positive for CD34, 32 for SMA and four for S-100. The expressions of CD44s and MMP-9 were statistically predominant in small intestinal GISTs. TIMP-1 and Ki-67 had no significant difference between the gastric and the small intestinal GIST. The expression of Ki-67 was negatively correlated to PTEN ( $P = 0.027$ ) and CD44s ( $P = 0.02$ ). In patients that died of gastric GIST, the expressions of MMP-9 and Ki-67 were statistically higher than in those who survived. In contrast, CD44s and PTEN were significantly lower. The difference in TIMP-1 was not significant.

In patients that died of small intestinal GIST, Ki-67 LIs were much higher than in those who survived, while PTEN was significantly lower. The other markers, includ-

GIST: Gastrointestinal stromal tumor.

ing CD44s, MMP-9, and TIMP-1, showed no significant difference.

### Significance of PTEN, Ki-67 and CD44s on GISTs prognosis

For gastric GISTs, PTEN LIs  $< 50\%$  was significantly correlated with lower specific survival rate ( $P = 0.006$ , Figure 2B), as was Ki-67 LIs  $\geq 5\%$  ( $P = 0.004$ , Figure 2C) and CD44s negativity ( $P = 0.006$ , Figure 2D). In a total of 13 patients who died of GIST, there were five with PTEN LIs  $< 50\%$ , six with Ki-67 LIs  $\geq 5\%$  and eight patients who lost the expression of CD44s. For small intestinal GISTs, Ki-67 LIs  $\geq 5\%$  significantly correlated with worse outcomes. Multivariate analysis did not reveal an independent factor for gastric or small intestinal GISTs. In a total of 15 patients who died of GIST, there were 10 with Ki-67 LIs  $\geq 5\%$ .

No statistically significant difference was observed in disease specific survival for the patients grouped by the expressions of MMP-9 or TIMP-1. The balance between MMP-9 and TIMP-1 also did not correlate with disease specific survival. We failed to find an independent prognosis indicator after constructing the univariate and multivariate COX hazard proportional model (Table 3).

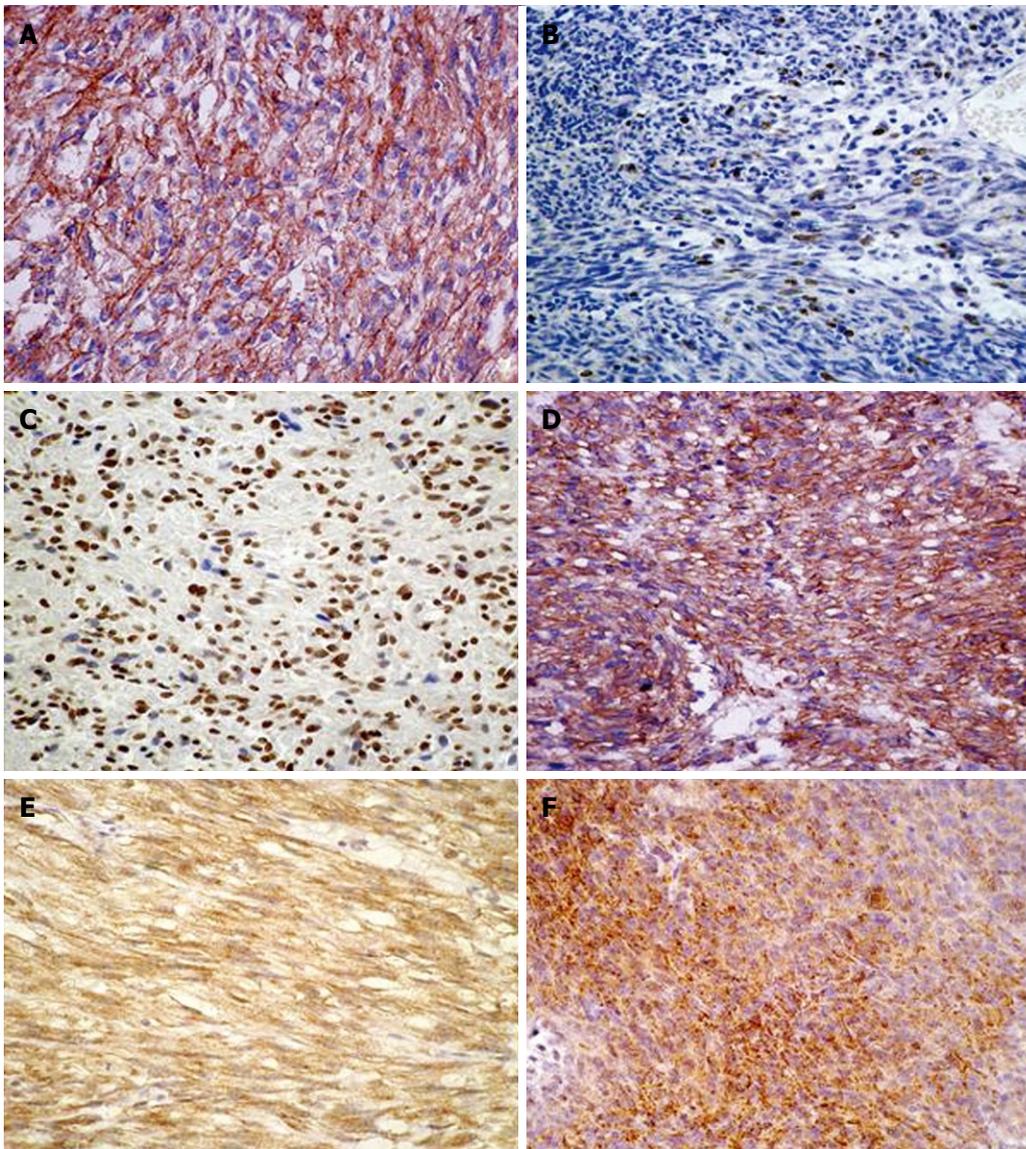

### Combined analysis of PTEN, Ki-67 and CD44s

Combined analysis revealed that for gastric GISTs, the

GIST: Gastrointestinal stromal tumor; MMP: Matrix metalloproteinase.

**Figure 1** Examples of the selected markers expressed in gastrointestinal stromal tumor. A: The tumor cells were strongly positive for CD117 with diffuse membrane staining; B: Nuclear positivity of Ki-67 in the tumor cells; C: Nuclear positivity of PTEN in gastrointestinal stromal tumor; D: CD44s was diffusely positive in tumor cell membrane; E: Matrix metalloproteinase 9 was diffusely positive in cytoplasm; F: TIMP-1 was diffusely positive in cytoplasm. Immunostains counterstained with hematoxylin-eosin, original magnifications  $\times 200$ .

**Figure 2** Kaplan-Meier cumulative survival plots of patients with gastric gastrointestinal stromal tumor. The end point was death due to gastrointestinal stromal tumor (GIST). A: High NIH risk assessment correlated significantly with worse outcomes in patients with gastric GIST ( $P = 0.004$ ); B: PTEN labeling indexes (LIs)  $\geq 50\%$  correlated significantly with favorable outcomes in patients with gastric GIST ( $P = 0.006$ ); C: In patients with gastric GIST, those with Ki-67 LIs  $< 5\%$  had significantly more favorable outcomes than those with Ki-67 LIs  $\geq 5\%$  ( $P = 0.004$ ); D: CD44s positivity was a significant, favorable indicator for patients with gastric GIST ( $P = 0.006$ ); E: For patients with small intestinal GIST, the immunophenotype of PTEN LIs  $\geq 50\%$  and Ki-67 LIs  $< 5\%$  was a favorable indicator ( $P = 0.009$ ); F: Gastric GIST patients with immunophenotype of PTEN LIs  $\geq 50\%$ , Ki-67 LIs  $< 5\%$  and CD44s positivity had significantly more favorable outcomes than those with other immunophenotypes ( $P = 0.011$ ).

survival rate of the patients with the expression pattern of PTEN LIs  $\geq 50\%$ , Ki-67 LIs  $< 5\%$  and CD44s positivity was significantly higher than those with other immunophenotypes ( $P = 0.009$ , Figure 2E). In the 13 patients who died of gastric GIST, 11 did not show the above immunophenotype. Of the two patients with the phenotype, one survived over 10 years after the resection of GIST and the other survived 53 mo.

For patients with small intestinal GIST, the survival rate was significantly higher in those with the combined

expressions of PTEN LIs  $\geq 50\%$  and Ki-67 LIs  $< 5\%$  relative to those with other immunophenotypes ( $P = 0.011$ , Figure 2F). In the 15 patients who died of small intestinal GIST, only two showed this favorable immunophenotype.

### Prognostic impact of NIH risk assessment

The NIH risk assessment showed excellent correlation with disease-specific survival. The patients were classified as higher risk with worse prognosis ( $P = 0.001$ ).

**Table 3** Univariate and multivariate COX regression analyses of molecular markers in gastric gastrointestinal and small intestinal stromal tumor

	Univariate analysis		Multivariate analysis	
	OR (95% CI)	P value	OR (95% CI)	P value
Gastric GIST				
PTEN	0.23 (0.07-0.74)	0.013	0.35 (0.10-1.20)	0.100
Ki-67	4.54 (1.45-14.16)	0.009	2.69 (0.73-9.87)	0.130
CD44s	0.21 (0.07-0.73)	0.013	0.43 (0.83-9.98)	0.320
PTEN, Ki-67, CD44s	5.92 (1.29-27.08)	0.022	1.35 (0.15-11.80)	0.780
MMP-9	4.22 (1.92-19.31)	0.042		
TIMP-1	0.90 (0.29-2.82)	0.862		
MMP-9/TIMP-1	0.72 (0.22-2.38)	0.586		
Small intestinal GIST				
Ki-67	3.29 (1.14-9.46)	0.019		
PTEN, Ki-67	4.02 (1.25-16.09)	0.021		

MMP: Matrix metalloproteinase; GIST: Gastrointestinal stromal tumor; OR: Odds ratio.

GIST arising from gastric and small intestine showed different recurrent potential; we subsequently analyzed the prognostic value of risk assessment in these two anatomic sites. For gastric GIST, high risk stratification was correlated with significantly worse prognoses ( $P = 0.004$ , Figure 2A). But for small intestinal GIST, the risk stratification had no significant correlation with DSS ( $P = 0.205$ ). Considering the disease-free survival rate, the risk stratification was significantly correlated with survival not only in small intestinal GISTs ( $P = 0.011$ ), but also in gastric GISTs ( $P = 0.044$ ).

### Ki-67 and risk assessment

In our series, 29 gastric patients who were graded as high risk had shorter survival time than the other three grades ( $61.31 \pm 17.28$  mo *vs*  $121.64 \pm 17.06$  mo). Fourteen gastric patients with Ki-67 LIs  $\geq 5\%$  had shorter survival time than those with Ki-67 LIs  $< 5\%$  ( $49.75 \pm 10.84$  mo *vs*  $111.46 \pm 15.26$  mo). Ten of these 14 cases were classified as high risk grade, four were not in this group but suffered relapse or metastasis.

For small intestinal GISTs, two cases with Ki-67 LIs  $\geq 5\%$  suffered relapse and one died of the GIST in 32 mo. Neither of these two cases were classified as high risk grade by NIH risk assessment.

## DISCUSSION

In this study based on follow-up data, we developed a cluster of immunohistochemical markers that can facilitate the assessment of GIST prognosis in Chinese patients. The expression patterns of PTEN, Ki-67 and CD44s can help clinicians evaluate the clinical outcome of the patients with gastric GIST, as can the combination of PTEN and Ki-67 for those with small intestinal GIST.

Although PTEN, Ki-67 and CD44s can individually assist the prognosis, there are still apparent limitations because each marker just focuses on some of the patients. When tested by follow-up data, although eight patients expressed PTEN LIs  $\geq 50\%$ , seven of them died of GIST within 5 years after the surgery resection. Such a

conflict phenomenon is also very common in patients with gastric GIST when the prediction is based only on Ki-67 or CD44s. This also occurs for Ki-67 or PTEN in patients with small intestinal GIST. Combining the expressions of PTEN, Ki-67 and CD44s can improve the specificity and accuracy of the prognosis.

Our results showed that Ki-67 LIs is negatively correlated with PTEN and CD44s. PTEN and Ki-67 are both involved in cell proliferation. PTEN can upregulate p27<sup>kip1</sup> resulting in apoptosis and cell cycle arrest, suppression of cell proliferation by a mechanism independent of Akt activity in nuclei<sup>[19]</sup>. Also, PTEN upregulates p53 activity by maintaining the high acetylation of p53<sup>[20]</sup>. In our study, PTEN was exclusively located in nuclei, and PTEN LIs  $< 50\%$  was statistically correlated with a worse outcome of gastric GIST. A similar result was also reported by Ricci, regarding the correlation of decreased PTEN expression with worse outcomes<sup>[10]</sup>.

Ki-67 is widely used to predict the proliferation potential of malignant tumors. Many reports have confirmed the prognostic value of Ki-67 in GIST<sup>[21-23]</sup>. The differences in these reports are the cut-off value of the Ki-67 index, which varied from 4.5% to 10%. Whether Ki-67 is one of best predictors is debatable. Nakamura proposed that Ki-67 LIs and risk assessment were useful for predicting GIST outcome<sup>[17]</sup>, while Wong considered that mitotic count<sup>[24]</sup>, not Ki-67 LIs, remained the best predictor of gastric GIST. Our results revealed that higher Ki-67 LIs were associated with worse outcomes. Interestingly, there were four cases of low risk gastric GISTs with high Ki-67 LIs that suffered worse outcomes. Another two cases of low risk intestinal GISTs that had high Ki-67 LIs also resulted in worse outcomes. This indicates that Ki-67 may enhance the NIH consensus criteria, especially when applied to patients of low risk. Though the absolute cut-off of Ki-67 LIs is difficult to define, Ki-67 may become one of the most robust indicators of GIST.

CD44 is now widely accepted as a stem cell marker in many kinds of carcinomas, including gastric cancer, colorectal cancer<sup>[25]</sup>, and breast cancer. While only a minority of the cancer cells have the capability of car-

cinogenesis, this portion of the cell population is stem cells; in Du's series, no more than 5% of the cells were positive for CD44. In GISTs, once CD44 is positive, it is diffusely expressed by nearly all the cells. Based on this finding, CD44 may not be a suitable stem cell marker for GIST. CD117 and CD34 are stem cell markers for the haematopoietic stem cells. In GIST, CD117 is the crucial diagnostic marker; CD34 is one of the most important differential diagnostic markers. The expression of these stem cell markers in GIST may support the hypothesis that GIST originates from mesenchymal stem cells. The suitable robust stem cell markers for GIST needs further investigation. CD44 and its associated partner proteins monitor changes in the extra-cellular matrix that influences cell growth, survival and differentiation. It can be a molecular switch between growth and arrest depending on the extra-cellular conditions. As reported for CD44-deficient fibroblasts, the recruited CD44s suppress metastasis and proliferation<sup>[26]</sup>. Furthermore, CD44 can promote tumor invasion by recruiting MMP-9<sup>[27]</sup>. In small intestinal GIST, the expressions of CD44s and MMP-9 are significantly higher than in gastric GISTs. The co-expression of CD44s and MMP-9 may be responsible for the high metastatic liability of small intestinal GIST.

The anatomic site of GIST is now believed to be a prognostic factor. Some experts believe that when GIST is considered as a location-specific entity, multiple clinicopathologic parameters can be used together to define the biological behavior. In the revised version of NIH risk stratification, anatomic location was considered to be an important factor in the assessment of moderate and high risk<sup>[6]</sup>. In our series, the small intestinal GIST was more aggressive than gastric GIST. Of the patients with small intestinal GIST, 52.38% suffered recurrence or metastasis, while only 25% of gastric GIST patients did. The molecular markers expressed in gastric and small intestinal GIST were also different, as were the prognostic indicators. CD44 had no impact on the prognoses for patients with small intestinal GIST, and a similar result has been reported for rectal GIST<sup>[28]</sup>. The dissimilar anatomic locations may be responsible for these difference. Based on these facts, we believe that GIST should be sub-grouped by anatomic location first and then assessed by other factors.

In conclusion, the expression patterns of PTEN, Ki-67 and CD44s are useful for the prognosis of patients with gastric GIST, and PTEN and Ki-67 are valuable outcome indicators for patients with small intestinal GISTs, Ki-67 LIs can enhance the NIH consensus criteria.

## COMMENTS

### Background

Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor of the digestive tract. Because the targeted therapy of imatinib and sunitinib has achieved great success, accurate prediction of GIST outcomes is becoming more and more important. The biological behavior of GIST is highly variable. NIH risk assessment is now widely used as a prognostic indicator, but further investigation of the prognostic factors is still needed.

### Research frontiers

NIH risk assessment is widely used for GIST risk stratification; the revised version is based on tumor location, diameter and mitotic index. Many investigators have analyzed the prognostic value of other factors including stage, grade, KIT mutation and immunohistochemical markers.

### Innovations and breakthroughs

Based on follow-up information on patients without targeted therapy, we comprehensively analyzed anatomic location, NIH risk assessment and a number of immunohistochemical markers including PTEN, Ki-67, CD44s, matrix metalloproteinase 9 and TIMP-1.

### Applications

This study provides a new cluster of prognostic markers for GIST. PTEN LIs  $\geq 50\%$ , Ki-67 LIs  $< 5\%$  and CD44s positivity correlates with favorable outcomes for gastric GISTs, as does PTEN LIs  $\geq 50\%$  and Ki-67 LIs  $< 5\%$  for small intestinal GISTs. Anatomic location is a prognostic indicator of GISTs; depending on location, GISTs may have different biological features. The intrinsic nature needs further investigation.

### Terminology

GIST is the most common mesenchymal tumor of digestive tract. Gain-of-function mutation of in *c-kit* or platelet derived growth factor  $\alpha$  are hypothesized as the principle molecular pathogenesis. Based on this point, the targeted therapy of imatinib or sunitinib has achieved great success. But the biological behavior of GIST is highly variable; many experts are investigating improvements in prognostic markers.

### Peer review

This is an interesting, well done and well written paper adding useful insights in the field.

### Abstract

**AIM:** To investigate the relationship between polymorphisms present in the vitamin D receptor (*VDR*) gene and colorectal cancer risk, a systematic meta-analysis of population-based studies was performed.

**METHODS:** A total of 38 relevant reports published between January 1990 and August 2010 were identified, of which only 23 qualified for this meta-analysis based on our selection criteria. Five polymorphic variants of the *VDR* gene, including *Cdx-2* (intron 1e) and *FokI* (exon 2) present in the 5' region of the gene, and *BsmI* (intron 8), *ApaI* (intron 8), and *TaqI* (exon 9) sites present in the 3' untranslated region (UTR), were evaluated for possible associations with colorectal

cancer risk. Review manager 4.2 was used to perform statistical analyses.

**RESULTS:** In the meta-analysis performed, only the *BsmI* polymorphism was found to be associated with colorectal cancer risk. In particular, the *BsmI* B genotype was found to be related to an overall decrease in the risk for colorectal cancer [*BB vs bb*: odds ratio (OR) = 0.87, 95% CI: 0.80-0.94,  $P = 3 \times 10^{-4}$ ; *BB vs Bb + bb*: OR = 0.90, 95% CI: 0.84-0.97,  $P = 5 \times 10^{-4}$ ]. Moreover, in subgroup analyses, the *BsmI* B genotype was significantly associated with colon cancer, and not rectal cancer. An absence of between-study heterogeneity was also observed.

**CONCLUSION:** A meta-analysis of 23 published studies identified the *BsmI* polymorphism of the *VDR* gene to be associated with an increased risk of colon cancer.

### INTRODUCTION

Colorectal cancer represents the third most common cancer worldwide, second only to lung cancer and gastric

cancer<sup>[1]</sup>. Furthermore, it is estimated that there are more than 370 000 cases of colon and rectal cancer diagnosed in Europe every year, with 200 000 cases resulting in death<sup>[2]</sup>. However, the underlying etiology of colorectal cancer, including cancerous growths of the colon, rectum, and appendix, remains poorly understood. It has been proposed that some categories of external agents, including physical, chemical, and biological carcinogens, may contribute to the development of this disease, and the role of these factors in carcinogenesis would depend largely on genetic factors. Correspondingly, a recent study showed that insufficient levels of vitamin D may result in colorectal cancer<sup>[3]</sup>. Furthermore, genetic variations in genes controlling vitamin D activity would be hypothesized to play an important role in determining susceptibility to colorectal cancer.

*In vivo*, vitamin D helps bones and muscles grow, and may also help prevent many diseases, such as prostate cancer and breast cancer. The biological activity of vitamin D is mediated by the vitamin D receptor (VDR)<sup>[4]</sup>, which interacts with other cell signaling pathways to influence cell behavior. Expression of VDR has been detected in various organs and tissues of the human body, including the kidney and bone cells. VDR is also expressed in normal colon mucosa<sup>[5]</sup>. In the intestine, VDR plays an important role in regulating cell proliferation, differentiation, and the induction of apoptosis<sup>[6]</sup>. Furthermore, VDR may be associated with the effects of calcium on colorectal epithelial proliferation<sup>[7]</sup>.

Molecular epidemiological studies have shown that polymorphisms in the VDR gene may be linked to biological functions of vitamin D. At the 5' end of the VDR gene, a *FokI* polymorphism (rs2228570/rs10735810, exon 2) has been associated with a frameshift in the VDR protein<sup>[8]</sup>. Moreover, polymorphisms in the 3' untranslated region (UTR), including *BsmI* (rs1544410, intron 8), *ApaI* (rs7975232, intron 9), and *TaqI* (rs731236, exon 9) sites, have been shown to influence gene transcription and mRNA stability<sup>[9]</sup>. Additionally, these polymorphisms have exhibited the potential for strong linkage disequilibrium (LD)<sup>[10,11]</sup>, and functional differences have been associated with the associated haplotypes<sup>[11,12]</sup>. Given that polymorphisms in the VDR gene could potentially influence the binding of 1, 25(OH)<sub>2</sub>D<sub>3</sub> and the anti-proliferative effects of vitamin D, VDR polymorphisms have been hypothesized to be associated with colorectal cancer risk.

In 2001, the first report of an association between colorectal cancer and the VDR gene was published by Kim and colleagues<sup>[13]</sup>. They identified a random subset of 393 cases of colorectal adenomas and 406 colonoscopy-negative controls from a clinic-based, case-control study conducted in the United States between 1991 and 1994. Based on their analysis, the *BsmI* BB genotype was found to be associated with a reduced risk of colorectal adenoma when intake of calcium and vitamin D was reduced. In addition to the *BsmI* site<sup>[12,14-23]</sup>. Other polymorphic sites present in the VDR gene, including *Cdx-2*<sup>[12,19,21,24,25]</sup>, *FokI*<sup>[12,15,16,18,19,21-24,26-33]</sup>, *ApaI*<sup>[12,16,19,21,34]</sup>, and

*TaqI*<sup>[12,16,19,23,24,29,31,33-35]</sup>, have been evaluated in genetic association studies. However, the results are inconsistent. Since it can be difficult for individual studies to achieve sufficient statistical power to detect associations between VDR polymorphisms and colorectal cancer risk, a meta-analysis that combines data from all published studies may detect genetic associations more accurately. In addition, a reduced probability of false-negatives might also be achieved<sup>[36]</sup>. Therefore, a systematic meta-analysis of population-based studies was performed to investigate the association between VDR polymorphisms and the risk of colorectal cancer. Based on the search strategy and criteria used, 23 studies were analyzed which identified several important polymorphic variants.

## MATERIALS AND METHODS

### Search strategy and data extraction

To examine the association between VDR polymorphisms and colorectal cancer risk, a search of the MEDLINE database (from January 1990 to August 2010) and the US National Library of Medicine's PubMed database (<http://www.ncbi.nlm.nih.gov/pubmed>) was performed. In addition, various scientific research tools available on the web were used to search relevant references such as Google (<http://scholar.google.com/>) and Scirus (<http://www.scirus.com/>). In particular, data relevant to five well-characterized polymorphic variants was identified, including: *Cdx-2*, *FokI*, *BsmI*, *ApaI*, and *TaqI* sites within VDR. Keywords used in searches included "vitamin D receptor" in combination with "polymorphism", "vitamin D", "genotype", "allele", "colorectal cancer", or "risk".

Papers selected for this meta-analysis included a case-control study and complete data, including the authors' names; the subjects' region/country; year of publication; numbers of cases and controls; mean age (or range) of the case/control group; diagnostic criteria used; and number of subjects with the VDR genotype in both case and control groups. All relevant references that met these inclusive criteria and that were published as articles or abstract containing original data, were included in this study. In contrast, case-only studies, studies with incomplete data, or studies with inadequate control groups were excluded. In addition, the data extracted needed to conform to the guidelines of MOOSE, a proposal for reporting meta-analyses of observational studies<sup>[37]</sup>. If the same or overlapping data were reported in multiple publications, the most recent publication was selected<sup>[38]</sup>.

### Statistical analysis

For each data set included in this study, the odds ratios (ORs) and corresponding 95% CI for the incidence of cancer in subjects with or without particular restriction sites (lowercase *vs* uppercase lettering), was compared. Furthermore, deviations from the Hardy-Weinberg equilibrium for each control group were assessed using the goodness-of-fit test. To estimate associations with colorectal cancer risk, various genotypic models were

selected, including codominant, additive, recessive, and dominant. Both the Peto Mantel-Haenszel fixed-effects model and the DerSimonian Laird random-effects model (with weights based on the inverse variance) were used to calculate summary ORs, and both within- and between-study variations were considered<sup>[39]</sup>. A *P*-value less than 0.10 was considered statistically significant when comparing trials showing heterogeneity, and random-effects analysis was selected. In contrast, fixed-effects analysis was used for comparing trials exhibiting homogeneity. Inverted funnel plots were also used to examine asymmetry, in which the ORs were plotted on a logarithmic scale against the inverse of their corresponding standard errors<sup>[40]</sup>. In the presence of publication bias, the funnel plot was asymmetric and the data showed remarkable skewness. There may be many reasons for this, most notably that some studies with negative findings are not published. In contrast, the plots were symmetric when bias was absent.

All statistical analyses were performed using the Statistical Package for Social Sciences (SPSS, version 13.0) and Review Manager (version 4.2, The Cochrane Collaboration), and all *P*-values were two-sided.

## RESULTS

### Characteristics of case-control studies included in the meta-analysis

According to the criteria defined above, 38 published studies relevant to the *VDR* gene and colorectal cancer

risk were reviewed. Fifteen of these papers were excluded due to insufficient clarity in data presentation, repeated literature, or significant differences were present in their study design compared with the other papers identified<sup>[41]</sup>. The remaining 23 eligible case-control studies are listed in Table 1, and were included in a meta-analysis to investigate possible associations between *Cdx-2*, *FokI*, *BsmI*, *ApaI*, and *TaqI* polymorphisms present in the *VDR* gene and the risk of colorectal cancer.

In 21/23 studies, data regarding the 5' end of the *VDR* gene were provided. In four of these studies, 2639 cases and 2948 controls were analyzed for the *Cdx-2* polymorphism, while 17 studies included 13 301 cases and 15 942 controls analyzed for the *FokI* polymorphism. In addition, the 3' UTR region of the *VDR* gene has been analyzed. For example, 12 studies containing 10 083 cases and 11 242 controls analyzed the *BsmI* polymorphism, 5 studies including 2739 cases and 3200 controls analyzed the *ApaI* polymorphism, and 9 studies including 2580 cases and 3016 controls analyzed the *TaqI* polymorphism.

Among controls, the frequency of the *c* allele at the *Cdx-2* site ranged from 65.6% in Berlin-Bush populations of Germany, to 80.0% in a United Kingdom population<sup>[12,19,21,24,25]</sup>. In contrast, the frequency of the *f* allele of *FokI* among controls ranged from 31.7% in Turkey, to 47.2% in a Singapore population<sup>[12,15,16,18,19,21-24,26-33]</sup>. The frequency of the *b* allele at *BsmI* among controls ranged from 56.1% in a Bulgarian population, to 94.7% in a Korean population<sup>[12,14-23]</sup>, while the frequency of the *a* allele at *ApaI*

among controls ranged from 23.0% in a Korean population to 49.3% in a population of the United Kingdom<sup>[12,16,19,21,34]</sup>. Lastly, the frequency of the *t* allele at *TaqI* among controls ranged from 8.8% in a Korean population to 43.6% in a population of the United States<sup>[12,16,19,23,24,29,31,33-35]</sup>.

**Qualitative assessment of included studies**

Genotyping of the *Cdx-2*, *FokI*, *BsmI*, *ApaI* and *TaqI* polymorphisms was performed using the polymerase chain reaction-restriction fragment length polymorphism technique in 75% of the studies included in this meta-analysis. Due to the low sensitivity of this classic technology, quality control of this genotyping was required, and included blindness to the case-control status, random repeats of samples, or validation using a different genotyping method. However, only 38.9% (7/18) of the eligible studies provided sufficient quality control. Regarding sample size, only 5/24 (20.8%) studies employed more than 1000 cases or controls. Moreover, most of these studies were associated with poor statistical power due to sample sizes that were less than 500 and in some cases contained less than 100 cases or controls.

Assessment of Hardy-Weinberg proportion is regarded as an important criterion for evaluating genetic association studies<sup>[38]</sup>. Most of the studies included in this meta-analysis reported genotype frequencies in their control groups that were consistent with Hardy-Weinberg proportions ( $P > 0.05$ ). For example, deviations from Hardy-Weinberg proportions in controls were observed in three studies for *FokI*<sup>[29,31,32]</sup>, two studies of *BsmI*<sup>[19,21]</sup>, one study of *ApaI*<sup>[19]</sup>, and two studies of *TaqI*<sup>[23,24]</sup>.

**Figure 1 A funnel plot was used to estimate the publication bias of the studies included in the meta-analysis performed.**

Funnel plotting was performed to evaluate whether publication bias was present in the meta-analysis performed. As shown in Figure 1, the shapes of the funnel plots obtained appear to be symmetrical in codominant, dominant, and recessive models, suggesting that publication bias is absent in the meta-analysis performed.

***Cdx-2*, *FokI*, *BsmI*, *ApaI*, *TaqI* polymorphisms and colorectal cancer risk**

A heterogeneity test of potential associations between the *Cdx-2*, *FokI*, *BsmI*, *ApaI*, and *TaqI* polymorphisms and risk of colorectal cancer are presented in Tables 2 and 3.

Table 3 The *BsmI* effect odds ratios stratified by anatomical site

Model	Colon cancer			Rectal cancer

<sup>1</sup>Test for overall effect and heterogeneity, respectively. OR: Odds ratios.

***Cdx-2* polymorphism:** Currently, only four studies have investigated the relationship between the *VDR Cdx-2* polymorphism and colorectal cancer risk, and all of these studies were in Hardy-Weinberg equilibrium<sup>[12,19,21,24,25]</sup>. Furthermore, in the overall and subgroup analyses performed, the *Cdx-2* polymorphism did not appear to be linked to colorectal cancer risk.

***FokI* polymorphism:** Seventeen studies included in the meta-analysis performed found the *FokI* polymorphism to be statistically heterogeneous in all genetic models ( $P \leq 0.01$ )<sup>[12,15,16,18,19,21-24,26-33]</sup>. Moreover, no significant association was found between *FokI* and colorectal cancer risk in overall and subgroup analyses.

***BsmI* polymorphism:** A total of 12 studies examined the association between colorectal cancer and the *BsmI* polymorphism, and there was little statistical evidence of heterogeneity among the studies ( $P \geq 0.28$ )<sup>[12,14-23]</sup>. Individuals with the *BB* genotype (OR = 0.87; 95% CI = 0.80-0.94,  $P = 3 \times 10^{-4}$ ;  $P = 0.65$  for heterogeneity), or the *Bb* genotype (OR = 0.94; 95% CI: 0.88-0.99,  $P = 0.03$ ;  $P = 0.48$  for heterogeneity), were associated with a significant decrease in colorectal cancer risk compared with patients carrying the *bb* genotype. The Dominant model (*BB + Bb vs bb*) and the recessive model (*BB vs Bb + bb*) also showed a significant association with colorectal cancer risk, with the associated ORs being 0.92 (95% CI: 0.87-0.97,  $P = 0.003$ ;  $P = 0.84$  for heterogeneity) and 0.90 (95% CI: 0.84-0.97,  $P = 0.006$ ;  $P = 0.28$  for heterogeneity), respectively (Figure 2). Although two of these studies were not consistent with Hardy-Weinberg proportions<sup>[17,21]</sup>, the effect was negligible. In addition, the *BB* genotype showed a decreased risk for colon cancer compared with the *bb* (OR = 0.80, 95% CI: 0.68-0.93,  $P = 0.004$ ;  $P = 0.21$  for heterogeneity), or *Bb + bb* genotypes (OR = 0.80, 95% CI: 0.69-0.92,  $P = 0.002$ ;  $P = 0.19$  for heterogeneity). However, no significant differences were observed between these polymorphisms and rectal cancer risk (Table 3).

***ApaI* polymorphism:** The association between the *ApaI* polymorphism and colorectal cancer was investigated in five studies, of which only one study was not consistent with Hardy-Weinberg proportions<sup>[12,16,19,21,34]</sup>. Moreover, although the codominant model (*AA vs aa*, OR = 0.83; 95% CI: 0.71-0.97,  $P = 0.02$ ) showed a

significant association with colorectal cancer risk, the *P* value of 0.05 suggested that this genetic model was statistically heterogeneous.

***TaqI* polymorphism.** Except for the recessive model (*tt vs Tt + TT*,  $P = 0.06$ ), there was little evidence of statistical heterogeneity among the nine studies that investigated an association between the *TaqI* polymorphism and colorectal cancer risk ( $P \geq 0.35$ )<sup>[12,16,19,23,24,29,31,33-35]</sup>. When the two studies in which controls were not in Hardy-Weinberg equilibrium were excluded, the pooled ORs for all genetic models for *TaqI* were shifted, yet the results remained null<sup>[23,24]</sup>.

## DISCUSSION

This study was undertaken to assess whether *VDR* polymorphisms in both the 5' (*Cdx-2* and *FokI*) and 3' (*BsmI*, *ApaI* and *TaqI*) regions of the *VDR* gene are associated with colorectal cancer risk. A total of 38 reports had previously evaluated a possible genetic association, and only 23 of these were eligible for this study based on the selection criteria employed. The pooled ORs (95% CI) for these studies were identical according to both fixed- and random-effects models. Moreover, only the polymorphic variant, *BsmI*, was found to be associated with increased risk for colorectal cancer. The meta-analysis performed also showed that the *BsmI B* genotype was related to a significant decrease in overall risk for colorectal cancer, with the co-dominant *BB* and the *BB + Bb vs bb* dominant model exhibiting 0.87- and 0.92-fold increases in the risk for disease, respectively. The *BB vs Bb + bb* recessive model also had a 90% decreased risk for colorectal cancer.

In addition, subgroup analyses by anatomical site identified the *BsmI* polymorphism to be significantly associated with colon cancer, and not rectal cancer. Furthermore, compared with the *bb* or *Bb + bb* genotypes, the *BB* genotype was associated with a 90% decrease in the risk for colon cancer. However, it remains unclear why the *BsmI* site is related to the risk of colon cancer, and not rectal cancer. It is possible that the difference in epithelial cells between the two cancers plays a role, with ciliated columnar epithelial cells being present in the lining of the colon, while squamous epithelial cells are present in the rectum. The role of the micro-environment may also be a contributing factor, since physical damage as a result of oxygen or poisonous food residues is more likely to influence the rectum than the colon. In addition,

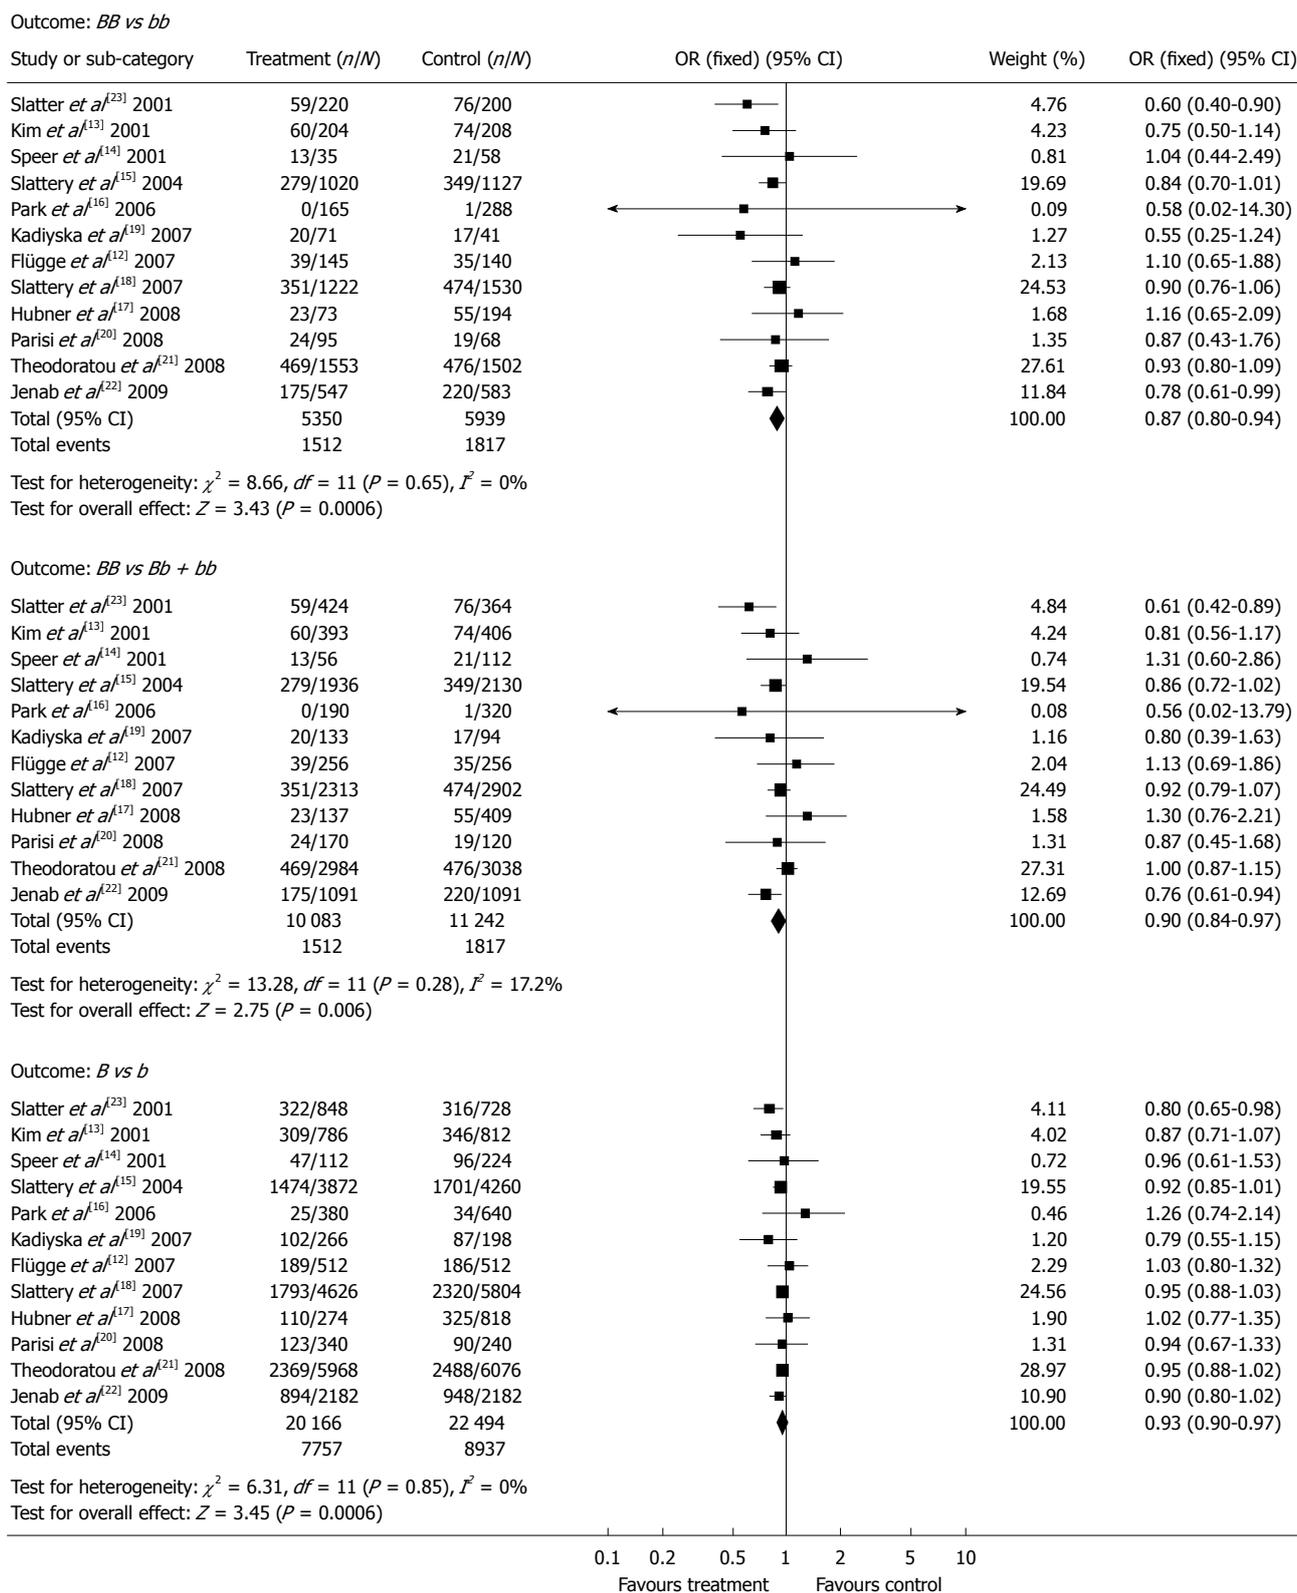

Figure 2 Forest plot of the meta-analysis performed to investigate the association between the *BsmI* polymorphism of the vitamin D receptor gene and colorectal cancer risk (fixed-effects model).

genetic factors may have a more important role in colon cancer than rectal cancer.

Based on the distribution differences observed between cases of colorectal cancer and controls, we hypothesized that the *BsmI* B allele might have a protective

effect against tumorigenesis. Correspondingly, of the 12 relevant reports reviewed, 9 studies supported this hypothesis. In these studies, the populations analyzed were from Asia ( $n = 1$ ), Europe ( $n = 4$ ), and the United States ( $n = 4$ ). In addition, Jenab *et al*<sup>[22]</sup> evaluated different Cau-

casian populations from 23 centers in Denmark, France, Greece, Germany, Italy, the Netherlands, Norway, Spain, Sweden, and the United Kingdom. In this study, the *BB* genotype, rather than the wild-type *bb* genotype, was associated with a reduced risk of colorectal cancer. The *BsmI BB* genotype was also found to be associated with a reduced risk of colorectal cancer among non-aspirin/NSAID users<sup>[42]</sup>. Thus, multiple lines of evidence support the hypothesis that the *BsmI B* allele mediates a protective effect against the development of cancers in the digestive tract, especially colon cancer.

The *BsmI* polymorphism is located in the 3' UTR of the *VDR* gene, and does not alter the amino acid sequence of the *VDR* protein. Thus, for a single *BsmI* polymorphism, there is a low probability that it directly influences *VDR* function<sup>[9]</sup>. The *BsmI* polymorphism also does not affect mRNA or protein levels of *VDR*<sup>[20]</sup>, or levels of 25(OH)<sub>2</sub>D<sub>3</sub> or 125(OH)<sub>2</sub>D<sub>3</sub><sup>[43]</sup>. However, the *BsmI* site does exhibit strong LD with other *VDR* polymorphisms, including *eTru9I*, *ApaI*, *TaqI*, and *Poly(A)* microsatellites. Based on these results, it appears that the *BsmI* polymorphism affects some type of biological function, and these could potentially include regulation of *VDR* transcription, translation, or RNA processing<sup>[9]</sup>. Other unidentified SNPs in the *VDR* gene, as well as SNPs in other genes such as *CYP3A5*<sup>[44]</sup>, may also affect the function of the *BsmI*. Furthermore, patients carrying the *BsmI* allele have also been shown to have significantly higher levels of *erbB-2* expression, suggesting other tumor-related molecules may also be involved in the function of the *BsmI* polymorphism<sup>[14]</sup>.

Although the *BsmI B* allele has been associated with a protective effect, the frequency of this effect has been found to be lower in Asian populations than in Caucasian populations. However, this is inconsistent with the incidence of colorectal cancer identified in recent epidemiological data<sup>[2]</sup>. Moreover, in the meta-analysis performed in the present study, no significant association was found between *VDR* genotypes and the risk of colorectal cancer in group analyses (not shown). In combination, these results suggest that other factors may be involved. For example, environment, food, and lifestyle may play a more significant role, in combination with genetic factors, in the occurrence and development of colorectal cancer than previously thought, which would potentially account for the inconsistent results obtained from previous studies.

## COMMENTS

### Background

Colorectal cancer is one of the most common cancers worldwide, and its incidence is increasing with each year. However, the underlying etiology of colorectal cancer remains unclear. Several epidemiologic studies have reported that 1, 25(OH)<sub>2</sub>D<sub>3</sub> can reduce the risk of colorectal cancer, and thus, vitamin D receptor (*VDR*), a crucial mediator of the cellular effects of 1, 25(OH)<sub>2</sub>D<sub>3</sub>, may play an important role in the occurrence and development of colorectal cancer.

### Research frontiers

Recently, several polymorphic variants of the *VDR* gene have been reported to be associated with the risk of colorectal cancer. However, the published findings remain inconsistent. In this study, the authors conducted a systematic meta-analysis to evaluate the evidence regarding this association.

## Innovations and breakthroughs

In the present study, all relevant reports published between January 1990 and August 2010 were reviewed, with a focus on five well-characterized polymorphic variants of *VDR*: *Cdx-2*, *FokI*, *BsmI*, *ApaI*, and *TaqI*. In the meta-analysis performed, *BsmI* was found to be associated with colorectal cancer, while the *Cdx-2*, *FokI*, *ApaI*, and *TaqI* sites did not exhibit any significant association. Moreover, the *BsmI* 'B' genotype was associated with a significant decrease in the risk of colorectal cancer, especially colon cancer. Based on these results, it is hypothesized that *BsmI* may mediate a protective effect on tumorigenesis.

## Applications

The results of this meta-analysis have the potential to partly explain the genetics that influence the pathogenesis of colorectal cancer. This study also helps provide a basis for clinical diagnosis and methods for early intervention.

## Peer review

The authors performed a systematic meta-analysis of population-based studies to investigate the association between *VDR* polymorphisms and colorectal cancer risk. The authors found a *BsmI* site in the 3' UTR of the *VDR* gene to be associated with colon cancer risk, and then analyzed the underlying mechanism. The results are interesting and may help explain the genetic mechanism of colorectal carcinogenesis.

### Abstract

**AIM:** To investigate the effects of heme oxygenase (HO)-1 on liver fibrosis and the expression of peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ) and nuclear factor-kappa B (NF- $\kappa$ B) in rats.

**METHODS:** Sixty Wistar rats were used to construct liver fibrosis models and were randomly divided into 5 groups: group A (normal, untreated), group B (model for 4 wk, untreated), group C (model for 6 wk, untreated), group D [model for 6 wk, treated with zinc protoporphyrin IX (ZnPP-IX) from week 4 to week 6], group E (model for 6 wk, treated with hemin from week 4 to week 6). Next, liver injury was assessed by measuring serum alanine aminotransferase (ALT), aspartate aminotransferase (AST) and albumin levels. The degree of hepatic fibrosis was evaluated by measuring serum hyaluronate acid (HA), type IV collagen (IV-C) and by histological examination. Hydroxyproline (Hyp) content in the liver homogenate was determined. The expres-

sion levels of alpha-smooth muscle actin ( $\alpha$ -SMA) in liver tissue were measured by real-time quantitative polymerase chain reaction (RT-PCR). The expression levels of PPAR $\gamma$  and NF- $\kappa$ B were determined by RT-PCR and Western blotting.

**RESULTS:** The expression of HO-1 increased with the development of fibrosis. Induction of HO-1 by hemin significantly attenuated the severity of liver injury and the levels of liver fibrosis as compared with inhibition of HO-1 by ZnPP-IX. The concentrations of serum ALT, AST, HA and IV-C in group E decreased compared with group C and group D ( $P < 0.01$ ). Amount of Hyp and  $\alpha$ -SMA in the liver tissues in group E decreased compared with group C ( $0.62 \pm 0.14$  vs  $0.84 \pm 0.07$ ,  $1.42 \pm 0.17$  vs  $1.84 \pm 0.17$ , respectively,  $P < 0.01$ ) and group D ( $0.62 \pm 0.14$  vs  $1.11 \pm 0.16$ ,  $1.42 \pm 0.17$  vs  $2.56 \pm 0.37$ , respectively,  $P < 0.01$ ). The expression of PPAR $\gamma$  at levels of transcription and translation decreased with the development of fibrosis especially in group D; and it increased in group E compared with groups C and D ( $0.88 \pm 0.15$  vs  $0.56 \pm 0.19$ ,  $0.88 \pm 0.15$  vs  $0.41 \pm 0.11$ , respectively,  $P < 0.01$ ). The expression of NF- $\kappa$ B increased with the development of fibrosis especially in group D; and it decreased in group E compared with groups C and D ( $1.43 \pm 0.31$  vs  $1.89 \pm 0.29$ ,  $1.43 \pm 0.31$  vs  $2.53 \pm 0.54$ , respectively,  $P < 0.01$ ).

**CONCLUSION:** Our data demonstrate a potential mechanism that HO-1 can prevent liver fibrosis by enhancing the expression of PPAR $\gamma$  and decreasing the expression of NF- $\kappa$ B in liver tissues.

## INTRODUCTION

Liver fibrosis is the mechanism of compensation and reparation after chronic hepatic injury, which is a necessary pathological stage for the development of chronic hepatitis. Heme oxygenase-1 (HO-1), also known as heat shock protein 32, is a microsomal enzyme and rate-limiting enzyme that catalyzes the degradation of heme into biliverdin, iron atoms and carbon monoxide (CO)<sup>[1]</sup>. HO-1 and its breakdown products play vital physiological roles in anti-inflammation, anti-oxidation and regulation of apoptosis according to reports<sup>[2,3]</sup>. Many researchers have recently confirmed that HO-1 has protective effects on liver cells under such conditions as acute liver injury, alcoholic liver disease, liver transplantation and ischemia/reperfusion injury<sup>[4-8]</sup>. In chronic liver disease, induction of HO-1 is important to prevent the development of liver fibrosis<sup>[9]</sup>. However, the underlying molecular mechanisms are still unknown.

Peroxisome proliferator-activated receptor (PPAR) is a ligand-activated transcription factor which is widely distributed in tissues<sup>[10]</sup>. Three PPAR subtypes have been identified, namely  $\alpha$ ,  $\beta$  and  $\gamma$ . PPAR $\gamma$  is mainly expressed in hepatic stellate cells (HSC). Studies have shown that the expression of PPAR $\gamma$  benefits the maintenance of HSC static phenotype<sup>[11]</sup>. Up-regulation of PPAR $\gamma$  resulted in a significant reduction of HSC activation, and reversed the development of liver fibrosis.

Nuclear factor-kappa B (NF- $\kappa$ B) is an important nuclear transcription factor, which plays an important role in the regulation of gene transcription such as cytokines, chemokines, adhesion molecules and other inflammatory mediators<sup>[12]</sup>. Up-regulating the activation of NF- $\kappa$ B promotes HSC proliferation and decreases HSC apoptosis. Therefore, inhibiting the activation of NF- $\kappa$ B resulted in reduction of HSC activation, promoting HSC apoptosis and decreasing extracellular matrix production<sup>[13,14]</sup>.

In the present study, we have evaluated the role of HO-1 in liver fibrosis caused by carbon tetrachloride (CCl<sub>4</sub>) in rat models, then observed the expression of PPAR $\gamma$  and NF- $\kappa$ B in liver after up-regulation of HO-1 by ferriprotoporphyrin IX chloride (hemin) or inhibition of HO-1 by zinc protoporphyrin IX (ZnPP-IX) pretreatment, and we finally hypothesize about a potential mechanism for the cytoprotection by HO-1.

## MATERIALS AND METHODS

### Reagents

ZnPP-IX is a selective HO inhibitor which can suppress the activity of HO-1 by blocking CO production and

restricting the transformation of heme to biliverdin<sup>[15]</sup>. Hemin is a well-known physiological substrate and potent inducer of HO activity<sup>[16]</sup>. Both ZnPP-IX and hemin were purchased from Sigma Chemical Co. (St. Louis, MO, United States). Polyclonal antibodies HO-1 and PPAR $\gamma$  were purchased from Cell Signaling (Danver, MA, United States). Anti-phospho-NF- $\kappa$ B p65 monoclonal antibody was purchased from Santa Cruz (Santa Cruz, CA, United States). Anti-beta actin antibody was purchased from Biogenesis (Bournemouth, United Kingdom). All other chemicals were of analytical grade and commercially available.

### Animals and experimental design

Male Wistar rats (Medical University Laboratory Animal Center, Shanxi, China) weighing 220 g-250 g were used to establish fibrogenesis models<sup>[17-19]</sup>. All procedures used in this study were approved by the Ethics Committee for the use of experimental animals at Shanxi Medical University. All rats were kept at 21 °C-25 °C under a 12 h dark/light cycle, drank normal water and were fed with 79.5% corn meal, 20% lard and 0.5% cholesterol for the first two weeks, then 99.5% corn meal and 0.5% cholesterol thereafter. Sixty rats were randomly divided into five groups (twelve rats/group); groups B, C, D and E received subcutaneous injections of 40% CCl<sub>4</sub> (a mixture of pure CCl<sub>4</sub> and olive oil, 0.3 mL/100 g) every four days for six weeks. The rats in group A were fed with normal diet and received a 0.9% NaCl subcutaneous injection. In the fourth week, Group B and some of group A were killed, while group D and group E began to be peritoneally injected with ZnPP-IX (20  $\mu$ mol/kg) or hemin (30  $\mu$ mol/kg) every other day until the sixth week when they were killed with group C and the remnants of group A. The dose and preparation of ZnPP and hemin solution were based on our preliminary studies and references<sup>[20-22]</sup>. The numbers of rats were reduced to 11, 9, 9 and 10 in groups B, C, D, and E, respectively, due to deaths during the process. A small portion of the liver was removed for histological analysis by fixation with 10% formalin and subsequent embedding in paraffin. The remaining liver was cut into pieces and frozen in liquid nitrogen and kept at -80 °C until it was used for extraction of total RNA and proteins.

### Serum biochemical and liver fibrosis indicator measurements

Markers of hepatic damage such as serum alanine aminotransferase (ALT), aspartate transaminase (AST) and albumin (ALB) levels were measured by using an automated biochemistry clinical analyzer (Hitachi, Japan) according to an automated procedure. The levels of serum hyaluronic acid (HA) and type IV collagen (IV-C) were determined using Chemiluminescence Quantitative Immunoassay Kit (Beijing Yuande Bio-Medical Engineering Co., Ltd.).

### Quantification of hydroxyproline assay

Hydroxyproline (Hyp) content in the liver specimens represented the total amount of collagen in livers, which

was quantified to evaluate the degree of liver fibrosis by using a colorimetric method<sup>[23]</sup>. Kits for the measurement were purchased from Nanjing Jiancheng Bioengineering. In brief, 100 mg of freeze-dried liver specimens were weighed and tested according to the manufacturer's directions. At the end of the experiment, absorbance of each sample was read at 550 nm using a spectrophotometer. The content was obtained according to a formula and expressed as micrograms Hyp/milligram liver. Each sample was analyzed in triplicate.

### Histologic evaluation

Liver tissues were fixed in 10% neutral formalin solution overnight, embedded in paraffin blocks, and then were sectioned at 4  $\mu$ m thickness for staining with hematoxylin and eosin (HE) or Masson by using standard techniques. The results were analyzed by light microscopy. Representative views of liver sections are shown.

### RNA isolation and real-time polymerase chain reaction

Total RNA was extracted from liver tissue using the RNA Trizol isolation reagent kit (Invitrogen, United States). cDNA was obtained by reverse transcription of RNA by using random primer and Moloney murine leukemia virus reverse transcriptase (Gibco BRL, Merelbeke, Belgium). The conditions were 25 °C for 5 min, 42 °C for 60 min and 70 °C for 5 min, finally cooling at 5 °C for use. Amplification reactions were performed with a SYBR green polymerase chain reaction (PCR) master mix (Applied Biosystems). Three microliters of diluted cDNA samples were used for quantitative analysis. The cycle conditions were 95Mul for 10 min for denaturation, followed by 50 cycles of 15 s at 95Mul, 30 s at 55Mul and 45 s at 72Mul. Each sample was analyzed in triplicate. The primers were as follows: HO-1, (forward) 5'-CAC GCA TAT ACC CGC TAC CT-3' and (reverse) 5'-AAG GCG GTC TTA GCC TCT TC-3'; PPAR $\gamma$ , (forward) 5'-CCC TGG CAA AGC ATT TGT AT-3' and (reverse) 5'-ACT GGC ACC CTT GAA AAA TG-3'; NF- $\kappa$ B, (forward) 5'-AAC ACT GCC GAG CTC AAG AT-3' and (reverse) 5'-CAT CGG CTT GAG AAA AGG AG-3'; alpha-smooth muscle actin ( $\alpha$ -SMA), (forward) 5'-TGT GCT GGA CTC TGG AGA TG-3' and (reverse) 5'-GAA GGA ATA GCC ACG CTC AG-3'; Beta-actin, (forward) 5'-GTC AGG TCA TCA CTA TCG GCA AT-3' and (reverse) 5'-AGA GGT CTT TAC GGA TGT CAA CGT-3'. Beta-actin was used as an internal control.

### Western blotting analysis

Proteins were extracted from frozen liver samples with radioimmuno-precipitation buffer containing 50 mmol/L Tris-HCl (pH 7.5), 100 mmol/L NaCl, 1% Nonidet P-40, 2  $\mu$ g/mL aprotinin, 1 mmol/L phenyl-methylsulphonyl fluoride, 1% sodium dodecyl sulfate (SDS) and 0.5% deoxycholate, then centrifuged at 10 000 *g* for 10 min at 4 °C. Samples were subjected to 12% SDS-polyacrylamide gel electrophoresis and proteins were transferred to nitrocellulose membranes. The membranes were blocked

overnight in 5% bovine serum albumin in tris buffer saline Tween20 buffer at 4 °C, and then incubated with a 1:1000 dilution of anti-HO-1 polyclonal antibody, a 1:1000 dilution of anti-PPAR $\gamma$  polyclonal antibody, a 1:1000 dilution of anti-NF- $\kappa$ B monoclonal antibody or anti-beta-actin monoclonal antibody overnight at 4 °C. Then the membranes were treated with horseradish peroxidase-conjugated secondary antibody. Blots were visualized using the Super ECL detection kit (Amersham Pharmacia Biotech) according to the manufacturer's instructions. Relative densities of the bands were analyzed using the Kodak Digital Science Imaging System.

### Statistical analysis

Data were expressed as mean  $\pm$  SE and were analyzed with SPSS Version 13.0. Differences between experimental groups were analyzed using one-way analysis of variance or Student's *t* test. All differences were considered statistically significant when *P* < 0.05.

## RESULTS

### Expression of HO-1 in the liver of rats in different groups

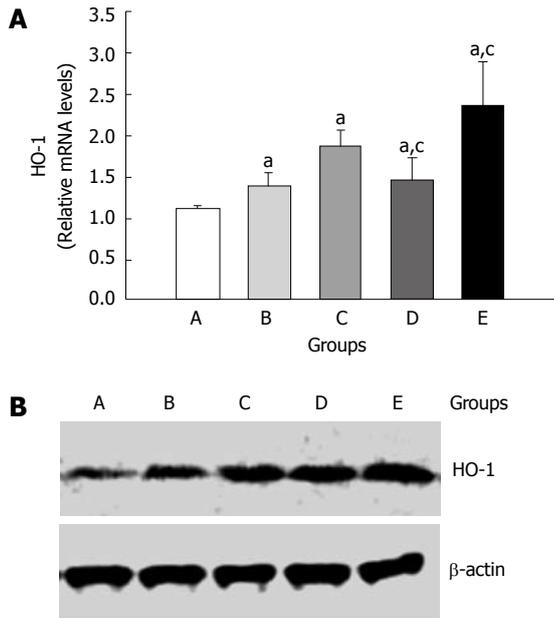

Long-term application of CCl<sub>4</sub> can induce hepatic fibrogenesis not only in humans but also in rats. We established CCl<sub>4</sub> rat models to evaluate the effect of HO-1 expression on liver fibrogenesis (Figure 1). The process lasted for 6 wk. In this study, we used two opposite reagents, i.e., hemin (induction of HO-1) and ZnPP-IX (inhibition of HO-1) from week 4 to week 6 to observe the regulation and mechanism of HO-1 in rat liver fibrosis. The mRNA and protein expressions of HO-1 in groups B and C were significantly higher than group A and increased with the severity of fibrosis, but all values were lower than in group E (*P* < 0.01); while those in group D were lower than in group C (*P* < 0.01), but still higher than in group A (*P* < 0.01).

### Effects of HO-1 expression on rat model of hepatic fibrogenesis

The rat model for group B exhibited inflammatory infiltration, hepatic steatosis and slight fibrosis (Figure 2B and G), while group C showed obvious fibrosis (Figure 2C and H). Treatment with hemin from week 4 to week 6 markedly reduced the severity of hepatic inflammatory infiltration and fibrosis (Figure 2E and J), whereas hepatic steatosis, inflammatory infiltration, especially fibrosis in hepatic portal areas, varying degrees of fibrosis around the central vein and extension to the hepatic lobule were aggravated in groups treated with ZnPP-IX (Figure 2D and I). These results indicate that HO-1 induction could protect rats from CCl<sub>4</sub>-induced liver injury and fibrosis.

### Effects of HO-1 on the levels of serum ALT, AST and ALB

The levels of serum ALT and AST increased with the development of fibrosis, and were higher in group C than in group B (Table 1). The increase in serum ALT and AST was markedly augmented by ZnPP-IX in group D (*P* < 0.01), but attenuated by hemin in group E com-

**Figure 1** Effects of hemin and zinc protoporphyrin on the expression of heme oxygenase-1 in the liver of rats with fibrosis caused by CCl<sub>4</sub>. Group A (normal, untreated); group B (model for 4 wk, untreated); group C (model for 6 wk, untreated); group D (model for 6 wk, treated with zinc protoporphyrin IX from week 4 to week 6); group E (model for 6 wk, treated with hemin from week 4 to week 6). A: Heme oxygenase-1 (HO-1) mRNA levels, determined by real-time quantitative polymerase chain reaction; B: HO-1 protein levels, detected by Western blotting. Data are expressed as the mean ± SE (*n* = 4 per group). <sup>a</sup>*P* < 0.01 vs the levels in group A; <sup>c</sup>*P* < 0.01 vs the levels in group C.

pared to group C (*P* < 0.01). The levels of ALB in group E increased significantly compared to group C (*P* < 0.01). Meanwhile, ALB levels decreased in group D but did not differ significantly from group C.

**Effects of HO-1 on the expression of fibrosis-related indicators**

To evaluate the effect of HO-1 induction on fibrosis, we assessed the expression levels of hepatic fibrosis-related indicators, i.e., HA, IV-C, Hyp and α-SMA. Rats in group D injected with ZnPP-IX showed enhanced expression of hepatic α-SMA and Hyp, which correlated with the levels of serum HA and IV-C. Meanwhile mice in group E injected with hemin exhibited depressed expression of these compared with group C (*P* < 0.01), which still did not recover to the levels of group B (*P* > 0.05) (Figure 3).

**Role of HO-1 in the expression of PPARγ and NF-κB at mRNA and protein levels**

Studies have shown that up-regulating the activation of PPARγ resulted in a significant reduction of type I collagen and α-SMA expression, inhibited HSC proliferation and even reversed the development of liver fibrosis<sup>[2-4]</sup>. Studies also have found that up-regulating the activation of NF-κB inhibited HSC apoptosis and promoted the release of inflammatory response factors<sup>[24]</sup>. To evaluate the mechanism of the effect of HO-1 on fibrosis, we explored the expression of PPARγ and NF-κB at levels of transcription and translation. Unlike the trends of HO-1,

**Table 1** Quantitation of alanine aminotransferase, aspartate aminotransferase and albumin in the serum from different groups of rats (mean ± SE)

Groups	<i>n</i>	ALT (U/L)	AST (U/L)	ALB (g/L)
A	12	20.80 ± 5.49	29.40 ± 4.45	40.2 ± 1.789
B	11	102.00 ± 24.54 <sup>b</sup>	122.00 ± 31.43 <sup>b</sup>	37.33 ± 2.42
C	9	166.50 ± 19.47 <sup>b</sup>	211.83 ± 29.16 <sup>b</sup>	28.50 ± 2.59 <sup>b</sup>
D	9	265.67 ± 43.61 <sup>b,d</sup>	323.83 ± 40.22 <sup>b,d</sup>	26.17 ± 2.93 <sup>b</sup>
E	10	114.40 ± 22.99 <sup>b,d</sup>	152.20 ± 25.65 <sup>b,d</sup>	32.80 ± 2.68 <sup>b,d</sup>

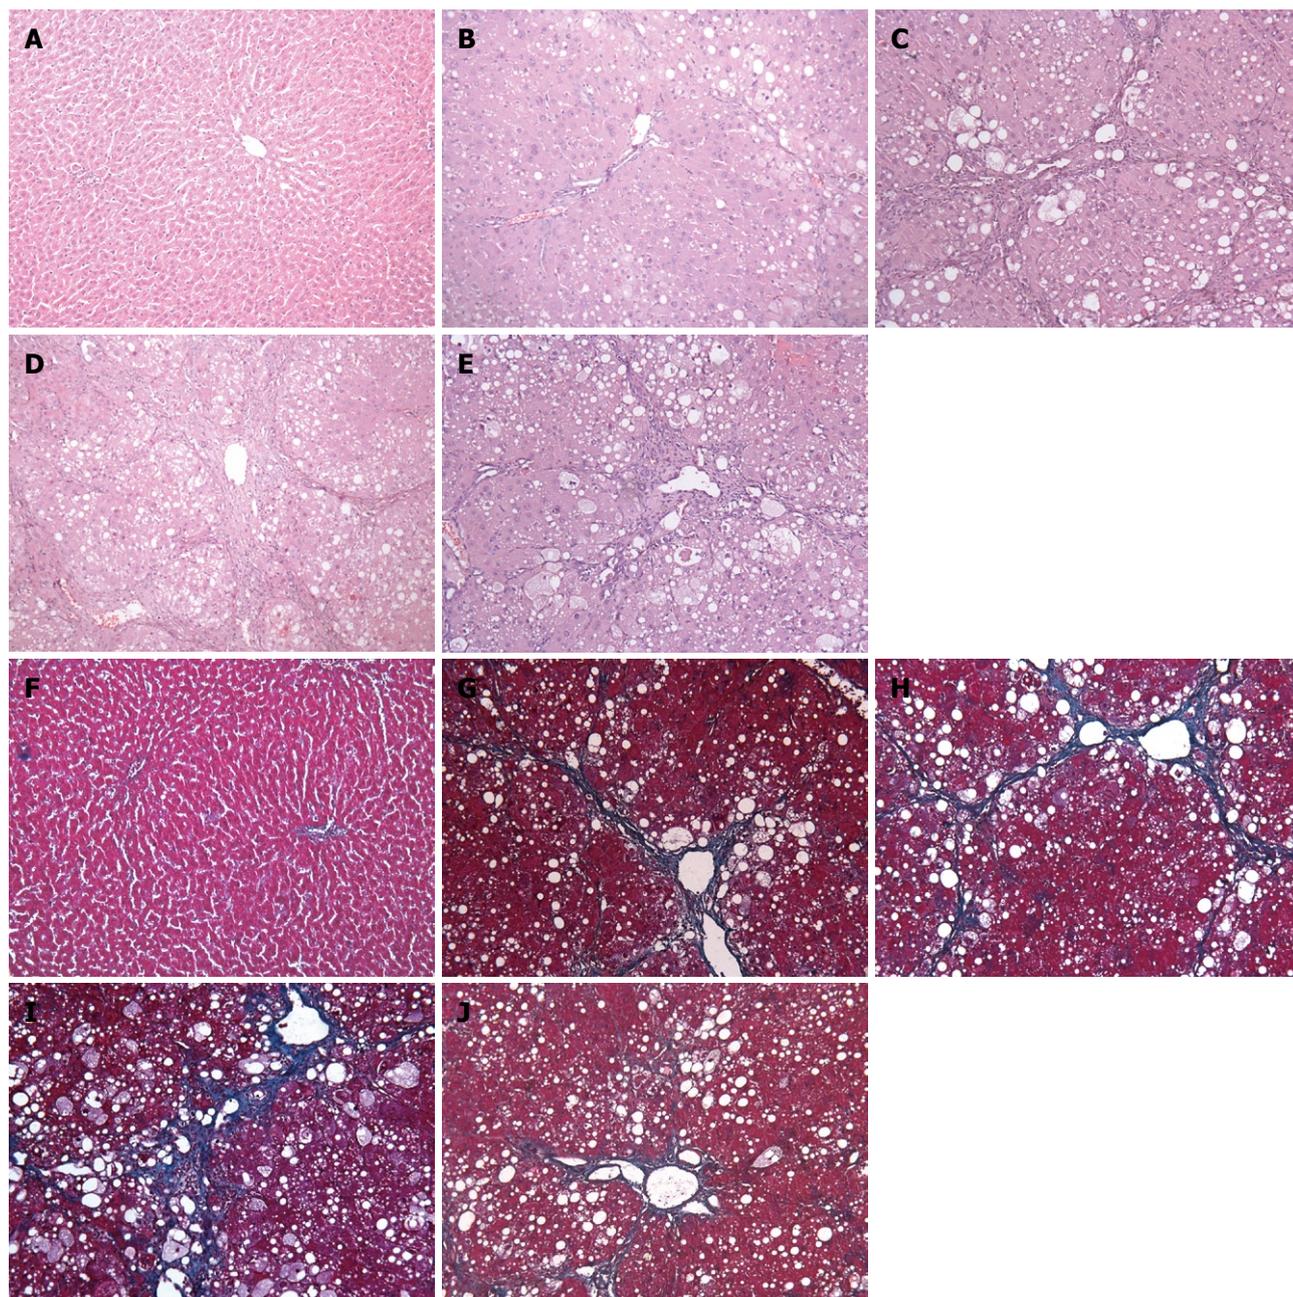

<sup>b</sup>*P* < 0.01 vs the levels in group A; <sup>d</sup>*P* < 0.01 vs the levels in group C. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ALB: Albumin.

real-time PCR and Western blotting showed that the expression of PPARγ decreased with the development of liver fibrosis (Figure 4A). The expression of PPARγ decreased more obviously after application of HO-1 inhibitor in group D as compared with group C (*P* < 0.05). On the contrary, PPARγ increased significantly after pretreatment with hemin in group E, and was higher than group C (*P* < 0.01). However, the expression of NF-κB gradually increased with the development of liver fibrosis, which was consistent with the change of HO-1 (Figure 4B). After using the inhibitor of HO-1 in group D, the expression of NF-κB increased as compared with group C, whereas expression decreased more significantly than group D and even group C when HO-1 was induced in group E (*P* < 0.01).

**DISCUSSION**

Liver fibrosis is the mechanism of compensation and reparation after chronic hepatic injury, which is a necessary pathologic stage from chronic hepatitis to cirrhosis. Previous studies have found that 25%-40% of liver fibrosis will eventually develop to cirrhosis and even liver cancer<sup>[25]</sup>. Therefore, it is essential to further clarify the mechanism of liver fibrosis in order to block and reverse the process of liver disease. We constructed liver fibrosis models in rats by using composite factors which had been confirmed successfully in the Department of Pathophysiology, Shanxi Medical University<sup>[18,19]</sup>. At the fourth week we observed inflammatory infiltration, hepatic steatosis and slight fibrosis in livers, and obvious liver cirrhosis could be seen at the sixth week.

HO-1 is the rate-limiting enzyme for heme degradation in a wide range of human and mammalian tissues. Prior clinical and animal research has confirmed that an external irritant could up-regulate the expression of HO-1 with increasing levels of oxygen-derived free radicals in cells<sup>[26]</sup>. It has previously been reported that induction of HO-1 is an important defense mechanism against many kinds of liver injuries. In chronic liver disease, especially liver fibrosis, induction of HO-1 can reduce the secretion of type I collagen, thus effectively preventing the development of liver fibrosis<sup>[27-30]</sup>. In this study, we also examined the effects of HO-1 inhibitor or inducer, and found that with the development of liver fibrosis, the expression of HO-1 was significantly

enhanced in liver of rats, whereas hemin pretreatment made this induction more prominent. We analyzed the biochemical parameters reflecting liver damage related to function and structure, such as serum ALT and AST levels, which indicated a remarkable decrease after HO-1 induction. Liver histopathology also clearly showed that HO-1 induction markedly reduced the severity of hepatic inflammatory infiltration and fibrosis. To further validate the protection by HO-1, we pretreated rats with concomitant ZnPP-IX (a competitive HO-1 inhibitor) and observed that the liver damage was more serious than in the control group and hemin-treated group. Then we assessed the levels of HA and IV-C in serum

and detected the content of Hyp and  $\alpha$ -SMA mRNA in rat liver tissues of the different groups, in order to determine the proliferation levels of fibrosis. Results showed that the induction of HO-1 could reduce all the biochemical indicators of fibrosis and attenuate the degree of fibrosis detected pathologically, while the inhibitor of HO-1 caused an opposite result. Taken together, we concluded that induction of HO-1 in hepatic tissues could produce anti-inflammatory effects and slow the process of liver fibrosis effectively; however the inhibition of HO-1 could enhance the liver fibrosis.

PPAR, including  $\alpha$ ,  $\beta$  and  $\gamma$  subtypes, are new steroid hormone receptors and ligand-activated transcription

factors. PPAR $\gamma$  plays an important role in many biological processes, including adipogenesis, inflammatory reaction, cell growth regulation and cell differentiation<sup>[31]</sup>. The expression of PPAR $\gamma$  is beneficial in maintaining the quiescent phenotype of HSC; however the inhibition of PPAR $\gamma$  may be an early event in HSC transformation from quiescent to activated state<sup>[11]</sup>. Studies found that the PPAR $\gamma$  agonist rosiglitazone could be used to increase the expression of PPAR $\gamma$  in activated HSC, which could reduce oxidative stress, decrease the expression of  $\alpha$ -SMA and the synthesis of type I collagen, inhibit cell proliferation and promote cell apoptosis<sup>[32]</sup>. Recent studies also found that PPAR $\gamma$  activation reduced TGF- $\beta$ 1-induced CTGF expression at both transcriptional and posttranscriptional levels in HSC<sup>[33]</sup>. Enhancement of PPAR $\gamma$  activity might interrupt the signaling pathways for platelet-derived growth factor and epidermal growth factor, and then suppress hepatic fibrogenesis<sup>[34]</sup>.

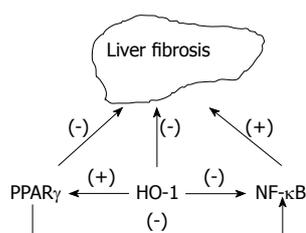

NF- $\kappa$ B is a nuclear transcriptional activator that plays a central role in stress response and inflammation<sup>[35]</sup>. Activation of NF- $\kappa$ B can promote HSC proliferation, reduce HSC apoptosis and increase the production of collagen and inflammatory chemokines in the process of liver fibrosis. But inhibiting the activation of NF- $\kappa$ B can induce apoptosis of HSC. Studies have found that a decrease of PPAR $\gamma$  was accompanied with an increase of NF- $\kappa$ B in lung tissues, which played an important role in the development of lung fibrosis<sup>[36]</sup>. PPAR $\gamma$  can inhibit the transcription and DNA synthesis of NF- $\kappa$ B by binding

p50/p65 subunits to form transcriptional repressor complexes directly or by binding p300 and CBP co-activating factors to inhibit the transcription and expression of NF- $\kappa$ B competitively<sup>[37]</sup>. Other research showed that a specific inducer of PPAR $\gamma$  such as troglitazone could interfere with NF- $\kappa$ B signaling pathway by activating PPAR $\gamma$ <sup>[38]</sup>.

Studies in other areas have shown that co-regulation exists between HO-1 and PPAR $\gamma$ . Research regarding the interaction of HO-1 and PPAR $\gamma$  in human vascular endothelial cells demonstrated that HO-1 enzymatic activity mediated antiinflammatory and antiproliferative effects exerted by PPAR ligands, and that a clinically relevant (GT)n dinucleotide length polymorphism within the human HO-1 promoter significantly influenced the transcriptional regulation of HO-1 by both PPAR $\alpha$  and PPAR $\gamma$ <sup>[39]</sup>. Li *et al.*<sup>[40]</sup> reported that induction of HO-1 could mediate the effect of PPAR $\gamma$  in suppressing the proliferation of rat pulmonary artery smooth muscle cells, but that this effect was blocked by knockdown of HO-1 through siRNA transfection. Recent studies demonstrated that HO-1, as an identifier of novel trophoblast invasion-related genes, controlled motility *via* up-regulation of PPAR $\gamma$ ; researchers found that up-regulation of PPAR $\gamma$  protein and activity by HO-1 was required to down-regulate cell motility, but blocking of PPAR $\gamma$  largely abolished the effect of HO-1<sup>[41]</sup>. Studies also found that there was an NF- $\kappa$ B binding site in the HO-1 promoter region. The activity of HO-1 was directly related to NF- $\kappa$ B<sup>[42]</sup>. HO-1 played an important

**Figure 4** Levels of peroxisome proliferator-activated receptor gamma mRNA and nuclear factor-kappa B mRNA in rat liver analyzed by real-time polymerase chain reaction assay and associated protein assessed by Western blotting. A: Peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ) mRNA and protein. The molecular weight of PPAR $\gamma$  is 55 kD; B: Nuclear factor-kappa B (NF- $\kappa$ B) mRNA and protein. The molecular weight of NF- $\kappa$ B is 50 kD.  $\beta$ -Actin was used as an invariant control. Values are expressed as mean  $\pm$  SE ( $n = 4$  per group). <sup>a</sup> $P < 0.01$  vs the levels in group A; <sup>c</sup> $P < 0.05$  vs the levels in group C; <sup>d</sup> $P < 0.01$  vs the levels in group D; <sup>e</sup> $P < 0.01$  vs the levels in group E. role in the down-regulation of NF- $\kappa$ B activation. Yeh *et al*<sup>[43]</sup> showed that HO-1 activation could attenuate the surge of inflammation-related cytokines and decrease the occurrence of cardiomyocytic apoptosis *via* inhibition of NF- $\kappa$ B and AP-1 translocation. Liu *et al*<sup>[44]</sup> indicated that up-regulation of HO-1 could alleviate severe acute pancreatitis-associated lung injury in rats by decreasing NF- $\kappa$ B activity drastically and inhibiting the serum levels of tumour necrosis factor alpha (TNF- $\alpha$ ) and interleukin-6 significantly. Overexpression of HO-1 could protect against TNF- $\alpha$ -mediated airway inflammation by dimin-

ishing NF- $\kappa$ B activation in both cultured human tracheal smooth muscle cells and the airways of mice<sup>[45]</sup>.

In this study, we found that the expression of PPAR $\gamma$  was decreased in group D, which was treated with ZnPP-IX to inhibit the expression of HO-1, whereas the expression of NF- $\kappa$ B was increased. But PPAR $\gamma$  was overexpressed in group E by treating with hemin to induce the expression of HO-1, whereas the expression of NF- $\kappa$ B was reduced. By examining the HE stained liver histology, we found that the degree of liver fibrosis was significantly higher in group D than in groups C and E. Masson staining for collagen showed the same results: that the collagen content in group D was significantly increased compared to group C, but was markedly reduced in group E compared with groups D and C. Thus we hypothesize that induction of HO-1 could alleviate the liver injury and reverse the process of liver fibrosis by up-regulating the expression of PPAR $\gamma$  and down-regulating the expression of NF- $\kappa$ B, and then affect the releasing of inflammatory cytokines such as TNF- $\alpha$  in NF- $\kappa$ B-related signal pathways or induce HSC apoptosis. Among these, the inhibition of NF- $\kappa$ B may be regulated directly by HO-1 on the one hand, or on the other hand be regulated by the expression levels of PPAR $\gamma$  which are associated with the expression of HO-1 (Figure 5). In conclusion, our data

demonstrate that the ability of HO-1 to alleviate liver fibrosis is correlated with the regulation of PPAR $\gamma$  and NF- $\kappa$ B, which construct a complex network system. Further study with regard to this mechanism will help us to form new strategies for the effective treatment of liver fibrosis.

## COMMENTS

### Background

Heme oxygenase-1 (HO-1) is a microsomal enzyme and rate-limiting enzyme. HO-1 and degradation products are important defense mechanisms against many kinds of liver injuries. In chronic liver disease, induction of HO-1 is important to prevent the development of liver fibrosis effectively. However, the underlying molecular mechanisms are still unknown.

### Research frontiers

Peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ) is a ligand-activated transcription factor which benefits the maintenance of the hepatic stellate cell (HSC) static phenotype. Nuclear factor-kappa B (NF- $\kappa$ B) plays an important role in the regulation of gene transcription which can promote HSC proliferation and decrease HSC apoptosis, then aggravate liver fibrosis. Studies have shown that co-regulation exists between HO-1 and PPAR $\gamma$ . HO-1 can mediate the effect of PPAR $\gamma$ . Studies have also found that there is an NF- $\kappa$ B binding site in the HO-1 promoter region. HO-1 plays an important role in the down-regulation of NF- $\kappa$ B activation.

### Innovations and breakthroughs

In this study, by establishing a model of liver fibrosis in rats, the authors attempted to investigate the effects of HO-1 on liver fibrosis, and to evaluate whether the role of HO-1 in liver protection was achieved by regulating the expression of PPAR $\gamma$  and NF- $\kappa$ B, which are both important in the process of liver fibrosis.

### Applications

This study further clarified one of the mechanisms of HO-1 in liver protection, which could help provide a new strategy for treating liver fibrosis.

### Terminology

HO-1, also known as heat shock protein 32, is a microsomal enzyme and rate-limiting enzyme that catalyzes heme degradation into biliverdin, iron atoms and carbon monoxide. HO-1 and its breakdown products play vital physiological roles in anti-inflammation, anti-oxidation and regulation of apoptosis according to reports. PPAR is a ligand-activated transcription factor which is widely distributed in the tissues. Three PPAR subtypes have been identified, namely  $\alpha$ ,  $\beta$  and  $\gamma$ . NF- $\kappa$ B is an important nuclear transcription factor, which plays an important role in the regulation of gene transcription such as cytokines, chemokines, adhesion molecules and other inflammatory mediators. Zinc protoporphyrin-IX is a selective HO inhibitor which can suppress the activity of HO-1 by blocking carbon monoxide production and restricting the transformation of heme to biliverdin. Hemin is a well-known physiological substrate and potent inducer of HO activity.

### Peer review

The authors explored the protective effect of HO-1 in the CCl $_4$  rat model of liver fibrosis. In order to determine the mechanism of such protection, the authors evaluated the expression of two important transcription factors, PPAR $\gamma$  and NF- $\kappa$ B. These transcription factors are involved in regulation of hepatic stellate cell activation, the primary cell responsible for liver fibrosis. This study proposes a pathway for the protective action of HO-1 in liver fibrosis. If reproduced by other investigators, this pathway could provide information that helps in designing new therapies for prevention and treatment of liver fibrosis.

### Abstract

**AIM:** To analyze the literature on the use of Chinese herbal medicines for the treatment of cholecystitis.

**METHODS:** The literature on treatment of cholecystitis with traditional Chinese medicines (TCM) was analyzed based on the principles and methods described by evidence-based medicine (EBM). Eight databases including MEDLINE, EMBASE, Cochrane Central (CCTR), four Chinese databases (China Biological Medicine

Database, Chinese National Knowledge Infrastructure Database, Database of Chinese Science and Technology Periodicals, Database of Chinese Ministry of Science and Technology) and Chinese Clinical Registry Center, were searched. Full text articles or abstracts concerning TCM treatment of cholecystitis were selected, categorized according to study design, the strength of evidence, the first author's hospital type, and analyzed statistically.

**RESULTS:** A search of the literature published from 1977 through 2009 yielded 1468 articles in Chinese and 9 in other languages; and 93.92% of the articles focused on clinical studies. No article was of level I evidence, and 9.26% were of level II evidence. The literature cited by Science Citation Index (SCI), MEDLINE and core Chinese medical journals accounted for 0.41%, 0.68% and 7.29%, respectively. Typically, the articles featured in case reports of illness, examined from the perspective of EBM, were weak in both quality and evidence level, which inconsistently conflicted with the fact that most of the papers were by authors from Level-3 hospitals, the highest possible level evaluated based on their comprehensive quality and academic authenticity in China.

**CONCLUSION:** The published literature on TCM treatment of cholecystitis is of low quality and based on low evidence, and cognitive medicine may function as a useful supplementary framework for the evaluation.

Dong ZY, Wang GL, Liu X, Liu J, Zhu DZ, Ling CQ. Treatment of cholecystitis with Chinese herbal medicines: A systematic review of the literature. *World J Gastroenterol* 2012; 18(14): 1689-1694 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i14/1689.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i14.1689>

## INTRODUCTION

Cholecystitis, defined as a type of acute or chronic inflammation occurring in the gallbladder caused by infection, bile stimulus, reflux of pancreatic juice to the biliary passage, as well as bilirubin and lipoid metabolic disorders *etc.* Cholecystitis is often secondary to previously asymptomatic gallstone disease<sup>[1]</sup>. Around 90%-95% of cholecystitis cases are claimed to be caused by gallstone disease, the incidence of which is 8%-10% in America and 3%-11% in China<sup>[2,3]</sup>. Recent epidemiological studies have shown that the incidence of cholelithiasis has been continuously rising, and the rate is doubling every 10 years<sup>[4]</sup>. The incidence rate of cholelithiasis grows steadily with age, varies by race, and occurs more frequently in female patients than in male patients<sup>[2]</sup>.

For symptomatic cholecystitis, antibiotics and antispasmodic treatment are conventional therapy while cholecystectomy or laparoscopic cholecystectomy are also appropriate modalities of treatment<sup>[5]</sup>. However gallstone disease of this type may recur within several months. Gallstones may also recur in the biliary tract after cholecystectomy<sup>[2]</sup>. Therefore, it is important to identify effective treatment options and adjuvant therapeutic methods for cholecystitis. Traditional Chinese medicines (TCM) has a long history of use for treating cholecystitis and has developed an integrate system of medical examination and treatment. Classic TCM works such as Huang Di Nei Jing and Shang Han Za Bing Lun have both expounded on this disease in depth. In TCM, cholecystitis is categorized as a type of illness with symptoms such as aching over the lateral torso, jaundice, hepatic distention, gallbladder distention and abdominal pain, *etc.*<sup>[6,7]</sup>. Cholecystitis is considered by TCM to be caused mainly by unrestrained food and drink, exogenous heat and moisture, chronic illness and/or injury<sup>[8]</sup>.

The large quantity of research literature on the TCM treatment of cholecystitis in China stimulates the development of innovative and improved therapeutic methods for the treatment of the disease. However, even basic information about the literature such as the level of evidence, quantity, trends in publication, and existence of research institutes remains unclear since they have not been sufficiently studied or evaluated outside of China due to barriers by language and access. Thus, a comprehensive analysis of this large quantity of literature is urgently required.

Based on the principles and methods described by evidence-based medicine (EBM), this study conducted an examination and statistical analysis of current literature on the treatment of cholecystitis with TCM, aiming to

discuss the necessity for a systematic review as well as producing a reference to enable better research of TCM.

## MATERIALS AND METHODS

### Literature search

Electronic literature searches were conducted on the following databases: China Biological Medicine Database (CBM), Chinese National Knowledge Infrastructure Database (CNKI), Database of Chinese Science and Technology Periodicals (VIP), Database of Chinese Ministry of Science and Technology (Wanfang), The Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE (*via* PubMed) and EMBASE. The databases were searched from the earliest possible date until June 1, 2009. The search terms included (“Cholecystitis” or “Acalculous Cholecystitis” or “Emphysematous Cholecystitis” or “Cholecystitis, Acute” or “Cholecystitis, Chronic”) and (“Chinese herbs” or “TCM” or “Chinese medicine” or “Integrated TCM WM” or “herb” or “herbs” or “traditional Chinese medicine” or “Drugs, Chinese Herbal”). The search terms were adjusted depending on the database being searched. Titles and abstracts of all citations were screened independently by two reviewers (Dong ZY and Wang GL).

### Literature selection criteria

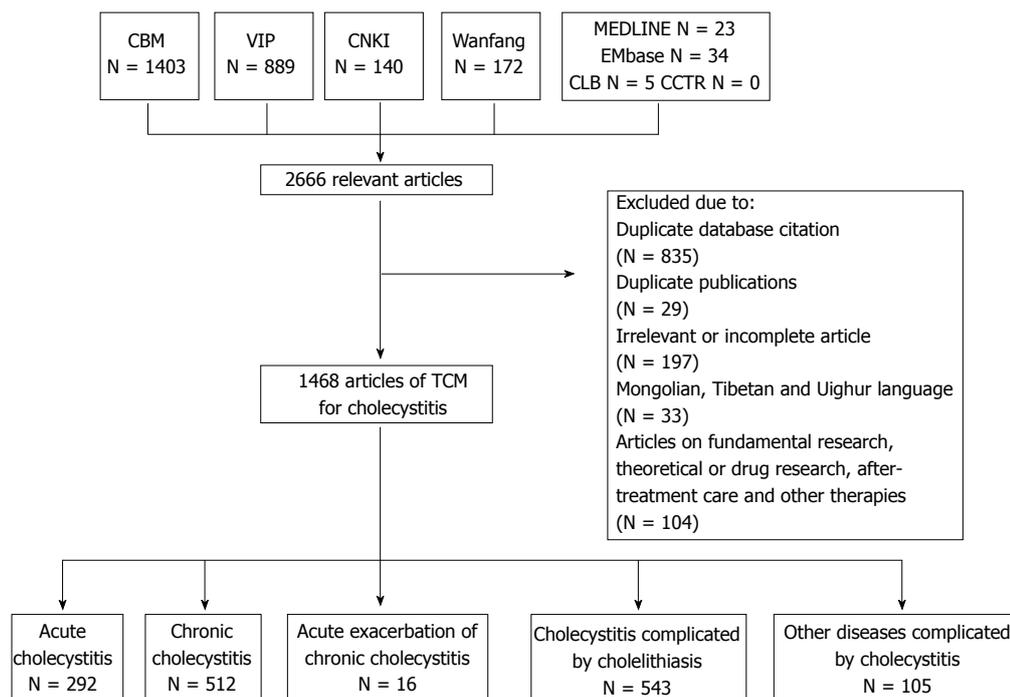

Articles on TCM treatment of cholecystitis were included; and articles on cholecystitis treated by integrated traditional Chinese and modern medicine were included.

### Data acquisition and quality assessment

The full-text of articles that met all the selection criteria was retrieved. The data were screened independently by two reviewers (Dong ZY and Wang GL) using a self-made data extraction form which collected the following information: year of publication, first author, the organization of the first author, the hospital level of the first author, titles of authors, study design, type of article, journal name, and indexed/citation situation by medical indexing databases. The first author of each article was contacted if there were any missing data. Articles that did not meet the inclusion criteria were excluded by reading the titles and summaries. Disagreements whether a paper was to be included were resolved by discussion.

### Methodology of data classification

Methodology of data classification were listed below. (1) Classified by types of study<sup>[9]</sup>; (2) Classified according to indexed/citation situation (evaluated according to 2008 edition of “Guide to the Core Journals”, and the list of MEDLINE contains Chinese journals 2008)<sup>[10,11]</sup>; (3) Classified according to the first authors’ hospital-level<sup>[12]</sup>: Level-3 hospital - The national, provincial, municipal large hospitals and affiliated hospitals of medical colleges; Level-2 hospital - General hospitals of cities, counties, districts, hospitals affiliated to factories, mining enterprises and institutions; Level-1 hospital - Country-

**Figure 1 Prism flow diagram.** CBM: China Biological Medicine Database; VIP: Database of Chinese Science and Technology Periodicals; CNKI: Chinese National Knowledge Infrastructure Database; CLB: The Cochrane Library; CCTR: Cochrane Central; TCM: Traditional Chinese medicines; N: Number.

side primary hospitals, townships or neighborhood community and private clinics and hospitals; and (4) Classified according to the strength of evidence (Grading quality of evidence and strength of recommendations, strength grading standards by Cochrane Collaboration)<sup>[13]</sup>.

### Statistical analysis

Statistical data were collected and recorded in Excel and SPSS 17.0. Percentages, percentage bar charts and trends lines were produced to analyze the situation and trends, while the constituent ratios were expressed in terms of percentages in order to perform a descriptive analysis.

## RESULTS

### Results of literature screening

Altogether 2666 potentially relevant articles were retrieved from eight databases, among which 1822 were written in Chinese and 835 were duplicate citations between databases. Twenty-nine duplicate articles were excluded; there were 197 irrelevant or incomplete articles; 33 articles were written in Mongolian, Tibetan and Uighur; and 104 articles were on fundamental research, theoretical or drug research, after-treatment care and other therapies. Thus, there were 1468 articles on the TCM treatment of cholecystitis in total. Among these articles, there were 292 concerning cholecystitis, 512 regarding chronic cholecystitis, 16 regarding acute exacerbation of chronic cholecystitis, 543 regarding cholecystitis complicated by cholelithiasis, and 105 on other diseases complicated by cholecystitis. Among the retrieved articles, 9 were foreign articles, including 2 in Bulgarian, 1 in Russian and 6 in English (Figure 1).

We also searched Evidence Based Complementary and Alternative Medicine (eCAM), The American Journal of Chinese Medicine (AJCM), Journal of Chinese Integrative Medicine (J Chin Integr Med), Chinese Journal of Integrated Traditional and Western Medicine and Alternative Medicine Review (Altern Med Rev). No relevant articles were found in any of these sources.

### Literature type

In total, 1468 articles on TCM treatment of cholecystitis were retrieved: 15 articles on treatment and care, 24 on animal and fundamental experimental research, 25 on theoretical research, 9 on relevant drug research and 22 on other therapies including massage, ear points, diet, infrared ray, acupuncture and ultrasonic therapy, *etc.* The data revealed that researches on clinical treatment covered the majority of the relevant literature, with the percentage as high as 93.92%, and that TCM was applied to treat almost all types of cholecystitis (Table 1).

### Evidence level of the literature

The 1468 articles were categorized according to the Cochrane collaboration criteria as shown in Table 2. No article was included into the category of the highest evidence strength, namely level I, while 136 (9.26%) articles were categorized into level II, 101 articles (6.88%) into level III, 961 articles (65.46%) into level IV; and 270 articles (18.39%) into level V. This revealed that, with randomized controlled trial (RCT) forming a low percentage, the evidence level of the research literature on TCM treatment of cholecystitis appears to be relatively low, requiring a further systematic evaluation of RCT in

Research institutes	0	7	0	6	2	15

order to determine the efficacy and safety of the TCM treatment of cholecystitis.

**General status of the literature included by databases**

Among the 1477 articles on TCM treatment of cholecystitis both in Chinese and English, 107 (7.24%) were included by core Chinese journals. The 10 articles included in MEDLINE and the 6 in SCI represented 0.68% and 0.41% of the articles, respectively. This reflects a seemingly inadequate writing quality, low research level of the literature, and a generally low international recognition.

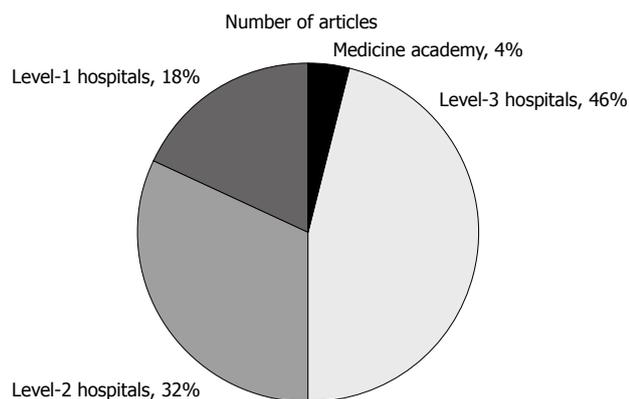

**Distribution of the first authors' hospitals**

The 1468 Chinese articles on TCM treatment of cholecystitis were categorized according to the first authors' hospital levels as shown in Table 3. Among the literature, authors from level-3 hospitals contributed 464 articles (31.61%); level-2 hospitals 538 (36.65%); medical schools

and universities 51 (3.47%); research institutes 15 (1.02%); and level-1 hospitals, township hospitals and private clinic/hospitals contributed 400 (27.25%). This shows that the authors of the research literature in this study mainly came from level-3 and level-2 hospitals, which accounted for 68.26% of the total. The RCT distributed as such: level-3 hospitals contributed 62 articles (45.59%); level-2 hospitals 43 (31.62%), level-1 hospitals and others 25 (18.38%); medical schools and universities 6 (4.41%) (Figure 2). Literature with a higher evidence level was also mainly contributed by authors from level-3 hospitals and medical schools/universities.

**DISCUSSION**

From the above analysis, two major weaknesses were revealed by the selected literature on TCM treatment of cholecystitis. The first one is that only few papers were

**Figure 2** Distribution of the hospitals where the first authors of the randomized controlled trial research on traditional Chinese medicines treatment of cholecystitis come from.

included by SCI and MEDLINE. Although it is not appropriate to evaluate the quality of papers merely according to whether they are included by SCI, MEDLINE and other core medical databases, it is an objective index to certain degrees, based on the strict selection rules and expert evaluation system of SCI and MEDLINE<sup>[14]</sup>.

The second weakness of the literature in general lies in its low evidence level. The concept of evidence levels originated from the emergence and development of EBM, and was first proposed by the clinical epidemiologist Dave Sackett from McMaster University of Canada in 1990<sup>[15-17]</sup>. High-quality papers and RCTs require an adequate high-quality research platform. Is the large quantity of papers with low evidence level given rise to by an inadequate platform for the research of TCM? To answer this question, after analyzing the distribution of the hospitals, institutions or universities of the first authors, we discovered that 35.08% of the papers were contributed by authors from level-3 hospitals and universities. This accounts for all the articles included by SCI or published in core journals not included in SCI, while 64.92% of the articles were from level-1 and level-2 hospitals with a relatively low research capacity, which indicates a close correlation between the quality of published papers and the research platform. We also found from the data that RCTs hold only less than 10% of all TCM clinical studies, which is an outstanding difference compared to the 70% share of RCTs in the clinical study of modern medicine. Why such a low percentage TCM clinical study is from RCTs is a significant question that deserves further consideration<sup>[18]</sup>.

EBM is a young discipline; the first International EBM Research Center was established in the United Kingdom in 1993, and the first EBM Research Center in China was set up three years later and quickly motivated the spread of EBM theory within China. Although the preference of Chinese TCM researchers for clinical study models somewhat limits the strict RCT research to a certain degree, TCM has its own unique treatment models and standards which deserves proper recognition. For example, it advocates individualized treatment and medication. Namely,

different treatment methods and medication might be applied to the same disease and even the same syndrome according to different physical conditions of the individual patient or even according to the different time and place that the illness occurs. This makes it hard for TCM to conduct a high-quality RCT which might be the major cause resulting in the low evidence level of these Chinese papers.

By examining the literature on the treatment of cholecystitis with TCM according to the principles of EBM, we hope to expose the problems and weakness in current TCM clinical studies so as to raise the quality of TCM research.

Here arises the question, how to evaluate the therapeutic effectiveness of TCM more scientifically? This is the right and urgent question that not only TCM but also the entire alternative and complementary medicine should address. EBM experts are trying to further perfect the research standard of RCTs and drafting research guidelines that can better meet the characteristics of TCM. Besides, more scholars are trying to improve the present frame of EBM. Professor Keine<sup>[18]</sup> from the Institute for Applied Epistemology and Medical Methodology in Germany has conducted a study of cognition-based medicine. Cognition-based medicine is a newly-developed methodological system of scientific medicine. Its primary element is the criteria-based assessment of therapeutic causality at the level of the individual patient<sup>[19]</sup>. Principles and criteria of single-case causality assessment have been analyzed and explained. Cognition-based medicine enables a methodological professionalization of clinical judgment as well as the explication of physician experience and expertise. Cognition-based medicine study design expands the current range of clinical research, extending from criteria-based causality assessment in single cases to new forms of cohort evaluations. Though cognition-based medicine studies only started recently, this trend is inspiring and promising. It will not only facilitate the evaluation of TCM, which greatly emphasize individualized medical treatment solution, but also accord with the trend of medical development which stresses the significance of individualized treatment, and cognition-based medicine, a beneficial complement to EBM, may play a significant role in clinical research<sup>[20,21]</sup>.

## ACKNOWLEDGMENTS

The authors are thankful to Maxim S Petrov (The University of Auckland, Auckland, New Zealand); Professor You-Ping Li (Chinese Cochrane Centre/Chinese Evidence-Based Medicine Centre/West China Hospital, Sichuan University, China); Dr. Li-Ting Xiao, Dr. Yi-Cai Xiao and Dr. Liang Peng (The First Affiliated Hospital of Guangxi Medical University, Nanning, China); Dr. Qian-Wei Shi (Changhai Hospital Affiliated Second Military Medical University, Shanghai, China); and Karin Dearnness (McMaster University, Canada) for their help in this study.

## COMMENTS

### Background

Epidemiological studies have shown that the incidence of cholelithiasis in recent years has been continuously rising and doubling every 10 years. For symptomatic cholecystitis, antibiotics and antispasmodic treatment are adopted clinically as conventional therapy while cholecystectomy or laparoscopic cholecystectomy are also considered as surgical modalities. However, gallstone disease of this type may recur within several months. Gallstones may also recur in the biliary tract after cholecystectomy. Therefore, it is important to identify effective treatment options and adjuvant therapeutic methods for cholecystitis.

### Research frontiers

By analyzing, from the perspective of evidence-based medicine, the substantial amount of Chinese literature over the past 10 years concerning the use of traditional Chinese medicine in the treatment of cholecystitis, the authors discovered the problems existing in these relevant studies, and proposed that cognitive medicine could provide supplementary methodology for future research.

### Innovations and breakthroughs

When reviewing the large amount of relevant Chinese literature according to the evaluation standards provided by evidence-based medicine, most of the articles appear to be of poor design, quality and evidence level. However, many of these studies showed that traditional Chinese medicine functions effectively in treating cholecystitis. Cognition-based medicine, a beneficial complement to evidence-based medicine, may play a significant role in clinical research.

### Applications

More appropriate randomized controlled trials with large samples should be designed and conducted in order to reasonably evaluate the efficacy of traditional Chinese medicine in the treatment of cholecystitis, and cognitive medicine also functions as a useful supplementary framework for the evaluation.

### Terminology

Evidence-based Medicine (EBM) aims to apply the best available evidence gained from the scientific method to clinical decision making. It seeks to assess the strength of evidence of the risks and benefits of treatments and diagnostic tests. Cognition-based medicine is a newly-developed methodological system of scientific medicine. Its primary element is the criteria-based assessment of therapeutic causality at the level of the individual patient. Principles and criteria of single-case causality assessment have been analyzed and explicated. Cognition-based medicine enables a methodological professionalization of clinical judgment as well as the explication of physician experience and expertise. Cognition-based medicine study designs expand the current range of clinical research, extending from criteria-based causality assessment in single cases to new forms of cohort evaluations. Though cognition-based medicine study only started in recent years, this trend is inspiring and promising.

### Peer review

The main stay of cholecystitis treatment is either laparoscopic cholecystectomy while it is a "hot" or conservative management with antibiotics and analgesia followed by laparoscopic cholecystectomy approximately 8 wk later. However, alternative medical therapies are used when the patient is unfit for surgical intervention. The article is suitable for publication in WJG.

### Abstract

Conventional manometry presents significant challenges, especially in assessment of pharyngeal swallowing, because of the asymmetry and deglutitive movements of oropharyngeal structures. It only provides information about intraluminal pressure and thus it is difficult to study functional details of esophageal motility disorders. New technology of solid high resolution impedance manometry (HRIM), with 32 pressure sensors and 6 impedance sensors, is likely to provide better assessment of pharyngeal swallowing as well as more information about esophageal motility disorders. However, the clinical usefulness of application of HRIM in patients with oropharyngeal dysphagia or esophageal dysphagia is not known. We experienced a case of Huntington's disease presenting with both oropharyngeal and esophageal dysphagia, in which HRIM revealed the mechanism of oropharyngeal dysphagia and provided comprehensive information about esophageal dysphagia.

### INTRODUCTION

Conventional manometry presents considerable challenges in evaluation of oropharyngeal dysphagia because of the asymmetry and deglutitive movements of oropharyngeal structures<sup>[1]</sup>. Introduction of high resolution manometry (HRM), which employs pressure sensors at 1 cm intervals across the entire anatomic region from the oropharynx to the stomach represented a significant improvement in data recording and diagnostic yield, especially in cases of functional dysphagia over conventional manometry<sup>[1,2]</sup>. However identifying a manometric abnormality does not equate to identifying a disease and thus achalasia and (perhaps) diffuse esophageal spasm are relevant to manometric findings, which have a functional correlate and can cause dysphagia<sup>[3]</sup>. Most recently, high resolution impedance manometry (HRIM) has been introduced to combine the benefits of HRM and impedance-based bolus transit assessment. Actually patients with normal manometry can have abnormal bolus transit, and patients with abnormal manometry can have normal bolus transit<sup>[4]</sup>. Koya *et al*<sup>[5]</sup> reported that abnormal impedance even in patients with normal manometry may be a sensitive indicator of esophageal functional abnormality as represented by the symptom of dysphagia in these patients.

To our knowledge, little is known with regard to in-

investigation of dysphagia using the HRIM technique. We experienced a case of Huntington's disease presenting with both oropharyngeal and esophageal dysphagia, in which HRIM revealed the mechanism of oropharyngeal dysphagia, and provided comprehensive information about esophageal dysphagia.

## CASE REPORT

### Present illness

A 65-year-old male was admitted to the hospital because of a 5-year history of progressive dysphagia. Five years before admission, he began to have difficulty in swallowing liquids such as tea and thin soup. Three years later he complained of difficulty in eating liquids as well as solid foods, pain extended up to the manubrium, and he had lost 12 kg in weight. Ten years before admission, the patient became aware of involuntary movements of all his limbs and face. In his family history, his mother and younger brother complained of the same symptoms.

### Physical study in general and neurological study

The patient had a history of pulmonary tuberculosis, which had been cured 30 years previously. He had smoked cigarettes for 40 years. He had drunk moderate amounts of alcohol for 40 years, but he had stopped drinking 3 years before admission. His body temperature was 36.5 °C, pulse was 85 bpm, and respirations were 18 breaths/min. Blood pressure was 125/85 mmHg. Physical examination revealed mild dysarthria, chorea, and limitation of down gaze in eye movement. No muscle rigidity, muscle atrophy or pathologic reflexes were noted. Brain magnetic resonance imaging exhibited ventriculomegaly and mild atrophy in all regions of his brain. The patient was finally diagnosed with Huntington's disease by the result that the CAG repeat numbers in the Huntington gene were 44 in comparison with the normal numbers of 10-35.

### Endoscopic study

The whole mucosa of the hypopharynx and esophagus was normal except for a mucosal break less than 5 mm from the esophagogastric junction. Endoscopy revealed relatively normal opening of the upper esophageal sphincter (UES) and low esophageal sphincter, and no presence of residual food in the esophagus. However, spastic contraction of the mid esophagus was noticed.

### Esophagogram study

Esophagography demonstrated barium retention with significant delay of contrast passage into the stomach. There were frequent irregular contractions between the mid and distal esophagus. There were no typical signs of primary esophageal motility disorder such as bird-beak appearance or corkscrew appearance.

### Video fluoroscopic swallowing study

On swallowing of a spoonful of pudding mixed with

barium powder, the patient had a tendency to eat rapidly. Labial closure was normal but disorganized tongue movement, as well as postural instability induced by chorea resulted in residual bolus in the vallecula and pyriform sinuses.

### HRIM study

A solid-state HRIM manometry assembly (Sandhill Scientific Instruments Inc. United States) was used to evaluate dysphagia in the patient. A HRIM study was also performed in 26 healthy persons to compare the characteristics of pharyngeal motility. The HRIM catheter was 4.0 mm diameter with 32 solid pressure sensors and 6 impedance sensors. The 4 active impedance channels were located in the traditional locations for analysis, i.e., 5, 10, 15 and 20 cm above the high pressure zone of the lower esophageal sphincter (LES). There were 32 pressure sensors which spanned the esophagus from UES to the LES to allow for evaluation of swallows from initiation of the swallow to closure of the LES. The zero mark on the probe was located at the channel used for LES analysis. The study was performed in a sitting position after at least 6-h fasting. The HRIM assembly was passed transnasally and positioned to record from the hypopharynx to the stomach with about 3-5 intragastric sensors. The catheter was fixed in place by taping it to the nose. The manometric protocol included a 5-min period to assess basal sphincter pressure, 10 5-mL saline swallows and 10 5-mL viscous swallows (so called standard method). Manometric data were acquired and stored using software (Sandhill Scientific Instruments Inc. United States). The HRIM catheter was pulled back by 10 cm and the same sessions were repeated because of inability to assess all the pharyngeal manometric information and bolus transit of pharyngoesophageal segment (so called modified method). Takasaki *et al*<sup>[6]</sup> reported that vocalizing "kakakaka" in investigation of pharyngeal swallow using high resolution manometry easily identified the locations of the velopharyngeal swallowing pressure. Therefore vocalizing "kakakaka" was added to the HRIM study using modified method.

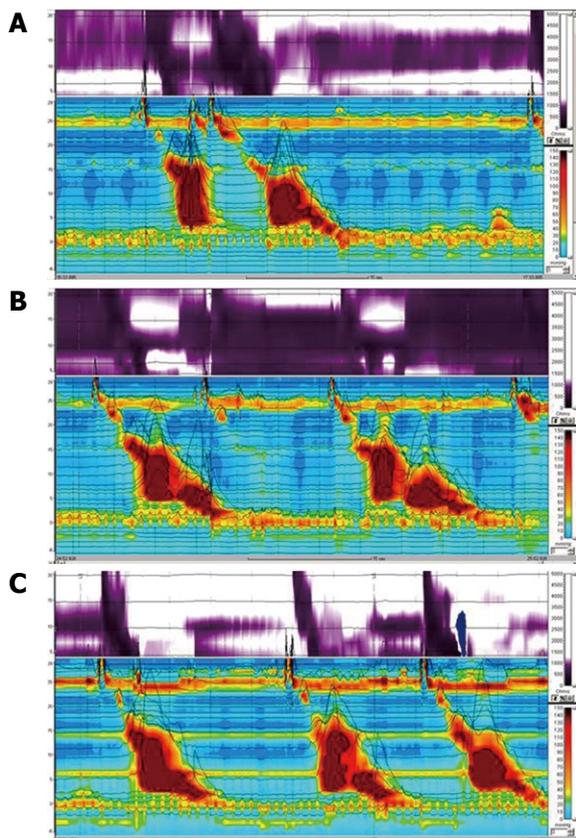

### Initial HRIM findings by the standard method

The results of HRIM by the standard method are summarized in Table 1. Impedance results demonstrated 100% swallowing with incomplete bolus transit of both the liquid and the viscous solution. Manometric results revealed high LES pressure with incomplete relaxation (Figure 1A). For liquid bolus, distal esophageal high pressure simultaneous repetitive contraction was observed in 70% of swallows on the manometric topographic view and abnormal liquid transit was noted on the impedance contour view. For viscous bolus, contractile pressures were higher, and simultaneous repetitive contractions were noted on the manometric topographic view, which was associated with the sensation of retrosternal bolus hold-up, chest pain, and abnormal viscous transit (Figure 1B).

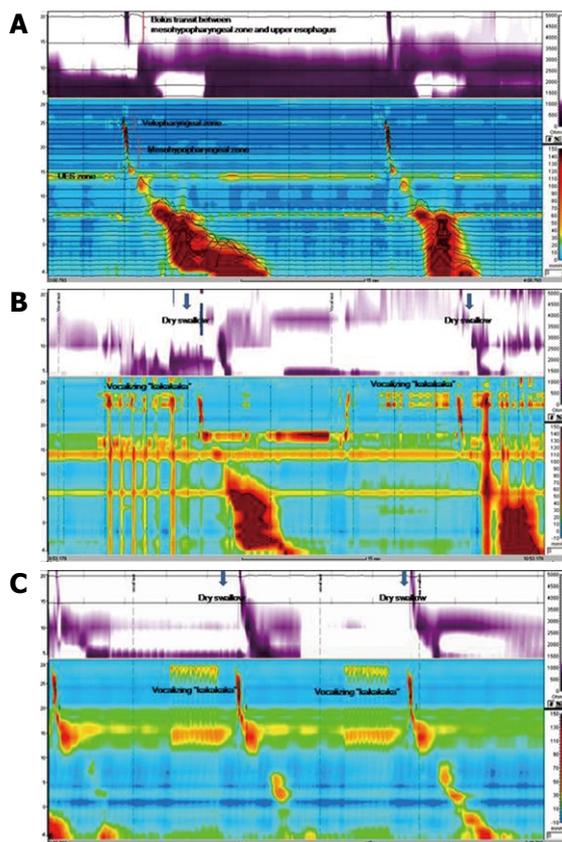

**Table 1 High resolution impedance manometric findings by the standard method**

	Initial finding	After botulinum toxin injection
<b>Manometry</b>		
LES pressure (mmHg)	44.2	37.2
<b>Relaxation of LES</b>		
Residual pressure (mmHg)	12.1	10.8
Duration (s)	10.1	9.3
Relaxation percent (%)	74	71
<b>Body peristalsis</b>		
Simultaneous contraction (%)	70	60
Peristaltic contraction (%)	30	40
Aperistalsis (%)	0	0
Amplitude of lower esophagus (mean, mmHg)	441	382
<b>Impedance</b>		
<b>Liquid swallow</b>		
Incomplete bolus transit (%)	100	70
Complete bolus transit (%)	0	30
<b>Viscous swallow</b>		
Incomplete bolus transit (%)	100	70
Complete bolus transit (%)	0	30

LES: Lower esophageal sphincter.

**Figure 1 High resolution impedance manometry findings using the standard protocol.** A: Liquid swallowing at admission reveals high amplitude, simultaneous contractions of esophageal body with incomplete lower esophageal sphincter relaxation, and incomplete bolus transit; B: Viscous swallowing at admission demonstrates higher amplitude, repetitive contractions and incomplete bolus transit; C: After injection of botulinum toxin, the isocontour of impedance shows considerably improved bolus transit compared with those at admission during saline swallows (Figure 1A), but spasms are still seen on the isocontour of manometry.

**Figure 2 High resolution impedance manometry findings using modified protocol.** A: Patient; unremarkable peristaltic contraction and bolus transit between the hypopharynx and upper esophagus are seen after pull back of the catheter; B: Patient; irregular contractions are seen at the velopharyngeal zone, and simultaneous contraction between velopharyngeal and mesohypopharyngeal zone accompanying impaired bolus transit of pharyngo-upper esophageal segment after vocalizing “kakakaka”; C: Healthy subject without dysphagia; regular contractions are noted at the velopharyngeal zone, and peristaltic contractions of pharyngo-upper esophageal segment are normal as well as bolus transit after vocalizing “kakakaka”.

**HRIM findings by the standard method after post-botulinum toxin injection**

Given the esophageal dysmotility with a spastic component, subsequent trials of a proton pump inhibitor, a nitrate, a calcium channel blocker, and a phosphodiesterase inhibitor were made for 1 mo. There was no response to these drugs in the patient. Treatment with 100 U botulinum toxin injected around the lower esophagus showed considerable improvement in the impedance results and in symptoms such as retrosternal bolus hold-up and chest pain despite no change in the manometry results (Figure 1C).

**Initial HRIM findings by the modified method**

HRIM using the standard method demonstrated normal UES relaxation and peristaltic pharyngeal pressure (UES pressure 41.1 mmHg, residual pressure -1.1 mmHg, duration 0.6 s, 100% relaxation). After withdrawal of the catheter by 10 cm, HRIM revealed unremarkable bolus transit and peristalsis between the meso hypopharynx and upper esophagus (Figure 2A). However, HRIM using the modified method and vocalizing “kakakaka”

revealed irregular contractions of the velopharyngeal zone, simultaneous contraction between the velopharyngeal and mesohypopharyngeal zone, and impaired bolus transit of the pharyngo-upper esophageal segment (Figure 2B). In contrast to the HRIM findings of our case, HRIM findings using the modified method from all healthy persons showed regular contractions of the velopharyngeal zone and normal bolus transit between mesohypopharyngeal zone and the upper esophagus (Figure 2C).

## DISCUSSION

To our knowledge, this report is the first study of Huntington's disease using HRIM, which indicated the combined oropharyngeal and esophageal dysphagia. The patient had difficulty in initiating swallowing and had retrosternal bolus hold-up. Insidious onset of dysphagia associated with some neurologic symptoms such as chorea and dysarthria suggested oropharyngeal dysphagia from a neurologic basis. A video fluoroscopic swallowing study provided the diagnosis of oropharyngeal dysphagia which resulted from a lack of coordination between the oral and pharyngeal stage. Unexpected involuntary movement in the oral cavity induced oropharyngeal incoordination. Oropharyngeal dysphagia in Huntington's disease results from tachyphagia, or rapid uncontrolled swallowing, secondary to impaired sensory and cognitive function<sup>[7]</sup>. Furthermore, it is caused by buccolingual chorea resulting in food being transferred impulsively<sup>[7]</sup>. Respiratory chorea, marked by involuntary respiratory movements, occurs in approximately 40% of patients, and interrupts the normal respiratory-deglutition cycle<sup>[8]</sup>. Given the anatomical structures involved in vocalization, the HRIM findings using the modified method may reflect the mechanism of oropharyngeal dysphagia in the Huntington's disease patient. In other words, the modified test may disclose oropharyngeal incoordination related to buccolingual chorea, which cannot be detected even with HRM or HRIM using the usual protocol such as the liquid and viscous swallow test. Further investigation should be carried out to confirm the role of the vocal test in either HRM or HRIM studies for assessing oropharyngeal dysphagia related to chorea.

HRIM results concerning esophageal dysphagia appeared to indicate diffuse esophageal spasm (DES) such as simultaneous contraction associated with > 10% of wet swallows, mean simultaneous contraction amplitude > 30 mmHg, and repetitive contractions. Esophageal dysmotility of the patient, however, can be better classified as an atypical disorder of LES relaxation because there was incomplete relaxation of the LES<sup>[9]</sup>. The esophageal dysmotility in this case may be an intermediate form between DES and achalasia because a few case reports have suggested a transition from DES to achalasia in some patients<sup>[10-12]</sup>.

Kagel *et al.*<sup>[13]</sup> reported esophageal dysphagia was relatively uncommon in Huntington's disease. It was most

likely secondary to the disruptive effects of chorea in the aerodigestive tract. To our knowledge there has been no report regarding spastic esophageal dysmotility in Huntington's disease. The cause of the spastic esophageal motility disorder in the patient was unknown. There are a few studies documenting acid reflux-induced esophageal spasm<sup>[12,14,15]</sup>. Simultaneous contractions from gastroesophageal reflux should be treated first by a proton pump inhibitor<sup>[16]</sup>. Reflux esophagitis in this case may be considered the cause of the esophageal dysmotility with a spastic component. However, there was no improvement under therapy with a proton pump inhibitor.

Considering dysphagia associated with chest pain attributable to esophageal spasm, subsequent trials of a nitrate, a calcium channel blocker, and a phosphodiesterase inhibitor were performed. There was no response to these drugs in the patient. Actually current treatments for esophageal spasm, including calcium channel blockers and nitrate donors, are limited by poor efficacy and side effects<sup>[17]</sup>. Recently botulinum toxin injections in the lower esophagus and at the level of the gastroesophageal junction have been reported to have a beneficial effect in patients suffering from DES<sup>[18-20]</sup>. These beneficial effects of botulinum toxin are perhaps related to the improved manometric results. Interestingly, injection of botulinum toxin in this case showed improvement in impedance results and symptoms despite no improved manometry results. It suggests that the esophageal symptoms are more closely related to disturbed bolus transport and impaired clearance than esophageal dysmotility *per se*<sup>[4]</sup>. It may also suggest that esophageal dysmotility in terms of abnormal contractility and impaired bolus transit is limited in explaining the dysphagia. Dysphagia symptoms are related to factors other than esophageal dysmotility, e.g., esophageal sensitivity disorder.

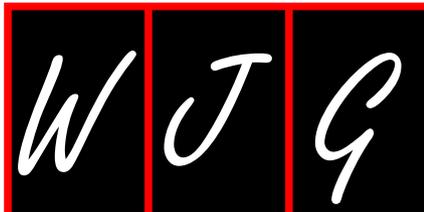

In conclusion, HRIM enabled us to obtain more detailed and important information in the Huntington's disease patient with both oropharyngeal dysphasia and esophageal spastic dysmotility. Further investigation of HRIM will be needed to assess its role in either oropharyngeal or esophageal dysphagia.

### Abstract

According to a review article by Biecker *et al* published in a previous issue of *World Journal of Gastroenterology* in March 2011, intestinal decontamination with norfloxacin remains the mainstay of primary prophylaxis of spontaneous bacterial peritonitis (SBP) at the expense of development of quinolone-resistant bacteria after long-term use. In our research, the administration of a 4-wk regimen with rifaximin 1200 mg/d reduced significantly the ascitic neutrophil count in cirrhotic patients with sterile ascites in line with a significant decrease in plasma endotoxin levels. Our observations concur with recent findings, showing a significantly reduced 5-year probability of SBP in cirrhotic patients taking rifaximin.

### TO THE EDITOR

We read with great interest the article by Biecker *et al*<sup>[1]</sup> regarding management of ascites published on *World J Gastroenterol* 2011; 17: 1237-1248. Development of spontaneous bacterial peritonitis (SBP) is a major complication of ascites and possibly the final step in a series of events, including intestinal bacterial overgrowth (IBO), bacterial translocation (BT) resulting in bacteremia, endotoxemia, and colonization of mesenteric lymph nodes, and finally seeding of bacteria into the ascitic fluid (AF). Indeed, SBP in non-hospitalized patients is mostly caused by gram-negative bacteria of intestinal origin. It has been hypothesized that patients at risk of SBP have probably sustained multiple episodes of colonization and resolution before they present with the first clinically apparent infection. In this respect, a previous study showed that higher neutrophil counts in sterile AF are associated with higher risk of subsequent development of SBP<sup>[2]</sup>. The high mortality of SBP warrants its prevention with administration of antibiotics aimed at decreasing the burden of gut bacteria, thus interrupting the sequence of events leading to AF infection. Norfloxacin is widely used for primary prophylaxis of SBP; however its extensive long-term use has increased the incidence of quinolone-resistant and gram-positive SBP<sup>[1]</sup>.

Rifaximin is an antibiotic with a broad-spectrum activity against gram-positive and gram-negative microorganisms within the gastrointestinal tract. The main

**Figure 1** Individual changes in ascitic fluid white blood cell (A), neutrophil count (B) and proportion of neutrophils (C), and plasma endotoxin levels (D) after administration of rifaximin for 4 wk.

advantage of rifaximin is that it is virtually unabsorbable, which minimizes the antimicrobial resistance and adverse events and renders the drug safe in all patient populations. In addition, rifaximin has a better activity against gram-positive organisms than norfloxacin<sup>[3]</sup>.

We investigated whether rifaximin can reduce the burden of gut flora and BT, which are the requisite effects of a drug used for SBP prophylaxis, by studying its effects on circulating endotoxin levels and AF neutrophil counts in cirrhotic patients with sterile ascites.

Sixteen cirrhotic patients with ascites with no history of previous SBP episodes who required regularly a large-volume paracentesis were included in our study. Cirrhosis was established by non-invasive and/or histological criteria; all patients were Child Pugh class C. The patients were studied at baseline and after a 4-wk regimen with rifaximin 1200 mg/d (Group 1, *n* = 9; alcohol/viral etiology: 7/2) or an observational period (Group 2, *n* = 7; alcohol/viral etiology: 5/2). Exploratory paracentesis was performed in association with each therapeutic paracentesis to exclude ascitic fluid infection. All patients were included after written informed consent was obtained from them and the local scientific-ethical committee approved the study. Criteria for inclusion were: (1) Abstinence from alcohol for at least 6 mo before inclusion; (2) Absence of clinical and laboratory signs of bacterial infections; (3) No history of variceal bleeding within the 2 wk preceding the study; and (4) No

treatment with antibiotics during the last 8 wk before inclusion. For ethical reasons, only patients with AF total protein concentration >1 g/dL were studied. AF white blood cell (WBC) and neutrophil count, the proportion of neutrophils in AF (AF% neutrophils), and plasma endotoxin levels were measured at baseline and at the end of observational or treatment period. For the detection of plasma endotoxin levels, the Limulus amoebocyte lysate chromogenic endpoint assay (Hycult biotech, Uden, The Netherlands) was used as instructed by the manufacturer. The Wilcoxon matched pairs test was used for comparing variations within the same group. Results were expressed as mean ± SE. Statistical significance was designated as *P* < 0.05.

Rifaximin caused significant reductions in AF WBC, neutrophil count, AF% neutrophil count, and plasma endotoxin levels (Table 1); the values of the abovementioned parameters decreased uniformly in all patients (Figure 1). No significant changes in the AF cytological characteristics or plasma endotoxin levels were noted in Group 2. No patient developed AF infection during the study period and no side-effects were noted by the use of rifaximin.

Our findings strongly suggest that rifaximin suppresses IBO, which in turn reduces BT and the subclinical activation of AF defence mechanisms from prior silent colonisations with bacteria in cirrhotic patients with sterile ascites. The reduction of endotoxemia by ri-

Table 1 Ascites cytological characteristics and plasma endotoxin levels in patients after rifaximin treatment or in observational period

	Group 1 (n = 9)			Group 2 (n = 7)		
	Baseline	4 wk	P value	Baseline	4 wk	P value
WBC count (per mm <sup>3</sup> )	147.7 ± 24.1	107.7 ± 16.6	0.004	164.5 ± 30.2	175 ± 20.8	NS
Neutrophil count (per mm <sup>3</sup> )	28.4 ± 9.3	13.5 ± 4.3	0.01	34.6 ± 6.4	37.9 ± 7.2	NS
AF% neutrophils	17.1 ± 3	11.2 ± 2.1	0.0008	21.6 ± 3.5	22.1 ± 2.5	NS
Plasma endotoxin (EU/mL)	3.3 ± 1.1	1.6 ± 0.5	0.03	2.9 ± 0.9	3 ± 0.8	NS

Data are expressed as mean ± SE. WBC: White blood cell; NS: Not significant; AF: Ascitic fluid. Group 1: 9 cirrhotic patients with refractory ascites at baseline and after 4-wk rifaximin treatment; Group 2: 7 patients in the observational period.

faximin may further reduce BT by causing a fall in portal pressures<sup>[4]</sup> considering that portal hypertension induces structural abnormalities in intestinal mucosa leading to an enhanced permeability<sup>[1]</sup>. Overall, the effects of rifaximin on IBO and BT in our study are consistent with recent findings, showing a significantly reduced 5-year probability of SBP in cirrhotic patients taking rifaximin<sup>[5]</sup>. In conclusion, the role of rifaximin as an alternative mean of preventing SBP deserves further attention in prospective studies.

## Events Calendar 2012

January 13-15, 2012  
 Asian Pacific *Helicobacter pylori*  
 Meeting 2012  
 Kuala Lumpur, Malaysia

January 19-21, 2012  
 American Society of Clinical  
 Oncology 2012 Gastrointestinal  
 Cancers Symposium  
 San Francisco, CA 3000,  
 United States

January 19-21, 2012  
 2012 Gastrointestinal Cancers  
 Symposium  
 San Francisco, CA 94103,  
 United States

January 20-21, 2012  
 American Gastroenterological  
 Association Clinical Congress of  
 Gastroenterology and Hepatology  
 Miami Beach, FL 33141,  
 United States

February 3, 2012  
 The Future of Obesity Treatment  
 London, United Kingdom

February 16-17, 2012  
 4th United Kingdom Swallowing  
 Research Group Conference  
 London, United Kingdom

February 23, 2012  
 Management of Barretts  
 Oesophagus: Everything you need  
 to know  
 Cambridge, United Kingdom

February 24-27, 2012  
 Canadian Digestive Diseases Week  
 2012  
 Montreal, Canada

March 1-3, 2012  
 International Conference on  
 Nutrition and Growth 2012  
 Paris, France

March 7-10, 2012  
 Society of American Gastrointestinal  
 and Endoscopic Surgeons Annual  
 Meeting  
 San Diego, CA 92121, United States

March 12-14, 2012  
 World Congress on  
 Gastroenterology and Urology  
 Omaha, NE 68197, United States

March 17-20, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 Orlando, FL 32808, United States

March 26-27, 2012  
 26th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

March 30-April 2, 2012  
 Mayo Clinic Gastroenterology and  
 Hepatology  
 San Antonio, TX 78249,  
 United States

March 31-April 1, 2012  
 27th Annual New Treatments in  
 Chronic Liver Disease  
 San Diego, CA 92121, United States

April 8-10, 2012  
 9th International Symposium on  
 Functional GI Disorders  
 Milwaukee, WI 53202, United States

April 13-15, 2012  
 Asian Oncology Summit 2012  
 Singapore, Singapore

April 15-17, 2012  
 European Multidisciplinary  
 Colorectal Cancer Congress 2012  
 Prague, Czech

April 18-20, 2012  
 The International Liver Congress  
 2012  
 Barcelona, Spain

April 19-21, 2012  
 Internal Medicine 2012  
 New Orleans, LA 70166,  
 United States

April 20-22, 2012  
 Diffuse Small Bowel and Liver  
 Diseases  
 Melbourne, Australia

April 22-24, 2012  
 EUROSON 2012 EFSUMB Annual

Meeting  
 Madrid, Spain

April 28, 2012  
 Issues in Pediatric Oncology  
 Kiev, Ukraine

May 3-5, 2012  
 9th Congress of The Jordanian  
 Society of Gastroenterology  
 Amman, Jordan

May 7-10, 2012  
 Digestive Diseases Week  
 Chicago, IL 60601, United States

May 17-21, 2012  
 2012 ASCRS Annual Meeting-  
 American Society of Colon and  
 Rectal Surgeons  
 Hollywood, FL 1300, United States

May 18-19, 2012  
 Pancreas Club Meeting  
 San Diego, CA 92101, United States

May 18-23, 2012  
 SGNA: Society of Gastroenterology  
 Nurses and Associates Annual  
 Course  
 Phoenix, AZ 85001, United States

May 19-22, 2012  
 2012-Digestive Disease Week  
 San Diego, CA 92121, United States

June 2-6, 2012  
 American Society of Colon and  
 Rectal Surgeons Annual Meeting  
 San Antonio, TX 78249,  
 United States

June 18-21, 2012  
 Pancreatic Cancer: Progress and  
 Challenges  
 Lake Tahoe, NV 89101, United States

July 25-26, 2012  
 PancreasFest 2012  
 Pittsburgh, PA 15260, United States

September 1-4, 2012  
 OESO 11th World Conference  
 Como, Italy

September 6-8, 2012  
 2012 Joint International

Neurogastroenterology and Motility  
 Meeting  
 Bologna, Italy

September 7-9, 2012  
 The Viral Hepatitis Congress  
 Frankfurt, Germany

September 8-9, 2012  
 New Advances in Inflammatory  
 Bowel Disease  
 La Jolla, CA 92093, United States

September 8-9, 2012  
 Florida Gastroenterologic Society  
 2012 Annual Meeting  
 Boca Raton, FL 33498, United States

September 15-16, 2012  
 Current Problems of  
 Gastroenterology and Abdominal  
 Surgery  
 Kiev, Ukraine

September 20-22, 2012  
 1st World Congress on Controversies  
 in the Management of Viral Hepatitis  
 Prague, Czech

October 19-24, 2012  
 American College of  
 Gastroenterology 77th Annual  
 Scientific Meeting and Postgraduate  
 Course  
 Las Vegas, NV 89085, United States

November 3-4, 2012  
 Modern Technologies in  
 Diagnosis and Treatment of  
 Gastroenterological Patients  
 Dnepropetrovsk, Ukraine

November 4-8, 2012  
 The Liver Meeting  
 San Francisco, CA 94101,  
 United States

November 9-13, 2012  
 American Association for the Study  
 of Liver Diseases  
 Boston, MA 02298, United States

December 1-4, 2012  
 Advances in Inflammatory Bowel  
 Diseases  
 Hollywood, FL 33028, United States

**GENERAL INFORMATION**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

**Maximization of personal benefits**

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copy-right" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

**Aims and scope**

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**Columns**

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### Published by

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>”. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Electronic journal (list all authors)**

- 15 Morse SS. Factors in the emergence of infectious dis-

eases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/eid/index.htm>

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

### Abstract

Restorative proctocolectomy (RP) is the treatment of choice in patients affected with refractory ulcerative colitis or familial adenomatous polyposis. Surgery in elective settings is often performed in 2 stages, fashioning an ileostomy which is closed 2-3-mo later. It is still debated whether omitting ileostomy could offer advantages in the management of patients undergoing RP.

### INTRODUCTION

Restorative proctocolectomy (RP) with ileopouch-anal anastomosis (IPAA) is considered the treatment of choice for patients affected by ulcerative colitis (UC) and familial adenomatous polyposis (FAP) who require surgery. RP removes the disease, reduces the long-term risk of carcinogenesis and preserves transanal defecation<sup>[1]</sup>. Short-term results demonstrate excellent functional outcomes with good quality of life, while some deterioration of function is reported in the long term. Pelvic sepsis is the most serious complication of RP, leading to pouch failure or malfunction<sup>[2,3]</sup>. Since the first description of IPAA<sup>[4]</sup>, many techniques have been introduced to prevent or limit the consequences of an IPAA leak; the necessity of fashioning a covering ileostomy at the time of RP remains controversial. The aim of this review is to establish the role of a covering ileostomy in patients undergoing RP for UC or FAP.

### ILEOSTOMY AND PELVIC SEPSIS/POUCH FAILURE

RP is generally performed in two stages in elective settings, but it can be performed as a single-stage procedure in order to avoid ileostomy and its complications<sup>[5,6]</sup>. Sugerman *et al*<sup>[5]</sup> reported a high rate of pelvic sepsis (12%) in 192 patients undergoing IPAA without covering ileostomy, with excellent function retained in 19 out of the 23 patients who developed pelvic sepsis. Teixeira *et al*<sup>[7]</sup> suggested that ileostomy does not eliminate the risk of pelvic sepsis; they found that an IPAA stricture was more frequent in patients undergoing IPAA without a covering ileostomy (31.3% *vs* 4.7%). Furthermore, Ikeuchi *et al*<sup>[8]</sup> found that the incidence of post-operative complications after the first intervention did not differ significantly between patients with or without an ileostomy: pouch-related complications affected 12 patients (8%) without ileostomy, with surgery being required in 5 cases (3.3%), and 4 patients (4.3%) with ileostomy, all of who were managed conservatively. Despite this, the authors reported that the

overall incidence of post-operative complications was significantly higher in the group with ileostomy than in the non-ileostomy group: 55.4% *vs* 32%.

It needs to be remembered that omitting ileostomy appears to expose the patient to a high risk of pouch failure due to early anastomotic leakage. In St. Mark's Hospital the rate of pouch failure was higher in patients undergoing IPAA without a covering ileostomy: 15% *vs* 8%<sup>[9]</sup>. Data from the Cleveland Clinic of 1965 patients undergoing RP revealed that anastomotic leak occurred in 5.3% of the patients with ileostomy, but in > 14% when ileostomy was omitted<sup>[10]</sup>. The global rate of complications after 1504 ileostomy closures was as high as 11.4%<sup>[11,12]</sup>.

## COMPLICATIONS/CONSEQUENCES OF ILEOSTOMY

Fashioning a covering ileostomy can be burdened by complications due to diversion, such as dehydration from excessive stoma output, the need for a second intervention and hospitalization to undergo ileostomy closure, the risk of anastomotic leak and a presumed increased risk of subsequent small-bowel occlusion, which some authors attribute to either internal hernias around the stoma or to adhesions in the proximity of the stoma site<sup>[5]</sup>. Complications such as irritation of the peristomal skin or stoma prolapse are well described in the literature<sup>[13]</sup>. Ileostomy closure is associated with longer hospitalization, and some authors report that this can increase the cost of the procedure<sup>[14]</sup>. Moreover, the preternatural anus, even if temporary, can have psychological effects and affect the patient's perception of their body<sup>[15,16]</sup>.

## ILEOSTOMY AND PRE-TAKEDOWN ASSESSMENT (SECOND-STAGE SURGERY)

A covering ileostomy after RP should be taken down after a minimum of 8 wk to allow IPAA healing. Takedown is usually performed after a clinical examination (often including pouchoscopy) and a pouch enema (pouchogram/pouchography)<sup>[17]</sup>; the latter can reportedly enable the detection of pouch or IPAA leaks and IPAA strictures<sup>[18,19]</sup>. Few studies have investigated the role of pouchography in the assessment of patients with IPAA scheduled for ileostomy closure. It has been hypothesized that a discontinuous ileoanal anastomotic ring at pouchography is sensitive (88%) but not specific (57%) in predicting a subsequent pelvic sepsis, whereas a leak is quite specific (81%) but not sensitive (56%) in predicting pelvic collections<sup>[20]</sup>. These data suggest that tiny tracts often heal spontaneously, and justify delaying ileostomy closure if a leak is observed. Pouch sinuses are tiny blind tracts originating from IPAA, and are seen at pouchography in < 8% of patients undergoing RP<sup>[21]</sup>. A leak leading to pelvic sepsis can reportedly occur even after radiological healing of a sinus<sup>[21]</sup>. A study from the Mayo Clinic suggests that pouch function is not affected by occult sinuses, ques-

tioning the utility of detecting asymptomatic defects<sup>[13]</sup>. Moreover, managing these tiny tracts aggressively could result in overtreatment. Previous studies have not clearly compared clinical data - obtained through anamnesis plus clinical examination - and pouchography. In our experience, a preoperative pouchogram in patients at risk of developing complications adds valuable information<sup>[20]</sup>, but it should not be intended as a routine examination in symptomatic UC patients with negative results of a clinical/endoscopic examination.

Comparison of data from two groups of clinically negative UC pouch patients who did ( $n = 37$ ) or did not ( $n = 33$ ) undergo pouchography before ileostomy takedown in our centre revealed that 10.8% of patients in the former group exhibited an asymptomatic radiological abnormality that was otherwise undetected (four pouch sinuses). However, the failure rate was similar in the two groups (3% *vs* 2.7%,  $P = \text{NS}$ ), as was the overall rate of complications. In addition, patients in the pouchography group who experienced failure had a normal pouchogram at the time of ileostomy closure<sup>[22]</sup>. We follow the following algorithm in our practice: a clinical/endoscopic assessment is always applied to patients scheduled to undergo ileostomy takedown, and a pouchography study is carried out if symptoms or the clinical examination make us suspect that a complication has occurred. The ileostomy of asymptomatic, clinically negative patients is closed without radiological evaluation of the pouch.

## ILEOSTOMY AND BASELINE DISEASE

Intuitively, patients undergoing a pelvic pouch procedure for non-inflammatory disease are at lower risk of developing septic complications, because they do not need to be treated with steroid medications. The findings of several studies suggest that a loop ileostomy can be safely omitted, even in patients undergoing IPAA for UC<sup>[8,23-30]</sup>. However, a recent retrospective multivariate analysis of patients undergoing RP at the Cleveland Clinic and at St. Mark's Hospital revealed that FAP is associated with a higher probability of a safe one-stage RP (odds ratio, 2.6)<sup>[31]</sup>.

## ILEOSTOMY AND STEROID DRUGS

Therapy for UC includes the use of steroid drugs, sometimes administered at a high dosage, and these patients are at risk of becoming steroid-dependent or steroid-refractory. Matikainen *et al*<sup>[23]</sup> stated that steroid therapy at the time of RP does not contraindicate one-stage surgery. However, most experienced centres consider a daily prednisone dose of  $\geq 20$  mg an exclusion criterion for a one-stage procedure<sup>[11,32]</sup>. Although not agreeing with this cut-off value, Sugerma *et al*<sup>[5]</sup> suggested that treatment with steroids is relevant to evaluating patients scheduled for RP. Ziv *et al*<sup>[33]</sup> considered that omission of ileostomy is an unacceptable procedure in patients treated with steroids at the time of RP. Ikeuchi *et al*<sup>[8]</sup> showed that patients taking steroids at the time of IPAA are more likely to develop

complications. Although they did not establish a cut-off value for steroid therapy, those authors suggest that steroid treatment is a relevant factor in selecting patients who are suitable for a one-stage procedure.

## ILEOSTOMY AND TYPE OF ILEOPOUCH-ANAL ANASTOMOSIS

During RP, the IPAA can be either hand-sewn (with or without mucosectomy) or stapled using a circular stapler introduced transanally. Some authors have reported that the type of IPAA can affect the outcome of patients undergoing RP with or without ileostomy. A hand-sewn IPAA is technically more difficult to perform, which has resulted in there being few reports of patients undergoing RP with a hand-sewn IPAA in the literature. Ikeuchi *et al*<sup>[8]</sup> reported one of the largest series, since they routinely use a hand-sewn technique. They compared 150 patients undergoing hand-sewn IPAA without ileostomy with 92 hand-sewn IPAA patients operated on with a two-stage procedure. While the rate of pouch-related complications was high, it did not differ significantly between the two groups. Some authors have reported that fashioning a hand-sewn IPAA leads to an unacceptably high risk of complications if a covering ileostomy is omitted, especially if steroid medications are taken at the time of RP. However, there is no definitive evidence regarding the impact of this factor on patient selection<sup>[11,33,34]</sup>.

With respect to the pouch shape, patients with a W-pouch are at higher risk of complications when ileostomy is omitted than those with a stapled J-pouch<sup>[31]</sup>.

## ILEOSTOMY AND TECHNOLOGICAL ADVANCES IN SURGERY

Surgical technology has made huge advances in recent years. Laparoscopic RP is widely used nowadays. Pouch surgery can be performed as a totally laparoscopic three-/four-trocar access procedure, as a laparoscopic-assisted procedure (with the pouch being constructed outside the body through a Pfannenstiel incision<sup>[35]</sup>), as a hand-assisted laparoscopic proctocolectomy (HALP), by means of a special port designed to allow the surgeon to introduce his or her hand inside the body while preserving the pneumoperitoneum<sup>[36]</sup>, and as single-access laparoscopic surgery (SILS)<sup>[37]</sup>. A recently introduced technique uses a laparoscopy-assisted robotic surgery approach to RP<sup>[38]</sup>. In the context of a minimally invasiveness, the omission of a protective ileostomy has definite advantages regarding the overall cosmetic result. Kienle *et al*<sup>[35]</sup> performed 59 laparoscopic RP procedures with extracorporeal pouch construction, omitting a primary ileostomy in 16 patients: 3 FAP (18.75%) and 6 UC (37.5%) patients developed complications (7 pelvic sepsis) requiring reoperation and secondary ileostomy. Agha *et al*<sup>[36]</sup> reported that HALP is a safe procedure with a rapid learning curve; in their experience of 19 patients undergoing RP, a protective ileostomy

was always fashioned. SILS RP is a viable procedure that produces good results if the surgeon is highly skilled in laparoscopic surgery. Gash *et al*<sup>[37]</sup> found that fashioning a protective ileostomy at the site of SILS trocar introduction seemed to be a prudent choice in their series of ten patients.

The minimally invasive approach *per se* probably does not reduce the need for a protective ileostomy. The selection criteria for the addition or omission of a protective ileostomy in minimally invasive RP remain to be clearly defined. In our opinion further studies are needed before definitive conclusions can be drawn about the advisability of avoiding an ileostomy using the most recent techniques<sup>[36-38]</sup>, with this also being dependent on the acquisition of better technical skills by surgeons and the use of longer follow-ups.

## ILEOSTOMY AND SAMPLE SIZE/STATISTICAL POWER

It should be noted that studies promoting a one-stage procedure generally lack significant statistical power, which thus renders evaluation of the pelvic sepsis rate unreliable. Heuschen *et al*<sup>[24]</sup> compared the results of 57 one-stage procedures with 114 controls and found that the rate of IPAA stricture was higher in patients with a covering ileostomy, but this finding could have been due to the selection of case patients.

Failure was more common at St. Mark's Hospital<sup>[9]</sup> when higher ileostomy was omitted (15% *vs* 8%). Conversely, in concurrent experience MacRae *et al*<sup>[39]</sup> found that the pouch failure rate was < 1% in patients undergoing one-stage RP. Recent multicentre studies<sup>[30,31]</sup> have involved wider series but only retrospective analyses. The lack of randomization, which is often incompatible with acceptable ethical conduct in such patients, represents a limitation that has yet to be overcome.

## ILEOSTOMY AND EVIDENCE BASED MEDICINE

Several factors make it difficult to perform randomized controlled trials around this topic: (1) the difficulty in enrolling sufficient patients for revealing statistically relevant differences; (2) **omitting a stoma is not indicated** in some patients because of surgical safety and (3) the unethical problems of randomizing patients at risk. With regard to UC, the most recent Consensus Paper of the European Crohn's and Colitis Organization stated that a diverting ileostomy is generally recommended, but that it can be avoided in selected patients (Evidence Level 3b, Recommendation Grade C)<sup>[40]</sup>. Currently the best way to select patients remains unclear.

## ILEOSTOMY AND PATIENTS

The responsibility regarding surgical outcomes has gained

such importance that it is now deemed necessary to involve the patient in surgical decision-making. Obese patients (body mass index  $\geq 30 \text{ kg/m}^2$ ) could benefit from stoma omission, since fashioning an ileostomy in these patients could be technically more difficult<sup>[5]</sup>. Most importantly, the patient's will to avoid ileostomy should be considered in light of the psychological implications, such that if complications do arise following one-stage surgery, the eventual subsequent need for an ileostomy will certainly affect a patient who has also undergone reintervention in an emergency setting<sup>[16]</sup>.

## PERSONAL EXPERIENCE

Between 1987 and 2011, we performed 241 RPs for UC, FAP or cancer (1 S-pouch, 121 W-pouches, and 119 J-pouches); 23 (9.5%) of these patients underwent one-stage RP. The global rates of pelvic sepsis were 7.7% and 13% among patients with or without ileostomy, respectively, while failure occurred in 5% and 4.3% of case. However, there were no statistically significant differences. Since our series covered a very long period of time (24 years), and considering the recent technical advancements, we stratified our experience into two periods, focusing on stoma omission. Between 1987 and 2000, we performed nine one-stage RPs, with a pelvic sepsis rate of 22.2% and a failure rate of 11.1%; these figures are higher than those for staged procedures (9.2% and 7%, respectively), although the difference did not reach statistical significance. Between 2001 and 2011, we performed 14 straight RPs: 7.1% of patients developed pelvic sepsis, while none of them experienced failure. Again, these data did not differ significantly from those of patients undergoing two-/three-stage procedures (pelvic sepsis in 6% and failure in 4%).

In addition to the increased level of expertise among surgeons, these improved findings are due to increasingly careful patient selection among those who could benefit from stoma omission. Most of the selected patients were female, overweight, young, affected with FAP and undergoing stapled J-pouch with stapled IPAA. Patients taking steroids were not considered suitable for a one-stage procedure. The type of surgery (laparoscopic, open or HALP) was not *per se* a selection criterion, since the choice was patient-tailored. Any bias could be attributable to us omitting ileostomy more frequently as our experience with the pelvic pouch procedure increased, especially when the surgeon had reached the plateau of the learning curve for the RP surgical technique. This is relevant, since we believe - in agreement with the great majority of the reported studies - that it is as now impossible to predict preoperatively whether a patient would be suitable for one-stage surgery. A straightforward surgery (e.g., contained blood loss, short operative time, lack of tension and good vascularization of the IPAA, no contamination, intraoperative testing of the anastomosis) is a desirable condition when choosing to omit ileostomy. These factors are definitively surgeon-related.

## CONCLUSION

At the present time, given the information in the literature and wider described series under the critical light of the EBM, the decision to omit ileostomy substantially represents an exercise in risk management. Most surgeons opt for a protective ileostomy because this is reported to diminish the risk of detrimental pelvic contamination, even if it does not abolish the risk of pelvic sepsis. Centres specializing in pelvic pouch procedures have reported that the rate of patients undergoing one-stage RP ranges between 15% and 25%<sup>[29,30]</sup>. By adopting stringent selective criteria, the rate of patients undergoing RP without an ileostomy did not reach 10% in our series. It is our opinion that omitting ileostomy is a viable alternative in a very limited number of patients who fit specific selection criteria; they must be highly motivated to avoid a stoma and well informed regarding the eventual subsequent risks. This option could be proposed to them, but it is only at the end of each pelvic pouch procedure that the surgeon will be able to take the final decision.

### Abstract

Inflammatory bowel disease (IBD), including both ulcerative colitis (UC) and Crohn's disease (CD), emerged and dramatically increased for about a century. Despite extensive research, its cause remains regarded as unknown. About a decade ago, a series of findings made me suspect that saccharin may be a key causative factor for IBD, through its inhibition on gut bacteria and the resultant impaired inactivation of digestive proteases and over digestion of the mucus layer and gut barrier (the Bacteria-Protease-Mucus-Barrier hypothesis). It explained many puzzles in IBD such as its emergence and temporal changes in last century. Recently I further found evidence suggesting sucralose may be also linked to IBD through a similar mechanism as saccharin and have contributed to the recent worldwide increase of IBD. This new hypothesis suggests that UC and CD are just two symptoms of the same morbidity, rather than two different diseases. They are both caused by a weakening in gut barrier and only differ in that UC is mainly due to increased infiltration of gut bacteria and the resultant recruitment of neutrophils and formation of crypt abscess, while CD is mainly due to increased infiltration of antigens and particles from gut lumen and the resultant recruitment of macrophages and formation of granulomas. It explained the delayed appearance but accelerated increase of CD over UC and many other phenomena. This paper aims to provide a detailed description of a unified hypothesis regarding

the etiology of IBD, including the cause and mechanism of IBD, as well as the relationship between UC and CD.

### INTRODUCTION

As we know, inflammatory bowel disease (IBD) refers to ulcerative colitis (UC) and Crohn's disease (CD), two highly related debilitating diseases of the digestive tract with similar clinical, pathological, and epidemiological features<sup>[1,2]</sup>. Although some descriptions in ancient books had been suspected as symptoms of IBD, clustered cases only started to emerge around the end of the 19th century<sup>[1]</sup>. Right now, IBD has become one of the most common chronic inflammatory conditions only after rheumatoid arthritis, with millions of patients all over the world<sup>[3]</sup>. It is most prevalent in young adults and remains regarded as incurable, with the patients usually requiring lifelong heavy medication and multiple devastating surgeries like bowel resection, proctocolectomy, ileostomy, and ileal pouch-anal anastomosis, *etc.*<sup>[2,4]</sup>. As stated by Dr. Kirsner, "ulcerative colitis and Crohn's disease today represent two of the more challenging diseases in all of medicine"<sup>[1]</sup>.

Since its appearance, people had been puzzled by the constant changes of manifestations of IBD in age, gender, ethnic, temporal and geographical distributions<sup>[3,5,6]</sup>. Great efforts have been taken to find out its cause. Many factors had been suspected, including bacteria such as

*Bacillus coli*, *Bacillus proteus*, *Bacillus pyocyaneus*, *Bacillus lactis aerogenes*, diplostreptococci, dysentery bacillus, *Spherophorus necrophorus*, *Bacillus morgagni*, *Escherichia coli*, spirochetes, Mycobacteria (*Mycobacteria tuberculosis*, *Mycobacteria paratuberculosis* and *Mycobacteria kansasii*), *Pseudomonas maltophilia*, *Bacillus vulgatus*, *Aerobacter aerogenes*, *Aerobacter coprococcus*, *Aerobacter bifidobacteria*, *Campylobacter fetus ssp. jejuni*, *Yersinia enterocolitica*, and *Chlamydia trachomatis*, *Aeromonas hydrophila*, *Plesiomonas shigelloides*, *Edwardsiella tarda*, *Blas-tocystis hominis*, *Bacteroides necrophorum*, *Bacteroides fragilis*, *Pseudomonas maltophilia*, *Helicobacter hepaticus* or pylori species<sup>[1,7,8]</sup>; fungi like *Histoplasma* and *Monilia*<sup>[1]</sup>; virus such as lymphopathia venereum, Behcet's virus, cytomegalovirus, Echo A, B adenovirus, Epstein-Barr, rotavirus, Norwalk virus, influenza, mumps, measles, herpes, Coxsackie A and B, Reovirus, Polio virus, Paramyxovirus<sup>[1,7,8]</sup>; protozoa and parasites like *Escherichia histolytica*<sup>[1]</sup>; vaccines such as the trivalent measles, mumps and rubella and **Bacillus Calmette-Guérin**<sup>[9,10]</sup>; microparticles of aluminum, titanium, silicon oxides, calcium phosphate from the diet, tooth paste, dust or soil<sup>[8,10-12]</sup>; drugs like oral contraceptives and non-steroid anti-inflammatory drugs (NSAIDs)<sup>[10,13]</sup>; dietary components like protein, fat, sugar, fruits and vegetables, margarine, dairy products, coffee, coca cola, fast food<sup>[10]</sup>, or glycoalkaloids in potato<sup>[14]</sup>, and carrageenan in seaweeds<sup>[15]</sup>; smoking<sup>[1]</sup>; and other factors like refrigeration (cold chain)<sup>[8,10,16]</sup>. Despite that, the cause of IBD remains virtually unknown, as none of them can well explain the dynamically changed profiles of IBD. For instance, smoking is currently regarded as the most determined environmental factor for IBD: it reduces the risk of UC, while exacerbates CD<sup>[2]</sup>. Despite that, the low prevalence of CD in heavily smoking countries like China and high prevalence of CD in the low smoking countries like Canada suggest the contribution of smoking in the general population being negligible and other factors in the environment would have played the predominant role<sup>[2]</sup>. Another example would be the Mycobacterium avium subspecies paratuberculosis (MAP), a bacteria that causes Johne's disease in cattle, that had been suspected the causative factor for CD as early as 1913<sup>[17]</sup>. Despite a century long research and debate, a causal relationship between MAP and CD still cannot be established<sup>[18,19]</sup>. MAP hypothesis also failed to explain the cause of UC, which has been the main form of IBD in most circumstances.

About a decade ago, I found that digestive proteases like trypsin and chymotrypsin can be inactivated by free (unconjugated or deconjugated) bilirubin but not conjugated bilirubin or biliverdin. Further pursuit in the literature led me to suspect that impairment in this process due to inhibition of gut bacteria (thus the major source of  $\beta$ -glucuronidase that is needed for deconjugation of the mostly conjugated biliary bilirubin) by dietary chemicals like saccharin may have played an important causative role in IBD, as the result of damage of the protective mucus layer and the underlying gut tissue by the poorly-inactivated digestive proteases<sup>[20]</sup>. Recently, I further found that sucralose, the new generation of arti-

ficial sweetener, may exert an even potent impact on gut bacteria than saccharin and have probably contributed to the record high incidence of IBD seen recently in many countries<sup>[21]</sup>. Based on the evidences gathered and thoughts evolved and developed in the last decade, this paper aims to provide a detailed description of a unified hypothesis regarding the etiology of IBD, including the cause and mechanism of IBD, as well as the relationship between UC and CD.

## LARGE COMMERCIAL MARKETING OF SACCHARIN IN 1887 AND THE EMERGE OF CLUSTERED CASES OF ULCERATIVE COLITIS SINCE 1888, STARTED FROM THE UNITED KINGDOM

### ***The discovery of saccharin in 1878 from coal tar and its large-scale production and marketing since 1887***

Saccharin was discovered in 1878 by Constantin Fahlberg, a young chemist from Germany who engaged in research in Professor Ira Remsen's laboratory at Johns Hopkins University in Baltimore, Maryland, the United States<sup>[22-24]</sup>. One evening, Fahlberg found extra sweetness of bread and his hand during dinner, and tracked to its source to a coal tar product in the lab. Later, it was revealed that this chemical was 300 to 500 times as sweet as sugar and had little toxicity<sup>[22-25]</sup>. In 1882, Constantin Fahlberg himself consumed 10 g of the chemical and experienced no adverse reactions<sup>[26]</sup>. Most of it passed the body unchanged, through urine or feces<sup>[22,25]</sup>. In 1884, associated with his uncle, Adolph List, of Leipzig, Germany, Fahlberg tried pilot experimental production of this chemical in New York and named it as saccharin (also called saccharine at some occasions)<sup>[23]</sup>. Due to the high expenses of labor and materials in New York, Fahlberg, together with his cousin, established the firm Fahlberg, List and Co. and built a factory in Salbke, Germany in 1886 for the commercial production of saccharin<sup>[22-24,27]</sup>. Large quantities of saccharin were produced and reached the market in 1887<sup>[28]</sup>. After that, more factories were established in Germany<sup>[22]</sup>. The production of saccharin in Germany before its ban by the end of 1902 is showed in Table 1<sup>[29-33]</sup>. Since later 1890s, factories were also built in other countries like France<sup>[34]</sup> and the Switzerland<sup>[31,35]</sup>. In 1901, John Francis Queeny established Monsanto in St. Louis, Missouri, the United States for the sole purpose of saccharin production<sup>[27,36]</sup>. For the first several years, all the saccharin it produced was sold to Coco Cola, then a small company in Atlanta<sup>[27,36]</sup>.

### ***The favorite use of saccharin in United Kingdom since 1887 but dislike or ban of saccharin in Germany and most of the other western countries in the early years***

Although saccharin was only produced in Germany in the early years after its marketing in 1887, only about 3% of saccharin was actually consumed in Germany<sup>[37]</sup>,

**Table 1 Saccharin production in Germany before its ban by the end of 1902**

Year	Number of factories	Production (tons)
1888	1	5.2 <sup>[29]</sup>
1889	1	14.6 <sup>[30]</sup>
1896	3	33.5 <sup>[31]</sup>
1897	4	34.7 <sup>[31]</sup>
1898	5	78.4 <sup>[31]</sup>
1899	6	130.3 <sup>[31]</sup>
1900	6	159.4 <sup>[32]</sup>
1901	6	189.7 <sup>[31]</sup>
1902	6	174.8 <sup>[31]</sup>
1903	1	40 <sup>[33]</sup>

mainly due to the bad image of this coal tar product in that country. Saccharin was regarded as being inferior and only consumed by people who could not afford the luxury of sugar<sup>[38]</sup>. A domestic servants' club even advocated a commitment not to working for people who sweetened their coffee with saccharin instead of sugar<sup>[38]</sup>. In 1902, saccharin production was eventually brought under strict control in Germany<sup>[24]</sup>. Only one firm, Fahlberg, List and Co, among the six factories was allowed to continue producing saccharin<sup>[24]</sup>, and it was regulated that saccharin can only be used for medicinal purpose and available through pharmacies<sup>[24]</sup>. The production of saccharin in Germany reduced from nearly 190 tons in 1901 to about 40 tons in 1903<sup>[33]</sup>, among which only 3 tons were consumed within Germany, with the remaining being exported to other countries<sup>[33]</sup>. Similar as Germany, many other countries like France, Italy, Spain, Belgium, Holland, Portugal, Russia, Austro-Hungary also put strict regulations on the importation, production, and use of saccharin during these early years<sup>[39,40]</sup>. These restrictions greatly stimulated the smuggling of saccharin in Europe, with saccharin being hidden in chocolate or match boxes, oil or milk cans, artificial stones or candles, coats, vests, suits with secret pockets, feed bags for horses, carousel, or even coffin<sup>[41]</sup>.

In contrast to the countries above, saccharin was greatly appreciated in the United Kingdom. Even before its appearance on the market, saccharin had been highly praised by some eminent authorities like Sir Henry E. Roscoe, who had been a member of the parliament, a fellow of royal society, and presidents of Chemical Society, the Society of Chemical Industry, and the British Association<sup>[42-44]</sup>. In the presidential inaugural address on August 27, 1886, he stated that: "the most remarkable instance is the production of an artificial sweetening agent, termed saccharine, prepared by a complicated series of reactions from coal tar"<sup>[42,43]</sup>. People were assured by official analysts and doctors that saccharin was harmless and enjoyable<sup>[45,46]</sup>. Pamphlets with detailed descriptions of many formulae and uses of saccharin were written by professor and editor and distributed to households<sup>[46,47]</sup>. As stated in a publication in early twenty century: "Here we now have a coal oil product deliberately recommended in England as a valuable and suitable agent for sweetening mineral

waters and, presumably, for use wherever it could take the place of genuine sugar. It is altogether different in France, where it has been entirely contraband and even in Germany, where it is manufactured to so considerable an extent, efforts are made to hold it under control"<sup>[48]</sup>. Therefore, it would be not surprising that, shortly after its marketing, saccharin soon appeared in almost any family grocer, instead of chemists' shop in United Kingdom<sup>[49]</sup>. As the result, United Kingdom was the biggest buyer of saccharin at that time. As stated in the publication: "the American trade (of saccharin) has been inconsequential. In 1891 the export to New York was only about eight hundred kilograms (1800 pounds approximately), while during the same period 7200 kg were shipped to England"<sup>[50]</sup>.

### **Emergence of clustered cases of ulcerative colitis since 1888, started from United Kingdom**

Although it was suspected that some forms of diarrhea described in ancient books could be sporadic case of UC<sup>[1]</sup>, it appeared that clustered cases of UC only started to emerge after 1888. As stated by Dr. Sidney Philips in his discussion during the first symposium on IBD in the world in 1909 that presented a collection of more than three hundreds of UC patients from 9 hospitals in London: "Ulcerative colitis appeared to be much more common now in this country than formerly. There was no mention of it in any of the published reports of any of the London hospitals before 1888, when Dr. Hale White published cases in Guy's Hospital Reports. It was not mentioned in St. Bartholomew's or Westminster Hospital Reports before 1893, nor in the London Hospital Reports till 1897. And the textbooks used twenty or thirty years ago, such as Bristowe's and Hilton Fagge's, made no allusion to it. The speaker himself had seen many cases at St. Mary's Hospital and elsewhere since 1888, but not before then"<sup>[51]</sup>. In addition, Dr. Philips even suspected that the increase in UC might be caused by some food additives. He stated: "Possibly the cause of acute ulcerative colitis was connected with our food supply; tinned or preserved foods might have something to do with it"<sup>[51]</sup>. Interestingly, saccharin was largely used in early years in canned foods to preserve vegetables, fruits and meats, taking the advantage of both its sweet and antiseptic properties<sup>[25,52]</sup>.

### **THE WIDESPREAD USE OF SACCHARIN DURING THE TWO WORLD WARS AND THE SPREAD OF ULCERATIVE COLITIS IN WESTERN COUNTRIES**

During World War I, the shortage of sugar caused great demand for saccharin<sup>[53,54]</sup>. Figure 1 demonstrated this dramatic increase of saccharin consumption in Germany<sup>[38,54]</sup>. The ban on saccharin was lifted in Germany and other countries, accompanied by a striking increase in saccharin production<sup>[53,54]</sup>. In 1916, saccharin production

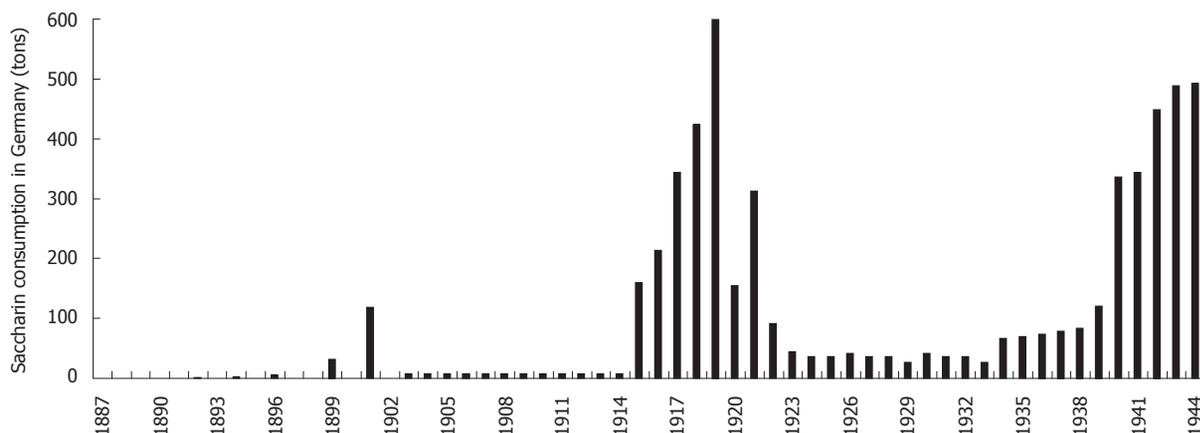

Figure 1 Saccharin consumption in Germany over time (1888-1944).

in Germany resumed to 1 ton per day<sup>[53]</sup>. In France, four more factories were equipped to produce saccharin<sup>[55]</sup>. In the United States, saccharin became allowed using in soft drinks and foods<sup>[56]</sup>. In addition to increased production, the importation of saccharin in the United States increased from 8 pounds in 1914 to 5617 pounds in 1915 and 12954 pounds in 1916<sup>[57]</sup>. Despite the increased production and importation, the price of saccharin in New York market increased from \$1.15-1.25 per pound in 1914 to \$2.85-11.50 in 1915, \$11.50-21.50 in 1916, and \$20.50-46.00 in 1917<sup>[53]</sup>, reflected the great increases in the demand and consumption of saccharin during this period.

In accordance with the spread use of saccharin since World War I, UC cases were also more frequently seen in countries other than United Kingdom. As stated by Dr. Evans: "During the recent war (1914-1918), while acting as surgeon to an improvised hospital for Turkish prisoners in Mesopotamia, and later as civil surgeon of Baghdad, an opportunity arose of observing a large number of cases of colitis; the majority were chronic and were complicated by scurvy. The combination of these two diseases made the colitis extremely intractable, and in consequence large numbers died. While in Mesopotamia I performed appendicostomy for intractable ulcerative colitis in ten patients-Turks, Arabs, and Indians"<sup>[58]</sup>. This helped the recognition of UC as an independent entity other than, for instance, dysentery. As stated by Lups S: "In the latter part of the nineteenth century most clinicians considered this affection which later was called 'ulcerative colitis' belonging to the dysentery group, even after 1903, when Boas expressed the view that ulcerative colitis was an independent disease. About 1914, however, there was a marked change in the viewpoints of many observers on this question although many still felt that it was of dysenteric origin. They knew full well that only in a few cases true dysenteric organisms were found"<sup>[59]</sup>. In another paper published in 1928, Dr. Thorlakson stated that: "the subject of ulcerative colitis has received a great deal of attention in the medical literature of all countries during the past decade. In reviewing the English, German, French and American

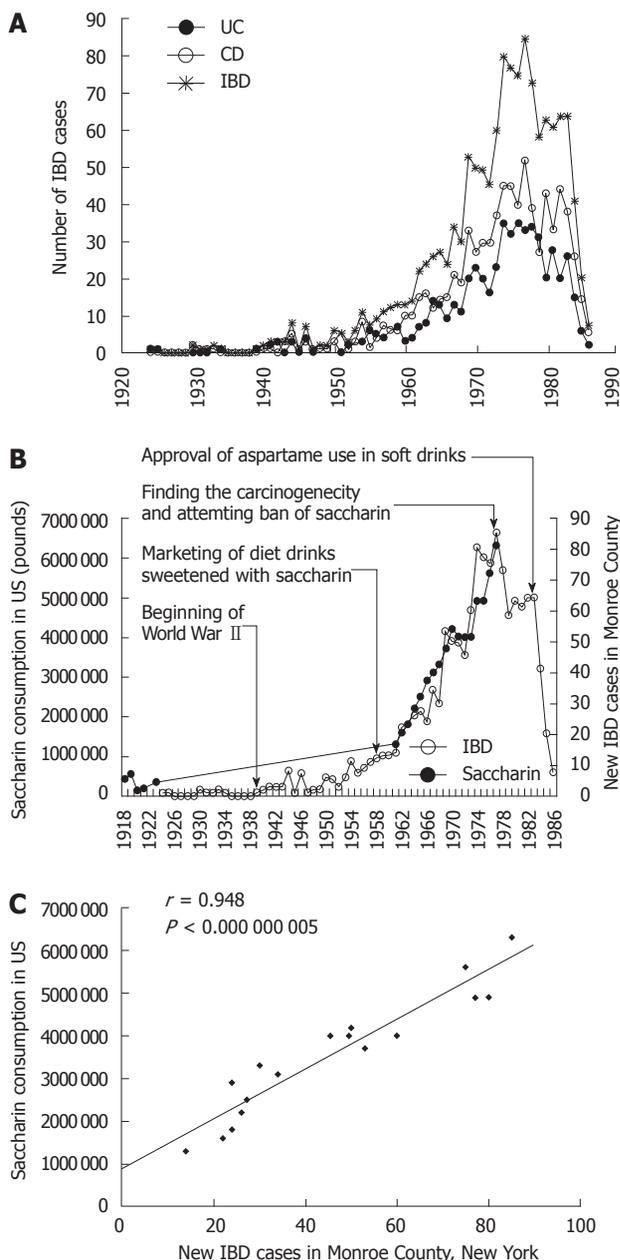

literature on this disease, one is struck by the similarity of the articles. It seems obvious that these writers from various countries are all dealing with the same condition, and not, as has been suggested, with different diseases brought under the same name-ulcerative colitis"<sup>[60]</sup>.

In the United States, more cases of UC were seen since World War I. For instance, Logan reported 117 cases of UC treated in Mayo Clinic up to 1918, with 19 cases being before 1915, 18 cases during 1915, 23 cases during 1916, 57 cases during 1917 and to April 1, 1918<sup>[61]</sup>, while there were 693 cases between 1923-1928<sup>[62,63]</sup>. In 1922, Dr. Yeomans in the Department of Surgery, Columbia University College of Physicians and Surgeons reported 65 cases of UC mostly observed during 1916 and 1921 with only 6 cases before that<sup>[64]</sup>. During this period, many UC patients were also reported in California<sup>[65]</sup>, Massachusetts<sup>[66]</sup>, and other places<sup>[67]</sup>.

World War II resulted in another jump in saccharin consumption (Figure 1). In the United States, Sigma Chemical Co. was formed to manufacture saccharin and Monsanto resumed large-scale production to meet the high demand<sup>[68]</sup>. Interestingly, record high incidence of IBD was also seen during this period. For instance, 525 cases of UC were diagnosed in male United States Army in 1944, with a rate as high as 12 per 100 000 in 40-45 age group<sup>[69]</sup>. This may relate to the preferred use of saccharin in the United States army. As early as in 1896, United States army had chosen saccharin rather sugar as the emergence ration for sweetening coffee or tea, taking the advantage of its immaterial weight as well as the anti-septic property to reduce the prevalence of diarrhea<sup>[70]</sup>.

## THE DRAMATIC INCREASE IN SACCHARIN CONSUMPTION SINCE 1950S AND THE REMARKABLE INCREASE IN INFLAMMATORY BOWEL DISEASE DURING 1950S AND 1970S IN COUNTRIES LIKE THE UNITED STATES

Although the shortage of sugar in World War I and II

**Figure 2** The dramatic increase in saccharin consumption since 1950s and the remarkable increase in inflammatory bowel disease during 1950s and 1970s in countries like the United States. A: Occurrence of ulcerative colitis (UC), Crohn's disease (CD), and inflammatory bowel disease [inflammatory bowel disease (IBD) = UC + CD] in Monroe County, New York during 1920s to 1980s; B: A comparison of the temporal change of IBD in Monroe County, New York and the saccharin consumption in the United States; C: Correlation between IBD in Monroe County, New York and the saccharin consumption in the United States.

led to increased consumption of saccharin as a sugar substitute, a huge increase only occurred since late 1950s, when low calorie high intensity sweetener began to be used in foods and drinks designated for special diets<sup>[56,71]</sup>. In 1976, approximately 7 million pounds of saccharin were consumed in the United States, with soft drinks accounted for 74 percent of those used in foods and beverages<sup>[72]</sup>. Saccharin had been used in juices and drinks, sauces and dressings, canned fruits, dessert toppings, coo-

kies, cereals, gums, jams, candles, ice cream and puddings, in addition to as a non-nutritive tabletop sweetener<sup>[72]</sup>. It was also used in drugs, toothpaste, mouthwashes, and cosmetics<sup>[72]</sup>.

In accordance with this dramatic increase in saccharin consumption, the incidence of IBD also showed a striking increase during this period. This was clearly demonstrated in the study by Stowe *et al*<sup>[73]</sup>, which showed the annual incidence of both UC and CD in Monroe County, New York between 1920s and 1986 (Figure 2A). From Figure 2B we can see the increase in IBD for up to later 1970s paralleled neatly with the increased consumption of saccharin during the same period<sup>[74]</sup>, with a very significant correlation (Figure 2C). The correlation coefficient between saccharin consumption in the United States and the new cases of UC, CD and IBD (UC + CD) in Monroe County were 0.930, 0.935 and 0.948, and the *P* value being  $3.43 \times 10^{-8}$ ,  $1.90 \times 10^{-8}$ , and  $3.85 \times 10^{-9}$ , respectively.

### DISCOVERY OF CARCINOGENICITY OF SACCHARIN IN LABORATORY ANIMALS IN 1970S AND THE LEVELING OFF OR DECREASE OF INFLAMMATORY BOWEL DISEASE OBSERVED IN MANY COUNTRIES SINCE THE SAME PERIOD

From Figure 2A, we can see the incidence of both UC and CD in Monroe County reached a peak in 1978, followed by a mysterious rapid decrease after that. Again, this change was in accordance with the finding of the carcinogenicity of saccharin in animals and the attempted ban for its use in the United States in 1977<sup>[26]</sup>. Due to the protest from the public the congress imposed a two year moratorium instead of a complete ban on saccharin, but passed the Saccharin Study and Labeling Act that required further studies on saccharin and putting a warning label on products containing saccharin<sup>[26]</sup>. Study showed that these events indeed affected saccharin consumption, especially for those with high education and families with children<sup>[75]</sup>. Not only in Monroe County in New York, the leveling off or decrease in IBD in later 1970s and 1980s was also seen in other cities of the United States such as Olmsted County, Minnesota<sup>[76]</sup>, as well as in many other countries such as Canada<sup>[77]</sup>, Denmark<sup>[78,79]</sup>, Germany<sup>[80]</sup>, Japan<sup>[81]</sup>, Israel<sup>[82]</sup>, Sweden<sup>[83-86]</sup> and United Kingdom<sup>[87-90]</sup> (Figure 3). In 1981 aspartame was approved by Food and Drug Administration (FDA) for use in dry food products<sup>[91]</sup>. On July 8, 1983 FDA further approved the use of aspartame in carbonated beverages and syrups<sup>[91]</sup>. Aspartame soon became the main high intensity sweetener in the market, with a sharp decline in saccharin use and consumption<sup>[91]</sup>, which was in accordance with the remarkable decrease in the incidence of UC and CD observed in Monroe County at this period (Figure 2A).

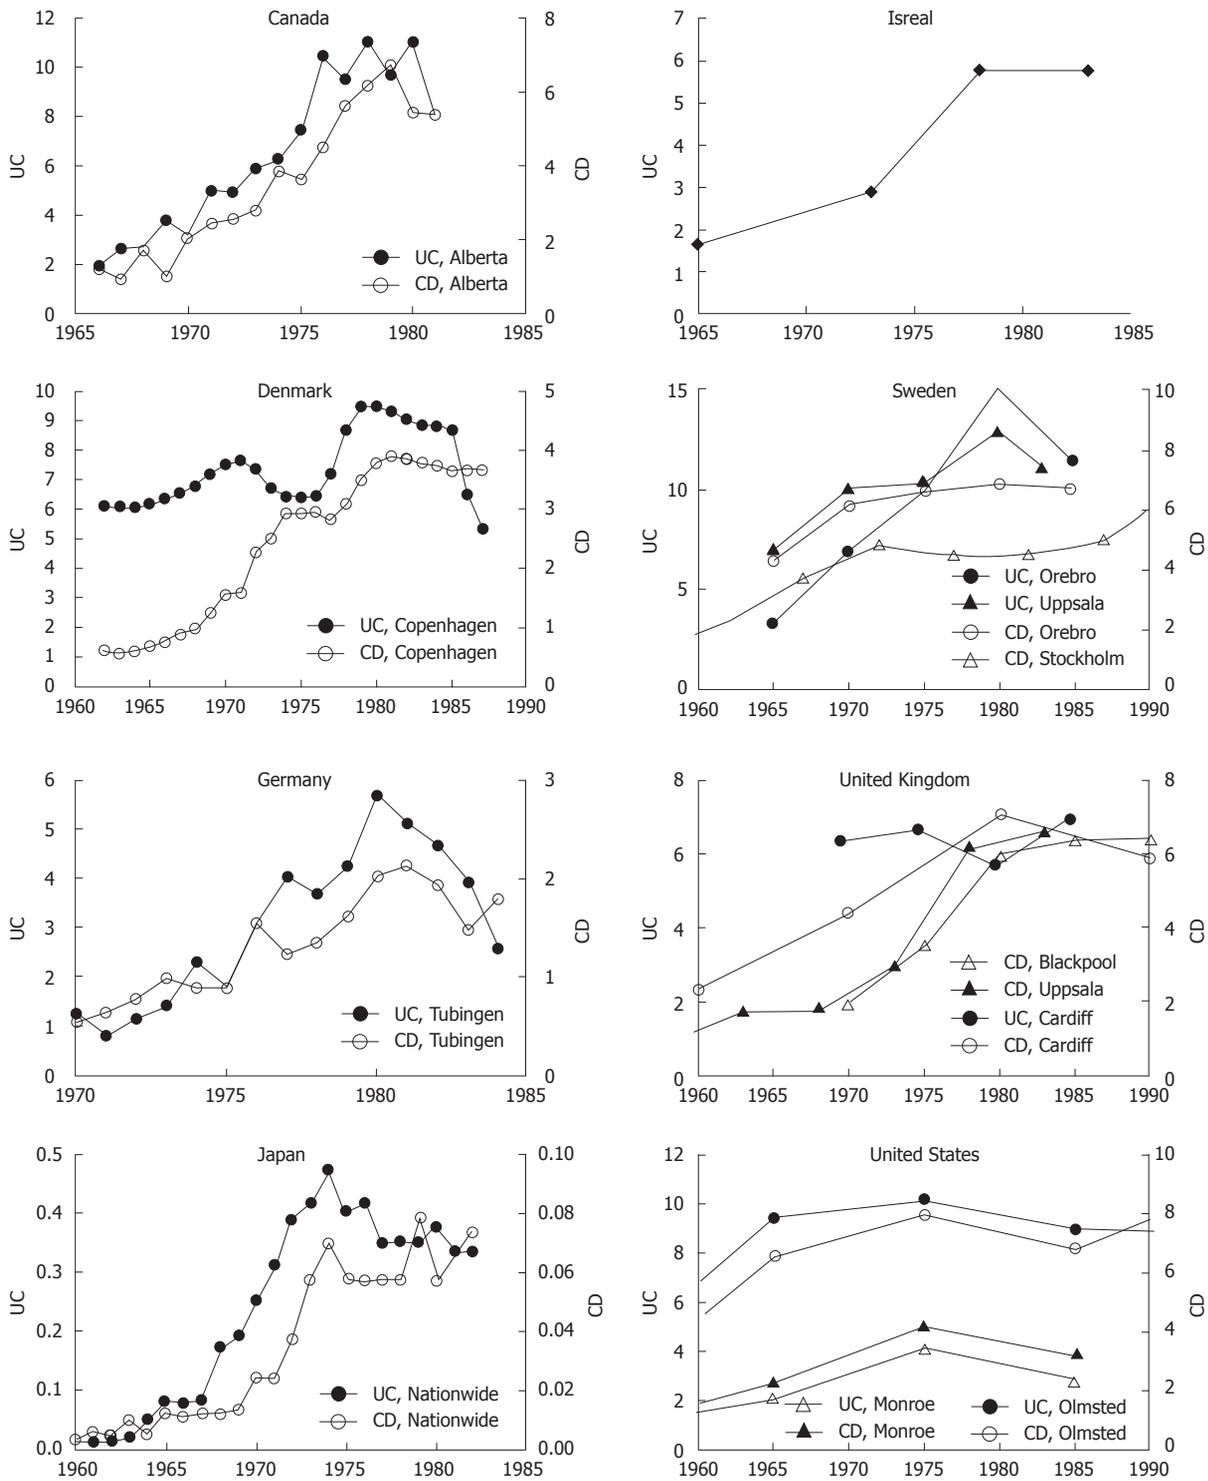

Figure 3 A leveling off or decrease of ulcerative colitis or Crohn's disease during 1970s and 1980s in the different countries such as Canada, Denmark, Germany, Japan, Israel, Sweden, United Kingdom, and United States. UC: Ulcerative colitis; CD: Crohn's disease.

### THE REBOUNDED USE OF SACCHARIN AND THE INCREASE AGAIN OF INFLAMMATORY BOWEL DISEASE SINCE 1990S

Although a leveling off or decrease in IBD was observed in many places (Figure 3) during the later 1970s and early

1980s, the increase again of IBD since 1990s was observed in many of these places such as Denmark<sup>[92]</sup>, Sweden<sup>[86,93,94]</sup>, United Kingdom<sup>[89]</sup>, and the United States<sup>[76]</sup>. This was again in accordance with the rebounded use of saccharin. After finding the carcinogenicity of saccharin in animals in 1970s, many studies were carried out. As the result, most studies failed to show a link between saccharin consumption and bladder cancer in humans<sup>[95,96]</sup>.

People gradually regained confidence in saccharin consumption. Saccharin production boomed again, largely because saccharin is very cheap and also very stable thus can be used in a wide range of drink and food products and put on the shelf for a long time<sup>[97,98]</sup>. In China, saccharin production increased from about 8000 tons in middle 1980s<sup>[99]</sup>, to 13 126 tons in 1991 and 29 175 tons in 1998, accompanied by dramatic increases in both domestic use and exportation<sup>[100]</sup>. The great adverse impact on sugar industry led the Chinese government adopting strict measures to limit the production and domestic use of saccharin. In the United States, after multiple times of renewal of the two year moratorium, the National Institute of Environmental Health Sciences finally delisted saccharin from carcinogen list in 2000 and the “Sweetest Act” of the Congress eliminated the requirement for putting the warning label on saccharin products<sup>[26]</sup>. This is accompanied by a dramatic increase in saccharin importation from 2 772 000 pounds in 2000 to 8 346 000 pounds in 2008<sup>[101]</sup>. In 2007, 52 212 000 pounds of saccharin were exported world wide, with millions of pounds of saccharin being imported in countries like Germany, Spain, United Kingdom, South Korea, Japan, India and Brazil<sup>[101]</sup>. These massive use of saccharin may have contributed to the worldwide increase of IBD in recent years<sup>[102]</sup>.

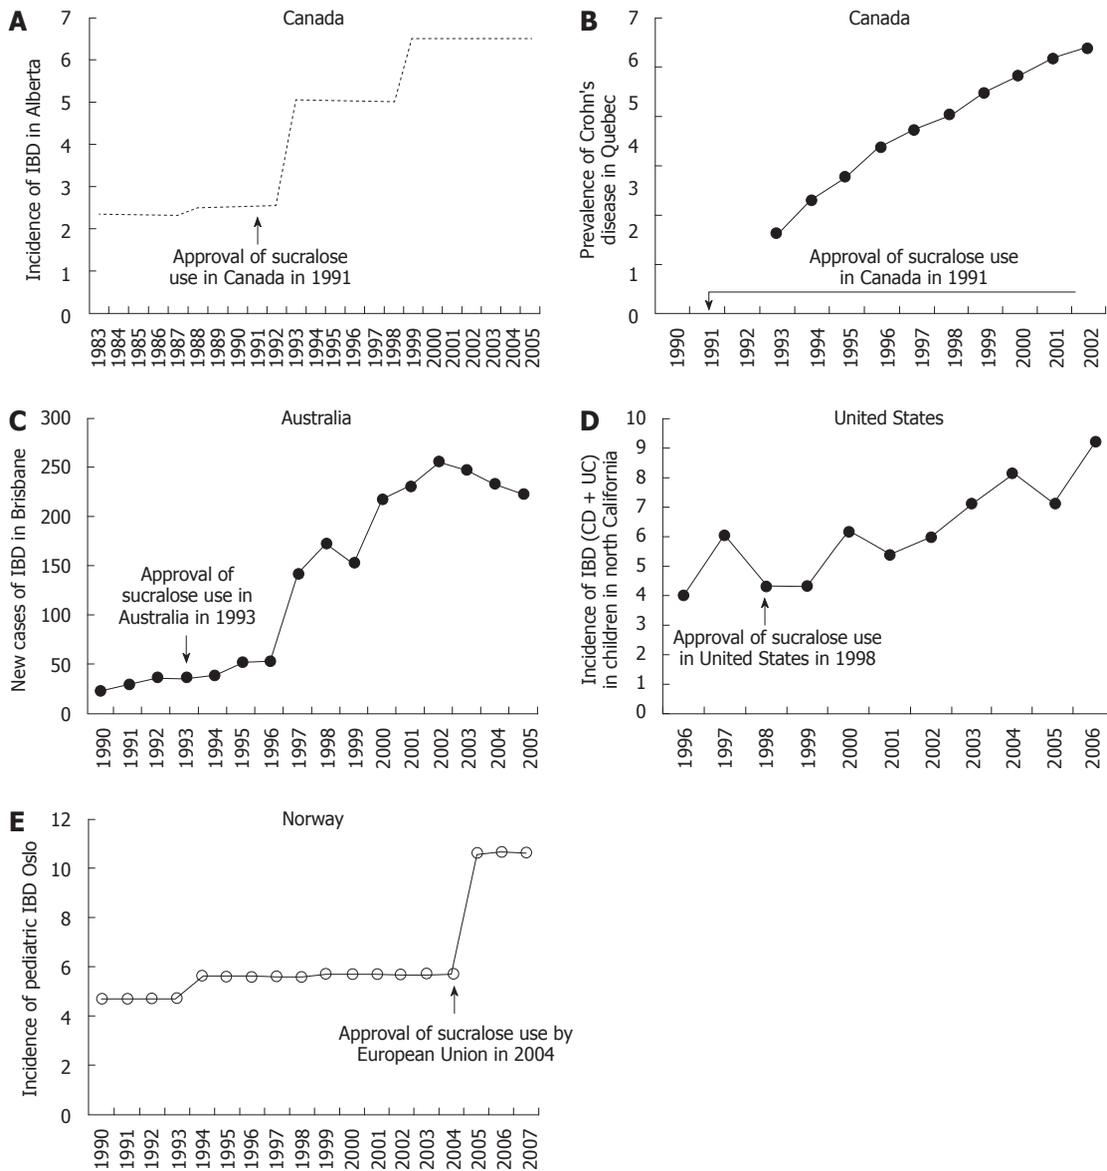

## **SUCRALOSE, A NEW GENERATION OF ARTIFICIAL SWEETENER, MIGHT BE ANOTHER IMPORTANT RISK FACTOR THAT CONTRIBUTED TO THE RECORD HIGH INCIDENCE OF INFLAMMATORY BOWEL DISEASE SEEN RECENTLY IN MULTIPLE COUNTRIES**

The evidences demonstrated above provided a simple explanation for many puzzles of IBD such as the emergence and temporal changes of IBD in last century. It suggests saccharin might be the key causative factor for IBD, by primarily its inhibition on gut bacteria<sup>[20]</sup>. This notion is supported by the recent large-scale studies showing antibiotics greatly increased the risk of IBD<sup>[103,104]</sup>. Although both saccharin<sup>[105-107]</sup> and antibiotics can inhibit bacteria, saccharin would have a much more great impact on the general population due to the wide extensive use<sup>[108]</sup>. When United States FDA attempted a ban on saccharin in 1977, saccharin was used as the only non-nutritive sweetener by up to 70 million Americans<sup>[74]</sup>. Saccharin was the first and oldest artificial sweetener. From its marketing in 1887 until a temporary decline in the market due to the heavy use of aspartame since 1980s saccharin had been the only or the predominant artificial sweetener, which made it a key dietary chemical in last century. However, more and more chemicals were introduced and became heavily used as food additives in modern society. It would be no surprising that some of them may also have a significant impact on gut bacteria,

thus IBD. Recently, I found evidences suggesting sucralose, the new generation of artificial sweetener, might be just an example. Sucralose is synthesized by replacing three hydroxyl groups of sucrose with three chlorides, which makes it 600 times as sweet as sucrose<sup>[109]</sup>. Like saccharin, sucralose is stable under heat and over a broad range of pH, and most of it passes through the body without further metabolism<sup>[97,109]</sup>. However, sucralose has a much lower absorption rate but a much high acceptable daily intake and thus a more potent impact on gut bacteria<sup>[97,110]</sup>. Sucralose was first approved for use in drinks and foods in Canada in 1991, which was in accordance with the dramatic increase of IBD seen in Alberta<sup>[111]</sup> and CD in Montreal<sup>[112]</sup> since early 1990s, as well as the finding in recent studies that Canada suddenly became a country with the highest incidence of IBD<sup>[113,114]</sup>. After Canada, sucralose was approved in Australia in 1993, in New Zealand in 1996, in the United States in 1998, and in the European Union in 2004, which was again in accordance with the dramatic increase or the record high incidence of IBD in Australia<sup>[115]</sup>, New Zealand<sup>[116]</sup>, the United States<sup>[117]</sup>, and Norway<sup>[118]</sup> (Figure 4)<sup>[21]</sup>. Currently, sucralose has been approved for use in more than 80 countries<sup>[119]</sup>, and started to appear in rivers and other surface waters of many countries<sup>[120]</sup>. In countries like the United States artificial sweeteners are now used by more than half of the population, with sucralose by far the number one in the market and being used in thousands of food and drink products<sup>[121]</sup>. This unrestricted use of sucralose may be also the explanation for the recent remarkable increase of IBD in children as observed in many studies<sup>[122]</sup>. We may expect to see more reports on record-breaking incidence of IBD, both in adults and children.

## **THE POSSIBLE MECHANISM OF INFLAMMATORY BOWEL DISEASE: THE BACTERIA-PROTEASE-MUCUS-BARRIER HYPOTHESIS**

After the emergence of IBD about a century ago, numerous hypotheses had been suggested as the possible mechanism, which included infection, toxicants, psychogenic disturbances, nutritional deficiencies, allergy to pollens or foods, abdominal trauma, impaired vascular or lymphatic circulation, lysozymes and other enzymes<sup>[1,123,124]</sup>, or the excessive or deficient immune response due to reduced exposure to bacteria or helminthes<sup>[125,126]</sup>. Most of them were invalidated and forgotten. Up to date, a full coherent mechanistic explanation for IBD is still lacking, but people start to realize that the pathogenesis of IBD involves four fundamental components: the environment, gut microbiota, the immune system and the gene<sup>[127-129]</sup>. Currently, the dominant theory regarding the increase of IBD (as well as other autoimmune and allergic diseases) in modern society is the “hygiene hypothesis”, which proposes that these diseases are caused by an aberrant

**Figure 4** Relationship between the increase of inflammatory bowel disease and approval of sucralose in countries like Canada, Australia, the United States and Norway. UC: Ulcerative colitis; CD: Crohn's disease.

development and response of the immune system due to the reduced exposure to microorganisms such as the microbes in the gut<sup>[127,128]</sup>. However, this theory neglected another fact: the increased intestinal permeability, which has been observed not only in these patients and their healthy relatives<sup>[130,131]</sup>, but also in their spouse<sup>[130,132]</sup>, suggesting likely a prerequisite condition for these diseases. As the gut contains such a large amounts of bacteria that are ten times of the number of cells of our body and can kill the host thousands of times over, I believe it would be the permeability of the gut rather than the absolute number of the bacteria in gut lumen that determined the level of exposure<sup>[133]</sup>. Therefore, the enhanced immune activities seen in these patients may just be a normal response to the increased infiltration of bacterial and dietary components from the gut lumen<sup>[133]</sup>. Then the key to the mystery would be to know what caused the increased intestinal permeability in modern society. Here I propose a mecha-

nism for the increased intestinal permeability as well as IBD, featured by the Bacteria-Proteases-Mucus-Barrier hypothesis.

As shown in Figure 5, this hypothesis proposes that the increased intake of dietary chemicals like saccharin and sucralose caused a significant reduction in gut bacteria, along with a failure for prompt replenishment due to the improved hygiene in modern society. This led to a remarkable decrease in  $\beta$ -glucuronidase in gut lumen, resulting in impaired deconjugation of the biliary bilirubin and the subsequent inactivation of digestive proteases. Then these poorly inactivated proteases work synergistically with the glycosides from the remaining bacteria to cause an accelerated degradation of the mucus layer, resulting in damage of the gut barrier (the Bacteria-Protease-Mucus-Barrier hypothesis). This will further result in infiltration of bacteria and their components (mainly in the large intestine) and recruitment of neutrophils lead-

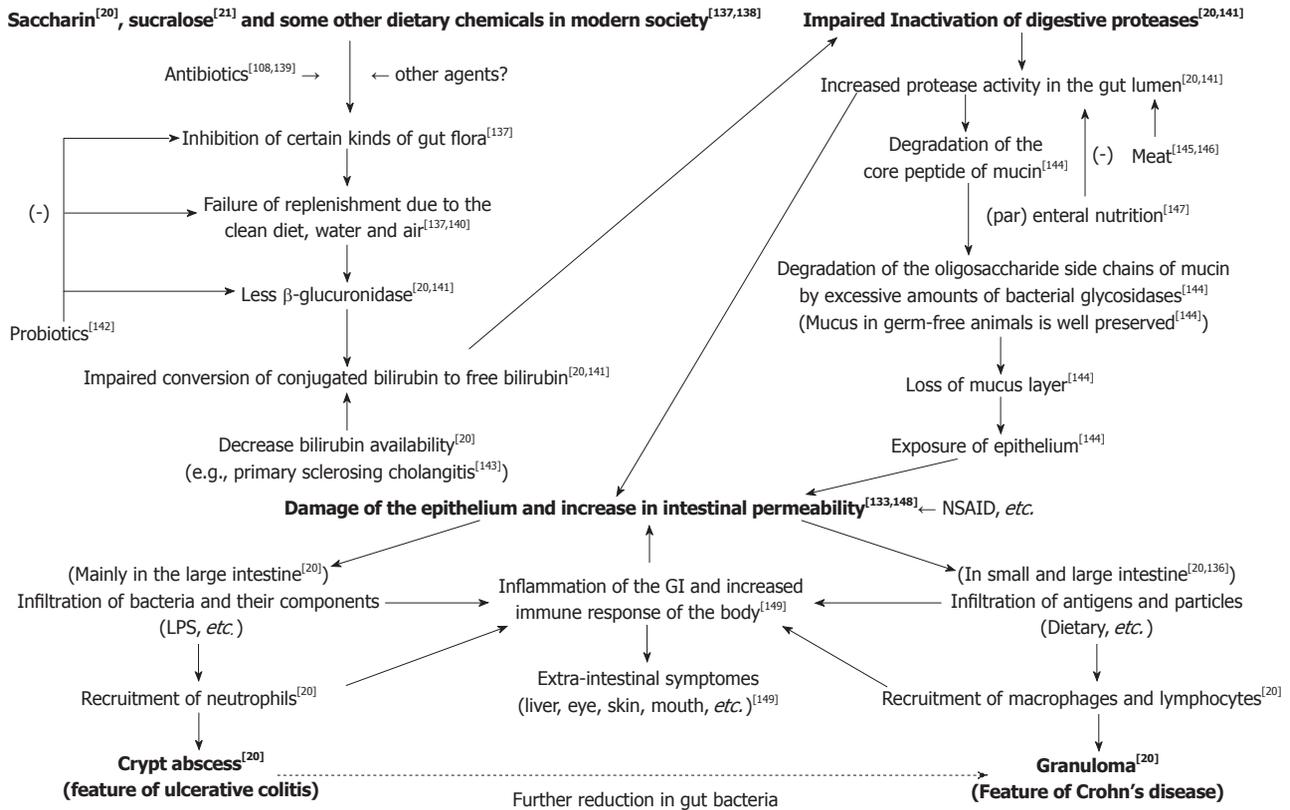

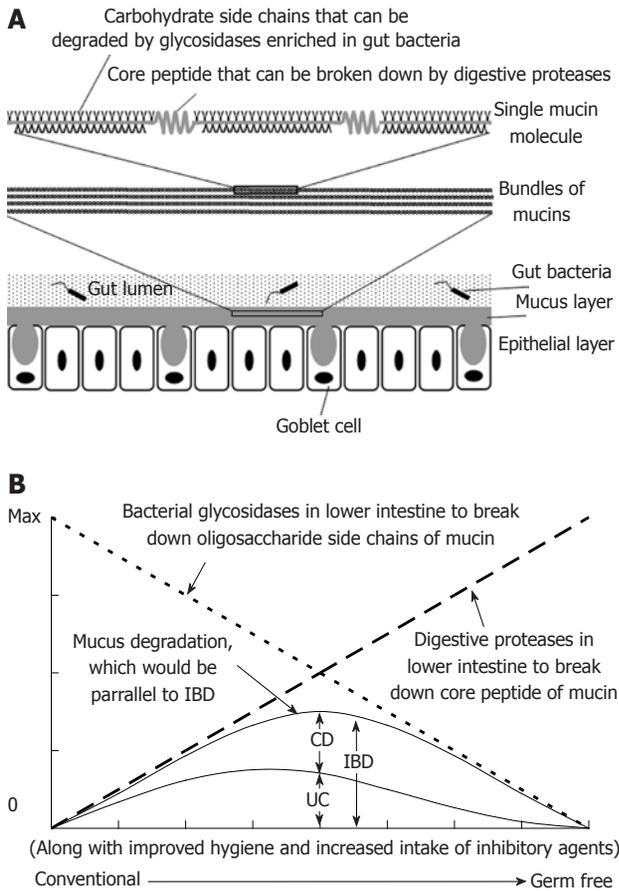

Figure 5 An overall hypotheses for the cause and mechanism of inflammatory bowel disease (both Crohn's disease and ulcerative colitis).

ing to the formation of crypt abscess<sup>[20]</sup>, the characteristic change of UC<sup>[134]</sup>; while at places or situations being relative sterile, the increased infiltration of antigens and particles from gut lumen would result in accumulation of macrophages and formation of inflammatory granulomas<sup>[20]</sup>, the hallmark of CD<sup>[134]</sup> (Figure 5). This would further induce enhanced immune response of the body, leading to further damage of the gut as well as extra-intestinal manifestations in the joints, skin, eyes, and mouth, *etc.*<sup>[135,136]</sup>. More detailed descriptions regarding the proposed mechanism can be found in the corresponding references<sup>[20,21,108,133,136-151]</sup>.

## ULCERATIVE COLITIS AND CROHN'S DISEASE ARE LIKELY JUST TWO SYMPTOMS OF THE SAME MORBIDITY RATHER THAN TWO DIFFERENT DISEASES

The Bacteria-Protease-Mucus-Barrier hypothesis and mechanism of IBD as described above and illustrated in Figure 5 suggest that UC and CD share virtually the same cause, thus UC and CD would be just two symptoms of the same morbidity rather than two different diseases. This notion contradicts the current main stream of thoughts that are trying to dissect UC and CD into multiple subtypes with different causes and diverse mechanisms<sup>[152]</sup>. Nevertheless, this new perception is in accor-

dance with many facts. Figure 6 further illustrated the mechanism of IBD as well as the relationship between UC and CD. It explained why gut damage and IBD started to appear and became more prevalent along with the improved sanitary condition but failed to develop under both conventional and germ-free condition<sup>[144]</sup>, and predicted a shift of predominance from the bacteria-mediated UC to antigen/particle-mediated CD along with the decrease in gut bacteria in modern society or other circumstances (Figure 6B). It provided a simple explanation for many big puzzles in IBD such as: (1) the discrepancy between the temporal changes of UC *vs* CD: Many studies had revealed a regular pattern that UC emerged first, then reached a plateau or even started to decrease, while CD showed a delayed appearance but accelerated increase with an eventual tendency to pass UC<sup>[2]</sup>. This would be just the pattern demonstrated in Figure 6B; (2) The increase in colonic CD over time: Studies in Stockholm County, Sweden found that colonic CD increased from 15% during 1959-1964 to 32% during 1980-1989, and further to 52% during 1990-2001, while the ileocaecal CD decreased from 58% during 1959-1964 to 41% during 1980-1989, and to 28% during 1990-2001<sup>[86,93]</sup>. Similar changes were also observed in other long-term studies such as the one conducted in Cardiff, United Kingdom<sup>[89]</sup>. Again, Figure 6B illustrated the anticipated shift of UC to colonic CD over time; (3) the inverse relationship between age and colonic CD in children: It is found that the younger the children, the more likely they had colonic CD<sup>[153]</sup>. This may be just due to the younger the children,

**Figure 6** Ulcerative colitis and Crohn's disease are likely just two symptoms of the same morbidity rather than two different diseases. A: The structure of mucin; B: Mechanistic sketch of the temporal changes of ulcerative colitis (UC) and Crohn's disease (CD) and their relationship. A reduction in gut bacteria along with the improved hygiene and increased intake of dietary chemicals like saccharin and sucralose will result in impairment in digestive proteases inactivation. The poorly inactivated proteases will work together with glycosidases from the gut bacteria to cause accelerated degradation of the mucus layer that is proposed here paralleling the risk of developing inflammatory bowel disease (IBD = UC + CD). UC and CD differ in that UC is caused by the increased infiltration of bacteria and the resultant recruitment of neutrophils and formation of crypt abscess, while CD is caused by increased infiltration of luminal antigens and particles and the resultant recruitment of macrophages and formation of granulomas. Thus the reduction in gut bacteria along with the modernization or other factors will result in a shift of predominance from the bacteria-mediated UC to antigen/particle-mediated CD. IBD: Inflammatory bowel disease.

the less population of bacteria in their gut; (4) the more pronounced increase in the risk of CD than UC along with the use of antibiotics<sup>[103]</sup>: again, this would be just the result of shift from UC to colonic CD along with the dramatic decrease in gut bacteria by the antibiotics; and (5) the proposed mechanisms as demonstrated in Figure 5 and Figure 6 may even provide some explanation for the similarities and discrepancies in the susceptible genes between UC and CD: UC and CD as well as other diseases like psoriasis and ankylosing spondylitis shared some common genes related to chronic inflammation such as interleukin-23 pathway, while CD being more associated with genes related to the function of macrophages such as NOD2 and autophagy, but UC being more associated

with genes related to neutrophil extravasation and epithelial defense such as LSP1<sup>[154]</sup>.

## CONCLUSION

Currently, tremendous efforts have been taking for research on the genes, the microbiota and the immune system: genome-wide association studies to find out the susceptible loci among the tens of thousands of genes in our body; metagenome, metaproteome, and metabolome analyses of gut microbiota that contains more than 100 times of genes than our own genome<sup>[155]</sup> to find out the bacteria responsible; and extensive studies on the many cells, signal pathways, mediators and cytokines of the immune system to find out aberrant immune response<sup>[127,128,156-158]</sup>. IBD emerged and became epidemic for about a century, suggesting the factors in environment rather than the gene or other factors within the body would be the primary cause. Increased risk of IBD in twins, families, or the same ethnic groups may attribute to not only the gene, but also environmental factors they shared such as the type of diet<sup>[159,160]</sup>. This article proposes saccharin being the key causative factor that contributed greatly to the emergence and epidemic of IBD in last century. As described above, there were big variations in saccharin regulation and consumption among the different countries and also in the different periods or even different parts (such as the different states in the United States<sup>[161]</sup>) within a country. This may explain the constant temporal changes and big geographical variations in IBD, and why similar changes were more likely seen within the border of a country rather than the closeness between cities<sup>[3,5]</sup>. In the developed countries, saccharin may be more frequently used by white collars working in the office, while saccharin may be more likely consumed by people in lower class in the developing countries due to its cheapness. This may contributed to the high incidence of IBD in high social, economical, educational status in the developed countries<sup>[162]</sup>, while some early study in India found almost all the patients belonged to the middle and poorer classes under poor hygiene condition<sup>[163]</sup>, in accordance with a heavy saccharin consumption in that country<sup>[164]</sup>. This would suggest improved hygiene itself might facilitate but still not be sufficient, while some dietary chemicals might be enough to cause significant impact on gut bacteria and IBD. This notion is also in accordance with the close relationship of IBD with westernization rather industrialization, as demonstrated by the much low incidence of IBD in the developed countries like Japan, Singapore and Hong Kong<sup>[138,156]</sup>. The recent increase again of IBD in the developed countries is also unlikely attribute to a further improvement in hygiene condition. At early times, saccharin was mainly used as a tabletop sweetener in the restaurants, tea houses or coffee shops, thus men may have more chance to consume than housewives. However, in modern society, dietary drinks or foods may be more consumed by young ladies for concerns on their body weight. This may account for the

changes and variations in gender and age of IBD over time<sup>[3,5,6]</sup>. The recent finding of the even stronger impact of sucralose on gut bacteria further provided a possible explanation for the record high IBD observed recently in multiple countries<sup>[21,114]</sup>, as well as the remarkable increase of IBD in children<sup>[122]</sup>. Epidemiological study revealed spotted areas with high IBD<sup>[165]</sup>. Probably we should add another thing to the checklist: to see if there is any famous bakery, restaurant, or bar where foods or drinks are sweetened heavily by these artificial sweeteners.

Although it is proposed here that saccharin and sucralose might be the key causative factors for IBD, it does not mean to rule out that some other genetic or environmental factors may also be capable of affecting or contributing to IBD one way or the other.

However, the peculiar changes of IBD such as the recent worldwide increase of IBD, especially in the developed countries in children, seems unlikely to be explained by any of the currently suspected factors like the genes, smoking, NSAIDs, conceptive, appendectomy, sunshine and vitamin D, refrigeration, reduced exposure to bacteria, virus or worms, *etc.* Therefore, a fundamental breaking through in IBD would largely depend on finding out the key causative factors in the environment and thus the root mechanism of IBD. This paper proposed that impaired inactivation of digestive proteases due to the inhibition of gut bacteria by dietary chemicals like saccharin and sucralose being the primary mechanism. This would suggest it is not any pathogen but the digestive proteases produced by our body to digest the food for survival being the principal culprit for IBD. Under conventional conditions, the commensal bacteria (the microbiota) would be a valuable partner of our body by helping promptly inactivating these destructive proteases, probably by simply providing their enriched  $\beta$ -glucuronidase needed for deconjugation of biliary bilirubin. Thus the gut microbiota should be treated as an “microbial organ” of the body and taken into consideration when assessing the toxicity of chemicals or the adverse effects and efficacy of drugs<sup>[150]</sup>. However, the microbiota could be beneficial and also could be detrimental. Once there were not enough gut bacteria to help maintaining the function of gut barrier, they would start to leak into the body and become the driving force for the chronic inflammation seen in IBD. Once getting into the body, none of the commensal bacteria will remain our friend and our body will fight desperately against it. It seems unlikely and might also be unnecessary to pin down to one or a couples strains of bacteria exclusively responsible for IBD by screening the tens of thousands of species of bacteria in gut microbiota<sup>[149]</sup>. The enhanced immune activity in IBD would be just the normal reaction to the infiltrated bacterial and dietary components from gut lumen rather than an unbalanced or aberrant immune response, which may explain the remarkable increase of both the Th1-mediated CD and Th2-mediated UC in modern society<sup>[133]</sup>. It is proposed here that UC and CD are just two symptoms of the same morbidity rather than two different diseases. Some recent studies revealed that colonic CD had be-

come the main form of CD<sup>[166-168]</sup>. Apparently, the CD we are talking about today is no more the “regional ileitis” when this disease was defined by Crohn *et al*<sup>[169]</sup> in 1932. These CD cases are also no more the resemblance of Johne’s disease in cattle, but rather IBD frequently seen in dogs and cats<sup>[146]</sup>. Many of the colonic CD diagnosed today would be just UC cases early. On the other hand, the advance in endoscopies and other technologies led to reveal that a substantial portion of UC patients have ileitis (backwash ileitis) and the prevalence of inflammation seen in the esophagus, stomach, and duodenum is comparable among CD and UC<sup>[170]</sup>, further suggesting the intimate similarities between UC and CD. As stated above, the discrepancy between the temporal changes of UC *vs* CD would actually reflect their intimate connection. Elucidating the true relationship between UC and CD would be the crucial step for a full understanding of IBD.

This paper proposed a unified hypothesis regarding the etiology for IBD, including the cause and mechanism of IBD as well as the relationship between UC and CD. It provides a simple explanation for many puzzles of IBD. However, just like all other hypothesis and even existing theories well written in textbooks, it must be tested against facts. In the last decade, I have contacted multiple national and international organizations and IBD professionals suggesting checking out the possible link between saccharin and IBD, but failed to raise any action. I have also tried multiple times to apply grants from different agents, but remain unsuccessful. Hope this article may draw more attention and efforts. IBD just emerged and became epidemic for about a century and would be preventable and also likely curable, but first we may need to find out the key causative factors and thus the primary and fundamental mechanism<sup>[171]</sup>.

### Abstract

The authors review the clinical outcome in patients with Crohn's disease (CD) based on studies describing the natural course of the disease. Population-based studies have demonstrated that the incidence rates and prevalence rates for CD have increased since the mid 1970s. The authors search for English language articles from 1980 until 2011. Geographical variations, incidence, prevalence, smoking habits, sex, mortality and medications are investigated. An increasing incidence and prevalence of CD have been found over the last three decades. The disease seems to be most common in northern Europe and North America, but is probably increasing also in Asia and Africa. Smoking is associated with an increased risk of developing CD. Age < 40 at diagnosis, penetrating/stricturing complications, need for systemic steroids, and disease location in terminal ileum are factors associated with higher relapse rates. A slight predominance of women diagnosed with CD has been found. Ileocecal resection is the most commonly performed surgical procedure, and within the first five years after the diagnosis about one third of the patients have had intestinal surgery. Smoking is associated with a worse clinical course and with increased

risk of flare-ups. In most studies the overall mortality is comparable to the background population. To date, the most effective treatment options in acute flares are glucocorticosteroids and Tumor Necrosis Factor (TNF)- $\alpha$ -blockers. Azathioprine/methotrexate and TNF- $\alpha$ -blockers are effective in maintaining remission.

### INTRODUCTION

The incidence rates for Crohn's disease (CD) and ulcerative colitis (UC) in Western countries have increased since the mid-1970s. The same trend, although less pronounced, is also seen in the developing world<sup>[1-3]</sup>. The reported geographical variations in incidence may in part be due to differences in diagnostic tools and study design, and many of the epidemiological studies have been retrospective and hospital-based<sup>[4]</sup>. CD is a disease with a broad spectrum of clinical manifestations, and the initial presentation is seldom a good predictor of the clinical course<sup>[5-7]</sup>. Patients with newly diagnosed CD often ask about expectations related to the course of the disease. To answer this question, information on the natural course of CD based on observational, population-based

cohort studies is crucial. The “natural course” in CD might be different in 2011 compared to the situation for instance in the 1980s, and there are at least two reasons for this: we now have better tools to diagnose the condition in an earlier phase, and we have new therapeutic agents that hopefully will alter the course of the disease.

The primary aim of this article is to review the clinical outcome in patients with CD based on population-based studies conducted over the last thirty years, focusing predominantly on studies describing the natural clinical course in representative cohorts of patients with CD.

The factors investigated include incidence, prevalence, age, sex, smoking, geographical differences, surgical aspects, extra-intestinal manifestations, mortality, medication, clinical course with focus on relapse and surgery, the location and behavior of the disease, and finally, the need for sick leave/unemployment. A Medline search (1980 to 2011) for English language articles was conducted.

The MESH term “Crohn disease” was combined with free text search for “population based” and “clinical”. This search yielded sixty-seven articles. All potential relevant articles were evaluated.

## EPIDEMIOLOGICAL ASPECTS OF CROHN'S DISEASE

### *Incidence, prevalence and time-trends*

The incidence of CD differs depending on the region studied. The United Kingdom, North America and the northern part of Europe are the areas with the highest incidence<sup>[8-10]</sup>. A Danish study from 1997 found that the mean incidence rate for men per 100 000 person years increased from 3.3 in 1981-1984 to 4.1 in 1989-1992<sup>[11]</sup>. For women in the same area and in the same time intervals, the incidence rate increased from 4.6 to 6.2. A peak incidence rate was found among 15-29-year-olds, with an incidence rate among men and women of 5.3 and 9.1, respectively. A recent study in which all new CD cases in Finland between 2000 and 2007 were included revealed an overall incidence rate of 9.2 per 100 000 inhabitants<sup>[12]</sup>. The incidence rate in Olmsted County, Minnesota, United States was 5.7 cases per 100 000 person years between 1940 and 1993<sup>[10]</sup>. During the study period, a marked increase in incidence was found: in 1940-1943 the incidence rate was 1.0, while the rate in 1984-1993 was 6.9. Traditionally, the incidence has been low in Asia and Africa. Studies from these areas suggest that the incidence of CD is increasing<sup>[2,13]</sup>.

The prevalence of CD in Europe varies from less than 10 to about 150 per 100 000 inhabitants<sup>[9,14]</sup>. An adjusted prevalence of 133 per 100 000 was found in Minnesota, United States in 1991<sup>[10]</sup>. One study from South Korea indicated prevalence of 11.2<sup>[15]</sup>. From the existing data, one can conclude that the incidence and prevalence rates of CD have increased over last decades.

### *Sex and age at diagnosis and smoking*

In a retrospective study from the United Kingdom on patients diagnosed with CD<sup>[16]</sup>, the patient population was

divided in three groups by year of diagnosis: 1986-1991, 1992-1997 and 1998-2003. Of a total of 341 subjects diagnosed with CD, 62% were females. In all time intervals, the median age at diagnosis was 30 years. In a prospective study from Denmark, all patients in Copenhagen County diagnosed with UC and CD from 2003 to 2005 were followed for 11.3 mo (median); 54% of the CD patients were females, and median age at diagnosis was 31 years<sup>[8]</sup>. A retrospective study from Olmsted County, Minnesota, United States showed that 54% of the patients were females, and the median age at diagnosis was 29.5 years<sup>[10]</sup>.

In Norway, the Inflammatory Bowel South-Eastern Norway (IBSEN) group, in a prospective study, has followed patients with inflammatory bowel disease (IBD) since the beginning of the 1990s<sup>[17]</sup>. This study reported a slight predominance of women diagnosed with CD, with a male/female-ratio of 0.95. The median age at diagnosis was 30 years. In Finland, no significant difference between the genders was found<sup>[12]</sup>. A population-based Canadian study<sup>[18]</sup> found a female predominance: 58% of the patients were women. Cigarette smoking is associated with increased risk of developing CD<sup>[19]</sup>. Smoking negatively influences the clinical course of CD and is also associated with the clinical recurrence of CD after surgical resection in CD patients<sup>[20]</sup>. Cosnes *et al*<sup>[21]</sup> found that smoking, particularly heavy smoking, markedly increased the risk of flare-ups of the disease.

Based on these studies, the conclusion is that there is a slight predominance of women diagnosed with CD, that the age at diagnosis is approximately 30, and that cigarette smoking is harmful in patients with CD.

### *Appendectomy*

The relationship between appendectomy and the risk of developing CD has been debated, and in 2009, a systematic review of the literature was performed<sup>[22]</sup>. The authors found that the relative risk (RR) for having CD diagnosed following an appendectomy was significantly elevated. Within the first year after the surgery, the RR was 6.69 (95% CI 5.42-8.25). An increase in the risk of developing CD also was found 1-4 years after the appendectomy, but thereafter the risk was not increased. Another study confirmed these results, but no increased risk of developing CD was found in patients who underwent appendectomy before the age of ten<sup>[23]</sup>. It seems that there was an inverse relationship between appendectomy and the development of UC, at least in patients who underwent appendectomy before the age of 20<sup>[24]</sup>.

### *Geographical differences*

The occurrence of CD seems to vary according to geographical location. A north-south axis has been found in both Europe and in the United States, with higher incidence and prevalence in the northern regions. In a study from 1996<sup>[25]</sup> on the incidence of IBD across Europe, incidence rates were found to be 80% higher in northern centers than in southern. A French study from 2006<sup>[26]</sup> also demonstrated a north-south gradient within France. Data from Columbia support the clinical experience that

CD is rare in South America<sup>[27]</sup>. Based on a prospective European population-based inception cohort of 380 CD patients, a difference in management was observed between northern and southern centers, indicating that CD patients in the north had a more severe disease course than did those in the south<sup>[28]</sup>. One problem is that there are still huge differences in diagnostic facilities. South Asians who live in Europe are more likely to develop IBD than South Asians who do not. In some regions of the world, there are diagnostic challenges due to overlap with intestinal tuberculosis<sup>[11]</sup>. In Brazil, Argentina, Puerto Rico and Panama, the prevalence of CD and UC together is between 20-100/100 000 inhabitants, but very few reports exist, and the ratio between CD and UC is uncertain. This is in marked contrast to the numbers from the United States and Canada, where the prevalence numbers vary between 320/100 000 and 511/100 000 inhabitants<sup>[27]</sup>. The reasons for these differences are not fully elucidated.

Hispanics in the United States are less prone to develop IBD than the non-Hispanic population. It is known that the *NOD2* gene on chromosome 16 is a marker for the susceptibility to CD. A recent study showed that 4.4% of Hispanics and 9.1% of the white population have *NOD2*<sup>[29]</sup>. This indicates that there are real differences in incidence/prevalence between North and South America.

### Clinical important risk factors

In many studies, risk factors predicting a disabling course of CD are described. The IBSEN group<sup>[30]</sup> has described the relapse rates and need for surgery one, five, and ten years after the diagnosis. Age < 40 at diagnosis and the need for systemic steroids to treat the first flare-up were factors associated with higher relapse rates. Age < 40 at diagnosis, disease location in terminal ileum and penetrating/stricturing complications were associated with higher risk for surgery (Tables 1 and 2). Beaugerie *et al*<sup>[31]</sup> also found that age < 40 at diagnosis of CD, presence of perianal disease, and initial requirement for steroids were independent factors predicting disabling disease during the first five years after the diagnosis. Henriksen *et al*<sup>[32]</sup> did not find any association between CRP levels and a risk of surgery for the CD group as a whole, but a significant linear association between CRP levels and a risk of surgery was found with L1 localization (disease localization in terminal ileum).

## SURGERY

### Bowel resection

Stenoses, fistulas and abscesses are the main reasons for bowel resection in patients with CD.

In a Danish study from 2003-2005, 12% of CD patients underwent bowel resection performed within one year after the diagnosis, and the median time from diagnosis to resection was one month (range 0-8 mo)<sup>[8]</sup>. The authors compared the results to what was seen in patients diagnosed with CD in the same area between 1962 and

1987. In the earlier period, as many as 35% of the CD patients underwent bowel resection performed within the first year of diagnosis. A shorter delay from the onset of symptoms to diagnosis and the introduction of more intensive immunosuppressive therapy might be among the explanations for this decreased risk of surgical resection.

The Montreal classification of CD includes the location (L) of the disease, where L1 is location in the terminal ileum, L2 is in the colon, L3 is an ileocolonic location, and L4 is an upper GI location<sup>[33]</sup>. In one study, patients with L1 location at diagnosis had increased likelihood of intestinal surgery<sup>[5]</sup>. Oral corticosteroid use within three months of diagnosis, stricturing disease and low age at diagnosis were also associated with increased likelihood of resection. In the IBSEN study, the cumulative probability of surgery was 13.6%, 27.0% and 37.9% at one, five, and ten years after diagnosis<sup>[30]</sup>, respectively. In this cohort, L1 location was strongly associated with surgery compared to L2 and L3 locations (Table 1).

A United Kingdom study of changes in medical treatment and surgical resection rates from 1986 to 2003 found a marked reduction in the proportion of patients needing intestinal surgery<sup>[16]</sup>. Within five years of diagnosis of CD, 59% of the patients diagnosed from 1986-1991 had intestinal surgery. In patients diagnosed between 1992-1997 and 1998-2003, 37% and 35%, respectively, had intestinal surgery within five years of diagnosis. In addition, there was a significant reduction in patients undergoing any surgical procedure (surgery for perianal disease or intestinal surgery) during an advanced stage of disease. Ileocecal resection was the most commonly performed procedure. The most striking reductions were seen in the numbers of ileocecal resections and in the numbers of panproctocolectomies.

A French retrospective study with 2573 CD patients<sup>[34]</sup> divided the cohort in five groups according to the year of diagnosis (1978-1982, 1983-1987, 1988-1992, 1993-1997 and 1998-2002). The main outcome criterion was the time to first intestinal resection. The cumulative probability to receive immunosuppressants [azathioprine (AZA), methotrexate (MTX)] increased from 0 in the 1978-1982 cohort to 0.56 in the 1998-2002 cohort. Interestingly, in contrast to the study from the United Kingdom<sup>[16]</sup>, one found that the year of diagnosis did not have any significant effect upon the need for surgery.

### Extra-intestinal manifestations

Extra-intestinal manifestations of CD include musculoskeletal, dermatologic, ocular, hepatobiliary, vascular and renal complications<sup>[35]</sup>. About 25%-46% of the patients with CD will experience extra-intestinal manifestations<sup>[36,37]</sup>. Primary sclerosing cholangitis (PSC) is in many ways the most serious, and the most serious complication from this condition is cholangiocellular carcinoma (CCC)<sup>[37]</sup>; 7% to 15% of the patients with PSC eventually develop CCC<sup>[38,39]</sup>, 60%-70% of the PSC patients are male, and the age at diagnosis is about 40 years. There is a close relationship between UC and PSC. The relationship

<sup>1</sup>Difficult to conclude because of an insufficient number of patients; <sup>2</sup>data unknown in 6 cases. There were none in the operated group; <sup>3</sup>data unknown in 2 cases; There was one in the operated group. Risk factors at diagnosis associated with surgery during follow-up analyzed by Cox regression. Ref: Reference variable; HR: Hazard ratio; CI: Confidence interval;

between CD and PSC is less pronounced but marked. Studies from Sweden and Holland showed that 72% and 73%, respectively, of the PSC patients with IBD had UC, and 7% and 25%, respectively, of the PSC patients with IBD had CD<sup>[40,41]</sup>.

In both studies, a certain proportion of patients with PSC did not have a diagnosis of IBD. To date, no medical treatment has been established to be effective. A hydrophilic dihydroxy bile acid, ursodeoxycholic acid, is used in the treatment of PSC, but the efficacy of the treatment is not well established. A recent study even concluded that serious adverse events were more common in the drug-treated group than in the placebo group<sup>[42]</sup>.

Five-year follow up data from the IBSEN study showed that the cumulative occurrence of peripheral arthritis related to CD is 14%; 6% had ankylosing spondylitis; 1% had psoriatic arthritis; and 19% had undifferentiated spondyloarthropathy<sup>[43-45]</sup>. In Canada, one study following the patients from 1984 to 1997 showed that 6027 patients suffering from IBD had a 40% increased risk of fractures compared to the control group<sup>[46]</sup>. The incidence rate ratio (IRR) for fracture at the hip was 1.59 (95% CI: 1.27-2.00,  $P < 0.001$ ); the IRR for fracture of the spine was 1.74 (95% CI: 1.34 -2.24,  $P < 0.001$ ); while the IRR for rib fracture was 1.25 (95% CI: 1.02-1.52,  $P = 0.03$ ). No differences were found in the IRR between CD and UC patients. A study from Olmsted County, United States, showed that the relative risk for osteoporotic fractures in CD patients was 1.4 (95% CI: 0.7-2.7), and the risk ratio for thoracolumbar vertebral fracture was 2.2 (95% CI: 0.9-5.5)<sup>[47]</sup>.

### Mortality

During the decades from 1970 to 1990, population-based studies have shown a slightly decreased life expectancy in CD patients<sup>[48-50]</sup>. Because these studies are from the era before the introduction of the immunomodulating agents, the applicability might be of limited value.

A meta-analysis from 2007<sup>[51]</sup> identified 13 papers that reported standardized mortality ratios (SMR). Most of these papers included patients diagnosed in the 1950s to the 1970s, although four of them included patients diagnosed from 1980 to 1985. In this study, an age-adjusted mortality risk in CD patients was more than 50% greater than in the general population, but three of the studies actually reported an SMR below 1.0. A meta-analysis from 2010<sup>[52]</sup> also confirmed slightly increased mortality in CD patients (SMR 1.39, 95% CI: 1.30-1.50). In a recent report, a complete 10-year follow-up was achieved in 197 of 237 patients<sup>[30]</sup>. Two deaths during follow-up were probably CD-related. Another study did not show any decrease in survival curves for the total group of 373 CD patients followed for five years compared to the background population, although a small subgroup of patients diagnosed at the age of 20-29 and a subgroup with extensive small bowel disease displayed slightly increased mortality<sup>[53]</sup>. In the Netherlands, 1187 patients diagnosed with IBD during a 12-year period from 1991 were included<sup>[54]</sup>. The mortality in CD, UC, and indeterminate colitis

was comparable to the background population, but the disease-specific mortality risk was significantly increased for gastrointestinal causes in both CD and UC patients. Overall, a slight increase in mortality was found in CD patients. This is mainly caused by malignant diseases in the gastrointestinal tract and in the lungs<sup>[52]</sup>.

### Medication

CD is a chronic disorder that, at least so far, is not curable. The induction and maintenance of symptom improvement and, at best, the induction and maintenance of mucosal healing are the goals of treatment<sup>[55]</sup>. Disease location, disease severity and complications should be taken into consideration when therapy is to be decided.

Even at high doses and prolonged administration, glucocorticosteroids (GCSs) induce endoscopic remission in less than one third of the patients with colonic CD<sup>[56]</sup>. Use of GCSs has a favorable effect on the symptoms of Crohn's disease of the small intestine but will not achieve a significant reduction in endoscopically observed inflammation<sup>[57]</sup>.

A few decades ago, a large clinical trial<sup>[58]</sup> showed that CD patients with colonic involvement were especially responsive to sulfasalazine, but a European multicenter double-blind study from the 1980s did not show any beneficial effects from sulfasalazine as compared to 6-methylprednisolone<sup>[59]</sup>. Oral mesalamine has been, and still is, widely used in the treatment of CD. A meta-analysis of three large, double-blind, randomized studies in the treatment of active CD showed that mesalamine 4 g/d was better than placebo in reducing the Crohn's Disease Activity Index, but the clinical significance was unclear<sup>[60]</sup>. The recently published European evidence-based consensus on the diagnosis and management of CD<sup>[61]</sup> concluded that active colonic CD may be treated with sulfasalazine if only mildly active, and that mesalamine should be considered no more effective than placebo in the treatment for active ileal or colonic CD.

The rationale for the use of antibiotics in the treatment of mild to moderate CD is the hypothesis that bacteria may cause or exacerbate CD. Metronidazole, 10 or 20 mg/kg per day, compared to placebo, did not show any difference in the ability to induce remission in patients with mild/moderate disease<sup>[62]</sup>. Comparison of ciprofloxacin and mesalamine did not reveal any consistent pattern<sup>[63]</sup>. About 50% in each group achieved clinical remission. A recent meta-analysis<sup>[64]</sup> concludes that long-term treatment with nitroimidazoles or clofazimine appeared to be effective in CD patients.

A recent review on the effect of AZA or 6-mercaptopurine for the maintenance of remission in CD<sup>[65]</sup> concluded that both AZA and 6-mercaptopurine had a positive effect on maintaining remission. The study reported weak evidence for a steroid-sparing effect of AZA. In a recent single-center study<sup>[66]</sup>, the authors found that MTX is efficient as a second-line immunomodulator in chronic active CD. In steroid-dependent CD patients, complete remission and steroid withdrawal were seen in 77% of the cases after 22.9 mo of treatment. After six months,

one, two, and three years on MTX, 95.3%, 89.5%, 70.6% and 62.8%, respectively, were in remission<sup>[67]</sup>. However, a high proportion of the patients developed side-effects (79% and 39%, respectively), including hepatotoxicity and hair loss<sup>[66,67]</sup>. Side effects associated with the use of AZA and 6-mercaptopurine include leucopenia, thrombocytopenia, pancreatitis and an increased risk of developing lymphoma<sup>[65]</sup>. The introduction of anti-tumor necrosis factor (TNF) agents has changed the treatment of refractory CD. Although the causes of CD are not known, many of the molecules involved in the disease process have been identified and can act as targets of biological treatment. TNF is a cytokine that promotes inflammatory responses in many diseases, including CD<sup>[68]</sup>. Infliximab is effective in both luminal and fistulizing CD<sup>[69,70]</sup> and is highly effective and safe in children<sup>[71]</sup>. The combination of infliximab and AZA is more effective in moderate-to-severe CD than infliximab alone<sup>[72]</sup>. One problem is that, each year, about 10% of patients, for different reasons, drop out of treatment<sup>[73]</sup>. Adalimumab is a human monoclonal antibody against TNF. It is administered subcutaneously and has proven effective in the treatment of luminal CD<sup>[74]</sup>. Certolizumab pegol is approved in the United States for the treatment of CD<sup>[68]</sup>. No trials exist that compare the three different anti-TNF agents, but it seems that infliximab, adalimumab and certolizumab pegol are comparable in efficacy. Anti-TNF agents definitely deserve to be considered as a treatment option for patients with CD; it is therefore widely discussed when patients should be introduced to these agents, and further studies are needed to establish this aspect of the approach to treatment.

In a review article, Vermeire *et al.*<sup>[75]</sup> summarized the therapies that have been shown to alter the natural history of CD. Mucosal healing, the need for hospitalizations/surgery together with decreased recurrence after surgery, are surrogate markers of changes in the natural course of the disease. Anti-TNF agents have shown the ability to induce mucosal healing and to reduce the need for surgery in randomized, placebo-controlled studies. It is not known, however, if they can reduce the risk of recurrence after surgery.

## CLINICAL COURSE

Markov models will show the probability of changes in state from one time-point to another. This model was used in a Danish study from 1995<sup>[6]</sup>. One found that the disease activity course in CD is not dependent on age, sex, or localization of the disease. The United Kingdom study and the French study<sup>[16,31]</sup> showed conflicting results, at least in the proportion of patients requiring surgery. The IBSEN study showed that ten years after the diagnosis was made, the course was generally better than in earlier reports<sup>[30]</sup>. The need for immunosuppressives and GCSs declined from the first five-year period to the second five-year period. The probability of surgery was 37.9%, and fewer patients than expected developed complicated disease behavior; however, the cumulative relapse

rate was as high as 90% (Table 2). Because we have had the opportunity for biological treatment for some years now, we are looking forward to evaluating new epidemiological studies on the clinical course of the disease.

## Sick leave/unemployment

There are just a few reports on sick leave/unemployment in patients with CD. In 2006, Bernklev *et al.*<sup>[76]</sup> found that 24.6% of women with CD were on a disability pension (DP) five years after the diagnosis was established, which was a three-fold increase compared to the background population (8.8%). Five years after the diagnosis, 53% of the CD patients reported taking sick leave during the prior six months; 23% of the sick leaves were CD-related. A Dutch study from 2002 also concluded that CD patients had a significantly higher frequency of sick leave than the controls (odds ratio 1.7, 95% CI: 1.2-2.6)<sup>[77]</sup>. Both studies concluded that having CD is correlated to an increased unemployment rate. An earlier Danish study did not find any differences in the state of employment between CD patients nine years after the diagnosis compared to a control group, and as few as 3% were on DP<sup>[78]</sup>.

## CONCLUSION

Population-based studies have demonstrated that the incidence and prevalence of CD have increased over the last three decades. CD is most common in northern Europe and North America, and there is a slight predominance of women diagnosed with the disease. The majority of patients experience progression from inflammatory disease to the development of strictures and fistulas. Within the first five years of the disease, at least one third of the patients have had intestinal surgery, where ileocecal resection is the most commonly performed procedure. Appendectomy is associated with an increased risk of having CD diagnosed within the first four years after the surgery. A rising incidence and a slight female predominance is found in CD. The diagnosis is made when the patients are approximately thirty years old. Smoking is associated with an increased risk of developing CD, with a negative clinical course in patients with CD, and with increased risk of flare-ups of the disease in both operated and non-operated patients.

The overall mortality in most studies is comparable to the background population, although subgroups of CD patients seem to have slightly increased mortality. New therapeutic approaches are promising. To date, the most effective treatment options in acute disease are GCSs and TNF- $\alpha$ -blockers. TNF- $\alpha$ -blockers and AZA/MTX are effective in maintaining remission.

### Abstract

**AIM:** To investigate the influence of macrophages on hepatocyte phenotype and function.

**METHODS:** Macrophages were differentiated from THP-1 monocytes *via* phorbol myristate acetate stimulation and the effects of monocyte or macrophage-conditioned medium on HepG2 mRNA and protein expression determined. The *in vivo* relevance of these findings was confirmed using liver biopsies from 147 patients with hepatitis C virus (HCV) infection.

**RESULTS:** Conditioned media from macrophages, but not monocytes, induced a transient morphological change in hepatocytes associated with upregulation of vimentin ( $7.8 \pm 2.5$ -fold,  $P = 0.045$ ) and transforming growth factor (TGF)- $\beta$ 1 ( $2.6 \pm 0.2$ -fold,  $P < 0.001$ ) and downregulation of epithelial cadherin ( $1.7 \pm 0.02$ -fold,  $P = 0.017$ ) mRNA expression. Microarray analysis revealed significant upregulation of lipocalin-2 (17-fold,  $P < 0.001$ ) and pathways associated with inflammation, and substantial downregulation of pathways related to hepatocyte function. In patients with chronic HCV, real-time polymerase chain reaction and immunohistochemistry confirmed an increase in lipocalin-2 mRNA (F0  $1.0 \pm 0.3$ , F1  $2.2 \pm 0.2$ , F2  $3.0 \pm 9.3$ , F3/4  $4.0 \pm 0.8$ ,  $P = 0.003$ ) and protein expression (F1  $1.0 \pm 0.5$ , F2  $1.3 \pm 0.4$ , F3/4  $3.6 \pm 0.4$ ,  $P = 0.014$ ) with increasing liver injury. High performance liquid chromatography-tandem mass spectrometry analysis identified elevated levels of matrix metalloproteinase (MMP)-9 in macrophage-conditioned medium, and a chemical inhibitor of MMP-9 attenuated the change in morphology and mRNA expression of TGF- $\beta$ 1 ( $2.9 \pm 0.2$  vs  $1.04 \pm 0.1$ ,  $P < 0.001$ ) in macrophage-conditioned media treated HepG2 cells. In patients with chronic HCV infection, hepatic mRNA expression of CD163 (F0  $1.0 \pm 0.2$ , F1/2  $2.8 \pm 0.3$ , F3/4  $5.3 \pm 1.0$ ,  $P = 0.001$ ) and MMP-9 (F0  $1.0 \pm 0.4$ , F1/2  $2.8 \pm 0.3$ , F3/4  $4.1 \pm 0.8$ ,  $P = 0.011$ ) was significantly associated with increasing stage of fibrosis.

**CONCLUSION:** Secreted macrophage products alter the phenotype and function of hepatocytes, with increased expression of inflammatory mediators, suggesting that hepatocytes actively participate in liver injury.

## INTRODUCTION

Most of the morbidity/mortality from chronic liver diseases occurs in subjects with advanced fibrosis or cirrhosis, who are at risk of developing complications of end-stage liver disease including hepatocellular cancer. Activated liver macrophages have a key role in the progression of liver injury and repair, and knowledge about their interaction with hepatocytes and other cells in the liver microenvironment may provide new targets for antifibrotic therapy. In experimental models of liver disease, an increase in the number of macrophages correlates with the extent of injury, and damage can be attenuated by depletion of these cells<sup>[1-6]</sup>. Similarly, in diseased human liver, particularly chronic viral hepatitis, there is an increase in the density and size of macrophages<sup>[7,8]</sup>. This is seen largely at inflammatory sites with prominent mononuclear cell infiltration or within inflamed portal tracts. These tissue-resident macrophages appear to be derived from circulating monocytes even in steady state conditions, although there is a marked increase in recruitment of these cells to the liver following inflammatory insults<sup>[9]</sup>. A recent study has demonstrated that monocytes increase in the circulation as well as in the liver of patients during progression of chronic liver disease, and that they are activated and release high amounts of proinflammatory cytokines and reactive oxygen species<sup>[10]</sup>.

Secreted products from activated macrophages contribute to stellate cell activation and fibrosis. However, relatively little is known about the influence of macrophages on hepatic epithelial cell phenotype and function. Early studies have shown that secretions from activated macrophages influence hepatocyte DNA synthesis and cytochrome P-450 metabolism<sup>[11-13]</sup>. In a more recent study

using a human cell co-culture model, macrophages triggered secretion of proinflammatory cytokines from bile duct epithelial cells, as well as apoptosis<sup>[14]</sup>. The authors speculated that this cellular interaction provided a mechanism to amplify chronic inflammation and bile duct destruction in vanishing bile duct syndromes<sup>[14]</sup>. The role of activated macrophages in modulating the hepatocyte inflammatory response to injury has not been determined. Accumulating data also suggest that during inflammatory liver injury, some hepatocytes and cholangiocytes may lose epithelial markers and acquire partial mesenchymal characteristics, although the direct role of macrophages and the contribution of this process to fibrogenesis have not been determined<sup>[15,16]</sup>.

The aim of this study was to investigate the influence of macrophages on hepatocyte phenotype and function, and in particular, to determine whether macrophage-secreted products induce a proinflammatory response in hepatocytes. In order to address this, the effect of monocyte and macrophage-conditioned medium on cell morphology and gene expression was examined in two hepatocyte cell lines, along with the macrophage-secreted products that modulated the hepatocyte phenotype. We also evaluated human liver samples from patients with chronic hepatitis C virus (HCV) infection. Our data indicate that secreted products from activated macrophages induce an inflammatory phenotype in hepatocytes, which may have implications for persistent inflammation and fibrogenesis.

## MATERIALS AND METHODS

### Cell culture

The human hepatoma-derived cell lines, HepG2 and Huh7, and the human acute monocytic leukemia cell line, THP-1, were purchased from American Type Culture Collection (ATCC) (Manassas, VA, United States). Cells were maintained at 37 °C and 5% CO<sub>2</sub>. Unless otherwise indicated, cells were cultured in “complete medium” comprising Dulbecco’s Modified Eagle’s Medium (Invitrogen, Carlsbad, CA, United States) supplemented with 10% foetal bovine serum (Invitrogen), 100 U/mL penicillin and 100 µg/mL streptomycin (Invitrogen), 2 mmol GlutaMAX™ (Invitrogen) and 20 µmol MEM non-essential amino acids (Invitrogen).

Macrophages were generated as described previously<sup>[17,18]</sup>. Briefly, THP-1 monocytes were seeded in six-well plates (Nunc, Roskilde, Denmark) at a density of  $4 \times 10^6$  cells per well in 3 mL of complete medium and incubated for 2 h. Cells were treated with phorbol myristate acetate (PMA) (200 nmol; Sigma-Aldrich, St. Louis, MO, United States) for 24 h, washed three times with  $1 \times$  phosphate buffered saline (PBS) and cultured for 42 h in 2 mL of fresh complete medium. The resulting macrophage-conditioned media (M $\phi$ CM) was collected, clarified by centrifugation at  $400 \times g$  and stored at -20 °C until use. Conditioned media from THP-1 monocytes (MonoCM) was harvested in a similar fashion. For some experiments, M $\phi$ CM was generated in the presence of matrix metalloproteinase (MMP)-9 Inhibitor I, (100 µmol, Cat# 444278, Calbiochem, Merck Pty Ltd, Kilsyth, Victoria, Australia).

**Table 1** Demographic and clinical features of patients with chronic hepatitis C virus infection

No. of patients	<i>n</i>	147
Age (yr)	mean ± SEM	42.3 ± 0.9
Sex	M/F	98/49
Viral genotype	1/ 2/ 3	80/6/61
Stage of fibrosis	0/1/2/3-4	13/65/44/25
Grade of steatosis	0/1/2-3	73/44/29
Necroinflammatory score	1-3/4-5/6-8	56/61/30
BMI (kg/m <sup>2</sup> )	mean ± SEM	26.2 ± 0.4
BMI	Lean, overweight, obese <sup>1</sup>	66/51/24
Alcohol - current (g/d)	Median (range)	1 (0-120)
Alcohol - past (g/d)	Median (range)	30 (0-500)
Creatinine (μmol/L)	mean ± SEM	77.8 ± 1.5
Platelets (× 10 <sup>9</sup> /L)	mean ± SEM	213 ± 6
Red blood cells (× 10 <sup>12</sup> /L)	mean ± SEM	4.8 ± 0.3
Total WBC (× 10 <sup>9</sup> /L)	mean ± SEM	7.2 ± 0.2
Neutrophils (× 10 <sup>9</sup> /L)	mean ± SEM	4.0 ± 0.1
Lymphocytes (× 10 <sup>9</sup> /L)	mean ± SEM	2.3 ± 0.06
Monocytes (× 10 <sup>9</sup> /L)	mean ± SEM	0.6 ± 0.02

<sup>1</sup>Lean: ≤ 25 kg/m<sup>2</sup>; overweight: > 25 and < 30 kg/m<sup>2</sup>; obese: ≥ 30 kg/m<sup>2</sup>. BMI: Body mass index; WBC: White blood cell.

HepG2 and Huh7 cells were seeded in six-well plates at a density of  $2 \times 10^5$  cells per well in 3 mL of complete medium. After 24 h, cells were washed and cultured with 50% MφCM or 50% MonoCM in complete media for 24 h unless indicated otherwise. Cell morphology was observed by phase contrast microscopy using the Nikon Eclipse TS100. Culture in CM did not influence cell viability as determined by trypan blue exclusion.

#### Microarray analysis of HepG2 cells treated with macrophage-conditioned media or MonoCM

Total RNA was extracted from untreated, monocyte CM and MφCM-treated HepG2 cells using TRI Reagent® (Sigma-Aldrich). RNA quality was assessed with an Agilent 2100 BioAnalyser (Agilent Technologies, Santa Clara, CA, United States) and only samples with a RNA integrity number above 8.0 were included. cRNA was generated from 500 ng total RNA using the Illumina TotalPrep cRNA Amplification Kit (Applied Biosciences, Carlsbad, CA, United States) and hybridised to Human HT-12 V3 Expression BeadChips (Illumina, San Diego, CA, United States). Array data were processed using the Illumina GenomeStudio software, transformed by variance stabilization transformation<sup>[19]</sup> and normalized by robust spline normalization<sup>[20]</sup> with Lumi<sup>[21]</sup>. Differential gene expression patterns between MφCM-treated and untreated HepG2 cells were identified using class comparison corrected for multiple testing with BRB ArrayTools (National Cancer Institute, Bethesda, MD, United States)<sup>[22]</sup>. Gene Ontology (GO), KEGG and BioCarta analyses were applied to the differentially expressed gene sets to identify altered pathways and cell functions. Least-squares (LS)/Kolmogorov-Smirnov (KS) permutation tests, Efron-Tibshirani's gene set analysis maxmean test and Goeman's global test were used to identify relevant pathways and a significance threshold of 0.005 was applied.

#### Patients and clinical data

The study involved 147 consecutive patients with chronic hepatitis C, who had undergone a liver biopsy at the Princess Alexandra Hospital, Brisbane, Australia. Informed consent was obtained from each patient and the protocol was approved by the University of Queensland and Princess Alexandra Hospital Research Ethics Committees. Diagnosis of chronic HCV infection was based on standard serological assays and abnormal serum aminotransferase levels for at least 6 mo. All patients were positive for HCV antibody by the third-generation enzyme-linked immunosorbent assay (Abbott Laboratories, North Chicago, IL, United States), with infection confirmed by detection of circulating HCV RNA by polymerase chain reaction (PCR) using the Amplicor HCV assay (Roche, New Jersey, United States). Viral genotyping was performed using the Inno-Lipa HCV II assay (Innogenetics, Zwijnaarde, Belgium). Patients with other forms of chronic liver disease or antibodies to human immunodeficiency virus were not considered for the analysis. Patients with comorbidity such as acute coronary artery disease, unstable angina, congestive heart failure, significant renal impairment, acute and chronic infectious diseases, autoimmune and rheumatic diseases, cancer, endocrine diseases or inflammatory bowel diseases were not included in the study. Demographic and clinical details for the patients are presented in Table 1.

A fragment of liver tissue (2-3 mm) was immediately frozen in liquid nitrogen at the time of biopsy and stored at -80 °C until extraction of RNA was performed. The remaining core was fixed in buffered formalin and embedded in paraffin. The degree of inflammation was graded according to the method of Ishak<sup>[23]</sup>, and fibrosis was staged (0-4) according to the method of Scheuer<sup>[24]</sup>. Steatosis was graded as follows: 0 (< 5% hepatocytes affected); 1 (5%-33% of hepatocytes affected); 2 (34%-66% of hepatocytes affected); or 3 (> 66% of hepatocytes affected).

#### Real-time polymerase chain reaction

Total RNA was extracted from liver biopsy tissue, Huh7, HepG2, Mφ and THP-1 cells using TRI Reagent® (Sigma-Aldrich) according to the manufacturer's instructions and reverse-transcribed to cDNA by SuperScript® III Reverse Transcriptase (Invitrogen). Liver tissue RNA quality was assessed using an Agilent 2100 Bioanalyser (Agilent Technologies) and the RNA 6000 Nano LabChip according to the manufacturer's instructions. The median RNA Integrity Number (RIN) of RNA extracted from the liver biopsy samples was 8.0 (range: 6.0-9.2). Semi-quantitative real-time PCR (qPCR) for genes of interest was performed using Platinum® SYBR® Green qPCR SuperMix (Invitrogen) and analysed with MxPro QPCR software for MxPro 3000P QPCR systems (Stratagene, La Jolla, CA, United States) as previously described<sup>[25]</sup>. The expression of the housekeeping genes glyceraldehyde-3-phosphate dehydrogenase, human acidic ribosomal protein and 18S ribosomal RNA was determined using a multiplex real-time PCR protocol as previously described<sup>[25]</sup>. The relative mRNA expression of genes of interest was normalized to

the geometric mean of the expression of the three house-keeping genes. Primers for SYBR<sup>®</sup> Green assays were custom made by Geneworks (Thebarton, SA, Australia). Custom made primer-probe sets were purchased from Sigma-Aldrich (Castle Hill, NSW, Australia). Specific primer and probe sequences are shown in Table 2.

### Immunofluorescence and immunohistochemistry

To visualise epithelial cadherin (E-cadherin) and vimentin protein expression, HepG2 and Huh7 cells were cultured, as described above, on sterile glass cover slips (Deckglaser, Freiburg, Germany). After treatment, cells were fixed with 4% paraformaldehyde (Thermo Fisher Scientific, Waltham, MA, United States), washed with 1% glycine in 1  $\times$  PBS and permeabilized for 5 min with 0.2% Triton X-100 (Sigma-Aldrich). Non-specific binding was blocked with 10% heat-inactivated goat serum (Sigma-Aldrich) for 30 min. Cells were incubated with primary antibodies (1/50 dilution in 1% heat-inactivated goat serum) against E-cadherin (mouse monoclonal, ab1416; Abcam, Cambridge, MA, United States) or vimentin (mouse monoclonal, ab8069; Abcam) for 1 h at room temperature. After washing, goat anti-mouse IgG conjugated with Alexa Fluor 488 (Invitrogen; 1/200 dilution) was added for 1 h at room temperature. Cell nuclei were stained with 4',6-diamidino-2-phenylindole (Invitrogen) and observed using the Zeiss LSM 510 Meta confocal microscope (Carl Zeiss, North Ryde, NSW, Australia).

Immunofluorescence was performed on sections of formalin-fixed, paraffin-embedded liver from patients with chronic HCV using monoclonal antibodies to MMP-9 (diluted 1/400, ab76003; Abcam) and CD163 (diluted 1/300, NB110-59935; Novus Biologicals, Littleton, CO, United

States). Antigen retrieval was performed with 10 mmol Tris/1 mmol EDTA, pH 9.0 solution and sections were blocked with 20% heat-inactivated goat serum (Sigma-Aldrich) to prevent non-specific binding. Positively stained macrophages were observed using the Zeiss LSM 510 Meta confocal microscope.

Immunohistochemistry was also performed on nine biopsy specimens using an antibody directed against lipocalin-2 (LCN2) (diluted 1/35, ab23477; Abcam). Immunoreactivity was revealed using the Novolink Polymer detection system (Leica Microsystems Pty Ltd, North Ryde, NSW, Australia) according to the manufacturer's instructions, and sections were photographed using the Nano-Zoomer (Olympus, Centre Valley, PA, United States). The sections were assessed for intensity of staining (weak, 1; moderate, 2; heavy, 3) and multiplied by the proportion of cells stained (0%-24%, 1; 25%-49%, 2; 50%-74%, 3; 75%-100%, 4) to give a value between 1 and 12.

### Identification of macrophage-secreted products

CM from M $\phi$  and THP-1 cells were subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) on 4%-20% polyacrylamide gels (Invitrogen) and stained with SimplyBlue<sup>™</sup> Safestain (Invitrogen). Bands differentially displayed in M $\phi$ CM ( $n = 10$ ) were precisely excised, de-stained, in-gel-trypsin-digested and analyzed by high performance liquid chromatography-tandem mass spectrometry (HPLC/MS/MS) and database searching<sup>[26,27]</sup>. One hundred and thirty-six proteins were identified. Following pruning to eliminate proteins of incorrect molecular weight or proteins not known to be secreted, database and literature searching identified probable candidates, of which MMP-9 was further investigated.

### Western blotting analysis

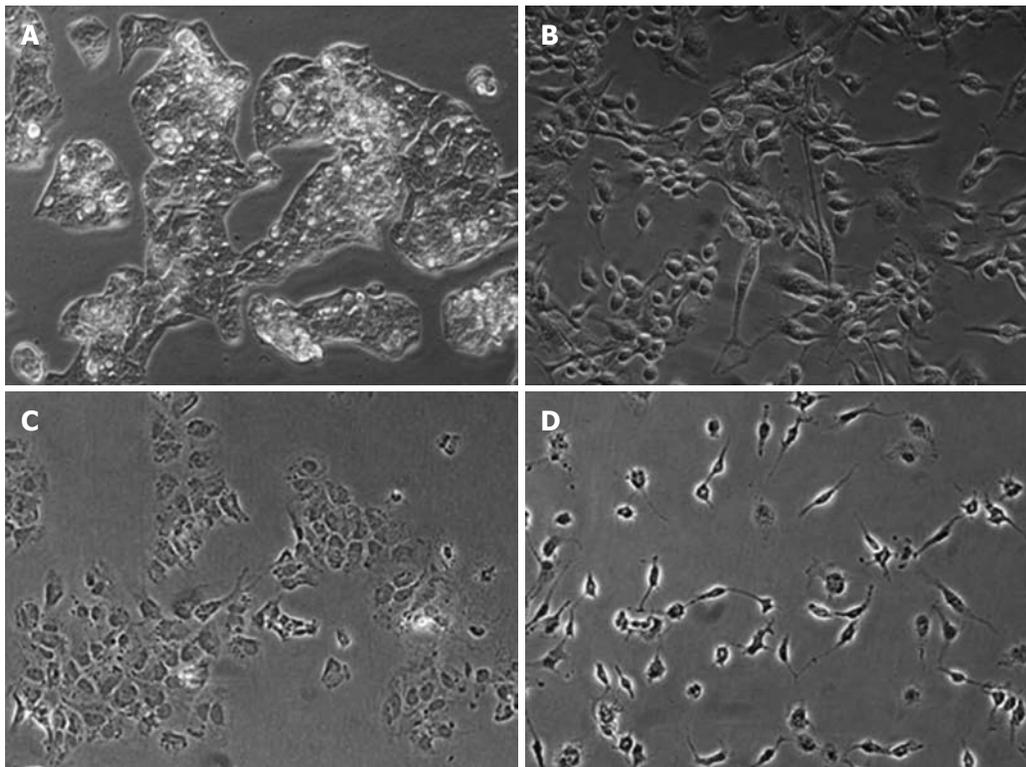

M $\phi$ CM (PMA-differentiated THP-1 cells) and MonoCM (THP-1 cells) was subjected to SDS-PAGE on 4%-20% polyacrylamide gels (Invitrogen) and transferred to Immobilon P membrane (Millipore) using standard methods. Blots were incubated overnight at 4  $^{\circ}$ C with monoclonal anti-MMP-9 (diluted 1/5000, ab76003; Abcam) followed by Envision horseradish-peroxidase-linked anti-mouse polymer (Dako Australia, Botany, NSW, Australia; dilution 1/30). Blots were washed as previously described<sup>[28]</sup>. Proteins were detected with the enhanced chemiluminescence (ECL+) system (GE Healthcare Bio-Sciences, Rydalmere, Sydney, NSW, Australia).

### Zymography

Zymography was performed on CM from M $\phi$ s (PMA-differentiated THP-1 cells) and monocytes (THP-1 cells) using Novex<sup>®</sup> 10% Zymogram (Gelatin) Gel (Invitrogen) according to the manufacturer's instructions. Gels were stained with SimplyBlue<sup>™</sup> Safestain (Invitrogen) to visualize bands of protease activity.

### Statistical analysis

Continuous normally distributed variables were represented graphically as mean  $\pm$  SEM. Grade of steatosis,

**Figure 1** Macrophage-conditioned media induces a fibroblast-like morphological change in hepatocytes. Phase contrast microscopy of HepG2 (A and B) and Huh7 cells (C and D) grown in complete media (A and C) or 50% macrophage-conditioned media in complete medium (B and D). The images shown are representative of six experiments of cells after 24 h of culture in the indicated medium.

grade of hepatic inflammation, stage of fibrosis, alcohol consumption and RIN were summarized as median and range. For normally distributed variables, analysis of variance (ANOVA) or Student's *t* test was performed to compare the means between groups. To determine differences between groups not normally distributed, medians were compared using the Kruskal-Wallis or Mann-Whitney *U* test.

Multivariate analysis was performed, including terms for age at biopsy, sex, viral genotype, stage of fibrosis, body mass index (BMI), alcohol consumption, total inflammatory score and grade of steatosis. Independent effects of normally distributed variables were assessed by ANOVA using general linear models. A backward elimination approach was used to remove non-significant variables and determine the most parsimonious model. All analyses were performed using SPSS version 17.0 (SPSS Inc, Chicago, IL, United States) and  $P < 0.05$  was considered significant.

## RESULTS

### **Macrophage-conditioned media induces transient morphological change in hepatocytes**

We began by assessing the effects of macrophage culture supernatants on hepatocyte morphology and gene expression. HepG2 and Huh7 cells typically form epithelial clusters with well-developed cell junctions (Figure 1A-C). Upon treatment with M $\phi$ CM, these hepatocytes displayed an observable change (Figure 1B-D), acquiring an elongated

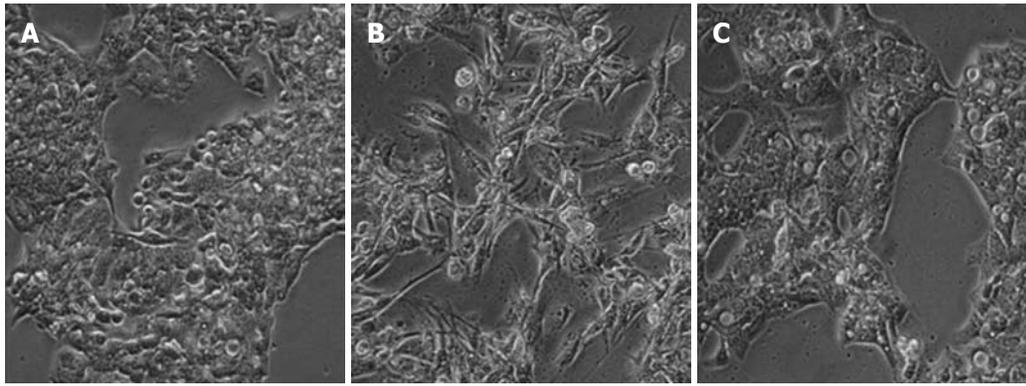

spindle shape with loss of cell-cell contact. To determine if the morphological change in hepatocytes was permanent, after the initial M $\phi$ CM treatment, HepG2 and Huh7 cells were washed and cultured in fresh growth medium for a further 2 d. Following release from treatment with M $\phi$ CM, cells that were initially elongated and spindle-shaped after 24 h of treatment, formed epithelial clusters similar to untreated hepatocytes (Figure 2).

In association with the observable morphological change, HepG2 and Huh7 cells treated with M $\phi$ CM demonstrated a substantial reduction in mRNA and protein expression of the epithelial marker E-cadherin (Figure 3A-C). mRNA and protein levels of vimentin, an intermediate filament and a marker of mesenchymal cells, were substantially enhanced in M $\phi$ CM-treated hepatocytes (Figure 3D-F). mRNA expression of the pro-fibrogenic cytokine transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) was also increased (HepG2, 2.9-fold induction,  $P < 0.001$ ; Huh7, 3.2-fold induction,  $P = 0.002$ ), whereas collagen and  $\alpha$ -smooth muscle actin (SMA) levels were not significantly altered (not shown).

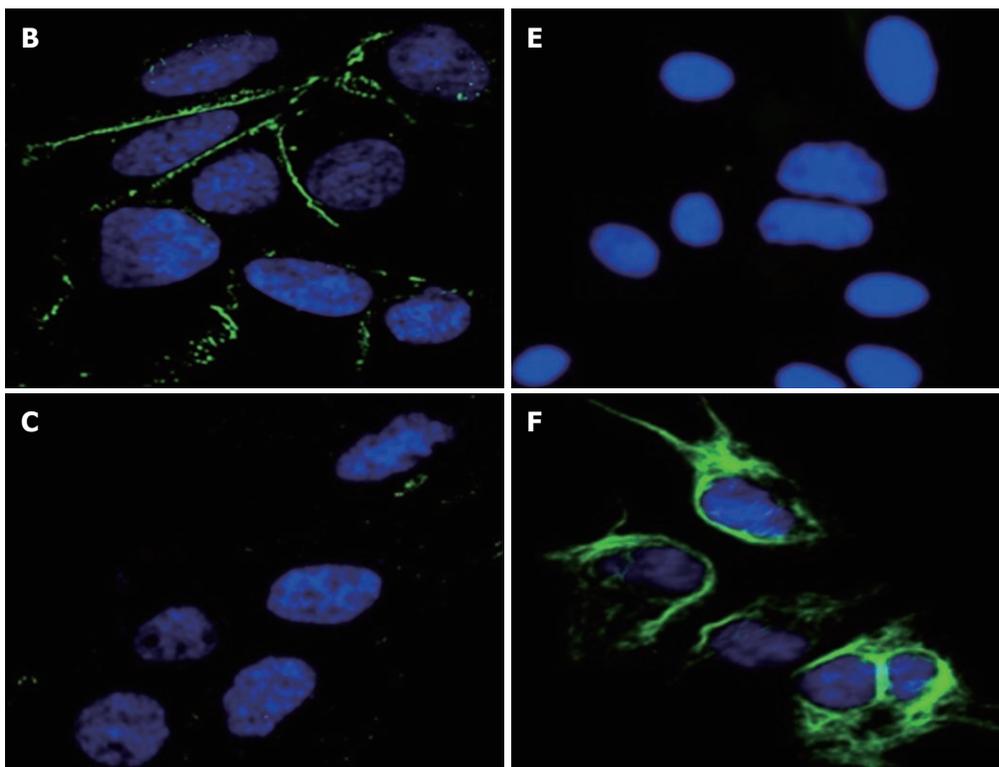

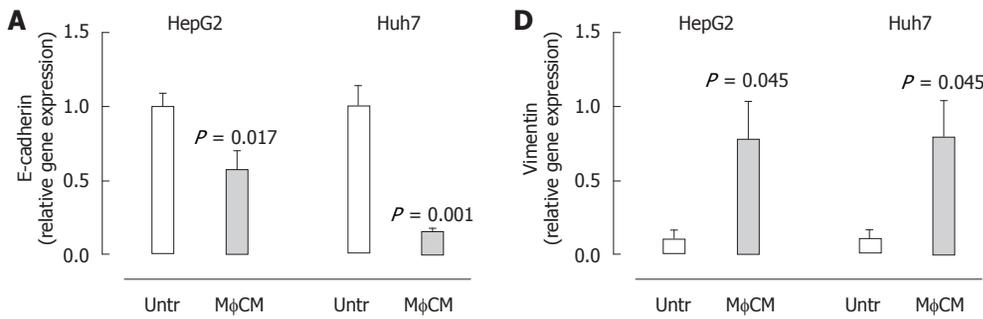

In contrast to M $\phi$ CM, no morphological changes or alteration in the levels of epithelial and mesenchymal markers were observed in hepatocytes treated with THP-1 monocyte CM (data not shown).

### **Differential gene expression in macrophage-conditioned media-treated HepG2 cells**

Our initial analysis of expression of epithelial and mesenchymal marker genes was next extended more globally

**Figure 2** Macrophage-conditioned media induces a transient change in hepatocytes. Phase contrast microscopy of HepG2 cells grown in complete media (A) for 72 h, macrophage-conditioned media (M $\phi$ CM) for 72 h (B) or M $\phi$ CM for 24 h followed by washing and culture in complete medium for a further 48 h (C). The images shown are representative of cells after 72 h of culture in the indicated medium.

**Figure 3** Expression of E-cadherin is reduced and vimentin is increased in hepatocytes treated with macrophage-conditioned media. A, D: Following culture in complete media or 50% macrophage-conditioned media (M $\phi$ CM) for 24 h, E-cadherin (A) and vimentin (D) mRNA levels in HepG2 and Huh7 cells were measured by real-time polymerase chain reaction. Results are expressed as fold of untreated cells (mean  $\pm$  SEM,  $n = 8$ ) ( $P < 0.05$  vs untreated); B, C: Immunofluorescence staining for E-cadherin (green) in untreated (B) and M $\phi$ CM-treated (C) Huh7 cells; E, F: Immunofluorescence staining for vimentin (green) in untreated (E) and M $\phi$ CM-treated (F) Huh7 cells. 4',6-diamidino-2-phenylindole stained nuclei blue (63  $\times$  magnification). through expression profiling. The microarray contained 48 000 probes; 34 693 of which were found to be expressed in at least one sample. Using this probe set, unsupervised hierarchical clustering showed good delineation between untreated and M $\phi$ CM-treated HepG2 cells. MonoCM-treated HepG2 cells did not cluster differently from untreated cells and were thus not included for further analysis.

GO, KEGG and BioCarta analyses revealed significant upregulation of genes associated with inflammatory pathways; the majority of which included responses to cytokines and reactive oxygen species in addition to antigen processing and presentation (Table 3). Pathway analysis also identified a number of significantly downregulated hepatocyte functional processes including fatty acid and

cholesterol metabolism and bile acid biosynthesis (Table 3).

To identify genes regulated by M $\phi$ CM in HepG2 cells, we carried out a two-sample *t* test (with random variance model) corrected for multiple comparisons. 2665 genes were identified as significantly differentially expressed between untreated and M $\phi$ CM-treated HepG2 cells with a *P* value  $\leq$  0.005 (corrected for false discovery rate). A significant > 4-fold change in expression was seen for 21 genes (17 upregulated and four downregulated) (Table 4). The most differentially expressed gene was LCN2 with an ~18-fold change in expression.

#### **Fibrosis, inflammation and steatosis are associated with increased expression of lipocalin-2**

To validate observations from the *in vitro* studies, we ex-

**Figure 4** Lipocalin-2 mRNA expression was increased in hepatitis C virus-infected patients with increasing stage of fibrosis (A), grade of inflammation (B) or grade of steatosis (C). D and E: Lipocalin-2 (LCN2) staining by immunohistochemistry was minimal in hepatitis C virus (HCV)-infected patients with stage 1 fibrosis (D; 400× magnification) compared with stage 4 fibrosis (E; 400 × magnification); F: Increased LCN2 protein expression in HCV-infected patients with stage 3/4 fibrosis.  $P < 0.05$  vs fibrosis stage 0 (A), inflammation grade 1/2 (B) steatosis grade 0 (C) or fibrosis stage 1 (D).

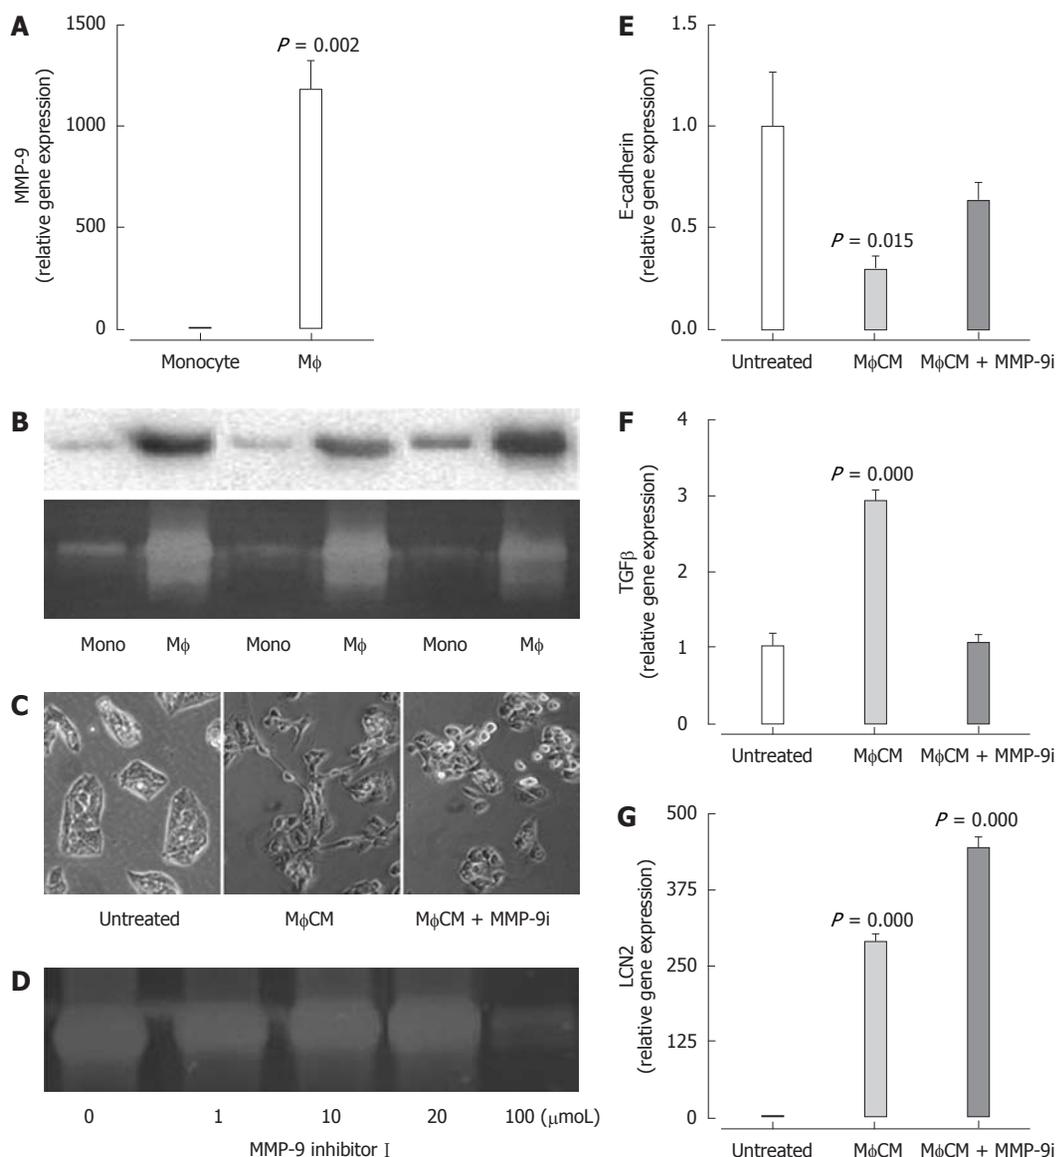

amined the expression of LCN2 in liver biopsies from patients with chronic HCV. A significant increase in hepatic mRNA levels of LCN2 was seen with increasing stage of fibrosis (Figure 4A), grade of inflammation (Figure 4B) and grade of steatosis (Figure 4C). Following multivariate analysis (correcting for BMI, age, sex, alcohol consumption, viral genotype, grade of inflammation and presence of stainable iron), stage of fibrosis (OR: 1.6, 95% CI: 1.1-2.2) and grade of steatosis (OR: 1.7, 95% CI: 1.1-2.5) remained independently associated with hepatic mRNA expression of LCN2.

Immunohistochemistry was performed on a subset of liver biopsies selected due to their varying levels of LCN2 mRNA expression. Although negligible LCN2 staining was observed in patients with minimal fibrosis,

enhanced protein expression was evident with increasing stage of fibrosis, predominantly within the hepatocyte cytoplasm, sparse sinusoidal neutrophils and some portal mononuclear cells (Figure 4D and E). To quantify LCN2 expression, tissue sections were scored for intensity of staining (1, weak; 2, moderate; 3, heavy) and multiplied by the proportion of cells stained (1, 1%-24%; 2, 25%-49%; 3, 50%-74%; 4, 75%-100%). In support of the mRNA data, enhanced LCN2 protein expression was observed in patients with stage 3-4 fibrosis (Figure 4F).

**Activated Mφs secrete matrix metalloproteinase-9 that contributes to changes in hepatocyte phenotype and function**

To address mechanisms by which macrophages may regulate hepatocyte function, we surveyed proteins present in

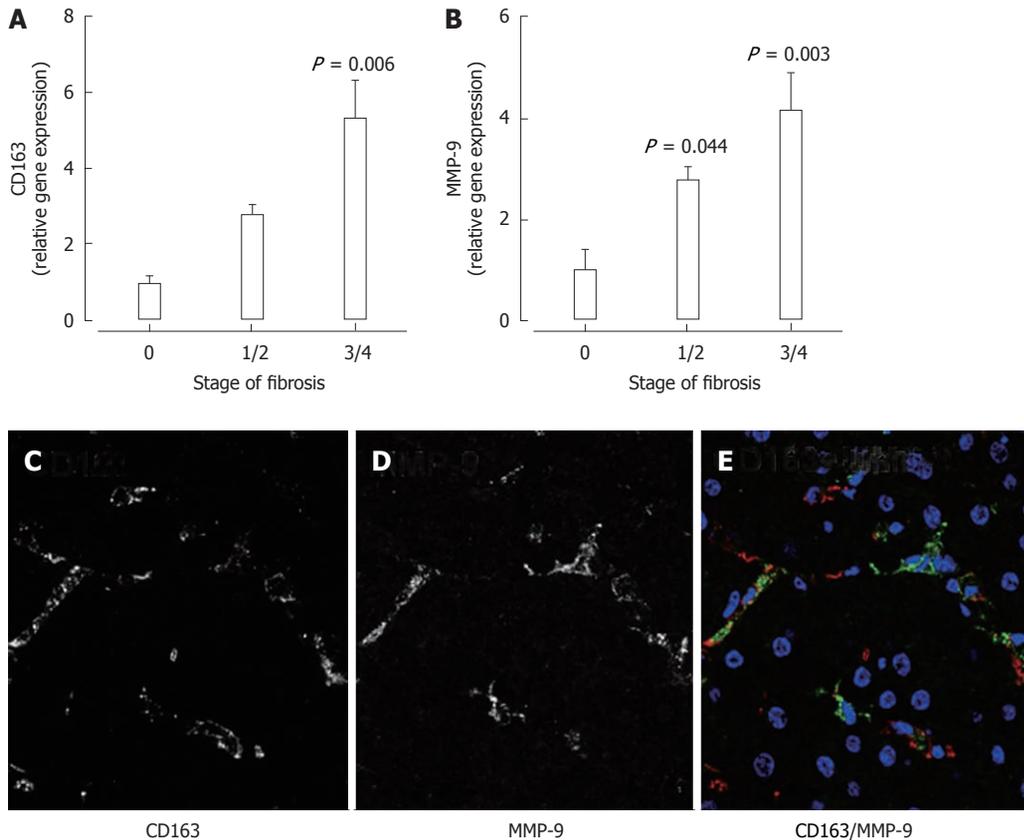

**Figure 5 Matrix metalloproteinase-9 mRNA expression is significantly increased in macrophages compared with THP-1 monocytes.** A: Results are expressed as fold of monocytes (mean  $\pm$  SEM,  $n = 6$ ) ( $P < 0.05$  vs monocytes); B: Western blotting analysis (top) and zymography (bottom) of matrix metalloproteinase (MMP)-9 in MonoCM and macrophage-conditioned media (M $\phi$ CM) from three independent experiments; C: Generation of M $\phi$ CM in the presence of MMP-9 inhibitor I (100  $\mu$ mol) prevented the M $\phi$ CM-induced morphological change in HepG2 cells; D: Zymography gel confirming MMP-9 inhibitor I reduces MMP-9 activity in M $\phi$ CM at 100  $\mu$ mol; E-G: MMP-9 Inhibitor I significantly attenuated downregulation of E-cadherin (E) and upregulation of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) (F) but not lipocalin-2 (LCN2) (G) mRNA expression in response to M $\phi$ CM. Results are expressed as fold of untreated cells (mean  $\pm$  SEM,  $n = 5$ ),  $P < 0.05$  vs untreated.

M $\phi$ CM (generated in serum-free medium). HPLC/MS/MS analysis identified the presence of MMP-9 in M $\phi$ CM but not MonoCM. qPCR (Figure 5A), Western blotting and zymography (Figure 5B) confirmed the significantly enhanced levels of MMP-9 expression in M $\phi$ CM. Generation of M $\phi$ CM in the presence of MMP-9 Inhibitor I (100  $\mu$ mol) prevented the M $\phi$ CM-induced morphological change in HepG2 cells (Figure 5C). The efficacy of MMP-9 inhibitor I (100  $\mu$ mol) was confirmed by zymography (Figure 5D). This reduction in MMP-9 activity significantly attenuated the downregulation of E-cadherin (Figure 5E) and the upregulation of TGF- $\beta$ 1 (Figure 5F). In contrast, inducible LCN2 expression was not attenuated by the MMP-9 inhibitor (Figure 5G).

**Fibrosis is associated with increased expression of CD163 and matrix metalloproteinase-9**

To validate observations from the *in vitro* studies, we examined expression of MMP-9 and the macrophage marker CD163 by qPCR and immunofluorescence in liver biopsies from patients with chronic HCV. Hepatic mRNA expression of the macrophage marker CD163 (Figure 6A) as well as MMP-9 (Figure 6B) was significantly associated with increasing stage of fibrosis. Immunofluorescence in liver biopsies from patients with chronic HCV demonstrated MMP-9 expression in CD163<sup>+</sup> macrophages (Figure 6C-E). Thus, macrophage-expressed MMP-9 may contribute to hepatocyte dysfunction during chronic liver disease, but macrophages are also likely to regulate hepatocyte

**Figure 6** In patients with chronic hepatitis C, increased hepatic mRNA expression of the macrophage marker CD163 (A) as well as matrix metalloproteinase-9 (B) was significantly associated with increasing stage of fibrosis ( $P < 0.05$  vs F0). C-E: Immunofluorescence in liver biopsies from patients with chronic hepatitis C demonstrated matrix metalloproteinase (MMP)-9 expression in CD163<sup>+</sup> macrophages.

function independently of this pathway, as demonstrated by the failure of the MMP-9 inhibitor to antagonize inducible LCN2 expression.

## DISCUSSION

Macrophages are a prominent feature of chronic inflammatory liver diseases and have a pivotal role in hepatic stellate cell activation and fibrogenesis<sup>[29]</sup>. This study was undertaken to determine whether macrophages also have a proinflammatory or profibrogenic effect on other cell populations within the hepatic microenvironment, specifically hepatocytes. Indeed, macrophage-secreted products induced a morphological change in hepatocytes accompanied by an altered gene expression program associated with the production of inflammatory mediators and fibrogenic agonists. This hepatocyte phenotypic change was transient, at least *in vitro*, with prompt reversal following removal of M $\phi$ CM.

Relatively little is known about the contribution of liver epithelial cells to the local inflammatory response to injury. Studies performed more than a decade ago showed that human hepatocytes secrete a narrow repertoire of inflammatory cytokines and chemokines in response to stimulation with interleukin (IL)-1 $\beta$  or tumor necrosis factor (TNF)- $\alpha$ <sup>[30]</sup>, and primary hepatocytes isolated from rat liver produce increased IL-8 in the presence of

conditioned medium from lipopolysaccharide-stimulated Kupffer cells<sup>[31]</sup>. In a more recent study, exposure of hepatocytes to bile acids led to increased production of inflammatory mediators, including cytokines, chemokines, adhesion molecules and other proteins that may modulate immune cell accumulation and function<sup>[32]</sup>. Analogous to hepatocytes, cholangiocytes alter their phenotype in response to co-culture with macrophages, with increased secretion of cytokines involved in inflammation as well as apoptosis<sup>[14]</sup>. These studies suggest that liver epithelial cells are not simply targets of injury, but actively participate in propagating liver injury by amplifying the inflammatory response.

In the current study, hepatocytes treated with M $\phi$ CM showed downregulation of genes associated with hepatic metabolism and biosynthetic functions, such as bile acid biosynthesis, fatty acid and cholesterol metabolism. In contrast, genes associated with a number of inflammatory pathways, including the CD40L, interferon- $\gamma$  and TNF receptor 2 signaling pathways were significantly upregulated. Our data therefore suggest that macrophages both perturb normal homeostatic hepatocyte functions and promote a proinflammatory phenotype within these cells.

M $\phi$ CM was a potent inducer of LCN2. LCN2 is a small glycoprotein that is secreted by macrophages and antagonizes the actions of bacterial siderophores. It therefore plays a crucial role in innate immunity by limiting

iron availability to bacterial pathogens<sup>[33]</sup>. It also has direct effects on inflammatory cells<sup>[34]</sup>, and can facilitate mucosal regeneration<sup>[35]</sup>. Some studies have also linked LCN2 expression to chronic disease. During chronic kidney disease progression, epidermal growth factor (EGF) receptor activation leads to LCN2 expression, which subsequently mediates the mitogenic effect of EGF<sup>[36]</sup>. Circulating LCN2 levels are elevated in obese subjects<sup>[37]</sup> and patients with non-alcoholic fatty liver disease<sup>[38]</sup>, and mRNA levels of the gene are markedly upregulated in the liver of db/db obese/diabetic mice compared with their lean littermates<sup>[37]</sup>. A recent study using chronic liver injury models in the rat showed increased expression of LCN2, *via* an IL-1 $\beta$ -nuclear factor- $\kappa$ B-dependent pathway, in hepatocytes and proliferative bile duct epithelia<sup>[39]</sup>. The authors suggested that measurement of this protein may have diagnostic value as a biomarker of inflammatory liver damage. In keeping with this view, we demonstrated for the first time that LCN2 was expressed in liver biopsy samples from subjects with chronic HCV infection, and that the level of expression was significantly associated with the extent of liver injury. Furthermore, immunohistochemistry demonstrated LCN2 protein expression in hepatocytes, neutrophils and other inflammatory cells, and immunoreactivity in hepatocytes was particularly prominent in subjects with severe fibrosis. The pathophysiological function of LCN2 in liver disease remains unclear. It is not known at present whether LCN2 has an anti-inflammatory, protective role or whether it contributes to injury. Nevertheless, it appears to be a very good surrogate marker of a proinflammatory state.

Together with the induction of a proinflammatory profile, hepatocytes exposed *in vitro* to M $\phi$ CM underwent a reversible change in cell shape. This was accompanied by a decrease in the epithelial marker E-cadherin, and increases in the expression of the mesenchymal marker vimentin, and the profibrogenic cytokine TGF- $\beta$ 1. These epithelial cells did not acquire  $\alpha$ -SMA or type 1 collagen expression however, consistent with the concept that the observed morphological change is a response to injury, rather than a permanent transition into a mesenchymal cell<sup>[40]</sup>. Recent studies in human chronic liver disease have shown dual expression of epithelial and mesenchymal markers in bile duct cells and in some hepatocytes adjacent to portal tracts<sup>[16]</sup>. In addition, strong expression of TGF- $\beta$ 1 mRNA was seen in epithelial cells comprising the ductular reaction at the interface with parenchyma. In a carbon-tetrachloride-induced liver fibrosis model, abundant TGF- $\beta$ 1 protein expression was seen, not only in inflammatory cells and myofibroblasts, but also in cells with the morphology of hepatocytes immediately adjacent to the scars<sup>[41]</sup>. Similarly, in liver biopsies from patients with chronic hepatitis, TGF- $\beta$ 1 was detected in the cytoplasm of hepatocytes at the portal tract interface and in close proximity to areas of fibrosis<sup>[42]</sup>. Our study confirms expression of another secreted protein, LCN2, in hepatocytes adjacent to inflammatory/fibrotic areas in patients with chronic liver disease. Hence, accumulating data suggest that, in response to injury or inflammatory stimuli,

hepatocytes are not simply bystanders but may directly contribute to the inflammatory/fibrogenic milieu. Importantly, our *in vitro* results provide support for the plasticity of this process, with reversal of the phenotypic change following withdrawal of the inflammatory stimulus. This is an important finding from a therapeutic perspective because it implies that, in a chronic setting, it may be possible to reverse the propagation of inflammation.

The inflammatory cell or signal driving the hepatocyte inflammatory response *in vivo* remains unclear. In the current study, MMP-9 was differentially expressed in M $\phi$ CM *vs* MonoCM, and its inhibition prevented the morphological change in hepatocytes and the increase in TGF- $\beta$ 1 production (although chemical inhibitors of MMPs may also inhibit other unknown proteins and so may not be as specific as claimed). In contrast, MMP-9 inhibition led to a paradoxical increase in hepatocyte LCN2 mRNA levels. LCN2 has been shown to co-localize with MMP-9 in chronic vascular disease<sup>[43]</sup> and in the urine of patients with cirrhosis<sup>[44]</sup>, where it may modulate proteolytic activity by binding to and preventing the degradation of MMP-9<sup>[45]</sup>. Further studies are required to determine the additional factors responsible for inducing the phenotypic change in hepatocytes.

In conclusion, this study provides evidence that macrophage-secreted products can induce transient phenotypic changes in hepatocytes that may contribute to chronic inflammation and fibrogenesis. Importantly, the data suggest that hepatocytes contribute to LCN2 production during inflammatory liver injury with recruitment and activation of liver macrophage populations. In the future, strategies aimed at blocking macrophage-mediated hepatocyte phenotypic changes could be considered as potential therapeutic approaches for diseases in which liver inflammation contributes to pathology.

## COMMENTS

### Background

Activated liver macrophages have a key role in the progression of chronic liver injury and repair, and knowledge about their interaction with hepatocytes and other cells in the liver microenvironment may provide new targets for antifibrotic therapy.

### Research frontiers

Macrophages are a prominent feature of chronic inflammatory liver diseases. Secreted products from activated macrophages contribute to stellate cell activation and fibrosis. Macrophages also contribute to secretion of proinflammatory cytokines from bile duct epithelial cells, as well as apoptosis. Currently, there is limited knowledge about the effects of macrophage secreted products on hepatic epithelial cell function.

### Innovations and breakthroughs

The current study found that macrophage-secreted products induced an altered gene expression program in hepatocytes associated with the production of inflammatory mediators and fibrogenic agonists. Macrophage-conditioned medium is a potent inducer of hepatocyte lipocalin-2 (LCN2) expression. In patients with chronic hepatitis C, fibrosis, inflammation and steatosis are associated with increased expression of LCN2.

### Applications

Strategies aimed at blocking macrophage-mediated hepatocyte phenotypic changes could be considered as potential therapeutic approaches for diseases in which liver inflammation contributes to pathology.

### Terminology

LCN2 is a small glycoprotein that has been implicated in the innate immune response to bacterial infection, obesity and in the regulation of chronic inflammatory diseases. However, its pathophysiological functions in liver disease remain unclear.

### Peer review

This is a well written and implemented research paper that explores the relationship between Kupffer cells and hepatocytes in human liver disease, using a model of cell lines (the effects of THP-1 conditioned medium, with or without differentiation to macrophages, on HepG2 or Huh7 cells). The importance of the findings with regard to LCN2 was confirmed using samples from human tissues. This is an emerging area of research that has not been studied in great detail. The study is well implemented and the findings are refreshingly not over-interpreted. The only change we would suggest is a comment or two on the fact that chemical inhibitors of matrix metalloproteinases may also inhibit other unknown proteins (so called specific inhibitors tend to not always be as specific as claimed), so the findings with regard to the inhibitors need to be interpreted with caution.

### Abstract

**AIM:** To identify differentially expressed genes in quiescent and activated hepatic stellate cells (HSCs) and explore their functions.

**METHODS:** HSCs were isolated from the normal Sprague Dawley rats by *in situ* perfusion of collagenase and pronase and density Nycodenz gradient centrifugation. Total RNA and mRNA of quiescent HSCs, and culture-activated HSCs were extracted, quantified and reversely transcribed into cDNA. The global gene expression profile was analyzed by microarray with Affymetrix rat genechip. Differentially expressed genes were annotated with Gene Ontology (GO) and analyzed with Kyoto encyclopedia of genes and genomes (KEGG) pathway using the Database for Annotation, Visualization and Integrated Discovery. Microarray data were validated by quantitative real-time polymerase chain reaction (qRT-PCR). The function of Wnt5a on human HSCs line LX-2 was assessed with lentivirus-mediated Wnt5a RNAi. The expression of Wnt5a in fibrotic liver of a carbon tetrachloride (CCl<sub>4</sub>)-induced fibrosis rat model was also analyzed with Western blotting.

**RESULTS:** Of the 28 700 genes represented on this chip, 2566 genes displayed at least a 2-fold increase or decrease in expression at a  $P < 0.01$  level with a false discovery rate. Of these, 1396 genes were upregulated, while 1170 genes were downregulated in culture-activated HSCs. These differentially expressed transcripts were grouped into 545 GO based on biological process GO terms. The most enriched GO terms included response to wounding, wound healing, regulation of cell growth, vasculature development and actin cytoskeleton organization. KEGG pathway analysis revealed that Wnt5a signaling pathway participated in the activation of HSCs. Wnt5a was significantly increased in culture-activated HSCs as compared with quiescent HSCs. qRT-PCR validated the microarray data. Lentivirus-mediated suppression of Wnt5a expression in activated LX-2 resulted in significantly impaired proliferation, downregulated expressions of type I collagen and transforming growth factor- $\beta$ 1. Wnt5a was upregulated in the fibrotic liver of a CCl<sub>4</sub>-induced fibrosis rat model.

**CONCLUSION:** Wnt5a is involved in the activation of HSCs, and it may serve as a novel therapeutic target in the treatment of liver fibrosis.

## INTRODUCTION

Liver fibrosis is a common pathological change characterized by excessive deposition of extracellular matrix (ECM) that occurs in most types of chronic liver diseases. Hepatic stellate cells (HSCs) are a major source of ECM and activation of HSCs is one of the key steps in the development of liver fibrosis<sup>[1,2]</sup>. However, the molecular mechanisms underlying the activation of HSCs are not fully understood.

Previous studies have reported the differentially expressed gene profiles in quiescent and activated HSCs with gene chip. De Minicis *et al.*<sup>[3]</sup> determined gene expression changes in three different models of HSC activation: culture-activated HSCs, HSCs isolated from CCl<sub>4</sub>-treated mice and mice underwent bile duct ligation (BDL). They found that the gene expression pattern of culture-activated HSCs was different from that of BDL- and CCl<sub>4</sub>-activated HSCs. Woo *et al.*<sup>[4]</sup> performed a time-based study to investigate the differences in gene expression patterns during the activation of HSCs with microarrays and revealed a number of newly discovered genes involved in fibrogenesis during the activation of HSCs. Sancho-Bru *et al.*<sup>[5]</sup> investigated the differences in phenotypic, genomic and functional characteristics between HSCs from human cirrhotic livers and HSCs from normal livers after prolonged culture. However, these three studies are lack of intense bioinformatics analyses.

In this study, we performed gene expression profile analyses using oligonucleotide microarrays to identify the genes involved in HSCs activation. These analyses revealed the altered expression of 2566 genes. On this basis, bioinformatics analyses were done to classify the function and explore the involved signaling pathway of these differentially expressed genes. Bioinformatics analyses revealed that these differentially expressed transcripts were grouped into 545 GO based on biological process GO terms. The most enriched GO terms included response to wounding, wound healing, regulation of cell growth, vasculature development, and actin cytoskeleton organization. It is reported that Wnt5a signaling takes part in wound healing, regulation of cell proliferation, vasculature development and the formation of cell polarity<sup>[6-9]</sup>. After intensive analyses of Kyoto encyclopedia of genes and genomes (KEGG) pathways, we found that Wnt5a signaling pathway participated in the HSCs activation, an observation verified by quantitative real-time polymerase chain reaction (qRT-PCR).

Because the role of Wnt5a in HSCs activation is unknown and the direct evidence has not been reported, we treated human HSCs line LX-2 with lentivirus-mediated Wnt5a ShRNA and found that knockdown of Wnt5a gene expression in LX-2 led to significantly impaired proliferation, downregulated expressions of type I collagen and transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1). Wnt5a was upregulated in fibrotic liver of a carbon tetrachloride (CCl<sub>4</sub>)-induced fibrosis rat model. Collectively, our data suggest that Wnt5a may play a role in HSCs activation and liver fibrogenesis. We expect that our results will

help illustrate the molecular mechanisms involved in liver fibrogenesis and provide preliminary experimental evidence for the feasibility of targeting Wnt5a in gene therapy of liver fibrogenesis.

## MATERIALS AND METHODS

### Cell isolation, identification and culture

HSCs were isolated from normal Sprague Dawley (SD) rats by collagenase-pronase perfusion and subsequent density centrifugation on Nycodenz gradients as described previously<sup>[10]</sup>. Purity was tested by retinoid autofluorescence and exceeded 95% in all isolations. HSCs were cultured in Dulbecco's modified Eagle medium (DMEM) containing 10% fetal bovine serum (FBS), glutamine, 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid buffer and antibiotics. After 1 (quiescent HSCs) and 7 (activated HSCs) d of culture, total RNA was extracted using an RNeasy mini-kit (Qiagen, Valencia, CA, United States). Human HSCs line LX-2 was cultured in DMEM (Invitrogen) supplemented with 10% FBS.

### Microarray experiments and bioinformatics analysis

We used rat genome 430 2.0 array gene chips (Affymetrix, Santa Clara, CA). The arrays were hybridized, washed and scanned according to the standard Affymetrix protocol. The gene chip tests were performed by professional staffs of Shanghai Biochip Company. Chips were scanned with a Genechip Scanner 3000 7G (Affymetrix). Data analysis was performed using GCOS1.2 software. After background correction, we performed normalization for each array and gene. Data were filtered based on both signal intensity and detection call. Gene activity was considered to differ between quiescent HSCs and culture-activated HSCs ( $P < 0.01$ ) when compared by the unpaired Student's *t* test using multiple testing correction (Benjamini and Hochberg False Discovery Rate). Molecular function and classification of differentially expressed genes were analyzed with GO and KEGG pathway using the Database for Annotation, Visualization and Integrated Discovery Bioinformatics Resources 6.7<sup>[11]</sup> (<http://david.abcc.ncifcrf.gov>).

### Quantitative real-time polymerase chain reaction

Five differentially expressed genes were selected for qRT-PCR analysis, with glyceraldehydes-3-phosphate dehydrogenase (GAPDH) as a control, to verify the reliability of the array data. The primer sequences of analyzed genes are shown in Table 1. Super Script III reverse transcriptase (Invitrogen) was used for reverse transcription reactions. PCR amplification was performed using TaqMan universal Master Mix (Applied Biosystems, Foster City, CA, United States). Amplified reactions were quantified using an ABI PRISM 7900 Sequence detection system (Applied Biosystems, Foster City, CA, United States). Experiments were performed in triplicate. Relative gene quantities were obtained using the comparative Ct method after normalization to GAPDH control genes.

Table 1 Primer sequences of genes validating the microarray analysis by quantitative real-time polymerase chain reaction

Gene name	Sense primer	Antisense primer
Wnt5a	AGGGCTCCTACGAGAGTGCT	GACACCCCATGGCACTTG
Frizzled2	TCTCTGAGGACGGTTATCGCA	CAGAATCACCCACCAGATGGA
Calcium calmodulin mediated kinase II delta	TCGGCTCACACAGTACATGGA	CCCCGAACGATGAAAGTGAA
$\alpha$ -1 type I collagen	ACAGACTGGCAACCTCAAGAAG	AAGCGTGCTGTAGGTGAATCG
Connective tissue growth factor	GTTGGCGAACAAATGGCCTT	TGCCTCCA AACCAGTCATAG
Glyceraldehydes-3-phosphate dehydrogenase	TCTGCACCACCAACTGCTTAG	AGTGGCAGTGATGCCATGGACT

### Construction of lentivirus-mediated Wnt5a RNAi

Lentiviral vector pII3.7 expressing human Wnt5a ShRNA targeting 5'-GGACUUUCUCAAGGACAGA-3' (538-556) was constructed by Shanghai Biyang Biotechnology. Plasmids from correct clones were amplified by transforming into DH5 $\alpha$  *Escherichia coli* cells. We used tronolab lentiviral vector system (pRsv-REV, pMDlg-pRRE and pMD2G) to perform lentivirus-mediated Wnt5a RNAi. An additional scrambled sequence was produced as a negative siRNA control. The scrambled sequence was not homologous with any known gene in mammalian cells as determined by a Basic Local Alignment Search Tool. 293T cells were transfected with polybrene. The crude virus lysates were amplified in 293T cells to generate higher titre viral stocks. Virus particles were purified and concentrated. The lentivirus titer was determined by a limited dilution plaque assay. LX-2 transfected with lentivirus-mediated pII3.7 Wnt5a ShRNA at concentrations of MOI 10 and MOI 20 was used as study cells; cells transfected with negative siRNA were negative controls, and cells without transfection were blank controls. The effect of Wnt5a knockdown was validated with Western blotting. Blots were developed with enhanced chemiluminescence detection reagents (Santa Cruz Biotechnology Inc., CA, United States), exposed on Kodak Xmat blue XB-1 film and quantified by BandsScan 5.0 software using  $\beta$ -actin as internal control.

### Effect of Wnt5a RNAi on cell proliferation

Cells were spread onto 96-well flat-bottom plates at a density of  $5 \times 10^4$ /mL, 100  $\mu$ L per well, and cultured in DMEM including 5% fetal calf serum. Subgroups included: control group, negative siRNA control group and Wnt5a ShRNA group. Each group was repeated for 6 wells. The plates were incubated in a 5% CO<sub>2</sub> humidified incubator at 37 °C for 24 h and 200  $\mu$ L of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) (5 mg/mL) was added into each well. The plates were then incubated for 4 h and the supernatants were removed. After 150  $\mu$ L DMSO was added into each well, the plates were agitated for 20 min to dissolve the crystals. Finally, the A values were measured using the enzyme-linked immunoassay at a wave-length of 450 nm.

### Effect of Wnt5a RNAi on the expression of collagen I and transforming growth factor- $\beta$ 1

Effects of Wnt5a RNAi on the expression of collagen I and TGF- $\beta$ 1 in LX-2 were analyzed with RT-PCR

*in vitro*. Experiments were performed in triplicate. The primer of  $\alpha$ -1 type I collagen (COL1A1) : sense primer: 5'-TGCCAAGGGAGATGCTGGTC-3', antisense primer: 5'-TTCACCCTTAGCACCAACAGCA-3', product size 238 bp; TGF $\beta$ 1: sense primer: 5'-TGCAAGAC-TATCGACATGGAG-3', antisense primer: 5'-ACTT-GAGCCTCAGCAGACGCA-3', product size 389 bp. The amplified products were applied to electrophoresis on 1% agarose gel analysis. The relative expression levels of COL1A1 and TGF $\beta$ 1 were assessed based on the  $\beta$ -actin control by calculating the average ratios of light density using symmetry computerized gel imaging system.

### Experimental fibrotic model

Liver fibrosis was induced by subcutaneous injection at hind leg of 40% CCl<sub>4</sub>-tea oil, 0.5 mL/100 g body weight for the first time and then 0.3 mL/100 g body weight twice a week for 8 wk. Control rats received only tea oil. The amount of CCl<sub>4</sub> administered was adjusted for body weight each week. Liver tissue samples obtained from CCl<sub>4</sub>-treated and non-treated control rats were dehydrated, embedded in paraffin, sectioned and stained with HE and Masson staining. The expression of Wnt5a was analyzed with Western blot with antibodies to Wnt5a (sc-30224, Santa Cruz, United States). The bands were semi-quantitatively evaluated by densitometric analysis. Protein expression levels of Wnt5a were thereby normalized to those of the housekeeping gene  $\beta$ -actin.

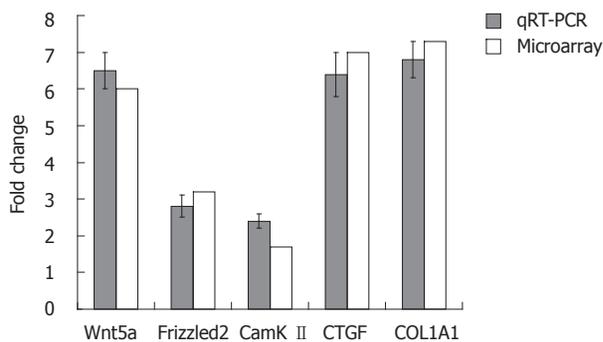

### Statistical analysis

Statistical analyses were performed using SPSS 13.0 software. Two-way analysis of variance was performed to detect the effects of Wnt5a knockdown on cell proliferation and Student *t* test was used to detect the difference between any two groups. The results were considered statistically significant at  $P < 0.05$ .

## RESULTS

### Microarray analysis and validation of microarray data

Culture-activated HSCs exhibited myofibroblast-like appearance. cRNAs, prepared from quiescent HSCs and culture-activated HSCs, were hybridized to a rat genome 430 2.0 array gene chips. Of the 28 700 genes represented therein, 2566 genes displayed at least a 2-fold increase or decrease in expression at the  $P < 0.01$  level with a false discovery rate. Of these, 1396 genes were upregulated, while 1170 genes were downregulated in culture-activated

	Wnt5a	Frizzled2	CamK II	CTGF	COL1A1
qRT-PCR	6.5	2.8	2.4	6.4	6.8
Microarray	6	3.2	1.7	7	7.3
SD	0.5	0.3	0.2	0.6	0.5

**Figure 1 Validation of microarray data by quantitative real-time polymerase chain reaction.** Comparison between expression values of five selected differently expressed genes estimated by quantitative real-time polymerase chain reaction (qRT-PCR) and gene expression data. The detected changes measured by qRT-PCR reflected different changes in gene expression between quiescent and activated hepatic stellate cells obtained by microarray analysis. SD: Sprague Dawley; CTGF: Connective tissue growth factor; CamK II: Calcium calmodulin mediated kinase II.

HSCs. As expected, genes such as COL1A1 and connective tissue growth factor (CTGF) were significantly upregulated. We were particularly interested in Wnt proteins in view of their potential role in HSCs activation. Wnt5a was upregulated by approximately 6-fold in activated HSCs in comparison with quiescent HSCs, its downstream factors Frizzled2 was upregulated by 3.2-fold and calcium calmodulin mediated kinase II (CamK II) was upregulated by 1.7-fold. Changes in gene expression profiles observed in the microarrays were validated by qRT-PCR analysis using the same total RNAs analyzed in the microarrays. We verified the upregulation of Wnt5a, Frizzled2 and CamK II as well as COL1A1, CTGF (Figure 1). This verification confirmed that all the qRT-PCR results were in agreement with the microarray data.

### Gene ontology analysis

To elucidate the relationship between gene differential expression patterns of quiescent HSCs and culture-activated HSCs, we examined the functional bias of 2566 differentially expressed transcripts according to Gene Ontology (GO) classifications. These differentially expressed transcripts were grouped into 545 GO based on biological process GO terms. The most enriched GO terms included response to wounding, wound healing and regulation of cell growth (Table 2). Analyses of GO also indicated that there were 102 GO terms identified by cellular component classification, and 90 GO terms identified by molecular function classification.

### Kyoto encyclopedia of genes and genomes pathway analysis

Analysis of KEGG pathways revealed many enrichment-related pathways including focal adhesion, ECM-receptor

interaction, regulation of actin cytoskeleton, pathways in cancer, dilated cardiomyopathy, hypertrophic cardiomyopathy, TGF- $\beta$  signaling pathway, chemokine signaling pathway, p53 signaling pathway, renal cell carcinoma, Wnt signaling pathway, leukocyte transendothelial migration, MAPK signaling pathway in HSCs activation. The top 20 significantly perturbed pathways are listed in Table 3. Of these, Wnt signaling pathway is shown in Figure 2. It revealed that Wnt5a/Frizzled2/PLC/CamK II pathway participated in the activation of HSCs.

### Effect of Wnt5a knockdown on LX-2 cells

LX-2 cells were infected with lentiviral vector encoding GFP at a multiplicity of infection (MOI) of 10, resulting in GFP expression in the majority of cultured cells. Western blot analysis showed that the protein expression levels of Wnt5a were lower in the Wnt5a ShRNA group than in the control and negative siRNA group ( $P < 0.01$ ) (Figure 3). MTT assay indicated that the proliferation of LX-2 cells was inhibited significantly after transfection with Wnt5a ShRNA as compared with the control and negative siRNA group ( $P < 0.05$ ) (Figure 4). RT-PCR showed that Wnt5a gene silencing remarkably decreased the levels of COL1A1 and TGF- $\beta$ 1 mRNA ( $P < 0.05$ , respectively) as shown in Figure 5.

### Upregulation of Wnt5a in a CCl<sub>4</sub>-induced fibrosis model

Next, we investigated whether Wnt5a was induced during liver fibrosis *in vivo*. Compared with the normal group, 8 wk after CCl<sub>4</sub> treatment, collagen deposition was increased, pseudolobules formed, and numerous inflammatory cells infiltrated the portal area. Western blotting revealed that Wnt5a was upregulated as significantly as  $\alpha$ SMA after 8 wk of CCl<sub>4</sub> treatment ( $P < 0.01$ ) (Figure 6).

## DISCUSSION

To discover novel genes involved in activation of HSCs, we compared gene expression profile between quiescent and culture activated HSCs. We showed that 2566 genes displayed at least a 2-fold increase or decrease in expression. Of these, 1396 genes were upregulated, while 1170 genes were downregulated in culture-activated HSCs. GO classification showed the most enriched GO terms included response to wounding, wound healing and regulation of cell growth. Analysis of KEGG pathways revealed that Wnt signaling pathway participates in HSCs activation. We were particularly interested in Wnt proteins in view of their potential role in HSCs activation.

The Wnt signaling pathway is a network of proteins best known for their roles in embryogenesis and cancer, but also involved in normal physiological processes in adult animals<sup>[12]</sup>. There are at least three different Wnt pathways: the canonical pathway, the planar cell polarity (PCP) pathway and the Wnt/Ca<sup>2+</sup> pathway. In the canonical Wnt pathway, Wnt ligands bind to the receptor of frizzled family, which transduce signal to  $\beta$ -catenin causing  $\beta$ -catenin to enter the nucleus and activate the target

genes. Wnt-Ca<sup>2+</sup> signaling is mediated through G proteins and phospholipases and leads to transient increases in cytoplasmic free calcium that subsequently activate the kinase protein kinase C and CamK II and the phosphatase calcineurin<sup>[13-15]</sup>.

With KEGG pathway analyses, we found that the canonical pathway, the PCP pathway and the Wnt/Ca<sup>2+</sup> pathway participated in the activation of HSCs. In recent years, researches have shown that activation of Wnt signaling pathway was closely related with the development and progress of fibroproliferative diseases, such as pul-

monary fibrosis<sup>[16-19]</sup>, renal fibrosis<sup>[20-22]</sup>, post-infarct cardiac remodeling<sup>[23]</sup> and hypertrophic scars<sup>[24,25]</sup>, which makes it easy to think that Wnt pathway may have a definite effect on liver fibrosis. It is reported that Wnt/ $\beta$ -catenin signaling contributes to “antiadipogenic” activation of HSCs and may be used as a new target for liver fibrogenesis<sup>[26]</sup>.

The study about the role of Wnt5a in HSCs activation is still in its initial stage. Jiang<sup>[27]</sup> reported that expressions of Wnt5a and its receptor Frizzled 2 were highly upregulated in culture-activated HSCs *in vitro*. In addition,

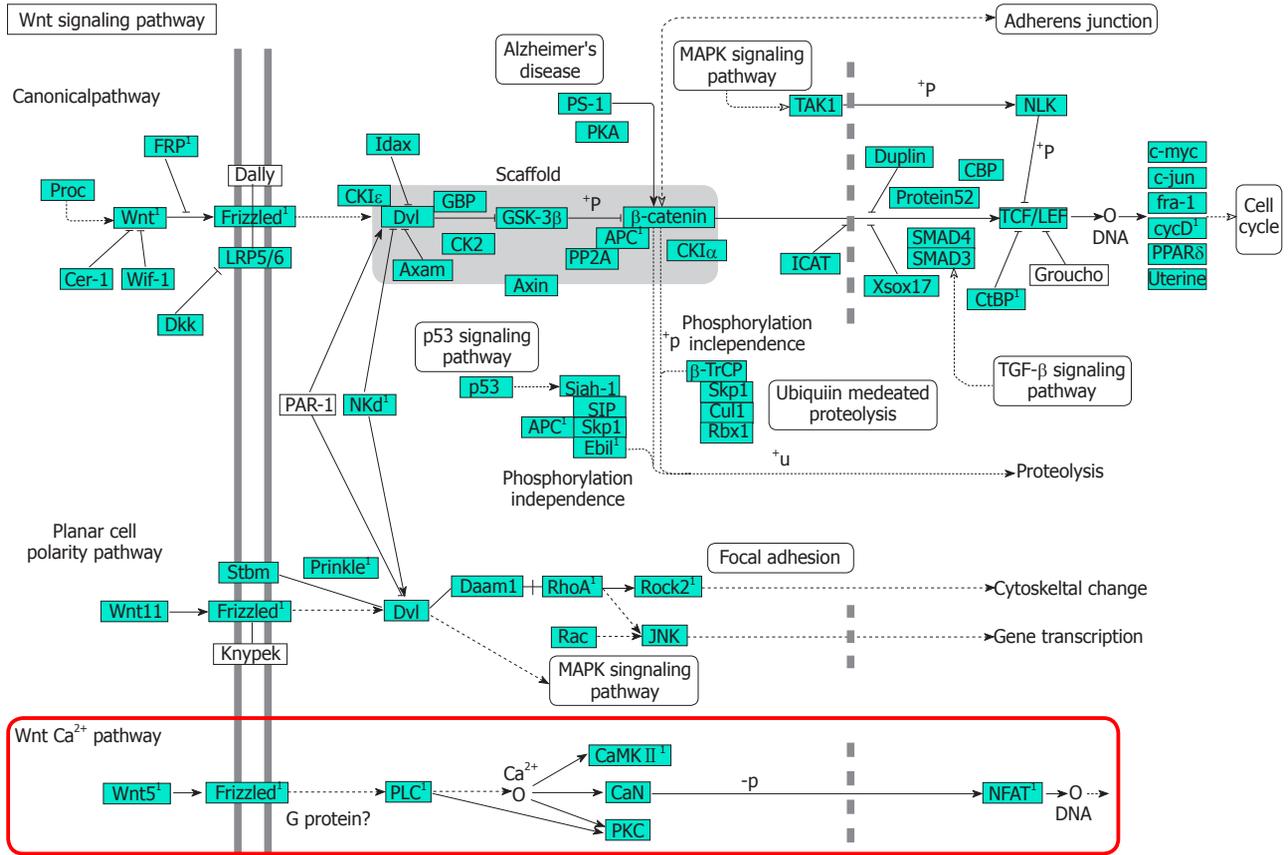

Figure 2 Wnt signaling pathway participated in the activation of hepatic stellate cells. <sup>1</sup>?? TGF-β1: Transforming growth factor-β1; LRP: GBP: APC: CBP: PKC: NFAT: PLC:

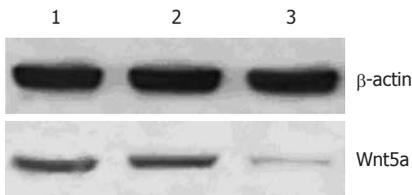

Figure 3 Expression levels of Wnt5a proteins in three groups detected by Western blotting. 1: Control; 2: Negative siRNA; 3: Wnt5a ShRNA.

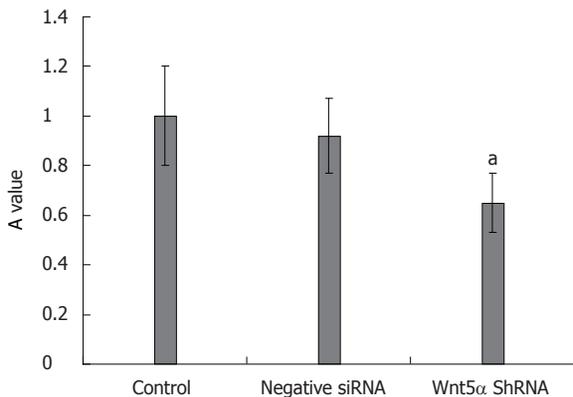

Figure 4 Knock down of Wnt5a decreases the cell proliferation. The role of Wnt5a in regulating LX-2 proliferation was determined by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay. Compared with the negative siRNA and control group, Wnt5a ShRNA could inhibit the proliferation of LX-2, <sup>a</sup>P < 0.05 vs control group.

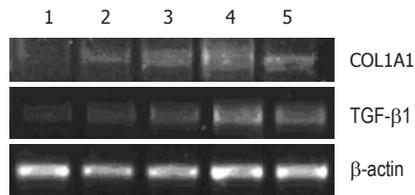

Figure 5 Knockdown of Wnt5a decreases expressions of α-1 type I collagen and transforming growth factor-β1. Experiments were repeated three times and representative results are shown. Compared with the negative siRNA, vector and control groups, the expressions of α-1 type I collagen (COL1A1) and transforming growth factor-β1 (TGF-β1) mRNA were downregulated remarkably in the Wnt5a shRNA group (P < 0.05). 1: Wnt5a ShRNA multiplicity of infection (MOI) 20; 2: Wnt5a ShRNA MOI 10; 3: Negative siRNA; 4: Vector; 5: Control.

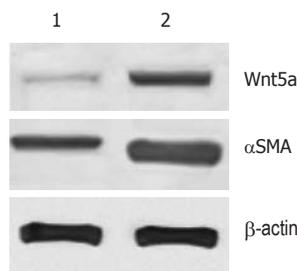

Figure 6 Expression of Wnt5a in fibrotic livers determined with Western blotting. The bands were semi-quantitatively evaluated by densitometric analysis. Wnt5a protein was upregulated as significantly as αSMA in the CCl4-induced liver fibrosis model when compared with the normal rats (P < 0.01). 1: Normal group; 2: Model group.

the expressions of Wnt5a and Frizzled2 in HSCs isolated from the mouse liver fibrosis model induced by bile duct ligation were higher as compared with HSCs isolated from normal mice. It suggests that Wnt5a signaling pathway may be involved in differentiation of quiescent HSCs into myofibroblasts. Shackel<sup>[28]</sup> reported the highly expression of Wnt5a in primary biliary cirrhosis. We found that Wnt5a was upregulated in activated HSCs in comparison with quiescent HSCs as well as its downstream factors such as Frizzled2 and CamK II. Changes in gene expression profiles observed in the microarrays were validated by qRT-PCR analysis. The direct evidence of Wnt5a on the activation of HSCs has not been reported. Because of this, we treated human HSCs line LX-2 with Wnt5a ShRNA, and found that knockdown of *Wnt5a* gene expression in LX-2 led to significantly impaired proliferation, downregulated expressions of type I collagen and TGF- $\beta$ 1. Wnt5a was upregulated in fibrotic liver of a CCl<sub>4</sub>-induced fibrosis rat model.

In summary, our data suggest that Wnt5a may play a role in HSCs activation and liver fibrogenesis, thus revealing the mechanism of HSCs activation from a new perspective, which may provide a novel means and therapeutic target for the prevention and treatment of liver fibrosis.

## COMMENTS

### Background

Hepatic stellate cells (HSCs) activation is one of the key steps in the development of liver fibrosis. However, the molecular mechanisms underlying the activation of HSCs are not fully understood. It is reported that the expression levels of Wnt5a and its downstream signaling molecules were significantly increased in activated HSCs and experimental liver fibrosis model, indicating that Wnt5a signaling pathways may be involved in liver fibrosis. But the direct evidence of Wnt5a on the activation of HSCs has not been reported. In this study, the authors aimed to identify differentially expressed genes in quiescent and activated HSCs and explore the role of Wnt5a in the activation of HSCs.

### Research frontiers

Chip technology is rapid and concise in detecting mRNA expression. Previous studies have reported the differentially expressed gene profiles between quiescent and activated HSCs with gene chip. But, intense bioinformatics analyses and functional assays are deficient. No study has provided the direct evidence of Wnt5a in the mechanism of HSCs activation.

### Innovations and breakthroughs

Bioinformatic analysis of the differentially expressed gene profiles between quiescent and activated HSCs reveals the role of Wnt5a signaling pathway in HSCs activation. This is the first study addressing the role of Wnt5a in the mechanism of HSCs activation.

### Applications

This study suggests that Wnt5a participates in the HSCs activation and liver fibrogenesis, which may provide a novel means and therapeutic target for the prevention and treatment of liver fibrosis.

### Terminology

Wnt signaling molecules are involved in diverse developmental and pathological processes. Based on the different intracellular events activated after Wnt-Frizzled binding, Wnt signaling is divided into two subclasses: the canonical pathway and the non-canonical pathway. Wnt5a is a non-canonical member of the Wnt family. In the Wnt5a signaling pathway, Wnt5a and Frizzled binding triggers the intra-cytoplasmic release of calcium. Increased intracellular calcium concentration activates calcineurin and calcium calmodulin mediated kinase II. Wnt5a signaling takes part in wound healing, regulation of cell proliferation, vasculature development and the formation of cell polarity.

### Peer review

The research is the in vitro experiments showing that Wnt5a ShRNA decreases proliferation, downregulates expression of collagen type I and transforming growth factor beta, that probes into a direct Wnt5a participation in the mechanism of HSC activation.

### Abstract

**AIM:** To investigate the effects of tectorigenin on human hepatocellular carcinoma (HCC) HepG2 cells.

**METHODS:** Tectorigenin, one of the main components of rhizome of *Iris tectorum*, was prepared by simple methods, such as extraction, filtration, concentration, precipitation and recrystallization. HepG2 cells were incubated with tectorigenin at different concentrations, and their viability was assessed by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay.

Apoptosis was detected by morphological observation of nuclear change, agarose gel electrophoresis of DNA ladder, and flow cytometry with Hoechst 33342, Annexin V-EGFP and propidium iodide staining. Generation of reactive oxygen species was quantified using DCFH-DA. Intracellular  $Ca^{2+}$  was monitored by Fura 2-AM. Mitochondrial membrane potential was monitored using Rhodamine 123. Release of cytochrome c from mitochondria to cytosol was detected by Western blotting. Activities of caspase-3, -8 and -9 were investigated by Caspase Activity Assay Kit.

**RESULTS:** The viability of HepG2 cells treated by tectorigenin decreased in a concentration- and time-dependent manner. The concentration that reduced the number of viable HepG2 cells by 50% ( $IC_{50}$ ) after 12, 24 and 48 h of incubation was 35.72 mg/L, 21.19 mg/L and 11.06 mg/L, respectively. However, treatment with tectorigenin at 20 mg/L resulted in a very slight cytotoxicity to L02 cells after incubation for 12, 24 or 48 h. Tectorigenin at a concentration of 20 mg/L greatly inhibited the viability of HepG2 cells and induced the condensation of chromatin and fragmentation of nuclei. Tectorigenin induced apoptosis of HepG2 cells in a time- and dose-dependent manner. Compared with the viability rate, induction of apoptosis was the main mechanism of the anti-proliferation effect of tectorigenin in HepG2 cells. Furthermore, tectorigenin-induced apoptosis of HepG2 cells was associated with the generation of reactive oxygen species, increased intracellular  $[Ca^{2+}]_i$ , loss of mitochondrial membrane potential, translocation of cytochrome c, and activation of caspase-9 and -3.

**CONCLUSION:** Tectorigenin induces apoptosis of HepG2 cells mainly *via* mitochondrial-mediated pathway, and produces a slight cytotoxicity to L02 cells.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the third most common cause of cancer-related mortality worldwide, with 600 000 deaths per year<sup>[1]</sup>. It often develops in patients with chronic liver diseases associated with hepatitis B virus or hepatitis C virus infections<sup>[1]</sup>. Although surgical techniques have been improved and several non-surgical treatment modalities have been developed, there is still no effective therapy for significant improvement of extremely poor prognosis of HCC patients<sup>[2]</sup>. Therefore, efforts have been made to search for mechanism-based agents, such as sorafenib<sup>[3]</sup>, chelidonine<sup>[4]</sup>, 5-allyl-7-gendifluoromethylenechrysin<sup>[5]</sup>, troglitazone<sup>[6]</sup>, chaga mushroom extract<sup>[7]</sup> and curcumin<sup>[8]</sup>, for treatment of HCC. Sorafenib is the first substance that proved to significantly prolong the survival of HCC patients. And multikinase inhibitor has shown to have anti-proliferative and anti-angiogenic properties<sup>[3]</sup>.

Apoptosis is a physiological process leading to cell deletion and regulates the balance between cell proliferation and death. The hallmark of cancer cells is the dysregulation of cell proliferation and apoptosis. The tumor growth depends on the cell proliferation rate and apoptosis. Therefore, induction of apoptosis of tumor cells has become a strategy in cancer treatment<sup>[5-7]</sup>. The integration of multiple survival and death signals determines whether a cell survives or undergoes apoptosis. In recent years, mitochondrial pathways and death receptor pathways have been identified as the two major mechanisms for induction of apoptosis<sup>[9,10]</sup>.

*Iris tectorum* (*I. tectorum*), a traditional Chinese medicine, has been widely used for treating liver-related diseases, including hepatitis, liver fibrosis, liver cirrhosis and liver cancer. As one of the main ingredients of *I. tectorum* rhizome<sup>[11]</sup>, tectorigenin has been reported to have *in vivo* and *in vitro* anti-angiogenic activities<sup>[12]</sup>. A previous study also showed that tectorigenin possessed anti-tumor activities in mice implanted with murine Lewis

lung carcinoma or bearing sarcoma 180<sup>[12]</sup>. Our previous studies revealed that tectorigenin possessed anti-proliferative and pro-apoptotic effects on hepatic stellate cells (HSCs)<sup>[13]</sup>. However, until now there has been no report about the anti-tumor effect of tectorigenin on human HCC HepG2 cells and the associated mechanisms. Considering that tectorigenin is one of the main components in rhizome of *I. tectorum* which had been used for the treatment of liver cancer for centuries, we hypothesized that tectorigenin may have anti-proliferation and pro-apoptosis effects on human HCC HepG2 cells. The aim of the present study was to examine whether tectorigenin could suppress the proliferation of HepG2 cells and induce apoptosis of HepG2 cells.

## MATERIALS AND METHODS

### Reagents

All reagents and solvents were purchased from commercial suppliers and were used without further purification. Roswell Park Memorial Institute (RPMI)-1640 medium was purchased from HyClone (Hyclone, UT, United States). Fetal bovine serum (FBS) was purchased from Hangzhou Sijiqing Biological Engineering Materials Co., Ltd. (Hangzhou, China). Annexin V-EGFP was purchased from PharMingen (San Diego, CA, United States). Propidium iodide (PI), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), Hoechst H33258, DCFH-DA, ethidium bromide (EB), Proteinase K, RNase A and Rhodamine 123 were purchased from Sigma Aldrich Co. (St. Louis, MO, United States). Fura 2-AM was purchased from Dojindo Laboratories (Kumamoto, Japan). The kits used for caspase activity assays were obtained from Beyotime Institute of Biotechnology (Nantong, Jiangsu, China). All other chemicals were of analytic grade.

### Plant materials

The rhizomes of *I. tectorum* were collected at Dafeng, Jiangsu Province, China. The voucher specimen (the registration number NJU-603) was identified by Prof. Gong ZN, Nanjing Normal University and deposited at the herbarium of Nanjing University, Nanjing, Jiangsu Province, China.

### Preparation of tectorigenin

The rhizomes (400 g) of *I. tectorum*, after ground on an electrical grinder, were extracted twice with 2000 mL of 80% ethanol under reflux for 3 h. The filtrate of the obtained 80% ethanol extract was condensed in vacuum to afford a dark-brown residue called Crude-Extract (73.1 g). The Crude-Extract was dissolved in 4000 mL 3% Na<sub>2</sub>CO<sub>3</sub> solution at 85 °C, and then the solution was filtrated. The pH of the filtrate was regulated to 3-4 by adding 18% HCl, and then the crude isoflavone part was precipitated from the acid liquor. The formed crude isoflavone (23.2 g) was collected by filtration and dissolved in 2000 mL 5% NaHCO<sub>3</sub> solution at 85 °C. The 5%

NaHCO<sub>3</sub> solution was extracted with 2000 mL EtOAc twice. The EtOAc extract was condensed in vacuum to afford a light-brown residue (11.5 g). The residue was washed by 2000 mL hot distilled water and 2000 mL ligarine successively, and sequentially dried at 50 °C. The dried residue (7.3 g) was recrystallized in ethanol twice to afford pure compound (4.45 g).

### Cell culture and treatment

Human liver carcinoma HepG2 cells were purchased from the Shanghai Institute of Cell Biology (Shanghai, China). These cells were grown in RPMI 1640 medium with 10% FBS in the presence of 100 U/mL penicillin and 100 µg/mL streptomycin and maintained at 37 °C in a humidified atmosphere containing 5% (v/v) CO<sub>2</sub>. L02 cells (a human hepatocyte cell line), purchased from Xiangya Central Experiment Laboratory, Central South University, China, were cultured in Dulbecco's Modified Eagle Medium (Gibco, NY, United States) supplemented with 100 U/mL penicillin, 100 µg/mL streptomycin, and 10% FBS, in a humidified atmosphere containing 5% (v/v) CO<sub>2</sub> at 37 °C. Tectorigenin was dissolved in dimethyl sulfoxide (DMSO) at 20 mg/mL as a stock solution and diluted to the required concentration with fresh medium immediately before use. The final DMSO concentration in cultures was < 0.1% (v/v), which did not influence cell growth when compared with the vehicle-free controls. Cells grown in the media containing an equivalent amount of DMSO without tectorigenin served as control.

### Cell viability assay

Cell viability was assessed by MTT method. Briefly, cells were seeded in 96-well plate at a density of  $1 \times 10^4$  cells/well. After 24 h incubation, tectorigenin at different concentrations was added to the cells while only DMSO (solvent) was added as a negative control. After growing for 12, 24 and 48 h, cells were incubated with MTT (0.5 mg/mL) for 4 h at 37 °C. During this incubation period, water-insoluble formazan crystals were formed, which were dissolved by the addition of 100 µL/well DMSO. The optical densities (*A*) at 570 nm were measured using an enzyme-linked immunosorbent assay plate reader. Wells containing culture medium and MTT but no cells acted as blanks. The percentage of cell viability was calculated as follows:  $A_{\text{drug-blank}}/A_{\text{control-blank}} \times 100\%$ .

### Morphological observation of nuclear change

Cell morphological assay was carried out according to Wu *et al.*<sup>[13]</sup> with minor modification. In this assay, cells were seeded in 24-well plates and treated with tectorigenin or vehicle (control). After 48 h incubation, cells were washed carefully with phosphate buffered saline (PBS), fixed with 4% paraformaldehyde for 10 min at room temperature, then washed with pre-chilled PBS three times and exposed to 5 µg/mL Hoechst 33258 at room temperature in the dark for 20 min. Samples were observed under a fluorescent microscope (Nikon UFX-II, Japan). Cells showing cytoplasmic and nuclear shrink-

age, chromatin condensation or fragmentation, were defined as apoptotic cells.

### Determination of DNA fragmentation

The integrity of DNA was assessed by agarose gel electrophoresis. Cells were harvested after 48 h incubation with 20 µg/mL tectorigenin by centrifugation (300 × *g*, 5 min) and lysed in lysis buffer containing 10 mmol/L Tris-HCl (pH 7.4), 10 mmol/L ethylenediaminetetraacetic acid (EDTA), and 0.1% of Triton X-100. Then cells were incubated with RNase A at 37 °C for 60 min and proteinase K at 50 °C for 120 min, respectively. After centrifugation (2000 × *g*, 10 min), supernatants were transferred to new tubes and precipitated by the addition of 0.5 volume of 7.5 mol/L ammonium acetate and 2.5 volumes of ethanol overnight. After centrifugation at 600 × *g* for 5 min, the pellets were dissolved in Tris-HCl EDTA buffer (TE buffer) (10 mmol/L Tris-HCl, pH 8.0, 1 mmol/L EDTA) and loaded on 1.5% agarose gel for electrophoresis. The gel was stained with EB and photographed with ultraviolet illumination.

### Assessment of apoptosis

Apoptosis could be determined by staining cells with Annexin V-EGFP and propidium iodide labeling. In this study, apoptosis was assessed according to Hai *et al.*<sup>[14]</sup>. Briefly, cells were harvested after having exposed to the indicated concentrations of tectorigenin for 24 or 48 h, washed twice with cold PBS and then resuspended in 1 mL binding buffer (10 mmol/L HEPES/NaOH (pH 7.4), 140 mmol/L NaCl, 2.5 mmol/L CaCl<sub>2</sub>) at a concentration of  $1 \times 10^6$  cells/mL. The cells were incubated with 5 µL Annexin V-EGFP (300 mg/L) for 10 min, and then 10 µL of 20 mg/L PI for 30 min in the dark. Cell fluorescence was measured on FACScan flow cytometer (Becton Dickinson) using an argon ion laser (488 nm).

### Measurement of reactive oxygen species generation

The cellular reactive oxygen species (ROS) was quantified using DCFH-DA according to Shi *et al.*<sup>[15]</sup>. Cells were seeded in black 96-well plates and incubated with tectorigenin at indicated concentrations for 1, 3, 6 or 24 h. Then cells were washed with PBS twice and incubated with 100 µmol/L DCFH-DA in the loading medium in 5% CO<sub>2</sub>/95% air at 37 °C for 30 min. After DCFH-DA was removed, the cells were washed with PBS and DCFH-DA-loaded cells were read in a Safire (Tecan, Crailsheim, Germany) fluorescence plate reader (excitation, 485 ± 12 nm; emission, 530 ± 12 nm). The fold increase in fluorescence per well was calculated by the formula  $[F_t/F_0]$ , where *F*<sub>0</sub> is the fluorescence without tectorigenin treatment and *F*<sub>t</sub> is the fluorescence with the tectorigenin treatment at the indicated concentration.

### Measurement of intracellular Ca<sup>2+</sup>

Intracellular Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>i</sub>) was monitored using the fluorescent Ca<sup>2+</sup>-sensitive dye, Fura 2-acetoxymethyl ester (Fura 2-AM)<sup>[15]</sup>. Cells were seeded in black 96-well plates

and incubated with tectorigenin at the indicated concentration for 3, 6 or 24 h. The cells were washed with PBS twice and incubated with 1  $\mu\text{mol/L}$  Fura 2-AM which was dissolved in HEPES buffer saline (20 mmol/L HEPES, 115 mmol/L NaCl, 5.4 mmol/L KCl, 1.8 mmol/L  $\text{CaCl}_2$ , 0.8 mmol/L  $\text{MgCl}_2$ , 13.8 mmol/L glucose, pH 7.4) for 30 min in the dark at 37 °C in a humidified incubator. They were then gently rinsed with HEPES buffer saline twice and incubated with HEPES buffer saline for 60 min at 37 °C in a humidified incubator. The fluorescence was measured at an emission wavelength of 510 nm and an excitation wavelength of 340 and 380 nm on a Safire (Tecan, Crailsheim, Germany) fluorescence plate reader. The ratio of fluorescence intensity of 340-380 nm (F340/F380) was used to estimate intracellular free calcium.

#### Measurement of mitochondrial membrane potential

As an index to determine mitochondrial dysfunction, mitochondrial membrane potential (MMP) was monitored using Rhodamine 123<sup>[16]</sup>. Cells were treated with tectorigenin at indicated concentration for 3, 6 or 24 h in a 6-well culture plate at  $1 \times 10^5$  cells/mL. The medium was then removed and washed three times with serum-free RPMI 1640 medium followed by incubation in fresh serum-free medium containing 3 mg/L Rhodamine 123 at 37 °C in dark for 30 min. Finally, the cells were collected and washed twice with PBS and then analyzed by a FACScan flow cytometer (Becton Dickinson, Franklin Lakes, NJ, United States).

#### Western blotting

HepG2 cells were seeded into 60-mm dishes ( $1 \times 10^6$  cells/dish). On the next day, after treated for 48 h with tectorigenin at 0, 5, 10 and 20 mg/L, respectively, HepG2 cells were harvested, resuspended in an ice-cold lysis buffer containing 50 mmol/L Tris-HCl, pH 8.0, 50 mmol/L KCl, 5 mmol/L dithiothreitol (DTT), 1 mmol/L EDTA, 0.1% sodium dodecyl sulfate (SDS), 0.5% Triton X-100, and protease inhibitor cocktail tablets (Roche, IN), incubated for 10 min on ice, disrupted in a micro-ultrasonic cell disrupter for 10 s and centrifuged at  $750 \times g$  for 15 min at 4 °C. The supernatant (cytosolic fraction) was removed and maintained at -80 °C. The pellet containing mitochondria was resolved in a lysis buffer. Protein level was measured using a standard colorimetric assay kit (BCA kit). Proteins were separated by polyacrylamide/SDS gel electrophoresis and transferred onto polyvinylidene fluoride membranes (Roche, IN). The membranes were probed with antibody (cytochrome c diluted at 1:1000, Cell Signaling Technology, MA, United States) overnight at 4 °C, and incubated with a Horseradish peroxidase (HRP)-coupled secondary antibody (HRP; 1:5000, Cell Signaling Technology, MA, United States). Detection was performed using a LumiGLO chemiluminescent substrate system (KPL, Guildford, United Kingdom).  $\beta$ -actin (1:200, Boster, Wuhan, China) as a loading control. Results were quantified with a scan-

ning densitometer (Bio-Rad, United States).

#### Caspase-3, -8 and -9 activity assay

Caspases activities were measured using Caspase Activity Assay Kit (Beyotime, C1115, C1151 and C1157) according to the manufacturer's instructions. Briefly, cultured HepG2 cells ( $5 \times 10^6$ ) were washed with cold PBS twice, resuspended in lysis buffer and left on ice for 20 min. The lysate was centrifuged at  $16\,000 \times g$  at 4 °C for 3 min. Supernatants were collected and protein concentrations were measured with a BCA kit. Caspase-3, -8 and -9 activities were measured by reaction buffer (containing DTT) and caspase substrate peptides Ac-DEVD-pNA, Ac-IETD-pNA and Ac-LEHD-pNA, respectively. The release of p-nitroanilide (pNA) was qualified by determining the absorbance with Tecan SUNRISE at 405 nm. The fold increase in absorbance was calculated by the formula  $[\text{OD}_i/\text{OD}_0]$ , where  $\text{OD}_0$  is the absorbance without tectorigenin treatment and  $\text{OD}_i$  is the absorbance with tectorigenin treatment at the indicated concentration.

#### Statistical analysis

All data were expressed as mean  $\pm$  SD. Origin Pro 7.0 statistical package was used to determine statistical significance. Difference between two groups was analyzed by two-tailed Student's *t* test, and difference among three or more groups was analyzed by one-way analysis of variance multiple comparisons.  $P < 0.05$  was considered statistically significant.

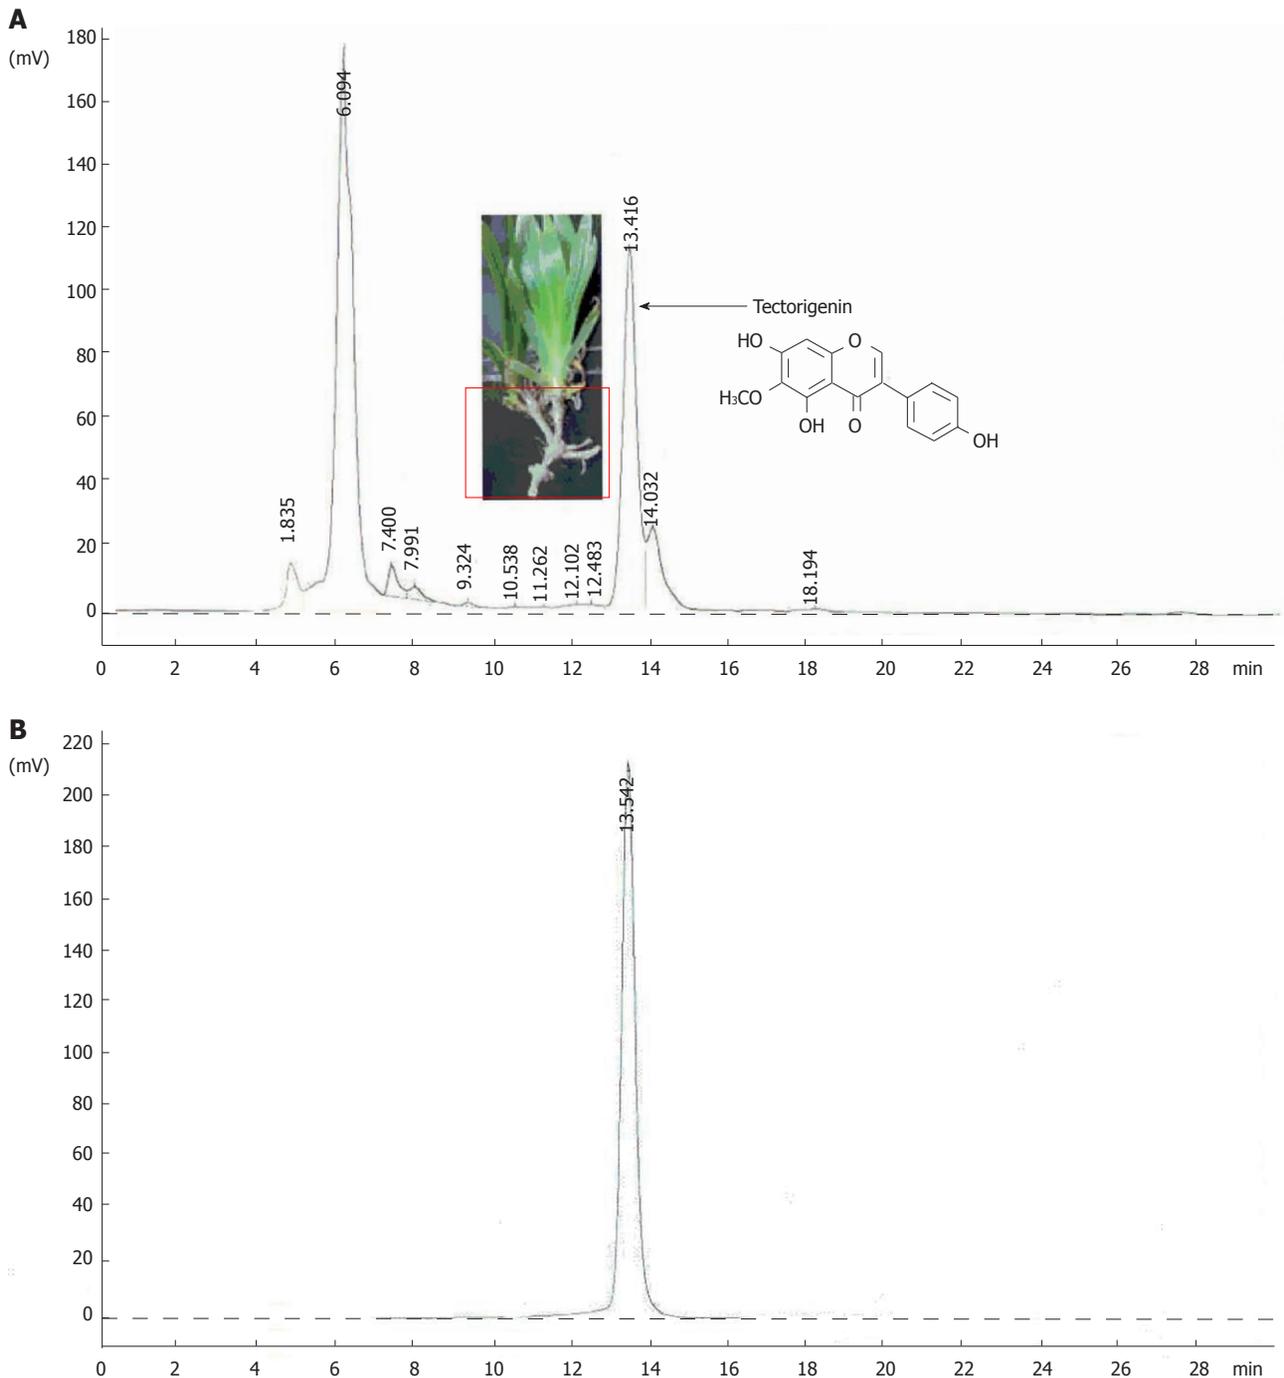

## RESULTS

#### Preparation of tectorigenin

As illustrated in Figure 1A, the high performance liquid chromatography (HPLC) profile for Crude-Extract revealed that tectorigenin is one of the main components of the rhizomes of *I. tectorum*. The compound was identified as tectorigenin (CAS registry number: 548-77-6) by chemical and spectral approaches. The structure is shown in Figure 1A. The purity of tectorigenin was above 98% (HPLC analysis, Figure 1B).

#### Effect of tectorigenin on viability of HepG2 and L02 cells

The effect of different concentrations of tectorigenin on the viability of HepG2 cells for 12, 24 and 48 h was assessed by the MTT assay. The number of viable HepG2 cells treated by tectorigenin decreased in a concentration- and time-dependent manner (Figure 2A). When HepG2 cells were treated with tectorigenin at 5, 10 and 20 mg/L for 24 h, the viability rate was 91%, 79% and 62%, respectively (Figure 2A). Whereas when HepG2 cells were treated with tectorigenin at 5, 10 and 20 mg/L for 48 h, the viability rate was reduced to 83%, 57% and 33%, respectively (Figure 2A). The concentration that reduced the number of viable HepG2 cells by 50% ( $\text{IC}_{50}$ ) after 12h, 24 h and 48h of incubation was 35.72, 21.19 and 11.06 mg/L, respectively. However, treatment with tectorigenin at 20 mg/L resulted in a very slight cytotoxicity to

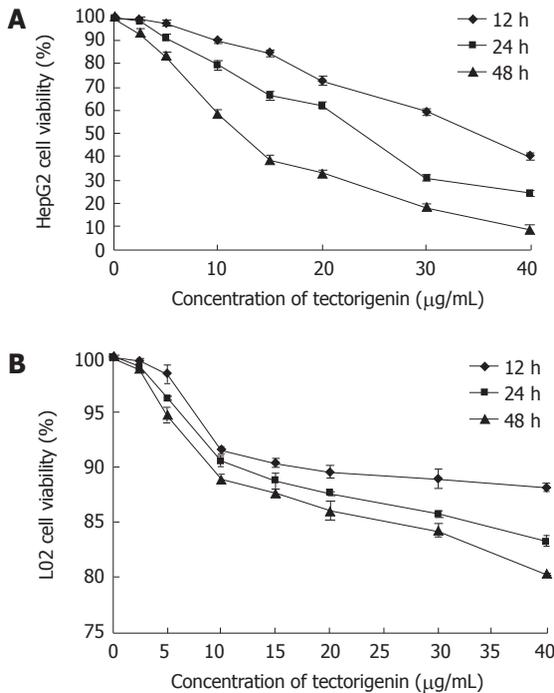

**Figure 1** The high-performance liquid chromatography profiles of the aqueous ethanol (80%) extract of *Iris tectorum* rhizomes (A) and tectorigenin (B). High-performance liquid chromatography analysis was accomplished at 25 °C on an instrument consisting of L-7110 (Hitachi) pump, L-7420 (Hitachi) ultraviolet detector (set at 254 nm) and Alltech Apollo C18 (4.6 mm × 250 mm) column using MeOH:EtOAc:H<sub>2</sub>O (60:1:40) mixture as a mobile phase at a flow rate of 1.0 mL/min. Sample injection: 10 μL of extract (2.5 g/L) or tectorigenin (100 mg/L) in MeOH.

L02 cells after incubation for 12, 24 or 48 h (Figure 2B).

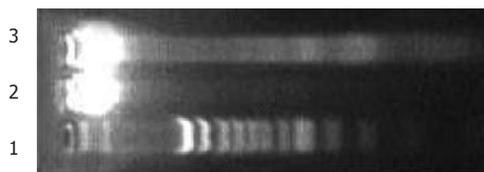

**Morphological changes of HepG2 cells after exposure to tectorigenin**

To verify tectorigenin-induced apoptosis of HepG2 cells, we observed the changes in cell morphology after tectorigenin exposure by Hoechst 33258 staining. As shown in Figure 3, regular and round-shaped nuclei were observed in the control HSC-T6 cells (Figure 3A). After

treated with 5, 10 and 20 mg/L (Figure 3B-D) tectorigenin for 48 h, the blue emission light became much brighter in apoptotic cells than in control cells. Condensed chromatin could also be found in many tectorigenin-treated cells and the structure of apoptotic bodies was formed in some cells, which is one of the classic characteristics of apoptotic cells. Moreover, after treated with 20 mg/L tectorigenin, the nuclei of HSC-T6 cells were further condensed with the number of apoptotic

**Figure 2** Effects of tectorigenin on the viability of HepG2 (A) and L02 cells (B). Cells were treated for 12, 24 and 48 h with tectorigenin at 2.5, 5, 10, 15, 20, 30 and 40 mg/L, respectively, followed by assessing the cell viability relative to that of untreated cells (control). Bars represent mean  $\pm$  SD.

**Figure 4** DNA fragmentation of HepG2 cells induced by tectorigenin. Cells were treated with tectorigenin at 20 mg/L for 48 h, then total DNA was isolated as described in Methods and analyzed by electrophoresis for detection of DNA fragmentation. 1: Marker; 2: Control; 3: Tectorigenin.

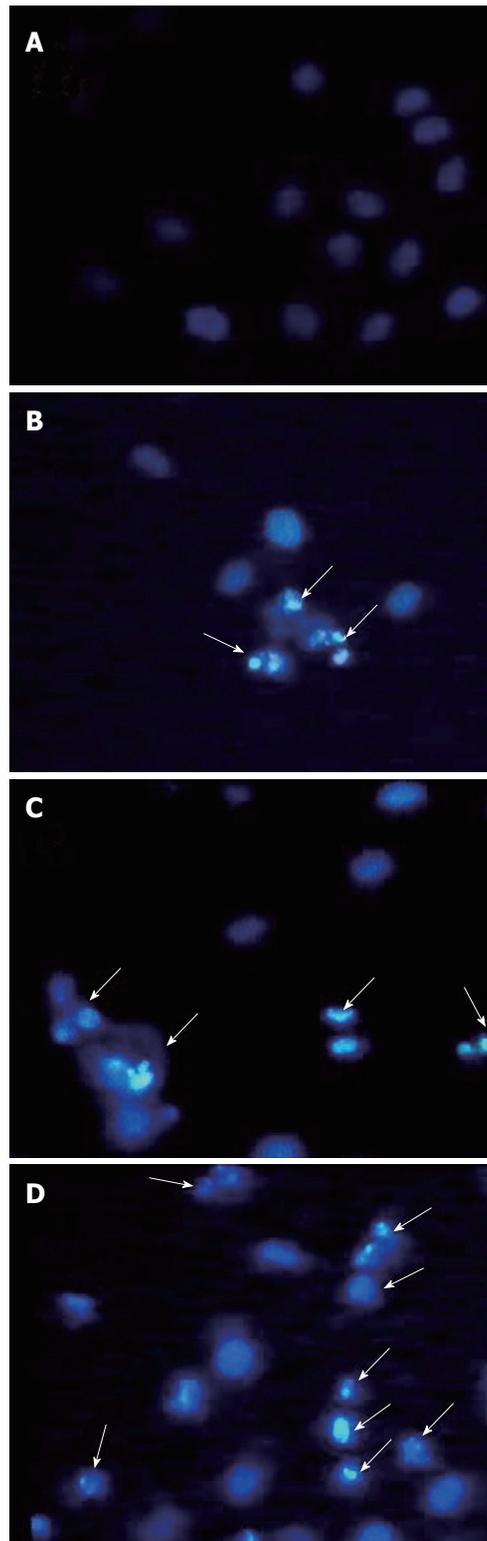

bodies sharply increased.

**DNA ladder of HepG2 cells treated with tectorigenin**

Genomic DNA was prepared from HepG2 cells that had been incubated in the presence or absence of 20 mg/L tectorigenin for 48 h. The integrity of the DNA was assessed by agarose gel electrophoresis. DNA isolated from HepG2 cells cultured with 20 mg/L tectorigenin for 48 h showed a “ladder” pattern of apoptosis (Figure 4). A comparison with molecular weight markers indicated that the fragments were multiples of approximately 180-200 base pairs.

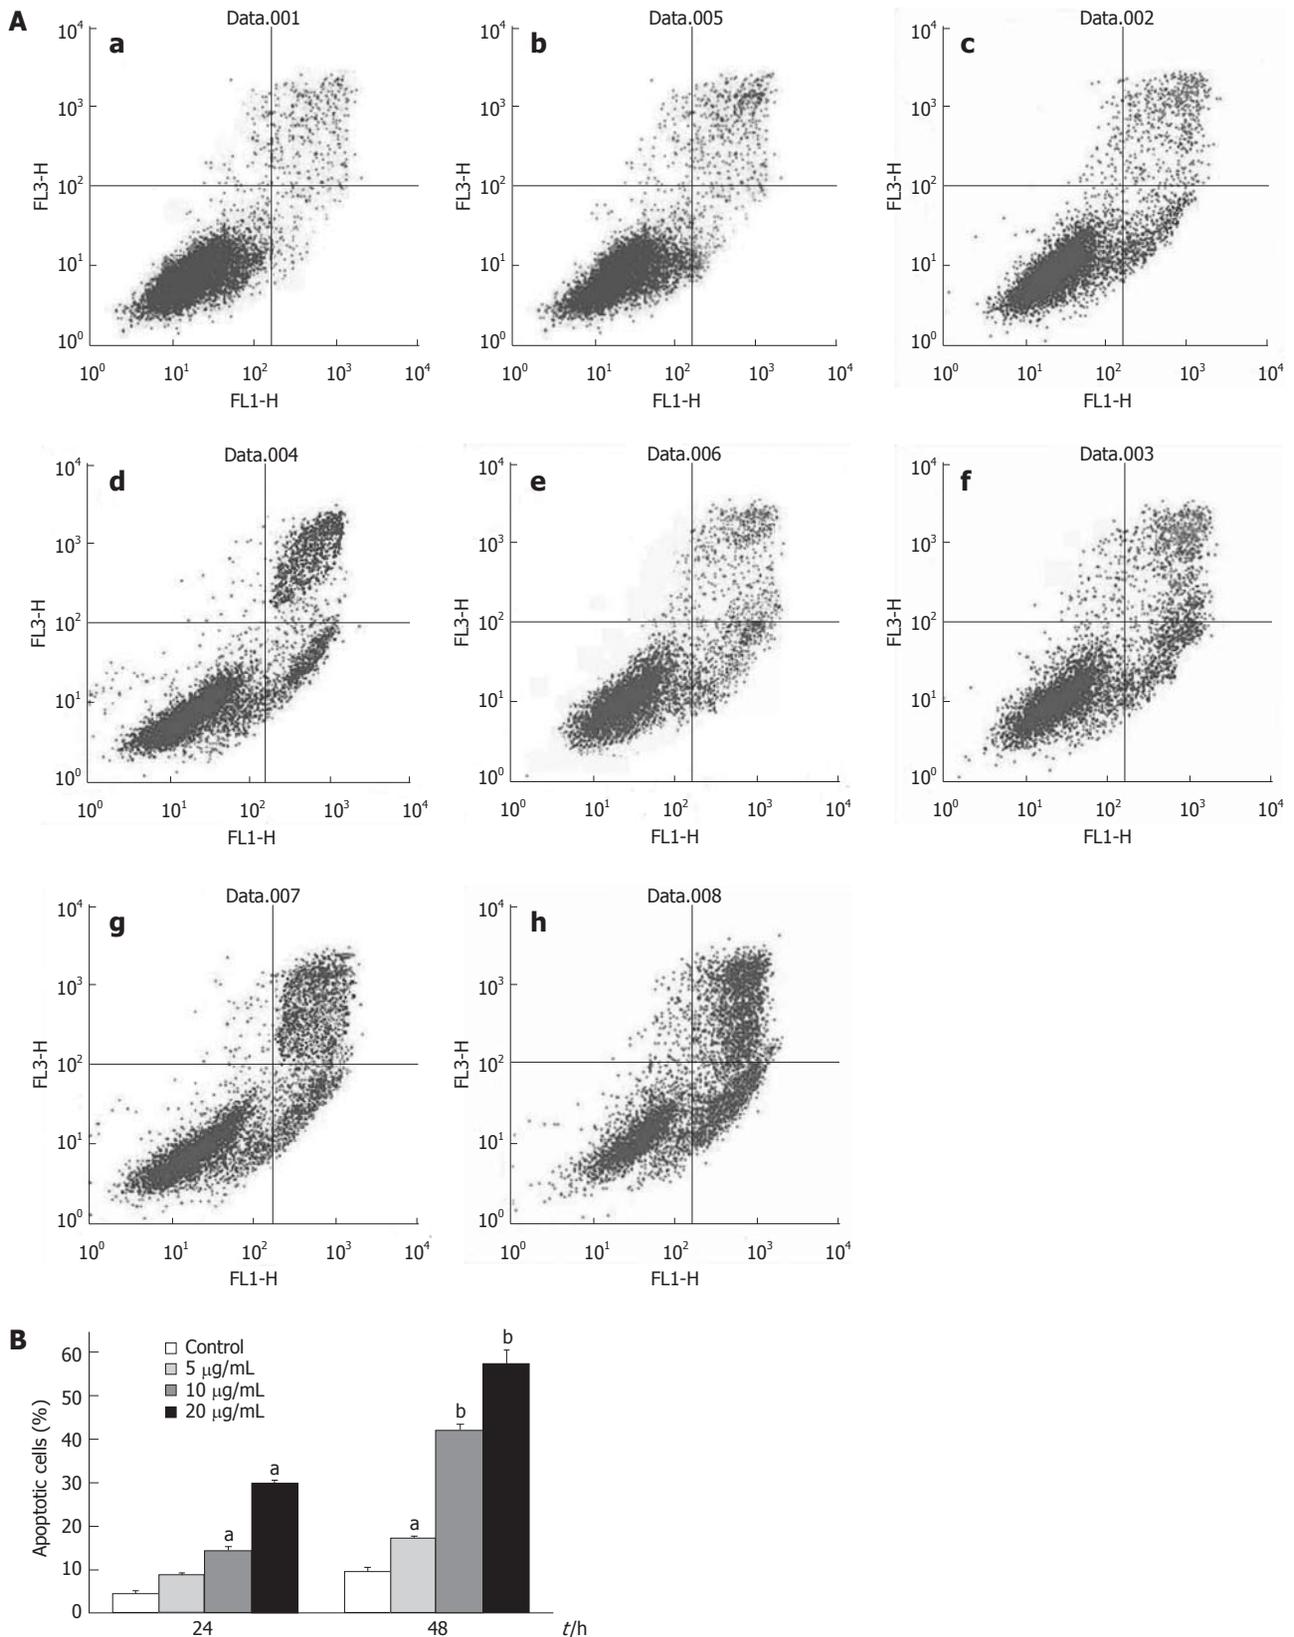

**Apoptotic rate of HepG2 cells treated with tectorigenin**

Treatment of HepG2 cells with tectorigenin resulted in significant increase of apoptotic cells in a time- and dose-dependent manner compared with that of non-treated cells quantified by Annexin V analysis (Figure 5B), as shown in Figure 5A. Apoptotic rate of HepG2 cells treated with 5, 10 and 20 mg/L tectorigenin for 24

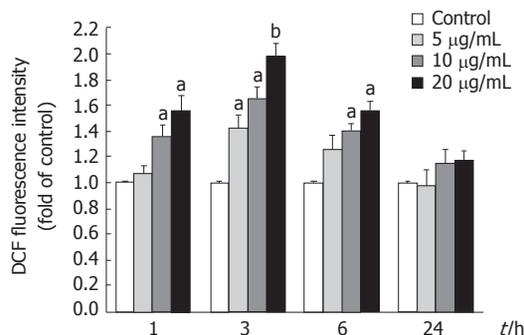

**Figure 3** Morphological changes of HepG2 cells after exposure to tectorigenin. HepG2 cells were treated with vehicle (A) and tectorigenin at 5 (B), 10 (C), 20 (D) mg/L for 48 h, the cells were then fixed and stained with Hoechst 33258 and observed under a fluorescent microscope (Leica DM IRB) (Magnification  $\times$  400). Tectorigenin significantly induced condensed chromatin and fragmented nuclei. The arrows in B-D indicate cells undergoing apoptosis.

h was 8%, 14%, and 30%, respectively. However, when HepG2 cells were treated with 5, 10 and 20 mg/L tectorigenin for 48 h, its apoptotic rate was 16%, 42% and

**Figure 5** Flow cytometric analysis of apoptosis in HepG2 cells treated with tectorigenin. HepG2 cells were incubated for 24 and 48 h with tectorigenin at 0, 5, 10, 20 mg/L, respectively. And then the cells were stained with EGFP-conjugated Annexin V and propidium iodide (PI). The EGFP and PI fluorescence was measured using flow cytometer with FL1 and FL3 filters, respectively. A: Representative dot plots of Annexin V/PI staining. a: Control, 24 h; b: 5 mg/L, 24 h; c: 10 mg/L, 24 h; d: 20 mg/L, 24 h; e: Control, 48h; f: 5 mg/L, 48 h; g: 10 mg/L, 48 h; h: 20 mg/L, 48 h. The lower left quadrant contains the vital (double negative) population. The lower right quadrant contains the early apoptotic (Annexin V+/PI-) population and upper right quadrant contains the late apoptotic/necrotic (Annexin V+/PI+) population; B: Data pooled from three independent experiments show the percentage of apoptotic cells. Difference was considered statistically significant when <sup>a</sup>P < 0.05 and <sup>b</sup>P < 0.01 vs control.

**Figure 6 Stimulation by tectorigenin of reactive oxygen species generation in HepG2 cells.** Reactive oxygen species was measured using an oxidation-sensitive fluorescent probe, DCFH-DA. Cells were treated with tectorigenin for 1, 3, 6 and 24 h, and then incubated for 30 min with DCFH-DA at 37 °C. After washing with phosphate buffered saline, the fluorescence intensity of the cells was analyzed with a fluorescence plate reader. Data are expressed as the mean of three individual experiments  $\pm$  SD. Difference was considered statistically significant when  $^aP < 0.05$  and  $^bP < 0.01$  vs control. DCF: Dichlorodihydrofluorescein.

58%, respectively. Compared with the viability rate in Figure 2, these results suggested that induction of apoptosis was the main mechanism of the anti-proliferative effect of tectorigenin in HepG2 cells.

#### Intracellular accumulation of ROS induced by tectorigenin

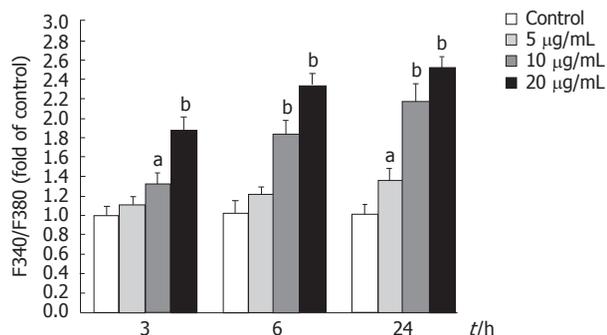

To determine whether tectorigenin could induce intracellular ROS generation, levels of ROS production in HepG2 cells were determined using the fluorescence probe DCFH-DA. As shown in Figure 6, HepG2 cells exposed to tectorigenin at 10 and 20 mg/L for 1 or 6 h displayed a significant increase in the intracellular level of ROS as compared with that in the control cells. When HepG2 cells were treated with tectorigenin at 5, 10 and 20 mg/L for 3 h, they displayed a maximal increase in the intracellular level of ROS. However, HepG2 cells incubated with tectorigenin at 5, 10 and 20 mg/L for 24 h, showed a mild but not significant increase in the intracellular level of ROS compared with that in the control cells.

#### Tectorigenin-induced increase of $[Ca^{2+}]_i$ in HepG2 cells

To determine whether tectorigenin influences the level of intracellular  $Ca^{2+}$ , the level of intracellular  $Ca^{2+}$  was measured with Fura 2-AM staining. As shown in Figure 7, treatment of HepG2 cells with tectorigenin at the concentrations of 5, 10 and 20 mg/L for 3 h increased the fluorescence ratio (F340/F380) by  $1.11 \pm 0.09$ ,  $1.32 \pm 0.11$  and  $1.86 \pm 0.13$  fold as compared with the control. When HepG2 cells were treated with tectorigenin for 6 and 24 h, they displayed a higher increase of the fluorescence ratio (F340/F380) in a dose- and time-dependent manner (Figure 7). Moreover, when the incubation time was prolonged from 3 h to 24 h with the incubation concentration of 20 mg/L, the F340/F380 value increased from  $1.86 \pm 0.13$  to  $2.52 \pm 0.17$ .

#### Tectorigenin-induced loss of MMP in HepG2 cells

To assess the effect of tectorigenin on the changes of

**Figure 7 Effects of tectorigenin on the increase of intracellular  $Ca^{2+}$  in HepG2 cells.** Cells were treated with tectorigenin at 5, 10 or 20 mg/L for different time points, and then loaded with Fura 2-acetoxymethyl ester. Intracellular  $Ca^{2+}$  was measured by fluorescence analysis. The data were presented as mean  $\pm$  SD ( $n = 6$ ). Difference was considered statistically significant when  $^aP < 0.05$  and  $^bP < 0.01$  vs control.

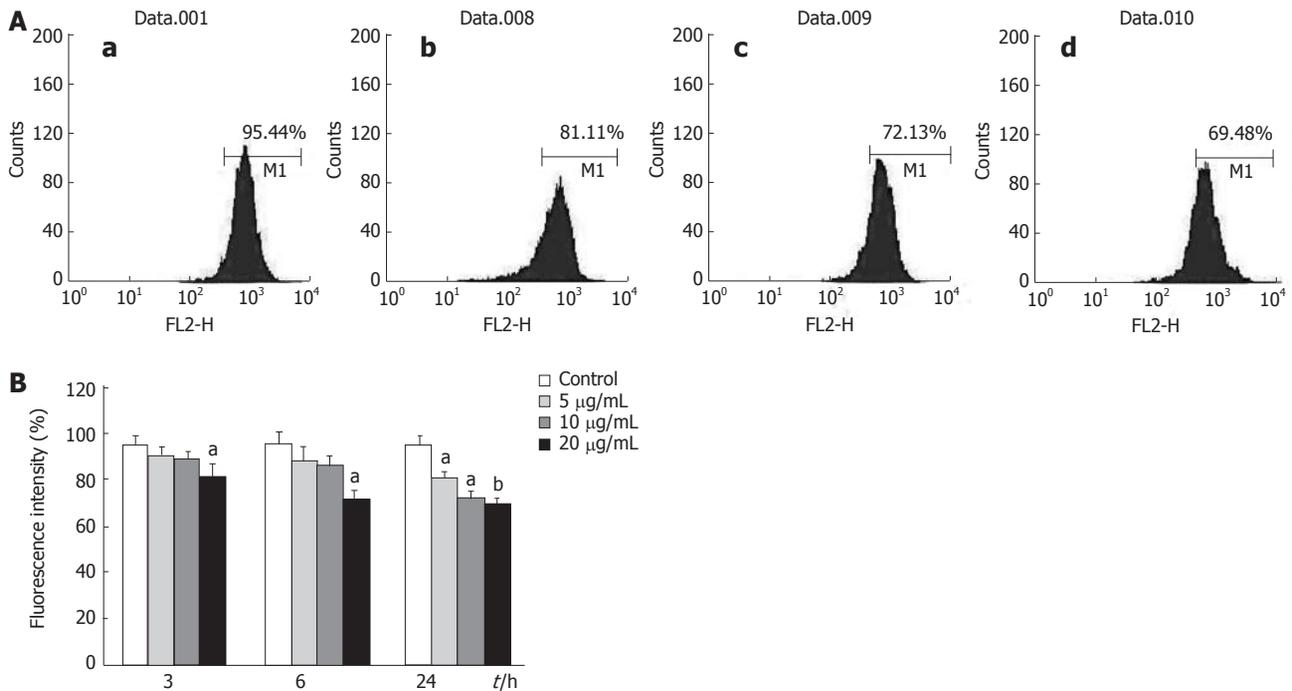

MMP in HepG2 cells, flow cytometric analysis was carried out to detect the fluorescence intensity of Rhodamine 123. As shown in Figure 8B, treatment of HepG2 cells with tectorigenin at the concentrations of 5 and 10 mg/L for 3 h and 6 h caused a moderate depolarization of MMP. However, HepG2 cells treated with tectorigenin at the concentrations of 5, 10 and 20 mg/L for 24 h (Figure 8A and B), as well as for 3 and 6h, displayed a remarkable depolarization of MMP corresponding to a much lower fluorescence intensity compared with the control, suggesting the collapse of the inner mitochondrial membrane and mitochondrial dysfunction. Compared with the control cells (without treatment of tectorigenin), HepG2 cells treated with 5, 10 and 20 mg/L tectorigenin for 24 h decreased the MMP from  $95.39\% \pm 5.47\%$  to  $81.39\% \pm 4.28\%$ ,  $72.55\% \pm 3.97\%$  and  $69.45\% \pm 3.28\%$ , respectively.

#### Effect of tectorigenin on cytochrome c release in HepG2 cells

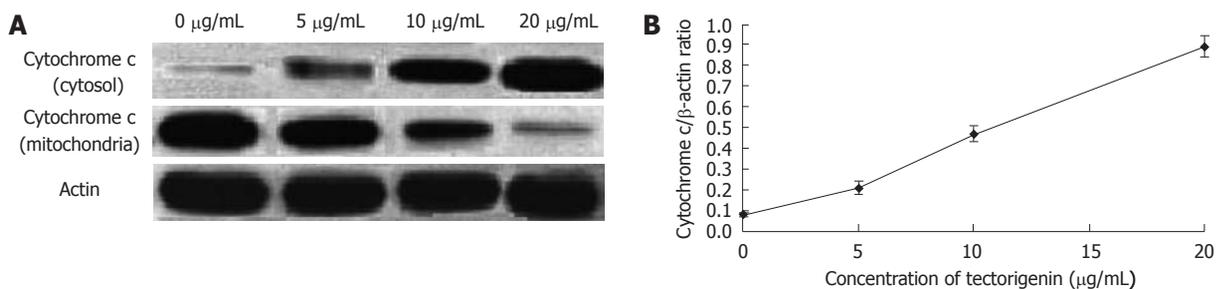

The cytosolic and mitochondrial levels of cytochrome c were measured to confirm apoptosis *via* the mitochondrial pathway in tectorigenin-treated HepG2 cells. The results indicated that mitochondrial cytochrome c was released into the cytosol in a dose-dependent manner (Figure 9A). Compared with control cells (without treatment of tectorigenin), HepG2 cells treated with tectorigenin at 5, 10 and 20 mg/L for 48 h showed an increase in levels (cytochrome c/ $\beta$ -actin ratio) of cytosolic cytochrome c from  $0.08 \pm 0.007$  to  $0.21 \pm 0.03$ ,  $0.47 \pm 0.04$  and  $0.89 \pm 0.05$ , respectively (Figure 9B).

#### Effect of tectorigenin on caspase-3, -8 and -9 activities in HepG2 cells

The apoptotic process included the activation of cysteine proteases, which represent both initiators and executors of cell death. Tectorigenin treatment caused a significant time- and dose-dependent increase in caspase-3 and -8 proteolytic activity in HepG2 cells (Figure 10A and C). However, HepG2 cells treated with tectorigenin displayed

**Figure 8** Effects of tectorigenin on integrity of mitochondrial membrane in HepG2 cells. Cells were treated with tectorigenin for different time points, then incubated with Rhodamine 123 and analyzed by flow cytometry. A: HepG2 cells were treated with 0 (a), 5 (b), 10 (c) and 20 (d) mg/L tectorigenin for 24 h. Mitochondrial membrane potential was measured by Rh123, a fluorescent probe, on FACSCalibur at FL2 channel with an excitation wavelength of 488 nm. Each test was performed 3 times and images presented were typical of 3 independent experiments; B: The data were presented as mean ± SD (n = 3). Difference was considered statistically significant when <sup>a</sup>P < 0.05 and <sup>b</sup>P < 0.01 vs control.

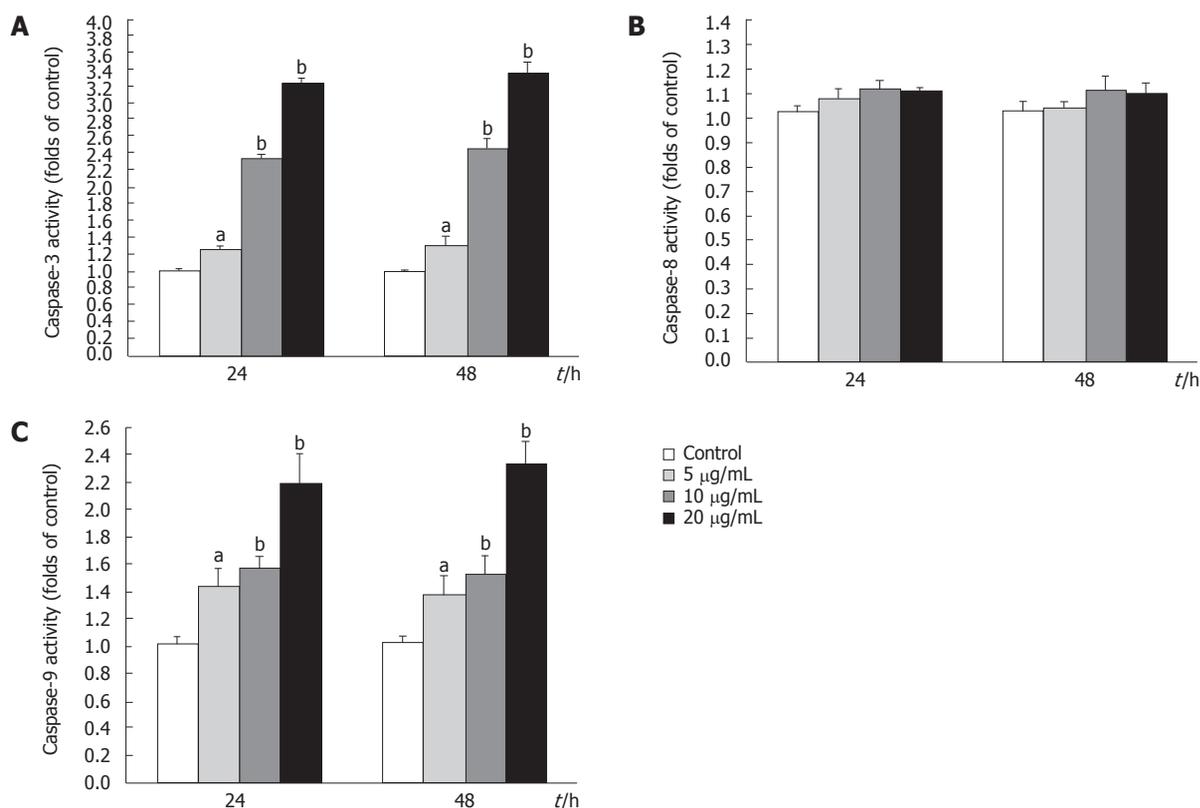

**Figure 9** Western blotting analysis. After 48-h exposure to tectorigenin at 0, 5, 10 and 20 mg/L, respectively, levels of cytochrome c in HepG2 cells (A), along with those of cytochrome c (B) in cytosol, were evaluated. Protein (50 μg) from each sample was resolved on 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis and β-actin was used as a loading control.

a very slight increase in caspase-8 activity (Figure 10B).

## DISCUSSION

*I. tectorum* is a kind of widely planted flower, which has been used in traditional Chinese medicine as a folk proven prescription for curing liver-related illnesses. By chemical analysis, we found that tectorigenin is one of the main components in the rhizome of *I. tectorum* (Figure 1) and another main component was tectoridin<sup>[11,17]</sup>. However, it has been reported that tectorigenin could be transformed from tectoridin by intestinal microflora<sup>[17]</sup>. Therefore, we hypothesized that the main active ingredient in the rhizome of *I. tectorum* might be tectorigenin. In fact, tectorigenin has been reported to have *in vivo* hepatoprotective<sup>[18]</sup>, estrogenic<sup>[19]</sup> and anti-inflammation

activities<sup>[20]</sup>, and pro-apoptotic effect on hepatic stellate cells<sup>[13]</sup>. Previous studies also have demonstrated a role for tectorigenin in regulating prostate cancer cell number by inhibiting proliferation through cell cycle regulation<sup>[21]</sup>. Tectorigenin also has pro-apoptotic effects and decreases tissue invasion by up-regulation of tissue inhibitor of metalloproteinase-3 in prostate cancer<sup>[22]</sup>. Therefore, its hepatoprotective activity and pro-apoptotic effect on hepatic stellate cells made us believe that tectorigenin is the substance base of the utilization of *I. tectorum* rhizome in the treatment of liver-related diseases. Considering that tectorigenin is one of the main components in the rhizome of *I. tectorum* (Figure 1) and *I. tectorum* has been used as a folk proven prescription for the treatment of liver cancer, we supposed that tectorigenin could be used for the treatment of HCC. The present study revealed

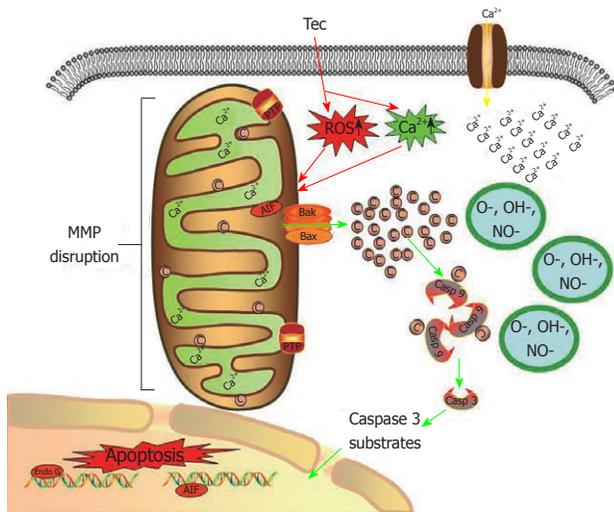

**Figure 10** Caspase activities in tectorigenin-treated HepG2 cells. Cells were treated with tectorigenin at the indicated concentrations for 24 and 48 h. Cytosolic extracts were prepared and assayed for caspase activities as described in "Materials and Methods". A: Alteration of caspase-3 activity in tectorigenin-induced HepG2 cells for indicated time; B: Effect of tectorigenin on caspase-8 activity in HepG2 cells; C: Changes of caspase-9 activity in tectorigenin-treated HepG2 cells at 5, 10 and 20 mg/L for 24 and 48 h. Data are expressed as the mean of three individual experiments  $\pm$  SD. Difference was considered statistically significant when  $^aP < 0.05$  and  $^bP < 0.01$  vs control.

that tectorigenin possessed considerable pro-apoptotic effects on human HCC HepG2 cells and reinforced our hypothesis that tectorigenin is the substance base of the utilization of *I. tectorum* rhizome in the treatment of liver cancer. Base on the results in the present study, we will further investigate the *in vivo* anticancer effects of tectorigenin. After 48 h of incubation,  $IC_{50}$  of tectorigenin against HepG2 cells was 11.06 mg/L and treatment with tectorigenin at 10 mg/L resulted in about 10% cell death of the normal L02 cells (Figure 2). The dosage of tectorigenin 10-15 mg/kg body weight is large enough to induce *in vivo* apoptosis of cancer cells.

In this study, compared with the viability rate (Figure 2), the high apoptotic cell percentage (Figure 5) suggested that induction of apoptosis was the main mechanism of the anti-proliferative effect of tectorigenin in HepG2 cells. The upstream apoptotic mechanism of tectorigenin in HepG2 cells was investigated based on the intracellular accumulation of ROS. A previous study has found that mitochondria are the major organelle where ROS was generated and excessive ROS could lead to lipid peroxidation, oxidation of proteins and DNA damage<sup>[23]</sup>. Theoretically, as a consequence of excessive ROS generation in cells, mitochondrial dysfunction should occur<sup>[24]</sup>. The intracellular ROS peaked when HepG2 cells were treated with different concentrations of tectorigenin for 3 h, then declined and when treated for 24 h it

declined to the approximately normal level (Figure 6). As expected, significant dissipation of MMP (Figure 8) was observed in the current study, indicative of mitochondrial dysfunction. Excessive ROS could raise the  $Ca^{2+}$  concentration in the cytoplasm<sup>[25,26]</sup>. Marked elevation in  $Ca^{2+}$  then causes the new ROS formation<sup>[27-29]</sup>. On the other hand, the increased  $Ca^{2+}$  may also impair mitochondrial function<sup>[29-31]</sup>, leading to a significant decrease in MMP. In this study, tectorigenin could significantly increase the  $[Ca^{2+}]_i$  in HepG2 cells.

In normal situation, cytochrome *c* resides in the mitochondrial intermembrane and serves as a transducer of electrons in the respiratory chain. However, the increment of ROS and  $[Ca^{2+}]_i$ , and subsequent mitochondrial dysfunction result in cytochrome *c* release<sup>[32]</sup>. In the present study, release of cytochrome *c* from mitochondria to cytosol was detected (Figure 9). After release from mitochondria, cytochrome *c* could bind with Apaf-1 and participate in the activation of caspase-9 (the initiator). The activated caspase-9 then activates caspase-3 (the effector). Initiator caspases and effector caspases act together to augment the death signal and finally lead to apoptosis<sup>[31-36]</sup>. In this study, we detected enhanced caspase-3 and -9 activities in tectorigenin-treated HepG2 cells (Figure 10A and C), which validated mitochondria-mediated apoptosis pathway. Similarly, in the study of Zhou *et al*<sup>[6]</sup>, troglitazone inhibited growth and induced

**Figure 11** Possible mechanisms by which tectorigenin induces apoptosis in human hepatocellular carcinoma HepG2 cells. Tectorigenin produces reactive oxygen species and increases  $Ca^{2+}$  concentration in cytoplasm of HepG2 cells, leading to the depletion of mitochondrial membrane potential and release of cytochrome c from mitochondria. Cytochrome c facilitates apoptosis of HepG2 cells by activating caspase cascade. Tec: Tectorigenin; ROS: Reactive oxygen species; C: Cytochrome c; Casp: Caspase; AIF: Apoptosis inducing factor; MMP: Mitochondrial membrane potential.

apoptosis of HepG2 cells in a dose-dependent manner, and induced activation of caspase-3 expression. Caspase-8 is an initiating caspase, which modulates the death receptor-dependent pathway. We found very mild increase in caspase-8 activity in tectorigenin-treated HepG2 cells (Figure 10B), which suggested that a death receptor-mediated pathway might be excluded in the apoptosis of HepG2 cells induced by tectorigenin. In the study of Tsagarakis *et al.*<sup>[37]</sup>,  $10^{-8}$  mol/L octreotide could significantly inhibit the proliferation of HepG2 cells and significantly increase caspase-3, caspase-8 and caspase-2 activities. In this study, tectorigenin increased the ROS production and  $Ca^{2+}$  concentration in cytoplasm of HepG2 cells, the intracellular accumulation of ROS and  $Ca^{2+}$  further induced the loss of MMP. The disruption of MMP caused release of cytochrome c from mitochondria to cytosol. Cytosolic cytochrome c activated the pro-caspase-9 and subsequently, caspase-9 activated the downstream effector caspases-3, eventually triggered apoptosis of HepG2 cells (Figure 11). In the study of Tan *et al.*<sup>[5]</sup>, 5-allyl-7-gen-difluoromethylenechrysin was found to exert its apoptotic effect by activation of Peroxisome proliferator-activated receptor gamma, down-regulation of nuclear factor kappa B and Bcl-2 protein expression, up-regulation of Bax protein expression, and reduction of the ratio of Bcl-2 to Bax.

Our previous research showed that tectorigenin suppressed the proliferation of HSC-T6 cells and induced apoptosis of HSC-T6 cells in a time- and dose-dependent manner<sup>[13]</sup>. Tectorigenin at a concentration of 100 mg/L greatly inhibited the viability of HSC-T6 cells and induced the condensation of chromatin and fragmentation of nuclei<sup>[13]</sup>. In this study, tectorigenin could inhibit the viability of HepG2 cells and induce apoptosis at a

lower concentration of 20 mg/L. Furthermore, tectorigenin-induced apoptosis of HSC-T6 cells was associated with the generation of ROS, increased intracellular  $[Ca^{2+}]$ , loss of mitochondrial membrane potential, translocation of cytochrome c, and activation of caspase-9 and -3<sup>[13]</sup>. In this study, tectorigenin could induce apoptosis of HepG2 cells by similar mechanisms. In contrast, in the study of Zhou *et al.*<sup>[6]</sup>, troglitazone not only drove apoptosis-inhibiting factor survivin to translocate incompletely from the nucleus to the cytoplasm, but also inhibited expression of survivin, while it did not affect expression of apoptosis-promoting factor Bax.

In conclusion, tectorigenin significantly inhibits the proliferation and induces apoptosis in human HCC HepG2 cells mainly *via* mitochondrial-mediated pathway. These observations indicated that tectorigenin is a promising chemotherapeutic and chemopreventive agent for the treatment of HCC.

## COMMENTS

### Background

Human hepatocellular carcinoma (HCC) is the fifth most common cancer in the world. Unfortunately, the disease is often diagnosed at a late stage. The hallmark of cancer cells is the dysregulation of cell proliferation and apoptosis. The growing of a tumor is determined by the rate of cell proliferation and the apoptosis. Therefore, the induction of apoptosis in tumor cells has become a strategy in cancer treatment and the mitochondrial-mediated pathways have been identified as one of the major mechanisms for induction of apoptosis. *Iris tectorum* (*I. tectorum*), a traditional Chinese medicine, has been widely used for treating liver-related diseases, including hepatitis, liver fibrosis, liver cirrhosis and liver cancer.

### Research frontiers

Recent studies have revealed that tectorigenin possessed anti-proliferative and pro-apoptotic effects on hepatic stellate cells (HSCs) and have potent *in vivo* anti-liver fibrosis activity. However, until now there is no report about the anti-tumor effect of tectorigenin on human HCC HepG2 cells and the associated mechanisms. In this study, tectorigenin was found to suppress the proliferation of HepG2 cells and induce apoptosis of HepG2 cells.

### Innovations and breakthroughs

This study revealed that tectorigenin possessed considerable pro-apoptotic effects on human HCC HepG2 cells, which confirmed that tectorigenin is the substance base of the utilization of *I. tectorum* rhizome in the treatment of liver cancer. To be known, this is the first study to report the apoptosis induction effects of tectorigenin on human HCC HepG2 cells.

### Applications

Tectorigenin significantly inhibits the proliferation and induces apoptosis in human HCC HepG2 cells mainly *via* mitochondrial-mediated pathway, and produces a slight cytotoxicity to L02 cells. These observations indicated that tectorigenin is a promising chemotherapeutic and chemopreventive agent for the treatment of HCC.

### Peer review

The paper investigates the effect of tectorigenin on proliferation and apoptosis in human hepatocellular carcinoma HepG2 cells. The study is of interest.

### Abstract

**AIM:** To evaluate the effects of diazoxide on ischemia/reperfusion (I/R)-injured hepatocytes and further elucidated its underlying mechanisms.

**METHODS:** Male Sprague-Dawley rats were randomized (8 for donor and recipient per group) into five groups: I/R group (4 h of liver cold ischemia followed by 6 h of reperfusion), Heme oxygenase-1 (HO-1) small interfering RNA (siRNA) group (injection of siRNA via donor portal vein 48 h prior to harvest), diazoxide (DZ) group (injection of DZ *via* donor portal vein 10 min prior to harvest), HO-1 siRNA + DZ group, and siRNA control group. Blood and liver samples were collected at 6 h after reperfusion. The mRNA expressions and protein levels of HO-1 were determined by reverse transcription polymerase chain reaction and Western blotting, and tissue morphology was examined by light and transmission electron microscopy. Serum transaminases level and cytokines concentration were also measured.

**RESULTS:** We observed that a significant reduction of HO-1 mRNA and protein levels in HO-1 siRNA and HO-1 siRNA + DZ group when compared with I/R group, while the increases were prominent in DZ group. Light and transmission electron microscopy indicated severe disruption of tissue with lobular distortion and mitochondrial cristae damage in HO-1 siRNA and HO-1 siRNA + DZ group as compared with DZ group. Serum alanine aminotransferase, aspartate transaminase, tumor necrosis factor- $\alpha$  and interleukin-6 levels increased in HO-1 siRNA and HO-1 siRNA + DZ group, and decreased in DZ group.

**CONCLUSION:** The protective effect of DZ may be induced by upregulation of HO-1. Inhibiting the expression of HO-1, this protection pretreated with DZ was abolished.

### INTRODUCTION

The ATP-sensitive potassium (KATP) channel was identified in cardiac muscle<sup>[1]</sup>. Later, a similar channel was described in liver<sup>[2]</sup>, brain<sup>[3,4]</sup> and skeletal muscle mitochondria<sup>[5]</sup>. The primary function of this channel is to allow K<sup>+</sup> transport into the mitochondrial matrix and this phe-

nomenon could be involved in maintaining mitochondrial volume homeostasis<sup>[6]</sup>. KATP channels that exist in the inner membrane of mitochondria<sup>[2]</sup> has been implicated to mediate ischemic preconditioning's protective effects in ischemic heart<sup>[7,8]</sup>. Diazoxide (DZ) is a selective mitochondria ATP-sensitive potassium (mitoKATP) channel opener, which has been reported to have protective effect on the heart<sup>[9,10]</sup>, brain<sup>[11,12]</sup> and spinal cord<sup>[13]</sup> following ischemia/reperfusion (I/R) injury. Several recent studies have suggested that mitoKATP channels may be only a trigger, but not a mediator of protection<sup>[14]</sup>. The exact mechanisms have not been fully clarified.

Ischemic preconditioning (IPC) is a well-known phenomenon in which brief episodes of ischemia and reperfusion confers a state of protection against subsequent sustained long-term I/R injury<sup>[15,16]</sup>. Although the exact underlying mechanisms of IPC are unknown, activation of mitoKATP channels has been proposed to play a pivotal role in preconditioning<sup>[17]</sup>. More studies have indicated that pretreatment with mitoKATP channel openers induces IPC-like protective effects<sup>[18]</sup>, and that IPC-induced protection is antagonized by mitoKATP channel inhibitors<sup>[19,20]</sup>. These findings support the hypothesis that IPC is mediated through the opening of mitoKATP channels.

Heme oxygenase-1 (HO-1) is the rate-limiting step in the oxidative degradation of heme. Overexpression of HO-1 exerts a cytoprotective function in a number of I/R injury and liver transplant model<sup>[21-23]</sup>. Recent studies suggested that IPC may protect against systemic inflammatory response *via* enhanced HO-1 overexpression<sup>[24-27]</sup>. The purpose of our study was to investigate that the protective action of DZ on I/R injury and expression of HO-1 after liver transplantation in rats. We explored the potential molecular mechanisms for DZ to reduce I/R injury. Using HO-1 small interfering RNA (HO-1 siRNA), we further observed the roles of HO-1 in DZ-induced action.

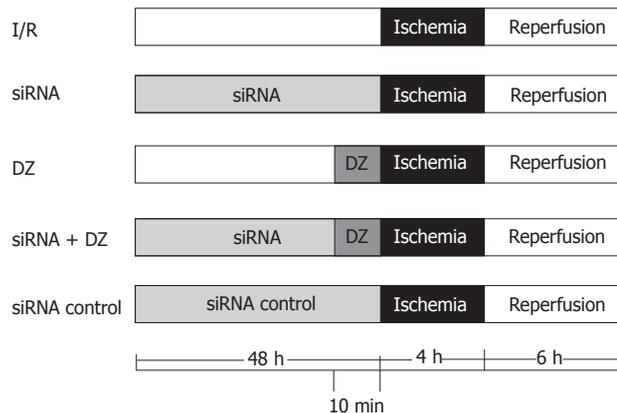

## MATERIALS AND METHODS

### Animals

Adult male Sprague-Dawley (S-D) rats (200-250 g) (Kunming Medical College Laboratory Animal Center, China) were used. Rats were maintained on a standard rodent chow and water *ad libitum* in a room according to the local animal welfare guidelines. All experiments were approved by the ethics committee for the use of experimental animals at Kunming Medical College.

### Heme oxygenase-1 siRNA design

The design of HO-1 siRNA was based on the characterization by Zhang *et al.*<sup>[28]</sup>. Additionally, a scrambled sequence was designed as a Negative Control siRNA. The targeted sequence of rat HO-1 siRNA was 5'-AAGC-CACACAGCACUAUGUdTdT-3' (sense) and 5'-ACAU-AGUGCUGUGGCCUdTdT-3' (antisense). siRNA duplexes were chemically synthesized by Guangzhou Rui Bo Biological Technology Co (Guangzhou, China).

**Figure 1** Experimental protocol. DZ: Diazoxide; siRNA: Small interfering RNA.

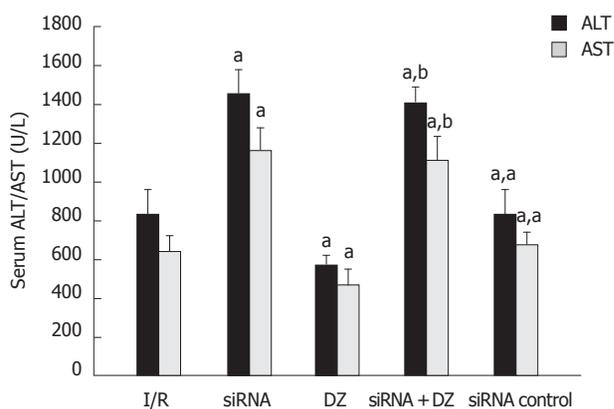

### Experimental protocol

S-D rats underwent ether anesthesia. The basic techniques of liver harvesting and orthotopic transplantation without hepatic arterial reconstruction were according to the method described previously by Kamada *et al.*<sup>[29]</sup>. After organ harvest, liver grafts were stored for 4 h in cold University of Wisconsin solution at 4 °C. Subsequently, syngeneic orthotopic liver transplantation (OLT) was performed and the anhepatic phase was estimated to be 11-13 min for all recipients. All transplant experiments in this study were performed by a single person. Separate groups of rats were killed at 6 h after their vessels were unclamped, then samples of blood and liver tissue were taken for further analysis.

Eighty rats (16 for every group) were divided randomly into five groups (Figure 1): (1) I/R group: OLT was performed according to method described previously; (2) siRNA group: Same treatment as I/R group, but donors were injected with HO-1 siRNA (200 nmol/kg of body weight) *via* portal vein 48 h before liver harvest; (3) DZ group: Same as I/R group, but donors were injected with DZ (5 mg/kg of body weight), a mitoKATP channel opener, *via* portal vein 10 min before liver harvest; (4) siRNA + DZ group: Same treatment as I/R group, donors were treated with HO-1 siRNA and DZ; and (5) siRNA control group: Same as I/R group, donors were injected with Negative Control siRNA (200 nmol/kg of body weight). DZ was purchased from Sigma Chemical Co. (St Louis, MO, United States) and dissolved in dimethyl sulfoxide (DMSO) (sigma, United States) before addition to experimental solutions. The final concentration of DMSO in the solution was less than 0.05%.

### Serum enzymes

At 6h following by liver reperfusion, blood was collected *via* abdominal aorta. After centrifugation of whole blood (3000 rpm, 15 min), serum was extracted and stored at -70 °C until analysis. Alanine aminotransferase (ALT) and aspartate transaminase (AST) levels were measured using a clinical chemistry system (7060 automatic analyzer, Hitachi, Japan).

**Figure 2** Serum alanine aminotransferase and aspartate transaminase levels after reperfusion. <sup>a</sup> $P < 0.05$  vs ischemia/reperfusion (I/R) group, <sup>b</sup> $P < 0.01$  vs diazoxide (DZ) group. ALT: Alanine aminotransferase; AST: Aspartate transaminase.

### Reverse-transcriptase polymerase chain reaction

Animals were sacrificed 6 h after transplantation. Liver samples were obtained, shock-frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  for further RNA isolation. Total RNA was extracted from 100 mg liver tissues with Trizol reagents (Invitrogen, United States) according to the manufacturer's guidelines and quantified by UV absorption. Following DNase I (Invitrogen, United States) digestion, 1  $\mu\text{g}$  of total RNA was subjected to reverse transcription polymerase chain reaction (RT-PCR) with M-MLV reverse transcriptase (Promega, United States), using oligo-dT as primers. The mixture was inactivated at  $42^{\circ}\text{C}$  for 60 min, and then the reverse transcriptase was inactivated by heating at  $70^{\circ}\text{C}$  for 10 min. Specific primers for rat HO-1 and  $\beta$ -actin (an internal standard) were designed by Primer Premier 5.0. For HO-1, the primers were 5'-TGGAAGAGGAGATAGAGCGA-3' (sense) and 5'-TGTTGAGCAGGAAGGCCGGTC-3' (antisense), generating a 451-base pair fragment. For  $\beta$ -actin, the primers used were 5'-CACGATGGAGGGGCCGGAC TCATC3' (sense) and 5'-TAAAGACCTCTATGC-CAACACAGT-3' (antisense), generating a 240-base pair fragment. PCR reaction constituents were as follows: 2  $\mu\text{L}$  of cDNA mixture was subjected to amplification in 20  $\mu\text{L}$  of final volume.  $94^{\circ}\text{C}$ , 2 min; then  $94^{\circ}\text{C}$ , 1 min;  $60^{\circ}\text{C}$ , 1 min;  $72^{\circ}\text{C}$ , 2 min, for 40 cycles; and  $72^{\circ}\text{C}$  5 min to end the reaction. The PCR products were subjected to electrophoresis on 2% agarose gel containing ethidium bromide and visualized by UV illumination. This semi-quantitative measure for HO-1 was expressed as ratios to  $\beta$ -actin.

### Western blotting analysis

Proteins extracts were isolated from liver tissue with radioimmunoprecipitation containing phenylmethyl sulfonylfluoride. Protein concentration was determined by a bicinchoninic acid protein assay reagent (Pierce Rockford, IL). Proteins (20  $\mu\text{g}$ /sample) in SDS-loading buffer were heated to  $100^{\circ}\text{C}$  for 5 min, and separated by 12% SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose membranes using an electroblotting ap-

paratus. The membrane was blocked overnight at  $4^{\circ}\text{C}$  in 5% nonfat dry milk and TBST buffer to block non-specific binding sites. Western blots were probed with primary antibodies (anti-HO-1, 1:200 dilution, Millipore, United States) at room temperature (RT) for 2 h. After being washed, blots were incubated with horseradish peroxidase-labeled goat anti-rabbit IgG antibodies (dilution, 1:50 000, Pierce Biotechnology) for 2 h at RT. Thereafter the proteins were visualized by ECL detection system (Amersham Pharmacia Biotech, Piscataway, New Jersey, United States) and analyzed by the Quantity One Analysis Software (Bio-Rad, United States).  $\beta$ -actin was used as protein loading control.

### Histology and electron microscopic examination

Livers were excised rapidly and fixed in conventional fixing solutions (10% neutral-buffered formalin) after 6 h reperfusion. Livers were paraffin embedded and sectioned into 3  $\mu\text{m}$ -thick slices with a tissue chopper. The sections were examined by hematoxylin and eosin staining. The histological severity of I/R injury was graded according to Suzuki's classification<sup>[30]</sup>. All slides were judged by the same investigator who had been blinded to the corresponding study group. The excised liver samples were cut into small pieces, and immersed in excessive volumes of 2.5% glutaraldehyde with 0.1 mol phosphate buffer (pH 7.2). Following fixation for 24 h, samples were further immersed in 2% osmium tetroxide ( $\text{OsO}_4$ ) in 0.1 mol cacodylate buffer (pH 7.2) for 2 h at  $4^{\circ}\text{C}$ , dehydrated, and embedded in epoxide resin (EPON812). Ultrathin sections were stained with lead citrate and uranylacetate, and examined using a JEM-1200EX transmission electron microscope.

### Enzyme-linked immunosorbent assay

Serum interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) levels of different groups were measured using commercially available ELISA kits (R and D System, United States) according to the test protocols. All samples, including standard and control solution, were assayed in duplicate. Values were expressed as pg/mL.

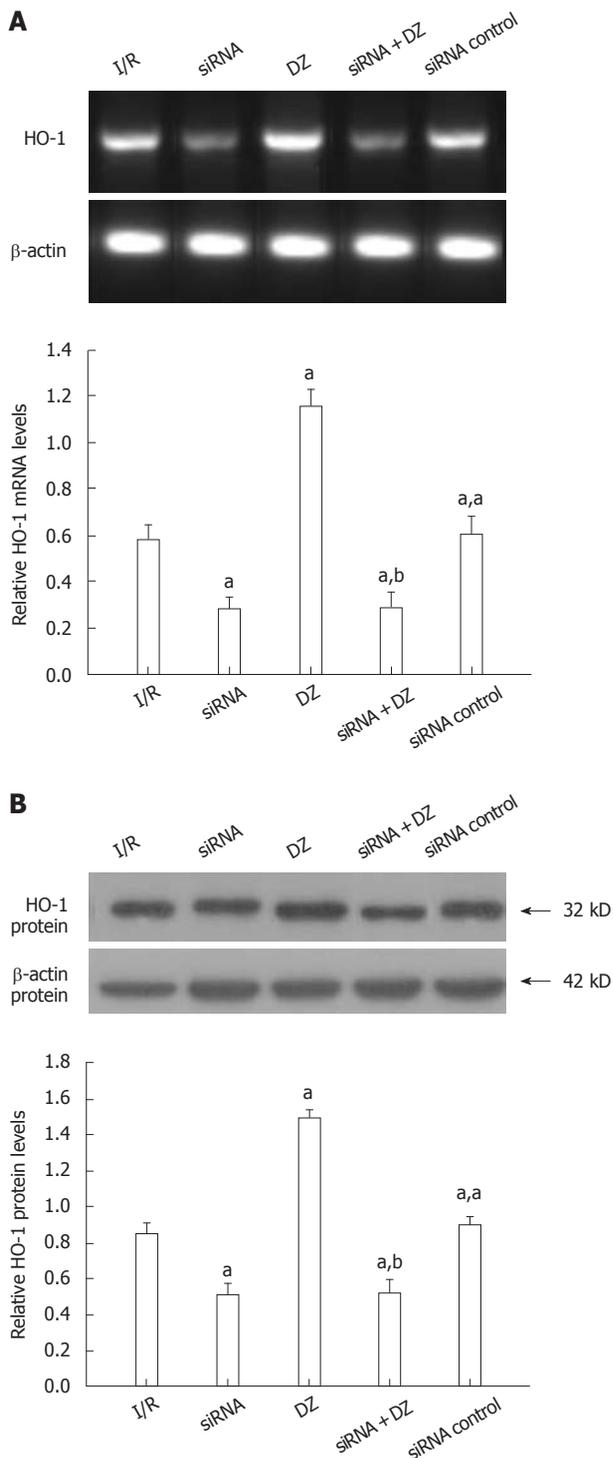

### Statistical analysis

Statistical analysis was performed using SPSS Version 13.0 for Windows (SPSS, Inc, Chicago, IL). Values are expressed as means  $\pm$  SD. Difference between experimental groups were analyzed by one-way analysis of variance.  $P$  values  $< 0.05$  were considered statistically significant.

## RESULTS

### Hepatic transaminases

The hepatocellular damage was measured with the determination of ALT and AST levels. Rats treatment with siRNA showed a significant increase in ALT and AST compared with I/R rats. Liver function measurement in the DZ group was significantly lower than those in the I/R group. There was no statistical difference between siRNA and siRNA + DZ group ( $P > 0.05$ ) (Figure 2).

**Figure 3** Liver heme oxygenase-1 mRNA and protein levels at 6 h after transplantation. <sup>a</sup>*P* < 0.05 vs ischemia/reperfusion (I/R) group, <sup>b</sup>*P* < 0.01 vs diazoxide (DZ) group.

### Heme oxygenase-1 mRNA and protein expression levels

The PCR products were separated on agarose gel and the relative expression of HO-1 were shown. As shown in Figure 3A, HO-1 mRNA expression was decreased in both siRNA and siRNA + DZ groups compared with the I/R group at 6 h after I/R injury. In contrast, DZ treatment significantly enhanced the hepatic HO-1 mRNA level. No statistical difference was observed between si-

RNA and siRNA + DZ group. HO-1 protein level was determined by western blotting. The results were almost the same as those obtained in the RT-PCR analyses. Compared with the I/R group, HO-1 protein expression was markedly downregulated in both siRNA and siRNA + DZ groups. The level of HO-1 was significantly higher in the DZ group than all other groups. Moreover, the difference between siRNA and siRNA + DZ group did not attain statistical significance (Figure 3B).

### Histology

Necrosis and liver damage were assessed with H and E-stained liver tissue 6 h after reperfusion. Liver specimens from rats subjected to I/R showed macrovesicular fatty changes, nuclear fragmentation, and sinusoidal congestion and congested with many red blood cells. In siRNA and siRNA + DZ groups, histological tissue damage was significantly aggravated. Moreover, multiple and extensive ballooning/hepatocellular necrosis and massive infiltration of neutrophils were observed. However, these pathological changes were significantly decreased in the DZ group (data not shown). There was no significant difference between I/R and siRNA control group (Figure 4A).

### Transmission electron microscopy

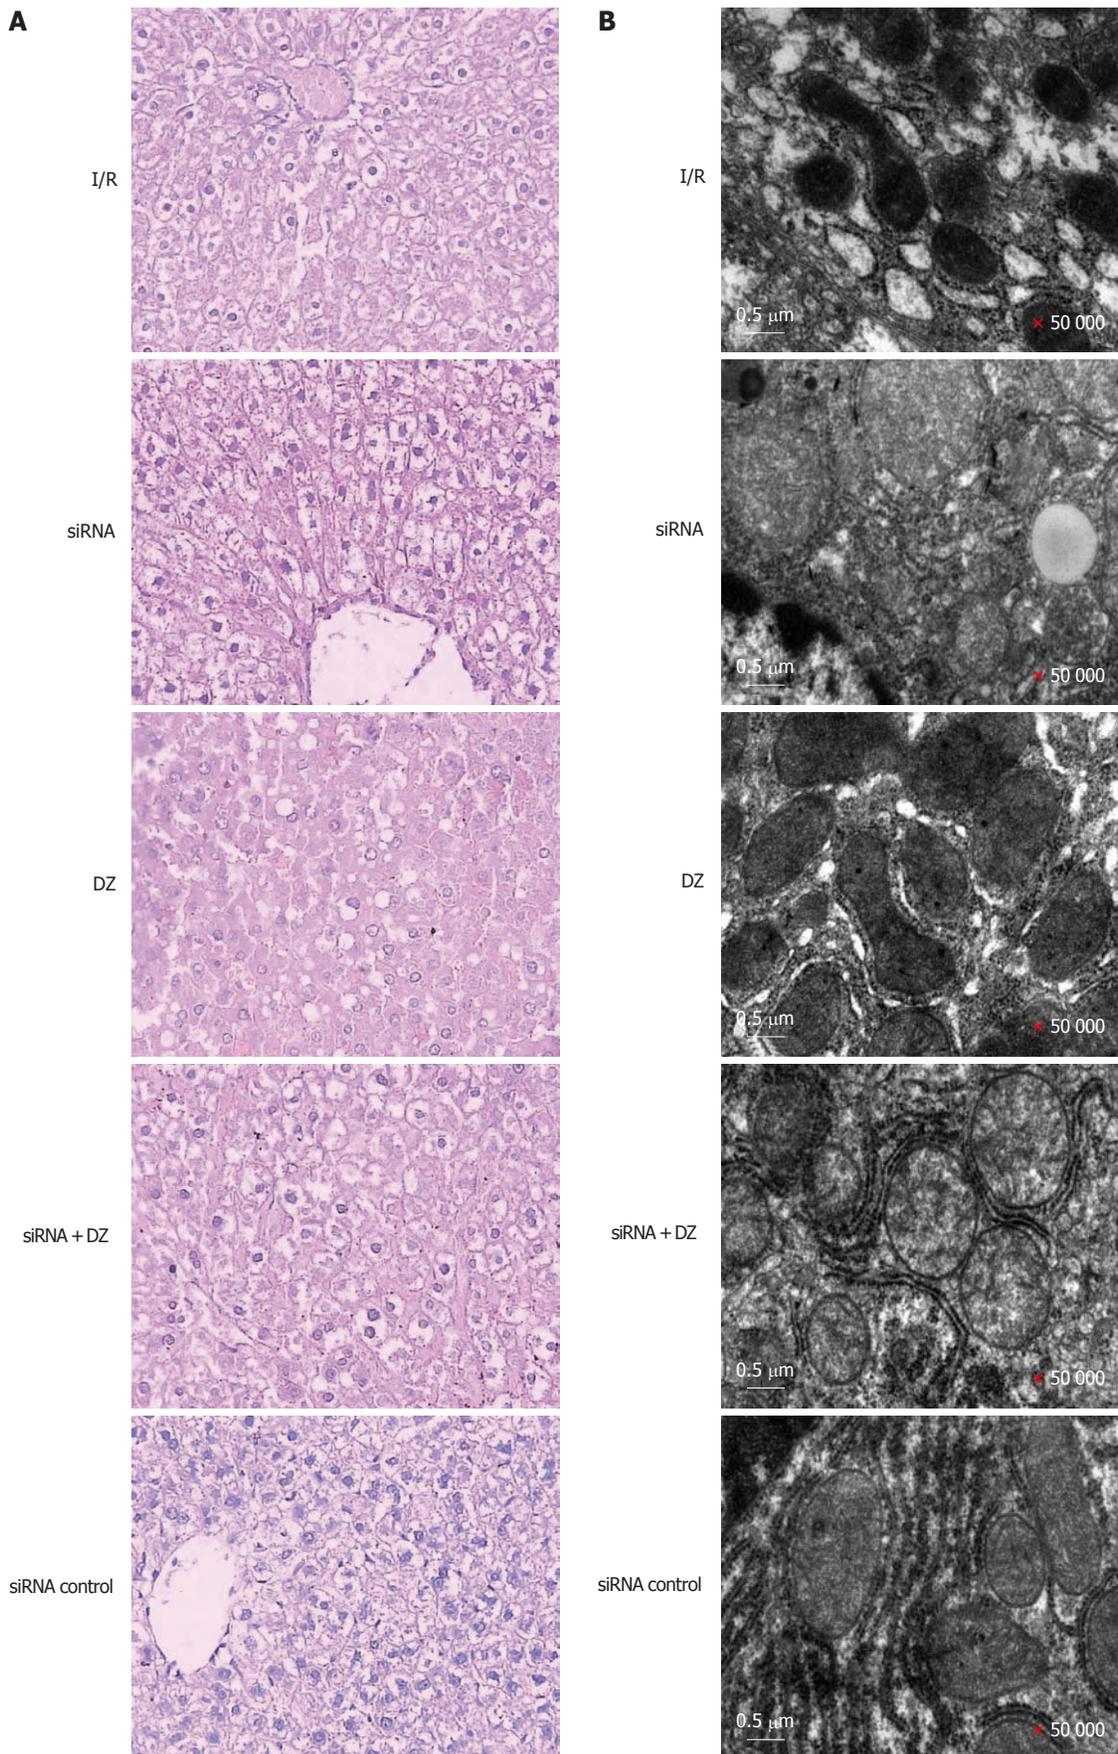

To further confirm hepatocytes ultrastructure alterations, we examined the liver grafts during cold ischemia and reperfusion by electron microscopy. In siRNA group, the nuclei of the hepatocytes were severe irregular in shape and contained damaged nuclear chromatin in the nucleoplasm. The hepatocytes appeared largely intact vacuolar structures with lipid droplets were present in the cytoplasm of the cells. The mitochondria and the smooth endoplasmic reticulum were dilated and even destroyed, and the mitochondria cristae were disorganized. By contrast, mitochondria from rats treated with DZ appeared markedly better with less mitochondrial membrane damage and swelling in the rat hepatocytes after ischemia and reperfusion. However, siRNA + DZ group treatment had markedly aggravated these damages as compared with DZ group. The I/R group and siRNA control group revealed lower hepatocytes damages than the siRNA group (Figure 4B).

### Cytokines assay

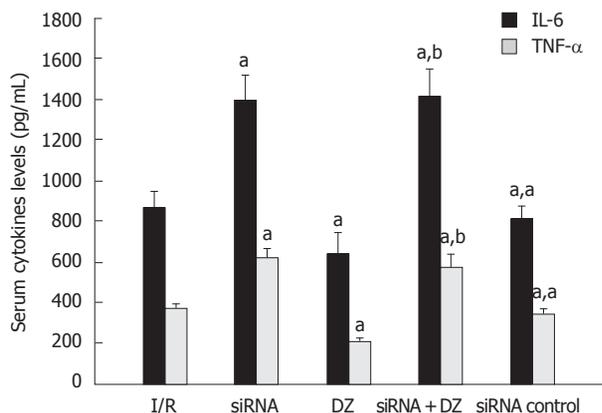

Serum cytokine levels (IL-6/TNF- $\alpha$ ) were determined by ELSA. The IL-6/TNF- $\alpha$  levels revealed a substantial increase in the siRNA group as compared with the I/R group. But groups pretreated with DZ had markedly decreased these products. Moreover, the cytokine levels (IL-6/TNF- $\alpha$ ) in the siRNA + DZ group were significantly higher, when compared to the DZ group. There was no statistical difference between I/R group and siRNA control group (*P* > 0.05) (Figure 5).

## DISCUSSION

HO-1 is up-regulated in response to oxidative stress and

**Figure 4** Liver histology and ultrastructural changes of hepatocytes. A: Ischemia/reperfusion (I/R) treated livers showed vacuolization, nuclear fragmentation, sinusoidal congestion, and hepatocyte necrosis. However, histological tissue damage was aggravated in the small interfering RNA (siRNA) and siRNA + diazoxide (DZ) group. In contrast, DZ treatment relieved liver damages (hematoxylin and eosin, × 400); B: The mitochondria and the smooth endoplasmic reticulum were dilated and even destroyed, and the mitochondria cristae were disorganized in I/R treated hepatocytes.

**Figure 5** Serum cytokine levels (interleukin-6/ tumor necrosis factor- $\alpha$ ) were measured. <sup>a</sup> $P < 0.05$  vs ischemia/reperfusion (I/R) group, <sup>b</sup> $P < 0.01$  vs diazoxide (DZ) group. IL-6: Interleukin-6; TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ .

catalyzes the degradation of pro-oxidant heme to carbon monoxide (CO), iron and bilirubin<sup>[31]</sup>. Three HO isoforms have been identified to date: HO-1, HO-2 and HO-3. HO-1 is inducible and distributed ubiquitously in mammalian tissue<sup>[32]</sup>, while HO-2 is expressed constitutively and found mainly in the central nervous system<sup>[33]</sup>. HO-3 is only described in the rat brain and has no activity. HO-1 expression is an adaptive and protective response to oxidative stress in a wide variety of cells<sup>[34,35]</sup>. HO-1 is induced by a variety of stimuli, including non-heme inducers and various agents that cause oxidative stress, and prevents the oxidative DNA damage caused by heat shock and reactive oxygen species (ROS).

Mitochondrial ATP-sensitive potassium channel opener is responsible for more effective oxidative phosphorylation<sup>[36]</sup> and regulation of ROS generation<sup>[37,38]</sup> in ischemic preconditioning. Prevention of mitochondrial failure improves cellular survival after an ischemic event. Pharmacological agents that maintain mitoKATP channels can prevent mitochondrial failure in a manner similar to that induced by ischemic preconditioning<sup>[13,39]</sup>. MitoKATP is shown to have protective effect on the heart, kidney and brain following I/R injury<sup>[40,41]</sup>. However, the detailed effect of mitoKATP in liver I/R injury has not fully studied. Diazoxide is mainly used as a vasodilator in the treatment of clinical hypertension. But in our study, we used DZ, the putative mitoKATP channel opener to evaluate the effects of mitoKATP channels in liver I/R injury in OLT.

In the present investigation, rats pretreated with DZ results in enhanced resistance to liver cold I/R injury and increased HO-1 expression levels. To examine whether HO-1 was responsible for the protective effect of DZ in liver I/R injury, we used HO-1 siRNA, which interferes with the enzymatic expression of HO-1 to examine its possible effect. Inhibition of the expression of HO-1 almost completely blocked the protection afforded by DZ. These results strongly indicated that the protection of DZ was mediated through upregulation of HO-1. We speculate that DZ induces an increase in HO-1 levels that protect liver I/R injury. The K<sup>+</sup> channel-independent ef-

fects of diazoxide to inhibit succinate oxidation<sup>[42]</sup> and succinate dehydrogenase<sup>[43]</sup> or inhibit opening of the mitochondrial membrane pore<sup>[44]</sup> may be responsible for its protective effects. When we inhibited the expression of HO-1 and the above effects of DZ remains, but the protection of DZ to hepatic I/R injury in rats almost disappeared. It is possible that DZ, through opening KATP channels, activated an unknown pathway, which directly or indirectly upregulated the expression of HO-1. Since HO-1 plays a critical role in protect liver I/R injury in rats OLT, inhibition of HO-1 activity may exaggerate I/R injury.

We measured serum cytokine levels (IL-6/TNF- $\alpha$ ) by ELISA to determine the effect on anti-inflammatory. Rats pretreated with DZ significantly decreased serum IL-6/TNF- $\alpha$  levels. However, they were markedly elevated in siRNA + DZ group than those in DZ group. Xu B *et al*<sup>[45]</sup> showed that DZ inhibit the production of the proinflammatory cytokines TNF- $\alpha$  and IL-6 by peripheral blood mononuclear cells (PBMCs) in normal pregnancy. But our study shows that DZ was able to reduce the release of cytokines. But when the expression of HO-1 was inhibited, the release of cytokines could not reduce. HO-1 has been shown to be expressed principally in Kupffer cells<sup>[21,46,47]</sup>. Our study suggests that the potential utility of HO-1 overexpression in preventing I/R injury results from inhibition of Kupffer cells activation<sup>[48]</sup>. Activated Kupffer cells release a large amount of proinflammatory cytokines<sup>[49-51]</sup> which lead to aggravation of I/R injury. Devey *et al*<sup>[52,53]</sup> reported that depletion of Kupffer cells using liposomal clodronate led to loss of hepatic HO-1 expression and much more severe injury. It has been demonstrated that overexpression of HO-1 played an important role in a number of I/R injury and liver transplant models. Therefore, we could think that the protective effect of DZ was by increasing HO-1 expression in our study.

In summary, DZ can attenuate hepatic I/R injury in rat liver transplantation and induce hepatic HO-1 expression. In addition, inhibiting HO-1 expression with a specific siRNA, this protection pretreated with DZ was abolished. Thus, the mechanism of the protective effects of DZ is dependent on HO-1. The upregulation of HO-1 results in an alleviation of hepatic I/R injury, as well as a decrease of the production of inflammatory cytokine such as IL-6 and TNF- $\alpha$ . Our results provide an insight into induction of HO-1, and suggest that DZ may have the potential to be developed as a hepatic HO-1 inducer for therapeutic purposes. Our work also raises an interest that HO-1 can be induced by DZ to stimulate protective process attenuating I/R injury.

## COMMENTS

### Background

Diazoxide (DZ) is a selective mitochondria ATP-sensitive potassium channel opener, which has been reported to have protective effect on the heart, brain and spinal cord following ischemia/reperfusion (I/R) injury. But the protective action of DZ on liver I/R injury are unknown and the exact underlying mechanisms are poorly understood.

### Research frontiers

Heme oxygenase-1 (HO-1) is the rate-limiting step in the oxidative degradation of heme. Overexpression of HO-1 exerts a cytoprotective function in a number of I/R injury and liver transplant model. HO-1 expression is an adaptive and protective response to oxidative stress in a wide variety of cells.

### Innovations and breakthroughs

The data represent a major advance in our understanding of ATP-sensitive potassium channel. DZ, can attenuate hepatic I/R injury in rat liver transplantation and induce hepatic HO-1 overexpression. In addition, the authors clearly demonstrated a direct correlation between expression of HO-1 and DZ. Thus, DZ may have the potential to be developed as a hepatic HO-1 inducer for therapeutic purposes.

### Applications

The study results suggest that the mechanism of the protective effects of DZ is dependent on HO-1. Further studies are needed to evaluate the safety and efficacy of DZ used in clinical.

### Peer review

This was a well designed study with excellent results. It was well written. It seemed almost too perfect. However, as long as they have a history of academic integrity.

### Abstract

**AIM:** To test the efficacy and safety of Profermin<sup>®</sup> in inducing remission in patients with active ulcerative colitis (UC).

**METHODS:** The study included 39 patients with mild to moderate UC defined as a Simple Clinical Colitis Activity Index (SCCAI) > 4 and < 12 (median: 7.5), who were treated open-label with Profermin<sup>®</sup> twice daily for 24 wk. Daily SCCAI was reported observer blinded *via* the Internet.

**RESULTS:** In an intention to treat (ITT) analysis, the mean reduction in SCCAI score was 56.5%. Of the 39 patients, 24 (62%) reached the primary endpoint, which was proportion of patients with  $\geq 50\%$  reduction in SCCAI. Our secondary endpoint, the proportion of patients in remission defined as SCCAI  $\leq 2.5$ , was in ITT analysis reached in 18 of the 39 patients (46%). In a repeated-measure regression analysis, the estimated mean reduction in score was 5.0 points (95% CI: 4.1-5.9,  $P < 0.001$ ) and the estimated mean time taken to obtain half the reduction in score was 28 d (95% CI: 26-30). There were no serious adverse events (AEs) or withdrawals due to AEs. Profermin<sup>®</sup> was generally well tolerated.

**CONCLUSION:** Profermin<sup>®</sup> is safe and may be effective in inducing remission of active UC.

### INTRODUCTION

Ulcerative colitis (UC) is a chronic relapsing bowel dis-

ease characterized by colonic mucosal inflammation. The goal of treatment in UC is to induce and maintain remission of the disease. Failure to induce remission occurs in 20%-30% of patients on current treatments, leaving colectomy as the only alternative in a proportion of patients<sup>[1,2]</sup>. Furthermore, many patients find the side effects of treatment with corticosteroids and other drug therapies unacceptable. Accordingly, new treatment alternatives are being sought. The pathogenesis of UC has still not been determined in detail; however, a major hypothesis is suggested to be an aggressive immune response to the intestinal content including, a subset of nonpathogenic enteric bacteria in genetically predisposed individuals. Clinical and experimental studies point towards alterations in the relative balance of aggressive and protective bacterial species in these disorders<sup>[3,4]</sup>. Interventions to alter the intestinal microflora in order to decrease proinflammatory stimuli and increase anti-inflammatory signaling are under investigation<sup>[5,6]</sup>. Some studies have suggested an effect of probiotics in the treatment of UC<sup>[5,7-9]</sup>. The effects of probiotics on the microflora may only be limited and transient because colonization and survival of the probiotics are difficult to achieve. However, remission from inflammatory bowel diseases may be induced by food for special medical purposes (FSMPs), e.g., elemental diets. In this study we investigated a new dietary product Profermin®, which is intended to be registered as a FSMP for the dietetic management of UC. It consists of fermented oats, *Lactobacillus plantarum* (*L. plantarum*) 299v, barley malt, lecithin and water. Our aim was to investigate the safety and possible efficacy of Profermin® in patients with mild to moderate UC. We also assessed the usefulness of a new online daily symptom registration system.

## MATERIALS AND METHODS

### Patients

The study was conducted between 2008 and 2009. Patients were eligible if they were between 18 and 50 years of age and had an established diagnosis of UC based on clinical, endoscopic and histological features. Active disease was assessed by Simple Clinical Colitis Activity Index (SCCAI) (Table 1) score  $> 4$  and  $< 12$ <sup>[10]</sup>. Patients who initiated treatment with azathioprine, 6-mercaptopurine, cyclosporin or methotrexate within 8 wk prior to inclusion or tumor necrosis factor- $\alpha$  inhibitors within 12 wk before inclusion or had changes in UC treatment within 2 wk before inclusion were ineligible for the study. Concomitant celiac disease, lactose intolerance and irritable bowel syndrome were also exclusion criteria. In addition any malignant or premalignant condition or recent gastroenteritis and irritable bowel syndrome rendered patients ineligible. Patients were recruited through advertisement on the website of the local patients' association, in local newspapers and through Google ads. The advertisement showed a link to a website that briefly described the trial and encouraged patients who were

interested and had the relevant disease characteristics to contact the trial nurse. The patients had to sign a declaration stating when and where they had been diagnosed with UC and describing the course of their disease including the fulfillment of the inclusion criteria. The data were confirmed by cross checking the patients' medical records. A specialist had diagnosed all patients.

Patients were excluded if UC medication was modified during the study period, however, a dose reduction of ongoing drugs was accepted. The patients were also excluded if new medication that may affect UC symptoms was prescribed for other conditions.

### Outcome measures

Our primary endpoint was to estimate the proportion of patients with a  $\geq 50\%$  reduction in SCCAI. Our secondary endpoint was to estimate the proportion of patients in remission defined as  $SCCAI \leq 2.5$ <sup>[11]</sup>.

### Study design and assessment of outcome measures

A prospective open-label study design was used to gain experience with time to response and remission and compliance for the later design of a comprehensive controlled study. After a run-in period of 6-14 d, the patients were followed for 24 wk with daily SCCAI score assessment. The SCCAI was chosen for the following reasons. The SCCAI score has been shown to correlate well with the more complex and invasive scoring systems and it facilitates daily and observer blinded symptoms registration<sup>[10,11]</sup>. Furthermore, colonoscopy may be experienced as painful and therefore compromise the patients' willingness to participate in a clinical trial. Internet software was developed by a company specialized in software development for interactive Internet solutions

(Franklyweb, Copenhagen, Denmark). The Internet platform was created according to protocol instructions and used for individual patient registration of SCCAI parameters. Regular access to a computer with Internet access was a criterion for inclusion. Each patient received a username and a password and was instructed to register the SCCAI parameters daily on the trial website. Each SCCAI parameter was formulated as a question e.g. "How many defecations have you experienced during daytime today? Click on the appropriate answer "1-3", "4-6", "7-9" or "> 9". Each SCCAI question needed to be answered before the patient could continue to the next question. After registration of the last SCCAI question, the patient was shown an overview of the answers to every SCCAI question and was asked to confirm or amend the information. After confirmation, the patient was shown a graph with the daily SCCAI scores from the first day of the run-in period up to the present date. The patients could communicate on the trial website with the nurse who checked the status of each patient at least twice a week and could send reminders if patients failed to register the daily symptoms. The symptoms were registered on a daily basis. When a patient failed to register a day's symptoms, the patient was reminded by the nurse about the lacking registration. The registration rate (registered days out of total number of days) was > 95%. The data were transferred from the patients *via* the Internet in encrypted form (Secure Sockets Layer) and stored on a secure server. The data were instantly copied - in raw and unprocessed form - to a similar server at the Technical University of Denmark, Department of Informatics and Mathematical Modelling, in order to secure the authenticity of the data and to analyze the data statistically.

Occasionally some patients did not have access to a computer with an Internet connection. In such cases, these patients received paper SCCAI questionnaires to be completed for each day of the relevant period. When access to the Internet was again established, the patients transferred the SCCAI parameters noted on the questionnaires to the website. During the screening process, 30 of the included patients (77%) had a face-to-face meeting with the trial nurse. There were no other face-to-face contacts with the patients. All other communication was electronic (phone or e-mail). The patients were instructed to report adverse events (AEs) *via* the trial website. Safety of Profermin® was assessed by analyzing the AE reports.

### Description of the intervention

Profermin® is manufactured as follows. Oat gruel is produced by mixing oats, water and a small amount of barley malt. The mixing process lasts for 1 h at 88 °C. The gruel is then cooled to 38 °C, and a *L. plantarum* 299v starter culture is added. The mixture is kept at 38 °C for 15 h with constant gentle stirring. The resulting oat-fermented gruel is cooled to about 8 °C. Lecithin is then added while the mixture is gently stirred and the resulting Pro-

fermin® is packed in 250-mL cartons under sterile conditions. The product is tested for pH and colony forming units (CFU) of Enterobacteriaceae, yeasts/moulds and *L. plantarum* 299v. The pH must be between 3.6 and 4.2 and the CFU of Enterobacteriaceae, yeasts/moulds must each be < 100/mL. The CFU of *L. plantarum* must be > 10<sup>8</sup>/mL.

After 6-14 d of run in, the Profermin® intervention was initiated by scaling the patient into a daily oral intake of Profermin®. The initial daily Profermin® dose was 125 mL as the first meal and 125 mL as the last meal of the day. After 2 d, the Profermin® dose was increased to 250 mL as the first meal and 250 mL as the last meal of the day. However, the protocol was open for periodical changes of the total dose of Profermin® in the interval of 25 mL to 500 mL taken once or twice daily, for example, if a patient experienced AEs during the introduction, the low Profermin® dose was prolonged for up to 2 wk. The median dose was 445 mL/d with an interquartile range of 408-500 mL/d. The patients reported their intake of Profermin® on a daily basis through the trial website and the mean self-reported adherence therapy was > 95%.

Patients were recommended to be cautious with consumption of dairy products and concentrated sugar products in accordance with routine dietetic recommendations widely used in Danish IBD clinics<sup>[6]</sup>. Compliance with this recommendation was not monitored. Patients continued their usual UC medication and clinical follow-up with gastroenterologists.

### Ethics, approvals and patient consent

The trial was approved by the Danish Data Protection Agency (2008-41-2961) and has been cleared with The Ethical Committees of the Copenhagen Region and registered (H-B-2008-FSP-20). As Profermin® is an FSMP and not a medicinal product, no authorization by the Danish Medicines Agency was required. All patients gave written informed consent according to the Helsinki declaration. The study was registered on www.clinicaltrials.gov (NCT01245465).

### Statistical analysis

In all analyses, we applied the principle of intention-to-treat (ITT). Data for patients who dropped out or who were excluded during the study period were included in the analysis by using the principle of last value carried forward. Unadjusted estimates for the primary and secondary endpoints were presented as total numbers and percentages. To gain further insight into the longitudinal effect of Profermin® on the possible decline in SCCAI over time adjusted for the starting value, we applied the following non-linear regression model:

$$Score_{ij} = \beta_0 + \beta_1 \times 2^{-Day_{ij}/\theta}$$

Where the dependent variable  $Score_{ij}$  was the score for person  $j$  on Day  $i$ . Time was denoted by the independent variable  $Day_{ij}$ . In the model, the parameters to be estimated had the following interpretation:  $\beta_0$  was the ultimate

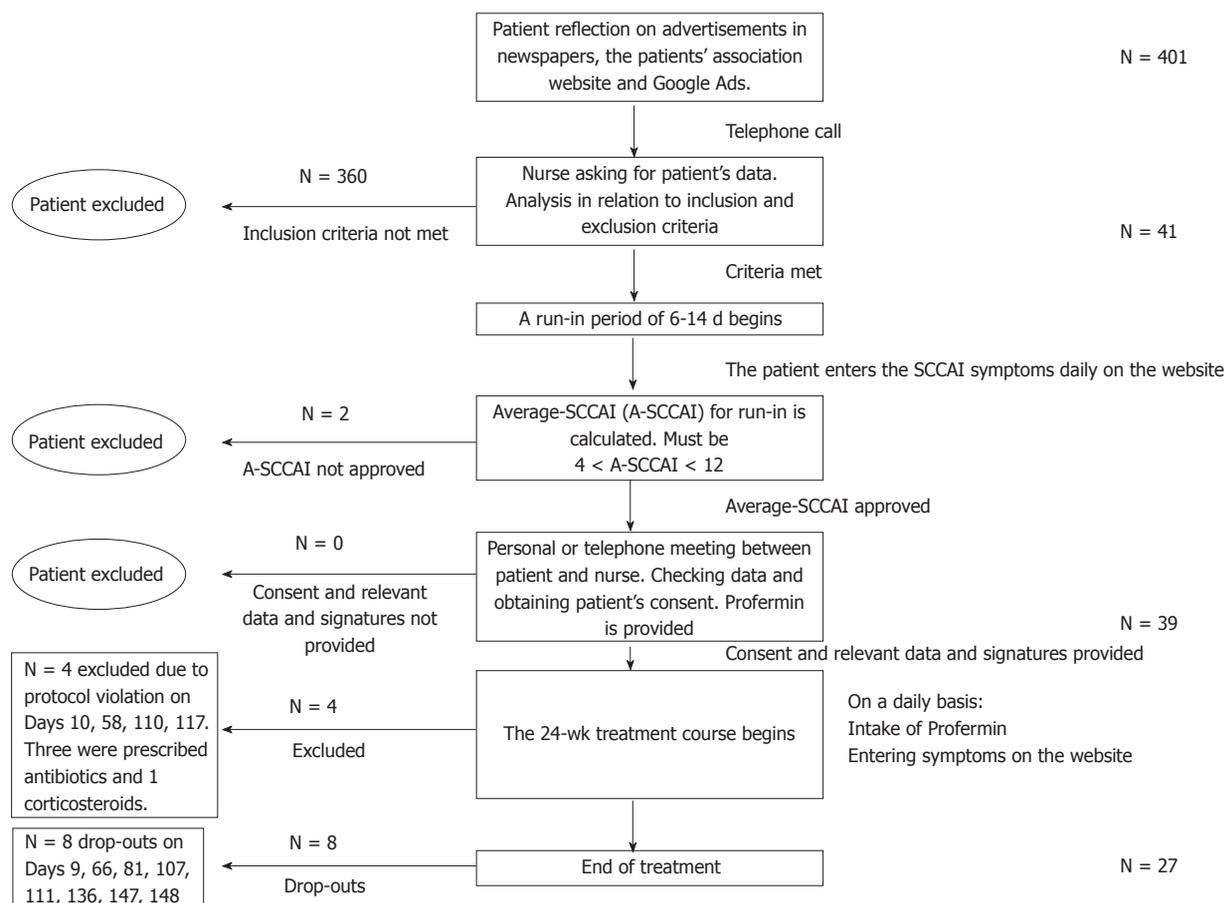

Figure 1 Patient flow diagram. SCCAI: Simple Clinical Colitis Activity Index.

score (or asymptote),  $\beta_1$  was the total reduction in score and  $\theta$  was the time taken to obtain half the reduction in score. Besides giving the parameters a marginal interpretation, it was of interest to describe the between-patient variation. Thus, we applied a nonlinear mixed-effects model, assuming that all three parameters in question followed a Gaussian distribution, i.e., each parameter was person-specific:

$$Score_{ij} = \beta_{0j} + \beta_{1j} \times 2^{-Day_i/\theta_j}$$

Here, we assumed that  $\beta_{0j} = N(\beta_0, \sigma_{\beta_0})$ ,  $\beta_{1j} = N(\beta_1, \sigma_{\beta_1})$  and  $\theta_j = N(\theta, \sigma_\theta)$ . The mixed-effect model led to the following interpretation: the estimated parameter  $\sigma_{\beta_0}$  was the between-person SD regarding the asymptote. Similarly,  $\sigma_{\beta_1}$  was the between-person SD related to the total reduction in score, and  $\sigma_\theta$  was the between-person SD related to the time taken to obtain half the reduction in score.

Before making inference, we examined both standardized residuals and estimated random effects for marginal normality by applying normal probability plots. In all statistical analysis, the software R and the package nlme were used. All tests were done as likelihood ratio tests with a significance level of 5%.

## RESULTS

The advertisements attracted 401 respondents, of whom 360 were excluded before the run-in period because the

inclusion criteria were not met (Figure 1). Reasons for exclusions were primarily SCCAI < 5 or recent change in oral corticosteroid treatment. During the run-in period, two additional patients were excluded because the SCCAI criteria were not met. The study comprised 39 patients who were available for ITT analysis: four were excluded and eight dropped out during the 24-wk treatment period (Figure 2 and Table 2).

Baseline characteristics and use of concomitant medications are shown in Tables 3 and 4.

### Safety and tolerability

No major AEs were reported and there were no drop-outs due to AEs. An increased number of bowel movements were reported by 11 patients (28%), bloating by four (10%) and an increased number of bowel movements and bloating by three (8%). All AEs were self-limiting or managed by dose adjustments. For example, if a patient experienced a presumable AE during the introduction of Profermin®, the period with the low Profermin® dose was prolonged for up to 2 wk. None of the eight dropout or four excluded patients left the trial due to deterioration in UC symptoms.

### Clinical response and remission

Of the 39 patients, 27 completed the entire study. For those completing the study, the mean follow-up was

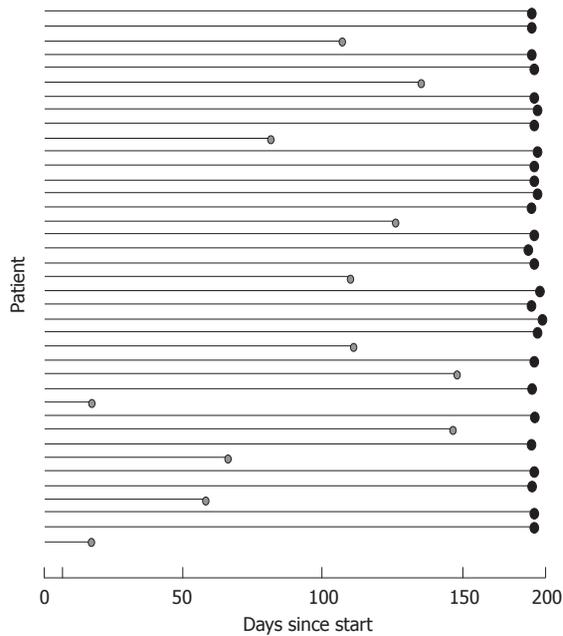

Figure 2 Point indicates that patient has dropped out.

176 d (range: 174-179 d). For those not completing the study, the mean follow-up was 94 d (range: 9-141 d). An ITT analysis showed that the mean reduction in SCCAI score was 56.5%. For the primary endpoint, ITT analysis showed that 24 of the 39 patients (62%) achieved a  $\geq 50\%$  reduction in SCCAI score (Figure 3A). In per protocol (PP) analysis, 85% reached the primary endpoint. In ITT analysis, four patients (10%) experienced deterioration in SCCAI but 13 (33%) experienced  $> 75\%$  improvement in SCCAI during the study (Figure 3B). Of the 39 patients, 18 reached the secondary endpoint and obtained remission defined as SCCAI score  $\leq 2.5$ , with an ITT success rate of 46% (Figure 3C). In PP analysis, 67% reached the secondary endpoint remission. Applying only the four defecation scores in the SCCAI (Table 1), four patients (10%) had deterioration and 17 (44%) had  $> 75\%$  improvement in defecations scores (Figure 3D).

When applying the nonlinear model for the ITT decline in SCCAI over time, the estimated ultimate score (or asymptote) was 2.8 points (95% CI: 92.0-3.6), the estimated mean reduction in score was 5.0 points (95% CI: 4.1-5.9,  $P < 0.0001$ ) and the estimated mean time taken to obtain half of the reduction in score was 28 d (95% CI: 26-30) (Figure 4).

**Descriptions of exclusions and dropouts**

Protocol violations accounted for the exclusion of four patients (10%) - days 10, 45, 100 and 116 (Table 4); three were prescribed antibiotics for pneumonia, salmonella infection and gastroenteritis, respectively, and one was prescribed corticosteroids for UC. Among those excluded, the mean SCCAI on inclusion was 9.0 (range: 8.0-11) and at exclusion 4.6 (range: 3.6-6.6). There were eight dropouts (20%) (Table 2). Among these, the mean SCCAI at inclusion was 7.0 (range: 4.6-9.0) and at drop-

Table 2 Description of four excluded patients and eight dropouts

Day	SCCAI run in	Reason for discontinuation	SCCAI dropout	Reduction	Increase
Excluded patients					
10	8.9	1	6.6	2.3	
45	8.0	1	4.1	3.9	
100	8.2	1	4.1	4.1

## DISCUSSION

In ITT analysis, 62% of the patients reached the primary endpoint, defined as  $\geq 50\%$  reduction in SCCAI, and 46% reached the secondary endpoint of remission, defined as an SCCAI score  $\leq 2.5$ . A study on endpoints

for clinical improvement and remission in UC found a relevant clinical improvement to be a decrease of 1.5 SCCAI points and the best cut-off to establish remission as an SCCAI of 2.5<sup>[11]</sup>. In ITT analysis, the average reduction was  $> 1.5$  SCCAI points 12 d after the intervention was initiated. After 32 d, the average reduction increased to  $> 3$  SCCAI points and after 84 d to  $> 4.5$  (Figure 4). In a repeated measure regression analysis, the mean reduction in SCCAI after 24 wk of Profermin® treatment, adjusted for baseline value, was 5.0 and the estimated ultimate score was calculated to be 2.8 (Figure 4), suggesting a clinically relevant and significant effect. A meta-analysis of response rates in the placebo arms of UC trials estimated the placebo rates of remission and response to be 13% (95% CI: 9-18) and 28% (95% CI: 23-33), respectively<sup>[12]</sup>. The ITT remission and response rates in our study were 33 and 34 percentage points above these standard placebo rates, supporting a possible clinical effect of Profermin® when compared with standard placebo rates of response and remission. The safety profile of Profermin® appears favorable with no major AEs and no withdrawals due to AEs. Mild AEs were observed mainly in the initial days of treatment and ceased within a few days or after dose adjustments. Safety and tolerability of Profermin® are comparable to those of probiotics<sup>[7-9]</sup>.

Profermin® is a complex product and the mode of action is probably complex as well. However, dietary management with Profermin® uses a novel approach and

cannot be categorized as a probiotic, prebiotic or symbiotic product<sup>[13]</sup>. The dietary effect may be related to the fermented oats components such as the relatively large amounts of secondary metabolites from the fermentation process and the composition of oats *per se*. The short chain fatty acids of secondary metabolites have been shown to serve as a major source of energy for colonocytes, and  $\beta$ -glucans have been described as biological response modifiers<sup>[14,15]</sup>. *L. plantarum* is a common species in the human gastrointestinal microbiota<sup>[16-18]</sup>. *L. plantarum* 299v survives passage through the gastrointestinal tract and has been isolated from feces and rectal and jejunal biopsies 11 d after 10 d administration to healthy volunteers, indicating at least transient colonization of the gut mucosa<sup>[19-21]</sup>. It has been shown that oat gruel fermented with *L. plantarum* 299v increases iron absorption by 50%, suggesting an important dietary effect for UC<sup>[22]</sup>. In addition, the phosphatidylcholine (PC) in lecithin may serve as an important food component because the content of PC in the colonic mucus of patients with UC is significantly lower compared with the content in healthy controls<sup>[23]</sup>. Lastly, the daily intake of relatively large quantities of fermented oats may change the intestinal contents and environment and thereby establish an altered platform for microbial activity.

In this study, we introduced a new online self-reporting Internet-based system for assessing daily activity in UC and for monitoring response to treatment. The system allows electronic monitoring of data and enables daily reporting with minimal interruption to the patient's daily life. The risk of patients being influenced in their self-assessment by health personnel is limited. Independent monitoring and statistical analyses can be achieved easily. In Denmark, where most people have Internet access, this system is a very useful research tool in a population of UC patients.

Our study had some limitations: (1) it was an uncontrolled study and the results need to be confirmed in a randomized trial; and (2) patients were informed to consider their consumption of dairy products and concentrated sugar products, in particular fresh milk and confectionary. This may have had an effect on UC or may have reinforced the effect of Profermin®.

The present study demonstrates that Profermin® is safe and may be effective in inducing remission of active UC. Randomized controlled studies are planned to explore further the clinical efficacy of Profermin®.

## ACKNOWLEDGMENTS

We thank Jørgen Villumsen for invaluable practical and technical assistance. We also thank Peter Møller and Carsten Toftager Larsen for important advice during the study.

## COMMENTS

### Background

Ulcerative colitis (UC) is a chronic relapsing bowel disease. The goal of treat-

ment in UC is to induce and maintain remission of the disease, however, failure to induce remission occurs in 20%-30% of patients on current treatments. Accordingly, new treatment alternatives and additives are being sought. Dietetic interventions may improve symptoms in UC.

### Research frontiers

Clinical and experimental studies point towards alterations in the relative balance of aggressive and protective bacterial species in UC. Interventions to alter the intestinal microflora in order to decrease disease activity are under investigation and prebiotics, probiotics and symbiotics have been investigated in UC but the reported efficacies have varied.

### Innovations and breakthroughs

This is believed to be the first study to assess Profermin® in UC. The study was an open label study that investigated safety and efficacy of Profermin® in patients with moderate active UC. Profermin® is a new developed product for the dietary management of UC. It is a fermented oat gruel with *Lactobacillus plantarum* 299v, barley malt, lecithin and water.

### Applications

Profermin® is safe and well tolerated and may be effective in reducing symptoms and inducing remission in UC. Larger randomized trials should be performed to investigate further the efficacy of Profermin® in UC.

### Terminology

Simple Clinical Colitis Activity Index (SCCAI) assessed active disease. SCCAI is a clinical scoring system for UC, based on bowel frequency day and night, urgency, fecal blood, general well being and extracolonic manifestations.

### Peer review

The authors have reported a study on the safety of Profermin®, a combination of fermented oats, probiotics and lecithin, in patients with mild to moderate UC. This is primarily an open-label safety study in patients. The agent was well-tolerated and may be efficacious.

### Abstract

**AIM:** To investigate the effect of glyceraldehyde-derived advanced glycation end-products (Glycer-AGEs) on hepatocellular carcinoma (HCC) cells.

**METHODS:** Two HCC cell lines (Hep3B and HepG2 cells) and human umbilical vein endothelial cells (HUVEC) were used. Cell viability was determined using the WST-8 assay. Western blotting, enzyme linked immunosorbent assay, and real-time reverse transcription-polymerase chain reactions were used to detect protein and mRNA. Angiogenesis was evaluated by assessing the proliferation, migration, and tube formation of HUVEC.

**RESULTS:** The receptor for AGEs (RAGE) protein was detected in Hep3B and HepG2 cells. HepG2 cells were

not affected by the addition of Glycer-AGEs. Glycer-AGEs markedly increased vascular endothelial growth factor (VEGF) mRNA and protein expression, which is one of the most potent angiogenic factors. Compared with the control unglycated bovine serum albumin (BSA) treatment, VEGF mRNA expression levels induced by the Glycer-AGEs treatment were  $1.00 \pm 0.10$  vs  $1.92 \pm 0.09$  ( $P < 0.01$ ). Similarly, protein expression levels induced by the Glycer-AGEs treatment were  $1.63 \pm 0.04$  ng/mL vs  $2.28 \pm 0.17$  ng/mL for the 24 h treatment and  $3.36 \pm 0.10$  ng/mL vs  $4.79 \pm 0.31$  ng/mL for the 48 h treatment, respectively ( $P < 0.01$ ). Furthermore, compared with the effect of the control unglycated BSA-treated conditioned medium, the Glycer-AGEs-treated conditioned medium significantly increased the proliferation, migration, and tube formation of HUVEC, with values of  $122.4\% \pm 9.0\%$  vs  $144.5\% \pm 11.3\%$  for cell viability,  $4.29 \pm 1.53$  vs  $6.78 \pm 1.84$  for migration indices, and  $71.0 \pm 7.5$  vs  $112.4 \pm 8.0$  for the number of branching points, respectively ( $P < 0.01$ ).

**CONCLUSION:** These results suggest that Glycer-AGEs-RAGE signaling enhances the angiogenic potential of HCC cells by upregulating VEGF expression.

Takino J, Yamagishi S, Takeuchi M. Glycer-AGEs-RAGE signaling enhances the angiogenic potential of hepatocellular carcinoma by upregulating VEGF expression. *World J Gastroenterol* 2012; 18(15): 1781-1788 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i15/1781.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i15.1781>

## INTRODUCTION

Advanced glycation end-products (AGEs) are formed by the Maillard reaction, a non-enzymatic reaction between the ketones or aldehydes of sugars and the amino groups of proteins, which contributes to aging and the pathological complications of diabetes<sup>[1,2]</sup>. Recent studies have suggested that AGEs can be formed not only from sugars, but also from carbonyl compounds derived from the autoxidation of sugars and other metabolic pathways<sup>[3,4]</sup>. Among the different AGEs, there is evidence that glyceraldehyde-derived AGEs (Glycer-AGEs) are associated with the complications of diabetes, as well as Alzheimer's disease, nonalcoholic steatohepatitis (NASH), and cancer<sup>[5-8]</sup>.

NASH is recognized as a component of metabolic syndrome and is associated with insulin resistance and abnormalities in glucose and lipid metabolism<sup>[9-11]</sup>. NASH is one of a group of nonalcoholic fatty liver diseases (NAFLD) that range from simple steatosis to steatohepatitis<sup>[12]</sup>. However, although simple steatosis appears to be a benign and non-progressive condition, NASH is a potentially progressive disease that can lead to cirrhosis, liver failure, and hepatocellular carcinoma (HCC)<sup>[13,14]</sup>. In fact, several case series of NASH-associated HCC have been reported<sup>[15,16]</sup>. HCC, which accounts for more than 90% of all primary liver cancers, is one of the most common malignancies worldwide<sup>[17]</sup>. Its incidence is particularly high in the Asian population<sup>[18]</sup>.

A recent study suggested that expression of the receptor for AGEs (RAGE) mRNA was lower in normal liver cells than in those of hepatitis and HCC patients<sup>[19]</sup>. Furthermore, we have demonstrated that Glycer-AGEs are present in significantly high concentrations in the sera of patients with NASH<sup>[8]</sup>. In addition, the interaction of Glycer-AGEs with the RAGE was found to increase C-reactive protein expression in Hep3B cells<sup>[20]</sup>. However, the effects of Glycer-AGEs on HCC cells remain poorly understood.

In the present study, we examined the effects of Glycer-AGEs on HCC cells and showed that Glycer-AGEs-RAGE signaling enhances the angiogenic potential of HCC cells by upregulating vascular endothelial growth factor (VEGF) expression.

## MATERIALS AND METHODS

### Preparation of glyceraldehyde-derived advanced glycation end-products

All chemicals were commercial samples of high purity and were used as supplied. Glycer-AGEs were prepared as described previously<sup>[21]</sup>. Briefly, 25 mg/mL of bovine serum albumin (BSA; A0281, Sigma-Aldrich) was incubated at 37 °C for 7 d under sterile conditions with 0.1 mol/L glyceraldehyde and 5 mmol/L diethylenetriaminepentaacetic acid (Dojindo Laboratories, Kumamoto, Japan) in 0.2 mol/L phosphate buffer (pH 7.4). As a control, unglycated BSA was incubated under the same con-

ditions, but without glyceraldehyde. The unglycated and glycated albumin were purified using a PD-10 column (GE Healthcare UK Ltd., Buckinghamshire, England) and dialysis against PBS. All preparations were tested for endotoxin using the Endospecy ES-20S system (Seikagaku Co., Tokyo, Japan). Protein concentrations were determined using the Dc protein assay reagent (Bio-Rad Laboratories, Richmond, CA, United States), using BSA as a standard. In all experiments, control unglycated BSA and Glycer-AGEs were used at culture medium concentrations of 100 µg/mL.

### Cell cultures

Hep3B and HepG2 cells were grown in Dulbecco's modified Eagle's medium (DMEM; Sigma-Aldrich) supplemented with 10% fetal bovine serum (FBS; Equitech-Bio, Kerrville, TX, United States) under standard cell culture conditions (humidified atmosphere, 5% CO<sub>2</sub>, 37 °C). Cells ( $1.5 \times 10^4$  cells/cm<sup>2</sup>) were then seeded in various plates or culture dishes (BD Biosciences, Franklin Lakes, NJ, United States) and incubated for 48 h before the start of all experiments, except the migration assay. The control unglycated BSA and Glycer-AGEs (100 µg/mL) treatments were carried out in serum free DMEM.

Human umbilical vein endothelial cells (HUVEC) were grown in endothelial cell growth medium (GM; Cell Applications, San Diego, CA, United States) under standard cell culture conditions.

### Preparation of cell lysate

Cells were washed with ice-cold Ca<sup>2+</sup> and Mg<sup>2+</sup> free PBS [PBS (-)] and subjected to lysis buffer [25 mmol/L Tris-HCl (pH 7.6), 150 mmol/L sodium chloride, 1% Nonidet P-40, 1% sodium deoxycholate, 0.1% sodium dodecyl sulfate (SDS), and 1 × protease inhibitor cocktail (complete, Mini; Roche)]. Subsequently, cell lysates were passed through a syringe several times for further homogenization and centrifuged at 10 000 × *g* for 10 min at 4 °C. Protein concentrations were measured using the Bradford assay (Bio-Rad Laboratories).

### Western blotting

Cell lysates (30 µg of proteins/lane) were dissolved in SDS sample buffer [62.5 mmol/L Tris-HCl (pH 6.8), 2% SDS, 10% glycerol, and 0.01% bromophenol blue] containing 5% 2-mercaptoethanol, boiled for 3 min at 95 °C, separated by SDS-polyacrylamide gel electrophoresis, and then electro-transferred onto polyvinylidene difluoride membranes (Millipore, Billerica, MA, United States). Biotinylated markers (Cell Signaling, Beverly, MA, United States) were used as molecular weight markers. Membranes were blocked for 1 h using 5% skimmed milk in phosphate buffered saline (PBS) containing 0.05% polyoxyethylene sorbitan monolaurate (PBS-T). After being washed twice with PBS-T, membranes were incubated overnight with goat anti-RAGE antibody (N-16), mouse anti-β-actin antibody (Santa Cruz, Santa Cruz, CA, United States), or rabbit anti-cyclooxygenase-2 (anti-COX-2)

antibody (Cayman Chemical, Ann Arbor, MI, United States). Subsequently, membranes were washed twice with PBS-T and incubated with anti-goat IgG antibody (Santa Cruz), anti-mouse Ig's antibody (Biosource, Camarillo, CA, United States), or anti-rabbit IgG and anti-biotin antibodies (Cell Signaling) for 1 h. After being washed a further three times with PBS-T, immunoreactive proteins were detected with ECL Plus Western Blotting Detection Reagents (GE Healthcare) using a luminescent image analyzer (LAS-1000UVmini; Fujifilm, Tokyo, Japan). The density of the bands was analyzed using a Multi Gauge version 3.0 (Fujifilm).

### Cell viability

Cell viability was determined using the WST-8 assay, which measures metabolic activity. After removing the medium from a 96-well microplate that had been used to culture cells as above, 100  $\mu$ L/well of 10% FBS/DMEM and 10  $\mu$ L/well of WST-8 solution (Dojindo Laboratories) were added, and cells were incubated for 2 h. Absorbance was then measured at 450 nm and 650 nm using a microplate reader (Labsystems Multiskan Ascent, Model No. 354; Thermo Fisher Scientific, Kanagawa, Japan). The net difference ( $A_{450}-A_{650}$ ) was used as a measure of cell viability.

### Real-time reverse transcription-polymerase chain reaction analysis

Total RNA was isolated from cells with ISOGEN (Nippon Gene, Tokyo, Japan), and 50 ng of RNA were reverse transcribed into cDNA with the PrimeScript™ reverse transcription (RT) reagent kit (Takara, Shiga, Japan) using a GeneAmp® 9700 polymerase chain reaction (PCR) System (Perkin-Elmer Applied Biosystems, Foster City, CA, United States). Real-time polymerase chain reaction was performed with SYBR Premix Ex Taq™ (Takara) using a Smart Cycler® II System (Takara). The reaction mixture (25  $\mu$ L) contained 1  $\times$  SYBR Premix Ex Taq™, 0.2  $\mu$ mol/L PCR forward primers, 0.2  $\mu$ mol/L PCR reverse primers, and 10 ng of cDNA as a template. The primers used were as follows: COX-2: 5'-GAGTACCGCAAACGCTTTATGC-3' and 5'-GCCGAGGCTTTTC-TACCAGAA-3', VEGF: 5'-TGCAGATTATGCGGATCAAACC-3' and 5'-TGCAITTCACATTTGTTGTGCTGTAG-3', and  $\beta$ -actin: 5'-TCCACCTCCAGCAGATGTGG-3' and 5'-GCATTTGCGGTGGACGAT-3'. All processes were performed according to the manufacturer's instructions. Expression levels of the target genes were calculated using a relative quantification method.  $\beta$ -Actin was used as an endogenous control gene to normalize target gene expression values. Product specificity was determined by a melting curve analysis.

### Enzyme linked immunosorbent assay

Cells were incubated with control unglycated BSA or Glycer-AGEs for 24 h or 48 h. The culture medium was collected and centrifuged at 200  $\times g$  for 10 min to remove any particles, and the resultant supernatant was analyzed

using the VEGF enzyme-linked immunosorbent assay kit (Ray Biotech, Norcross, GA, United States). All processes were performed according to the manufacturer's instructions.

### Migration assay

The migratory capacity of Hep3B cells was evaluated using the Oris™ Cell Migration Assay (Platypus Technologies, Madison, WI, United States). Cells ( $1.5 \times 10^5$  cells/mL) were incubated with 10% FBS/DMEM for 24 h. After removing the stopper covering the center of the well, fluorescently-labeled cells were incubated with control unglycated BSA or Glycer-AGEs for 24 h. The number of cells that had migrated to the center was assessed at excitation and emission wavelengths of 485 nm and 530 nm, respectively, using a fluorescence microplate reader (Labsystems Fluoroskan Ascent CF, Type 374; Thermo Fisher Scientific).

### Preparation of conditioned medium

Hep3B cells were incubated with control unglycated BSA or Glycer-AGEs for 48 h. The culture medium was collected and filtered to remove any particles. The CM was then frozen at -80 °C until it was used in the experiments.

### Human umbilical vein endothelial cells proliferation assay

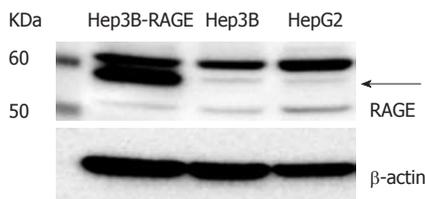

HUVEC ( $0.75 \times 10^4$  cells/cm<sup>2</sup>) were incubated with GM for 24 h, before being cultured in DMEM or CM in 10% FBS for 72 h. HUVEC proliferation was determined using the WST-8 assay.

### Human umbilical vein endothelial cells migration assay

The migratory capacity of HUVEC was evaluated using the BD BioCoat™ Angiogenesis System-Endothelial Cell Migration assay (BD Biosciences). In this assay, the upper and lower culture compartments were separated by fluorescence blocking polyethylene terephthalate filters (3  $\mu$ m pore size) coated with human fibronectin. Cells ( $3.3 \times 10^5$  cells/mL) in serum-free DMEM were added to each of the upper chambers for 20 h. Then, 0.5% FBS/CM was added to the lower chamber and used as a chemoattractant. The number of fluorescently-labeled cells that had migrated to the opposite side of the chamber was then assessed at excitation and emission wavelengths of 485 nm and 530 nm, respectively, using a fluorescence microplate reader (Thermo Fisher Scientific).

### Tube formation assay

The tube formation assay was performed with the BD BioCoat™ Angiogenesis System-Endothelial Cell Tube Formation assay (BD Biosciences). Before the start of the assay, the Matrigel matrix was polymerized for 30 min at 37 °C under a 5% CO<sub>2</sub> environment. Cells ( $4 \times 10^5$  cells/mL) were incubated with 0.5% FBS/CM for 12 h and then photographed under a microscope, and the number of branch points was counted in five randomly chosen fields.

**Figure 1** The receptor for advanced glycation end-products expression in hepatocellular carcinoma cells. The receptor for advanced glycation end-products (RAGE) expression as measured by Western blotting. Cell lysates (30  $\mu$ g of proteins/lane) were loaded onto a 10% polyacrylamide gel. Size markers (kDa) are shown on the left. Equal protein loading was verified using an anti- $\beta$ -actin antibody. The arrow indicates full-length RAGE.

### Statistical analysis

All experiments were performed in duplicate and repeated at least two or three times, with each experiment yielding essentially identical results. Data are expressed as the mean  $\pm$  SD. The significance of the differences between group means was determined by a one-way analysis of variance. *P* values of less than 0.05 were considered significant.

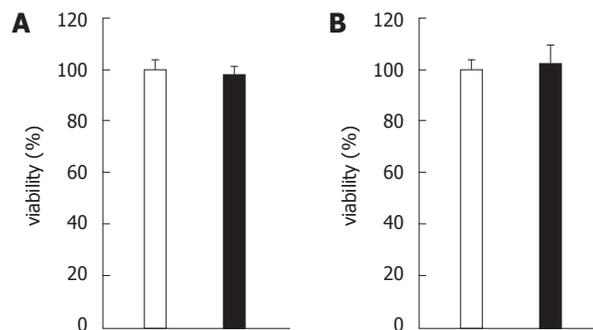

## RESULTS

To investigate whether RAGE proteins were present in Hep3B and HepG2 cells, we carried out Western blotting using an anti-RAGE antibody. RAGE proteins of different molecular weights were detected in Hep3B and HepG2 cells (Figure 1). In full-length RAGE cDNA-transfected Hep3B cells, the major band (57 kDa) (indicated by an arrow in Figure 1) represented the full-length RAGE protein. Likewise, the full-length RAGE protein was also detected in Hep3B and HepG2 cells, and there was no difference in its expression level between the two cell types.

We examined the effect of Glycer-AGEs on the viability of Hep3B and HepG2 cells. Cell viabilities resulting from treatment with the control unglycated BSA or the Glycer-AGEs for 24 h were  $100\% \pm 3.5\%$  *vs*  $97.8\% \pm 3.3\%$  in Hep3B cells (Figure 2A), and  $100\% \pm 4.3\%$  *vs*  $102.3\% \pm 6.7\%$  in HepG2 cells (Figure 2B). Thus, Glycer-AGEs did not have any effect on the viability of Hep3B and HepG2 cells.

To investigate whether Glycer-AGEs affected the malignancy of HCC cells, we examined COX-2 mRNA and protein expression. COX-2 mRNA expression levels induced by the control unglycated BSA or the Glycer-AGEs treatment were  $1.00 \pm 0.27$  *vs*  $2.16 \pm 0.34$  ( $P < 0.01$ ) (Figure 3A), and COX-2 protein expression levels were increased by Glycer-AGEs at 24 h in Hep3B cells (Figure 3B), whereas no such change was detected in HepG2 cells (Figure 3B).

We also evaluated the influence of Glycer-AGEs on cell migration, which is an index of malignancy in Hep3B cells. However, migration indices for the control unglycated BSA or the Glycer-AGEs treatment were  $18.2 \pm 0.6$  *vs*  $18.7 \pm 0.5$  (Figure 3C), and Glycer-AGEs did not

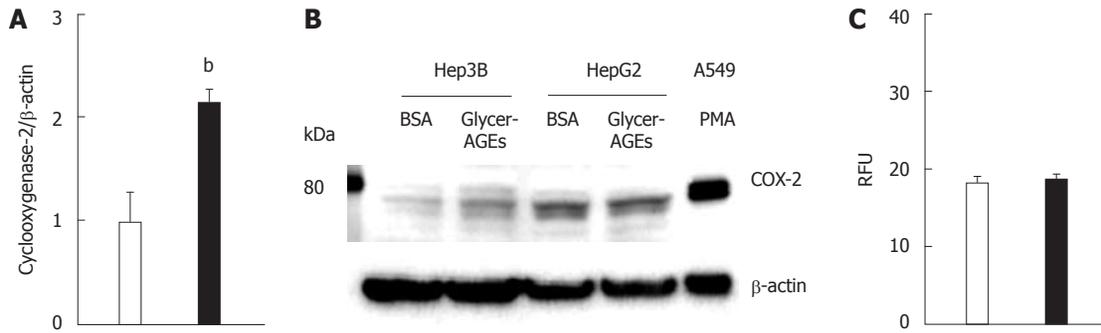

**Figure 2** Effect of glyceraldehyde-derived advanced glycation end-products on the viability of hepatocellular carcinoma cells. Cell viability was determined using the WST-8 assay. Hep3B (A) and HepG2 (B) cells were incubated with control unglycated bovine serum albumin (BSA) or glyceraldehyde-derived advanced glycation end-products (Glycer-AGEs) (100  $\mu$ g/mL) for 24 h. The open and filled bars represent results for cells treated with control unglycated BSA and Glycer-AGEs, respectively. Data are shown as the mean  $\pm$  SD ( $n = 6$ ).

affect the migratory capacity of Hep3B cells; i.e., Glycer-AGEs did not increase the malignancy of Hep3B cells.

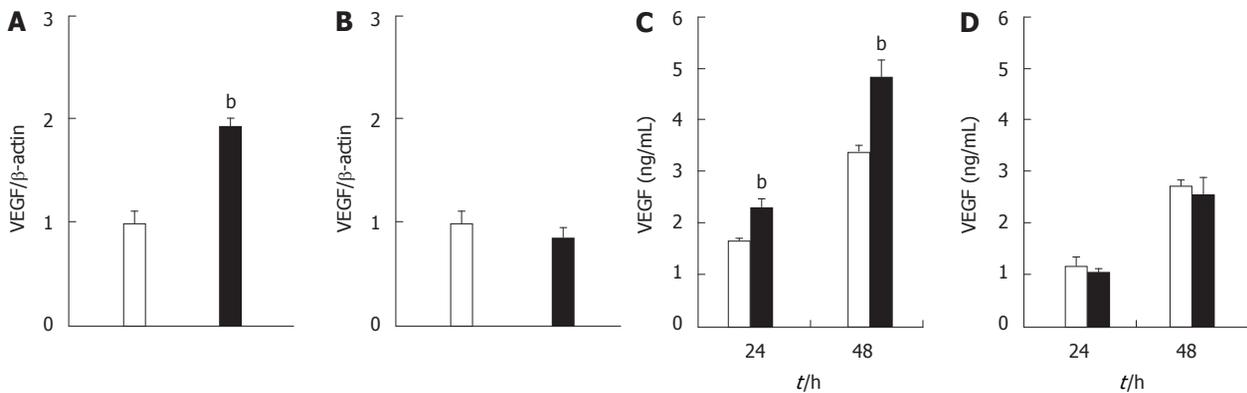

To investigate whether Glycer-AGEs affected the angiogenesis of HCC cells, we examined the expression levels of VEGF mRNA and protein. VEGF mRNA expression levels induced by the control unglycated BSA or the Glycer-AGEs treatment were  $1.00 \pm 0.10$  *vs*  $1.92 \pm 0.09$  in Hep3B cells ( $P < 0.01$ ) (Figure 4A), and  $1.00 \pm 0.11$  *vs*  $0.87 \pm 0.10$  in HepG2 cells (Figure 4B). The expression levels of the VEGF protein induced by the control unglycated BSA or the Glycer-AGEs treatment for 24 and 48 h were  $1.63 \pm 0.04$  ng/mL *vs*  $2.28 \pm 0.17$  ng/mL (24 h,  $P < 0.01$ ), and  $3.36 \pm 0.10$  ng/mL *vs*  $4.79 \pm 0.31$  ng/mL (48 h,  $P < 0.01$ ), respectively, in Hep3B cells (Figure 4C). In HepG2 cells, the results were  $1.15 \pm 0.19$  ng/mL *vs*  $1.04 \pm 0.03$  ng/mL (24 h), and  $2.70 \pm 0.10$  ng/mL *vs*  $2.53 \pm 0.32$  ng/mL (48 h), respectively, (Figure 4D). Thus, the VEGF mRNA expression of Hep3B cells was increased by Glycer-AGEs at 24 h, and VEGF protein expression levels in these cells were also increased by Glycer-AGEs at 24 and 48 h. However, no such changes were observed in HepG2 cells.

We then examined the effect of CM-Glycer-AGEs on the viability of HUVEC. Cell viabilities resulting from treatment with the control unglycated BSA or the Glycer-AGEs for 72 h were  $100\% \pm 6.4\%$  *vs*  $96.2\% \pm 5.4\%$ , and the control unglycated BSA-treated CM (CM-BSA) or the CM-Glycer-AGEs for 72 h were  $122.4\% \pm 9.0\%$  *vs*  $144.5\% \pm 11.3\%$  ( $P < 0.01$ ) (Figure 5). There was no difference in viability between the Glycer-AGEs-treated and control unglycated BSA-treated cells, whereas cell viability in cells treated with CM-Glycer-AGEs was significantly higher than that of those treated with CM-BSA.

Finally, we examined the effect of CM-Glycer-AGEs on the migration and tube formation of HUVEC. Migration and tube formation of endothelial cells play key roles in tumor angiogenesis. Migration indices for the CM-BSA or the CM-Glycer-AGEs treatment were  $4.29 \pm 1.53$  *vs*  $6.78 \pm 1.84$  ( $P < 0.05$ ) (Figure 6A), and cell migration

**Figure 3** Effect of glycer-AGEs on the malignancy of hepatocellular carcinoma cells. Hep3B and HepG2 cells were incubated with control unglycated bovine serum albumin (BSA) or glycer-AGEs for 24 h. A: In Hep3B cells, COX-2 mRNA expression levels were analyzed using real-time reverse transcription-polymerase chain reactions, and results were normalized to the  $\beta$ -actin mRNA level ( $n = 3$ );  $^bP < 0.01$  vs control unglycated BSA. B: COX-2 expression as measured by Western blotting. Cell lysates (30  $\mu$ g of proteins/lane) were loaded onto a 10% polyacrylamide gel. Size markers (kDa) are shown on the left. Equal protein loading was verified using an anti- $\beta$ -actin antibody. As a positive control, A549 cells were incubated with phorbol 12-myristate 13-acetate (PMA: 100 nmol) for 6 h; C: The migratory capacity of Hep3B cells was evaluated using the Oris cell migration assay ( $n = 8$ ). Cells were incubated with control unglycated BSA or Glycer-AGEs for 24 h, and the number of migrating cells was then assessed using a fluorescence microplate reader. RFU: Relative fluorescence units. The open and filled bars represent results for cells treated with control unglycated BSA and Glycer-AGEs, respectively. Data are shown as the mean  $\pm$  SD.

**Figure 4** Effect of glycer-AGEs on the angiogenesis of hepatocellular carcinoma cells. A and B: Hep3B and HepG2 cells were incubated with control unglycated bovine serum albumin (BSA) or glycer-AGEs for 24 h. Vascular endothelial growth factor (VEGF) mRNA expression was analyzed using real-time reverse transcription-polymerase chain reactions, and results were normalized to the  $\beta$ -actin mRNA level; C and D: Hep3B and HepG2 cells were incubated with control unglycated BSA or Glycer-AGEs for 24 or 48 h. The conditioned medium was collected, and VEGF expression levels of the cells were determined by enzyme-linked immunosorbent assay. The open and filled bars represent results for cells treated with control unglycated BSA and Glycer-AGEs, respectively. Data are shown as the mean  $\pm$  SD ( $n = 3$ );  $^bP < 0.01$  vs control unglycated BSA.

with the CM-Glycer-AGEs treatment was significantly higher than that of the CM-BSA treatment. In tube formation, the CM-Glycer-AGEs-treated HUVEC showed an increased number of tube-like structures and larger tube networks (Figure 6B). Furthermore, the number of branching points for the CM-BSA or the CM-Glycer-AGEs treatment were  $71.0\% \pm 7.5\%$  vs  $112.4\% \pm 8.0\%$  ( $P < 0.01$ ) (Figure 6C), and the number of branching points with the CM-Glycer-AGEs treatment was significantly higher than that of the CM-BSA treatment (Figure 6C).

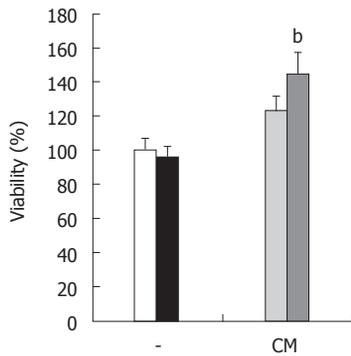

These results showed that Glycer-AGEs enhance the angiogenic potential of HCC cells by upregulating VEGF expression.

## DISCUSSION

The incidence of HCC in developed countries has been increasing over the last 20 years<sup>[22]</sup>. Although hepatitis C

virus is responsible for half of the recent increase in the prevalence of HCC, the etiologies of 15%-50% of new HCC cases remain unclear<sup>[23]</sup>. NASH, a component of metabolic syndrome, is thought to be responsible for some of these cases<sup>[15,16]</sup>. AGEs are one possible mechanistic link between metabolic syndrome and NASH, and Glycer-AGEs have been reported to be involved in NASH<sup>[8,24]</sup>; however, their role in HCC has barely been investigated.

A recent study suggested that the expression of RAGE mRNA was lower in normal liver tissue than in the liver cells of hepatitis and HCC patients. In addition, in HCC, RAGE mRNA expression was high in well and moderately differentiated tumors, but declined as the tumors dedifferentiated to poorly differentiated HCC<sup>[19]</sup>. The Hep3B and HepG2 cells used in this experiment were well-differentiated HCC cell lines. RAGE protein was detected in both Hep3B and HepG2 cells and there was no difference in its expression between the two cell lines.

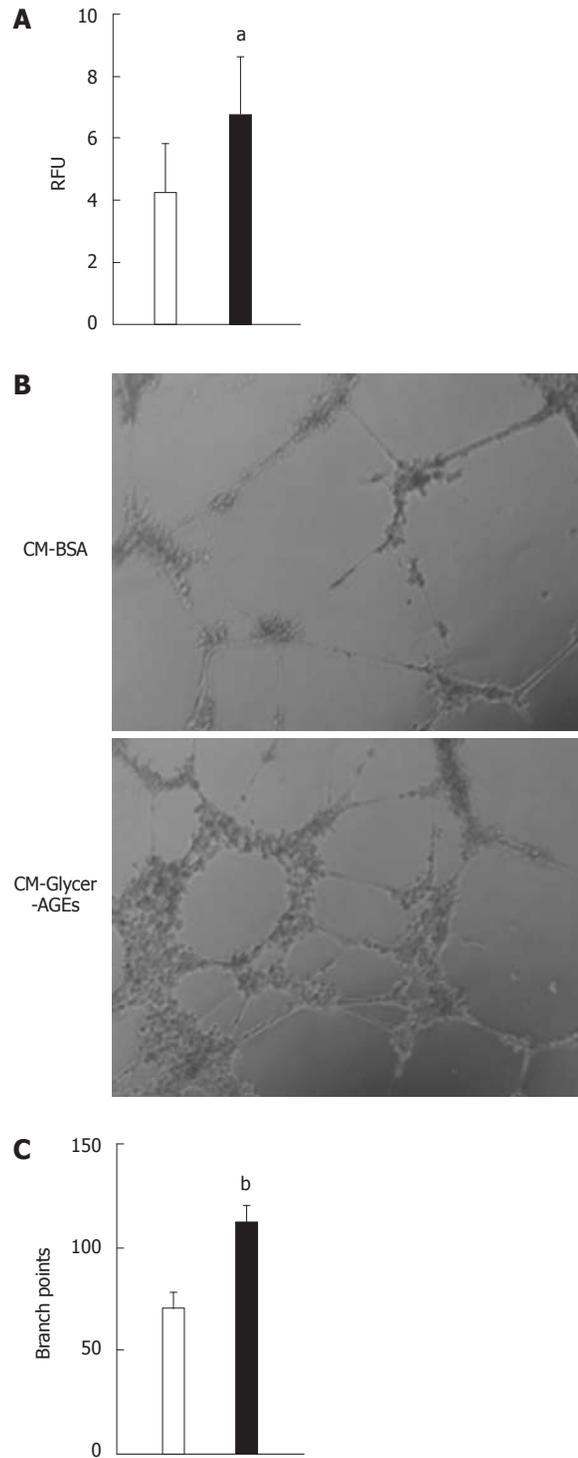

**Figure 5** Effect of glycer-aldehyde-derived advanced glycation end-products-treated CM on human umbilical vein endothelial cells proliferation. Cell viability was determined with the WST-8 assay. Human umbilical vein endothelial cells were incubated with control unglycated bovine serum albumin (BSA), glycer-aldehyde-derived advanced glycation end-products (Glycer-AGEs) (100  $\mu$ g/mL), CM-BSA, or CM-Glycer-AGEs for 72 h. The open and filled bars represent results for cells treated with control unglycated BSA and Glycer-AGEs, respectively, and the light grey and the black grey bars represent results for cells treated with CM-BSA and CM-Glycer-AGEs, respectively. Data are shown as the mean  $\pm$  SD ( $n = 6$ ); <sup>b</sup> $P < 0.01$  vs CM-BSA.

However, the effects of Glycer-AGEs differ between Hep3B and HepG2 cells. A previous report found that Hep3B cells activate AGEs signaling through RAGE<sup>[20]</sup>. On the other hand, it was reported that HepG2 cells did not express the RAGE protein on their cell surfaces and were not affected by Glycer-AGEs<sup>[25]</sup>. HepG2 cells were also not affected by Glycer-AGEs in our study.

In this study, Glycer-AGEs did not increase cell growth or migration of Hep3B cells. However, Glycer-AGEs slightly increased COX-2 protein expression levels in these cells. This protein plays important roles in HCC malignancy by producing prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), including cell growth, migration, and invasion<sup>[26,27]</sup>, and PGE<sub>2</sub> promotes the migration of HCC cell lines in  $> 1.5 \mu$ g/mL<sup>[28-30]</sup>. Indeed, PGE<sub>2</sub> protein expression levels induced by COX-2 increased by Glycer-AGEs, but the quantity was  $< 6$  pg/mL (data not shown). The results imply that although Glycer-AGEs induced increases in the expression levels of COX-2 and PGE<sub>2</sub> protein, they were not sufficient to increase cell growth or migration.

On the other hand, Glycer-AGEs markedly increased the VEGF protein expression levels of Hep3B cells. VEGF is one of the most potent angiogenic factors<sup>[31]</sup>, and angiogenesis plays a significant role in HCC progression<sup>[32-34]</sup>. Proliferation, migration, and tube formation of endothelial cells are important events in angiogenesis<sup>[35]</sup>. In addition, CM-Glycer-AGEs significantly increased the proliferation, migration, and tube formation of HUVEC. The results suggested that Glycer-AGEs indirectly increased angiogenesis in HCC. The formation of new blood vessels is initiated by hypoxic or ischemic conditions<sup>[36]</sup>. Interestingly, it was reported that HCC cell lines that are resistant to hypoxia displayed higher levels of RAGE expression, and RAGE expression in these cell lines increased under hypoxic conditions<sup>[19]</sup>. These results suggest that Glycer-AGEs-RAGE signaling is increased

**Figure 6** Effect of glycer-aldehyde-derived advanced glycation end-products-treated CM on human umbilical vein endothelial cells angiogenesis. A: The migratory capacity of human umbilical vein endothelial cells (HUVEC) was evaluated using the endothelial cell migration assay. Cells were incubated with CM-bovine serum albumin (BSA) or glycer-aldehyde-derived advanced glycation end-products-treated CM (CM-Glycer-AGEs) for 22 h, and the number of migrating cells was assessed using a fluorescence microplate reader. RFU: relative fluorescence units ( $n = 8$ ); B and C: The tube formation of HUVEC was evaluated using the endothelial cell tube formation assay ( $n = 5$ ). The open and filled bars represent results for cells treated with CM-BSA and CM-Glycer-AGEs, respectively. Data are shown as the mean  $\pm$  SD; <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs CM-BSA.

during the early stages of tumorigenesis, which occurs in hypoxic conditions.

In summary, we have demonstrated that Glycer-AGEs-RAGE signaling enhances the angiogenic potential of HCC cells by upregulating VEGF expression. These results suggest that Glycer-AGEs-RAGE signaling plays a critical role in the progression of HCC, and hence, is a potential target for therapeutic intervention.

## COMMENTS

### Background

Advanced glycation end-products (AGEs) are formed by the Maillard reaction, a non-enzymatic reaction between the ketones or aldehydes of sugars and the amino groups of proteins that contributes to aging and the pathological complications of diabetes. Among the different AGEs, there is evidence that Glycer-AGEs are associated with the complications of diabetes, as well as nonalcoholic steatohepatitis (NASH) and cancer. NASH is a potentially progressive disease that can lead to cirrhosis, liver failure and hepatocellular carcinoma (HCC). In fact, several case series of NASH-associated HCC have been reported. However, the effects of Glycer-AGEs on HCC cells remain poorly understood.

### Research frontiers

Angiogenesis plays a significant role in HCC progression, and vascular endothelial growth factor (VEGF) is one of the most potent angiogenic factors. In this study, the authors examined the effects of Glycer-AGEs on the angiogenesis of HCC cells.

### Innovations and breakthroughs

This study reported the Glycer-AGEs enhanced the angiogenic potential of HCC cells by upregulating VEGF expression.

### Applications

The experimental data can be used in further studies as a potential target for therapeutic intervention.

### Terminology

AGEs: AGEs are formed by the Maillard reaction, a non-enzymatic reaction between the ketones or aldehydes of sugars and the amino groups of proteins that contributes to aging and the pathological complications of diabetes; RAGE: RAGE is a multi-ligand member of the immunoglobulin superfamily of cell surface molecules, and interacts with distinct molecules implicated in homeostasis, development, and inflammation properties; NASH: NASH is a disease having the histopathological findings typical of alcoholic liver disease in patients without a history of significant alcohol abuse; VEGF: VEGF, which is also known as vascular permeability factor, is a specific mitogen to endothelial cells.

### Peer review

The work presented is very interesting, and I am sure further work in the future will extend to clinical studies as a potential target for therapeutic intervention.

### Abstract

**AIM:** To prospectively confirm whether a small amount of polyethylene glycol (PEG) ingested after swallowing endoscopy capsule improves image quality and completion rate.

**METHODS:** Forty-four consecutive patients referred to us for capsule endoscopy (CE) were randomized to two groups. All patients were restricted to clear fluids for 12 h before the examination. Patients in group A (22 cases) received no additional preparation, while those in group B (20 cases) ingested 500 mL of PEG within a 2 h period starting 30 min after swallowing the capsule. Clear fluids and meals were allowed 2 h and 4 h after capsule ingestion, respectively. Image quality was assessed as the percentage of visualized bowel surface area as follows: 1: < 25%; 2: 25%-49%; 3: 50%-74%; 4: 75%-89%; 5: > 90%. The small bowel record was divided into five segments by time, and the score for each segment was evaluated. All CE examinations were performed with the Pillcam SB capsule endoscopy sys-

tem (Given Imaging Co. Ltd., Yoqnem).

**RESULTS:** This study ended in December 2009, because sample size was considered large enough. A total of 44 patients were enrolled. Two patients in group B were excluded from the analysis because small bowel images could not be obtained from these patients; one had a full stomach, while the other presented with a massive gastric bleed. Thus, 22 patients from group A and 20 patients from group B completed the study. There was no significant difference in age ( $P = 0.22$ ), sex ( $P = 0.31$ ), and indication for CE. No significant adverse events occurred in any of the study patients. In group A, image quality deteriorated as the capsule progressed distally. However, in group B, image quality was maintained to the distal small bowel. In each of the five segments, the visibility score was significantly higher in group B than in group A (segment 1:  $4.3 \pm 0.7$  vs  $4.7 \pm 0.5$ ;  $P = 0.03$ , segment 2:  $4.2 \pm 0.9$  vs  $4.8 \pm 0.4$ ;  $P = 0.01$ , segment 3:  $4.0 \pm 1.0$  vs  $4.6 \pm 0.7$ ;  $P = 0.04$ , segment 4:  $3.6 \pm 1.1$  vs  $4.5 \pm 0.6$ ;  $P = 0.003$ , segment 5:  $2.7 \pm 1.0$  vs  $4.4 \pm 0.8$ ;  $P = 0.00004$ ). Thus, the use of PEG during CE examination significantly improved image quality in all time segments, and this effect was more pronounced in the distal ileum. The completion rate to the cecum was not significantly different between groups A and B (81.8% vs 85.0%;  $P = 0.89$ ). There was no difference in the gastric transit time between groups ( $36.2 \pm 35.0$  min vs  $54.0 \pm 56.6$  min;  $P = 0.23$ ), but the small bowel transit time was significantly longer in group A than in group B ( $246.0 \pm 107.0$  min vs  $171.0 \pm 104.0$  min;  $P = 0.04$ ).

**CONCLUSION:** The ingestion of a small amount of PEG after the swallowing of an endoscopy capsule significantly improved CE image quality, but did not enhance the completion rate to the cecum.

## INTRODUCTION

Capsule endoscopy (CE) is the first-line procedure to explore small bowel pathology<sup>[1-4]</sup>. The preparation for CE suggested by the manufacturers of CE systems consists only of a clear liquid diet and an 8 h fast. Preparing the bowel with simethicone has been reported to bring about significantly better visibility by reducing intraluminal bubbles<sup>[5,6]</sup>. The diagnostic yield of CE, however, can be limited due to reduced visibility of the mucosal surface caused by residual material or dark colored bile, especially in the distal small bowel. In addition, CE sometimes fails to reach the cecum within the battery life of the capsule, resulting in a failure to visualize the distal small intestine<sup>[7]</sup>. It has been suggested that ingesting a small amount of polyethylene glycol (PEG) after the ingestion of the capsule may improve both the quality of the CE images and the likelihood that the cecum will be visualized before the capsule's battery life ends (completion rate to the cecum)<sup>[8,9]</sup>. This study aimed to prospectively confirm whether a small amount of PEG solution ingested after the swallowing of the endoscopy capsule improves CE image quality and the completion rate to the cecum.

## MATERIALS AND METHODS

This study was a single-center, prospective, single-blind, parallel, randomized controlled trial that was approved by the ethical committee at Kanto Medical Center NTT EC. This study was registered on February 9, 2009 in the UMIN-Clinical Trials Registry with a test ID of UMIN 000001696 (<https://upload.umin.ac.jp/cgi-bin/ctr/ctr.cgi?function=brows&action=brows&type=detail&receptno=R000002039&admin=0&language=J>) and was carried out in our hospital during a period from March 2009 to December 2009. Written informed consent was obtained from all patients, and the study was carried out in accordance with the Declaration of Helsinki (1989). There was no funding or other support for this study.

Patients referred to our institution for CE during the aforementioned period were prospectively randomized by the envelope method to group A or B. Randomization was done by means of sealed opaque envelopes.

Envelopes were provided by the study coordinator at our institute. Gastroenterologists enrolled the participants, and an assistant at the Endoscopy Center of our institute assigned patients to group A or B by the envelope method. All patients were restricted to clear fluids for 12 h before the examination, ingested 80 mg of simethicone at the time of capsule ingestion, and were then placed in the right lateral position for an hour. Patients in group A received no further preparation, but 30 min after swallowing the endoscopy capsule, the patients in group B ingested 500 mL of a PEG solution within a 2 h period. Clear fluids and meals were allowed 2 h and 4 h after capsule ingestion, respectively. After that, patients were free to leave the hospital, with instructions to return at the end of the 8 h study period to have the data recorder removed. All CE examinations were performed with the Pillcam SB capsule endoscopy system (Given Imaging Co. Ltd., Yoqnem). A single experienced reviewer blinded to the preparation analyzed each capsule study using Rapid Reader 5 software (Given Imaging Co. Ltd.). The primary outcome measures of the study were CE image quality and completion rate to the cecum, while the secondary outcome measures were gastric transit time (GTT) and small bowel transit time (SBTT). The image quality was evaluated only in cases in which the capsule reached the cecum within the examination period. The visibility of the mucosal surface was assessed as the percentage of visualized bowel surface area as follows: 1: < 25%; 2: 25%-49%; 3: 50%-74%; 4: 75%-89%; 5: > 90% (8). The small bowel record was divided into five segments by time, and the score for each segment was evaluated. The completion rate to the cecum was assessed based on the CE images.

Based on the preliminary examination, the sample size was determined based on the number of subjects needed to detect a 15% change in the mean visualization score and a 30% change in the mean transit time between the two groups at  $P$  (alpha) = 0.05 and power = 0.70. Interpretation of significance was adjusted for multiple comparisons by the Bonferroni's method. Parametric data were expressed as mean  $\pm$  SD. The Students' two-sided  $t$ -test was used to compare parametric data between the groups. Nonparametric data were expressed as frequencies and were compared between the groups with the  $\chi^2$  test. A  $P$  value of less than 0.05 was regarded as statistically significant in all tests. Patients in group B were excluded from the analysis because small bowel images could not be obtained from these patients; one had a full stomach, while the other presented with a massive gastric bleed. Thus, 22 patients from Group A and 20 patients from group B completed the study. The demographic data of the 2 groups, as well as the indication for each CE, are shown in Table 1. There was no significant difference in age ( $P = 0.22$ ), sex ( $P = 0.31$ ), and indication for CE. No significant adverse events occurred in any of the study patients. In group A, the image quality deteriorated as the capsule progressed distally. However, in group B, image quality was maintained to the distal small bowel (Figure 1). In each of the 5 segments, the visibility

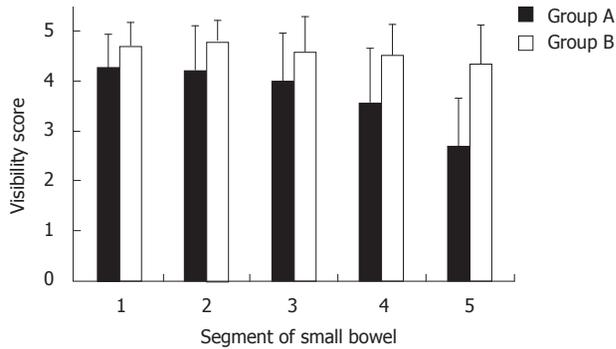

Figure 1 Visualization scores of groups A and B.

score was significantly higher in group B than in group A (segment 1:  $4.3 \pm 0.7$  vs  $4.7 \pm 0.5$ ;  $P = 0.03$ , segment 2:  $4.2 \pm 0.9$  vs  $4.8 \pm 0.4$ ;  $P = 0.01$ , segment 3:  $4.0 \pm 1.0$  vs  $4.6 \pm 0.7$ ;  $P = 0.04$ , segment 4:  $3.6 \pm 1.1$  vs  $4.5 \pm 0.6$ ;  $P = 0.003$ , segment 5:  $2.7 \pm 1.0$  vs  $4.4 \pm 0.8$ ;  $P = 0.00004$ ). The completion rate to the cecum was not significantly different between groups A and B (81.8% vs 85.0%;  $P = 0.89$ ) (Table 2). There was no difference in the GTT between groups ( $36.2 \pm 35.0$  min vs  $54.0 \pm 56.6$  min;  $P = 0.23$ ), but the SBTT was significantly longer in group A than in group B ( $246 \pm 107$  min vs  $171 \pm 104$  min;  $P = 0.04$ ).

## DISCUSSION

Some studies have suggested that bowel preparation that utilizes large amounts of purgatives can lead to higher quality CE images and/or accelerate the gastrointestinal transit of the CE<sup>[10-15]</sup>. On the other hand, others have failed to demonstrate image quality improvement in studies utilizing a large amount of purgatives in the bowel preparation<sup>[16-20]</sup>. All of these studies examined the effects of bowel preparation given prior to CE. In the present study, we examined the effects of PEG on CE image quality and completion rate to the cecum when PEG is given during, not before, the CE procedure. One great advantage of CE is its extreme non-invasiveness. However, it is a considerable burden for patients to have to take the large amount of purgatives needed as preparation for CE. Thus, we previously tried to see whether a small amount of PEG given during the CE procedure could improve the CE image quality and completion rate. In that retrospective study, we suggested that such an enhancement may improve both CE image quality and cecal completion rate<sup>[8]</sup>. The present study was undertaken to confirm those effects in a prospective randomized controlled study. PEG passes smoothly through the intestine. As such, it is assumed to move much faster through the intestine than an endoscopy capsule. Therefore, if PEG is given before capsule ingestion, it may well be completely cleared from an area of the intestine by the time the endoscopy capsule reaches that area. Thus, we administered the solution after capsule ingestion. In addition, PEG is completely transparent. As such, the clarity of a view through PEG was thought to be superior to

that of a view through natural intestinal fluid. The PEG solution was given starting 30 min after the swallowing of the capsule because the median pylorus passing time of an endoscopic capsule is approximately 20 min in our department (data not shown).

The present study confirmed that a small amount of PEG given after endoscopy capsule ingestion significantly improves image quality, especially in the lower segments of the small intestine. As CE imaging is disturbed by residual material or dark colored bile, especially in the distal small bowel, we feel that the image enhancing effect of this intervention is of significant worth. Furthermore, this procedure causes almost no discomfort to patients.

In regards to the completion rate to the cecum, conflicting results have been reported. Some have suggested that purgatives have completion enhancing effects<sup>[10,11]</sup> while others have failed to show such an effect<sup>[12,16,18,19]</sup>. Our previous retrospective study described above suggested that a small amount of PEG given after capsule ingestion may improve the cecal completion rate of CE<sup>[8]</sup>, but the present prospective single blinded randomized study failed to confirm that effect. However, the present study did show that the SBTT is shortened by this enhancement. Therefore, the administration of an additional intervention that can shorten the GTT in conjunction with a small amount of PEG given after capsule ingestion may be useful in improving completion rate. One intriguing possibility for such an intervention would be prokinetics, as they have been suggested to shorten the GTT and improve completion rate to the cecum<sup>[21-25]</sup>.

In conclusion, we show that as little as 500 mL of a PEG solution given after the swallowing of an endoscopy capsule can significantly improve the quality of the CE images in a prospective randomized study. Therefore, we recommend the ingestion of a small amount of PEG after the swallowing of the capsule as a standard enhancement of CE.

## COMMENTS

### Background

Capsule endoscopy (CE) is the first-line procedure to explore small bowel pathology. The preparation for CE suggested by the manufacturers of CE systems consists only of a clear liquid diet and an 8 h fast. Preparing the bowel with simethicone has been reported to bring about significantly better visibility by reducing intraluminal bubbles. The diagnostic yield of CE, however, can be limited due to reduced visibility of the mucosal surface caused by residual material or dark colored bile, especially in the distal small bowel. In addition, CE sometimes fails to reach the cecum within the battery life of the capsule, resulting in a failure to visualize the distal small intestine.

### Research frontiers

It has been suggested that ingesting a small amount of polyethylene glycol (PEG) after the ingestion of the capsule may improve both the quality of the CE images and the likelihood that the cecum will be visualized before the capsule's battery life ends (completion rate to the cecum). This study aimed to prospectively confirm whether a small amount of PEG solution ingested after the swallowing of the endoscopy capsule improves CE image quality and the completion rate to the cecum.

### Innovations and breakthroughs

In the present study, the beneficial effects of a small amount of PEG solution on CE image quality were demonstrated in a prospective single-blinded random-

ized controlled study. In the study group without preparation, the image quality deteriorated as the capsule progressed distally. However, in the group that took 500 mL of PEG solution after capsule ingestion, image quality was maintained to the distal small bowel.

### Applications

Ingestion of as little as 500 mL of PEG solution brings about an excellent clarity in CE images without any discomfort. This study prospectively confirmed the suggested beneficial effect of PEG solution on CE images, and can provide evidence for an effective, safe, cost-effective and minimally invasive preparation of capsule endoscopy in clinical practice.

### Peer review

Here is an interesting single-blinded prospective randomized controlled study regarding the effects of PEG on capsule endoscopy image quality and completion rate to the cecum when PEG is given during, and not before, the capsule endoscopy procedure. Data on this topic is limited and therefore the study is welcome. What is more, the study has an excellent methodology and the results are really interesting.

### Abstract

**AIM:** To correlate cyclo-oxygenase-2 (COX-2) expression profile with clinical and pathological variables to assess their prognostic/predictive value in colorectal carcinoma (CRC).

**METHODS:** Archival tumor samples were analyzed using immunohistochemistry for COX-2 expression in 94 patients with CRC. Patients were diagnosed and treated

at the Departments of Surgery and Oncology, King Abdulaziz University Hospital, Saudi Arabia.

**RESULTS:** Fifty-six percent of the tumors showed positive cytoplasmic COX-2 expression, whereas 44% of cases were completely COX-2-negative. There were no significant correlations between COX-2 expression and sex, age, grade or tumor location. However, COX-2 expression revealed a significant correlation with tumor stage ( $P = 0.01$ ) and distant metastasis ( $P = 0.02$ ), and a borderline association with lymph node involvement ( $P = 0.07$ ). Tumors with high COX-2 expression showed a higher recurrence rate than tumors with no expression ( $P < 0.009$ ). In univariate Kaplan-Meier survival analysis, there was a significant ( $P = 0.026$ ) difference in disease-free survival between COX-2-positive and negative tumors in favor of the latter. COX-2 expression did not significantly predict disease-specific survival, which was much shorter for COX-2-positive tumors. In multivariate (COX) models, COX-2 did not appear among the independent predictors of disease-free survival or disease-specific survival.

**CONCLUSION:** COX-2 expression seems to provide useful prognostic information in CRC, while predicting the patients at high risk for recurrent disease.

## INTRODUCTION

Numerous epidemiological and clinical studies have shown that non-steroidal anti-inflammatory drugs (NSAIDs) can reduce the number and size of adenomas in patients with familial adenomatous polyposis and decrease the incidence of colorectal cancer (CRC)<sup>[1,2]</sup>. Recent studies have shown that regular use of aspirin after the diagnosis of CRC is associated with a lower risk of mortality, particularly when the tumors overexpress cyclooxygenase-2 (COX-2)<sup>[3,4]</sup>. It is suggested that this effect is mediated through inhibition of COX-2, an enzyme involved in prostaglandin metabolism, inflammation and carcinogenesis<sup>[4,5]</sup>. Elevated levels of COX-2 have been detected in 85%-95% of CRC samples, and in 40%-50% of adenomas, and elevated mRNA levels of COX-2 in 86% of CRC and 43% of adenomas, in contrast to no or weak expression of COX-2 protein or mRNA in normal colorectal mucosa<sup>[6,7]</sup>. There is some recent evidence that COX-2 is related to apoptosis inhibition, induction of Bcl-2 expression, as well as stimulation of angiogenesis<sup>[8-10]</sup>. However, the role of COX-2 in colorectal carcinogenesis remains unclear.

Increased COX-2 expression has been reported in several human malignancies including uterine cervix<sup>[11]</sup>, non-small cell lung carcinoma<sup>[12]</sup>, prostate<sup>[13]</sup>, stomach<sup>[9]</sup> and breast cancer<sup>[14]</sup>, as well as in nonepithelial tumors such as gastrointestinal stromal tumors<sup>[15]</sup> and Hodgkin's lymphoma<sup>[16]</sup>. The aim of the present study was to explore the relationship between COX-2 expression profile and clinicopathological features of CRC as well as its value as a predictor of disease outcome.

## MATERIALS AND METHODS

The material of the present study consists of a series of 94 CRC specimens, retrospectively collected from the archives of Anatomical Pathology Laboratory in King Abdulaziz University, Jeddah, Saudi Arabia, covering the period from January 2005 to December 2009. Serial sections were cut from paraffin blocks, stained with hematoxylin and eosin for routine histological examination, classification, grading and staging following the American Joint Committee on Cancer staging system<sup>[17]</sup>. The pertinent clinicopathological data (sex, age, stage, grade and lymph node status), and follow-up results were retrieved from the patients' records after obtaining the relevant ethical approval (Table 1). The mean age of the patients was 58 years (median: 59 years, range: 24-90 years).

### Immunohistochemical procedures

Four-micrometer-thick tissue sections were cut from the paraffin blocks (containing both tumor and benign tissues), mounted on charged poly-L-lysine-coated slides,

LN: Lymph node; COX-2: Cyclooxygenase-2.

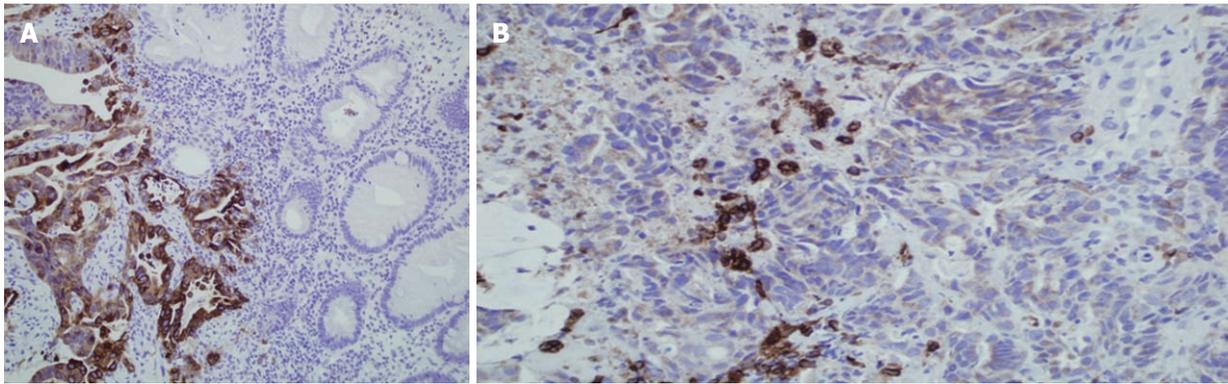

and subjected to immunohistochemistry using the Avidin Biotin detection system, following the manufacturer's instructions. The antibody used was a mouse anti-human COX-2 monoclonal antibody (Dako Cytomation Norden A/S, Glostrup, Denmark; dilution 1:50). Immunohistochemistry was carried out by an automatic immunostainer (Ventana Bench Mark XT; Ventana Inc., Tucson, AZ, United States). In each analysis, positive controls were used consisting of CRC samples previously shown to stain with this antibody. Tris-buffered saline in place of the primary antibody was used as a negative control.

### Interpretation of immunohistochemical staining

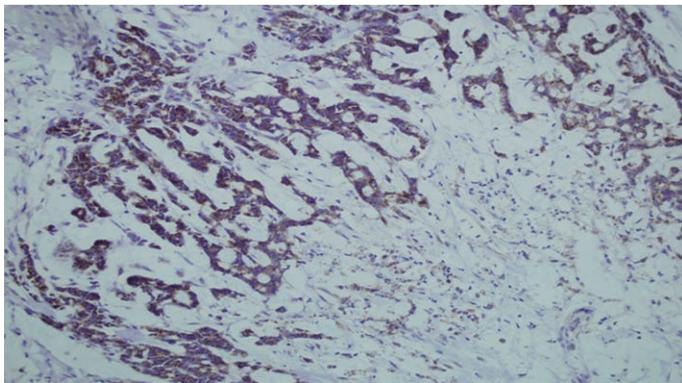

Cells were considered positive for COX-2 when distinct cytoplasmic yellow to brown staining was identified. The extent and intensity of the staining were recorded on a scale from 0 to +++; +++ implied strong staining that was maximally intense throughout the specimen, and 0 implied negative staining. When dichotomized for statistical risk assessment [odds ratio (OR) calculation], negative (-) and weak (+) staining were defined as low expression, whereas moderate (++) and intense (+++) staining were included in the high expression category.

### Statistical analysis

Statistical analyses were performed using SPSS (IBM, New York, NY, United States) and Stata (Stata Corp., College Station, TX, United States) software (PASW Sta-

**Figure 1 Cyclooxygenase-2 expression.** A: Strong diffuse brown cytoplasmic cyclooxygenase-2 (COX-2) expression in colorectal adenocarcinoma cells, in contrast to negative expression in normal colonic cells; B: Negative COX-2 expression in poorly differentiated colorectal adenocarcinoma. Note the positive expression of stromal inflammatory cells.

istics for Windows, version 18.0.2 and STATA/SE version 11.1). Frequency tables were analyzed using the  $\chi^2$  test, with likelihood ratio or Fischer's exact test to assess the significance of the correlation between the categorical variables. OR and 95% confidence interval (CI) were calculated when appropriate, using the exact method. Differences in the means of continuous variables were analyzed using nonparametric tests (Mann-Whitney or Kruskal-Wallis) for two and multiple independent samples, respectively. Analysis of variance was only used to derive the mean values (and 95% CI) of each individual stratum. Univariate survival analysis for the outcome measure [disease-specific survival (DSS) and disease-free survival (DFS)] was based on the Kaplan-Meier method, with log-rank (Mantel-Cox) comparison test. To assess the value of COX-2 as an independent predictor, multivariate survival analysis was performed, using the Cox proportional hazards regression model, controlling for the confounding by the following variables: age, sex, tumor localization, tumor stage, grade, (for DFS), and recurrence as additional variable for DSS. In all tests,  $P < 0.05$  was regarded as statistically significant.

## RESULTS

### **Cyclo-oxygenase-2 expression profiles**

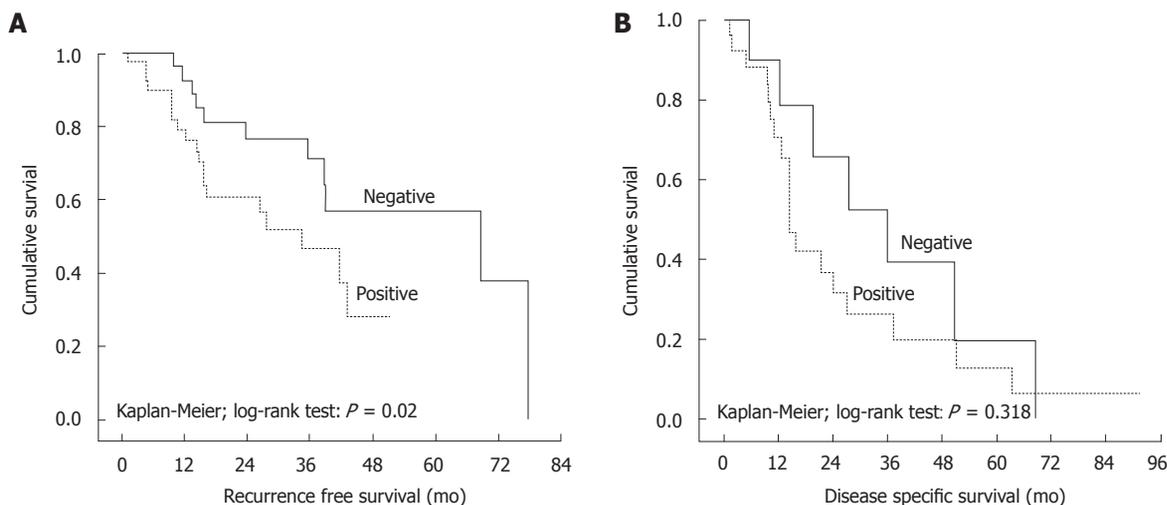

Normal colorectal mucosa showed no or weak COX-2

expression, but weak cytoplasmic expression was detected in a few inflammatory mononuclear cells (Figure 1). In cancer cells, COX-2 expression appeared as yellow-brown staining and was observed mainly in the cytoplasm and occasionally in the nuclear envelope (Figures 1 and 2). Expression was high in 53 (56%) cases, and low in 41 cases (44%).

### **Correlation of cyclo-oxygenase-2 expression with the clinicopathological features**

The associations between COX-2 expression and clinicopathological features are presented in Table 1. Sex, age, grade, or tumor location had no significant relationship with the expression of COX-2. However, the tumor stage and distant metastasis were significantly associated with COX-2 expression, with higher expression being more common in advanced tumors ( $P < 0.01$ ), and fewer distant metastases being found in tumors with negative expression ( $P < 0.02$ ). Of particular interest was the borderline association between lymph node (LN) involvement and expression of COX-2 ( $P < 0.07$ ); 63% of the tumors with LN involvement tested positive for COX-2, whereas only 37% of the cases with no COX-2 expression had LN involvement.

Similarly, COX-2 expression showed a clear association with DFS in that the patients who developed early recurrence (22 mo) had positive COX-2 expression, in

**Figure 3** Impact of cyclooxygenase-2 expression on survival in univariate (Kaplan-Meier) analysis. A: Disease-free survival ( $P = 0.026$ ); B: Disease-specific survival ( $P = 0.318$ ).

contrast to those with no expression of COX-2 who developed recurrence much later (32 mo) ( $P = 0.009$ ). The same trend was observed in DSS time, with patients with COX-2 negative tumors living significantly longer ( $P = 0.009$ ).

In Kaplan-Meier survival analysis, there was a significant ( $P = 0.02$ ) difference in DFS between patients with COX-2-negative tumors (longer DFS) and those with COX-2-positive tumors (Figure 3A). As to DSS, COX-2 did not show any predictive power in Kaplan-Meier analysis ( $P = 0.32$ ) (Figure 3B).

To assess the value of COX-2 as an independent predictor, a multivariate survival analysis was done, using the Cox proportional hazards regression model controlling for confounding by the following covariates: age, sex, tumor localization, T, grade, (for DFS), and recurrence as additional variable for DSS. In the final multivariate model, only tumor grade ( $P = 0.023$ ) and tumor stage ( $P = 0.0001$ ) remained significant predictors of DFS, decreasing with progressing dedifferentiation and increasing stage, as expected. In a similar model for DSS (including recurrence as a covariate), none of the included covariates were independent predictors of DSS.

## DISCUSSION

The aims of the present study were to cast further light on the issues related to prognostication of CRC, and assess the value of COX-2 expression profiles as predictive and prognostic markers. We focused on stage II-IV disease, in which molecular and other markers may help to pinpoint a subgroup of patients who would eventually benefit from the use of adjuvant therapy. This important therapeutic decision involves a careful weighing of the risks of drug toxicity and complications against the potential curability of the disease<sup>[18]</sup>. It is well established that early CRCs can be cured with radical surgical resection alone<sup>[19]</sup>. Unfortunately, however, some 30% of all patients who undergo curative resection subsequently

present with relapse and eventually die of their disease<sup>[20]</sup>. Prediction of disease outcome in individual patients after curative resection is still far from reliable<sup>[21]</sup>. However, there is some hope for improvement, and in fact, our results suggest that COX-2 expression assessed by immunohistochemistry might be helpful in this respect. In addition, more rational decisions can be done as soon as we learn more of the markers and other diagnostic tools for accurate prediction of disease outcome in individual patients<sup>[22,23]</sup>.

On the basis of the present results, we do believe that this detection can be improved using the assessment of COX-2 expression in the primary tumors. In this assessment, quantifying the COX-2 expression seems to be important. We compared different methods of grading this expression, and found the dichotomized negative/positive grading to provide the most consistent and meaningful correlations to the clinicopathological variables and outcome. This leads us to suggest that classifying CRCs as COX-2 positive/negative is the clinically most relevant approach.

In our series, 56% of the primary CRCs expressed COX-2, whereas the results in previous studies have shown that COX-2 was expressed in 85%-95% of CRCs<sup>[6,7]</sup>. This implies its important role in cancer progression. The discrepancy of these observations might be explained by differences in the technical aspects of recording COX-2 expression or by differences of interpretation of expression profiling. The possibility that these discrepancies may have a genetic basis is one favored hypothesis. However, the markedly different expression of COX-2 in normal and cancer tissues substantiates the view that paracrine effects in the crosstalk between normal and cancer cells are likely to be involved in the upregulation of COX-2 in the tumor tissue.

In the present cohort, several potentially important observations were made, all implying that the quantitatively measurable COX-2 expression in tumor cells could

provide significant prognostic information in CRC. First, positive expression of COX-2 was more common among advanced stage tumors than in early stage tumors. This is in agreement with a study by Lim *et al.*<sup>[24]</sup> who showed that COX-2 expression was correlated with the depth of invasion and advanced tumor stage. Similarly, we observed a significant correlation between COX-2 expression and distant metastasis, and tumors with more COX-2 expression revealed more distant metastasis than did those with no expression. This observation also substantiates the data of Tomozawa *et al.*<sup>[25]</sup>, who have reported that COX-2 overexpression was significantly associated with tumor recurrence, and especially with hematogenous metastasis. In contrast to these results, however, the study by Fujita *et al.*<sup>[26]</sup> failed to establish any correlation between COX-2 overexpression and metastasis.

A trend with borderline significance was observed between COX-2 and LN involvement; 63% of the tumors with LN involvement showed positive expression of COX-2, whereas only 37% of the cases not expressing COX-2 had LN involvement. Xiong *et al.*<sup>[27]</sup> have reported that among 45 cases of CRC with LN metastasis, COX-2 detection rate was 87% in the primary tumors, whereas diffuse cytoplasmic COX-2 staining in the cancer cells was detected in 100% of the LN metastatic lesions. The preferential expression of COX-2 in LN metastases is consistent with the view of clonal selection of tumor cells with COX-2 expression, conferring upon them a growth advantage with a higher potential of metastasis. This could be how COX-2 expression is related to progression of CRC. Altogether, these observations implicate COX-2 as a biological factor that might affect the behavior of tumor cell populations. Some studies have shown that higher expression of COX-2 is found in benign breast tissue adjacent to breast carcinoma<sup>[28]</sup>.

Obviously, one of the most important observations of the present study is that linking COX-2 expression with disease outcome, that is, disease recurrence and length of DFS. This is clinically relevant for several reasons. Some CRC patients at different stages are at high risk of recurrence, thus, it is of paramount importance to develop reliable markers that accurately predict those patients so that they may be considered for adjuvant therapy. In the present series, 37% of the patients eventually developed a recurrent disease within the median follow-up time of 15.6 mo (mean, 22 mo; range: 15.8-28.2 mo). This is a substantially high rate, particularly for a group of LN-negative (stage II) CRC patients. Importantly, our data showed that the patients who developed an early recurrence (mean DFS of 22 mo) had positive COX-2 expression, in contrast to patients with negative expression, who developed recurrence with a significantly longer delay (mean DFS of 32 mo).

As shown in Figure 3, at 5 years follow-up, only 40% of the patients with negative COX-2 expression had recurrence, as compared to 85% of those with COX-2-expressing tumors. This is in agreement with the study by Wan *et al.*<sup>[29]</sup>, who showed that the recurrence and metastasis rates were significantly higher in COX-2-posi-

tive patients than in their negative counterparts. Similarly, Tomozawa *et al.*<sup>[25]</sup> also have found that COX-2 overexpression was correlated with disease recurrence and hematogenous metastasis, with DFS time being significantly shorter for patients with high expression of COX-2 compared with low expression. Furthermore, COX-2 was the only independent predictor of survival time when adjusted for other prognostic factors, including age, histological type, and tumor size and stage. Therefore, COX-2 overexpression is considered to be correlated with recurrence and metastasis of CRC. Tsujii *et al.*<sup>[30]</sup> also have found that metastatic potential increases with COX-2 overexpression. These important results suggest that selective COX-2 inhibitors might be useful chemopreventive agents, not only in growth of the primary tumor but also for prevention of hematogenous metastasis of CRC. When adjusted for other potential predictors in multivariate Cox regression model, COX-2 expression lost its value as a significant independent predictor of DFS.

As to DSS, COX-2 expression was shown to be high (positive) more often among patients who eventually died of their disease as compared with those staying alive at the completion of the follow-up, although the difference was not significant ( $P = 0.30$ ). However, the difference in DSS time between COX-2-positive and -negative tumors was significant ( $P = 0.009$ ); being shorter for the former. However, this difference did not appear significant in univariate (Kaplan-Meier) or multivariate (Cox) survival analysis. These observations suggest that CRC tumors with positive COX-2 expression are at high risk for local or distant recurrence and, because of the strong adverse impact of the latter on survival (i.e., none of the patients without recurrence died of disease in our cohort), these patients are also more likely to eventually die of their disease. These patients should be appropriate candidates for close and frequent postoperative follow-up and eventual adjuvant therapy.

Taken together, COX-2 expression did not correlate with sex, age or tumor grade, as confirmed by other studies<sup>[27,31]</sup>. However, COX-2 expression showed significant associations with tumor stage and metastasis. Furthermore, positive COX-2 staining was related to a higher recurrence rate as compared to COX-2-negative tumors, suggesting a link towards development of a metastatic phenotype. Finally, positive COX-2 expression was associated with shorter DSS, as compared with COX-2-negative CRCs, implying some differences in the inherent malignancy of CRC that become manifest after a reasonable follow-up period. To elucidate this fully, however, we would need a larger cohort and a substantially longer follow-up time to provide the basis for clinical trials that evaluate the contribution of COX-2 inhibitors in therapy and prevention of CRC.

## COMMENTS

**Background**

Phospholipase A2 (PLA2) is a key regulatory enzyme in arachidonic acid metabolism, which leads to synthesis of prostaglandins via the cyclo-oxygenase (COX)-1 and COX-2 pathways. Inhibition of COX-2 results in suppression of tumor development and growth, and it has been proposed that prostaglandins may have an important role in tumor growth in colorectal cancer (CRC). Prostaglandin E2 induces *bcl-2* gene expression and inhibits apoptosis in human colorectal cell lines, which may partially explain the COX-2-mediated tumor growth. Thus, in addition to COX, functional defects in PLA2 in tumor cells may interfere with the regulatory mechanisms of tumor growth. Therefore, COX-2 represents a potential molecular target in colorectal management and specific COX-2 inhibitors may be useful as chemopreventive as well as therapeutic agent in humans.

**Research frontiers**

It is mandatory to find new prognostic factors capable of identifying high-risk stage II CRC patients for better targeting of treatment options.

**Innovations and breakthroughs**

COX-2 expression did not correlate with sex, age or tumor grade, as confirmed by other studies. However, COX-2 expression showed significant associations with tumor stage and metastasis. Furthermore, positive COX-2 staining was related to a higher recurrence rate as compared to COX-2-negative tumors, suggesting a link towards development of a metastatic phenotype. Finally, positive COX-2 expression was associated with shorter disease-specific survival, as compared with COX-2-negative CRC, implying some differences in the inherent malignancy of CRC that become manifest after a reasonable follow-up period. To elucidate this fully, however, we would need a larger cohort and a substantially longer follow-up time to provide the basis for clinical trials that evaluate the contribution of COX-2 inhibitors in therapy and prevention of CRC.

**Applications**

Quantification of COX-2 expression seems to provide valuable prognostic information in CRC, particularly in selecting the patients at high risk for recurrent disease who might benefit from adjuvant therapy.

**Peer review**

Although this manuscript makes the point that COX-2 expression can predict disease outcomes in CRC, it is clear that COX-2 expression is not an independent predictor, and in fact, in the multivariate analysis, only tumor grade and stage were independent predictors.

### Abstract

**AIM:** To investigate perception of natural orifice transluminal endoscopic surgery (NOTES) as a potential technique for appendectomy.

**METHODS:** One hundred patients undergoing endoscopy and 100 physicians were given a questionnaire describing in detail the techniques of NOTES and laparoscopic appendectomy. They were asked about the reasons for their preference, choice of orifice, and extent of complication risk they were willing to accept.

**RESULTS:** Fifty patients (50%) and only 21 physicians (21%) preferred NOTES ( $P < 0.001$ ). Patients had previously heard of NOTES less frequently (7% vs

73%,  $P < 0.001$ ) and had undergone endoscopy more frequently (88% vs 36%,  $P < 0.001$ ) than physicians. Absence of hernia was the most common reason for NOTES preference in physicians (80% vs 44%,  $P = 0.003$ ), whereas reduced pain was the most common reason in patients (66% vs 52%). Physicians were more likely to refuse NOTES as a novel and unsure technique ( $P < 0.001$ ) and having an increased risk of infection ( $P < 0.001$ ). The preferred access site in both groups was colon followed by stomach, with vagina being rarely preferred. In multivariable modeling, those with high-school education [odds ratio (OR): 2.68, 95% confidence interval (CI): 1.23-5.83] and prior colonoscopy (OR: 2.10, 95% CI: 1.05-4.19) were more likely to prefer NOTES over laparoscopic appendectomy. There was a steep decline in NOTES preference with increased rate of procedural complications. Male patients were more likely to consent to their wives vaginal NOTES appendectomy than male physicians ( $P = 0.02$ ).

**CONCLUSION:** The preference of NOTES for appendectomy was greater in patients than physicians and was related to reduced pain and absence of hernia rather than lack of scarring.

## INTRODUCTION

Minimally invasive surgery has been challenging traditional open surgery. Laparoscopic surgery is less traumatic than open surgery, and is generally associated with fewer local and systemic complications, less postoperative pain, faster recovery and better cosmesis<sup>[1]</sup>. Natural orifice transluminal endoscopic surgery (NOTES) is a novel technique that takes advantages of natural orifices. It may be even less invasive than traditional laparoscopic surgery because it avoids abdominal incisions<sup>[2]</sup>. To date, a variety of surgical procedures using natural orifices have been performed in animals and humans<sup>[3,4]</sup>.

The advantages of NOTES have not yet been fully confirmed in randomized trials<sup>[4]</sup>, but are expected to include lack of scarring, a less profound systemic response, faster recovery, less pain and absence of hernia. Due to limited maneuverability and lack of efficient and safe closure of NOTES access sites, hybrid procedures involving additional laparoscopic instruments or vaginal access with hand-sutured closures have been used in most human procedures<sup>[5-7]</sup>. The overall complication rates reported in the first human studies have not exceeded those of laparoscopic surgery, but these findings remain to be proven in controlled trials<sup>[7]</sup>. Ultimately, the acceptance of NOTES procedures by both patients and physicians will be crucial in determining whether this new approach will become a part of our routine clinical practice.

Results of the few studies that have addressed the perception of NOTES have been variable. A very high patient preference of almost 80% for NOTES over laparoscopic cholecystectomy has been reported<sup>[8]</sup>. In contrast, the perception of NOTES among surgeons in another survey was receptive overall, but more cautious<sup>[9]</sup>. The aim of our study was to evaluate the perception of NOTES appendectomy among patients and physicians. Furthermore, we aimed to determine reasons for their preference, the preferred access site, and the extent of acceptable complication risk.

## MATERIALS AND METHODS

### Patients and physicians

A group of consecutive patients scheduled to undergo procedures in the endoscopy unit were given a questionnaire by a staff member and asked to complete it anonymously. Physicians in various departments of our hospital (cardiology, cardiac surgery, gastroenterology, general surgery, diabetology, nephrology and radiology) also participated in the study and were given the same questionnaire. One hundred questionnaires were completed by each group and were evaluated. Participation in the study was voluntary. Only subjects with an intact appendix were included. Prior to beginning the study, the questionnaire was evaluated for consistency and clarity in a group of 20 medical students.

### Questionnaire

The first page of the questionnaire described acute ap-

pendicitis and its management in detail. The technique of laparoscopic appendectomy with its benefits and risks was explained. Then, the concept of NOTES was described; stating clearly that it is still an experimental technique with its benefits and risk being only estimated. It was stated that the technique was not available in our hospital and that the response of the patients would in no way influence their further medical management.

This information was followed by a list of 12 questions. Age, sex, educational status, prior awareness of NOTES and prior experience with endoscopy or laparoscopy were queried first. Then, preference between NOTES and laparoscopic appendectomy was determined. Those who preferred laparoscopy were asked for reasons for their preference with options being safety and efficiency of the technique, willingness to tolerate scars and pain, and because NOTES is new, concerns about the technique and risk of infection. The options offered to those preferring NOTES were less pain, absence of scars and hernia, and a new unique technique. Patients who chose NOTES were asked to score their preference for access site (1, 2 or 3, mouth/stomach, anus/colon, vagina in women). Men were also asked if they would object to a vaginal NOTES procedure for their wives. Those who preferred NOTES were asked about their tolerance for procedure-related complications (less, equal to, 1.5 times or two times greater than that of laparoscopic appendectomy), given a complication rate of laparoscopic appendectomy of around 8%.

### Statistical analysis

We hypothesized a 56% preference of NOTES based on evidence available at the time of study design<sup>[10]</sup>. We expected physicians' preference to be 75% of that of patients. Thus, assuming a power of 0.8 and  $\alpha$  of 0.05, 99 patients and physicians needed to be included to show a statistically significant difference.

Data were analyzed for all participants overall and for both groups separately. The between-group differences were compared using a two-sample *t* test for continuous variables and Fisher's exact test for categorical variables. Odds ratio (OR) and 95% confidence interval (CI) were calculated. A two-tailed  $P < 0.05$  was required for statistical significance. To assess the effect of individual factors, multiple logistic regression was used. Analyses were performed using R software for statistical computing<sup>[11]</sup>.

## RESULTS

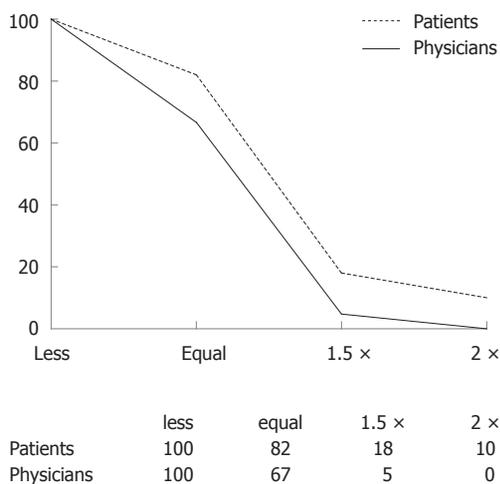

### Patients vs physicians

Questionnaires were obtained from a 100 patients and 100 physicians, and evaluated. Characteristics of the study subjects are summarized in Table 1. Fifty-six patients (56%) and 53 physicians (53%) were male. The mean age of patients was higher than that of physicians (52 years *vs* 41 years, respectively,  $P < 0.001$ ). Previously, 88 patients (88%) had an endoscopy; 67 (67%) had upper gastrointestinal endoscopy and 60 (60%) had colonoscopy. Only 36 phy-

sicians (36%) had a previous endoscopy (*P* < 0.0001); 28 (28%) had upper gastrointestinal endoscopy (*P* < 0.0001) and 14 (14%) had colonoscopy (*P* < 0.0001). There was no statistically significant difference in prior laparoscopy experience (20 patients *vs* nine physicians, *P* > 0.05).

Fifty patients (50%) and only 21 physicians (21%) preferred NOTES over laparoscopic appendectomy (*P* < 0.01). For the patients, the OR for NOTES preference was 1 (95% CI: 0.676-1.480), and none of the queried characteristics influenced the preference for NOTES. For physicians, the OR for NOTES preference was low (OR: 0.152, 95% CI: 0.069-0.337). However, the OR for NOTES preference was significantly higher in female *vs* male physicians (OR: 2.875, 95% CI: 1.044-7.919).

The most common reasons for NOTES preference in patients was absence of pain [33 (66%)], followed by ab-

**Table 2 Association between participant characteristics and natural orifice transluminal endoscopic surgery preference**

	Odds ratio	<i>P</i> value	Confidence interval
Female	1.473	0.259	0.785-2.761
Age	0.985	0.587	0.960-1.011
High school education <sup>1</sup>	2.678	0.003	1.230-5.826

Prior laparoscopy	1.462	0.412	0.584-3.659

<sup>1</sup>University education serving as baseline. NOTES: Natural orifice transluminal endoscopic surgery.

sence of hernia [22 (44%)] and cosmetic issues [15 (30%)]. The most common reasons in physicians were absence of hernia [17 (80%)] followed by cosmetic issues and absence of pain [11 (52%) each]. Absence of hernia was given as a reason for NOTES preference by significantly more physicians than patients (80% *vs* 44%, *P* < 0.001).

In both groups, the most frequently chosen reasons for preference of laparoscopy were proven safety [33 (66%) *vs* 65 (82%)] followed by absence of cosmetic concerns [31 (62%) *vs* 43 (54%)] and proven efficiency [20 (40%) *vs* 43 (54%)]. Physicians were more likely to chose laparoscopy for the reason that NOTES was a novel, unproven technique [33 (42%) *vs* 6 (12%), *P* < 0.0001] and had a greater risk of infection [25 (32%) *vs* 2 (4%), *P* = 0.0001].

The preferred NOTES access site was the colon in both groups [25 (50%) *vs* 12 (57%)], followed by the stomach [19 (38%) *vs* 8 (38%)] with the vagina being rarely preferred [6 (27%) *vs* 1 (7%)]. Forty-two of 49 male patients (86%) but only 29 of 46 male physicians (63%) did not object to vaginal NOTES for their wives (*P* = 0.02). There was a steep decline in NOTES preference with an increased rate of procedural complications in both study groups (Figure 1). When the NOTES complication rate was lower than or equal to that of laparoscopic appendectomy ( $\leq$  8%), it was acceptable for a vast majority of those preferring NOTES. Once the complication rate increased to twofold that of laparoscopy, the NOTES preference rate dropped to 10%.

**Natural orifice transluminal endoscopic surgery vs laparoscopy**

When the study subjects were analyzed based on the overall NOTES preference *vs* laparoscopy, those with a university education [NOTES *vs* laparoscopy, 34 (27%) *vs* 94 (73%), *P* = 0.002], those who had heard of NOTES [20 (25%) *vs* 60 (75%), *P* = 0.02] and those who had not had prior colonoscopy [35 (28%) *vs* 91 (72%), *P* = 0.004] were more likely to prefer laparoscopic over NOTES appendectomy. In multivariable modeling, lower education status (high school) (OR: 2.678, 95% CI: 1.230-5.826) and prior colonoscopy (OR: 2.098, 95% CI: 1.050-4.192) were significantly associated with NOTES preference (Table 2).

## DISCUSSION

NOTES is an experimental surgical approach in which an endoscope is passed through a natural opening (e.g., mouth, anus or vagina) and then through an internal incision in the stomach, colon or vagina. So far, NOTES has been limited primarily to animal procedures. Although a variety of procedures are technically possible in animals and the first laparoscopically assisted procedures have been performed in humans, the efficiency and safety of NOTES as well as its expected benefits, such as less trauma, remain to be shown<sup>[12]</sup>. Wide adoption of NOTES will depend largely on public acceptance.

Public acceptance and demand have previously been shown to play a major role in adoption of a surgical technique. In the 1980s when a totally new technique of gallbladder surgery, laparoscopic cholecystectomy, was introduced, medical professionals expressed little interest in the new approach. The early reports did not even show much benefit of the new concept except for cosmesis<sup>[13]</sup>. However, public demand influenced in part by industry marketing spurred adoption of this minimally invasive technique despite unproven benefits and increased risks. In spite of the early difference in patient and physician perception of laparoscopy, the technique has gained significant importance in abdominal surgery with laparoscopy cholecystectomy now representing a gold standard procedure. In parallel to this interesting phenomenon, we aimed to determine the perception of NOTES among patients and physicians.

Our study results show a discrepancy between patient and physician perception of this new technique. Half the patients questioned would prefer to undergo NOTES appendectomy despite the fact that the vast majority had never heard of the technique before. In contrast, most physicians refused the novel technique in favor of laparoscopic appendectomy. A few differences between the groups may have contributed to this result. First, the medical profession is known for its general skepticism of a new technique with an unproven rate of complications; thus the sensitivity to potential NOTES-associated risks was expected from the physicians<sup>[14]</sup>. Second, the mean age of the patients was older than that of the physicians; however, older age has previously been associated with decreased NOTES preference. Third, a majority of patients had previously undergone an endoscopy, and a previous positive experience with endoscopy may have contributed to their preference for NOTES, being partly an endoscopic technique.

Patients' preference for NOTES in our study was lower than previously reported. Almost 80% of patients preferred NOTES over laparoscopy in a study performed by Varadarajulu *et al.*<sup>[8]</sup> in 2008. The preference decreased to 56% in a study reported in 2009 by Swanstrom *et al.*<sup>[10]</sup>. The observed decline may result from differences in the study design, chosen procedure or questioned populations. It may also reflect an actual trend of NOTES moving out of the public focus.

Physicians' negative perception of NOTES is not

completely new. In a recent study by Volckmann *et al.*<sup>[9]</sup>, surgeons were asked whether they would choose personally to undergo NOTES cholecystectomy. Only 26% of them opted for NOTES over laparoscopy, with most of the surgeons citing that NOTES was too new and was more risky. In another study by Thele *et al.*<sup>[15]</sup>, only 29% of gynecologists would recommend NOTES to their patients even if NOTES presented the same surgical risks as the laparoscopic approach. Interestingly however, female physicians in our study were almost three times more likely to choose NOTES than male physicians. The reason for this finding is unclear.

In patients, decreased postoperative pain was the major determinant for favoring NOTES. In physicians, the major determinant was absence of hernia. Surprisingly, cosmesis was considered important by only a third of patients and half of physicians. However, such a finding is consistent with a survey comparing NOTES and laparoscopy by Strickland *et al.*<sup>[16]</sup>, in which only 44% of women were concerned with scarring after laparoscopy. Even though we did not ask our subjects specifically for reasons for refusing NOTES, those who favored laparoscopic appendectomy most frequently reported proven safety of laparoscopy as their reason. The second most common reason was absence of cosmesis concerns, further supporting the above stated finding of cosmesis being a relatively infrequent reason for choosing NOTES. Thus, the most striking benefit of scarless surgery may not be the most important one for potential patients.

In our study, patients with high-school education and those with prior colonoscopy experience were significantly more likely to choose NOTES over laparoscopic appendectomy. However, this finding resulting from a multivariate analysis of the pooled data needs to be interpreted with caution. Our two groups of subjects differed a priori in their educational status, with all physicians having a university education. Furthermore, the frequency of prior colonoscopy was much lower in the physicians group. Thus, university education and low rate of prior colonoscopy experience were inherent attributes of the physicians group having a low preference for NOTES. Multivariate analysis of the patient group itself did not reveal any characteristics suggestive of NOTES preference.

Interestingly, in both groups, the preferred route of access was the colon, with the vagina preferred by only a minority of women. This finding was surprising given the very unpleasant bowel preparation required for transcolonic NOTES as opposed to transgastric and transvaginal NOTES, and is in contrast with some previously reported results<sup>[8]</sup>. It may be speculated that for some patients, removal of diseased organs may be better tolerated when performed via the anus as compared to the mouth. Another reason might be the high rate of prior colonoscopy experience in our subjects. The reserved attitude of women to transvaginal access is in contrast with previously published data<sup>[17]</sup>, and deserves attention because most of the current procedures are offered via

the transvaginal route due to uncertainty of transgastric or transcolonic closure.

The preference for NOTES decreased dramatically, even in those who preferred it, once the indicated rate of complications increased. This phenomenon was observed in both patients and physicians and has been reported previously by others<sup>[8]</sup>. However, in our study population, the NOTES preference was significantly lower than that reported by Swanstrom *et al*<sup>[10]</sup>. In their study group, almost 20% of patients would have still elected NOTES even if the complication risk was 10 times greater than that of laparoscopy. Only less than 5% of our patients tolerated only twice the risk of laparoscopic appendectomy.

Interestingly, physicians were less willing than patients to consent to their wives vaginal NOTES procedure. This finding may be explained in part by the negative perception of NOTES itself by physicians as well as their better awareness of the possible complications associated with transvaginal procedures such as dyspareunia, infection and infertility.

Several limitations of our study should be noted. Only patients undergoing an endoscopic procedure were questioned. Such a study population may not accurately represent the general public. Next, our patients were asked about their perception of NOTES appendectomy. Acceptance of NOTES may be disease related and may thus be different for another procedure. Furthermore, our patients did not suffer from complaints of acute appendicitis and their decision was being made only based on description of the disease. They may also have been biased in favor of NOTES due to attending an endoscopy clinic as opposed to a surgical clinic. Finally, only a theoretical description of the benefits and risks was provided, which may change as more data are available.

In conclusion, the survey results show that there is considerable public interest in a new and experimental technique of transluminal surgery. In contrast, physicians would be reluctant to undergo NOTES. Decreased pain and absence of hernia were the most frequently reported reasons for choosing NOTES in patients and physicians, with cosmesis being of minor importance. Physicians were much more concerned than patients about the risk of infection. The study indicates that NOTES should be seriously considered as a potential technique with considerable public demand. However, it also highlights the importance of further development of the technique and outcomes data reporting to enlighten physicians about NOTES.

## COMMENTS

### Background

Natural orifice transluminal endoscopic surgery (NOTES) is a novel surgical technique that takes advantages of natural orifices. It may be even less invasive than traditional laparoscopic surgery because it avoids abdominal incisions.

### Research frontiers

Wide adoption of NOTES will depend largely on public acceptance. Results of the few studies that have addressed perception of NOTES have been variable.

### Innovations and breakthroughs

The study shows that there is a considerable public interest for NOTES, even though it has declined over time. Physicians remain reluctant to undergo transluminal surgery.

### Applications

The study indicates that NOTES should be seriously considered as a potential technique, with considerable public demand. However, further development is needed to convince physicians about the potential benefits of NOTES.

### Terminology

NOTES is a minimally invasive surgical technique that eliminates abdominal incision. Flexible endoscopes are used to create a transvisceral opening via natural orifice access to enter the peritoneal cavity.

### Peer review

This is a survey evaluating the acceptance of NOTES among patients and physicians. The authors found considerable acceptance, which at some points contrasts with previous studies, and is important to report.

### Abstract

**AIM:** To investigate the association of Rab27A and Rab27B expression with clinicopathological characteristics and prognosis of hepatocellular carcinoma (HCC).

**METHODS:** We used reverse transcription polymerase chain reaction (RT-PCR), real-time PCR, and western blotting to detect Rab27A and Rab27B mRNA and protein expression in 5 human HCC lines and the immortalized hepatic HL-7702 cell line. We further examined 148 primary HCC samples matched with adjacent normal tissue and 80 non-HCC specimens by immunohistochemistry to evaluate the correlation of Rab27A and Rab27B expression with clinicopathological features and prognosis.

**RESULTS:** Our data showed that Rab27A and Rab27B

were differentially expressed in cell lines and primary HCC tumors. Rab27A mRNA and protein were detected in 67% (4/6) of human cell lines and 80% (4/5) of HCC cell lines, while Rab27B was found in 50% (3/6) of human lines and 40% (2/5) of HCC lines. Rab27A expression was higher in primary HCC (46.2%, 66/143) than in matched adjacent tissue (24.3%, 33/136;  $P < 0.001$ ), whereas immunopositivity for Rab27B was lower in primary HCC (57.4%, 81/141) than in matched adjacent tissue (87.5%, 119/136;  $P < 0.001$ ). Analysis of clinicopathological characteristics of 148 HCC specimens revealed significant correlations between Rab27A and Rab27B expression and tumor tumor-node-metastasis (TNM) classification ( $P = 0.046$  and  $P = 0.027$ , respectively), and between strong Rab27A expression and tumor differentiation grade ( $P = 0.008$ ). Survival analyses revealed that patients with Rab27A<sup>+</sup> or Rab27B<sup>+</sup> tumors had significantly reduced overall survival compared with that of patients with Rab27A<sup>-</sup> or Rab27B<sup>-</sup> tumors ( $P = 0.015$  and  $P = 0.005$ , respectively). Risk analyses revealed that Rab27B<sup>+</sup> and TNM III-IV were independent poor prognosis factors associated with a 3.36- and 3.37-fold higher relative risk of death, respectively.

**CONCLUSION:** Rab27A and Rab27B expression were closely correlated with tumor progression and can be valuable prognostic indicators for HCC patients.

Xiao WH, Dong WW, Mou Q, Chen J, Cui JT, Li WM. Differential expression of Rab27A/B correlates with clinical out-

come in hepatocellular carcinoma. *World J Gastroenterol* 2012; 18(15): 1806-1813 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i15/1806.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i15.1806>

## INTRODUCTION

Primary hepatocellular carcinoma (HCC) is one of the top 10 most frequent tumor types globally, carrying a high mortality rate and accounting for more than 1 million deaths annually<sup>[1]</sup>. The identification of novel biomarkers correlating with HCC progression is critical in order to optimize treatment strategies. A large body of evidence indicates that vesicle trafficking and exocytosis are important in tumorigenesis, with many reports implicating the Rab family of proteins<sup>[2-4]</sup>. Rabs are a ubiquitously expressed family of small (20-29 kDa) monomeric Ras-like GTPases<sup>[5]</sup> composed of more than 60 mammalian members, each thought to localize to a distinct subcellular organelle. Rabs function as molecular switches, oscillating between GTP- or GDP-bound conformations, which enables them to reversibly recruit GTP-dependent effectors and elicit their regulatory functions at multiple stages of vesicular transport<sup>[6]</sup>. Rab27A and Rab27B constitute the Rab27 subfamily and share 71% identity<sup>[7]</sup>. Rab27A is expressed in a wide variety of secretory cell types, including exocrine, endocrine, ovarian, and hematopoietic cells, most of which function specifically in regulated exocytic pathways<sup>[8,9]</sup>. Loss-of-function mutations in the human *Rab27A* gene result in Griscelli syndrome, a rare autosomal disorder characterized by a combination of partial cutaneous albinism and severe immunodeficiency<sup>[10,11]</sup>. Its clinical picture appears to be the manifestation of defects in 2 specialized lysosome-related organelles: the failure to distribute melanosomes in melanocytes and the inability to release the contents of lytic granules in cytotoxic T lymphocytes<sup>[12]</sup>. In contrast to Rab27A, Rab27B expression is much more restricted, and is mainly expressed in platelets, the stomach, large intestine, pancreas, pituitary, and bladder<sup>[13-16]</sup>. Unlike Rab27A, Rab27B has not been well characterized, and no human disease or animal strain with mutations in the *Rab27B* gene has been identified<sup>[8]</sup>.

Several members of the Rab family have been well studied in cancer. Rab25, for example, has been shown to decrease apoptosis as well as increase the proliferation and aggressiveness of ovarian and breast cancer<sup>[17-19]</sup>. Increased expression of Rab25 has also been noted in prostate cancer<sup>[20]</sup>, transitional cell carcinoma of the bladder<sup>[21]</sup>, and in colon cancer cells<sup>[22]</sup>. Hou *et al.*<sup>[23]</sup> showed that the *Rab23* gene is over-expressed in gastric cancer, and has an important role in invasion. In addition, Rab11, Rab4, Rab14 and Rab35, among others, have been studied in various cancers<sup>[24]</sup>. However, research on Rab27 in cancer has been limited, and focused exclusively on breast cancer. These studies have shown that Rab27A, along with several other metastasis-associated genes, have vesicle trafficking roles, and were differentially expressed in murine xenograft models of breast cancer metastasis<sup>[25,26]</sup>.

Wang *et al.*<sup>[27]</sup> showed that Rab27A is associated with the invasive and metastatic potential of human breast cancer cells. Overexpression of Rab27A protein in breast cancer cells altered the cell cycle and increased the invasive and metastatic abilities both *in vitro* and *in vivo*. However, in another study, it was shown that Rab27B, not Rab27A, regulates invasive growth and metastasis in ER-positive breast cancer cell lines, with increased expression associated with poor prognosis in humans<sup>[28]</sup>. Despite the link between Rab27 and breast cancer, alterations in Rab27 expression have yet to be explored in other tumor types.

During a previous study of vesicle transport and metastasis in gastric cancer and colorectal cancer (unpublished data), we found a significant correlation between Rab27A and Rab27B expression and clinicopathological characteristics and prognosis. We then examined Rab27A and Rab27B expression in HCC to determine if a similar correlation was present. To accomplish this, we evaluated the expression of Rab27A and Rab27B mRNA and protein in 5 HCC cell lines and the human hepatic HL-7702 cell line. Additionally, we performed parallel immunohistochemical staining of Rab27A and Rab27B in 148 primary HCCs in order to analyze the association with clinicopathological characteristics and clarify the distinct roles of Rab27A and Rab27B in the progression of HCC.

## MATERIALS AND METHODS

### Patients and tissues

One hundred forty-eight HCC specimens and 80 non-HCC specimens were collected from 182 men and 46 women (age, 29-72 years; mean  $\pm$  SD, 51.6  $\pm$  8.9 years) who were inpatients at the PLA General Hospital, Beijing, China, from 2005 to 2009. Survival data were available for 120 patients; 52 of 120 patients (43.3%) died of cancer metastasis or local recurrence after surgery. Patient data are shown in Table 1. All patients underwent surgery, and no patients had received chemotherapy or radiation therapy. Tissue microarray blocks containing formalin-fixed and paraffin-embedded human tissues were constructed in our laboratory as described previously<sup>[29]</sup>. Tumor stage was classified according to the American Joint Committee on Cancer tumor-node-metastasis (TNM) classification. The study was approved by the Research Ethics Boards of the hospitals, and informed consent was obtained from all patients.

### Cell lines and cell culture

The human HCC cell lines MHCC97L and MHCC97M3 were a kind gift from Professor Ye SL (FuDan University, Shanghai). Cell lines BEL-7402, Huh-7, SMMC-7721 and HL-7702 were routinely cultured in our laboratory. HL-7702 was cultured in Roswell Park Memorial Institute medium (RPMI 1640, Gibco, Grand Island, NY, United States), supplemented with 20% fetal bovine serum (FBS; Gibco). BEL-7402 and SMMC-7721 cell lines were cultured in RPMI 1640 medium supplemented with 10% fetal bovine serum. The remaining cell lines were cultured in Dulbecco's modified Eagle's medium (DMEM, Gibco)

<sup>1</sup>Comparing the strong positive group with the other groups. TNM: Tumor-node-metastasis; NS: Not significant; HBV: Hepatitis B virus; AFP: Alpha fetoprotein.

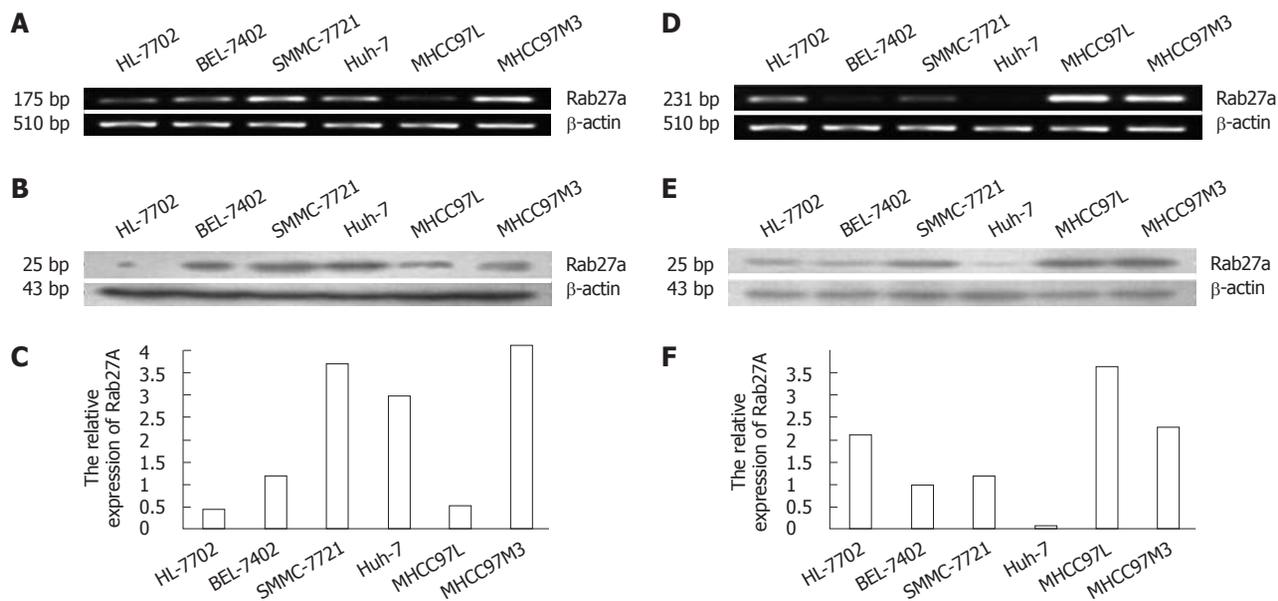

supplemented with 5% FBS. All media contained 100 units/mL penicillin and 100 µg/mL streptomycin. All cell lines were maintained at 37 °C in 5% CO<sub>2</sub>.

### Tissue microarray immunohistochemistry

Antigen retrieval was performed for 2.5 min in citrated buffers using a pressure cooker. A mouse monoclonal antibody specific to human Rab27A (diluted 1:50; cat. ab55667, Abcam, United Kingdom) was incubated on the sections for 36 h at 4 °C, followed by incubation with a rabbit anti-Rab27B polyclonal antibody (diluted 1:100; cat. 13412-1-AP, Proteintech Group, United States) overnight at 4 °C. The rest of the immunohistochemistry (IHC) procedure has been previously described<sup>[30]</sup>. Fewer than 5% specimens were missing from the tissue microarrays. Phosphate buffered saline was substituted for the primary antibodies for a general negative control. All sections were examined microscopically in a blinded fashion and scored by 2 independent pathologists. Rab27A and Rab27B IHC signal was scored on the following scale, taking into account both the proportion of cells stained and the intensity of staining in those cells: score 0: Weak or absent cytoplasmic staining, with less than 5% of cancer cells showing Rab27A or Rab27B localized on the plasma membrane; score 1: Cytoplasmic staining and between 5% and 30% of cancer cells showing Rab27A or Rab27B localized prominently on the plasma membrane; score 2: Cytoplasmic staining and more than 30% of the cancer cells containing Rab27A or Rab27B localized prominently on the membrane.

### Reverse transcription-polymerase chain reaction and real-time polymerase chain reaction

Total RNA was extracted from cell lines using TRIzol (Qiagen, United States). The prepared RNA (5 µg) was mixed with oligo-dT primers and reverse-transcribed with MMLV reverse transcriptase (Promega, United States) for 60 min at 37 °C, followed by polymerase chain reaction (PCR) amplification with specific primers for Rab27A (F,5'-GAAGCCATAGCACTCGCAGAG-3',R,5'-ATGACCATTGATCGCACCA-3') or Rab27B (F,5'-TGC-GGGACAAGAGCGGTTCCG-3',R,5'-GCCAGTTCGGAGCTTGCCGTT-3'). PCR amplification was performed in 20 µL using a thermocycler (Biometra, Germany) with the following PCR program: pre-denaturation for 3 min at 94 °C, denaturation for 45 s at 94 °C, annealing for 45 s at 56 °C, extension for 45 s at 72 °C, and a final elongation at 72 °C for 10 min. β-Actin served as an internal positive control. PCR was performed for 24-30 cycles (β-actin 24 cycles; Rab27A 28 cycles; Rab27B 30 cycles). PCR products were analyzed by electrophoresis on a 1.5% agarose gel, and band intensity was measured directly on an AlphaImager 2200 system (Alpha Innotech, San Leandro, CA). Real-time PCR reactions were carried out using Applied Biosystem's 7500 QPCR System (ABI, Foster, CA). Results were normalized to individual β-actin expression, and data were analyzed according to the relative standard curve. Melting curves for each PCR reaction were generated to ensure the purity of the amplified products.

**Figure 1** Detection of Rab27A and Rab27B mRNA and protein in 6 human cell lines. A and C: Reverse transcription polymerase chain reaction (RT-PCR) and real-time PCR, respectively, of Rab27A in 5 hepatocellular carcinoma cell lines and the human HL-7702 line; D and F: RT-PCR and real-time PCR, respectively, of Rab27B; B and E: Western blotting of Rab27A and Rab27B protein levels, respectively.  $\beta$ -actin served as an internal control.

### Western blotting

Equal amounts of protein were electrophoresed on a 12% sodium dodecylsulfate polyacrylamide gel electrophoresis gel and transferred to a polyvinylidene difluoride membrane using standard techniques. Immunoreactivity was tested with anti-Rab27A (diluted 1:100; cat. ab55667, Abcam, United Kingdom) or anti-Rab27B (diluted 1:1200; cat. 13412-1-AP, Proteintech Group, United States) antibodies. Nonspecific binding was blocked by a 5% fat-free milk solution. Rab27A and Rab27B proteins were detected by an enhanced chemiluminescence system (Amersham Pharmacia Biotech).

### Statistical analysis

Statistical analyses were performed using the SPSS software package (version 16.0; SPSS Inc., United States). The  $\chi^2$  test was used to evaluate relationships between clinicopathological variables and Rab27A and Rab27B expression. Kaplan-Meier survival analysis with the log-rank test was used to evaluate the prognosis of patients according to their levels of Rab27A and Rab27B expression. Multivariate analysis was performed with the Cox proportional hazards regression model to assess the effects of different variables on patient survival. Differences were considered significant at  $P < 0.05$ .

## RESULTS

### Expression of Rab27A and Rab27B in hepatocellular carcinoma cell lines

Rab27A and Rab27B mRNA and protein expression were examined in 5 HCC cell lines and the human hepatocyte line HL-7702. As shown in Figure 1, Rab27A mRNA and protein were detected in all 6 cell lines, though at very low intensities in some cell lines, whereas Rab27B was more differentially expressed. Rab27A pro-

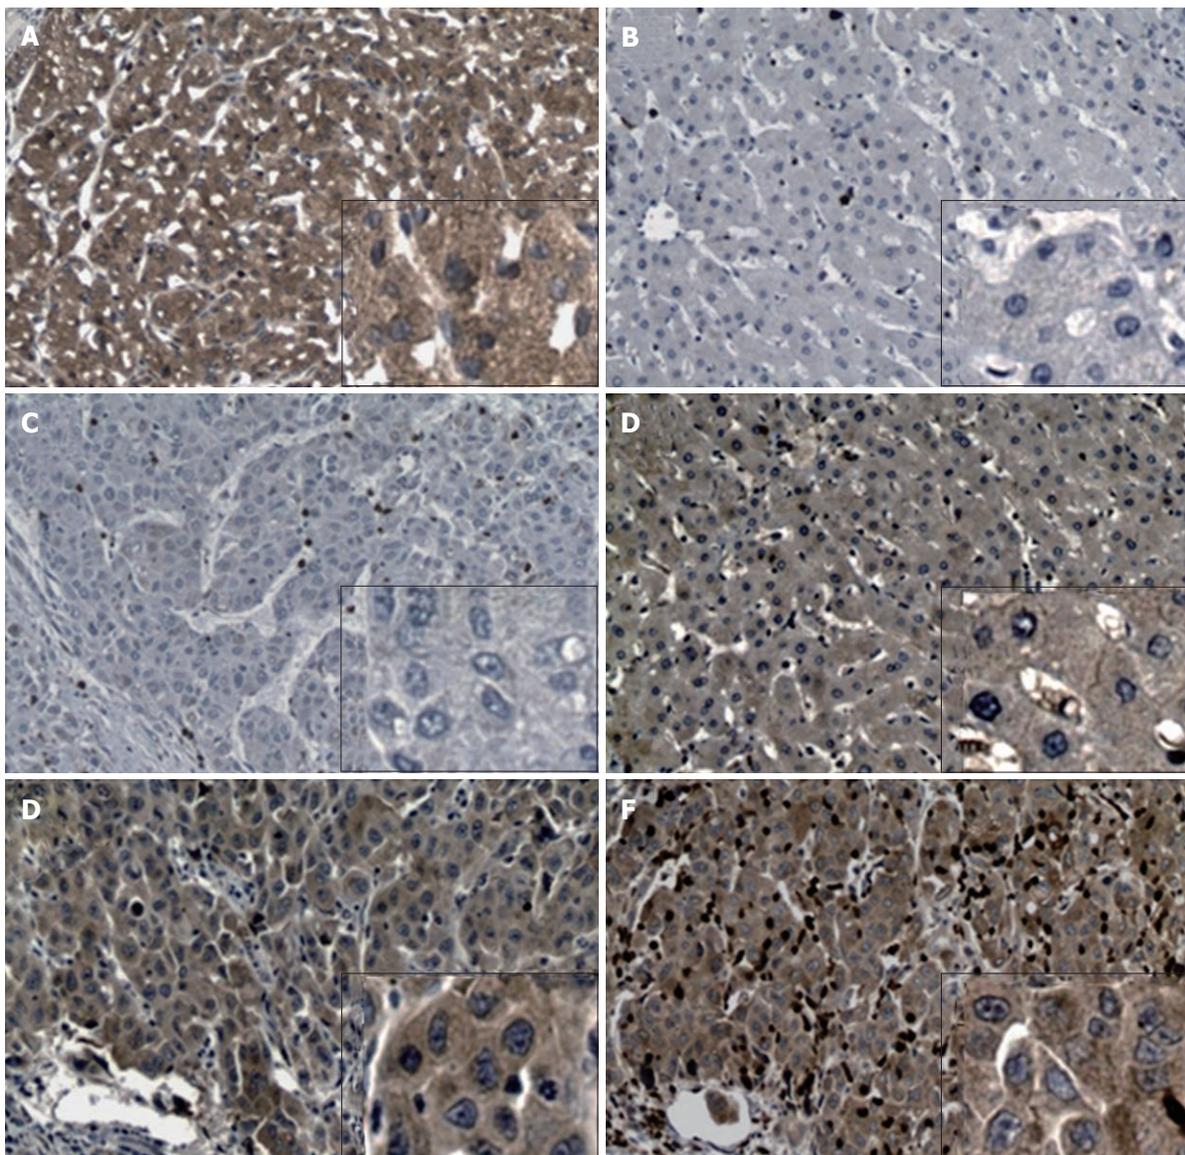

tein and mRNA were highly expressed in 67% (4/6) of all cell lines and 80% (4/5) of HCC cell lines; Rab27B protein and mRNA were highly expressed in 50% (3/6) of all cell lines and 40% (2/5) of HCC cell lines. Interestingly, Rab27A expression was weaker in the low metastatic cell line MHCC97L than in the high metastatic cell line MHCC97H, whereas Rab27B expression was higher in MHCC97L than in MHCC97H. In addition, Rab27A had only negligible expression in the immortal human hepatocyte line HL-7702, while Rab27B was moderately expressed.

### Rab27A and Rab27B expression in primary hepatocellular carcinoma specimens

To determine Rab27A and Rab27B expression in HCC specimens, IHC was performed on tumor tissue, tumor-adjacent normal tissue, unrelated normal hepatic tissue, and hepatitis or cirrhosis tissues. In primary HCC tumors, Rab27B and Rab27A were detected in 57.4% (81/141) and 46.2% (66/143) of specimens, respectively (Table 1, Figure 2). In adjacent tissue, Rab27A expression was less apparent, with significantly less positivity (24.3%, 33/136) than that in HCC specimens ( $P < 0.001$ ); however, Rab27B showed strong immunopositivity (87.5%, 119/136), with significantly higher expression than that in HCC specimens ( $P < 0.001$ ). In addition, we found no differences in immunostaining for Rab27A and Rab27B between normal ( $n = 40$ ) and hepatitis or cirrhosis tissues ( $n = 50$ ), excluding the possibility that alterations in Rab27A and Rab27B expression in primary HCC tumors were caused by hepatitis or liver cirrhosis (Table 1).

### Association of Rab27A and Rab27B expression in hepatocellular carcinoma specimens with clinicopathological features

Analysis of the clinicopathological characteristics of the

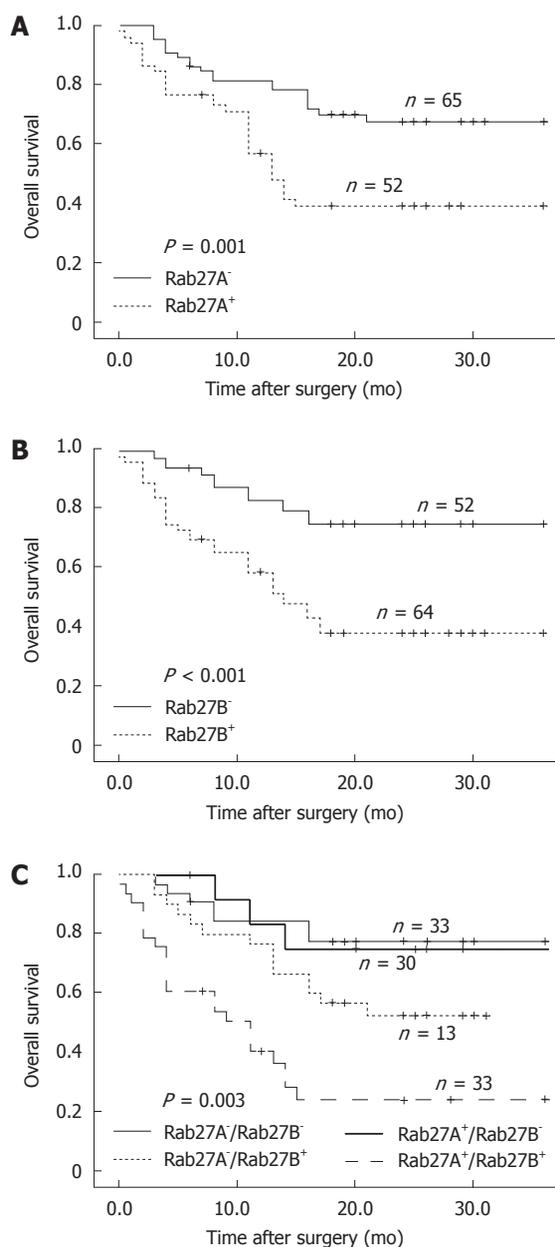

**Figure 2** Differential expression of Rab27A and Rab27B in hepatocellular carcinoma patients. A: Positive staining of Rab27A in hepatocellular carcinoma (HCC) tissue; B: Negative staining of Rab27A in adjacent tissue; C: Negative staining of Rab27B in HCC tissue; D: Positive staining of Rab27B in adjacent tissue; E and F: Positive staining of Rab27A and Rab27B, respectively, in the same HCC tissue. Both Rab27A and Rab27B were observed in the cytoplasm and plasma membrane of human cells. Original magnification  $\times 100$ ; the inset boxes are at original magnification  $\times 400$ .

148 HCC specimens revealed significant correlations between Rab27A and Rab27B expression and tumor TNM classification ( $P = 0.046$  and  $P = 0.027$ , respectively; Table 1), as well as strong Rab27A expression with tumor differentiation ( $P = 0.008$ , Table 1). Moreover, there was a statistically significant correlation between the expression of Rab27A and Rab27B in HCC ( $P = 0.017$ ;  $r = 0.192$ ). However, we found no relationship between Rab27A or Rab27B positivity and hepatitis B virus (HBV) status, alpha fetoprotein level, or type of hepatoma. Further subdivision of the HCC specimens using Rab27A and Rab27B expression as covariables (i.e., Rab27A<sup>-</sup>/Rab27B<sup>-</sup>, Rab27A<sup>-</sup>/Rab27B<sup>+</sup>, Rab27A<sup>+</sup>/Rab27B<sup>-</sup>, and Rab27A<sup>+</sup>/Rab27B<sup>+</sup> specimens) showed no significant differences between the 4 groups in relation to clinicopathological features (data not shown).

#### **Survival analyses of patients according to Rab27A and Rab27B expression status after surgery**

Survival data were available for 120 patients. The overall 1-year survival rate was 71%. Patients with Rab27A<sup>+</sup> or Rab27B<sup>+</sup> tumors had significantly reduced overall survival compared with that of patients with Rab27A<sup>-</sup> or Rab27B<sup>-</sup> tumors ( $P = 0.015$  and  $P = 0.005$ , respectively; Figure 3A and B). Subsequently, we analyzed the survival curves of the 4 groups according to the expression status of Rab27A and Rab27B. Patients with Rab27A<sup>-</sup>/Rab27B<sup>-</sup> tumors had the longest survival, with the Rab27A<sup>+</sup>/Rab27B<sup>-</sup> group showing a similar survival curve; the Rab27A<sup>-</sup>/Rab27B<sup>+</sup> group had lower survival, while the Rab27A<sup>+</sup>/Rab27B<sup>+</sup> group had the poorest survival ( $P = 0.003$ , Figure 3C).

To determine relative risk, we analyzed the data with

**Figure 3** Kaplan-Meier overall survival analysis of Rab27A and Rab27B in hepatocellular carcinoma patients. A: Survival analysis of hepatocellular carcinoma patients by expression of Rab27A; B: Survival analysis by expression of Rab27B; C: Survival analysis with expression of Rab27A and Rab27B as covariables.

a Cox proportional hazards model using tumor differentiation grade, TNM stage, HBV status, hepatoma type, and Rab27A and Rab27B expression status as covariates. The positive expression of Rab27B as well as TNM III-IV were independent poor prognosis factors associated with a 3.36- and 3.37-fold higher relative risk of death, respectively (95% CI, 1.33-8.5 and 1.391-8.186;  $P$  value, 0.01 and 0.007, respectively).

## DISCUSSION

To the best of our knowledge, this is the first study investigating the expression of Rab27A and Rab27B in a large

series of HCC patients. Utilizing RT-PCR, real-time PCR, Western blotting, and IHC, we found that Rab27A and Rab27B were strongly associated with tumor TNM stage and may serve as useful biomarkers to monitor the clinical course of patients with HCC. Although the expression of Rab27A and Rab27B was closely related, Rab27B seemed to play a key role in determining prognosis.

Our results revealed that Rab27A and Rab27B were differentially expressed in HCC cell lines and tissue specimens; this indicates that Rab27A and Rab27B may be related to malignant transformation in this carcinoma. In the present study, we found that Rab27A and Rab27B were expressed in the cytoplasm and plasma membrane of hepatic cells. Rab27A was expressed at higher levels in primary HCC than in matched adjacent tissue, whereas Rab27B expression was lower in primary HCC than in matched adjacent tissue. In accordance with these data, Rab27A and Rab27B mRNA and protein were differentially expressed in the 6 human cell lines. The results from the tissue specimens were mirrored in the immortal human hepatocyte line HL-7702, low metastatic cell line MHCC97L, and high metastatic cell line MHCC97H. In addition, Rab27A mRNA and protein were expressed in all 6 cell lines, albeit at different intensities, whereas Rab27B was differentially expressed; this finding is consistent with the findings of previous studies that Rab27A is more widely expressed than Rab27B.

We further analyzed the association between Rab27A and Rab27B expression and clinicopathologic variables utilizing IHC. In HCC specimens, positive expression of Rab27A and Rab27B was strongly correlated with stage III/IV, while negative expression was correlated with stage I/II. Furthermore, strong expression of Rab27A (score 2) also correlated with tumor differentiation. Our study is the first to identify that Rab27A and Rab27B strongly correlate with tumor progression, and provides evidence that Rab27A might function in cell differentiation. Previous research demonstrated that when Rab27A effectors are bound by another protein, Rab27B plays an important role in the regulation of many secretory mechanisms<sup>[31]</sup>. Another study showed that Rab27A and Rab27B play both redundant and distinct roles in regulating the secretion and released quantity of platelet dense granules<sup>[9]</sup>. In agreement with these studies, our results provide evidence that Rab27A and Rab27B may have redundant and distinct functions. In addition, numerous studies have demonstrated that tumor cells use exosomes (endosome-derived membrane vesicles) to communicate with surrounding tissues and immune cells, creating a suitably immunosuppressive microenvironment for tumor growth, invasion, and metastasis<sup>[32-35]</sup>. We hypothesize that Rab27A and Rab27B are associated with tumor progression because of their functions as transport vesicles.

Our study also showed that patients with Rab27A<sup>+</sup> or Rab27B<sup>+</sup> tumors had significantly reduced overall survival compared with that of patients with Rab27A<sup>-</sup> or Rab27B<sup>-</sup> tumors. Moreover, patients with Rab27A<sup>-</sup>/Rab27B<sup>-</sup> tumors had the longest survival, while those with Rab27A<sup>+</sup>/Rab27B<sup>+</sup> tumors had the poorest survival. An analysis of

the tumor variables as risk factors showed that Rab27B<sup>+</sup> and TNM III-IV were independent poor prognosis factors, conferring a 3.36-fold and 3.37-fold greater relative risk of death. These results provide further evidence that Rab27A and Rab27B can serve as useful biomarkers for determining prognosis as well as monitoring the clinical course of patients with HCC. Furthermore, Rab27B is more useful than Rab27A as an independent prognosis factor.

Although studies on Rab27 in breast cancer have provided contradictory results, previous findings are partially consistent with our results. Wang *et al.*<sup>[27]</sup> showed that overexpression of Rab27A is associated with invasive and metastatic potential in human breast cancer cells both *in vitro* and *in vivo*. However, they found no Rab27B expression in breast cancer. This discrepancy may be because they utilized cell lines and samples from nude mice, rather than human breast cancer tissue. Another study on Rab27 and breast cancer showed that Rab27B regulates invasive growth and metastasis in ER-positive breast cancer cell lines and that increased expression is associated with poor prognosis in humans<sup>[28]</sup>. However, they found no expression of Rab27A in normal tissue ( $n = 5$ ) or primary breast carcinoma ( $n = 20$ ), though this may have been due to the small sample size. Additionally, the results of our previous study on GC and CRC were not consistent with our HCC results. Expression of Rab27A and Rab27B was much lower in primary GC and CRC than in adjacent mucosal tissue. Among these patients, those with Rab27A<sup>+</sup>/Rab27B<sup>+</sup> tumors had the longest survival, while the Rab27A<sup>-</sup>/Rab27B<sup>-</sup> group had the poorest survival; a Cox proportional hazards model showed that Rab27A<sup>+</sup>/Rab27B<sup>+</sup> expression was a protective prognosis factor in both GC and CRC (unpublished data). These findings show that Rab27A and Rab27B may have different molecular mechanisms in HCC compared with those in GC and CRC.

In conclusion, our study demonstrated that Rab27A and, to a greater degree, Rab27B were correlated with tumor progression and may serve as valuable prognostic indicators for HCC patients. However, further investigation is required to determine the molecular mechanism of Rab27A and Rab27B in HCC.

## COMMENTS

### Background

Primary hepatocellular carcinoma (HCC) carries a high mortality rate and is one of the top 10 most frequent tumor types globally. The identification of novel biomarkers correlating with HCC progression is crucial to monitor clinical disease course and provide corresponding therapy strategies. A large body of evidence indicates that vesicle trafficking and exocytosis are important in tumorigenesis, with many reports implicating the Rab family of proteins.

### Research frontiers

Several members of the Rab family, such as Rab25, Rab23 and Rab11, have been well studied in cancer. However, research on Rab27 in cancer is both limited and contradictory, and has focused exclusively on breast cancer. Due to the high mortality rate and lack of efficacious therapy strategies, the identification of Rab27 expression on primary HCC as a novel biomarker of the disease may allow for the development of improved therapy strategies.

### Innovations and breakthroughs

This is the first study to investigate the expression of Rab27A and Rab27B in a large series of HCC patients. It was found that Rab27A and Rab27B expression were closely linked and both Rab27A and Rab27B were strongly associated with tumor progression, which can be valuable prognostic indicators for HCC patients.

### Applications

Rab27A and Rab27B were closely related with tumor progression and may serve as useful biomarkers to monitor the clinical course of patients with HCC. The relationship between the expression of Rab27A and Rab27B and tumor progression may be due to their functions as transport vesicles, which may provide potential therapeutic targets for HCC.

### Terminology

Rabs are a ubiquitously expressed family of small monomeric Ras-like GTPases. They function as molecular switches, oscillating between GTP- or GDP-bound conformations, which enables them to reversibly recruit GTP-dependent effectors and elicit their regulatory functions at multiple stages of vesicular transport; Rab27A is expressed in a wide variety of secretory cell types, most of which function specifically in regulated exocytic pathways. Loss-of-function mutations in the human Rab27A gene result in Griscelli syndrome; Rab27A and Rab27B constitute the Rab27 subfamily and share 71% identity. Rab27B expression is much more restricted than that of Rab27A and no human disease or animal strain with mutations in the *Rab27B* gene has been identified.

### Peer review

In the present study, the authors found that Rab27A and Rab27B were expressed differently in HCC. Rab27A was expressed at higher levels in primary HCC, whereas Rab27B expression was lower in primary HCC. In agreement with these findings, Rab27A and Rab27B mRNA and protein were also differentially expressed in 6 human cell lines. Survival analysis further showed that Rab27 expression may be used as an indicator for prognosis in HCC patients, providing important information for the treatment of patients.

### Abstract

**AIM:** To compare the endomicroscopic image quality of integrated confocal laser endomicroscopy (iCLE) and sedation efficacy of propofol vs midazolam plus fentanyl (M/F).

**METHODS:** Consecutive outpatients undergoing iCLE were prospectively recruited and randomized to the propofol group (P group) or M/F group. The patient, performing endoscopist and endoscopic assistant were blinded to the randomization. The quality of endomicro-

scopic images and anesthetic efficacy outcomes were blindly evaluated after iCLE examination.

**RESULTS:** There were significantly more good quality endomicroscopic images in the propofol group than in the M/F group (72.75% vs 52.89%,  $P < 0.001$ ). The diagnostic accuracy for upper gastrointestinal mucosal lesions using confocal laser endomicroscopy favors the P group, although this did not reach statistical significance. Adverse events and patient assessment were not significantly different for M/F vs propofol except for more frequent intraprocedural recall with M/F. Procedure duration and sedation times were significantly longer in the M/F group, while the scores of endoscopist, anesthetist and assistant assessment were all significantly better in the P group.

**CONCLUSION:** Sedation with propofol might increase the proportion of good quality endomicroscopic images, and may result in improved procedural efficacy and diagnostic accuracy during iCLE examination.

## INTRODUCTION

Confocal laser endomicroscopy (CLE) is a novel technique for gastrointestinal (GI) endoscopy. It enables high-resolution analysis of cellular structure during endoscopy. Clinical applications of CLE have been validated in various GI diseases, such as Barrett's esophagus, gastric cancer, colorectal cancer, ulcerative colitis and celiac disease<sup>[1-5]</sup>. Recent studies have expanded its application for *in vivo* molecular imaging of GI cancer<sup>[6]</sup>. However, integrated CLE (iCLE) is more cumbersome than a standard gastroscope because iCLE has a larger outer diameter (12.8 mm) and a longer rigid tip (43 mm) which contains the scanning head (tip angulations: up/down 130 degrees). In addition, since endomicroscopic imaging can only be achieved by placing the confocal imaging window directly onto the area of interest, patients may suffer from more discomfort, especially when the lesion is located at the pylorus or gastroesophageal junction. Moreover, motion artifacts, which are the most common cause of endomicroscopic image artifacts, can often be caused by patients' movement and unstable endoscope positions. Thus, compared with conventional esophago-gastroduodenoscopy (EGD), iCLE might require more patients' cooperation and better sedation to get images of good quality and make an accurate diagnosis.

Conscious sedation is routinely used during endoscopic examination because it can provide adequate anxiolysis, acceptance, and amnesia for most patients *vs* no sedation, and is safer than deep sedation<sup>[7,8]</sup>. The combined use of a benzodiazepine (e.g., midazolam) and narcotics (e.g., fentanyl) is the most widely applied sedative regimen for GI endoscopy<sup>[9]</sup>. Recent data suggest that the use of propofol for sedation is increasing<sup>[10]</sup>. In some endoscopic centers, benzodiazepines, narcotics or propofol have been administered during iCLE<sup>[11-13]</sup>. However, the most effective and satisfactory sedation agent for iCLE examination has not yet been investigated.

Recently, propofol has been advocated as an alternative to the commonly used combination of midazolam and narcotic regimen (fentanyl, meperidine)<sup>[7,14-19]</sup>. Compared with midazolam, propofol is a short-acting sedative-hypnotic agent with a faster recovery profile, and its application is associated with some additional advantages, such as being easy to maintain an appropriate sedation level and satisfactory amnestic effect<sup>[7,14,15,18,19]</sup>. Several studies have reported the effect of sedation of propofol *vs* midazolam on the quality of upper and lower GI endoscopy by randomized trials<sup>[16,17,20]</sup>, however, no investigation has compared propofol with midazolam plus fentanyl (M/F) as sedatives for iCLE. Therefore, the aim of the present study was to compare the quality of endomicroscopic images and sedation efficacy outcomes between propofol and M/F as sedatives for iCLE.

## MATERIALS AND METHODS

### Patients

Consecutive outpatients who underwent iCLE were re-

cruited prospectively from the endoscopy clinic of Qilu Hospital, Shandong University, from February to May 2010. The exclusion criteria: < 18 years of age, known or suspected strictures or stenosis, coagulopathy, acute upper digestive tract bleeding, pregnancy or breast feeding, allergy to propofol, fentanyl, midazolam or fluorescein sodium, contraindications to sedation, mental disorders or did not provide written informed consent. Informed consent was obtained from all patients who underwent endoscopic examination in this study. The study was approved by the Ethical committee of Qilu Hospital and was conducted in accordance with the revised Declaration of Helsinki (1989). This trial was registered at www.clinicaltrials.gov, ID number NCT01053871.

### Sample size calculation and randomization

The sample size was calculated to achieve a statistical power of 0.8 at an alpha value of 0.05. For patients sedated with midazolam and fentanyl, the rate of good quality endomicroscopic images was estimated to be 66% according to previously reported data<sup>[13]</sup>. We defined that sedative iCLE examination using propofol increases the rate of good quality endomicroscopic images by 21% as compared with the administration of midazolam and fentanyl. This resulted in a calculated sample size of 100 patients (50 per group). Therefore, we proposed recruiting 104 eligible patients to allow an attrition rate of 4%.

Patients were randomized at a 1:1 ratio into a propofol group (P group) or an M/F group using a computer-generated list. The respective randomization results were kept in sealed envelopes that were opened before the endoscopy by the anesthetist. Because the apparent difference in the color of the sedative agents in this study, the anesthetist was not blinded to the study agents. However, in order to maintain the patients, the endoscopist and the other investigators blinded about the study group, an opaque curtain was placed upon the patient's infusion arm during the following procedure.

### Confocal laser endomicroscopy

CLE is an advanced method which allows living tissue to be viewed *in situ*, providing real-time histology during endoscopy. The confocal microscope integrated into the distal tip of a conventional video endoscope can collect images with an adjustable depth of scanning ranging from 0 to 250  $\mu\text{m}$ , a field of view of 475  $\mu\text{m} \times 475 \mu\text{m}$ , an optical slice thickness of 7  $\mu\text{m}$ , and a lateral resolution of 0.7  $\mu\text{m}$ . The plane depth was controlled using two additional buttons on the back of the handpiece.

### Clinical procedure

After routine preparations for gastroscopy, intravenous access was established for both groups of patients. Patients in P group received a bolus of 0.8-1.0 mg/kg of 1% propofol before the start of endoscopy. Further bolus of 0.5 mg/kg of 1% propofol was evaluated by an anesthetist, and would be given if the sedation was judged as insufficient by the endoscopist. Patients in M/F group received a bolus of 0.05 mg fentanyl, followed by

3-4 mg midazolam before the start of endoscopy. Further bolus of 1-2 mg midazolam was administered by the anesthetist at certain intervals or when the sedation was judged as inadequate by the endoscopist. A reversal agent of midazolam (flumazenil) was administered after iCLE examination in the M/F group if needed. Endoscopic intubation commenced once the patient showed spontaneous eye closure, but responsive to name called.

All patients received supplemental oxygen (2-4 L/min) by nasal cannula. Their oxygen saturation, pulse rate and arterial blood pressure were continuously monitored and recorded every 5 min by pulse oxymetry and sphygmomanometry. Sedation was performed in accordance with the guidelines for conscious sedation and monitored by a professional anesthetist (Liu XP)<sup>[8]</sup>.

Patients in both groups received standard white-light endoscopic and endomicroscopic examinations using a Pentax EC-3870K confocal laser endomicroscope (Pentax, Tokyo, Japan). All endoscopic procedures were performed by one experienced endoscopist (Zuo XL), who had performed more than 300 iCLE procedures before the present study. After successful intubation of the endoscope into the duodenum, 5 mL fluorescein was administered intravenously to facilitate the endomicroscopic imaging. Endoscopic mucosal lesions (such as mucosal color changes, elevation, depression, ruggedness) and 9 standard locations (duodenal bulb, lesser and greater curvature of the antrum and gastric body, incisura angularis, fundus, gastric cardia and esophagus) were sequentially examined using iCLE. Serial endomicroscopic images were obtained from each examined area using the "movie mode" on the iCLE displaying screen and stored in separate files for further analysis of image quality. Image collection was started when the performing endoscopist activated the endomicroscopic scanning by pressing a control button on the handpiece of the endoscope, and it was stopped when the endoscopist pressed twice on the same button. Real-time endoscopic and endomicroscopic diagnoses were made during the procedure by the performing endoscopist and targeted biopsy specimens were obtained for histopathological assessment.

One endoscopic assistant (Zhen L) was responsible for the data collection, and not involved in patient selection or the randomization. The demographic data, history of alcohol or smoking, and the American Society of Anesthesiologists status were recorded for both groups of patients<sup>[21]</sup>.

### Outcome measures

**Assessment of endomicroscopic image quality:** Endomicroscopic images of each patient were reevaluated after the procedure by one investigator (Rui J), who was blinded to the patients' data and endoscopic findings. Good quality endomicroscopic images were defined as "no moving artifacts, and single cells can be differentiated". And the number of good quality endomicroscopic images was counted for each examined area<sup>[1]</sup>.

**Sedation-related outcomes:** The procedure duration

was recorded (from the first injection of the sedatives to the moment of the withdrawal of the endoscope), and the time required for sedation (start of the sedation to passage of the larynx). In addition, patient monitoring/complications, including oxygen de-saturation (< 90%), hypotension (SBP < 80 mmHg) and bradycardia (< 40 b/min) were also noted.

**Patient assessment:** After the endoscopic procedure, patients were transferred to a separate recovery area when vital signs were stable as judged by the anesthesiologist responsible for the sedation. As the patients awoke, a brief questionnaire was asked and collected by a blinded endoscopic assistant (Zhen L). Patient assessment of the procedure involved 4 parameters, including satisfaction (scores ranging from 1 to 10: 1 for "poor" and 10 for "excellent"), pain or discomfort (scores ranging from 0 to 10: 0 for "none" and 10 for "severe") and intraprocedure recall (scores ranging from 0 to 10: 0 for "none" and 10 for "complete"). Additionally, the patients were also asked whether they would prefer lighter, deeper or the same level sedation for their next EGD.

**Endoscopist assessment:** The endoscopist's assessment of the procedure had 4 parameters, including satisfaction with sedation (scores ranging from 1 to 10: 1 for "poor" and 10 for "excellent"), level of sedation (apparently inadequate, inadequate, adequate, oversedated), patient cooperation and quality of endoscopy (a scale ranging from 1 to 4: 1 for "very poor"; 2 for "poor"; 3 for "fair"; and 4 for "good").

In addition, the endoscopic assistant and anesthetist also scored their satisfaction of sedation at the end of each procedure independently using a 10-point scale: 1 (poor) to 10 (excellent).

### Statistical analysis

Continuous outcomes were compared using the independent sample *t* test for normally distributed data and the Mann-Whitney *U* test for nonparametric data. The  $\chi^2$  test and the Fisher exact test were applied for the comparison of categorical variables between the two groups. A *P* value less than 0.05 was considered statistically significant. Statistical analysis was performed using the SPSS 13.0 statistical software package (SPSS, Chicago, IL, United States). The study was reported in accordance with the Consolidated Standards of Reporting Trials<sup>[22]</sup>.

## RESULTS

Over the 3-mo study period, 156 subjects who required for sedated iCLE examination were screened for possible enrollment. In the end, 52 patients were excluded according to predefined exclusion criteria, including 15 cases of known or suspected strictures or stenosis, 4 cases of acute bleeding, 26 cases of contraindications to sedation, and 7 cases refused to participate. A total of 100 patients completed the study and were eligible for data analysis (49 in P group and 51 in M/F group) (Figure 1). The patient

characteristics for both groups are summarized in Table 1. The mean dosage of sedation used was 194 mg for propofol (range 50-380 mg) and 5.4 mg for midazolam (range 3-8 mg).

**Endoscopic image assessment**

Endoscopic mucosal lesions of the duodenum, stomach and esophagus were examined by iCLE. In addition, if multiple lesions, such as multiple polyps of the stomach, were detected, the endoscopic images obtained from lesions in the same anatomical compartment (e.g., antrum, incisura angularis, gastric body/fundus and cardia) were poorly analyzed for image quality. The proportion of good quality endoscopic images in each examined area is shown in Table 2. Propofol showed superiority to midazolam plus fentanyl in obtaining good

Continuous variables were given as the mean ± SD. Non-normally distributed variables were expressed as median (the 1st-3rd interquartile) and compared with the Mann-Whitney *U* test. P group: Propofol group; M/F group: Midazolam plus fentanyl group.

and neoplasia was significantly lower than that of the M/F group. The diagnostic sensitivity and specificity of the P group were higher than that of the M/F group, but the differences were not significant (Table 4). The assessment of intestinal metaplasia included only gastric mucosal lesions and the metaplastic esophageal mucosal lesions.

### Quality of sedation

Patients in M-group required significantly more time to achieve sedation (4.47 ± 2.40 min) than P group (3.22 ± 1.70 min). Procedure duration was also longer in M/F group (28.45 ± 8.04 min) than in P group (25.00 ± 6.51 min). Three patients in the P group and one patient in the M-group experienced a decrease in systolic blood pressure below 80 mmHg which were successfully recti-

fied by intravenous fluid administration. There was no case of de-saturation < 90% or bradycardia during or after the procedure.  $\chi^2$  analysis showed that there were no statistical differences between the two groups in terms of the above-mentioned parameters ( $P = 0.339$ ) (Table 5). In addition, the hemodynamic parameters, including the mean values of heart rate, hemoglobin oxygen saturation, and mean arterial pressure were all similar in both groups ( $P = 0.087$ ,  $P = 0.903$ ,  $P = 0.244$ ).

The results of patient assessment for the procedure are shown in Table 5. No significant differences were observed between the two groups in terms of patient satisfaction and pain or discomfort. However, the amnesic effect was significantly better in the P group than in M/F group ( $P = 0.006$ ). With regard to the patients' preference of sedation for their next EGD, some patients in the M/F group seemed to prefer deeper sedation and more patients in the P group preferred lighter sedation. The majority of the two groups (40 patients of each group) would like to receive the same level of sedation.

The endoscopists, based on the mean sedation score as judged by the performing endoscopist (Zuo XL), were significantly in favor of the P group *vs* the M/F group. In addition, the quality of endoscopy and patient cooperation were also rated as significantly superior in the P group. The level of sedation, as estimated by endoscopist immediately after the procedure, was significantly more adequate for the P group than for the M/F group ( $P = 0.014$  comparing "apparently inadequate and inadequate" *vs* "adequate"). Furthermore, the assistant and anesthetist scores for overall sedation also favored the P group receiving propofol as compared with the M/F group receiving midazolam plus fentanyl ( $P = 0.001$  and  $P < 0.001$ ) (Table 5).

## DISCUSSION

CLE is a new endoscopic device that can instantly validate tissue pathology via viewing endomicroscopic images during ongoing endoscopy. Good quality endomicroscopic images can be obtained by achieving full vertical contact of the confocal imaging window with the mucosa<sup>[28]</sup>. The main cause of reduced quality of endomicroscopic images is to the movement artifacts. Therefore, an adequate level of sedation is desirable to

make iCLE examination more tolerable to the patient and easier to perform for the endoscopist. So far, several sedative agents, such as midazolam and propofol, have been applied in iCLE examination to achieve conscious sedation. However, no investigation has yet compared the sedation efficacy of propofol with the regimen of benzodiazepines and narcotics during iCLE. Results of this prospective randomized study showed that the proportion of good quality endomicroscopic images increased by propofol (P group) as the sedative agent rather than midazolam plus fentanyl (M/F group).

Based on our results, the proportion of good quality endomicroscopic images is significantly influenced by the regimen of sedation. Propofol showed clear superiority, either for iCLE scanning of the 9 standard locations or endoscopic mucosal lesions of the upper GI tract. The diagnostic sensitivity, specificity, PLR and NLR were mostly better in patients receiving propofol, although these did not reach statistical significance except for PLR in diagnosing neoplasia and NLR in diagnosing intestinal metaplasia and neoplasia. In our opinion, the reason might be that patients under propofol sedation tolerated inflation of the stomach and the attachment of the iCLE onto the tissue to a greater extent than patients under midazolam and fentanyl sedation, who still tend to experience some retching and belching. The more frequent patient movement in the M/F group not only interferes in the full vertical contact of the confocal window on the interested area, but also disturbs the endoscopist's attention on making a definite judgment.

In addition, our findings suggest that propofol is more efficient compared to the regimen of midazolam plus fentanyl in the sedation of patients undergoing iCLE. The procedure duration and sedation time were all significantly longer in the M/F group. Since the number, endoscopic location and histological spectrum of mucosal lesions were well matched between the two groups, we therefore interpreted the prolonged procedure time in M/F sedation as being a consequence of the necessity for short-term interruptions of the endoscopic procedure due to the time interval required until repeated administrations of midazolam effectively resedated the patients. Adverse event and postprocedure patient assessment were not significantly different except for more frequent intraprocedural recall with midazolam and fentanyl. The endoscopist assessment, assistant satisfaction and anesthetist satisfaction all favor the use of propofol. These were in accordance with previously published data comparing the sedation effect of propofol *vs* midazolam-based regimen during endoscopy<sup>[7,17,18,29]</sup>. A prior study reported that propofol caused more pain on administration, thus leading to a lower acceptance rate by patients<sup>[30]</sup>. In this study, propofol was often mixed with lidocaine (50 mg of 2% lidocaine mixed with 200 mg of 1% propofol) at the time of injection, and no patient experienced pain or complained of pain.

Considering the extensive clinical application of the combined use of midazolam and fentanyl, we choose this regimen as a comparison arm to the increasingly advo-

cated anesthetic drug propofol in the present study. Thus the independent role of midazolam compared with propofol in sedative endomicroscopy may not be clear according to the present research. However, previous data showed that the addition of a narcotic to midazolam may result in better patients' cooperation, easier insertion of the gastroscope, and increased endoscopists' satisfaction with the procedure<sup>[31,32]</sup>. Nevertheless, further studies are warranted to explicit the independent role of midazolam in this procedure.

Our study has certain limitations. First, the difference of the proportion of good quality endomicroscopic images between the two groups did not reach the estimated value (19.86% *vs* 21%) with the current sample size (100 patients), which will certainly weaken the statistical power of this study. However, we did not expand patient recruitment because the predetermined study period has terminated. Anyway,  $\chi^2$  analyses demonstrated statistical significance either for total number of good quality endomicroscopic images or for each examined area between the two groups. Therefore, the results of this study need to be warranted in further researches with a larger sample size. Second, although the target level of sedation in this study was conscious sedation, it is possible that some patients may move to deeper sedation during the procedure since they were not continuously called or shaken in order to judge their sedation level when being examined. In addition, there have been reports comparing the sedation depth of propofol *vs* midazolam and meperidine, which demonstrated that propofol was more likely to produce a deeper level of sedation than midazolam and meperidine<sup>[17,19]</sup>. Given the narrow therapeutic window of propofol, the onset of sedation may be deeper at first, with effect moderating over time. Indeed, the anesthetic agents in both groups were titrated according to patient safety and comfort rather than sedation. Nevertheless, all patients in the present study were monitored with continuous pulse oxymetry and noninvasive arterial blood pressure measured at 5-min intervals, and no severe side effects were observed in either group of patients in this study.

In conclusion, propofol was superior to midazolam and fentanyl for conscious sedation in achieving good quality endomicroscopic images which an accurate endomicroscopic diagnosis is based on. The sedation related outcomes, such as procedure duration, sedation duration, amnesia, endoscopist satisfaction and patient cooperation, also favor the application of propofol. Therefore, conscious sedation using propofol rather than midazolam and fentanyl might be recommended for iCLE examinations. However, the results of the present study need to be further validated with a larger population in multiple centers.

## COMMENTS

### Background

Confocal laser endomicroscopy (CLE) is a novel endoscopic modality which enables real-time visualization of cellular and subcellular structures *in vivo*. Yet in-

egrated CLE (iCLE) examination might require more patients' cooperation and better sedation so as to get endomicroscopic images of good quality and make an accurate diagnosis. Although benzodiazepines, narcotics or propofol have been administered during iCLE procedures, the most effective and satisfactory sedation agent for iCLE examination has not yet been investigated.

### Research frontiers

The clinical applications of iCLE have been validated in various gastrointestinal (GI) diseases, including Barrett's esophagus, early esophageal and gastric cancer, ulcerative colitis, and colorectal neoplasia. The most widely used sedative combination for GI endoscopy is benzodiazepine and narcotics. Recent data suggest that the use of propofol for sedation is increasing.

### Innovations and breakthroughs

This study first validated that sedation with propofol could increase the proportion of good quality endomicroscopic images, and may result in improved procedural efficacy and diagnostic accuracy during iCLE examination.

### Applications

The results of the present study help make a preferable anesthetic regimen for sedative iCLE examination. Conscious sedation using propofol rather than midazolam and fentanyl might be recommended for iCLE examinations.

### Terminology

CLE is an outgrowth of conventional laboratory confocal microscope. Currently, there are 2 CLE imaging system available in clinical practice: one is the integrated CLE (iCLE) with a miniaturized confocal microscope integrated at the distal tape of a conventional endoscope, the other is a probe-based CLE (pCLE) which is ultrathin and can be passed through the working channel of standard endoscopes.

### Peer review

Sedation is a big issue in endoscopic procedures. The authors evaluated the quality of endomicroscopic images under anesthetic condition. For getting the good quality of endomicroscopic image, extremely sedative condition is required. Therefore, the authors used variable anesthetic medicines. However, the adverse effects of sedatives are sometimes very severe. In this study, the authors found similar side effects and good quality images in propofol group. That is an important study for the future application of sedative endomicroscopy.

### Abstract

**AIM:** To investigate and compare the decompression effect on small bowel obstruction of a long tube inserted using either endoscopic or fluoroscopic placement.

**METHODS:** Seventy-eight patients with small bowel obstruction requiring decompression were enrolled in the study and divided into two groups. Intubation of a long tube was guided by fluoroscopy in one group and by endoscopy in the other. The duration of the procedure and the success rate for each group were evaluated.

**RESULTS:** A statistically significant difference in the mean duration of the procedure was found between the fluoroscopic group ( $32.6 \pm 14.6$  min) and the endoscopic group ( $16.5 \pm 7.8$  min) among the cases classified as successful ( $P < 0.05$ ). The success rate was significantly different between the groups: 88.6% in the fluoroscopic group and 100% in the endoscopic group ( $P < 0.05$ ).

### INTRODUCTION

Small bowel obstruction (SBO) is a major cause of morbidity and financial expenditure in hospitals worldwide. The etiology of SBO has changed in recent decades; whereas SBO was once predominantly due to hernias, it is now largely a result of adhesions<sup>[1-3]</sup>. It has been reported that about 50% to 80% of SBOs are caused by adhesions, mostly postoperative, with a minority being secondary to peritonitis<sup>[4-6]</sup>. Patients with partial adhesive SBO are usually given conservative management, including fasting, intravenous hydration, and decompression with a nasogastric tube<sup>[7]</sup>. Unfortunately, such treatments are successful in only 40% of cases<sup>[8]</sup>. Recently, clinical application of a long tube to decompress the obstructed intestine by aspirating the intestinal contents has achieved favorable outcomes<sup>[9]</sup>. However, because the procedure involves fluoroscopy, it is difficult to intubate a long tube

into the small bowel, which results in a protracted procedure, severe patient distress, increased x-ray exposure, and a low success rate. In this report, we describe our experience using an endoscopic technique to place a long tube into the small bowel, and evaluate the efficacy of the long tube to achieve decompression for treatment of SBO.

## MATERIALS AND METHODS

### Patients

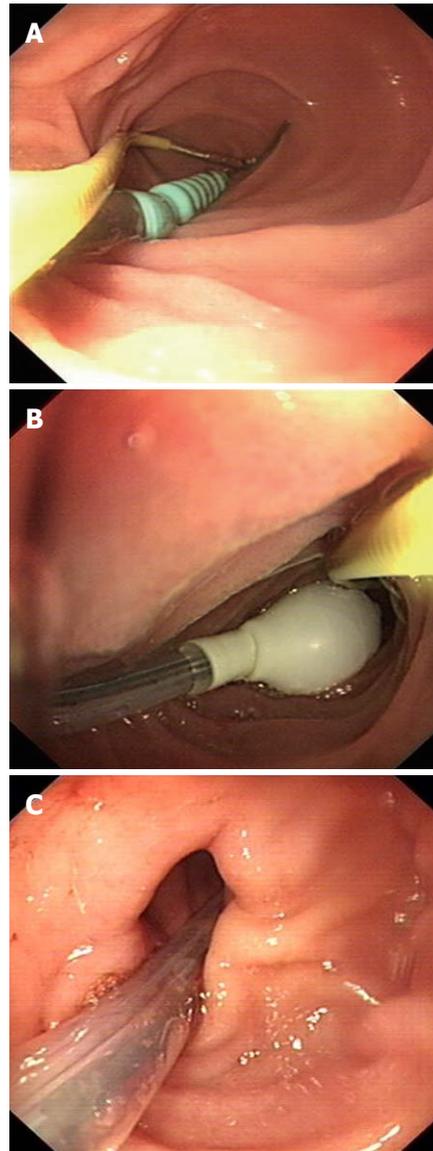

From April 2004 to August 2010, 78 patients with clinical and radiographic evidence of SBO were enrolled in this study (44 male and 34 female, age 20 to 94 years, average 58.6 years). None of the patients had contraindications for long-tube decompression, such as strangulation obstruction, incarcerated hernias, radiation enteritis, and peritonitis. The presenting manifestations were abdominal pain in 75 cases (96.2%), distension in 63 cases (80.8%), constipation in 47 cases (60.3%), and nausea and vomiting in 39 cases (50%). The study was conducted in compliance with the Helsinki Declaration and in accordance with local legislation, and was approved by the Ethics Committee of First Affiliated Hospital, Dalian Medical University. Written informed consent was obtained from all patients or their relatives before the study. The patients were divided into two groups: group A ( $n = 35$ ), in which the procedure was performed under fluoroscopy; group B ( $n = 43$ ), in which the procedure was performed with the assistance of gastroscopy.

### Instruments

A hydrophilic long tube (Create Medic, Tokyo, Japan) was used. It has an outer diameter of 16F, a working length of 3000 mm, an anterior balloon and a posterior balloon at its tip, a guidewire channel, and an injection channel with an anti-reflux valve. In addition to the tip hole, there are 8 side holes near the distal end of the tube. The guidewire was 1.24 mm in diameter and 3500 mm long (Create Medic). An endoscope (GIF Q260J; Olympus, Tokyo, Japan) was used in group B.

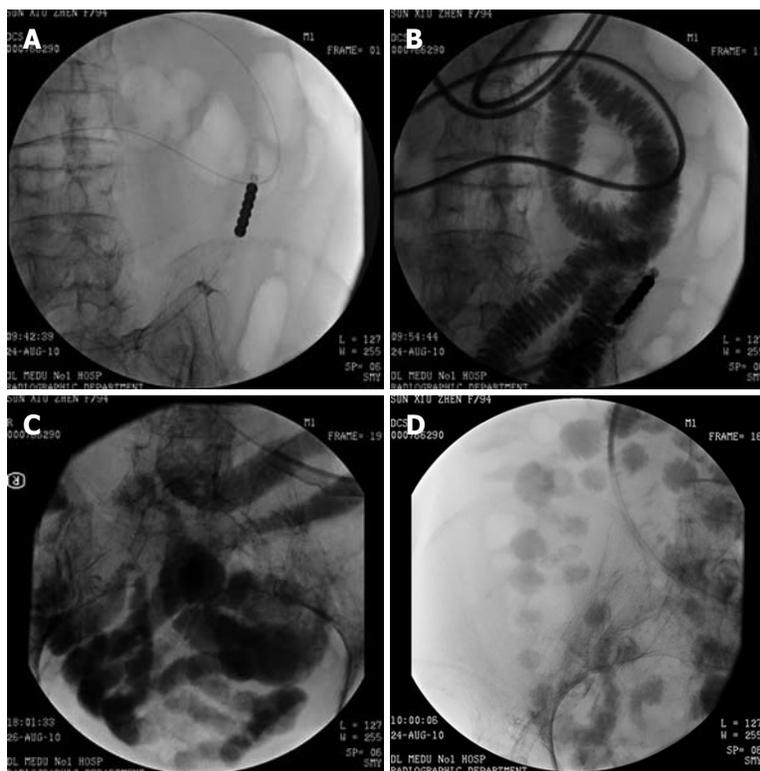

### Procedures

Tetracaine jelly was applied to the long tube to lessen both patient discomfort and the friction between the tube and the endoscope. In order to advance the long tube more easily, a guidewire was inserted into the tube to make it more rigid. The nasogastric tube was removed and a long tube was gently inserted through the nose and esophagus into the stomach. In group B, along with the long tube, an endoscope was also inserted through the mouth and esophagus into the stomach, with the patient in the left lateral decubitus position. The guidewire was placed 2 cm above the tip of the long tube so that it could be grasped easily by the biopsy forceps. The scope and tube were passed through the pylorus and advanced as far as possible (Figure 1A). Then the anterior balloon was fully inflated by injecting 20 ml of distilled water

**Figure 1** Endoscopic progress of a long-tube insertion. A: The guidewire was grasped with biopsy forceps and the scope and tube were passed through the pylorus to reach the duodenojejunal flexure; B: The anterior balloon was inflated to engage the wall of the bowel; C: The guidewire was released and the scope was withdrawn while maintaining the long tube in the small bowel.

to engage the wall of the bowel (Figure 1B), the biopsy forceps and the guidewire were released and the scope was withdrawn while maintaining the long tube in the small bowel (Figure 1C). The tube was advanced through the nose 5 cm per hour by gastrointestinal peristalsis. In group A, the long tube was inserted under fluoroscopic guidance. Postural change of the patients and transabdominal manipulation were frequently used to facilitate passage of the tube through the pyloric ring. After the long tube had reached the descending part of the duodenum, the anterior balloon was fully inflated to engage the wall of the bowel, as described above. Successful intubation was defined as insertion of the long tube into the descending part of the duodenum. The time required for the tube-insertion procedure was determined for the 2 groups. In group A, it was regarded as a failure for

**Figure 2** Abdominal flat plate images after long tube insertion. A: Location of the long tube; B: Jejunum after ingestion of contrast medium through the long tube; C: Ileum; D: Colon, showing complete relief of the small bowel obstruction after insertion of the long tube.

Table 1 Demographic characteristics of 78 patients with small-bowel obstruction		
	Group A (n = 35)	Group B (n = 43)
Gender: male to female	20:15	24:19
Age (yr)		
mean (SD)	55.6 (16.4)	56.5 (17.4)
Median (range)	57.4 (20-83)	59.3 (22-94)
Symptoms		
Abdominal pain	34	41
Distension	29	34
Constipation	22	25
Nausea/Vomiting	18	21

fluoroscopy-guided intubation if endoscopic assistance was required. During the procedure, vital signs and O<sub>2</sub> saturation were monitored if necessary. After insertion of the long tube, intermittent continuous suction was performed to reduce intraluminal pressure in the small bowel, and fluid and electrolyte deficits were corrected. Abdominal flat plate images were taken daily to evaluate the progress of the tube and the degree of decompression (Figure 2A). In some cases, water-soluble contrast medium was given through the long tube to determine the cause of the SBO, whether the obstruction was partial or complete, and whether it was completely relieved by this nonsurgical treatment (Figure 2B-D).

### Statistical analysis

Data analysis was performed using SPSS 10.0 software

(Chicago, IL, United States). Analysis of variance (ANOVA) or Wilcoxon statistical methods were used to determine statistical significance. All measurements in this study were expressed as mean ± SD. *P* < 0.05 was considered statistically significant.

## RESULTS

There was no statistically significant difference in the mean age, male-to-female ratio, and causes of bowel obstruction between the 2 groups (Table 1). The time required for placement of the long tube in the descending part of the duodenum in groups A and B was 32.6 ± 14.6 min and 16.5 ± 7.8 min, respectively (*P* < 0.05). The success rate of intubation was 88.6% in group A and 100% in group B (*P* < 0.05). Four intubations in group A failed under the guidance of fluoroscopy but were completed with the assistance of endoscopy; all 4 of these patients were male. No severe complications relevant to the procedure occurred in either group.

The obstructive symptoms of most patients were relieved within 3 d. Suction was discontinued and the balloon was aspirated when the patient had flatus. If the clinical and radiographic signs remained stable, oral intake was initiated. As the oral intake changed to full liquids, the tube was removed. Sixty-eight cases (87.2%) had complete remission. Patients who required operative intervention were defined as treatment failures. All 10 such cases (12.8%) in our study underwent laparotomy. Among them, 7 cases (9.0%) had neoplasms in the small

**Table 2** Characteristics of patients with small bowel obstruction who underwent surgery

Adhesiolysis	2	1

bowel and received bowel resections. The other 3 cases (3.8%) failed to respond to long-tube decompression because of the complete SBO and underwent adhesiolysis (Table 2).

## DISCUSSION

As one of the major causes of hospitalization and surgical consultation, SBO can come from many causes<sup>[10]</sup>. It used to be a fatal condition, with mortality as high as 50%. Since 1933, when Wangsteen used a long tube to decompress the obstructed intestine and achieved favorable results, this method has been widely used in clinical practice with improved technique<sup>[11-14]</sup>. Various long tubes have been developed for this purpose<sup>[15,16]</sup> which resulted in a remarkable reduction in mortality from bowel obstruction<sup>[9,17]</sup>. Studies<sup>[15,18]</sup> demonstrated that the decompression effect achieved with a long tube is superior to that of a nasogastric tube for the treatment of obstruction because a long tube can automatically pass into the deeper portion of the intestine by balloon transport, come closer to the obstruction and reduce the intraluminal pressure more effectively. However, because insertion of a long tube has traditionally been performed under the guidance of fluoroscopy, it is difficult to insert a long tube blindly into the small bowel, and this has many drawbacks such as prolonged procedural time, severe patient distress, and increased X-ray exposure. But direct observation by endoscopy makes it much easier and quicker to guide the tube through the pyloric ring<sup>[19]</sup>. However, the long tube is easily disturbed when the endoscope is withdrawn because of the strong friction between the tube and the endoscope. To avoid this in our studies, we fully inflated the anterior balloon to engage the wall of the bowel before withdrawing the endoscope. By using this method we improved both the success rate and the time required for tube placement. Because the entire procedure was performed by endoscopy, fluoroscopy was only used to confirm the position of the tube, thus improving the safety for both the medical staff and patients.

Postoperative adhesion is the major cause of SBO<sup>[2,3]</sup>, and adhesive SBO can be a complication of any abdominal surgery<sup>[20-24]</sup>. Long-tube decompression can aspirate

the intestinal contents, decrease edema of the bowel wall<sup>[25]</sup>, enhance bowel motility, and prevent bacterial translocation<sup>[26]</sup>. Long-tube decompression successfully relieves the obstructive symptoms in most patients with SBO<sup>[9]</sup>, especially adhesive obstructions, and may ultimately help to avoid abdominal operations in the majority of patients<sup>[2]</sup>.

Long-tube decompression achieved favorable outcomes, including reduced edema, improved circulation of the involved intestine, and correction of intestinal kinking, so that both normal size and function are restored in the distended loops of the bowel<sup>[9]</sup>. In our study, most patients with SBO were relieved of the obstruction within 72 h, and about 87.2% of the patients experienced full recovery following long-tube decompression and without the need for surgical intervention, which is consistent with other reports<sup>[9]</sup>. Moreover, no serious complications were found during the long-tube decompression treatment, which is also similar to other studies.

Although most SBOs can be resolved with tube decompression alone, surgical treatment may be required in some patients<sup>[27]</sup> because of neoplasm or strangulation. For adhesive SBO, if ileus persists more than 3 d after insertion of a long tube, or the drainage volume is still > 500 mL on day 3, surgery should be recommended to replace the conservative management<sup>[28-30]</sup>.

In our study, 10 cases underwent laparotomy. Among them, 7 cases received bowel resection because of neoplasms and 3 cases underwent adhesiolysis due to complete and multiple-site obstructions. However, even for those patients receiving laparotomy, long-tube decompression should be done before surgery to prevent the occurrence of perforation.

In conclusion, decompression with a long tube should be considered for all patients with clinical and radiographic evidence of SBO but without a strangulation obstruction or other contraindications. Long-tube insertion facilitated by endoscopy is superior to the conventional fluoroscopic method for SBO, as evidenced by the procedural success rate and time required.

## ACKNOWLEDGMENTS

The authors thank Kang Sun, Ying Sun, Professor Ai-Xia Gong and Guo-Gang Liang for performing the long-tube insertion procedures. There was no funding resource for this study.

## COMMENTS

### Background

Small bowel obstruction (SBO) is still one of the major causes of morbidity and financial expenditure in hospitals around the world. It has been reported that about 50%-80% of small bowel obstruction are caused by adhesions, mostly postoperative. Patients with partial adhesive small-bowel obstruction are usually given conservative management including fasting, intravenous hydration, and decompression with a nasogastric tube. But such treatment was successful only in 40% of all cases.

### Research frontiers

Recently, a long tube has been applied clinically to decompress the obstructed

intestine by aspirating the intestinal contents and achieved favorable outcomes. However, because the procedure used to be performed under fluoroscopy, it was difficult to incubate a long tube into the small bowel, which resulted in long procedure time, severe patient distress, increased X-ray exposure and low success rate.

### Innovations and breakthroughs

In this study, we introduced an easy technique to place a long tube assisted by endoscopy which was effective to relieve the small bowel obstruction. Compare with conventional method under fluoroscopy, the new method has advantage of less procedure time and high success rate.

### Applications

The study shows that decompression with a long tube should be considered for all patients with clinical and radiographic evidence of small bowel obstruction but without a strangulation obstruction or other contraindications. And long-tube insertion facilitated by endoscopy is superior to the conventional fluoroscopic method for small bowel obstruction according to procedural success and time required.

### Terminology

SBO: small bowel obstruction involves a partial or complete blockage of the bowel that results in the failure of the intestinal contents to pass through, mostly caused by adhesion. It can be divided into simple and strangulation obstruction according to whether the vascular supply to intestinal wall is compromised.

### Peer review

This is a good descriptive study in which authors describe their experience using an endoscopic technique to place a long tube into the small bowel, and evaluate the efficacy of the long tube to achieve decompression for treatment of SBO. The results suggest that long-tube decompression is recommended for patients with adhesive small bowel obstruction, and long-tube insertion by endoscopy was superior to fluoroscopic placement.

### Abstract

**AIM:** To investigate the function of the *KISS-1* gene in gastric carcinoma cells and to explore its potential mechanism.

**METHODS:** A *KISS-1* eukaryotic expression vector was constructed and transfected into BGC-823 cells. Resistant clones were obtained through G418 selection. reverse transcription-polymerase chain reaction and western blotting were used to detect *KISS-1* and matrix metalloproteinase-9 (MMP-9) expression in transfected cells. The growth of transfected cells was investigated by 3-(4, 5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide (MTT) proliferation assays, and the cells' invasive potential was analyzed by basement membrane (Matrigel) invasion assays. The anti-tumor effects of *KISS-1* were tested *in vivo* using allografts in nude mice.

**RESULTS:** The expression level of *KISS-1* mRNA and

protein in BGC-823/*KISS-1* transfected cells were significantly higher than in BGC-823/pcDNA3.1 transfected cells ( $P < 0.05$ ) or the parental BGC-823 cell line ( $P < 0.05$ ). The expression level of MMP-9 mRNA and protein in BGC-823/*KISS-1* were significantly less than in BGC-823/pcDNA3.1 ( $P < 0.05$ ) or BGC-823 cells ( $P < 0.05$ ). MTT growth assays show the proliferation of BGC-823/*KISS-1* cells at 48 h ( $0.642 \pm 0.130$ ) and 72 h ( $0.530 \pm 0.164$ ) were significantly reduced compared to BGC-823/pcDNA3.1 ( $0.750 \pm 0.163$ ,  $0.645 \pm 0.140$ ) ( $P < 0.05$ ) and BGC-823 cells ( $0.782 \pm 0.137$ ,  $0.685 \pm 0.111$ ) ( $P < 0.05$ ). Invasion assays indicate the invasive potential of BGC-823/*KISS-1* cells ( $16.50 \pm 14.88$ ) is significantly reduced compared to BGC-823/pcDNA3.1 ( $20.22 \pm 14.87$ ) ( $P < 0.05$ ) and BGC-823 cells after 24 h ( $22.12 \pm 16.12$ ) ( $P < 0.05$ ). *In vivo* studies demonstrate the rate of pcDNA3.1-*KISS-1* tumor growth is significantly slower than pcDNA3.1 and control cell tumor growth in nude mice. Furthermore, tumor volume of pcDNA3.1-*KISS-1* tumors ( $939.38 \pm 82.08 \text{ mm}^3$ ) was significantly less than pcDNA3.1 ( $1250.46 \pm 44.36 \text{ mm}^3$ ) and control tumors ( $1284.36 \pm 55.26 \text{ mm}^3$ ) ( $P < 0.05$ ). Moreover, the tumor mass of pcDNA3.1-*KISS-1* tumors ( $0.494 \pm 0.84 \text{ g}$ ) was significantly less than pcDNA3.1 ( $0.668 \pm 0.55 \text{ g}$ ) and control tumors ( $0.682 \pm 0.38 \text{ g}$ ) ( $P < 0.05$ ).

**CONCLUSION:** *KISS-1* may inhibit the proliferation and invasion of gastric carcinoma cells *in vitro* and *in vivo* through the downregulation of MMP-9.

## INTRODUCTION

KISS-1 has been identified as a human melanoma metastasis suppressor gene using subtractive hybridization between the metastatic human melanoma cell line C8161 and non-metastatic variants generated after microcell-mediated transfer of chromosome 6 into C8161<sup>[1]</sup>. The *KISS-1* gene maps to chromosome 1 bands q32-q41 and encodes a largely hydrophobic 145-amino-acid protein<sup>[2]</sup>. The 54-amino-acid, C-terminally amidated fragment of the KISS-1 protein (amino acids 68-121) is termed metastin, while the full-length protein is called kisspeptin<sup>[2,3]</sup>. Expression of KISS-1 is detectable in normal heart, brain, liver and lung. In human tumors, KISS-1 expression is weak or undetectable. The *KISS-1* gene product functions as tumor metastasis suppressor and is reported to act after binding with hOT7T175, an orphan G-protein-coupled receptor. Previous studies demonstrated KISS-1 could suppress metastasis of human malignant melanoma and human breast carcinoma cells without affecting tumorigenicity<sup>[4,5]</sup>. Although the loss of KISS-1 expression has been associated with tumor progression and poor prognosis in various cancers, the mechanism underlying this activity is still unknown. Investigating the role of KISS-1 in other cancers and identifying its potential mechanism in suppressing tumor metastasis will require additional experiments.

## MATERIALS AND METHODS

### Construction of recombinant expression vectors

Two primers, K1(5'-CGAAGCTTATGAACTCACTGGTTTCT-3', carrying a *HinD* I site, underlined) and K2(5'-CTGGATCCTCACTGCCCCGCACCTG-3', carrying a *BamH* I site, underlined), were designed for the *KISS-1* gene's CDS (sequence coding for amino acids in protein) domain. This sequence was amplified by quantitative reverse transcription-polymerase chain reaction (RT-PCR) with primer K1 and K2 from 50 g of human gastric tissue derived from 5 cm of the edge of gastric carcinoma lesions. Quantitative RT-PCR conditions were as follows: denaturing at 94 °C for 1 min, annealing at 48 °C for 30 s, and extension at 72 °C for 1 min. The PCR was run for 30 cycles. Final extension was performed at 72 °C for 10 min. The fragment carrying both the *HinD* I and *BamH* I site was acquired by quantitative RT-PCR. This PCR produced a product of 454 bp. The product was subjected to a double digestion with *HinD* I and *BamH* I enzymes, and the digested DNA product was ligated into a 5.4-kb fragment of pcDNA3.1 (Invitrogen, United States) that was digested with the same enzymes.

The ligated product was transformed into JM109 cells. Restriction endonuclease analysis, quantitative RT-PCR and plasmid sequencing were performed to validate the recombinant plasmid reading frame.

### Cell culture and transfection

The BGC-823 cells (a gift from Zheng Zhou University) were cultured in RPMI 1640 medium supplemented with 10% bovine calf serum, 100 U/mL penicillin and 100 U/mL streptomycin. Cells were cultured at 37 °C in a humidified incubator with 5% CO<sub>2</sub>. NIH3T3 cells cultured in the same conditions were used as controls. Twelve hours before transfection, cells were seeded onto 24-well plates at a density of 1-2 × 10<sup>5</sup> cells per well. Cells were transfected when plate confluence was approximately 90%-95%. The cells were transfected with 1.25 μL/well of pcDNA3.1-KISS-1 vector using 1 μL Lipofectamine (Invitrogen). The culture medium was replaced with a selection medium containing G418 (at concentrations ranging from 100 μg/mL to 1000 μg/mL, Alexis Biochemicals) forty-eight hours later. When stably transfected cells were obtained, the cells were continuously maintained in 200 μg/mL of G418. BGC-823 cells were transfected with the empty pcDNA3.1 vector as a control.

### Reverse transcription-polymerase chain reaction

Total RNA was isolated from cells using Trizol purification (Gibco). After denaturing RNA at 94 °C for 5 min, 500 ng of RNA was transcribed into cDNA. Next, cDNA was amplified using the following primers: KISS-1 sense (5'-ATGAACTCACTGGTTTCTTGGCAG-3'), KISS-1 antisense (5'-TCACTGCCCCGCACCTG-3'); MMP-9 sense (5'-AGGAGCGGCTCTCCAAGAAG-3') and MMP-9 antisense (5'-GGGCACTGCAGGATGTCATAG-3'). Duplex amplification was performed using a thermocycler for 30 cycles according to the following program: 1 min at 94 °C, 30 s at 48 °C (KISS-1), 60 °C (MMP-9) and 1 min at 72 °C. PCR fragments were separated by electrophoresis on a 1.5% agarose gel, with glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (315 bp) as an internal standard. PCR products were quantitated using SYNGENE gel analysis software, and GAPDH was used to normalize the data.

### Western blotting

For Western blotting protein analysis, 40 μg of total protein was separated by 10%-15% gel gradient SDS-PAGE under reducing conditions. Proteins were subsequently transferred to a polyvinylidene fluoride (PVDF) membrane. The PVDF membrane was incubated with blocking buffer (PBS containing 5% non fat milk) for 2 h at room temperature. Primary antibodies were either rabbit anti-KISS-1 (Boshide, China) or goat anti-MMP-9 (Santa Cruz, United States). Membranes were incubated overnight at 4 °C with gentle shaking. The membrane was washed twice with PBS for 5 min and incubated with secondary antibodies (Zhongshan, China) for 2 h at room temperature. After washing, KISS-1 and MMP-9 were detected using a chemiluminescence reaction. The results

were analyzed with TotalLab2.0 software. Protein levels were normalized to  $\beta$ -actin protein.

### Cell proliferation assay

Cells were seeded at  $5 \times 10^3$  cells per well in a 96-well plate and cultured in the presence of 10% fetal bovine serum for 24, 48 or 72 h. The cells were pulsed with 3-(4,5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide (MTT, Sigma, United States) 20  $\mu$ L/well [5 mg/mL in phosphate-buffered saline (PBS)] to measure cell growth. The purple-blue MTT formsazan precipitate was dissolved in 200  $\mu$ L of DMSO and swirled for 30 min. Absorbance (UA) was measured at 570 nm with a spectrophotometer. Experiments were repeated five times.

Proliferation inhibition rates (%) =  $(1 - \text{UAE}/\text{UAC}) \times 100\%$

UAE: Average UA value of experimental group; UAC: Average UA value of control group.

### Invasion assays

For invasion assays, transwell polycarbonate filters (8- $\mu$ m pore size, Millipore, United States) were coated with 100  $\mu$ L of matrigel (Sigma, United States) at a dilution of 1:20 in serum-free medium and were then air-dried for 24 h.  $5 \times 10^5$  cells in 400  $\mu$ L of complete medium were seeded into the upper chamber. Next, 200  $\mu$ L of medium was added to the lower chamber, and the plate was incubated at 37 °C in a 5% CO<sub>2</sub> incubator for 24 h. Cells on the lower surface of the filter were stained with hexamethylpararosaniline and counted. The experiment was performed in triplicate for three different cell lines.

The invasion index is defined as the number of cells that migrated through the 8  $\mu$ m pores of the filter in the experimental group divided by the number of cells that migrated through the filter in the control group  $\times 100\%$ .

The cell invasion inhibition rate is equal to the number of cells that migrated through the filter in the control group minus the number of cells that migrated through the filter in the experimental group divided by the number of cells that migrated through the filter in the control group  $\times 100\%$ .

### Tumor development in nude mice

Fourteen 4-6 wk old athymic female nude BALB/c mice (weighing 18-22 g) were purchased from the Experimental Animal Center of Shanghai, Academia Sinica. These mice were bred in specific pathogen-free conditions and were randomly divided into three groups of 8 mice per group. Three different cell lines (pcDNA3.1-KISS-1, pcDNA3.1, BGC-823) were each suspended at a concentration of  $5 \times 10^7$  cells per 0.1 mL serum-free RPMI 1640. Cells were injected subcutaneously into the right forelimb. Tumor diameters were measured every 3 d. Tumor volume was calculated according to the following formula: volume (V) =  $0.5236AB^2$  (A and B represent the long and short tumor diameter respectively). The *in vivo* growth curve of cancer cells was drawn. The animals were sacrificed 45 d after inoculation, and tumors were weighed. Inhibition rate (%) =  $[\text{tumor volume (mass)}$

of control group-tumor volume (mass) of experiment group / tumor volume (mass) of control group]  $\times 100\%$ .

### Statistical analysis

Data were analyzed using the SPSS13.0 software. Analysis of variance was conducted followed by independent-sample *t*-tests. A *P* value less than 0.05 was considered to be statistically significant.

## RESULTS

### Construction and identification of recombinant plasmids

Full-length human KISS-1 CDS domain cDNA was inserted into a pcDNA3.1 vector at the *HinD* I / *Bam* H I site to form the recombinant plasmid pcDNA3.1-KISS-1. Recombinant pcDNA3.1-KISS-1 vectors containing the *KISS-1* gene were selected through  $\alpha$ -complementation. The expression vector was further analyzed by digestion with the restriction endonucleases *HinD* I / *Bam* H I. The resulting fragment sizes were consistent with the expected fragments predicted by the expression vector map.

### Transfection of the KISS-1 gene increased expression of KISS-1 and downregulated matrix metalloproteinase-9 expression in BGC-823 cells

Strong expression of KISS-1 was observed in pcDNA3.1-KISS-1 transfected BGC-823 cells by RT-PCR and Western blotting. BGC-823 cells transfected with pcDNA3.1-KISS-1 also showed a significant reduction in MMP-9 expression ( $P < 0.05$ ). The expression of KISS-1 in pcDNA3.1-transfected BGC-823 cells and control BGC-823 cells remained low ( $P < 0.05$ ) (Figure 1).

### Transfection of KISS-1 gene suppressed cell growth

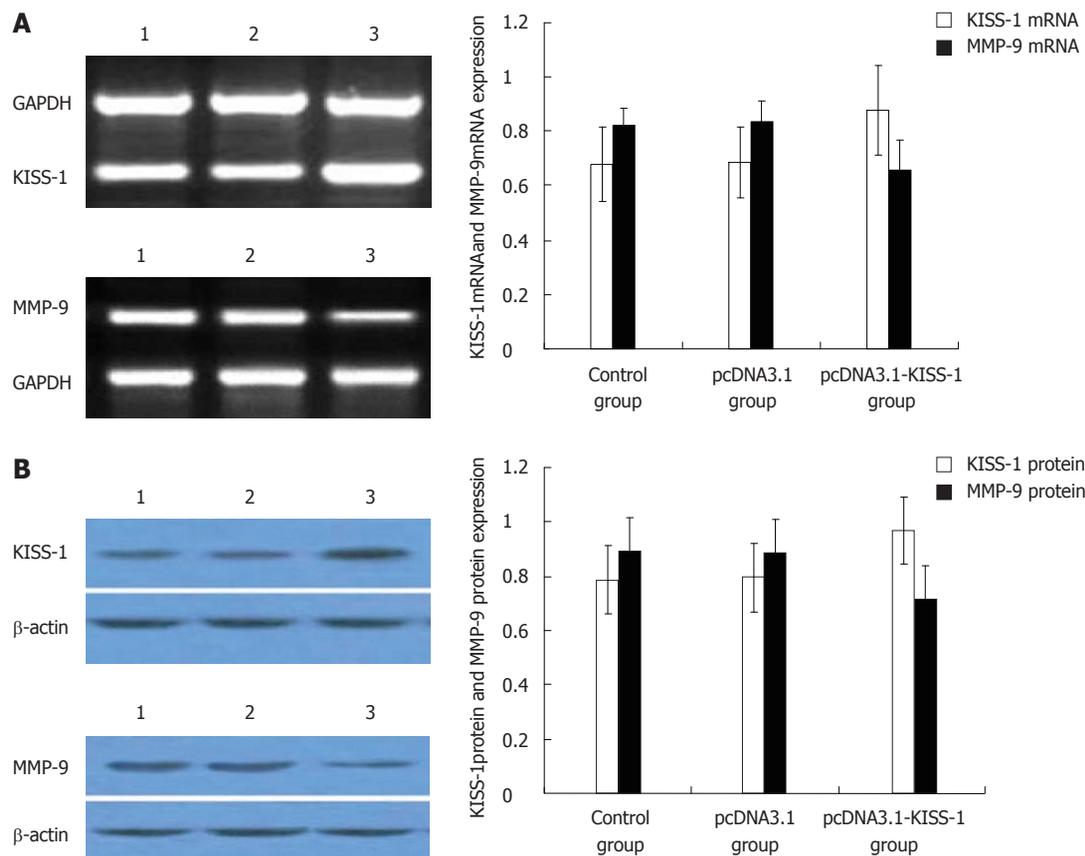

At 48 and 72 h after transfection, the absorbance values (570 nm) of pcDNA3.1-KISS-1-transfected BGC-823 cells were significantly different from those of the pcDNA3.1-transfected ( $P < 0.05$ ) and control BGC-823 cells ( $P < 0.05$ ). KISS-1 transfection decreased cell proliferation by 17.90% compared to pcDNA3.1-transfected cells and by 22.63% compared to control BGC-823 cells. These results indicate KISS-1 protein expression in BGC-823 cells strongly inhibits cell proliferation (Table 1).

### Effects of KISS-1 transfection on cell invasion

In order to invade surrounding tissue, epithelial cancer cells must degrade the underlying basement membrane. The numbers of cells that digested Matrigel and migrated through the 8- $\mu$ m pores in the filter were counted after 24 h (Figure 2). The total number of pcDNA3.1-KISS-1 transfected cells that migrated through the transwell polycarbonate filter was significantly less than the number of migrating cells in the pcDNA3.1 transfected group and control group ( $P < 0.05$ ). These data suggest that transfection with the KISS-1 expression vector results in a significant decrease in invasive capacity (Table 2).

### Tumor growth

Tumor volume was assessed 7 d after injection of tumor

**Figure 1** The expressions of KISS-1 and matrix metalloproteinase-9 mRNA and protein in BGC-823 cells. A: The expression level of KISS-1 mRNA was distinctly higher and the expression level of MMP-9 mRNA was distinctly lower in pcDNA3.1- KISS-1 group than that in pcDNA3.1 group ( $P < 0.05$ ) and control group ( $P < 0.05$ ); B: The expression level of KISS-1 protein was distinctly higher and the expression level of MMP-9 protein was distinctly lower in pcDNA3.1-KISS-1 group than that in pcDNA3.1 group ( $P < 0.05$ ) and control group ( $P < 0.05$ ). Lane 1: Control group; Lane 2: pcDNA3.1 group; Lane 3: pcDNA3.1- KISS-1group. MMP-9: Matrix metalloproteinase-9; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

pcDNA3.1-KISS-1 group	0.691 ± 0.131	7.12	0.642 ± 0.130 <sup>a</sup>	17.90	0.530 ± 0.164 <sup>a</sup>	22.63

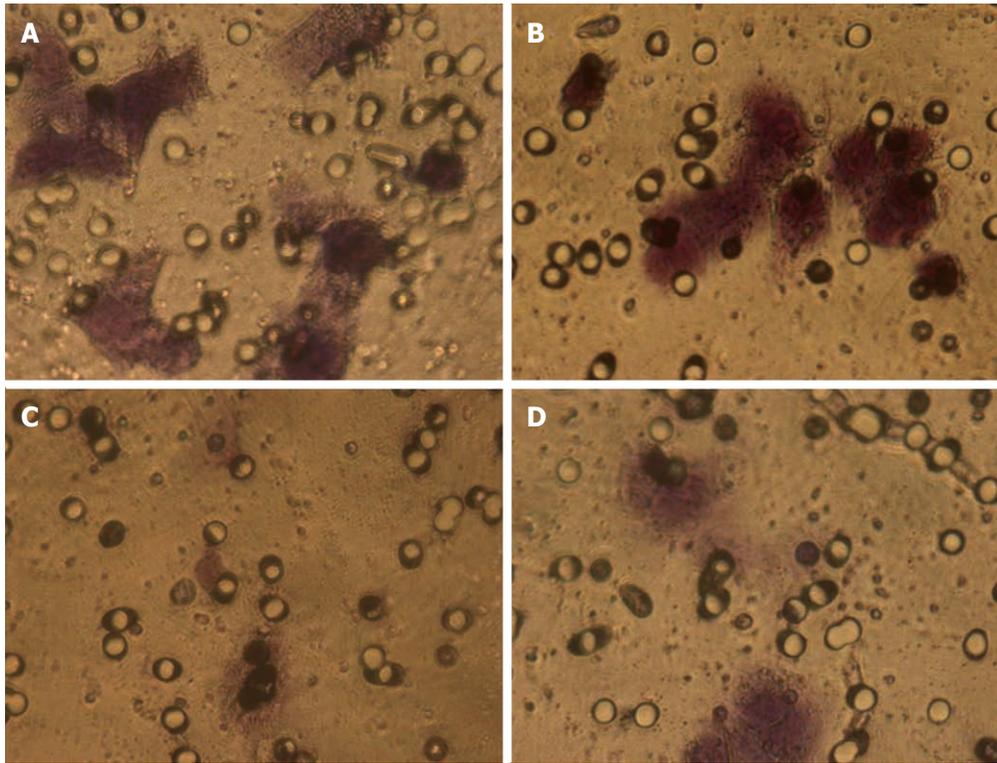

<sup>a</sup> $P < 0.05$  vs control group and pcDNA3.1 group.

cells and every 3 d thereafter until 45 d. Time curves show the percentage increase in tumor size (Figure 3). The tumor volume and mass in the pcDNA3.1-KISS-1 transfected group were both significantly less than the tumor volume and mass in the pcDNA3.1-transfected group and the control group ( $P < 0.05$ ). The tumor volume and mass inhibition rates for the pcDNA3.1-KISS-1 transfected group were 26.86% and 27.57%, respectively. No lung or liver metastatic nodules were observed. As a result of KISS-1 transfection, tumor growth was reduced (Table 3).

## DISCUSSION

The vast majority of gastric cancer deaths result from

complications caused by tumor cell metastasis rather than as a consequence of the original tumor growth. Metastasis is a multistep process involving complex interactions between tumor cells and host cells. To become metastatic, primary tumor cells must migrate from the tumor, dissociate from the tumor mass and travel to nearby or distant secondary sites. Single cells, homotypic clusters of cells, or heterotypic emboli subsequently arrest at a distant site with the use of both organ specific and nonspecific mechanisms. Next, these cells invade the surrounding tissue and respond to growth signals at the secondary site<sup>[6-9]</sup>. Interference at any one of these steps can block the metastatic cascade and prevent the formation of metastatic tumor growths. Consequently, there is increasing interest in researching the metastatic process to identify

possible ways to inhibit metastatic tumor progression.

Metastasis suppressor genes, which inhibit the spread of cancers to secondary sites, have become the target of mounting clinical and basic cancer research. Recently, the *KISS-1* gene was reported to be a novel metastasis suppressor gene in human melanoma and breast carcinoma cells<sup>[4,5]</sup>. *KISS-1* was found to reduce tumor cell invasive and migratory properties without affecting their tumorigenicity<sup>[5]</sup>. Kisspeptin, the product of the *KISS-1* gene, belongs to the RF-amide family of peptides that possess an Arg-Phe-amide sequence motif at the C terminus. This family of peptides is involved in the control of reproduction and tumor metastasis in mammals. In 2001, kisspeptin was first shown to be the endogenous ligand for the orphan G protein-coupled receptor GPR54 (or KISS1R). Kisspeptin is also called metastatin in consideration of its suppressive effects on tumor growth and tumor metastasis<sup>[2]</sup>. Blocked or reduced expression of

*KISS-1* has been found in a variety of tumor metastasis, including breast cancer, bladder cancer and pancreatic cancer<sup>[4,10,11]</sup>. These studies suggest that *KISS-1* is a human metastasis suppressor gene, and loss of *KISS-1* and its receptor may correlate with human tumor progression and metastasis. The mechanism of *KISS-1* suppression is still unknown. Recent publications suggest possible mechanisms for *KISS-1* metastasis suppression. Metastatin (this peptide is encoded from the *KISS-1* gene) induces Ca<sup>2+</sup> in receptor-transfected CHO cells<sup>[2]</sup>, as well as phosphorylation of ERK1/2 and weak phosphorylation of p38/MAPK but not of SAPK/JNK3. Metastatin inhibits motility, chemotaxis, and invasion *in vitro*<sup>[2,12]</sup>, possibly by repressing the transcription of MMP-9 via the induction of cytosolic IκBα<sup>[13]</sup>. Metastatin also induces excessive formation of focal adhesions and stress fibers in hOT7T175-transfected B16/BL6 and induces the phosphorylation of FAK and paxillin<sup>[13]</sup>, possibly through Rho<sup>[14]</sup>. Our previous work has shown that loss of *KISS-1* gene expression in tumors has a significant correlation with lymph node metastasis from gastric carcinoma. The purpose of this study was to determine whether *KISS-1* might function as a metastasis suppressor and to investigate a possible mechanism for this action in gastric carcinoma.

We constructed a eukaryotic vector containing the full-length human *KISS-1* cDNA and transfected it into BGC-823 cells. Selection with G418 enabled stably transfected cells expressing high levels of *KISS-1* protein to be obtained. In this study, we demonstrate a significant reduction in the growth of BGC-823 cells transfected

**Figure 3** Inhibition effects on growth of BGC-823 by KISS-1 transfection *in vivo*. The tumor volume in pcDNA3.1-KISS-1 transfected group was significantly lower compared with pcDNA3.1 transfected group and control group.

**Table 3** The comparison of average tumor volume and tumor weight and inhibition rate in groups

<sup>a</sup>P < 0.05 vs BGC-823 group and pcDNA3.1 group.

with an exogenous *KISS-1* gene. Additionally, the colony-forming ability of KISS-1-transfected cells was reduced *in vitro*, and tumor growth in nude mice was inhibited. Using a reconstituted basement membrane assay (Matrigel), we showed a reduction in the number of invading KISS-1 transfected BGC-823 cells. This finding indicates that the propensity for local/regional invasion and distant metastasis of gastric cancer may be dependent on its ability to invade the basement membrane. These results are similar to those reported by Lee *et al.*<sup>[4]</sup> using a breast carcinoma cell line.

Cancer mortality is largely due to distant metastases and subsequent organ failure. Metastasis involves the degradation of the basement membrane and stromal extracellular matrix (ECM) and subsequent migration into the adjacent blood vessels. This phenomenon results in tumor growth in distant organs<sup>[8,15]</sup>. Degradation of the basement membrane and ECM involve the secretion of several proteases, such as one or more members of the MMP family<sup>[16-18]</sup>. MMP-9 can cleave ECM proteins to promote cell invasion and mobility and has been described as a negative prognostic marker of metastasis and disease-free interval<sup>[19,21]</sup>. We transfected KISS-1 cDNA into BGC-823 cells and subsequently monitored the expression of MMP-9 by western blotting and RT-PCR. Our results show *KISS-1* gene transfection decreases the expression of MMP-9 and suggests that KISS-1 could downregulate expression of MMP-9.

In summary, KISS-1 is able to be exogenously expressed in eukaryotic cells. Its transient expression significantly suppresses the growth and invasion of tumor cells. Importantly, our data suggests that the effect of KISS-1 on tumor growth and invasion might occur by decreasing expression of MMP-9. In the future, additional experiments will be required to determine a role for KISS-1 in other cancers and to explore the exact mechanism of KISS-1 function.

## COMMENTS

### Background

KISS-1 has been identified as a putative metastasis-suppressor gene in human melanomas and breast-cancer cell lines. However, the mechanism of how KISS-1 works and the effects of a synthesized truncated KISS-1 protein on the proliferation and invasive ability remain unknown. Our previous studies have shown that the loss of KISS-1 expression was correlated with lymph node metastasis in gastric carcinoma tissue.

### Research frontiers

This study investigated the function of KISS-1 in gastric carcinoma cells and explored its possible mechanism.

### Innovations and breakthroughs

This study explored KISS-1 inhibits the proliferation and invasion of gastric carcinoma cells *in vitro* and *in vivo* and concluded the mechanism is mediated through the downregulation of matrix metalloproteinase-9.

### Applications

By understanding the relationship between KISS-1 and tumor-cell proliferation and invasion in gastric carcinoma, this study may be useful in the clinical management of patients with gastric carcinoma.

### Peer review

This topic is an import topic for research and the manuscript is good.

### Abstract

**AIM:** To evaluate the predictive value of preoperative predictors for portal vein thrombosis (PVT) after splenectomy with periesophagogastric devascularization.

**METHODS:** In this prospective study, 69 continuous patients with portal hypertension caused by hepatitis B cirrhosis underwent splenectomy with periesophagogastric devascularization in West China Hospital of Sichuan University from January 2007 to August 2010. The portal vein flow velocity and the diameter of portal vein were measured by Doppler sonography. The hepatic congestion index and the ratio of velocity and diameter were calculated before operation. The prothrombin time (PT) and platelet (PLT) levels were measured before and after operation. The patients' spleens were weighed postoperatively.

**RESULTS:** The diameter of portal vein was negatively correlated with the portal vein flow velocity ( $P < 0.05$ ). Thirty-three cases (47.83%) suffered from postoperative PVT. There was no statistically significant difference in the Child-Pugh score, the spleen weights, the PT, or PLT levels between patients with PVT and without PVT. Receiver operating characteristic curves showed four variables (portal vein flow velocity, the ratio of velocity and diameter, hepatic congestion index and diameter of portal vein) could be used as preoperative predictors of postoperative portal vein thrombosis. The respective values of the area under the curve were 0.865, 0.893, 0.884 and 0.742, and the respective cut-off values (24.45 cm/s, 19.4333/s, 0.1138 cm/s<sup>-1</sup> and 13.5 mm) were of diagnostically efficient, generating sensitivity values of 87.9%, 93.9%, 87.9% and 81.8%, respectively, specificities of 75%, 77.8%, 86.1% and 63.9%, respectively.

**CONCLUSION:** The ratio of velocity and diameter was the most accurate preoperative predictor of portal vein thrombosis after splenectomy with periesophagogastric devascularization in hepatitis B cirrhosis-related portal hypertension.

## INTRODUCTION

As a potentially fatal complication, portal vein thrombosis (PVT) can aggravate liver damage and increase the risk of gastrointestinal bleeding<sup>[1]</sup>. PVT can also increase the difficulty of future liver transplantation<sup>[2,3]</sup>. The incidence of PVT including splenic vein, superior mesenteric vein, or portal vein thrombosis after splenectomy with periesophagogastric devascularization in hepatitis B cirrhosis-related portal hypertension is 13.4%-43.5%. At present, most of patients with PVT undergo specific treatments after the diagnosis with color Doppler, computed tomography or magnetic resonance imaging. Alternatively, some patients undergo preventive measure, such as antiplatelet and anticoagulation therapy. However, it is not clear in PVT correlates with an increase in blood platelets count. The preventive effect of antiplatelet and anticoagulation therapy on PVT is also not conclusive. The prevention of PVT after splenectomy with periesophagogastric devascularization remains uncertain. A preoperative predictor of PVT is urgently required to guide clinical practice, to assist in the selection of an appropriate surgical procedure, and for considering the success of future liver transplantation.

## MATERIALS AND METHODS

### Subjects

From January 2007 to August, 2010, 69 patients with portal hypertension caused by hepatitis B cirrhosis underwent splenectomy with periesophagogastric devascularization in the same medical group in the West China Hospital of Sichuan University. Thirty-three (47.83%) cases suffered from postoperative PVT. The ages of the cases ranged from 35 to 68 years (mean  $37.3 \pm 10.7$  years). The inclusion criteria included clinically diagnosed portal hypertension caused by hepatitis B-induced cirrhosis in patients with a history of upper gastrointestinal hemorrhage or severe hypersplenism (white blood cell counts  $< 3 \times 10^3$ /dL or/and platelet (PLT)  $< 50 \times 10^3$ /dL). The values of the patients' platelet count ranged from  $9 \times 10^3$ /dL to  $85 \times 10^3$ /dL (mean  $33.2 \times 10^3 \pm 15.9 \times 10^3$ /dL). White blood cell counts ranged from  $0.9 \times 10^3$ /dL to  $5.7 \times 10^3$ /dL (mean  $2.4 \times 10^3 \pm 1.0 \times 10^3$ /dL). All 69 patients underwent routine preoperative endoscopic examination. The esophageal varices were evaluated by Dagradi classification<sup>[4,5]</sup>. All patients had endoscopically confirmed esophageal varices, with four mild cases, 15 moderate cases, and 50 severe cases. Sixteen cases were associated with the red-color sign. Thirty-nine cases had gastric fundus varices. Thirty patients had at least one previous instance of upper gastrointestinal bleeding. Before surgery, 33 cases were grade A according to the

**Figure 1** The anatomy of the lower part of the esophagus and periesophagogastric area after surgery. 1: Gastric branch of gastric coronary vein; 2: Esophageal branch of gastric coronary vein; 3: High esophageal branch of gastric coronary vein; 4: Aberrant high esophageal branch of gastric coronary vein; 5: Gastric short vein; 6: Gastric posterior vein; 7: Left subphrenic vein.

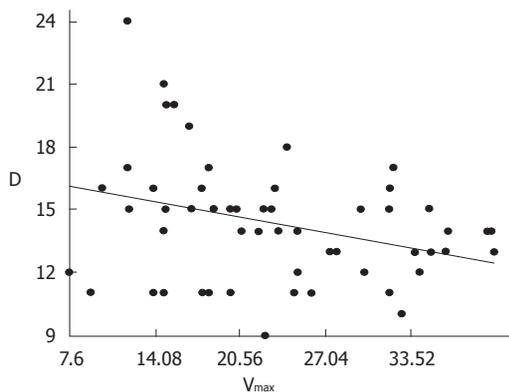

Child classification. Twenty-four cases were grade B and 12 cases were grade C. According to the Pugh-modified Child's score scale, the patients' scores ranged from 7 to 11 (mean  $7.59 \pm 1.22$ ). According to the model for end-stage liver disease score scale, the patients' score ranged from 5 to 12 (mean  $7.71 \pm 2.43$ ).

### Operation

Patients underwent surgery similar to that previously described in detail by Yang and Qiu<sup>[6]</sup>. In brief, an extended left subcostal incision or incision of the left upper abdomen was used for extreme splenomegaly. Routine splenectomy was an important part of periesophagogastric devascularization. The right gastric vein was disconnected near the gastric angular incisura. Then, the gastric branch of the right gastric vein and 5-8 small branches of the gastric coronary veins were disconnected. The esophageal branch was then disconnected and suture-ligated up to 7-9 cm of the esophageal inferior segment. The high esophageal branch went anteriorly and upward near the left-lateral hepatic lobe, and entered into the esophageal muscular layer at 4-6 cm above the cardia, and this branch should be disconnected. The gastric posterior veins and short gastric veins were ligated with sutures, and then the left subphrenic vein was also ligated. In addition, the arteries accompanied by the veins, including the left gastric artery, left gastroepiploic artery, gastric posterior artery, and left subphrenic artery, were disconnected. The net weight of the spleens were determined after surgery (Figure 1).

### Perioperative treatment

Preoperatively, patients underwent treatment to improve their functional hepatic reserve and blood clotting function [Vitk1 (20 mg), qd; 10% GS (500 mL) + 10% KCl (15 mL) + MgSO<sub>4</sub> (5 g) + RI (10 U), qd; BCAA (500 mL), qd]. On the day of surgery, Vitk1 (20 mg) and Reptilase (2000 U) were administered. On postoperative day (POD) 1, only Vitk1 (20 mg) was used. After POD 1, no hemostatic agent was administered. Postoperative patients

**Figure 2** The diameter of the portal vein is negatively correlated with the preoperative maximum portal vein flow velocity.  $V_{max}$ : The mean maximum portal blood flow velocity; D: Portal vein diameter.

underwent treatment to improve their functional hepatic reserve.

### Color Doppler ultrasound detection

Color Doppler ultrasound detection was performed by a color Doppler ultrasound system (Biosound AU 4, Esaote, Italy) on preoperative day 1 and postoperative day 7, respectively. For each measurement, at least three reproducible patterns were created to calculate the mean maximum portal blood flow velocity ( $V_{max}$ ) at the midposition of the main portal vein. The mean portal blood velocity ( $V_{mean}$ ) was calculated using the formula " $V_{mean} = 0.57 \times V_{max}$ " as described by Moriyasu *et al*<sup>[7]</sup>. The portal vein diameter was also measured at the midposition of the main portal vein. Hepatic congestion index (CI) and the ratio of velocity and diameter ( $V_{max}/D$ ) were calculated before surgery.

CI = portal vein cross sectional area/portal vein mean flow velocity =  $(\pi \times D^2/4) / V_{mean} = (\pi \times D^2/4) / 0.57 \times V_{max}$

Ratio of velocity and diameter = the maximum portal blood flow velocity/ the diameter of the portal vein =  $V_{max}/D$

All patients underwent routine PLT and prothrombin time (PT) tests on preoperative day 1 and postoperative day 7.

### Statistical analysis

Numeration data: patients were divided into two groups according the presence or absence of postoperative PVT, or were divided into two groups respectively according to the respective cut-off values of  $V_{max}$ ,  $V_{max}/D$ , CI and D. Numeration data was analyzed by  $\chi^2$  tests. Measurement data: results were expressed as mean  $\pm$  SD and were analyzed by paired-sample *t* test and by receiver operating characteristic (ROC) curves. All calculations were performed using the SPSS 12.0 statistical software. Results with *P* values < 0.05 (paired-tailed test) were considered statistically significant.

The Ethics Committee of our hospital approved the study, and all patients gave their informed consent prior to their inclusion into this investigation.

## RESULTS

### Postoperative complications

After surgery, 33 cases suffered from PVT, including splenic vein, superior mesenteric vein, or portal vein thrombosis. One case suffered from main portal vein complete obstruction, superior mesenteric vein, and splenic vein thrombosis and died on POD 7. The patient had suffered from hepatic encephalopathy and upper gastrointestinal hemorrhage before surgery, and had no opportunity to undergo liver transplantation. No patient suffered from hepatic encephalopathy after surgery. The remaining 68 patients have remained well postoperatively.

### Correlation between preoperative maximum portal blood flow velocity and the diameter of portal vein

The preoperative maximum portal blood flow velocity of the 69 cases ranged from 7.6 cm/s to 40.0 cm/s, and the mean value was  $(24.18 \pm 9.08)$  cm/s. The diameters of their portal veins ranged from 9mm to 24mm (mean value  $14.22 \pm 2.86$  mm). The diameter of portal vein was negatively correlated with the portal vein flow velocity, with the linear regression equation being  $Y = 1.6955 - 0.0113X$  ( $F = 9.88$ ,  $P < 0.05$ ) (Figure 2).

### Analytic results of the differences between the portal vein thrombosis and non-portal vein thrombosis groups

The preoperative maximum portal blood flow velocity of the group with PVT was  $18.06 \pm 5.97$  cm/s (7.6-32.3 cm/s), the preoperative maximum portal blood velocity of the group without PVT was  $29.79 \pm 7.75$  cm/s (14.0-40.0 cm/s). The diameter of portal vein of the group with PVT was  $15.39 \pm 2.97$  mm (11-24 mm), the diameter of portal vein of the group without PVT was  $13.17 \pm 2.31$  mm (9-21mm). The hepatic congestion index of the group with PVT was  $0.2126 \pm 0.1243$  cm/s<sup>-1</sup> (0.0641-0.6614 cm/s<sup>-1</sup>), hepatic congestion index of the group without PVT was  $0.0942 \pm 0.0702$  cm/s<sup>-1</sup> (0.041881-0.410575 cm/s<sup>-1</sup>). The ratio of velocity and diameter of the group with PVT was  $12.1774 \pm 4.7493/s$  (5-23.63636/s), the ratio of velocity and diameter of the group without PVT was  $23.3167 \pm 6.7956$  cm/s<sup>-1</sup> (7.047619-32.9/s). All of the above-mentioned four variables showed the statistically significant difference between the two groups ( $P < 0.05$ ). There was no statistically significant difference in the Child-Pugh score, the net weight of the patients' spleens, the value of PT and PLT count between the two groups (Table 1).

### Receiver operating characteristic curve analysis

The ROC curve (Figure 3) showed that the two variables  $V_{max}$  and  $V_{max}/D$  could be used as preoperative predictors of postoperative portal vein thrombosis. The respective values of the area under the curve were 0.865 (asymptotic 95% confidence interval: 0.780-0.950) and 0.893 (asymptotic 95% confidence interval: 0.815-0.970), and the respective cut-off values (24.45 cm/s and 19.4333 /s) were diagnostically efficient, with sensitivities of 87.9% and 93.9%, respectively, specificities of 75% and 77.8%, respectively (Figure 3).

Table 1 Differences between patients with and without portal vein thrombosis

Group	Group with PVT ( <i>n</i> = 33)	Group without PVT ( <i>n</i> = 36)	Tort' value	<i>P</i> value
Preoperative maximum portal blood velocity (cm/s)	18.06 ± 5.97	29.79 ± 7.75	6.9978	< 0.05
The diameter of portal vein (mm)	15.39 ± 2.97	13.17 ± 2.31	3.4935	< 0.05
Hepatic congestion index (cm/s <sup>-1</sup> )	0.2126 ± 0.1243	0.0942 ± 0.0702	4.812	< 0.05
The ratio of velocity and diameter (/s)	12.1774 ± 4.7493	23.3167 ± 6.7956	7.9439	< 0.05
The net weight of spleen (g)	619.4 ± 132.6	636.4 ± 235.3	0.3736	> 0.05
Preoperative PLT count (× 10 <sup>9</sup> /L)	31.5 ± 14.3	34.8 ± 17.2	0.8622	> 0.05
Postoperative PLT count (× 10 <sup>9</sup> /L)	237.8 ± 84.4	267.7 ± 137.6	1.0978	> 0.05
Preoperative PT value (s)	15.6 ± 1.4	15.9 ± 1.3	0.923	> 0.05
Postoperative PT value (s)	16.0 ± 1.8	16.4 ± 1.6	0.9772	> 0.05
Child-Pugh score	7.54 ± 1.24	7.63 ± 1.22	0.3037	> 0.05

PVT: Portal vein thrombosis; PLT: Platelet; PT: Prothrombin time.

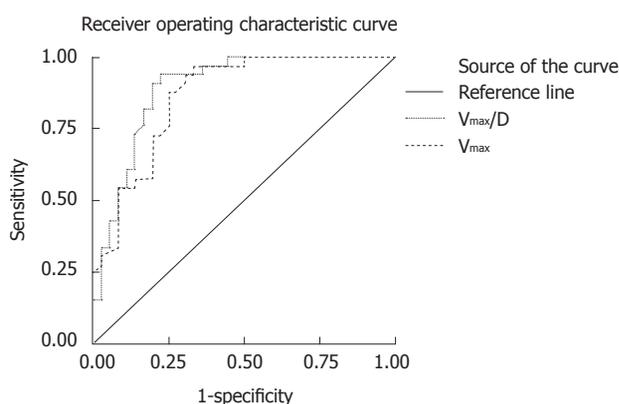

Figure 3 Receiver operating characteristic curve of the mean maximum portal blood flow velocity and  $V_{\max}$ /portal vein diameter.  $V_{\max}$ : The mean maximum portal blood flow velocity; D: Portal vein diameter.

#### Analytic results for the difference between cases with $V_{\max}$ under 24.45 cm/s ( $V_{\max} \leq 24.45$ cm/s) and cases with $V_{\max}$ above 24.45 cm/s ( $V_{\max} > 24.45$ cm/s)

The mean preoperative maximum portal blood velocity of the group with  $V_{\max}$  under 24.45 cm/s ( $n = 38$ ) was  $17.10 \pm 4.60$  cm/s (7.6-24.2 cm/s). The mean preoperative maximum portal blood velocity of the group with  $V_{\max}$  above 24.45 cm/s ( $n = 31$ ) was  $32.85 \pm 4.46$  cm/s (24.7-40.0 cm/s). Twenty-nine cases suffered from PVT in the group with  $V_{\max}$  under 24.45 cm/s (29/38, 76.32%); only four cases suffered from PVT in the group with  $V_{\max}$  above 24.45 cm/s (4/31, 12.90%). The incidence of PVT in the cases with  $V_{\max}$  under 24.45 cm/s was significantly higher than in the cases with  $V_{\max}$  above 24.45 cm/s ( $\chi^2 = 27.51$ ,  $P < 0.05$ ) (Table 2).

#### Analytic results for the differences between cases with $V_{\max}/D$ under 19.43/s ( $V_{\max}/D \leq 19.43$ /s) and cases with $V_{\max}/D$ above 19.43/s ( $V_{\max}/D > 19.43$ /s)

The mean value of cases with  $V_{\max}/D$  under 19.43/s ( $n = 39$ ) was  $(11.79 \pm 3.99)$ /s (5.00-19.00/s), the mean value of cases with  $V_{\max}/D$  above 19.43/s ( $n = 30$ ) was  $(26.05 \pm 3.82)$ /s (19.87-32.90/s). Thirty-one cases suffered from PVT in the group with  $V_{\max}/D$  under 19.43/s (31/39, 79.49%); only two cases suffered from PVT in the group with  $V_{\max}/D$  above 19.43/s (2/30, 6.67%). The incidence

of PVT in the cases with  $V_{\max}/D$  under 19.43/s was significantly higher than in the cases with  $V_{\max}/D$  above 19.43/s ( $\chi^2 = 36.04$ ,  $P < 0.05$ ) (Table 2).

#### Receiver operating characteristic curve analysis of variable congestion index and D

This ROC curve (Figure 4) showed that the two variables (CI and D) could also be used as preoperative predictors of postoperative portal vein thrombosis. The respective values of the area under the curve were 0.884 (asymptotic 95% confidence interval: 0.799-0.970) and 0.742 (asymptotic 95% confidence interval: 0.624-0.861), and the respective cut-off values (0.1138 cm/s<sup>-1</sup> and 13.5 mm) were diagnostically efficient, with sensitivities of 87.9% and 81.8%, respectively, and specificities of 86.1% and 63.9%, respectively (Figure 4).

#### Analytic results for the differences between cases with congestion index under 0.1138 cm/s<sup>-1</sup> and cases with congestion index above 0.1138 cm/s<sup>-1</sup>

The mean CI of cases with CI under 0.1138 cm/s<sup>-1</sup> ( $n = 35$ ) was  $0.0733 \pm 0.0190$  cm/s<sup>-1</sup> (0.041881-0.112652 cm/s<sup>-1</sup>). The mean CI of cases with CI above 0.1138 cm/s<sup>-1</sup> was  $0.2306 \pm 0.1193$  cm/s<sup>-1</sup> (0.114922-0.661389 cm/s<sup>-1</sup>). Twenty-nine cases suffered from PVT in the group with CI above 0.1138 cm/s<sup>-1</sup> (29/34, 85.29%); four cases suffered from PVT in the group with CI under 0.1138 cm/s<sup>-1</sup> (4/35, 11.43%). The incidence PVT in the cases with CI above 0.1138 cm/s<sup>-1</sup> was significantly higher than in the cases with CI under 0.1138 cm/s<sup>-1</sup> ( $\chi^2 = 37.71$ ,  $P < 0.05$ ) (Table 2).

#### Analytic results for the differences between cases with D under 13.5 mm and cases with D above 13.5 mm

The mean diameter of cases with D under 13.5 mm ( $n = 40$ ) was  $11.79 \pm 1.21$  mm (9-13 mm). The mean diameter of cases with D above 13.5mm was  $16.00 \pm 2.35$  mm (14-24 mm). Twenty-seven cases suffered from PVT in the group with  $V_{\max}/D$  above 13.5 mm (27/40, 67.5%). Six cases suffered from PVT in the group with D under 13.5 mm (6/29, 20.69%). The incidence of PVT in the cases with D above 13.5mm was significantly higher than in the cases with D under 13.5 mm ( $\chi^2 = 14.76$ ,  $P < 0.05$ ) (Table 2).

Table 2 Analysis of respective variables

Variable(s)	Area under the curve	Cut-off value	Sensitivity (%)	Specificity (%)	Cases above the value	Cases with PVT	Cases under the value	Cases with PVT	$\chi^2$ value	P value
$V_{\max}$	0.865	24.45 cm/s	87.9	75	31	4	38	29	27.51	< 0.05
$V_{\max}/D$	0.893	19.4333/s	93.9	77.8	30	2	39	31	36.04	< 0.05
CI	0.884	0.1138 cm/s <sup>-1</sup>	87.9	86.1	34	29	35	4	37.71	< 0.05
D	0.742	13.5 mm	81.8	63.9	40	27	29	6	14.76	< 0.05

## DISCUSSION

The causes of PVT after splenectomy with periesophago-gastric devascularization are disputed. Extrahepatic portal vein thrombosis frequently results from multiple concurrent factors, including procoagulant states and underlying myeloproliferative disorders (MPDs). The JAK2 V617F mutation is a point mutation in the Janus kinase 2 (JAK2) tyrosine kinase that is variably present in MPDs. The role of screening for the JAK2 V617F mutation in patients presenting with thrombosis without overt MPD is unclear, but appears justified in cases of idiopathic splanchnic vein thrombosis<sup>[8]</sup>. Silvia's research showed that pre-operative splenic vein diameter is a risk factor for portal-splenic vein thrombosis after laparoscopic splenectomy<sup>[9]</sup>. Shetty's research showed that among the acquired thrombophilias, MPD are the most frequent cause, while antiphospholipid antibodies and hyperhomocysteinemia have not shown very strong association with PVT<sup>[10]</sup>. Many scholars think that the rebound in PLT count post splenectomy and the hypercoagulable state cause postoperative PVTs in hepatitis B cirrhosis-related portal hypertension. Similar to Roberto's research<sup>[11]</sup>, our research showed that there was no statistically significant difference in the Child-Pugh score, the net weight of the patients' spleens, the value of PT and the PLT count between the group with PVT and group without a PVT. However, our research did show a statistically significant difference in the preoperative maximum portal blood velocity and the diameter of the portal vein between the two groups. This indicated that the rebound in PLT

count was not the main cause of postoperative PVTs. The occurrence of postoperative PVTs also did not show any correlation with the Child-Pugh score or the net weight of spleens.

Our research showed that preoperative maximum portal vein flow velocity in patients with postoperative PVT was significantly lower than in patients without postoperative PVT. The diameter of the portal vein in patients with a PVT was significantly wider than in patients without a PVT. Thus, the preoperative portal vein flow velocity and the diameter of portal vein were the important factors influencing the incidence of postoperative PVT. Our study showed that the diameter of the portal vein was negatively correlated with the preoperative maximum portal vein flow velocity. Considering to that result, the hepatic CI and the ratio of velocity and diameter ( $V_{\max}/D$ ) were both calculated before surgery.

ROC curves showed that four variables ( $V_{\max}$ ,  $V_{\max}/D$ , CI and D) could be used as preoperative predictors of postoperative portal vein thrombosis. The area under the curve of  $V_{\max}/D$  was the largest (0.893); therefore,  $V_{\max}/D$  was the most accurate preoperative predictor of portal vein thrombosis after splenectomy with periesophago-gastric devascularization in hepatitis B cirrhosis-related portal hypertension.

After surgery, four (21.90%) cases suffered from PVT in the group with  $V_{\max}$  above 24.45 cm/s and only two (6.67%) cases suffered from PVT in the group with  $V_{\max}/D$  above 19.43/s. Four cases (11.43%) suffered from PVT in the group with CI under 0.1138 cm/s<sup>-1</sup> and six cases (20.69%) suffered from PVT in the group with D under 13.5 mm. Okuda *et al.*<sup>[12]</sup> reported that the natural incidence of PVT was 6.6% in patients with hepatitis B cirrhosis-related portal hypertension that have not undergone surgery. We also showed that the incidence of PVT was very low in the patients with  $V_{\max}$  above 24.45 cm/s,  $V_{\max}/D$  above 19.43/s, CI under 0.1138 cm/s<sup>-1</sup>, or D under 13.5 mm.

Reports concerning the incidence of portal vein thrombosis splenectomy with periesophago-gastric devascularization are very uniform. Our study showed that postoperative portal vein thrombosis is mainly due to the change of portal vein blood flow dynamics, rather than a change in the value of PT or the PLT count. The incidence of postoperative PVT did not show any correlation with the Child-Pugh score or the net weight of the patients' spleens. The change of portal vein blood flow dynamics in patients with portal hypertension included

decreased portal vein velocity and increased portal vein diameter<sup>[13,14]</sup>. The decreased blood flow velocity can lead to the development of thrombus, and even the formation of eddy currents; increased portal vein diameter would lead to a vortex, causing venous intimal damage and “atherosclerosis-like” changes. In part, endothelial cells’ detachment and collagen exposure would lead to blood cell adhesion and thus thrombosis. When  $V_{\max}/D$  was above 19.43/s, postoperative thrombosis very unlikely to occur. According to the report of Deng *et al.*<sup>[15]</sup>, thrombosis mainly occurs in the perioperative period (within about one month after surgery). Thus, these patients with  $V_{\max}/D$  above 19.43/s should have a relatively good prognosis, but it still require long-term follow-up. When the  $V_{\max}/D$  is under 19.43/s, it is necessary to pay special attention to the prevention of a potential PVT after splenectomy with periesophagogastric devascularization. Further study is required to determine whether such patients require liver transplantation, but not splenectomy with periesophagogastric devascularization.

## COMMENTS

### Background

As a potentially fatal complication, portal vein thrombosis (PVT) can aggravate liver damage and increase the risk of gastrointestinal bleeding. PVT can also increase the difficulty of the future liver transplantation. The incidence of PVT, including splenic vein, superior mesenteric vein or portal vein thrombosis after splenectomy with periesophagogastric devascularization in hepatitis B cirrhosis-related portal hypertension, is 13.4%-43.5%.

### Research frontiers

The preventive effect of antiplatelet and anticoagulation therapy on PVT is not conclusive. It is still unknown as to how to prevent PVT after splenectomy with periesophagogastric devascularization. A preoperative predictor of PVT is urgently required to guide clinical practice.

### Innovations and breakthroughs

In this prospective study, 69 patients with portal hypertension caused by hepatitis B cirrhosis underwent splenectomy with periesophagogastric devascularization in West China Hospital of Sichuan University from January 2007 to August 2010. The portal vein flow velocity and diameter of portal vein were measured by Doppler sonography. Hepatic congestion index and the ratio of velocity and diameter were calculated before surgery, and the prothrombin time values and platelet levels were detected before and after surgery. The patients’ spleens were weighed after surgery.

### Applications

The ratio of velocity and diameter was most accurate as a preoperative predictor of portal vein thrombosis after splenectomy with periesophagogastric devascularization in hepatitis B cirrhosis-related portal hypertension.

### Peer review

This is a prospective study of preoperative predictors for the risk of portal vein thrombosis after splenectomy with periesophagogastric devascularization.

### Abstract

Hereditary hemorrhagic telangiectasia (HHT) is a rare autosomal-dominantly inherited disease that occurs in approximately one in 5000 to 8000 people. Clinical diagnosis of HHT is made when a person presents three of the following four criteria: family history, recurrent nosebleeds, mucocutaneous telangiectasis, and arteriovenous malformations (AVM) in the brain, lung, liver and gastrointestinal (GI) tract. Although epistaxis is the most common presenting symptom, AVMs affecting

the lungs, brain and GI tract provoke a more serious outcome. Heterozygous mutations in endoglin, activin receptor-like kinase 1 (ACVRL1; ALK1), and SMAD4, the genes involved in the transforming growth factor- $\beta$  family signaling cascade, cause HHT. We report here the case of a 63 year-old male patient who presented melena and GI bleeding episodes, proven to be caused by bleeding from multiple gastric angiodysplasia. Esophagogastroduodenoscopy revealed multiple angiodysplasia throughout the stomach. Endoscopic argon plasma coagulation was performed to control bleeding from a gastric angiodysplasia. The patient has been admitted several times with episodes of hemoptysis and hematochezia. One year ago, the patient was hospitalized due to right-sided weakness, which was caused by left basal ganglia hemorrhage as the part of HHT presentation. In family history, the patient's mother and elder sister had died, due to intracranial hemorrhage, and his eldest son has been suffered from recurrent epistaxis for 20 years. A genetic study revealed a mutation in exon 3 of ALK1 (c.199C > T; p.Arg67Trp) in the proband and his eldest son presenting epistaxis.

Gastric angiodysplasia in a hereditary hemorrhagic telangiectasia type 2 patient. *World J Gastroenterol* 2012; 18(15): 1840-1844 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i15/1840.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i15.1840>

## INTRODUCTION

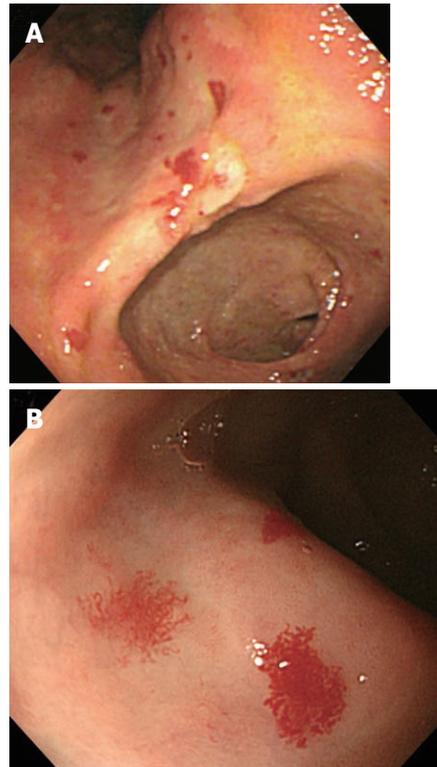

Hereditary hemorrhagic telangiectasia (HHT), also called Osler-Weber-Rendu syndrome, is a rare autosomal dominant genetic disorder occurring in about one in 5000 to 8000 people worldwide<sup>[1-3]</sup>. HHT is characterized by family history, recurrent nosebleeds, mucocutaneous telangiectasis, and arteriovenous malformations (AVMs) in the brain, lung, liver and gastrointestinal (GI) tract<sup>[4,5]</sup>. Clinical diagnosis of HHT is made when a person presents with three of these four symptoms<sup>[6]</sup>. However, due to the highly variable onset and penetrance of these clinical symptoms, HHT is often misdiagnosed. Epistaxis and skin telangiectasis are the most common presenting symptoms that appear in over 90% of HHT patients aged over 60 years<sup>[7]</sup>. Cerebral and pulmonary AVMs occur in around 10%-20% and 50% of HHT patients, respectively, and are associated with high mortality and morbidity due to stroke or brain abscess<sup>[8]</sup>. AVMs in the GI tract can lead to melena, brisk GI bleeding, and hematochezia. Most elderly HHT patients suffer from anemia due to epistaxis and GI bleeding.

Genetic studies have shown that heterozygous mutations in endoglin (*ENG*) or activin receptor-like kinase 1 (*ALK1*; *ACVRL1*) cause HHT<sup>[9-12]</sup>. HHT by *ENG* or *ALK1* mutations is designated as HHT1 or HHT2, respectively, although they are clinically indistinguishable. Some juvenile polyposis (JP) patients with *SMAD4* heterozygous mutations have shown to present HHT symptoms and are designated as JP-HHT<sup>[13,14]</sup>. Two additional genetic loci in chromosomes 5 (HHT3) and 7 (HHT4) have been identified<sup>[15,16]</sup>. HHT1 and HHT2 account for over 80% of HHT worldwide<sup>[17]</sup>.

In this report, we describe a case of a patient presenting with multiple gastric angiodysplastic lesions, intracranial hemorrhage (ICH), and a family history of ICH and epistaxis. Through genetic testing, we found a known mutation in *ALK1* (c.199 C > T; p.Arg67Trp) in the proband<sup>[18-23]</sup>. Additionally, the patient's son had been suffering from epistaxis. To our knowledge, this is the first case in Korea of genetic confirmation of HHT2 with multiple gastric angiodysplasia.

## CASE REPORT

A 63-year-old male was admitted due to melena. Examination revealed stable vital signs with normal blood pressure and heart rate, but routine laboratory tests revealed mild anemia with a hemoglobin level of 9.6 g/dL. Esophagogastroduodenoscopy (EGD) revealed multiple angiodysplastic lesions throughout the stomach (Figure 1A and B). Conservative treatment, including proton pump inhibitors, led to a stable clinical condition. The patient was subsequently hospitalized again due to hemoptysis, and then once more due to hematochezia; all were managed by conservative treatment regimens. We carefully investigated the patient's medical and family history. The patient's mother and older sister died from ICH. His eldest son had been suffering from recurrent epistaxis

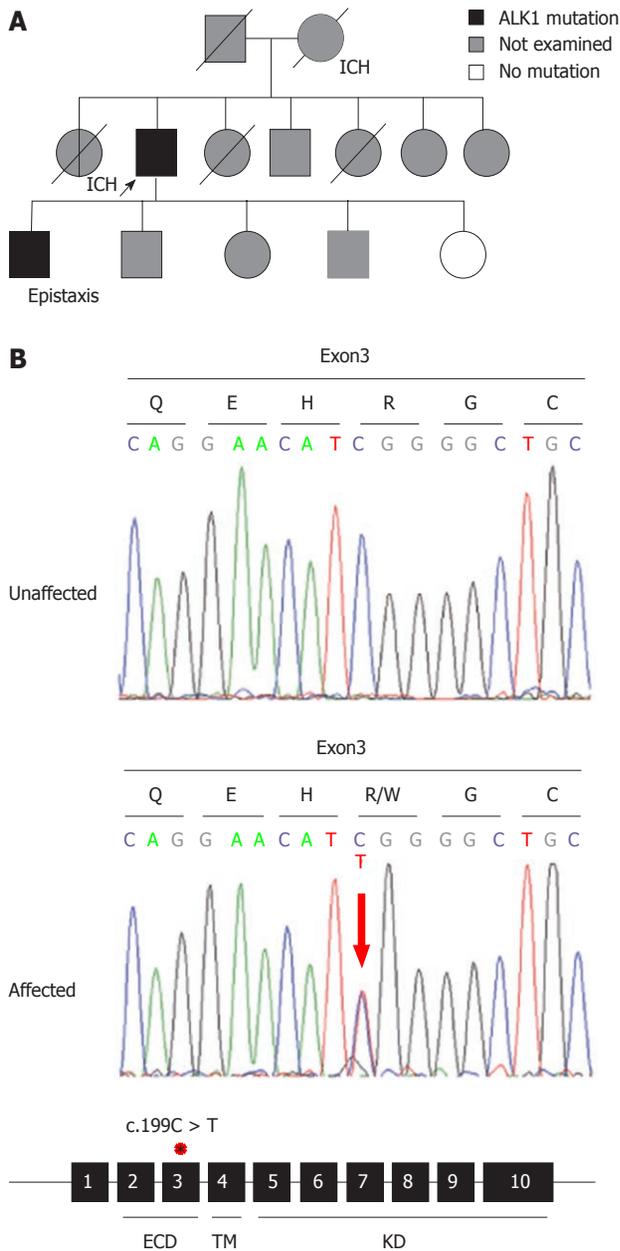

**Figure 1** Multiple angiodysplastic lesions were noted in the entire stomach upon endoscopic examination. A: A view of the lesser curvature of the angle showing multiple scattered angiodysplastic lesions; B: A view of the anterior wall of the antrum, magnified view of angiodysplastic lesions showing vessel-pulled appearance.

for 20 years (Figure 2A). Therefore, due to the presumptive diagnosis of HHT, we carried out genetic screening for the *ENG* and *ALK1* genes. A heterozygous mutation in *ALK1* was detected from the proband of both the patient and his eldest son, but not from a daughter who did not show any apparent HHT-related symptoms (Figure 2B). A single nucleotide substitution from “C” to “T” at the 199th coding nucleotide (c.199 C > T) in exon 3 changed the 67th amino acid, arginine, to tryptophan (p.Arg67Trp), resulting in loss of *ALK1* function (Figure 2B)<sup>[18-23]</sup>. Abdomino-pelvic computed tomography (CT) scan of the proband, performed for evaluation of a gallbladder stone, revealed multiple intrahepatic AV shunts (Figure 3A). Later, the proband received peritoneoscopic cholecystectomy, and then the patient was hospitalized again due to the sudden onset of right-sided weakness. Brain CT revealed ICH at the left basal ganglion, and he was transferred to a local rehabilitation facility (Figure 3B). The patient was recently admitted for percutaneous endoscopic gastrostomy insertion.

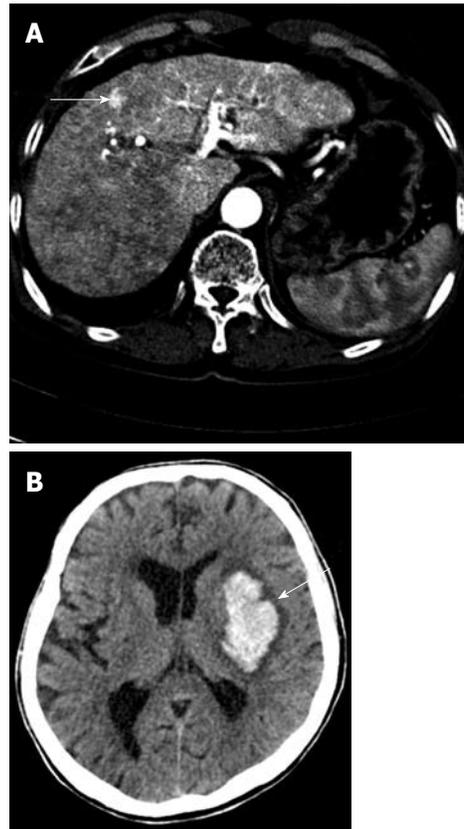

## DISCUSSION

In the present case, we report a patient with multiple angioplatic lesions in the stomach, chronic hemorrhages in the GI tract, and stroke by ICH. Presence of ICH and epistaxis in his immediate family members (mother, sister and son) led us to diagnose HHT. Genetic screen-

**Figure 2** Pedigree and genetic analysis of an hereditary hemorrhagic telangiectasia family. A: Pedigree of a family with genetic mutations and/or symptoms of hereditary hemorrhagic telangiectasia (HHT) and intracranial hemorrhage (ICH). The proband is indicated by an arrow. A divided symbol represents the individual with ICH. Deceased individuals are indicated by a slash; B: Genetic studies of unaffected and affected family members. The affected member had a heterozygous *ALK1* mutation (c.199C > T; p.Arg67Trp). The amino acid translation is shown above each codon. The mutation (a) was found in exon 3. Protein domains of *ALK1* are indicated under the exons: extracellular domain (ECD), transmembrane domain (TM), and kinase domain (KD).

ing of two HHT genes, *ALK1* and *ENG*, revealed a substitution mutation at the 199th coding nucleotide of the *ALK1* gene, specifically in the proband and the son presenting as epistaxis, but not in the daughter who had no apparent symptoms<sup>[18-23]</sup>. These data confirmed the clinical diagnosis and showed that the patient carries the HHT2 subtype. HHT1 and HHT2 are clinically similar in presentation, but genotype-phenotype correlation studies have shown that occurrence of pulmonary AVMs is sig-

**Figure 3** Hepatic arterio-venous shunt and cerebral hemorrhage. A: Abdominal computed tomography (CT) showing an intra-hepatic arterio-venous shunt; B: Cerebral hemorrhage was noted in the left basal ganglia on brain CT.

nificantly higher in HHT1, whereas liver AVM tend to be more common in HHT2<sup>[20,21,24-28]</sup>. Cerebral involvement and spinal AVMs are reported in 10%-20% and 1%-2% of HHT1 and HHT2 cases, respectively<sup>[18,27]</sup>. Whether genetic or environmental factors contributed to this observation in this family or the wider Korean HHT population remains to be determined. The mutation found in this family (c.199 C > T; p.Arg67Trp) has previously been reported by five other groups<sup>[18-23]</sup>. The 67th amino acid is located in the ligand binding domain of *ALK1*. Previous biochemical analysis of the Arg67Gln substitution resulted in a deficiency in signal transduction, suggesting a null mutation<sup>[29]</sup>. Life-threatening cerebral and pulmonary AVMs that form during development and the neonatal period are often asymptomatic for a prolonged period. Manifestations of epistaxis, skin telangiectasia, and GI AVMs are generally absent at birth, but develop over puberty and progressively worsen with age<sup>[7,30,31]</sup>. Genetic screening of asymptomatic family members would allow detection of deadly forms of vascular lesions in advance, before complications arise.

GI bleeding associated with HHT occurs in about 15%-30% of patients, and GI telangiectasia, including angiodysplasia, is a relatively common manifestation of HHT<sup>[7,32,33]</sup>. However, reports of this syndrome in the form of angiodysplasia on EGD in the GI tract, including the stomach, are rare.

Together with epistaxis, GI bleeding is a serious is-

sue for elderly HHT patients. Recent studies indicate that environmental factors such as injury and inflammation, in addition to genetic predisposition (*ALK1* or *ENG* mutations), are critical for development of AVMs in adults<sup>[34,35]</sup>. Multiple anti-inflammatory, anti-angiogenic, and anti-oxidants drugs such as thalidomide, bevacizumab and N-acetyl-cysteine have been tested as potential therapies for ameliorating epistaxis and GI bleeding<sup>[7,36]</sup>. We report here that the proband had multiple angiodysplastic lesions in the stomach and also hematochezia, indicating that vascular lesions had spread to the lower GI tract. In addition, close monitoring for GI bleeding is needed. Capsule endoscopy and conventional endoscopy may provide important information on whether these drugs can induce regression of existing vascular lesions.

In summary, we report the case of a patient in whom we found multiple gastric angiodysplastic lesions. With both clinical evaluation and genetic screening, we confirmed that the patient was suffering from HHT2. Family history and other HHT symptoms should be carefully evaluated when a patient shows multiple angiodysplastic lesions. Genetic screening has tremendous benefit not only for confirming the diagnosis but also in preventing asymptomatic family members developing life-threatening complications.

### Abstract

Most cases of Peutz-Jeghers type polyps of the stomach are associated with mucocutaneous pigmentation and multiple intestinal polyposis. A solitary Peutz-Jeghers type polyp of the stomach is rare. We here report a case of a 71-year-old woman with a solitary Peutz-Jeghers type polyp of the stomach who presented with intolerable epigastric pain and weight loss of 5 kg over the prior two months. During the hospital treatment course for this patient, endoscopic examination revealed a bulging lesion with a central hole, mucosal ulceration, an asymmetrical wall thickness and a narrowing of the gastric lumen. A gastric biopsy further revealed ulceration with moderate dysplasia. The patient received endoscopic ultrasonography which showed a second subepithelial lesion that measured 4 cm × 3 cm. Computed tomography of the abdomen subsequently showed a thickened gastric wall with three visibly enlarged lymph nodes, all greater than 1 cm. The suspected diagnosis was malignant gastric cancer with lymph node metastases. The other lesion,

which measured 2 cm × 2 cm × 1 cm was noted in the submucosa of the jejunum during surgery. The patient was treated using a subtotal gastrectomy and partial resection of the jejunal tumor. The final pathological report indicated a gastric Peutz-Jeghers type polyp with proliferation of smooth muscle bundles in the submucosal layer, and hyperplastic glands in the mucosal layer and ectopic pancreas of the jejunum. This is the first reported clinical case of a solitary Peutz-Jeghers type polyp of the stomach accompanying a lymph node enlargement and ectopic pancreas in the jejunum that simulates stomach cancer with lymph node metastases.

### INTRODUCTION

A solitary Peutz-Jeghers type polyp of the stomach is rare<sup>[1-4]</sup> and most cases are associated with mucocutaneous pigmentation and multiple intestinal polyposis<sup>[5,6]</sup>. Peutz-Jeghers type polyposes occur mainly in the small intestine, colon, and stomach, and these hamartomatous polyps are characterized by hyperplastic epithelia and by the proliferation of smooth muscle bundles around the mucosal glands<sup>[5]</sup>. We here report a case of a woman who had a rare solitary gastric Peutz-Jeghers type polyp of the stomach that mimicked gastric cancer with lymph node metastases.

**Figure 1** Image findings of gastric Peutz-Jeghers type stomach polyp. A: Abdominal computed tomography scans of the patient revealing a thickened gastric wall over the antrum of the stomach (arrow); B: Gastroendoscopy revealing a bulging lesion (4 cm × 3 cm) of the antrum (arrow); C: The bulging lesion displayed a central hole (arrow); D: Endoscopic ultrasonography demonstrating that the appearance of a lesion was due to a thickened subepithelial layer (second layer lesion), submucosal layer thickened (third layer, green arrow), and corresponding hole (red arrow) over the antrum of the stomach.

## CASE REPORT

A 71-year-old woman presented at our hospital with an extremely rare case of a solitary gastric Peutz-Jeghers type polyp of the stomach. This patient had experienced intolerable epigastric pain over the previous two months and also 5 kg of weight loss during this time. She attended the emergency room and was subsequently admitted to the hospital to receive treatment for pain. During her hospitalization, emergency computed tomography (CT) scans of the abdomen were performed and revealed a thickened gastric wall in the antrum (Figure 1A). Three enlarged lymph nodes greater than 1 cm were also detected. The CT report thus indicated a diagnosis of gastric cancer with lymph node metastases.

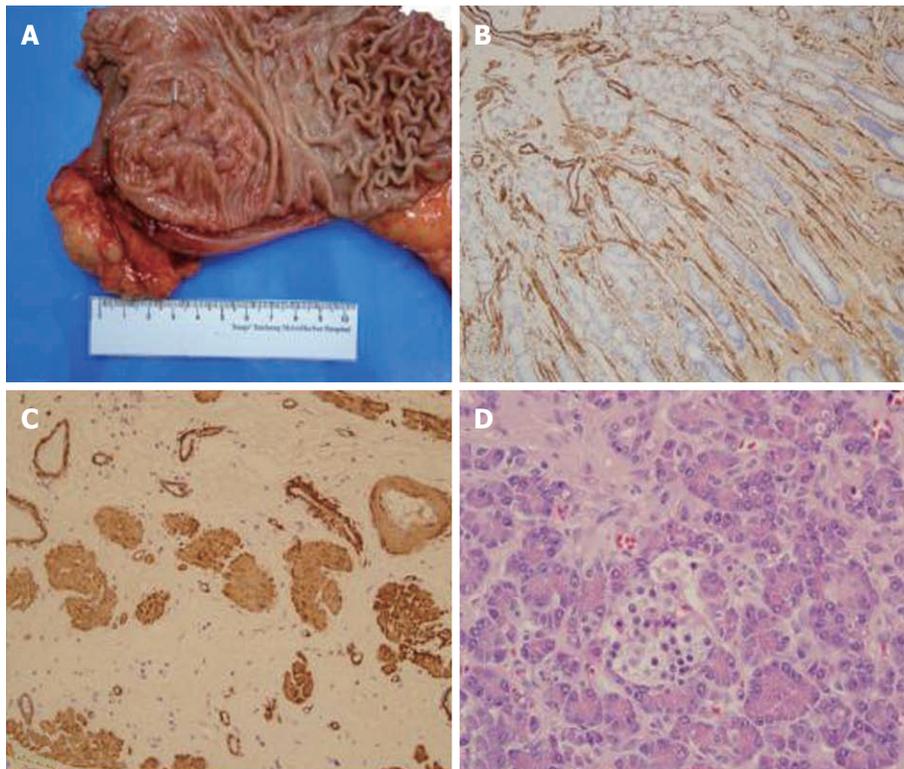

A gastroduodenoscopy was also performed and showed a bulging gastric lesion of 4 cm × 3 cm with a central hole (Figure 1B and C), in addition to an asymmetrical wall thickness and narrowing of gastric lumen in the antrum. A gastric biopsy revealed ulceration with moderate dysplasia of the mucosal glands. The patient's pain was not relieved by antacids. Further studies *via* endoscopic ultrasonography showed the presence of a subepithelial lesion of 4 cm × 3 cm with a central hole (Figure 1D).

The patient additionally underwent a diagnostic endoscopic mucosectomy (EMR), and a gastric specimen measuring 1.3 cm × 0.9 cm × 0.2 cm was thereby obtained. The subsequent pathology report identified this specimen as a hamartomatous polyp with proliferation of smooth

muscle bundles in the submucosal layer and hyperplastic glands in the mucosal layer. Because the results of the clinical examination and pathology were conflicting, a clinical diagnosis of malignant gastric cancer with lymph node metastases was made. The patient then underwent a subtotal gastrectomy. An additional lesion measuring 2 cm × 2 cm × 1 cm was noted in the submucosa of the jejunum during this surgery. Partial resection of the lesion in the jejunum was thus performed and the specimens were sent for pathological examination.

Gross examination of the lesion revealed a 4 cm × 3 cm polypoid tumor, with a central ulceration over the antrum of the stomach after diagnostic endoscopic mucosectomy (Figure 2A). Seventeen lymph nodes were dissected from the perigastric region measuring up to 1.2 cm in diameter. A submucosal lesion measuring 2 cm × 2 cm × 1 cm was also noted in the jejunum region. Histopathological examination of the lesion that had been diagnosed as a hamartomatous polyp of the stomach revealed a characteristic cell growth that increased the thickness of the mucosal glands to a maximum of about 9 mm and of the muscularis propria to 11 mm (Table 1). Smooth muscle bundles were found to be interspersed around the glands (Figure 2B), and smooth muscle bundles were observed to have proliferated over the submucosal layer (Figure 2C).

The 17 dissected lymph nodes showed reactive hyperplasia without tumor metastasis. The jejunum lesion contained ectopic pancreatic tissue with ducts, acini and

**Figure 2** Pathological findings of gastric Peutz-Jeghers type stomach polyp. A: Gross examination of a stomach specimen from the patient showed a polyp-like lesion (4 cm × 3 cm) over the antrum following endoscopic mucosectomy; B: Immunohistochemical staining of smooth muscle actin in the mucosal layer revealed a proliferation of smooth muscle bundles (× 200); C: Submucosal layer of the lesion revealed a proliferation of smooth muscle bundles (× 200); D: Photomicrogram demonstrating the presence of an ectopic pancreas in the submucosa of the jejunum and of pancreatic ducts, acini and islet cells (hematoxylin and eosine staining, original magnification × 200).

	Patient	Normal (n = 3)
Mucosa layer (mm)	5-9	3-5
Smooth muscle bundles	Diffuse increase	Focal few
Muscularis mucosa (μm)	10-30	10-30
Submucosal layer (mm)	3-5	3-5
Diffuse increase	Smooth muscle bundles	none
Muscle propria (mm)	5-11	5-7

islet cells, with interspersed smooth muscle bundles (Figure 2D). Immunohistochemical staining revealed strong cytoplasmic signals for smooth muscle actin between the mucosal glands (Figure 2B) and the submucosal layer (Figure 2C). A gastrointestinal stromal tumor was ruled out by negative staining for c-Kit (c-Kit pharmDx™; Dako Corporation, Glostrup, Denmark). The final pathological determination was a gastric Peutz-Jeghers type polyp and jejunal ectopic pancreas. This is therefore the first reported case of a solitary Peutz-Jeghers type polyp of the stomach that presented with clinical signs mimicking a stomach cancer with lymph node metastases.

## DISCUSSION

A solitary Peutz-Jeghers type polyp of the stomach is found in fewer than 0.1% of all endoscopic examina-

tions<sup>[5]</sup>. Bartholomew *et al*<sup>[5]</sup> have previously observed that polyps are present in the stomach in only 24% of cases of Peutz-Jeghers syndrome associated with intestinal polyposis, mainly in the small intestine. Moreover, only 27 cases of gastric solitary hamartomatous polyps have been reported thus far in the literature. The predominant components of hamartomas are hyperplastic mucosal glands and smooth muscle bundles in the mucosal layer<sup>[1-4]</sup>. Some authors have concluded that solitary Peutz-Jeghers type polyps are histologically identical to those in Peutz-Jeghers syndrome<sup>[4]</sup>. In contrast, other investigators have suggested that solitary Peutz-Jeghers type polyps of the stomach have less branching of the muscularis mucosae than those of the familial form<sup>[3]</sup>. Our current case demonstrated extensive branching of the muscularis mucosae to the mucosal layer that also extended to the submucosal layers. This distinct finding of a proliferation of smooth muscle bundles in the submucosal layer has not been previously reported.

Gastric hamartomatous polyps are usually asymptomatic, and most cases are found incidentally during a routine gastric endoscopy. Few previous cases have presented with intestinal obstruction or anemia due to chronic blood loss, or were found to be accompanied by a transformation to adenocarcinoma<sup>[6-9]</sup>. Our patient presented with intolerable epigastric pain and weight loss of 5 kg during the two months prior to admission to our hospital. CT scans of this patient's abdomen revealed three

enlarged lymph nodes, all of which measured more than 1 cm. In addition, a submucosal lesion over the jejunum was noted. Our patient showed extensive proliferation of smooth muscle bundles in the submucosal layer, which gave the gastric lesion the appearance of a submucosal tumor. These characteristics thus need to be differentiated from those of a submucosal gastrointestinal stromal tumor (GIST). A diagnosis of gastric GIST was ruled out in our current case by negative c-Kit (CD117) staining.

In conclusion, this is the first reported case of a solitary Peutz-Jeghers type polyp that was associated with symptoms mimicking a gastric tumor with lymph node metastases. In addition, the association of an ectopic pancreas with solitary Peutz-Jeghers type polyp of stomach has also not been reported previously.

### Abstract

We read with great interest the editorial article by Meshikhes AWN published in issue 25 of *World J Gastroenterol* 2011. The article described the advantages of emergency laparoscopic appendectomy compared with interval appendectomy as a new safe treatment modality for the appendiceal mass. The author concluded that the emergency laparoscopic appendectomy was a safe treatment modality for the appendiceal mass, and might prove to be more cost-effective than conservative treatment, with no need for interval appendectomy. However, we would like to highlight certain issues regarding the possibility of percutaneous catheter drainage to successfully treat the appendiceal mass, with no need for appendectomy, too.

**Key words:** Appendiceal mass; Percutaneous drainage; Antibiotic therapy; Interval appendectomy; Laparoscopic appendectomy

### TO THE EDITOR

We commend Meshikhes AWN<sup>[1]</sup> for an interesting editorial article about the advantage of emergency laparoscopic appendectomy (LA) compared with interval appendectomy (IA) as a new and safe treatment modality for the appendiceal mass. The author concluded that the emergency LA was a safe treatment modality for the appendiceal mass, and might prove to be more cost-effective than conservative treatment, with no need for IA. LA is associated with a much shorter hospital stay and it obviates the need for long-term intravenous antibiotic treatment. If emergency LA becomes the standard of care, IA will certainly become 'something' of the past.

However, on the basis of our long-term experience<sup>[2]</sup>, we would like to highlight certain issues regarding the possibility of percutaneous catheter drainage (PCD) as the treatment modality which can successfully solve the appendiceal mass formed after acute perforated appendicitis, thereby obviating the need for an emergency appendectomy. LA is less aggressive than open surgery, but it is a much more aggressive procedure as compared with PCD performed under ultrasound or computerized

tomography. The latter can be performed without general anesthesia and with less tissue dramatization. We strongly believe that PCD followed by vigorous irrigation can achieve good results in the majority of patients with appendiceal mass.

A few years ago, we conducted a randomized controlled trial<sup>[2]</sup> in order to evaluate whether PCD could successfully and completely treat the appendiceal mass, thereby avoiding the need for appendectomy. The conclusion of our study was that PCD with antibiotics administration was a safe and effective treatment protocol for acute perforated appendicitis. The appendicitis recurrence rate was rather low and very often interval appendectomy was not required. For patients with appendiceal mass  $\geq 3$  cm in diameter, antibiotic treatment alone was insufficient and the recurrence rate was high.

Our hypothesis was based on the estimation that obstruction of proximal appendiceal lumen by fecaliths, foreign bodies, tumors, parasites, and lymphoid hyperplasia accounted for approximately 70% of the causes of appendicitis<sup>[2]</sup>. Obstruction of appendiceal lumen is followed by mucus secretion, bacterial overgrowth, increasing intraluminal pressure and wall tension, vascular congestion, gangrene, perforation, and disintegration of appendix distal to the site of obstruction. Our idea was derived from the fact that appendiceal lumen obliteration

with subsequent fibrosis of the rest of perforated appendix after drainage of necrotic content and pus so that appendicitis could be resolved without appendectomy<sup>[2]</sup>.

We agree that the advantage of emergency laparoscopic appendectomy lies in the detection of hidden pathologies. However, hidden pathology can be encountered occasionally and failure to detect it can be avoided by performing appropriate follow-up investigations to exclude its presence.

In summary, we believe that PCD is technically feasible in the majority of patients with appendiceal mass. Therefore, PCD with continuous drainage and followed by vigorous irrigation and proper administration of antibiotics should be considered the therapy of choice for some patients with appendiceal mass formed after acute perforated appendicitis.

---

## INSTRUCTIONS TO AUTHORS

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

#### Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copyright” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

#### Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

#### Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word ‘significantly’ should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read “Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest” from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator’s national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

eases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/eid/index.htm>

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

---

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### *Language evaluation*

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### *Copyright assignment form*

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### *Responses to reviewers*

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Links to documents related to the manuscript*

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### *Science news releases*

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### *Publication fee*

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

# World Journal of *Gastroenterology*

*World J Gastroenterol* 2012 April 28; 18(16): 1851-1998

## Editorial Board

2010-2013

The *World Journal of Gastroenterology* Editorial Board consists of 1352 members, representing a team of worldwide experts in gastroenterology and hepatology. They are from 64 countries, including Albania (1), Argentina (8), Australia (33), Austria (15), Belgium (14), Brazil (13), Brunei Darussalam (1), Bulgaria (2), Canada (21), Chile (3), China (82), Colombia (1), Croatia (2), Cuba (1), Czech (6), Denmark (9), Ecuador (1), Egypt (4), Estonia (2), Finland (8), France (29), Germany (87), Greece (22), Hungary (11), India (32), Indonesia (2), Iran (10), Ireland (6), Israel (13), Italy (124), Japan (140), Jordan (2), Kuwait (1), Lebanon (4), Lithuania (2), Malaysia (1), Mexico (11), Morocco (1), Moldova (1), Netherlands (32), New Zealand (2), Norway (13), Pakistan (2), Poland (11), Portugal (6), Romania (4), Russia (1), Saudi Arabia (3), Serbia (3), Singapore (11), Slovenia (1), South Africa (3), South Korea (46), Spain (43), Sri Lanka (1), Sweden (17), Switzerland (12), Thailand (1), Trinidad and Tobago (1), Turkey (30), United Arab Emirates (2), United Kingdom (95), United States (285), and Uruguay (1).

### Abstract

Recognition and management of gastrointestinal and hepatic complications of hematopoietic stem cell transplantation has gained increasing importance as indications and techniques of transplantation have expanded in the last few years. The transplant recipient is at risk for several complications including conditioning chemotherapy related toxicities, infections, bleeding, sinusoidal obstruction syndrome, acute and chronic graft-versus-host disease (GVHD) as well as other long-term problems. The severity and the incidence of many complications have improved in the past several years as the intensity of conditioning regimens has diminished and better supportive care and GVHD prevention strategies have been implemented. Transplant clinicians,

however, continue to be challenged with problems arising from human leukocyte antigen-mismatched and unrelated donor transplants, expanding transplant indications and age-limit. This review describes the most commonly seen transplant related complications, focusing on their pathogenesis, differential diagnosis and management.

### INTRODUCTION

The indications of both autologous and allogeneic hematopoietic stem cell transplantation have expanded over the past decade including for malignant and nonmalignant disorders<sup>[1,2]</sup>. Transplant clinicians routinely encounter gastrointestinal and hepatic disorders and complications before, during and after the transplant. The outcome of transplant is often closely related to how well these complications are managed. This review provides a current overview of these disorders including pathogenesis, clinical diagnosis and management.

**Table 1** Emetogenic potential of chemotherapeutic agents used in stem cell transplantation

	Chemotherapeutic agent
High (90%) emetogenic risk	Carmustine > 250 mg/m <sup>2</sup> Cyclophosphamide > 1500 mg/m <sup>2</sup>
Moderate (30%-90%) emetogenic risk	Busulfan Cytarabine > 200 mg/m <sup>2</sup>
Low (10%-30%) emetogenic risk	Melphalan Etoposide
Minimal (< 10%) emetogenic risk	Fludarabine Rituximab

## EVALUATION OF TRANSPLANT CANDIDATE

Patients referred for hematopoietic stem cell transplantation undergo a detailed evaluation including history and physical examination which encompasses the history of disease requiring transplant as well as pre-existing conditions including dental problems, vaccination, travel, blood transfusion and infectious disease exposure history<sup>[3,4]</sup>. Imaging studies including computerized tomography (CT) with/without positron emission tomography scan or magnetic resonance imaging (MRI) can be performed to localize and restage the malignancy. Infectious disease markers including human immunodeficiency virus (HIV)-1 and (HIV)-2, human T-cell leukemia virus (HTLV)-1 and (HTLV)-2, hepatitis B virus (HBV) and hepatitis C virus serologies, cytomegalovirus (CMV), Epstein-Barr virus (EBV), herpes simplex virus (HSV)-1 and (HSV)-2, varicella zoster virus (VZV) and rubella titers are checked within 30 d prior to transplant admission. In addition to routine blood count, liver function and coagulation studies are obtained. Donors for allogeneic transplant also undergo the same serologic testing within 30 d of stem cell collection. Donors with viral hepatitis B and hepatitis C pose the risk of disease transmission to the recipient up to 30% and 100% respectively<sup>[5,6]</sup>. The risk of fatal HBV infection in recipients who become HBsAg positive is about 12%<sup>[5]</sup>. By contrast, HCV transmission during transplant does not usually pose an increased short or mid-term clinical risk to the recipient yet does increase the long-term risk of cirrhosis<sup>[7]</sup>. Therefore donors should be treated with anti-viral agents; pegylated interferon  $\alpha$  (IFN- $\alpha$ ), famciclovir or lamivudine for hepatitis B and IFN- $\alpha$  plus ribavirin for hepatitis C before stem cell collection if time permits<sup>[8,9]</sup>. Of note, IFN- $\alpha$  should be stopped at least 1 wk before stem cell collection to avoid engraftment problems.

Patients with existing nausea, heartburn, dysphagia, abdominal pain, diarrhea, Crohn's disease or ulcerative colitis should be investigated with endoscopy prior to transplant to rule out mucosal ulcers and infections as the risk of bleeding is increased during the periods of thrombocytopenia.

Abnormal liver enzymes and organomegaly should be investigated with ultrasound, CT or MRI. Liver biopsy is

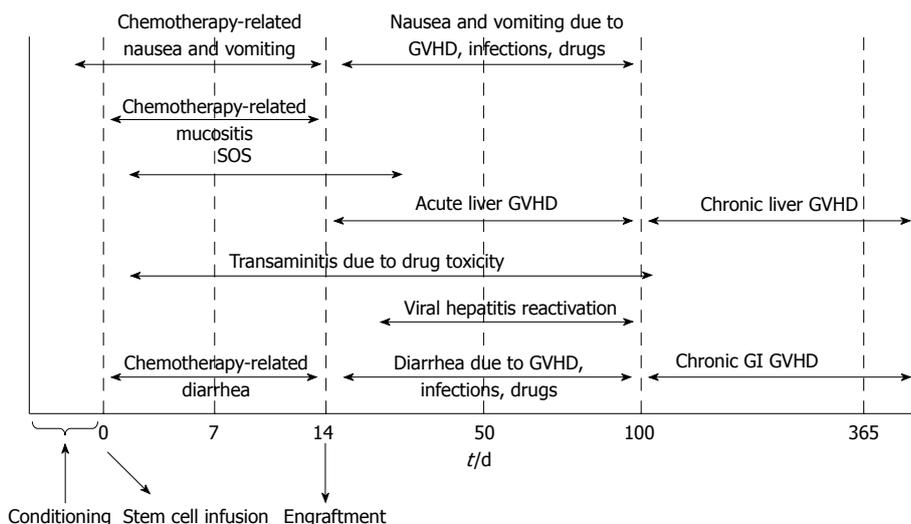

indicated in patients with positive hepatitis B surface antigen or hepatitis C antibody to rule out hepatic fibrosis or cirrhosis which increases the risk of fatal sinusoidal obstruction syndrome (SOS)<sup>[10]</sup>. Evidence of advanced liver fibrosis is a contraindication to proceed to stem cell transplantation because of excess transplant-related mortality. Pre-existing liver dysfunction can be secondary to viral hepatitis as well as alcoholic or non-alcoholic steatohepatitis, iron overload, fungal infection, chemotherapy-induced cholestatic injury or hepatocyte damage, fibrosis, extramedullary hematopoiesis or prior liver irradiation<sup>[11]</sup>. Myeloablative conditioning regimens, recent exposure to alkylating agents (especially cyclophosphamide) and exposure to newer drugs, such as imatinib and gemtuzumab ozogamicin, are known associations with increased risk of SOS<sup>[12-14]</sup>.

Hepatitis B infected transplant candidates are at risk for hepatitis flare and fulminant hepatitis can occur in up to 50% of transplant recipients in the absence of antiviral prophylaxis<sup>[15,16]</sup>. In the presence of isolated HBV core antibody, observation or prophylaxis are both acceptable approaches. If HBV surface antigen is detected, it is usually recommended that prophylaxis with oral nucleoside therapy is initiated prior to transplant and that HBV DNA levels are monitored frequently during the post-transplant period<sup>[17]</sup>. Even in the absence of cirrhosis, HCV infected patients have an increased risk of SOS especially if pre-transplant aspartate aminotransferase is elevated<sup>[18]</sup>. There is no effective prophylaxis or treatment of hepatitis C for transplant recipients as pegylated IFN- $\alpha$  is contraindicated due to myelosuppression and has the potential to exacerbate graft-versus-host disease (GVHD). Ribavirin alone can be tried while patient is on immunosuppressive therapy.

Patients with conditions causing transfusion dependency such as myelodysplastic syndrome, leukemia, lymphoma and aplastic anemia should be screened for iron overload as excess iron can impair Kupffer cell function and increase the risk for mold infections<sup>[19]</sup>. The excess iron can be demonstrated either by quantification of iron in liver biopsy tissue or MRI of the liver. Patients with severe iron overload can benefit from chelation pre-transplant. However the urgent need for the transplant may preclude this option. The relationship between iron overload and transplant-related toxicity has not been well established and in most cases chelation can be postponed after the transplant.

## NAUSEA AND VOMITING

Many chemotherapeutic agents, with or without total body irradiation used in the conditioning regimens, have significant emetogenic potential (Table 1). The pathogenesis includes stimulation of the chemotherapy trigger zone in the brainstem which activates the vomiting center by increasing efferent output to target organs in the gastrointestinal tract, resulting in subsequent emesis. Chemotherapy also causes cell damage in the gastroin-

**Figure 1** Timeline summary of hepatic and gastrointestinal complications of stem cell transplantation. GVHD: Graft-versus-host disease; SOS: Sinusoidal obstruction syndrome; GI: Gastrointestinal.

testinal (GI) tract, resulting in the release of neuroactive agents and vagal stimulation, increasing afferent input to the chemotherapy trigger zone and the vomiting center in the brainstem.

Patients usually experience the chemotherapy related side effects during the early post-transplant (15 d) period before engraftment (Figure 1). Nausea and vomiting in later phases may be due to other potential etiologies including upper GI acute GVHD and infections such as HSV, VZV, CMV, adenovirus, fungus and *Helicobacter pylori*. Persistent or recurrent nausea not responsive to routine anti-emetic regimens should be investigated further for GVHD with upper GI endoscopy which may show mucosal edema and erythema and biopsy findings consistent with local lymphocytic infiltrates and epithelial apoptosis<sup>[20,21]</sup>. Specimens should also be studied for bacterial or fungal cultures, HSV and CMV infections as viral infections can be detected in the GI tract without the presence of virus DNA in serum. Other common medical etiologies such as medication intolerance, gastroparesis, intestinal obstruction, intraabdominal infections, neurologic and metabolic causes should also be considered.

Prevention is the key to success in managing nausea and vomiting during the peri-transplant period<sup>[22]</sup>. Acute emesis prevention (up to 24 h after chemotherapy) can be achieved with a combination of corticosteroids (dexamethasone 10-20 mg iv/po daily or methylprednisolone 40-125 mg iv/po daily) and 5-hydroxytryptamine-3 receptor antagonists (ondansetron 16-24 mg iv/po daily or granisetron 1-2 mg daily). Delayed emesis (up to 5 d after treatment) can usually be prevented with corticosteroids. Aprepitant neurokinin-1 antagonist is an effective agent for this purpose; however it may interact with several post-transplant immunosuppressive agents and therefore is sparingly and cautiously used, especially in the allogeneic stem cell transplant setting.

Treatment options for breakthrough nausea and vomit-

ing include phenothiazines (prochlorperazine, promethazine), metoclopramide, lorazepam, haloperidol, dronabinol and corticosteroids<sup>[23]</sup>.

## OROPHARYNGEAL MUCOSITIS AND DYSPHAGIA

Breakdown of mucosal barrier presenting as mucositis is a common complication during the early post-transplant period. It affects up to 80% of transplant recipients, especially with radiation-based myeloablative regimens<sup>[24]</sup>. Chemotherapeutic agents commonly causing mucositis include busulfan, etoposide, melphalan and methotrexate. Pre-existing periodontal disease and prior radiation to the head and neck area increase the risk of post-transplant complications. Mucositis can result in significant oral pain and dysphagia, decreased oral caloric intake as well as bleeding, infection, upper airway edema and obstruction. Clinically apparent mucositis usually starts 5-10 d after initiation of the conditioning regimen (Figure 1). Initial erythema and atrophy is followed by ulceration and healing phases. It may take up to two weeks for healing of chemotherapy-induced mucositis.

Infectious causes of mucositis include CMV, HSV, VZV, varicella zoster virus, *Candida* species and bacterial pathogens. The incidence of viral and fungal infections has been significantly lower since the standardization of antiviral and antifungal prophylaxis regimens. Other noninfectious causes of dysphagia should be included in the differential diagnosis such as acid-reflux disease, pill esophagitis and acute and chronic GVHD with esophageal strictures.

Prevention and early treatment is critical to minimize the duration and severity of symptoms. Frequent mouth rinsing with topical agents and oral cryotherapy with ice chips are started with chemotherapy and continued until

engraftment. Keratinocyte growth factor (palifermin) has been shown to decrease the incidence of mucositis by 40% in patients receiving autologous stem cell transplant with aggressive total body irradiation (TBI)-based regimens<sup>[25,26]</sup>. It is administered iv for 3 d before and after cytotoxic therapy. Other supportive measures include saline and bicarbonate rinses, mucosal coating agents (such as aluminum hydroxide), topical anesthetics such as lidocaine rinse and/or narcotic analgesia, topical nystatin for signs of candidiasis and proton-pump inhibitor prophylaxis. Total parenteral nutrition should be considered for patients who are unable to tolerate oral supplementation for more than 7 d.

## DIARRHEA

Diarrhea occurs in almost half of patients receiving high-dose chemotherapy conditioning and radiotherapy. It is most commonly associated with toxicity of conditioning regimens within the first 2 wk after transplant (Figure 1). Alkylating agents, busulfan and combination regimens are frequent etiologies and cause diarrhea due to mucosal inflammation. Several other etiologies should be considered in patients having diarrhea in the post-transplant period (Table 2). Acute GVHD is the most common reason for diarrhea after engraftment (> 15 d) in allogeneic transplants<sup>[27]</sup>; persistent or new diarrhea beyond 3 wk of transplant should be investigated for GVHD. The diarrhea

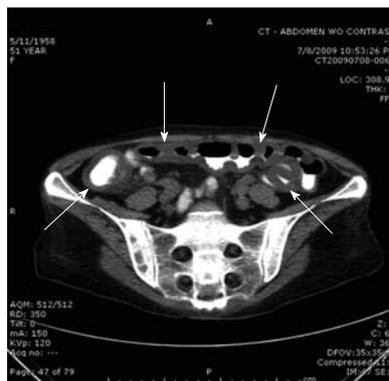

Figure 2 Bowel wall edema in a patient with gastrointestinal graft-versus-host disease.

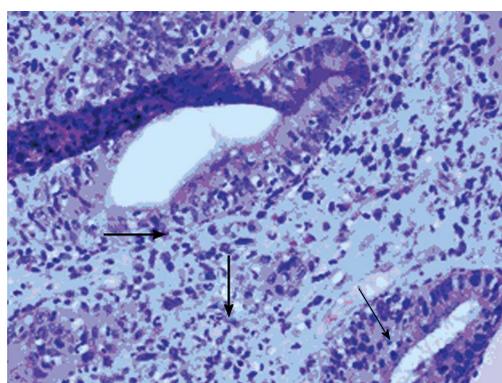

Figure 3 Histologic findings of acute graft-versus-host disease of the colon (hematoxylin and eosin stain, x 400). Thin arrow marks apoptotic bodies; thick arrow marks pericryptal acute inflammation.

with GVHD can be watery, mucoid and in large volumes; can be accompanied by vomiting, gastrointestinal bleeding and severe abdominal pain<sup>[28]</sup>. Infectious etiologies account for only 10%-15% of cases, yet diarrhea at any time after transplant should still prompt obtaining stool studies for *Clostridium difficile* toxin<sup>[29,30]</sup> as well as bacterial, viral and parasitic cultures if indicated. Abdominal imaging with CT may show bowel wall edema and/or pneumatosis intestinalis which may be associated with either GVHD or CMV infection (Figure 2). If cultures are negative, patients are usually treated with loperamide 4 mg po once followed by 2 mg/24 h as needed up to 24 mg/24 h. If diarrhea persists, strategies include scheduling loperamide every 4-6 h, adding atropine and diphenoxylate or tincture of opium. Octreotide starting at 150 mg iv every 8 h can be considered for protracted cases and can be titrated to response<sup>[31]</sup>. Other critical measures include maintaining adequate hydration and electrolyte supplementation, treating infections, discontinuation of medications causing diarrhea and assessment of nutritional status. Persistent symptoms despite the above measures and/or new diarrhea presenting after engraftment should be investigated with endoscopy and biopsy.

Visual findings of acute GVHD may include mucosal

**Table 3** Staging of acute graft-versus-host disease (modified Keystone criteria)

Stage	Intestinal tract	Liver	Skin
0	Diarrhea $\leq$ 500 mL/d	Bilirubin < 2.0 mg/dL	No rash
1	Diarrhea 501-1000 mL/d or nausea ( $\pm$ vomiting)	Bilirubin 2.0-3.0 mg/dL	Maculopapular rash < 25% of body surface
2	Diarrhea 1001-1500 mL/d	Bilirubin 3.1-6.0 mg/dL	Maculopapular rash 25%-50% of body surface
3	Diarrhea > 1501 mL/d	Bilirubin 6.1-15 mg/dL	Generalized erythroderma
4	Severe abdominal pain +/- ileus	Bilirubin > 15 mg/dL	Generalized erythroderma with blister/bullous formation and desquamation

**Table 4** Grading of acute graft-versus-host disease (modified Keystone criteria)

Grade	Gut	Liver	Skin
0 (none)	0	0	0
I (mild)	0	0	1-2
II (moderate)	1	1 or	3 or
III (severe)	2-4	2-3 or	0-3
IV (life-threatening)		4	4 or

edema/erythema and ulceration/bleeding. The diagnostic yield is the best when biopsies are obtained either from the stomach and distal colon or from the colon and ileum<sup>[32]</sup>. Histologic findings include crypt epithelial cell apoptosis and dropout, crypt destruction (Figure 3), pericapillary hemorrhage and variable lymphocytic and eosinophilic infiltration of the epithelium and lamina propria<sup>[33]</sup>. It is also important to study the biopsy specimens for CMV involvement which is the only common infectious cause of enteritis after transplant that requires biopsy for diagnosis. The negative predictive value of other infectious studies in stools is high and therefore usually does not necessitate endoscopy.

The severity of acute GVHD is clinically determined by the amount of diarrhea which helps defining the staging and grading (Tables 3 and 4). In addition to the general management measures described above, patients with high clinical suspicion for  $\geq$  grade II acute GVHD or biopsy proven acute GVHD should be promptly started on high dose steroids<sup>[34]</sup>; methylprednisolone 0.5-2.0 mg/kg per day iv in addition to their existing GVHD prophylaxis regimens. Half of the patients respond to steroid treatment<sup>[35]</sup> which can be tapered starting after approximately 1 wk. Patients who do not respond to steroids tend to have a poor prognosis; several second line immunosuppressive agents have been tried with variable success<sup>[34]</sup>. Other supportive measures consist of addition of oral non-absorbable steroids (budesonide)<sup>[36]</sup> and cholestyramine as well as dietary adjustments (bowel rest and start-

**Table 5** Differential diagnosis for liver function abnormalities after hematopoietic stem cell transplantation

First 3 wk post-transplant
Drug toxicity
Conditioning regimens (cyclophosphamide, total body irradiation, bis-chloroethylnitrosourea, busulfan)
Calcineurin inhibitors
Azole antifungals
SOS
Sepsis, candidiasis
Ischemic liver disease
From 3 wk to 3 mo post-transplant
Acute GVHD
Drug toxicity
SOS
Hepatitis (fulminant, acute or chronic):
Viral (HBV, HCV, HSV, VZV, adenovirus) reactivation
Bacterial or fungal Infection
Fungal abscess
Gall bladder disease/cholecystitis
Hyperalimentation
Post-transplant lymphoproliferative disorder (EBV-related)
After 3 mo post-transplant
Chronic GVHD
Iron overload
Chronic viral hepatitis
Drug toxicity
Liver fibrosis or cirrhosis:
SOS
Viral infections
Hemosiderosis
Disease recurrence or new malignancy including hepatocellular carcinoma, lymphoproliferative disorder
Nodular regenerative hyperplasia
Gallbladder disease

GVHD: Graft-versus-host disease; SOS: Sinusoidal obstruction syndrome; EBV: Epstein-Barr virus; HBV: Hepatitis B virus; HCV: Hepatitis C virus; HSV: Herpes simplex virus; VZV: Varicella zoster virus.

ing total parenteral nutrition) particularly for moderate to severe diarrhea.

## GASTROINTESTINAL BLEEDING

The incidence of bleeding has been significantly reduced (1%-2%) as post-transplant care has improved with routine anti-viral, anti-fungal and GVHD prophylaxis, yet it remains one of the major causes of transplant related mortality, particularly among patients with GVHD<sup>[37,38]</sup>. Common infectious etiologies include CMV, VZV, adenovirus, fungal and clostridial infections. Mucosal necrosis from conditioning therapy, acute and chronic GVHD, peptic ulcer disease, mycophenolate-related ulcerations and gastric antral vascular ectasia (GAVE) are the common known etiologies of noninfectious causes of bleeding. Treatment is mainly focused on supportive care (platelet transfusion and continuous octreotide infusion) as well as implementing prophylaxis for viral infections and GVHD. Treating the underlying cause is important as the benefit of endoscopic methods alone is limited to focal lesions.

**Table 6 Risk factors for sinusoidal obstruction syndrome**

Existing liver disease:
Chronic viral hepatitis
Alcohol related hepatitis
Steatohepatitis
Cirrhosis, lobular fibrosis
Cholestatic disorders
Extramedullary hematopoiesis with sinusoidal fibrosis
Prior history of:
SOS
Extensive chemotherapy and stem cell transplantation
Hepatic radiation
Drugs
Recent gemtuzumab ozogamicin use
Conditioning agents:
High dose TBI (> 14 Gy)
Cyclophosphamide metabolite: acrolein
Busulfan
Melphalan
Concomitant use of sirolimus during conditioning

SOS: Sinusoidal obstruction syndrome; TBI: Total body irradiation.

## LIVER FUNCTION ABNORMALITIES AND JAUNDICE

Severe liver dysfunction after transplant (total serum bilirubin > 4 mg/dL) may be an indicator of poor outcome as there is often no curative treatment<sup>[39]</sup>. Therefore, efforts are usually geared towards identifying the transplant candidates at risk as well as routine implementation of prophylactic measures such as ursodiol<sup>[40]</sup> (through 80 d post transplant), viral and fungal prophylaxis and careful selection of conditioning regimens to minimize hepatotoxicity<sup>[41]</sup>. The incidence of liver-related complications has declined significantly over the past decade with the preventive measures integrated into standard care. Some common etiologies for liver function abnormalities after transplant are summarized in Table 5. Drug toxicity, sepsis, GVHD and SOS are the most common etiologies for liver dysfunction. Calcineurin inhibitors (cyclosporine and less commonly tacrolimus, sirolimus), azole antifungal agents, trimethoprim-sulfamethoxazole, ribavirin, busulfan and bis-chloroethylnitrosourea are commonly associated with cholestasis. A declining incidence of acute GVHD is observed in 20%-25% of allogeneic transplant recipients due to widespread use of prophylactic immunosuppressive drugs, with peak incidence after engraftment (day 15) until the first 100 d of transplant<sup>[42]</sup>. It typically follows skin and/or GI GVHD and manifests by progressive parallel elevations of serum bilirubin and alkaline phosphatase; serum aminotransferase enzymes are elevated up to 10 times the upper limit of normal (Tables 3 and 4). Hepatic-variant of GVHD has also been described where serum aminotransferase enzymes are elevated more than 10 times the upper limit of normal and clinical presentation resembles acute viral hepatitis<sup>[43]</sup>. The diagnosis is usually made by transjugular liver biopsy which typically reveals lymphocytic infiltration of small bile ducts with epithelial cell apoptosis<sup>[44]</sup>. Routine ursodiol prophylaxis is

usually continued through day 80 of allogeneic transplants and reduces the incidence of GVHD<sup>[45]</sup>. The initial treatment of acute hepatic GVHD is similar to cutaneous and GI GVHD with high dose steroids as described above. However, only 30%-50% of patients respond to initial treatment and half of patients develop chronic GVHD.

## SINUSOIDAL OBSTRUCTION SYNDROME

SOS (AKA veno-occlusive disease or VOD) is a clinical entity characterized by tender hepatomegaly, elevated serum bilirubin levels and weight gain which typically complicates myeloablative hematopoietic stem cell transplantation (HSCT) and was first described in 1979<sup>[46]</sup>. SOS is a well-recognized conditioning-related toxicity. The incidence is quite variable, ranging from less than 5% to as high as 70% in different reports<sup>[47,48]</sup>.

Endothelial injury appears to be the initiating event triggering the hepatic changes and clinical manifestation of SOS. The prevailing hypothesis centers on damage to the hepatic venular and sinusoidal endothelium as an initial trigger inducing a hypercoagulable state by activation of the coagulation cascade, favoring clot formation over natural anticoagulation<sup>[49,50]</sup>. As a result, the venular and sinusoidal lumen is reduced due to an edematous concentric subendothelial zone containing fragmented red cells and fibrillar material, inducing partial to complete fibrotic obliteration of the venular lamina.

There are several risk factors for SOS and patients may present with elevated transaminase levels prior to the conditioning regimen due to various pre-existing conditions (Table 6). Previous cumulative exposure to high doses of cytotoxic agents may contribute to these risks including a second HSCT. Infection with hepatitis B is not considered a risk factor alone for SOS unless it is complicated with cirrhosis. The relationship between HCV infection and SOS is somewhat controversial. One report supports the increased risk even in the absence of cirrhosis<sup>[18]</sup> while another cohort did not confirm the association although there was an increased long term risk of non-relapse mortality for transplant patients who had chronic hepatitis C<sup>[51]</sup>. Other risk factors include certain conditioning regimens such as cyclophosphamide, busulfan, and/or total body irradiation<sup>[52-54]</sup>.

Cyclophosphamide is a common conditioning agent with the highest incidence of SOS, which becomes a particular concern in regimens combined with TBI and busulfan. The hepatotoxicity is usually dependent on the toxic metabolite acrolein and the exposure to toxic metabolites can be minimized by metabolism-based dosing. The incidence of SOS seems to be higher in transplant recipients who receive TBI doses over 14 Gy<sup>[53]</sup>. Various fractionated schedules of TBI have been associated with decreased incidence. Increasing the interval between TBI and cytotoxic therapy also may decrease the risk. Busulfan exposure, on the other hand, is not proven to be directly related to SOS although it potentiates the toxicity of cyclophosphamide especially when it is administered

after this drug<sup>[54]</sup>. Oral busulfan has a variable and unpredictable absorption and studies have shown that the risk of SOS increases when the area under the curve for busulfan is greater than 1500  $\mu\text{mol}/\text{min}$ . When busulfan is adjusted to normal drug levels by close monitoring, a decreased incidence has been reported<sup>[54]</sup>.

Gemtuzumab ozogamicin may induce sinusoidal injury<sup>[55]</sup> (15%-40% risk) especially if it is administered preceding a cyclophosphamide-based conditioning regimen.

Most cases are observed within the first 3 wk after transplantation. Usually, an unexplained weight gain is the first symptom. This weight gain, attributable to water and sodium retention by the kidney, appears within 6 d to 8 d following the transplant in 95% of patients. This is often followed by varying degrees of hyperbilirubinemia and elevation in aspartate aminotransferase and alkaline phosphatase levels. Most patients develop ascites and pain in the upper right quadrant, and clinical examination usually reveals a firm and painful hepatomegaly. Platelet refractoriness is a common occurrence<sup>[56]</sup>. Renal insufficiency in the form of hepatorenal syndrome is also present in 50% of patients developing SOS (mainly patients with severe form) and 25% of them will require hemodialysis. Finally, patients with advanced disease can display severe encephalopathy and/or multiorgan failure.

Doppler ultrasound of the liver usually shows reversal of portal and/or hepatic venous flow in severe cases. Most patients are diagnosed on clinical basis, given the risk of liver biopsy in the setting of coagulopathy and platelet refractoriness. Nevertheless where feasible, the clinical suspicion should be confirmed by transjugular liver biopsy which is the gold standard for diagnosis. Hepatic venous pressure gradients are often measured at the time of biopsy; a gradient greater than 10 mmHg is highly specific for SOS<sup>[57]</sup> and correlates with worse prognosis.

Given the very high mortality rate in patients with severe SOS, it is critical to implement preventive measures such as ursodeoxycholic acid which has been shown to reduce the incidence of SOS<sup>[40]</sup>. The efficacy of low-dose heparin has not been confirmed and is usually not part of standard management.

Up to 70% of patients with SOS will recover spontaneously and the focus of treatment is supportive care such as maintaining intravascular volume and renal perfusion without causing fluid overload by optimizing sodium restriction and diuretics and transfusions to keep hematocrit levels higher than 40%. The role of albumin or other colloids is unclear but could be considered in patients with severe hypoalbuminemia and large third space fluid accumulations. Low-dose dopamine has been used in patients with renal insufficiency because the mechanism of renal dysfunction appears to be hepatorenal in origin. Avoidance of other hepatotoxic drugs is important in these patients, and infections should be identified and treated promptly. Therapeutic paracentesis can help relieve symptoms in patients with large, tense ascites and may help improve renal function. Also, use of hemodialysis or continuous venous hemofiltration is reported to

help with fluid overload in patients with a poor response to diuretics.

There are no effective established treatments for patients with severe SOS characterized by rapidly increasing serum bilirubin and transaminase levels, portal vein thrombosis and multiorgan failure. Several antithrombotic agents have been tested with mixed results. Defibrotide which is an antithrombotic agent without significant systemic effects and with a manageable side effect profile, has been reported to improve signs and symptoms of SOS in 42% of patients<sup>[58]</sup>. Its mechanism of action is poorly understood. Other tested agents include prostaglandin E1 and tissue plasminogen activator with or without concurrent heparin, intravenous N-acetylcysteine, human antithrombin III concentrate, activated protein C and prednisone. None of these approaches are considered a part of standard management.

## LONG-TERM COMPLICATIONS

### *Chronic GVHD*

Long-term survivors of stem cell transplantation are at increased risk of several serious complications related to chronic GVHD which may affect liver, GI tract, skin, mucosal surfaces, lungs, joints, eyes and bone marrow; these patients should be followed regularly. Complications may occur in up to 50% of transplant recipients. Liver GVHD usually manifests with progressive or sudden elevation of alkaline phosphatase and gamma glutamyl transpeptidase. Hyperbilirubinemia is usually a late manifestation that coincides with development of cirrhosis and findings of small bile destruction in biopsy<sup>[44]</sup>. Viral etiologies should be excluded and liver biopsy should be performed to establish the diagnosis, followed by initiation of immunosuppressive therapy which usually includes steroids with or without a calcineurin inhibitor. An improvement in liver function studies is usually observed within four weeks of treatment and 50%-80% of patients respond to the initial therapy with improvement in histopathologic findings. Addition of ursodeoxycholic acid should also be considered and this is usually well tolerated. The prognosis of patients who do not respond to immunosuppressive regimens is poor and correlates with shortened survival<sup>[59]</sup>.

Chronic GVHD may affect several parts of the GI tract, causing esophageal webs and strictures leading to dysphagia, failure to thrive and chronic aspiration. Early lesions can be reversible with immunosuppression, proton pump inhibitors and dilatation. Patients may also experience chronic intermittent diarrhea, clinically and histologically similar to acute GVHD, which may respond to non-absorbable steroids. Chronic malabsorption is rare and is usually a result of long term inadequate treatment.

### *Chronic viral hepatitis and cirrhosis*

Longstanding viral hepatitis C and B can lead to end-stage liver disease in transplant survivors. Rate of progression to cirrhosis in patients with chronic hepatitis

B is comparable to non-transplant patients whereas the incidence of cirrhosis in transplant patients with chronic hepatitis C infection seems to be higher than controls and it can be as high as 24% after 20 years<sup>[60]</sup>. Otherwise these patients are also at risk of developing hepatocellular carcinoma (HCC) (2%-8% per year) and lymphoproliferative disorders. Patients with chronic hepatitis C should therefore be routinely monitored for viral load and considered for combination therapy with ribavirin and pegylated IFN- $\alpha$ . They should also be screened for HCC with  $\alpha$ -feto-protein and ultrasound every 6 mo. Close monitoring is essential for treatment complications such as neutropenia and thrombocytopenia secondary to pegylated IFN- $\alpha$  or exacerbation of coexisting chronic GVHD. Screening and treatment of iron overload may augment the success of anti-viral therapy. Liver transplantation for end-stage liver disease or HCC can be considered, especially from the original stem cell donor<sup>[61]</sup>.

Patients with chronic hepatitis B may have atypical serologic course due to immunosuppression. They may benefit from clearance of antigenemia particularly if the donor has natural HBV immunity. Patients should be monitored for HBV DNA levels and alanine transaminase levels and considered for antiviral treatment at times of tapering of immunosuppressive therapy as well as initiation of new chemotherapy, as they are at risk of flares of hepatitis<sup>[62]</sup>.

### Iron overload

The etiology of iron overload in transplant survivors is usually multifactorial, including transfusion dependency and abnormal iron transport by the intestine due to bone marrow dysfunction. It can be an important contributor to chronic liver disease and should be considered in the differential diagnosis<sup>[63]</sup>. It affects cardiac, endocrine and pancreatic function as well as increasing the risk of opportunistic infections. HFE gene testing should be considered when patients have unexpectedly high levels of iron stores. Clinically significant iron overload usually occurs when serum ferritin exceeds 1000  $\mu\text{g}/\text{dL}$ <sup>[64]</sup>. In the presence of other inflammatory conditions such as chronic GVHD, serum ferritin levels may be falsely elevated. Liver biopsy or noninvasive methods such as liver MRI or FerriScan can be utilized to document the severity of iron overload. Patients with severe iron overload may benefit from mobilization with improved hepatic and cardiac function<sup>[65]</sup>. If liver iron content is greater than 15 000  $\mu\text{g}/\text{g}$  dry weight, both phlebotomy and chelation should be offered. The liver iron content of 7000-15 000  $\mu\text{g}/\text{g}$  dry weight should be treated with phlebotomy only and if it is less than 7000  $\mu\text{g}/\text{g}$  dry weight, treatment is needed only if there is liver disease<sup>[66]</sup>.

### Acute hepatocellular injury

Long term transplant survivors may present with acute elevations of transaminases. The differential diagnosis should include flares of chronic viral hepatitis, hepatitis presentation of chronic GVHD, VZV, HSV infection or drug-induced (antihypertensives, statins, hypoglycemic

agents, antibiotics) liver injury.

### Malignancies

The risk of new malignancies among transplant survivors increases significantly after 10 years. Patients with chronic hepatitis C have accelerated incidence of HCC<sup>[67]</sup> and lymphomas<sup>[68]</sup>.

## CONCLUSION

Gastrointestinal and hepatic complications count for a significant part of the morbidity during and after hematopoietic stem cell transplant. Recent advances in transplant approaches have changed the outcome and the post-transplant course of many patients<sup>[69]</sup>. As most transplant survivors are affected by multiple complications, it is imperative that they should receive long-term and systematic follow-up without compromising from individualized care.

### Abstract

Recently introduced in the treatment algorithms and guidelines for the treatment of ulcerative colitis, biological therapy is an effective treatment option for patients with an acute severe flare not responsive to conventional treatments and for patients with steroid dependent disease. The reduction in hospitalization and surgical intervention for patients affected by ulcerative colitis after the introduction of biologic treatment remains to be proven. Furthermore, these agents seem to be associated with increase in cost of treatment and risk for serious postoperative complications. Restorative proctocolectomy with ileal pouch-anal anastomosis is the surgical treatment of choice in ulcerative colitis patients. Surgery is traditionally recommended as salvage therapy when medical management fails, and, despite advances in medical therapy, colectomy rates

remain unchanged between 20% and 30%. To overcome the reported increase in postoperative complications in patients on biologic therapies, several surgical strategies have been developed to maintain long-term pouch failure rate around 10%, as previously reported. Surgical staging along with the development of minimally invasive surgery are among the most promising advances in this field.

### INTRODUCTION

Ulcerative colitis (UC) is a mucosal inflammatory process affecting the rectum and the colon. It is characterized by contiguous inflammation starting in the rectum and progressing for variable distance proximally<sup>[1]</sup>. Intermittent exacerbations are typical, with symptoms characterized by bloody diarrhea associated with urgency and tenesmus<sup>[2]</sup>. The activity of disease can range from complete remission to fulminant symptoms along with systemic toxic effects<sup>[3]</sup>.

Although the exact pathogenesis of UC remains poorly

understood, the most credited model states that the intestinal flora triggers and drives an aberrant intestinal immune response and subsequent inflammation in a genetically susceptible host<sup>[4]</sup>. Medical therapy aims at the control of symptoms and the resolution of the underlying inflammatory process, classically by a variety of agents in combination, such as 5-aminosalicylates, corticosteroids, and immunosuppressants, including purine antimetabolites and cyclosporine<sup>[5]</sup>. Treatment schemes are based on disease severity, (defined as mild, moderate or severe based on clinical and laboratory parameters) and on the extent of the disease (pancolitis, left-sided colitis, rectosigmoiditis or proctitis)<sup>[6]</sup>. However, about a quarter of patients with UC end up needing a colectomy because of failure of medical therapy, onset of unacceptable side effects of chronic therapy, occurrence of acute complication of UC (fulminant colitis, severe bleeding, toxic megacolon, perforation), or development of malignancy<sup>[7]</sup>.

For all of these patients, the removal of the colon and rectum represents a definitive cure for their disease, with cessation of symptoms, withdrawal of morbid medical therapy, and avoidance of the risk of developing a malignancy associated with the persistence of inflammation<sup>[8]</sup>.

However, surgery is not without risks and can significantly affect patients' lifestyle, therefore, is traditionally deemed as a salvage treatment when medical therapy is ineffective<sup>[1]</sup>.

During the last three decades astounding progress has been accomplished both in medical and surgical treatments, which might lead to substantial changes in the traditional principles for the management of UC patients. Medical therapy of UC has recently entered the era of biologic treatments with the approval by Food and Drug Administration (FDA) in 2005 of Infliximab, a monoclonal antibody directed against tumor necrosis factor- $\alpha$ . The initial enthusiasm raised by the promise to reduce the colectomy rate in acute presentations, was subsequently partially dampened by conflicting reports regarding Infliximab's safety and impact on the need for surgery in urgent/emergent setting<sup>[9-13]</sup>.

As the number of available medications increases, more and more often patients are referred for surgery severely malnourished, immunocompromised, and experiencing the side effects of corticosteroids, immunomodulators, and biological agents. Whether they are referred for colectomy in an acute or chronic setting, these patients represent a unique challenge for colorectal surgeons, given the compromised general conditions and poor nutritional status in the former, and the side effects of long term corticosteroid use in the latter<sup>[14-16]</sup>.

Together with the advances in medical therapy, the surgical treatment and techniques in UC has evolved as well. Restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) is today considered the gold standard and, in experienced hands, can now be performed safely for UC with a low postoperative complication rate and a long-term pouch failure rate reported less than 10%<sup>[17-19]</sup>. Moreover, the introduction of minimally invasive tech-

niques might further decrease postoperative morbidity and improve patients' satisfaction, with reduced impact on body image and better cosmesis<sup>[20-22]</sup>.

The purpose of this report is to discuss the recent advances in medical and surgical treatment of UC patients addressing surgical concerns in the era of biologic therapy.

## BIOLOGIC THERAPY IN UC: THE GASTROENTEROLOGIST'S VIEW

The primary goals of medical therapy in the treatment of UC are to induce remission of symptoms and maintain it on a long-term basis: by reducing the number of relapses, which occurs in 67% of patients and, at least, once over a 10-year period<sup>[23]</sup>, medical therapy lowers the risk of long-term complications and improves patients' quality of life.

The majority of UC patients present with moderate-to severe disease (80%) rather than mild disease (20%)<sup>[24]</sup> and, during their illness, nearly 20% of patients afflicted with UC will experience a severe acute episode that requires hospitalization<sup>[25]</sup>.

Despite the progress accomplished in medical therapy, which broadened the horizon of possible treatments after failure of corticosteroids<sup>[26,27]</sup>, the need for surgery in this patient population seems to be unchanged or slightly decreased over time. Reported colectomy rates are steadily ranging between 20% and 30% in most of the epidemiological studies with additional risk for needing a resection as the extent and severity of the disease increase<sup>[8,28-31]</sup>. Beside a 10% who have surgery for cancer or pre-neoplastic degeneration, the vast majority of patients need an operation for acute colitis with severe complications not responsive to medical therapy<sup>[32,33]</sup>. The advantage of prolonged medical therapy *vs* surgery in patients with acute severe colitis failing initial high dose corticosteroids is still debated. About one third of these patients undergo a colectomy within one year, most likely in an emergency setting, and even if second-line medical therapy may reduce the need for immediate colectomy, most of them will require colectomy by 10 years<sup>[32,34]</sup>. In this setting, early subtotal colectomy and ileostomy combined with a late reconstructive surgery remains a safe alternative<sup>[19]</sup> since second-line medical therapy carries with it a not negligible mortality risk<sup>[35]</sup>.

Additionally, about 20% of patients with UC have a persistent active disease often requiring several courses of systemic steroids, but followed by relapse of symptoms during steroid tapering or soon after their discontinuation, a condition known as steroid-dependency. Steroid dependency is associated with serious complications, which, for a significant proportion of patients, become an indication for surgery<sup>[36]</sup>.

Although surgery is curative of the underlying inflammation and restorative proctocolectomy with IPAA preserves the normal anatomic route for defecation, the procedure may lead to new symptoms, such as diarrhea,

incontinence, nocturnal leakage, and in some patients does not obviate the need for medication. In several surgical series that follow patients a minimum of 5 years, up to 60% of patients are still having more than 8 bowel movements daily, with 55% of patients experiencing incontinence, and 50% nocturnal leakage<sup>[37-39]</sup>. Even if surgical techniques have dramatically evolved, surgery is still associated with significant early and late postoperative complications, e.g. anastomotic leak, pelvic sepsis, small bowel obstruction, pouchitis, sexual dysfunction, reduced fecundity in women and pouch failure<sup>[40,41]</sup>. Repeated surgery is sometimes necessary. A population-based study reported that approximately 20% of patients who had undergone IPAA required at least one additional surgery, and 15% of patients required at least two additional surgeries<sup>[42]</sup>. Pouch leak and the associated pelvic sepsis rate in large series have been reported to range from 5% to 15%<sup>[43]</sup>; incidence of late small-bowel resection after IPAA ranges from 12% to 35%. Pouchitis is the most frequent long-term complication of the IPAA<sup>[1]</sup>. It has been reported in 12% to 50% of patients postoperatively, and some patients (5%-19%) require chronic therapy. Finally, the risk of long-term pouch loss has been reported to range from 1% to 20% in different studies with an overall rate of pouch loss less than 10%, needing diverting ileostomy, pouch excision and end ileostomy, or pouch revision<sup>[17-19]</sup>.

### Acute severe ulcerative colitis

According to current treatment algorithms, in case of acute colitis, unless toxic megacolon, perforation or severe bleeding-which are absolute indication for surgery-occur, patients are started on high-dose iv steroids<sup>[44]</sup>. Response to treatment is assessed by objective measures (e.g., Oxford index or Sweden index) on day 3-4. Two different strategies have been developed in the attempt of avoiding surgery when a first course of steroids fails to control an acute flare. The standard approach in the '80s was to prolong the administration of steroids for other 7-10 d, which did not show any reduction in colectomy rates<sup>[45-47]</sup>. Ten years later, cyclosporine was found to be effective in patients with acute severe UC non responsive to steroids, and has been used as rescue therapy<sup>[44,48-51]</sup>. In a randomized controlled trial (RCT) 82% of patients on cyclosporine improved, while no patient improved in the placebo group<sup>[52]</sup>. However, as many as 50% of patients that responded to cyclosporine, required colectomy in subsequent studies with longer follow-up<sup>[35,53]</sup>. Moreover, the management of patients under cyclosporine can represent a real challenge, given the risk of severe and potentially fatal toxicities, which greatly limit the use of this medication.

Infliximab, an anti-tumor necrosis factor (TNF) antibody, has been approved recently by the United States FDA for the treatment of UC to reduce signs and symptoms, to induce clinical remission and healing of the intestinal mucosa, and to eliminate the use of corticosteroids in patients presenting with moderately-to-severely

active UC without adequate response or who are intolerant or have medical contraindications to therapy with corticosteroids or immune modulators<sup>[54]</sup>.

Response to infliximab has been assessed in RCTs with various endpoints such as clinical response, remission and colectomy rates. In patients with severe, steroid-refractory UC, the initial small trials demonstrated modest efficacy after single infusions when early clinical response was determined. The first published trial by Sands *et al*<sup>[55]</sup> in 2001 randomized 11 patients with steroid refractory UC to a single infliximab infusion or placebo, and noted a 50% (4/8) clinical response rate with infliximab at a week 2 evaluation. Subsequent studies by Probert *et al*<sup>[56]</sup> and Järnerot *et al*<sup>[51]</sup> also enrolled patients with steroid-refractory disease. The first study failed to show any significant difference between placebo and 2 infusions of infliximab 5 mg/kg in inducing remission as measured by endoscopy or clinical score. However, Järnerot *et al*<sup>[51]</sup> demonstrated in patients with moderate and severe steroid-refractory UC that only 7/24 (29%) patients who received a single infliximab infusion underwent colectomy within 90 d, compared with 14/21 (67%) who received placebo. The superiority of infliximab was only statistically significant in patients with moderate to severe disease, but not in those with more severe disease on the fulminant colitis score, although the study was not powered to detect differences between these two last groups. Even though a later report showed that at 2 years follow-up, the colectomy rate in patients who received infliximab had increased to 46%<sup>[57]</sup>, these studies positioned infliximab as a therapeutic option for patients with steroid-refractory disease. The first controlled trial<sup>[58]</sup> involving patients who had moderate to severe disease that were neither steroid-dependent nor steroid-refractory, reported superior clinical response rates compared to those seen in steroid-refractory populations. These trials reported high response rates (100% and 83%, respectively), but follow-up was short (9.7 and 3 mo, respectively). The active ulcerative colitis trial (ACT) 1 and ACT 2 trials<sup>[59]</sup> each randomized 364 patients with moderate to severe UC who were failing conventional therapy (but did not require hospitalization) to either placebo or induction/maintenance infliximab 5 mg/kg or 10 mg/kg. Both in ACT 1 and ACT 2, eligible patients had moderate to severe UC despite concurrent treatment with corticosteroids, alone or in combination with azathioprine or mercaptopurine, but ACT 2 also required that the patient had failed 5-aminosalicylic acid (5-ASA) therapy. In ACT 1, both doses of infliximab (5 mg/kg and 10 mg/kg) resulted in a statistically significant clinical response at week 8 (68.4% and 61.5% respectively,  $P < 0.01$ , compared to a placebo response of 37.2%). This was similar in ACT 2, with clinical response at week 8 in 64.5% of patients in the infliximab 5 mg/kg group and 69.2% in the infliximab 10 mg/kg group, compared to a 29.3% response rate in the placebo group ( $P < 0.001$ ). Clinical remission rates in the infliximab arms at week 8 ranged from 27.5% to 38.8% across both studies compared to

placebo-induced remission rates of 14.9% (ACT 1) and 5.7% (ACT 2). Mucosal healing and steroid-free remission rates were also superior in the infliximab arms of these studies. Sandborn *et al*<sup>[60]</sup> reported colectomy rates in ACT 1 and ACT 2 patients in a follow-up study. The cumulative colectomy rate at 54 wk was 10% in patients treated with infliximab, compared with 17% in those treated with placebo. These colectomy rates were not unexpected since the enrolled patients had moderate to severe disease, however in 13% of the enrolled patients the colectomy follow-up data was unavailable. The ACT 1 and ACT 2 studies were well-designed, large studies, with comprehensive assessment of clinical and secondary endpoints. They provided important data to support the use of infliximab in patients with moderate to severe UC who have failed other therapies such as steroids, immunomodulators and mesalamine. However, infliximab is not a panacea for all; the proportion of patients who started the study on steroids and were able to come off and remain in remission, was low (20%)<sup>[59]</sup>.

In a recent study by Colombel *et al*<sup>[61]</sup>, the association between early mucosal healing (defined as Mayo endoscopy subscore at week 8 endoscopy) and clinical outcomes in ACT-1 and ACT-2 patients was investigated. The authors observed that a low week 8 endoscopy subscore was significantly associated with a lower rate of colectomy at 54 wk follow-up ( $P = 0.0004$ ; placebo  $P = 0.47$ ) and better outcomes in terms of symptoms and need for steroids at weeks 30 and 54 ( $P < 0.0001$ , infliximab;  $P < 0.01$ , placebo), especially for those patients who did not achieve clinical remission at week 8<sup>[61]</sup>.

A Cochrane meta-analysis of RCTs concluded that, when compared to placebo, treatment with infliximab is three-fold as effective in inducing clinical remission [relative risk (RR) 3.22; 95% CI: 2.18-4.76] and nearly twice as effective in inducing clinical response (RR: 1.99; 95% CI: 1.65-2.41) or endoscopic remission (RR: 1.88; 95% CI: 1.54-2.28) at week 8 in patients presenting with moderate-to-severe UC refractory to conventional treatment with corticosteroids and/or immune modulators<sup>[10]</sup>.

### **Steroid dependent ulcerative colitis**

Another specific pattern of UC disease is represented by steroid-dependent patients, in whom a response can be obtained with systemic steroids, but the relapse will occur as the dose is tapered or a few weeks or months after discontinuation, making it necessary to increase the dosage again or resume treatment to achieve control of symptoms<sup>[6]</sup>. As UC patients become dependent-upon or refractory to corticosteroids, the range of action from a medical standpoint become limited and a colectomy becomes a treatment option as the disease is deemed as refractory to medical treatment, or because of the occurrence of complications either related to the disease or associated with side effects of medications<sup>[1]</sup>.

Often, immunomodulator therapies, such as azathioprine or mercaptopurine (6-mercaptopurine) are considered

in these patients before surgery as a steroid-sparing treatment. However, the efficacy of azathioprine or mercaptopurine in UC is still debated<sup>[62]</sup>. Thiopurines are an effective maintenance therapy for patients who require repeated courses of steroids, however the quality of available data is quite poor, as stated in a recent Cochrane review<sup>[63]</sup>. Currently, the recommendation for using thiopurines in UC is based on the evidence shown by only one RCT of Ardizzone *et al*<sup>[64]</sup> which found steroid-free, clinical and endoscopic remission in 53% patients on azathioprine compared with 21% given only 5-ASA [odds ratio (OR) on intention to treat analysis 4.78, 95% CI: 1.57-14.5]. Azathioprine maintenance treatment of UC is beneficial for at least 2 years if patients have achieved remission while taking the drug, but not in those with chronic activity despite the drug<sup>[65]</sup>.

When a steroid-dependent patient fails to benefit from thiopurines or shows intolerance to them, there are very few alternatives to conventional drugs, which lack of current definitive evidence of efficacy. Methotrexate has been tested and, although some uncontrolled studies suggested some benefit with its use<sup>[66-68]</sup>, the only double-blind, placebo-controlled trial, showed no therapeutic benefit<sup>[69]</sup>. Therefore, current guidelines do not consider methotrexate as an evidence-based therapy in steroid-dependent UC.

After the demonstration of clinical efficacy of infliximab in the treatment of moderate-severe resistant UC, few small series have included steroid dependent patients. Only one study from Italy<sup>[70]</sup> specifically evaluated steroid dependent UC in an open-label study on 20 patients randomized to infliximab or methylprednisolone. This was the first RCT to implement a regimen of a triple infliximab infusion for induction followed by infusions to maintain remission. Even if this study was statistically underpowered, it demonstrated the benefit of infliximab therapy for responders, who were able to taper and then discontinue steroids during the maintenance phase (9 of 10 patients), as compared with the methylprednisolone group (8 of 10 patients), where responders required continued steroid therapy.

## **BIOLOGIC THERAPY IN UC: THE SURGEON'S VIEW**

Biologic therapy has shown the ability to induce and maintain remission, but, as we stated above, its introduction in the therapeutic algorithm did not substantially affect the overall rate of colectomies, suggesting that it is effective only in delaying but not in avoiding surgery for a subgroup of patients who at some point will require an operation<sup>[54,59,60,71]</sup>. The clinical efficacy of infliximab in UC still remains unpredictable. Induction therapy is not always effective, and, to date, clinical and/or molecular predictors of response have not been identified. No RCT has been conducted comparing infliximab and cyclosporine in severe UC. Most of the current knowledge comes from the ACT 1 and ACT 2 trials. Those results are in part influenced by the heterogeneity of the sample (in-

Table 1 Literature-based comparison of postoperative complication risk associated with preoperative use of infliximab

IFX: Infliximab; OR: Odd ratio; NR: Not reported; CI: Confidence interval.

cluding both steroid-dependent and/or immunomodulator-dependent and steroid responsive and/or immunomodulator-responsive patients). More studies are needed to assess the role of concomitant administration of immunosuppressants and infliximab<sup>[59]</sup>. Furthermore, data on maintenance therapy with infliximab in UC are scant and the benefits of continued maintenance therapy, as well as its long-term safety, are poorly known. The results of the ACT-1 and ACT-2 extension studies conducted on the 229 patients who achieved improvements with infliximab during the trials, showed that the benefits observed in the main studies are basically maintained up to 3 additional years, however an high drop-off rate was observed, due to adverse events (10.5%), lack of efficacy (4.8%), need for surgery (0.4%), or other reasons (14.8%)<sup>[72]</sup>. Furthermore, it is not clear to what extent postponing surgery by the means of a quite morbid medical therapy represents a safe and effective strategy.

Because of the early onset and chronic nature of inflammatory bowel diseases, patients can be expected to utilize considerable health care resources. Costs analysis are complicated, because they must calculate the impact that such therapies have on the direct costs of health care and the indirect costs for both the patient and their families and the health care system<sup>[73]</sup>. Surgeries and hospitalizations account for the majority of health care direct costs in inflammatory bowel disease (IBD), and medication costs, on the other hand, accounted for a quarter of total direct medical costs. Moreover, the cost data are right-skewed, with 25% of patients accounting for 80% of total costs<sup>[74]</sup>. This division of health care costs implies that the most effective cost-containment measure would be the one that reduces the number of hospitalizations and surgeries. With the improved response and remission rates seen with the use of infliximab for induction and maintenance treatment in IBD patients, the clinical benefits may likely translate into economic benefits as well<sup>[75]</sup>. Surprisingly, many of the cost-effectiveness and utility analyses suggested that infliximab use was associated with rather high incremental cost per quality adjusted year life<sup>[73]</sup> and the expanding use of infliximab has not significantly impacted the use of surgical procedures for patients with either UC or Crohn's disease, and rates of nonsurgical hospitalizations have actually increased<sup>[76,77]</sup>. This belief is supported by

the observation that in the United States the hospitalization rates for IBD increased between 1998 and 2004, leading to a concurrent rise in the economic burden, with medical hospitalizations accounting for the largest proportion (58%) of inpatient services costs and biologic agents representing the most costly medications<sup>[78,79]</sup>. Further pharmaco-economic analyses are needed to accurately assess the impact of infliximab treatment on the costs associated with the treatment of UC.

#### **Surgery in the biologic era: Treatment in evolution**

The concept of pushing conservative treatment until surgery is strictly required may be risky, as it has been shown that mortality three years after elective colectomy for UC (3.7%) is significantly lower than that after admission without surgery (13.6%) or when an emergency operation is performed (13.2%)<sup>[80]</sup>. Moreover, a British study recently reported a significantly higher risk to develop major complications at a 5 year follow up for patients who received a longer course of medical therapy for acute severe UC before surgery, suggesting that the threshold for elective surgery may be too high in current practice<sup>[81]</sup>.

While it's well known that high-dose systemic corticosteroid therapy (> 40 mg/d prednisolone-equivalent) is a widely recognized risk factor for pouch-related septic complications after restorative surgery<sup>[82]</sup>, whether or not the preoperative administration of infliximab may increase the rates of septic complications is still controversial (Table 1)<sup>[9,12,13,83-86]</sup>. Nevertheless, the group from the Cleveland Clinic has found a covariate-adjusted risk of early complication for patients treated with infliximab 3.54 times higher, with the rate of sepsis increased by 13.8 folds, despite a significantly higher rate of three-stage procedures in the infliximab group<sup>[85]</sup>. Similar results have been shown in a paper by Mayo Clinic, where patients treated with infliximab prior to pouch surgery had a significantly higher incidence of anastomotic leaks, pouch specific and infectious complications, with the administration of anti-TNF-alpha as the only factor independently associated with septic complications (OR 3.5)<sup>[13]</sup>. In another study, a synergic interaction in increasing surgical morbidity was found between infliximab and cyclosporine A when administered together in the preoperative time<sup>[12]</sup>. These concerns are supported by a recent meta-analysis conducted including 5 studies and 706 patients, which revealed an

increased risk of short-term post-operative complications (OR 1.80, 95% CI: 1.12-2.87) associated with preoperative infliximab use, along with a trend towards increased post-operative infection<sup>[87]</sup>.

Given the concern of increased rate of complications in patients on aggressive medical management, several different surgical approaches have been proposed. First described by Parks and Nichols in 1978, restorative proctocolectomy with IPAA has progressively gained acceptance to become the gold standard in the surgical treatment of UC for the last 25 years<sup>[88,89]</sup>. The introduction of this technique—most often fashioned as a J pouch created with the terminal ileum and anastomosed to the anal canal—was a real breakthrough, offering a curative treatment to these patients without the need for a permanent stoma, thus preserving their body image, achieving a quality of life comparable to that of the general population<sup>[38,90]</sup>. However, the procedure is technically demanding and is associated with a significant morbidity rate (around 30%), and an incidence of postoperative pelvic sepsis ranging between 5%-24%<sup>[91]</sup>. Since it has been shown that the occurrence of a pelvic infection can dramatically affect the functional outcome of the pouch, and considering that long-term steroid use and malnutrition are recognized risk factors for pelvic sepsis, surgical strategies have been developed in order to minimize the occurrence of infectious complications, especially in this subset of patients<sup>[92,93]</sup>. A total abdominal colectomy with end ileostomy is the operation of choice as first step of a restorative procedure, as it can be performed safely and quickly in the hands of an experienced colorectal surgeon, allowing the patient to overcome the colitis, wean off the medications, and return to an optimal health and nutritional status<sup>[94,95]</sup>. Moreover, as it is well known that a postoperative diagnosis of indeterminate colitis or Crohn's disease is not rare after colectomy in these patients<sup>[96]</sup>, a multistep surgical procedure allows for selecting the most appropriate reconstructive surgery on the basis of the pathological findings of the colectomy specimen<sup>[19,94,97]</sup>.

The removal of the rectum and the restoration of the bowel continuity with IPAA are performed as a second step when the patient has fully recovered, and the creation of a temporary ileostomy, although adding the need for one more operation, can further reduce the risk of local sepsis secondary to anastomotic leaks<sup>[98,99]</sup>. Albeit restorative surgery is not free from long term complications, such as incontinence and soiling (10%-60% of patients, depending on series and entity), pouchitis (about 50% of patients), and sexual dysfunction (20%-25% of cases), with a rate of pouch failure requiring excision ranging between 5%-15%, the majority of these conditions are manageable with medical and physical therapy, which explains the overall satisfaction in patients after IPAA, which exceeds the 90% in most series<sup>[40,98,100-105]</sup>.

Indeed, most recent researches have shown that social and sexual function as well as overall quality of life is significantly improved after restorative surgery, when compared to the period with active UC or diverting ileostomy<sup>[106-109]</sup>.

The application of minimally invasive techniques to the surgical treatment of UC at the beginning of the 1990s contributed in significantly improving the acceptance and tolerability of the procedure<sup>[110]</sup>. Numerous case series and, finally, two meta-analyses have been published since then, demonstrating the feasibility and safety of the laparoscopic approach, at the cost of longer operative times<sup>[110-117]</sup>. A subsequent RCT showed that operative time could be significantly reduced with the adoption of a hand-assisted technique, which at the same time allows for preserving the advantages of a minimal invasive approach<sup>[118]</sup>. Scant data is available so far regarding long-term outcomes, however the few series with adequate follow-up report laparoscopy pouch function results as good as the ones achieved with open surgery<sup>[21,119]</sup>. Laparoscopy has also been adopted with good results in the emergency setting<sup>[120,121]</sup>, and similarly as for open surgery, a staged approach to a minimally invasive restorative procedure should be preferred which is as effective in significantly reducing the rate of postoperative pelvic sepsis<sup>[121-123]</sup>. Furthermore, when a staged procedure is planned, laparoscopy has been shown to decrease postoperative adhesion formation with less intraoperative adhesiolysis required during subsequent completion proctectomy and IPAA<sup>[124]</sup>. Similarly, a study by Indar and colleagues on 34 patients who underwent laparoscopic IPAA, where a laparoscopic exploration of the abdominal cavity was performed during the ileostomy closure, found that no patient had dense adhesion and only a minority of patients had filmy avascular adhesion to the abdominal wall (32%) and to the adnexa (29%), which represents a significant improvement compared to the rates reported for open surgery (as high as 90%)<sup>[125]</sup>.

Despite the lack of strong evidence about the benefits attainable with laparoscopy in terms of short-term outcomes<sup>[21,126]</sup>, it has been proven that patients treated laparoscopically are more satisfied with the cosmetic results and perceive a better body image—anything but negligible in this usually young and socially active patient population—especially in the women's subset, as confirmed by the results of a RCT with a median follow-up of 2.7 years<sup>[21,119]</sup>. More recently, the quest for further minimizing surgical trauma and extent of incisions, has led to the development of single incision laparoscopy (SIL), which has already been applied in the field of colorectal diseases with proven benefits in terms of short-term outcomes over standard laparoscopy<sup>[127-131]</sup>. To date only few cases of SIL for UC has been reported, but preliminary results show that particularly for the total abdominal colectomy, this “no scar” approach have the potential for improving not only the cosmesis, but also the postoperative course, with less pain and reduced need for narcotics, which may translate in shorter hospital stay and faster return to normal activities<sup>[132-135]</sup>. Considering the excellent outcome of restorative surgery, heightened by the potentials of minimal invasive techniques, surgery should not be considered the last resort when everything has failed, but rather a valid alternative to an expensive and risky medical therapy<sup>[136]</sup>.

## CONCLUSION

Medical therapy in UC is rapidly evolving and the introduction of modern biological drugs has led to substantial changes in the traditional principles of management. Infliximab, the first biological agent used as rescue therapy after failure of steroids in UC, appears to be effective in reducing the need for urgent colectomy, although its efficacy in the long-term is not proven. In addition, concerns have been raised regarding the economic burden related to this drugs and the risk for serious postoperative complications.

Surgery continues to play an important role in UC treatment and its evolution keeps pace with the advance in medical therapy and the risk associated with it. Restorative proctocolectomy with IPAA, staged procedures, and minimally invasive surgery are important treatment tools to limit postoperative morbidity and achieve excellent long-term outcomes in these patients.

In an attempt at avoiding surgery, aggressive medical therapy is not without complications. A complex decision making process in a multidisciplinary fashion should take into consideration the excellent results of modern surgical therapies to avoid unnecessary morbidity.

### Abstract

In the past, there has been considerable focus on a host of drugs and chemicals that may produce colonic toxicity. Now, a variety of new biological monoclonal antibody agents, usually administered by infusion, have appeared in the clinical realm over the last decade or so to treat different chronic inflammatory or malignant disorders. For some of these agents, adverse effects have been documented, including apparently new forms of immune-mediated inflammatory bowel disease. In some, only limited symptoms have been recorded, but in others, severe colitis with serious complications, such as bowel perforation has been recorded. In others, adverse effects may have a direct vascular or ischemic basis, while other intestinal effects may be related to a superimposed infection. Some new onset cases of ulcerative colitis or Crohn's disease may also be attributed to the same agents used to treat these diseases, or be responsible for disease exacerbation. Dramatic and well documented side effects have been observed with ipilimumab, a humanized monoclonal antibody developed to reduce and overcome cytotoxic T-lymphocyte antigen 4, a key negative feedback regulator of the T-cell anti-tumor response. This agent has frequently been used in the treatment of different malignancies, notably, malignant melanoma. Side effects with this agent occur in up to 40% and these are believed to be largely immune-mediated. One of these is a form of enterocolitis that may be severe, and occa-

sionally, fatal. Other agents include rituximab (an anti-CD20 monoclonal antibody), bevacizumab (a monoclonal antibody against the vascular endothelial growth factor) and anti-tumor necrosis factor agents, including infliximab, adalimumab and etanercept.

### INTRODUCTION

Different patterns of inflammatory disease involving the small and large intestine have been historically recognized over the past century or so, and their features are well detailed in clinical textbooks especially focused on inflammatory bowel diseases. Crohn's disease, for example, is recognized as a pattern of inflammatory disease that may involve any site along the length of the gastrointestinal tract, usually in a segmental or focal distribution, typically with transmural involvement, and frequently, granulomas may be demonstrated. Ulcerative colitis has been traditionally defined by its colonic distribution, a more continuous pattern of mucosal involvement extending proximally within the colon from the rectum for variable distances. In reality, however, clinical and pathological overlap may occur frequently, and in many patients, precise differentiation of these different forms of chronic

inflammatory disease based on these descriptive parameters may not be so precise.

In the past, a variety of drugs have been used to control the inflammatory process in these disorders and improve quality of life. In addition, a host of biological agents have also emerged in recent years to treat a number of chronic inflammatory disorders, including Crohn's disease and ulcerative colitis, as well as a lengthening list of malignant disorders. Some of these biological agents have also been associated with the appearance of novel forms of colonic inflammatory disease, often severe and potentially fatal, as well as apparent paradoxical intestinal complications, including the *de novo* appearance or worsening of an underlying or unrecognized intestinal inflammatory disorder that may, in themselves, lead to serious complications.

Although a number of administered drugs and chemicals causing colonic toxicity have been enumerated elsewhere and reviewed in detail during the past 3 decades<sup>[1-3]</sup>, this review focuses on newer agents, largely administered by the parenteral route, that interfere with key regulatory biological molecules. These include ipilimumab, rituximab, bevacizumab and a number of anti-tumor necrosis factor agents.

## IPILIMUMAB-INDUCED COLITIS

A relatively novel strategy has emerged in cancer treatment in recent years to induce tumor regression and prolong patient survival involving control and reduction of the effect of specific immune regulatory molecules, such as the cytotoxic T-lymphocyte antigen 4 (CTLA-4). Ipilimumab is a fully human monoclonal antibody that has been developed to reduce and overcome cytotoxic CTLA-4, a key negative regulator of the T-cell anti-tumor immune response. In recent years, evidence has appeared showing tumor regression with prolonged time to progression in melanoma patients treated with CTLA-4 antibodies<sup>[4,5]</sup>. Ipilimumab plus dacarbazine showed improved survival in malignant melanoma compared to dacarbazine alone, a drug most frequently compared with new agents in randomized treatment trials on melanoma<sup>[5]</sup>. In addition to melanoma, prolonged effects with ipilimumab have been noted in other malignancies including ovarian cancer<sup>[6]</sup>, prostate cancer<sup>[7]</sup> and renal cell cancer<sup>[8]</sup>. Inhibition of CTLA-4 with this antibody is also associated with characteristic side effects in an estimated 40%<sup>[4]</sup>. These are believed to be largely immune-mediated and include an ever-lengthening list of adverse effects such as dermatitis, endocrinopathies, particularly hypophysitis, uveitis, nephritis, inflammatory myopathies, hepatitis, and diarrhea or colitis<sup>[9,10]</sup>. Similar immune-related adverse events may result from another monoclonal CTLA-4 antibody, tremelimumab, used for the treatment of metastatic melanoma<sup>[11]</sup>.

Colonic toxicity has been recorded in about 20% and appears to occur relatively rapidly after administration of ipilimumab, sometimes within days marked by the onset of abdominal cramping pain and profuse diarrhea, often bloody<sup>[9,12]</sup>. In others with few or mild symptoms, colitis could still be present since only those with more severe

symptoms were recorded<sup>[12]</sup>. Up to 5% of patients may suffer a fatal outcome attributed to a significant complication, a protracted clinical course or failure of prompt treatment, sometimes related to limited compliance<sup>[12]</sup>. Colonoscopy and ileoscopy as well as upper endoscopy with duodenal biopsies have documented both small bowel and colonic inflammatory changes. In some, a diffuse, but non-specific colitis may occur, in the absence of any detectable infectious agent, while in others, the inflammatory process may be patchy or segmental in distribution. The appearances may not be distinguishable by endoscopy from other forms of inflammatory bowel disease. Endoscopic biopsies may show a non-specific acute and chronic inflammatory infiltrate, including cryptitis as well as crypt abscess formation. Colon biopsy samples show a colitis that has an abundant T-cell infiltrate<sup>[13]</sup>. Granulomatous inflammation has not been recorded.

Treatment for this enterocolitis largely based upon supportive measures, specifically, fluid and electrolyte replenishment and, sometimes, parenteral nutrition. In addition, the colitis has often been treated with intravenous high dose steroids (or oral budesonide) and, if the response to steroids fails or has been limited, infusions of infliximab have been used<sup>[14,15]</sup>. If no response for the colitis is evident, diverting ileostomy or partial/complete colectomy has been recommended. The incidence of life-threatening colon perforation has been recorded at 4 in 700 cases with doses of ipilimumab of 3 mg/kg or more (i.e., less than 1%). Even during treatment with steroids or infliximab for the colitis, the anti-tumor response for metastatic melanoma still appears to be sustained. In a recent study of ipilimumab with dacarbazine for previously untreated metastatic melanoma, rates of intestinal adverse events were reported to be lower, while the rates of altered liver chemistry test changes were higher<sup>[5]</sup>.

## RITUXIMAB-ASSOCIATED COLITIS

Rituximab is an anti-CD20 monoclonal antibody that has been used in the management of nephrotic syndrome in children and adults<sup>[16-18]</sup> as well as a form of B-cell targeted therapy in rheumatoid arthritis<sup>[19,20]</sup>. It appears to result in depletion of systemic as well as intestinal B cell populations. Although the agent appears to be efficacious, adverse effects have been noted in about 27% of children treated with rituximab for refractory nephrotic syndrome<sup>[21]</sup>. Some of the reported adverse effects have included fever and chills, mucocutaneous reactions, fatal infusion reactions, progressive multifocal leukoencephalopathy, and bowel perforation<sup>[18,22]</sup>. New onset ulcerative colitis<sup>[23]</sup> and an exacerbation of previously documented colitis have been recorded<sup>[24]</sup>. In a later report, it was hypothesized that a severe colitis that developed after rituximab therapy may have been related to an infectious torovirus agent<sup>[22]</sup>.

## BEVACIZUMAB-ASSOCIATED COLONIC ULCERATION

Bevacizumab is a humanized monoclonal antibody against

the vascular endothelial growth factor receptor. This antibody has shown promise in the treatment of recurrent and metastatic colorectal cancer as well as metastatic non-small cell lung cancer. The agent has also been used to treat other malignancies, including ovarian cancer. Several mechanisms of action have been proposed, including an ability to restrict or deprive tumors of their neovascularity required to permit tumor progression and growth.

A number of cases have now been reported describing bowel perforation following bevacizumab treatment<sup>[25-29]</sup>. There also appears to be an especially increased risk of leakage at anastomotic suture sites following surgery for either ulcerative colitis or colorectal cancer<sup>[26]</sup>. In some, delayed anastomotic complications have been observed, some more than 1 year after surgery. Some hypothesized risk factors included anastomotic leakage during the original operative procedure or prior pre-operative pelvic irradiation<sup>[27]</sup>. Other mechanisms that have been recorded include an ischemic pathogenesis with anastomotic perforation after a partial colectomy<sup>[28]</sup> or more diffuse perforation associated with histological evidence of ischemia in a patient with non-small cell lung cancer<sup>[29]</sup>.

## ANTI-TUMOR NECROSIS FACTOR ADVERSE EVENTS

Most intriguing is the recent increased recognition of paradoxical adverse events following therapy with anti-tumor necrosis factor. In selected patients with inflammatory bowel disease, improved symptoms and mucosal changes may result. Similar treatment effects have been recorded for different agents including the chimeric monoclonal agent, infliximab, along with more humanized forms, such as adalimumab. Interestingly, in some treated with these agents for other disorders, in particular spondyloarthropathies or rheumatoid arthritis, so-called “paradoxical” adverse effects have been recorded, including flares or new onset inflammatory bowel disease<sup>[30]</sup>. Initially, in this early evaluation, intestinal effects appeared to occur more often with etanercept than either of the monoclonal antibody agents<sup>[30]</sup>. Later, however, other effects appeared to develop during arthritis treatment, particularly the skin disorder, *pyoderma gangrenosum*<sup>[31,32]</sup>. Later, new onset ulcerative colitis was initially recorded during infliximab treatment<sup>[33]</sup> as well as adalimumab<sup>[34]</sup>. Similar cases of new onset inflammatory bowel disease, specifically, Crohn’s disease have also been recorded usually after etanercept therapy administered for spondyloarthropathy (as opposed to Crohn’s disease where etanercept has not been effective)<sup>[35-39]</sup>. Some have suggested that the *de novo* appearance of inflammatory bowel disease following anti-tumor necrosis factor therapy may simply be related to “unmasking” of an underlying inflammatory disease process<sup>[40]</sup>. Others have documented a superimposed infectious agent<sup>[41,42]</sup>. A large retrospective study concluded that paradoxical adverse events of anti-tumor necrosis factor therapy may occur, but none were agent specific<sup>[43]</sup>.

## CONCLUSION

Several intestinal, particularly colonic complications have been recorded with the emerging armamentarium of monoclonal antibody agents used in the management of different inflammatory or malignant disorders. For some, immune-mediated adverse events may occur regularly, while for others, a complication may be rare and the mechanism not so evident. The precise frequency of colonic complications after treatment with these agents has been difficult to determine. In large part, this has been related to the clinical focus being largely directed to the most severely symptomatic cases. Although selected patients treated for either ulcerative colitis or Crohn’s disease with these biological agents has increased over the past decade, in retrospect, it may be that some labeled as “refractory” or not responsive to these agents may simply have been made worse. Published clinical trials may not always detail a failed therapeutic event as an adverse event. Future awareness of the possible adverse intestinal effects of monoclonal agents may be important.

### Abstract

**AIM:** To study the effects of probiotic metabolites on maturation stage of antigen-presenting immune cells.

**METHODS:** Ganeden *Bacillus coagulans* 30 (GBC30) bacterial cultures in log phase were used to isolate the secreted metabolite (MET) fraction. A second fraction was made to generate a crude cell-wall-enriched fraction, by centrifugation and lysis, followed by washing. A preparation of MET was subjected to size exclusion centrifugation, generating three fractions: < 3 kDa, 3-30 kDa,

and 30-200 kDa and activities were tested in comparison to crude MET and cell wall in primary cultures of human peripheral blood mononuclear cell (PBMC) as a source of antigen-presenting mononuclear phagocytes. The maturation status of mononuclear phagocytes was evaluated by staining with monoclonal antibodies towards CD14, CD16, CD80 and CD86 and analyzed by flow cytometry.

**RESULTS:** Treatment of PBMC with MET supported maturation of mononuclear phagocytes toward both macrophage and dendritic cell phenotypes. The biological activity unique to the metabolites included a reduction of CD14<sup>+</sup> CD16<sup>+</sup> pro-inflammatory cells, and this property was associated with the high molecular weight metabolite fraction. Changes were also seen for the dendritic cell maturation markers CD80 and CD86. On CD14<sup>dim</sup> cells, an increase in both CD80 and CD86 expression was seen, in contrast to a selective increase in CD86 expression on CD14<sup>bright</sup> cells. The co-expression of CD80 and CD86 indicates effective antigen presentation to T cells and support of T helper cell differentiation. The selective expression of CD86 in the absence of CD80 points to a role in generating T regulatory cells.

**CONCLUSION:** The data show that a primary mechanism of action of GBC30 metabolites involves support of more mature phenotypes of antigen-presenting cells, important for immunological decision-making.

## INTRODUCTION

Bacteria are ubiquitous in the environment, having colonized every extreme of nature. This includes the human body where they outnumber human cells by an order of magnitude. The biggest reservoir of these symbiotic bacteria on the human body is the lower gastrointestinal tract<sup>[1]</sup> where large numbers of coexisting (commensal) bacteria participate in nutrient assimilation including the breakdown of indigestible carbohydrates. They also produce amino acids and vitamins for their host and play a key role in healthy immune system development.

The immune system recognizes both pathogenic and commensal bacteria through a family of pattern recognition receptors known as the toll-like receptor (TLR) family<sup>[2]</sup>. These receptors interact with molecules present on the exterior surface of bacteria and include lipopolysaccharide (LPS), flagellin, lipoteichoic acid and lipoproteins as well as bacterial DNA. Toll-like receptors are present on cells participating in both innate and adaptive immunity such as monocytes/macrophages and dendritic cells (DC) as well as epithelial cells of the intestinal mucosa.

The emerging picture is that commensal bacteria have an enormous impact on health. While a healthy microbiota can aid the host by increasing nutrient absorption and training the immune system to not respond to self, conversely an unhealthy (i.e., unbalanced) microbiota can lead to malabsorption, inflammation and disease<sup>[3-5]</sup>. A growing body of evidence suggests that these effects, both positive and negative, of the microbiota on the host are mediated by the immune system. Probiotics are defined as microorganisms that when ingested in a sufficient amount confer a health benefit upon the host and are known to interact with the immune system. Probiotic microorganisms have a long history of human consumption in the form of fermented foods and have shown health benefits in treating dysbiosis, irritable bowel syndrome, and eczema<sup>[6]</sup>. GaneddenBC30™ (*Bacillus coagulans* GBI-30, 6086) (GBC30) is a proprietary strain of the gram positive, lactic acid producing spore-forming bacteria known as *Bacillus coagulans*. This strain of *B. coagulans* can survive extremes of heat and pressure in manufacturing as well as the harsh, acidic environment of the human gastrointestinal tract, leading to a very high survival rate and germination in the lower intestinal tract. The safety of consumption of this strain was documented in acute and sub-chronic studies in rats<sup>[7]</sup>.

One way in which commensal bacteria modulate the immune response is by the secretion of certain bioactive compounds. This suggests that metabolites of commensal bacteria have effects of their own and that there may be unique health benefits to be derived from the consumption of live probiotic cultures or probiotic metabolite preparations. Recent studies on the bacterial compound polysaccharide A from *Bacteroides fragilis* have shown the ability of this molecule to prevent intestinal inflammation caused by *Helicobacter pylori* infection and to correct the symptoms of encephalomyelitis in mice, an animal model for human multiple sclerosis<sup>[8-10]</sup>. The recent sequencing data from 178 commensal microbial genomes has identified over 30 thousand potential protein-coding sequences of which 97% are unique<sup>[11]</sup>. This suggests a vast untapped reservoir of novel genes including those coding for potential secreted compounds.

The work presented here build on a previous study that showed both enhancement of innate immune responses as well as anti-inflammatory effects of GBC30 *in vitro*<sup>[12]</sup>. In particular, the data presented here has aimed at investigating the differences between a crude preparation versus the metabolite fraction in more detail with a particular focus on modulation of key regulatory immune cells by specific size-selected fractions of GBC30 metabolite (MET) compounds.

## MATERIALS AND METHODS

### Reagents

The following buffers and reagents were obtained from Sigma-Aldrich (St. Louis, MO): Histopaque 1077 and 1119, phosphate-buffered saline (PBS), RPMI-1640 culture medium, fetal calf serum, L-glutamine 200 mmol/L, penicillin-streptomycin 100X solution, and bovine serum albumin. CD80-FITC, CD86-PE, CD16-PE and CD14-PerCP were obtained from BD Biosciences (San Jose, CA). Sodium Azide (NaN<sub>3</sub>) was obtained from LabChem Inc. (Pittsburgh, PA). Low-binding 100 μm zirconium beads were obtained from OPS Diagnostics (Lebanon, NJ) and 0.2 μm cellulose acetate filters from Whatman (Florham Park, NJ). The *Bacillus coagulans* strain (GaneddenBC30™) was obtained from Ganedden Biotech Inc. (Mayfield Height, OH).

### Preparation of *Bacillus coagulans* metabolite fractions

Using sterile technique, two separate samples of 2.0 g of GaneddenBC30™ spores were each placed into 25 mL PBS and heated at 70 °C for 30 min. Spores were then centrifuged at 2400 rpm for 5 min, PBS was removed and each tube of spores re-suspended and placed in culture flasks containing 25 mL of RPMI-1640 culture medium. The cultures were incubated at 37 °C for 24 h at which time an additional 20 mL of RPMI-1640 was added and the cultures incubated for an additional 24 h. Following 48 h of incubation, the bacterial cultures contained 5 × 10<sup>7</sup> bacteria/mL.

Preparation of GaneddenBC30™ culture supernatant as

a source of metabolites (MET): Cultures were transferred to 50 mL centrifuge tubes and initially spun at 1000 rpm for 2 min to remove any remaining spores. The liquid containing the bacteria and metabolites was decanted into new tubes and centrifuged at 3500 rpm for 20 min. The supernatant was decanted from the large bacterial pellets and combined in a single tube followed by filtration twice through a 0.2  $\mu\text{m}$  cellulose acetate syringe filter. This filtrate was either frozen directly as 250  $\mu\text{L}$  aliquots (crude metabolite fraction) or spun through Amicon Ultra protein size separation columns from Millipore (Bedford, MA) followed by aliquot preparation and storage at  $-20\text{ }^{\circ}\text{C}$ . Separation of the metabolites into different molecular weight fractions was performed in the following manner: for the fraction that is  $< 3\text{ kDa}$ , the crude metabolite preparation was placed onto a 3 kDa molecular weight cutoff centrifuge column and spun at 2500 rpm for 10 min. The filtrate that passed through the filter contained material that was less than 3 kDa. Aliquots were made from this material and frozen (metabolites  $< 3\text{ kDa}$  fraction). The material that did not pass through the column was then placed into a tube containing a 30 kDa molecular weight cutoff filter and spun at 2500 rpm for 10 min. The filtrate that passed through this filter contained material that was 3-30 kDa. Aliquots were made from this material and frozen (metabolites 3-30 kDa fraction). The remaining metabolite material that did not pass through the 30 kDa molecular weight filter was also aliquoted and frozen and this fraction was called metabolites 30-200 kDa fraction. It is important to note that these size separations are not exact and that while large molecules are excluded from the fractions containing the smaller molecules, some small molecules may still remain in the fractions containing the larger molecules.

Preparation of GanedenBC30<sup>TM</sup> crude cell wall (CW): The two bacterial pellets were each processed separately and then combined after the final bead milling step. Following centrifugation of the bacterial culture at 3500 rpm for 20 min and decanting of the supernatant, the bacterial pellets were washed twice in 45 mL of PBS with subsequent pelleting by centrifugation at 2500 rpm for 10 min. The washed pellets went through one freeze/thaw cycle followed by multiple bead milling cycles. In brief, the pellets were resuspended in 4 mL of PBS and then 4 mL of 100  $\mu\text{m}$  low-binding zirconium beads were added. One cycle of bead milling consisted of 60 one-second pulses of the bacteria/bead mixture on a vortex mixer. Ten of these cycles were performed. The bacteria/bead mixture was placed on ice in between bead milling cycles. At the end of the 10 bead-milling cycles, the beads were allowed to settle in the tubes and the liquid removed from the two tubes and combined. The liquid containing the fragmented bacteria was spun at 3500 rpm for 20 min followed by transfer of the liquid to Eppendorf tubes and centrifugation at 14 000 rpm for 5 min. The high speed centrifugation was necessary to remove any large fragments of bacteria that were not disrupted by the bead milling. The final solution was brought up to 45 mL with PBS and fil-

tered through a 0.2  $\mu\text{m}$  cellulose acetate filter and stored directly at  $-20\text{ }^{\circ}\text{C}$  as 250  $\mu\text{L}$  aliquots (crude cell wall). It is important to note that the cell wall preparation will also contain some GBC30 cellular contents in addition to cell wall components.

### **Purification of peripheral blood mononuclear cells**

Healthy human volunteers between the age of 20 years and 60 years served as blood donors after obtaining written informed consent, as approved by the Sky Lakes Medical Center Institutional Review Board. Isolation of peripheral blood mononuclear cell (PBMC) was performed as previously described<sup>[13]</sup>.

### **Cell surface staining of CD14 positive mononuclear phagocytes**

Complete cell culture media used for the culture of PBMC consisted of RPMI-1640 supplemented with 10% fetal bovine serum, 2 mmol/L L-glutamine, 100 U/mL penicillin and 100  $\mu\text{g}/\text{mL}$  streptomycin. Peripheral blood mononuclear cells were cultured for 3 d in the presence of serial dilutions of BC30 metabolite fractions or crude cell wall followed by cell surface immunostaining with CD14, CD80, CD86 and CD16 monoclonal antibodies. Processing of cells for immunostaining was performed as previously described<sup>[13]</sup> with the following modifications: optimal amounts of monoclonal antibodies per sample were 3  $\mu\text{L}$  for CD14-PerCP and 4  $\mu\text{L}$  for CD80-FITC, CD86-PE and CD16-PE. Experiments were performed three times using PBMC isolated from three different blood donors. Each test condition was performed in duplicate and untreated and LPS-treated controls were tested in quadruplicate and triplicate, respectively.

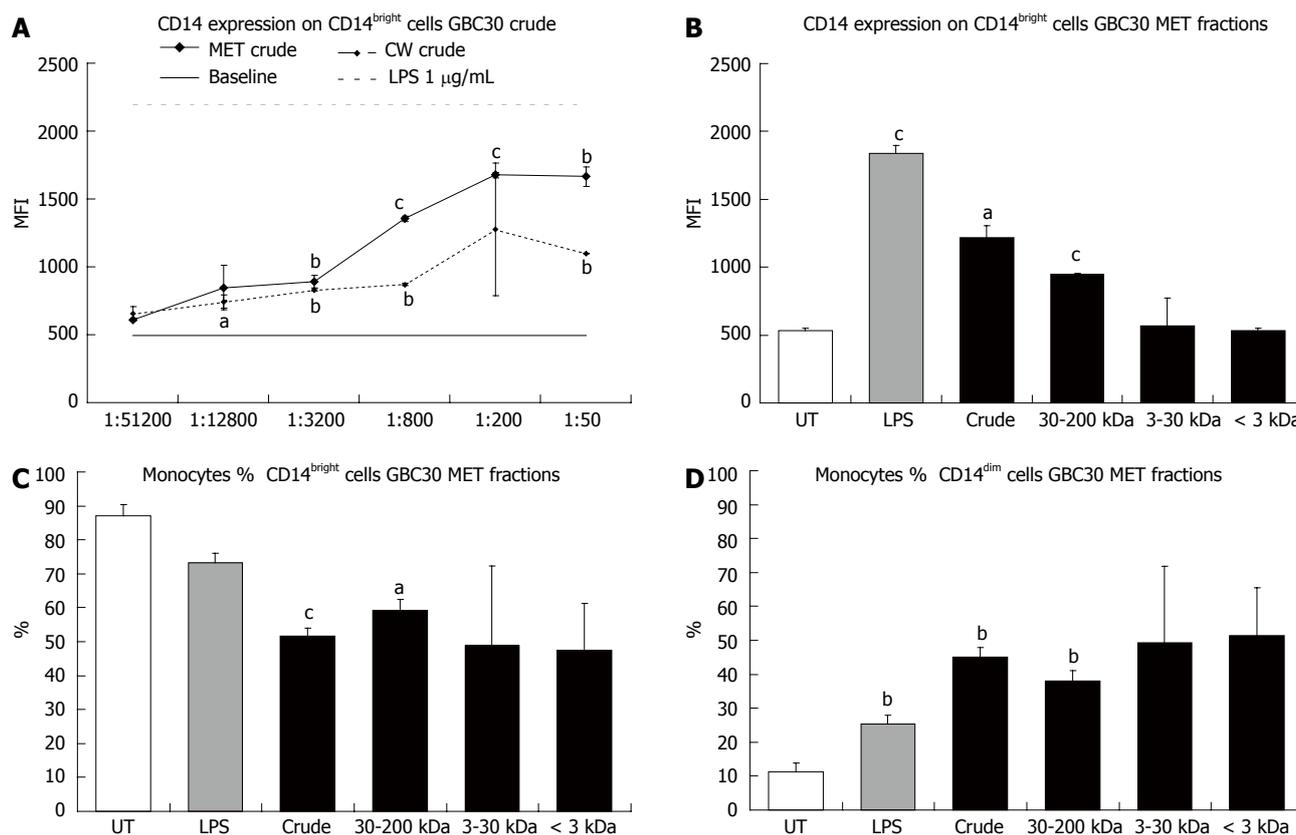

### **Statistical analysis**

Statistical significance was tested using Student's *t*-test performed with Microsoft Excel. All *P* values were two-sided and were considered significant when  $P < 0.05$  and highly significant when  $P < 0.01$ . Only statistically significant *P* values are reported.

## **RESULTS**

### **GBC30 effects on mononuclear phagocyte differentiation**

Mononuclear phagocyte differentiation in 3-d primary PBMC cultures was examined by cell surface staining for proteins expressed by monocytes/macrophages and dendritic cells. These included CD14 (Figure 1) and CD80 and CD86 (Figures 2 and 3). CD14 expression on CD14<sup>bright</sup> cells was increased following exposure of cells to GBC30 crude MET and CW fractions (Figure 1A). Treatment of cells with crude MET showed a strong dose-dependent response with statistically significant increases occurring with the 4 highest doses. As expected, LPS treatment of cells greatly increased CD14 expression<sup>[14]</sup>. Crude CW also led to statistically significant increases in CD14 expression. When the effects of crude and size-selected MET fractions of GBC30 at a 1:200 dilution

**Figure 1 CD14 expression on mononuclear phagocytes.** Mononuclear phagocytes present in 3-d peripheral blood mononuclear cell cultures exposed to either the Ganeden *Bacillus coagulans* 30 (GBC30) metabolites (MET), cell wall-enriched (CW), or MET fractions, were identified using electronic gating of the flow cytometry data by gating on forward scatter/side scatter followed by gating for CD14 positivity. A comparison was made between cells that were untreated (UT), exposed to lipopolysaccharide (LPS) or to the different GBC30 fractions. A: Comparison of CD14 mean fluorescence intensity showed a dose-dependent increase in CD14 expression in cells treated with crude MET. A milder increase was seen for cells treated with crude CW. The baseline indicates CD14 expression on untreated cells; B: The increase in CD14 expression was primarily caused by high molecular weight compounds present in MET; C: The percent of CD14<sup>bright</sup> cells in the mononuclear phagocyte population was decreased by all fractions of MET; D: The percent of CD14<sup>dim</sup> cells in the mononuclear phagocyte population was increased by treatment of cells with all MET fractions. Bar graphs show data from 1:200 dilutions of each MET fraction and lipopolysaccharide (1 μg/mL). <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 and <sup>c</sup>P < 0.001. For each data point, the mean ± SD are shown for each duplicate data set. Graphs show data representative of 1 out of 3 experiments. MFI: Mean fluorescence intensity.

were compared (Figure 1B), high molecular weight fractions (crude and 30-200 kDa) increased CD14 expression while PBMC treated with either the 3-30 kDa or < 3 kDa fractions showed CD14 expression levels similar to untreated cultures.

**Reduction of CD14<sup>bright</sup> cells**

Because CD14 expression on mononuclear phagocytic cells varies and expression levels have been correlated with different cell populations, the percent of CD14<sup>bright</sup> versus CD14<sup>dim</sup> cells was determined for PBMC cultures exposed to different GBC30 MET fractions. All fractions of MET at a 1:200 dilution led to decreased numbers of CD14<sup>bright</sup> cells (Figure 1C) while an inverse pattern of response was seen regarding changes in CD14<sup>dim</sup> cell numbers (Figure 1D). In this case all fractions of MET led to increases in the percent of CD14<sup>dim</sup> cells.

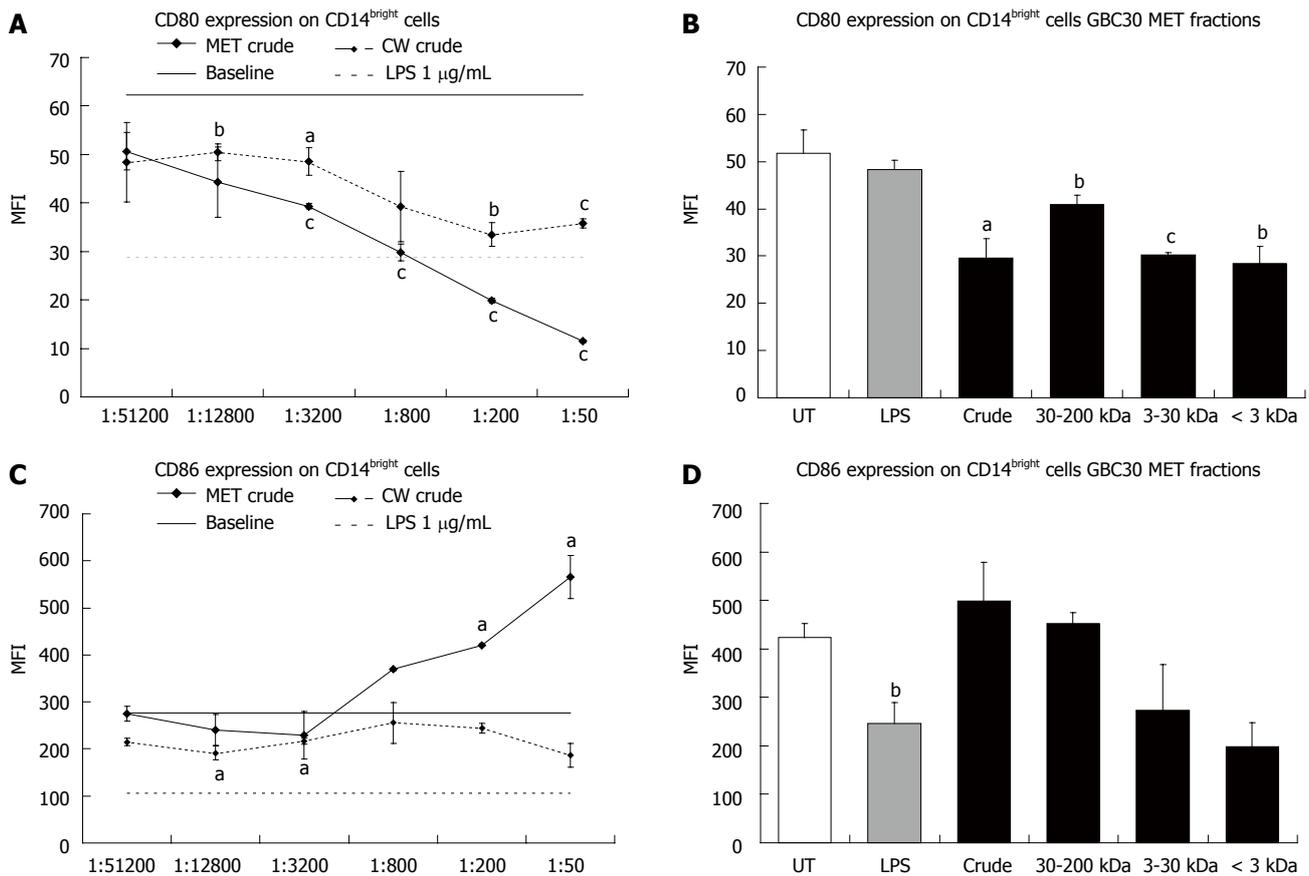

**CD14<sup>bright</sup> cells: Effects of GBC30 metabolite and cell wall on CD80 and CD86 expression**

Next, CD80 and CD86 expression was determined for the CD14<sup>bright</sup> cell population. Both MET and CW crude

fractions led to statistically significant decreases in CD80 expression on CD14<sup>bright</sup> cells (Figure 2A) while only MET crude increased CD86 expression (Figure 2C). When crude and size selected fractions of MET were compared at the 1:200 dilution all fractions of MET led to similar statistically significant decreases in CD80 expression (Figure 2B). A comparison of the effect of MET fractions on CD86 expression showed that the 3-30 kDa and < 3 kDa fractions led to a decrease but these changes were not statistically significant (Figure 2D).

**CD14<sup>dim</sup> cells: Effects of GBC30 metabolite and cell wall on CD80 and CD86 expression**

When expression of the co-stimulatory molecules CD80 and CD86 was determined for the CD14<sup>dim</sup> cell population, both MET and CW crude increased CD80 (Figure 3A) and CD86 (Figure 3C) expression with MET crude having the biggest effect, particularly on CD86 expression. When crude and size selected fractions of MET were compared at the 1:200 dilution, only the crude and 30-200 kDa fractions led to statistically significant increases in CD80 expression (Figure 3B). A comparison

**Figure 2** Expression of the co-stimulatory molecules CD80 and CD86 on CD14<sup>bright</sup> mononuclear phagocytes from 3-d peripheral blood mononuclear cell cultures. A: Comparison between the effects of serial dilutions of Ganeden *Bacillus coagulans* 30 (GBC30) crude metabolites (MET) or cell wall enriched (CW) fractions on CD80 expression on CD14<sup>bright</sup> cells showed dose-dependent decreases in CD80 expression. Both MET and CW reduced CD80 expression to levels similar to those seen with Lipopolysaccharide (LPS) treatment; B: A comparison of the effects of size-fractionated MET on CD80 expression on CD14<sup>bright</sup> cells shows that all MET fractions reduce expression; C: Comparison between the effects of serial dilutions of crude MET or CW on CD86 expression on CD14<sup>bright</sup> cells showed dose-dependent increases in CD86 expression when cells were exposed to the three most concentrated dilutions of MET. Treatment of cells with CW resulted in a uniform modest decrease in CD86 expression; D: The effect on increased CD86 expression is present only in the crude preparation of MET. Bar graphs show data from 1:200 dilutions of each MET fraction and lipopolysaccharide (1 μg/mL). <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 and <sup>c</sup>P < 0.001. For each data point, the mean ± SD are shown for each duplicate data set. Graphs show data representative of 1 out of 3 experiments. MFI: Mean fluorescence intensity; UT: Untreated.

of the effect of MET fractions on CD86 expression showed that crude MET increased CD86 expression while the 3-30 kDa and < 3 kDa fractions decreased expression (Figure 3D).

**Reduction in CD14+ CD16+ cells**

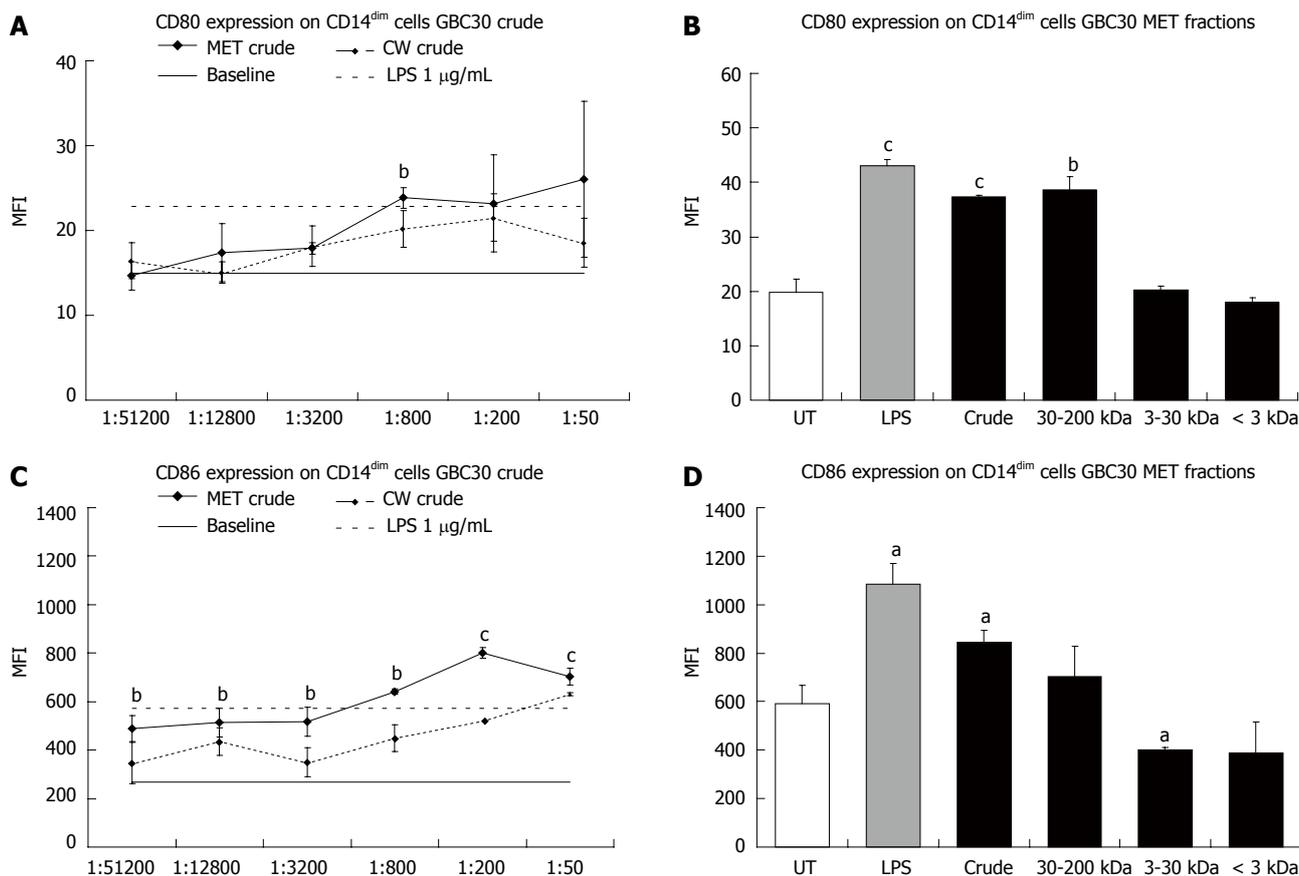

Mononuclear phagocytes have also been classified according to expression of the cell surface protein CD16 with CD14+ CD16+ cell subsets considered to be pro-inflammatory<sup>[15]</sup>. The effect of crude MET and CW fractions on the percent of CD14+ CD16+ and CD14+ CD16- cells in 3-d PBMC cultures was investigated. Crude MET treatment of cells resulted in a dose dependent decrease in CD14+ CD16+ cells (Figure 4A) and an increase in CD14+ CD16- cells (Figure 4C). Crude CW had a much milder effect that mirrored that of crude MET. When cells were exposed to the crude or size fractionated preparations of MET at a 1:200 dilution, it was the fractions with the largest compounds (crude and 30-200 kDa) that showed the greatest effect on CD14+ CD16+ (Figure 4B) and CD14+ CD16- (Figure 4D) cell numbers although

the 3-30 kDa and < 3 kDa fractions also produced statistically significant reductions in the number of CD14+ CD16+ cells.

**DISCUSSION**

The work presented here investigated the effects of MET and CW fractions of the GBC30 probiotic strain on mononuclear phagocyte phenotypes in primary PBMC cultures. The cellular model for examining the immune effects was carefully chosen, and primary PBMC cultures were used because this allows the simultaneous interaction of multiple cell types and has been shown to support the survival of blood dendritic cells without the addition of exogenous cytokines<sup>[16]</sup>. One of the main findings was the biological activities of the metabolites and the data showed that a primary mechanism of action of BC30 metabolites involved support of more mature phenotypes of antigen-presenting cells, important for immunological decision-making.

Compounds present in the MET crude fraction con-

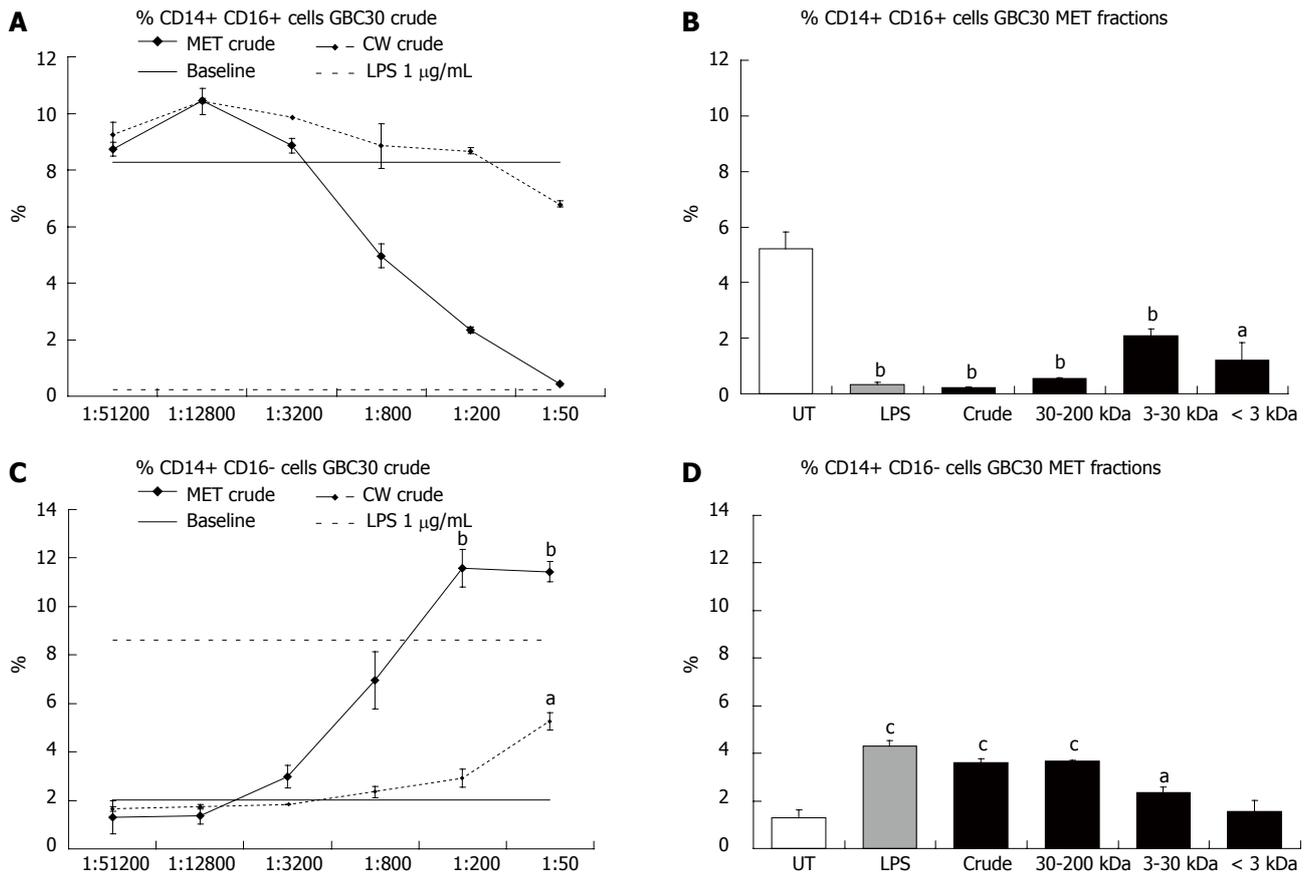

**Figure 3** Expression of the co-stimulatory molecules CD80 and CD86 on CD14<sup>dim</sup> mononuclear phagocytes from 3-d peripheral blood mononuclear cell cultures. A: Comparison between the effects of serial dilutions of Ganeden *Bacillus coagulans* 30 (GBC30) crude metabolites (MET) or cell wall enriched (CW) fractions on CD80 expression on CD14<sup>dim</sup> cells showed that both MET and CW led to increased expression; B: The increase in CD80 expression following treatment of cells with MET was due to high molecular weight compounds; C: Comparison of CD86 expression on CD14<sup>dim</sup> cells exposed to crude fractions of MET or CW resulted in increased CD86 expression; D: Size-selected fractions of MET did not have uniform effects on CD86 expression on CD14<sup>dim</sup> cells. Crude MET increased expression while 3-30 kDa and < 3 kDa fractions decreased expression. Bar graphs show data from 1:200 dilutions of each MET fraction and lipopolysaccharide (1 µg/mL). <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 and <sup>c</sup>*P* < 0.001. For each data point, the mean ± SD are shown for each duplicate data set. Graphs show data representative of 1 out of 3 experiments. MFI: Mean fluorescence intensity; UT: Untreated; LPS: Lipopolysaccharide.

sisted entirely of compounds that were secreted by GBC30 into the culture media. The CW crude fraction was isolated from whole bacteria and may contain some compounds present in the MET preparation in addition to compounds unique to the cell wall. Size fractionation of crude MET was used to evaluate immune modulating compounds based on MW and their association with one or more fractions.

Probiotic organisms support mucosal immunity and similar to commensal bacteria in the human gut, they interact with mononuclear phagocytic cells such as dendritic cells and macrophages<sup>[17-19]</sup>. The expression levels of CD80 and CD86 co-stimulatory molecules can be used to indicate the differentiation of mononuclear phagocytes to that of antigen presenting cells such as dendritic cells. While CD14 is still present on some subsets of dendritic cells, typically when mononuclear phagocytes adopt a dendritic cell identity, CD14 expression is down regulated with the concurrent up regulation of CD80 and CD86<sup>[20]</sup>. The differential roles of the co-stimulatory molecules CD80 and CD86 suggests that co-expression of both molecules on dendritic cells leads to T helper cell differentiation, whereas the predominant expression of CD86 support T regulatory cells, and supports an anti-inflammatory cyto-

kine profile by decreasing Interferon-gamma production and increasing interleukin (IL)-4 production<sup>[21]</sup>. Since the current literature suggests that mononuclear phagocytes present in the circulation are already committed in their developmental path<sup>[22]</sup>, the changes seen in CD14 expression suggest that MET and CW simultaneously enhance the maturation of two separate subpopulations of mononuclear phagocytic cells (CD14<sup>bright</sup> and CD14<sup>dim</sup>) towards their corresponding macrophage and dendritic cell phenotypes. The effect of GBC30 on putative DC maturation in PBMC cultures, suggests that DC may be responsible for the IL-6 production that was previously shown *in vitro*<sup>[12]</sup>, and this increased IL-6 production may reflect normal physiological interactions between DC and commensal bacteria in the human gut<sup>[17,23]</sup>.

The data suggest that live GBC30 in the gut lumen would provide metabolites from GBC30, different from the immune modulating compounds associated with the cell wall enriched fraction, and support the interpretation that the live metabolically active GBC30 has stronger immune modulating activity than accounted for by its cell wall alone. Immune modulating activity has been identified from the supernatant of the probiotic strains *Lactoba-*

**Figure 4** Changes in the percent of CD14+ CD16+ and CD14+ CD16- cell populations following exposure of 3-d peripheral blood mononuclear cell cultures to Ganeden *Bacillus coagulans* 30. A: Exposure of cells to serial dilutions of Ganeden *Bacillus coagulans* 30 (GBC30) crude metabolites (MET) led to a strong dose-dependent decrease in CD14+ CD16+ double positive cells while exposure to cell wall enriched (CW) did not reduce this cell population; B: Treatment of cells with size-selected MET fractions show that all fractions of MET reduce the number of CD14+ CD16+ cells; C: The percent of CD14+ CD16- cells in peripheral blood mononuclear cell cultures increased in cultures treated with crude MET and CW. Treatment with MET resulted in a very strong dose-dependent increase while CW treatment produced a milder increase at the two highest concentrations; D: Treatment of cells with size-selected MET fractions show that only fractions containing high molecular weight compounds increase the number of CD14+ CD16- cells. Bar graphs show data from 1:200 dilutions of each MET fraction and lipopolysaccharide (1 µg/mL). <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 and <sup>c</sup>*P* < 0.001. For each data point, the mean ± SD are shown for each duplicate data set. Graphs show data representative of 1 out of 3 experiments. UT: Untreated; LPS: Lipopolysaccharide.

*Lactobacillus casei* Shirota<sup>[24]</sup> and *Bifidobacterium breve*<sup>[25]</sup>, the probiotic yeast *Saccharomyces boulardii*<sup>[26]</sup>, the commensal bacterium *Faecalibacterium prausnitzii*<sup>[27]</sup> and gut-derived lactobacilli and bifidobacteria<sup>[28]</sup>. In the case of *Faecalibacterium prausnitzii*, injection of the supernatant completely protected mice from trinitrobenzenesulphonic acid induced colitis while live bacteria provided only partial protection<sup>[27]</sup>. Most of these studies focused on cytokine production in monocyte-derived dendritic cell cultures<sup>[26,27]</sup> and have determined this to occur through a TLR2 dependent mechanism. In one study, it was determined that the active component in the supernatant from *Lactobacillus casei* was a polysaccharide peptidoglycan complex<sup>[24]</sup> while another study has suggested that the immune boosting effect of common botanical extracts is through effects of bacterial lipoproteins and lipopolysaccharides (derived from endophytes, the resident bacteria present in all plants) on macrophage activation<sup>[29]</sup>.

Thus, due to direct effects on mononuclear phagocyte differentiation, GBC30 metabolites lend support to two important cell types responsible for antigen recognition, presentation to cells within the adaptive immune system,

and execution of regulatory functions, including immunological memory. The effect of dried/reconstituted material was tested in three different bioassays previously reported to show bioactivity<sup>[12]</sup>, including anti-inflammatory effects (data not shown), and no significant difference was seen between this and frozen/thawed material. The stability of the bioactive compounds in the metabolite fraction holds promise for development of a consumable product.

Results from the GBC30 MET fractions suggest that the metabolic activity of this probiotic organism is an integral part of its immune modulating functions, and that multiple different compounds act in synergy to support key aspects of mucosal immune protection. These results suggest specific mechanisms of action and may give insight into some aspects of previous clinical studies showing reduced symptoms from irritable bowel syndrome<sup>[30]</sup>. We suggest that further studies include *ex vivo* evaluation of mononuclear cells isolated from lamina propria and Peyer's patches, in terms of antigen presentation, dendritic cell and B lymphocyte maturation, and IgA production. Further clinical work is warranted, not only

in populations with inflammatory syndromes, but also in populations with reduced mucosal immune protection, and should include assessment of inflammatory markers in serum, as well as secretion of IgA.

In conclusion, the biological activities reported here for the metabolites point to a unified mechanism of action directed at the differentiation and maturation state of antigen-presenting cells such as the macrophage/dendritic cells. In terms of immune regulation, this plays a pivotal role in decision-making, for example in whether T lymphocytes are induced into immunological anergy (unresponsiveness, tolerance) or whether they are triggered into proliferation, cytokine production, and other mechanism of inter-cellular communication. It is conceivable that metabolites are absorbed into the mucosal immune tissue along the intestinal track and help direct more efficient antigen-recognition, while reducing immune reactivity towards harmless food-borne antigens. This may provide a mechanism to explain the improved immune protection, while also seeing a reduction in food allergies and associated inflammatory reactions with consumption of certain probiotic strains.

## COMMENTS

### Background

The mucosal surface of the human gastrointestinal tract is an interface between the external and internal environments, separated by a single epithelial cell layer. On the one side are food antigens, commensal bacteria and potential pathogens while cells of the immune system reside on the other. Oral tolerance refers to the ability of the immune system to not react towards food and commensal bacterial antigens while still evoking a robust immune response towards pathogens. Probiotic bacteria interact with the host immune system and elicit beneficial immune modulating effects that include a reduction in inflammation in inflammatory bowel disease, amelioration of antibiotic-induced diarrhea, and protection from pathogen infection.

### Research frontiers

Recent evidence suggest that the interaction of commensal bacteria and probiotics with the immune system is more than a mechanical engagement of bacterial cell wall components with immune cell receptors and includes an active cross-talk between live bacteria and the host through secreted substances (metabolites). This is an active area of research and data from microbiome genomic sequencing suggests that the majority of predicted genes encode proteins with unknown functions.

### Innovations and breakthroughs

Most of the published work on probiotics interacting with the immune system has focused on the bacterial cell wall activating the immune system through engagement of the Toll-like receptor (TLR) family, in particular TLR2 and TLR4. Much less research has focused on secreted metabolites and very little is known about what these secreted compounds are. The data presented here showed that a primary mechanism of action of Ganeden *Bacillus coagulans* 30 (GBC30) metabolites involved support of more mature phenotypes of antigen-presenting cells, important for immunological decision-making. An immature antigen presenting cell may fail in triggering an appropriate immune defense reaction, while either inducing immunological unresponsiveness (anergy) towards the antigen, or induce an allergic reaction to the antigen.

### Applications

The support of antigen-presenting cells *in vitro* by GBC30 metabolites suggests that consumption of GBC30 may lead to *in vivo* effects of improved decision-making in the gut-associated lymphoid tissue (GALT), translating into clinical observations of improved immunity against infections, and reduced immunological anergy and allergy.

### Terminology

Cluster of differentiation 14 is a monocyte marker and functions as a co-

receptor for bacterial lipopolysaccharide recognition. It is highly expressed on the cell surface of monocytes and macrophages; GALT is a mucosa-associated lymphoid tissue lining the gastrointestinal tract from the esophagus to the colon. It contains immune cells and plays an important part in preventing the immune system from reacting to the resident microflora as well as defence from pathogens; Anergy refers to the absence of a normal immune response to a specific antigen or allergen.

### Peer review

The authors present a paper that aimed to investigate any differences between the effects of a crude preparation of GBC30 bacterial culture metabolites compared to the fractionated preparations on the maturation of peripheral blood mononuclear cell. It demonstrates that probiotic bacteria produce metabolites that activate cells of the immune system, beyond what is expected from simple bacterial cell wall components.

### Abstract

**AIM:** To investigate the effects of antithrombin III (AT III) injection *via* the portal vein in acute liver failure.

**METHODS:** Thirty rats were intraperitoneally challenged with lipopolysaccharide (LPS) and D-galactosamine (GalN) and divided into three groups: a control group; a group injected with AT III *via* the tail vein; and a group injected with AT III *via* the portal vein. AT III (50 U/kg body weight) was administered 1 h after challenge with LPS and GalN. Serum levels of inflammatory cytokines and fibrin degradation products, hepatic fibrin deposition, and hepatic mRNA expression of hypoxia-

related genes were analyzed.

**RESULTS:** Serum levels of alanine aminotransferase, tumor necrosis factor- $\alpha$  and interleukin-6 decreased significantly following portal vein AT III injection compared with tail vein injection, and control rats. Portal vein AT III injection reduced liver cell destruction and decreased hepatic fibrin deposition. This treatment also significantly reduced hepatic mRNA expression of lactate dehydrogenase and heme oxygenase-1.

**CONCLUSION:** A clinically acceptable dose of AT III injection into the portal vein suppressed liver damage, probably through its enhanced anticoagulant and anti-inflammatory activities.

### INTRODUCTION

In some patients with acute liver injury (ALI), the liver disease proceeds to acute liver failure (ALF); a severe condition associated with a high mortality rate. Liver transplantation is an effective treatment for patients with

severe ALF<sup>[1]</sup>, whereas artificial liver support systems such as plasma exchange and hemodiafiltration are less effective<sup>[2,3]</sup>. The difficulties associated with the development of effective treatments for ALF may be attributed to the incomplete understanding of the mechanisms involved in disease progression.

ALF is pathologically characterized by massive hepatocellular necrosis, therefore, intrahepatic microcirculatory disturbances are involved in the pathogenesis and progression of liver disease. Observation of sinusoidal fibrin deposition, increased fibrinogen catabolism and decreased platelet counts suggest that the intrahepatic coagulation system may be activated in ALF, and the following microcirculatory disturbances may play a role in the formation of massive hepatocellular necrosis<sup>[4]</sup>. The hypothesis that activation of the intrahepatic coagulation system is a fundamental pathogenic factor underlying the development of ALF has prompted researchers to develop new treatments using anticoagulants in experimental animal models and in clinical trials. Intravenous injection of antithrombin III (AT III), which inhibits serine proteases involved in the coagulation cascade, has been reported to attenuate the progression of liver disease in animal models of ALF induced by concanavalin A, dimethylnitrosamine (DMN) and endotoxin<sup>[5-8]</sup>. However, the need for high doses of AT III (200-400 U/kg body weight) to suppress liver damage makes it difficult to apply this treatment in clinical practice. Therefore, the development of regimens using clinically acceptable doses of AT III is necessary.

It has been shown that direct drug delivery into the target organs is more efficient than systemic administration. Direct delivery of 5-fluorouracil and cisplatin into the hepatic artery has been reported to control tumor progression and to extend the median survival time of patients with unresectable hepatocellular carcinoma, which is resistant to systemic chemotherapy<sup>[9]</sup>. Similarly, we have reported that the progression of severe ALI toward fulminant liver failure is inhibited by transcatheter arterial steroid injection, in which methylprednisolone is directly delivered into the diseased liver *via* the hepatic artery<sup>[10]</sup>. The effectiveness of direct steroid delivery into the liver has been confirmed in an experimental animal model. Injection of steroids *via* the portal vein in rats with lipopolysaccharide (LPS)- and D-galactosamine (GalN)-induced ALF more effectively suppresses hepatic inflammation and improves survival than injection *via* the tail vein<sup>[11]</sup>. These observations suggest that the direct delivery of AT III into the liver, *via* the hepatic artery or portal vein, may improve liver damage more effectively than peripheral injection of AT III.

In this study, we administered a clinically acceptable dose of AT III *via* the portal vein or a peripheral vein (tail vein) in rats with LPS/GalN-induced ALF. The suppressive effects of AT III on hepatic inflammation were estimated based on the serum levels of transaminase and inflammatory cytokines, and hepatic histology. The extent of damage to the intrahepatic coagulation system was estimated by determining sinusoidal fibrin deposition.

Hypoxia in the diseased liver, which is caused by hepatic microcirculatory disturbances, was estimated by analyzing the hepatic mRNA expression of hypoxia-related genes. These parameters were compared among three groups: a control group; rats injected with AT III *via* the tail vein; and rats injected *via* the portal vein. Our observations suggest that the injection of AT III *via* the portal vein suppresses liver damage more effectively than *via* the tail vein, because of its enhanced anticoagulant and anti-inflammatory activities.

## MATERIALS AND METHODS

### Chemicals

Human concentrated AT III (Anthrabin P500) was purchased from CSL Bering (King of Prussia, PA, United States). LPS (*Escherichia coli*, 055:B5), GalN and other chemicals were purchased from Sigma (St. Louis, MO, United States). All experiments were performed using the same lot of LPS.

### Animals

Eight-week-old male Wistar rats weighing 200 g were purchased from Japan SLC (Hamamatsu, Japan). Rats were maintained under controlled conditions with free access to standard chow and water. All studies were performed in accordance with the Guide for the Care and Use of Laboratory Animals (National Institutes of Health) and approved by the Animal Care Committee of Kyushu University.

### Animal treatment

LPS (5 µg/kg body weight) and GalN (500 mg/kg body weight) dissolved in 500 µL phosphate buffered solution (PBS) were injected intraperitoneally into rats. One hour after the injections, the animals were anesthetized with pentobarbital sodium, and AT III (50 U/kg body weight) dissolved in 200 µL of PBS was injected into the portal or tail vein. Control animals underwent sham injections. Each group consisted of 10 rats.

### Transaminase and cytokine assays

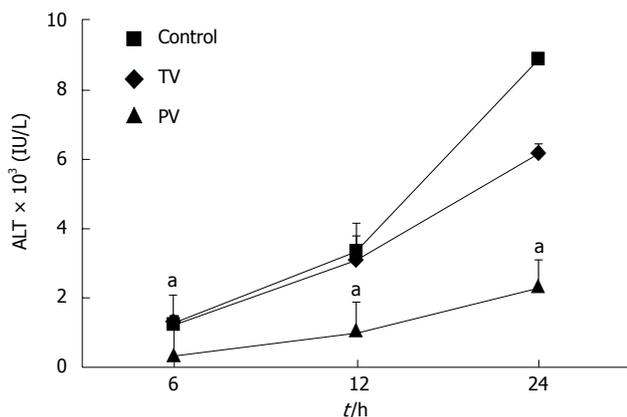

Blood samples were taken from the tail vein at 6 h, 12 h and 24 h after injection of LPS and GalN. The serum levels of alanine aminotransferase (ALT) were estimated by Transaminase C-test (Wako Pure Chemical Industry, Osaka, Japan). Tumor necrosis factor-α (TNF-α), interferon-γ (IFN-γ) and interleukin-6 (IL-6) were measured using enzyme linked immunosorbent assay (ELISA) kits (Endogen, Rockford, IL, United States).

### Assay of serum fibrin degradation products

Blood samples were taken from the tail vein 24 h after injection of LPS and GalN. Serum fibrin degradation products (FDPs) levels were measured using an ELISA kit (Cusabio Biotech, Barksdale, DE, United States).

### Histology

Liver tissue samples were collected 24 h after injecting LPS and GalN, fixed in 10% formalin, and embedded in

**Figure 1** Effects of antithrombin III on serum alanine aminotransferase levels in rats with acute liver failure. Lipopolysaccharide (LPS) and D-galactosamine (GalN) were injected intraperitoneally into 8-wk-old Wistar rats. One hour after the challenge, antithrombin (AT) III (50 U/kg body weight) was injected into the portal or tail vein. Serum alanine aminotransferase (ALT) levels were measured at 6 h, 12 h and 24 h after injection of LPS and GalN. Control: Untreated; TV: AT III injection *via* the tail vein; PV: AT III injection *via* the portal vein. Values are mean  $\pm$  SD ( $n = 10$  rats/group). <sup>a</sup> $P < 0.01$  vs the control group.

paraffin. The sections were stained with hematoxylin and eosin to assess hepatic damage. To determine intrasinusoidal fibrin deposition, the sections were stained with phosphotungstic acid-hematoxylin<sup>[12]</sup>.

### Reverse transcription polymerase chain reaction

Total RNA from liver tissue was prepared with TRIzol reagent (Invitrogen, Carlsbad, CA, United States) and cDNA was synthesized from 1.0  $\mu$ g RNA by GeneAmp RNA polymerase chain reaction (PCR) (Applied Biosystems, Branchburg, NJ, United States) using random hexamers. Real-time PCR was performed using LightCycler FastStart DNA Master SYBR Green I (Roche, Basel, Switzerland). The reaction mixture (20  $\mu$ L) contained Master SYBR Green I, 4 mmol MgCl<sub>2</sub>, 0.5  $\mu$ mol upstream and downstream PCR primers, and 2  $\mu$ L first-strand cDNA as a template. To control variations in reactions, all PCR data were normalized against glyceraldehyde 3-phosphate dehydrogenase expression. The forward and reverse PCR primers were 5'-ACTTTCAGAAGGGT-CAGGTGTCC-3' and 5'-TTGAGCAGGAAGGCG-GTCTTAG-3', respectively, for heme oxygenase-1 (HO-1) and 5'-AGACTGCCGTCCCGAACAAC-3' and 5'-ACATCCACCAGGGCAAGCTC-3', respectively, for lactate dehydrogenase (LDH), respectively.

### Statistical analysis

All results are expressed as means  $\pm$  SD. Significant differences between two groups were assessed using Wilcoxon's rank-sum test. A value of  $P < 0.05$  was considered to be statistically significant.

## RESULTS

### Portal vein AT III injection reduced liver cell destruction more effectively than tail vein injection

In the control group, the serum levels of ALT increased

over time, reaching  $1262 \pm 240$ ,  $3381 \pm 808$  and  $8906 \pm 766$  U/L (Figure 1) at 6, 12 and 24 h, respectively. Injection of AT III into the tail vein did not affect ALT levels at 6 h or 12 h after the injection of LPS and GalN. However, at 24 h, the ALT levels in the tail vein injection group were significantly lower than those in the control group ( $8906 \pm 766$  U/L *vs*  $6181 \pm 823$  U/L,  $P < 0.01$ ). This suggests that the suppressive effects of AT III injected *via* the tail vein may be limited to the late stage of liver disease. In contrast, in rats injected with AT III *via* the portal vein, ALT levels were reduced during the early stage (i.e., 6 h,  $369 \pm 141$  U/L), which was maintained at all time-points. At 24 h, the ALT levels in this group were significantly lower than those in the control group ( $2352 \pm 760$  U/L *vs*  $8906 \pm 766$  U/L,  $P < 0.01$ ).

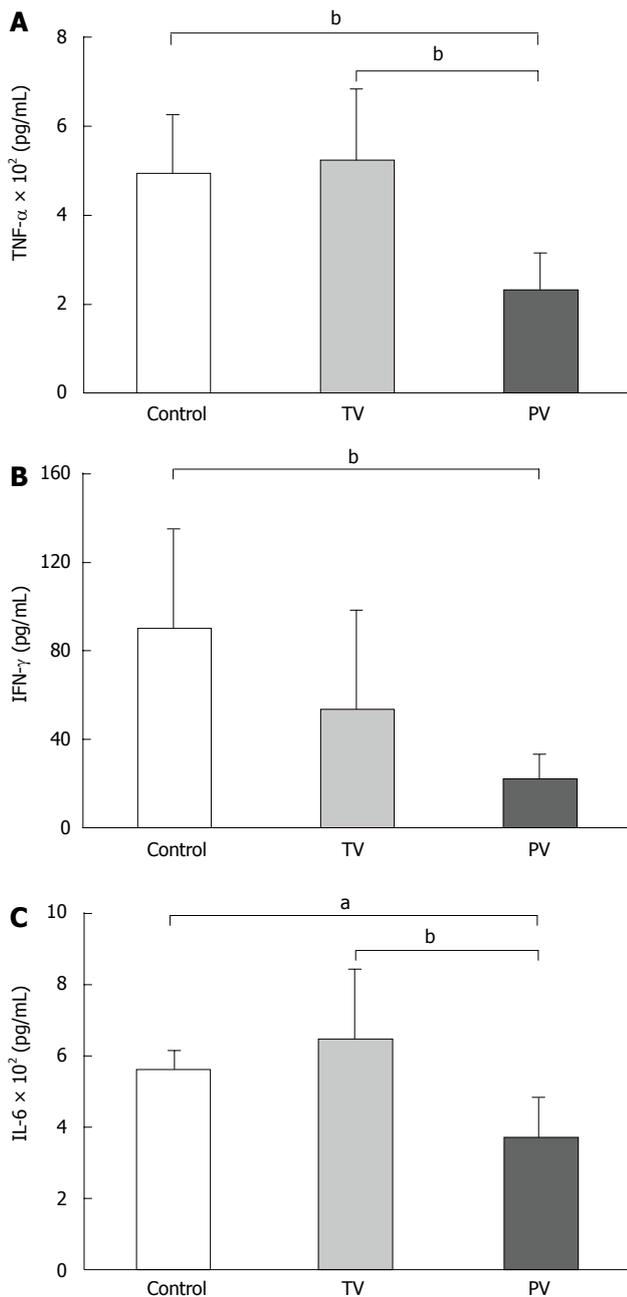

To support the effects of these treatments on the suppression of liver damage, the serum levels of inflammatory cytokines were measured. The cytokine levels demonstrate the greater anti-inflammatory effects of AT III injected *via* the portal vein. TNF- $\alpha$  levels in the tail vein injection group were similar to those in the control group. In contrast, TNF- $\alpha$  levels in the portal vein injection group were significantly lower than those in the control group ( $235 \pm 79$  pg/mL *vs*  $500 \pm 127$  pg/mL,  $P < 0.01$ , Figure 2A). AT III injection *via* the tail vein reduced the IFN- $\gamma$  levels compared with the controls, but the difference was not significant. As with other cytokines, IFN- $\gamma$  was significantly reduced in the portal vein group compared with the control group ( $21 \pm 12$  pg/mL *vs*  $89 \pm 45$  pg/mL,  $P < 0.05$ , Figure 2B). The IL-6 levels showed similar trends to those observed for TNF- $\alpha$ . AT III injection *via* the tail vein did not suppress IL-6 levels, whereas its injection *via* the portal vein significantly reduced IL-6 levels compared with those in the control group ( $368 \pm 120$  pg/mL *vs*  $572 \pm 47$  pg/mL,  $P < 0.01$ , Figure 2C).

### Effects of AT III on liver damage analyzed by liver histology

Histological examination showed extensive hepatocellular necrosis and hemorrhaging in the control liver (Figure 3A). In tail-vein-injected rats, extensive hepatocellular necrosis was not found but areas with confluent necrosis were scattered throughout the liver (Figure 3B). Consistent with the suppression of ALT and inflammatory cytokine levels, prominent histological improvement was noted in the liver of rats injected with AT III *via* the portal vein, because relatively few, scattered areas of necrosis with disordered hepatic cords were observed (Figure 3C).

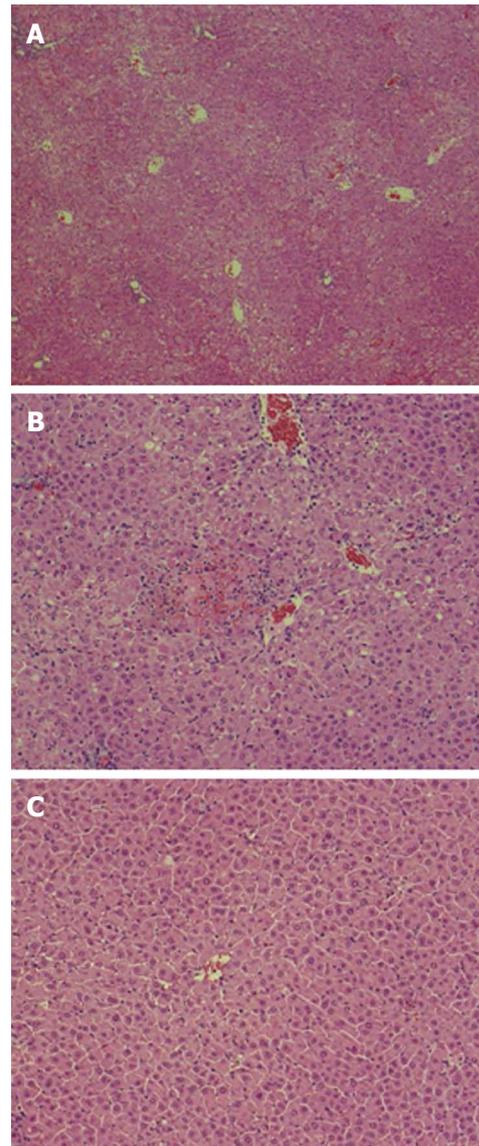

### Effects of AT III on hepatic mRNA expression of hypoxia-related genes in ALF

To evaluate the extent of hepatic hypoxia, as induced by microcirculatory disturbances, we determined the hepatic expression of hypoxia-related genes such as LDH and HO-1. LDH is an essential enzyme for anaerobic respiration, and its expression increases in cells exposed to hypoxia<sup>[13-15]</sup>. The transcriptional expression of HO-1 is also increased in hypoxia, resulting in increased produc-

**Figure 2** Effects of antithrombin III on serum inflammatory cytokine levels. The serum levels of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) (A), interferon- $\gamma$  (IFN- $\gamma$ ) (B) and interleukin (IL)-6 (C) were determined 24 h after injection of lipopolysaccharide and D-galactosamine. Control: Untreated; TV: Antithrombin (AT) III injection *via* the tail vein; PV: AT III injection *via* the portal vein. Values are means  $\pm$  SD ( $n = 10$  rats/group). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

tion of carbon monoxide, a vasodilator, and bilirubin, an antioxidant<sup>[16,17]</sup>. Increased serum LDH levels and hepatic expression of HO-1 have been reported in patients with ALF and might be useful to predict prognosis<sup>[18,19]</sup>. Therefore, we speculated that the expression of these genes could reflect the extent of hypoxia in the diseased liver. Tail vein AT III injection did not affect the expression of LDH, suggesting that peripheral administration of AT III does not improve hepatic hypoxia. In contrast, LDH expression was significantly reduced in rats injected with

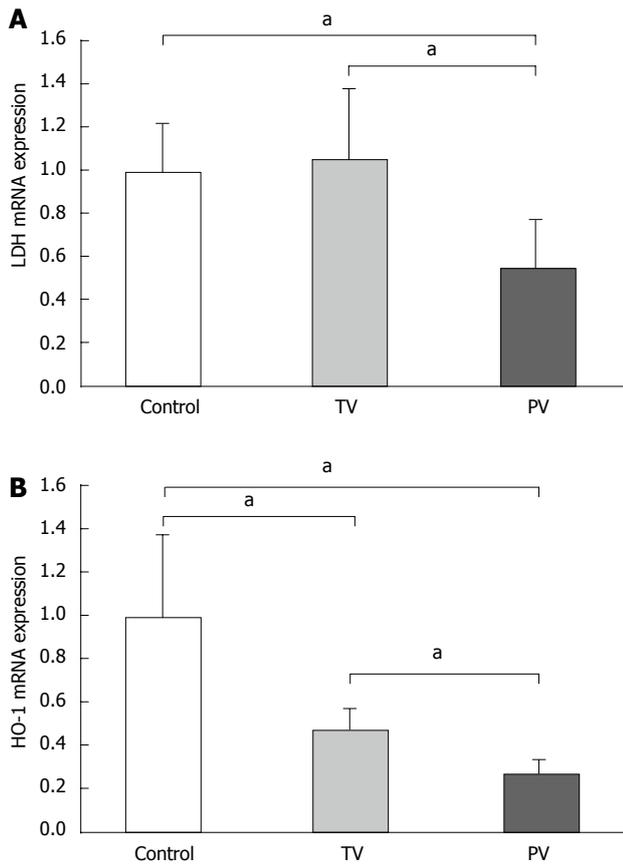

**Figure 3** Effects of antithrombin III on liver histology. Liver samples were obtained 24 h after lipopolysaccharide and D-galactosamine injection and stained with hematoxylin and eosin (magnification,  $\times 200$ ). A: Control; B: Antithrombin (AT) III injected *via* the tail vein; C: AT III injected *via* the portal vein.

AT III *via* the portal vein compared with the tail vein, and the control group (Figure 4A). The expression patterns of HO-1 differed from those of LDH. AT III injection *via* the tail vein significantly reduced HO-1 expression levels compared with those in the control group, and its expression was further reduced by AT III injection *via* the portal vein (Figure 4B). These observations suggest that AT III injection *via* the portal vein reduces intrahepatic hypoxia, probably by controlling the microcirculatory disturbances.

#### **Portal vein injection of AT III injection improved activity of the deteriorated coagulation system**

Serum levels of FDPs are a marker for the extent of deterioration in the coagulation system in ALF<sup>[20,21]</sup>. Injection of AT III *via* the tail vein did not change FDP levels, whereas injection of AT III *via* the portal vein significant-

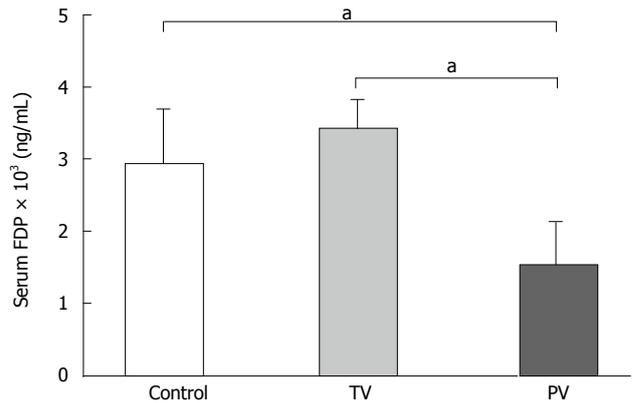

**Figure 4** Effects of antithrombin III on hepatic mRNA expression of lactate dehydrogenase and heme oxygenase-1. Hepatic mRNA expression of lactate dehydrogenase (LDH) (A) and heme oxygenase (HO)-1 (B) was determined by real-time polymerase chain reaction. Reactions were normalized for glyceraldehyde-3-phosphate dehydrogenase expression and the relative expression in the untreated liver was used as a control. Control: Untreated; TV: Antithrombin (AT) III injection *via* the tail vein; PV: AT III injection *via* the portal vein. Values are means  $\pm$  SD ( $n = 10$  rats/group). <sup>a</sup> $P < 0.05$  vs the tail vein group and the control group.

ly reduced FDP levels compared with those in the control and tail vein groups (Figure 5). Taken together, improvements in the coagulation system were only achieved by injecting AT III directly into the diseased liver.

**Effects of AT III on intrahepatic fibrin deposition**

Fibrin deposition in hepatic sinusoids has been observed in ALF. It is recognized as a manifestation of disturbances in the intrahepatic coagulation system and is mainly caused by sinusoidal endothelial cell injury<sup>[22]</sup>. In our study, phosphotungstic acid-hematoxylin staining revealed that fibrin was diffusely deposited in the sinusoids in the control liver, suggesting intrahepatic coagulation (Figure 6A). In rats treated with AT III *via* the tail vein, hepatic fibrin deposition was reduced but it was still sparsely distributed (Figure 6B). Meanwhile, injection of AT III *via* the portal vein diminished fibrin deposition in the liver parenchyma, which suggests that it may affect the maintenance of the intrahepatic coagulation system (Figure 6C).

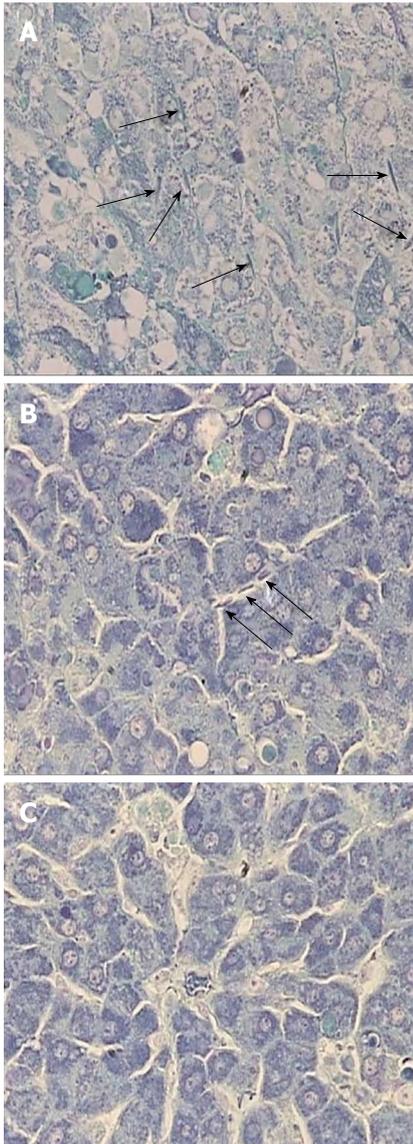

**Figure 5** Effects of antithrombin III on serum fibrin degradation product levels. The serum fibrin degradation product (FDP) levels were determined 24 h after injection of lipopolysaccharide and D-galactosamine. Control: Untreated; TV: Antithrombin (AT) III injection *via* the tail vein; PV: AT III injection *via* the portal vein. Values are means  $\pm$  SD ( $n = 10$  rats/group). <sup>a</sup> $P < 0.05$  vs control and tail vein groups.

**DISCUSSION**

We demonstrated that directly injecting AT III into the portal vein improved liver damage in a rat model of ALF induced by LPS and GalN. AT III injection *via* the portal vein suppressed the increases in serum ALT and inflammatory cytokine levels, and intrahepatic fibrin deposition, and reduced the mRNA expression of hypoxia-related genes associated with ALF. These effects were accomplished by administering a relatively low dose of AT III that should be acceptable in clinical practice.

Microcirculatory disturbances are involved in the pathogenesis of ALF. Activation of the inflammatory cascade may affect the coagulation system and the resulting intrahepatic coagulation may worsen sinusoidal blood flow, leading to massive liver necrosis; a histological feature of ALF<sup>[23]</sup>. Activation of macrophages, as represented by the elevated serum levels of CD163 and osteopontin in ALF patients, seems to be a trigger for this inflammatory process<sup>[24]</sup>. Following the onset of inflammation, disturbances in the intrahepatic coagulation system may enhance the destruction of liver cells. In patients with ALF, electron microscopy has revealed disorders in sinusoidal endothelial cells (SECs)<sup>[25]</sup>. Moreover, reduced mRNA expression of anticoagulants such as tissue factor pathway inhibitor and thrombomodulin are observed in SECs. Following the activation of tissue factor, intrahepatic coagulation causes sinusoidal fibrin deposition and thus restricts blood circulation in the diseased liver<sup>[26-28]</sup>.

Based on these observations, AT III treatment has been tested in animal models of ALF because of its anti-coagulant activity. Systemic injection of AT III (500 U/kg body weight) prevented Con-A-induced liver injury by inhibiting macrophage inflammatory protein-2 release and endothelial cell production of prostacyclin<sup>[7]</sup>. Meanwhile, a similar dose of AT III (400 U/kg body weight) reduced

**Figure 6** Effects of antithrombin III on hepatic phosphotungstic acid-hematoxylin staining. To estimate the extent of intrasinusoidal coagulation, fibrin deposition was analyzed by phosphotungstic acid-hematoxylin staining (magnification,  $\times 400$ ). Fibrin deposition was observed as a dense rod-like structure (arrow). A: Control; B: Antithrombin (AT) III injected *via* the tail vein; C: AT III injected *via* the portal vein.

liver damage in an ALF model with coagulopathy induced by DMN, which was characterized by marked intrasinusoidal fibrin deposition and elevated serum fibrin monomer complexes<sup>[5]</sup>. However, large doses of AT III, which are unacceptable in clinical practice, were used to suppress liver injury in these experimental models.

The effects of AT III for the treatment of ALF patients seem to be limited. Fujiwara *et al.*<sup>[29]</sup> treated 26 patients with fulminant hepatic failure with daily infusion of 3000 U AT III. Notably, survival time was longer in patients with plasma AT III levels within the normal range compared with levels beyond the normal range. However, the survival rates were not significantly different between patients treated with AT III and control patients. Another research group treated 13 ALF patients

with 3000 U AT III, followed by a further 1000 U every 6 h. However, survival time was not improved by AT III and the extent of intravascular coagulation was similar between AT-III-treated and control patients<sup>[30]</sup>. These different outcomes of clinical trials and animal experiments might be due to the insufficient concentration of AT III in the patients' liver. Indeed, the relative doses of AT III per body weight used in patients were  $< 10\%$  of those used in animals. Moreover, even though the plasma concentrations of AT III were maintained within the normal ranges, the survival rate was not improved, which suggests that the intrahepatic concentration of AT III did not reach the levels needed to maintain the integrity of the coagulation system in the diseased liver because of impaired sinusoidal circulation.

From our previous experience of treating ALF rats with methylprednisolone, we have demonstrated that direct delivery of steroid into the liver suppresses liver damage more effectively than does systemic injection. We found that injecting methylprednisolone *via* the portal vein significantly increased the survival rate, reduced serum cytokine levels, and decreased the number of apoptotic liver cells compared with tail vein injection<sup>[11]</sup>. Therefore, we speculated that the anticoagulant activity of AT III would be more effective when injected *via* the portal vein than *via* a peripheral vein. In our study, significant reductions in the serum FDP levels and fibrin deposition were only observed in rats injected with AT III *via* the portal vein, suggesting that direct drug delivery is necessary to achieve therapeutic concentrations of AT III in the diseased liver. Of particular interest is that, using this method, we reduced the dose of AT III to levels acceptable for clinical practice.

Anti-inflammatory activities of AT III have been reported in addition to its anticoagulant activity. In septic patients, AT III improves lung injury by suppressing the production of inflammatory cytokines, and prevents liver and kidney failure<sup>[31,32]</sup>. The mechanisms involved in the anti-inflammatory activities of AT III have been analyzed in rats treated with endotoxin<sup>[33]</sup>. AT III prevents pulmonary vascular injury by inhibiting leukocyte activation mediated by the enhanced release of prostacyclin from endothelial cells. Additionally, AT III has been reported to inhibit the activation of inflammatory signaling cascades in several cell types, including the activation of nuclear factor (NF)- $\kappa$ B in human monocytes and vascular endothelial cells<sup>[34]</sup>; the production of TNF- $\alpha$  and IL-6 in LPS-stimulated murine macrophages<sup>[35]</sup>; and human neutrophil migration<sup>[36]</sup>. In our study, portal vein injection of AT III significantly reduced serum TNF- $\alpha$ , IFN- $\gamma$  and IL-6 levels compared with tail vein injection, and the control group. These results support two possible actions of AT III injected *via* the portal vein to suppress inflammation: (1) the anti-inflammatory activity of AT III was enabled because the tissue concentration reached effective levels following direct drug delivery; and (2) the reduced liver cell destruction mediated by the anticoagulant activity of AT III suppressed the activation of surrounding inflammatory cells. We are currently unable to postulate

which action of AT III might be dominant; however, it seems reasonable to suggest that the anticoagulant and anti-inflammatory activities of AT III may act together to suppress tissue inflammation.

In patients with ALF, it has been reported that micro-circulatory disturbances induce hypoxia in the liver<sup>[18,19]</sup>. Increased serum LDH levels and hepatic HO-1 expression are markers for the extent of hypoxia, reflecting the damage to the hepatic microcirculation. In this study, serum LDH levels were significantly reduced in rats injected with AT III *via* the portal vein, whereas hepatic HO-1 expression was decreased in both groups of rats injected with AT III compared with the control group. Expression of LDH and HO-1 are induced by hypoxia-inducible factor-1, therefore, the different expression patterns of these genes are unlikely to be due to hypoxia-mediated transcriptional regulation<sup>[37]</sup>. In contrast, the expression of HO-1 is transactivated by activator protein-1 and NF- $\kappa$ B, which are transcriptional factors that can activate various inflammatory signals<sup>[38]</sup>. In this context, we speculate that the reduced HO-1 expression in rats injected with AT III *via* the tail vein may partly reflect decreased hepatic inflammation; however, the hypoxia may only be improved by injecting AT III *via* the portal vein.

In conclusion, we demonstrated that injecting AT III *via* the portal vein suppressed liver damage in a rat model of ALF. The increased concentration of AT III in the diseased liver following direct drug delivery might enhance its anticoagulant and anti-inflammatory activities. Furthermore, the dose of AT III used in this method was < 10% of that used in previous studies where AT III was injected *via* peripheral veins. We believe that further studies are needed to establish this method as an effective treatment for ALF.

## COMMENTS

### Background

Acute liver damage occasionally progresses to acute liver failure (ALF) with extremely high mortality. Liver transplantation is the only effective treatment for patients with ALF. Plasma exchange and hemodiafiltration have been used as artificial liver support systems for affected patients but are only partially effective.

### Research frontiers

Intravascular coagulation is thought to be involved in the pathogenesis of ALF. Anticoagulation therapy using antithrombin (AT) III effectively suppresses liver damage in experimental models of ALF; however, extremely high doses of AT III (200-500 U/kg body weight) are necessary. In this study, the authors demonstrated that injection of AT III into the portal vein may help to improve the efficiency of AT III compared with injected into peripheral vein.

### Innovations and breakthroughs

The authors found that injection of AT III *via* the portal vein showed superior effects to those achieved by tail vein injection in terms of lowering the serum levels of transaminase and inflammatory cytokines, reducing damage to the intrahepatic coagulation system, and improving hypoxia in the diseased liver. A clinically acceptable dose of AT III injected *via* the portal vein suppressed liver damage, therefore, direct delivery of AT III into the diseased liver could enhance the anticoagulant and anti-inflammatory activities of AT III.

### Applications

The development of injection of AT III *via* the portal vein might be useful to enhance the effects of AT III and ultimately improve the outcomes of patients with ALF, such as increasing the survival rate and reducing the number of patients

who need liver transplantation.

### Terminology

AT III inhibits serine proteases involved in the coagulation cascade. Additionally, AT III is reported to inhibit activation of inflammatory signaling cascades, including the activation of nuclear factor- $\kappa$ B, production of tumor necrosis factor- $\alpha$  and interleukin-6 in various cell types.

### Peer review

The manuscript is clearly written and the authors discuss their findings in an adequate way. Moreover, the reduction of the dose of AT III *via* injection in the portal vein has clinical implications.

### Abstract

**AIM:** To investigate the relationship between over-expression of urokinase plasminogen activator (uPA) and hepatitis B virus (HBV) related liver diseases in a transgenic mouse model.

**METHODS:** Albumin-tetracycline reverse transcriptional activator and tetO-uPA transgenic mice were generated respectively through pronuclear injection and crossed to produce the double transgenic in-alb-uPA mice, for which doxycycline (Dox)-inducible and liver-specific over-expression of uPA can be achieved. Hydrodynamic transfection of plasmid adeno-associated virus (AAV)-1.3HBV was performed through the tail veins of the Dox-induced in-alb-uPA mice. Expression of uPA and HBV antigens were analyzed through double-staining immunohistochemical assay. Cytokine production was detected by enzyme linked immunosorbent assay and  $\alpha$ -fetoprotein (AFP) mRNA level was evaluated through real-time quantitative polymerase chain reaction.

**RESULTS:** Plasmid AAV-1.3HBV hydrodynamic trans-

fection in Dox-induced transgenic mice not only resulted in severe liver injury with hepatocarcinoma-like histological changes and hepatic AFP production, but also showed an increased serum level of HBV antigens and cytokines like interleukin-6 and tumor necrosis factor- $\alpha$ , compared with the control group.

**CONCLUSION:** Over-expression of uPA plays a synergistic role in the development of liver injury, inflammation and regeneration during acute HBV infection.

### INTRODUCTION

Hepatitis B virus (HBV) infection causes a necroinflammatory liver disease of variable duration and severity, with a high risk of developing cirrhosis and hepatocellular carcinoma. The immune response to HBV-encoded antigens is responsible both for viral clearance and for disease pathogenesis during HBV infection<sup>[1]</sup>. However,

the roles of urokinase plasminogen activator (uPA)/uPA's receptor (uPAR) systems as important inflammatory mediators have not yet been well investigated in acute and chronic hepatitis B, a common inflammatory disease in China<sup>[2]</sup>. Clinical studies almost focused on the correlation of uPA levels with the liver disease severity in hepatitis B patients. And the role of uPA in the HBV-induced liver injury, especially in the early stage, is less investigated.

uPA is one kind of plasminogen activator that catalyzes the conversion of plasminogen to plasmin. Together with uPAR, uPA participate in fibrinolysis, innate and adaptive immunity, and pathology<sup>[3]</sup>. In cancer cells, the effects of uPA and uPAR were thought to be related to cell migration<sup>[4]</sup>, metastasis<sup>[5]</sup>, and a more recent role of uPA in cancer growth has emerged<sup>[6]</sup>. The levels of uPA and uPAR have been found to be increased in tissues, plasma and other body fluids of cancer patients and to be markers of cancer development and metastasis, such as in patients with colon adenocarcinoma<sup>[7]</sup>, lymphomas and leukemia<sup>[8]</sup>.

The tetracycline (Tet)-inducible expression system is one of the most prominent and widely-used systems, which allows relatively stringent, reversible, and quantitative regulation of transgene expression in a wide range of cells in culture as well as in transgenic animals<sup>[9,10]</sup>. It consists of two parts: the ligand-dependent transactivator tetracycline reverse transcriptional activator (rtTA) as the effector and a tetO-cytomegalovirus (CMV) minimal promoter cassette regulating the expression of the transgene as the responder<sup>[11]</sup>. When doxycycline (Dox) is present, rtTA binds to the tetO-sequence and induces expression of the target gene<sup>[12]</sup>. Together with a tissue-specific promoter, it can result in transgene expression in a temporally and spatially defined fashion.

In this study, an effective inducible and liver specific uPA expression mouse model was constructed in which the murine uPA expression was controlled by rtTA which is regulated by murine albumin enhancer/promoter. Through administration of Dox, the inducible expression of uPA specifically in mouse liver can be achieved with lower mortality. Then hydrodynamic injection of pAAV-1.3HBV, which contained inverted terminal repeat elements of adeno-associated virus (AAV) and 1.3 copies of HBV genome (ayw subtype), was performed to mimic the acute HBV infection. The mouse liver showed specific and inducible expression of uPA. Plasmid AAV-1.3HBV transfection in Dox-induced transgenic mice resulted in severer liver injury, higher HBV antigen and cytokine expression compared to the control group. These data further indicated for the first time in mice that the over-expression of uPA may have accelerative role in the development of liver injury, inflammation and liver regeneration during acute HBV infection.

## MATERIALS AND METHODS

### Plasmid construction

For liver-specific expression of rtTA, the transgenic construct albumin-rtTA was generated, which has rtTA gene

under the control of the liver-specific albumin promoter and was based the plasmid pTet-on (Clontech Lab, Inc). To introduce appropriate restriction sites in pTet-on, linker sequences were designed as follows, Tet-on-linker-F: 5'-CTAGGATATCACTAGTGGTACCGGGCCCGC-GGCCGCG-3' and Tet-on-linker-R: 5'-AATTTCGCG-GCCGCGGGCCCGGTACCACTAGTGATATC-3'. The linkers were annealed at 95 °C for 10 min and then were digested with *EcoR* I and *Spe* I and ligated to pTet-on digested with the same restriction enzymes, and the construct was named pTet-on-link. The albumin promoter fragment and enhancer fragment (Genbank accession no. AC140220.4) were separately amplified by polymerase chain reaction (PCR) using genomic DNA extracted from C57BL/6 mouse liver as the template. The primers for albumin enhancer were Alb-En-FP: 5'-GCCGAGCTCCTGCCGGCTAGCTTCCTTAGCATG-3' and Alb-En-RP: 5'-GGGTTAAGGATCCCAAG CTGGAG-3'. The primers for albumin promoter were Alb-Pro-FP: 5'-CGGGATCCACAGCTCCAGATGGCAAACATAC-3' and Alb-Pro-RP: 5'-TTTGC-CAGAGGCTAGTGGG GTTG-3'.

The albumin enhancer PCR product was digested with *BamH* I and cloned into pGEM-7ZF, then the albumin promoter sequence was inserted behind the enhancer at the site of *BamH* I, and the plasmid was named p7ZF-Albumin, which was confirmed by restriction enzyme digestion analysis and DNA sequence analysis. Then p7ZF-Albumin was digested by *Sac* I and *Kpn* I, and the released 2233bp fragment was ligated to pTet-on-link digested by *EcoR* V and *Kpn* I, to yield the recombinant construct named pTet-on-Albumin.

For rtTA responsive expression of uPA, the transgenic construct pTRE<sub>2</sub>-uPA was generated which is based on the plasmid pTRE<sub>2</sub> containing tetO. The uPA cDNA and uPA exon 11 was amplified by reverse transcription polymerase chain reaction (RT-PCR) and PCR from the total RNA and genomic DNA extracted from the kidney of C57BL/6 mouse, respectively. For uPA DNA, the primers were uPA-cDNA-F: 5'-CGGGATCC ATGAAAGTCTGGCTGGCGAGCCTG-3' and uPA-cDNA-R: 5'-CGGTCCGACCATCAGAAGGCC-CAGACCTTCTCTTC-3'. The RT-PCR product was ligated to pMD18T and the construct pMD18T-uPA cDNA was confirmed by sequence analysis. The uPA exon 11 was amplified by PCR from the genomic DNA template, the primers were uPA-3'-F: 5'-CGGTCCGAC-GCCCTCAGGTAGCTGAGGGAAG-3' and uPA-3'-R: 5'-CGGTCCGACGTGAAACCGACATTTAGT-GCTAGTC-3'. The PCR product was ligated to the *Sal* I site of pMD18T-uPA cDNA to yield the construct pMD18T-uPA and sequence was confirmed. Then the uPA (cDNA + exon 11) fragment was subcloned into the *Pvu* II and *Xba* I sites of pTRE<sub>2</sub> to yield pTRE<sub>2</sub>-uPA.

### Generation and PCR analysis of the albumin-rtTA and tetO-uPA transgenic mice

The albumin-rtTA and tetO-uPA transgenic mice were generated in C57BL/6 × CBA F1 zygotes using standard

pronuclear injection, which was performed by Shanghai Research Center for Biomedicine. For microinjection, the 6034 bp fragment of transgene albumin-rtTA and the 5739 bp fragment of transgene tetO-uPA were excised from the vector backbone of pTet-on-albumin by *Xho* I digestion and pTRE2-uPA by *Pvu* I digestion, respectively, isolated and purified using QIA quick gel extraction kit (Qiagen), and then microinjected into the pronuclei of one cell-stage fertilized embryos. The DNA injected fertilized eggs were implanted into the oviducts of 12 pseudopregnant recipient mice. All together 9 positive albumin-rtTA transgenic mice and 5 tetO-uPA positive ones were confirmed by PCR. One upstream pair and one downstream pair of primers, which were designed to amplify the sequences between vector and inserted fragment were designed for albumin-rtTA as follows, 1-up-F: 5'-GTGCAGCTTGGCTTGAACCTCGTTC-3'; 1-up-R: 5'-GAGTATGGTGCCTATCTAACATCTC-3'; 1-down-F: 5'-GACGCGCTAGACGATTTTCGATCTG-3'; 1-down-R: 5'-ACCTTGCACAGATAGCGTGGTC-3'. By the same way, one upstream pair and one downstream pair of primers were designed for tetO-uPA as follows 2-up-F: 5'-GTTTAGTGAACCGTCAGATCGCCTG-3'; 2-up-R: 5'-CTAGGCTAATAGCATCAGGTCTG-3'; 2-down-F: 5'-GGTAGCTTAGGAGTAGAGACACT-3'; 2-down-R: 5'-GACAATGTTGTCAACAGAGTAG-3'. The PCR conditions were the same for each of the primer pairs: 34 cycles of 94 °C for 30 s, 54 °C for 30 s, 72 °C for 30 s. Genomic DNA from wild-type mice was amplified as negative control. The PCR positive mice were the transgenic founders.

#### Mouse propagation and PCR analysis

At 6-8 wk of age, founder mice were backcrossed with wild-type C57BL/6J mice to generate F1. Genomic DNA were isolated from tail biopsy samples of F1 mice at 4 wk and analyzed by PCR, for which the protocols were mentioned above.

#### rtTA expression in different tissues of albumin-rtTA F1 transgenic mice

The isolation of total RNA from different tissues of 6-8 wk old F1 PCR-positive and negative offsprings of the founders was performed using the RNeasy Mini Kit (Qiagen) following the instructions. Purified RNA was eluted in 40 µL DNA-free water. 400 ng of total RNA reverse transcribed with the Takara RNA LA PCR Kit (AMV)Ver1.1 (TaKaRa), the reaction condition was 30 °C for 10 min, 42 °C for 30 min, 99 °C for 5 min, 5 °C for 5 min. The oligonucleotide primers used for RT-PCR were rtTA-F: 5'-GACGCGCTAGACGATTTTCGATCTG-3'; rtTA-R: 5'-ACCTTGCACAGATAGCGTGGTC-3', the PCR reaction condition was 34 cycles of 94 °C for 30 s, 54 °C for 30 s, 72 °C for 30 s. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) served as internal control, the primers were GAPDH-F: 5'-TTCACCACCATG-GAGAAGGC-3' and GAPDH-R: 5'-CCTCAGTGTAGCCCAAGATGC-3', PCR reaction condition was 34 cycles of 94 °C for 30 s, 48 °C for 30 s, 72 °C for 30 s.

The total protein was isolated from different tissues of 6-8 wk old F1 PCR-positive and negative offsprings of the founders by using the Tissue Lysis Buffer (50 mmol/L Tris-HCl, 150 mmol/L NaCl, 5 mmol/L EDTA, 0.2 mmol/L sodium orthovanadate, 1% Triton X-100, 1% sodium deoxycholate, 1% sodium dodecyl sulfate) supplemented with aprotinin (2 µg/mL), pepstatin A (0.7 µg/mL), leupeptin (0.5 µg/mL), phenylmethanesulfonyl fluoride (PMSF) (1 mmol/L). Aprotinin, Pepstatin A, Leupeptin, PMSF were purchased from Amresco. For Western blotting analysis, 25 µg of the total protein was used for each loading; the primary antibody for rtTA was TetR monoclonal antibody (Clontech) (used in 1:1000 dilution), and the primary antibody for GAPDH was an anti-GAPDH polyclonal antibody (Sigma) (1:10000 dilution); and the second antibodies were HRP-labeled goat anti-mouse IgG and goat anti-rabbit IgG (both in 1:5000 dilution), respectively. For imaging results, the SuperSignal WestDura Trial Kit (Pierce) was used following the instructions.

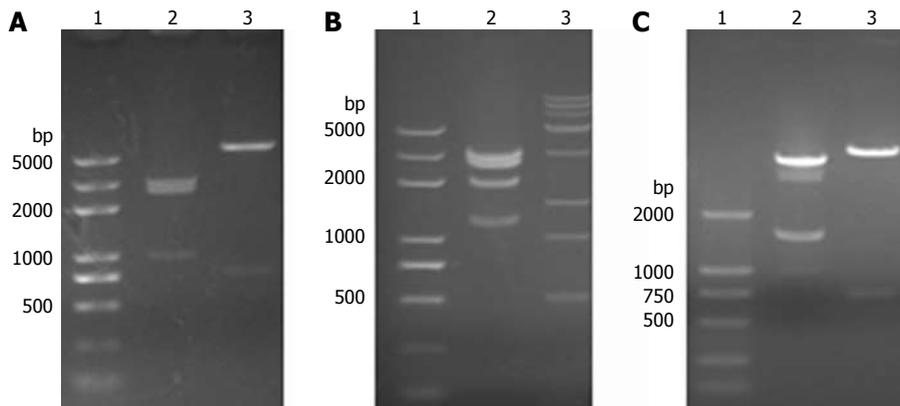

#### Generation of double transgenic mice in-alb-uPA and Doxycycline administration

Double transgenic in-alb-uPA and wild type female offspring were generated from a cross between the albumin-rtTA F1 transgenic positive mice and the tetO-uPA F1 positive mice. 20 d after born, these mice were given two intramuscular injection of 2 mg Dox in 0.2 mL 0.9% NaCl-solution each week for a period of 3 wk. Another group of each type of mice was maintained off doxycycline administration.

#### Hydrodynamic transfection of AAV-HBV and histological analysis

After 3 weeks' induction, a 20 µg pAAV-HBV1.3 DNA was injected hydrodynamically into the tail veins of the in-alb-uPA mice within 5 seconds. A control group of in-alb-uPA mice was injected with pAAV-internal ribosome entry site (IRES). At 20 d post transfection, mice were sacrificed and the livers were fixed with 4% (v/v) phosphate-buffered formalin, and paraffin-embedded liver sections were prepared and stained with hematoxylin and eosin. Semi-quantitative assessment of liver injury in each group was evaluated by the area of liver necrosis on the whole slide in each group. NP for no necrosis; P1 for < 10% area of necrosis; P2 for 10%-30% area of necrosis; P3 for > 30% area of necrosis. All the evaluation of liver damage was conducted by two independent observers. The average score of three mice in each group was taken as score for that group.

For uPA and HBV antigens detection, the expression of uPA protein and hepatitis B core antigen (HBcAg) were identified by double-staining with a polyclonal rabbit anti-rodent urokinase (uPA) antibody (American diagnostica Inc) and monoclonal anti-HBcAg antibody (Thermo Scientific). Diamino-benzidine and alkaline phosphatase substance (ZhongShan Goldenbridge biotech, Beijing, China) were used to visualize the uPA and HBV antigens.

**Figure 1** Identification of pTet-on-link, pTet-on-Albumin and pTRE<sub>2</sub>-urokinase plasminogen activator by restriction endonucleases. A1 and B1: 2K plus DNA Marker; A2: pTet-on-link/*EcoR* V + *Sal* I; A3: pTet-on-link/*EcoR* V + *Bam*H I; B2: pTet-on-Albumin/*Bam*H I; B3: 15K DNA marker; C1: 2K DNA marker; C2: pTRE<sub>2</sub>-urokinase plasminogen activator (uPA)/*pvu* II; C3: pTRE<sub>2</sub>-uPA/*Sal* I.

### Enzyme linked immunosorbent assay for HBV antigens and cytokine production

At 10 d and 20 d post transfection, mouse serum samples from different groups were harvested. The HBeAg and HBsAg enzyme linked immunosorbent assay (ELISA) kit (Wantai Biotech, Beijing) were used for the detection of the serum HBV antigens respectively. And interleukin (IL)-6 and tumor necrosis factor (TNF)- $\alpha$  ELISA kit (Dakewei Biotech, Beijing) were used for the quantitation of the serum cytokines. Serum ALT were measured with an Olympus Model 640 automated analyzer.

### qRT-PCR analysis of $\alpha$ -fetoprotein mRNA expression in the livers of AAV-HBV transfected in-alb-uPA mice

The isolation of total RNA from livers of the AAV-HBV transfected in-alb-uPA mice was performed using the RNeasy Mini Kit (Qiagen) following the instructions. Purified RNA was eluted in 40  $\mu$ L DNA-free water and 400 ng of total RNA in a 10  $\mu$ L reaction mixture was reverse transcribed with the Takara RNA LA PCR Kit (AMV) Ver1.1 (TaKaRa). Relative quantization of the  $\alpha$ -fetoprotein (AFP) mRNA level was performed using RNA Master SYBR Green1 (Roche Diagnostics) by Eppendorf Replex. The primers used for amplification were AFP-real-F: 5'-TCT-GCTGGCACGCAAGAAG-3' and AFP-real-R: 5'-TCG-GCAGGTTCTGGAAACTG-3'. GAPDH serves as a control and the primers were GAPDH-real-F: 5'-TCAC-CACCATGGAGAAGGC-3' and GAPDH-real-R: 5'-GC-TAAGCAGTGTGGTGGTGCA-3'. The amplification conditions included initial denaturation at 95  $^{\circ}$ C for 2 min, followed by 40 cycles of denaturation at 95  $^{\circ}$ C for 15 s, annealing at 55  $^{\circ}$ C for 15 s, extension at 68  $^{\circ}$ C for 30 s.

### Statistical analysis

Results are expressed as mean  $\pm$  SE. Statistical analysis was performed using Student's *t* test.

## RESULTS

### Construction and identification of pTet-on-albumin and pTRE<sub>2</sub>-uPA

For inserting the albumin enhancer and promoter se-

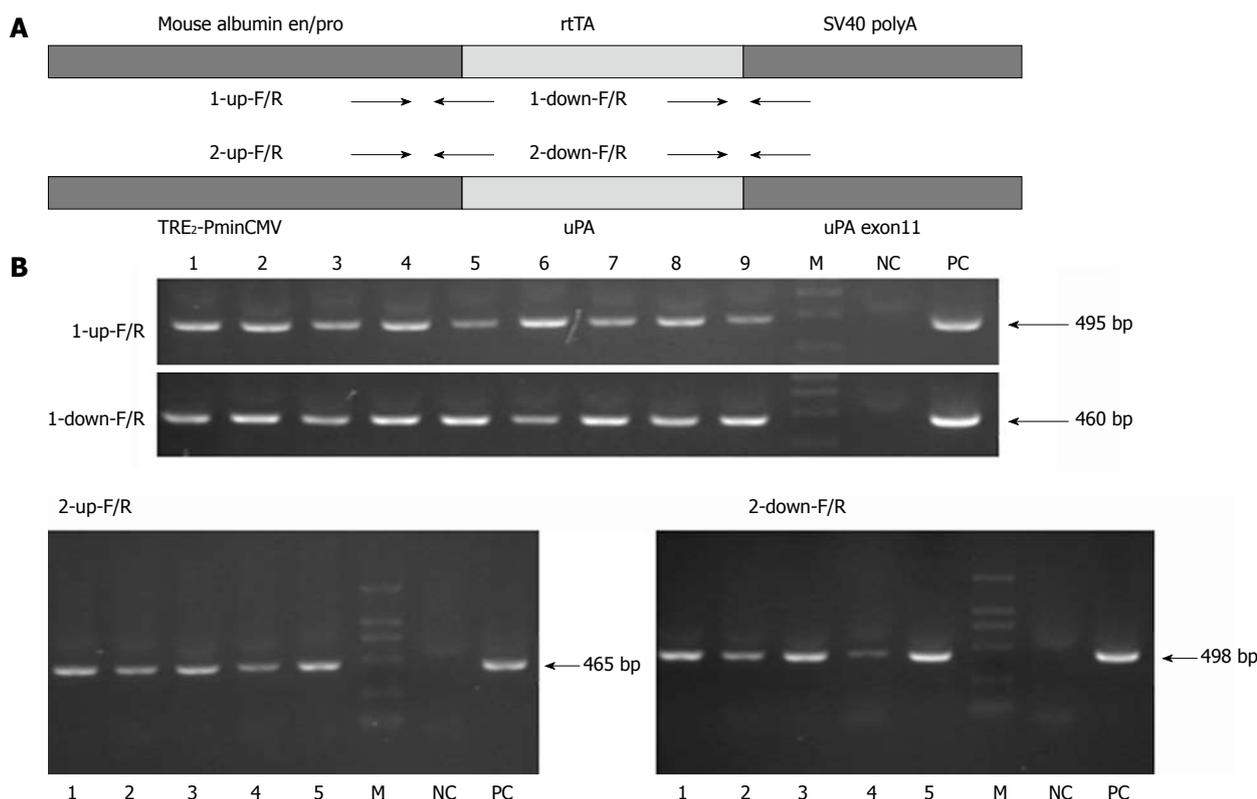

quence into pTet-on in place of the CMV promoter, a linker as designed and the following restriction sites were introduced: *Spe* I, *EcoR* V, *Spe* I, *Kpn* I, *Apa* I, *Not* I, *EcoR* I. pTet-on-link was identified by *EcoR* V/*Sal* I and *EcoR* V/*Bam*H I double digestion respectively (Figure 1A), and results showed that the linker was introduced into pTet-on. pTet-on-Albumin was identified by *Bam*H I digestion (Figure 1B), the expected 5022 bp, 2689 bp and 1284 bp fragment can be observed. pTRE<sub>2</sub>-uPA was identified by *pvu* II and *Sal* I respectively (Figure 1C). In addition, DNA sequence analysis of the albumin enhance/promoter and uPA sequence shows complete accordance with those in the National Center for Biotechnology Information database (data not shown).

### Generation of the albumin-rtTA and tetO-uPA transgenic mice and PCR analysis

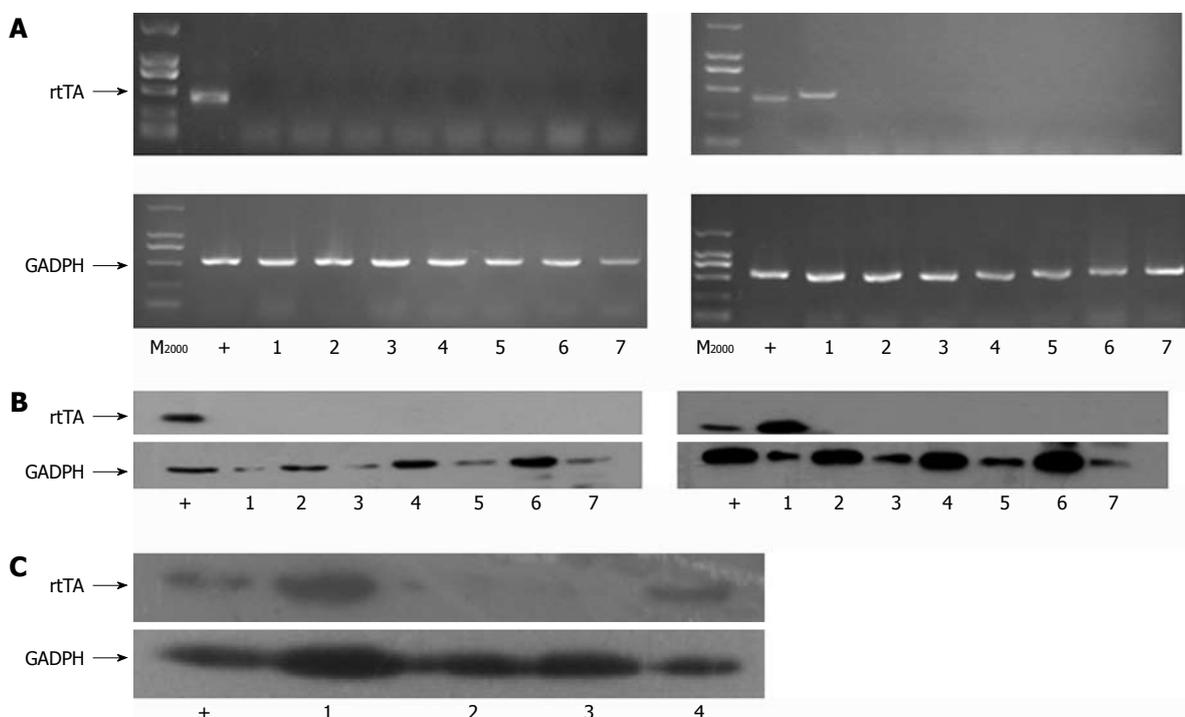

The albumin-rtTA expression unit contains the mouse albumin enhancer/promoter, rtTA coding sequence and SV40 polyA, and the tetO-uPA expression unit contains the TRE<sub>2</sub>-PminCMV, uPA cDNA and uPA exon11 (Figure 2A). In the end, 9 albumin-rtTA transgenic founder mice and 5 tetO-uPA transgenic founder mice were confirmed positive by PCR for both the upstream and downstream primers (Figure 2B).

### Specific expression of rtTA in the livers of albumin-rtTA and in-alb-uPA transgenic mice

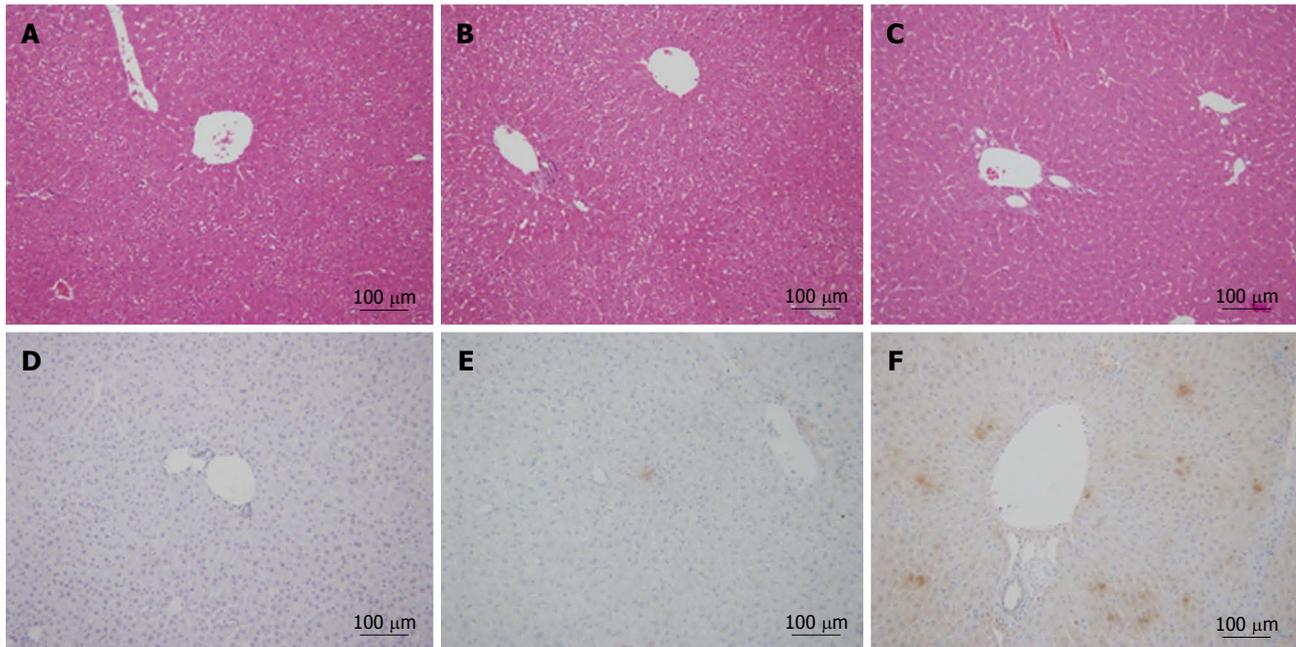

To identify the liver-specific expression of uPA in the livers of transgenic mice, RT-PCR and Western blotting analysis was performed. The data showed that rtTA mRNA expressed specifically in the livers of F1 albumin-rtTA transgenic positive mice (Figure 3A, right image), while there was no rtTA mRNA expression in all the tissues of the albumin-rtTA transgenic negative mouse (Figure 3A, left image). GAPDH mRNA was expressed equally in different tissues of these mice (Figure 3A). Results from Western blotting analysis (Figure 3B) were in accordance with those from RT-PCR analysis. By Western blotting analysis, rtTA expression was also confirmed specifically in the livers of in-alb-uPA transgenic mice and albumin-rtTA transgenic mice (Figure 3C). The cell

A, B: Reverse transcription polymerase chain reaction (A) and Western blotting (B) analysis of tetracycline reverse transcriptional activator (rtTA) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) expression in different tissues of the 6-8 wk old F1 albumin-rtTA PCR-negative (left for A, B) or positive (right for A, B) transgenic mice. 1: Liver; 2: Brain; 3: Thymus; 4: Heart; 5: Lung; 6: Kidney; 7: Spleen; C: Western blotting analysis of rtTA and GAPDH expression in the liver extracts of mice with different genotypes. 1: In-alb-urokinase plasminogen activator (uPA) mice group; 2: Liver extracts of wild type mice group; 3: tetO-uPA mice group; 4: Albumin-rtTA mice group. pTet-on transfected Huh7 cell extracts were used as positive control (+).

**Figure 4** The expression of urokinase plasminogen activator in the livers of in-alb-urokinase plasminogen activator transgenic mice. A: Histology of livers from wild type (WT) mice; B: Histology of livers from in-alb-urokinase plasminogen activator (uPA) mice without doxycycline (Dox) induction; C: Histology of livers from in-alb-uPA mice with Dox induction; D: uPA expression in hepatocytes from WT mice; E: uPA expression in hepatocytes from in-alb-uPA mice without Dox induction; F: uPA expression in hepatocytes from in-alb-uPA mice with Dox induction. Magnification,  $\times 20$ .

extract from Huh7 transfected with pTet-on was used as positive control while tetO-uPA and WT mice served as negative control.

#### **Histological change of liver in in-alb-uPA transgenic mice after Dox induced uPA expression**

To confirm the expression of uPA in liver and its role on the hepatocytes, uPA expression and the histological changes of liver was analyzed with immunohistochemistry and HE staining respectively. The results showed light degeneration of hepatocytes and mild inflammation in the livers with in-alb-uPA double transgenic mice after 3 wk of Dox induction when compared to that of double transgenic mice without Dox or the control group mice (Figure 4A-C), which was coincident with that of uPA expression with immunohistochemistry in the livers of in-alb-uPA double transgenic mice after Dox induction while almost no expression of uPA detected in double transgenic mice without Dox. The data showed that the specific expression of uPA after Dox induction induced slight histological changes in the liver of this in-alb-uPA double transgenic mice.

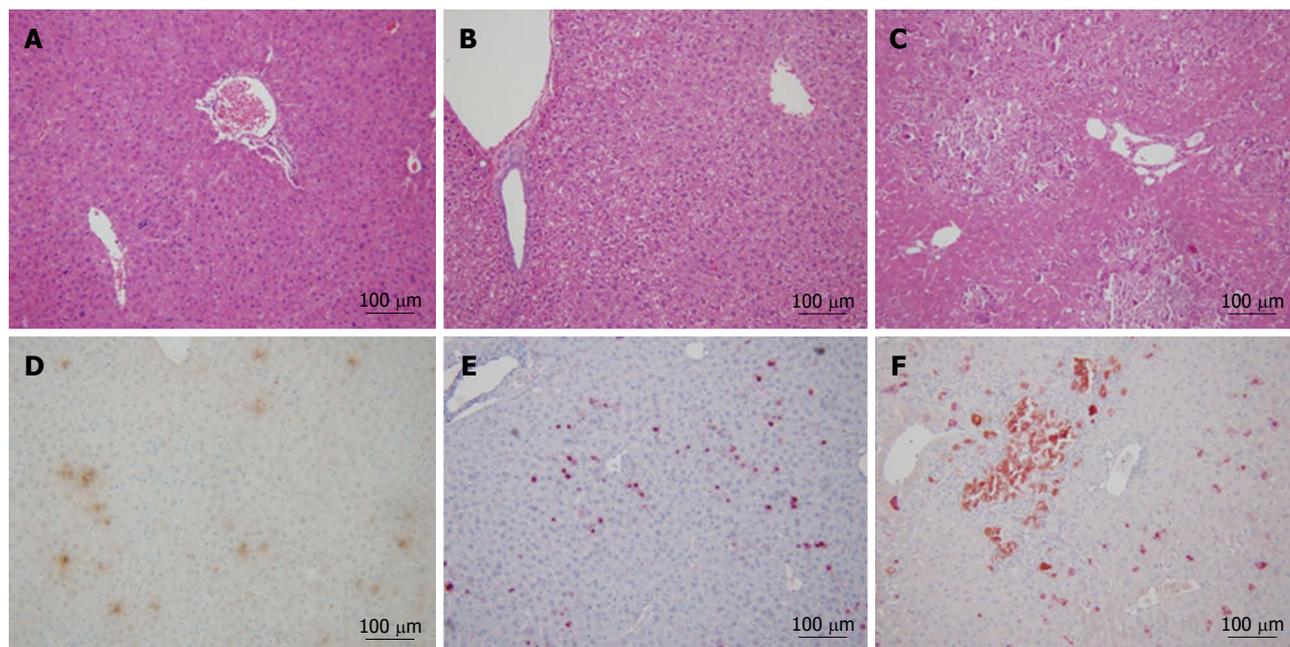

#### **Synergistic liver injury in in-alb-uPA transgenic mice after AAV-1.3HBV transfection**

Although uPA plays critical role in hepatic repair via proteolysis of matrix elements and clearance of cellular debris from the field of injury, clinical data showed that the levels of uPA and uPAR in patients with acute and chronic hepatitis B significantly higher than that in healthy controls, which indicated that uPA level was closely related to the degree and period of inflammation and liver injury<sup>[13]</sup>. To confirm if the coexisting uPA ex-

pression and HBV replication induced serious acute liver injury, the in-alb-uPA transgenic mice were transfected with pAAV-1.3HBV, a plasmid which could mediated the production of replicative HBV virus<sup>[14]</sup> *in vivo*. Large area necrosis was observed 20 d later in the liver of Dox-induced in-alb-uPA double transgenic mice that were transfected with pAAV-1.3HBV (Figure 5C), compared with that of non-induced in-alb-uPA mice transfected with pAAV-1.3HBV (Figure 5B) or with the control plasmid pAAV-IRES (Figure 5A). Double-staining immunohistochemical analysis confirmed both uPA expression (in brown) and HBcAg expression (in red) in the AAV-HBV transfected Dox-induced in-alb-uPA mice (Figure 5F). Interestingly, the coexpression of uPA and HBcAg exist in the most of the necrosis areas and the hepatocytes with HBcAg expression alone were morphological intact. The severe liver damage in the mice after HBV transfection indicated that the expression of uPA accelerated the liver injury. The result was confirmed by a statistics analysis that about 86.7% of the AAV-HBV transfected Dox-induced in-alb-uPA mice experienced severe liver pathogenic changes compared with the 20% AAV-HBV transfected non-induced in-alb-uPA mice, which could be explained by the leaky expression of uPA due to the tet-on inducible system. And about 40% of the AAV-HBV transfected Dox-induced in-alb-uPA mice experienced severe liver injury (Table 1).

#### **Comparison of the serum HBV antigens and cytokines produced in mice from different groups**

Previous reports have shown that HBV infection is associated with the production of a broad range of pro-inflammatory cytokines and chemokines such as IL-1 $\beta$ ,

**Figure 5 Synergistic injury of liver in in-alb-urokinase plasminogen activator transgenic mice after adeno-associated virus-1.3hepatitis B virus transfection.** Histological and immunohistochemical staining for hepatitis B core antigen in the livers of different groups of mice 20 d later after adeno-associated virus (AAV)-1.3hepatitis B virus (HBV) transfection. **Table 1 Statistical analysis of the liver pathogenic rates for mice in different groups (%)**

Group	1	2	3
NP	8 (100)	8 (80)	2 (13.3)
P1	0	2 (20)	2 (13.3)
P2	0	0	5 (33.3)
P3	0	0	6 (40)
Total	8	10	15

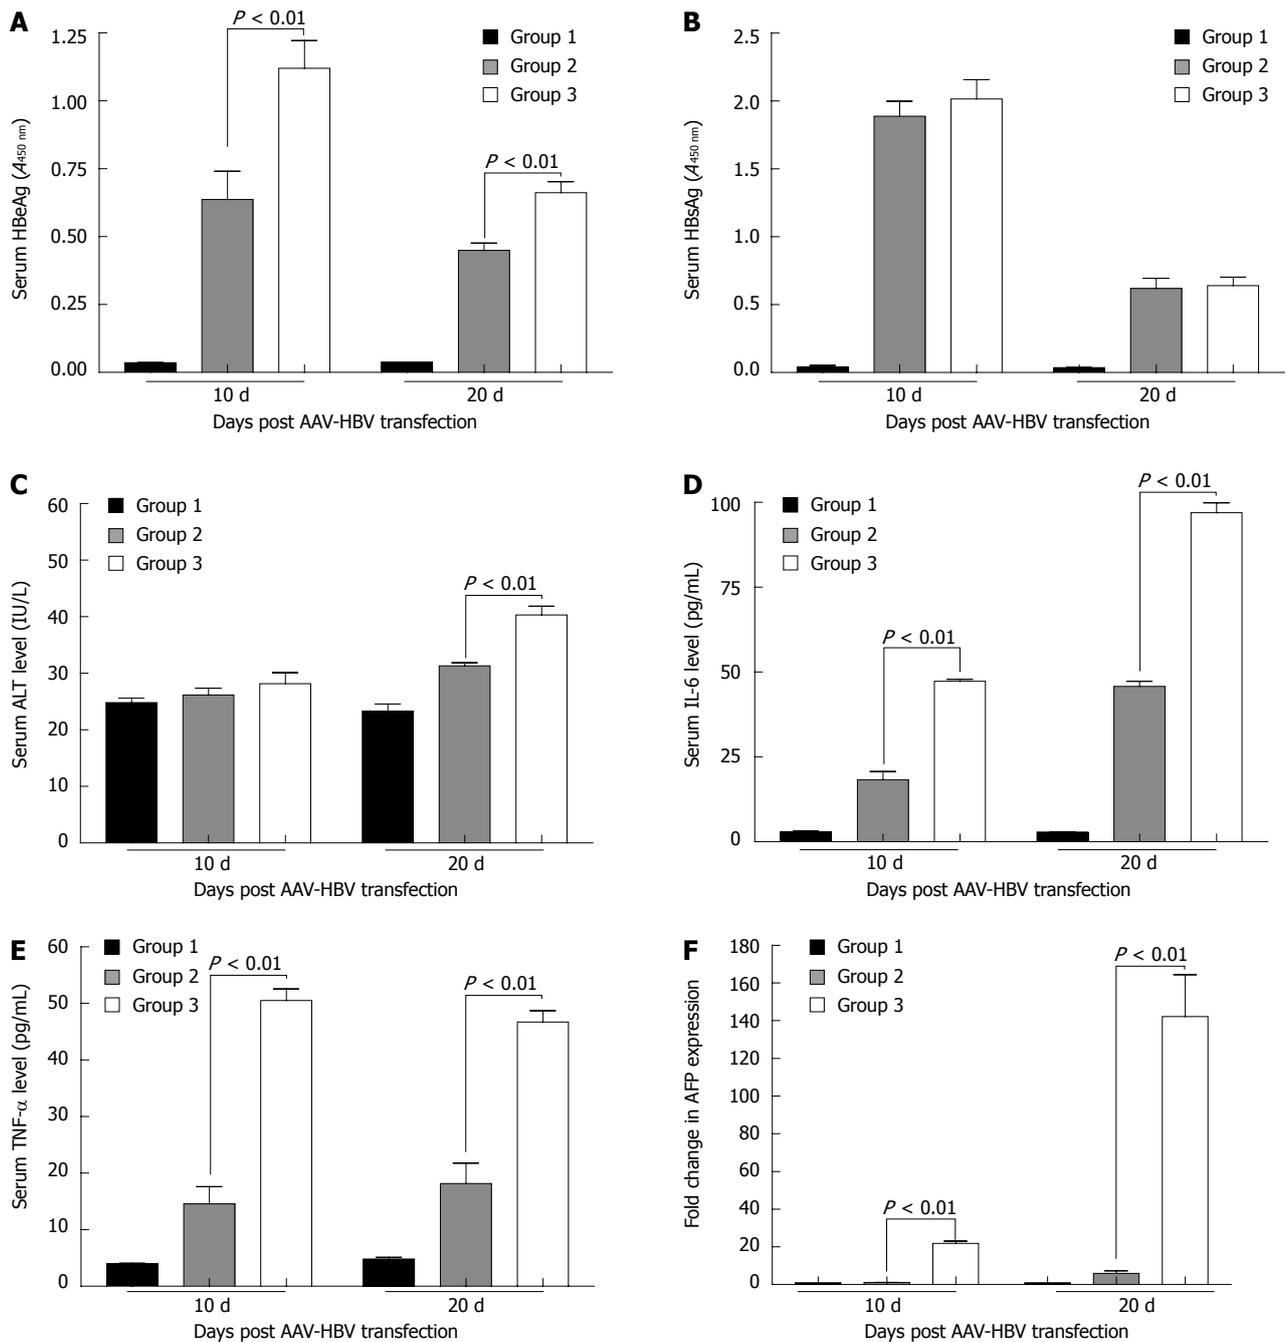

Group 1: Adeno-associated virus (AAV)-internal ribosome entry site transfected doxycycline (Dox)-induced in-alb-urokinase plasminogen activator (uPA) mice; Group 2: AAV-hepatitis B virus (HBV) transfected non-induced in-alb-uPA mice; Group 3: AAV-HBV transfected Dox-induced in-alb-uPA mice. NP stands for number of the non-pathogenic mice; P1 stands for number of mice in which the liver pathogenic area is below 10%; P2 stands for number of mice in which the liver pathogenic area ranges between 10% and 30%; P3 stands for number of mice in which the liver pathogenic area is above 30%.

IL-6, IL-8, IL-12, TNF- $\alpha$  and IFN- $\gamma$ <sup>[15-17]</sup>, among which IL-6 and TNF- $\alpha$  are important components of the early signaling pathway that lead to liver regeneration<sup>[18]</sup>. In this study, results also confirmed the elevation of serum IL-6 and TNF- $\alpha$  levels in the AAV-HBV transfected in-alb-uPA mice (Figure 6). 10 d and 20 d after AAV-HBV transfection, the serum IL-6 level for the Dox-induced in-alb-uPA mice was  $47.28 \pm 0.57$  and  $96.97 \pm 2.91$  (pg/mL), while the level for the non-induced in-alb-uPA mice was  $18.32 \pm 2.38$  (pg/mL) and  $45.83 \pm 1.50$  (pg/mL) ( $P < 0.01$ ) (Figure 6D). The serum TNF- $\alpha$  level for the Dox-induced in-alb-uPA mice was  $50.55 \pm 2.01$  (pg/mL)

and  $46.72 \pm 2.01$  (pg/mL), while the level for the non-induced in-alb-uPA mice was  $14.58 \pm 3.05$  (pg/mL) and  $18.17 \pm 3.63$  (pg/mL) ( $P < 0.01$ ) (Figure 6E). Compared with the non-induced in-alb-uPA mice, the average serum HBeAg level of the Dox-induced in-alb-uPA mice was significantly higher both at 10 d and 20 d after AAV-HBV transfection ( $P < 0.01$ ) (Figure 6A), while there was no significant difference between the average serum HBeAg level of the Dox-induced and non-induced mice (Figure 6B). Compared with the non-induced in-alb-uPA mice, the average serum ALT level of the Dox-induced in-alb-uPA mice was slightly higher at 20 d after AAV-HBV transfection ( $P < 0.01$ ) (Figure 6C).

**Relative quantitative analysis of AFP mRNA expression in the livers of AAV-HBV transfected in-alb-uPA mice**

It has been reported that AFP level *in vivo* decreases abruptly soon after birth and remains at a low level throughout life. And reactivation of AFP production occurs during liver regeneration<sup>[19]</sup>. In this study, we found that, compared with the non-induced in-alb-uPA mice that were transfected by AAV-HBV, the AFP mRNA level for the Dox-induced in-alb-uPA mice that were transfected by AAV-HBV was greatly higher. 10 d after AAV-HBV transfection, the average level of the AFP mRNA for those induced in-alb-uPA mice increased about 21.8 times, while the fold change further increased to 142.1 times at 20 d after AAV-HBV transfection (Figure 6F). The data further confirmed our hypothesis that uPA expression and HBV

**Figure 6** Comparison of the serum hepatitis B e antigen, hepatitis B surface antigen, interleukin-6, tumor necrosis factor- $\alpha$ , alanine aminotransferase levels and hepatic  $\alpha$ -fetoprotein mRNA levels between mice from different groups. Group 1: Adeno-associated virus (AAV)-internal ribosome entry site transfected doxycycline (Dox)-induced in-alb-urokinase plasminogen activator (uPA) mice ( $n = 6$ ); Group 2: AAV-hepatitis B virus (HBV) transfected non-induced in-alb-uPA mice ( $n = 6$ ); Group 3: AAV-HBV transfected Dox-induced in-alb-uPA mice ( $n = 6$ ). HBeAg: Hepatitis B e antigen; HBsAg: Hepatitis B surface antigen; ALT: Alanine aminotransferase; IL: Interleukin; TNF: Tumor necrosis factor; AFP:  $\alpha$ -fetoprotein.

infection have close relations and HBV infection further accelerated liver injury and regeneration when uPA was overexpressed.

## DISCUSSION

Tet-inducible expression system is one of the most suitable inducible systems which could be used to investigate the function of a given gene *in vivo*, which including the

tTA (Tet-off) system<sup>[20]</sup> and rtTA (Tet-on) system<sup>[21]</sup>, and facilitates not only the understanding of gene function in development and pathogenesis, but also in transgenic mouse modeling<sup>[22-24]</sup>. On the other hand, tissue-specific expression of a target gene relies on tissue-specific promoters. Tissue-specific expression is vital for gene function research in organism development and can reduce immunological response and side effects in gene therapy applications. Many liver-specific promoters have been

identified so far, such as the AFP promoter<sup>[25]</sup>, the albumin promoter, mouse major urinary protein promoter<sup>[26]</sup>, hSAP promoter (human serum amyloid P component promoter)<sup>[27]</sup>, and apoE promoter (human apolipoprotein E promoter)<sup>[28]</sup>, which have been applied in liver-specific expression of target genes. In addition, elements like enhancers influence the transcriptional activity of the these tissue-specific promoters<sup>[29]</sup>.

The urokinase plasminogen activator (uPA) is a serine protease that can activate the plasminogen into plasmin, and perform multiple functions in fibrinolysis, immunity and pathology<sup>[3]</sup>. Previous studies showed uPA diverse functions in tissue remodeling, angiogenesis, wound healing and protective effects in liver diseases<sup>[30]</sup>. The levels of uPA have been found to be increased in tissues, plasma and other body fluids of cancer patients and to be markers of cancer development and metastasis. And in human immunodeficiency virus (HIV)-infected patients, the serum levels of uPA have been found to be increased<sup>[2]</sup>. Also, the abnormal levels of plasma uPA in the patients with acute or chronic hepatitis B were observed, and it seems that the plasma levels of uPA are closely related to the degree and period of inflammation for these patients<sup>[13]</sup>. Although the clinical significance of uPA in viral chronic hepatitis B, hepatitis induced liver cirrhosis and HCC has been evaluated, the role of uPA in the process is less well understood, especially in the early stage.

In 1990, an Alb-uPA transgenic mouse which carried the mouse uPA gene under the control of the mouse albumin enhancer/promoter, was developed by Dr. Brinster's team to study the pathophysiology of plasminogen hyperactivation<sup>[31]</sup>. The over-expression of the uPA gene in the liver resulted in high plasma uPA levels and hypofibrinogenemia, which led to severe and sometimes abdominal bleeding soon after birth. And the high mortality also increases the difficulty for the generation of human liver chimeric mice<sup>[32,33]</sup> and the study of hepatitis C virus infections *in vivo*<sup>[34-36]</sup>. In this study, we established an uPA inducible double transgenic mouse in-alb-uPA, in which uPA can be expressed specifically in the liver only after Dox induction. Hypofibrinogenemia and neonatal hemorrhaging were not observed in the Dox-induced in-alb-uPA mice, which greatly brought down the mortality rate. Also the inducible expression of uPA makes it possible for us to study and illuminate the relations of uPA over-expression and HBV infection clinically.

Hydrodynamic transfection method was suitable for the AAV-mediated delivery of HBV genome *in vivo*<sup>[37]</sup>. To investigate the risk of HBV induced liver injury in the case of uPA over-expression, the hydrodynamic transfection of pAAV-HBV1.3, which could mediated the production of replicative HBV virus *in vivo*, was performed. In the Dox-induced in-alb-uPA mice that were hydrodynamically transfected by AAV-1.3HBV, severe liver histological changes were observed in the liver (Figure 5). Also uPA over-expression in the liver resulted in higher HBV antigen expression, higher IL-6 and TNF- $\alpha$  produc-

tion and slight elevation of serum ALT level (Figure 6). Our results also found a significant increase of the AFP mRNA level in the AAV-HBV transfected Dox-induced in-alb-uPA mice (Figure 6). Produced by the embryonic yolk sac and fetal liver, the AFP level decreases abruptly soon after birth and remains at a low level throughout life. And reactivation of AFP production occurs during liver regeneration<sup>[19]</sup>. As IL-6 and TNF- $\alpha$  are proinflammatory cytokines that lead to liver regeneration, we came to the conclusion that the uPA over-expression in AAV-HBV transfected mice increased the liver necrosis injury, inflammation and liver regeneration, which reflects a process that may eventually lead to hepatocellular carcinoma.

It is generally considered that cell-mediated immunity and inflammation are the main mediators of the hepatic pathology induced by HBV infection. In this study, we found that HBV infection further accelerated liver injury and regeneration when uPA was overexpressed, indicating a close relation between uPA expression and HBV infection. Also as clinical data showed that the increased level of uPA in HIV infected patients, this study may in part explain the increased risk of liver disease during HIV and HBV coinfection.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection causes a high risk of developing liver diseases, such as cirrhosis and hepatocellular carcinoma (HCC). The immune response to HBV-encoded antigens is responsible both for viral clearance and for disease pathogenesis during HBV infection. The urokinase plasminogen activator (uPA) is a serine protease that can activate the plasminogen into plasmin, and perform multiple functions in fibrinolysis, immunity and pathology. However, the roles of uPA/uPA's receptor (uPAR) systems as important inflammatory mediators have not yet been well investigated in acute and chronic hepatitis B, a common inflammatory disease in China. Clinical studies almost focused on the correlation of uPA levels with the liver disease severity in hepatitis B patients. And the role of uPA in the HBV-induced liver injury, especially in the early stage, is less investigated.

### Research frontiers

Various researchers have found the levels of uPA to be increased in tissues, plasma and other body fluids of cancer patients and to be markers of cancer development and metastasis. And in human immunodeficiency virus (HIV)-infected patients, the serum levels of uPA have been found to be increased. Also, the abnormal levels of plasma uPA in the patients with acute or chronic hepatitis B were observed, and it seems that the plasma levels of uPA are closely related to the degree and period of inflammation for these patients. Although the clinical significance of uPA in viral chronic hepatitis B, hepatitis induced liver cirrhosis and HCC has been evaluated, the role of uPA in the process is less well understood, especially in the early stage.

### Innovations and breakthroughs

In this study, an inducible liver-specific uPA transgenic mice model was developed. Plasmid adeno-associated virus-1.3HBV transfection in doxycycline (Dox)-induced transgenic mice resulted in severer liver injury, higher HBV antigen and cytokine expression compared to the control group. These data further indicated for the first time in mice that the over-expression of uPA may have accelerative role in the development of liver injury, inflammation and liver regeneration during acute HBV infection. Also as clinical data showed that the increased level of uPA in HIV infected patients, this study may in part explain the increased risk of liver disease during HIV and HBV coinfection.

### Applications

This study deepens our knowledge of uPA function in HBV-induced liver diseases, which may not only facilitate the elucidation of the molecular mechanism

of HBV pathogenesis, but also provide a basis for the uPA-targeted anti-HBV therapies.

### Terminology

uPA is one kind of plasminogen activator that catalyzes the conversion of plasminogen to plasmin. Together with uPAR, uPA participate in fibrinolysis, innate and adaptive immunity, and pathology. Tetracycline (Tet)-inducible expression system consists of two parts: the ligand-dependent transactivator rTA as the effector and a tetO-CMV minimal promoter cassette regulating the expression of the transgene as the responder. When Dox is present, rTA binds to the tetO-sequence and induces expression of the target gene. Together with a tissue-specific promoter, it can result in transgene expression in a temporally and spatially defined fashion.

### Peer review

The authors studied the role of uPA and found that the over-expression of uPA may have a synergistic role in the development of liver injury, inflammation and liver regeneration during acute HBV infection. They added as such new information to the field on the knowledge about uPA function in HBV-induced liver diseases.

### Abstract

**AIM:** To investigate the effects of small interference RNA (siRNA) targeting of Cdx2 on human gastric cancer MGC-803 cells *in vitro* and *in vivo*.

**METHODS:** The recombinant pSilencer 4.1-Cdx2 siRNA plasmids were constructed and transfected into gastric cancer MGC-803 cells *in vitro*. The stable transfectants were selected. The effects of Cdx2 siRNA on growth, proliferation, cell cycle, apoptosis, migration and invasiveness of human gastric cancer MGC-803 cells were evaluated and the expression of phosphatase and tensin homolog (PTEN), caspase-9 and caspase-3 was observed *in vitro* by reverse transcription polymerase

chain reaction (RT-PCR) and Western blotting analysis. We also investigated the effect of Cdx2 siRNA on growth of MGC-803 cells in nude mice *in vivo*.

**RESULTS:** Cdx2 siRNA led to inhibition of endogenous Cdx2 mRNA and protein expression as determined by RT-PCR and Western blotting analysis. Cdx2 siRNA significantly inhibited cell growth and proliferation, blocked entry into the S-phase of the cell cycle, induced cell apoptosis, and reduced the motility and invasion of MGC-803 cells. Cdx2 siRNA also increased PTEN expression, and activated caspase-9 and caspase-3 in MGC-803 cells *in vitro*. In addition, siRNA targeting of Cdx2 inhibited the growth of MGC-803 cells and promoted tumor cell apoptosis *in vivo* in nude mice tumor models.

**CONCLUSION:** Cdx2 was involved in regulating progression of human gastric cancer cells MGC-803. Manipulation of Cdx2 expression may be a potential therapeutic strategy for gastric cancer.

### INTRODUCTION

The transcription factor, Cdx2, is a member of the caudal-related homeobox gene family, and is mainly expressed in

the intestine. Cdx2 plays important roles in early differentiation, proliferation, and maintenance of intestinal epithelial cells, and in the transcription of genes such as multidrug resistance 1<sup>[1,2]</sup>. Overexpression of Cdx2 in the small intestine is associated with reduced postnatal growth, early epithelial maturation, alterations in the development of a differentiated phenotype in crypt base organization, and changes in paneth and goblet cell lineages<sup>[3]</sup>.

Initially, Cdx2 was reported to be a tumor suppressor. Several investigators reported that low levels of Cdx2 is a characteristic feature of human colon and squamous esophageal cancer<sup>[4,5]</sup>, and overexpression of Cdx2 could decrease mobility and antagonize metastasis of colon cancer cells<sup>[6]</sup>. However, other studies showed that strong and robust expression of Cdx2 was found in > 80% of colorectal cancers and non-small cell lung cancer<sup>[7,8]</sup>. In addition, Cdx2 was found to enhance proliferation and have tumorigenic potential in the human colon cancer cell lines, LoVo and SW48<sup>[9]</sup>. These studies suggested that Cdx2 also had oncogenic property. Together, these conflicting findings point to a complex role for Cdx2 in the regulation of cell proliferation.

Gastric cancer is the third most common cancer in China, and is one of the most frequent causes of cancer-related mortality in China, with an incidence of 0.4 million new cases and 0.3 million deaths annually<sup>[10]</sup>. Intestinal metaplasia has been shown to be a precursor of intestinal-type gastric adenocarcinoma. Since intestinal metaplasia cannot be eradicated, it is important to determine how to reduce the morbidity from intestinal metaplasia to gastric cancer. However, the histogenesis of intestinal metaplasia and factors in the metaplastic epithelium that lead to its development into carcinoma is still in dispute<sup>[11,12]</sup>. In adult humans, Cdx2 has been reported to be associated with intestinal metaplasia in the stomach in which ectopic expression of Cdx2 is speculated to cause the gastric epithelial cells to trans-differentiate and take the intestinal phenotype<sup>[13]</sup>. In addition, Cdx2 transgenic mice have been shown to induce intestinal metaplasia and have a high incidence of gastric carcinoma<sup>[14,15]</sup>. This indicates a direct relationship between Cdx2-induced intestinal metaplasia and gastric carcinogenesis.

In the present study, we constructed small interference RNA (siRNA) sequences targeting of Cdx2, transfected them into the human gastric cancer cell line MGC-803, selected the stable transfectants, and explored changes in growth, proliferation, cell cycle, apoptosis, metastasis and invasiveness. We also observed the effect of Cdx2 siRNA on the expression of phosphatase and tensin homolog (PTEN), caspase-9, and caspase-3. Moreover, we investigated the effects of Cdx2 downregulation on the growth and apoptosis of MGC-803 cells in nude mice.

## MATERIALS AND METHODS

### Cell culture

The human gastric carcinoma cell line, MGC-803, was supplied by the Cell Bank of Shanghai Institute of Cell

Biology, Chinese Academy of Sciences. Cells were cultured in Dulbecco's modified Eagle's medium (DMEM) (Invitrogen, Gaithersburg, MD, United States). All media were supplemented with 10% fetal bovine serum (FBS), penicillin (100 U/mL), and streptomycin (100 µg/mL). Cells were cultured in an incubator with 5% CO<sub>2</sub> at 37 °C with medium changes every 3 d.

### Antibodies

Anti-Cdx2, anti-β-actin and secondary antibody were obtained from Santa Cruz Biotechnology Inc., Santa Cruz, CA, United States. Antibodies specific for PTEN, pro-caspase-9, cleaved caspase-9, pro-caspase-3, cleaved caspase-3, and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were from Cell Signaling Technology, Beverly, MA, United States.

### Plasmid construction and transfection

Double strand siRNA oligonucleotides were obtained from Gima Biotechnology Company (China). There were two reversed repeated sequences with 21 inserted sequences (GACAAATATCGAGTGGTGTAC, TA-ACCCGCGATCTGTTCTGCA) in the complementary sequence, with *Bam*H I and *Hind*III sites for ligation into the pSilencer 4.1 vector, which contained a neomycin resistance marker for the selection of stable transfectants in the presence of G418. The siRNA targeting site of the transcribed product was nucleotides 115-818 of Cdx2 mRNA (GeneBank No. NM-001265). The negative control was the siRNA sequence with no homology to any human gene sequence.

After ligation, the plasmid was transformed into *Escherichia coli* TOP10 cells, and then cultured on solid LB medium (LB solid medium containing 50 ng/L ampicillin and 2% agarose gel) at 37 °C for 16 h. Positive clones were identified by DNA sequence analysis (Majorbio Biotech Co., Ltd), and the resulting plasmid was named pSilencer 4.1-Cdx2(+) or pSilencer 4.1-Cdx2(-). Six-well plates were inoculated with MGC-803 cells (1 × 10<sup>5</sup>), and cells were transfected with pSilencer 4.1-Cdx2(+) recombinant plasmids. For selection of stable transfectants, G418 (Life Technologies) was added to the cells 48 h after transfection. The concentration of G418 for selection was gradually decreased as follows: 1 mg/mL for 4 d; 750 µg/mL for 4 d; 500 µg/mL for 4 d; and 250 µg/mL as a sustaining dose. At day 20 after transfection, G418-resistant clones were isolated. The selected cell colonies were transferred from 10-mm dishes to 96-well plates, and then from 96-well plates to 24-well plates. The transformants selected by G418 were analyzed by measuring the expression of Cdx2 mRNA and protein. The negative control cells were transfected with vector pSilencer 4.1-Cdx2(-) alone, and maintained under identical conditions. In the case of cells that were selected in medium containing G418, antibiotics were routinely included in their growth medium until 1 to 2 d before experiments were carried out. The cells were divided into 3 groups: MGC-803/Cdx2 siRNA, MGC-803/Cdx2 negative control and MGC-803 group.

### Semi-quantitative reverse transcription polymerase chain reaction

Total RNA was extracted from the positive cell clone using TRIzol Reagent (Invitrogen). Neo gene segments were amplified and verified by semi-quantitative reverse transcription polymerase chain reaction (RT-PCR). Complementary deoxyribonucleic acids (cDNAs) were reverse-transcribed from 2  $\mu\text{g}$  of total RNA. Primers used in this study were as follows: Cdx2 forward primer (5'-CGGCAGCCAAGTGAAC-3') and reverse primer (5'-GATGGTGATGTAGCGACTGTAGTG-3'), PCR product: 100 base pairs (bp);  $\beta$ -actin forward primer (5'-AACTCCATCATGAAGTGTGA-3') and reverse primer (5'-ACTCCTGCTTGCTGATCCAC-3'), PCR product: 247 bp. The PCR products were checked by agarose gel electrophoresis, and the abundance of each mRNA was detected and normalized to that of  $\beta$ -actin mRNA.

### Western blotting analysis

Cell lysates were prepared in a buffer containing 100 mmol/L NaCl, 10 mmol/L Tris-Cl (pH 7.6), 1 mmol/L ethylenediaminetetraacetic acid (pH 8.0), 1  $\mu\text{g}/\text{mL}$  aprotinin, 100  $\mu\text{g}/\text{mL}$  phenylmethylsulfonyl fluoride, and 1% (v/v) NP-40. After protein quantitation using the Lowry protein assay, equal amounts of proteins were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis, and blotted onto nitrocellulose membranes by the semi-dry blotting method using a three buffer system. The membrane was blocked with 5% bovine serum albumin in phosphate buffer solution Tween-20 (PBST) (PBS, pH 7.5, containing 0.1% Tween-20), and incubated with a 1:500 dilution of primary antibody (anti-Cdx2) overnight at 4  $^{\circ}\text{C}$ . The membrane was then washed with PBST and incubated with a peroxidase-conjugated secondary antibody (1:1000) for 1 h. Specific antibody binding was detected using a chemiluminescence detection system (Pierce, Rockford, IL, United States), according to the manufacturer's recommendations. Western blotting film was scanned, and the net intensities of the bands were quantified using Image-QuanT software (Molecular Dynamics, Sunnyvale, CA, United States). After development, the membrane was stripped and reprobed with antibody against  $\beta$ -actin (1:1000) to confirm equal sample loading.

### Cell growth and proliferation assay

The growth of MGC-803 cells was determined by an 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay using a CellTiter 96 AQueous assay system (Promega, Madison, WI, United States), according to the manufacturer's instructions. This assay measures dehydrogenase enzyme activity in metabolically active tumor cells, as reflected by the conversion of MTT to formazan, which is soluble in tissue culture medium and is detected by absorbance ( $A$ ) at 490 nm. The production of formazan is proportional to the number of living cells, with the intensity of the produced color serving as an indicator of cell viability. Briefly, MGC-803

cells were plated at a density of  $5 \times 10^3$  cells/well in 96-well plates, and cultured for 72 h. The percentage of cell survival was calculated using the background-corrected absorbance: % proliferation rate =  $100 \times A$  of experimental well/ $A$  of untreated control well. All experiments were performed at least three times.

### Colony formation assay

Cell suspensions from each group were diluted in DMEM with 10% FBS, and immediately re-plated in 6-well plates at a density of 20 cells/ $\text{cm}^2$ . The plates were incubated until cells in control wells formed sufficiently large colonies. After that, the colonies were fixed in 6% glutaraldehyde and stained with 0.5% crystal violet. The plates were photographed and their digital images were analyzed manually to determine colony number.

### Cell cycle analysis by flow cytometry

For cell cycle analysis, MGC-803 cells ( $1 \times 10^6$ ) were washed twice with ice-cold PBS, treated with trypsin, and then fixed in 70% cold ethanol at 4  $^{\circ}\text{C}$  for 30 min. The cell pellet was incubated in a solution containing 50 ng/mL propidium iodide, 0.2 mg/mL RNase, and 0.1% Triton X-100 at room temperature for 30 min, and then analyzed by flow cytometry using a FACscan (Becton Dickinson, Mountain View, CA, United States). Data were analyzed with the MultiCycle for Windows (Phoenix Flow Systems, San Diego, United States).

### Apoptosis assay by flow cytometry

Apoptotic cells were determined using the Annexin V-fluorescein isothiocyanate (FITC) Apoptosis Detection Kit (Jingmei Biotech Co., Shenzhen, China) and an EPICS XL-MCL flow cytometer (Becton Dickinson) according to the manufacturer's instructions. Briefly,  $1 \times 10^6$  cells were stained with Annexin V/FITC for 30 min at 4  $^{\circ}\text{C}$  in the dark and then stained with propidium iodide for 10 min before flow cytometric analysis.

### Wound healing assay

The cells were cultured to confluence in 6-well plates, and were then treated with mitomycin C to inhibit cell proliferation. A central linear wound was made with a 200  $\mu\text{L}$  sterile pipet tip. Media were changed gently to remove any floating cells. Phase micrographs of the wound cultures were taken at 0 and 36 h. The photographs were analyzed by measuring the distance from the wound edge of the cell sheet to the original wound site. Migratory activity was calculated as the mean distance between edges of three points in 12 fields per well. Relative motility = (mean original distance - mean distance at a time point)/mean original distance  $\times 100\%$ . Each test group was assayed in triplicate.

### Cell invasion assay

Cell invasion was assessed using Transwell chambers (6.5 mm; Corning, New York, United States) with 50  $\mu\text{L}$  serum-free DMEM containing 1  $\mu\text{g}/\text{mL}$  Matrigel (De-

partment of Biology, Beijing University, China) in the upper chamber. The lower chamber was filled with 50  $\mu$ L DMEM containing 0.1  $\mu$ g/mL fibronectin (Beijing University). Cells ( $1 \times 10^5$ ) were suspended in 100  $\mu$ L DMEM with 1% fetal calf serum and plated into the upper chamber. PBS (5%) 500  $\mu$ L was added in the lower chamber. After a 24 h incubation with 5% CO<sub>2</sub> at 37 °C, the number of cells with Giemsa staining on the under-surface of the polycarbonate membranes was scored visually in five random fields at a 400  $\times$  magnification by light microscopy.

#### Analyses of PTEN, caspase-9 and caspase-3 expression

Semi-quantitative RT-PCR was performed as previously described. Primers used in this study were as follows: (1) PTEN forward primer (5'-CTGGAAAGGGAC-GAACTG-3') and reverse primer (5'-AGGTAACG-GCTGAGGGA-3'), PCR product: 368 bp; (2) Caspase-9 forward primer (5'-GGCTGTCTACGGCACAGAT-GGA-3') and reverse primer (5'-CTGGCTCGGGGT-TACTGCCAG-3'), PCR product: 200 bp; (3) Caspase-3 forward primer (5'-AAGCGAATCAATGGACTC-3') and reverse primer (5'-TTCCTGACTTCATATTTCAA-3'), PCR product: 192 bp; (4) GAPDH (a) forward primer (5'-ACAGCAACAGGGTGGTGGAC-3') and reverse primer (5'-TTTGAGGGTGCAGCGAACTT-3'), PCR product: 252 bp; and (5) GAPDH (b) forward primer (5'-ACCACAGTCCATGCCATCAC-3') and reverse primer (5'-TCACCACCCTGTTGCTGTA-3'), PCR product: 450 bp. Western blotting analysis was carried out as previously described.

#### Animal studies

BALB/c male nude mice at 5 wk old were obtained from Guangxi Animal Center, China. All animals were kept under specific pathogen-free conditions and tended to in accordance with institutional guidelines. All experimental studies were approved by the Guangxi Medical University Animal Care and Use Committee. MGC-803/Cdx2 siRNA cells, MGC-803/Cdx2 negative control cells and MGC-803 cells were used for tumor implantation. There were six mice in each group. Approximately  $2 \times 10^6$  tumor cells were implanted subcutaneously into the flanks of the nude mice. Tumor sizes were measured every 4 d with a caliper, and the diameters were recorded. The tumor volume (TV) was calculated by the formula:  $TV = W^2 \times L/2$ , where L was the length and W was the width of the tumor. The relative tumor volume (RTV) was calculated by the formula:  $RTV = V_t/V_0$  ( $V_0$  is the TV at the day when the chemicals were given, and  $V_t$  is the TV of subsequent measurement). After mice were killed, total RNA and protein were extracted from tumor tissues. The expression of Cdx2 mRNA and protein were detected by semi-quantitative RT-PCR and Western blotting analysis, respectively. Tumor cells were assessed for apoptosis using *in situ* terminal deoxynucleotidyl transferase-mediated 2'-deoxyuridine, 5'-triphosphate nick end labeling assays (TUNEL). Apoptosis was evaluated

by counting the positive cells (brown-stained cells) as well as the total number of cells in 10 arbitrarily selected fields at 400  $\times$  magnifications in a double-blinded manner. The apoptotic index (per 400  $\times$  microscopic field) was calculated as the number of apoptotic cells  $\times$  100/total number of cells. Brown-stained nuclei immediately at the edge of a tissue section were excluded from cell counts to minimize false positives.

#### Statistical analysis

Data are expressed as mean  $\pm$  SE. Statistical significance was determined using  $\chi^2$  test, student's *t* test, or one-way analysis of variance. Statistical analysis were carried out using SPSS, version 13.0 (SPSS Inc., Chicago, IL, United States) or Origin 7.5 software programs (OriginLab Co., Northampton, MA, United States). A value of  $P < 0.05$  was considered as statistically significant.

## RESULTS

#### pSilencer 4.1-Cdx2(+) inhibits Cdx2 mRNA and protein expression

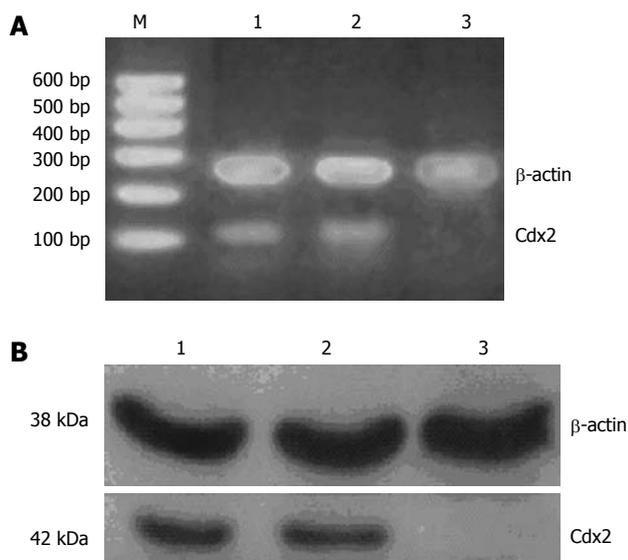

Recombinant pSilencer 4.1-Cdx2(+) and pSilencer 4.1-Cdx2(-) sequences were verified by DNA sequenced analysis (data not shown) which demonstrated that the inserted siRNA coding frames and frame sequences were correct. This confirmed that the construction of Cdx2 siRNA expression plasmid was successful.

The transfection of pSilencer 4.1-Cdx2(+) plasmid into MGC-803 cells led to remarkable inhibition of Cdx2 mRNA and protein expression. Densitometric analysis showed that Cdx2 mRNA and protein in MGC-803/Cdx2 siRNA cells were about 11- and 7-fold lower, respectively, than those in the two control groups ( $P < 0.05$ ), while no differences were found between MGC-803/Cdx2 negative control cells and MGC-803 cells (Figure 1).

#### Cdx2 siRNA inhibits cell growth and proliferation in gastric cancer MGC-803 cells

Next, we determined the *in vitro* survival rates of gastric tumor cells stably transfected with pSilencer 4.1-Cdx2(+) plasmids, using the gastric carcinoma cell line, MGC-803, as a model for gastric cancer. As shown in Figure 2, Cdx2 siRNA significantly reduced cell survival, as assessed by the MTT assay. We observed that MGC-803/Cdx2 siRNA cells obviously grew slower than MGC-803/Cdx2 negative control cells and MGC-803 cells ( $P < 0.05$ ), which was consistent with the decreased levels of Cdx2 in MGC-803/Cdx2 siRNA cells. Additionally, MGC-803/Cdx2 negative control cells and MGC-803 cells exhibited about 3-fold higher mean proliferation rates than MGC-803/Cdx2 siRNA cells ( $P < 0.05$ ). These results indicate a suppressive effect of Cdx2 siRNA on MGC-803 cell growth and survival.

To confirm the inhibitory effect of Cdx2 siRNA on the growth of MGC-803 cells, we performed colony formation assays to measure the capability of the cells to grow in an anchorage-independent environment by

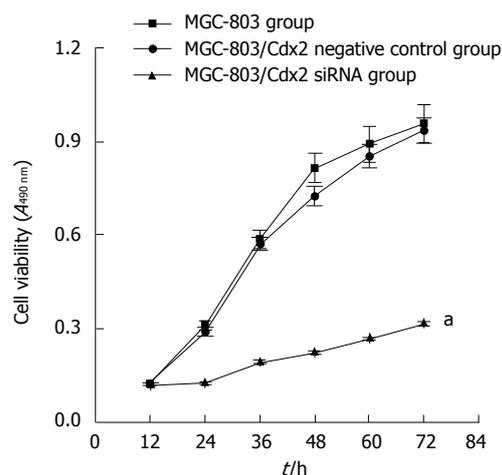

**Figure 1** Cdx2 small interference RNA significantly reduced Cdx2 mRNA and protein expression in MGC-803 cells. A: Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) analysis. The RNA samples (2  $\mu$ g in each) extracted from MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells were subjected to RT-PCR for Cdx2 and  $\beta$ -actin mRNAs. RT-PCR for  $\beta$ -actin was performed in parallel to show an equal amount of total RNA in the sample; B: Western blotting analysis. Whole protein extracts (100  $\mu$ g in each) were prepared from MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 siRNA cells. The expression of Cdx2 protein was determined by Western blotting with an anti-Cdx2 antibody. The  $\beta$ -actin expression levels were determined as a control for equivalent protein loading. Lane 1: MGC-803 group; Lane 2: MGC-803/Cdx2 negative control group; Lane 3: MGC-803/Cdx2 siRNA group; M: 600 bp marker.

culturing the cells in soft agarose. As shown in Figure 3, three cell lines were able to form colonies in soft agarose, but the number of colony formation in MGC-803/Cdx2 siRNA cells after 3 wk was  $51.4 \pm 3.2$ , with a 60.1% and 57.6% decrease, compared to the two control groups, respectively ( $P < 0.05$ ). Together, these data suggest that Cdx2 siRNA inhibits cell growth and proliferation in gastric cancer cells.

#### Effect of Cdx2 siRNA on cell cycle control in gastric cancer MGC-803 cells

We used flow cytometry to determine whether the inhibitory effect of Cdx2 siRNA on MGC-803 cell proliferation was mediated, at least in part, through affecting cell cycle progression. We found that MGC-803/Cdx2 siRNA cells were 73.1% in G0/G1 phase and 18.2% in S phase, with a 13.8% and 16.2% increase in the G0/G1 phase cell population, and a 17% and 18% decrease in the S phase cell population, compared to MGC-803 cells and MGC-803/Cdx2 negative control cells ( $P < 0.05$ ) (Figure 4). These data indicate that cell growth inhibition by Cdx2 siRNA is associated with significant cell cycle arrest in G0/G1 phase, and suggest that siRNA directed against the Cdx2 gene suppresses cell proliferation by controlling the G1 and S checkpoints and inducing a specific block in cell cycle progression.

**Figure 2** Cdx2 small interference RNA inhibits cell proliferation in MGC-803 cells. MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells were treated with 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide at days 1-3. The cell viability in each group was presented. Each time point represented the mean of cell viability for each group. <sup>a</sup> $P < 0.05$  for MGC-803/Cdx2 siRNA group vs MGC-803 and MGC-803/Cdx2 negative control group.

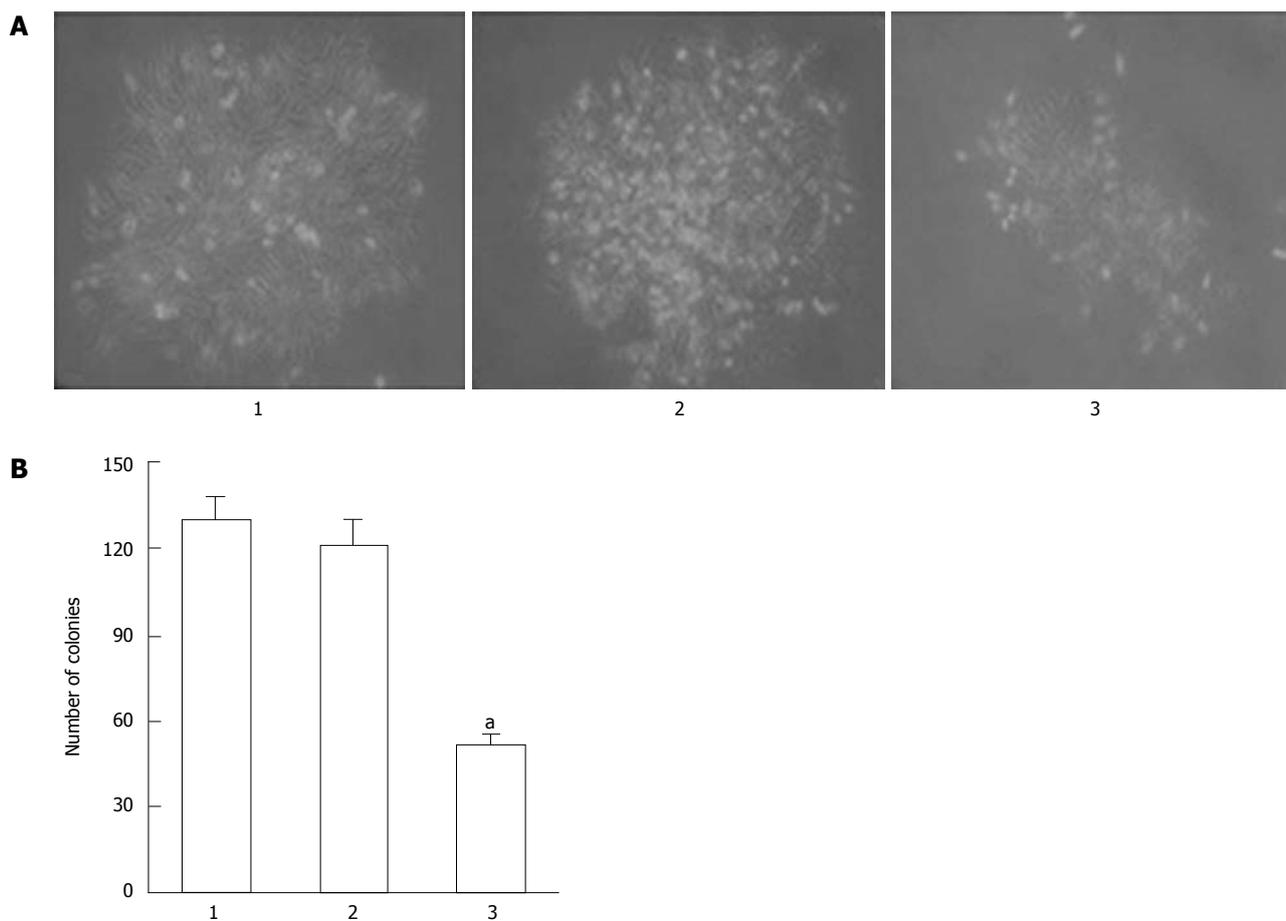

#### Cdx2 siRNA induces cellular apoptosis

To further study the effect of Cdx2 siRNA on MGC-803 cell apoptosis, cells were stained with Annexin V-FITC and propidium iodide, and then subsequently analyzed by flow cytometry. The dual parameter fluorescent dot plots showed that the viable cells were in the lower left quadrant, and the apoptotic cells were in the right quadrant. As shown in Figure 5, the apoptotic percentage of MGC-803/Cdx2 siRNA cells was  $11.7\% \pm 2.2\%$ , which was significantly higher than that of MGC-803/Cdx2 negative control ( $5.3\% \pm 1.3\%$ ) and MGC-803 cells ( $5.6\% \pm 1.1\%$ ) ( $P < 0.05$ ). This implies that inhibition of Cdx2 is able to induce apoptosis in gastric cancer MGC-803 cells.

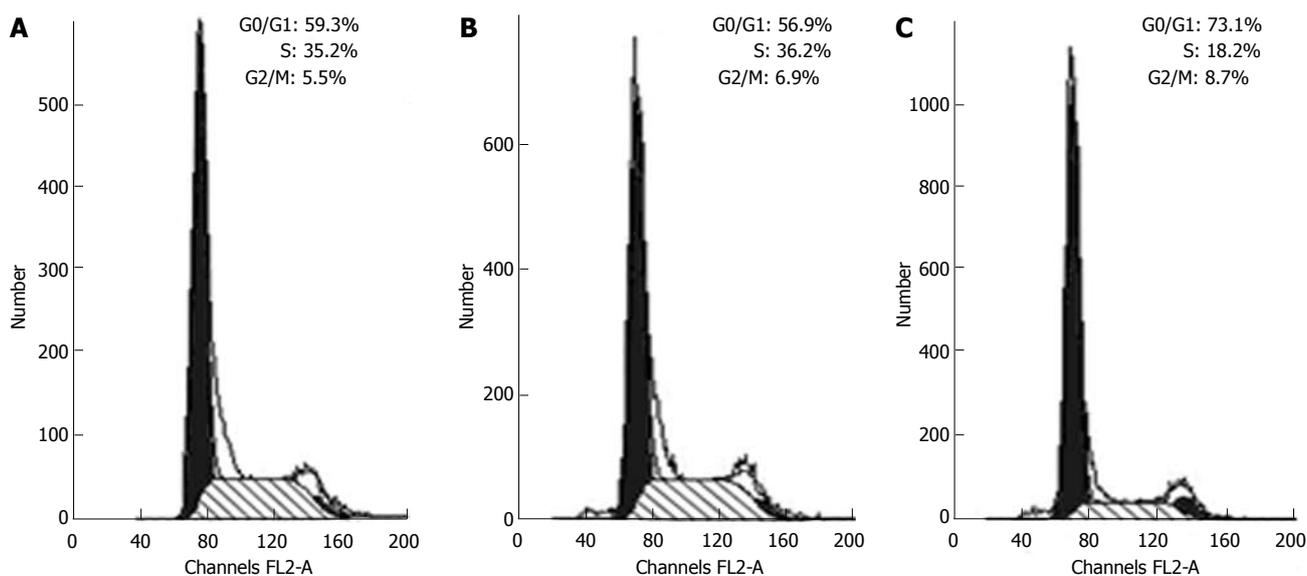

#### Cdx2 siRNA decreases migration and invasion of gastric cancer cells

We measured the migratory ability of three cell groups using the wound healing assay by scratching the single-layer cells. As shown in Figure 6, the distance between the wound edges was determined at 0 and 36 h and the healing rate was calculated in the three groups. MGC-803/Cdx2 siRNA cells showed a lower migratory ability at 36 h than MGC-803/Cdx2 negative control and MGC-803 cells. The healing rate of MGC-803/Cdx2 siRNA cells after 36 h was  $53.7\% \pm 7.2\%$ , with a 39.9% and 40.8% decrease, as compared to MGC-803/Cdx2 negative control cells and MGC-803 cells ( $P < 0.05$ ).

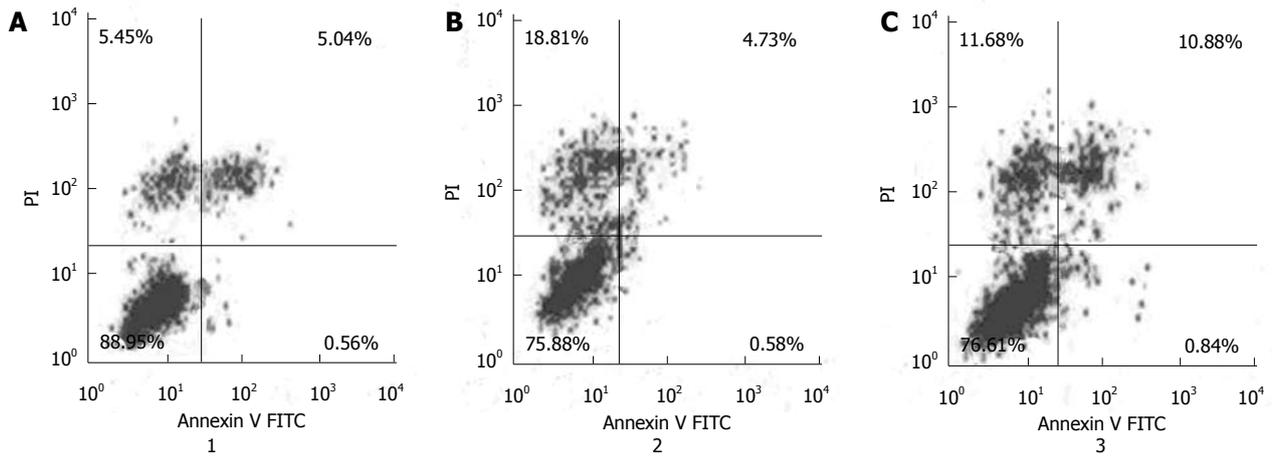

Since siRNA targeting of Cdx2 inhibited the expression of Cdx2 gene in gastric cancer cells, we assessed its ability to inhibit cell invasion. After incubation for 24 h in the invasion assay, the numbers of MGC-803/Cdx2 negative control and MGC-803 cells invaded through the membrane of Matrigel chamber were 2.9- and 3.0-fold greater than that of MGC-803/Cdx2 siRNA cells, re-

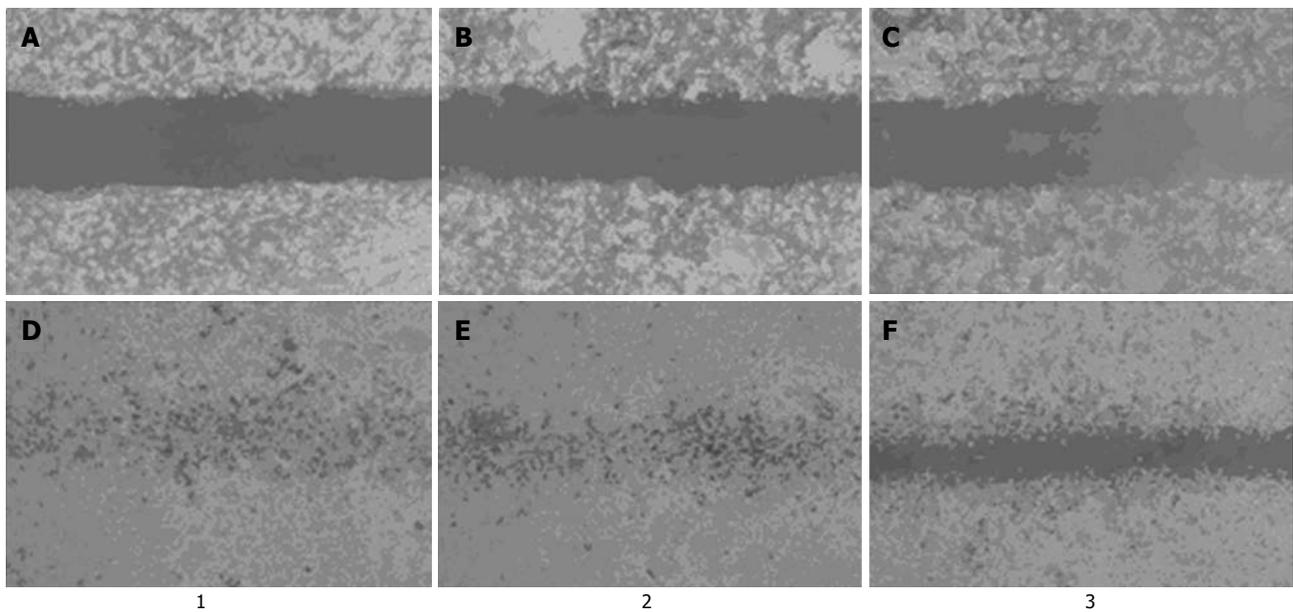

**Figure 3** MGC-803/Cdx2 small interference RNA cells exhibited fewer colonies than MGC-803/Cdx2 negative control cells or MGC-803 cells. A: MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells were plated in 6-well plates at a density of 20 cells/cm<sup>2</sup>, and the colonies were observed under optical microscope at 13 d (×100); B: The surviving fraction of cells (visible colonies) was stained with gentian violet, and counted manually. MGC-803/Cdx2 siRNA cells exhibited fewer colonies than MGC-803/Cdx2 negative control cells or MGC-803 cells. Each column presents as mean ± SE from 3 independent experiments. <sup>a</sup>*P* < 0.05 for MGC-803/Cdx2 siRNA group vs MGC-803 and MGC-803/Cdx2 negative control group. Lane 1: MGC-803 group; Lane 2: MGC-803/Cdx2 negative control group; Lane 3: MGC-803/Cdx2 siRNA group.

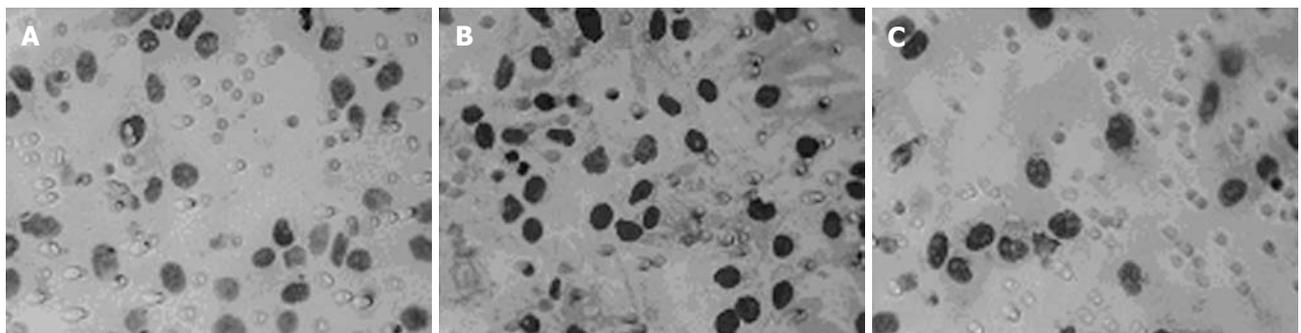

**Figure 4** Cdx2 small interference RNA caused cell cycle arrest in the G0/G1 phase. Cell cycle was analyzed by flow cytometry in MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells. The data were representative of 3 independent experiments. A: MGC-803 group; B: MGC-803/Cdx2 negative control group; C: MGC-803/Cdx2 siRNA group.

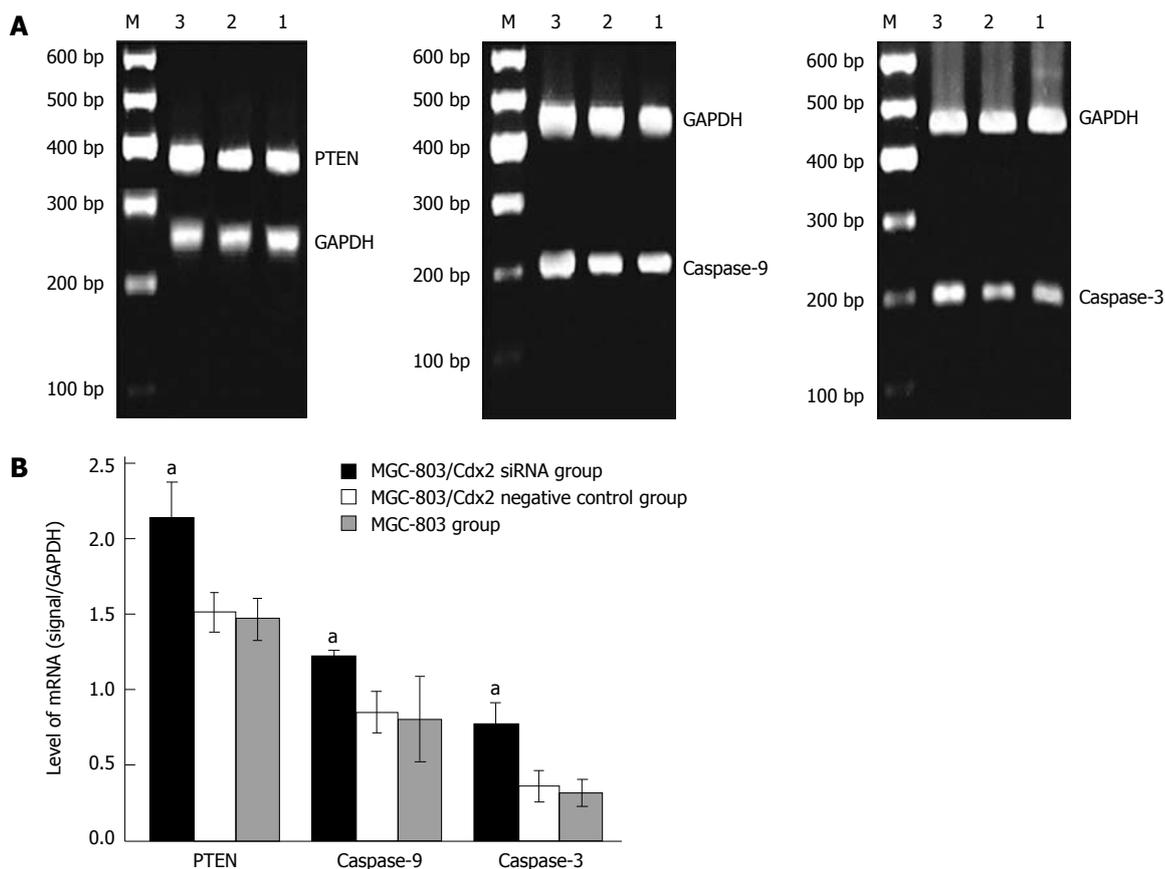

**Figure 5** The mean apoptotic rate in MGC-803/Cdx2 small interference RNA cells was significantly higher than that in MGC-803/Cdx2 negative control or MGC-803 cells. Percentages of apoptotic cells analyzed by flow cytometry. Numbers in the quadrants reflected the percentage of cells. **Figure 7** Cdx2 small interference RNA decreased invasion of MGC-803 cells. MGC-803 cells (A), MGC-803/Cdx2 negative control cells (B) and MGC-803/Cdx2 small interference RNA cells (C) were loaded onto Matrigel-coated upper chambers of Transwell plates. Filtrated cells on the undersurface of the polycarbonate membranes were stained and counted under a optical microscope at 24 h ( $\times 200$ ).

**Figure 8** Cdx2 small interference RNA upregulated phosphatase and tensin homolog, caspase-9 and caspase-3 mRNA expression. A: Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) analysis. The RNA samples (2 μg in each) extracted from MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells were subjected to RT-PCR for phosphatase and tensin homolog (PTEN), caspase-9, caspase-3 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNAs. RT-PCR for GAPDH was performed in parallel to show an equal amount of total RNA in the sample. Lane 1: MGC-803 group; Lane 2: MGC-803/Cdx2 negative control group; Lane 3: MGC-803/Cdx2 siRNA group; M: 600 bp marker; B: PTEN, caspase-9 and caspase-3 mRNA levels were measured at three groups, normalized to those of GAPDH and presented as mean ± SE. <sup>a</sup>*P* < 0.05 for MGC-803/Cdx2 siRNA group vs MGC-803 and MGC-803/Cdx2 negative control group.

spectively (*P* < 0.05) (Figure 7). The results indicate that Cdx2 siRNA reduces the migratory and invasion ability of gastric cancer MGC-803 cells.

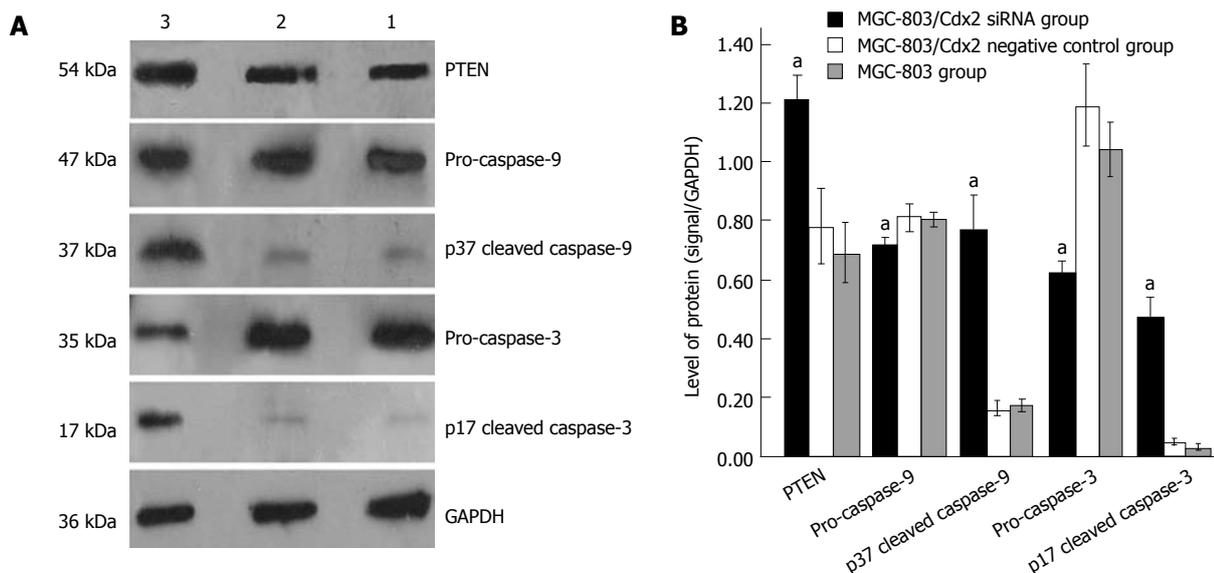

**Cdx2 siRNA increases PTEN expression, and activates caspase-9 and caspase-3**

To investigate the mechanism by which Cdx2 siRNA induces apoptosis in MGC-803 cells, we detected expression levels of several apoptotic family members including PTEN, caspase-9, and caspase-3 by semi-quantitative RT-PCR and Western blotting analysis. As shown in Figure 8, densitometric analysis showed that PTEN, caspase-9, and caspase-3 mRNA of MGC-803/Cdx2 siRNA cells were higher than that in MGC-803 cells and MGC-803/Cdx2 negative control cells (*P* < 0.05), while no differences were found between MGC-803/Cdx2 negative control cells and MGC-803 cells. As shown in Figure 9, Cdx2 siRNA led to the cleavage of pro-caspase-9 (47 kDa) and pro-caspase-3 (35 kDa) into other multiple, cleaved, maturation products (data not shown), but only the 37-kDa form of cleaved caspase-9 and the 17-kDa form of cleaved caspase-3 were observed. Den-

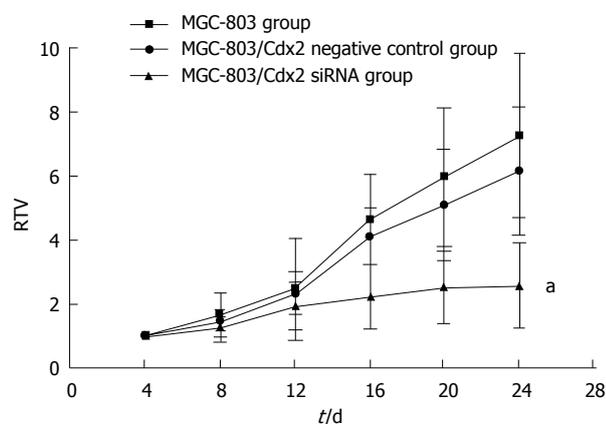

sitometric analysis showed that PTEN, p37 cleaved caspase-9, and p17 cleaved caspase-3 protein of MGC-803/Cdx2 siRNA cells were higher, while pro-caspase-9 and pro-caspase-3 were lower than that in MGC-803 cells and MGC-803/Cdx2 negative control cells (*P* < 0.05). No differences were found between MGC-803/Cdx2 negative control cells and MGC-803 cells.

**Inhibitory effect of Cdx2 siRNA in vivo**

We also examined the effect of Cdx2 siRNA on growth of MGC-803 cells *in vivo* by implanting MGC-803/Cdx2 siRNA cells subcutaneously into the flanks of BALB/c nude mice. Four weeks after implantation, tumor weight from MGC-803/Cdx2 siRNA cells was 0.773 ± 0.054 g, which was significantly less than 2.334 ± 0.087 g from MGC-803 cells, and 2.356 ± 0.092 g from MGC-803/Cdx2 negative control cells (*P* < 0.05). As shown in Figure 10, the tumor growth curves indicate the significant growth inhibition in MGC-803/Cdx2 siRNA cells (*P* < 0.05). Densitometric analysis showed that Cdx2 mRNA expression in MGC-803/Cdx2 siRNA cells (0.305 ± 0.053) was lower than that in MGC-803 cells (1.524 ±

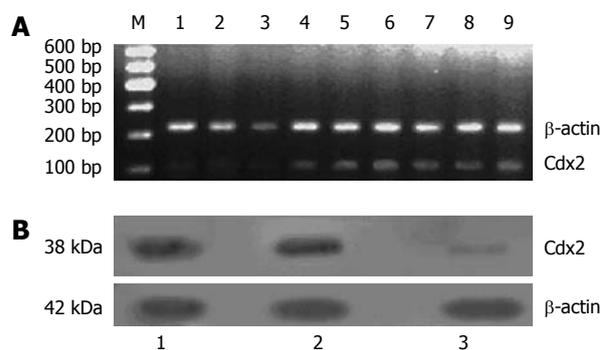

**Figure 9** Cdx2 small interference RNA significantly increased phosphatase and tensin homolog, cleaved caspase-9 and cleaved caspase-3 protein concentrations while pro-caspase-9 and pro-caspase-3 are decreased. **A:** Western blotting analysis. Whole protein extracts (100  $\mu$ g in each) were prepared from MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells. The expression of phosphatase and tensin homolog (PTEN), pro-caspase-9, p37 cleaved caspase-9, pro-caspase-3, and p17 cleaved caspase-3 was determined by Western blotting with an anti-PTEN, pro-caspase-9, cleaved caspase-9, pro-caspase-3 and cleaved caspase-3 antibody. The glyceraldehyde-3-phosphate dehydrogenase (GAPDH) protein expression levels were determined as a control for equivalent protein loading. Lane 1: MGC-803 group; Lane 2: MGC-803/Cdx2 negative control group; Lane 3: MGC-803/Cdx2 siRNA group; **B:** PTEN, pro-caspase-9, p37 cleaved caspase-9, pro-caspase-3 and p17 cleaved caspase-3 protein levels were measured at three groups, normalized to those of GAPDH and presented as mean  $\pm$  SE. \* $P < 0.05$  for MGC-803/Cdx2 siRNA group vs MGC-803 and MGC-803/Cdx2 negative control group.

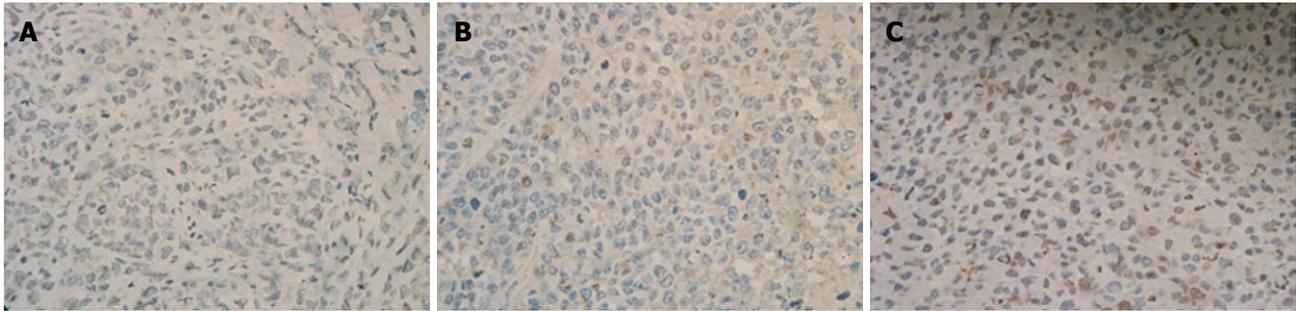

**Figure 10** Tumor growth curve showed a significant growth tendency in MGC-803 cells and in MGC-803/Cdx2 negative control cells, while the tumor growth in MGC-803/Cdx2 small interference RNA cells was obviously inhibited. MGC-803 cells, MGC-803/Cdx2 negative control cells and MGC-803/Cdx2 small interference RNA (siRNA) cells were implanted subcutaneously into the flanks of the nude mice. The relative tumor volume (RTV) of nude mice in each group were presented. Each time point represented the mean of RTV for each group; \* $P < 0.05$  for MGC-803/Cdx2 siRNA group vs MGC-803 and MGC-803/Cdx2 negative control group.

0.323) and MGC-803/Cdx2 negative control cells (1.441  $\pm$  0.269), as determined by semi-quantitative RT-PCR ( $P < 0.05$ ) (Figure 11A). In addition, the relative protein expression of Cdx2 in MGC-803/Cdx2 siRNA cells (0.134  $\pm$  0.087) also significantly decreased ( $P < 0.05$ ), when compared to MGC-803 cells (0.634  $\pm$  0.156) and MGC-803/Cdx2 negative control cells (0.569  $\pm$  0.167),

**Figure 11** Cdx2 mRNA and protein expression was suppressed in MGC-803/Cdx2 small interference RNA tumor tissue. **A:** Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) analysis. Total RNAs (2  $\mu$ g in each) extracted from tumor tissue were subjected to RT-PCR for Cdx2 and  $\beta$ -actin mRNAs. RT-PCR for  $\beta$ -actin was performed in parallel to show an equal amount of total RNA in the sample; Lanes 1-3: MGC-803/Cdx2 small interference RNA (siRNA) group; Lanes 4-6: MGC-803/Cdx2 negative control group; Lanes 7-9: MGC-803 group; M: 600 bp marker; **B:** Western blotting analysis. Equal amounts of protein extracts (100  $\mu$ g in each) were prepared from tumor tissue. The expression of Cdx2 protein was determined by Western blotting with an anti-Cdx2 antibody. The  $\beta$ -actin expression levels were determined as a control for equivalent protein loading. Lane 1: MGC-803 group; Lane 2: MGC-803/Cdx2 negative control group; Lane 3: MGC-803/Cdx2 siRNA group.

as determined by Western blotting analysis (Figure 11B). As shown in Figure 12, the percent of apoptotic tumor cells in MGC-803/Cdx2 siRNA cells was 16.7%  $\pm$  5.6%, which was more than 10.5%  $\pm$  4.1% in MGC-803/Cdx2 negative control cells and 11.2%  $\pm$  4.3% in MGC-803 cells, as determined by the TUNEL method.

**Figure 12 Cdx2 small interference RNA promoted tumor cells apoptosis.** Tumor cells were assessed for apoptosis using terminal deoxynucleotidyl transferase-mediated 2'-deoxyuridine, 5'-triphosphate nick end labeling assay. The apoptotic cells were brown-stained and counted under a optical microscope ( $\times 400$ ). A: MGC-803 group; B: MGC-803/Cdx2 negative control group; C: MGC-803/Cdx2 small interference RNA group.

## DISCUSSION

The Cdx2 homeobox gene, which is homologous to the *Drosophila* gene caudal, has an essential role during early development<sup>[4]</sup>. In adults, Cdx2 expression is restricted to intestinal epithelial cells. Overexpression of Cdx2 in human colon cancer cells induces a less malignant phenotype, inhibiting proliferation, invasion, and migration<sup>[16]</sup>, and Cdx2 expression is progressively reduced in gastric cancer<sup>[17]</sup>. Moreover, heterozygous-null Cdx2 mice are more sensitive to azoxymethane-induced colonic adenocarcinomas<sup>[18]</sup>, and mice that are compound heterozygotes for Cdx2 and the tumor suppressor Adenomatous Polyposis Coli (Apc) developed more adenomatous polyps in the colon than their heterozygous Apc littermates<sup>[19]</sup>. These studies suggested that Cdx2 is a putative tumor suppressor.

However, other reports have shown that Cdx2 plays a pivotal role in the development of intestinal metaplasia<sup>[20,21]</sup>. The implication of Cdx2 in intestinal metaplasia has been demonstrated in intestinal metaplasia of the stomach where Cdx2 was ectopically overexpressed, suggesting that it could play a major role during intestinal metaplasia formation in the stomach<sup>[21]</sup>. Intestinal metaplasia is a precursor of intestinal-type gastric adenocarcinoma. Long-term intestinal metaplasia induced gastric adenocarcinoma in the Cdx2-transgenic mouse stomach, and no significant changes were noted in wild-type littermates<sup>[14]</sup>. The tumor incidence was 100% at 100 wk after birth<sup>[15]</sup>. It can thus be concluded that Cdx2-induced intestinal metaplasia itself is a precancerous lesion leading to gastric carcinoma. Furthermore, Cdx2 is overexpressed in most colorectal tumors compared to matched normal mucosa in adults<sup>[7]</sup>. Dang *et al.*<sup>[22]</sup> showed that Cdx2 does not suppress tumorigenicity in the human gastric cancer cell line, MKN45. It can be concluded that, in contrast to the prevailing paradigm, Cdx2 does not serve as a tumor suppressor in the development of most sporadic colorectal tumors. Rather, in the context of earlier observations of its role in promoting the neoplastic phenotype in some cells and tissues, many observations suggest the intriguing possibility that Cdx2 could serve as an oncogene in the gastrointestinal

tract<sup>[9,23]</sup>. This suggests that the level of Cdx2 expression may contribute to its function<sup>[9]</sup>, thereby raising the possibility that intervening with Cdx2 expression in gastric cancer cells with RNA interference may control their growth rate.

Our study indicated that Cdx2 siRNA led to remarkable inhibition of Cdx2 mRNA and protein expression in MGC-803 cells, inhibited cell growth, caused cell cycle arrest in the G0/G1 phase, and induced cell apoptosis. Furthermore, RNAi-directed targeting of Cdx2 in MGC-803 cells reduced the capability of cell motion, invasion, and colony formation. Moreover, a strong anti-tumor effect of Cdx2-siRNA *in vivo* was observed, as tumor growth was suppressed and tumor apoptosis was increased in nude mice when Cdx2 mRNA and protein was silenced by Cdx2 siRNA. These findings suggest that Cdx2 has tumorigenic potential in the human gastric cancer cell lines MGC-803.

However, our previous study showed that Cdx2 overexpression in human gastric cancer MGC-803 cells produce similar results as Cdx2 siRNA<sup>[24]</sup>. Moreover, Cdx2 overexpression was associated with cell cycle arrest in the G0/G1 phase which was the same as Cdx2 siRNA. This suggests that Cdx2 plays a double role in the regulation of MGC-803 cell growth and death. Thus, we can only speculate on potential explanations for these observed contrasts. First, appropriate activity and expression levels of Cdx2 are necessary for the normal cell cycle, even in promoting tumor proliferation and regression. Just like E2F-1, both the upregulation and downregulation of E2F-1 can suppress human gastric cancer MGC-803 cell growth *in vitro*<sup>[25,26]</sup>. Second, these two conflicting results may involve different mechanisms. Our previous data showed that overexpression of Cdx2 inhibits MGC-803 cell progression *via* the Wnt signaling pathway (unpublished data). In this result, PTEN, caspase-9 and caspase-3 expression were all increment when Cdx2 was downregulated. The PTEN protein product is a lipid phosphatase that antagonizes PI3K function and consequently inhibits downstream signaling transduction through Akt<sup>[27]</sup>. Caspase-9, a member of the protease family, is intimately associated with the initiation of apoptosis, and is thought to be activated while

Akt is inhibited<sup>[28]</sup>. Activated caspase-9 is able to cleave caspase-3 *in vitro*, leading to apoptosis<sup>[29]</sup>. Therefore, in the present study, inhibition of Cdx2 expression may increase PTEN expression directly or indirectly, leading to activation of caspase-9 and caspase-3 *via* the PI3K/Akt signaling pathway, which is responsible for inhibition of MGC-803 cell growth *in vitro* and *in vivo*. Further studies are needed to confirm our results.

Gastric cancer is a worldwide problem. Besides the undetermined etiological factors, there are also limitations in surgery, chemotherapy and radiotherapy, which to date, are the major therapies for gastric cancer<sup>[30]</sup>. Many patients lose the chance of surgery because of their systemic condition, while many cannot tolerate the side effects of chemotherapy or radiotherapy. It is important to find a new way to effectively inhibit cancer cell growth and avoid the side effects of drugs or radioactive rays. Gene target therapies have proved to be a promising way to achieve this goal<sup>[26]</sup>. In this study, we showed that Cdx2 plays a critical role in gastric cancer cell proliferation, invasion, and apoptosis. The down-regulation of Cdx2 using RNAi successfully reduced the progression of gastric cancer MGC-803 cells *in vitro* and *in vivo*. In conclusion, this study lays the foundation for treatment of gastric cancer through manipulation of Cdx2 expression.

## COMMENTS

### Background

Gastric cancer is a worldwide problem. Besides the undetermined etiological factors, there are also limitations in surgery, chemotherapy and radiotherapy, which to date, are the major therapies for gastric cancer. It is important to find a new way to effectively inhibit cancer cell growth and avoid the side effects of drugs or radioactive rays. Gene target therapies have proved to be a promising way to achieve this goal. The caudal-type homeobox gene, Cdx2, plays an important role in intestinal metaplasia, and is a precursor of intestinal-type gastric carcinoma. However, the effect of Cdx2 in gastric cancer is still not very clear.

### Research frontiers

Cdx2 plays important roles in early differentiation, proliferation and maintenance of intestinal epithelial cells. The role of Cdx2 as an oncogene or a tumor suppressor gene is still in dispute at the present time. The Cdx2 research hotspot is how it affect the progression of human cancer.

### Innovations and breakthroughs

This study for the first time demonstrated that Cdx2 small interference RNA (siRNA) significantly inhibited cell growth and proliferation, blocked entry into the S-phase of the cell cycle, induced cell apoptosis, and reduced the motility and invasion of MGC-803 cells. Cdx2 siRNA also increased phosphatase and tensin homolog expression, and activated caspase-9 and caspase-3 in MGC-803 cells *in vitro* as determined by reverse transcription polymerase chain reaction and Western blotting analysis. In addition, siRNA targeting of Cdx2 inhibited the growth of MGC-803 cells and promoted tumor cell apoptosis *in vivo* in nude mice tumor models.

### Applications

This study lays the foundation for treatment of gastric cancer through manipulation of Cdx2 expression.

### Terminology

The transcription factor, Cdx2, is a member of the caudal-related homeobox gene family, and is mainly expressed in the intestine. It is also known to be a key factor in the development of intestinal metaplasia.

### Peer review

In this study, the authors constructed recombinant pSilencer 4.1-Cdx2 siRNA

plasmids and transfected them into human gastric cancer MGC-803 cells *in vitro*. The authors demonstrated that Cdx2 siRNA led to inhibition of endogenous Cdx2 mRNA and protein expression and Cdx2 siRNA significantly inhibited cell growth and proliferation, blocked entry into the S-phase of the cell cycle, induced cell apoptosis, and reduced the motility and invasion of MGC-803 cells. The authors conclude that Cdx2 is involved in the regulation of tumor growth, proliferation, apoptosis and invasion of gastric cancer cells. Overall this is a well-conducted pilot study.

cancers were constructed into tissue microarrays. The first set consisted of 122 gastric/gastro-oesophageal cancer cases not exposed to neoadjuvant chemotherapy and the second set consisted of 97 gastric/gastro-oesophageal cancer cases exposed to pre-operative platinum-based chemotherapy. Expression of CK-18 and caspase-cleaved CK-18 was investigated using immunohistochemistry.

**RESULTS:** CK18 was commonly expressed in gastro-oesophageal tumours (92.6%). Fifty-six point seven percent of tumours previously exposed to neoadjuvant chemotherapy were positive for caspase-cleaved CK-18 expression compared to only 24.6% of tumours not previously exposed to neoadjuvant chemotherapy ( $P = 0.009$ ). In patients who received neoadjuvant chemotherapy, caspase-cleaved cytokeratin-18 expression correlated with favourable TRG response (TRG 1, 2 or 3,  $P = 0.043$ ).

**CONCLUSION:** This is the largest study to date of CK-18 and caspase-cleaved CK-18 expression in gastro-oesophageal tumours. We provide the first evidence that caspase-cleaved CK-18 predicts tumour regression with neoadjuvant chemotherapy.

### Abstract

**AIM:** To examine cytokeratin-18 (CK-18) and caspase-cleaved CK-18 expression in tumours and correlate with clinicopathological outcomes including tumour regression grade (TRG) response.

**METHODS:** Formalin-fixed human gastro-oesophageal

with neoadjuvant chemotherapy. *World J Gastroenterol* 2012; 18(16): 1915-1920 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i16/1915.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i16.1915>

## INTRODUCTION

Neoadjuvant platinum-based chemotherapy followed by surgery is the standard of care for patients with gastro-oesophageal adenocarcinoma<sup>[1,2]</sup>. However, there is an urgent need to develop predictive markers to individualize patient therapy<sup>[3]</sup>. We have recently shown that tumour regression grade (TRG) is a marker of histopathological response and tumour down-staging in tumours receiving neoadjuvant chemotherapy<sup>[4]</sup>. TRG was defined as per Mandard's criteria<sup>[5]</sup>. TRG1 (complete regression) showed absence of residual cancer and fibrosis extending through the different layers of the oesophageal wall; TRG2 was characterised by the presence of rare residual cancer cells scattered through the fibrosis; TRG3 was characterised by an increase in the number of residual cancer cells but fibrosis predominated; TRG4 showed residual cancer outgrowing fibrosis; and TRG5 was characterised by the absence of regressive changes<sup>[5]</sup>. In patients who received neoadjuvant chemotherapy (CS group), 46.7% of gastric/gastro-oesophageal junction adenocarcinomas and 45.5% of lower third oesophageal adenocarcinomas had TRG 1, 2 or 3 compared to 13.7% in patients who did not receive neoadjuvant chemotherapy but proceeded to primary surgery. In the CS group, responders (TRG 1, 2 or 3) showed significant tumour down-staging [early ypT-stage disease ( $P = 0.002$ )]. In gastric cancers specifically, additional associations were seen with negative nodal disease ( $P = 0.044$ ) and absence of vascular invasion ( $P = 0.027$ )<sup>[4]</sup>. More recently, we have also demonstrated that favourable tumour regression predicts better clinical outcomes in patients receiving neoadjuvant chemotherapy in gastro-oesophageal adenocarcinomas<sup>[6]</sup>.

The anticancer activity of chemotherapeutic agents is directly related to the induction of apoptosis in tumours. Whilst the apoptotic pathway is complex, the intrinsic mitochondrial pathway is the predominant apoptotic pathway in cancer cells. In the intrinsic pathway, the mitochondrial release of cytochrome c activates caspase-9, which in turn activates caspase-3 and caspase-7<sup>[7,8]</sup>. Among the several cellular substrates of the capsases, members of the cytokeratin family, including cytokeratin-18 (CK-18), contribute to cellular collapse and apoptosis. Caspase-cleaved CK-18 is a specific marker of epithelial cell death and correlates with apoptosis in gastrointestinal epithelial cancers<sup>[9-11]</sup>.

In the current study we have evaluated full length CK-18 and caspase-cleaved CK-18 protein expression using immunohistochemistry. We show for the first time that caspase-cleaved CK-18 expression in tumours correlates with histopathological tumour regression in early stage gastro-oesophageal adenocarcinomas.

## MATERIALS AND METHODS

### Patients

We identified patients referred to our centre with resectable gastric, gastro-oesophageal junction (GOJ) and lower third oesophageal adenocarcinomas between January 2001 and May 2008. GOJ tumours were defined as per Siewert's classification<sup>[12]</sup>. The Union for International Cancer Control TNM staging system for oesophageal and gastric cancer was used in this study. The study was approved by the Ethics Committee of Nottingham University Hospitals.

### Construction of tissue micro-array

Tissue micro-arrays (TMAs) were constructed. In brief, HE-stained slides (5  $\mu\text{m}$ ) were used to identify and mark out representative areas of viable tumour tissue. Then 0.6 mm-diameter needle core biopsies from the relevant areas of corresponding paraffin-embedded blocks were placed at defined coordinates in the recipient paraffin array blocks using a tissue microarrayer (Beecher Instruments, Sun Prairie, WI). Array blocks were constructed at a density of 80-150 cores per array. Two broad sets of TMA blocks were constructed. An array set of 97 patient cores to include gastric and gastro-oesophageal tumours that had received neoadjuvant chemotherapy and an array set of 122 cores of patients who had received no neoadjuvant chemotherapy were constructed. These TMA blocks were constructed in triplicate, each containing one sample from a different region of the tumour.

### Immunohistochemistry

A standard streptavidin-biotin complex technique was used. In brief, 5  $\mu\text{m}$  TMA sections were deparaffinised with xylene and rehydrated through graded alcohol. Endogenous peroxidase was blocked with 0.3% hydrogen peroxide in methanol for 20 min. Antigen retrieval was carried out by microwave treatment of the slides in sodium citrate buffer (pH 6) for 10 min at 750 W followed by 10 min at 300 W. The slides were rinsed in phosphate buffer saline (PBS) and incubated with Vectastain blocking serum diluted in PBS to block non-specific absorption. The slides were incubated for 30 min with the primary antibody M30 to detect caspase-cleaved CK-18 (Peviva, Bromma, Sweden) at a dilution of 1:75 and primary antibody M6 to detect full length CK-18 (Peviva, Bromma, Sweden) at a dilution of 1:150 at room temperature. After washing with PBS, sections were incubated with secondary antibody (Vectastain) for 30 min followed by avidin-biotin complex for a further 30 min. 3-3' Diaminobenzidine tetrahydrochloride was used as a chromogen. All sections were counterstained with Gill's haematoxylin, dehydrated and mounted using DPX (a mixture of disterene, plasticizer, and xylene; Sigma).

### Evaluation of staining

Evaluation of staining was performed with the observer blinded to the corresponding clinicopathological data. For

full length CK-18 expression, cytoplasmic expression in cancer cells was considered positive. For caspase-cleaved CK-18 expression, TMA cores from tumour showing any positively stained apoptotic cells were considered positive. Caspase-cleaved CK-18 positive apoptotic cells were counted in TMA cores and the total number of positive cells from each tumour was taken as the number of positive cells.

### Statistical analysis

All statistical analyses were carried out using SPSS package (version 15 for Windows, SPSS, Inc.). Associations between categorical variables were examined using cross-tabulation and the Pearson  $\chi^2$  test. Kaplan Meier curves were derived to assess disease-specific survival, and the significance of differences in disease-specific survival between groups was calculated using the log-rank test. Patients whose death related to their oesophago-gastric cancer were considered in the disease-specific survival calculations. This was determined by death certification entries. Deaths resulting from non-oesophago-gastric cancer-related causes were censored. Survival rates were calculated from the date of diagnosis until the 13th January 2009, when any remaining survivors were censored

and Kaplan Meier curves were plotted. In all cases,  $P < 0.05$  was considered statistically significant.

## RESULTS

### Patient demographics

There were 2 groups of patients: those who received neoadjuvant chemotherapy (neoadjuvant group) and those who underwent primary surgery only (primary group). There were 97 patients in the neoadjuvant group with a median age of 64 years; 76% ( $n = 74$ ) were male and 51.5% ( $n = 50$ ) of cases were T3 tumours. There were 122 cases in the primary group with a median age of 74.5 years; 75.4% ( $n = 92$ ) were male and 53.2% ( $n = 65$ ) had T3 tumours. Patients in the primary surgery group did not receive any adjuvant chemotherapy after surgery. In the neoadjuvant group, 78% of patients had received all the planned three cycles of neoadjuvant ECF/ECX chemotherapy (adenocarcinomas) and 96.4% had received all the planned two cycles of neoadjuvant CF chemotherapy (squamous cell carcinomas). Of the patients who received all three cycles of ECF/ECX chemotherapy, 42% went on to receive a further three cycles of ECF/ECX chemotherapy. There was no significant difference between the primary surgery group and the perioperative chemotherapy group (gastric/GOJ) with regards to T stage [T2 (33.6% *vs* 29.8%), T3 (53.2% *vs* 51.5%)] and N stage [N0 (26.2% *vs* 31.9%),  $> N0$  (73.8% *vs* 68.1%)]. Only adenocarcinomas were included in the immunohistochemical and survival analyses in this study (Table 1).

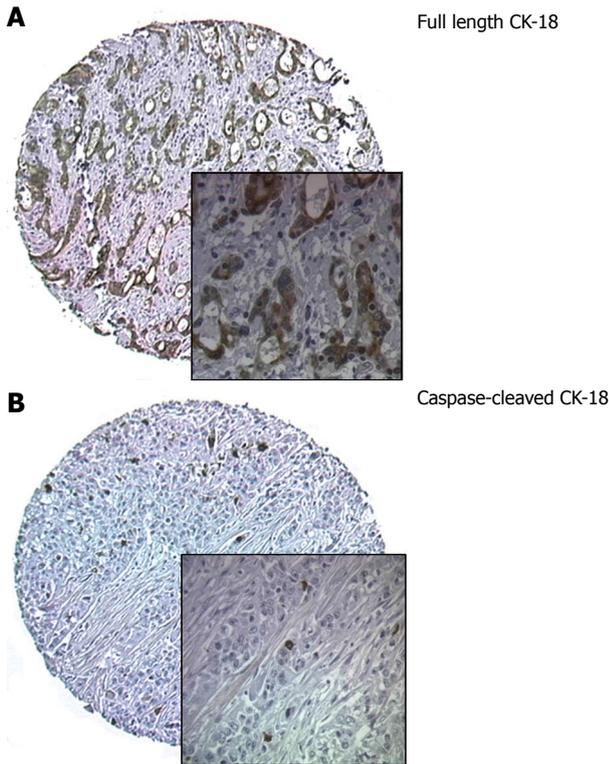

### Full length cytokeratin-18 expression

All 122 tumours in the primary surgery group were available for CK-18 analyses. One hundred and thirteen tumours stained positive for CK-18 (92.6%) (Figure 1A) and 9 cores were negative for CK-18 expression. There was no statistically significant correlation between tumour differentiation, T stage, N stage, vascular/perineural invasion, resection margin involvement and full length CK-18 expression in tumours.

### Caspase-cleaved cytokeratin-18 expression

All tumours were suitable for caspase-cleaved CK-18 expression analyses (Figure 1B). In tumours previously exposed to neoadjuvant chemotherapy (neoadjuvant TMA,  $n = 97$ ), 56.7% of tumours (55/97) were positive compared to 24.6% (30/122) of tumours not previously exposed to neoadjuvant chemotherapy (primary TMA). This was statistically significant ( $P = 0.009$ ). The mean total number of caspase-cleaved CK-18 positive cancer cells per tumour was 4.16 in the neoadjuvant group (range: 1-92) compared to 2.7 in the primary surgery group (range: 1-51).

We have previously demonstrated that TRG as assessed using Mandard's criteria is a useful tool to assess response to neoadjuvant chemotherapy in gastro-oesophageal adenocarcinomas; favourable TRG correlated with tumour down-staging in that study<sup>[4]</sup>. In the current study we

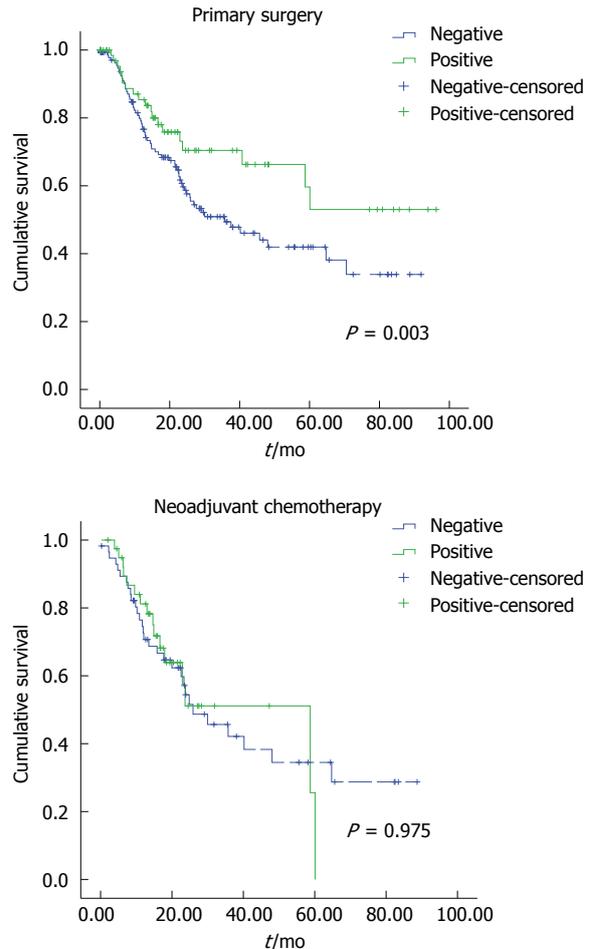

**Figure 1** Immunohistochemical staining of full length cyokeratin-18 and caspase-cleaved cyokeratin-18. A: Immunohistochemical staining of full length cyokeratin-18 (CK-18) showing strong cytoplasmic staining; B: Immunohistochemical staining for caspase-cleaved CK-18. Cores from tumour showing positively-stained apoptotic cells. Original magnification  $\times 100$ ; insets  $\times 400$ .

Caspase-cleaved CK-18	TRG1, TRG2, TRG3	TRG4, TRG5	Total
Negative	10 (23.8)	32 (76.2)	42 (100)
Positive	24 (43.6)	31 (56.4)	55 (100)
Total	34 (35.1)	63 (64.9)	97 (100)

CK-18: Cyokeratin-18; TRG: Tumour regression grade.

evaluated whether caspase-cleaved CK-18 expression correlated with TRG. We found that 43.6% of tumours that were positive for caspase-cleaved CK18 also had a favourable tumour response (TRG 1-3) compared to 23.8% that were negative for caspase-cleaved CK-18 expression (Table 2). This was statistically significant ( $P = 0.043$ ). There was no statistically significant correlation between tumour differentiation, T stage, N stage, vascular/perineural invasion, resection margin involvement and caspase-cleaved CK-18 positivity.

Clinicopathological correlations were also observed in tumours not exposed to neoadjuvant chemotherapy. Well-differentiated tumours were more likely to be caspase-cleaved CK-18 positive (62.5%) compared to poor- and moderately-differentiated tumours which were only positive in 23.6% and 19% of tumours respectively ( $P = 0.031$ ). However, no differences between T, N stage, vascular/perineural invasion, resection margin involvement

**Figure 2** Kaplan Meier curves representing the relationship between caspase-cleaved cyokeratin-18 and disease-specific survival. A: In months from time of diagnosis in patients who received primary surgery only; B: In patients who received neoadjuvant chemotherapy.

and caspase-cleaved CK-18 positivity were observed. Regarding patients who had not received neoadjuvant chemotherapy, Kaplan Meier plot showed that in patients whose tumours stained positive for caspase-cleaved CK-18, a longer disease-specific survival was observed compared to patients whose tumours were negative (mean 84 mo *vs* 51 mo,  $P = 0.003$ ) (Figure 2). However, in patients who had received neoadjuvant chemotherapy, no statistically significant differences were observed (mean 37.3 mo *vs* 41.6 mo,  $P = 0.975$ ) (Figure 2).

Those factors found to be significant in univariate analyses were also included in a multivariate logistic regression analysis to estimate the independent effect of each factor after adjusting for the contributions of other factors. There was no one factor in the cohort of patients studied that showed significance on multivariate analysis (Table 3).

## DISCUSSION

The ability to predict response to chemotherapy and individualize patient treatment is a high priority in gastro-oesophageal adenocarcinomas. Whilst the role of multi-

modality therapy in improving patient outcomes is well established, these treatments are toxic and have a considerable impact on patient morbidity. In the United Kingdom, neoadjuvant chemotherapy followed by surgery is routinely offered to patients who are fit with no significant co-morbidities. Accordingly, these patients generally tend to be young and can tolerate toxic chemotherapy. Patients considered not suitable for chemotherapy are usually elderly with significant co-morbidities. Moreover, until 2006 in the United Kingdom, the standard treatment for patients with early stage gastro-oesophageal adenocarcinoma was surgery only and patients were not routinely offered adjuvant chemotherapy. With the publication of results from a large United Kingdom trial of perioperative chemotherapy<sup>[1]</sup>, neoadjuvant chemotherapy was established as a standard treatment option for patients. This is reflected in the differences in mean age between the two groups in our study.

In the current study we have evaluated the potential role of full length CK-18 and caspase-cleaved CK-18 as biomarkers in gastro-oesophageal adenocarcinomas. To evaluate the prognostic significance of full length CK-18 in gastro-oesophageal adenocarcinomas, we first evaluated CK-18 expression in tumours not exposed to neoadjuvant chemotherapy ( $n = 122$ ). We found that CK-18 was commonly expressed in tumours. This is consistent with a previously reported study<sup>[13]</sup>. Although Xu *et al*<sup>[13]</sup> demonstrated that CK18 mRNA expression correlated with lymph node metastasis and tumour differentiation in gastric cancer, we were unable to demonstrate any positive clinicopathological correlations in our study.

Caspase-cleaved CK-18 has recently emerged as a promising marker of apoptosis in gastrointestinal cancers<sup>[11]</sup>. We therefore evaluated caspase-cleaved CK-18 expression in gastro-oesophageal adenocarcinomas. Fifty-six point seven percent of tumours previously exposed to neoadjuvant chemotherapy were positive for caspase-cleaved CK-18 expression, compared to only 24.6% of tumours not previously exposed to neoadjuvant chemotherapy ( $P = 0.009$ ). This provides direct evidence that chemotherapy exposure leads to apoptosis-induced increased caspase-cleaved CK-18 expression in gastro-oesophageal tumours. We then demonstrated, for the first time, that the caspase-cleaved CK-18 expression correlated well with favourable tumour regression in patients receiving neoadjuvant chemotherapy ( $P = 0.043$ ). Factors found to be significant in univariate analyses were not significant in a multivariate logistic regression analysis. This may be because the current study is a small retrospective study and a larger prospective study is required to confirm our observations. However, our study provides evidence that caspase-cleaved CK-18 may be a promising predictive biomarker in gastro-oesophageal adenocarcinomas. Moreover, our study also supports a rational hypothesis for evaluating serial blood caspase-cleaved CK18 secretion, using a recently developed assay<sup>[11,14,15]</sup>, as a promising non-invasive biomarker in operable gastro-oesophageal adenocarcinomas where patients routinely receive three cycles of platinum-based neoadjuvant chemotherapy<sup>[1,2]</sup>. In a recent study of advanced colorectal cancer, serum levels of caspase-cleaved CK18 were significantly higher in patients who responded to chemotherapy compared to those who did not<sup>[11]</sup>. Similar results were also reported in advanced colorectal, oesophageal and gastric adenocarcinoma patients receiving palliative chemotherapy<sup>[16]</sup>. Although these results are promising, whether tumour tissue and serum caspase CK-18 levels are related to each other is not clear. Moreover, whether similar results could be achieved in early stage gastro-oesophageal adenocarcinoma patients receiving neoadjuvant chemotherapy is an area of ongoing investigation in our laboratory.

We also made interesting clinicopathological observations in tumours not exposed to chemotherapy. Caspase-cleaved CK18 expression correlated with better differentiation and improved survival in this group. Although the reason for this unexpected finding is not clear, whether host immune factors such as lymphocytic infiltration could contribute to cancer cell death is currently unknown and is an area of ongoing investigation.

In summary, we have conducted a study of full length CK-18 and caspase-cleaved CK-18 expression in gastro-oesophageal cancer. We provide evidence that caspase-cleaved CK-18 is a promising predictive biomarker in patients who receive platinum-based neoadjuvant chemotherapy.

## COMMENTS

### Background

Neoadjuvant chemotherapy followed by surgery is a standard treatment option in patients with early stage gastro-oesophageal adenocarcinomas. However, only 40% of patients respond to chemotherapy. There is an urgent need to develop predictive biomarkers.

### Research frontiers

Development of a serum biomarker test that can predict response to chemotherapy is highly desirable in gastro-oesophageal adenocarcinomas.

### Innovations and breakthroughs

Cytokeratin-18 (CK-18) is commonly expressed in epithelial tumours. Caspase-cleaved CK-18 is expressed in cancer cells undergoing apoptosis following chemotherapy. Caspase-cleaved CK-18 is also secreted by tumour cells and can be evaluated using a blood test. In early stage gastrooesophageal cancers, the authors show that caspase-cleaved CK-18 is prevalent in tumour tissue following chemotherapy and that this correlates with tumour regression. The study suggests that serum testing of caspase-cleaved CK-18 may be feasible to predict response in early stage gastro-oesophageal adenocarcinomas.

### Applications

A prospective study of serial serum testing of caspase-cleaved CK-18 elevation and correlation with tumour response to chemotherapy is required to evaluate CK-18 as a promising predictive biomarker in early stage gastro-oesophageal adenocarcinomas.

### Terminology

CK-18 is widely expressed in epithelial cancers. Caspase-cleaved CK-18: in epithelial cells undergoing apoptosis, caspase-cleaved CK-18 is expressed and can be detected by immunohistochemistry.

### Peer review

This is a study to evaluate whether caspase-cleaved CK-18 can predict response to chemotherapy in gastro-oesophageal adenocarcinomas receiving neoadjuvant chemotherapy. Data presented here support a rational hypothesis to test if secretion of caspase-cleaved CK-18 in blood can be used as a marker of response to chemotherapy in patients.

### Abstract

**AIM:** To investigate the mucosal morphology in Barrett's oesophagus by chromo and magnifying endoscopy.

**METHODS:** A prospective pilot study at a tertiary medical centre was conducted to evaluate the use of acetic acid pulverisation combined with virtual chromoendoscopy using Fujinon intelligent chromoendoscopy (FICE) for semiological characterization of the mucosal morphology in Barrett's oesophagus and its neoplastic complications. Upper endoscopy using high definition white

light, 2% acid acetic pulverisation and FICE with high definition videoendoscopy were performed in 20 patients including 18 patients who presented with aspects of Barrett's oesophagus at endoscopy examination. Two patients used as controls had normal endoscopy and histological results. Prospectively, videos were watched blind from histological results by three trained FICE technique endoscopists.

**RESULTS:** The videos of patients with high-grade dysplasia showed an irregular mucosal pattern in 14% using high definition white light endoscopy and in 100% using acid acetic-FICE combined. Videos did not identify irregular vascular patterns using high definition white light endoscopy, while acid acetic-FICE combined visualised one in 86% of cases.

**CONCLUSION:** Combined acetic acid and FICE is a promising method for screening high-grade dysplasia and early cancer in Barrett's oesophagus.

## INTRODUCTION

Barrett's oesophagus is a premalignant lesion of oesophageal adenocarcinoma and endoscopic surveillance has been proposed for the diagnosis of this condition<sup>[1,2]</sup>. A stepwise four quadrant biopsy protocol is considered the gold standard procedure<sup>[3]</sup>. Current guidelines advise that biopsies should be obtained from any visible abnormality and that four random quadrant biopsies every 2 cm should be taken to detect inconspicuous dysplasia during endoscopic surveillance<sup>[4,5]</sup>. In theory, a high sensitivity endoscopic technique for the detection of high-grade dysplasia or early carcinoma is warranted and targeting biopsies and a four quadrant biopsy protocol will be unnecessary to improve Barrett's oesophagus cancer detection.

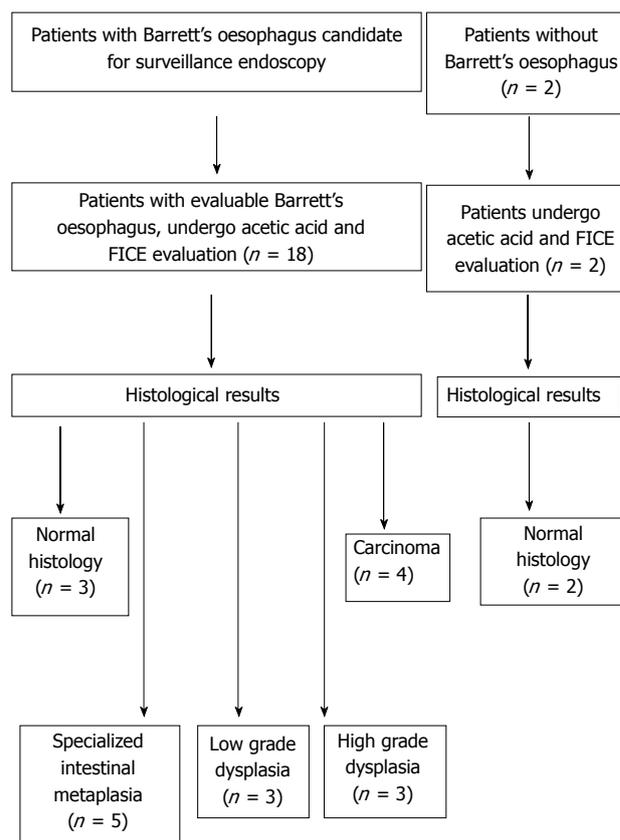

Chromoendoscopy with methylene blue, acetic acid, or virtual chromoendoscopy have been proposed to improve the detection of preneoplastic lesions of Barrett's oesophagus. Although acid acetic pulverisation improves visibility of the mucosal pattern by removing the superficial mucus and enhancing the pit pattern, virtual chromoendoscopy was developed to identify abnormalities from superficial mucosal or vascular patterns, and, therefore, facilitate diagnosis of Barrett's associated neoplasias<sup>[6,7]</sup>. Virtual chromoendoscopy using narrow band imaging (NBI) was first studied in this indication and abnormalities of pit and vascular patterns have been described<sup>[6]</sup>. Improvements in endoscopic material allows functional imaging to be incorporated, which, in turn, permits visualisation of more detail in mucosal and vascular patterns and may complement high-resolution endoscopy to increase the sensitivity of the endoscopic detection of early neoplasia in Barrett's oesophagus. Kim *et al*<sup>[8]</sup> showed that NBI was not reproducible and had a sensitivity of 89% in detecting preneoplastic lesions of Barrett's oesophagus. Virtual chromoendoscopy using Fujinon intelligent chromoendoscopy (FICE) has been shown to be a useful tool in identifying gastric lesions<sup>[9]</sup>. Pohl *et al*<sup>[10]</sup> failed to show, in a single prospective study, significant differences between FICE and acetic acid combined with conventional chromoendoscopy for the detection of high-grade dysplasia or early cancer in patients with Barrett's oesophagus. No study has shown any benefit with the combination of acetic acid and FICE. These two techniques could be complementary, since acetic acid enhances visualisation of the pit pattern and FICE allows detection of vascular abnormalities in Barrett's oesophagus. With the Pohl *et al*<sup>[10]</sup> study in mind, we conducted a pilot study to evaluate the combination of 2% acetic acid pulverisation and FICE for semiological characterization of the mucosal morphology in Barrett's oesophagus.

These two techniques could be complementary, since acetic acid enhances visualisation of the pit pattern<sup>[11]</sup> and FICE allows detection of vascular abnormalities in Barrett's oesophagus.

## MATERIALS AND METHODS

### Ethics

All patients enrolled in this study gave written informed

**Figure 1** Patient selection for the present study. FICE: Fujinon intelligent chromoendoscopy.

consent. The study was in accordance with the Declaration of Helsinki and the Institutional review board (Centre de protection des personnes d'Ile de France III) approved the study (ref: CPP: AT102).

### Patients

The study population consisted of patients with Barrett's oesophagus, as confirmed by pathological analysis. None of the patients had received previous therapy for Barrett's oesophagus. The eligibility criteria also included a four-quadrant biopsy protocol, a standardized procedure as described above and a video record of the overall procedure. Patients were required to have at least one dysplastic lesion that could be evaluated. Data were collected retrospectively from a review of the electronic medical records and endoscopy database of our institution from November 2006 to September 2009. Eighteen patients had endoscopic Barrett's oesophagus (Figure 1). Of these patients, fifteen had specialized intestinal metaplasia, dysplasia or carcinoma and three patients had normal histology results. In addition, two patients with no history of Barrett's oesophagus or endoscopic lesions, and normal biopsies were included as controls.

### Endoscopy procedure

All explorations were performed using a high definition Fujinon 1.3-million-pixel EG 490 ZW5 gastroscope zoom with optical magnification up to 100 times equipped with

**Table 1** Clinical characteristics of patients undergoing combined acetic acid and Fujinon intelligent chromoendoscopy endoscopy

	Normal mucosa	SIM or LGD	HGD or carcinoma	All patients
Number of patients (%)	5 (25)	8 (40)	7 (35)	20

Sex (men/women)	5/0	7/1	7/0	19/1
Concomitant therapy PPI (%)	60	100	100	90
Median Barrett's oesophagus Length (cm) $\pm$ IQR	1 (0-1)	2.3 (2-3.3)	3.5 (2.5-3.6)	2 $\pm$ 1.3

SIM: Specialized intestinal metaplasia; LGD: Low-grade dysplasia; HGD: High-grade dysplasia; PPI: Proton-pump inhibitor; IQR: Interquartile range.

a short soft transparent hood by one expert endoscopist and were video recorded. In each case, videos of the oesophagus were taken before biopsies. Endoscopies were carried out following total intravenous anaesthesia of the patient using Propofol. The endoscopic technique was standardized as follows: first the oesophagus was examined with high definition white light endoscopy, followed by 6-10 mL of 2% acetic acid pulverisation, and, finally, FICE was activated. Acetic acid pulverisation was performed with a spray catheter PW-1V-1 (Olympus Optical Co., Ltd., Japan) and the endoscopist gently sucked up excess acetic acid from the oesophageal lumen before inspection. In the case of macroscopic abnormalities in colour or pit-pattern, the zoom was used with a magnification of 10-15. Videos were made with high definition white light and with the combination of acetic acid and FICE. FICE channels 4, 7 and 0 were used following previous studies using FICE in upper endoscopy<sup>[9,10]</sup>. In the case of macroscopic abnormalities, separate biopsy samples were performed and then systematic biopsies were used in "normal macroscopic areas" of Barrett's oesophagus using Radial Jaw® Single-Use Biopsy Forceps (Boston Scientific, Fremont, CA, United States) with jumbo capacity.

### Histological analysis

All biopsies were evaluated by two pathologists with extensive experience in Barrett's neoplasia, and reviewed by a third pathologist in cases of dysplasia. Histological results were classified according to the revised Vienna classification<sup>[12]</sup>. The highest grade of dysplasia obtained from any biopsy sample was used to determine the diagnosis in each patient.

### Evaluation of Barrett's oesophagus

Retrospectively, videos were watched blind from histological results by three FICE trained endoscopists. For each patient, the most severe lesion was selected for evaluation. Experts noted the characteristics of Barrett's oesophagus and any other abnormalities with and without combined

acetic acid-FICE: macroscopic appearance of the lesion using the Paris classification<sup>[12]</sup>, type of mucosal pattern (regular: ridged/villous, circular, irregular), vascular pattern characteristics (regular, irregular) using the Sharma classification<sup>[13]</sup>, raised lesion, ulcerous lesion, pigmented lesion; and spontaneous bleeding lesion. The last four items were considered on clinical findings.

### Statistical analysis

Means and standard deviations were used to summarize continuous variables with an apparently Gaussian distribution, whereas the median and the interquartile range (IQR) were used to summarize variables with a skewed distribution. Kappa statistics with their 95% confidence intervals (CI) were used to test for inter-observer agreement of the 3-step classification system using arbitrary interpretation by Landis and Koch (0, poor agreement; 0.00-0.20, slight agreement; 0.21-0.40, fair agreement; 0.41-0.60, moderate agreement; 0.61-0.80, substantial agreement; 0.80-1.00, almost perfect agreement)<sup>[14]</sup>. Because Kappa statistics can only be calculated with pair-wise observations, Kappa values were calculated for all pair-wise combinations obtained by the observers.

## RESULTS

### Patient characteristics

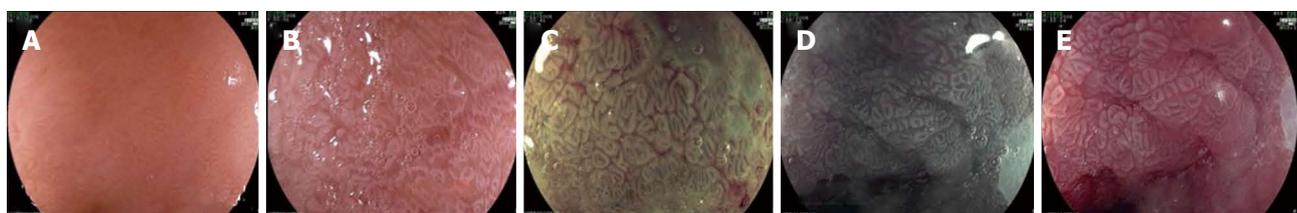

Twenty patients were included. The patients' characteristics are shown in Table 1. Histological results were normal histology, specialized intestinal metaplasia, low-grade dysplasia, high-grade dysplasia, and carcinoma in 25%, 25%, 15%, 15%, and 20%, respectively. With high definition white light endoscopy, abnormalities in mucosal or vascular pattern were detected in one patient (6%) out of the 18 patients with suspected Barrett's oesophagus. With combined acetic acid-FICE, seven patients (39%) out of the 18 with suspected Barrett's oesophagus had a visible irregular mucosal pattern (Table 2). All of these patients had high-grade dysplasia or carcinoma (sensitivity: 100%). With combined acetic acid-FICE, six patients (33%) out of the 18 with suspected Barrett's oesophagus had a visible irregular vascular pattern. All had high-grade dysplasia or carcinoma (sensitivity: 100%). No patient with metaplasia or low-grade dysplasia had visible irregular mucosal vascular patterns, raised lesions, or spontaneous bleeding (Figure 1).

An irregular mucosal pattern was identified in patients with high-grade dysplasia or carcinoma using high definition white light endoscopy or the combination of acetic acid-FICE in 14% and 100%, respectively. An irregular vascular pattern was identified in patients with high-grade dysplasia or carcinoma using high definition white light endoscopy or the combination of acetic acid-FICE in 0% and 86%, respectively (Figures 2 and 3). An irregular mucosal or vascular pattern was not identified in patients without high-grade dysplasia or carcinoma using the combination of acetic acid and FICE (specificity 100%).

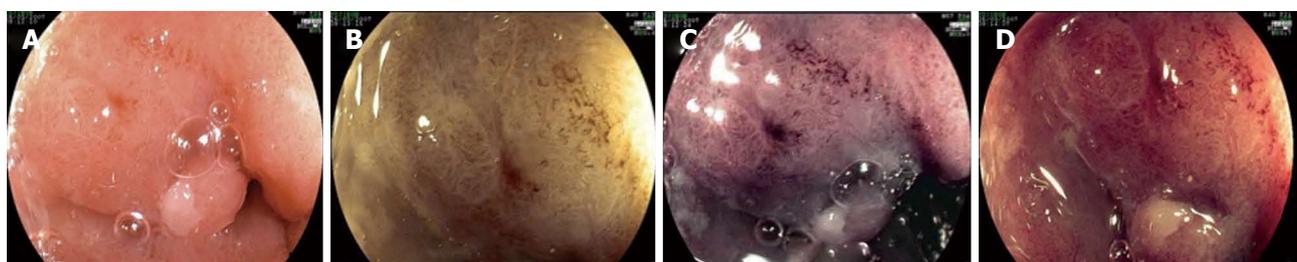

**Table 2** Correlation of the predominant mucosal and vascular patterns with histological results during high resolution white light endoscopy or after 2% acetic acid pulverisation and Fujinon intelligent chromoendoscopy 0, 4 and 7

	High resolution white light			Acetic acid pulverisation and FICE		
	Normal histology	SIM or LGD	HGD or carcinoma	Normal histology	SIM or LGD	HGD or carcinoma
Number of patients (%)	5	8	7	5	8	7
Regular or not visualized mucosal pattern <sup>1</sup> (%)	100	100	86	100	100	0
Irregular mucosal pattern (%)	0	0	14	0	0	100
Regular or not visualized vascular pattern <sup>1</sup> (%)	100	100	100	100	100	14
Abnormal blood vessels (%)	0	0	14	0	0	86
Raised lesion (%)	0	0	14	0	0	71

FICE: Fujinon intelligent chromoendoscopy; SIM: Specialized intestinal metaplasia; HGD: High-grade dysplasia; LGD: Indicate Low grade dysplasia. <sup>1</sup>Endoscopists were not able to exactly classify the mucosal pattern according to Sharma's classification of mucosal pattern due to lack of visibility, but they judged that the mucosa was regular.

**Figure 2** Acetic acid and Fujinon intelligent chromoendoscopy image of the oesophagus. Specialized intestinal metaplasia using high definition white light (A), 2% acetic acid (B), and the combination of acetic acid with Fujinon intelligent chromoendoscopy (FICE) 4 (C), FICE 0 (D) and FICE 7 (E).

**Figure 3** Acetic acid and Fujinon intelligent chromoendoscopy image of an oesophageal carcinoma. Irregular pit pattern and abnormal vascularisation is shown with 2% acetic acid (A), or following the combination of acetic acid and Fujinon intelligent chromoendoscopy (FICE) 4 (B), FICE 0 (C) and FICE 7 (D).

Among the 7 patients with high-grade dysplasia, 4 patients (57%) presented with early carcinoma on biopsy. The sizes of the lesions were 1 cm, 0.5 cm and 0.4 cm. The lesion size was not recorded in one patient. All patients underwent a mucosectomy within 2 mo of the primary endoscopy.

Definitive histological staging was intramucosal carcinoma (pT1m) for 3 of 4 patients following mucosectomy histological analysis, and resection margins were healthy. Only high-grade dysplasia was found in the fourth patient.

**Interobserver agreement for mucosal morphology**

When the evaluations by the experts were grouped together, the interobserver agreement for mucosal morphology assessed on high definition white light images was substantial on 5 items (mucosal pattern:  $\kappa = 0.97$ , raised lesion:  $\kappa = 1.00$ , pigmented lesion:  $\kappa = 1.00$ , bleeding lesion:  $\kappa = 1.00$ , and ulcerous lesion:  $\kappa = 1.00$ ) and

moderate on 2 items (vascular pattern:  $\kappa = 0.73$ , abnormal blood vessels:  $\kappa = 0.76$ ). There was no difference in interobserver agreement between high definition white light images and combined acetic acid-FICE images, except for 3 evaluations (abnormal blood vessels, vascular pattern and pigmented lesion). In the evaluation of abnormal blood vessels using high definition white light images, the interobserver agreement ( $\kappa = 0.76$ ; 95% CI: 0.64-1.00) was lower than that of combined acetic acid-FICE images ( $\kappa = 0.91$ ; 95% CI: 0.86-1.00). In the evaluation of vascular pattern using high definition white light images, the interobserver agreement ( $\kappa = 0.73$ ; 95% CI: 0.64-0.91) was lower than that of combined acetic acid-FICE images ( $\kappa = 0.83$ ; 95% CI: 0.76-0.88). In the evaluation of pigmented lesion using high definition white light images, the interobserver agreement ( $\kappa = 1.00$ ; 95% CI: 0.64-1.00) was better than that of combined acetic acid-FICE images ( $\kappa = 0.37$ ; 95% CI: 0.28-0.54).

## COMMENTS

### Background

Barrett's oesophagus is a pre-neoplastic lesion with an estimated rate of transformation to carcinoma of approximately 0.3%-0.6% each year. Guidelines from the American College of Gastroenterology proposed a surveillance programme to detect high-grade dysplasia or carcinoma in Barrett's oesophagus. This screening programme recommends performing 4 quadrant biopsies every 2 cm at 1 year in low-grade dysplasia and every 3 mo in high-grade dysplasia.

### Research frontiers

Acetic acid pulverisation is a simple and inexpensive method of improving visibility of the pit pattern, but does not allow appreciation of the vascular pattern. Acetic acid instillation increased the detection of cancer compared to white light endoscopy with or without high resolution endoscopy. Whereas acetic acid instillation, indigo carmine chromoendoscopy, narrow-band imaging and chromoendoscopy by Fujinon intelligent chromoendoscopy (FICE) seem to be interesting new techniques, each technique alone seems to be insufficient to warrant abandonment of the Seattle protocol of multiple blind sample biopsies. The authors showed significant differences between FICE and chromoendoscopy with acetic acid for the detection of high-grade dysplasia or early cancer in patients with Barrett's oesophagus. Both the acetic acid and FICE techniques showed separate per-lesion sensitivity of up to 87% for the detection of high-grade neoplasia and early cancer in patients with Barrett's oesophagus. The authors conducted a video study to evaluate the combined acetic acid and FICE technique.

### Innovations and breakthroughs

Virtual chromoendoscopy has begun to receive greater attention as a potential technique in the diagnosis of Barrett's oesophagus. In the series, the study highlight the positive effect of the combination of acetic acid and virtual chromoendoscopy. The study confirms the usefulness of FICE technique combined with acetic acid using video reviews. However, the generalization of the results is made difficult by the author's small population size. Therefore, a larger study is warranted to confirm the author's results. The data suggest a high sensitivity and specificity with this combination, however, data are lacking on a real-time basis rather than relying on subsequent video reviews. The report, for the first time, on the benefit of the combination of acetic acid and FICE in identifying high-grade dysplasia or early oesophageal neoplasia.

### Applications

By using the presented procedure of acetic acid and FICE, this may represent a future strategy for the diagnosis of Barrett's oesophagus lesions. In the study, taking into account two criteria (irregular mucosal and/or vascular patterns), 100% of patients with high-grade dysplasia or carcinoma were identified by endoscopy, with no errors in the diagnosis of high-grade dysplasia or carcinoma. The study showed that combined acetic acid and FICE had a positive benefit in the identification of high-grade dysplasia or carcinoma. By combining the two techniques of acetic acid and FICE, the results showed improvement in the quality of endoscopic images obtained and visualisation of both mucosal and vascular patterns or irregularities. The endoscopic detection of high-grade dysplasia or carcinoma was enhanced by this combination method as compared to using high definition white light imaging alone. In order to further verify the high sensitivity and specificity findings in this study, future prospective multi-centre studies of patients presenting for endoscopic evaluation of Barrett's oesophagus with all levels of early neoplasia are required to definitively compare the combination imaging algorithm of acetic acid and FICE to Seattle Protocol random biopsies.

### Peer review

This is an interesting study, which adds information to how to tackle detection and surveillance of Barrett's esophagus.

### Abstract

**AIM:** To identify the factors associated with overall survival of elderly patients with hepatocellular carcinoma (HCC).

**METHODS:** A total of 286 patients with HCC (male/female: 178/108, age: 46-100 years), who were diagnosed and treated by appropriate therapeutic procedures between January 2000 and December 2010, were enrolled in this study. Patients were stratified into two groups on the basis of age: Elderly ( $\geq 75$  years old) and non-elderly ( $< 75$  years old). Baseline clinical characteristics as well as cumulative survival rates were then compared between the two groups. Univariate and

multivariate analyses were used to identify the factors associated with prolonged overall survival of patients in each group. Cumulative survival rates in the two groups were calculated separately for each modified Japan Integrated Stage score (mJIS score) category by the Kaplan-Meier method. In addition, we compared the cumulative survival rates of elderly and non-elderly patients with good hepatic reserve capacity ( $\leq 2$  points as per mJIS).

**RESULTS:** In the elderly group, the proportion of female patients, patients with absence of hepatitis B or hepatitis C viral infection, and patients with coexisting extrahepatic comorbid illness was higher (56.8% vs 31.1%,  $P < 0.001$ ; 27.0% vs 16.0%,  $P = 0.038$ ; 33.8% vs 22.2%,  $P = 0.047$ ; respectively) than that in the non-elderly group. In the non-elderly group, the proportion of hepatitis B virus (HBV)-infected patients was higher than that in the elderly group (9.4% vs 0%,  $P = 0.006$ ). The cumulative survival rates in the elderly group were 53.7% at 3 years and 32.9% at 5 years, which were equivalent to those in the non-elderly group (55.9% and 39.4%, respectively), as shown by a log-rank test ( $P = 0.601$ ). In multivariate analysis, prolonged survival was significantly associated with the extent of liver damage and stage ( $P < 0.001$  and  $P < 0.001$ , respectively), but was not associated with patient age. However, on individual evaluation of factors in both groups, stage was significantly ( $P < 0.001$ ) associated with prolonged survival. Regarding mJIS scores of  $\leq 2$ , the rate of female patients with this score was higher in the elderly group when compared to that in the non-elderly group ( $P = 0.012$ ) and patients  $\geq 80$  years of age tended to demonstrate shortened survival.

**CONCLUSION:** Survival of elderly HCC patients was associated with liver damage and stage, but not age, except for patients  $\geq 80$  years with mJIS score  $\leq 2$ .

Factors associated with the overall survival of elderly patients with hepatocellular carcinoma. *World J Gastroenterol* 2012; 18(16): 1926-1932 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i16/1926.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i16.1926>

## INTRODUCTION

Hepatocellular carcinoma (HCC), one of the most common causes of mortality worldwide, usually occurs in a cirrhotic liver<sup>[1-3]</sup>. Moreover, the number of elderly HCC patients is increasing, and the average age of patients with hepatitis C is increasing in Japan<sup>[4-8]</sup>. This trend indicates the need to investigate and identify the optimal treatment of HCC in elderly patients. Elderly patients have a high incidence of comorbid illnesses and the risks of major surgery are usually higher in these patients when compared to those in younger patients. Therefore, radical surgical resection of HCC is less feasible in elderly patients than in younger patients.

Some studies have indicated that treatment outcomes in elderly patients are essentially similar to those in non-elderly patients; moreover, there are several studies comparing different treatment procedures<sup>[9-16]</sup>. However, the prognostic factors for survival in elderly patients remain obscure. This article aims to review a retrospective cohort of elderly ( $\geq 75$  years) and non-elderly ( $< 75$  years) patients in order to clarify the characteristics of elderly HCC patients and reveal the factors associated with prolonged survival of these patients.

## MATERIALS AND METHODS

### Study population

A total of 286 patients with HCC treated at Aiseikai-Yamashina Hospital between January 2000 and December 2010 were enrolled in this study. A follow up study of patient survival was performed until the end of December 2010. This study was conducted in accordance with the Declaration of Helsinki. We explained our therapeutic strategy and other regimens to each patient prior to every treatment procedure and obtained written informed consent from all patients.

The 286 patients who fulfilled the inclusion criteria were categorized into two groups as elderly ( $\geq 75$  years) and non-elderly ( $< 75$  years old). The breakpoint of 75 years old was chosen because it enabled comparison with other relevant reports. Moreover, in Japan, patients  $\geq 75$  years of age are covered by a health insurance system

which is different from that of patients  $< 75$  years.

### Etiology of liver disease

The etiology of liver disease was classified as follows: (1) hepatitis B virus (HBV), if patients were hepatitis B surface antigen (HBsAg) positive; (2) HCV, if patients were anti-HCV positive; (3) HCV and HBV, if patients were both HBsAg and anti-HCV positive; and (4) non-B non-C, if patients were negative for both HBsAg and anti-HCV.

### Diagnosis of hepatic reserve capacity

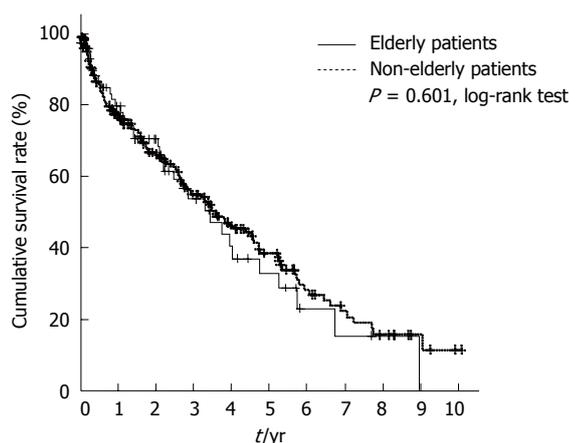

The severity of liver damage was scored according to the Liver Damage Classification scheme proposed by the Liver Cancer Study Group of Japan (LCSGJ)<sup>[17]</sup>.

### Diagnosis and staging of hepatocellular carcinoma

The diagnosis of HCC was based on histopathology and/or imaging studies such as ultrasonography (US), computed tomography (CT) scans, angiography, CT angiography, and magnetic resonance imaging. The final diagnosis was confirmed when at least two diagnostic modalities identified the presence of HCC. The tumor stage was defined on the basis of the LCSGJ. To compare treatment outcomes with those of other institutions, the modified Japan Integrated Stage score (mJIS score) was selected as the integrated staging system for HCC<sup>[17]</sup>.

### Treatment

After diagnosis of HCC, the most appropriate therapeutic procedure was selected according to the tumor status and underlying hepatic reserve capacity of each patient. As a general rule, we treated all patients except for those with uncontrollable ascites or hepatic encephalopathy and those who rejected any treatment. Hepatic resection (HR) was particularly considered in patients with localized HCC and preserved hepatic reserve capacity. Nonsurgical treatments, such as transcatheterarterial chemoembolization (TACE), transcatheterarterial infusion chemotherapy (TAI), percutaneous ethanol injection therapy (PEIT), radiofrequency ablation therapy (RFA), and hepatic arterial infusion chemotherapy (HAIC) were considered when the patients refused surgical treatment or HR was not feasible. TACE was performed using doxorubicin hydrochloride or cisplatin with iodized oil (Lipiodol Ultra Fluide; Laboratoire Guerbet, Roissy, France) and gelatin sponge particles. TAI was performed using doxorubicin hydrochloride or cisplatin. Locoregional ablative therapies such as PEIT and RFA were considered in patients with one to three tumor nodules that were devoid of vascular invasion and not associated with extrahepatic metastases. All locoregional ablative therapies were CT- or US-assisted. HAIC was performed using intra-arterial hepatic injections with low-dose 5-fluorouracil/cisplatin<sup>[18]</sup>. In many cases, patients were treated by a combination of several procedures. These therapies were repeated when HCC relapsed until patients reached maximum tolerability. The best supportive care was considered when the pa-

**Figure 1** Cumulative survival rates by Kaplan-Meier method in elderly (*n* = 74, thin line) and non-elderly groups (*n* = 212, thick line).

tient had compromised hepatic reserve capacity or when he/she refused any treatment for HCC.

**Comorbid illnesses**

The presence of malignant tumors other than HCC, cardiovascular diseases, renal diseases, pulmonary diseases, and neurological diseases, all of which could have potential impact on the prognosis, were recorded.

**Statistical analysis**

To evaluate the differences in clinical features of the patients and tumor characteristics, the Mann-Whitney *U* and Pearson  $\chi^2$  tests were used for continuous and discrete data, respectively. The analytical data were first collected on the day of initial HCC diagnosis. The patients were followed-up as long as they lived or, in some cases, until their last visit to the hospital. The primary outcome was overall survival. Cumulative survival rates were calculated using the Kaplan-Meier method and compared using the logrank test. Patient survival was followed up to 31 December, 2010. For the analysis of predictors of survival, a Cox proportional hazards model was used, in which the following parameters were evaluated: age ( $\geq 75$  years or  $< 75$  years), gender, presence of comorbid illnesses, HCV positivity, serum alpha-fetoprotein  $\geq 200$  ng/mL, serum des-gamma-carboxyprothrombin  $\geq 200$  mAU/mL, and liver damage classification and stage. A *P* value of  $\leq 0.05$  was considered statistically significant. All statistical analyses were performed using the SPSS 19.0 statistical package (SPSS Incorporated, Chicago, Illinois, United States).

**RESULTS**

**Clinical features of patients**

The clinical profiles of 286 patients, divided into elderly ( $\geq 75$  years) and non-elderly ( $< 75$  years) groups, are shown in Table 1. In the elderly group, the number of female patients, patients with comorbid illness, and patients with absence of HBV and HCV infection (non-B non-C) were significantly higher (*P* < 0.001, *P* = 0.047, *P* = 0.038,

**Table 1** Clinical characteristics of the patients

	Elderly patients ( <i>n</i> = 74 )	Non-elderly patients ( <i>n</i> = 212 )	<i>P</i> value

respectively) than those in the non-elderly group. In the non-elderly group, the proportion of patients with HBV infection was significantly (*P* = 0.006) higher than that in the elderly group.

**Overall survival rates**

Over a median follow-up of 1.8 years, 148 patients died, of whom 35 were elderly and 113 were non-elderly patients. The median survival period was comparable in the two groups [elderly: 3.46 years, 95% confidence interval (CI), 2.26-4.66; non-elderly: 3.56 years, 95% CI, 2.58-4.55; *P* = 0.167] (Figure 1). The survival rates at one, three, five, and 10 years were 79.7%, 53.7%, 32.9%, and 0.0% in the elderly group, and 77.9%, 55.9%, 39.4%, and 12.4% in the non-elderly group, respectively. There were no significant differences in survival rates between the two groups (*P* = 0.601).

With regard to the cause of mortality, 10 patients (28.6%) in the elderly group and 18 patients (16.8%) in the non-elderly group died from causes other than hepatic diseases (tumor progression, hepatic failure, variceal bleeding, or other complications of cirrhosis), and there were no significant differences between the two groups (*P* = 0.095, Table 1). In addition, we performed an analysis of survival rates after excluding patients who died from causes other than hepatic diseases. As a result, the survival rates at one, three, five, and 10 years were 86.8%, 64.0%, 42.3%, and 0.0% in the elderly group, and 80.8%, 60.7%, 44.9%, and 18.6% in the non-elderly group, respectively. There were no significant differences in survival rates between the two groups (*P* = 0.779, data not shown).

III / IV	NS	< 0.001	< 0.001	< 0.001

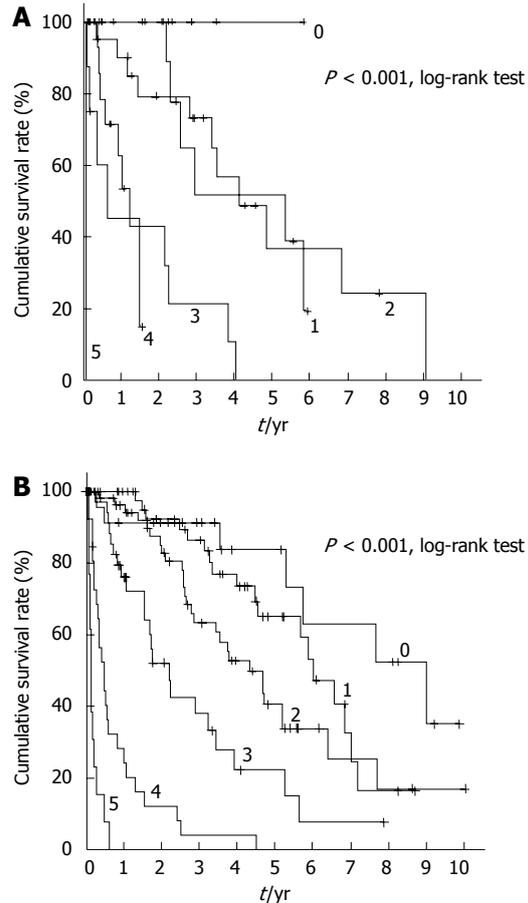

NS: Not significant; HCV: Hepatitis C virus; AFP: α-fetoprotein; DCP: Des-gamma-carboxy prothrombin.

**Factors affecting survival**

The factors affecting survival in all patients were calculated by multivariate analysis, and liver damage and stage were selected as the significant factors (Table 2). In elderly patients, multivariate analysis demonstrated that stage was independently associated with survival. In non-elderly patients, multivariate analysis demonstrated that liver damage and stage were independently associated with survival (Table 3). Gender, comorbid illness, HCV positivity, and tumor markers were not associated with survival in both groups.

**Survival curve according to the mJIS score**

Because survival was influenced by both liver damage and stage, we applied mJIS scores to both patient groups, and reached the conclusion that there was no clear association between these scores and survival in elderly patients (Fig-

**Figure 2** Cumulative survival rates by Kaplan-Meier method in each modified Japan Integrated Stage score group in elderly and non-elderly patients are shown. A: Elderly patients; B: Non-elderly patients.

ure 2A), whereas there was a clear association between the two in non-elderly patients (Figure 2B).

Furthermore, we analyzed the clinical profile of patients with mJIS scores of ≤ 2 in both groups (Table 4). The 5-year survival rate of these patients was expected to be ≥ 50%. In the elderly group, the proportion of females with this score was higher than that in the non-elderly group. In the non-elderly group, the proportion of patients with HBV infection was higher than that in the elderly group. Other clinical factors were not statistically different. There was no significant difference in survival rates between patients with this score in both groups ( $P = 0.386$ , Figure 3A). Furthermore, we analyzed the survival rate of elderly patients with mJIS scores ≤ 2 by dividing them into two subgroups, one comprising patients between 75 and 80 years of age and the other comprising patients ≥ 80 years of age. The survival rates tended to deteriorate in the latter group of patients, although the difference was not significantly different ( $P = 0.335$ , Figure 3B).

**DISCUSSION**

In this study, we reviewed HCC cases by dividing them into two groups and demonstrated that the survival rates of elderly patients ≥ 75 years of age were generally

**Table 4** Clinical characteristics of the patients whose modified Japan Integrated Stage score were two or less

	Elderly patients (n = 47)	Non-elderly patients (n = 136)	P value

NS: Not significant; HCC: Hepatocellular carcinoma; HBV: Hepatitis B virus; HCV: Hepatitis C virus.

equivalent to those of non-elderly patients < 75 years of age. There have been many previous studies reporting the efficiency and safety of each treatment modality for HCC in elderly patients, and most reports have shown similar survival rates and safety when compared with those of non-elderly patients<sup>[9-16]</sup>. However, in clinical practice, HCC is treated with several modalities in Japan. A previous paper, which evaluated the total survival rates of older HCC patients in comparison with those of younger HCC patients<sup>[19-21]</sup>, reported cumulative survival rates similar to those reported in our present study.

Our elderly and non-elderly HCC patients differed in several clinical characteristics. Elderly patients were more likely to be female and negative for both HBV and HCV. This was expected since all these factors are known to influence the age of HCC development. The peak age of HCC occurrence in females is 5 years later than that in males<sup>[22]</sup>. HCV infection is generally acquired during adult life<sup>[23]</sup>, while HBV infection frequently occurs in childhood<sup>[24]</sup>. A multifactorial etiology accelerates the progression of chronic liver disease, hence anticipating the appearance of HCC<sup>[22,25]</sup>.

Despite a higher prevalence of comorbid illnesses and a difference of 14.7 years in the mean age, elderly patients demonstrated an overall 5-year survival similar to that of their younger counterparts. This unexpected result could be because of the low survival rate of both groups (overall survival of approximately < 40% at 5 years). The Liver Cancer Study Group of Japan has reported the 5-year overall survival rate after initial HCC diagnosis as 35.4%<sup>[5]</sup>. There may be many specific factors that influence the treatment strategy for elderly patients. Aggressive and risky treatments in these patients may be avoided due to comorbid illnesses. However, the impact of HCC occurrence on life expectancy outweighs that

**Figure 3** The analysis of the survival rate with modified Japan Integrated Stage score two points or less. A: Cumulative survival rates by Kaplan-Meier method in elderly (n = 47, thick line) and non-elderly groups (n = 136, thin line) whose modified Japan Integrated Stage (mJIS) score is two points or less; B: Cumulative survival rates by Kaplan-Meier method in 75-80 year-olds (n = 25, thick line), 80 years old or more (n = 22, thin line) and non-elderly groups (n = 136, dotted line) whose mJIS score is two points or less are shown.

of both comorbid illnesses and age. We suggest that comorbid conditions and therapeutic procedures (including hepatectomy) had little effect on the survival of the patients especially the elderly ones.

Before analyzing the prognostic factors in each group, it was expected that the presence of comorbid illnesses may be a poor prognostic factor for elderly patients. However, this factor was not statistically associated with survival rates in either the elderly or non-elderly patient groups. The analysis of prognostic factors revealed that liver damage and stage were significantly associated with survival rates in both groups. Furthermore, stage was a very strong factor in elderly patients. Patients who have a sufficient hepatic reserve capacity may survive long enough for HCC to develop. The association of other factors with survival in elderly HCC patients seems insignificant in comparison with that of stage.

We also analyzed patients with a good hepatic reserve capacity ( $\leq 2$  points as per mJIS), whose 5-year survival rate was expected to exceed 50% (Figure 3A). However, there was no statistical difference between survival rates of patients  $\geq 75$  and < 75 years of age. Interestingly,

when divided into subgroups, the survival of patients  $\geq 80$  years of age was shorter than that of patients in the other subgroup (Figure 3B). In other words, extreme old age influenced the survival rate even in patients with good hepatic reserve capacity.

With regard to the cause of death, there was no difference between elderly and non-elderly patients (Table 1). Similar to non-elderly patients, elderly patients also died from liver-associated diseases. If the HCC patients  $\geq 80$  years of age were divided into two subgroups (treated and untreated), there were obvious differences in the prognosis (data not shown). Further studies with a larger sample of patients will clarify this issue in future.

In conclusion, survival of elderly HCC patients ( $\geq 75$  years old) was associated with liver damage and stage. The effectiveness of treatment for HCC was equivalent in elderly and non-elderly patients. Survival was unaffected by age; however, when individually evaluated for patients with a mJIS score of  $\leq 2$ , those  $\geq 80$  years of age tended to demonstrate shortened survival.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC), one of the most common causes of mortality worldwide, usually occurs in a cirrhotic liver. At present, the number of elderly HCC patients is increasing, as is the average age of hepatitis C is increasing in Japan. However, the factors associated with overall survival of patients with HCC especially the elderly ( $\geq 75$  years old) are not adequately investigated.

### Research frontiers

Some studies have indicated that treatment outcomes in elderly patients are essentially similar to those in non-elderly patients. In addition, there are several studies comparing different treatment procedures. The research hotspot is to clarify general prognostic factors for survival in elderly HCC patients in Japan.

### Innovations and breakthroughs

In the elderly HCC patients of Japan, the proportion of female patients, patients with absence of hepatitis B or hepatitis C viral infection, and patients with co-existing extrahepatic comorbid illness was higher than that in the non-elderly group. The cumulative survival rates in the elderly group were 53.7% at 3 years and 32.9% at 5 years, which were equivalent to those in the non-elderly group, as shown by a log-rank test. In multivariate analysis, prolonged survival was significantly associated with the extent of liver damage and stage, but was not associated with patient age. Patients  $\geq 80$  years of age tended to demonstrate shortened survival.

### Applications

In the present study, the authors have reached the conclusion that survival of the HCC patients treated by appropriate procedures depends on liver damage and stage, but not on patient age. Only patients  $\geq 80$  years of age tended to demonstrate shortened survival.

### Terminology

The modified Japan Integrated Stage score (mJIS score) is the integrated staging system which combined the degree of liver damage and the degree of tumor stage.

### Peer review

This is a good descriptive study in which authors analyze the factors associated with overall survival of patients with HCC especially the elderly ( $\geq 75$  years old). The results are interesting and give a useful information to the hepatologists in the world.

### Abstract

**AIM:** To evaluate the effectiveness of hepatic arterial infusion chemotherapy (HAIC) for advanced hepatocellular carcinoma (HCC) resistant to transarterial chemoembolization (TACE).

**METHODS:** This study was conducted on 42 patients who received HAIC for advanced HCC between 2001

and 2010 at our hospital. 5-fluorouracil (5-FU) was administered continuously for 24 h from day 1 to day 5 every 2-4 wk *via* an injection reservoir. Intra-arterial cisplatin or subcutaneous interferon was administered in combination with the 5-FU. The patients enrolled in this retrospective study were divided into two groups according to whether or not they fulfilled the criteria for resistance to TACE proposed by the Japan Society of Hepatology in 2010 (written in Japanese); one group of patients who did not fulfill the criteria for TACE resistance (group A,  $n = 23$ ), and another group who fulfilled the criteria for TACE resistance (group B,  $n = 19$ ). We compared the outcomes in terms of the response and survival rates between the two groups.

**RESULTS:** Both the response rate and tumor suppression rate following HAIC were significantly superior in group A than in group B (response rate: 48% *vs* 16%,  $P = 0.028$ , tumor suppression rate: 87% *vs* 53%,  $P = 0.014$ ). Furthermore, both the progression-free survival rate and survival time were significantly superior in group A than in group B (3-, 6-, 12-, and 24-mo = 83%, 70%, 29% and 20% *vs* 63%, 42%, 16% and 0%, respectively,  $P = 0.040$ , and 9.8 mo *vs* 6.2 mo,  $P = 0.040$ ). A multivariate analysis (Cox proportional hazards regression model) showed that resistance to TACE was an independent predictor of poor survival ( $P = 0.007$ ).

**CONCLUSION:** HAIC administering 5-FU was not effective against advanced HCC resistant to TACE. Other tools for treatment, i.e., molecular-targeting agents may be considered for these cases.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant diseases around the world, and the number of HCC-related deaths has been increasing worldwide<sup>[1-5]</sup>. HCC has a poor prognosis due to its rapidly-infiltrating growth characteristic and occurrence in a background of liver cirrhosis (LC). Surgical treatment is only indicated in a small proportion of patients, due to the frequently large tumor size, presence of multiple tumors, and poor hepatic function<sup>[6,7]</sup>. Regional interventional therapies have led to major breakthroughs in the management of HCC; transarterial chemoembolization (TACE) has been reported as an effective treatment modality for patients with advanced HCC, especially those with multiple nodules<sup>[8-15]</sup>, therefore, it is often repeated several times for the treatment of recurrent HCC. Furthermore, advances in implantable drug delivery systems have made it possible to administer repeated arterial infusions of anticancer agents, and recent studies, including our previous reports, have shown the effectiveness of combined therapy with intra-arterial 5-fluorouracil (5-FU) plus cisplatin or subcutaneous interferon (IFN) therapy in patients with advanced HCC<sup>[16-24]</sup>. We previously reported a case of unresectable advanced HCC with portal vein tumor thrombosis (PVTT) who was treated successfully by combined intra-arterial 5-FU plus subcutaneous pegylated interferon- $\alpha$ 2b (PEG-IFN- $\alpha$ 2b) therapy<sup>[23]</sup>, and also a retrospective cohort study of this combined hepatic arterial infusion chemotherapy (HAIC)<sup>[24]</sup>. However, the precise efficacy of HAIC in patients with advanced HCC resistant to TACE still remains unclear.

In the present cohort study, we evaluated the effectiveness and outcomes, in terms of the overall survival rate, median survival time and response to therapy, of HAIC in patients with unresectable advanced HCC with and without a resistance to TACE.

## MATERIALS AND METHODS

### Patients and eligibility

The subjects of this study were 42 patients with HCC in

**Table 1** Criteria for transarterial chemoembolization resistance

The evaluation was performed on the day of TACE and 1 mo after the TACE; the following were observed at least two times
Staining with the injected agent (lipiodol-anticancer agent emulsion) was considered insufficient with evaluation CT [the occupation rate was less than 50% of lesion(s)]
Appearance of multiple new recurrent lesions on the evaluation CT
Appearance of vessel invasion after TACE
Appearance of distal metastasis after TACE
Persistent elevation of tumor marker(s) regardless of TACE

TACE: Transarterial chemoembolization; CT: Computed tomography.

whom the diagnosis was made on the basis of the pathological or radiological findings between January 2001 and December 2010 at Yokohama City University Hospital, Kanagawa, Japan. Of the 42 patients, 5 had not received any treatment before enrollment in this study, 27 had been treated by TACE, 8 had undergone hepatic resection, and 2 had been treated by local ablation therapy before enrollment in this study. All the patients satisfied the following criteria: Child-Pugh class A or B, white blood cell > 2000/ $\mu$ L, neutrophil count > 1000/ $\mu$ L, Plt > 50 000/ $\mu$ L, total bilirubin < 3.0 mg/dL, serum creatinine < 1.5 mg/dL, unresectable or unsuitable for local ablation therapy, 4 or more lesions throughout the liver or presence of vessel invasion, Eastern Cooperative Oncology Group Performance Status, 0-2<sup>[25]</sup>, absence of extra-hepatic metastases, and absence of past history of treatment with 5-FU. The PVTT grade and tumor stage were determined according to the criteria of the Liver Cancer Study Group of Japan<sup>[26]</sup>. All patients gave written informed consent for participation in this study, and the study was conducted with the approval of the Ethics Committee of Yokohama City University Graduate School of Medicine. The patients enrolled in this retrospective study were divided into two groups according to whether or not they fulfilled the criteria for resistance to TACE proposed by the Japan Society of Hepatology in 2010 (written in Japanese) (Table 1); one group of patients who did not fulfill the criteria (group A,  $n = 23$ ), and another group of patients who fulfilled the criteria for TACE resistance (group B,  $n = 19$ ). We compared the outcomes in terms of the response and survival rates between the two groups. A comparison of the patient characteristics between the two groups before the start of HAIC is shown in Table 2. The duration of treatment from the first detection of HCC to the time of the HAIC (i.e., to enrollment in this study) was significantly longer in group B than in group A (36.2 mo *vs* 16.3 mo,  $P = 0.004$ ). The liver function parameters did not differ significantly between the two groups.

### Arterial catheterization

The arterial catheter was inserted into the right or left femoral artery by the Seldinger method. A heparin-coated catheter (Clinical Supply, Gifu, Japan) was inserted into the femoral artery and its tip was advanced to the

HCV: Hepatitis C virus; HBV: Hepatitis B virus; LC: Liver cirrhosis; PT: Prothrombin time; INR: International ratio; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; GGT:  $\gamma$  glutamyl transferase; AFP:  $\alpha$ -fetoprotein; WBC: White blood cell; DCP: Des- $\gamma$ -carboxyprothrombin; HAIC: Hepatic arterial infusion chemotherapy; TACE: Transarterial chemoembolization; 5-FU: 5-fluorouracil; IFN: Interferon; PEG-IFN- $\alpha$ 2b: Pegylated interferon- $\alpha$ 2b.

common hepatic artery or proper hepatic artery. The other end of the catheter was connected to the injection reservoir, already implanted into a subcutaneous pocket created in the right or left lower quadrant of the abdomen. The gastroduodenal and right gastric arteries were occluded with coils to prevent potential gastroduodenal injury by the anticancer agents.

### Treatment protocol

Patients received arterial infusions of the anticancer agents

*via* the injection reservoir. Each chemotherapy cycle lasted 2-4 wk. 5-FU (300 mg/m<sup>2</sup> per day, Kyowa Hakko, Tokyo, Japan) was administered continuously for 24 h *via* the infusion pump on days 1 to 5 of each of the two weeks. PEG-IFN- $\alpha$ 2b (PEG-INTRON, MSD KK, Tokyo, Japan) on Day 1 of every week or natural IFN- $\alpha$  (OIF, Otsuka Pharmaceuticals, Tokyo, Japan) on Days 1, 3, 5 of every week was administered by the subcutaneous route. The administered dose of PEG-IFN- $\alpha$ 2b was adjusted by the weight of each patient (50  $\mu$ g-100  $\mu$ g), and the dose of natural IFN- $\alpha$  was fixed at 5.0 × 10<sup>6</sup> unit. In another HAIC regimen, cisplatin (10 mg/body per day, Nihon-Kayaku Pharmaceuticals, Tokyo, Japan) was combined with 5-FU (250 mg/body per day) administered continuously for 24 h *via* the infusion pump on days 1 to 5 of each of the four weeks. Each of the HAIC therapy regimens was repeated for a total of at least 2 cycles until the response changed to progressive disease (PD) or a severe adverse reaction appeared.

### Evaluation

The duration of the progression-free survival was measured from the date of start of HAIC to the date on which the response was judged to have changed to PD. The response to the HAIC was evaluated by contrast-enhanced computed tomography (CT) after every 2 cycles of treatment. The response criteria of the Response Evaluation Criteria in Solid Tumors were used<sup>[27]</sup>. The duration of the response was measured from the date of start of treatment to the date of documented progression. Adverse reactions were assessed every week during therapy based on the United States National Cancer Institute Common Toxicity Criteria (NCI-CTC; version 3.0)<sup>[28]</sup>.

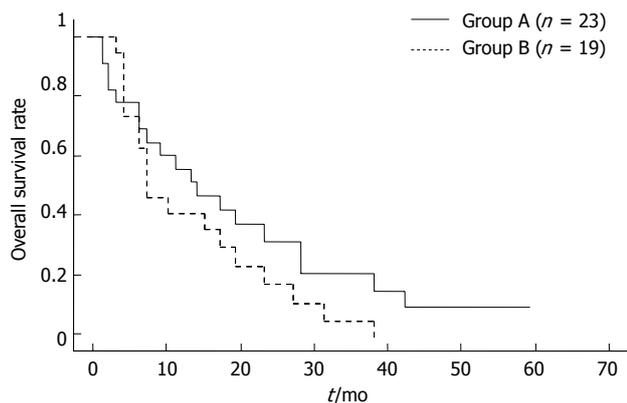

### Statistical analysis

The statistical analysis was performed using the StatView software, version 5.0 (SAS, Cary, NC). Group comparisons were performed by the chi-square test for independence or by Fisher's exact test for comparison of more than two independent groups. The overall survival rate of each group was evaluated by the Kaplan-Meier method and the logrank test from the start of HAIC until the patient's death, and the progression-free survival rate was evaluated until the effect of the HAIC changed to PD. *P* values of < 0.05 were considered to denote significance in all the statistical tests. The closing date of the study was May 31, 2011.

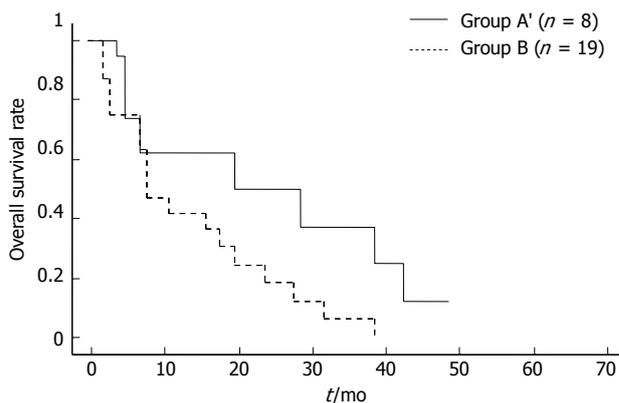

## RESULTS

### Response to the HAIC

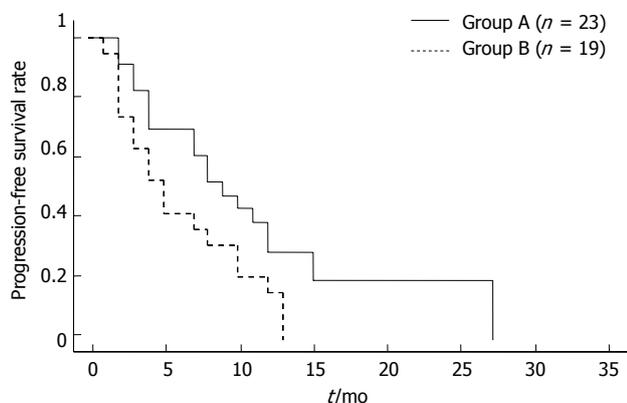

In group A, 2 patients (8.7%) showed complete response (CR), 9 patients (39.1%) showed partial response (PR), 9 patients (39.1%) showed stable disease (SD), and the remaining 3 patients (13.1%) showed PD. On the other hand, in group B, none of the patients (0%) showed CR, 3 patients (15.8%) showed PR, 7 patients (36.8%) showed SD, and the remaining 9 patients (47.4%) showed PD.

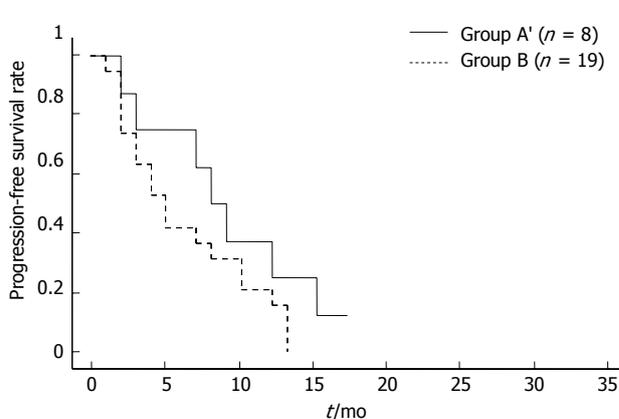

**Figure 1** The overall survival rate tended to be superior in group A (a solid line) than in group B (a dotted line) (3-, 6-, 12-, 24-, and 36 mo = 82.6%, 78.3%, 56.5%, 32.8% and 21.9% vs 94.7%, 73.7%, 42.1%, 18.4%, and 6.1%, respectively,  $P = 0.203$ ).

**Figure 3** The overall survival rate and survival time tended to be superior in group A' (a solid line) than in group B (a dotted line) (3-, 6-, 12-, 24-, and 36 mo = 75.0%, 75.0%, 62.5%, 50.0% and 37.5% vs 94.7%, 73.7%, 42.1%, 18.4%, and 6.1%, respectively,  $P = 0.095$ ).

**Figure 2** The progression-free survival rate was significantly superior in group A (a solid line) than in group B (a dotted line) (3-, 6-, 12-, and 24 mo = 82.6%, 69.6%, 29.3%, and 19.6% vs 63.2%, 42.1%, 15.8% and 0%, respectively,  $P = 0.040$ ).

**Figure 4** The progression-free survival rate and time tended to be superior in group A' (a solid line) than in group B (a dotted line) (3-, 6-, 12-, and 24 mo = 75.0%, 75.0%, 25.0%, and 0% vs 63.2%, 42.1%, 15.8% and 0%, respectively,  $P = 0.192$ ).

Both the response rate [CR and PR patients/all patients  $\times 100(\%)$ ] and the tumor suppression rate [CR, PR, and SD patients/all patients  $\times 100(\%)$ ] following HAIC were significantly superior in group A than in group B (response rate: 47.8% vs 15.8%,  $P = 0.028$ , tumor suppression rate: 86.9% vs 52.6%,  $P = 0.014$ ).

**Survival**

The overall survival rate and survival time tended to be superior in group A than in group B (3-, 6-, 12-, 24-, and 36 mo = 82.6%, 78.3%, 56.5%, 32.8% and 21.9% vs 94.7%, 73.7%, 42.1%, 18.4%, and 6.1%, respectively,  $P = 0.203$  (Figure 1), and 18.8 mo vs 14.0 mo,  $P = 0.267$ ). Furthermore, the progression-free survival rate and time were significantly superior in group A than in group B (3-, 6-, 12-, and 24 mo = 82.6%, 69.6%, 29.3%, and 19.6% vs 63.2%, 42.1%, 15.8% and 0%, respectively,  $P = 0.040$  (Figure 2), and 9.8 mo vs 6.2 mo,  $P = 0.040$ ).

**Subgroup analysis**

In group A, both the patients who received TACE once or twice ( $n = 8$ ) and who did not receive TACE ( $n = 15$ ) were

included. Therefore, to evaluate the effectiveness of HAIC after TACE, we performed subgroup analysis compared the patients who received TACE in group A (group A',  $n = 8$ ) to group B. In group A', 1 patient (12.5%) showed CR, 3 patients (37.5%) showed PR, 3 patients (37.5%) showed SD, and the remaining 1 patient (12.5%) showed PD. Both the response rate and the tumor suppression rate following HAIC tended to be superior in group A' than in group B (response rate: 50.0% vs 15.8%,  $P = 0.064$ , tumor suppression rate: 87.5% vs 52.6%,  $P = 0.087$ ).

The overall survival rate and survival time tended to be superior in group A' than in group B (3-, 6-, 12-, 24-, and 36 mo = 75.0%, 75.0%, 62.5%, 50.0% and 37.5% vs 94.7%, 73.7%, 42.1%, 18.4%, and 6.1%, respectively,  $P = 0.095$  (Figure 3), and 24.0 mo vs 14.0 mo,  $P = 0.086$ ). Furthermore, the progression-free survival rate and time also tended to be superior in group A' than in group B (3-, 6-, 12-, and 24 mo = 75.0%, 75.0%, 25.0%, and 0% vs 63.2%, 42.1%, 15.8% and 0%, respectively,  $P = 0.192$  (Figure 4), and 9.1 mo vs 6.2 mo,  $P = 0.143$ ). These results of comparison between group A' and group B was similar to that between group A and group B.

**Table 3** Multivariate analysis (Cox proportional hazards regression model) to identify factors influencing the survival

	Odds ratio	95% CI	P value
Age > 66 (yr)	0.284	0.077-1.044	NS ( $P = 0.058$ )
Gender: female	3.995	0.704-22.662	NS ( $P = 0.118$ )
Resistance to TACE	8.264	1.770-38.461	$P = 0.007$
AFP > 200 (ng/mL)	0.385	0.121-1.230	NS ( $P = 0.107$ )
DCP > 200 (mAU/mL)	1.181	0.218-6.390	NS ( $P = 0.847$ )
Albumin > 3.5 (g/dL)	0.012	0.001-0.181	$P = 0.001$
Total bilirubin > 1.0 (mg/dL)	4.000	1.004-15.933	$P = 0.049$
PT (INR) > 1.20	0.490	0.155-1.551	NS ( $P = 0.225$ )
ALT > 50 (U/L)	1.229	0.378-3.999	NS ( $P = 0.732$ )
Plt > 15.0 ( $\times 10^4/\mu\text{L}$ )	1.251	0.330-4.736	NS ( $P = 0.742$ )
Number of tumors > 6	0.403	0.090-1.794	NS ( $P = 0.233$ )
Size of the largest tumor > 5.0 cm	0.913	0.215-3.884	NS ( $P = 0.902$ )
Clinical stage: IVA	13.800	1.638-116.257	$P = 0.016$
Response to HAIC: CR, PR	0.024	0.004-0.160	$P = 0.0001$
Child-Pugh: B	0.251	0.019-3.307	NS ( $P = 0.293$ )
Hepatic encephalopathy: presence	0.643	0.123-3.347	NS ( $P = 0.599$ )
Ascites: presence	3.471	0.835-14.419	NS ( $P = 0.087$ )

TACE: Transarterial chemoembolization; AFP:  $\alpha$ -fetoprotein; DCP: Des- $\gamma$ -carboxyprothrombin; PT: Prothrombin time; INR: International ratio; ALT: Alanine aminotransferase; HAIC: Hepatic arterial infusion chemotherapy; CR: Complete response; PR: Partial response; CI: Confidence interval.

### Multivariate analysis to identify factors influencing the survival

A multivariate analysis (Cox proportional hazards regression model) was performed to identify factors that might influence the survival following HAIC, which identified resistance to TACE [odds ratio (OR): 8.264,  $P = 0.007$ ], serum albumin > 3.5 g/dL (OR: 0.012,  $P = 0.001$ ), serum total bilirubin > 1.0 mg/dL (OR: 4.000,  $P = 0.049$ ), clinical stage IVA (OR: 13.800,  $P = 0.016$ ), and CR, PR to HAIC (OR: 0.024,  $P = 0.0001$ ) as significant independent predictors influencing of the survival (Table 3).

### Adverse reactions

The common systemic adverse reactions were fever, loss of appetite and general fatigue, however, none exceeded Grade 1 to 2 in severity. Furthermore, no case of serious leukopenia or thrombocytopenia was observed, with the severity of these adverse reactions not exceeding Grade 1 to 2 in any of the cases; none of the patients required administration of granulocyte-colony-stimulating factor or blood transfusion. On the other hand, among the 42 patients, there were 3 patients who developed Grade 2 generalized skin rash, 3 patients who developed obstruction of hepatic artery, and 2 patients who developed infection of reservoir. There were no cases of adverse event-related death.

## DISCUSSION

According to the treatment algorithm for hepatocellular carcinoma in the Clinical Practice Guidelines for Hepatocellular Carcinoma in Japan<sup>[15]</sup>, TACE and HAIC are recommended when the number of HCCs is four or more,

with preserved liver function. In a large prospective cohort study of 8510 patients with a long follow-up period of 8 years, Takayasu *et al.*<sup>[14]</sup> reported that TACE using an anticancer agent-lipiodol emulsion with or without gelatin sponge particles improved the survival of patients with advanced HCC, with overall 1-, 3-, 5-, and 7-year survival rates of 82%, 47%, 26%, and 16%, respectively, and a median survival duration of 34 mo. We also reported the superior effectiveness of TACE using a cisplatin- or epirubicin-lipiodol emulsion as compared with that of palliative treatment in a recent study of patients with advanced HCC<sup>[13]</sup>; both the overall survival rate and median survival time in patients who received TACE were significantly superior to those in patients who received only palliative treatment (1-, 2-, 5-, and 8-year survival rates of 98%, 90%, 56% and 16% *vs* 47%, 39%, 23% and 0%, respectively; median survival duration, 25 mo *vs* 10 mo). However, repeat sessions of TACE were often required which can potentially result in deterioration of the liver function<sup>[29]</sup>. Another group reported that selective TACE using conventional doses of anticancer drugs can cause persistent, serious worsening of the liver function<sup>[50]</sup>.

Several recent studies have reported the effectiveness and survival benefit of combined therapy with intra-arterial 5-FU plus cisplatin or systemic various IFN in patients with unresectable advanced HCC<sup>[16-24]</sup>. Ando *et al.*<sup>[21]</sup> investigated the outcomes of HAIC using a combination 5-FU plus cisplatin for HCC patients with complicating PVTT ( $n = 48$ ), and reported a response rate of 48%, median survival time of 31.6 mo, and 1-, 2-, 3- and 5-year survival rates of 45%, 31%, 25% and 11%, respectively. Obi *et al.*<sup>[18]</sup> reported an objective response rate of 52.6% (61/116 patients) in 116 patients with advanced HCC and Vp 3 or 4 treated with a combination of 5-FU plus natural IFN- $\alpha$ . A recent study conducted by us demonstrated the effectiveness of combined therapy with 5-FU plus subcutaneous PEG-IFN- $\alpha$ 2b for unresectable advanced HCC ( $n = 18$ ); the response rate was 33.3%, the median survival time was 17.7 mo, and the 6-, 12-, 24- and 36-mo survival rates were 89%, 71%, 39% and 29%, respectively<sup>[24]</sup>. However, few reports have investigated the effectiveness of HAIC in patients with advanced HCC resistant to TACE. This study revealed that HAIC yielded an unsatisfactory survival rate and survival time in patients with HCC resistant to TACE, and a multivariate analysis identified resistance to TACE as one of the independent predictors of poor survival in these patients.

Recently, a multikinase inhibitor, sorafenib, was approved as the first molecular targeted agent for advanced HCC, and two global phase III trials<sup>[31,32]</sup> showed survival benefit with this drug administered orally for advanced HCC patients with preserved liver function. The SHARP Study was a randomized double-blind placebo-controlled multicenter study conducted in western countries, which showed that both the overall survival and the time to progression were significantly superior in the sorafenib group ( $n = 299$ ) than in the placebo group ( $n = 303$ ) (10.7 mo *vs* 7.9 mo, and 5.5 mo *vs* 2.8 mo, respectively). Interestingly, 86 patients (29% of sorafenib group) and 90 patients (30%

of placebo group) who had previously received TACE were included in the SHARP Study. Galle *et al.*<sup>[33]</sup> reported that among 176 patients after TACE, the overall survival and the time to progression were superior in the sorafenib group ( $n = 86$ ) than in the placebo group ( $n = 90$ ) (11.9 mo *vs* 9.9 mo, and 5.8 mo *vs* 4.0 mo, respectively) in sub-analysis of the SHARP Study. These results suggest that sorafenib may be an effective treatment agent for patients with advanced HCC resistant to TACE. Furthermore, the Asia-Pacific Study, performed in eastern Asian countries, also showed, similar to the SHARP study, significant survival prolongation in the sorafenib group as compared with that in the placebo group. Therefore, in Japan, sorafenib has recently been recommended for the treatment of patients with advanced HCC and extra-hepatic metastasis or major vessel invasion with preserved liver function, e.g., Child-Pugh class A<sup>[34,35]</sup>.

In conclusion, although the evaluation needs to be conducted in a larger number of patients and the study was a retrospective cohort study, the results of this study revealed that HAIC administered with 5-FU exerted insufficient effect against advanced HCC resistant to TACE. Molecular-targeting agents may need to be considered in the future for patients with HCC resistant to TACE.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the most common malignant diseases around the world, and interventional therapies such as transarterial chemoembolization (TACE) or hepatic arterial infusion chemotherapy (HAIC) has been performed for patients with advanced HCC, especially those with multiple nodules, therefore, it is often repeated several times for the treatment of recurrent HCC. However, the precise efficacy of HAIC in patients with advanced HCC resistant to TACE still remains unclear.

### Research frontiers

Advances in implantable drug delivery systems have made it possible to administer repeated arterial infusions of anticancer agents, and recent studies, including our previous reports, have shown the effectiveness of combined therapy with intra-arterial 5-fluorouracil (5-FU) plus cisplatin or subcutaneous interferon (IFN) therapy in patients with advanced HCC which have multiple intra-hepatic lesions or portal vein tumor thrombosis.

### Innovations and breakthroughs

The study was considered the first report which investigated the effectiveness of HAIC administering 5-FU for advanced HCC resistant to TACE. The patients enrolled in their study were divided into two groups according to whether or not they fulfilled the criteria for resistance to TACE proposed by the Japan Society of Hepatology in 2010 (written in Japanese) (Table 1); one group of patients who did not fulfill the criteria for TACE resistance (group A,  $n = 23$ ), and another group who fulfilled the criteria for TACE resistance (group B,  $n = 19$ ). They compared the outcomes in terms of the response and survival rates between the two groups. Both the response rate and tumor suppression rate following HAIC were significantly superior in group A than in group B. Furthermore, both the progression-free survival rate and survival time were significantly superior in group A than in group B. A multivariate analysis (Cox proportional hazards regression model) showed that resistance to TACE was an independent predictor of poor survival.

### Applications

The results of this study revealed that HAIC administered with 5-FU exerted insufficient effect against advanced HCC resistant to TACE.

### Terminology

HAIC administering 5-FU was not effective against advanced HCC resistant to

TACE, and our study showed the limitation of interventional therapies to prolong the survival for advanced HCC and consideration of new strategy including other tools for treatment, i.e., molecular-targeting agents.

### Peer review

In this study, the authors report that patients with HCC resistant to TACE exhibit a poorer response to HAIC. This paper is clearly written and the topic material is important.

### Abstract

**AIM:** To evaluate safety and feasibility of microcoil embolization of the common hepatic artery under proper or distal balloon inflation in preoperative preparation for en bloc celiac axis resection for pancreatic body cancer.

**METHODS:** Fifteen patients (11 males, 4 females; median age, 67 years) with pancreatic body cancer involving the nerve plexus surrounding the celiac artery underwent microcoil embolization. To alter the total hepatic blood flow from superior mesenteric artery (SMA), microcoil embolization of the common hepatic artery (CHA) was conducted in 2 cases under balloon inflation at the proximal end of the CHA and in 13 cases under distal microballoon inflation at the distal end of the CHA.

**RESULTS:** Of the first two cases of microcoil embolization with proximal balloon inflation, the first was successful, but there was microcoil migration to the proper hepatic artery in the second. The migrated microcoil

was withdrawn to the CHA by an inflated microballoon catheter. Microcoil embolization was successful in the other 13 cases with distal microballoon inflation, with no microcoil migration. Compact microcoil embolization under distal microballoon inflation created sufficient resistance against the vascular wall to prevent migration. Distal balloon inflation achieved the requisite 1 cm patency at the CHA end for vascular clamping. All patients underwent en bloc celiac axis resection without arterial reconstruction or liver ischemia.

**CONCLUSION:** To impede microcoil migration to the proper hepatic artery during CHA microcoil embolization, distal microballoon inflation is preferable to proximal balloon inflation.

### INTRODUCTION

The overall 5-year survival rate after surgical resection for pancreatic cancer is extremely poor (< 10%)<sup>[1-3]</sup>. There is an ongoing effort toward treating this difficult disease and improving survival. Surgery plays a main role for a complete

cure of pancreatic body cancer. En bloc celiac axis resection (modified Appleby operation) has been introduced to expand the surgical treatment for pancreatic body cancer with celiac axis involvement<sup>[4,5]</sup>, and Hirano *et al*<sup>[6]</sup> report a promising estimated 5-year survival rate of 42% for locally advanced pancreatic body cancer. This surgical procedure has the aim of en bloc lymphadenectomy together with resection of the spleen, pancreatic body, and tail by ligation of the celiac trunk artery and common hepatic artery (CHA). The safety of this operation is based on the rationale that hepatic arterial blood is supplied from the superior mesenteric artery *via* the pancreaticoduodenal arcades following ligation of the CHA. However, weak pulsation of the proper hepatic artery was observed in some patients during surgery, immediately after surgical ligation of the CHA<sup>[7-9]</sup>. When poor pulsation of the proper hepatic artery is observed after clamping of the CHA, arterial reconstruction is necessary because liver necrosis is fatal once it occurs<sup>[10-13]</sup>. To avoid this complicated procedure, Kondo *et al*<sup>[14]</sup> reported the preparatory technique of enlarging the collateral pathways from the SMA before surgery, by preoperative embolization of the CHA using interlocking detachable coils. Following this report, surgeons first asked interventional radiologists to embolize the CHA in preoperative management to enlarge the collateral pathways from the superior mesenteric artery (SMA). However, exact microcoil embolization of the short segment of the CHA is not easy, even for experienced interventional radiologists, because of its rapid arterial flow and, of particular concern, the possibility of coil migration to the proper hepatic artery. In our case, the surgeon also asked that we retain vascular lumen patency 1 cm from the distal end of the common hepatic artery and the proximal celiac artery trunk, to enable clamping of these vessels. In response to these requirements, we conducted microcoil embolization of the CHA under either proximal or distal microballoon inflation. The purpose of this clinical study is to describe these techniques and to evaluate their safety and feasibility.

## MATERIALS AND METHODS

### Patients

Approval of the Institutional Ethics Committee of our institution was obtained for this clinical trial prior to initiation of the study. All patients were fully informed of the extent of their diseases and of the risks and benefits associated with preoperative CHA embolization and en bloc resection.

In cases of right or common hepatic artery branching from the SMA, it was not necessary to conduct microcoil embolization of the CHA. Between May 2007 and January 2010, 15 patients with pancreatic body cancer involving the nerve plexus surrounding the celiac artery were scheduled for surgical radical pancreatectomy and underwent microcoil embolization preoperatively. Tumor stage was T4 in 14 patients and T3 in 1 patient according to the tumor, node and metastasis classification of the Union for

International Cancer Control (UICC)<sup>[15]</sup>. Eleven patients were male and 4 were female; age ranged from 46 to 79 years (median, 67 years) (Table 1). All patients suffered from severe back pain and/or abdominal pain. Enhanced computed tomography using contrast medium revealed tumors sized 10-76 mm located in the body to the tail of the pancreas and involving the celiac, splenic, and/or common hepatic arteries, but with no evidence of liver metastases or invasion to the superior mesenteric artery. Microcoil embolization of the common hepatic artery was performed 7 d to 14 d before surgery. Two interventional radiologists, each with more than 7 years experience in transcatheter arterial embolization, conducted the following procedure.

### Interventional procedure

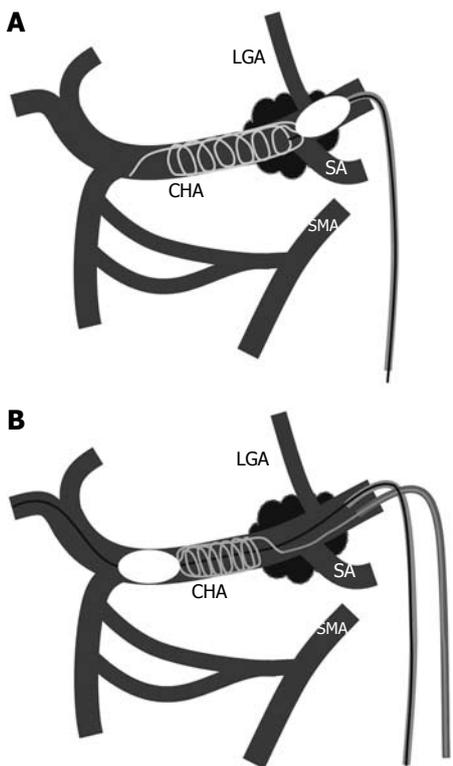

**Microcoil embolization under proximal balloon inflation:** A 5F balloon catheter (balloon diameter 10 mm; Seilecon MP, Catheter Rosch II; Terumo, Tokyo, Japan) was inserted into the celiac artery through a 6F long sheath (Terumo) *via* the right femoral artery. After celiac arteriography, a 5F balloon catheter was advanced to the CHA using a guide wire (0.035, angle type; Radiofocus, Terumo). Under balloon inflation at the proximal end of the CHA, a microcatheter with two markers for detachable coil embolization (Rapidtransit, Johnson and Johnson, New Brunswick, NJ) was inserted coaxially and advanced to the distal CHA, 1 cm before the branching of the gastroduodenal artery. Detachable microcoils (interlocking detachable coil, Boston Scientific, Boston, MA) of diameter at least 1 mm greater than that of the CHA were deployed by making a lengthwise and/or sidewise frame (Figure 1A).

**Microcoil embolization under distal balloon inflation:** 6F and 4F long sheaths (Terumo) were inserted *via* the right and left femoral arteries, respectively. A 6F guiding catheter (Elway, Terumo Clinical Supply, Tochigi, Japan) was advanced through a 6F sheath to the celiac artery. After celiac arteriography, a 3.3F microballoon catheter (8 mm in maximum inflated diameter, 1 cm in length; Iiguman, Fuji System, Tokyo, Japan) was inserted into the common hepatic artery through a 6F guiding catheter and placed at the distal end of the CHA (Figure 1B). The microballoon was inflated, taking care not to interrupt blood flow in the gastroduodenal artery (Figure 2A). A 4F catheter (Rosch celiac type, Medikit, Tokyo, Japan) was advanced through a 4F sheath to catheterize the celiac artery, and a microcatheter with two markers was then advanced to the proximal end of the balloon inflation (Figure 2A). Detachable coils of diameter greater than that of the CHA were used initially, and fiber coils (Tornado, Boston Scientific) were added to fill the space if necessary. Microcoils were placed in the CHA from the proximal end of the microballoon inflation to the inlet of the left gastric artery (LGA) branching from the celiac trunk artery (Figure 2B). In fluoroscopic guidance, the tube angle that enabled the best visualization of the CHA or LGA was used. After microcoil embolization, the microballoon catheter was deflated and withdrawn.

**Figure 1** Schematic drawing of microcoil embolization under proximal balloon inflation (A) and distal balloon inflation (B) in the common hepatic artery. LGA: Left gastric artery; CHA: Common hepatic artery; SA: Splenic artery; SMA: Superior mesenteric artery.

**Microcoil embolization under distal balloon inflation and proximal balloon inflation at the time of withdrawal:** After microcoil embolization of the CHA under distal balloon inflation, as described above, a 5F balloon catheter (Selecon MP, Catheter Rosch II, Terumo) was inserted *via* the femoral artery to the celiac artery through a 6F long sheath. This 5F balloon catheter was used to prevent microcoil migration from the CHA to the celiac

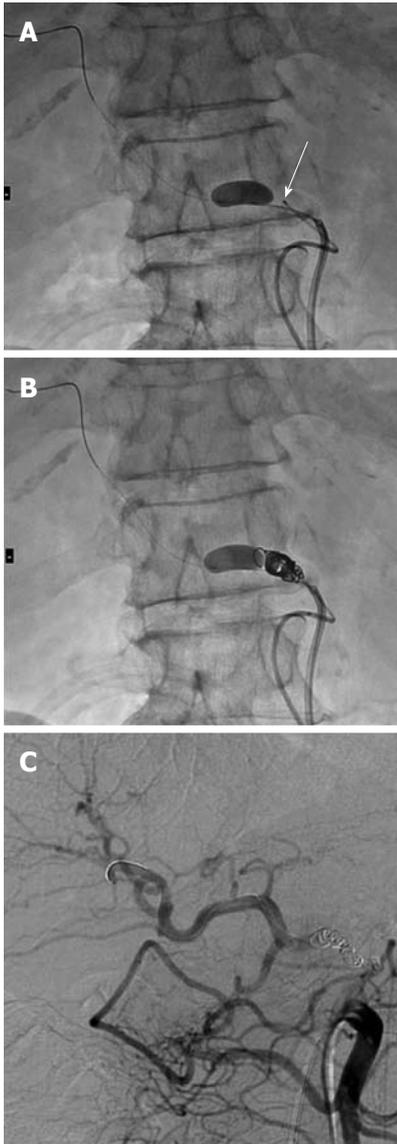

trunk artery. Specifically, when the distal balloon catheter was deflated and withdrawn, the 5F balloon catheter was inflated at the CHA proximal end or celiac trunk artery. After confirming no proximal coil migration, the proximal balloon catheter was deflated, and both balloon catheters were removed.

After coil embolization in each procedure, superior mesenteric arteriography was conducted to confirm the alteration of blood flow from the SMA to the hepatic artery (Figure 2C). We aimed for total hepatic arterial blood flow to be supplied from the superior mesenteric artery. When the left hepatic artery branched from the LGA, microcoil embolization of left gastric artery was also performed.

## RESULTS

In the present series, the first two patients underwent microcoil embolization of the CHA under proximal balloon inflation. Successful microcoil embolization of the CHA was completed in the first case. However, in the second case, distal migration of the microcoils occurred from the CHA to the proper hepatic artery after deflation of the proximal balloon catheter following microcoil placement. When this occurred, we immediately inserted the deflated microballoon catheter into the proper hepatic artery, advanced the catheter beyond the migrated microcoil, inflated the balloon catheter, and successfully withdrew the migrated coil to the common hepatic artery (Figure 3).

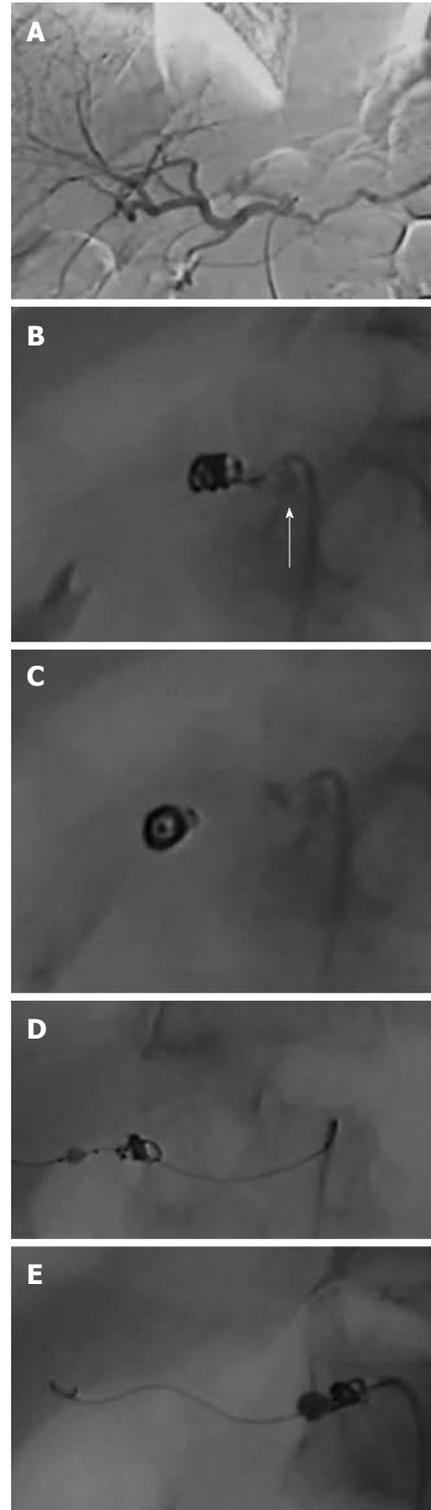

The third case underwent microcoil embolization under distal microballoon inflation. At the time of withdrawing the distal deflated balloon catheter located at the distal end of the CHA, we inflated the proximal balloon at the proximal end of the CHA to prevent microcoil migration from the CHA to the celiac trunk artery. However, we realized that the second (proximal) balloon catheter was not necessary because of the rigid fixation of the microcoils against the vascular wall. Thereafter, the distal

**Figure 2 Microcoil embolization under distal balloon inflation.** A: Radiograph during catheterization shows microcatheter (arrow) insertion to the common hepatic artery (CHA) via the celiac artery under distal microballoon inflation in the CHA; B: Radiograph during microcoil embolization shows a tight widthwise frame; C: Superior mesenteric arteriography after microcoil embolization shows blood flow from the superior mesenteric artery to the proper hepatic artery via the pancreaticoduodenal arcades.

deflated microballoon catheter was withdrawn without the assistance of proximal balloon inflation. There was no microcoil migration in the following 12 cases under distal microballoon inflation (Table 1). Accordingly, distal balloon inflation achieved the 1 cm patency at the end of the CHA required for vascular clamping.

In three cases having the variation of left hepatic artery branching from the LGA, we performed additional embolization of the LGA trunk using microcoils. In two of these three cases, total hepatic arterial blood flow was confirmed in superior mesenteric arteriography to come from the SMA via intrahepatic communication between the right and left hepatic arteries. In the remaining case, there was communication between the LGA and the

**Figure 3 Distal migration of the microcoils and the successful withdraw.** A: Following celiac arteriography; B: Microcoil embolization under proximal balloon inflation (arrow) was performed; C: Microcoil migration from the common hepatic artery (CHA) to the proper hepatic artery occurred after deflation of the proximal balloon catheter; D: Under fluoroscopic guidance using the tube angle that enabled the best visualization of the CHA and with the assistance of a microwire, a microballoon catheter was then inserted through the migrated coil and inflated; E: The migrated coils were withdrawn to their original position in the CHA by the inflated balloon catheter.

short gastric artery and left gastroepiploic artery, which

branched from the splenic artery. In this case, LGA and the splenic artery were embolized, aiming to achieve total hepatic blood flow from the SMA. However, following these embolizations, hepato-petal blood flow did not come from the SMA but from the inferior phrenic artery. No evidence of liver ischemia was observed during surgery, enabling radical pancreatectomy to be performed.

Superior mesenteric arteriography after embolization showed good hepato-petal blood flow from the SMA to the proper hepatic artery in all cases except that described above. All patients successfully underwent radical pancreatectomy without liver or gastric ischemia, and experienced no problems or complications related to the microcoil embolization.

## DISCUSSION

In the present series, microcoil embolization under distal balloon inflation was superior to that under proximal balloon inflation in terms of impeding distal embolization. White<sup>[16]</sup> described two techniques of coil placement in the pulmonary artery: an anchor technique in which the microcoil tip was hooked into the small branch, and a scaffold technique in which a long frame was created lengthwise to increase friction against the vessel wall and fill the feeding artery. There are no small branch arteries from the CHA; therefore, using the scaffold technique we made a lengthwise and sidewise frame, by pushing and pulling the coils. If the microcoils continued to push out under proximal balloon inflation, then they tended to move to a more peripheral site than intended; in this case, the microcoils needed to be pulled back. In the second case of the present series, under proximal balloon inflation the microcoils migrated to the proper hepatic artery despite the microcoils having a diameter 3 mm greater than that of the CHA; this probably occurred because the loose frame of placed microcoils did not create sufficient friction against the vascular wall. The migrated microcoils were pulled back by the distal inflated balloon catheter to the original CHA site. We found that microcoils placed under distal balloon inflation became more compact than those under proximal balloon inflation, creating enough friction against the vascular wall to prevent migration.

We anticipated that the microcoils could migrate from the CHA to the celiac trunk artery or abdominal aorta after retrieval of the deflated distal microballoon catheter following microcoil embolization. For this reason, in the third case of this series, an additional balloon catheter was inserted and inflated in the celiac trunk artery, with the aim of blocking proximal coil migration from the CHA to the celiac trunk. However, this precaution proved unnecessary. The rigid friction of the microcoils against the vessel wall resulted in no proximal migration when the distal deflated microballoon catheter was retrieved. The use of detachable coils of diameter 1-2 mm greater than that of the CHA was sufficient to create increased friction in the subsequent 12 cases under distal microballoon inflation.

As an additional positive outcome of the described technique, the long dimension of the inflated microballoon (10 mm) enables patency to be maintained at the distal CHA end. Accordingly, the distal microballoon inflation method fulfilled the surgeon's requirement to retain 1 cm patency at the distal CHA end for vascular clamping.

It is a weakness of the distal microballoon catheter method that performing the procedure is somewhat complicated. However, the dual femoral artery approach is minimally invasive, and maneuvering the microballoon catheter does not have a steep learning curve.

In conclusion, the distal microballoon inflation method in CHA microcoil embolization was preferable to the proximal balloon inflation method, in terms of creating a compact microcoil frame that caused no coil migration to the proper hepatic artery, and of supplying a sufficient length of CHA patency to enable vascular clamping.

## COMMENTS

### Background

In preoperative management to avoid liver ischemia during surgery for pancreatic body cancer, the surgeons requested the interventional radiologists to embolize the common hepatic artery, to enlarge the collateral pathways from the superior mesenteric artery.

### Research frontiers

This surgical procedure has the aim of en bloc lymphadenectomy together with resection of the spleen, pancreatic body, and tail by ligation of the celiac trunk artery and common hepatic artery (CHA). The safety of this operation is based on the rationale that hepatic arterial blood is supplied from the superior mesenteric artery via the pancreatico-duodenal arcades following ligation of the CHA.

### Innovations and breakthroughs

The previous method using microcoils was conducted to occlude CHA without a balloon catheter. The present study occluded the CHA using microcoil embolization with the assistance of a microballoon catheter.

### Applications

As the actual application for CHA occlusion, the distal microballoon inflation method in CHA microcoil embolization was preferable to the proximal balloon inflation method, in terms of creating a compact microcoil frame that caused no coil migration to the proper hepatic artery, and of supplying a sufficient length of CHA patency to enable vascular clamping.

### Terminology

For surgical treatment for pancreas body cancer, en bloc lymphadenectomy is performed together with resection of the spleen, pancreatic body, and tail by ligation of the celiac trunk artery and CHA. Because of the risk of liver ischemia following ligation of the CHA during surgery, preoperative occlusion of the CHA using microcoil embolization is necessary.

### Peer review

This study describes an interesting variant of interventional radiology that allows to minimize ischemic hepatic damage in Appleby operation. All technical steps are well and clearly described. Results are encouraging and convincing. Figure are clear and pertaining. The study is important for surgeons and interventional radiologists, even if only 15 patients have been enrolled.

### Abstract

**AIM:** To evaluate long-term clinical course of Budd-Chiari syndrome (BCS) and predictive factors associated with the development of hepatocellular carcinoma (HCC) and survival.

**METHODS:** We analyzed 67 patients with BCS between June 1988 and May 2008. The diagnosis of BCS was confirmed by hepatic venous outflow obstruction shown on abdominal ultrasound sonography, computed tomography, magnetic resonance imaging, or venogra-

phy. The median follow-up period was  $103 \pm 156$  [interquartile range (IQR)] mo.

**RESULTS:** The median age of the patients was  $47 \pm 16$  (IQR) years. At diagnosis, 54 patients had cirrhosis, 25 (37.3%) Child-Pugh class A, 23 (34.3%) Child-Pugh class B, and six (9.0%) patients Child-Pugh class C. During the follow-up period, HCC was developed in 17 patients, and the annual incidence of HCC in patients with BCS was 2.8%. Patients in HCC group ( $n = 17$ ) had higher hepatic venous pressure gradient (HVPG) than those in non-HCC group ( $n = 50$ ) ( $21 \pm 12$  mmHg vs  $14 \pm 7$  mmHg,  $P = 0.019$ ). The survival rate of BCS patients was 86.2% for 5 years, 73.8% for 10 years, and 61.2% for 15 years. In patients with BCS and HCC, survival was 79% for 5 years, 43.1% for 10 years, and 21.5% for 15 years.

**CONCLUSION:** The incidence of HCC in patients with BCS was similar to that in patients with other etiologic cirrhosis in South Korea. The HVPG is expected to provide additional information for predicting HCC development in BCS patients.

Hepatocellular carcinoma in Budd-Chiari syndrome: A single center experience with long-term follow-up in South Korea. *World J Gastroenterol* 2012; 18(16): 1946-1952 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i16/1946.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i16.1946>

## INTRODUCTION

Budd-Chiari syndrome (BCS) is a rare hepatic disease caused by occlusion of the hepatic venous outflow. Thrombogenic conditions among the known causes of BCS are well documented, such as coagulopathy, chronic intake of contraceptives, myeloproliferative diseases, autoimmune diseases, and others<sup>[1]</sup>. Hepatic venous outflow block can also be caused by malignant tumors<sup>[2]</sup>. BCS was initially defined as a symptomatic occlusion of the hepatic veins, but with increasing reports on various obstructive cases in the hepatic portion of the inferior vena cava (IVC), it became to include obstructive IVC lesions as well as the major hepatic veins. BCS induces chronic liver congestion so that it causes hepatomegaly, ascites, leg edema, collateral venous dilatation in the body trunk and portal hypertension<sup>[3]</sup>. Several studies have suggested that hepatic congestion caused by obstruction of hepatic venous outflow can lead to cirrhosis and hepatocellular carcinoma (HCC)<sup>[4,5]</sup>. The incidence of HCC in patients with BCS has varied according to regions and investigators<sup>[3,6-9]</sup>. Japan and South Africa showed relatively higher incidences compared to those of United States and France: 6.4%-47.5% vs 4%-20%<sup>[5,7,9,10]</sup>. Prognosis of HCC in BCS has varied as well<sup>[5,6,11]</sup>.

We followed BCS patients treated at our hospital for more than 20 years, and our long term follow-up data can be helpful to understand the prognosis of BCS patients and natural course of the disease. Thus, we (1) evaluated the incidence and cumulative annual risk of HCC in BCS patients; (2) analyzed the characteristics associated with the development of HCC in BCS patients; and (3) investigated the prognosis of BCS and HCC in BCS patients.

## MATERIALS AND METHODS

### Patients

From June 1988 to May 2008, 95 consecutive patients who were diagnosed with BCS at Severance Hospital were studied retrospectively. Among them, 28 patients were excluded based on the criteria as follows: patients with secondary BCS [occlusion of the hepatic venous outflow by an outside structure (HCC, a Klatskin tumor, and renal cell carcinoma)], hematologic diseases which could result in venous obstructive disease, hepatic septic emboli of colon cancer, or post-operative complication of HCC. Finally 67 patients who were diagnosed with primary BCS were investigated. The study protocol conformed to the ethical guidelines of the 1975 Helsinki Declaration and was approved by the institutional review board of our institute.

### Methods

We retrospectively reviewed patients' age, gender, and presenting symptoms of decompensate liver cirrhosis such as ascites, encephalopathy and variceal bleeding. We also investigated their history of medication which can induce thrombosis such as oral contraceptive, herbal

medication, and steroid. Patients were assessed for other risk factors of cirrhosis and HCC such as alcohol, hepatitis B virus and hepatitis C virus (HCV) infections.

Laboratory tests included complete blood count, prothrombin time, alanine aminotransferase (ALT), bilirubin, albumin, creatinine, viral markers such as hepatitis B virus surface antigen (HBsAg) and anti-HCV antibody. Based on laboratory and physical examination results, Model for End-Stage Liver Disease (MELD) score and Child Pugh score were calculated to evaluate liver function. Every 3-6 mo, imaging studies such as computed tomography (CT), ultrasonography or magnetic resonance imaging (MRI) were performed, and alpha-fetoprotein (AFP) level was checked for HCC surveillance.

### Diagnosis of BCS and HCC

The diagnosis of BCS was confirmed by hepatic venous outflow obstruction shown on ultrasound sonography (US), contrast-enhanced CT, MRI, or venography. Patients were confirmed to have HCC according to the American Association for the Study of Liver Disease practice guidelines for the HCC diagnosis<sup>[12]</sup>. Briefly, patients were diagnosed with HCC if they had a tumor with a maximum diameter of > 2 cm and the typical features of HCC on dynamic CT (defined as enhancement in the arterial phase and early washout in the portal phase), and an AFP > 200 ng/mL<sup>[12]</sup>. If the maximum diameter of the tumor was 1 cm to 2 cm, dynamic CT and MRI were performed. HCC was diagnosed if coincidental typical features of HCC were noted. If the tumor did not satisfy above criteria, a biopsy was performed. During hospital stay, abdominal ultrasonography was carried out to evaluate the presence of cirrhosis and hepatocellular carcinoma.

### Measurement of hepatic venous pressure gradient

The hepatic venous pressure gradient (HVPG) was measured through catheterization during venography or angioplasty. Forty-five patients underwent venography or angioplasty when diagnosed with BCS or during follow up period. Patients were diagnosed with clinical liver cirrhosis if they satisfied one or more of the following 3 conditions: (1) a platelet count < 100 000/ $\mu$ L and ultrasonographic findings suggestive of cirrhosis including a blunted, nodular liver edge accompanied by splenomegaly (> 12 cm)<sup>[13,14]</sup>; (2) the presence of esophageal or gastric varices; and (3) overt complications of liver cirrhosis, including ascites, variceal bleeding, and hepatic encephalopathy.

### Statistical analysis

Statistical analysis was performed using the Statistical Package for the Social Sciences (SPSS, version 17.0). Descriptive statistics were computed for all variables, including median  $\pm$  interquartile range (IQR) and percentiles for continuous variables and frequencies for categorical factors. Mann-Whitney *U* test and  $\chi^2$ -test were used to compare HCC and non-HCC groups. Kaplan-Meier analysis was performed to estimate the cumulative incidence

of HCC from the time of BCS diagnosis and survival of all BCS patients and those who developed HCC. To evaluate the factors associated with the development of HCC in patients with BCS, multivariate Cox regression analysis was used. A two-sided *P* value < 0.05 was considered to indicate a significant difference.

## RESULTS

### Baseline clinical characteristics of the patients

The baseline characteristics of the 67 patients are shown in Table 1. The site of obstruction was IVC in 56 patients (83.6%), hepatic vein in five patients (7.4%), and both IVC and hepatic vein sites in six patients who were classified as “combined”. There was no patient with history of chronic use of medication such as oral contraceptive, herbal medication, and steroid. Patients with heavy alcohol consumption defined as over 80 g/d were 20 (29.9%). HBsAg was positive in 3 patients (4.5%) and there was no patient with positive for anti-HCV antibody. Fifty-

four patients had underlying liver cirrhosis at the time of BCS diagnosis. Twenty-five of them (37.3%) were classified as Child-Pugh class A, 23 (34.3%) as class B, and six (9.0%) as class C. The median MELD score was 11 ± 6 (IQR). Twenty three patients (34.3%) had decompensated liver cirrhosis symptoms such as variceal bleeding, uncontrolled ascites or hepatic encephalopathy higher than grade 3. Twenty-seven (40.3%) patients were treated with percutaneous angioplasty, four (5.9%) with shunt operation, three (4.5%) with transjugular intrahepatic portosystemic shunt (TIPS), and one (1.5%) with thrombolysis. Thirty-two (47.7%) patients received only symptomatic medical treatment. The median follow up period was 103 ± 156 (IQR) mo.

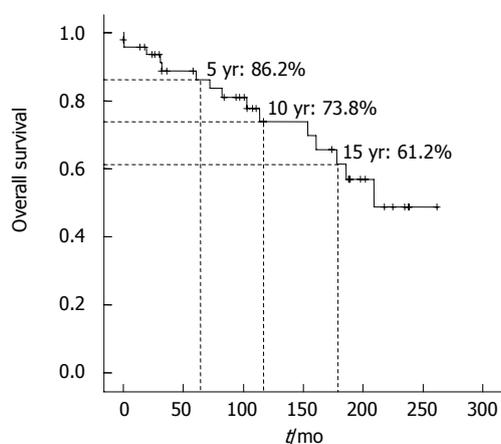

### Development of HCC in the patients with BCS

During follow-up periods, HCC was occurred in 17 patients. At the time of diagnosis of HCC, the median age of the patients was 53 ± 12 (IQR) years, and time period between diagnoses of BCS and HCC was 51 ± 115 (IQR) mo (Table 2). HCC was histologically confirmed in 2 patients with hepatic resection. According to the Kaplan-Meier analysis, as shown in Figure 1, the cumulative probability was 18.5% at 5 years, 30.3% at 10 years, and 42.6% at 15 years. The annual occurrence of HCC in BCS patients was 2.8%.

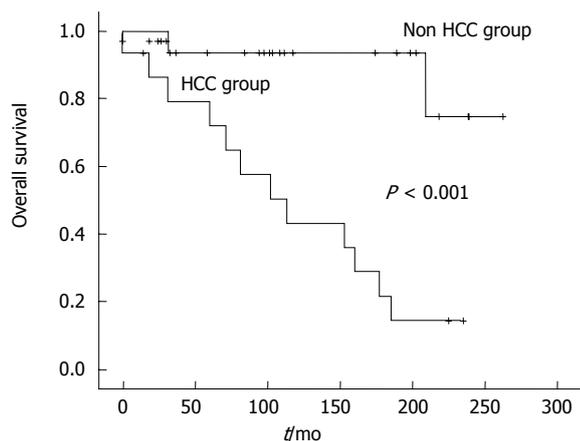

We compared the baseline characteristics (at the time of diagnosis with BCS) of HCC group (*n* = 17) with non-HCC group (*n* = 50). The differences between the two groups are shown in Table 3. There were no significant differences in the comparison of age, gender, obstruction site, alcohol consumption and presence of viral markers between two groups. HVPG was significantly higher in HCC group [21 ± 12 (IQR) mmHg] than in non-HCC

**Figure 1** Cumulative probability of hepatocellular carcinoma in patients with Budd-Chiari syndrome ( $n = 17$ ).

**Figure 2** Overall survival of patients with Budd-Chiari syndrome.

**Prognosis and survival of patients with BCS and patients who were diagnosed with HCC**

We estimated the overall survival rates of all 67 BCS patients using the Kaplan-Mayer method. The overall survival rate was 86.2% at 5 years, 73.8% at 10 years, and 61.2% at 15 years (Figure 2). During the follow-up periods, three patients among 17 who were diagnosed with HCC died, and two of them died from hepatic failure and the other from massive variceal bleeding. In HCC group, the 5-year survival rate was 79%, 10-year rate 43.1%, and 15-year rate 21.5% (Figure 3). Meanwhile, non-HCC group ( $n = 50$ ) showed significantly higher survival rates than HCC group: 93.4% for 5 years and 74.7% for 15 years ( $P < 0.001$ ).

**DISCUSSION**

BCS is caused by obstruction of hepatic venous outflow at any level from the small hepatic veins to the junction of the IVC with the right atrium. There are two forms of BCS according to the obstruction site: primary hepatic vein obstruction (classical BCS) and obstruction of the

HCC: Hepatocellular carcinoma; BCS: Budd-Chiari syndrome; Tx.: Treatment; TAE: Transarterial embolization; TACE: Transarterial chemoembolization; iA: Intra-arterial; LT: Liver transplantation. <sup>1</sup>Coagulopathy harbored factor V Leiden; <sup>2</sup>Female gender showed an odds ratio of 6.02 with  $P < 0.001$  in Cox regression analysis; IVC: Inferior vena cava.

hepatic portion of the inferior vena cava (IVCO). The IVCO form is common in Asia and Africa but rarely reported in Western countries<sup>[9,15]</sup>. Most of our patients (83.6%) had the IVCO form, which is similar to previous studies which reported the predominance of IVCO form in Asia. The major difference between classical BCS and IVCO is that the former is rarely associated with HCC, while the latter is frequently complicated by HCC<sup>[3,8]</sup>. In our study, HCC was developed in 17 of 67 patients, and the annual incidence was 2.8%, similar to the incidence in patients with other etiologic cirrhosis in South Korea<sup>[16,17]</sup>.

Until now, the accurate pathogenesis of HCC in BCS has not been elucidated yet. Gwon *et al.*<sup>[6]</sup> suggested that chronic liver injuries and congestion caused by obstruction of hepatic venous outflow might contribute to a fibrotic process and development of nodular type of HCC. Prolonged congestion can lead to hepatocyte necrosis, and its replacement with fibrous tissue results in fibrosis, which is assumed to be the mechanism of cirrhosis and HCC development<sup>[18-20]</sup>. This hypothesis is supported by frequent findings of liver parenchymal cirrhotic change adjacent to HCC in BCS context<sup>[7]</sup>.

The HVPG was significantly higher in HCC group than non-HCC group in our study. HVPG has been accepted as the gold standard for assessing the severity of portal hypertension<sup>[21]</sup>. With the pathogenesis proposed above, the higher pressure gradient means a greater degree of portal hypertension and hepatic congestion; this might have contributed to a higher pressure gradient in HCC group in our study. Our study that showed significantly

high HVPG in HCC group is worthy, which supports the hypothesis of development of HCC in patients with BCS. Until now, there were several published reports to analyze the risk factors for HCC in patients with BCS. Although Moucarri *et al.*<sup>[7]</sup> showed that BCS patients with HCC compared with those without HCC presented with IVC obstruction more frequently, there was no report that showed direct differences of pressure gradient as our data presented. For comparison, other published data concerning the prevalence and characteristics of HCC in patients with BCS were reviewed in Table 4.

Varying survival results of BCS have been reported, and the 5-year survival rate ranges from 69% to 87%<sup>[22,23]</sup>. In our data, the overall survival rate was 86.2% for 5 years, 73.8% for 10 years, and 61.2% for 15 years. In patients with BCS and HCC, the survival rate was 79% for 5 years, 43.1% for 10 years, and 21.5% for 15 years in our study. This is comparable with the results of other published reports<sup>[6,24]</sup>. Improvement in availability and techniques of diagnostic tools and development of treatment modalities may allow earlier diagnosis of BCS patients and better prognosis<sup>[18-20]</sup>.

Although our study has an advantage of long-term follow up data of patients with BCS, there are still some limitations. First, this was retrospective and therefore has the limitations of such an investigational design. Another limitation was that the values of HPVG obtained during venography were not checked in all patients. Because of invasiveness of venography, it could not be performed on all patients for HVPG measurement. These days,

Doppler US is used to non-invasively assess the HPVG with portal vein velocity. Considering the low incidence of BCS, a multicenter study should be performed to overcome the limitations of patient number and insufficient information. Despite these limitations, this study is worthy to analyze the incidence and prognosis of HCC in BCS with long-term follow-up periods in South Korea.

In conclusion, the annual incidence of HCC in patients with BCS was similar to the incidence in patients with other etiologic cirrhosis in South Korea. Furthermore, the HVPVG can be a possible predictive factor of BCS-associated HCC development. Thus, BCS patients who are expected to have high pressure gradient should be actively managed as a high risk group for HCC development. An intervention to decrease the pressure gradient in BCS patients may be helpful to reduce the incidence of HCC. A large-scale study will be necessary to further investigate whether the treatment of congestion decreases the incidence of HCC.

## COMMENTS

### Background

Budd-Chiari syndrome (BCS) is a rare disease caused by obstruction of the hepatic venous outflow. BCS induces chronic liver congestion so that it causes hepatomegaly, ascites, leg edema, collateral venous dilatation in the body trunk, and portal hypertension. Several studies have suggested that hepatic congestion caused by obstruction of hepatic venous outflow can lead to cirrhosis and hepatocellular carcinoma (HCC). However, the incidence of HCC in patients with BCS has varied according to regions and investigators and there has been a lack of reports for long-term prognosis of HCC in patients with BCS.

### Research frontiers

Although BCS is a relatively rare disease as contrasted with other viral liver disease that can lead to advanced liver disease such as liver cirrhosis or HCC, several studies have reported the association between BCS and HCC. Long-term follow-up data of BCS may help to understand not only the prognosis of BCS but also the process of HCC in patients with BCS.

### Innovations and breakthroughs

This study showed that the hepatic venous pressure gradient (HVPVG) was significantly higher in HCC group than non-HCC group. Although the accurate pathogenesis of HCC in BCS has not been elucidated, there were several suggestions that chronic liver injuries and congestion caused by obstruction of hepatic venous outflow might contribute to a fibrotic process and development of HCC. The study is worthy because it supports this hypothesis about the development of HCC in patients with BCS.

### Applications

From the study, it was suggested that the HVPVG can be a possible predictive factor of BCS-associated HCC development. Thus, BCS patients who are expected to have a high pressure gradient should be actively managed as a high risk group for HCC development. An intervention to decrease the pressure gradient in BCS patients may be helpful to reduce the incidence of HCC.

### Peer review

This study provides basic and essential data for the clinical care of the patients with BCS.

Transparent-cap-fitted colonoscopy shows higher performance with cecal intubation time in difficult cases. *World J Gastroenterol* 2012; 18(16): 1953-1958 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i16/1953.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i16.1953>

### Abstract

**AIM:** To investigate the efficacy of cap-fitted colonoscopy (CFC) with regard to cecal intubation time.

**METHODS:** Two hundred and ninety-five patients undergoing screening colonoscopy at Gospel Hospital, Kosin University College of Medicine were enrolled in this randomized controlled trial between January and December 2010. Colonoscopies were conducted by a single endoscopist. Patient characteristics including age, sex, body mass index, history of abdominal surgery, quality of preparation, and the presence of diverticulosis were recorded.

**RESULTS:** One hundred and fifty patients were allocated into a CFC group and 145 into a non-CFC (NCF) group. Cecal intubations were achieved in all patients. Cecal intubation time in the CFC group was significantly shorter than in the NCF group for specific conditions: age  $\geq$  60 years, prior abdominal surgery, and poor bowel preparation. The number of detected adenomas was higher in the CFC group than in the NCF group ( $P = 0.040$ ).

### INTRODUCTION

Colorectal cancer is a major cause of cancer-related mortality and morbidity, and it is evident that this fatality rate has led to an increase in colonoscopy preventative treatment<sup>[1-3]</sup>. A multinational and multicenter survey performed in Asia has shown that the overall prevalence of advanced colorectal neoplasm in asymptomatic individuals is comparable with that in the West<sup>[4]</sup>. Removal of colonic adenomas by screening colonoscopy could reduce colorectal cancer incidence and mortality rate.

Colonoscopy, however, can be a complicated procedure and requires a skillful endoscopist<sup>[5-7]</sup>. The anatomical factors of difficult cecal intubation can usually be categorized into one of two problems: (1) an angulated and/or narrowed sigmoid colon; and (2) a redundant colon<sup>[8]</sup>. These anatomical difficulties are commonly observed in specific cases, such as female patients, older age, previous gynecologic surgery, and the presence of diver-

ticulosis<sup>[9-17]</sup>. Published studies have suggested the use of a narrower instrument shaft or one with both a narrower shaft and a shorter bending section for use in angulated or narrowed sigmoid colons, and a stiffened shaft with simultaneous application of abdominal pressure for overcoming the problems associated with redundant colons<sup>[8,18,19]</sup>. However, these maneuvers are not always successful and may require the endoscopist to change instruments during the procedure.

Several studies have evaluated the efficacy of transparent cap-fitted colonoscopy (CFC) compared to that of non CFC (NCF), and have found no difference in cecal intubation time between CFC and NCF<sup>[20-22]</sup>. The one established advantage of CFC is that it is more sensitive to polyp detection than is NCF<sup>[20,21]</sup>. However, these results are not consistent with our daily experience, in that CFC requires a shorter time for cecal intubation than does NCF.

Short cecal intubation time is important for several reasons: less anesthetic medication is required; colonic inflation results in less discomfort; and sufficient withdrawal time for accurate examination. The purpose of this study was to evaluate whether CFC could result in shorter cecal intubation time compared with NCF. Additionally, we compared the detection rate of colonic adenomas in this study.

## MATERIALS AND METHODS

### Patients

From January to December 2010, 300 consecutive patients scheduled for their first ever colonoscopy as a routine health check at Gospel Hospital, Kosin University College of Medicine were included in the study. Exclusion criteria were as follows: age < 18 years; hospitalization due to other diseases undergoing colonoscopy investigation; evidence of acute or chronic renal failure; cardiovascular diseases including recent myocardial infarction, congestive heart failure, unstable angina, and cardiac arrhythmias; ascites; electrolyte imbalance; active inflammatory bowel disease, ileus and/or suspected bowel obstruction; pregnant or breast feeding; or child-bearing potential without adequate contraception. Patient medical history, demographic data, and body weight were recorded. For all patients, clinical hemodynamic, hematological, and biochemical measurements, including whole blood count, blood sugar, blood urea nitrogen, creatinine, and serum electrolyte (sodium, potassium, chloride, phosphorus, ionized calcium and magnesium) levels were measured. After initial evaluations, patients who had no exclusion criteria were randomized to receive CFC or NCF by one physician who was blinded to the results of previous colonoscopies. This study was approved by the Institutional Review Board of Kosin University College of Medicine, Busan, South Korea.

### CFC and NCF

After providing informed consent, patients in both groups

were encouraged to adhere to a clear liquid diet from 06:00 h to midnight on the day before colonoscopy, and further oral intake was not allowed after midnight. All patients drank 4 L of polyethylene glycol electrolyte lavage solution, starting 7 h before colonoscopy at a rate of 250 mL every 15 min until all of the solution had been consumed, as recommended by the manufacturer (Olympus Optical Corp, Tokyo, Japan). Before colonoscopy, a physical examination and clinical hemodynamic measurements were repeated. The transparent plastic cap (D-14304; Olympus Optical Corp., Tokyo, Japan) used for CFC was 14 mm in outer diameter, 10 mm in length, and had a 1 mm wall thickness. This cap can be fitted and fixed to the tip of the colonoscope (CIF H260; Olympus Optical Corp.). To ensure consistency in the evaluations, all colonoscopies were performed by the same attending endoscopist using the standard technique of negotiating the colon with as little air insufflation as possible. The principal examination was carried out during withdrawal. Ileal intubation was attempted when it was relevant.

### Variables

For evaluating the efficacy of CFC against NCF, the duration time of insertion up to the cecum was compared between the CFC and NCF groups. Additionally, the number of adenomas detected during colonoscopy was calculated. Factors presumed to influence cecal intubation time were sex, age, body mass index, and history of abdominal surgery; all of which were evaluated before colonoscopy. The quality of preparation was classified as follows: grade 0, percentage of visible mucosa > 90%, excellent visibility (small volume of clear liquid requiring minimal suctioning for adequate visualization), and no intestinal bubbles; grade 1, percentage of visible mucosa > 90%, good visibility (large volume of clear liquid or small amount of fecal residue, not preventing a reliable examination), and small number of intestinal bubbles; grade 2, percentage of visible mucosa > 90%, fair visibility (some semi-solid stool that could be suctioned or washed away, preventing a reliable examination), and moderate number of intestinal bubbles; and grade 3, percentage of visible mucosa < 90%, poor visibility (large amount of semi-solid stool that could not be suctioned or washed away, not allowing a complete examination to be done), and large number of intestinal bubbles. The number of adenomas was calculated during colonoscopy. Discomfort of each patient was recorded using a four-point scale (1: easy; 2: tolerable; 3: some pain; 4: severe pain).

### Statistical analysis

Statistical analysis was performed using SPSS version 16.0 (SPSS, Chicago, IL, United States). For normally distributed continuous variables, Student's *t* test was used to assess differences between the two groups. For categorical variables, Fisher's exact test was used. Cox multivariate regression analysis was performed to produce statistically significant variables in the present study. Two-sided *P* values < 0.05 were considered statistically significant.

## RESULTS

Initially, 150 patients volunteered for each group. However, five patients in the conventional endoscopy group withdrew their consent after finishing all examinations; therefore, 150 patients for cap-assisted colonoscopy and 145 patients for conventional colonoscopy were enrolled. There were no significant differences in the backgrounds between the group with CFC and that with NCF (Table 1).

Cecal intubation was achieved in all cases regardless of method. The average time for insertion from anus to cecum was shorter in the CFC group than in the NCF group, but the difference was not statistically significant (262 ± 154 s *vs* 281 ± 138 s, *P* = 0.057). CFC showed greater adenoma detection than did NCF (2.0 ± 2.5 *vs* 1.2 ± 1.6; *P* = 0.040), especially for sessile adenomas (1.8 ± 1.9 *vs* 1.0 ± 0.9; *P* = 0.039). There was no significant difference between the two groups regarding patient discomfort scores during colonoscopy (2.3 ± 1.0 *vs* 2.3 ± 0.8, *P* = 0.741). These results are shown in Table 2.

Multivariate analyses revealed that cecal intubation time was significantly longer in patients aged > 60 years, with a history of abdominal surgery, and two or three points in quality of bowel preparation as described in Table 3.

Multivariate analyses revealed that CFC required a significantly shorter cecal intubation time than did NCF in specific patients, including older patients (244 ± 123 s

*vs* 330 ± 213 s; *P* = 0.009), those with history of abdominal surgery (240 ± 106 s *vs* 351 ± 219 s; *P* = 0.012), and those with bowel preparation score 2 or 3 (224 ± 96 s *vs* 302 ± 176 s; *P* = 0.006), as shown in Table 4.

## DISCUSSION

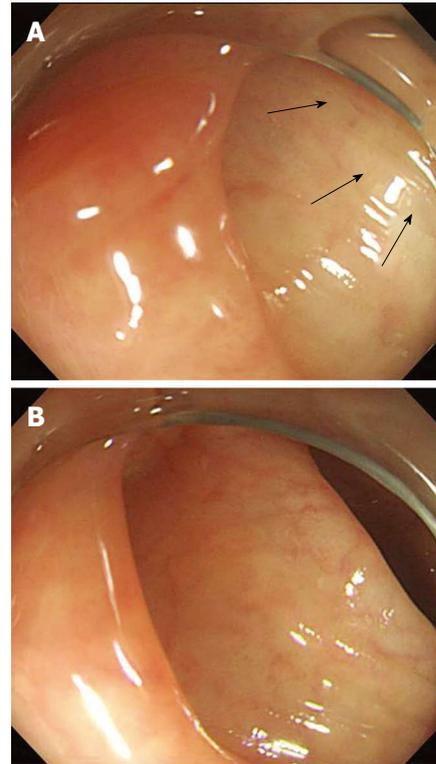

Colonoscopy is a common endoscopic procedure. It is widely used for the investigation of lower gastrointestinal tract disorders and screening for colorectal adenomas<sup>[23]</sup>. However, failure to reach the cecum occurs in up to 10% of cases<sup>[10,24]</sup>. A transparent cap was initially designed for mucosectomy and was later used during colonoscopy to enhance colonic polyp detection<sup>[22]</sup>. CFC is an effective rescue method for patients who fail to achieve cecal intubation<sup>[25]</sup>. This benefit is more apparent for inexperienced colonoscopists<sup>[26]</sup>. Moreover, it has been shown that such a device can shorten cecal intubation time among experienced colonoscopists<sup>[27]</sup>. However, the present study

**Figure 1 Advantage of cap-fitted colonoscopy for preventing red-out.** A: Although the precise direction could not be judged, colonoscopy showed a slight fold (white arrows) without red-out; B: A subtle movement showed a dark area at the 11 o'clock position (white arrow); C: Following the dark area at the 11 o'clock position enabled the colonoscopist to find the direction of insertion (black arrows).

showed that there was no significant difference between CFC and NCF in cecal intubation time, although the average cecal intubation time of CFC was shorter than that for NCF.

Although there was no significant difference in cecal intubation time between the two groups, CFC showed a shorter time than did NCF in several specific situations: age  $\geq 60$  years, history of abdominal surgery, and poor bowel preparation. In previous studies, predictive factors for incomplete colonoscopy were female sex, older age, previous gynecologic surgery, and the presence of diverticulosis<sup>[9-12]</sup>. In addition, female sex and older age are well known factors responsible for longer cecal intubation times<sup>[13-17]</sup>. Consistent with these previous results, CFC in the current study displayed a shorter cecal intubation

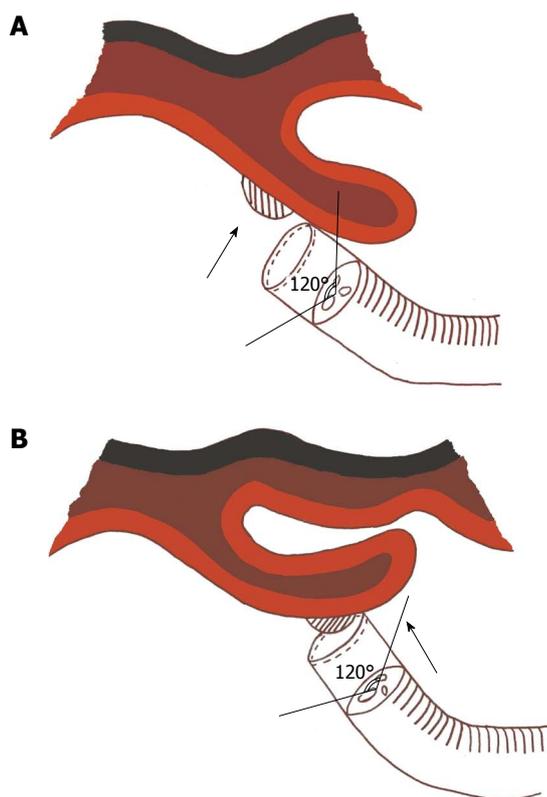

**Figure 2 Advantage of cap-fitted colonoscopy for observing lateral side.** A: The colonoscopist easily noticed the route of insertion because the transparent cap showed the small dark lumen at the 1 o'clock position through its lateral wall (black arrows); B: Following the route shown through the lateral wall of the transparent cap, a wide lumen was found easily.

time in difficult cases, such as in older patients, and those with a history of abdominal surgery, and poor bowel preparation. In our study, a single experienced endoscopist performed all procedures; this might be the reason why there was no difference between the two groups in cecal intubation time.

A possible explanation for this difference is less air insufflation during CFC than with NCF. A recent study revealed that the limited use of low-air insufflation in the rectum and sigmoid colon shortened the cecal intubation time and decreased post-procedural abdominal bloating<sup>[28]</sup>. Low-air insufflation causes less bowel inflation and produces less angulations of the bowel, thus enhancing cecal intubation. The use of CFC requires extremely low air insufflations. Experts in CFC can advance a cap-fitted colonoscope by pushing and pulling using meticulous lever manipulation without air insufflation, especially in the rectum and sigmoid colon. Extremely low air insufflation can be achieved in CFC because the cap prevents the mucosa from touching the lens directly and enables continuous lumen observation (Figure 1)<sup>[21]</sup>. Another important CFC characteristic is that the lateral side can be observed through the transparent wall of the cap (Figure 2)<sup>[21]</sup>. In the hepatic and splenic flexures, observing the lateral side through the transparent wall of the cap can help endoscopists determine the next step of the colonoscopy.

Another advantage of CFC in cecal intubation was that more adenomas were observed in the CFC group

**Figure 3** The opposite, blind side of the folds could be observed with fewer problems during colonoscopy. A: Compressing the tip of a fold straightened the entire fold and improved the view; B: Bending the tip of the endoscope allowed a front view of the lesion at the blind side of the fold.

during withdrawal compared to those in the NCF group. Cap usage greatly facilitates the identification of small adenomas. During insertion and withdrawal of the cap-fitted colonoscope, the lumen of the colon can always be seen clearly because the mucosa never directly touches the lens<sup>[21]</sup>. The opposite, blind side of the folds can easily be observed and treated with fewer problems in CFC because they can be straightened to improve the view (Figure 3)<sup>[20]</sup>, and the lateral side can be observed through the transparent wall of the cap<sup>[21]</sup>. Fecal matter may stick to the inside of the cap in cases of poor bowel preparation, thereby impairing the view. Using the water insufflation button or simple flushing through the biopsy channel can lead to ineffective cap clearing. The cap, however, was easily cleaned in CFC by pressing the whole circumference of the cap against the mucosal surface and then flushing the biopsy channel<sup>[20]</sup>. Moreover, CFC enhanced cecal intubation compared to that of NCF in cases of poor bowel preparation (scores of 2 and 3).

In conclusion, CFC has advantages in overcoming the problems associated with angulated and/or narrowed sigmoid and redundant colon, thereby resulting in significantly higher performance in cecal intubation time in difficult cases such as old age, prior abdominal operation, and poor bowel preparation. Furthermore, CFC displayed a higher sensitivity in detecting colonic adenomas than did NCF.

## ACKNOWLEDGMENTS

We acknowledge the contribution of Miss Da Hyun Ahn, first grade student in Kosin University College of Medicine, for creating the figures to explain the efficacy of CFC.

## COMMENTS

### Background

Colorectal cancer is a major cause of cancer-related mortality and morbidity, and it is evident that this fatality rate has led to an increase in colonoscopy preventative treatment. Colonoscopy, however, can be a complicated procedure and requires a skillful endoscopist. The anatomical factors of difficult cecal intubation can usually be categorized into one of two problems: (1) an angulated and/or narrowed sigmoid colon; and (2) a redundant colon. These anatomical difficulties are commonly observed in specific cases, such as female patients, older age, previous gynecological surgery, and the presence of diverticulosis. Published studies have suggested the use of a narrower instrument shaft or one with both a narrower shaft and a shorter bending section for use in angulated or narrowed sigmoid colons, and a stiffened shaft with simultaneous application of abdominal pressure for overcoming the problems associated with redundant colons.

### Research frontiers

Several studies have evaluated the efficacy of a transparent cap-fitted colonoscopy (CFC) compared to that of non-CFC (NCF) and found that there was no difference in cecal intubation time between CFC and NCF. The one established advantage of CFC is that it is more sensitive to polyp detection than is NCF.

### Innovations and breakthroughs

The transparent plastic cap is made by Olympus Optical Corp., Tokyo, Japan. It is 17 mm in outer diameter, with a 2 mm wall thickness and 10 mm in length, and can be fitted and fixed to the tip of the colonoscope. This can cause less air insufflation during CFC than with NCF. Low-air insufflation causes less bowel inflation and produces less angulations of the bowel, thus enhancing cecal intubation. The present study aimed to evaluate whether CFC could result in shorter cecal intubation time compared with NCF. Additionally, the study compared the detection rate of colonic adenomas.

### Applications

CFC has advantages in overcoming the problems associated with angulated and/or narrowed sigmoid and redundant colon, thereby resulting in significantly higher performance in cecal intubation time in difficult cases, such as elderly patients, and those with prior abdominal operation, and poor bowel preparation. Furthermore, CFC displayed a higher sensitivity in detecting colonic adenomas than did NCF.

### Terminology

Transparent CFC: a colonoscopic procedure with a transparent cap at the front view of the colonoscope.

### Peer review

The present study showed that CFC had shorter cecal intubation time in difficult cases. This is an interesting and good study.

### Abstract

**AIM:** To evaluate the feasibility and safety of laparoscopic distal pancreatectomy (LDP) compared with open distal pancreatectomy (ODP).

**METHODS:** Meta-analysis was performed using the databases, including PubMed, the Cochrane Central Register of Controlled Trials, Web of Science and BIOSIS Previews. Articles should contain quantitative data of the comparison of LDP and ODP. Each article was reviewed by two authors. Indices of operative time, spleen-preserving rate, time to fluid intake, ratio of malignant tumors, postoperative hospital stay, incidence rate of pancreatic fistula and overall morbidity rate were analyzed.

**RESULTS:** Nine articles with 1341 patients who underwent pancreatectomy met the inclusion criteria. LDP was performed in 501 (37.4%) patients, while ODP was performed in 840 (62.6%) patients. There were significant differences in the operative time, time to fluid in-

take, postoperative hospital stay and spleen-preserving rate between LDP and ODP. There was no difference between the two groups in pancreatic fistula rate [random effects model, risk ratio (RR) 0.996 (0.663, 1.494),  $P = 0.983$ ,  $I^2 = 28.4\%$ ] and overall morbidity rate [random effects model, RR 0.81 (0.596, 1.101),  $P = 0.178$ ,  $I^2 = 55.6\%$ ].

**CONCLUSION:** LDP has the advantages of shorter hospital stay and operative time, more rapid recovery and higher spleen-preserving rate as compared with ODP.

Laparoscopic distal pancreatectomy is as safe and feasible as open procedure: A meta-analysis. *World J Gastroenterol* 2012; 18(16): 1959-1967 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v18/i16/1959.htm> DOI: <http://dx.doi.org/10.3748/wjg.v18.i16.1959>

### INTRODUCTION

With improvement of advanced surgical techniques and endoscopic instrument, laparoscopic distal pancreatectomy (LDP) is becoming a primary modality for the treatment of benign or borderline tumors of distal pancreas<sup>[1-3]</sup>.

Recently, several researches have shown the advantages of LDP of shorter hospital stay and operative time and less intraoperative blood loss<sup>[4-5]</sup>. But the efficacy of LDP compared with open distal pancreatectomy (ODP) required further assessment, especially the incidence of pancreatic fistula (PF) which may lead to further com-

plications such as an intra-abdominal abscess, sepsis or lethal bleeding<sup>[6]</sup>. With a better understanding of the anatomy and immune function of spleen, especially the increased risks of overwhelming post splenectomy infection (OPSI) and long-term lung thrombosis<sup>[7]</sup>, laparoscopic spleen preserving distal pancreatectomy (LSPDP) was performed first by Kimura *et al*<sup>[8]</sup> and Warshaw<sup>[9]</sup>. However, the role of “laparoscopy” in the spleen preservation is still unclear.

All the published studies we retrieved were based on a small number of patients and no randomized trials were available. Therefore, we strictly established the inclusion criteria and conducted a comprehensive meta-analysis to evaluate more systematically the feasibility and safety of LDP.

## MATERIALS AND METHODS

### Search strategy

We searched databases of PubMed, The Cochrane Central Register of Controlled Trials, Web of Science and BIOSIS Previews for the literatures comparing LDP and ODP published between January 1995 and June 2011. The language of the publications was confined to English. Two investigators reviewed the titles and abstracts, and assessed the full text to establish the eligibility. The search strategies were as follows (Table 1).

### Inclusion criteria

All clinical studies should meet the following criteria for the meta-analysis: (1) published in English with data comparing ODP and LDP; (2) with clear case selection criteria, containing at least the following information: the number of cases, surgical methods and perioperative data; (3) continuous variables (e.g., operative time and hospital stay) expressed in mean  $\pm$  SD. Dichotomous variables (e.g., incidence of PF and number of death) such as odds ratio (OR) and 95% confidence interval (CI); and (4) if there was overlap between authors, centers, or patient cohorts, the higher quality or recent literatures were selected.

### Exclusion criteria

The papers containing any of the followings were excluded: (1) intra-operative conversion of LDP to an open laparotomy, which was classified into the laparoscopic group; (2) single surgical procedure; and (3) laparoscopy-assisted DP or hand-assisted LDP.

### Data extraction and quality assessment

Two authors independently extracted the data using a unified datasheet, and decided the controversial issues through discussion. Extracted data included: first author, study period, the number of cases, operative time, spleen preservation, hospital stay, cases of malignant tumors, incidence of post-operative complications, and PF. Selected documents were rated according to the Grading of the Centre of Evidence-Based Medicine (Oxford, United Kingdom; www.cebm.net).

### Statistical analysis

This meta-analysis was performed according to the Meta-analysis of Observational Studies in Epidemiology (MOOSE) and the Quality of Reporting of Meta-analyses (QUORUM) as a guideline<sup>[10,11]</sup>. Weighted mean differences (WMD) were used for continuous variables, and relative risk for dichotomous variables. *P* values < 0.05 indicated statistically significant difference between the two groups. When heterogeneity test showed no significant differences (*P* > 0.05), we used fixed effects model to calculate the summary statistics. When the heterogeneity test showed statistically significant differences (*P* < 0.05), we used random effects model based on DerSimonian and Laird method. If the heterogeneity was high or extracted data were less than three sets, we performed descriptive analysis. The potential publication bias was determined by the Begg's test and funnel plots based on the dichotomous variables. All data were analyzed using Stata SE11.0 software.

## RESULTS

We retrieved 1663 papers in English. After the titles and abstracts were reviewed, papers without comparison of LDP and ODP were excluded. As a result, a total of 20 studies<sup>[12-31]</sup> were collected, of which 11 studies were excluded because of intraoperative conversion and using “assisted” approach. However, we preserved them for the analysis as “conversion to open”. Finally, 9 studies<sup>[23-31]</sup> were included and extracted for detailed data. A flow chart of search strategies is illustrated in Figure 1.

Totally, 1341 patients (sample sizes ranging from 44 to 310) entered into this meta-analysis, including 501 (37.4%) cases of LDP and 840 (62.6%) cases of ODP. The detailed study design and surgical techniques in 10 trials are summarized in Table 2.

**Figure 1** A flow chart of search strategies. The initial search strategy retrieved 1663 papers in English. Finally 9 studies were included and extracted for detailed data. LDP: Laparoscopic distal pancreatectomy; ODP: Open distal pancreatectomy.

### Intraoperative effects

The operative time was reported in four articles<sup>[23,24,26,28]</sup>. Meta-analysis of the pooled data showed that the operative time of ODP was significantly shorter than LDP [random effects model, WMD 44.947 (13.857, 76.037),  $P = 0.005$ ] (Figure 2A).

In the included articles, five studies<sup>[23,25,27,29,30]</sup> covered the spleen-preserving DP, 95 cases (29.6%) of LSPDP were conducted among 321 cases of LDP as compared with 76 cases (13.3%) of SPDP among 571 cases of ODP. The pooled data showed that the spleen-preserving rate in LDP was significantly higher than in ODP [random effects model, RR 2.380 (1.177, 4.812),  $P = 0.016$ ,  $I^2 = 73.2\%$ ], (Figure 3A). Although there was moderate heterogeneity, spleen-preservation occurred more often in LDP. Most authors tended to use the “Kimura method”, and “Warshaw method” was used in a few LDPs and in cases with severe adhesion or vessels involved in tumors. Technical details of spleen-preservation are listed in Table 3.

Among 714 cases of LDP, 100 cases (14.0%) converted to open surgery and 6 cases converted to the hand-assisted approach as shown in 20 articles<sup>[12-31]</sup> because of severe bleeding, abdominal adhesions, large tumor, organ injury, and difficult anatomy.

The techniques of pancreatic stump closure in the included studies are summarized in Table 4. Because the pooled data was derived from 9 institutions, no single technique was used for both procedures, but similar principles were applied. In LDP, the gland was divided by staplers and in ODP, stapler or scalpel + suture was used. In some cases, bio-sealant was attached to the stump reported by Baker, DiNorcia, Kim and Aly<sup>[23,24,27,30]</sup>.

### Postoperative outcome

Three studies<sup>[23,26,30]</sup> contained information about time to post-operative fluid intake. Meta-analysis of the pooled

data showed that time to fluid intake was shorter in LDP than in ODP [random effects model, WMD -0.948 (-1.863, 0.032),  $P = 0.042$ ] (Figure 2B). Another three studies<sup>[23,26,28]</sup> reported the postoperative hospital stay. The pooled data showed that postoperative hospital stay was significantly shorter in LDP than in ODP [random effects model, WMD -2.713 (-3.799, 1.628),  $P = 0.00$ ] (Figure 3B).

The proportion of malignant tumors reported by four articles<sup>[24,26,28,31]</sup> was 20% (36/180) in LDP and 20.1% (54/269) in ODP, and most of them were adenocarcinomas. The proportion of malignant tumors in LDP was not significantly different as compared with ODP [fixed effects model, RR 1.036 (0.708, 1.516),  $P = 0.000$ ,  $I^2 = 0\%$ ] (Figure 3C). There was no difference in patient selection between the two groups.

All studies illustrated the criteria for PF. Seven articles followed the criteria by International Study Group for Pancreatic Fistula (ISGPF): any measurable volume of fluid on or after postoperative day 3 with an amylase level > 3 times that of normal serum amylase level. Eom *et al.*<sup>[28]</sup> used the following PF criteria: drainage exceeding 30 mL with an amylase level > 600 U/dL on or after postoperative week 1. Kim *et al.*<sup>[30]</sup> chose the PF criteria: a level of drain amylase five times greater than the serum level and drainage of more than 30 mL 5 d or longer after the operation.

One study was excluded<sup>[31]</sup> due to no available data, 8 studies reported 50 (12.5%) PF cases in 401 LDP (12.5%) and 99 (13.4%) PF cases in ODP. The pooled data showed no significant difference between the two groups [random effects model, RR 0.996 (0.663, 1.494),  $P = 0.983$ ,  $I^2 = 28.4\%$ ] (Figure 2C) and no publication bias was found by Begg's test (Figure 4). Similarly, there was no significant difference in the overall morbidity between LDP and ODP [random effects model, RR 0.81 (0.596, 1.101),  $P = 0.178$ ,  $I^2 = 55.6\%$ ] (Figure 5), although there was moderate heterogeneity.

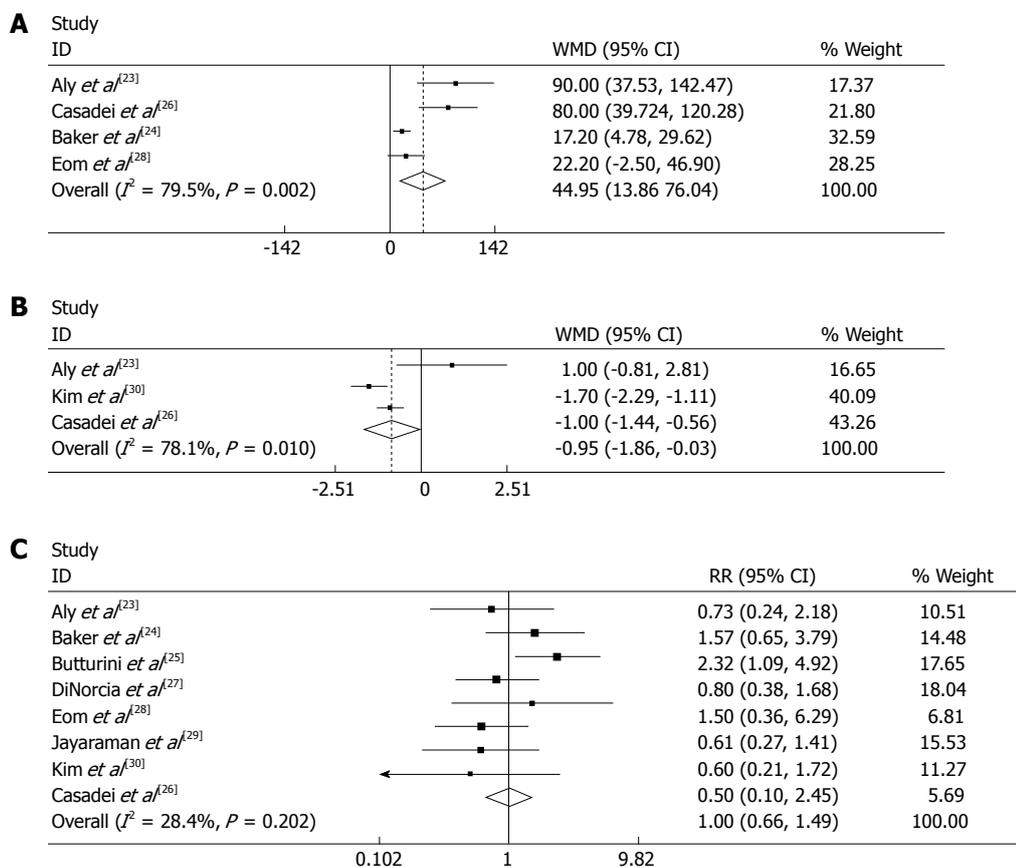

## DISCUSSION

Since Cuschieri and Gagner<sup>[32,33]</sup> documented the earliest attempts at LDP in humans, there have been an increasing number of reports indicating the advantages of LDP of minimal trauma, rapid recovery, and shorter hospital stay. But due to the high postoperative morbidity and a high level of laparoscopic technical requirements and extensive experiences in open pancreatic surgery, the progression of LDP was considerably restricted. In particular, the randomized clinical trials (RCT), which are the ideal objects of meta-analysis, have been extremely difficult to achieve. The published articles comparing LDP and ODP were all retrospective studies with common defects such as long-term research, small number of cases and incomplete data. With the development of surgical technology, potential bias and inappropriate results could be produced from the recent literature analyzed with the earlier clinical data. Furthermore, due to a relatively low incidence of left pancreas diseases, there are few LDP

LDP: Laparoscopic distal pancreatectomy; ODP: Open distal pancreatectomy; NA: Not available.

studies with large sample sizes. Therefore, with strictly defined inclusion and exclusion criteria, we performed a comprehensive analysis to assess the current status of LDP *vs* ODP.

The proportions of malignant tumors were 20% in both LDP and ODP, which showed no difference in the

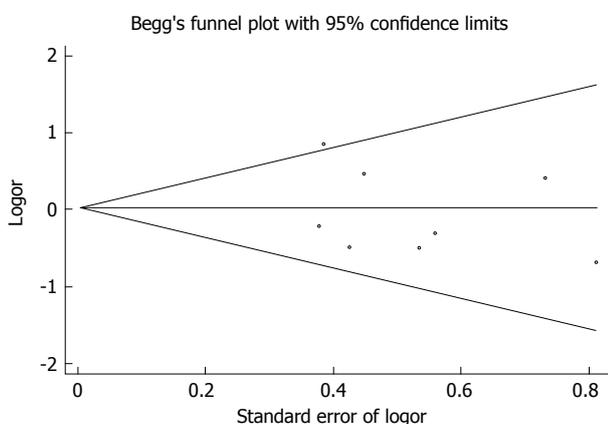

patient selection between the two groups. DP was most frequently used in the treatment of benign or borderline tumors, which was in agreement with previous studies<sup>[34,35]</sup> using either “laparoscopy” or “open”.

The most important indicators to represent the operative effect were shorter operative time, time to fluid

**Table 4** Technique of pancreatic stump closure

Ref.	Technique description	
Aly <i>et al</i> <sup>[23]</sup>	LDP	The pancreatic parenchyma was transected using a laparoscopic linear stapler
	ODP	The pancreatic parenchyma was transected using a scalpel, and the main pancreatic duct was ligated using nonabsorbable sutures. The pancreatic stump was closed with fish-mouth sutures. A linear stapler was used to transect the pancreatic parenchyma
Baker <i>et al</i> <sup>[24]</sup>	LDP	The gland was divided by one of 3 mechanisms: vascular stapler, harmonic scalpel, or harmonic scalpel following ablation at the pancreatic resection margin with the Habib 4*3 microsealer device
	ODP	Directly ligate the pancreatic duct when visible with a monofilament absorbable suture. The neck of the gland was oversewn with nonabsorbable monofilament suture
Butturini <i>et al</i> <sup>[25]</sup>	LDP	The pancreatic body was transected by a linear endostapler
	ODP	Pancreatic parenchyma was sharply transected. The main pancreatic duct was closed with nonabsorbable sutures (polypropylene 4/0). Subsequently the pancreatic stump was oversewn with interrupted mattress nonabsorbable sutures or closed using a linear stapler
Casadei <i>et al</i> <sup>[26]</sup>	LDP	The pancreas was divided at the neck using an endo-GIA instrument
	ODP	The pancreas was divided using GIA 55
DiNorcia <i>et al</i> <sup>[27]</sup>	LDP	Sutures, staples, sutures and staples combined, or staples with bioabsorbable staple-line reinforcement
	ODP	
Eom <i>et al</i> <sup>[28]</sup>	LDP	The pancreas was transected using the 48- or 35-mm vascular endoscopic linear stapler
	ODP	The pancreatic parenchyma was divided using a blade and electrocautery. The main pancreatic duct was ligated with nonabsorbable sutures, and the transected pancreas was occluded with interlocking interrupted mattress sutures of 4-0 black silk and reinforced with 4-0 polypropylene
Jayaraman <i>et al</i> <sup>[29]</sup>	LDP	The pancreas was stapled using a vascular stapler with or without a Seamguard attachment
	ODP	Ligate pancreas with staples, or via suture ligation, or a combination of techniques
Kim <i>et al</i> <sup>[30]</sup>	LDP	For pancreatic transaction, straight endoscopic linear staplers of various sizes (staple height, 3.5-4.2 mm) were used according to the thickness or hardness of the pancreas. Four or five small titanium clips were applied along the stapling line
	ODP	The pancreatic stump underwent main duct ligation, multiple suture ligation of the branch duct exposed at the resection margin, and reinforcement of the mattress suture to the pancreas stump
Vijan <i>et al</i> <sup>[31]</sup>	LDP	The pancreatic parenchyma is divided with the harmonic scalpel (preferred) or with an Endo GIA stapler
	ODP	NA

LDP: Laparoscopic distal pancreatectomy; ODP: Open distal pancreatectomy; NA: Not available; GIA: Gastrointestinal incision anastomose.

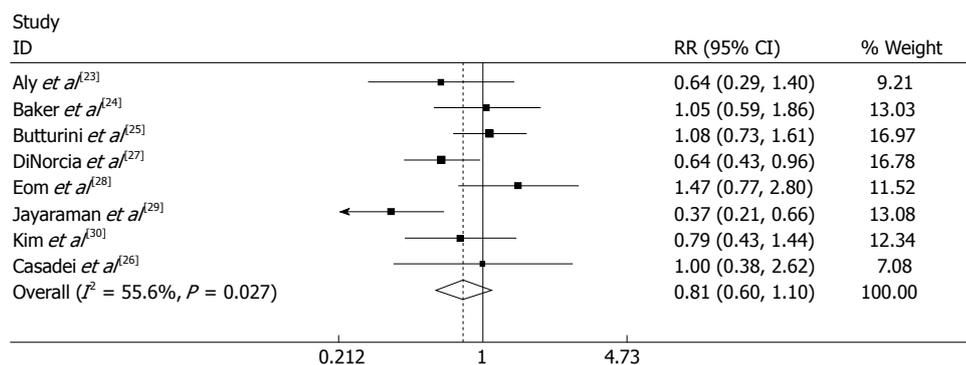

**Figure 4** Begg's test showing no publication bias of pancreatic fistula occurrence.

intake and hospital stay, and less blood loss, low conversion rate and high spleen-preserving rate. These indicators have demonstrated the safety and feasibility of the laparoscopic procedures. In this meta-analysis, the operative time of LDP was longer than ODP (WMD 44.947,  $P = 0.005$ ), but a recent research showed that operative time is becoming shorter with the improved expertise of surgeons<sup>[17]</sup>. And the time to fluid intake and post-operative hospital stay were also shorter in LDP than in ODP (WMD -0.948,  $P = 0.042$ ) and (WMD -2.713,  $P = 0.00$ ). Blood loss estimate was not conducted in this

study because of different numeric types. The results of the included articles showed that blood loss was less in LDP than in ODP, which were similar with other literatures<sup>[18,19]</sup>. In addition, conversion rate of LDP from the pooled data showed a low level of 14% in 714 LDPs because of severe bleeding and abdominal adhesion<sup>[14]</sup>.

The rate of spleen-preservation ranged from 15.5% to 44.2% in LDP and from 5.7% to 15.6% in ODP as shown in Table 3. Kimura method was more frequently used as compared with Warshaw method used when intraoperative bleeding, adhesion, and blood vessels embedded by the tumors occurred. Effects of the two surgical methods have long been a concern. Rodriguez *et al*<sup>[36]</sup> retrospectively reported Kimura method used in 185 cases compared with Warshaw method in 74 cases of LDP from 1994 to 2004; the two groups had no statistically significant difference in occurrence of ascites (9% *vs* 8%), intra-abdominal abscess (14% *vs* 8%), pancreatic leakage (33% *vs* 36%) and incision complications (10% *vs* 8%). Although Warshaw method was proved to be sufficiently safe<sup>[37,38]</sup>, due to individual differences of the short gastric vessels, spleen relied entirely on the short gastric blood vessels which inevitably brought some uncertainties. In the event of severe splenic infarction, reoperation was often required. So spleen-preservation by Kimura method was widely accepted in LDP, but under some special conditions, such as bleeding, adherent tumor and difficult anatomy, Warshaw method could elevate the spleen-preserving rate. In this meta-

**Figure 5** There was no significant difference in overall morbidity between laparoscopic distal pancreatectomy and open distal pancreatectomy [random effects model, risk ratio 0.81 (0.596, 1.101),  $P = 0.178$ ,  $I^2 = 55.6\%$ ] and there was moderate heterogeneity. Weights are from random effects analysis. CI: Confidence interval; RR: Risk ratio.

analysis, five articles described the spleen-preserving DP, the pooled data showed that the spleen-preserving rate of LDP was significantly higher than that of ODP (RR 2.380,  $P = 0.016$ ,  $I^2 = 73.2\%$ ). Although there was moderate heterogeneity, spleen-preservation occurred more often in LDP. The reasons for the high spleen-preserving rate in LDP may be as follows: (1) surgeons in different stages of learning curve may achieve different clinical outcomes. In the early period, because of the immature LDP technique, especially laparoscopic vascular treatment, fewer cases of LSPVP were performed; and (2) many cases of ODP without spleen-preservation were included in each study, leading to a low spleen-preservation rate of ODP.

PF was the most important complications after DP which resulted in serious consequences such as extended hospital stay, poor quality of life, even intra-abdominal bleeding, and infection. Although at some high-volume centers, PF after DP has declined over the past decade, the incidence of PF still kept from 5% to 30%<sup>[39-41]</sup>. In this study, a large variation in the PF rate was recorded, ranging from 8.1% to 27.9% in LDP and 6.5% to 18.2% in ODP. The major reason for the variability may be lacking uniform criteria for PF. The diagnostic criteria of PF were generally based on clinical signs and laboratory indicators, including the occurrence time, the daily amount of leakage, leakage amylase, the duration, *etc.* The ISGPF criterion<sup>[42]</sup> was most frequently used, but it failed to explain whether the drainage amount was related to the diagnosis of PF. Because of the lack of different quantitative indicators, other criteria were also questioned<sup>[43,44]</sup>.

The original disease, pancreatic transection, pancreas texture, blood supply, and stump closure are factors affecting the incidence of PF. Recently, body mass index  $> 25 \text{ kg/m}^2$  was also reported contributing to the increased incidence of PF after DP<sup>[45]</sup>. However, the treatment of pancreatic stump is a unique controllable factor for preventing PF. In order to reduce the incidence of PF, a variety of stump closure techniques were applied or used in combination, but the coexistence of methods may reflect the lacking of a widely accepted and effective method. In this study, stapler was used in LDP while both stapler/scalpel + suture were used in ODP. The surgeons

could choose different staplers according to the pancreatic texture and size in LDP. And in some groups, small titanium clips were applied along the stapling line<sup>[50]</sup> and fibrin glue was splashed over the pancreatic stump in an attempt to prevent PF and postoperative bleeding<sup>[23,24,27,30]</sup>. Subset analysis could not be accomplished as no detailed data was available. A published meta-review analyzed 16 articles with 2286 patients who underwent DP and compared the preventive effect for PF between 671 cases with stapler closure and 1615 cases with suture closure. The results showed no significant differences between suture and stapler closure of the pancreatic remnant with respect to the PF or intra-abdominal abscess<sup>[46]</sup>. Likewise, the pooled data of this study showed no significant difference both in the incidence of PF (RR 0.996,  $P = 0.983$ ) and overall morbidity between LDP and ODP (RR 0.81,  $P = 0.178$ ).

The authentication strength of this study may be affected by the following factors: (1) publication bias: some gray literatures which contained negative results were difficult to obtain because most authors tended to show positive results; (2) grouping bias: notwithstanding the literatures dealing with significantly different diseases and surgical methods have been excluded in this study, in practice, patients should be grouped inevitably according to the disease condition and surgeons' choices; and (3) observation bias: due to the varied measurement methods used by different authors, significantly different results were almost inevitable in the non-RCT or non-blind RCT studies.

In summary, LDP has shown the advantages of intra-operative effects, rapid recovery and spleen-preservation for benign and borderline tumors. But the superiority has not been displayed in preventing the overall morbidity and occurrence of PF. Thus, the RCT studies with a large sample size should be conducted and new surgical techniques should be introduced in future studies.

## COMMENTS

### Background

Laparoscopic distal pancreatectomy (LDP) is becoming a primary treatment

modality for benign or borderline tumors of distal pancreas. But due to the high postoperative morbidity and a high level of laparoscopic technical requirements and extensive experiences in open pancreatic surgery, the progression of LDP was considerably restricted.

### Research frontiers

Recently, several studies have shown shorter hospital stay and operative time and less intraoperative blood loss in LDP. But the efficacy of LDP compared with open distal pancreatectomy (ODP) required further assessment.

### Innovations and breakthroughs

Pancreatic fistula (PF) and spleen-preservation in LDP have been the major concern after the surgery. What the role of "laparoscopy" in the spleen preservation and PF prevention is unclear. In this meta-analysis, the authors pointed out that LDP has the advantages of shorter hospital stay and operative time, more rapid recovery and higher spleen-preserving rate compared with ODP.

### Applications

Due to a relatively low incidence of left pancreas diseases, fewer LDP studies with a large sample size have been published. Especially the RCT clinical study, which is the ideal object of meta-analysis, is extremely difficult to accomplish. This meta-analysis assessed the safety and feasibility of LDP compared with ODP based on the review of the literature published over the past 15 years.

### Peer review

This paper is a systematic review of the laparoscopic distal pancreatectomy. The summary of LDP experiences and results is interesting.

### Abstract

**AIM:** To study the therapeutic efficacy of a new transnasal ileus tube advanced endoscopically for adhesive small bowel obstruction.

**METHODS:** A total of 186 patients with adhesive small bowel obstruction treated from September 2007 to February 2011 were enrolled into this prospective randomized controlled study. The endoscopically advanced new ileus tube was used for gastrointestinal decompression in 96 patients and ordinary nasogastric tube (NGT) was used in 90 patients. The therapeutic efficacy was compared between the two groups.

**RESULTS:** Compared with the NGT group, the ileus tube group experienced significantly shorter time for relief of clinical symptoms and improvement in the findings of abdominal radiograph ( $4.1 \pm 2.3$  d vs  $8.5 \pm 5.0$  d) and laboratory tests ( $P < 0.01$ ). The overall effectiveness rate was up to 89.6% in the ileus tube group and 46.7% in the NGT group ( $P < 0.01$ ). And 10.4% of the patients in the ileus tube group and 53.3% of the NGT group underwent surgery. For recurrent adhesive bowel obstruction, ileus tube was also significantly more effective than NGT ( $95.8\%$  vs  $31.6\%$ ). In the ileus tube group, the drainage output on the first day and the length of hospital stay were significantly different depending on the treatment success or failure ( $P < 0.05$ ). The abdominal radiographic improvement was correlated with whether or not the patient underwent surgery.

**CONCLUSION:** Ileus tube can be used for adhesive small bowel obstruction. Endoscopic placement of the ileus tube is convenient and worthy to be promoted despite the potential risks.

## INTRODUCTION

Gastrointestinal decompression is the most effective approach to treat the patients with acute bowel obstruction without any indications of strangulation<sup>[1,2]</sup>. The traditional nasogastric tube (NGT) is not long enough for suctioning the distal intestine and its decompression efficacy is relatively low. Since the 1930s, the concept of nasointestinal decompression and use of nasointestinal tubes have been developed and applied in clinical practice. Some studies have verified the efficacy of long nasointestinal tubes in treating adhesive small bowel obstructions (SBO)<sup>[3-7]</sup>. However, a prospective randomized trial demonstrated no significant differences with regard to the decompression achieved, the success of non-surgical treatment, or the morbidity rate after surgical intervention as compared with the use of short NGT<sup>[8]</sup>. In 2003, a new hydrophilic silicon triple-lumen ileus tube was first introduced and used in Japan for nasointestinal decompression. It could be advanced through the gastroscope in shorter time with a higher tolerance<sup>[9]</sup>. Up till now, there has been no randomized controlled study about the efficacy of the ileus tube. This randomized controlled trial attempted to investigate and compare the decompression efficacy between the new ileus tube and the traditional NGT for patients with adhesive SBO.

## MATERIALS AND METHODS

### Patients

Approved by the hospital's ethics committee, a total of 186 patients with acute adhesive SBO who were admitted to the Gastroenterology and Colorectal Surgery wards of the First Affiliated Hospital, College of Medicine, Zhejiang University and its Ningbo Branch Hospital from September 2007 to February 2011 were enrolled into this study. The entry criteria were as follows: (1) clinical symptoms and physical signs arising from acute bowel obstruction; (2) a diagnosis of adhesive SBO based on abdominal plain films and computed tomography (CT) scans confirmed by at least two attending radiologists; and (3) admission to the hospital within 12 h after bowel obstruction onset. All patients who presented with symptoms of fever, vomiting or hematemesis, hematochezia, severe or sudden abdominal pain, and the signs of tachycardia, leukocytosis, abdominal tenderness, peritoneal irritation, asymmetric abdominal distension or isolated swelling bowel loops and even shock, should be suspected of strangulation obstruction, which needed immediate operation. Besides, patients who had contraindications for endoscopy, or with postoperative adynamic obstruction or malignancy, or who had been treated in other hospitals before admission were excluded. Patients were randomized into two groups by the sealed envelope method: the ileus tube group and the NGT group; an opaque box containing an equal number of envelopes that indicated either ileus tube or NGT, was used for randomization. Written informed consents were obtained

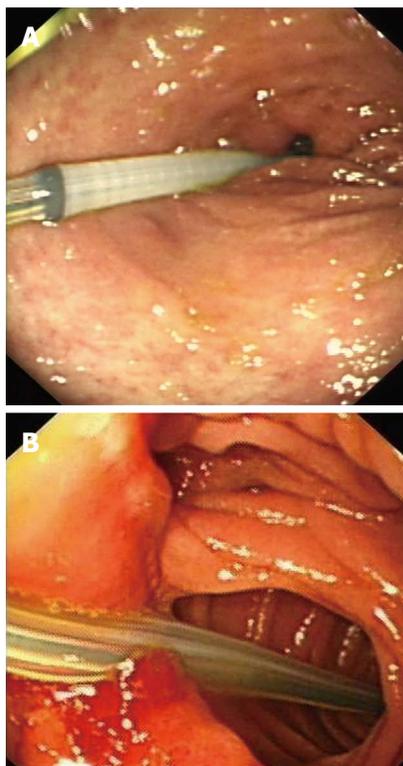

from all the patients before enrollment. This trial conformed to the provisions of the World Medical Association Declaration of Helsinki. Ileus tube was used in 96 patients (56 men and 40 women) for gastrointestinal decompression; their ages ranged from 21 to 86 years (mean, 58 years). Among the 96 patients, 25 had a history of prior adhesion, and 89 patients received prior abdominal surgery. Ninety patients (56 men and 34 women) treated with NGT served as the control group; their ages ranged from 19 to 86 years (mean, 54 years). Among the 90 patients, 38 had a history of prior adhesion, and 86 had a history of abdominal surgery.

### Patient preparation

On admission, all patients underwent abdominal plain film radiography and CT scanning to confirm acute bowel obstruction. Patients requiring emergency surgery were excluded. Performed by the same technicians, the ileus tube was advanced endoscopically and the traditional NGT was inserted for gastrointestinal decompression at a similar negative pressure level for constant suction. For all patients, routine laboratory blood tests were performed, and C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) were determined.

### Instrument and procedures

The CLINY Ileus Tube suite (Create Medic, Tokyo, Japan) and the ordinary NGT (Terumo Medic, Hangzhou, China) were used. The ileus tube is 300 cm in length and 16 Fr with three channels (suction channel, injection channel and balloon channel) and two balloons (anterior balloon and posterior balloon). Beside the tip hole, there are side holes in the distal end of the tube. Compared with other long tubes, this tube has weighted tip which consists of several metal balls for easier advancing. The posterior balloon is intended for contrast radiography. Water and contrast medium can be injected into the tube for lavage and imaging. Under some instances, the tube can directly remove the obstruction by its weighted tip. The guidewire is 350 cm long and 1.24 mm in diameter. The NGT is 110 cm in length and 16 Fr. All patients received gastrointestinal decompression within 12 h after admission. In the ileus tube group, the tube was pre-set through the nasal cavity to the stomach. The guidewire was inserted into the main channel to the tips. After endoscopic suction of stomach contents, the wire was moved into the descending duodenum by forceps, and the tube was inserted into the duodenum while the wire was kept fixed (Figure 1). Then the anterior balloon was inflated with 20 mL distilled water. The gastroscope was withdrawn after the long tube was fixed to the cheek. The tube was propelled by bowel peristalsis and its weighted tip, and the outside terminal of the tube was connected to a spontaneous negative pressure bag. Intermittent lavage (twice a day) through the long tube was performed from the second day after intubation, and the length of the advanced tube was carefully measured. In the control group, the NGT was inserted from nose to stomach to

**Figure 1** Endoscopic placement of ileus tube. A: An ileus tube is passed through the pylorus under gastroscopy in a patient with postoperative adhesive small bowel obstruction; B: An ileus tube led by a guidewire is endoscopically advanced into the efferent loop in a patient who had distal partial gastrectomy.

a depth of 45-55 cm. All patients were supported with total parenteral nutrition and received nothing by mouth. Emergency surgery was performed when the patient was suspected to have developed bowel ischemia. The potential risks for endoscopic placement of the ileus tube were throat injury, upper gastrointestinal perforation and bleeding, aspiration pneumonia and cardiovascular events.

### Outcome measurement

We compared the clinical and laboratory variables before intubation, including age, sex, type of prior surgery, symptoms and physical signs, and laboratory indexes on admission between the two groups. Physical examination (every 2 h), laboratory test (once a day) and abdominal imaging (days 2-7) were conducted frequently after intubation. The clinical and laboratory findings included: the time for relief of abdominal symptoms; time for abdominal radiographic improvement and recovery of white blood cell (WBC) counts, CRP level and ESR; drainage volume on the first day; surgery rate, the overall efficacy and the different therapeutic responses to the two kinds of tubes. The therapeutic effectiveness in the ileus tube group was defined as clinical or radiological improvement, relief of abdominal symptoms, decreased drainage volume, disappearance of air-fluid levels or reduced gas and fluid in bowel loops. Oral feeding was then administered gradually and the tube was removed. If the patient

presented no improvement 72 h after decompression, or even progressed into strangulation, surgery is recommended<sup>[4]</sup>. In the NGT group, if a fairly prompt response occurs within 48 h, especially within the first 8-12 h after nasogastric decompression and resuscitation, the obstruction will probably be resolved without surgery<sup>[10,11]</sup>. Surgery was recommended if patients showed no response 72 h after non-surgical treatment, which was defined as treatment failure<sup>[12]</sup>, otherwise, conservative treatment was continued.

### Sample size calculation

Determination of the sample size was based on the previous studies<sup>[4,9]</sup>. The effectiveness rate was 51% in the short tube decompression while 85.7% in the long nasointestinal tube. If the effectiveness rate of the NGT and the ileus tube was defined as 50% and 80%, respectively, a study with 48 patients per group would have a 90% power to detect a difference at a two-sided significance level of 0.05. We extended our sample size to account for potential dropouts

### Statistical analysis

Statistical analysis was performed using SPSS software version 16.0 (SPSS Inc, Chicago). Results were expressed as mean  $\pm$  SD. The  $\chi^2$  test was used to identify differences in the effectiveness rate between the two groups. The Student's *t* test was used for unpaired data to determine differences in means between the two groups. Odds ratios (ORs) were determined by logistic regression analysis. Two-tailed *P* value of  $< 0.05$  was considered statistically significant.

### Study limitations

This study was designed as a randomized controlled trial (RCT), but it was not double-blinded. No standard criteria are available for the treatment success by this long tube in the literature. The two kinds of tubes were placed by different methods, while the patients in ileus tube group suffered more during intubation.

## RESULTS

### Patient clinical characteristics

Of the 186 patients, 96 were treated with ileus tube, and 90 were randomized into NGT group. There was no significant difference between the two groups with regard to clinical characteristics and laboratory variables documented on admission, including age, sex, abdominal symptoms, and laboratory indexes such as WBC counts, CRP, and ESR ( $P > 0.05$ ). The type of prior surgery and obstruction also did not differ significantly ( $P > 0.05$ ). In this study, the ileus tube or NGT was successfully placed in all the patients, without any obvious complications. Patient characteristics of the two groups are shown in Table 1.

### Therapeutic efficacies

The time for improvement in abdominal symptoms, ra-

CI: Confidence interval; CRP: C-reaction protein; ESR: Erythrocyte sedimentation rate; NGT: Nasogastric tube; OR: Odds ratio; SD: Standard deviation; WBC: White blood cells.

diographic findings, and laboratory variables was significantly shorter ( $P < 0.01$ ) in the ileus tube group as compared with the NGT group. In addition, more patients had relief from abdominal pain or distention within 48 h in the ileus tube group ( $P < 0.01$ ). The drainage volume on the first day after intubation was  $698 \pm 428$  mL in the ileus tube group and  $280 \pm 167$  mL in the NGT group, with a significant difference ( $P < 0.01$ ,  $t = 8.9$ ). After ileus tube decompression, 86 patients presented clinical or radiographic relief (Figure 2), the tube was removed one week after oral feeding was started, with an effectiveness rate up to 89.6% (86/96). The other 10 patients defined as treatment failure by gastroenterography underwent operation to determine the site of the obstruction (Figure 3). In follow-up study, 6 patients still had recurrent adhesive SBO confirmed by surgery, the intervals varied from one month to seven months. In the control group, the total effectiveness rate was 46.7% (42/90); the other 48 patients defined as treatment failure were managed with surgery. However, 16 patients had recurrent adhesive SBO after successful treatment, the recurrence peak occurred between 3 mo and 5 mo (Table 1).

### Therapeutic outcome in ileus tube group treated with or without surgery

In the ileus tube group, 10 patients without initial relief underwent surgery to remove the obstruction. Significant differences were found in the drainage output on the first day and the length of hospital stay ( $P < 0.05$ ). Besides, no patient showed abdominal radiographic improvement within 72 h in decompression in the surgical group as compared to 51.2% (44/86) in the non-surgical group. These results are summarized in Table 2.

## DISCUSSION

Conservative treatment is usually administered to the patients with acute bowel obstruction when ischemic bowel is excluded. Surgeons are inclined to choose conservative treatment for adhesive bowel obstruction because of the risk of recurrence along with surgery<sup>[13]</sup>. Since the 1930s, various types of tubes have been devised and used for nasointestinal decompression<sup>[14,15]</sup>. A tube was designed specifically for endoscopic placement and the ileus tube has been developed with three channels and two bal-

**Figure 2 Radiographs of ileus tube decompression.** Plain abdominal radiographs (A) and (B) reviewed 3 d after ileus tube decompression compared with scans on admission in a patient with postoperative adhesive small bowel obstruction. A: The diffuse distended loops of small bowel that was filled with gas and fluid before intubation; air-fluid levels were seen in the enteric cavity; B: Reviewed 3 d after intubation; the previous gas-filled or fluid-filled small bowel loops showed no evidence of distention, the air-fluid levels disappeared, and the long tube had moved downward while the tip reached the distal jejunum.

**Figure 3 Diagnostic radiographic enteroclysis.** Gastroenterography displayed on the 5th day of ileus tube decompression in a patient with postoperative adhesive small bowel obstruction. The tip of the tube had reached to the distal jejunum. After the anterior balloon was inflated with gas, angiografin was injected into the tube for gastrointestinal imaging to locate the lesion or stenosis in the bowel. Stenosis was found (arrow) in the small intestine with a filling defect, but none was developed in the distal bowel.

loons. A study confirmed an efficacy rate of ileus tube of up to 85.7% for intraluminal decompression in the bowel<sup>[9]</sup>. Intubation methods then changed from fluoroscopy to direct placement under endoscopy and afforded safety and high success rates<sup>[16-21]</sup>. However, if there is

any side effect along with the endoscopic placement procedure, the tube should be pulled out and endoscopic treatment for gastrointestinal bleeding or perforation should be given if possible. If patients have aspiration pneumonia, antibiotics and mechanical ventilation should be considered. Intensive care and emergent therapy are needed for any cardiovascular event. Our clinical practice testified the safety and flexibility of the endoscopic placement of the ileus tube, and the procedure and the instruments we used are available in most hospitals. However, the long tube and endoscopy cost more than ¥4000 RMB, that is 20 times more than an ordinary NGT, even though it is much lower than surgery. The cost as well as the discomfort caused by endoscopy may limit the promotion of the use of ileus tube.

From the data of this study, we found a great comparability between our two groups with regard to sex, age, past laparotomies, symptoms, and radiographic signs as well as laboratory findings on admission. It is known that delayed visit to hospital leads to a higher failure in conservative measures, so we selected the patients admitted within 12 h after obstruction onset to enforce the rigidity of the study. With bowel peristalsis and the weighted tip, the ileus tube passes downward to the small bowel and decompression can be achieved. As the tip can reach to the site of obstruction, thorough suctioning can be performed, leading to a rapid relief of the symptoms, as shown in our results. In addition, the recovery time for laboratory variables of inflammatory markers was shorter in ileus tube group, probably because of the improvement in the blood supply to the bowel wall, which can reduce the local inflammatory response and bacterial multiplication. A previous study demonstrated no significant differences in therapeutic efficacy between the long and short tube decompression<sup>[8]</sup>. However, we found that in the ileus tube group the effectiveness rate was significantly higher and the surgery rate was lower than that in the control group. We attribute it to the ad-

vanced technique of the tube and the endoscopic placement method that can avoid the delay by passing beyond the pylorus. Another study confirmed that a previous episode of adhesive bowel obstruction and the duration of the tips not advancing (> 72 h) were highly correlated with a recurrence of obstruction. If patients fail to respond 3 d after decompression or have indications of ischemic bowel or the drainage volume is > 500 mL on the third day, surgery is recommended<sup>[22,23]</sup>. For NGT decompression, after 48 h of non-operative management, the risk of complications increases substantially, and the probability for resolving the obstruction diminishes. Surgery is required if a patient's condition has deteriorated or has not significantly improved within 72 h. In the ileus tube group, intermittent lavage was performed from the second day after intubation so that we could record the drainage volume on the first 24 h to compare the decompression responses with the NGT group.

We admitted relatively a large number of patients with adhesive SBO for this study. Our results showed that for adhesive SBO, the ileus tube had the decompression efficacy that was significantly superior to the NGT, especially for patients with recurrent adhesive SBO. Although a tendency toward recurrence can not be avoided after successful treatment using the ileus tube in patients with past episodes, it is still superior to the traditional NGT treatment and should be therefore recommended in clinical practice. The ileus tube has many advantages in addition to thorough decompression. It can remove the kinks in the obstructed bowel loops when the tip progresses downward, and the long tube itself can perform through a straddle mechanism to arrange the bowel and reduce the adhesion recurrence rate. Diagnostic radiographic enteroclysis studies are facilitated, which are helpful to surgeons for preoperative preparation<sup>[24,25]</sup>.

Previous studies have confirmed the efficacy of nasointestinal decompression through a long tube for SBO, especially for adhesive SBO<sup>[3-7]</sup>. The approach of endoscopic placement of the long tube was also advised<sup>[15,26]</sup>. According to our clinical application, the ileus tube has a prospective therapeutic efficacy for adhesive SBO. However, surgical intervention can easily be undertaken when NGT decompression failed, because it is thought to be the most immediate modality for remission. Another focus is that water-soluble contrast agent (WSCA) is helpful in the diagnosis and treatment of adhesive SBO according to a recent meta-analysis<sup>[27]</sup>, appearance of contrast in the colon within 4-24 h after administration had a sensitivity of 96% and a specificity of 98% in predicting resolution of SBO. The WSCA can draw fluid from intravascular and extracellular spaces into bowel lumen because of its high osmolarity, thus promoting proximal bowel distension and peristalsis, and avoiding the operative interference. However, as there are potential risks of renal failure and anaphylaxis, these agents still can not take the place of gastrointestinal decompression, which is thought to be the key to the treatment of bowel obstruction. Based on our results, we highly recommend

this triple-lumen tube for patients with adhesive SBO. The endoscopic placement of the tube is convenient, and with close monitoring and intermittent lavage, surgeries can be avoided.

We also tried to find certain indications for surgical interventions in the patients treated with ileus tube. Compared with patients who underwent surgery in the ileus tube group, those who were successfully managed without surgery had a significantly shorter hospital stay and a larger drainage output on the first day after intubation. Up to 51.2% of the patients showed abdominal radiographic improvement within the first 3 d in the non-surgical group while no patient achieved relief in the surgical group. This indicates that the drainage output on the first day and radiographic improvement could be two independent factors for evaluating the therapeutic efficacy of nasointestinal decompression. They may also be indications for surgery. Further studies should be performed to identify the clinical value of the ileus tube within the parameters of indications for surgery.

In summary, we believe that endoscopic placement of transnasal ileus tube is safe, effective, and convenient and is worth being promoted in clinical practice. The ileus tube can quickly relieve the clinical symptoms and reduce the rate of surgical indications. It is greatly superior to the NGT in treating patients with adhesive SBO. However, the potential risks and extra costs should be taken into consideration when selecting patients. For patients with recurrent adhesive SBO, the use of triple-lumen ileus tube is the optimal choice. Close observation of drainage output and abdominal radiographic changes during decompression can help provide some clues for indications of surgery.

## COMMENTS

### Background

Adhesive small bowel obstruction is a worldwide problem characterized by a high incidence rate and repeated episodes. Gastrointestinal decompression is one of the important approaches in conservative therapy. However, surgical intervention can easily be undertaken when nasogastric tube decompression failed. Long intestinal tube for nasointestinal decompression is a new method for adhesive small bowel obstruction and has been successfully applied in clinical practice and the therapeutic efficacies were satisfactory.

### Research frontiers

A new long tube named ileus tube was first introduced in Japan in 2003, and later studies have confirmed its therapeutic value in adhesive small bowel obstruction. However, there had been no randomized controlled study about the efficacy of the ileus tube. This randomized controlled trial attempted to investigate and compare the decompression efficacy between the new ileus tube and the traditional nasogastric tube (NGT) for patients with adhesive small bowel obstruction.

### Innovations and breakthroughs

The previous studies of long intestinal tube for gastrointestinal decompression were mainly described retrospectively. This research compared the therapeutic efficacies between the new long tube and the ordinary NGT in a large number of patients. The authors confirmed the superiority of the new ileus tube to the ordinary NGT through a series of statistical analysis. The authors also introduced the detailed procedure of the endoscopic placement of this long tube.

### Applications

The study indicated the therapeutic value of the new ileus tube. The application

of the ileus tube can significantly reduce the surgery rate and the hospital-stay cost, and the endoscopic placement method introduced by the authors can be applied in almost all the hospitals. Thus, the use of ileus tube is worthy to be promoted.

### Peer review

This is an important area and the work represents a significant advance in clinical therapy. As it is possible not only to increase efficacy on a single intervention but also reduce the need for subsequent intervention, the technology provides the possibility to lower costs and reduce intervention to the patient.

### Abstract

**AIM:** To identify factors related to serious postoperative bacterial and fungal infections in the first 3 mo after living donor liver transplantation (LDLT).

**METHODS:** In the present study, the data of 207 patients from 2004 to 2011 were reviewed. The pre-, intra- and post-operative factors were statistically analyzed. All transplantations were approved by the ethics committee of West China Hospital, Sichuan University. Patients with definitely preoperative infections and infections within 48 h after transplantation were excluded from current study. All potential risk factors were analyzed using univariate analyses. Factors significant at a  $P < 0.10$  in the univariate analyses were involved in the multivariate analyses. The diagnostic accuracy of the identified risk factors was evaluated using receiver operating curve.

**RESULTS:** The serious bacterial and fungal infection rates were 14.01% and 4.35% respectively. *Enterococcus faecium* was the predominant bacterial pathogen, whereas *Candida albicans* was the most common fun-

gal pathogen. Lung was the most common infection site for both bacterial and fungal infections. Recipient age older than 45 years, preoperative hyponatremia, intensive care unit stay longer than 9 d, postoperative bile leak and severe hyperglycemia were independent risk factors for postoperative bacterial infection. Massive red blood cells transfusion and postoperative bacterial infection may be related to postoperative fungal infection.

**CONCLUSION:** Predictive risk factors for bacterial and fungal infections were indentified in current study. Pre-, intra- and post-operative factors can cause postoperative bacterial and fungal infections after LDLT.

### INTRODUCTION

Despite the major advances in immunosuppressant regimens, perioperative management and medical care have contributed to improvements in the survival rate of solid organ transplant recipient, infection continues to be a leading cause of postoperative mortality and morbidity resulting from the poor preoperative condition, immunosuppressive therapy and exposure to nosocomial pathogens<sup>[1,2]</sup>. Liver transplantation has one of the highest rates

of postoperative infection among all solid organ transplant procedures<sup>[3]</sup>. It has been reported that the postoperative bacterial infection rate may up to more than 60% and accounted for an in-hospital mortality rate of 30%-50%<sup>[4]</sup>. Previous studies have reported that the incidence of postoperative fungal infection ranged from 5% to 40%, and the mortality associated with fungal infection was between 25% and 69%<sup>[5]</sup>. Moreover, the mortality of patient with *aspergillus* has been found to approach 100% if untreated<sup>[6]</sup>. Accordingly, to identify which factors may cause postoperative bacterial and fungal infections is important to transplant surgeon. However, this issue is still not well established until now. In current study, we used a large cohort to identify the pattern and risk factors associated with postoperative bacterial and fungal infections that occurred within the first 3 postoperative months after living donor liver transplantation.

## MATERIALS AND METHODS

### Study group

Patients who received adult-to-adult living donor liver transplantation (LDLT) from 2004 to 2011 at our center were considered in present study. All transplantations were approved by the ethics committee of West China Hospital, Sichuan University. Patients with definitely preoperative infections and infections within 48 h after transplantation were excluded from current study.

### Donor selection

Donors must be healthy close relatives with compatible ABO blood types. Serological testing for viral hepatitis and human immunodeficiency virus antibodies as well as testing for other acute or chronic diseases was negative. Volumetric computed tomography with contrast was performed to evaluate the hepatic volume of the donors. Right hepatic lobe without middle hepatic vein of the donors need to be at least 0.8% of the recipient's standard weight and the remnants must be at least 40% of the donor's liver volume. Magnetic resonance cholangiopancreatography was performed to assess the anatomy of the biliary tree<sup>[7,8]</sup>.

### Immunosuppression

The postoperative immunosuppression consisted of tacrolimus, mycophenolate mofetil and steroids. Steroids were withdrawn as soon as possible. Acute rejection episodes were confirmed by pathology. Steroid pulse therapy was conducted to patient with rejection<sup>[9]</sup>. OKT3 monoclonal antibody was administrated to patients with persistent rejection or steroid-resistant rejection. When necessary, these treatments were repeated<sup>[10]</sup>.

### Infection prophylaxis

Antimicrobial prophylaxis consisted of Cefoperazone and Sulbactam for three to five days. Fluconazole was administrated to patients with risk factors of fungal infection for one to two weeks after liver transplantation.

### Definitions

Serious infection was defined as the culture-positive bacterial or fungal infection in blood, sputum, urine, or ascetic fluid which was obtained on the basis of clinical suspicion of an infection<sup>[11,12]</sup>. Preoperative renal dysfunction was defined as the level of serum creatinine greater than 1.5 mg/dL<sup>[13]</sup>. Bile leak was defined as bilirubin concentration in the drainage greater than the plasma level<sup>[14]</sup>. Model for end-stage liver disease (MELD) scores were calculated according to the formula: MELD score =  $9.57 \times \text{Ln creatinine (mg/dL)} + 11.2 \times (\text{Ln INR}) + 3.78 \times \text{Ln bilirubin (mg/dL)} + 6.43$ <sup>[15]</sup>. Massive red blood cells (RBCs) transfusion was defined as transfusion not less than 6 packed RBCs in the first 24 h of surgery<sup>[16]</sup>. Severe hyperglycemia was defined as glucose concentrations more than or equal to 20 mg/dL<sup>[17]</sup>. Hyponatremia was defined as a serum sodium concentration of less than 130 mEq/L<sup>[18]</sup>.

### Statistical analysis

All continuous variables were presented as mean  $\pm$  SD and compared using one way analysis of variance.  $\chi^2$  test or Fisher's exact test was used for comparing categorical variables. Independent risk factors were identified by Cox regression. Factors significant at a  $P < 0.10$  in the univariate analyses were involved in the multivariate analyses. The diagnostic accuracy of the identified risk factors was evaluated using receiver operating curve (ROC). All analyses were performed using SPSS 16.0. We considered a  $P$  value of less than 0.05 to be significant.

## RESULTS

### Patient characteristics

A total of 207 patients were included in current study. The mean age was  $42.93 \pm 8.77$  years for the recipients, whereas the mean age was  $34.83 \pm 9.99$  years for the donors. Twenty-seven patients were female, whereas eighty-one donors were female. Nine patients had pre-transplant diabetes mellitus. Sixteen patients suffered from preoperative renal dysfunction. The mean MELD score was  $16.40 \pm 9.84$ . The mean graft to recipient weight ratio (GRWR) was  $0.94\% \pm 0.18\%$ . The causes for transplantation were hepatitis B ( $n = 116$ ), hepatocellular carcinoma ( $n = 75$ ), hepatolithiasis ( $n = 3$ ), hepatitis C ( $n = 3$ ), alcoholic cirrhosis ( $n = 3$ ), polycystic liver ( $n = 1$ ), primary biliary cirrhosis ( $n = 2$ ), hepatic hydatidosis ( $n = 1$ ), huge hepatic hemangioma ( $n = 1$ ), trauma ( $n = 1$ ), autoimmune hepatitis ( $n = 1$ ).

### Pattern of infection

During the first 3 postoperative months, serious bacterial infection was observed in 29 recipients, whereas serious fungal infection was found in 9 patients. Among the 9 patients with fungal infection, 6 patients were combined with or secondary to bacterial infection. Only 3 patients infected fungal infection alone. Four patients had two kinds of bacterial infection. One patient suffered from three kinds of bacterial infection. *Enterococcus faecium* ( $n = 8$ ) was the most common pathogen in patients with bacterial infec-

tion, followed by *Escherichia coli* ( $n = 6$ ), *Staphylococcus aureus* ( $n = 4$ ), *Bowman acinetobacter* ( $n = 4$ ), *Hemolytic streptococcus* ( $n = 3$ ), *Pseudomonas aeruginosa* ( $n = 2$ ), *Burkholderia cepacia* ( $n = 1$ ), *Acinetobacter lwoffii* ( $n = 1$ ), *Xanthomonas maltophilia* ( $n = 1$ ), *Haemophilus influenzae* ( $n = 1$ ), *Klebsiella pneumoniae* ( $n = 1$ ), *Enterobacter cloacae* ( $n = 1$ ), *Leuconostoc pseudomesenteroides* ( $n = 1$ ). The most common bacterial infective site was lung ( $n = 15$ ), followed by abdominal cavity ( $n = 12$ ), blood ( $n = 3$ ). *Candida albicans* ( $n = 6$ ) was the most common pathogen in patients with fungal infection, follow by *Saccharomyces* ( $n = 2$ ), *Aspergillus* ( $n = 1$ ). Fungal infections were observed in lung in 7 patients and in gastrointestinal tract in 2 recipients.

### Risk factors related to bacterial infection

As shown in Table 1, recipient age, starting albumin level < 2.8 g/dL, preoperative hyponatremia, postoperative bile leak, severe hyperglycemia, rejection and longer intensive care unit (ICU) stay were potential risk factors in univariate analysis. ROC curve analysis showed the best cut-off values for recipient age and ICU stay were 45 years and 9 d respectively (Figures 1 and 2). The corresponding are under the ROC were 0.641 and 0.680 respectively (Figures 1 and 2). When we analyzed the potential risk factors using Cox regression, only recipient age > 45 years, preoperative hyponatremia, postoperative bile leak, severe hyperglycemia and length of ICU stay > 9 d were independent risk factors for bacterial infection (Table 2).

**Figure 1** Receiver operating curve curve for recipient age.**Figure 2** Receiver operating curve curve for the length of intensive care unit stay.

### Risk factors related to fungal infection

As listed in Table 3, we studied the factors may be related to fungal infection using univariate analysis. Correlation testing showed preoperative hyponatremia, massive intraoperative RBCs transfusion and postoperative bacterial infection may be contributed to postoperative fungal infection. These potential risk factors were further examined with Cox regression analysis. Only bacterial infection and massive intraoperative RBCs transfusion showed prognostic power in multivariate analysis (Table 4).

## DISCUSSION

Postoperative infection is one of the most common complications in liver transplant recipients. In our current study, the incidences of bacterial and fungal infections were 14.01% and 4.35%, which were lower than previous reports<sup>[19-21]</sup>. We suggested this difference may be related to the different definition of infection. In current study, only culture-positive infections were included. Consistent with previous studies, gram-negative bacteria, especially *Enterococcus faecium* and *Escherichia coli*, were the predomi-

nant bacterial pathogens, whereas *Candida albicans* was the most common fungal pathogen<sup>[22]</sup>.

Postoperative bile leak was an independent risk factor for bacterial infection of LDLT in current study. This risk factor was not considered in some studies following deceased donor liver transplantation (DDLTL)<sup>[23]</sup>. This difference was related to the low incidence of postoperative bile leak in patients underwent DDLTL. However, bile leak was one of the most common complications in LDLT recipients. This factor should not be ignored in LDLT. Patients with postoperative bile leak suffered from longer abdominal drainage which may increase the risk of intraabdominal and wound infection<sup>[24]</sup>. Additionally, bile leak can cause biloma that often progress to an infected abscess<sup>[25]</sup>.

**Table 4** Multivariate analysis for risk factors for postoperative fungal infection

Bacterial infection	2.429	0.711	11.686	0.001	11.346	2.819	45.673

SE: Standard error; CI: Confidence interval; RBC: Red blood cell.

It was interesting that patient more than 45 years old was a risk factor related to postoperative bacterial infection. We acknowledge the cut-off value of recipient age was so young in our study. The mean recipient age in current study was 42.93 ± 8.77 years. This was a potential explanation. Similar to our results, Nayaranan *et al*<sup>[26]</sup> suggested patient's age greater than 42 years old was significantly associated with a poor long-term survival. This finding suggested the incidence of postoperative bacterial infection may be increased with the increasing of recipient age.

Preoperative diabetes mellitus didn't increase the risk of postoperative infection in our study. However, John *et al*<sup>[27]</sup> suggested pretransplant diabetes was associated with increased postoperative morbidity and mortality. Recently, Ling *et al*<sup>[28]</sup> confirmed preexisting diabetes was not a contraindication for liver transplantation. Well controlled pretransplant diabetes will not increase the risk of postoperative complication. In our practice, the nine patients with pretransplant diabetes had normal blood sugar level at the time of transplantation. Contrary to pretransplant diabetes mellitus, severe postoperative hyperglycemia was an independent risk factor for bacterial infection in current study. However, after transplantation, the administration of immunosuppressive agents, including cyclosporine, steroids and tacrolimus, may cause postoperative hyperglycemia. Ata *et al*<sup>[29]</sup> confirmed postoperative hyperglycemia was the most important risk factor for surgical site infection in general surgery patients. Rueda *et al*<sup>[30]</sup> reported hyperglycemia will increase the risk for and severity of pneumonia among non-diabetic patients.

It was easy to understand prolonged ICU stay and hyponatremia were associated with postoperative bacterial infection. Mnatzaganian *et al*<sup>[31]</sup> confirmed the incidences of bloodstream and urinary infections of patients in ICU were higher than those in regular ward. Suljagic *et al*<sup>[32]</sup> confirmed the incidence of nosocomial bloodstream infection of ICU patients was higher than non-ICU patients. Stormont *et al*<sup>[33]</sup> confirmed hyponatremia was associated with pneumonia. Zilberberg *et al*<sup>[34]</sup> suggested hyponatremia was associated with worsened clinical outcomes among patients with pneumonia.

Although the relationship between massive RBCs transfusion and bacterial infection was well established in previous studies, there were little information of the correlation of massive RBCs transfusion and fungal in-

fection. Current study suggested massive RBCs transfusion will increase the risk of fungal infection after liver transplantation. Blood transfusion can cause transfusion-related immunomodulation which will suppress the recipient's immune function<sup>[35]</sup>. However, it remains unclear why massive transfusion was not a risk factor for bacterial infection in current study.

Postoperative bacterial infection showed significantly prognostic power for fungal infection in current study. Antibiotics, especially broad-spectrum antibiotics, were administered to patients with bacterial infection in the case of lacking culture results. Broad-spectrum antibiotics might lead to dysbacteriosis and increase fungal infection<sup>[36]</sup>. However, a recent study which was performed by Nafady-Hego *et al.*<sup>[37]</sup> suggested bacterial infection was not a risk factor for fungal infection after pediatric LDLT. Younger recipient age, lower dosages of immunosuppressive agents and different infection prophylaxis might be the potential explanation for this difference.

In conclusion, preoperative hyponatremia, recipient age > 45 years, longer ICU stay, postoperative bile leak and severe hyperglycemia may be related to postoperative bacterial infection, whereas massive intraoperative RBCs transfusion and postoperative bacterial infection may lead to postoperative fungal infection. Current finding suggested postoperative bacterial and fungal infections were associated with pre-, intra- and post-operative factors.

## COMMENTS

### Background

Infection is a leading cause of postoperative mortality and morbidity after liver transplantation. To identify the pattern and risk factors related to postoperative bacterial and fungal infections is important to transplant surgeon.

### Research frontiers

The pattern and risk factors of postoperative infections following living donor liver transplantation are not well established. This study was performed to identify the pattern and risk factors related to bacterial and fungal infections in the first 3-mo after living donor liver transplantation.

### Innovations and breakthroughs

This study outlines a comprehensive experience of 207 patients over an eight year period of infections in the first 3-mo following living donor liver transplantation. It documents the site of infection, organisms involved and the predictive risk factors.

### Applications

This study could guide the clinical management of early bacterial and fungal infections after living donor liver transplantation.

### Terminology

Serious infection was defined as the culture-positive bacterial or fungal infection in the blood, sputum, urine, or ascetic fluid which was obtained on the basis of clinical suspicion of an infection.

### Peer review

The article is well written. The analysis of the data is sound and the conclusions reached appear valid. Overall, it significantly contributes to a relevant issue in this field and should be considered for publication.

### Abstract

**AIM:** To investigate the correlation between peri-operative fluid therapy and early-phase recovery after liver transplantation (LT) by retrospectively reviewing 102 consecutive recipients.

**METHODS:** Based on whether or not the patients had pulmonary complications, the patients were categorized into non-pulmonary and pulmonary groups. Twenty-eight peri-operative variables were analyzed in both groups to screen for the factors related to the occurrence of early pulmonary complications.

**RESULTS:** The starting hemoglobin (Hb) value, an intra-operative transfusion > 100 mL/kg, and a fluid balance  $\leq$  -14 mL/kg on the first day and the second or third day post-operatively were significant factors for

early pulmonary complications. The extubation time, time to initial passage of flatus, or intensive care unit length of stay were significantly prolonged in patients who had not received an intra-operative transfusion  $\leq$  100 mL/kg or a fluid balance  $\leq$  -14 mL/kg on the first day and the second or the third day post-operatively. Moreover, these patients had poorer results in arterial blood gas analysis.

**CONCLUSION:** It is important to offer a precise and individualized fluid therapy during the peri-operative period to the patients undergoing LT for cirrhosis-associated hepatocellular carcinoma.

### INTRODUCTION

Liver transplantation (LT) is the optimal therapy for end-stage liver diseases. Although LT has undergone a rapid progress, early pulmonary complications are common and known to contribute significantly to the morbidity and mortality of the patients<sup>[1-4]</sup>. Post-operative pulmonary complications may be caused by many factors during the patient's recovery, and fluid therapy is an important

factor<sup>[5,6]</sup>. Individualized fluid therapy during the peri-operative period may be a significant strategy to achieve a better early-phase recovery after LT. In this study, early-phase refers to the first month after LT.

In a previous study, we investigated and assessed the use of fluid therapy in all the patients undergoing LT<sup>[7]</sup>. This study focused on the patients with cirrhosis-associated hepatocellular carcinoma (HCC), and fluid transfusion was administered based on the body weight of the patients per kg.

The purpose of this study was to investigate the clinical significance of the correlation between peri-operative fluid therapy and early-phase recovery after LT in an attempt to establish a precise and individualized fluid therapeutic strategy in the peri-operative period of LT.

## MATERIALS AND METHODS

The medical records of all consecutive patients with cirrhosis-associated HCC who underwent orthotopic LT at the First Affiliated Hospital of Guangxi Medical University between July 1996 and July 2009 were retrospectively reviewed. Patients aged from 23-72 years with a mean  $\pm$  SD of  $45.26 \pm 9.54$  years. This series represents the first 102 consecutive LT recipients with cirrhosis-associated HCC in our cohort study.

All LT procedures were performed using the piggy-back technique without venovenous bypass. In addition to fluid transfusion given intra-operatively, small amounts of vasopressors (dopamine and noradrenaline) and shallow anesthesia were used to maintain hemodynamic stability. All patients were admitted to the intensive care unit (ICU) immediately after surgery and extubated as soon as they met standard criteria for termination of mechanical ventilation, such as the presence of adequate gas exchange function, hemodynamic stability, and ability to protect the airway. Antibiotics and anti-fungals for infection were used prophylactically.

Radiographic analysis was standardized by assessment of eight separate observations designed to determine the presence of pulmonary edema<sup>[8]</sup>. Acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) were defined according to the American-European Consensus Conference<sup>[9]</sup>, and pneumonia was defined according to a Joint Committee of the American Thoracic Society and Infectious Diseases Society of America<sup>[10]</sup>.

### All variables

Twenty-five peri-operative variables affecting post-operative early-phase recovery were as follows: age; body weight index; hemoglobin (Hb); hematocrit (HCT); serum creatinine (CRE); blood urea nitrogen (BUN); serum uric acid (UA); American Society of Anesthesiologists (ASA) grade; Child-Pugh score; acute physiology and chronic health evaluation (APACHE) II score; model for end-stage liver disease (MELD) score; warm ischemia time; cold ischemia time; anhepatic phase; operative time; diabetes; lung function; volume of intra-operative blood transfusion;

volume of intra-operative packed red blood cell (RBC) transfusion; volume of intra-operative plasma transfusion; volume of intra-operative fluid transfusion; volume of intra-operative bleeding; intra-operative fluid balance; transfused volume and fluid balance on the first post-operative day. Bivariate correlation analysis for the relationship between these intra-operative variables and occurrence of pulmonary complications showed the following significant variables: blood transfusion  $> 30$  mL/kg ( $P = 0.046$ ); packed RBC transfusion  $> 0.05$  U/kg ( $P = 0.041$ ); plasma transfusion  $> 25$  mL/kg ( $P = 0.042$ ); fluid transfusion  $> 100$  mL/kg ( $P = 0.014$ ); bleeding  $> 10$  mL/kg ( $P = 0.018$ ); fluid balance  $> 64$  mL/kg ( $P = 0.037$ ); fluid transfusion volume on the first post-operative day  $\leq 44$  mL/kg ( $P = 0.010$ ); and fluid balance on the first post-operative day  $\leq -14$  mL/kg ( $P = 0.018$ ). The threshold values of these variables were obtained by bivariate correlation analysis between the volume of intra-operative transfusion and post-operative pulmonary complications. The statistically significant threshold value was 100 mL/kg. If no statistically significant threshold value was obtained, the lowest  $P$  value was recorded. The critical value of other fluid variables was determined by the same analysis.

Because of the special importance of the first 3 post-operative days for patients' recovery, the following three variables were analyzed: fluid balance  $\leq -14$  mL/kg on the first day and the second or the third day after operation ( $P = 0.010$ ); fluid balance  $\leq -14$  mL/kg on post-operative  $\geq 1$  d ( $P = 0.612$ ); and fluid balance  $\leq -14$  mL/kg on post-operative  $\geq 2$  d ( $P = 0.014$ ).

Other variables analyzed included the worst outcome of arterial blood gas analysis in the first 7 post-operative days. The outcome variables reflecting post-operative recovery included: extubation time; time to initial passage of flatus; and ICU length of stay.

In this study, fluid balance in the surgery did not include the "third space" loss, evaporative loss, and insensible loss. So far, no method has provided estimated losses for LT.

### Statistical analysis

Data were presented as the mean  $\pm$  SD, median/range, or percentage (%). Group means were compared using Student's  $t$  test or the Mann-Whitney  $U$  test as appropriate. The  $\chi^2$  test was used to compare percentages. Bivariate correlation was used to determine the significant threshold value of peri-operative fluid variables. Multivariate regression analysis was performed with stepwise elimination of non-significant variables. A  $P < 0.050$  was considered significant. All analyses were performed with SPSS 12.0 software (SPSS, Chicago, IL, United States).

## RESULTS

Of the 102 patients (89 males and 13 females), 47 patients (46.08%) had pulmonary complications after LT. No hypoxia was found preoperatively. Pulmonary edema (PE;  $n = 8$ , 17.02%), acute lung injury (ALI;  $n = 12$ ,

**Table 1 Comparison of 25 variables between the groups with and without pulmonary complications**

Variables	Non-pulmonary complication group (n = 55)	Pulmonary complication group (n = 47)	P value
Age (yr)	46.29 ± 9.14	44.06 ± 9.95	0.242
Weight index (kg/m <sup>2</sup> )	22.78 ± 3.35	22.36 ± 3.29	0.531
Hb (g/L)	122.79 ± 21.12	109.54 ± 25.25	0.005

c (%)	25.45	6.38	0.010
d (%)	72.73	68.09	0.612
e (%)	36.36	14.89	0.014

Hb: Hemoglobin; HCT: Hematocrit; CRE: Creatinine; BUN: Blood urea nitrogen; UA: Serum uric acid; ASA: American Society of Anesthesiologists; APACHE: Acute physiology and chronic health evaluation; MELD: Model for end-stage liver disease. a, transfused volume on the first post-operative day ≤ 44 mL/kg; b, fluid balance on the first post-operative day ≤ -14 mL/kg; c, fluid balance ≤ -14 mL/kg on the first day and the second or the third day after operation; d, fluid balance ≤ -14 mL/kg on ≥ 1 d of the first 3 d after operation; e, fluid balance ≤ -14 mL/kg on ≥ 2 d after operation. ASA grade I was assigned a score of 1, grade II was assigned a score of 2, grade III was assigned a score of 3, and grade IV was assigned a score of 4. Mean ± SD was used for continuous variables, otherwise percentage was used (%).

25.53%), adult respiratory distress syndrome (ARDS; n = 6, 12.77%), and pneumonia (n = 21, 44.68%) occurred after surgery. Four patients survived no more than one month after LT.

Table 1 shows the comparison of 28 variables between the non-pulmonary and pulmonary complication groups. The following variables were found significant: Hb; HCT; Child-Pugh score; operative time; intra-operative blood

**Table 2 Summary of the logistic regression model and odds ratios**

Variables	Beta	SE	Sig	Exp (B)	95% CI
Hb	-0.025	0.010	0.11	0.975	0.956-0.994
Volume of intra-operative transfusion	1.097	0.496	0.27	2.995	1.132-7.922
c	2.037	0.722	0.05	7.670	1.862-31.603

SE: Standard error; Sig: Statistical significance; CI: Confidence interval; Hb: Hemoglobin. c, fluid balance ≤ -14 mL/kg on the first day and the second or the third after operation. When the volume of intra-operative transfusion ≤ 100 mL/kg, the variable was assigned a score of 0, and when the variable > 100 g/L, the variable was assigned a score of 1.

**Table 3 Comparison of outcome variables reflecting post-operative recovery between groups A and B**

	Group A (n = 32)	Group B (n = 70)	Z or t	P value
Extubation time (h)	12/8-99	16.5/5-504	-2.779	0.005
Time to initial passage of flatus (h)	78.66 ± 21.05	90.51 ± 45.28	-1.411	0.161
ICU length of stay (h)	36.5/8-144	62/14-600	-4.173	0.000

Values are given as the mean ± SD (median/range). ICU: Intensive care unit.

transfusion > 30 mL/kg; intra-operative packed RBC transfusion > 0.05 U/kg; intra-operative plasma transfusion > 25 mL/kg; intra-operative fluid transfusion > 100 mL/kg; intra-operative bleeding > 10 mL/kg; intra-operative fluid balance > 64 mL/kg; fluid transfusion volume on the first post-operative day ≤ 44 mL/kg; fluid balance ≤ -14 mL/kg on the first post-operative day; fluid balance ≤ -14 mL/kg on the first day and the second or the third day after operation; and fluid balance ≤ -14 mL/kg ≥ 2 d after operation.

The statistically significant variables were regarded as independent variables, and post-operative pulmonary complications were regarded as dependent variables. Multivariate regression analysis was performed to screen out the variables related to early pulmonary complications. Table 2 shows the statistically significant variables: Hb; intra-operative transfusion > 100 mL/kg; and fluid balance ≤ -14 mL/kg on the first day and the second or the third day after operation.

The 32 patients who received an intra-operative transfusion ≤ 100 mL/kg were referred to as group A and the other 70 patients who received an intra-operative transfusion > 100 mL/kg were as group B. Table 3 shows the comparison of outcome variables reflecting post-operative recovery between the two groups. As expected, both the extubation time and ICU length of stay in group A were shorter than in group B (P < 0.01). A comparison of the worst outcome of arterial blood gas in the first 7 post-operative days between the two groups showed that both PaO<sub>2</sub> and arterial partial pressure of oxygen (PaO<sub>2</sub>)/fraction of inspired oxygen (FiO<sub>2</sub>) ratio in group A were higher than in group B (110.422 ± 28.305 vs 90.641 ± 31.169, P < 0.01 for PaO<sub>2</sub>; and 272.355 ±

**Table 4** Comparison of outcome variables reflecting post-operative recovery between groups A and B

	Group A (n = 17)	Group B (n = 85)	Z or t	P value
Extubation time (h)	12/7-32	15/5-504	-2.708	0.007
Time to initial passage of flatus (h)	59.71 ± 12.17	92.21 ± 40.96	-6.094	0.000
ICU length of stay (h)	40/13-219	60/8-600	-1.590	0.112

Values are given as the mean ± SD (median/range). ICU: Intensive care unit.

79.486 *vs* 219.649 ± 86.462, *P* < 0.01 for PaO<sub>2</sub>/FiO<sub>2</sub>).

The 17 patients who received a fluid balance ≤ -14 mL/kg on the first day and the second or the third day after operation served as group A and the other 85 patients who did not receive a fluid balance ≤ -14 mL/kg served as group B. Table 4 shows a comparison of outcome variables reflecting post-operative recovery between the two groups. As expected, both the extubation time and the time to initial passage of flatus in group A were shorter than in group B (*P* < 0.01). Table 5 shows the comparison of the worst outcome of arterial blood gas in the first 7 post-operative days between the two groups. Both PaO<sub>2</sub> and PaO<sub>2</sub>/FiO<sub>2</sub> in group A were higher than in group B (*P* < 0.01).

## DISCUSSION

The LT recipients in this study presented the following characteristics: (1) All had chronic liver cirrhosis with water-sodium retention to some degree; (2) Because of the operative injury for LT, the capillary leak syndrome (CLS) created a “third space” effect; (3) Intra-operative fluid overload was common in order to maintain stable hemodynamics; and (4) A large-dose methylprednisolone was used to avoid reject reaction during and after surgery. All these factors contributed to aggravated water-sodium retention. Therefore, a precise and individualized fluid therapy is strongly recommended.

Collective studies demonstrated the importance of intra-operative fluid management to maintain body fluid equilibrium by restricting the volume of fluid infusion. Excessive fluid administration was associated with a higher risk of post-operative complications<sup>[11-14]</sup>. Aduen *et al*<sup>[15]</sup> reported that pulmonary complications interfered with the peri-operative course of patients undergoing LT and portended a worse outcome. Meanwhile, the time for extubation, ICU stay and hospital stay were significantly prolonged.

The restrictive intra-operative fluid management may be advantageous because it reduces morbidity and mortality and shortens mechanical ventilation, the time to initial passage of flatus, intensive care, and hospital stay<sup>[16-21]</sup>.

In this study, binary logistic regression revealed that an intra-operative transfusion > 100 mL/kg (Table 2) was an independent risk factor for post-operative pulmonary complications. The incidence of post-operative pulmonary complications in group A was significantly lower than in group B (28.13% *vs* 54.29%, *P* = 0.014).

**Table 5** Comparison of the worst outcome of arterial blood gas in the first 7 post-operative days between groups A and B

	Group A (n = 17)	Group B (n = 85)	t	P value
PH	7.436 ± 0.041	7.437 ± 0.055	-0.108	0.914
PaO <sub>2</sub>	117.471 ± 31.283	92.722 ± 30.105	3.075	0.003
PaCO <sub>2</sub>	44.094 ± 7.168	44.787 ± 12.038	-0.229	0.819
BE	4.459 ± 4.207	4.789 ± 4.062	-0.305	0.761
PaO <sub>2</sub> /FiO <sub>2</sub>	295.891 ± 92.741	224.243 ± 81.820	3.223	0.002

Values are given as the mean ± SD. PH: Power of hydrogen; PaO<sub>2</sub>: Arterial partial pressure of oxygen; PaCO<sub>2</sub>: Arterial pressure of carbon dioxide; BE: Base excess.

The extubation time and ICU length of stay were also significantly shorter than in group B (Table 3). Group A had higher PaO<sub>2</sub> and PaO<sub>2</sub>/FiO<sub>2</sub> than group B. These outcomes demonstrated that intra-operative fluid therapy was very important, which was associated with the incidence of pulmonary complications and the post-operative recovery.

Post-operative fluid overload is an independent risk factor for post-operative pulmonary complications after LT. Alsous *et al*<sup>[22]</sup> demonstrated that a fluid balance ≤ -500 mL on ≥ 1 d of the first 3 d of septic shock was associated with fewer pulmonary complications and better recovery. Our results demonstrated that it is a significant means to keep a fluid balance ≤ -14 mL/kg on the first day and the second or the third day after LT (Table 2). The incidence of post-operative early pulmonary complications in group A was lower than in group B (17.65% *vs* 51.76%, *P* = 0.01). This fluid therapy contributed to a better recovery (Tables 4 and 5) possibly because a fluid balance at ≤ -14 mL/kg within 3 d after LT could prevent edema, thus improving the blood supply and promoting recovery.

Of the four variables (fluid balance on the first post-operative day ≤ -14 mL/kg, fluid balance ≤ -14 mL/kg on the first day and the second or the third day after surgery, fluid balance ≤ -14 mL/kg on ≥ 1 d after surgery, and fluid balance ≤ -14 mL/kg on ≥ 2 d after surgery), only the fluid balance ≤ -14 mL/kg on the first day and the second or the third day after operation was included in the logistic regression analysis of outcome. It suggested that precise and individualized fluid balance in the peri-operative period should be accomplished as early as possible. In contrast, a negative fluid balance in the peri-operative period should be achieved to some extent.

The first 3 d after operation comprise the stress phase. Vascular recovery time varied from 36 h to 72 h after surgery. The transition points from positive to negative fluid balance also occurred. LT recipients need a large-dose methylprednisolone after operation, especially during the first few days. However, methylprednisolone would cause and aggravate water-sodium retention which may appear post-operatively, so the transition points would be postponed. Fluid balance during the first 3 d after surgery is crucial for recovery. If a positive fluid balance lasts too long, it is difficult for patients to recover. Thus, fluid bal-

ance should be properly managed as early as possible, and the quantity and time of negative fluid balance should be assessed individually.

Under the circumstances of stable hemodynamics, we should extrude the sequestered fluid from the peripheral circulation and the “third space” back to the central circulation. Whether or not a negative fluid balance is needed, the quantity and time of a negative fluid balance should be assessed by the following measurement: blood pressure, pulse, central venous pressure, HCT, the estimated volume of transfusion on the second day, and liquid intake and output volume of the preceding day. The fluid balance on the second post-operative day could be accomplished by adjusting the urine volume per hour. With administration of diuretics and colloid, urine volume could be controlled as needed. If hemodynamics were unstable, blood volume should be supplemented and inotropic drugs, such as dopamine, should be properly used.

We also found that Hb was an independent risk factor for post-operative pulmonary complications, which may be a significant factor for early recovery. When the patients with hepatic cirrhosis developed hypersplenism, which was always parallel with a reduction of hemocytes, their immune function became obviously lower and their hepatic function was poorer than other patients without a reduction of hemocytes. A low level of Hb may result in oxygen deficiency.

It is important to keep a fluid balance during the peri-operative period of LT. The precise and individualized fluid administration at the first 3 d after surgery significantly decreased the incidence of early pulmonary complications after LT. The strategies of an intra-operative transfusion  $\leq 100$  mL/kg and a fluid balance  $\leq -14$  mL/kg on the first day and the second or the third day after LT should be recommended. This study was limited by its small sample size. The shortcomings may limit the extrapolation of these results to all LT recipients. The hypothesis should be re-examined and verified in a much larger cohort before it is used for improving the prognosis and patient management. Nonetheless, if validated by future prospective studies, the fluid therapy used in this study would provide a simple and inexpensive method of augmenting the current prognostic indicators, and would be of obvious benefit for the anxious family members and care providers as well.

## COMMENTS

### Background

Liver transplantation (LT) is the optimal therapy for end-stage liver disease. Early-phase complications after LT are common and known to contribute significantly to morbidity and mortality of the patients. Individualized fluid therapy during the peri-operative period may be a significant strategy to achieve a better early-phase recovery after LT.

### Research frontiers

Recently, more attention has been paid to peri-operative fluid therapy. Fluid therapy is an important factor related to pulmonary complications and patient recovery.

### Innovations and breakthroughs

This research focused on the LT recipients with cirrhosis-associated hepatocellular carcinoma, and fluid was administrated based on the body weight in kilograms so as to guarantee a precise and individualized fluid therapy peri-operatively.

### Applications

It is important to offer a precise and individualized fluid therapy during the peri-operative period to the patients undergoing LT for cirrhosis-associated hepatocellular carcinoma. With an intra-operative transfusion  $> 100$  mL/kg and a fluid balance  $\leq 14$  mL/kg on the first day and the second or the third day after LT can significantly improve the early-phase recovery after LT.

### Terminology

The capillary leak syndrome is a rare condition characterized by recurrent episodes of generalized edema and severe hypotension associated with hypo-proteinemia. A shift of fluid and protein from the intravascular to the interstitial space results in hypovolaemia. Attacks vary in frequency, severity, and duration, and can be fatal.

### Peer review

Authors have investigated the clinical significance of the correlation between peri-operative fluid therapy and early-phase recovery after LT. The topic is interesting and offers points of reflection. The manuscript is original and may be useful to clinicians.

Following abdominal lavage and drainage, the patient was successfully treated with total parenteral nutrition and octreotide.

### Abstract

We report a case of acute chylous ascites formation presenting as peritonitis (acute chylous peritonitis) in a patient suffering from acute pancreatitis due to hypertriglyceridemia and alcohol abuse. The development of chylous ascites is usually a chronic process mostly involving malignancy, trauma or surgery, and symptoms arise as a result of progressive abdominal distention. However, when accumulation of "chyle" occurs rapidly, the patient may present with signs of peritonitis. Pre-operative diagnosis is difficult since the clinical picture usually suggests hollow organ perforation, appendicitis or visceral ischemia. Less than 100 cases of acute chylous peritonitis have been reported. Pancreatitis is a rare cause of chyloperitoneum and in almost all of the cases chylous ascites is discovered some days (or even weeks) after the onset of symptoms of pancreatitis. This is the second case in the literature where the patient presented with acute chylous peritonitis due to acute pancreatitis, and the presence of chyle within the abdominal cavity was discovered simultaneously with the establishment of the diagnosis of pancreatitis. The patient underwent an exploratory laparotomy for suspected perforated duodenal ulcer, since, due to hypertriglyceridemia, serum amylase values appeared within the normal range. Moreover, abdominal computed tomography imaging was not diagnostic for pancreatitis.

### INTRODUCTION

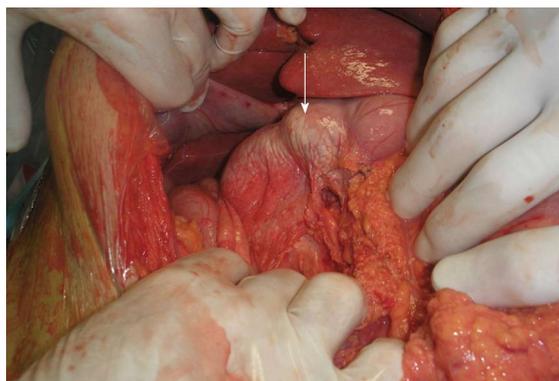

Accumulation of lymph within the peritoneal cavity is a rare pathological entity described as chylous ascites. Most cases occur progressively and the patient suffers from abdominal distention, nausea, vomiting, fatigue or low grade fever. A small number of cases have reported an acute development which may present as a surgical urgency mimicking appendicitis, hollow organ perforation and generalized peritonitis (acute chylous peritonitis). We hereby document a rare case of acute chylous peritonitis in a 46-year-old man with a history of alcoholism presenting with hypertriglyceridemia and acute pancreatitis.

### CASE REPORT

A 46-year-old man presented to the emergency department with an 8-h history of abdominal pain localized to the right abdomen. The pain was of acute onset and was primarily felt at the epigastrium. The patient also men-

**Figure 1** Preoperative abdominal computed tomography image showing inflammatory changes surrounding the head of the pancreas (arrow).

**Figure 2** Intraoperative photo showing the milky-like appearance of the wall of the distal portion of the stomach and the duodenum due to congestion of the intestinal lymphatic drainage (arrow).

tioned nausea and one episode of vomiting but no fever or diarrhea. Apart from a history of ankylosing spondylitis he also admitted systematical alcohol consumption over a period of several years (> 120 mg/d).

The patient's overall health condition was not gravely affected, showing a temperature of 37.2 °C, heart rate at 100 bpm and arterial pressure of 125/75 mmHg. On examination, no bowel sounds could be heard and right upper and lower abdominal quadrants appeared tender at palpation with rebound tenderness. Rectal digital examination did not reveal blood or tenderness.

Laboratory investigation showed no elevation of white blood cell count (7.740/mL with 57% polymorphonuclear leukocytes) while C-reactive protein values were only slightly affected (14 mg/L). The patient's biochemistry showed a mild elevation of hepatic enzymes (aspartate aminotransferase: 107 IU/L, alanine aminotransferase: 45 IU/L, alkaline phosphatase: 165 IU/L and total bilirubin: 1.6 mg/dL). Amylase values were normal both in blood (55 IU/L) and urine samples (404 IU/L). The laboratory notes mentioned that the blood sample of the patient was not totally appropriate for analysis because of a high concentration of lipids. Plain chest and abdominal X-rays (supine and elevated position) revealed no significant pathology such as free air or ileus. The computed tomography (CT) scan showed the presence of free fluid in the abdominal cavity, mainly at the subhepatic space and the right paracolic space, with mild inflammatory changes around the pancreatic head (Figure 1). No atrophy of the pancreas or calcification of the main pancreatic duct was demonstrated.

The patient was subsequently taken to the operating room for an exploratory laparotomy. In the peritoneal cavity a great amount of "milky" peritoneal fluid was discovered. Specimens were taken for biochemistry and microbiology. Careful examination of the abdomen revealed a bulky and rigid pancreatic head. Moreover, the surface of the distal stomach, duodenum and upper segment of posterior peritoneum had a white, milky-like appearance (Figure 2). A laceration in the peritoneum (at the root of the transverse mesocolon) was discovered, through which the milky fluid, apparently of retroperitoneal origin, entered the peritoneal cavity. Attempts to obtain a biopsy

specimen from the pancreas (with a biopsy needle) were unsuccessful because of hemorrhage after the first attempt due to the pancreatic edema. After a thorough peritoneal lavage and the insertion of 3 drain tubes the midline incision was closed.

During the initial postoperative days, serum samples from the patient appeared to be of high lipidemic concentration, with normal serum amylase values. Only after serial dilutions with the assay buffer were we able to obtain a proper sample for analysis, showing serum amylase values of 870 IU/L. Total cholesterol reached as high as 618 IU/L (normal values up to 200) and triglycerides had a concentration greater than 1.000 mg/dL (normal values up to 175). No elevation of white blood cell count was documented at any time. Analysis of samples from free peritoneal fluid that was collected intraoperatively showed 337 mg/dL cholesterol and 2800 mg/dL triglyceride thus establishing the diagnosis of chylous ascites. Laboratory investigation of the fluid from the drain tubes showed values of amylase to be as high as 60 000 IU/L, decreasing to normal at postoperative day 7, at which time all of the tubes had been removed. Cancer markers  $\alpha$ -fetoprotein, carcinoembryonic antigen and carbonic anhydrase 19-9 were within normal values.

The patient received nothing po for 10 d and then was restored gradually to a full (fat-free) diet. Total fat-free parenteral nutrition was given intravenously from postoperative day 4 and for the subsequent 2 wk. Broad spectrum antibiotics were administered for 1 wk postoperatively and were not stopped because the patient suffered outbursts of fever during the end of the first week. Twenty five days after the first operation a second procedure was undertaken, this time due to persisting ileus. The laparotomy revealed adhesions in the peritoneal cavity. Octreotide (0.1 mg) was administered every 8 h from the day of the first surgery until the time of discharge, which came to be after 33 d of hospitalization.

## DISCUSSION

Under normal circumstances, lymph from the lower parts of the body as well as from the viscera is circulated

through lymphatic vessels that follow a retroperitoneal course before emptying in the cisterna chyli and finally the thoracic duct and the venous system. This fluid consists of converted long-chain triglycerides at high concentrations that originate from the gut during ingestion. In cases where a disruption to this normal flow occurs, the peritoneal cavity may be filled with a high-density, milky-like fluid that is called “chyle”. Although there are no unequivocal diagnostic criteria, it is generally agreed that a high concentration of lipids is indicative<sup>[1]</sup>. A sample of ascites fluid (either acquired by paracentesis or during laparotomy) showing values of triglycerides 2 to 8 times that of plasma is characterized as chyle and the situation “chylous ascites” or “chyloperitoneum”. Some authors have set absolute indicators such as a peritoneal lipid content greater than 200 mg/dL<sup>[2]</sup>. Other characteristics of chyle are a protein concentration ratio > 0.5 compared to that of plasma, a low cholesterol level (lower than plasma) and elevated amylase values in case of pancreatitis<sup>[3]</sup>.

The formation of chylous ascites is usually a chronic procedure, and the patient typically mentions symptoms of progressive and painless distention of the abdomen for some time before the diagnosis is established. Multiple causes for this relatively rare pathological entity have been described. Aalami *et al*<sup>[1]</sup> present a detailed classification of them in a comprehensive review published in 2000. Whereas congenital abnormalities in the formation of the lymphatic vessels (lymphatic hypoplasia or lymphangiectasia) are a frequent cause in infants, surgery and malignancy (especially lymphoma) are among the most common causes in adults<sup>[4]</sup>. In particular, surgery involving the thoracic cavity or the aorta and the retroperitoneal space has often been associated with the pathogenesis of chylous ascites by means of interrupting the normal lymphatic drainage<sup>[5]</sup>. Chyloperitoneum may also be the result of trauma to the intestines or mesentery. Idiopathic retroperitoneal fibrosis, sarcoidosis and abdominal or pelvic radiation therapy have also been mentioned in the literature. Infectious diseases are another possible cause, such as filariasis in tropical countries, and tuberculosis mostly in countries with low social and economical level<sup>[1]</sup>.

However, in rare cases the accumulation of chyle within the peritoneal cavity may occur rapidly and the patient may present with symptoms and signs of acute abdomen<sup>[6]</sup>. Vettoretto *et al*<sup>[6]</sup> found less than a 100 cases of acute chylous peritonitis in their review of 2008. The pain appears to be diffuse, possibly due to peritoneal distention and irritation of the root of the mesentery as the retroperitoneal space expands, since the fluid itself is not irritating to the peritoneum. During clinical examination, rebound tenderness and guarding may be documented, which is often localized at the right iliac fossa and this can possibly be explained by pooling of chyle at the right paracolic gutter. Thus the clinical picture may be misleading, with appendicitis, hollow organ perforation and visceral ischemia being the most commonly suspected diagnosis preoperatively<sup>[3,7-9]</sup>. Chyloperitoneum is usually discovered during exploratory laparotomy, and in some

cases this is the only intraoperative finding. Negative laparotomies have been reported<sup>[3,6,10,11]</sup>, in which the underlying cause was never discovered<sup>[11]</sup>.

Pancreatitis is a rare cause of chylous ascites formation<sup>[12]</sup>. It is believed that either lymph may actually leak through destroyed lymphatics due to pancreatic enzyme erosion or that chylous accumulation is the result of exudation of chyle, caused by the obstruction of lymphatic channel flow secondary to severe inflammatory changes that take place in the retroperitoneal space surrounding the pancreas<sup>[1]</sup>. Most cases involve chronic pancreatitis<sup>[1,13]</sup>, though acute pancreatitis has also been recognized as the causative reason, with the first such report dating back to 1984<sup>[12]</sup>. Since then, only a few cases of chylous ascites secondary to acute pancreatitis have been documented<sup>[8,13-15]</sup>. In almost all of them, the presence of chyle into the peritoneal cavity was discovered at some time after the episode of pancreatitis, usually days or weeks<sup>[13-15]</sup>. However, Khan *et al*<sup>[16]</sup> reported a case of acute hyperlipidemic pancreatitis-with normal serum amylase as in our case-that presented with acute chylous peritonitis and was treated conservatively. Smith *et al*<sup>[3]</sup> operated on a patient with relapsing pancreatitis and acute chylous ascites formation, due to a clinical resemblance with appendicitis.

Therapeutic choices may vary in accordance with the underlying pathology. Thorough lavage of the abdomen and adequate drainage has proven to be an excellent treatment modality for acute chylous peritonitis, since resolution of chylous ascites usually occurs within the next few days. However, successful conservative treatment has also been reported<sup>[13,16-18]</sup>. This requires proper preoperative diagnosis, which is often difficult due to the exceptional rarity of this pathological condition and its resemblance to other surgical urgencies that call for immediate laparotomy. Long-term fasting supported by total parenteral nutrition offers resolution in many cases. Alternatively, a high-protein and low fat diet has proven to be efficacious in reducing the amount of chyle produced. Administration of octreotide remains controversial<sup>[1,13]</sup>.

In our case, the localization of the pain at the epigastrium and its later course mimicking peritonitis, together with the mild inflammatory changes of the pancreatic head demonstrated on CT imaging, as well as normal amylase values, drew the attention towards a possible duodenal perforation, thus leading the patient to the operating room. Only in the subsequent day and after serial dilutions of the serum samples with the assay buffer were we able to detect an abnormally high level of serum amylase. The interference of excessive serum triglyceride concentrations in the measurement of serum amylase is a known reason for false-negative results and this was also the case with our patient<sup>[16]</sup>. Moreover, routine serum lipase measurement is not available in our hospital, which could otherwise serve as an adjunct in the diagnosis of acute pancreatitis. However, it should be noted that serum lipase levels too can appear normal in patients with triglyceride-rich serum<sup>[16]</sup>. In our patient, peritoneal lavage and adequate drainage offered sufficient treatment, while

the patient was gradually restored to a full fat-free diet in order to deal with the pancreatitis. Finally, the patient was encouraged to cease alcohol use.

In conclusion, acute abdominal pain due to sudden accumulation of chyle in the peritoneal cavity is a rare situation that the clinician should be aware of in cases of acute abdomen.

### Abstract

Henoch-Schönlein purpura (HSP) is a small-vessel vasculitis mediated by IgA-immune complex deposition. It is characterized by the clinical tetrad of non-thrombocytopenic palpable purpura, abdominal pain, arthritis and renal involvement. The diagnosis of HSP is difficult, especially when abdominal symptoms precede cutaneous lesions. We report a rare case of paroxysmal drastic abdominal pain with gastrointestinal bleeding presented in HSP. The diagnosis was verified by renal damage and the occurrence of purpura.

### INTRODUCTION

Henoch-Schönlein purpura (HSP) is the most common systemic vasculitis in children. The diagnostic criteria include palpable purpura with at least one other manifestation including abdominal pain, IgA deposition, arthritis or arthralgia, and renal involvement<sup>[1,2]</sup>. Immune complex deposits induce necrosis of the walls of small- and medium-sized arteries with infiltration of the tissue by neutrophils and the deposition of nuclear fragments, a process called leukocytoclastic vasculitis<sup>[3]</sup>. It is often associated with infection, certain medications, or tumors. It may coexist with or mimic Crohn's disease<sup>[4]</sup>. Periumbilical and epigastric pain worsen with meals due to bowel angina. Bleeding is usually occult or, less commonly, associated with melena. Intussusception is the most common surgical complication. Perforations, usually ileal, may occur spontaneously or be associated with intussusception. An ultrasound, recommended as the first diagnostic test, and computed tomography (CT) scans may reveal intussusception and asymmetric bowel wall thickening mainly involving the jejunum and ileum. There are a range of

possible endoscopic findings including gastritis, duodenitis, ulceration, and purpura, with the second portion of the duodenum characteristically being involved more than the bulb. Intestinal biopsies show IgA deposition and leukocytoclastic vasculitis in the submucosal vessels<sup>[3]</sup>. Superficial biopsies may show inflammation, ulceration, edema, hemorrhage, and vascular congestion, presumably due to vasculitis-induced mucosal ischemia<sup>[5]</sup>. The efficacy of corticosteroids in preventing severe complications or relapses is controversial. The majority of patients, however, improve spontaneously.

## CASE REPORT

A 15-year-old boy was referred from another hospital to our institution in November 2010. He was previously healthy without any remarkable past medical history and denied any recent non-steroidal anti-inflammatory drug use or illicit drug use. He complained of progressive epigastrium and periumbilical pain, nausea and mild diarrhea with melena that had lasted for 3 wk. No rash was noticed on the skin. On physical examination, his vital signs were normal, except for epigastric pressing pain and suspicious rebound pain. Importantly, no skin rash was observed.

Laboratory blood examinations showed the following indexes (normal range in parentheses): hemoglobin, 109 g/L (120-140 g/L); peripheral white cell count,  $20.09 \times 10^9/L$  ( $5-10 \times 10^9/L$ ); neutrophils, 83.7% (40%-60%); peripheral red cell count,  $5.43 \times 10^{12}/L$  ( $4.0-4.5 \times 10^{12}/L$ ); platelet count,  $267 \times 10^9/L$  ( $100-300 \times 10^9/L$ ); C-reactive protein, 68.0 mg/L (0-6.0 mg/L); erythrocyte sedimentation rate, 14 mm/h (0-20 mm/h); albumin, 24.8 mg/L (36-51 mg/L); and total immunoglobulin (Ig), 17.6 mg/L (25.0-35.0 mg/L); IgA, 2.292 g/L (0.7-3.3 g/L); total bilirubin, 6.3  $\mu\text{mol}/L$  (4-23.9  $\mu\text{mol}/L$ ); alkaline phosphatase, 38 U/L (35-125 U/L); c-glutamyl transpeptidase, 12 U/L (7-50 U/L); aspartate aminotransferase, 15 U/L (14-40 U/L); alanine aminotransferase, 21 U/L (5-35 U/L); prothrombin time, 13.8 s (11.0-14.5 s); creatinine, 453  $\mu\text{mol}/L$  (31.8-91.0  $\mu\text{mol}/L$ ), and blood urine nitrogen, 33 g/L (31.8-91.0 g/L). A routine urine test did not reveal any RBCs or proteins on the first day of hospitalization. Autoimmune-related indicators and tuberculosis (TB)-related antibodies were not found in the blood, and the TB-purified protein derivative (PPD) skin test was negative. Hepatitis B and C markers were also negative.

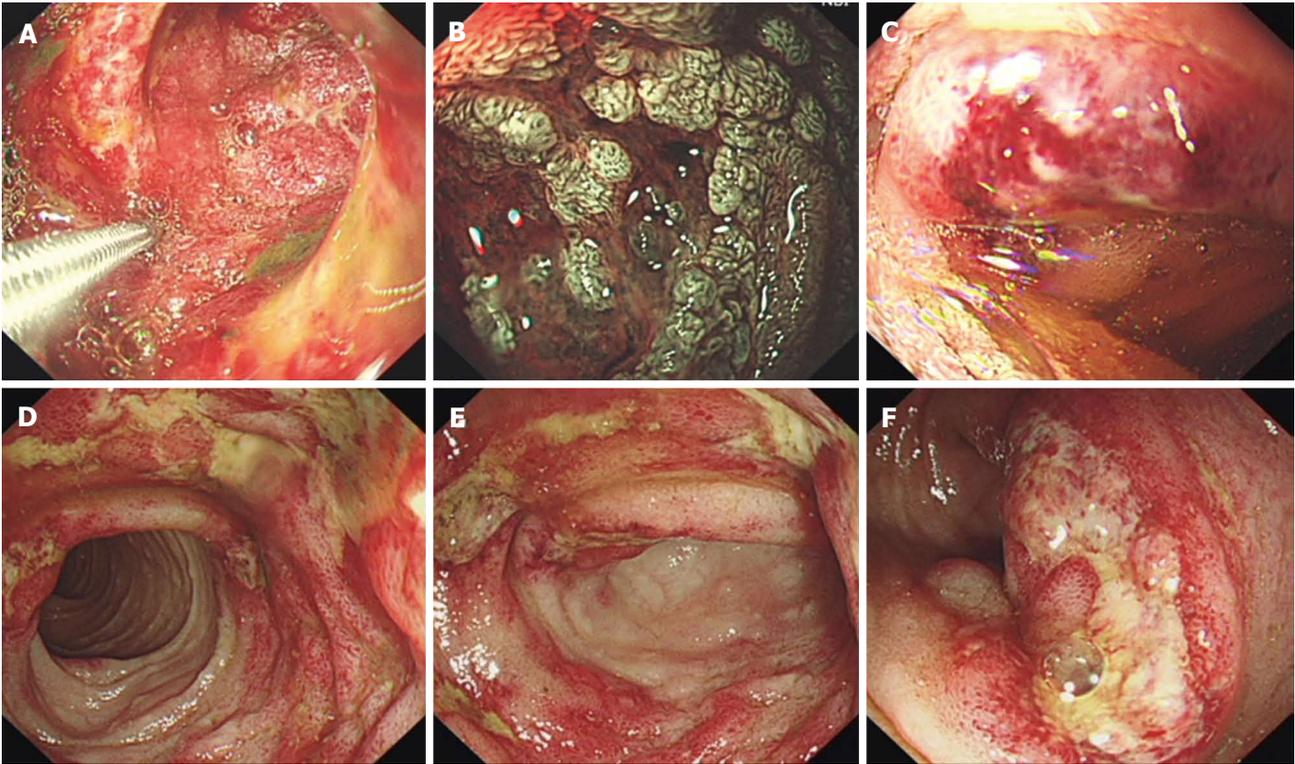

Plain abdominal radiography revealed incomplete small-intestine obstruction. Gastroscopy and colonoscopy revealed some mucosal swelling, erosion, and active ulcers with hemorrhage in the duodenum and terminal ileum (Figure 1), but not in the stomach or colon. The histopathology of duodenal mucosa and ileal mucosa showed a chronic mucosal inflammation with necrosis (data not shown). Ultrasound endoscopy (EUS) and abdominal CT examinations revealed the presence of thickened intestinal mucosa with submucosal hemorrhage and enlarged mesenteric and retroperitoneal lymph nodes (Figure 2). EUS-guided fine-needle aspiration (EUS-FNA)

biopsy of the enlarged lymph nodes revealed an inflammatory reaction without lymphoma (data not shown). Positron emission tomography and computed tomography also indicated that the enlarged lymph nodes were a sign of inflammation, not of a malignant tumor (data not shown).

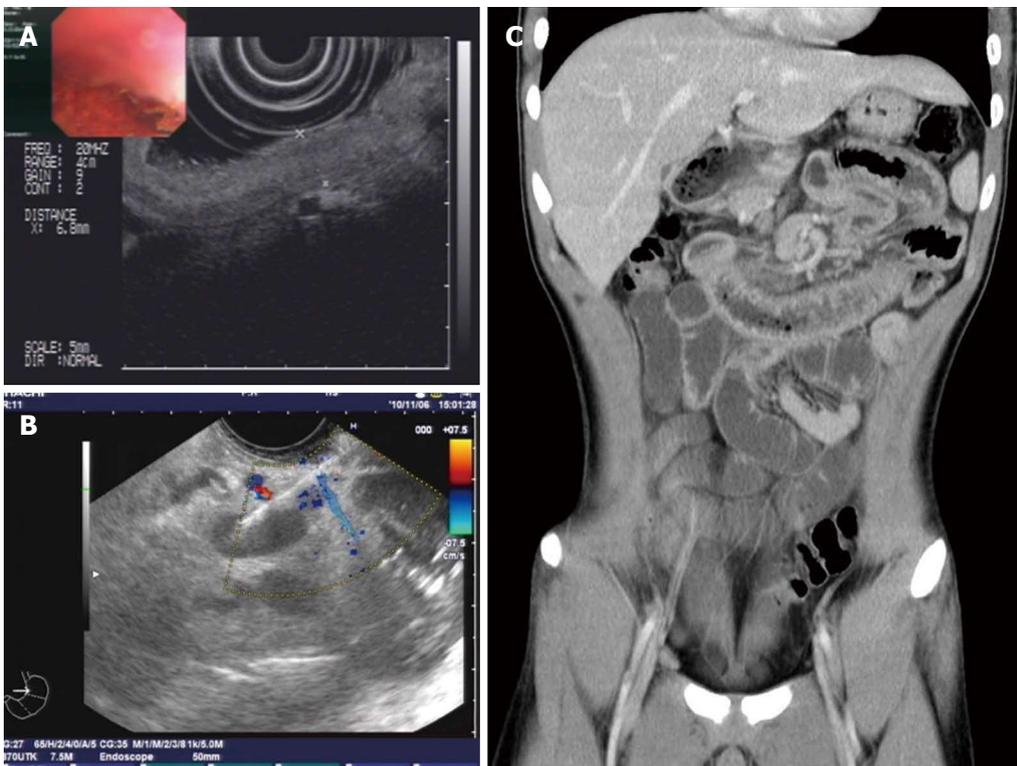

During the first two weeks of hospitalization, the patient accepted treatment with antibiotics and a proton pump inhibitor (pantoprazole 40 mg, twice daily), but his abdominal pain was not alleviated, and the paroxysmal abdominal pain worsened progressively. After two weeks of hospitalization, the patient's urine test revealed significant albuminuria. Levels of urine albumin increased to 1170 mg/L (0-20 mg/L), and 24-h total urine protein increased to 4.08 g (0-0.12 g). Further, the urine protein analysis showed a remarkable increase in kappa and lambda light chain levels to 62.5 mg/L (0-7.1 mg/L) and 28.8 mg/L (0-3.9 mg/L), respectively. The level of urine IgA increased to 102 mg/L (0-17.5 mg/L). Therefore, the diagnoses were considered to be an autoimmune-related disorder such as Crohn's disease and multiple vasculitis or lymphoma. The patient was treated with corticosteroid therapy in the form of intravenous methylprednisolone (40 mg/d). By the next day, the drastic abdominal pain was rapidly alleviated, and the melena also gradually disappeared. After one week of methylprednisolone therapy, the treatment was changed to the oral administration of prednisolone therapy (30 mg/d). During the fourth week of corticosteroid therapy, palpable purpura appeared over the patient's lower extremities. A diagnosis of HSP was ultimately established. After four weeks of corticosteroid treatment, endoscopy and EUS showed that the patient's mucosal damage had improved significantly, and the mucosal edema was observably mitigated (Figure 3). A percutaneous renal biopsy revealed focal segmental endocapillary crescent-like proliferation (Figure 4). Positive immunofluorescence staining for mesangial IgA was also observed (data not shown). The histopathology of renal biopsies supported the diagnosis of anaphylactoid purpura nephritis (APN), which was classified as ISKDC IV according to the classification criteria of the International Study of Kidney Disease in Children<sup>[6]</sup>.

## DISCUSSION

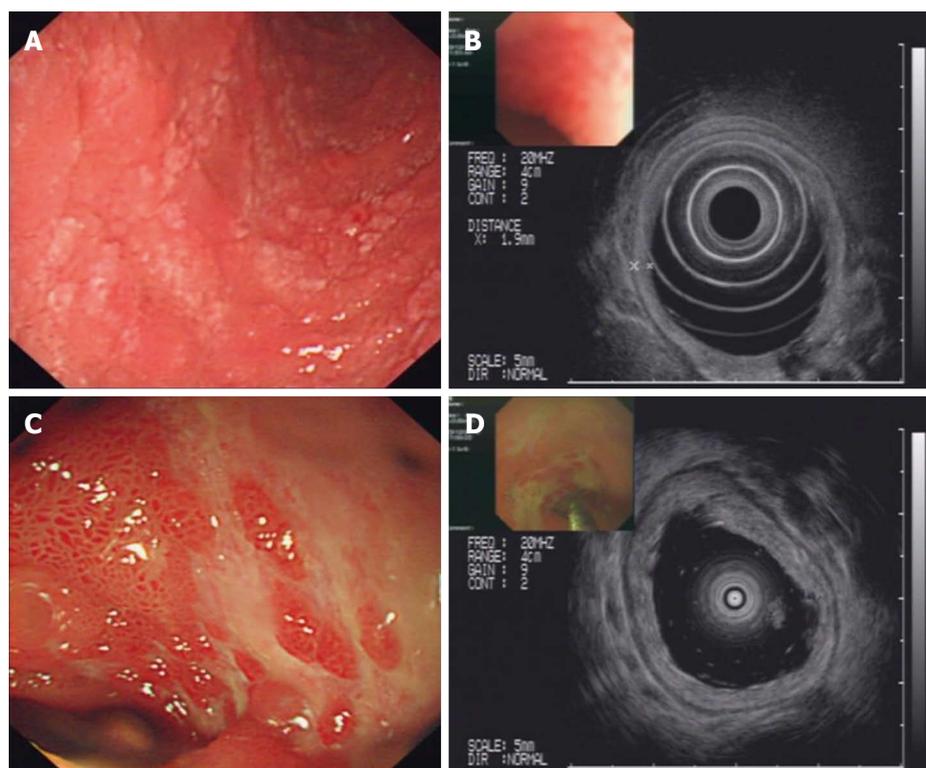

HSP is a form of blood vessel inflammation or vasculitis, also referred to as anaphylactoid purpura. Vasculitis is involved in many conditions<sup>[1]</sup>. Each of the forms of vasculitis tends to involve certain characteristic blood vessels. HSP is a multisystem disorder predominantly affecting the skin, joints, gastrointestinal tract and kidneys, but other organs can be affected as well. Neurological, pulmonary, cardiac and genitourinary complications rarely occur. HSP results in a skin rash (most prominent over the buttocks and behind the lower extremities) associated with joint inflammation (arthritis) and sometimes cramping pain in the abdomen. The condition primarily affects children (over 90% of cases); occurrences in adults have

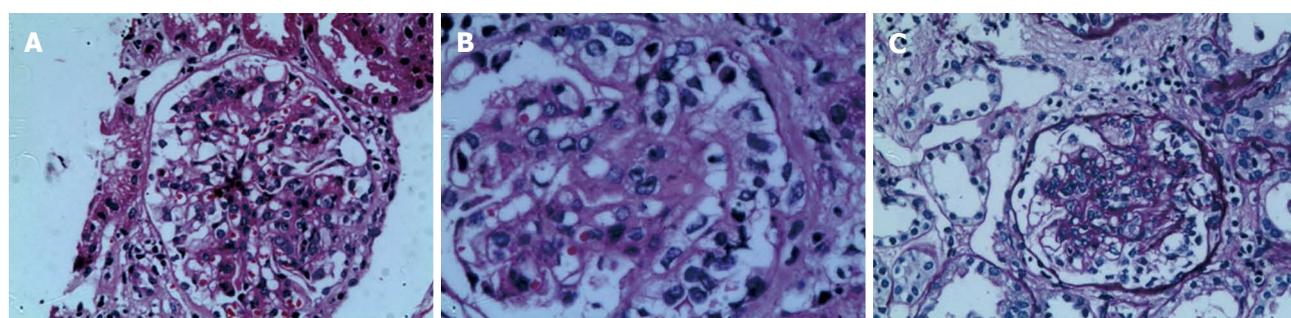

**Figure 1** The endoscopy examination revealed intestinal damage. A-C are gastroscopic images, which show significant damage to the duodenum. **Figure 2** The ultrasound endoscopy and the computed tomography scan indicated the presence of thickened intestinal mucosa and enlarged abdominal lymph nodes. A, B: Ultrasound endoscopy scan images; C: Computed tomography scan images.

**Figure 3** The extent of damage to the intestinal mucosa improved after treatment. A: Gastroscopic image of the duodenum; B: Ultrasound endoscopy (EUS) image of the duodenum; C: Colonoscopic image of the terminal ileum; D: EUS image of the terminal ileum.

**Figure 4** A percutaneous renal biopsy revealed focal segmental endocapillary crescent-like proliferation. A: HE staining, 200 ×; B: HE staining, 400 ×; C: Periodic acid-Schiff staining, 200 ×. HE: Hematoxylin and eosin.

rarely been reported (3.4 to 14.3 cases per million)<sup>[3]</sup>. HSP occurs most often in the spring and frequently follows an infection of the throat or breathing passages. HSP seems to represent an unusual reaction of the body's immune system in response to this infection (either bacterial or viral). In addition to infection, drugs can trigger the condition. HSP occurs most commonly in children, but people of all age groups can be affected.

HSP is usually diagnosed based on skin, joint, and kidney findings. Throat culture, urinalysis, and blood tests for inflammation and kidney function are used to determine the diagnosis. A biopsy of the skin, and less commonly, the kidneys, can be used to demonstrate the presence of vasculitis. Special staining techniques (direct immunofluorescence) of the biopsy specimen can be used to document antibody deposits of IgA in the blood

vessels of involved tissue. Renal involvement is rarely severe and is observed in approximately 50% of patients<sup>[1,2]</sup>.

According to the diagnostic criteria of the European League against Rheumatism and the Paediatric Rheumatology European Society published in 2006, palpable purpura often presents with one of the following: diffuse abdominal pain, a biopsy showing predominant IgA expression, acute arthritis/arthralgia, or renal involvement defined as any hematuria or proteinuria. However, when gastrointestinal manifestations occur alone or precede dermatological or renal disease, the diagnosis is difficult<sup>[7,8]</sup>. Typically, palpable purpura will not precede renal involvement<sup>[9,10]</sup>. However, in this case, purpura occurred during the seventh week of onset, and renal involvement occurred during the fourth week of onset, which delayed the diagnosis of HSP. HPS may coexist with Crohn's

disease or mimic its symptoms (e.g., ileitis or ulcerative colitis)<sup>[4,11,12]</sup>. The clinical manifestations of HSP in the gastrointestinal tract are similar to gastrointestinal tuberculosis, lymphoma, inflammatory bowel disease, and other autoimmune disorders, which renders the diagnosis of HSP difficult. In this case, paroxysmal drastic abdominal pain with gastrointestinal bleeding was presented as the princeps clinical situation. The characteristic endoscopic findings included diffuse mucosal redness, small ring-like petechiae, hemorrhagic erosions and ulcers. These manifestations created confusion until the diagnosis of HSP was verified by the presence of renal damage and purpura. Mucosal lesions develop anywhere within the gastrointestinal tract. The small intestine is considered to be the most frequently affected site, and duodenal involvement was more prominent in the second part of the duodenum than in the bulb and stomach or colon.

Gastrointestinal involvement is frequent in HSP. The diagnosis of HSP may be difficult, especially when abdominal symptoms precede the characteristic palpable purpura. Typical endoscopic findings may alert gastroenterologists to the need to consider this diagnosis early in treatment and thus avoid unnecessary laparotomy.

### Abstract

Regional portal hypertension is a rare cause of upper gastrointestinal bleeding. We reported an extremely rare case in which regional portal hypertension was associated with both the splenic arteriovenous fistula and chronic pancreatitis. In June 2010, our patient, a 41-year-old man, was admitted to a local hospital due to a sudden melena and dizziness without haematemesis and jaundice. The splenic arteriovenous fistula in this patient was successfully occluded through transcatheter arterial embolization. At the 12-mo follow-up, our patient was in good condition.

### INTRODUCTION

Regional portal hypertension is a rare cause of upper gastrointestinal bleeding, with pancreatitis disease being the most frequently reported cause in the literature<sup>[1,2]</sup>. Splenic arteriovenous fistulas are also rare. Until now, there are approximately 126 reported cases of splenic arteriovenous fistula in the database of PubMed. Herein, we reported an extremely rare case in which regional portal hypertension was associated with both the splenic arteriovenous fistula and chronic pancreatitis.

### CASE REPORT

A 41-year-old man was admitted to a local hospital in June 2010 due to a sudden melena and dizziness without haematemesis and jaundice. He was managed conservatively, with fluid support and blood transfusion. No melena occurred again, and the symptom of dizziness was reduced. With the melena of unknown causes, he was referred to our institution for further diagnosis and treatment. On admission, his temperature was 36.7 °C, pulse was 85 times/min, respiration was 19 times/min, and blood pressure was 124/76 mmHg. Splenomegaly was found in physical examination. The liver was not palpable and no signs of jaundice were observed. The patient had a history of alcohol abuse, but no history of liver disease, trauma and surgery. Five years ago, the patient had an acute pancreatitis which recurred for five times. The details of laboratory tests were as follows: red blood

**Figure 1** The main findings of enhanced computed tomography and angiography. A: An oval cystic low-density lesion located in the area of splenic hilum; B: The lesion was enhanced significantly on the arterial phase; C: Significantly enhanced on the portal phase of contrast-enhanced scan; D: A normal portal pressure and an increased pressure of splenic vein of 23.5 mmHg; E: Splenic arteriovenous fistula manifested by angiography; F: Splenic arteriovenous fistula being totally occluded after embolization.

cell  $4.13 \times 10^{12}/L$ , hemoglobin 119 g/L, platelet  $246 \times 10^9/L$ , white blood cell  $6.90 \times 10^9/L$ , total bilirubin  $13.3 \mu\text{mol}/L$ , albumin 42.9 g/L, creatinine (CREA)  $572.9 \mu\text{mol}/L$ , glucose (GLU)  $0.953 \text{ mmol}/L$ , GLU120  $21.75 \text{ mmol}/L$ , prothrombin time 12.0 s, and alpha-fetoprotein 1.36 ng/mL. Tests for HBsAg, HBeAg, anti-HBe, anti-HBc, anti-HCV and anti-HBs were all negative, except for anti-HBs. Gastroscopy revealed severe gastric varices and non-atrophic gastritis with bile reflux. Unenhanced computed tomography (CT) scanning of upper abdomen showed an oval cystic low-density lesion located in the area of splenic hilum, which was easily misdiagnosed as pancreatic pseudocyst on unenhanced CT (Figure 1A) and as pseudoaneurysm on contrast-enhanced scan. The lesion was significantly enhanced on the arterial phase of contrast-enhanced scan (Figure 1B). And on the portal phase of contrast-enhanced CT scan, this lesion was further enhanced and collateral vessels could be shown at the fundus of the stomach (Figure 1C). Additionally, thrombosis in the splenic vein was also found on the portal phase of contrast-enhanced CT scan. Biopsy of the liver was not performed. The current diagnosis was regional portal hypertension considered to be related to chronic pancreatitis. Under local anesthesia, a percutaneous transjugular approach was used to estimate the portal venous pressure; the portal pressure was normal and an increased pressure of splenic vein was 23.5 mmHg (Figure 1D). Through a percutaneous femoral approach, splenic artery angiography showed, on the arterial phase, a smaller splenic artery, splenic vein aneurysmal expansion, and esophageal and gastric varices, suggesting the formation of splenic arteriovenous fistula (Figure 1E).

With splenic artery being extremely tortuous, it was difficult for conventional catheter to track the orifice of the fistula through target vessels, therefore embolization of the fistula was performed using a micro-catheter. Post-operative angiography revealed that splenic arteriovenous fistula had been totally occluded (Figure 1F).

## DISCUSSION

Regional portal hypertension, also known as sinistral or left-sided portal hypertension, is a rare cause of upper gastrointestinal bleeding, with pancreatitis disease being the most frequently reported cause in the literature<sup>[1,2]</sup>. Splenic arteriovenous fistula is a rare but potentially curable cause of portal hypertension. The fistula may be congenital or acquired. It is thought that they arise from rupture of a splenic artery aneurysm or after abdominal trauma, surgery or pancreatitis<sup>[3]</sup>. To our best knowledge, splenic arteriovenous fistulas related to pancreatitis have been rarely reported and its pathogenesis remains unclear<sup>[4]</sup>. In this case, the fistula arose from pancreatitis, and regional portal hypertension was caused by splenic arteriovenous fistula and splenic vein thrombosis, with the former playing a major role. As for regional portal hypertension, the key point is to make the correct diagnosis as soon as possible, because it is curable. It should be considered in the presence of gastrointestinal bleeding with normal liver function tests and splenomegaly. Surgical excision of splenic arteriovenous fistula is technically difficult, and is sometimes unsuccessful because of the remote location of the lesion, presence of numerous portal collaterals, and adhesion. Interventional radiologic technique, such as transcatheter arterial embolization, has

been demonstrated to be a safe and effective alternative to surgery<sup>[5]</sup>. The splenic arteriovenous fistula in our patient was successfully occluded through transcatheter arterial embolization. At the 12-mo follow-up, this patient was found in good condition.

**GENERAL INFORMATION**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

**Maximization of personal benefits**

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the “priority” and “copy-right” of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers’ names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

**Aims and scope**

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**Columns**

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Thomson Reuters, 2010 Impact Factor: 2.240 (35/71 Gastroenterology and Hepatology).

### Published by

Baishideng Publishing Group Co., Limited

## SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only

homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically

for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

## Instructions to authors

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of “To investigate/study/...”; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315215714.htm](http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of *P* values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, “Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>”. If references are cited directly in the text, they should be put together within the text, for example, “From references<sup>[19,22-24]</sup>, we know that...”.

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315223018.htm](http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (<http://www.wjgnet.com/1007-9327/office/>). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to [wjg@wjgnet.com](mailto:wjg@wjgnet.com).

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222818.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm).

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1007-9327/g\\_info\\_20100315222607.htm](http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm).

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

*WJG* is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
